**Screen 165. BRI Trunk - Page 2 (using a TN2198/TN556B circuit pack)**

**NOTE:**

You cannot change the Endpt Init, SPID, or Endpt ID port parameters unless that port is busied out or unadministered. It is possible to change all other fields on this page even if the corresponding port is active.

**NOTE:**

If the Interface field on page 1 contains a valid value when the screen is submitted, the contents of the fields on page 2 for that port are validated. If the Interface field is blank when the screen is submitted, the fields on this page for that port reset to their default values.

## Directory Number

These 10-digit fields contain the directory numbers assigned to the interface, which it views as being allocated to 2 separate endpoints.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                              |                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| Any string of 1 to 10 digits | These fields must be administered in pairs. That is, if you enter a value in one field, you must enter a value in the other. |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------|

## Endpt ID

A 2-digit field containing the Endpoint Identifier expected by the far end. Avaya MultiVantage blocks you from changing this field unless the port is busied out or unadministered.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                 |                                                        |
|-----------------|--------------------------------------------------------|
| <b>00 to 62</b> | Leading zeroes considered significant and not ignored. |
|-----------------|--------------------------------------------------------|

## Endpt Init

Indicates whether the far end supports endpoint initialization. Avaya MultiVantage blocks you from changing this field unless the port is busied out or unadministered.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                              |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | If set to <b>y</b> , the SPID field must <i>not</i> be blank. Avaya MultiVantage blocks you from changing this field and the SPID field unless that port is busied out or unadministered. |
| <b>n</b>             | If set to <b>n</b> , the SPID and Endpt ID fields must be blank.                                                                                                                          |

## Interworking Message

This field determines what message the switch sends when an incoming ISDN trunk call interworks (is routed over a non-ISDN trunk group).

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                         |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PROGress</b>      | Normally select this value. PROGress asks the public network to cut through the B-channel and let the caller hear tones such as ringback or busy tone provided over the non-ISDN trunk.                                                                                                                              |
| <b>ALERTing</b>      | ALERTing causes the public network in many countries to play ringback tone to the caller. Select this value only if the DS1 is connected to the public network, and it is determined that callers hear silence (rather than ringback or busy tone) when a call incoming over the DS1 interworks to a non-ISDN trunk. |

## Max NCA TSC

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                       |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 through 63.</b> | This 2-digit field gives the maximum number of Non-Call-Associated Temporary Signaling Connections allowed on this BRI D-channel. This field's function is the same as the field with the same name on the Signaling Group screen. |

## Port

This is a display-only field. It shows the port number to which parameters administered on the row apply.

## SPID

A 12-digit field containing the SPID expected by the far end. Avaya MultiVantage blocks you from changing this field unless the port is busied out or unadministered. The only protocol supported for SPID initialization is Bellcore (Country Code 1). Trunks will not be put in service if SPID installation is not successful.

| <b>Valid entries</b>         | <b>Usage</b>                                          |
|------------------------------|-------------------------------------------------------|
| Any string of 1 to 12 digits | Leading zeroes considered significant and not ignored |

## XID Test

| <b>Valid entries</b> | <b>Usage</b>                                                 |
|----------------------|--------------------------------------------------------------|
| y/n                  | Indicates whether the far end supports the Layer 2 XID test. |

## Trunk Member Administration

Administer BRI trunk members using the following scheme to address the individual B-channels:

- B-channel 1 uses the port address of the BRI Trunk Port.
- B-channel 2 uses the port address of B-channel 1 incremented by 16.

When adding a BRI trunk to an ISDN trunk-group, Avaya MultiVantage blocks you from administering a Signaling Group for that trunk member.

Avaya MultiVantage blocks you from administering a BRI trunk member if the port has not yet been administered on the BRI Trunk screen.

For example, administer the B-channels on a TN2185 circuit pack inserted in slot 01A10 as follows:

| <b>Port</b> | <b>B-channel 1</b> | <b>B-channel 2</b> |
|-------------|--------------------|--------------------|
| 1           | 01A1001            | 01A1017            |
| 2           | 01A1002            | 01A1018            |
| 3           | 01A1003            | 01A1019            |
| 4           | 01A1004            | 01A1020            |
| 5           | 01A1005            | 01A1021            |
| 6           | 01A1006            | 01A1022            |
| 7           | 01A1007            | 01A1023            |
| 8           | 01A1008            | 01A1024            |

## Interactions

The **add bri-trunk board PPCSS** command is rejected if PPCSS identifies a TN556B circuit pack, and a port on that circuit pack has already been assigned to a station or data-module. If a TN556B circuit pack has been administered as a BRI trunk circuit pack, any port on that circuit pack is prevented from being assigned to a station or data-module.

## Language Translations

---

When you want to use a language other than English, French, Italian, and Spanish to display messages on your display phones, use the Language Translation screens to define the messages. Set up your messages using Roman letters, punctuation, digits and blank spaces. Diacritical marks are not supported.

All button names can be assigned a user-defined name. For more information, see [“Telephone feature buttons” on page 131](#).

### NOTE:

If “user-defined” is entered for the display language on the station screen or attendant screen, and no messages are defined on these screens, a string of asterisks appears on all display messages.

In this section, the field descriptions are listed before the screens

## English

This is a display-only field. It contains the English version of the message on the display.

## Meaning of English term

This is a display-only field. It explains the abbreviated English message.

## Translation

Enter the message you want to appear on the phone display in place of the English message. Remember that a long message may be shortened on phones that display fewer than 32 characters.

**Screen 215. Language Translations — Softkey-Labels**

In order to provide unique labeling for abbreviated dialing button types for softkey-labels, the switch replaces the last two characters with digits for the 12-key 8400 and 15-key 8434D phones.

On the softkey label language translation screen, the digits following the “AD” are derived from the button position. If the first button is an AD button, then it is AD1 and the fifteenth button is AD15. All the AD buttons between 1 and 15 have the position number appended to “AD.”

## Listed Directory Numbers

Allows Direct Inward Dialing (DID) numbers to be treated as public Listed Directory Numbers (LDNs). When one of these numbers is direct inward dialed, the calling party is routed to the attendant. The attendant display indicates a Listed Directory Number call and the name associated with the dialed extension.

The number of Listed Directory Numbers that can be assigned varies depending on system configuration. See the *Avaya MultiVantage™ Solutions Hardware Guide* for maximum values.

```

## List Usage Report for node-name

```
list usage node-name inde-e72

 LIST USAGE REPORT
Used By
Processor Channel Channel Number 4 Destination Node
TFTP Server Local Node
```

### Screen 223. List Usage Report for local node

The node name, inde-e72, displays as Local Node if it was defined as the local node name on the TFTP Server screen.

### Local Node Name

Displays when the node name is used on the TFTP Server screen as the local node name.

### TFTP Server

Displays when the node name is used on the TFTP Server screen as the local or server node name.

```
list usage node-name inde-e72

 LIST USAGE REPORT
Used By
Processor Channel Channel Number 4 Destination Node
TFTP Server Server Node Name
```

**Screen 224. List Usage Report for server node name**

The node name, inde-e72, displays as Server Node Name if it was defined as the server node name on the TFTP Server screen.

**Server Node Name**

Displays when the node name is used on the TFTP Server screen as the TFTP server node name.

**TFTP Server**

Displays when the node name is used on the TFTP Server screen as the local or server node name.

**List Usage Report for ip-address**

---

```
list usage ip-address 135.9.76.72

 LIST USAGE REPORT
Used By
IP Route Route Number 2 Destination Node
Node Name IP Name inde-372 IP Address
Processor Channel Channel Number 4 Destination Node
TFTP Server Local Node
```

**Screen 225. List Usage Report for local node**

The node name, inde-e72, displays as Local Node if it was defined as the local node name on the TFTP Server screen.

## Local Node Name

Displays when the IP address is used on the TFTP Server screen as the local node.

## TFTP Server

Displays when the IP address is used on the TFTP Server screen as the local or server node name.

```
list usage ip-address 135.9.76.72
```

### LIST USAGE REPORT

|                   |                |          |                  |
|-------------------|----------------|----------|------------------|
| Used By           |                |          |                  |
| IP Route          | Route Number   | 2        | Destination Node |
| Node Name         | IP Name        | inde-372 | IP Address       |
| Processor Channel | Channel Number | 4        | Destination Node |

## Screen 226. List Usage Report for server node name

The node name, inde-e72, displays as Server Node Name if it was defined as the TFTP server node name on the TFTP Server screen.

## Server Node Name

Displays when the IP address is used on the TFTP Server screen as the server node name.

## TFTP Server

Displays when the IP address is used on the TFTP Server screen as the local or server node name.

## Locations

---

Use the Locations screen to provide daylight savings time displays to users, to set the area code for each location, and to administer different location information for each location. You can administer up to 64 location specifications depending on the configuration of your switch if the Multiple Locations field is **y** on the System Parameters Customer Options screen. Otherwise, information for location 1 applies to all your locations.

**Screen 227. Locations screen**

**ARS Prefix 1 Required for 10-Digit NANP Calls?**

| Valid entries | Usage                                                                  |
|---------------|------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> when a 1 must be dialed before all 10-digit NANP calls. |

**Daylight-Savings Rule**

This field must be filled in for each administered location.

| Valid entries    | Usage                                                                                                                              |
|------------------|------------------------------------------------------------------------------------------------------------------------------------|
| 0                | No Daylight Savings                                                                                                                |
| 1 to 15 or blank | Specifies the number for each Daylight-Savings Rule (set up on the Daylight Savings Rule screen) that is applied to this location. |

**Name**

Identifies the switch associated with each location number.

| Valid entries                    | Usage                                                                                |
|----------------------------------|--------------------------------------------------------------------------------------|
| up to 15 alphanumeric characters | A name you use for the location. Names are easier to remember than location numbers. |

## Number

Displays the location number (**1 to 44**). Corresponding entries in each row define the numbering plan and daylight savings rule for each location number.

## Number Plan Area Code

| <b>Valid entries</b> | <b>Usage</b>                                                  |
|----------------------|---------------------------------------------------------------|
| <b>0 to 9</b>        | Enter the 3-digit numbering plan area code for each location. |

## Timezone Offset

Timezone offset is actually 3 fields (+/-, hour, and minute) that specify how much time each location differs from the system time. This field must be completed for each administered location. Use +00:00 for the time zone offset for a single location switch.

| <b>Valid entries</b> | <b>Usage</b>                                                                                   |
|----------------------|------------------------------------------------------------------------------------------------|
| +                    | Shows that the time set on this location is a certain amount of time ahead of the system time. |
| -                    | Shows that the time set on this location is a certain amount of time behind the system time.   |

| <b>Valid entries</b> | <b>Usage</b>                                                                |
|----------------------|-----------------------------------------------------------------------------|
| <b>0 to 23</b>       | Shows the number of hours difference between this location and system time. |

| <b>Valid entries</b> | <b>Usage</b>                                                                  |
|----------------------|-------------------------------------------------------------------------------|
| <b>0 to 59</b>       | Shows the number of minutes difference between this location and system time. |

## Login Administration

When your Avaya MultiVantage is delivered, one customer super-user login and password combination is already defined. You must administer additional logins and passwords, if needed. If you are the super-user, you have full customer permissions and can customize any login you create. The maximum number of customer logins is 11.

As super-user, you can establish permissions for the other logins in your system. You can block access to any object that may compromise switch security. Once the user login is established, set permissions using the Command Permission Categories screen.

**Screen 228. Login Administration**

**Password of Login Making Change**

You can make changes to any login with permissions less than your own. You must enter your password to save any changes you make to this screen.

**Valid entries      Usage**

|                      |                      |
|----------------------|----------------------|
| <b>User password</b> | Enter your password. |
|----------------------|----------------------|

**LOGIN BEING ADMINISTERED**

**Access to INADS Port**

This field only appears when the Customer Access to INADS Port field is set to y on the Maintenance-Related System-Parameters screen.

**Valid entries      Usage**

|            |                                                                          |
|------------|--------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to allow a user to access the remote administration port. |
|------------|--------------------------------------------------------------------------|

## Disable Following a Security Violation

This field only appears when the SVN Login Violation Notification field is set to y on the Security-Related System-Parameters screen.

| <b>Valid entries</b> | <b>Usage</b>                                                              |
|----------------------|---------------------------------------------------------------------------|
| y/n                  | Enter <b>y</b> to have the login disabled following a security violation. |

## Login's Name

This display-only field shows the login name specified with the add command.

## Login Type

| <b>Valid entries</b> | <b>Usage</b>                                                                                                         |
|----------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Customer</b>      | Enter <b>customer</b> to indicate the login belongs to a customer. This is the only valid value for customer logins. |

## Service Level

| <b>Valid entries</b>  | <b>Usage</b>                                                                                                                                                                    |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>super-user</b>     | Enter super-user to indicate the user is a super-user. Super-user logins can use the add, change, display, list, and remove commands for all customer logins and passwords.     |
| <b>non-super-user</b> | Enter non-super-user to indicate the user is a non-super-user. Non-super-user logins can change their own password, but are otherwise limited to permissions set by super-user. |

## LOGIN'S PASSWORD INFORMATION

### Login's Password

Passwords must be 4 to 11 characters in length and contain at least 1 alphabetic and 1 numeric character. Passwords do not display as you type.

| <b>Valid entries</b>                                        | <b>Usage</b>                                                      |
|-------------------------------------------------------------|-------------------------------------------------------------------|
| <b>A-Z, a-z, 0-9, and ! &amp;<br/>* ? ; ' ^ ( ) , . : -</b> | Enter the initial password for login, assigned by the super-user. |

## Password Aging Cycle Length (Days)

For security, you should assign password aging to all passwords. The system tracks a password from the day the login was created, or the day the user last changed the password.

| <b>Valid entries</b> | <b>Usage</b>                                         |
|----------------------|------------------------------------------------------|
| 1 through 99         | Enter the number of days the password remains valid. |

## Re-enter Login's Password

Passwords do not display as you type.

| <b>Valid entries</b>                         | <b>Usage</b>                                                             |
|----------------------------------------------|--------------------------------------------------------------------------|
| A-Z, a-z, 0-9, and ! & * ? ; ' ^ ( ) , . : - | Re-enter the initial password for the login, assigned by the super-user. |

## LOGOFF NOTIFICATION

### Facility Test Call Notification

For security, this field should be set to y for all logins.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                        |
|----------------------|---------------------------------------------------------------------------------------------------------------------|
| y/n                  | Enter <b>y</b> to have the user receive notification at logoff if Facility Test Notification is still administered. |

### Facility Test Call Notification — Acknowledgment Required

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                  |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------|
| y/n                  | Enter <b>y</b> to require the user to acknowledge they want to logoff while Facility Test Notification is still administered. |

### Remote Access Notification

For security, this field should be set to y for all logins.

| <b>Valid entries</b> | <b>Usage</b>                                                                                           |
|----------------------|--------------------------------------------------------------------------------------------------------|
| y/n                  | Enter <b>y</b> to have the user receive notification at logoff if remote access is still administered. |

## Remote Access Notification — Acknowledgment Required

| Valid entries | Usage                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to require the user to acknowledge they want to logoff while remote access is still administered. |

## ACCESS SECURITY GATEWAY

### Access Security Gateway

This field appears only if the Access Security Gateway (ASG) field on the System-Parameters Customer-Options screen is set to y.

| Valid entries | Usage                                                     |
|---------------|-----------------------------------------------------------|
| y/n           | Enter <b>y</b> to have ASG administered for the login ID. |

### Field descriptions for page 2

This page only appears if the Access Security Gateway field is set to **y** on page 1.

### Screen 229. Access Security Gateway Login Administration

## Blocked

Setting the Blocked field to **y** does not remove the login ID from the system.

| <b>Valid entries</b> | <b>Usage</b>                                                                                            |
|----------------------|---------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to temporarily disable the login ID from accessing the system through the ASG interface. |

## Expiration Date

Expiration of the login ID occurs at 23:59:59 of the entered date. This field consists of three fields separated by forward slashes (for example, 01/01/1999). Expiration of a login ID does not remove the login ID from the system. The system accepts administration of year 2000 dates.

If an login ID requiring ASG authentication has expired, the login ID for the standard login is not available. If an login ID not requiring ASG login has expired, the login ID still may be active for the standard login as long as expiration criteria associated with that component of the login has not been satisfied.

| <b>Valid entries</b>                                                       | <b>Usage</b>                                         |
|----------------------------------------------------------------------------|------------------------------------------------------|
| <b>mm = month, dd = day, and yyyy = year</b> (later than the current date) | Enter the date when the associated login ID expires. |

## Number of Sessions

Expiration of a login ID administered with both Expiration Date and Number of Sessions expiration criteria is based on whichever criteria is satisfied first.

| <b>Valid entries</b> | <b>Usage</b>                                                                                   |
|----------------------|------------------------------------------------------------------------------------------------|
| <b>1 to 999</b>      | Enter the number of times the login ID can be used to access the system via the ASG interface. |

## Restrict Days of Week

This field consists of seven subfields that correspond to the seven days of the week. Each subfield specifies whether the corresponding login ID is restricted from accessing the system via ASG on the day indicated. Access restrictions imposed by this field apply to the entire day unless limited by time restrictions.

| <b>Valid entries</b> | <b>Usage</b>                                                                                      |
|----------------------|---------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to restrict the login from accessing the system on the associated day of the week. |

## Restrict From Time and Restrict to Time

These two fields are separated by colons, for example, hh:mm where hh = hour and mm = minute. Periods that span an interval that crosses a day boundary are specified by setting the Restrict From Time field greater than the Restrict To Time field. For example, a Restriction From Time of 17:00 and a Restrict To Time of 08:00 limits access to the traditional working hours, 8 to 5.

When used with the Restrict Days of Week field, overnight periods start on the days where access is not restricted by the Restrict Day of Week field.

If the Restrict Days of Week field is not specified, the restricted time interval specified by the Restrict From Time to Restrict To Time fields applies to every day of the week.

| <b>Valid entries</b>  | <b>Usage</b>                                                                                              |
|-----------------------|-----------------------------------------------------------------------------------------------------------|
| <b>00:00 to 23:59</b> | Enter the time interval each day the login ID is blocked from accessing the system via the ASG interface. |

## Secret Key

The value of this field is only displayed during the initial add or change login command to allow it to be programmed into any ASG Site Manager, ASG Mobile, or ASG Pass-Key used to interact with ASG for user authentication.

If the System Generated Secret Key field is set to **y**, the system generates the secret key. If the System Generated Secret Key field is set to **n**, the administrator is required to enter a 20-digit octal value. It is important to note the value of the secret key so you can enter it into response generation devices.

| <b>Valid entries</b>                               | <b>Usage</b>                                                                                                                                                                      |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20-digit octal string using 0-7 as possible digits | Enter the 20-digit octal value used by both the lock and the key to verify user authenticity. The last digit must be 0 and the second to last digit must be either 0, 2, 4, or 6. |

## System Generated Secret Key

| <b>Valid entries</b> | <b>Usage</b>                                                                                 |
|----------------------|----------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to generate the secret key by the system and display it to the administrator. |

## Loudspeaker Paging

The Loudspeaker Paging screen administers voice paging, deluxe voice paging, and chime paging.

**Screen 230. Loudspeaker Paging**

### CDR

This field determines whether CDR data is collected for the paging ports.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|     |                                                                                |
|-----|--------------------------------------------------------------------------------|
| y/n | Enter <b>y</b> if you want the switch to collect CDR data on the paging ports. |
|-----|--------------------------------------------------------------------------------|

### Code Calling — COR

This field assigns a Class of Restriction to a paging zone.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|               |                                                                     |
|---------------|---------------------------------------------------------------------|
| 0 through 95. | You can assign different classes of restriction to different zones. |
|---------------|---------------------------------------------------------------------|

|       |                                                 |
|-------|-------------------------------------------------|
| blank | Leave this field blank for unused paging zones. |
|-------|-------------------------------------------------|

## Code Calling Playing Cycles

This field sets the number of times a chime code will play when a user makes a chime page. To determine the best setting, consider who your code calling users are and whether they are likely to hear the code chime the first time.

| Valid entries | Usage                                                                               |
|---------------|-------------------------------------------------------------------------------------|
| 1 to 3        | Enter the number of times you want the chime code to play when a user makes a page. |
| blank         | The field may not be blank when you administer chime paging (code calling).         |

## Code Calling — TAC

This field assigns a Trunk Access Code (TAC) to a paging zone. Users dial this code to make a page to a specific zone. One TAC must be assigned to each zone you want to use. Two zones cannot have the same TAC. If you enter a TAC in the ALL field, users may activate speakers in all the zones by dialing that code.

| Valid entries  | Usage                                                      |
|----------------|------------------------------------------------------------|
| 1- to 4-digits | Enter a Trunk Access Code (TAC) allowed by your dial plan. |
| *              | May be used as first digit.                                |
| #              | May be used as first digit.                                |
| blank          | Leave this field blank for unused paging zones.            |

## Code Calling — TN

| Valid entries                                                                                   | Usage                                                                                                                   |
|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| 1 to 20<br>(DEFINITY SI,<br>CSI)                                                                | If your system uses Tenant Partitioning, you may use this field to assign a paging zone to a specific tenant partition. |
| 1 to 100<br>(DEFINITY R,<br>S8300 Media<br>Server, S8700<br>IP-Connect, S8700<br>Multi-Connect) |                                                                                                                         |

**Location**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                               |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 to 27 characters   | Assign a descriptive name for the physical location corresponding to each zone. Typical entries might be “conference room A,” “warehouse,” or “storeroom.” |

**Port**

This field assigns a port on an auxiliary trunk circuit pack to a paging zone. Enter the necessary characters.

| <b>Valid entries</b>                                                                                                                                                                                        | <b>Usage</b>                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <b>01</b> through <b>44</b><br>(DEFINITY R) or<br><b>01</b> through <b>03</b><br>(DEFINITY CSI, SI) or<br><b>1</b> through <b>64</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server) | First and second characters are the cabinet number |
| <b>A</b> through <b>E</b>                                                                                                                                                                                   | Third character is the carrier                     |
| <b>0</b> through <b>20</b>                                                                                                                                                                                  | Fourth and fifth character are the slot number     |
| <b>01</b> through <b>04</b><br>(Analog TIE trunks)<br><b>01</b> through <b>31</b>                                                                                                                           | Six and seventh characters are the circuit number  |
| <b>1</b> through <b>80</b><br>(DEFINITY R, CSI) or<br><b>1</b> through <b>10</b> (DEFINITY SI) or<br><b>1</b> through <b>250</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server)     | Gateway                                            |
| <b>V1</b> through <b>V9</b>                                                                                                                                                                                 | Module                                             |
| <b>01</b> through <b>31</b>                                                                                                                                                                                 | Circuit                                            |
| blank                                                                                                                                                                                                       | Leave this field blank for unused paging zones.    |

## Voice Paging — COR

This field assigns a Class of Restriction to a paging zone.

| Valid entries | Usage                                                               |
|---------------|---------------------------------------------------------------------|
| 0 through 95. | You can assign different classes of restriction to different zones. |
| blank         | Leave this field blank for unused paging zones.                     |

## Voice Paging — TAC

This field assigns a Trunk Access Code (TAC) to a paging zone. Users dial this code to make a page to a specific zone. One TAC must be assigned to each zone you want to use. Two zones cannot have the same TAC. If you enter a TAC in the ALL field, users may activate speakers in all the zones by dialing that code.

| Valid entries  | Usage                                                      |
|----------------|------------------------------------------------------------|
| 1- to 4-digits | Enter a Trunk Access Code (TAC) allowed by your dial plan. |
| *              | May be used as first digit.                                |
| #              | May be used as first digit.                                |
| blank          | Leave this field blank for unused paging zones.            |

## Voice Paging Timeout (sec)

This field limits the duration of voice pages. When this interval ends, calls are disconnected. To determine the best setting, time the typical pages you expect to broadcast and then add another 4 to 5 seconds.

| Valid entries      | Usage                                                          |
|--------------------|----------------------------------------------------------------|
| 10 to 600 seconds. | Enter the maximum number of seconds you want any page to last. |
| blank              | The field may not be blank when you administer voice paging.   |

### NOTE:

To use a port that has no hardware associated with it, place an 'X' in this field.

## Voice Paging — TN

| Valid entries                                                                                   | Usage                                                                                                                   |
|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| 1 to 20<br>(DEFINITY SI,<br>CSI)                                                                | If your system uses Tenant Partitioning, you may use this field to assign a paging zone to a specific tenant partition. |
| 1 to 100<br>(DEFINITY R,<br>S8300 Media<br>Server, S8700<br>IP-Connect, S8700<br>Multi-Connect) |                                                                                                                         |

### Screen 231. Media-Gateway Administration screen

**Identifier**

This field is for the controller to identify the gateway.

| <b>Valid entries</b>        | <b>Usage</b>                                                                  |
|-----------------------------|-------------------------------------------------------------------------------|
| 1 to 20 characters or blank | Enter the serial number or other alpha-numeric characters for identification. |

**IP Address**

A display-only field containing the IP address of the media gateway. This field displays a blank until the media gateway registers for the first time.

**Location**

This field refers to a time-zone offset, daylight savings rule and number plan area code.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                   |
|----------------------|----------------------------------------------------------------------------------------------------------------|
| 1 through 10         | Enter a number between 1-X or blank where X is the maximum value for the different communications controllers. |

**MAC Address**

A display-only field containing the MAC address of the media gateway.

**Module Type**

Fields V1 through V4 list the Media Gateway media modules.

| <b>Valid entries</b> | <b>Usage</b>                            |
|----------------------|-----------------------------------------|
| <b>analog</b>        | Enter the actual hardware media module. |
| <b>bri</b>           |                                         |
| <b>dcp</b>           |                                         |
| <b>icc</b>           |                                         |
| <b>voip</b>          |                                         |
| <b>ds1</b>           |                                         |

Field V8 lists a “virtual” media modules (available in August).

| <b>Valid entries</b>             | <b>Usage</b>                                 |
|----------------------------------|----------------------------------------------|
| <b>messaging-analog</b> or blank | Messaging will be administered in this slot. |

Field V9 lists a “virtual” media modules (available in December).

| <b>Valid entries</b>                     | <b>Usage</b>                                    |
|------------------------------------------|-------------------------------------------------|
| <b>gateway-announcements</b><br>or blank | Announcement will be administered in this slot. |

## **Name**

This field is for customer naming of the gateway.

| <b>Valid entries</b>                            | <b>Usage</b>                                           |
|-------------------------------------------------|--------------------------------------------------------|
| 1- to 20-alphanumeric character string or blank | Enter the alpha-numeric characters for identification. |

## **Network Region**

This field is used by the communications controller to allocate resources from the nearest media gateway.

| <b>Valid entries</b>                                                                                                                     | <b>Usage</b>                                                                                                   |
|------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>1</b> through <b>80</b> (DEFINITY CSI, SI)<br><b>1</b> through <b>250</b> (S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect) | Enter a number between 1-X or blank where X is the maximum value for the different communications controllers. |

## **Number**

A display-only field showing the assigned media-gateway number.

## **Registered**

A display-only field indicating whether a Media Gateway is registered with a communications controller.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                   |
|----------------------|----------------------------------------------------------------------------------------------------------------|
| 1 character          | Enter a number between 1-X or blank where X is the maximum value for the different communications controllers. |

## Site Data

This field is for general site information.

### Valid entries

2 lines of 20 characters or blank

### Usage

Enter the alpha-numeric characters for identification.

## Meet-me Vector Directory Numbers

### Field descriptions for page 1

```
list meet-me-vdn
```

#### MEET-ME VECTOR DIRECTORY NUMBER

| Name                         | Ext  | Access |     |    | Vec Control |       |
|------------------------------|------|--------|-----|----|-------------|-------|
|                              |      | Code   | COR | TN | Num         | Ext   |
| Secure Meet-me Conference    | 4000 | *      | 1   | 1  | 1           |       |
| Nonsecure Meet-me Conference | 4006 |        | 1   | 1  | 2           | 84590 |

### Screen 232. Meet-me Vector Directory Numbers screen

If the Access Code field shows an asterisk (\*), an access code is assigned. If the Access Code field is blank, no access code is assigned. The access code displays for administrators with super-user permissions (such as *init*).

## Mode Code Related System Parameters

This screen establishes parameters associated with the Mode Code Voice Mail System Interface.

### ⇒ NOTE:

You can only administer this screen if the Mode Code Interface field on the Feature-Related System Parameters screen is set to **y**.

**MODDE CODES (FROM SWITCH TO VMS)**

**Direct Dial Access - Trunk**

This value defines a mode code that the switch sends when an external caller dials the VMS access number.

| <b>Valid entries</b>     | <b>Usage</b>                                       |
|--------------------------|----------------------------------------------------|
| <b>0 to 9, #, *, #00</b> | Up to six digits that may include these characters |

**Direct Inside Access**

This value defines a mode code that the switch sends when a caller at an internal extension dials the Voice Mail System (VMS) access number.

| <b>Valid entries</b>     | <b>Usage</b>                                       |
|--------------------------|----------------------------------------------------|
| <b>0 to 9, #, *, #00</b> | Up to six digits that may include these characters |

## External Coverage

This value defines a mode code that the switch sends when an external caller tries to reach a user at another extension and the call goes to the user's voice mail coverage.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <b>0 to 9, #, *, #00</b> | Up to six digits that may include these characters |
|--------------------------|----------------------------------------------------|

## Internal Coverage

This value defines a mode code that the switch sends when an internal caller tries to reach a user at another extension and the call goes to the user's voice mail coverage.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <b>0 to 9, #, *, #00</b> | Up to six digits that may include these characters |
|--------------------------|----------------------------------------------------|

## Refresh MW Lamp

This value defines a mode code that the switch sends during a system level 3 or higher reset that requests the VMS to refresh the Message Waiting (MW) lamps.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <b>0 to 9, #, *, #00</b> | Up to six digits that may include these characters |
|--------------------------|----------------------------------------------------|

## System In Day Service

This value indicates to the VMS that the Avaya MultiVantage has changed from Night to Day Service.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <b>0 to 9, #, *, #11</b> | Up to six digits that may include these characters |
|--------------------------|----------------------------------------------------|

## System In Night Service

This value indicates to the VMS that the Avaya MultiVantage has changed from Day to Night Service.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                          |                                                    |
|--------------------------|----------------------------------------------------|
| <b>0 to 9, #, *, #12</b> | Up to six digits that may include these characters |
|--------------------------|----------------------------------------------------|

## **OTHER RELATED PARAMETERS**

---

### **DTMF Duration On**

| <b>Valid entries</b>                                | <b>Usage</b>                                                                                      |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------------|
| Between <b>75</b> and <b>500</b> in multiples of 25 | Define in milliseconds the length of mode code digits sent to the VMS. This field cannot be blank |

### **Off**

| <b>Valid entries</b>                                | <b>Usage</b>                                                                                                       |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Between <b>75</b> and <b>200</b> in multiples of 25 | Define in milliseconds the pause between mode code digits as they are sent to the VMS. This field cannot be blank. |

### **Remote VMS Extensions - First**

You can administer this field if the Mode Code for Centralized Voice Mail field on the System-Parameters Customer-Options screen is set to **y**. Specifies the first remote UDP VMS hunt group extension.

| <b>Valid entries</b>                 | <b>Usage</b>                                  |
|--------------------------------------|-----------------------------------------------|
| Remote assigned hunt group extension | Enter the first UDP VMS hunt group extension. |

### **Remote VMS Extensions - Second**

You can administer this field if the Mode Code for Centralized Voice Mail field on the System-Parameters Customer-Options screen is set to **y**. Specifies the second remote UDP VMS hunt group extension.

| <b>Valid entries</b>                 | <b>Usage</b>                                                                                                        |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Remote assigned hunt group extension | Enter the second UDP VMS hunt group extension. This extension cannot be the same as the first Remote VMS Extension. |

### **Sending Delay**

| <b>Valid entries</b>                        | <b>Usage</b>                                                                                                                                                                      |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>75</b> to <b>1000</b> in multiples of 25 | Define in milliseconds the delay between the time the switch receives answer supervision from the VMS and the time the first mode code digit is sent. This field cannot be blank. |

## VMS Hunt Group Extension

A check is made to verify that a valid hunt group extension is entered, but a check is not made to verify that the hunt group members are VMI extensions.

### Valid entries

### Usage

Extension of a hunt group containing VMI extensions.

## Modem Pool Group

There are two types of conversion resources for Modem Pooling. The first type, an *integrated conversion resource*, is a circuit pack that emulates a Trunk Data Module connected to a 212A-type modem. Two conversion resources are on each circuit pack.

The second type, a *combined conversion resource*, is a separate Trunk Data Module and modem administered as a unit. The Trunk Data Module component of the conversion resource may be either a Modular Trunk Data Module (MTDM) or 7400A Data Module and connects to a digital port using Digital Communications Protocol (DCP); the modem connects to an analog port.

**Screen 235. Modem Pool Group — Combined screen if Group Type is combined**

**⇒ NOTE:**

The Speed, Duplex, and Synchronization fields cannot be filled out for the “integrated” pooled modem screens but can be assigned on the “combined” pooled modem screen. The integrated conversion resource automatically will adjust its speed and synchronization to the endpoint it is connected to. In synchronous mode, the integrated modem pool can operate at 1200 baud. In asynchronous mode, it can operate at 300 or 1200 baud. Full-duplex operation is always used.

**Answer Supervision Timeout (sec)**

Enter the period of time to wait before the far-end answers. This field appears only when the Group Type field is **combined**.

| Valid entries | Usage                 |
|---------------|-----------------------|
| 1–255         |                       |
| 0             | No answer supervision |

## CF-CB Common

This field appears only when the Group Type field is **integrated**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to indicate that the CF and CB leads on the conversion resource are logically connected. |
|------------|---------------------------------------------------------------------------------------------------------|

## Direction

Enter the direction of the call for which modem pool will operate. This field appears only when the Group Type field is **combined**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                 |                                                                   |
|-----------------|-------------------------------------------------------------------|
| <b>incoming</b> | Converts an analog signal to digital for the data endpoint.       |
| <b>outgoing</b> | Converts analog to digital (or digital to analog) for data calls. |
| <b>two-way</b>  | Allows incoming and outgoing data communication.                  |

## Duplex

Display-only when the Group Type field is **integrated**. When the Group Type field is **combined**, enter the duplex mode of the conversion resources in the group.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|             |                                          |
|-------------|------------------------------------------|
| <b>full</b> | Can talk and listen at the same time.    |
| <b>half</b> | Cannot talk and listen at the same time. |

## Group Number

A display-only field when the screen is accessed using an administration command such as **add** or **change**.

## Group Type

This field designates what physical model pool you are going to.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                   |                                                                           |
|-------------------|---------------------------------------------------------------------------|
| <b>integrated</b> | Maps to the Pooled Modem circuit pack.                                    |
| <b>combined</b>   | Maps to an external modem pool (when you have a data module and a modem). |

**Hold Time (min)**

Enter the maximum number of minutes that a conversion resource in the group may be held while a call waits in a queue or reserved after Data Call Preindication.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

1 through 99

**Loss of Carrier Disconnect**

This field appears only when the Group Type field is **integrated**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

**y/n** Enter **y** to permit conversion resource to disconnect if it detects a dropped carrier.

**Modem Name**

Indicates the name of the modem pool. This field appears only when the Group Type field is **combined**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

1- to 6-alphanumeric character string

**Receive Space Disconnect**

This field appears only when the Group Type field is **integrated**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

**y/n** Enter **y** to allow the conversion resource to disconnect after receiving 1.6 seconds of space.

**Receiver Responds to Remote Loop**

This field appears only when the Group Type field is **integrated**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

**y/n** Enter **y** to allow the far-end modem to put conversion resource into loop back mode.

## Send Space Disconnect

This field appears only when the Group Type field is **integrated**.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to allow the conversion resource to send 4 seconds of space before disconnecting. |
|------------|--------------------------------------------------------------------------------------------------|

## Speed

Display-only when the Group Type field is **integrated**. When the Group Type field is **combined**, enter the communication speed in bits per second of the conversion resources in the group. Enter one to three speeds separated by slashes (for example, 300/1200/2400) to indicate a maximum of three running speeds.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                        |
|------------|------------------------|
| <b>LOW</b> | 0 to 300 blind sampled |
|------------|------------------------|

**300**

**1200**

**2400**

**4800**

**9600**

**19200**

## Synchronization

Display-only when the Group Type field is **integrated**. When the Group Type field is **combined**, enter the synchronization mode of the conversion resources in the group.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|             |             |
|-------------|-------------|
| <b>sync</b> | Synchronous |
|-------------|-------------|

|              |              |
|--------------|--------------|
| <b>async</b> | Asynchronous |
|--------------|--------------|

**CIRCUIT PACK ASSIGNMENTS** are optional on “integrated” conversion resource screens only.

### Time Delay

Enter the time delay in seconds to insert between sending the ringing to the modem and the off-hook alert to the data module. This field appears only when the Group Type field is **combined**.

**Valid entries**

**Usage**

---

0 through 255

## CIRCUIT PACK ASSIGNMENTS

### Circuit Pack Location

Displays when the Group Type field is **integrated**. Enter the port associated with the conversion resource on the integrated modem pool circuit pack. Enter the necessary characters.

**Valid entries**

**Usage**

---

**01** through **44**  
(DEFINITY R) or  
**01** through **03**  
(DEFINITY CSI, SI) or

First and second characters are the cabinet number

**1** through **64**  
(S8700 IP-Connect /  
S8700 Multi-Connect /  
S8300 Media Server)

**A** through **E**

Third character is the carrier

**0** through **20**

Fourth and fifth character are the slot number

**01** through **04**  
(Analog TIE trunks)

Six and seventh characters are the circuit number

**01** through **31**

**1** through **80**  
(DEFINITY R, CSI) or  
**1** through **10** (DEFINITY  
SI) or

Gateway

**1** through **250**  
(S8700 IP-Connect /  
S8700 Multi-Connect /  
S8300 Media Server)

**V1** through **V9**

Module

**01** through **31**

Circuit

For example, 01A0612 is in cabinet 01, carrier A, slot 06, and circuit number (port) 12.

**PORT PAIR ASSIGNMENTS** are optional on “combined” pooled modem screens only.

## **PORT PAIR ASSIGNMENTS**

---

### **Analog Digital**

Displays when the Group Type field is **combined**. Enter the port numbers of the modem/TDM pair in a conversion resource.

Two port entries are required. Enter the necessary characters.

| <b>Valid entries</b>                                                                                                                                                                                        | <b>Usage</b>                                       |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <b>01</b> through <b>44</b><br>(DEFINITY R) or<br><b>01</b> through <b>03</b><br>(DEFINITY CSI, SI) or<br><b>1</b> through <b>64</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server) | First and second characters are the cabinet number |
| <b>A</b> through <b>E</b>                                                                                                                                                                                   | Third character is the carrier                     |
| <b>0</b> through <b>20</b>                                                                                                                                                                                  | Fourth and fifth character are the slot number     |
| <b>01</b> through <b>04</b><br>(Analog TIE trunks)<br><b>01</b> through <b>31</b>                                                                                                                           | Six and seventh characters are the circuit number  |
| <b>1</b> through <b>80</b><br>(DEFINITY R, CSI) or<br><b>1</b> through <b>10</b> (DEFINITY SI) or<br><b>1</b> through <b>250</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server)     | Gateway                                            |
| <b>V1</b> through <b>V9</b>                                                                                                                                                                                 | Module                                             |
| <b>01</b> through <b>31</b>                                                                                                                                                                                 | Circuit                                            |

#### **NOTE:**

For example, 01A0612 is in cabinet 01, carrier A, slot 06, and circuit number (port) 12.

## Multifrequency-Signaling-Related System Parameters

This screen sets the system parameters associated with multifrequency signaling. [Screen 236 on page 1045](#) appears when Incoming Call Type is **group-ii-mfc** and Outgoing Call Type is **none**. [Screen 237 on page 1054](#) appears when both Incoming Call Type and Outgoing Call Type are **group-ii-mfc**.

If the field, Use COR for All Group II Responses, is set to **y**, the Group II Called Party Category and Use COR for Calling Party Category fields do not appear.

```
change system-parameters multifrequency-signaling Page 1 of 4

MULTIFREQUENCY-SIGNALING-RELATED SYSTEM PARAMETERS

Incoming Call Type: ANI Prefix:
Outgoing Call Type: ANI for PBX:
Maintenance Call Type: NEXT ANI DIGIT

### Screen 236. Multifrequency-Signaling-Related System Parameters

The ANI Prefix, ANI for PBX, and Collect All Digits Before Seizure fields appear only when the value of the Outgoing Call Type field is **group-ii-mfc** or **mfe**.

If Collect All Digits Before Seizure is **y**, Overlap Sending on Link-to-Link Tandem Calls and Convert First Digit End-of-ANI are not displayed.

**ANI for PBX**

This field appears only when Outgoing Call Type is **group-ii-mfc** or **mfe**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                               |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>2 to 15</b>       | Enter the PBX identification number that is sent to the CO when ANI is requested (by the CO) on a particular call but is not available, such as on tandem tie trunk calls. |
| blank                | Use for tandeming. If this field is blank, you must enter a value in the ANI-Not-Available field.                                                                          |

**ANI Prefix**

This field appears only when Outgoing Call Type is **group-ii-mfc** or **mfe**.

| <b>Valid entries</b>   | <b>Usage</b>                                                          |
|------------------------|-----------------------------------------------------------------------|
| 1 to 6 digits or blank | Enter the prefix to apply to an extension when ANI is sent to the CO. |

**Backward Cycle Timer (sec)**

Appears when the Incoming Call Type field is **mfe**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                   |
|----------------------|------------------------------------------------------------------------------------------------|
| <b>1 to 255</b>      | Enter the number of seconds to wait to send the check frequency after receiving an MFE signal. |

**Collect All Digits Before Seizure**

Appears when the Outgoing Call Type is **group-ii-mfc** or **mfe**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | The system collects all the digits before seizing the trunk and the ANI Req field on the AAR and ARS Digit Conversion Table does not apply. |
| <b>n</b>             | Enter <b>n</b> to control ANI collection via the ARS screens.                                                                               |

### Convert First Digit End-of-Dial To

Appears when the Private Group II Permissions and Public Interworking field is **y**.

| Valid entries                              | Usage                                                                                                                  |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>0</b> to <b>9</b> , <b>#</b> , or blank | Enter the digit used when the incoming initial end-of-ani or end-of-dial MF signal is converted on a per-switch basis. |

### Forward Cycle Timer (sec)

Appears when the Incoming Call Type field is **mfe**.

| Valid entries          | Usage                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1</b> to <b>255</b> | Enter the number of seconds to wait to receive the check frequency after sending an MFE signal. The switch drops the call if the time runs out before it receives check frequency. |

### Group II Called Party Category

Appears when the Outgoing Call Type field is **group-ii-mfc** and the Use COR for All Group II Responses field is **n**. Enter the type of group II signals that should be used on the outgoing R2-MFC call.

**⇒ NOTE:**

For India, the ANI can be requested without the Incoming Call Type information.

| Valid entries    | Usage                                                                                                                                                                                                          |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>user-type</b> | The type of phone making the call determines the type of group II signal that the PBX sends (normal = ordinary phone set, attendant = attendant console, data-call = data modules and similar data endpoints). |
| <b>call-type</b> | The dialed digits determine the type of group II signal that the PBX sends.                                                                                                                                    |

This field defines the signal type that a CO uses to place an incoming call to the PBX.

| Valid entries           | Usage                                                                                                                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>group-ii-mfc</b>     | If the value of this field is <b>group-ii-mfc</b> , the second page of the screen will display entries for all group-I, group-II, group-A, and group-B signal types with a set of default values (see page 2 of screen). |
| <b>non-group-ii-mfc</b> | If the value is <b>non-group-ii-mfc</b> , the second page displays only group-I and group-A signal types.                                                                                                                |
| <b>mfe</b>              | Use only in Spain (multi-frequency Espanol)                                                                                                                                                                              |

### Incomplete Dial Timer (sec)

Appears when the Incoming Call Type field is **mfe**.

| Valid entries    | Usage                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>45 to 255</b> | Enter the number of seconds to wait from the start of a call until the end of the check frequency of the last signal. The switch drops the call if the time runs out before it receives the check frequency. |

### Interdigit Timer (sec)

Specify the maximum number of seconds the switch will wait for the first forward signal (digit) to arrive, and for subsequent digits to arrive. Intercept returns to the calling party if this timer expires.

| Valid entries   | Usage                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------|
| <b>1 to 255</b> | This number must be less than the number of seconds entered in the short interdigit timer. |

### Maintenance Call Type

Appears when the Incoming Call Type field is **group-ii-mfc** or **non-group-ii-mfc**.

| Valid entries | Usage                                                                                    |
|---------------|------------------------------------------------------------------------------------------|
| <b>1</b>      | The Belgium maintenance sequence is indicated when the CO sends an MFC maintenance tone. |
| <b>2</b>      | The Saudi Arabian sequence is indicated when the CO sends an MFC maintenance tone.       |
| <b>none</b>   |                                                                                          |

## Maximum Resent Requests

| <b>Valid entries</b> | <b>Usage</b>                                                                                       |
|----------------------|----------------------------------------------------------------------------------------------------|
| <b>1 to 99</b>       | Enter the threshold number of resend type MFC signals your switch accepts during an outgoing call. |
| <b>1</b>             | The call is dropped if one resend signal is received.                                              |
| <b>blank</b>         | An unlimited number of resend requests is allowed.                                                 |

## MF Signaling Intercept Treatment - Incoming

| <b>Valid entries</b> | <b>Usage</b>                                                                              |
|----------------------|-------------------------------------------------------------------------------------------|
| <b>y</b>             | Send the group B signal for the intercept to the CO and play intercept tone on the trunk. |
| <b>n</b>             | Use normal DID/TIE/ISDN intercept treatment.                                              |

## MF Signaling Intercept Treatment - Outgoing

Displays when the Outgoing Call Type field is **group-ii-mfc**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                            |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>announcement</b>  | Plays a recorded announcement for outgoing calls that cannot be completed as dialed. You select and record the message.<br><br>Enter the extension number for the announcement in the associated field. |
| <b>tone</b>          | Plays intercept tone for outgoing calls that cannot be completed as dialed.                                                                                                                             |

## MFE Type

This field only appears when Incoming Call Type is **mfe**.

| <b>Valid entries</b> | <b>Usage</b>                                           |
|----------------------|--------------------------------------------------------|
| <b>2/5</b>           | Determines which public signaling the switch will use. |
| <b>2/6</b>           |                                                        |

## Outgoing Call Type

This field defines the signal type that the PBX uses to place an outgoing call into a CO.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                           |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>group-ii-mfc</b>  | If the content of this field is <b>group-ii-mfc</b> , the system displays the third page of the screen. The third page displays entries for all group-I, group-II group-A, and group-B signal types with a set of default values.                                                                                      |
| <b>mfe</b>           | Use only in Spain (multi-frequency Espanol)                                                                                                                                                                                                                                                                            |
| <b>none</b>          | If the content of this field is <b>none</b> , the system does not display the third page. In addition, Outgoing Forward Signal Present Timer, Outgoing Forward Signal Absent Timer, ANI Prefix, ANI for PBX, Next ANI Digits, and Collect All Digits Before Seizure will not display on Field descriptions for page 1. |

## Outgoing Forward Signal Absent Timer (sec)

This field appears only when the content of Outgoing Call Type is **group-ii-mfc**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                       |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>11 to 255</b>     | Enter the maximum number of seconds to elapse between forward signals on outgoing calls. The timer starts (and restarts) when a forward tone is taken off the link and it stops when the next forward tone is applied to the link. |

## Outgoing Forward Signal Present Timer (sec)

This field appears only when the value of Outgoing Call Type is **group-ii-mfc**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                    |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 255</b>      | Enter the maximum number of seconds to elapse between signals on a call. This timer runs when MFC tones are being sent or received on an outgoing call. The timer starts (and restarts) when the switch begins sending a forward signal and stops when the switch receives the backward signal. |

### Outgoing Start Timer (sec)

Appears when the Incoming Call Type field is **mfe**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                   |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 to 255             | Enter the number of seconds to time from seizure until the beginning of the first Group A signal from the receiving end, and from the end of the check frequency until the beginning receipt of the first digit following the Group II signal. |

### Outgoing Shuttle Exchange Cycle Timer (sec)

Appears when the Incoming Call Type field is **group-ii-mfc** or **non-group-ii-mfc** and the Outgoing Call Type field is **group-ii-mfc** or **none**. This field applies only to calls made from Avaya MultiVantage.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                         |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 to 25              | Enter the number of seconds to time an exchange cycle (starts when the far end requests a digit until Avaya MultiVantage sends the requested digit). |

### Overlap Sending on Link-to-Link Tandem Calls

Does not appear if the Collect All Digits Before Seizure field is **y**. An Avaya MultiVantage with this field set to **y**, when tandeming calls between switches will send ANI for PBX to the terminating switch if that switch requests ANI before the Avaya MultiVantage receives it from the originating switch. The terminating switch may request ANI before the receipt of the last address digit if it is not an Avaya MultiVantage or it is an Avaya MultiVantage with the Request Call Category at Start of Call field set to **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                       |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | If <b>y</b> , Avaya MultiVantage sends and receives digits one digit at a time instead of enbloc. (With enbloc, digits are not sent until the entire group of digits is received). |

### Private Group II Permissions and Public Interworking

Displays when the Incoming Call Type field is **group-ii-mfc** or **non-group-ii-mfc** and the Outgoing Call Type field is **group-ii-mfc** or **none**.

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | <p>If <b>y</b>, Avaya MultiVantage:</p> <ul style="list-style-type: none"> <li>— Sends the category for MFC ANI for the COR of the originating party for non-private-MFC-trunk to MFC-private-trunk calls.</li> <li>— Sends the Group II category received over the incoming private trunk as the outgoing Group II category on tandem private MFC calls.</li> <li>— Applies MFC group II-CPC termination restrictions on incoming MFC private trunk calls.</li> <li>— Checks station permissions if you call forward off-net.</li> </ul> |

### Received Signal Gain (dB)

| Valid entries | Usage                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -15 to 3      | Enter the number for the loss/gain when the MFC port listens to the trunk port. Your switch listens with a range of -5 to -35 and this value moves the range (for example, a value of -5 provides a range of -10 to -40). |

### Request Incoming ANI (non-AAR/ARS)

Appears when the Incoming Call Type field is **group-ii-mfc** or **mfe** and the Outgoing Call Type field is **group-ii-mfc** or **mfe**. This field only applies if the incoming call via the R2-MFC trunk is terminating to a local station on this PBX.

| Valid entries | Usage                                                           |
|---------------|-----------------------------------------------------------------|
| y/n           | If <b>y</b> , ANI should be requested on incoming R2-MFC calls. |

### Test Call Extension

Appears when the Incoming Call Type field is **group-ii-mfc** or **non-group-ii-mfc**

| Valid entries           | Usage                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------|
| An unassigned extension | Specifies the destination of a call between the CO and the PBX that tests R2-MFC signaling. |
| 1                       | A test call extension is the destination.                                                   |

### Transmitted Signal Gain (dB)

| Valid entries | Usage                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -15 to 3      | Enter the number for the loss/gain when the trunk port listens to the MFC port. The MFC port generates at -5 for MFC and -8 for MFE, and this field adds gain or loss to the starting value of -5. |

### Use COR for All Group II Responses

Appears if the Outgoing Call Type field is **group-ii-mfc**.

| Valid entries | Usage                                                                                                                    |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to allow the COR administered category to be used for both the calling party and called party categories. |

### Use COR for Calling Party Category

Appears when the Outgoing Call Type field is **group-ii-mfc** and the Use COR for All Group II Responses field is **n**. Indicates the category to send with ANI if requested on an outgoing R2-MFC call.

| Valid entries | Usage                                                        |
|---------------|--------------------------------------------------------------|
| y             | Use the calling facility's COR to determine category.        |
| n             | Use the calling party's user-type COR to determine category. |

### NEXT ANI DIGIT

#### Incoming

Appears when the Incoming Call Type field is **group-ii-mfc** and the Outgoing Call Type field is **group-ii-mfc** or **mfe**.

| Valid entries                            | Usage                                                                                                                                                                            |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| next-digit<br>next_ani_digit<br>send-ani | Enter a value to determine whether the Next ANI Digit signal will be the same as the "send-ani" signal or the "next-digit" signal or another signal defined as "next_ani_digit." |

## Outgoing

Appears when the Outgoing Call Type field is **group-ii-mfc**.

| Valid entries                                                 | Usage                                                                                                                                                                            |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>next-digit</b><br><b>next_ani_digit</b><br><b>send-ani</b> | Enter a value to determine whether the Next ANI Digit signal will be the same as the “send-ani” signal or the “next-digit” signal or another signal defined as “next_ani_digit.” |

## Field descriptions for page 2

The fields on Page 2 define call category and ANI information. For India, the ANI can be requested without the call category information.

## Address Digits Include End-of-Digits Signal

Indicates that an outgoing forward Group I end-of-digit signal is always sent after completion of address digits upon request from the Central Office for outgoing calls.

| Valid entries | Usage                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to send an outgoing forward Group I end-of-digit signal after completion of address digits upon request from the Central Office for outgoing calls. |

### ANI Source for Forwarded & Covered Calls

| Valid entries    | Usage                                                      |
|------------------|------------------------------------------------------------|
| <b>caller</b>    | Send the calling party's ANI when calls are redirected.    |
| <b>forwarder</b> | Send the forwarding party's ANI when calls are redirected. |

### Call Category for Vector ii-digits

Allows you to use the call category digit as the ii-digits on call vector steps.

| Valid entries | Usage                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | If <b>y</b> , the call category digit, which is a part of ANI, is used as the ii-digits on call vector steps. |

### Do Not Send Group B Signals to CO

This field appears only if the Incoming Call Type field is **group-ii-mfc**. This field allows completion of a call without Group-B signals.

| Valid entries | Usage                                                                     |
|---------------|---------------------------------------------------------------------------|
| <b>y</b>      | If <b>y</b> , does not send Group-B signals to complete an incoming call. |
| <b>n</b>      | If <b>n</b> , sends Group-B signals to complete an incoming call.         |

### Number of Incoming ANI Digits

| Valid entries  | Usage                                                  |
|----------------|--------------------------------------------------------|
| <b>0 to 15</b> | Enter the number of ANI digits for incoming MFC calls. |

## Number of Outgoing ANI Digits

This field applies to Russian shuttle trunks, and MFC and MFE trunks.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 15</b> | <p>Enter the number of ANI digits for outgoing MFC calls.</p> <p>In India or any country where end-of-ani and end-of-digits are not defined for Tones to CO on Outgoing Forward Calls – Group I, Avaya MultiVantage appends ANI-Not-Available digits to ANI digits if the actual ANI length is less than the number entered in this field.</p> <p>If end-of-ani or end-of-digits are defined, this field is used in conjunction with Truncate Station Number in ANI as a maximum ANI length.</p> <p>For India, even if the length of ANI is defined, if the timeout occurs during the ANI collection, the call is routed with the ANI digits already collected.</p> |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Request Call Category at Start of Call

Indicates that the Send-ANI backward signal requesting for the caller-category information will be sequenced differently in the MFC signaling flow. The Caller-category Request backward signal is disjointed from the ANI request.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | <p>If <b>y</b>, the Send-ANI backward signal corresponds exclusively to the caller-category request. In response to this signal, Avaya MultiVantage sends a forward signal containing the caller-category information on outgoing calls. On incoming calls, Avaya MultiVantage sends the Send-ANI backward signal upon receipt of the first address signal.</p> |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Request CPN at Start of Call

This field appears only if the Incoming Call Type field is **group-ii-mfc**. Provides for the switch to collect ANI and call category immediately after receipt of the first address digit.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | <p>If <b>y</b>, provides ANI (Calling Party Number (CPN) and call category) immediately after receiving the first address digit.</p> |
|------------|--------------------------------------------------------------------------------------------------------------------------------------|

## Restart ANI from Caller Category

Display-only field.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                          |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | If <b>y</b> , Avaya MultiVantage sends the caller-category signal later again when the signals for Caller-Category and ANI requests are the same and this signal is received after the Next-Digit forward signals have been received. |

**Truncate Station Number in ANI**

This field applies to Russian shuttle trunks, and MFC and MFE trunks.

| <b>Valid entries</b>       | <b>Usage</b>                                                                                                                                                                                                                                                                                                                |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>beginning ending no</b> | This field defines the side of the extension number from which to truncate when station ANI is sent to the CO and the combined length of the ANI prefix and extension number is greater than Number of Outgoing ANI Digits. The ANI prefix (either MFC or COR) is not truncated. There is no effect if ANI for PBX is sent. |

**INCOMING / OUTGOING**

---

**ANI Available**

| <b>Valid entries</b>    | <b>Usage</b>                                                     |
|-------------------------|------------------------------------------------------------------|
| <b>1 to 15 or blank</b> | Enter the number of incoming and outgoing ANI-Available signals. |

**ANI Not Available**

You must enter a value if the ANI for PBX field is blank

| <b>Valid entries</b>    | <b>Usage</b>                                                                                                                                                                                                                                                                                                                 |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 15 or blank</b> | Enter the number of the incoming and outgoing ANI-Not-Available signals.<br><br>Your switch outputs the End-of-Dial backward signal when the ANI-Not-Available forward signal is received on incoming calls. Your switch outputs the ANI-Not-Available forward signal to the CO on outgoing calls where ANI is not possible. |

**Field descriptions for page 3**

The fields shown on Page 3 of the Multifrequency-Signaling-Related System Parameters screen define the meaning of MFC tones for calls originated at the CO. See “Definitions of Group I, II, A, and B signals” on page 1063 for more information. This screen appears only if the Incoming Call Type field is **group-ii-mfc** or **non-group-ii-mfc**.

When the screen initially appears, either of two sets of default values is possible. One set is for the group II call type; the other set is for non-group II call type. In each set, the default value for each field is set to the most common value.

Screen 238 shows the defaults when the Incoming Call Type field is **group-ii-mfc**. A variation appears if Incoming Call Type is **non-group-ii-mfc**. When Incoming Call Type is **non-group-ii-mfc**, group II and group B columns do not appear.

| INCOMING FORWARD SIGNAL TYPES<br>(Tones from CO) |            | INCOMING BACKWARD SIGNAL TYPES<br>(Tones to CO) |               |

### Definitions of Group I, II, A, and B signals

#### Group I signals

Group I signals are a set of forward signals generated by the originating switch.

##### **ani-avail**

Used in Hungary. If this signal is defined and ANI is requested on outgoing R2-MFC calls, ANI is sent to the CO before ANI caller digits are sent. This signal is sent after the ANI caller category signal.

### **ani-not-avail**

Used on DOD calls in Brazil and Columbia. The switch sends this signal to the CO when it receives an ANI request and the caller's number is not available.

### **digits 1 to 10**

The signals from group I.1 to I.10 are reserved for address digits 0 to 9.

### **drop**

When this signal is received from the CO, the switch starts the disconnect sequence and drops the call.

### **end-of-ani**

This signal is used on DOD and DID calls. The switch sends this signal to indicate the end-of-ANI digits when ANI digits are sent to the CO.

### **end-of-dial**

This signal is used when open numbering is used on DID calls. The CO sends this signal to indicate the end-of-dial digits and the switch responds with a request for a group II signal.

### **end-of-digits**

This signal is sent by the origination switch that makes outgoing calls, sends digits, and receives a next-digit group A signal from the destination switch when there are no more digits to be sent.

This signal is also sent when the switch does not have end-of-ani assigned, makes an outgoing call, sends ANI, and receives a call-info-ani group A signal from the destination switch when there are no more ANI digits to be sent.

If both end-of-digits and end-of-ani are assigned, the switch uses end-of-ani after it sends the last ANI digit and end-of-digits after sending the last called-number digit.

### **ignored**

If this signal is received from the CO, the switch sends a corresponding signal (A.1, and so on) but no action is taken in the response and it is not counted as a digit. In Belgium, this signal is not acknowledged.

### **maint-call**

The CO sends a signal to indicate that a call is a maintenance call and the switch prepares the special maintenance call sequences for the CO. This signal may be used on DID calls in Saudi Arabia.

### **send-congestion**

When the switch receives this signal from the CO on a DID call, it returns a congestion signal (group A), in compel (not pulse) mode, to the CO.

## **Group II signals**

Group II signals are a more elaborate set of forward signals generated by the originating switch.

### **attendant**

If the switch receives this signal on DID calls, the call terminates at an attendant regardless of the extension dialed. On DOD calls, this signal is sent to the CO if the CO requests calling-category information and the originating extension is an attendant. This signal is used on both DID and DOD calls.

### **busy-rt-attd**

If the switch receives this signal on DID calls, the call terminates at an attendant if the called extension is busy or at the called extension if it is not busy. This signal is used on DID calls.

### **data-call**

This signal is treated the same as the data-verify signal except that it does not require a terminating extension to be a data extension.

### **data-verify**

If the switch receives this signal on DID calls and the terminating extension is not a data extension, it sends intercept treatment. On DOD calls, this signal is sent to the CO if the CO requests calling-category information and the originating extension is a data extension. This signal is used on both DID and DOD calls.

### **drop**

When this signal is received from the CO, the switch starts the disconnect sequence and drops the call.

### **maint-call**

The CO sends a signal to indicate that a call is a maintenance call and the switch prepares the special maintenance call sequences for the CO.

### **normal**

This signal indicates that the caller is a normal subscriber. If it is received on a DID call, the call is terminated at the called extension. For an outgoing MF signaling call that uses group II signaling, this signal is sent to the CO when the CO requests calling-category information and the originating extension is a station. This signal is used in both DID and DOD calls.

### **send-intercept**

If the switch receives this signal from the CO on a DID call, it returns group B intercept signal to the CO.

### **toll-auto**

This signal is used in China. This signal indicates that a call is an automatic toll call. When the call terminates at a busy station and a special busy signal is defined, the busy signal is sent to the CO. You can define the special busy signal by choosing the option toll-busy on the incoming group B signals.

### **toll-operator**

This signal, used in China, is treated as a normal subscriber signal. See the normal definition.

## **Group A signals**

Group A signals are backward signals generated by the destination switch.

### **send-ani**

The CO sends this signal to request calling-party category and sends additional signals to request ANI digits. This signal is sent to the CO when Avaya MultiVantage requests ANI digits on DID calls. This signal is used on both DOD and DID calls.

### **congestion**

The CO sends this signal to indicate that it is experiencing network congestion. When the switch receives this signal on DOD calls, the switch drops the trunk and plays reorder tone to the calling party. This signal is used on DOD calls.

### **drop**

When this signal is sent, the receiving switch starts the disconnect sequence.

### **end-of-dial**

This signal is sent to indicate the end of the address digit string. For MF group II calls, this signal requests a group II signal and switches the sender over to the group B signaling mode. This signal is used on both DID and DOD calls.

### **intercept**

The CO sends this signal to indicate the call has been terminated to an invalid destination. When the switch receives this signal on DOD calls, the switch drops the trunk and plays intercept tone to the calling party. This signal is used on DOD calls.

### **resend-digit**

The switch sends this signal to adjust the outpulsing pointer so that the last digit can be resent again. This signal is used on DOD calls.

### **last-digit**

The switch sends this signal to adjust the outpulsing pointer so that the last 2 digits can be resent. This signal is used on DOD calls.

### **last-2-digits**

The switch sends this signal to adjust the outpulsing pointer so that the last 3 digits can be resent. This signal is used on DOD calls.

### **last-3-digits**

The switch sends this signal to adjust the outpulsing pointer so that the last 4 digits can be resent. This signal is used on DOD calls.

### **next-digit**

The switch sends this signal to request the next digit. This signal is used on both DID and DOD calls.

### **next-ani-digit**

The switch sends this signal to request the next ANI digit. This signal is used on DID and DOD calls.

### **restart**

The switch sends this signal to request the whole digit string again. This signal is used on DOD calls.

### **setup-sppath**

The CO sends this signal to the switch to set up a speech path. This signal is used on DOD calls and on DID calls in Belgium.

## Group B signals

Group B signals enhance group A signals for backward signaling from the destination switch by providing the status of the called party. In addition, if the originating switch uses group II signals, the destination switch answers with group B signals. Group B signals are as follows:

### **busy**

This signal is sent to indicate that the called party is busy. On DID calls, the signal is sent to the CO if there is no coverage point to terminate the call. If the switch receives this signal on DOD calls, it plays busy tone to the calling party and drops the trunk.

### **congestion**

This signal is sent to indicate that the system is congested and the call cannot be terminated successfully. On DID calls, the signal is sent to the CO to indicate that a resource is not available. On DOD calls, if the switch receives this signal, reorder tone is played to the calling party and the trunk is dropped.

### **free**

This signal indicates that the called party is idle. On DID calls, the signal is sent to the CO to indicate that the called party is idle and the call is terminated successfully. If the switch receives this signal on DOD calls, it connects the trunk to the calling party.

### **intercept**

This signal indicates that the called party number is not in service or is not correct. On DID calls, if intercept treatment is set to provide a tone, tone is sent to the CO to indicate that the called number is not valid. If the switch receives the signal on DOD calls, the switch plays intercept tone to the calling party and drops the trunk.

### **mct**

This signal identifies the call as one that needs to be traced by the CO. Avaya MultiVantage then generates an MFC Call Trace Backward Signal (administered on the Multifrequency-Signaling-Related System-Parameters screen) during call setup instead of the “free” signal. If the terminating station’s COR has this feature set to **y**, the CO collects trace information before releasing the calling party.

### **NOTE:**

If the station’s COR has MF Incoming Call Trace set to **y** and the “mct” signal is not defined, then the “free” signal is sent.

### **tariff-free**

This signal is sent when the trunk group provides an “800” service. Avaya MultiVantage generates an MFC tariff-free backward signal (administered on the System-Parameters Multifrequency-Signaling screen) during call setup instead of the “free” signal, facilitating CO billing.

#### **⇒ NOTE:**

If the trunk is administered as a tariff-free trunk and the “tariff-free” signal is not defined, then the “free” signal is sent.

### **tie-free**

This signal is used only when an incoming call is received and defined and the incoming facility is a tie trunk. Otherwise, the free signal is used.

### **toll-busy**

This signal, used in China, is sent to indicate that the called party is busy if the call is an automatic toll call.

## **Music Sources**

---

This screen defines music sources for Tenant Partitions. Each music source defined on the screen can be used by one or more Tenant Partitions. However, a partition may have only one music source.

#### **⇒ NOTE:**

If you use equipment that rebroadcasts music or other copyrighted materials, you may be required to obtain a copyright license from, or pay fees to, a third party such as the American Society of Composers, Artists, and Producers (ASCAP) or Broadcast Music Incorporated (BMI). You can purchase a Magic Hold<sup>®</sup> system, which does not require such a license, from Avaya.

### Screen 240. Music Sources

#### Description

Enter a description of the administered music source. This field appears only if you entered **music** or **tone** in Type.

#### NOTE:

When Tenant Partitioning is enabled, Music/Tone on Hold on the Feature-Related System Parameters screen disappears. However, the value in that field (tone, music, or none) will appear as the first entry on the Music Sources screen. If the value was **music**, the port number also appears on the Music Sources screen. When Tenant partitioning is disabled, Music/Tone on Hold reappears on the Feature-Related System Parameters screen, along with and the values from the Music Sources screen.

#### Valid entries

#### Usage

20 alpha-numeric character (maximum)

**Port**

Enter the auxiliary trunk or analog port address of the music source. Duplicates are not allowed. This field appears only if you entered **music** in Type. Enter the necessary characters.

| <b>Valid entries</b>                                                                                                                                                                   | <b>Usage</b>                                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <b>01 through 44</b><br>(DEFINITY R) or<br><b>01 through 03</b><br>(DEFINITY CSI, SI) or<br><b>1 through 64</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server) | First and second characters are the cabinet number |
| <b>A through E</b>                                                                                                                                                                     | Third character is the carrier                     |
| <b>0 through 20</b>                                                                                                                                                                    | Fourth and fifth character are the slot number     |
| <b>01 through 04</b><br>(Analog TIE trunks)<br><b>01 through 31</b>                                                                                                                    | Six and seventh characters are the circuit number  |
| <b>1 through 80</b><br>(DEFINITY R, CSI) or<br><b>1 through 10</b> (DEFINITY SI) or<br><b>1 through 250</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server)     | Gateway                                            |
| <b>V1 through V9</b>                                                                                                                                                                   | Module                                             |
| <b>01 through 31</b>                                                                                                                                                                   | Circuit                                            |

**Source**

Display only field - the number assigned to this source. The maximum number of music sources is 20 for DEFINITY CSI and SI and 100 for DEFINITY R. This screen appears with the appropriate pages to accommodate the number of music sources your system can support.

## Type

If you entered a value in Music/Tone on Hold on the Feature-Related System Parameters screen, that value will appear in this field.

| Valid entries | Usage                                                           |
|---------------|-----------------------------------------------------------------|
| <b>music</b>  | Enter the type of treatment to be provided by the music source. |
| <b>tone</b>   | Only one music source may use this value.                       |
| <b>none</b>   |                                                                 |

## Packet Gateway Board

Use this screen to administer the Packet Gateway (PGATE) circuit pack.

### ⇒ NOTE:

The PGATE screen is used with DEFINITY R configurations.

## Field descriptions for page 1

```
change pgate xxxxx
 PACKET GATEWAY BOARD
Board Location: _____ Name: _____
Application: X.25
External cable type: rs232
Port configuration: 1) rs232 2)rs232 3)rs232 4)rs232
```

Page 1 of 1

### Screen 241. Packet Gateway Board screen

## Application

Display-only field that shows the communications protocol used to transmit messages over the PGATE.

## Board Location

Enter the slot location of the PGATE circuit pack.

| Valid entries | Usage                                                   |
|---------------|---------------------------------------------------------|
| <b>1-x</b>    | cabinet (Maximum value varies according to switch type) |
| <b>A-E</b>    | carrier                                                 |
| <b>0-20</b>   | slot                                                    |

### External Cable Type

Display-only field that shows the type of physical interface between the PGATE port and the adjunct.

#### Name

| Valid entries                    | Usage                                                                         |
|----------------------------------|-------------------------------------------------------------------------------|
| Up to 15 alphanumeric characters | Enter the name of the adjunct with which the PGATE circuit pack communicates. |

### Port Configuration

Display-only field that shows that the port is configured for “rs232” communication.

## Partition Route Table

Use this table to identify routing for partition groups associated with an ARS analysis entry.

| change partition route-table |                  |       |       |       |       |       |       |       | Page 1 of X |

**Screen 243. Personal CO Line Group**

The following fields are unique to this screen.

### Analog Loss Group

This field determines which administered 2-party row in the loss plan applies to this trunk group if the call is carried over an analog signaling port in the trunk group.

| <b>Valid entries</b> | <b>Usage</b>                                       |
|----------------------|----------------------------------------------------|
| 1 to 17              | Shows the values from the loss plan and tone plan. |

### Coverage Path

| <b>Valid entries</b> | <b>Usage</b>                                                                                    |
|----------------------|-------------------------------------------------------------------------------------------------|
| 1 to 9999            | Enter the number of the call coverage path you want to use for incoming calls.                  |
| t1 to t999           | Enter the number of a time-of-day table.                                                        |
| blank                | Assigning a coverage path is optional: leave this field blank if you do not want to assign one. |

### Digital Loss Group

This field determines which administered 2-party row in the loss plan applies to this trunk group if the call is carried over a digital signaling port in the trunk group.

| <b>Valid entries</b> | <b>Usage</b>                                       |
|----------------------|----------------------------------------------------|
| 1 to 17              | Shows the values from the loss plan and tone plan. |

### DS1 Echo Cancellation

Allows you to administer echo cancellation per channel.

| <b>Valid entries</b> | <b>Usage</b>                                             |
|----------------------|----------------------------------------------------------|
| y/n                  | Enter <b>y</b> to activate echo cancellation capability. |

### Security Code

| <b>Valid entries</b> | <b>Usage</b>                                                                                                      |
|----------------------|-------------------------------------------------------------------------------------------------------------------|
| 4 digits             | Enter a 4-digit code that users must dial to retrieve voice messages and to use the Demand Print Message feature. |
| blank                | Leave this field blank if you do not want to use a security code to control access.                               |

## Trunk Direction

| Valid entries   | Usage                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>incoming</b> | Enter the direction of the traffic on this trunk group. The entry in this field affects which timers appear on the Administrable Timers page. For WATS Group Types, only <b>incoming</b> or <b>outgoing</b> may be entered. |
| <b>outgoing</b> |                                                                                                                                                                                                                             |
| <b>two-way</b>  |                                                                                                                                                                                                                             |

## Trunk Name

| Valid entries      | Usage                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 to 10 characters | Enter a descriptive name for this trunk. Don't use the group type (CO, FX, WATS) here. For example, you might use names that identify the vendor and function of the trunk group: USWest Local; Sprint Toll, etc. |
| blank              |                                                                                                                                                                                                                   |

## Trunk Port

Enter the necessary characters.

| Valid entries                                                                                                                                                                                               | Usage                                              |

### Screen 244. Personal CO Line Group

#### Ext

This display-only field shows the extension of phones that have a CO Line button.

#### Name

This display-only field shows the name assigned to phones that have a CO Line button.

### Field descriptions for page 3

---

Administrable timers for Personal CO Line groups appear on Field descriptions for page 3. See [“Trunk Group” on page 1233](#) for standard field definitions of the available timers.

## Related topics

---

See [“Adding a PCOL trunk group” on page 420](#) for instructions.

See [“Trunk Group” on page 1233](#) for definitions of all trunk group fields that are *not* unique to the PCOL screen.

## Pickup Group

This screen implements call pickup groups with up to 50 extensions per group. A pickup group is a group of users authorized to answer calls to a phone extension within that group of users. A phone extension number can only belong to one pickup group.

### Screen 245. Pickup Group

#### Ext

Enter the extension assigned to a station.

#### Valid entries

An extension number.

#### Usage

A VDN cannot be assigned to a Call Pickup group.

## Extended Group Number

This field appears only when the Group Call Pickup field is set to **flexible** on the Feature-Related System Parameters screen. The extended group is a collection of pickup groups that can answer calls from other pickup groups in the same extended group.

|  | Enter a Pickup Group number when completing a paper screen. |
|--|-------------------------------------------------------------|

## Name

This display-only field shows the name assigned to the above extension number when the users and their associated extensions were administered.

## PRI Endpoint

---

This screen administers PRI Endpoints for the Wideband Switching feature.

 **NOTE:**

A PRI Endpoint with a width greater than 1 may be administered only if the Wideband Switching feature has been enabled on the System-Parameters Customer-Options screen.

A PRI Endpoint is an endpoint application connected to line-side ISDN-PRI facilities and has standard ISDN-PRI signaling interfaces to the system. For information on endpoint applications connected to line-side non-ISDN T1 or E1 facilities, see [“Access Endpoint” on page 593](#) in this module.

A PRI Endpoint is defined as 1–31 adjacent DS0s/B-channels, addressable via a single extension, and signaled via a D-channel (Signaling Group) over a standard T1 or E1 ISDN-PRI interface.

**Screen 246. PRI Endpoint**

**COR**

| Valid entries | Usage                                                                             |
|---------------|-----------------------------------------------------------------------------------|
| 0 to 95       | Enter class of restriction (COR) to determine calling and called party privileges |

**COS**

| Valid entries | Usage                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------------|
| 0 to 15       | Enter the Class of Service (COS) to determine the features that can be activated by, or on behalf of, the endpoint. |

**Extension**

A display-only field when the screen is accessed using an administration command such as **change** or **display**.

| Valid entries | Usage                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------|
|               | This is the extension number used to access the PRI endpoint. Enter a valid unassigned extension number when completing a paper screen. |

## Maintenance Tests

| Valid entries | Usage                                                                |
|---------------|----------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to run hourly maintenance tests on this PRI Endpoint. |

## Name

Identifies the endpoint.

| Valid entries                     | Usage |
|-----------------------------------|-------|
| Up to 27 alphanumeric characters. |       |

## Originating Auto Restoration

| Valid entries | Usage                                                                                                                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to automatically restore calls originating from this PRI Endpoint (while maintaining endpoint call status) in the case of network failure if the call is over SDDN network facilities. |

## Signaling Group

| Valid entries                                                                                               | Usage                                                                                                                                      |
|-------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 1 to 416 or blank<br>(DEFINITY R,<br>S8300 Media<br>Server, S8700<br>IP-Connect,<br>S8700<br>Multi-Connect) | Enter the D-channel or D-channel pair that will provide the signaling information for the set of B-channels that make up the PRI Endpoint. |
| 1 to 110 or blank<br>(DEFINITY CSI,<br>SI)                                                                  |                                                                                                                                            |

## Simultaneous Calls

| Valid entries | Usage                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to specify that multiple simultaneous calls can be placed to/from the PRI Endpoint. |

**(Starting) Port**

Enter the seven-character starting port of the PRI Endpoint. Enter the necessary characters.

| <b>Valid entries</b>                                                                                                                                                                                        | <b>Usage</b>                                       |

**TN**

| <b>Valid entries</b>                                                                 | <b>Usage</b>                       |
|--------------------------------------------------------------------------------------|------------------------------------|
| <b>1–20</b> (DEFINITY CSI, SI)                                                       | Enter the Tenant Partition number. |
| <b>1–100</b> (DEFINITY R, S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect) |                                    |

**Width**

Enter the number of adjacent DS0 ports beginning with the specified Starting Port, that make up the PRI Endpoint. This field cannot be blank.

| <b>Valid entries</b>  | <b>Usage</b>                                                                           |
|-----------------------|----------------------------------------------------------------------------------------|
| <b>1</b> to <b>31</b> | A width of <b>6</b> defines a PRI Endpoint that can support data rates up to 384 Kbps. |

---

## WIDEBAND SUPPORT OPTIONS

---

### Contiguous

Specifies whether to hunt contiguous NXDS0 channels. This field only appears if **y** is entered in NXDS0. The hunt algorithm to satisfy an NXDS0 call is as follows:

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to specify the “floating” scheme. NXDS0 calls are placed on a contiguous group of B-channels large enough to satisfy the requested bandwidth without constraint on the starting channel (no fixed starting point trunk).                     |
| <b>n</b>             | Enter <b>n</b> to specify the “flexible” scheme. NXDS0 calls are placed on any set of B-channels on the same facility as long as the requested bandwidth is satisfied. There are no constraints, such as contiguity of B-channels or fixed starting points. |

### H0

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                     |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to specify the ISDN information transfer rate for 384 Kbps of data, which is comprised of six B-channels. When a PRI Endpoint is administered to support H0, the hunt algorithm to satisfy a call requiring 384 Kbps of bandwidth uses a fixed allocation scheme. |

### H11

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                       |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to specify the ISDN information transfer rate for 1536 Kbps of data, which is comprised of 24 B-channels. When a PRI Endpoint is administered to support H11, the hunt algorithm to satisfy a call requiring 1536 Kbps of bandwidth uses a fixed allocation scheme. |

## Sig Grp

| Valid entries | Usage                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------|
| 1 through 110 | Enter the assigned signaling group number for DEFINITY CSI, SI.                                          |
| 1 through 416 | Enter the assigned signaling group number for DEFINITY R.                                                |
| 1 through 650 | Enter the assigned signaling group number for S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect. |

## Subscriber Number

You can enter up to 28 subscriber numbers.

| Valid entries            | Usage                                                                                                                   |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------|
| 0 through 9, *, 'x', 'X' | Enter a subscriber number up to 20 characters in length. You can use wildcards 'x' and 'X' to enter subscriber numbers. |

## TSC Index

You must complete the TSC Index field for each machine ID.

| Valid entries     | Usage                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------|
| 1 through 64      | Enter the assigned signaling group number for <b>qsig-mwi</b> application type on the Signaling Group screen. |
| 0 through 9, *, # | Enter up to 4-digit access code.                                                                              |

## Remote Access

The Remote Access screen is used to implement the Remote Access feature. Remote Access permits a caller located outside the system to access the system through the public or private network and then use the features and services of the system.

Remote Access users can dial into the system using central office (CO), Foreign Exchange (FX), Wide Area Telecommunications trunks (WATS), and Integrated Services Digital Network Primary Rate Interface (ISDN-PRI) trunks. In addition, a dedicated Remote Access Direct Inward Dialing number can be provided.

 **SECURITY ALERT:**

*Avaya designed the Remote Access feature incorporated in this product that, when properly administered by the customer, enables the customer to minimize the ability of unauthorized persons to gain access to the network. It is the customer's responsibility to take the appropriate steps to properly implement the features, evaluate and administer the various restriction levels, protect access codes and distribute them only to individuals who have been advised of the sensitive nature of the access information. Each authorized user should be instructed concerning the proper use and handling of access codes.*

*In rare instances, unauthorized individuals make connections to the telecommunications network through use of remote access features. In such an event, applicable tariffs require the customer pay all network charges for traffic. Avaya cannot be responsible for such charges, and will not make any allowance or give any credit for charges that result from unauthorized access.*

To ensure the security of your system, consider the following:

- Make all remote access facilities unlisted directory telephone numbers.
- Require users to enter a Barrier Code of at least seven random digits AND an Authorization Code of at least 13 random digits to make network calls.
- Make Authorization Codes nonconsecutive (random) and change them, at least, quarterly.
- Deactivate Authorization Codes immediately if the user leaves the company or changes assignments.
- Assign the minimum level of calling permissions required to each Authorization Code.
- Block off-hours and weekend remote access calling, when possible. Use Alternative Facility Restriction Levels, if available.
- Use a voice recording, warble tone, or no tone and avoid use of a dial tone as a prompt when the remote access unit answers.
- Assign the lowest possible FRL to only allow internal switch calls.

As an additional step to ensure System security, you can permanently disable the Remote Access feature if you do not intend to use it now or in the future. If you do decide to permanently disable the feature, it will require Avaya Services intervention to activate the feature again.

**CAUTION:**

*Your attempt to disable the Remote Access feature will be lost if the switch is rebooted without saving translations. Therefore, execute a “save translation” command after permanently disabling the Remote Access feature.*

To assist you in maintaining the security of your system, Avaya MultiVantage provides the status remote access command, which provides status and information on each remote access barrier code and on the remote access feature. A sample Status Remote Access screen follows the Remote Access screen.

**Screen 249. Remote Access Status**

**Authorization Code Required**

When you use an authorization code in conjunction with a barrier codes it increases the security of the Remote Access feature.

**Valid entries**

**Usage**

**y/n** Enter **y** to require an authorization code be dialed by Remote Access users to access the system's Remote Access facilities.

**Barrier Code**

You must assign a barrier code that conforms to the number entered in the Barrier Code Length field. You may enter up to 10 barrier codes per system. Duplicate entries are not allowed. You must keep your own records regarding the distribution of these barrier codes to your personnel.

**Valid entries**

**Usage**

**0 to 9 or blank** Enter a 4- to 7-digit number in any combination of digits.

**none** Must be specified in the first Barrier Code field, if the Barrier Code Length field is blank.

## Barrier Code Length

Assign a barrier code length of 7 to provide maximum security.

| <b>Valid entries</b> | <b>Usage</b>                                               |
|----------------------|------------------------------------------------------------|
| 4 to 7 or blank      | Enter a number to indicate the length of the barrier code. |

## Calls Used

This display-only field shows the number of calls placed using the corresponding barrier code. This field is incremented each time a barrier code is successfully used to access the Remote Access feature. A usage that exceeds the expected rate indicates improper use.

## COR

Assign the most restrictive class of restriction (COR), that provides only the level of service required, to provide the maximum security.

| <b>Valid entries</b> | <b>Usage</b>                                                                                      |
|----------------------|---------------------------------------------------------------------------------------------------|
| 0 to 95              | Enter the COR number associated with the barrier code that defines the call restriction features. |

## COS

Assign the most restrictive class of service (COS), that provides only the level of service required to provide the maximum security.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                          |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| 0 to 15              | Enter the COS number, associated with the barrier code, that defines access permissions for Call Processing features. |

## Disable Following a Security Violation

This field appears on the screen when the SVN Authorization Code Violation Notification Enabled field on the Security-Related System Parameters screen is set to **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n                  | Enter <b>y</b> to disable the remote access feature following detection of a remote access security violation. The system administrator can re-enable Remote Access using the enable remote access command. |

## Expiration Date

Assign an expiration date based on the expected length of time the barrier code will be needed. If it is expected the barrier code is to be used for a 2-week period, assign a date two weeks from the current date. If the Expiration Date is assigned, a warning message is displayed on the system copyright screen seven days prior to the expiration date. The system administrator can modify the expiration date to extend the time interval if needed.

| <b>Valid entries</b>                          | <b>Usage</b>                                        |
|-----------------------------------------------|-----------------------------------------------------|
| A date greater than the current date or blank | Enter the date you want the barrier code to expire. |

## No. of Calls

The Expiration Date and No. of Calls fields can be used independently or in conjunction to provide the maximum security. If both the Expiration Date and No. of Calls fields are assigned, the corresponding barrier code expires when the first of these criteria is satisfied.

| <b>Valid entries</b>    | <b>Usage</b>                                                                                  |
|-------------------------|-----------------------------------------------------------------------------------------------|
| 1 through 9999 or blank | Enter the number of Remote Access calls that can be placed using the associated barrier code. |

## Permanently Disable

Reactivation of remote access to the interface requires Avaya Services intervention.

| <b>Valid entries</b> | <b>Usage</b>                                                                       |
|----------------------|------------------------------------------------------------------------------------|
| y/n                  | Enter <b>y</b> to permanently block remote access to the administration interface. |

## Remote Access Dial Tone

Set this field to **n** for maximum security. This field appears when the Authorization Code Required field is set to **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                       |
|----------------------|--------------------------------------------------------------------|
| y/n                  | Enter <b>n</b> so that there is no Remote Access Dial Tone prompt. |

## Remote Access Extension

The remote access extension is used as if it was a DID extension. Only one DID extension can be assigned as the remote access extension. Calls to that number are treated the same as calls on the remote access trunk.

When a trunk group is dedicated to Remote Access, the remote access extension number is administered on the trunk group's incoming destination field.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                          |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Extension number     | Enter the extension number for Remote Access associated with each trunk that supports the Remote Access feature. You cannot assign a Vector Directory Number (VDN) extension as the remote access extension.<br><br>May be blank if no barrier codes. |

## TN

| <b>Valid entries</b>                                                                        | <b>Usage</b>                                   |
|---------------------------------------------------------------------------------------------|------------------------------------------------|
| <b>1 to 20</b><br>(DEFINITY CSI, SI)                                                        | Enter the appropriate Tenant Partition number. |
| <b>1 to 100</b><br>(DEFINITY R, S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect)) |                                                |

## Related Topics

See [“Setting up remote access” on page 370](#) for step-by-step instructions for configuring remote access.

## Remote Call Coverage Table

The Remote Call Coverage Table allows you to provide automatic redirection of certain calls to alternate non-local answering positions in a coverage path.

Non-local numbers may be any ARS or AAR number, any number on the public network, any international number, or a UDP/DCS extension up to 16 digits or blank, which includes any ARS/AAR facility access code, any trunk dial access code (TAC), long distance dialing code, or international dial code. Up to 999 remote call coverage points can be entered on the 23 pages of this screen.

**Screen 252. RHNPA Table**

**CODES**

Display-only field showing the desired 100-block, for example 000 through 099 or 900 through 999 based upon the **change rhnpa** command. A separate screen displays for each 100-block.

**Code-Pattern Choice Assignments**

| Valid entries | Usage                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| 1 through 12  | Enter a Pattern Choice number from the list above to choose the route pattern for each prefix code. For Server R. |
| 1 through 24  | For S8700 IP-Connect.                                                                                             |

## Pattern Choices

There are 12 pattern choices for DEFINITY R, CSI, SI, S8100 Media Server with a G600, and S8100 Media Server with a CMC1; there are 24 pattern choices for the S8300 Media Server, S8700 IP-Connect, and S8700 Multi-Connect. Enter the route pattern number you want associated with each code. The pattern choice you list on one screen automatically defaults to the other screens of the same table. If you use one pattern for most of the codes, assign that pattern to choice 1.

| <b>Valid entries</b>  | <b>Usage</b>                                                                        |
|-----------------------|-------------------------------------------------------------------------------------|
| <b>1-640</b> or blank | For DEFINITY R, S8100 Media Server with a G600, and S8100 Media Server with a CMC1. |
| <b>1-999</b> or blank | For S8300 Media Server, S8700 IP-Connect, and S8700 Multi-Connect                   |
| <b>1-254</b>          | For DEFINITY SI and CSI.                                                            |

## RHNPA TABLE

Display-only field indicating the table number.

## Route Pattern

---

The Route Pattern screen defines the route patterns used by your switch. Each route pattern contains a list of trunk groups that can be used to route the call. The maximum number of route patterns and trunk groups allowed depends on the configuration and memory available in your system.

Use this screen to insert or delete digits so AAR or ARS calls route over different trunk groups. You can convert an AAR number into an international number, and insert an area code in an AAR number to convert an on-network number to a public network number. Also, when a call directly accesses a local central office (CO), if the long-distance carrier provided by your CO is not available, your switch can insert the dial access code for an alternative carrier into the digit string.

| change route-pattern 1 |     |     |     |     |      |     |          |       |      |      |        |  |  |  | Page 1 of X        |      |  |      |  |

| 1:  | y     | y | y | y | n | y   | none   | ---     | both | ept  | outwats-bnd     | ---  | --- | ---       | none |
| 2:  | y     | y | y | y | n | y   |        |         | rest |      | _____           | ---  | --- | ---       | next |
| 3:  | y     | y | y | y | n | y   |        |         | rest |      | _____           | ---  | --- | ---       | rehu |
| 4:  | y     | y | y | y | n | y   |        |         | rest |      | _____           | ---  | --- | ---       | none |
| 5:  | y     | y | y | y | n | y   |        |         | rest |      | _____           | ---  | --- | ---       | none |
| 6:  | y     | y | y | y | n | y   |        |         | rest |      | _____           | ---  | --- | ---       | none |

**Screen 253. Route Pattern**

**Band**

Enter a number that represents the OUTWATS band number (US only).

WATS is a voice-grade service that provides both voice and low-speed data transmission calls to defined areas (bands) for a flat rate charge.0

This field appears when the Services/Features field is **outwats-bnd** and when ISDN-PRI or ISDN-BRI Trunks field is **y** on the System-Parameters Customer-Options screen. Band is required by Call-by-Call Service Selection.

**BCC Value**

Bearer Capability Class (BCC) identifies the type of call appropriate for this trunk group, such as voice calls and different types of data calls. This field appears when the ISDN-PRI or ISDN-BRI Trunks field is **y** on the System-Parameters Customer-Options screen.

**Valid entries      Usage**

**y/ n**      Enter **y** in appropriate BCC column (0, 1, 2, 3, 4, or W) if the BCC is valid for the associated route pattern. A trunk group preference may have more than one BCC.

The following table explains BCC values:

| <b>BCC Value</b> | <b>Description</b>               |
|------------------|----------------------------------|
| 0                | Voice-Grade Data and Voice       |
| 1                | 56-kbps Data (Mode 1)            |
| 2                | 64-kbps Data (Mode 2)            |
| 3                | 64-kbps Data (Mode 3)            |
| 4                | 64-kbps Data (Mode 0)            |
| W                | 128 to 1984-kbps Data (Wideband) |

### **BCIE (Bearer Capability Information Element)**

Use BCIE to determine how to create the ITC codepoint in the setup message. This field applies to ISDN trunks and appears if ITC is **both**.

| <b>Valid entries</b>      | <b>Usage</b> |
|---------------------------|--------------|
| <b>ept</b> (endpoint)     |              |
| <b>unr</b> (unrestricted) |              |

### **CA-TSC Request**

Use CA-TSC on ISDN B-channel connections.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                        |
|----------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>as-needed</b>     | The CA-TSC is set up only when needed. This causes a slight delay. Avaya recommends this entry for most situations. |
| <b>at-setup</b>      | The CA-TSC is automatically set up for every B-channel call whether or not it is needed.                            |
| <b>none</b>          | No CA-TSC is set up. Permits tandeming of NCA-TSC setup requests0.                                                  |

### **DCS/QSIG Intw**

This field only appears if the Interworking with DCS field on the System-Parameters Customer-Options screen is set to **y**.

| <b>Valid entries</b> | <b>Usage</b>                                    |
|----------------------|-------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to enable DCS/QSIG Interworking. |

**FRL**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 7</b>        | Enter the Facility Restriction Level (FRL) associated with the entries on this row (preference). 0 is the least restrictive and 7 is the most restrictive. The calling party's FRL must be greater than or equal to this FRL to access the associated trunk-group. |

**SECURITY ALERT:**

*For system security reasons, Avaya recommends using the most restrictive FRL possible.*

**Grp No**

| <b>Valid entries</b> | <b>Usage</b>                                                                                 |
|----------------------|----------------------------------------------------------------------------------------------|
| <b>1 to 666</b>      | Enter the trunk group number associated with this row (preference). For DEFINITY R, CSI, SI. |
| <b>1 to 2000</b>     | For S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect.                               |

**Hop Lmt**

Enter the number of hops for each preference. A hop is when a call tandems through a switch to another destination. Limiting the number of hops prevents circular hunting, which ties up trunk facilities without ever completing the call. Avaya MultiVantage blocks a hop equal to or greater than the number you enter.

| <b>Valid entries</b> | <b>Usage</b>                                                                |
|----------------------|-----------------------------------------------------------------------------|
| blank                | Indicates that there is no limit to the number of hops for this preference. |
| <b>1 to 9</b>        | To limit the number of hops if using the tandem hop feature.                |
| <b>1 to 32</b>       | If using the transit feature.                                               |

## Inserted Digits

Enter the digits you want inserted for routing. The switch can send up to 52 digits. This includes up to 36 digits you may enter here plus up to 18-digits originally dialed. Special symbols count as two digits each.

| Valid entries  | Usage                                                                                                                                                                                                                                                |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| (0 to 9)       | Enter the digits you want inserted for routing.                                                                                                                                                                                                      |
| 0 to 36 digits |                                                                                                                                                                                                                                                      |
| *              | When * is in the route pattern and the outgoing trunk is signaling type "mf", the MFC tone for the "end-of-digits" is sent out to the CO in place of the *.                                                                                          |
| #              | When # is in the route pattern and the outgoing trunk is signaling type "mf", the MFC tone for the "end-of-digits" is sent out to the CO in place of the #.                                                                                          |
| ','            | Use 2 places. Creates a 1.5 second pause between digits being sent. Do not use as the first character in the string unless absolutely necessary. Misuse can result in some calls, such as Abbreviated Dialing or Last Number Dialed, not completing. |
| +              | Wait for dial tone up to the Off Premises Tone Detection Timer and then send digits or intercept tone based on Out Pulse Without Tone y/n on the Feature-Related System Parameters screen.                                                           |
| %              | Start End-to-End Signaling.                                                                                                                                                                                                                          |
| !              | Wait for dial tone without timeout and then send DTMF digits.                                                                                                                                                                                        |
| &              | Wait for ANI (used for Russian pulse trunks)                                                                                                                                                                                                         |

## ITC (Information Transfer Capability)

Use Information Transfer Capability (ITC) to identify the type of data transmission or traffic that this routing preference can carry. The ITC applies only to data calls (BCC 1 through 4).

This field must be **unre** or **both** if the BCC is **y** and the BCC value is **W**

| Valid entries          | Usage                                                                          |
|------------------------|--------------------------------------------------------------------------------|
| <b>both</b>            | Calls from restricted and unrestricted endpoints can access the route pattern. |
| <b>rest(ri</b> cted)   | Calls from restricted endpoints can access the route pattern.                  |
| <b>unre(</b> stricted) | Calls from unrestricted endpoints can access the route pattern.                |

## IXC

Inter-Exchange Carrier (IXC) identifies the carrier, such as AT&T, used for calls that route via an IXC, and for Call Detail Recording (CDR).

This field appears when the ISDN-PRI or ISDN-BRI Trunks field is **y** on the System-Parameters Customer-Options screen.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                         |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Valid carrier code   | Identifies the carrier for IXC calls                                                                                                                                                                                 |
| <b>user</b>          | For presubscribed carrier. Used when an IXC is not specified.                                                                                                                                                        |
| <b>none</b>          | This field must be <b>none</b> for non-ISDN trunk groups and for Bellcore NI-2 Operator Service Access. If you need to send an IXC code for a non-ISDN trunk group, enter the IXC code in the Inserted Digits field. |

## LAR

Enter the routing-preference for Look Ahead Routing.

| <b>Valid entries</b> | <b>Usage</b>                                                                              |
|----------------------|-------------------------------------------------------------------------------------------|
| <b>next</b>          | Go to the next routing preference and attempt the call again.                             |
| <b>rehu</b>          | Rehunt within the current routing-preference for another trunk to attempt the call again. |
| <b>none</b>          | Look Ahead Routing is not enabled for the preference.                                     |

## No. Del. Digits

Use this field to modify the dialed number so an AAR or ARS call routes over different trunk groups that terminate in switches with different dial plans

| <b>Valid entries</b>    | <b>Usage</b>                                                                                                                                                                                                                                                                                                                            |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 28</b> or blank | Enter the total number of digits you want the system to delete before it sends the number out on the trunk. Use for calls that route: <ul style="list-style-type: none"><li>■ to or through a remote switch</li><li>■ over tie trunks to a private network switch</li><li>■ over Central Office (CO) trunks to the serving CO</li></ul> |

## No. Dgts Subaddress

Allows a caller to reach a number where switch digit processing deletes the dialed number and inserts the listed directory number (LDN). The LDN then is sent to the destination address and the dialed extension is sent in the calling party subaddress information element (IE). At the receiving end, the call terminates to the user indicated by the subaddress number instead of the attendant.

Administrable when, on the System-Parameters Customer-Option screen, the ISDN Feature Plus field is **y**.

### Valid entries

### Usage

| Valid entries | Usage                                                                         |
|---------------|-------------------------------------------------------------------------------|
| 1 through 5   | Enter the number of dialed digits to send in the calling party subaddress IE. |
| blank         |                                                                               |

## NPA

This entry is not required for AAR.

### Valid entries

### Usage

| Valid entries  | Usage                                                                                                                                                                                                                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3-digit number | Enter the 3-digit Numbering Plan Area (NPA) (or area code) for the terminating endpoint of the trunk group. Call your local telephone company to verify this number if you need help.<br><br>For WATS trunks, the terminating NPA is the same as the home NPA unless the Local Exchange Carrier requires 10 digits for local NPA calls. |
| blank          | For AAR calls and for tie trunks                                                                                                                                                                                                                                                                                                        |

## Numbering Format

This field applies only to ISDN trunk groups. Enter a value from table below. This field specifies the format of the routing number used for the trunk group for this preference.

This field appears when the ISDN-PRI or ISDN-BRI Trunks field is **y** on the System-Parameters Customer-Options screen.

| Valid entries | Numbering Plan Identifier | Type of Numbering   |
|---------------|---------------------------|---------------------|
| blank         | E.164(1)                  | 1-MAX               |
| natl-pub      | E.164(1)                  | national(2)         |
| intl-pub      | E.164(1)                  | international(1)    |
| locl-pub      | E.164(1)                  | local/subscriber(4) |

| Valid entries                                                             | Numbering Plan Identifier       | Type of Numbering   |
|---------------------------------------------------------------------------|---------------------------------|---------------------|
| pub-unk                                                                   | E.164(1)                        | unknown(0)          |
| lev0-pvt                                                                  | Private Numbering Plan - PNP(9) | local(4)            |
| lev10-pvt<br>(enter to allow<br>Network Call<br>Redirection/<br>Transfer) |                                 |                     |
| lev1-pvt                                                                  | Private Numbering Plan - PNP(9) | Regional Level 1(2) |
| lev2-pvt                                                                  | Private Numbering Plan - PNP(9) | Regional Level 2(1) |
| unk-unk                                                                   | unknown(0)                      | unknown(0)          |

**⇒ NOTE:**

To access Bellcore NI-2 Operator Service Access, the Inserted Digits field must be **unk-unk**.

### Pattern Number

This display-only field shows the route pattern number (**1 to 640**).

### Prefix Mark

This entry is not required for AAR. For ARS, enter a number from **0 to 4** or blank.

Prefix Marks set the requirements for sending a prefix digit 1, indicating a long-distance call. Prefix Marks apply to 7- or 10-digit Direct Distance Dialing (DDD) public network calls. A prefix digit 1 is sent only when call type is foreign number plan area (FNPA) or home numbering plan area (HNPA) in the ARS Digit Analysis table.

For a WATS trunk, the Prefix Mark is the same as the local CO trunk.

**Valid entries**

**Usage**

- 
- 0**
    - Suppress a user-dialed prefix digit 1 for 10-digit FNPA calls.
    - Leave a user-dialed prefix digit 1 for 7-digit HNPA calls.
    - Leave a prefix digit 1 on 10-digit calls that are not FNPA or HNPA calls.

Do not use Prefix Mark 0 in those areas where all long-distance calls must be dialed as 1+10 digits. Check with your local network provider.
  - 1**
    - Send a 1 on 10-digit calls, but not on 7-digit calls.

Use Prefix Mark 1 for HNPA calls that require a 1 to indicate long-distance calls.
  - 2**
    - Send a 1 on all 10-digit and 7-digit long-distance calls.

Prefix Mark 2 refers to a Toll Table to define long distance codes.
  - 3**
    - Send a 1 on all long-distance calls and keep or insert the NPA (area code) so that all long distance calls are 10-digit calls. The NPA is inserted when a user dials a Prefix digit 1 plus 7-digits.

Prefix Mark 3 refers to a Toll Table to define long distance codes.
  - 4**
    - Always suppress a user-dialed Prefix digit 1.

Use Prefix Mark 4, for example, when ISDN calls route to a switch that rejects calls with a prefix digit 1.
  - blank** For tie trunks, leave this field blank.

**Service/Feature**

Enter up to 15 characters to identify the Service/Feature carried by the information element (IE) in a call in this route pattern. This field is required by Call-by-Call Service Selection, and Network Call Redirection and Transfer.

Service/Feature appears when ISDN-PRI or ISDN-BRI Trunks is **y** on the System-Parameters Customer-Options screen.

**Valid entries**

|------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to allow Call-Associated TSCs, and to allow incoming Non-Call-Associated TSC requests to be tandemed out for each preference. |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------|

**Security-Related System Parameters**

You use this screen to determine when the switch reports a security violation. Many of the fields on this screen repeat for each type of security violation. We have explained them once here, but the usage is the same for all. See *“Security violations notification” on page 1813* for more information on security violations notification.

#### SECURITY VIOLATION NOTIFICATION PARAMETERS

#### SVN Login (Violation Notification, Remote Access, Authorization Code) Enabled

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|     |                                                                                                                                                                                                                           |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n | Set to <b>y</b> if you want the switch to notify you when a login violation occurs. If this field is <b>y</b> , the next 5 fields appear so you can establish the parameters for what is considered a security violation. |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

#### Announcement Extension

If you enter a value in this field, the switch calls the referral destination, then plays this announcement upon answer.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                 |                                                                      |
|-----------------|----------------------------------------------------------------------|
| Valid extension | The announcement extension where SVN violation announcement resides. |
|-----------------|----------------------------------------------------------------------|

## Login (Barrier Code, Authorization Code) Threshold

The value assigned to this field, in conjunction with Time Interval, determines whether a security violation has occurred. For example, if this field is 5, and time interval is 0:03, then five invalid access attempts within three minutes constitutes a security violation.

| <b>Valid entries</b>                               | <b>Usage</b>                                                                                                                                                                                                                                     |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1–99, 1–255</b><br>for Station<br>Security code | Enter the number of access attempts that are permitted before a referral call is made. In general, it is good to keep this number low. If you are doing testing and do not want to generate alarms, you might change this threshold temporarily. |

## Originating Extension

The originating extension initiates the referral call in the event of a security violation. It also sends the appropriate alerting message or display to the referral destination.

| <b>Valid entries</b>    | <b>Usage</b>                                                                                                                                                                                                                                                           |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| An unassigned extension | If you establish notification for more than one type of security violations, you must assign a different extension to each one. When the switch generates a referral call, this extension and the type of violation appear on the display at the referral destination. |

## Referral Destination

The referral destination receives the referral call when a security violation occurs. The referral destination telephone must have a display, unless the you assign an Announcement Extension.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| An extension         | Enter the extension of the telephone, attendant console, or vector directory number (VDN) that you want to receive the referral call for each type of violation. This can be the same extension for all type of violations.<br><br>If you use a VDN, you must complete the Announcement Extension field. You can also use Call Vectoring Time-of-Day routing to route the referral call to different destinations based on the time of day or the day of the week. |

## Time Interval

The value of this field, in conjunction with Threshold, determines whether a security violation has occurred.

| Valid entries | Usage                                                                                                                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0:01 to 7:59  | The range for the time interval is one minute to eight hours. Entered in the screen "x:xx." For example, if you want the time interval to be one minute, you enter 0:01. If you want the time interval to be seven and one-half hours, you enter 7:30. |

## SVN Remote Access Violation Notification Enabled

Use these fields to establish parameters for remote access security violations. A remote access violation occurs if a user enters incorrect barrier codes. You cannot set the system to disable remote access following a security violation unless you have turned this on here.

## SVN Authorization Code Violation Notification Enabled

**Screen 256. Security-Related System Parameters for DEFINITY SI and DEFINITY CSI**

**SECURITY VIOLATION NOTIFICATION PARAMETERS**

---

**SVN Station Security Code Violation Notification Enabled**

Station Security codes are used to validate logins to a particular extension (for example, a home agent using an extender, or two part-time workers using the same telephone, but different extensions, through personal station access.) Enter y here to establish parameters for this.

**STATION SECURITY CODE VERIFICATION PARAMETERS**

---

**Minimum Station Security Code Length**

This determines the minimum required length of the Station Security Codes that you enter on the Station screen.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|            |                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>3-8</b> | Longer codes are more secure. If station security codes are used for external access to telecommuting features, the minimum length should be 7 or 8. |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------|

## Security Code for Terminal Self Administration Required

Specifies if a Personal Station access code is required to enter the Self-Administration mode.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                              |
|------------|--------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to indicate that a security code is required. |
|------------|--------------------------------------------------------------|

## ACCESS SECURITY GATEWAY PARAMETERS

These eight fields appear only if the Access Security Gateway (ASG) field on the System-Parameters Customer-Options screen is **y**.

The following 4 fields display only for the DEFINITY R version:

### MAINT

A direct connection to the EPN maintenance circuit pack RS-232 interface.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

### SYSAM-LCL

A direct cable connection to the SYSAM-LCL G3-MT (local system administrator's terminal) port on the System Access and Maintenance circuit pack on the active DEFINITY R processor carrier. For more information on the circuit pack, see the *Avaya MultiVantage™ Solutions Hardware Guide*.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

### SYS-PORT

A dialed-in (or out) connection to the System Access Port.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

**SYSAM-RMT**

A dialed-in (or out) connection to the SYSAM-RMT port on the System Access and Maintenance circuit pack in the active DEFINITY R processor carrier. For more information on the circuit pack, see the *Avaya MultiVantage™ Solutions Hardware Guide*.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

The following fields display only for the DEFINITY SI and CSI versions:

**EPN**

A direct connection to the Expansion Port Network.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

**INADS**

A direct cable connection to the Initialization and Administration System used to remotely initialize and administer Avaya MultiVantage.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

**MGR1**

The direct connect system administration and maintenance access interface located on the processor circuit pack. For more information on the circuit pack, see the *Avaya MultiVantage™ Solutions Hardware Guide*.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

## NET

A dialed-in (or out) connection to the Network Controller circuit pack. For more information on the circuit pack, see the *Avaya MultiVantage™ Solutions Hardware Guide*.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                    |
|------------|--------------------------------------------------------------------|
| <b>y/n</b> | Any entry attempt through this port receives a challenge response. |
|------------|--------------------------------------------------------------------|

## Translation-ID Number Mismatch Interval (days)

A display-only field for all logins except init; only init logins can change this field. This field specifies the interval (in days) that the system allows a mismatch between the translation ID stored in the Processor circuit pack(s) and on the flash card. Following expiration of this interval, the ability to execute system administration commands that modify translation data is denied for all logins, except for init.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|             |                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------|
| <b>1-90</b> | Enter a number to indicate the number of days the system allows access to system administration commands. |
|-------------|-----------------------------------------------------------------------------------------------------------|

## Signaling Group

Use this screen to establish signaling group parameters for ISDN-PRI, H.323, and ATM trunks. Because these trunk types vary in the types of parameters needed, the fields that appear on this screen change depending on the value of the Group Type field

**Field descriptions for page 1**

```

 SIGNALING GROUP
 Page 1 of 5

Group Number ___ Group Type: atm___ Name:
 Associated Signaling? Max Number of NCA TSC: ___
 Primary D-Channel: Max number of CA TSC: ___
 Trunk Group for NCA TSC: ___

Trunk Group for Channel Selection: ___
Supplementary Service Protocol: _ Network Call Transfer? n
CIRCUIT PARAMETERS
Virtual Path Identifier: 0
Virtual Channel Identifier: 0

 Signaling Mode: isdn-pri Circuit Type: T1
 Idle Code: 11111111 Connect: network
Interface Companding: mulaw
Country Protocol: 1
Protocol Version: d
 DCP/Analog Bearer Capability: 3.1kHz
 Interworking Message: PROGRESS

```

**Screen 257. Signaling Group**

**Group Number**

A display-only field identifying the signaling group.

**Group Type**

This field describes the signaling group type.

**Valid entries      Usage**

**atm**

**h.323**

**isdn-pri**

**sip**                      For S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect only.

**Name**

Appears when the Group Type field is **atm**.

**Valid entries      Usage**

Enter 15 alphanumeric characters for identification.

**Associated Signaling**

Appears when the Group Type field is **isdn-pri**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|          |                                                          |
|----------|----------------------------------------------------------|
| <b>y</b> | Enter <b>y</b> to use associated signaling.              |
| <b>n</b> | Enter <b>n</b> to use non-facility associated signaling. |

### Remote Office

Appears when the Group Type field is **h.323**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|            |                                                               |
|------------|---------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> if the signaling group serves a remote office. |
|------------|---------------------------------------------------------------|

### D Channel

Appears when the Group Type field is **atm**. Enter the necessary characters.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|                                                                                                                                                                                        |                                                    |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| <b>01 through 44</b><br>(DEFINITY R) or<br><b>01 through 03</b><br>(DEFINITY CSI, SI) or<br><b>1 through 64</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server) | First and second characters are the cabinet number |
| <b>A through E</b>                                                                                                                                                                     | Third character is the carrier                     |
| <b>0 through 20</b>                                                                                                                                                                    | Fourth and fifth character are the slot number     |
| <b>01 through 04</b><br>(Analog TIE trunks)<br><b>09 through 32</b>                                                                                                                    | Six and seventh characters are the circuit number  |

### Primary D Channel

Appears when the Group Type field is **isdn-pri**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|  |                                                                            |
|--|----------------------------------------------------------------------------|
|  | Enter cabinet number (1-44), carrier (A-E), slot (00-20), circuit (09-32). |
|--|----------------------------------------------------------------------------|

### Max number of NCA TSC

Appears when the Group Type field is **atm**, **h.323**, or **isdn-pri**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0-256</b>         | Maximum number of simultaneous non-call-associated Temporary Signaling Connections. The TSCs carry signaling for features not associated with a specific call, for example, signals to turn on Leave Word Calling. |

### Max number of CA TSC

Appears when the Group Type field is **atm**, **h.323**, or **isdn-pri**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                           |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0-619</b>         | Maximum number of simultaneous call-associated Temporary Signaling Connections that can exist in the signaling group. Typically this is the number of ISDN-PRI trunk group members controlled by this signaling group. |
| <b>0-400</b>         | For DEFINITY SI only.                                                                                                                                                                                                  |

### Trunk Group for NCA TSC

| <b>Valid entries</b>   | <b>Usage</b>                                                                                                                                                    |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1-666</b> or blank  | Enter the ISDN-PRI trunk group number whose incoming call-handling table will be used to handle incoming NCA-TSCs through this signaling group. For DEFINITY R. |
| <b>1-2000</b> or blank | For S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect.                                                                                                  |
| <b>1-99</b> or blank   | For DEFINITY SI only.                                                                                                                                           |

## Trunk Group for Channel Selection

| Valid entries  | Usage                                                                                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-666 or blank | Enter the trunk group number. If there is more than one trunk group assigned to this signaling group, the group entered in this field will be the one that can accept incoming calls. For DEFINITY R. |
| 1-99 or blank  | For DEFINITY SI only.                                                                                                                                                                                 |
| 1-2000         | For S8300 Media Server, S8700 IP-Connect, S8700 Multi-Connect.                                                                                                                                        |

## X-Mobility/Wireless Type

Appears when the Group Type field is **isdn-pri**. This field indicates the type of X-Mobile endpoints allowed.

| Valid entries | Usage                                                                                                                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DECT          | Indicates to the switch that the remote end of the trunk group controlled by the signaling group is a DECT mobility controller. This allows X-Mobility to work over ISDN-PRI trunks between the switch and adjunct. |
| NONE          |                                                                                                                                                                                                                     |

## Supplementary Service Protocol

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                                           |

| Valid entries | Usage                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>e</b>      | Allows DCS with rerouting. DCS with Rerouting must be <b>y</b> , and the Used for DCS field on the trunk group screen must be <b>y</b> .                      |
| <b>f</b>      | Feature Plus                                                                                                                                                  |
| <b>g</b>      | ANSI. Available only if, on the System-Parameters Customer-Options screen, the ISDN-PRI or ISDN-BRI field is <b>y</b> or the Used for DCS field is <b>y</b> . |

### Network Call Transfer

Appears when the Group Type field is **atm**. For more information, see *Avaya MultiVantage™ Network Call Redirection*.

| Valid entries | Usage                                               |
|---------------|-----------------------------------------------------|
| <b>y/n</b>    | Enter y to indicate D-channels are supporting ENCT. |

### Near-end Node Name

Appears on the DEFINITY R when the Group Type field is **atm** or **sip**. Enter the node name for the C-LAN IP interface on this switch. The node name is administered on the Node Names screen and the IP Interfaces screen.

| Valid entries    | Usage                       |
|------------------|-----------------------------|
| Character string | Describe the near-end node. |

### Far-end Node Name

Appears when the Group Type field is **atm** or **sip**. Enter the node name for the far-end C-LAN IP interface used for trunks assigned to this signaling group. The node name is administered on the Node Names screen.

| Valid entries                | Usage                      |
|------------------------------|----------------------------|
| Match the Node Names screen. | Describe the far-end node. |

### Circuit Parameters

---

#### Virtual Path Identifier

A display-only field that appears when the Group Type field is **atm**. This field always sets to **0**.

| Valid entries    | Usage                                    |
|------------------|------------------------------------------|
| 32-1023 or blank | Enter a number between 32-1023 or blank. |

### Virtual Channel Identifier

Appears when the Group Type field is **atm**.

| Valid entries    | Usage                                    |
|------------------|------------------------------------------|
| 32-1023 or blank | Enter a number between 32-1023 or blank. |

### Near-end Listen Port

Appears when the Group Type field is **h.323** or **sip**.

| Valid entries            | Usage                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------|
| 1719, 1720, or 5000-9999 | Enter an unused port number. Avaya recommends 1720. Enter <b>1719</b> if LRQ is <b>y</b> . |

### Far-end Listen Port

Appears when the Group Type field is **h.323** or **sip**.

| Valid entries    | Usage                                                               |
|------------------|---------------------------------------------------------------------|
| 1-65535 or blank | Enter the same number as entered in the Near-end Listen port field. |

### Far-end Network Region

Appears when the Group Type field is **h.323** or **sip**. The number of the network region number that is assigned to the far-end of the trunk group.

| Valid entries  | Usage                                                                                                                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-250 or blank | Enter the network region number that is assigned to the far end of the trunk group. The region is used to obtain the codec set used for negotiation of trunk bearer capability. Leave blank to select the region of the near-end node. |

### LRQ Required

Appears when the Group Type field is **h.323**.

| Valid entries | Usage                                                                                                                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>n</b> if the far-end switch is an Avaya MultiVantage. Enter <b>y</b> if the far-end switch is a non-DEFINITY and requires a location request to obtain a signaling address in its signaling protocol. If <b>y</b> , "Calls Share IP Signaling Connection" must be <b>n</b> . |

### Signaling Mode

A display-only field that appears when the Group Type field is **atm**. This field always sets to **isdn-pri**.

### Circuit Type

Appears when the Group Type field is **atm**.

| Valid display | Usage                                     |
|---------------|-------------------------------------------|
| T1            | Results in page 2 displaying 24 channels. |
| E1            | Results in page 2 displaying 31 channels. |

### RRQ Required

Appears when the Group Type field is **h.323**. This field specifies the signaling group that serves as a gateway rather than gatekeeper.

| Valid display | Usage                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Displays <b>y</b> if the signaling group serves a remote office (gateway). Displays <b>n</b> if the signaling group serves a gatekeeper. |

### Idle Code

Appears when the Group Type field is **atm**.

| Valid entries | Usage                    |
|---------------|--------------------------|
| 0, 1          | Enter an 8-digit string. |

### Connect

Appears when the Group Type field is **atm**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

**host**

**network**

**pbx**

### **Calls Share IP Signaling Connection**

Appears when the Group Type field is **h.323** or **sip**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                                                                                                                                |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> for inter-MultiVantage connections. If <b>y</b> , then “LRQ Required” must be n. Enter <b>n</b> if the local and/or remote switch is a non-MultiVantage switch. |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### **Interface Companding**

Appears when the Group Type field is **atm**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

**alaw**

**mulaw**

### **Bypass If IP Threshold Exceeded**

Appears when the Group Type field is **h.323** or **sip**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                                                                                                                                                                |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to automatically remove from service trunks assigned to this signaling group when IP transport performance falls below limits administered on the Maintenance-Related System Parameters screen. |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### **Country Protocol**

Appears when the Group Type field is **atm**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

**1-25**

**etsi**

### Protocol Version

Appears when the Group Type field is **atm**.

| Valid entries | Usage |
|---------------|-------|
| a             |       |
| b             |       |
| c             |       |
| d             |       |

### Direct IP-IP Audio Connections

Appears when the Group Type field is **h.323**. Allows direct audio connections between IP endpoints.

| Valid entries | Usage                                                                                                      |
|---------------|------------------------------------------------------------------------------------------------------------|
| y/n           | Enter to <b>y</b> to save on bandwidth resources and improve sound quality of voice over IP transmissions. |

### IP Audio Hairpinning

Appears when the Group Type field is **h.323**. Allows IP endpoints to be connected through the IP circuit pack on the switch.

| Valid entries | Usage                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to allow IP endpoints to be connected through the IP circuit pack on the switch in IP format, without going through the MultiVantage TDM bus. |

### DCP/Analog Bearer Capability

Appears when the Group Type field is **atm**.

| Valid entries | Usage |
|---------------|-------|
| 3.1kHz        |       |
| speech        |       |

## Interworking Message

Appears when the Group Type field is **atm**, **h.323**, or **sip**. This field determines what message the switch sends when an incoming ISDN trunk call interworks (is routed over a non-ISDN trunk group).

| Valid entries   | Usage                                                                                                                                                                                                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PROGress</b> | Normally select this value. PROGress asks the public network to cut through the B-channel and let the caller hear tones such as ringback or busy tone provided over the non-ISDN trunk.                                                                                                                              |
| <b>ALERTing</b> | ALERTing causes the public network in many countries to play ringback tone to the caller. Select this value only if the DS1 is connected to the public network, and it is determined that callers hear silence (rather than ringback or busy tone) when a call incoming over the DS1 interworks to a non-ISDN trunk. |

## Signaling Group screen (page 2)

| 16:  |      |      |      |

### Screen 258. Signaling Group screen (when the Group Type field is atm)

#### Chan Port

Displays when the Group Type field is **atm**. If the Circuit Type field on page 1 is **T1**, this field displays 24 channels; if you specified **E1**, it displays 31 channels.

You must fill this screen in for ATM signaling groups. This provides two things:

- It allows you to define fractional T1 and fractional E1 facilities, specifying how many and which channels to use.
- It allows you to choose the port numbers to use (port numbers must be unique for all signaling groups on the same ATM board).

The signaling channel (port 16 for an E1 and port 24 for a T1) must be a port between **9** and **32**. Any port number used on this screen may not be used on any other ATM signaling group on the same board.

The channels used must match exactly the channels used on the other end of the signaling group. For example, if your T1 is set up to use channels 1 through 5, 7, and 24 (the signaling channel), the far end must use channels 1 through 5, 7, and 24.

**Valid entries                      Usage**

---

**009** through **256** or blank      Enter the port number for non-signaling channels.

**Signaling Group screen (page 2)**

|---------------|-------|
|---------------|-------|

Enter the extension of the ISDN interface.

**Enabled**

| <b>Valid entries</b> | <b>Usage</b>                                       |
|----------------------|----------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to enable the administered NCA-TSC. |

**Established**

Used to indicate the strategy for establishing this administered NCA-TSC.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                     |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>permanent</b>     | Use permanent so that the administered NCA-TSC can be established by either the near end or the far end.                                                                         |
| <b>as-needed</b>     | Use as-needed so that the administered NCA-TSC will be established the first time the administered NCA-TSC is needed; it can be set up either by the near end or far end switch. |

**Dest. Digits**

| <b>Valid entries</b>                 | <b>Usage</b>                               |
|--------------------------------------|--------------------------------------------|
| Up to 15 characters <b>0-9, *, #</b> | Enter the extension of the ISDN interface. |

**Appl.**

Specifies the application for this administered NCA-TSC.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>audix</b>         | Use this for ISDN-PRI D-channel DCS Audix feature.                                                                                                                                                          |
| <b>dcs</b>           | Use this for the DCS Over ISDN-PRI D-channel feature.                                                                                                                                                       |
| <b>gateway</b>       | Use this when the administered NCA-TSC is used as one end in the gateway channel connecting to a BX.25 link. If gateway is entered, then the ISDN TSC Gateway Channel Assignments screen must be completed. |
| <b>masi</b>          | Use this when the NCA-TSC is one end of a multimedia application server interface.                                                                                                                          |
| <b>qsig-mwi</b>      | Use this to convert messages from an administered AUDIX NCA-TSC to a QSIG CISC. If you use this application type, then you must enter a Machine ID between 1 and 20.                                        |

## Mach ID

You can enter up to 20 machine IDs.

| Valid entries             | Usage                                                                                                                               |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 1 through 20              | Enter a unique machine ID. The system does not allow you to specify an ID that you already entered on the Processor Channel screen. |
| 1 through 63 for DCS      | For S8700 IP-Connect.                                                                                                               |
| 1 through 99 for Audix    |                                                                                                                                     |
| 1 through 15 for MASI     |                                                                                                                                     |
| 1 through 20 for QSIG-MWI |                                                                                                                                     |
| blank                     |                                                                                                                                     |

## Site Data

Use this screen to enter information about buildings, floors and telephone set colors. You must supply values on this screen before you can enter information in the Site Data section of the Station screen.

### Field descriptions for pages 1, 2 and 3

These pages are available for you to enter descriptive information about the buildings, floors and phone set colors. You may enter any valid keyboard character. If you want to indicate that a particular floor is in a particular building, you must include this in the floor entry, for example, B301-F14.

## Station

This section provides descriptions of all of the fields that may appear on Station screens. Some of the fields are used for specific phone types; others are used for all phone types. To make it easier to find a specific field, they are listed in alphabetical order by field name.

**Screen 266. Station screen**

The standard station fields are organized alphabetically for easy access.

**1-Step Clearing**

| <u>Valid entries</u> | <u>Usage</u>                                                                                            |
|----------------------|---------------------------------------------------------------------------------------------------------|
| y/n                  | If set to <b>y</b> , the call terminates again at the WCBRI terminal when the user drops from the call. |

### Abbreviated Dialing List1, List2, List3

You can assign up to 3 abbreviated dialing lists to each phone.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                    |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>enhanced</b>      | Allows the phone user to access the enhanced system abbreviated dialing list.                                                                                   |
| <b>group</b>         | Allows the phone user to access the specified group abbreviated dialing list. If you enter <b>group</b> , you also must enter a group number.                   |
| <b>personal</b>      | Allows the phone user to access and program their personal abbreviated dialing list. If you enter <b>personal</b> , you also must enter a personal list number. |
| <b>system</b>        | Allows the phone user to access the system abbreviated dialing list.                                                                                            |

### Active Station Ringing

Defines how call rings to the phone when it is off-hook. This field does not affect how calls ring at this phone when the phone is on-hook.

| <b>Valid entries</b>  | <b>Usage</b>                                                                                                                                                                                                                      |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>continuous</b>     | Enter <b>continuous</b> to cause all calls to this phone to ring continuously.                                                                                                                                                    |
| <b>single</b>         | Enter <b>single</b> to cause calls to this phone to receive one ring cycle and then ring silently.                                                                                                                                |
| <b>if-busy-single</b> | Enter <b>if-busy-single</b> to cause calls to this phone to ring continuously when the phone is off-hook and idle and calls to this phone to receive one ring cycle and then ring silently when the phone is off-hook and active. |
| <b>silent</b>         | Enter <b>silent</b> to cause all calls to this station to just ring silently.                                                                                                                                                     |

## Adjunct Supervision

Adjunct Supervision appears when the Type field is **500, 2500, k2500, 8110, ops, ds1fd, ds1sa, VRU, VRUFD, or VRUSA.**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> if an analog disconnect signal is sent automatically to the port after a call terminates. Analog devices (such as answering machines and speakerphones) use this signal to turn the devices off after a call terminates.                            |
| <b>n</b>             | Set this field to <b>n</b> so hunt group agents are alerted to incoming calls. In a hunt group environment, the disconnect signal blocks the reception of zip tone and incoming call notification by an auto-answer station when a call is queued for the station. |

## Assigned Member — Ext

The system automatically assigns this extension. This is the extension of the user who has an associated Data Extension button and shares the module.

## Assigned Member — Name

Display-only field that shows the name associated with the extension shown in the Assigned Member - Ext field.

## Att. Call Waiting Indication

Attendant call waiting allows attendant-originated or attendant-extended calls to a busy single-line phone to wait and sends distinctive call-waiting tone to the single-line user.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to assign Attendant Call Waiting to the phone.<br><br>You should not set this field to <b>y</b> , if the Data Restriction field is <b>y</b> or the Switchhook Flash field is <b>n</b> , or if Data Privacy is enabled for the phone's class of service (COS). If any of these conditions are true, the phone cannot accept or handle call waiting calls. |

## Audible Message Waiting

The Audible Message Waiting tone indicates that the user has a waiting message. This field appears only if Audible Message Waiting is set to **y** on the System-Parameters Customer-Options screen.

Note that this field does not control the Message Waiting lamp.

| Valid entries | Usage                                                                                                                         |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> if you want the phone user to receive stutter dial tone when they have a waiting message and they go off-hook. |

## Audix Name

Specifies which AUDIX is associated with the station.

| Valid entries                      | Usage                                                                                               |
|------------------------------------|-----------------------------------------------------------------------------------------------------|
| Names assigned to an AUDIX adjunct | Must contain a user-defined adjunct name that was previously administered in the Node-Names screen. |

## Auto Answer

In EAS environments, the auto answer setting on the Agent LoginID screen can override a station's setting when an agent logs in there.

### ⇒ NOTE:

For analog stations, if Auto Answer is set to **acd** and the station is off-hook and idle, only the ACD split/skill calls and direct agent calls auto answer; non-ACD calls receive busy treatment. If the station is active on an ACD call and a non-ACD call arrives, the Agent receives call-waiting tone.

| Valid entries | Usage                                                                                                                                                                                 |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>all</b>    | Enter <b>all</b> to allow all calls (ACD and non-ACD) terminated to an idle station to be cut through immediately. Does not allow automatic hands-free answer for intercom calls.     |
| <b>acd</b>    | Enter <b>acd</b> to allow only ACD split /skill calls and direct agent calls to auto answer. If this field is set to <b>acd</b> , Non-ACD calls terminated to a station ring audibly. |
| <b>none</b>   | Enter <b>none</b> to cause all calls terminated to this station to receive an audible ringing treatment.                                                                              |
| <b>icom</b>   | Enter <b>icom</b> to allow a phone user to answer an intercom call from the same intercom group without pressing the intercom button.                                                 |

## Automatic Moves

Automatic Moves allows a phone to be unplugged from one location and moved to a new location without additional switch administration. The switch automatically associates the extension to the new port.

### CAUTION:

*When a phone is unplugged and moved to another physical location, the Emergency Location Extension field must be changed for that extension or the USA Automatic Location Identification data base must be manually updated. If the Emergency Location Extension field is not changed or if the USA Automatic Location Identification data base is not updated, the DID number sent to the Public Safety Network could send emergency response personnel to the wrong location.*

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| always        | Enter always and the phone can be moved anytime without additional administration by unplugging from one location and plugging into a new location.                                                                                                                                                                                               |
| once          | Enter once and the phone can be unplugged and plugged into a new location once. After a move, the switch sets the field to done the next time routine maintenance runs on the phone.<br><br>Use once when moving a large number of phones so each extension is removed from the move list. Use once to prevent automatic maintenance replacement. |
| no            | Enter no to require administration in order to move the phone.                                                                                                                                                                                                                                                                                    |
| done          | Done is a display-only value. The switch sets the field to done after the phone is moved and routine maintenance runs on the phone.                                                                                                                                                                                                               |
| error         | Error is a display-only value. The switch sets the field to error, after routine maintenance runs on the phone, when a non-serialized phone is set as a movable phone.                                                                                                                                                                            |

## Auto Select Any Idle Appearance

| Valid entries | Usage                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to allow automatic selection of any idle appearance for transferred or conferenced calls. The system first attempts to find an idle appearance of the call being transferred or conferenced. If that attempt fails, the system selects the first idle appearance. |

## Automatic Selection of DID Numbers

The switch chooses a 2- to 5-digit extension from a predetermined list of numbers and assigns the extension to a hotel room phone.

| Valid entries | Usage                                                                                 |
|---------------|---------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to use the Automatic Selection of DID Numbers for Guest Rooms feature. |

## BCC

Appears when ISDN-PRI or ISDN-BRI Trunks is enabled on the System-Parameters Customer-Options screen. Display-only field set to **0** for stations (that is, indicates voice or voice-grade data).

See [“Generalized route selection” on page 1687](#) for a detailed description of Bearer Capability Classes (BCC) and their ability to provide specialized routing for various types of voice and data calls. The BCC value is used to determine compatibility when non-ISDN facilities are connected to ISDN facilities (ISDN Interworking).

## Bridged Call Alerting

If Bridged Call Alerting is **n** and Per Button Ring Control is **n**, audible ringing is suppressed for incoming calls on bridged appearances of another phone’s primary extension.

| Valid entries | Usage                                                                                                 |
|---------------|-------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to enable audible ringing for TEG, PCOL, bridged appearances, or Data Extension calls. |

## Building

Enter a valid building location. See [“Signaling Group screen \(page 2\)” on page 1123](#) for valid entries.

## Busy Auto Callback Without Flash

Appears only if, on the Feature-Related System Parameters screen, the Without Flash field is **y**. This field then defaults to **y** for all analog phones that allow Analog Automatic Callback.

| Valid entries | Usage                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to provide automatic callback for a calling analog station without flashing the hook. |

## Button Assignments

Enter the abbreviated software name to assign a feature button. For a list of feature buttons, see [“Telephone feature buttons” on page 131](#).

### ⇒ NOTE:

If you want to use Terminal Translation Initialization (TTI), you must assign a call appearance (call-app) to the first button position. TTI needs the button on the first call appearance to get dial tone.

## Cable

You can use this field to identify the cable that connects the phone jack to the system. You also can enter this information in the Blank column on the Port Assignment Record.

## Caller ID Message Waiting Indication

Appears when the Type field is **CallrID**. For CallrID type phones or analog phones with Caller ID adjuncts only.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                                                                            |
|------------|----------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to allow aliasing of various non-Avaya phones and adjuncts. |
|------------|----------------------------------------------------------------------------|

### ⇒ NOTE:

The Caller ID Message Waiting Indication administration is independent of the administration of LED or NEON lamp Avaya MultiVantage Message Waiting Indication (MWI). For example, it is possible to administer a Caller ID phone with the Caller ID Message Waiting Indication field set to **n** and the Message Waiting Indicator field set to **neon**.

## Calls Allowed

Appears if the XMOBILE Type field is **EC500** and the Mapping Mode field is **termination** or **both**. Used to identify the EC500 call filter type for an XMOBILE station. This field allows an XMOBILE station to function as a bridge and still be restricted.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                 |                                                                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>internal</b> | External calls are blocked. Internal calls terminate to the XMOBILE station. Attendant-originated and attendant-delivered calls are not delivered |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------|

| Valid entries   | Usage                                                                                                                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>external</b> | Internal calls are blocked. External calls terminate to the XMOBILE station.                                                                                                                                                                   |
| <b>all</b>      | All calls terminate to the XMOBILE station.                                                                                                                                                                                                    |
| <b>none</b>     | Prevents calls from terminating to the XMOBILE station. Can be used to prevent business-related calls from accruing phone charges on cell phones that are lost, being transferred to a new user, or being disabled for other business reasons. |

**⇒ NOTE:**

Interswitch calls on DCS trunks are treated as internal calls. When the Calls Allowed field is set to **internal** or **all**, DCS calls are delivered to the cell phone. When the Calls Allowed field is set to **external** or **none**, DCS calls are not delivered.

**⇒ NOTE:**

Incoming calls from other EC500 users are internal if office caller ID is enabled for the XMOBILE station associated with the cell phone. When the Calls Allowed field is set to **internal** or **all**, calls from other EC500 users are delivered. When the Calls Allowed field is set to **external** or **none**, calls from other EC500 users are not delivered.

**⇒ NOTE:**

The calling party receives busy treatment when call filtering blocks calls to a standalone XMOBILE. Calls delivered to standalone XMOBILE stations that are not answered will follow the call coverage or call forwarding paths administered for the standalone XMOBILE.

## Call Waiting Indication

This allows user, attendant-originated, and outside calls to busy single-line phone to wait and sends a distinctive call-waiting tone to the single-line user. This feature is denied if Data Restriction is **y** or Switchhook Flash is **n**, or if Data Privacy is active via the phone COS assignment.

| Valid entries | Usage                                                              |
|---------------|--------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to activate Call Waiting Termination for the phone. |

## CDR Privacy

This option allows digits in the called number field of an outgoing call record to be blanked, on a per-station basis. You administer the number of blocked digits system-wide in the Privacy - Digits to Hide field on the CDR System Parameters screen.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                         |
|------------|---------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to enable Call Privacy for each station. |
|------------|---------------------------------------------------------|

## Cell Phone Number

Contains the unformatted cell phone's published external number. This field may contain a 3-digit area code plus the 7-digit main number. If the same Cell Phone Number is administered on multiple XMOBILE station screens, then the Dial Prefix associated with each instance of the Cell Phone Number must be the same.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                    |                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 through 9</b> | Enter 1-15 digits. Avaya recommends that you enter a full 10-digit Cell Phone Number regardless of whether the cell phone is local or not. Note that your ARS screen has to be administered to handle this. |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Configuration Set

This field is used to administer the Configuration Set number that contains the call treatment options desired for the XMOBILE station. This field must be administered if:

- The XMOBILE Type field is **EC500**.
- The Mobility Trunk Group field is a trunk group number and the administered trunk group is non-DECT or non-PHS.
- The Mobility Trunk Group field is **aar** or **ars**.

If the Mobility Trunk Group field is a trunk group number and the administered trunk group is **DECT** or **PHS**, this field may be left blank.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                      |                                                                            |
|----------------------|----------------------------------------------------------------------------|
| <b>1-10</b> or blank | Enter any value corresponding to the appropriate Configuration Set screen. |
|----------------------|----------------------------------------------------------------------------|

## COR

Enter a Class of Restriction (COR) number to select the desired restriction.

## Cord Length

Enter a number to specify the length (in feet) of the cord attached to the receiver.

## COS

Enter the desired Class of Service (COS) number to select allowed features.

## Country Protocol

Enter the protocol that corresponds to your supported initialization and codesets. The Country Protocol must match any previously-administered endpoint on the same port.

| Valid entries | Usage                                  |
|---------------|----------------------------------------|
| 1             | United States (Bellcore National ISDN) |
| 2             | Australia                              |
| etsi          | ETSI (Europe)                          |
| 3             | Japan                                  |
| 6             | Singapore                              |

## Coverage After Forwarding

This field governs whether an unanswered forwarded call is provided coverage treatment.

| Valid entries | Usage                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y             | Coverage treatment is provided after forwarding regardless of the value of the Coverage After Forwarding field on the System Parameters - Call Coverage/Call Forwarding screen.                                                                                |
| n             | No coverage treatment is provided after forwarding regardless of the value of the Coverage After Forwarding field on the System Parameters - Call Coverage/Call Forwarding screen.                                                                             |
| s(system)     | Indicates that call processing uses the Coverage After Forwarding field on the <a href="#">“System Parameters Call Coverage / Call Forwarding”</a> screen. To override the system-wide parameter for a given station, set this field to <b>y</b> or <b>n</b> . |

## Coverage Msg Retrieval

Applies if the phone is enabled for LWC Reception.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|     |                                                                                                                          |
|-----|--------------------------------------------------------------------------------------------------------------------------|
| y/n | Enter <b>y</b> to allow users in the phone's Coverage Path to retrieve Leave Word Calling (LWC) messages for this phone. |
|-----|--------------------------------------------------------------------------------------------------------------------------|

## Coverage Module

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|   |                                                                                                                                                                                               |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y | Enter <b>y</b> to indicate that a coverage module is connected to the station. Once you enter y, the system displays an additional page that allows you to assign the buttons for the module. |
|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Coverage Path 1 or Coverage Path 2

Enter a coverage-path number or time-of-day table number from a previously-administered Call Coverage Path screen or Time of Day Coverage Table screen.

 **NOTE:**

If Modified Misoperation is active (Misoperation Alerting is **y** on the Feature-Related System Parameters screen), you must assign a Coverage Path to all stations on the switch.

## CRV Length

Only for ASAI stations. Enter **1** or **2** to indicate the length of CRV for each interface.

## Custom Selection of VIP DID Numbers

Custom Selection of VIP DID numbers allows you to select the DID number assigned to a room when a guest checks in.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|     |                                                                                                 |
|-----|-------------------------------------------------------------------------------------------------|
| y/n | Enter <b>y</b> to allow you to select the DID number assigned to a room when a guest checks in. |
|-----|-------------------------------------------------------------------------------------------------|

## Data Extension

Enter the extension assigned to the data module.

## Data Option

| Valid entries | Usage |

|---------------|-------|

|        |  |
|--------|--|
| analog |  |
|--------|--|

|             |  |
|-------------|--|
| data module |  |
|-------------|--|

|      |  |
|------|--|
| none |  |
|------|--|

## Data Restriction

Data restriction provides permanent protection and cannot be changed by the phone user. Do not assign a Data Restriction if Auto Answer is **all** or **acd**. If **y**, whisper page to this station is denied.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                                                                                            |
|------------|--------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to prevent tones, such as call-waiting tones, from interrupting data calls. |
|------------|--------------------------------------------------------------------------------------------|

## Default Dialing Abbreviated Dialing Dial Code

Appears only when the Special Dialing Option is set to default. Enter a list number associated with the abbreviated dialing list.

When the user goes off-hook for a data call and presses the Return button following the DIAL prompt, the system dials the AD number. The data call originator also can perform data-terminal dialing by specifying a dial string that may or may not contain alphanumeric names.

## Dial Prefix

Contains the unformatted sequence of digits or characters that are prepended to the cell phone's published cell phone number before dialing. If the same Cell Phone Number is administered on multiple XMOBILE station screens, then the Dial Prefix associated with each instance of the Cell Phone Number must be the same.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                  |                   |
|------------------|-------------------|
| <b>0-9, *, #</b> | Enter 1-4 digits. |
|------------------|-------------------|

## Direct IP-IP Audio Connections

Allows direct audio connections between IP endpoints.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to save on bandwidth resources and improve sound quality of voice over IP transmissions. |
|------------|---------------------------------------------------------------------------------------------------------|

## Display Caller ID

Appears when the Type field is **CallrID**. For CallrID type phones or analog phones with Caller ID adjuncts only.

| Valid entries | Usage |
|---------------|-------|

|     |                                                                                                      |
|-----|------------------------------------------------------------------------------------------------------|
| y/n | Enter <b>y</b> to allow transmission of calling party information to the Caller ID phone or adjunct. |
|-----|------------------------------------------------------------------------------------------------------|

## Display Cartridge

For 7404 D phones only. Enter **y** to indicate there is a display cartridge associated with the station. This displays an additional page to allow you to assign display buttons for the display cartridge.

## Display Client Redirection

Only administrable if Hospitality is enabled on the System-Parameters Customer-Options screen. This field affects the phone display on calls that originated from a station with Client Room Class of Service.

**⇒ NOTE:**

For stations with an audix station type, AUDIX Voice Power ports, or ports for any other type of messaging that needs display information, Display Client Redirection must be set to **y**.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|          |                                                                                                                                                                                                                                                                                                                   |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b> | When set to <b>y</b> , the redirection information for a call originating from a Client Room and terminating to this station displays.                                                                                                                                                                            |
| <b>n</b> | When set to <b>n</b> , this station's display does not show the redirection information for all calls originating from a Client Room (even redirected calls) that terminate to this station. Only the client name and extension (or room, depending on what is administered on the "Hospitality" screen) display. |

## Display Language

Specifies the display language.

| <b>Valid entries</b> | <b>Usage</b>                                                |
|----------------------|-------------------------------------------------------------|
| <b>english</b>       | Enter the language you want users to see on their displays. |
| <b>french</b>        |                                                             |
| <b>italian</b>       |                                                             |
| <b>spanish</b>       |                                                             |
| <b>user-defined</b>  |                                                             |

## Display Module

| <b>Valid entries</b> | <b>Usage</b>                                       |
|----------------------|----------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> if this phone has a display module. |

## Distinctive Audible Alert

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                               |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> so the phone can receive the 3 different types of ringing patterns which identify the type of incoming calls.<br><br>Distinctive ringing may not work properly for off-premises telephones. |

## Emergency Location Ext

The Emergency Location Ext field defaults to the phone's extension. This extension identifies the street address or nearby location when an emergency call is made.

| <b>Valid entries</b> | <b>Usage</b>                                            |
|----------------------|---------------------------------------------------------|
| 1-8 digits           | Enter the Emergency Location Extension for this station |

## Endpt ID

Appears only if Endpt Init is **y**. Enter a unique 2-digit number (**00–62**) for this endpoint. Each Endpt ID field must have a unique value for each endpoint on the same port.

This field provides for multipoint configuration conformance to the Bellcore Terminal Initialization procedures. In these procedures, a multipoint configuration requires the last 2 digits of the Service Profile Identifier (SPID) be between 00 and 63 and be binary unique for each endpoint. This field, combined with the SPID, gives the effective SPID administered into the terminal. Bellcore ISDN-1 requires the SPID programmed into the endpoint contain at least 9 digits.

For example, if the SPID is **1234**, and Endpt ID is **01**, then the SPID administered on the terminal is 000123401. The three leading zeros are necessary to create a 9-digit SPID.

## Endpt Init

Endpoint initialization is a procedure, required for multipoint operation, by which User Service Order Profile (USOP) is associated with an endpoint on the ISDN-BRI. This association is made via the SPID, administered into the system, and entered into the ISDN-BRI terminal. For an ISDN-BRI terminal to be operational in a multipoint configuration, both the administered SPID and the SPID programmed into the ISDN-BRI terminal must be the same. Therefore, the SPID of new or reused terminals must be programmed to match the administered SPID value. Appears only if MIM Support is **y** and indicates the terminal's endpoint initialization capability.

| Valid entries | Usage                                                                                       |
|---------------|---------------------------------------------------------------------------------------------|
| <b>y</b>      | Enter <b>y</b> if the terminal supports Bellcore ISDN-1 terminal initialization procedures. |
| <b>n</b>      | Enter <b>n</b> for all other country protocols.                                             |

## Expansion Module

| Valid entries | Usage                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> if this phone has an expansion module. This will enable you to administer the buttons for the expansion module. |

## Extension

Displays the extension for this station—this is either the extension you specified in the station command or the next available extension (if you used add station next).

For a virtual extension, enter a valid physical extension or a blank. Blank allows an incoming call to the virtual extension to be redirected to the virtual extension's "busy" or "all" coverage path.

Avaya recommends that you consider the display for emergency notification when you complete the name field on the station screen. Put the most important identifying information at the beginning of the field. When an emergency call is made and a crisis alert station with a 27-character display is notified, only 17 characters of the name field appear on the first display line, followed by the extension. The second line contains the last 3 characters of the name field, followed by the word "EMERGENCY." Characters 18 through 24 of the name field do not appear at all.

## Feature Module

Enter **y** to indicate the station is connected to a feature module. Entering **y** displays an additional page to allow you to assign feature buttons to the module.

## Fixed TEI

This field appears only for ISDN-BRI data modules and ASAI links. It indicates that the endpoint has a fixed Terminal Endpoint Identifier (TEI).

The TEI identifies a unique access point within a service. You must administer TEIs for fixed TEI terminals. However, for terminals with the automatic TEI capability, the system dynamically assigns the TEI.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                         |
|------------|-------------------------------------------------------------------------|
| <b>y/n</b> | Entering <b>y</b> displays the TEI field.<br>For ASAI, enter <b>y</b> . |
|------------|-------------------------------------------------------------------------|

## Floor

Enter a valid floor location. See "[Translation-ID Number Mismatch Interval \(days\)](#)" on page 1112 for valid entries.

## H.320 Conversion

Allows H.320 compliant calls made to this phone to be converted to voice-only. Because the system can only handle a limited number of conversion calls, you may need to limit the number of telephones with H.320 conversion.

## Headset

Enter **y** if the telephone has a headset.

## HOT LINE DESTINATION — Abbreviated Dialing Dial Code

Appears only when Special Dialing Option is **hot-line**.

Use Hot Line Service when very fast service is required and when you use a telephone only for accessing a certain facility. Hot Line Service allows single-line telephone users, by simply lifting the handset, to automatically place a call to a preassigned destination (extension, telephone number, or feature access code).

The Hot Line Service destination number is stored in an Abbreviated Dialing List. When the user goes off-hook on a Data Hot Line call, the system dials the AD number.

A Direct Department Calling (DDC), a Uniform Call Distribution (UCD), a Terminating Extension Group (TEG) extension, or any individual extension within a group can be a Hot Line Service destination. Also, any extension within a DDC group, UDC group, or TEG can have Hot Line Service assigned.

Loudspeaker Paging Access can be used with Hot Line Service to provide automatic access to paging equipment.

## HOT LINE DESTINATION — Abbreviated Dialing List Number

Enter the abbreviated dialing list where you stored the hotline destination number.

## HOT LINE DESTINATION — Dial Code

Enter the dial code in the specified abbreviated dialing list where you stored the hotline destination number.

## Hunt-to Station

Enter the extension the system should hunt to for this phone when the phone is busy. This field allows you to create a station hunting chain (by assigning a hunt-to station to a series of phones).

## Idle Appearance Preference

Indicate which call appearance is selected when the user lifts the handset and there is an incoming call.

| Valid entries | Usage                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>      | If you enter <b>y</b> , the user connects to an idle call appearance instead of the ringing call.                       |
| <b>n</b>      | If you enter <b>n</b> , the Alerting Appearance Preference is set and the user connects to the ringing call appearance. |

## Ignore Rotary Digits

If this field is **y**, the short switch hook flash (50 -150) from a 2500-type set is ignored.

| Valid entries | Usage                                                                         |
|---------------|-------------------------------------------------------------------------------|
| <b>y</b>      | Enter <b>y</b> to indicate that rotary digits from the set should be ignored. |
| <b>n</b>      | Enter <b>n</b> to make sure they are not ignored.                             |

## IP Audio Hairpinning

Allows IP endpoints to be connected through the IP circuit pack on the switch.

| Valid entries | Usage                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to allow IP endpoints to be connected through the IP circuit pack on the switch in IP format, without going through the MultiVantage TDM bus. |

## IP Emergency calls

Use this field to tell the switch how to handle emergency calls from the IP phone. This field appears when either the IP Softphone field or the Remote Office Station field is set to **y** on the Station screen.

### CAUTION:

*An Avaya IP endpoint can dial emergency calls (for example, 911 calls in the U.S.). It only reaches the local emergency service in the Public Safety Answering Point area where the telephone system has local trunks. Please be advised that an Avaya IP endpoint cannot dial to and connect with local emergency service when dialing from remote locations that do not have local trunks. You should not use an Avaya IP endpoint to dial emergency numbers for emergency services when dialing from remote locations. Avaya Inc. is not responsible or liable for any damages resulting from misplaced emergency*

*calls made from an Avaya endpoint. Your use of this product indicates that you have read this advisory and agree to use an alternative telephone to dial all emergency calls from remote locations.*

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>extension</b>     | Enter <b>extension</b> to send the extension entered in the Emergency Location Extension field, to the Public Safety Answering Point (PSAP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>block</b>         | <p>Enter <b>block</b> to prevent the completion of emergency calls. Use this entry for users who move around but always have a circuit-switched phone nearby, and for users who are farther away from the switch than an adjacent area code served by the same 911 Tandem office.</p> <p>When users attempt to dial an emergency call from an IP Telephone and the call is blocked, they can dial 911 from a nearby circuit-switched phone instead.</p>                                                                                                                                                                                                                                                                                                                                                                         |
| <b>cesid</b>         | <p>Enter <b>cesid</b> to allow the switch to send the CESID information supplied by the IP Softphone to the PSAP. The end user enters the emergency information into the IP Softphone.</p> <p>Use this entry for IP Softphones with road warrior service that are near enough to the switch that an emergency call routed over the switch's trunk reaches the PSAP that covers the switch.</p> <p>If the switch uses ISDN trunks for emergency calls, the digit string is the telephone number, provided that the number is a local direct-dial number with the local area code, at the physical location of the IP Softphone. If the switch uses CAMA trunks for emergency calls, the end user enters a specific digit string for each IP Softphone location, based on advice from the local emergency response personnel.</p> |
| <b>option</b>        | <p>Enter <b>option</b> to allow the user to select the option (extension, block, or cesid) that the user selected during registration and the IP Softphone reported. Use this entry for extensions that are swapped back and forth between IP Softphones and a phone with a fixed location.</p> <p>The user chooses between <b>block</b> and <b>cesid</b> on the softphone. A DCP or IP phone in the office automatically selects <b>extension</b>.</p>                                                                                                                                                                                                                                                                                                                                                                         |

## IP Softphone

Appears only for DCP station types and IP Telephones.

| Valid entries | Usage                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> indicate that this extension is either a PC-based multifunction station or part of a telecommuter complex with a call-back audio connection. |

## ITC (Information Transfer Capability)

Indicates the type of transmission facilities to be used for ISDN calls originated from this endpoint. The field does not display for voice-only or BRI stations.

| Valid entries       | Usage                                                                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>restricted</b>   | If you set to <b>restricted</b> , either restricted or unrestricted transmission facilities are used to complete the call. A restricted facility is a transmission facility that enforces 1's density digital transmission (that is, a sequence of 8 digital zeros are converted to a sequence of 7 zeros and a digital 1). |
| <b>unrestricted</b> | If you set to <b>unrestricted</b> , only unrestricted transmission facilities are used to complete the call. An unrestricted facility is a transmission facility that does not enforce 1's density digital transmission (that is, digital information is sent exactly as is).                                               |

## Lock Messages

| Valid entries | Usage                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to restrict other users from reading or canceling the voice messages or retrieving messages via Voice Message Retrieval. |

## Loss Group

This field determines which administered 2-party row in the loss plan applies to each station. Does not appear for stations that do not use loss (for example, x-mobile stations and MASI terminals).

| Valid entries | Usage                                              |
|---------------|----------------------------------------------------|
| 1-17          | Shows the index into the loss plan and tone plans. |

## LWC Activation

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | <p>Enter <b>y</b> to allow internal telephone users to leave short LWC messages for this extension.</p> <p>If the system has hospitality, enter <b>y</b> for guest-room telephones if the extension designated to receive failed wakeup messages should receive LWC messages that indicate the wakeup calls failed.</p> <p>Enter <b>y</b> if LWC Reception is <b>audix</b>.</p> |

## LWC Log External Calls

Appears only where the LWC Reception field is available. When an external call is not answered, the switch keeps a record of up to 15 calls (provided information on the caller identification is available) and the phone's message lamp lights. The phone set displays the names and numbers of unsuccessful callers.

| Valid entries | Usage                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to make unanswered external call logs available to end-users. Each record consists of the latest call attempt date and time. |

## LWC Reception

| Valid entries  | Usage                                                                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>audix</b>   | Enter <b>audix</b> if the messages are stored on the Audio Information Exchange System.                                                               |
| <b>none</b>    |                                                                                                                                                       |
| <b>msa-spe</b> | Enter <b>msa-spe</b> if LWC messages are stored in the system or on the Messaging Server Adjunct - Switch Processor (for DEFINITY SI / DEFINITY CSI). |
| <b>spe</b>     | Enter <b>spe</b> if LWC messages are stored in the system or on the Switch Processor (for DEFINITY R).                                                |

## Mapping Mode

Controls the mode of operation in which the cell phone will operate when mapped to this XMOBILE extension. An XMOBILE station can be bridged to a deskset. These restrictions/modes exist because the COR of a bridge is ignored; instead the principal's COR is used. This field allows an XMOBILE station to function as a bridge and still be restricted.

When a cell phone is mapped to more than one XMOBILE station, then only one of the mapped XMOBILE station may have **origination** or **both** as its Mapping Mode. Therefore, only one of the XMOBILE stations mapped to the cell phone number is permitted to originate calls.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>both</b>          | The cell phone can be used to originate and terminate calls from its associated XMOBILE extension. This is the default when the XMOBILE Type field is PHS or DECT. |
| <b>none</b>          | The XMOBILE station is disabled administratively and cannot originate and terminate calls from its associated internal extension.                                  |
| <b>origination</b>   | The cell phone may be used only to originate calls from its associated internal XMOBILE extension by dialing into the office switch.                               |
| <b>termination</b>   | The cell phone may be used only to terminate calls from its associated internal XMOBILE extension. This is the default when the XMOBILE Type field is EC500.       |

**Map-to Station**

This is the physical phone used for calls to a virtual extension. Do not use an xmobile, xdid or another virtual extension.

| <b>Valid entries</b>   | <b>Usage</b>                                                                     |
|------------------------|----------------------------------------------------------------------------------|
| Valid extension number | Enter the extension of the physical phone used for calls to a virtual extension. |

**Media Complex Ext**

When used with Multi-media Call Handling, indicates which extension is assigned to the data module of the multimedia complex. Users can dial this extension to place either a voice or a data call, and voice conversion, coverage, and forwarding apply as if the call were made to the 1-number.

For an IP Telephone or an IP Softphone, this is the extension already administered as an H.323 station type. You can administer this field if the IP Station field on the System-Parameters Customer-Options screen is **y**.

| <b>Valid entries</b>       | <b>Usage</b>                                                                                                                                                                                                                                                                  |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A valid BRI data extension | For MMCH, enter the extension of the data module that is part of this multimedia complex.                                                                                                                                                                                     |
| H.323 station extension    | For 4600 series IP Telephones, enter the corresponding H.323 station.<br><br>For IP Softphone, enter the corresponding H.323 station. If you enter a value in this field, you can register this station for either a road-warrior or telecommuter/Avaya IP Agent application. |
| blank                      | Leave this field blank for single-connect IP applications.                                                                                                                                                                                                                    |

### Message Lamp Ext

Enter the extension of the station you want to track with the message waiting lamp. This field appears only when Type is **7101A**, **7103A**, **8110**, or **VRU**.

### Message Server Name

Specifies which Message Server is associated with the station.

| <b>Valid entries</b>                     | <b>Usage</b>                                                                                        |
|------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Names administered in alphabetical order | Must contain a user-defined adjunct name that was previously administered in the Node-Names screen. |

### Message Waiting Indicator

This field appears only for ISDN-BRI data modules and for 500, 2500, K2500, 7104A, 6210, 6218, 6220, 8110, and VRU telephones. (This field is independent of the administration of the Caller ID Message Waiting Indication for CallrID phones.)

| <b>Valid entries</b> | <b>Usage</b>                                                                       |
|----------------------|------------------------------------------------------------------------------------|
| <b>led</b>           | Enter <b>led</b> if the message waiting indicator is a light-emitting diode (LED). |
| <b>neon</b>          | Enter <b>neon</b> if the indicator is a neon indicator.                            |

**MIM Mtce/Mgt**

Indicates if the telephone supports MIM Maintenance and Management capabilities other than endpoint initialization. Appears only if MIM Support is **y**.

**MIM Support (Management Information Message Support)**

This field appears only for ISDN-BRI data modules and ASAI. This field supports MIM endpoint initialization (SPID support) and other Maintenance or Management capabilities.

| <b>Valid entries</b> | <b>Usage</b>                                           |
|----------------------|--------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> to display Endpt Init and MIM Mtce/Mgt. |
| <b>n</b>             | Enter <b>n</b> for ASAI.                               |

**Mobility Trunk Group**

This field associates the XMOBILE station to a trunk.

| <b>Valid entries</b>                                                               | <b>Usage</b>                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1-x</b> (where x is 666) for DEFINITY R                                         | Enter a valid trunk group number for mobility routing. This trunk group is used for routing. The Configuration Set field may be blank if the trunk group is DECT or PHS. If the trunk group is non-DECT or non-PHS, administer the Configuration Set field. |
| <b>2000</b> for S8700 IP Connect and S8700 Multi-Connect                           |                                                                                                                                                                                                                                                             |
| <b>99</b> for DEFINITY CSI, S8300 Media Server, and S8100 Media Server with a CMS1 |                                                                                                                                                                                                                                                             |
| blank                                                                              |                                                                                                                                                                                                                                                             |
| <b>aar</b>                                                                         | The routing capabilities of the switch will be used to direct the call to an ISDN trunk. If no ISDN trunk is available, the call will not be extended out of the switch. It will provide ringback to the calling company and may eventually go to coverage. |
| <b>ars</b>                                                                         | The routing capabilities of the switch will be used to direct the call to an ISDN trunk. If no ISDN trunk is available, the call will not be extended out of the switch. It will provide ringback to the calling company and may eventually go to coverage. |

### Multimedia Early Answer

Allows you to establish multimedia early answer on a station-by-station basis.

| <b>y</b>             | Enter <b>y</b> if this phone is not located in the same building with the system. If you enter <b>y</b> , you must complete R Balance Network. |
| <b>n</b>             | Enter <b>n</b> if the phone is located in the same building with the system.                                                                   |

## PCOL/TEG Call Alerting

Appears only for 510 telephones.

| <b>Valid entries</b> | <b>Usage</b>                                                                                |
|----------------------|---------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to alert the station for Personal CO Line/Terminating Extension Group calls. |

## Per Button Ring Control

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | <p>Enter <b>y</b> to allow users to select ring behavior individually for each call-appr, brdg-appr, or abrdg-appr on the station and to enable Automatic Abbreviated and Delayed ring transition for each call-appr on the station.</p> <p>Also, enter <b>y</b> if you do not want the system to automatically move the line selection to a silently alerting call unless that call was audibly ringing earlier.</p> |
| <b>n</b>             | <p>Enter <b>n</b> if you want calls on call-appr buttons to always ring the station and calls on brdg-appr or abrdg-appr buttons to always ring or not ring based on the Bridged Call Alerting field value.</p> <p>Also, enter <b>n</b> if you want the system to move line selection to a silently alerting call if there is no call audibly ringing the station.</p>                                                |

## Personalized Ringing Pattern

Personalized Ringing allows users of some telephones to have one of 8 ringing patterns for incoming calls. Users working closely in the same area can each specify a different ringing pattern. This enables the users to distinguish their own ringing telephone from other telephones in the same area. For virtual stations, this field dictates the ringing pattern on its mapped-to physical phone.

Enter a Personalized Ringing Pattern. (L = 530 Hz, M = 750 Hz, and H = 1060 Hz)

| <b>Valid entries</b> | <b>Usage</b>           |
|----------------------|------------------------|
| 1                    | MMM (standard ringing) |
| 2                    | HHH                    |
| 3                    | LLL                    |
| 4                    | LHH                    |
| 5                    | HHL                    |
| 6                    | HLL                    |
| 7                    | HLH                    |
| 8                    | LHL                    |

## Per Station CPN - Send Calling Number

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                       |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------|
| y                    | All outgoing calls from the station will deliver the Calling Party Number (CPN) information as "Presentation Allowed."             |
| n                    | No CPN information is sent for the call.                                                                                           |
| r                    | Outgoing non-DCS network calls from the station will deliver the Calling Party Number information as "Presentation Restricted."    |
| blank                | The sending of CPN information for calls is controlled by any administration on the outgoing trunk group the calls are carried on. |

## Port

Enter 7 characters to specify a port, or an x. If this extension is registered as an IP endpoint, this field will display S00000.

| Valid entries                         | Usage                                                                                                   |
|---------------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>01 through 44</b><br>(DEFINITY R)  | First and second numbers are the cabinet number                                                         |
| <b>01 through 03</b><br>(DEFINITY SI) |                                                                                                         |
| <b>A through E</b>                    | Third character is the carrier                                                                          |
| <b>01 through 20</b>                  | Fourth and fifth characters are the slot number                                                         |
| <b>01 through 32</b>                  | Sixth and seventh characters are the circuit number                                                     |
| <b>x</b>                              | Indicates that there is no hardware associated with the port assignment. Use for AWOH and CTI stations. |
| <b>IP</b>                             | Automatically entered for IP phones.                                                                    |

For DCP sets, the port can only be assigned once. ISDN-BRI provides a multipoint configuration capability that allows a previously assigned port to be specified more than once as follows: 2 stand-alone voice endpoints, 2 stand-alone data endpoints, or 1 integrated voice and data endpoint.

However, for the following cases, the port is assumed to be fully assigned:

- Maximum number of users (currently 2) are assigned on the port.
- One of the users on the port is a fixed TEI station.
- One of the users on the port has B-channel voice and B-channel data capability.
- One of the users on the port has no SPID assigned, which includes telephones that have no SPID initialization capability.
- This field is display-only for H.323 set types and 4600 set types. The system assigns an “IP” when the station is first administered.

## R Balance Network

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>      | Enter <b>y</b> to select the R Balance Capacitor network. In all other cases except for those listed under <b>n</b> , enter <b>y</b> .                                                                                                                                                                                                                                               |
| <b>n</b>      | Enter <b>n</b> to select the standard resistor capacitor network. You must complete this field if Off-Premise Station is <b>y</b> . Enter <b>n</b> when the station port circuit is connected to terminal equipment (such as SLC carriers or impedance compensators) optioned for 600-ohm input impedance and the distance to the equipment from the system is less than 3,000 feet. |

## Recall Rotary Digit

This field only appears if type is 500 or 2500.

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to allow the user of a rotary phone to dial the administered Recall Rotary Digit to receive recall dial tone. This will enable this user to perform conference and transfer operations.<br><br>You establish the Recall Rotary Digit on the <a href="#">Feature-Related System Parameters</a> screen. |

## Redirect Notification

| Valid entries | Usage                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to give a half ring at this phone when calls to this extension are redirected (via Call Forwarding or Call Coverage).<br><br>Enter <b>y</b> if LWC Reception is <b>audix</b> . |

## Remote Office Phone

| Valid entries | Usage                                                                               |
|---------------|-------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to use this station as an endpoint in a remote office configuration. |

## Restrict Last Appearance

| <b>Valid entries</b> | <b>Usage</b>                                                                                                              |
|----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to restrict the last idle call appearance for incoming priority calls and outgoing call originations only. |

## Room

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Up to 10 characters  | To identify the phone location.                                                                                                                                                                                    |
| Up to 5 characters   | To identify the guest room number, if this station is one of several to be assigned a guest room and the Display Room Information in Call Display is <b>y</b> on the Hospitality-Related System Parameters screen. |

## Security Code

Enter the security code required by users for specific system features and functions, including Personal Station Access, Redirection of Calls Coverage Off-Net, Leave Word Calling, Message Retrieval, and Demand Printing. The required security code length is determined by Minimum Security Code Length on the Feature-Related System Parameters screen.

## Select Last Used Appearance

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> to indicate a station's line selection is not to be moved from the currently selected line button to a different, non-alerting line button. If you enter <b>y</b> , the line selection on an on-hook station only moves from the last used line button to a line button with an audibly alerting call. If there are no alerting calls, the line selection remains on the button last used for a call. |
| <b>n</b>             | Enter <b>n</b> so the line selection on an on-hook station with no alerting calls can be moved to a different line button, which may be serving a different extension.                                                                                                                                                                                                                                               |

## Service Link Mode

The service link is the combined hardware and software multimedia connection between an Enhanced mode complex's H.320 DVC system and the Avaya MultiVantage which terminates the H.320 protocol. When the user receives or makes a call during a multimedia or IP Softphone or IP Telephone session, a "service link" is established.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>as-needed</b>     | Use this setting for most multimedia, IP Softphone, or IP Telephone users. Setting the Service Link Mode to as-needed leaves the service link connected for 10 seconds after the user ends a call so that they can immediately place or take another call. After 10 seconds the link is dropped and a new link would have to be established to place or take another call. |
| <b>permanent</b>     | Use <b>permanent</b> for busy call center agents and other users who are constantly placing or receiving multimedia, IP Softphone, or IP Telephone calls. In permanent mode, the service link stays up for the duration of the multimedia, IP Softphone, or IP Telephone application session.                                                                              |

## Set Color

Enter a valid set color as defined in the [Signaling Group screen \(page 2\)](#) screen. Valid entries include the following colors: beige, black, blue, brown, burg (burgundy), gray, green, ivory, orng (orange), red, teak, wal (walnut), white, and yel (yellow).

## Speakerphone

This field controls the behavior of speakerphones.

| Valid entries     | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1-way</b>      | Enter <b>1-way</b> to indicate that you want the speakerphone to be listen-only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>2-way</b>      | Enter <b>2-way</b> to indicate that you want the speakerphone to be both talk and listen.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>grp-listen</b> | Group Listen works with only 6400-series and 2420 phones.<br><br>Group Listen allows a phone user to talk and listen to another party with the handset or headset while the phone's 2-way speakerphone is in the listen-only mode. Others in the room can listen, but cannot speak to the other party via the speakerphone. The person talking on the handset acts as the spokesperson for the group. Group Listen provides reduced background noise and improves clarity during a conference call when a group needs to discuss what is being communicated to another party. |
| <b>none</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Special Dialing Option

This field identifies the type of dialing for calls when this data module originates calls.

| Valid entries   | Usage                                  |
|-----------------|----------------------------------------|
| <b>hot-line</b> |                                        |
| <b>default</b>  |                                        |
| blank           | For regular (normal) keyboard dialing. |

## SPID — (Service Profile Identifier)

Enter a variable length parameter. This field appears only if the Endpt Init field is **y**.

The SPID is a numeric string, which means that the value of 00 is different from 000. The SPID must be different for all terminals on the BRI and from the Service SPID. The SPID should always be assigned. If the SPID is not assigned for the first BRI on a port, any other BRI assignment to that port are blocked.

### ⇒ NOTE:

If you have set the Port field to X for an ISDN-BRI extension and intend to use Terminal Translation Initialization (TTI) to assign the port, then the SPID number must equal the station number.

**Station Lock Active**

| <b>Valid display</b> | <b>Usage</b>                              |
|----------------------|-------------------------------------------|
| yes/no               | Shows the phone's status of Station Lock. |

**Switchhook Flash**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                               |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> to allow users to use the switchhook flash function to activate Conference/Transfer/Hold and Call Waiting.                                                                                  |
| <b>n</b>             | Enter <b>n</b> to disable the flash function so that when the switchhook is pressed while active on a call, the call drops. If this field is <b>n</b> , you must set Call Waiting Indication to <b>n</b> . |

**TEI**

Appears only when the Fixed TEI field is **y**.

| <b>Valid entries</b> | <b>Usage</b>         |
|----------------------|----------------------|
| <b>0 to 63</b>       | 1- or 2-digit number |

**Tests**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> to enable port maintenance tests.                                                            |
| <b>n</b>             | If the equipment (dictaphone) connected to the port does not support these tests, you must enter <b>n</b> . |

**TN**

Enter the Tenant Partition number.

**Type**

For each station that you want to add to your system, you must specify the type of telephone in the Type field. This is how you distinguish between the many different types of telephones.

The following table lists the telephones, virtual phones, and personal computers that you can administer on the Avaya MultiVantage. To administer telephones that are not in the table, use the Alias Station screen.

**NOTE:**

You cannot change an analog phone administered with hardware to a virtual extension if TTI is **y** on the Feature-Related System Parameters screen. Contact your Avaya representative for more information.

**Table 17. Telephones**

| <b>Telephone type</b>                    | <b>Model</b>                                  | <b>Administer as</b> |
|------------------------------------------|-----------------------------------------------|----------------------|
| Single-line analog                       | 500                                           | 500                  |
|                                          | 2500, 2500 w/ Message Waiting Adjunct         | 2500                 |
|                                          | 6210                                          | 6210                 |
|                                          | 6211                                          | 6210                 |
|                                          | 6218                                          | 6218                 |
|                                          | 6219                                          | 6218                 |
|                                          | 6220                                          | 6220                 |
|                                          | 6221                                          | 6220                 |
|                                          | Analog phone w/Caller ID                      | CallrID              |
|                                          | 7101A, 7102A                                  | 7101A                |
|                                          | 7103A Programmable and Original               | 7103A                |
|                                          | 7104A                                         | 7104A                |
|                                          | 8110                                          | 8110                 |
|                                          | DS1FD                                         | DS1FD                |
|                                          | 7302H, 7303H                                  | 7303S                |
| VRU (voice response unit) with C&D tones | VRU                                           |                      |
| VRU without C&D tones                    | 2500                                          |                      |
| Single-line DS1/DSO (Lineside T1/DS1)    | DS1 device without forward disconnect         | ops                  |
|                                          | VRU with forward disconnect without C&D tones | ds1fd or ds1sa       |

**XID**

Appears only for an ISDN-BRI data module or an ASAI link. Used to identify Layer 2 XID testing capability.

**XMOBILE Type**

When the Type field is **XMOBILE**, the Mobility Trunk Group field must be administered.

| <b>Valid entries</b> | <b>Usage</b>                                                            |
|----------------------|-------------------------------------------------------------------------|
| <b>DECT</b>          | For the DECT Access System or the AGCS (ROAMEO) IS-136 (TDMA cellular). |

| <b>PHS</b>           | For the DENSO 300M.                                                     |

## System Parameters Call Coverage / Call Forwarding

This screen sets the system-wide parameters for call coverage and call forwarding.

### Field descriptions for page 1

```

change system-parameters coverage-forwarding page 1

SYSTEM PARAMETERS -- CALL COVERAGE / CALL FORWARDING

CALL COVERAGE/FORWARDING PARAMETERS
 Local Cvg Subsequent Redirection/CFWD No Ans Interval (rings): _
 Off-Net Cvg Subsequent Redirection/CFWD No Ans Interval (rings): _
 Coverage - Caller Response Interval (seconds): _
 Threshold for Blocking Off-Net Redirection of Incoming Trunks Calls: 1

COVERAGE
 Keep Held SBA at Coverage Point? _
 External Coverage Treatment for Transferred Incoming Trunk Calls? _
 Immediate Redirection on Receipt of PROGRESS Inband Information? _
 Maintain SBA At Principal? _
 QSIG VALU Coverage Overrides QSIG Diversion with Rerouting? _
 Station Hunt Before Coverage? n

FORWARDING
 Call Forward Override? _
 Coverage After Forwarding? _

```

### Screen 267. System-Parameters — Call Coverage / Call Forwarding

#### CALL COVERAGE / FORWARDING PARAMETERS

##### Coverage - Caller Response Interval (seconds)

The time in seconds the caller (internal caller only) has before a call redirects to the called party's first coverage point. The calling party either can hang up, use Leave Word Calling, or press the GO TO COVER button during this time interval.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|              |  |
|--------------|--|
| 0 through 10 |  |
|--------------|--|

**Local Cvg Subsequent Redirection/CFWD No  
Ans Interval (rings)**

This field specifies:

- the number of rings applied at a local coverage point before a call redirects to the next coverage point
- the number of rings applied at the principal before a call forwards when Call Forwarding Busy/Don't Answer is activated.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|      |                 |
|------|-----------------|
| 1–99 | See note below. |
|------|-----------------|

**Off-Net Cvg Subsequent Redirection/CFWD No  
Ans Interval (rings)**

This field specifies:

- the number of rings applied at an off-net coverage point before a call is redirected to the next coverage point
- the number of rings applied at an off-net forwarded-to destination before the call is redirected to coverage.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|      |                 |
|------|-----------------|
| 1–99 | See note below. |
|------|-----------------|

**⇒ NOTE:**

When ringing local destinations (say in an office environment), a short interval often is appropriate because the intended party either is near the phone or not present. However, when ringing off-net locations, you cannot assume how near the intended party is to the phone. If the call is left at an off-net destination for only a short interval, the call may be redirected to the next destination before the intended party has any real chance of answering the call.

## Threshold for Blocking Off-Net Redirection of Incoming Trunk Calls

This field applies for those occasions when an incoming call to a station redirects off-net. At that time, the Call Forward timer activates to block any further incoming calls to that station from being redirected off-net until the timer expires.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                     |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>1-7</b>           | The number of allowed calls to be routed off-net before blocking commences.                                                      |
| <b>n (all)</b>       | Call processing never activates the Call Forward timer. Therefore, any number of calls to a principal may be redirected off-net. |

## COVERAGE

### External Coverage Treatment for Transferred Incoming Trunk Calls

This field governs how an transferred incoming trunk call is handled if the call redirects to coverage.

| <b>Valid entries</b> | <b>Usage</b>                                                                                            |
|----------------------|---------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> to allow external coverage treatment for incoming trunk calls that redirect to coverage. |
| <b>n</b>             | Enter <b>n</b> to allow internal coverage treatment for incoming trunk calls that redirect to coverage  |

### Immediate Redirection on Receipt of PROGRESS Inband Information

This field appears only if one of the following is true:

- The Coverage of Calls Redirected Off-Net Enabled field on the System Parameters Coverage/Forwarding screen is **y**.
- The Value-Added Avaya (VALU) field on the System Parameters Customer Options, Page 6, screen is **y**.

This field pertains only to CCRON and QSIG VALU coverage calls redirected over end-to-end ISDN facilities. Some cellular phone providers send an ISDN PROGRESS message with the Progress Indicator field set to 'inband information' when a cellular phone is unavailable to receive a call. In these circumstances, the message indicates that an announcement is being played to the originating party and we should move the call immediately to the next available coverage point.

However, a PROGRESS message with a Progress Indicator of 'inband information' may be received for reasons other than an unavailable cellular phone. In this case, you probably do not want to redirect the call to the next coverage point.

There is no way for the Avaya MultiVantage to know the actual intent of such a PROGRESS message, yet you may choose how the system should handle this message. It is essentially an educated, but blind, choice and you should be aware that there will be instances when this choice leads to inappropriate call handling.

Avaya MultiVantage queries this field on receipt of a qualifying PROGRESS message and acts according to your instruction on how to treat it.

As a guide, users in European countries following the ETSI standard and redirecting to GSM cellular phones may want to consider setting this field to **y**.

In the United States, PROGRESS messages with the Progress Indicator field set to 'inband information' are sent for a variety of reasons not associated with unavailable cell phones and you should set this field to **n**.

| <b>Valid entries</b> | <b>Usage</b>                                                                               |
|----------------------|--------------------------------------------------------------------------------------------|
| <b>y</b>             | Immediately redirect an off-net coverage/forwarded call to the next coverage point.        |
| <b>n</b>             | Do not immediately redirect an off-net coverage/forwarded call to the next coverage point. |

### **Keep Held SBA at Coverage Point**

This field governs how a covering user who has placed an answered coverage call on hold is treated if the original principal bridges onto the call.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                     |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Keeps the coverage party on the call. The coverage party remains on hold, but may enter the call along with the principal and the calling party. |
| <b>n</b>             | Drops the coverage party from the call.                                                                                                          |

### Maintain SBA At Principal

Allows a user to maintain a simulated bridged appearance when a call redirects to coverage.

| Valid entries | Usage                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>      | Enter <b>y</b> to maintain a simulated bridged appearance (SBA) on the principal's phone when a call redirects to coverage. DCS with rerouting will not be attempted after coverage.                                            |
| <b>n</b>      | When set to <b>n</b> , no SBA is maintained on the principal's phone. DCS with rerouting will be attempted, and if successful, the principal will lose the bridged appearance and the ability to bridge onto the coverage call. |

### QSIG VALU Coverage Overrides QSIG Diversion with Rerouting

This field appears if, on the System-Parameters Customer-Options screen, the Basic Supplementary Services and Supplementary Services with Rerouting fields are **y**.

This field specifies whether, with both QSIG Diversion with Rerouting and QSIG VALU turned on, the Coverage After Forwarding option on the Station screen will work for a user for calls that go to remote coverage. Normally, with QSIG Diversion with Rerouting turned on, the local system passes control of a forwarded call to the remote QSIG switch on which the forwarding destination resides. In this case, the forwarded call cannot return to coverage for the user who originally received the call, even when the remote destination is busy or does not answer.

However, you can enter **y** in this field to have QSIG VALU call coverage take precedence. In this case, if the Coverage After Forwarding option on the Station screen is enabled for a user, then QSIG Diversion with Rerouting is not be attempted.

| Valid entries | Usage                                                                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to allow Coverage After Forwarding to work when it is activated on a user's Station screen and Diversion with Rerouting is also turned on. |

### Station Hunt Before Coverage

This field allows you to choose whether a call to a busy station performs station hunting before going to coverage.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                     |
|------------|-----------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to use Station Hunt Before Coverage. |
|------------|-----------------------------------------------------|

### FORWARDING

---

#### Call Forward Override

This field specifies how to treat a call from a forwarded-to party to the forwarded-from party.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|          |                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------|
| <b>y</b> | Overrides the Call Forwarding feature by allowing a forwarded-to station to complete a call to the forwarded-from station. |
| <b>n</b> | Directs the system to forward calls to a station even when they are from the forwarded-to party.                           |

#### Coverage After Forwarding

This field governs whether an unanswered forwarded call is provided coverage treatment.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|          |                                                                                                                    |
|----------|--------------------------------------------------------------------------------------------------------------------|
| <b>y</b> | Coverage treatment is provided to unanswered forwarded calls.                                                      |
| <b>n</b> | No coverage treatment is provided to unanswered forwarded calls. The call remains at the forwarded-to destination. |

**Field descriptions for page 2**

```
change system-parameters coverage-forwarding page 2

 SYSTEM PARAMETERS -- CALL COVERAGE / CALL FORWARDING

COVERAGE OF CALLS REDIRECTED OFF-NET (CCRON)
 Coverage Of Calls Redirected Off-Net Enabled? y
 Activate Answer Detection (Preserves SBA) On Final CCRON Cvg Point? y
 Ignore Network Answer Supervision? y
 Disable call classifier for CCRON over ISDN trunks? n
```

**Screen 268. System-Parameters Coverage-Forwarding**

**COVERAGE OF CALLS REDIRECTED OFF-NET (CCRON)**

**Activate Answer Detection (Preserves SBA) On Final CCRON Cvg Point**

This field appears only if the Coverage of Calls Redirected Off-Net Enabled field on this screen is **y**.

When the system redirects a call off-net at the final coverage point in a coverage path, the system can apply no further coverage treatment even if the call is unanswered. The only reason for activating answer detection on such a call is to maintain the simulated bridged appearance (SBA) on the principal's phone that allows the principal to answer or bridge onto the call. However, when the system monitors the call through use of a call classifier port, there is an inherent cut-through delay following the detection of answer at the far end. This field has no consequence when the off-net call is carried end-to-end by ISDN facilities; the SBA is maintained and there is no cut-through delay.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                  |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Directs the system to maintain a simulated bridged appearance on the principal when redirecting to a final off-net coverage point.                                                                                                            |
| <b>n</b>             | Allows the system to drop the SBA on the principal's phone when the call redirects off-net at the last coverage point, eliminating the cut-through delay inherent in CCRON calls, but sacrificing the principal's ability to answer the call. |

## Coverage Of Calls Redirected Off-Net Enabled

This field allows you to enable/disable the Coverage of Calls Redirected Off-Net (CCRON) feature. This field provides a quick means of disabling this feature if the demand on the call classifier port resources degrades other services provided by the switch.

To set this field to **y**, first set the Cvg Of Calls Redirected Off-net field on the System-Parameters Customer-Options screen to **y**. The Coverage of Calls Redirected Off-Net field on this screen must be **y** to administer this field.

| Valid entries | Usage                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>      | Avaya MultiVantage monitors off-net coverage/forwarded calls and provides further coverage treatment for unanswered calls.                   |
| <b>n</b>      | Avaya MultiVantage does not monitor offnet coverage/forwarded calls. No further coverage treatment is provided if such calls are unanswered. |

## Disable call classifier for CCRON over ISDN trunks

When a CCRON call routes offnet over ISDN end-to-end facilities, no call classifier is attached to the call. If, subsequently during the call, an ISDN PROGRESS or ALERT message is received that indicates that interworking has occurred, a call classifier is normally attached to the call and assumes precedences over ISDN trunk signalling. This field provides a customer the means of directing the switch to dispense with the call classifier on interworked calls and rely on the ISDN trunk signalling messages.

| Valid entries | Usage                                                                                          |
|---------------|------------------------------------------------------------------------------------------------|
| <b>y</b>      | Use <b>y</b> to disable the call classifier for CCRON calls over interworked trunk facilities. |
| <b>n</b>      | Use <b>n</b> to enable the call classifier for CCRON calls over interworked trunk facilities.  |

## Ignore Network Answer Supervision

This field appears only if the Coverage of Calls Redirected Off-Net Enabled field on this screen is **y**.

CCRON may use a call classifier port to determine whether an off-net coverage or forwarded call has been answered, discarding other information that may indicate an answered state. However, some customers pay the operating company to

provide network answer supervision on their trunks and desire that CCRON not discard that information. They may preserve this service by setting this field to **n**.

On the other hand, beware when you tandem a call over a tie trunk through another switch node from where it redirects to the public network over non-ISDN facilities. If the trunk on the far-end node sends a timed answer supervision, that may get tandemed back to the originating switch as a network answer. In such a scenario, the originating switch interprets the call as answered, leading to some undesirable behavior. To avoid these calls from mistakenly be treated as answered, set this field to **y**. An unfortunate consequence is that a short cut-through delay that is inherent to call classification is introduced when the call is answered.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|          |                                                                                                         |
|----------|---------------------------------------------------------------------------------------------------------|
| <b>y</b> | Ignore network answer supervision and rely on the call classifier to determine when a call is answered. |
| <b>n</b> | Treat network answer supervision as a true answer.                                                      |

## System Parameters Country-Options

This screen implements parameters associated with certain international (including North American) call characteristics. You cannot change this screen. See your Avaya representative if you want to modify any of the values here.

See the following table for country codes throughout this screen.

### Country code table

| <b>Code</b> | <b>Country</b>         |
|-------------|------------------------|
| <b>1</b>    | United States, Canada  |
| <b>2</b>    | Australia, New Zealand |
| <b>3</b>    | Japan                  |
| <b>4</b>    | Italy                  |
| <b>5</b>    | Netherlands            |
| <b>6</b>    | Singapore              |

|                |                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 25</b> | See the <a href="#">Country code table</a> at the beginning of this screen description. For more information on, see Audible Ringing Patterns in <i>Avaya MultiVantage™ Solutions Hardware Guide</i> . |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

 **NOTE:**

If the Analog Ringing Cadence is set to 3, 10, 11, or 25, then the Message Waiting Indicator on K2500 phones does not flash.

### Analog Line Transmission

The country code identifies the transmission and signaling parameters.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|             |                                                                                         |
|-------------|-----------------------------------------------------------------------------------------|
| <b>1-25</b> | See the <a href="#">Country code table</a> at the beginning of this screen description. |
|-------------|-----------------------------------------------------------------------------------------|

### Base Tone Generation Set

The country code identifies the base tone generation set to be used. This field is meaningful only if the system tone detector is a TN780, vintage 4 or a TN2182.

A TN780 vintage 5 or greater or a TN2182 is required if Belgian Tones (Country code 8) are specified.

| Valid entries | Usage                                                                                   |
|---------------|-----------------------------------------------------------------------------------------|
| 1–25          | See the <a href="#">Country code table</a> at the beginning of this screen description. |

## Companding Mode

Identifies the companding algorithm to be used by system hardware.

| Valid entries | Usage                         |
|---------------|-------------------------------|
| A-law         | Generally used outside the US |
| Mu-law        | Generally used in the US      |

## Disconnect on No Answer by Call Type

Drops outgoing trunk calls (except DCS and AAR) that users leave unanswered too long.

| Valid entries | Usage                                                         |
|---------------|---------------------------------------------------------------|
| y/n           | Enables the system to disconnect calls that are not answered. |

## Display Character Set

Appears only for 607, 46xx, 64xx, and 84xx telephone sets.

| Valid entries | Usage                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------------|
| cyrillic      | Indicate the enhanced character set to display. See <a href="#">Enhanced Telephone Display</a> for more information. |
| katakana      |                                                                                                                      |
| roman         |                                                                                                                      |
| ukranian      |                                                                                                                      |

 **NOTE:**  
Cyrillic, Roman, and Ukranian map to the Eurofont character set.

## Enable Busy Tone Disconnect for Analog Loop-start Trunks

This field allows the switch to recognize a busy tone from the central office as a disconnect signal.

| Valid entries | Usage                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to allow the switch to disconnect the trunk when a busy tone is received from the central office. |

### Howler After Busy

Plays howler tone when users leave their analog phone off-hook too long.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                      |
|------------|----------------------|
| <b>y/n</b> | Enables howler tone. |
|------------|----------------------|

### Set Layer 1 timer T1 to 30 seconds

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                           |
|------------|-----------------------------------------------------------|
| <b>y/n</b> | Specifies whether the Layer 1 timer is set to 30 seconds. |
|------------|-----------------------------------------------------------|

## STONE DETECTION PARAMETERS

### Dial Tone Validation Timer

Displays number of milliseconds that the dial tone validation routine will use to sample transmissions. This field appears only when Tone Detection Mode is equal to **4** or **5**. (Valid with TN420C or later Tone Detector circuit pack.)

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|               |                     |
|---------------|---------------------|
| <b>0–6375</b> | in increments of 25 |
|---------------|---------------------|

### Interdigit Pause

Specifies the maximum length of the inter-digit pause. Breaks lasting less than this range will be bridged or ignored. (Valid with TN420C or later Tone Detector circuit pack.)

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|              |           |
|--------------|-----------|
| <b>short</b> | 5 to 30ms |
|--------------|-----------|

|             |            |
|-------------|------------|
| <b>long</b> | 20 to 40ms |
|-------------|------------|

### Tone Detection Mode

The country code specifies the type of tone detection used on a TN420B (or later) tone-detection circuit pack.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|          |                                          |
|----------|------------------------------------------|
| <b>1</b> | Precise Italian tone detection algorithm |
|----------|------------------------------------------|

|          |                                             |
|----------|---------------------------------------------|
| <b>2</b> | Precise Australian tone detection algorithm |
|----------|---------------------------------------------|

|          |                                     |
|----------|-------------------------------------|
| <b>3</b> | Precise UK tone detection algorithm |
|----------|-------------------------------------|

| Valid entries | Usage                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------|
| 4             | Imprecise normal broadband filter algorithm (valid with TN420C or later Tone Detector circuit pack) |
| 5             | Imprecise wideband filter algorithm (valid with TN420C or later Tone Detector circuit pack)         |
| 6             |                                                                                                     |

End-to-End total loss (dB) in a n-party conference:  
 3: \_\_\_\_\_ 4: \_\_\_\_\_ 5: \_\_\_\_\_ 6: \_\_\_\_\_

### Screen 271. System Parameters Country-Options

#### Customize

Display-only field that appears when, on the System-Parameters Customer-Options screen, the Digital Loss Plan Modification field is **y**.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|     |                                                  |
|-----|--------------------------------------------------|
| y/n | Enables customization on the 2-party loss table. |
|-----|--------------------------------------------------|

## Digital Tone Plan

Provides the default values for tone loss for the selected country.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|              |                                                                                         |
|--------------|-----------------------------------------------------------------------------------------|
| 1 through 25 | See the <a href="#">Country code table</a> at the beginning of this screen description. |
|--------------|-----------------------------------------------------------------------------------------|

## End-to-End total loss (dB) in a n-party conference

Provides total loss for a conference call with the designated number of parties.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|              |                                                                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 through 99 | The higher the number listed for a call with a fixed display number of parties, the more loss the switch adds into a conference call with that number of parties; therefore, the conference call is quieter. |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## FROM / TO

Display-only fields that identify the variable digital tone values.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|               |                                                                                    |
|---------------|------------------------------------------------------------------------------------|
| -3 through 15 | An unsigned number is a loss, while a number preceded with a minus sign is a gain. |
|---------------|------------------------------------------------------------------------------------|

## Screen 272. System Parameters Country-Options

## Cadence Step

Display-only fields that identify the number of each tone cadence step.

| <b>Valid entries</b> | <b>Usage</b>                                     |
|----------------------|--------------------------------------------------|
| 1–15                 | Identifies the number of each tone cadence step. |

## Duration (msec)

There is one dynamic Duration field associated with each of the 15 Tone (Frequency/Level) fields on each screen page. Initially, when Tone is blank, this field does not appear. However, when a non-blank value other than **goto** is entered in a Tone field, the associated Duration field appears, and must be used to specify the duration (in milliseconds) of the specified tone.

| <b>Valid entries</b>                               | <b>Usage</b>                                        |
|----------------------------------------------------|-----------------------------------------------------|
| <b>50</b> through <b>12750</b> in increments of 50 | To describe the duration of each administered tone. |

## Step

There is one dynamic Step field associated with each of the 15 Tone (Frequency/Level) fields shown on a screen page. Initially, when Tone is blank, this field does not appear. However, when **goto** is entered in a Tone field, the associated Step field appears, and must be used to specify the cadence step to begin repeating from

| <b>Valid entries</b> | <b>Usage</b>                                                 |
|----------------------|--------------------------------------------------------------|
| Cadence Step (1–14)  | Beginning the repeated sequence for a “ <b>goto</b> ” entry. |

## Tone Name

Each entry uses one of the keywords below to indicate which of the individually administrable tones this screen modifies. This field (with its associated Tone (Frequency/Level), Duration, and Step fields) is meaningful only if the system tone detector is a TN780, vintage 4 or greater, or a TN2182.

| <b>Valid entries</b>      | <b>Usage</b>                                                                                        |
|---------------------------|-----------------------------------------------------------------------------------------------------|
| blank                     | If this field is blank, all entries in the corresponding Frequency and Duration fields are ignored. |
| <b>1-call-wait</b>        |                                                                                                     |
| <b>2-call-wait</b>        |                                                                                                     |
| <b>3-call-wait</b>        |                                                                                                     |

| 1004/0.0             |                                                                                                                                                                                       |
| 1004/-16.0           |                                                                                                                                                                                       |
| 1209/-7.5            |                                                                                                                                                                                       |
| 1336/-7.5            |                                                                                                                                                                                       |
| 1400/-11.0           |                                                                                                                                                                                       |
| 1477/-7.5            |                                                                                                                                                                                       |
| 1633/-7.5            |                                                                                                                                                                                       |
| 2025/-12.1           |                                                                                                                                                                                       |
| 2100/-12.1           |                                                                                                                                                                                       |
| 2225/-12.1           |                                                                                                                                                                                       |
| 2804/-16.0           |                                                                                                                                                                                       |

## System-Parameters Customer-Options

This screen shows you which optional features are enabled for your system as determined by the installed license file. If you have any questions about disabling or enabling one of these features contact your Avaya representative.

### Field descriptions for page 1

```

display system-parameters customer-options page 1
 OPTIONAL FEATURES
 Used
G3 Version: V10 Maximum Ports: 2800 1041
Location: 1 Maximum XMOBILE Stations: 0 0
Platform:
IP PORT CAPACITIES
 Maximum Administered IP Trunks: 100 96
Maximum Concurrently Registered IP Stations: 10 10
Maximum Administered Remote Office Trunks: 0 0
Maximum Concurrently Registered Remote Office Stations: 0 0
Maximum Concurrently Registered IP eCons: 0 0
Maximum Number of DS1 Boards with Echo Cancellation: 0 0
Maximum VAL Boards: 1 0
(NOTE: You must logoff & login to effect the permission changes.)

```

### Screen 273. System Parameters Customer-Options

#### G3 Version

Identifies the version of Avaya MultiVantage being used.

#### Location

Indicates the location of this switch. 1 indicates Canada or the United States. 2 indicates any other location, and allows the use of International Consolidation circuit packs and telephones.

#### Maximum Ports

Number of ports active, per contract.

#### Maximum XMOBILE Stations

Specifies the maximum number of allowable XMOBILE stations. In general, each XMOBILE station is assigned to a wireless handset. Each XMOBILE station counts as a station and a port in terms of system configuration.

## **Platform**

A display-only field that identifies, via a number mapping, the platform being used for a specific customer.

## **IP PORT CAPACITIES**

---

### **Maximum Administered IP Trunks**

Defines limits of the number of IP trunks administered.

### **Maximum Administered Remote Office Trunks**

Defines limits of the number of IP endpoints based on the endpoint. Use the smaller of this number or the number based on product ID on page 7 of this screen.

### **Maximum Concurrently IP eCons**

Specifies the maximum number of IP SoftConsoles that may be registered at one time. The maximum number depends on the type of system.

### **Maximum Concurrently Registered IP Stations**

Specifies the maximum number of IP stations that may be registered at one time. Must be less than or equal to the Maximum Ports field on this page. The switch will use the smaller of this number or the number based on product ID on page 7 of this screen.

### **Maximum Concurrently Registered Remote Office Stations**

Specifies the maximum number of remote office stations that may be registered at one time. Must be less than or equal to the Maximum Ports field on this page. The switch will use the smaller of this number or the number based on product ID on page 7 of this screen.

### **Maximum Number of DS1 Boards with Echo Cancellation**

Shows the number of DS1 circuit packs that can have echo cancellation.

## Maximum VAL Boards

| Valid entries                                                                    | Usage                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0-10</b><br>(DEFINITY R and S8700 Media Servers)                              | This display-only field indicates the maximum number of TN2501AP (Voice Announcement over LAN) boards allowed in this system.                                                                                                                                                             |
| <b>0-5</b><br>(DEFINITY SI and CSI, S8100 Media Servers, and S8300 Media Server) | <ul style="list-style-type: none"> <li>■ For values greater than 1, the Val Full 1-Hour Capacity field on page 4 of the System-Parameters Customer-Options screen must be set to <b>y</b>.</li> <li>■ This field updates the System Limit field on the System Capacity report.</li> </ul> |

 OPTIONAL FEATURES

Abbreviated Dialing Enhanced List? Audible Message Waiting?
Access Security Gateway (ASG)? Authorization Codes?
Analog Trunk Incoming Call ID? CAS Branch?
A/D Grp/Sys List Dialing Start at 01? CAS Main?
Answer Supervision by Call Classifier? Change COR by FAC?
 ARS? Computer Telephony Adjunct Links?
 ARS/AAR Partitioning? Co-Res DEFINITY LAN Gateway?
 ARS/AAR Dialing without FAC? Cvg Of Calls Redirected Off-net?
 ASAI Link Core Capabilities? DCS (Basic)?
 ASAI Link Plus Capabilities? DCS Call Coverage?
 Async. Transfer Mode (ATM) PNC? DCS with Rerouting?
 Async. Transfer Mode (ATM) Trunking?
 ATMS? Digital Loss Plan Modification?
 Attendant Vectoring? DS1 MSP?
 DS1 Echo Cancellation?

```

## Screen 274. System Parameters Customer-Options

### Abbreviated Dialing Enhanced List

Provides the capability to store and retrieve dialing lists that simplify or eliminate dialing. You dial an abbreviated code or depress an assigned button. The stored entries are organized in number lists. There are three types of number lists: personal, group, and enhanced.

### Access Security Gateway (ASG)

Provides an additional level of security for remote administration of the switch.

### **A/D Grp/Sys List Dialing Start at 01**

Allows you to number Abbreviated Dialing group or system lists starting with 01, rather than simply 1. This allows Avaya MultiVantage Abbreviated Dialing to operate like it does with the DEFINITY G2 system.

### **Analog Trunk Incoming Call ID**

This field allows collection and display the name and number of an incoming call information on analog trunks.

### **Answer Supervision by Call Classifier**

This circuit pack detects tones and voice-frequency signals on the line and determines whether a call has been answered. This field is set to **y** if the system contains a call-classifier circuit pack.

### **ARS**

Provides access to public and private communications networks. Long-distance calls can be routed over the best available and most economical routes. Provides partitioning of ARS routing patterns.

### **ARS/AAR Partitioning**

Provides the ability to partition AAR and ARS into 8 user groups within a single Avaya MultiVantage. Can establish individual routing treatment for each group.

### **ARS/AAR Dialing without FAC**

Provides for Automatic Alternate Routing (AAR) and Automatic Route Selection (ARS) calls without dialing a Feature Access Code (FAC).

### **ASAI Link Core Capabilities**

Provides linkage between Avaya MultiVantage and adjuncts. CallVisor ASAI improves the call handling efficiency of ACD agents and other system users by allowing an adjunct to monitor, initiate, control, and terminate calls on the switch.

#### **⇒ NOTE:**

ASAI Link Core Capabilities only applies to links administered as type asai. This field was previously named ASAI Interface.

If the ASAI Link Core Capabilities field is administered to **y** then it will be associated with the following ASAI capability groups:

- Adjunct Control

- Domain Control
- Event Notification
- Single Step Conference
- Request Feature
- II Digits
- Set Value
- Value Query

For more information, see the *Avaya MultiVantage™ CallVisor® ASAI Technical Reference*.

### **ASAI Link Plus Capabilities**

Provides linkage between Avaya MultiVantage and adjuncts. If the `ASAI Link Plus Capabilities` field is administered to **y**, then the following ASAI capability groups are enabled:

- Adjunct Routing
- Answering Machine Detection
- Selective Listening
- Switch Classified Outbound Calls
- ISDN Redirecting Number Information - the original dialed number information is provided within the ASAI messages if it arrives in ISDN SETUP messages from the public networks as either Original Dialed Number or Redirecting Party Number.

 **NOTE:**

ASAI Link Plus Capabilities only applies to links administered as type `asai`.

For more information, see the *Avaya MultiVantage™ CallVisor® ASAI Technical Reference*.

### **Asynch. Transfer Mode (ATM) PNC**

ATM PNC can be enabled only if:

- all prior fiber-link administration has been removed
- all “switch-node” and “dup-switch-node” carrier types have been removed

### **Asynch. Transfer Mode (ATM) Trunking**

If ATM trunking is enabled, multiple ISDN-PRI T1 or E1 trunks can be emulated on one ATM pipe. Can only be enabled if the ISDN-PRI field is set to **y**. Enables circuit emulation service (CES).

### **ATM WAN Spare Processor**

Appears on DEFINITY R only. An ATM WAN spare processor acts as a PPN in the event of network failure, and can function as an SPE if the main PPN is not functional. Cannot be set to **y** if the Async. Transfer Mode (ATM) Trunking field is **n**.

### **ATMS**

Provides for voice and data trunk facilities to be measured for satisfactory transmission performance.

### **Attendant Vectoring**

Allows you to use attendant vectoring. Cannot be set to **y** if the CAS Main and CAS Branch fields are **y**.

### **Audible Message Waiting**

Provides audible message waiting.

### **Authorization Codes**

Permits you to selectively specify levels of calling privileges that override in-place restrictions. In addition to facilities access, authorization codes are used for unique identification for billing security purposes.

### **CAS Branch**

Provides Centralized Attendant Service - Branch. See CAS Main for more information. Cannot be set to **y** if the Attendant Vectoring and Centralized Attendant fields are **y**.

### **CAS Main**

Provides multi-location switch customers served by separate switching vehicles to concentrate attendant positions at a single main Avaya MultiVantage location. The main Avaya MultiVantage is served by an attendant queue that collects calls from all locations (main and branch). Each branch location switches all of its incoming calls to the centralized attendant positions over release link trunks (RLTs). The calls are then extended back to the requested extension at the branch

switch over the same RLT. When the call is answered, the trunks to the main switch are dropped and can be used for another call. Cannot be set to **y** if the Centralized Attendant and CAS Branch fields are **y**.

### Change COR by FAC

Provides certain users the ability to change the class of restriction of local extensions and local attendants via a phone by using a feature access code (FAC). Cannot be set to **y** if the Tenant Partitioning field is **y**.

### Co-Res DEFINITY LAN Gateway

(For S8100 Media Servers and S8300 Media Server only.) Provides communications between TCP/IP clients and MultiVantage call processing. Cannot be set to **y** if the ASAI Link Core Capabilities and Computer Telephony Adjunct Links fields are **n**.

For more information see the *Avaya MultiVantage™ CallVisor® ASAI Technical Reference*.

### Computer Telephony Adjunct Links

Provides linkage between Avaya MultiVantage and adjuncts. Includes both the ASAI Link Core and ASAI Link Plus capabilities, plus the Phantom Calls and CTI Stations.

#### NOTE:

Computer Telephony Adjunct Links only applies to links administered as type **adjlk**. This field was previously named ASAI Proprietary Adjunct Links.

For more information see the *Avaya MultiVantage™ CallVisor® ASAI Technical Reference*.

### Cvg Of Calls Redirected Off-net

Provides continued monitoring for calls redirected to off-network (remote) coverage points. Uses call classification via call classifier circuit pack or ISDN trunk signaling.

### DCS (Basic)

Provides transparent operation of selected features across a Distributed Communications System (DCS). Users on one switch can use features located on another switch. Includes 4- and 5-digit uniform dialing and 1–4 digit steering. Does not support a 6/7-digit dial plan.

### DCS Call Coverage

Provides DCS-based transparency of the call coverage feature across a DCS network of switches.

### DCS with Rerouting

Provides for rerouting calls transferred among DCS nodes, enabling rerouting of the call for more effective use of facilities. Cannot be set to **y** if the ISDN PRI field is **n**.

### Digital Loss Plan Modification

Allows you to customize the digital loss and digital tone plans.

### DS1 MSP

Provides the ability to change fields on DS1 circuit pack screen without removing the related translations of all trunks from the trunk group.

### DS1 Echo Cancellation

Removes perceivable echo from the system.

 OPTIONAL FEATURES
```

```
Emergency Access to Attendant? ISDN Feature Plus?
 Enable 'dadmin' login? ISDN Network Call Redirection?
 Enhanced Conferencing? ISDN-BRI Trunks?
 Enhanced EC500? ISDN-PRI?
 Extended Cvg/Fwd Admin? Local Spare Processor?
 External Device Alarm Admin? Malicious Call Trace?
Five Port Networks Max Per MCC? Mode Code for Centralized Voice Mail?
 Flexible Billing?
Forced Entry of Account Codes? Multifrequency Signaling?
 Global Call Classification? Multimedia Appl.Server Interface(MASI)?
 Hospitality (Basic)? Multimedia Call Handling (Basic)?
Hospitality (G3V3 Enhancements)? Multimedia Call Handling(Enhanced)?
 H.323 Trunks? Multiple Locations?
 Personal Station Access (PSA)?
 IP Attendant Consoles?
 IP Stations?
```

### Screen 275. System Parameters Customer-Options

### **Emergency Access to Attendant**

Provides for emergency calls to be placed to an attendant. These calls can be placed automatically by Avaya MultiVantage or dialed by users.

### **Enable 'dadmin' Login**

Provides business partners the ability to install, administer, and maintain DEFINITY switches.

### **Enhanced Conferencing**

Enhanced Conferencing allows the customer to use the Meet-me Conference, Selective Conference Party Display, Drop, and Mute, and No Hold Conference features. Must be **y** for Enhanced Conferencing.

### **Enhanced EC500**

Provides mobile call services including "Anytime Anywhere" accessibility with One Number availability and Origination mapping.

### **Extended Cvg/Fwd Admin**

Provides basic telecommuting package capability for Extended User Administration of Redirected Calls.

### **External Device Alarm Admin**

Provides for analog line ports to be used for external alarm interfaces. Allows identification of port location, adjunct associated with port location, and the alarm level to report.

### **Five Port Networks Max Per MCC**

Available only for DEFINITY R and S8700 Multi-Connect. Allows system administration to create five port networks in a multi-carrier cabinet. If there are any cabinets with more than 2 PNs assigned, this field cannot be set to **n**.

### **Flexible Billing**

Provides an internationally accepted standard interface for end-to-end digital connectivity. Used with a T1 interface and supports twenty-three 64-KBPS voice or data B-Channels and one 64-Kbps signaling D Channel for total bandwidth of 1.544 Mbps.

## Forced Entry of Account Codes

Allows system administration to force account users to enter account codes based on user or trunk class of restriction, or by an option on the Toll Analysis table. FEAC provides an easy method of allocating the costs of specific calls to the correct project, department, etc.

## Global Call Classification

Provides call classification outside of North America. Listens for tones and classifies tones detected. Required for Call Coverage Off Net and Outgoing Call Management.

## Hospitality (Basic)

Provides access to basic features including: Attendant Crisis Alert, Attendant Room Status, Automatic Wakeup, Custom Selection of VIP DID Numbers, Do Not Disturb, Names Registration, Single-Digit Dialing, and Mixed Station Numbering.

## Hospitality (G3V3 Enhancements)

Software required for Property Management System and Automatic Wakeup. Property Management System Interface activates Forward PMS Messages to INTUITY Lodging and PMS Protocol Mode (transmit in ASCII mode). Cannot be set to **y** if the Hospitality (Basic) field is **n**.

Usage Note: standard hospitality features are included in basic system software.

## Internet Protocol (IP) PNC

This field is only for the Avaya S8700 IP-Connect and then should be set to **y**. This field cannot be administered if:

- the Asynch. Transfer Mode (ATM) PNC field is **y**
- the PNC Duplication field is **y**
- If fiber is administered

## IP Trunks

Controls permission to administer H.323 trunks. Must be **y** for IP trunks.

## IP Attendant Consoles

Controls permission to administer the IP Attendant Console.

## IP Stations

Controls permission to administer H.323 and/or SoftPhone stations. Must be **y** for IP phones.

## ISDN Feature Plus

Provides ISDN Feature Plus signaling. This option is enabled when either the ISDN-BRI Trunks field or the ISDN-PRI field is **y**.

## ISDN Network Call Redirection

Administrable if the ISDN-PRI or ISDN-BRI Trunk field is **y**. Network Call Redirection (NCR) redirects an incoming ISDN call from an Avaya MultiVantage system to another PSTN endpoint. Used in Call Centers with Best Service Routing and Lookahead Interflow. For more information, see *Avaya MultiVantage Network Call Redirection*.

## ISDN-BRI Trunks

Provides the capability to add ISDN-BRI trunks to the switch. If enabled, can add isdn trunk groups and the following screens are accessible:

- network-facilities
- private-numbering
- public-unknown- numbering

## ISDN-PRI

Provides Integrated Services Digital Network (ISDN-PRI) software for either a switch-hardware platform migration only or a switch-hardware platform migration in combination with a software version upgrade. Also provides signaling support for H.323 signaling. Must be **y** for IP trunks.

## Local Spare Processor

A display-only field that indicates that the switch is a Local Spare Processor (LSP). If **y**, the S8300 Media Server is configured to provide standby call processing in case the primary media server is unavailable.

## Malicious Call Trace

Provides ability to retrieve certain information related to a malicious call.

### **Mode Code for Centralized Voice Mail**

This feature provides the ability to share a Voice Mail System among several switches using the Mode Code - Voice Mail System Interface.

### **Multifrequency Signaling**

Provides for a screen of number signaling used between the switch and the central office.

### **Multimedia Appl. Server Interface (MASI)**

Allows users of the Multimedia Communications Exchange (MMCX) to take advantage of certain Avaya MultiVantage telephony features.

### **Multimedia Call Handling (Basic)**

Allows administration of desktop video-conferencing systems as data modules associated with Avaya MultiVantage voice stations in a multimedia complex. Users can dial one number to reach either endpoint (voice or data) in the complex. Also provides support for IP SoftPhones.

### **Multimedia Call Handling (Enhanced)**

Allows a multifunction phone to control a multimedia call like a standard voice call.

### **Multiple Locations**

Allows you to establish numbering plans and time zone and daylight savings plans that are specific for each cabinet in a port network.

### **Personal Station Access (PSA)**

Provides basic telecommuting package capability for Personal Station Access.

**Screen 276. System Parameters Customer-Options**

**PNC Duplication**

This field only appears on Avaya DEFINITY R. If set to **y**, the Enable Operation of PNC (*Port Network Connectivity*) Duplication field appears on the System Parameters Duplication screen. The Enable Operation of PNC Duplication field is set with the Enable Operation of SPE (*Switch Processing Element*) Duplication field to provide non-standard reliability levels (high, critical, or ATM PNC Network Duplication).

**Port Network Support**

Indicates that the switch is operating as a stand-alone Internal Communications Controller (ICC) when set to **n** and is used to disable traditional port networking. Set to **y** to indicate that traditional DEFINITY port networks are in use.

**Processor and System MSP**

Allows the customer administrator or technician to maintain processor and system circuit packs.

**Private Networking**

Upgrades PNA or ETN software RTU purchased with earlier systems.

### **Processor Ethernet**

Appears only on S8100 Media Server with a CMC1, S8100 Media Server with a G600, S8700 IP-Connect, S8700 Multi-Connect, and S8300 Media Server. Used to enable use of the ethernet card resident in the processor cabinet for use by the DEFINITY Call Processing software in place of a C-LAN card (located in a port network).

### **VAL Full 1-Hour Capacity**

If this is enabled, you have the Enhanced offer, which allows up to 60 minutes storage capacity per pack and multiple integrated announcement circuit packs.

### **Remote Office**

Allows administration of a remote office.

### **Restrict Call Forward Off Net**

The system can monitor the disposition of an off-call and, if it detects busy, bring the call back for further processing, including call coverage.

### **Secondary Data Module**

Provides ability to use any data module as a secondary data module.

### **Station and Trunk MSP**

Provides the customer administrator or technician to maintain station and trunk circuit packs.

### **Station as Virtual Extension**

Allows **virtual** to be entered in the type field of the station screen, which allows multiple virtual extensions to be mapped to a single physical analog phone. The user can also administer a specific ringing pattern for each virtual extension. Useful in environments such as college dormitories, where three occupants can have three different extensions for one physical phone.

### **Survivable Remote Processor**

This field can be set to **y** only if, on the System-Parameters Maintenance screen, the CPE Alarm Activation Level field is **none**. This applies only to DEFINITY SI systems.

### **System Management Data Transfer**

Indicates the switch is accessible by Network Administration.

## **Tenant Partitioning**

Provides for partitioning of attendant groups and/or stations and trunk groups. Typically this is used for multiple tenants in a building or multiple departments within a company or organization.

## **Terminal Trans. Init. (TTI)**

Allows administrators of Terminal Translation Initialization (TTI) to merge an station administered with X in the Port field, to a valid port by dialing a system-wide TTI security code and the extension from a terminal connected to that port. Must be set to **y** for Automatic Customer Telephone Rearrangement.

## **Time of Day Routing**

Provides AAR and ARS routing of calls based on the time of day and day of the week. You can take advantage of lower calling rates during specific times.

## **Uniform Dialing Plan**

Provides 3- to 7-digit Uniform Dial Plan (UDP) and 1–7 digit steering. Also allows you to use Extended Trunk Access and Extension Number Portability features.

## **Usage Allocation Enhancements**

Provides for assigning ISDN-PRI or ISDN-BRI Services/Features for Usage Allocation Plans. To use this enhancement, first set either the ISDN-PRI or ISDN-BRI Trunks fields to **y**.

## **Wideband Switching**

Provides wideband data software for switching video or high-speed data. You can aggregate DSO channels up to the capacity of the span. Wideband supports H0, H11, and H12 standards, where applicable, as well as customer-defined data rates.

## **Wireless**

Provides right to use for wireless applications in certain Network Systems sales. You may purchase it from Avaya Network Wireless Systems.

## Screen 277. Call Center Optional Features

### ACD

Automatic Call Distribution (ACD) automatically distributes incoming calls to specified splits or skills. Provides the software required for the Call Center Basic, Plus, Deluxe, and Elite features for the number of agents specified. Cannot be set to **n** if the Call Work Codes field is **y**.

### BCMS (Basic)

Provides real-time and historical reports about agent, ACD split, Vector Directory Number (VDN) and trunk group activity.

### BCMS/VuStats Service Level

Allows you to set up hunt groups or Vector Directory Numbers (VDNs) with an acceptable service level. An acceptable service level defines the number of seconds within which a call must be answered to be considered acceptable.

### Business Advocate

Software that provides an integrated set of advanced features to optimize call center performance. If set to **n**, the Least Occupied Agent field displays. For information on CentreVu® Advocate, contact your Account Executive.

## **Call Center Release**

Displays the call center release installed on the system.

## **Call Work Codes**

Allows agents to enter digits for an ACD call to record customer-defined events such as account codes or social security numbers. Cannot be set to **y** if the ACD field is **n**.

## **DTMF Feedback Signals For VRU**

Provides support for the use of C and D Tones to VRUs.

## **Dynamic Advocate**

Software that provides an integrated set of advanced features to optimize call center performance.

## **EAS-PHD**

Increases the number of skills an agent can log in to from four to 20. Increases the number of agent skill preference levels from two to 16.

## **Expert Agent Selection (EAS)**

Provides skills-based routing of calls to the best-qualified agent.

## **Forced ACD Calls**

See Multiple Call Handling.

## **Least Occupied Agent**

Appears only if the Business Advocate field is **n**. Allows call center calls to be routed to the agent who has been the least busy, regardless of when the agent last answered a call. Cannot be set to **y** if the Expert Agent Selection (EAS) field is **n**.

## **Lookahead Interflow (LAI)**

Provides Look-Ahead Interflow to balance the load of ACD calls across multiple locations. Cannot be set to **y** if the Vectoring (Basic) field is **n**.

## **Multiple Call Handling (On Request)**

Allows agents to request additional calls when active on a call.

### **Multiple Call Handling (Forced)**

Forces an agent to be interrupted with an additional ACD call while active on an ACD call. Splits or skills can be one forced, one per skill, or many forced. Cannot be set to **y** if the ACD field is **n** and the Forced ACD Calls field is **y**.

### **PASTE (Display PBX Data on Phone)**

Provides an interface between the display of a DCP telephone set and PC-based applications.

### **Reason Codes**

Allows agents to enter a numeric code that describes their reason for entering the AUX work state or for logging out of the system. Cannot be set to **y** if the Expert Agent Selection (EAS) field is **n**.

### **Service Observing (Basic)**

Allows a specified user to observe an in-progress call on a listen-only or listen-and-talk basis.

### **Service Observing (Remote/By FAC)**

Allows users to service observe calls from a remote location or a local station using this feature's access codes.

### **Service Observing (VDNs)**

Provides the option of observing and/or monitoring another user's calls.

### **Timed ACW**

Places an auto-in agent in ACW for an administered length of time after completion of the currently active ACD call.

### **Vectoring (Basic)**

Provides basic call vectoring capability.

### **Vectoring (Prompting)**

Allows flexible handling of incoming calls based on information collected from the calling party or from an ISDN-PRI message.

### **Vectoring (G3V4 Enhanced)**

Allows the use of enhanced comparators, wildcards in digit strings for matching on collected digits and ANI or II-digits, use of Vector Routing Tables, multiple audio/music sources for use with wait-time command and priority level with the oldest-call-wait conditional.

### **Vectoring (ANI/II-Digits Routing)**

Provides for ANI and II-Digits vector routing.

### **Vectoring (G3V4 Advanced Routing)**

Provides for Rolling Average Speed of Answer Routing, Expected Wait Time Routing, and VDN Calls Routing.

### **Vectoring (CINFO)**

Provides the ability to collect ced and cdpd from the network for vector routing. To use this enhancement, first set either the ISDN-PRI or ISDN-BRI Trunks fields to **y**.

### **Vectoring (Best Service Routing)**

Enables the Best Service Routing™ feature. Through special vector commands, Best Service Routing allows you to compare splits or skills at local and remote locations and queue a call to the resource that will give the caller the best service.

### **Vectoring (Holidays)**

Enables the Holiday Vectoring feature. It simplifies vector writing for holidays.

## Field descriptions for Call Center Optional Features

 Logged-In ACD Agents: 500
 Logged-In Advocate Agents: 500
 Logged-In IP Softphone Agents: 500

```

### Screen 278. Call Center Optional Features

#### Logged-In ACD Agents

Number of ACD Agents contracted for. This field limits the number of logged-in ACD agents to a number no more than the maximum purchased. The value of this field indicates the total of ACD agents that can be logged-in simultaneously.

The limit applies to ACD agents on ACD and EAS calls. Auto-Available Split (AAS) agent ports are counted when they are assigned. AAS split or skill members are also counted. If the port for an AAS split/skill member is logged out, (for example, when a ringing call is redirected) the logged-in agent count is not updated. These counts are updated only during administration.

#### Logged-In Advocate Agents

Appears when the CentreVu Advocate field is **y**. Number of CentreVu Advocate Agents contracted for.

The total number of logged-in CentreVu Advocate agents must be equal to or less than the number allowed in the Logged-In ACD Agents field. The number of logged-in CentreVu Advocate agents counts towards the total number of logged-in ACD agents.

## Logged-In IP Softphone Agents

Number of IP Softphone Agents contracted for. This field limits the number of logged-in IP Softphone agents to a number no more than the maximum purchased. The value of this field indicates the total of IP Softphone agents that can be logged-in simultaneously.

## VDN of Origin Announcement

Provides a short voice message to an agent indicating the city of origin of the caller or the service requested by the caller based on the VDN used to process the call.

## VDN Return Destination

Allows an incoming trunk call to be placed back in vector processing after all parties, except the originator, drop.

## VuStats

Allows you to present BCMS statistics on phone displays.

## VuStats (G3V4 Enhanced)

Allows you to use the G3V4 VuStats enhancements including historical data and thresholds.

## Field descriptions for QSIG Optional Features

```
display system-parameters customer-options Page 7 of X
 QSIG OPTIONAL FEATURES
 Basic Call Setup? n
 Basic Supplementary Services? n
 Centralized Attendant? n
 Interworking with DCS? n
Supplementary Services with Rerouting? n
 Transfer into QSIG Voice Mail? n
 Value-Added (VALU)? n
```

## Screen 279. QSIG Optional Features

### Basic Call Setup

Provides basic QSIG services: basic connectivity and calling line ID number. To use this enhancement, either the ISDN-PRI or ISDN-BRI Trunks fields must be **y**.

## Basic Supplementary Services

To use this enhancement, either the ISDN-PRI or ISDN-BRI Trunks fields must be **y**. Provides the following QSIG Supplementary Services:

- Name ID
- Transit Capabilities; that is, the ability to tandem QSIG information elements
- Support of Notification Information Elements for interworking between QSIG and non-QSIG tandemed connections
- Call Forwarding (Diversion) by forward switching. No reroute capabilities are provided
- Call Transfer by join. No path replacement capabilities are provided.
- Call Completion (also known as Automatic Callback)

## Centralized Attendant

Can be enabled only if the Supplementary Services with Rerouting field is **y**. Cannot be set to **y** if the CAS Main and CAS Branch fields are **y**. Allows all attendants in one location to serve users in multi locations. All signaling is done over QSIG ISDN lines. If this field is **y**, the IAS fields on the Console Parameters screen do not display.

## Interworking with DCS

Allows the following features to work between a user on a DCS-enabled switch in a network and a QSIG-enabled switch:

- Called/calling party name display
- Called/calling party number display

This field cannot be set to **y** if the DCS (Basic) field is **n**.

## Supplementary Services with Rerouting

Provides the following QSIG Supplementary Services:

- Transit Capabilities; that is, the ability to tandem QSIG information elements.
- Support of Notification Information Elements for interworking between QSIG and non-QSIG tandemed connections.
- Call Forwarding (Diversion) by forward switching. In addition, reroute capabilities are provided.
- Call Transfer by join. In addition, path replacement capabilities are provided.

## Transfer Into QSIG Voice Mail

Can be enabled only if the Basic Supplementary Services field is **y** and either the ISDN-PRI Trunk or ISDN-BRI Trunk field is **y**. Allows transfer directly into the voicemail box on the voicemail system when a QSIG link connects Avaya MultiVantage and the voice mail.

## Value Added (VALU)

Provides additional QSIG functionality, including the ability to send and display calling party information during call alerting. See *Administration for Network Connectivity for Avaya MultiVantage™ Software* for more information.

## Field descriptions for ASAI (page 8)

Page 8 of X

change system-parameters customer options

ASAI FEATURES

CTI Stations? n  
Phantom Calls? n

ASAI PROPRIETARY FEATURES

Agent States? n

## Screen 280. ASAI Features when the ASAI Link Plus Capabilities field is y

### Agent States

Appears when the Computer Telephony Adjunct Links field is **y**. The Agent States field provides proprietary information used by Avaya applications. For more information, contact your Avaya representative.

#### NOTE:

The Agent States field only applies to links administered as type adjlk. This field was previously named Proprietary Applications.

### CTI Stations

Appears when the ASAI Link Plus Capabilities field is **y**. This field needs to be enabled for any application (using a link of Type ASAI) that uses a CTI station to receive calls.

For more information see the *Avaya MultiVantage™ CallVisor® ASAI Technical Reference*.

## Phantom Calls

Appears when the ASAI Link Plus Capabilities field is **y**. Enables phantom calls. The Phantom Calls field only applies to links administered as type ASAI.

For more information see the *Avaya MultiVantage™ CallVisor® ASAI Technical Reference*.

|-----------------------|-----------------------------------|
| 0 to 99 or<br>blank   | Release number of the IP endpoint |

## System Parameters OCM Call Classification

---

This screen enters the tone characteristics for your country for Outbound Call Management (OCM) applications. It is not required for United States OCM applications. If you cannot access this screen, contact your Avaya representative.

This screen appears when Global Call Classification field on the System Parameters Customer Options screen is set to y, or when the Enable Busy Tone Disconnect for Analog loop-start Trunks field on the System Parameters Country Options screen is set to y. This screen defines the busy tone and cadence and can be administered with up to 4 on and off steps, which is four valid cycles to determine busy tone.

Avaya recommends that you use a minimum of two on and off steps to determine a valid busy tone. If the cadence is administered with one on and off step, any time the classifier hears the cadence it is considered BTM signal.

**Field descriptions for page 1**

|                                           |             |

**Screen 283. System Parameters OCM Call Classification screen**

**Cadence Step**

A display-only field identifying the number of each tone cadence step and indicating whether the tone is on or off during this cadence step.

**Duration Maximum**

Specifies the upper limit in milliseconds of the tone duration.

**⇒ NOTE:**

On the Feature-Related System Parameters screen, set the Off-Premises Tone Detect Timeout Interval field to its maximum value.

**Valid entries      Usage**

**75 – 6375**      Enter in increments of 25 msec.

**Duration Minimum**

Specifies the lower limit in milliseconds (msec) of the tone duration.

**Valid entries      Usage**

**75 – 6375**      Enter in increments of 25 msec.

## Instance

Enter the instance number of the tone. If the system identifies a tone that matches the characteristics defined on more than one page of this screen the system applies the tone definition from the earlier page.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 1–8                  | The number distinguishes tones that have the same name but more than one definition of silence and tone-on characteristics. |

## Tone Continuous

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                   |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------|
| y                    | Indicates a continuous tone. If you enter <b>y</b> , you cannot enter data in the Duration Minimum or Duration Maximum fields. |
| n                    | Indicates a non-continuous tone.                                                                                               |

## Tone Name

This field is required for tone definition outside of the U.S. and Canada.

If the Global Call Classification field on the System Parameters Customer Options screen is **n**, only busy can be entered into this Tone Name field. If Busy Tone Disconnect is enabled, only busy can be entered into this field.

| <b>Valid entries</b> | <b>Usage</b>                                                 |
|----------------------|--------------------------------------------------------------|
| <b>busy</b>          | Enter the name of the tone that you are adding or modifying. |
| <b>information</b>   |                                                              |
| <b>intercept</b>     | Enter <b>busy</b> for Busy Tone Disconnect.                  |
| <b>reorder</b>       |                                                              |
| <b>ringback</b>      |                                                              |

## Telecommuting Access

---

This screen allows the System Administrator to administer the extension which allows remote users to use the feature.

## Field descriptions for page 1

---

```
add telecommuting-access
 TELECOMMUTING ACCESS
 Telecommuting Access Extension: _____
```

### Screen 284. Telecommuting Access

#### Telecommuting Access Extension

This only allows remote access to the Telecommuting Access feature.

| <b>Valid entries</b>                        | <b>Usage</b>                                                                                                |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Unassigned extension of 1-7 digits or blank | Enter an extension that conforms to your system's dial plan and is not assigned to any other system object. |

#### Related Topics

---

See [“Configuring Avaya MultiVantage for telecommuting” on page 357](#) for information about setting up telecommuting.

#### Tenant

---

This screen defines tenants to the system. If your switch uses tenant partitioning, see [“Tenant Partitioning” on page 1870](#) for more information.

## Field descriptions for page 1

```

change tenant 18

 Tenant 18

Tenant Description: _____

Attendant Group: 1

Ext Alert Port (TAAS): _____ Ext Alert (TAAS) Extension: ____

Night Destination: _____

Music Source: 1

Attendant Vectoring VDN:

Emergency Number:

```

### Screen 285. Tenant screen

#### Attendant Group

This required information relates a tenant to an attendant group.

#### NOTE:

The default for the system is that all attendant groups exist. However, the attendant group will be empty if no consoles are assigned to it.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|      |                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------|
| 1-28 | See <i>Avaya MultiVantage™ Solutions Hardware Guide</i> , for your system's range of allowable attendant group numbers. |
|------|-------------------------------------------------------------------------------------------------------------------------|

#### Attendant Vectoring VDN

This field appears only if, on the System-Parameters Customer-Options screen, the Attendant Vectoring field is **y** and the Tenant Partitioning field is **n**. Enter the assigned Attendant VDN extension or blank. When set to **y**, the VDN and Vector screens display.

#### Emergency Number

Enter the phone number you want to use for this tenant's emergency calls. If your system is in a No-License mode, these will be the only numbers that the tenant can dial. The number may contain the feature access code for Emergency Access to the Attendant, trunk access codes, or any number, \*, or #.

## Ext Alert Port (TAAS)

Enter the necessary characters. Enter Trunk Answer Any Station (TAAS) alert port information, if any. The port type and the object type must be consistent, and the port can be assigned to only one tenant.

| Valid entries                                                                                                                                                                                                                            | Usage                                              |

| <b>1</b> through <b>80</b><br>(DEFINITY R, CSI) or<br><b>1</b> through <b>10</b> (DEFINITY SI) or<br><b>1</b> through <b>250</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server)                                  | Gateway                                            |
| <b>V1</b> through <b>V9</b>                                                                                                                                                                                                              | Module                                             |
| <b>01</b> through <b>31</b>                                                                                                                                                                                                              | Circuit                                            |

## Ext Alert (TAAS) Extension

This field appears only if you entered an **X** in Ext Alert Port (TAAS).

| Valid entries     | Usage                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------|
| A valid extension | If you entered an <b>X</b> in Ext Alert Port (TAAS), you must enter extension information in this field. |

## Music Source

| Valid entries | Usage                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------|
| 1–20          | Enter the music/tone source for this partition. These sources are defined on the <a href="#">Music Sources</a> screen. |

## Night Destination

| Valid entries     | Usage                                                                                 |
|-------------------|---------------------------------------------------------------------------------------|
| A valid extension | Enter the night service station extension, if you want night service for this tenant. |

## Tenant

This is a display only field. It contains the tenant number that you entered on the command line.

## Tenant Description

| Valid entries                        | Usage                                                                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 40 alpha-numeric characters or blank | You may leave the description field blank, but future administration will be easier if you provide descriptive information. |

## Screen 286. Tenant

## Calling permissions

The system default allows each tenant to call only itself and Tenant 1. If you want to change that, you can do that on this screen.

| Valid entries | Usage                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to establish calling permission between the tenant number that you entered on the command line and any other tenant. |

## Tenant

This is a display only field. It contains the tenant number that you entered on the command line.

## Terminal Parameters

This screen administers system-level parameters and audio levels for the 603 CALLMASTER telephones and the 4600-series, 6400-series, 8403, 8405B, 8405B+, 8405D, 8405D+, 8410B, 8410D, 8411B, 8411D, 8434D, and 2420 phones.

**⇒ NOTE:**

Only authorized Avaya personnel can administer this screen.

**Default Parameter Set**

Determines which default set of telephone options and levels will be used. This field corresponds to the country codes. See [“System Parameters Country-Options”](#) on page 1175 for the country code listing.

## Customize Parameters

Indicates whether the administrator wishes to change one or more of the default parameters.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                            |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | If this field is <b>y</b> (yes), the OPTION and LEVEL fields appear and all fields can be edited.                                                       |
| <b>n</b>             | If this field is <b>n</b> (no), the system uses all default parameters associated with the Default Parameter Set field and all fields are display-only. |

## OPTIONS

---

### Display Mode

Determines how the #) and ~ characters appear on the phone's display. This field only appears if Customize Parameters is **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>1</b>             | If this field is set to <b>1</b> , the # and ~ do not change.                                                               |
| <b>2</b>             | If this field is set to <b>2</b> , the phone displays a # as a British pound sterling symbol and a ~ as a straight overbar. |

### DLI Voltage Level

Determines whether DCP Line Voltage used by the telephones is forced high, forced low, or allowed to automatically adjust. This field only appears if Customize Parameters is **y**.

### Handset Expander Enabled

Determines whether the telephone will reduce noise on the handset. This field appears only if Customize Parameters is **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                       |
|----------------------|--------------------------------------------------------------------|
| <b>y</b>             | If the field is <b>y</b> , the telephone reduces background noise. |

### Primary levels

The following fields only appear if Customize Parameters is set to **y**. In each case, if the field is blank, the system uses the default setting from the Default Parameter Set. Also, these fields all require the same input; valid entries are from **-44.0** db through **+14.0** db in 0.5 increments (for example, -44.0, -43.5, -43.0 and son on).

## Volume for DCP Types

This field allows the DCP phone volume to be adjusted while the call is in progress.

| <b>Valid entries</b>                            | <b>Usage</b>                                                                               |
|-------------------------------------------------|--------------------------------------------------------------------------------------------|
| <b>default speaker, handset unchangeable</b>    | The speaker resets to the default settings while the adjusted handset setting is retained. |
| <b>default settings used to begin each call</b> | No adjusted handset and speaker settings are retained.                                     |
| <b>retain handset and speaker between calls</b> | The adjusted handset and speaker settings are retained.                                    |
| <b>retain speaker, handset unchangeable</b>     | Only the adjusted speaker setting is retained.                                             |

## Volume for IP Types

This field allows the IP phone volume to be adjusted while the call is in progress.

### NOTE:

If you use this field, Avaya recommends that you not change any values in the PRIMARY LEVELS or BUILT-IN SPEAKER LEVELS areas.

| <b>Valid entries</b>                            | <b>Usage</b>                                                                               |
|-------------------------------------------------|--------------------------------------------------------------------------------------------|
| <b>default speaker, handset unchangeable</b>    | The speaker resets to the default settings while the adjusted handset setting is retained. |
| <b>default settings used to begin each call</b> | No adjusted handset and speaker settings are retained.                                     |
| <b>retain handset and speaker between calls</b> | The adjusted handset and speaker settings are retained.                                    |
| <b>retain speaker, handset unchangeable</b>     | Only the adjusted speaker setting is retained.                                             |

## PRIMARY LEVELS

### Touch Tone Sidetone (dB)

Determines the touchtone volume fed back from the telephone when a users presses a button.

### Touch Tone Transmit (dB) —

Determines the touchtone volume fed outbound from the telephone.

### **Voice Receive (dB)**

Determines the volume of voice inbound to the telephone.

### **Voice Sidetone (dB)**

Determines the volume of voice fed back from the handset voice microphone to the user's ear.

### **Voice Transmit (dB)**

Determines the volume of voice outbound from the telephone.

#### **NOTE:**

You cannot administer all five of the Primary Level fields to +14.0 dB. If you attempt to submit the Terminal Parameters screen with all Primary Levels set to +14.0 dB, you receive an error message.

## **ADJUNCT LEVELS**

---

The following fields appear only if you are administering 8400-series telephones and if Customize Parameters is **y**. In each case, if the field is blank, the system uses the default setting from the Default Parameter Set. Also, these fields all require the same input; valid input is listed in "Primary levels" above.

### **Touch Tone Sidetone (dB)**

Determines the touchtone volume fed back from the telephone when a users presses a button.

### **Voice Receive (dB)**

Determines the volume of voice inbound to the adjunct.

### **Voice Sidetone (dB)**

Determines the volume of voice fed back from the handset voice microphone to the user's ear.

### **Voice Transmit (dB)**

Determines the volume of voice outbound from the adjunct.

## Terminating Extension Group

This screen defines a Terminating Extension Group (TEG). Any phone can be assigned as a TEG member; however, only a multi-appearance phone can be assigned a TEG button with associated status lamp. The TEG button allows the phone user to select a TEG call appearance for answering or for bridging onto an existing call.

The TEG members are assigned on an extension number basis. Call reception restrictions applicable to the group are specified by the group class of restriction (COR). The group COR takes precedence over an individual member's COR. The members could all be termination restricted but still receive calls if the group is not restricted.

The system allows for as many as 32 TEGs with up to 4 members each. An extension number can be assigned to more than one TEG but can have only one appearance of each group.

### Field descriptions for page 1

```

change term-ext-group 1 Page 1 of 1
 TERMINATING EXTENSION GROUP

 Group Number: 1 Group Extension:
 Group Name: Coverage Path:
 Security Code: COR: 1

 2: 4: 51002 26 character name sta 51002

```

### Screen 290. Terminating Extension Group

#### AUDIX Name

Name of the AUDIX machine as it appears in the Node Names screen. Only appears for an DEFINITY R configuration.

#### Valid entries      Usage

Unique identifiers for adjunct equipment.

## COR

| <b>Valid entries</b>       | <b>Usage</b>                                                                        |
|----------------------------|-------------------------------------------------------------------------------------|
| <b>0</b> through <b>95</b> | Enter the class of restriction (COR) number that reflects the desired restrictions. |

### Coverage Path

Enter a number for the call coverage path for this group. A TEG cannot serve as a coverage point; however, calls to a TEG can redirect to coverage.

| <b>Valid entries</b>     | <b>Usage</b>      |
|--------------------------|-------------------|
| <b>1</b> to <b>9999</b>  | path number       |
| <b>t1</b> to <b>t999</b> | time of day table |
| blank                    |                   |

### Group Extension

Enter the extension of the terminating extension group.

| <b>Valid entries</b> | <b>Usage</b>                                                                 |
|----------------------|------------------------------------------------------------------------------|
| 1 to 7 digits        | Unused extension number (may not be a VDN extension).<br>Do not leave blank. |

### Group Name

Enter the name used to identify the terminating extension group.

### Group Number

A display-only field when the screen is accessed using an administration command such as **add** or **change**.

## ISDN Caller Disp

This field is required if, on the System-Parameters Customer-Options screen, the ISDN-PRI or ISDN-BRI Trunks field is **y**.

| Valid entries   | Usage                                                                                                                         |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>grp-name</b> | Specify whether the TEG group name or member name (member of TEG where call terminated) will be sent to the originating user. |
| <b>mbr-name</b> | Specify whether the TEG group name or member name (member of TEG where call terminated) will be sent to the originating user. |
| blank           | If the ISDN-PRI or ISDN-BRI Trunks field is <b>n</b> , leave blank.                                                           |

## LWC Reception

Defines the source for Leave Word Calling (LWC) messages.

| Valid entries  | Usage                                                                                                                                       |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>audix</b>   | For G3i systems, if LWC is attempted, the messages are stored in AUDIX.                                                                     |
| <b>msa-spe</b> | For G3i systems, if LWC is attempted, the messages are stored in the system processing element (spe).                                       |
| <b>none</b>    | For G3i systems, if LWC is attempted, the messages are not stored.                                                                          |
| <b>audix</b>   | For DEFINITY R systems and S8700 IP-Connect, if LWC is attempted, the messages are stored in AUDIX.                                         |
| <b>msa</b>     | For DEFINITY R systems and S8700 IP-Connect, if LWC is attempted, the messages are stored in the Message Server Adjunct - Switch Processor. |
| <b>spe</b>     | For DEFINITY R systems and S8700 IP-Connect, if LWC is attempted, the messages are stored in the system processing element (spe).           |
| <b>none</b>    | For DEFINITY R systems and S8700 IP-Connect, if LWC is attempted, the messages are not stored.                                              |

## Messaging Server Name

### NOTE:

You first must administer the “[IP Node Names](#)” screen.

Name of the server as it appears in the Node Names screen. Only appears for DEFINITY R and S8700 IP-Connect configurations.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

Unique identifiers for messaging server equipment.

## **Security Code**

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                       |                                                 |
|-----------------------|-------------------------------------------------|
| 4-digit security code | This code is used for the Demand Print feature. |
|-----------------------|-------------------------------------------------|

## **TN**

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|          |                                    |
|----------|------------------------------------|
| 1 to 100 | Enter the Tenant Partition number. |
|----------|------------------------------------|

## **GROUP MEMBER ASSIGNMENTS**

---

### **Ext**

Enter the extension number (may not be a VDN extension) assigned to a station.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

An extension number of 1-7 digits.

### **Name**

This display-only field shows the name assigned to the preceding extension number when the TEG member's phone is administered.

## TFTP Server

The Trivial File Transfer Protocol screen allows specification of the TFTP server the Avaya Call Processing engine uses to get download files.

```

change tftp-server Page 1 of 1
 TFTP Server Configuration

Local Node Name:
TFTP Server Node Name:
TFTP Server Port: 69
File to Retrieve:

File Status:
File Size:
Filename in Memory:

```

### Screen 291. TFTP Server screen

#### Filename in Memory

A display-only field showing the name of the file currently in ACP memory.

#### File Size

A display-only field showing the number of bytes transferred.

#### File Status

A display-only field showing Download In Progress, Download Failed, File Not Found, or Download Completed.

#### File to Retrieve

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|  |                                                                                                                                   |
|--|-----------------------------------------------------------------------------------------------------------------------------------|
|  | Enter the name of the file you are going to retrieve using up to 32 alpha-numeric, case sensitive, characters for identification. |
|--|-----------------------------------------------------------------------------------------------------------------------------------|

#### Local Node Name

The local node name must be a valid entry from the IP Node Names screen. The node must be assigned to a CLAN ip-interface or **procr** (processor CLAN).

| Valid entries   | Usage                                                                             |
|-----------------|-----------------------------------------------------------------------------------|
| 1-15 characters |                                                                                   |
| <b>procr</b>    | Processor CLAN for S8300 Media Server, S8700 Multi-Connect, and S8700 IP-Connect. |

**TFTP Server Node Name**

The TFTP server node name must be a valid entry from the IP Node Names screen.

| Valid entries   | Usage |
|-----------------|-------|
| 1-15 characters |       |

**TFTP Server Port**

| Valid entries | Usage                                   |
|---------------|-----------------------------------------|
| 1-64500       | Enter a number for the remote TCP port. |

**Time of Day Coverage Table**

This screen allows up to five different coverage paths, associated with five different time ranges, for each day of the week. Only one coverage path can be in effect at any one time.

**Field descriptions for page 1**

change coverage time-of-day 3

**Screen 292. Time of Day Coverage Table**

## Act Time

Specify the activation time of the coverage path administered in the next CVG PATH field. Enter the information in 24-hour time format.

| <b>Valid entries</b>  | <b>Usage</b>                                                                                                                                                                                                                                             |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>00:01 to 23:59</b> | If there are time gaps in the table, there will be no coverage path in effect during those periods. The first activation time for a day is set to 00:00 and cannot be changed. Activation times for a day must be in ascending order from left to right. |

## CVG Path

Enter the coverage path number.

| <b>Valid entries</b>           | <b>Usage</b>                                           |
|--------------------------------|--------------------------------------------------------|
| <b>1 through 9999 or blank</b> | For the DEFINITY R configurations and S8700 IP-Connect |
| <b>1 through 999</b>           | For the DEFINITY SI configurations                     |

## Time of Day Coverage Table

A display-only field when the screen is accessed using an administration command. Specifies the Time of Day Coverage Table number. Up to 999 can be administered.

## Time of Day Routing Plan

---

Use this screen to set up Time of Day Routing Plans. You can route AAR and ARS calls based on the time of day each call is made. You can design up to 8 Time of Day Routing Plans, each scheduled to change up to 6 times a day for each day in the week.

Match the Time of Day Routing Plan PGN# with the PGN# field on the Partition Routing Table for the route pattern you want to use.

### NOTE:

Automatic Route Selection (ARS) or Private Networking, AAR/ARS Partitioning, and Time of Day Routing must be enabled on the

System-Parameters Customer-Options screen before you can use Time of Day Routing.

change time-of-day

**Screen 293. Time Of Day Routing Plan**

**Act Time**

Specifies the time of day the route pattern (identified by PGN) begins.

**Valid entries      Usage**

**00:00 to 23:59**      Time is represented using a 24 hour clock. List times for the same day in increasing order. There must be at least one entry for each day.

**PGN #**

Identifies the route pattern for activation time listed.

**Valid entries      Usage**

**1 to 8**      Enter a PGN that matches the PGN and route pattern on the Partition Routing Table. There must be at least one entry for each day.

**Time of Day Routing Plan**

Displays the Time of Day Routing Plan number (1 through 8).

**Toll Analysis**

**NOTE:**

The Toll List field on this screen does not interact with or relate to the ARS Toll Table.

This screen associates dialed strings to the system's Restricted Call List (RCL), Unrestricted Call List (UCL), and Toll List. You can force users to dial an account code if you associate dialed strings with CDR Forced Entry of Account Codes.

To maximize System security, Avaya recommends that toll calling areas be restricted as much as possible through the use of the RCL (Restricted Call List) and Toll List fields on this screen.

| change toll 1 |       | TOLL ANALYSIS |     |           |          |                              |   |   |   |   |   | Page 1 of 1     |   |   |    |   |   |   |   |

Screen 294. Toll Analysis

**CDR FEAC**

| Valid entries | Usage                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------|
| x             | Enter <b>x</b> to require an account code from a call whose facility COR requires a Forced Entry of Account Code. |

**Dialed String**

| Valid entries                                 | Usage                                                   |
|-----------------------------------------------|---------------------------------------------------------|
| digits <b>0 to 9</b><br>(up to 18 characters) | Enter the dialed string you want the switch to analyze. |
| <b>*, x, X</b>                                | wildcard characters                                     |

**Location**

Display-only field. Values other than **all** appear if the Multiple Locations field on the System Parameters Customer Options is **y**.

| Valid display  | Usage                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------|
| <b>1 to 44</b> | Defines the switch location for this Toll Analysis Table.                                        |
| <b>all</b>     | Indicates that this Toll Analysis Table is the default for all port network (cabinet) locations. |

**Max**

| <b>Valid entries</b> | <b>Usage</b>                                                                                       |
|----------------------|----------------------------------------------------------------------------------------------------|
| Min to <b>28</b>     | Enter the maximum number of user-dialed digits the system collects to match to this dialed string. |

**Min**

| <b>Valid entries</b> | <b>Usage</b>                                                                                       |
|----------------------|----------------------------------------------------------------------------------------------------|
| 1 to Max             | Enter the minimum number of user-dialed digits the system collects to match to this dialed string. |

**Percent Full**

Display-only field showing the percentage (**0 to 100**) of the system's memory resources that have been used by AAR/ARS. If the figure is close to 100%, you can free-up memory resources.

**RCL**

Enter **x** to assign the Dialed String to the Restricted Call List (RCL).

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x</b>             | All entries of <b>x</b> and their associated dialed strings are referred to as the System's Restricted Call List. The RCL can be assigned to any COR. A call attempt from a facility whose COR is marked as being associated with the RCL and whose dialed string matches a RCL dialed string field will be denied. The caller receives intercept treatment. |

**Toll List**

| <b>Valid entries</b> | <b>Usage</b>                                                 |
|----------------------|--------------------------------------------------------------|
| <b>x</b>             | Enter <b>x</b> to assign the Dialed String to the Toll List. |

| <b>Dialed String</b> | <b>Min</b> | <b>Max</b> | <b>Toll List</b> |
|----------------------|------------|------------|------------------|
| 0                    | 1          | 23         | x                |
| 1                    | 4          | 23         | x                |
| 20                   | 10         | 10         | x                |
| 21                   | 10         | 10         | x                |
| 30                   | 10         | 10         | x                |

| Dialed String | Min | Max | Toll List |
|---------------|-----|-----|-----------|
| 31            | 10  | 10  | x         |
| 40            | 10  | 10  | x         |
| 41            | 10  | 10  | x         |
| 50            | 10  | 10  | x         |
| 51            | 10  | 10  | x         |
| 60            | 10  | 10  | x         |
| 61            | 10  | 10  | x         |
| 70            | 10  | 10  | x         |
| 71            | 10  | 10  | x         |
| 80            | 10  | 10  | x         |
| 81            | 10  | 10  | x         |
| 90            | 10  | 10  | x         |
| 91            | 10  | 10  | x         |

### Unrestricted Call List

| Valid entries | Usage                                                                                            |
|---------------|--------------------------------------------------------------------------------------------------|
| x             | Enter <b>x</b> to assign the dialed string to one of the system's Unrestricted Call Lists (UCL). |

## Trunk Group

---

Use the Trunk Group screen to set basic characteristics for every type of trunk group and to assign ports to the group. This section lists and describes all the fields you might see on the screen. Many fields are dependent on the settings of other fields and only appear when certain values are entered in other fields on the screen. For example, the entry in the Group Type field may significantly change the content and appearance of the Trunk Group screen.

For descriptions of the unique fields used with ISDN trunks, see [“ISDN trunk group”](#) on page 936.

### Field descriptions for page 1

---

The figure below shows a common configuration for page 1 of the Trunk Group screen when the Group Type field is **tie**. This screen is only an example, and the fields shown below may change or disappear according to specific field settings.

```

add trunk-group next Page 1 of x
 TRUNK GROUP

Bit Rate: _____ Synchronization: ___ Duplex: ___
Disconnect Supervision - In? _ Out? _
Answer Supervision Timeout: ___ Receive Answer Supervision? _

```

**Screen 295. Tie Trunk Group**

**Analog Gain**

Use this field to reduce the strength of incoming signals on TN2199 ports if users regularly experience echo, distortion, or unpleasantly loud volume. Experiment to find the best setting for your situation. This field appears if the Country field is **15** and the Trunk Type (in/out) field is **2-wire-ac**, **2-wire-dc**, or **3-wire**.

| Valid entries | Usage                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------|
| <b>a</b>      | Reduces the incoming signal by -3dB.                                                            |
| <b>b</b>      | Reduces the incoming signal by -6dB.                                                            |
| <b>c</b>      | Reduces the incoming signal by -8dB.                                                            |
| <b>none</b>   | No reduction. Don't change this setting unless the trunk group's sound quality is unacceptable. |

**Analog Loss Group**

This field determines which administered 2-party row in the loss plan applies to this trunk group if the call is carried over an analog signaling port in the trunk group.

| Valid entries  | Usage                                             |
|----------------|---------------------------------------------------|
| <b>1 to 17</b> | Shows the index into the loss plan and tone plan. |

## Answer Supervision Timeout

If the Receive Answer Supervision field is **n**, use this field to set the answer supervision timer for outgoing and two-way trunks. During a cut-through operation, timing begins after each outgoing digit is sent by the switch and timing ceases after the far-end sends answer supervision. If the timer expires, the switch acts as if it had received answer supervision. On senderized operation, the timer begins after the last digit collected is sent by the switch.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                 |                                                                                                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 250</b> | Enter the number of seconds you want the switch to wait before it acts as though answer supervision has been received from the far-end. Set this field to <b>0</b> if Receive Answer Supervision is <b>y</b> . |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

 **NOTE:**

This field's setting does not override answer supervision sent from the network or from DS1 port circuit timers. To control answer supervision sent by DS1 firmware, set the Outgoing End of Dial (sec) field on the Administrable Timers page of the trunk group screen.

## Auth Code

This field affects the level of security for tandemed outgoing calls at your switch. This field appears if the Direction field is incoming or two-way, and it can only be **y** if the Authorization Codes field is **y** on the System-Parameters Customer-Options screen.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to require callers to enter an authorization code in order to tandem a call through an AAR or ARS route pattern. The code will be required even if the facility restriction level of the incoming trunk group is normally sufficient to send the call out over the route pattern. |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Auto Guard

This field appears if the Group Type field is **co** or **fx**. This field controls ports only on TN438B, TN465B, and TN2147 circuit packs. TN438B ports have hardware support for detecting a defective trunk. TN465B and TN2147 ports consider a trunk defective if no dial tone is detected on an outgoing call, and the Outputpulse Without Tone field is **n** on the Feature-Related System Parameters screen.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                                                                              |
|------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to prevent repeated seizures of a defective trunk. The switch will do a maintenance busy-out on these trunks. |
|------------|------------------------------------------------------------------------------------------------------------------------------|

## BCC

Generalized Route Selection uses the BCC to select the appropriate facilities for routing voice and data calls. Far-end tandem switches also use the BCC to select outgoing routing facilities with equivalent BCC classes. The entry in the Bearer Capability Class field is used to select the appropriate facilities for incoming ISDN calls. Avaya MultiVantage compares the entry in the BCC field to the value of the Bearer Capability information element for the incoming call and routes the call over appropriate facilities. For example, a call with BCC 4 will only be connected through facilities that support 64 kbps data transmission.

The Bearer Capability Class field appears when all of the following are true:

- Either the ISDN-BRI Trunks field or the ISDN-PRI field on the System Parameters Customer-Options screen is **y**.
- The Group Type field is **access, co, fx, tandem, tie, or wats**.
- The Comm Type field is **data, avd, or rbavd**.

| <b>Valid entries</b> | <b>Usage</b>                                                       |
|----------------------|--------------------------------------------------------------------|
| <b>0</b>             | For voice and voice-grade data                                     |
| <b>1</b>             | For 56 kbps synchronous data transmitted with robbed-bit signaling |
| <b>2</b>             | Less than 19.2 kbps synchronous or asynchronous data               |
| <b>3</b>             | For 64 kbps data and LAPD protocol                                 |
| <b>4</b>             | For 64 kbps data on unrestricted channels                          |

## Bit Rate

This field specifies the baud rate to be used by pooled modems. This field appears when the Comm Type field is **avd** or **rbavd**. It also appears if the Comm Type field is **data**, but only if the ISDN-PRI field is **y** on the System-Parameters Customer-Options screen.

| <b>Valid entries</b> | <b>Usage</b>                                                         |
|----------------------|----------------------------------------------------------------------|
| <b>300</b>           | Enter the speed of the fastest modem that will use this trunk group. |
| <b>1200</b>          |                                                                      |
| <b>2400</b>          |                                                                      |
| <b>4800</b>          |                                                                      |
| <b>9600</b>          |                                                                      |
| <b>19200</b>         |                                                                      |

## Busy Threshold

Use this field if you want attendants to control access to outgoing and two-way trunk groups during periods of high use. When the threshold is reached and the warning lamp for that trunk group lights, the attendant can activate trunk group control: internal callers who dial out using a trunk access code will be connected to the attendant, and the attendant can prioritize outgoing calls for the last remaining trunks. Calls handled by AAR and ARS route patterns go out normally.

| <b>Valid entries</b>                                    | <b>Usage</b>                                                                                                                                                                                                                                     |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 99</b><br>(DEFINITY SI,<br>CSI)                 | Enter the number of trunks that must be busy in order to light the warning lamp on the Attendant Console. For example, if there are 30 trunks in the group and you want to alert the attendant whenever 25 or more are in use, enter <b>25</b> . |
| <b>1 to 255</b><br>(DEFINITY R,<br>S8700<br>IP-Connect) |                                                                                                                                                                                                                                                  |

## Call Still Held

This field appears if the Group Type field is **co** or **fx**. This field is used when the receiving switch initiates the disconnection of incoming calls. It effectively extends the Incoming Glare Guard timer by 140 seconds. This field affects only TN438B, TN465B, and TN2147 ports and is used primarily when the Country Code field is **2**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                    |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to prevent glare by delaying an outgoing seizure of a trunk for at least 140 seconds after it is released from an incoming call. |

## CDR Reports

| Valid entries  | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y              | All outgoing calls on this trunk group will generate call detail records. If the Record Outgoing Calls Only field on the CDR System Parameters screen is <b>n</b> , then incoming calls on this trunk group will also generate call detail records.                                                                                                                                                                                                                                                                                                                                                      |
| n              | Calls over this trunk group will not generate call detail records.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| r (ring-intvl) | CDR records will be generated for both incoming and outgoing calls. In addition, the following ringing interval CDR records are generated: <ul style="list-style-type: none"> <li>■ Abandoned calls: The system creates a record with a condition code of “H,” indicating the time until the call was abandoned.</li> <li>■ Answered calls: The system creates a record with a condition code of “G,” indicating the interval from start of ring to answer.</li> <li>■ Calls to busy stations: The system creates a record with a condition code of “I,” indicating a recorded interval of 0.</li> </ul> |

### NOTE:

For ISDN trunk groups, the Charge Advice field affects CDR information. For CO, DIOD, FX, and WATS trunk groups, the Analog PPM field affects CDR information.

## CESID I Digits Sent

For emergency 911 service, your switch may send Caller’s Emergency Service Identification (CESID) information to the central office or E911 tandem switch. This digit string is part of the E911 signaling protocol. This field appears when Group Type is cama.

| Valid entries | Usage                                                                        |
|---------------|------------------------------------------------------------------------------|
| 1 to 3 digits | Determine the correct entry for this field by talking to your E911 provider. |

## Comm Type

Use this field to define whether the trunk group carries voice, data, or both.

 **NOTE:**

Comm Types of **avd**, **rbavd** and **data** require trunk member ports on a DS1 circuit pack.

### Valid entries

### Usage

---

- |              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>avd</b>   | <p>Enter <b>avd</b> for applications that mix voice and Digital Communication Protocol data, such as video conferencing applications. The receiving switch discriminates voice calls from data calls and directs each to an appropriate endpoint. Neither originating nor terminating switches insert a modem poll for any calls when Comm Type is <b>avd</b>.</p> <p>The Signaling Mode field on the DS1 circuit pack screen must be set for either <b>common-chan</b> or <b>CAS</b> signaling.</p> |
| <b>data</b>  | <p>Enter <b>data</b> only when all calls across the trunk group originate and terminate at Avaya MultiVantage digital data endpoints. Public networks don't support <b>data</b>: supported by Avaya's DCP protocol, this entry is used almost exclusively for the data trunk group supporting DCS signaling channels.</p> <p>The Signaling Mode field on the DS1 circuit pack may be set to <b>robbed-bit</b> or <b>common-chan</b>.</p>                                                             |
| <b>rbavd</b> | <p>For digital trunk groups that carry voice and data with robbed-bit signaling.</p> <p>The Signaling Mode field on the DS1 circuit pack screen must be set to <b>robbed-bit</b> unless mixed mode signaling is allowed on the DS1 circuit pack. In that case, the Signaling Mode field may be <b>isdn-ext</b> or <b>isdn-pri</b>.</p>                                                                                                                                                               |
| <b>voice</b> | <p>For trunk groups that carry only voice traffic and voice-grade data (that is, data transmitted by modem). Analog trunk groups must use <b>voice</b>.</p>                                                                                                                                                                                                                                                                                                                                          |

## COR

| Valid entries | Usage                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------------|
| 0 to 95       | Enter a class of restriction (COR). Classes of restriction control access to trunk groups, including trunk-to-trunk transfers. |

### Tip:

*Remember that facility restriction levels (FRL) are assigned to classes of restriction. Even if 2 trunk groups have classes of restriction that allow a connection, different facility restriction levels may prevent operations such as off-net call forwarding or outgoing calls by remote access users.*

## CO Type

This field appears when the Country field is **14** and is used only by trunk group members administered on a TN464D vintage 2 or later DS1 circuit pack.

| Valid entries | Usage                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------|
| analog        | This field specifies whether the trunk group is connected to analog or digital facilities at the central office. |
| digital       |                                                                                                                  |

## Country

This field is administered at installation and sets numerous parameters to appropriate values for the public network in which the switch operates. For example, the value of this field, with the values of the Trunk Termination and the Trunk Gain fields, determines the input and trans-hybrid balance impedance requirements for ports on TN465B, TN2146, and TN2147 circuit packs.

This field appears for the trunk groups that connect Avaya MultiVantage to a central office in the public network — CO, DID, DIOD, FX, and WATS trunk groups.

### CAUTION:

*Don't change this field. If you have questions, contact your Avaya representative.*

| Valid entries | Usage                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------|
| 1 to 25       | Set at installation.                                                                                                         |
| 11            | If the Country field is 11, Avaya MultiVantage is administered for Public Network Call Priority (Call Retention and Rering). |
| 14            | If the Country field is 14 and the Group Type is DID or DIOD, the CO Type field appears.                                     |

**Valid entriesUsage**

---

- 15** If the Country field is 15, Avaya MultiVantage is administered for Public Network Call Priority (Intrusion and Rering). Also, the Protocol Type field appears for Group Type DID or DIOD.
- 18** If the Country field is 18, Avaya MultiVantage can be administered for Public Network Call Priority (Mode of Release Control, Forced Disconnect, and Rering).
- 23** If the Country field is 23 and the Group Type field is either CO or DID, Avaya MultiVantage is administered for Block Collect Calls.

**Cut-Through**

This field appears when the Outgoing Dial Type field is either **rotary** or **tone**.

 **SECURITY ALERT:**

*Entering **y** in this field will reduce your ability to prevent toll fraud.*

**Valid entries Usage**

---

- y** Enter **y** to allow users to get dial tone directly from the central office. Outgoing calls over this trunk group will bypass AAR/ARS (if you're using it) and any of your administered restrictions (such as COR or FRL).
- n** Enter **n** and the user will receive switch dial tone. Instead of digits being sent to the central office, they will be collected and checked against administered restrictions. If no restrictions apply, the digits are sent to the central office.

**Cyclical Hunt**

When a call is offered to a trunk group, the switch searches for an available trunk. This field, which appears when the Direction field is **two-way** and the Trunk Type field is **loop-start**, controls the starting point of the search.

You can change this field from **n** to **y** at any time. To change from **y** to **n**, however, all the trunks in the group must be idle or busied out.

**Valid entries Usage**

---

- y** Enter **y** to have the switch start its search from the last trunk seized. This method is faster, and thus better suited for high-traffic trunk groups.
- n** Enter **n** to have the switch start each search at member 1 (the first trunk administered on the Group Member Assignments page).

## Dial Access

This field controls whether users can route outgoing calls through an outgoing or two-way trunk group by dialing its trunk access code. Allowing dial access does not interfere with the operation of AAR/ARS.

### **SECURITY ALERT:**

*Calls dialed with a trunk access code over WATS trunks bypass AAR/ARS and aren't restricted by facility restriction levels. For security, you may want to leave the field set to n unless you need dial access to test the trunk group.*

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                              |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Allows users to access the trunk group by dialing its access code.                                                                                        |
| <b>n</b>             | Does not allow users to access the trunk group by dialing its access code. Attendants can still select this trunk group with a Trunk Group Select button. |

## Dial Detection

Applies only to TN2199 ports. The Country field must be **15**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
| <b>A-wire</b>        |              |
| <b>B-wire</b>        |              |

## Digit Absorption List

This field assigns a digit absorption list, when used, to a trunk group that terminates at a step-by-step central office.

| <b>Valid entries</b>   | <b>Usage</b>                                                               |
|------------------------|----------------------------------------------------------------------------|
| <b>0 to 4 or blank</b> | Enter the number of the digit absorption list this trunk group should use. |

## Digits

This field is used with the Digit Treatment field, and its meaning depends on the entry in that field. If the Digit Treatment field is **absorption**, this field specifies *how many* digits are deleted. If the Digit Treatment field is **insertion**, this field identifies the *specific digits* that are added.

| <b>Valid entries</b>              | <b>Usage</b>                                                        |
|-----------------------------------|---------------------------------------------------------------------|
| 1 to 5                            | Enter the number of digits to be deleted (absorbed).                |
| Up to 4 digits, including * and # | Enter the actual digits to be added (inserted).                     |
| blank                             | This field can be blank only if the Digit Treatment field is blank. |

## Digit Treatment

Use this field to modify an incoming digit string (as on DID and tie trunks, for example) by adding or deleting digits. You'll need to do this if the number of digits you receive doesn't match your dial plan.

| <b>Valid entries</b> | <b>Usage</b>                                             |
|----------------------|----------------------------------------------------------|
| blank                | The incoming digit string is not changed.                |
| <b>absorption</b>    | Deletes digits, starting at the beginning of the string. |
| <b>insertion</b>     | Adds digits, starting at the beginning of the string.    |

If you enter absorption or insertion, then you must enter a value in the Digits field.

### NOTE:

In a DCS network, DCS features that use the remote-tgs button (on phones at a remote switch) do not work when the incoming trunk group at your switch deletes or inserts digits on incoming calls. The remote-tgs button on a remote switch, for example, tries to dial a TAC on your switch. If your switch adds or deletes digits, it defeats this operation. If you need to manipulate digits in a DCS network (for example, to insert an AAR feature access code), do it on the outgoing side based on the routing pattern.

## Digital Loss Group

This field determines which administered 2-party row in the loss plan applies to this trunk group if the call is carried over a digital signaling port in the trunk group.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|         |                                                   |
|---------|---------------------------------------------------|
| 1 to 17 | Shows the index into the loss plan and tone plan. |
|---------|---------------------------------------------------|

## Direction

Enter the direction of the traffic on this trunk group. The entry in this field affects which timers appear on the Administrable Timers page. This field appears for all trunk groups except DID and CPE.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                 |  |
|-----------------|--|
| <b>incoming</b> |  |
|-----------------|--|

|                 |  |
|-----------------|--|
| <b>outgoing</b> |  |
|-----------------|--|

|                |                                             |
|----------------|---------------------------------------------|
| <b>two-way</b> | Enter two-way for Network Call Redirection. |
|----------------|---------------------------------------------|

## Disconnect Supervision-In

This field indicates whether the switch receives disconnect supervision for incoming calls over this trunk group. It appears when the Direction field is **incoming** or **two-way**. (If the Direction field is **outgoing**, the switch internally sets this field to **n**.)

The entry in this field is crucial if you allow trunk-to-trunk transfers. (To allow trunk-to-trunk transfers involving trunks in this group, this field must be **y** and the Trunk-to-Trunk Transfer field on the Feature-Related System Parameters screen must be **y**). If a user connects 2 trunks through conference or transfer, and neither far-end switch on the resulting connection provides disconnect supervision, the trunks involved will not be released because Avaya MultiVantage can't detect the end of the call. Avaya MultiVantage will not allow trunk-to-trunk transfers unless it believes that at least one party on the call can provide disconnect supervision.

Therefore, setting this field incorrectly may cause trunks to become unusable until the problem is detected and the trunks are reset.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                  |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> to allow trunk-to-trunk transfers involving trunks in this group.<br><br>Enter <b>y</b> if the far-end switch sends a release signal when the calling party releases an incoming call, and you want to make the far-end switch responsible for releasing the trunk.<br><br>Enter <b>y</b> to enhance Network Call Redirection. |
| <b>n</b>             | Enter <b>n</b> if the far-end switch doesn't provide a release signal, if your hardware can't recognize a release signal, or if you prefer to use timers for disconnect supervision on incoming calls. Entering <b>n</b> prevents trunk-to-trunk transfers involving trunks in this group.                                                    |

 **CAUTION:**

*In general, U.S. central offices provide disconnect supervision for incoming calls but not for outgoing calls. Public networks in most other countries do not provide disconnect supervision for incoming or outgoing calls. Check with your network services provider.*

## Disconnect Supervision-Out

This field indicates whether the switch receives disconnect supervision for outgoing calls over this trunk group. It appears when the Direction field is either **outgoing** or **two-way**. (If the Direction field is **incoming**, the switch internally sets this field to **n**.)

The entry in this field is crucial if you allow trunk-to-trunk transfers. (To allow trunk-to-trunk transfers involving trunks in this group, this field must be **y** and the Trunk-to-Trunk Transfer field on the Feature-Related System Parameters screen must be **y**). If a user connects 2 trunks through conference or transfer, and neither far-end switch on the resulting connection provides disconnect supervision, the trunks involved will not be released because Avaya MultiVantage can't detect the end of the call. Avaya MultiVantage will not allow trunk-to-trunk transfers unless it believes that at least one party on the call can provide disconnect supervision. Therefore, setting this field incorrectly may cause trunks to become unusable until the problem is detected and the trunks are reset.

Also, remember that Avaya MultiVantage must receive *answer* supervision on outgoing analog CO, FX, WATS, Tie, Tandem, and Access trunks before it will recognize a disconnect signal. If this trunk group does not receive *answer* supervision from the far-end switch, and you enter **y** in this field, Avaya MultiVantage will internally set the field to **n**.

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>      | <p>Enter <b>y</b> to allow trunk-to-trunk transfers involving trunks in this group.</p> <p>Enter <b>y</b> if the far-end switch sends a release signal when the called party releases a call an outgoing call, and you want to make the far-end switch responsible for releasing the trunk.</p> <p>The Answer Supervision Timeout field must be <b>0</b> and the Receive Answer Supervision field must be <b>y</b> for the switch to recognize a <b>y</b> entry.</p> <p>Enter <b>y</b> to enhance Network Call Redirection.</p> |
| <b>n</b>      | <p>Enter <b>n</b> if the far-end switch doesn't provide a release signal, if your hardware can't recognize a release signal, or if you prefer to use timers for disconnect supervision on outgoing calls. Entering <b>n</b> prevents trunk-to-trunk transfers involving trunks in this group.</p>                                                                                                                                                                                                                               |

### CAUTION:

*Do not set this field to **y** unless you are certain that the far-end switch will provide answer supervision and disconnect supervision. Most public networks do not provide disconnect supervision over analog trunks. Check with your network services provider.*

## Disconnect Timing (msec)

This field specifies the minimum time in milliseconds that the central office or far-end switch requires to recognize that your switch has disconnected from a call. This timer does not affect ports on a circuit pack that uses the administrable Incoming Disconnect and Outgoing Disconnect timers; in fact, settings on those two timers override this field.

| Valid entries                                      | Usage                                                                                                                                                                                                                    |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>140 to 2550</b><br>ms in<br>increments of<br>10 | The default of <b>500</b> is an industry standard and you shouldn't change it. If you set this field too high, your switch won't disconnect sometimes when it should; too low, and it will disconnect when it shouldn't. |

## Disconnect Type

This field indicates which side or user controls the disconnect, where A refers to the *calling* party and B refers to the *called* party. Appears only if the Country field is **15** and the Trunk Type field is **2-wire-ac**, **2-wire-dc**, or **3-wire**.

This applies *only* to the TN2199 port.

| Valid entries | Usage |
|---------------|-------|
| <b>AandB</b>  |       |
| <b>AorB</b>   |       |

## Drop Treatment

This field only applies to DID trunks. It determines what the calling party hears when the called party terminates an incoming call.

| Valid entries    | Usage                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------|
| <b>intercept</b> | Select one. For security reasons, it's better to apply a tone: silence could provide an opening for hackers. |
| <b>busy</b>      |                                                                                                              |
| <b>silence</b>   |                                                                                                              |

### ⇒ NOTE:

In Italy, the Drop Treatment field must be administered as **intercept** for all DID trunk groups.

## Duplex

This field specifies whether a two-way trunk group allows simultaneous transmission in both directions. This field appears when the Comm Type field is **avd** or **rbavd**. It also appears if the Comm Type field is **data**, but only if the ISDN-PRI field is enabled on the System-Parameters Customer-Options screen.

**NOTE:**

Even if the trunk group supports full-duplex transmission, other equipment in a circuit may not.

| <b>Valid entries</b> | <b>Usage</b>                                                                                             |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>full</b>          | Enter <b>full</b> in most cases: this allows simultaneous two-way transmission, which is most efficient. |
| <b>half</b>          | Enter <b>half</b> to support only one transmission direction at a time.                                  |

## End-to-End Signaling

Auxiliary equipment such as paging equipment and music sources may be connected to Avaya MultiVantage by auxiliary trunks. The switch may send DTMF signals (touch tones) to these devices. This field, which appears when the Group Type field is **cpe** (customer-provided equipment trunk groups), sets the duration of these tones.

| <b>Valid entries</b>                          | <b>Usage</b>                                                                                                         |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>60 to 360 ms</b><br>in increments<br>of 10 | Use this field to set the duration in milliseconds of the touch-tone signal that is sent to the connected equipment. |

**NOTE:**

For trunks that do not receive real answer supervision, a “connect” Event report is sent when the Answer Supervision Timeout occurs.

## Expected Digits

**NOTE:**

Set this field to **blank** if the Digit Treatment field is set to **insert** and the Digits field contains a feature access code (for example, AAR or ARS) followed by digits. In this case, the number of digits expected are set on the AAR and ARS Digit Analysis Table and AAR and ARS Digit Conversion Table.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                          |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 18</b>       | Enter the number of digits that the far-end switch sends for an incoming connection. If your switch is absorbing digits on this trunk group, the entry in this field must be larger than the entry in the Digits field.<br><br>If you leave this field blank, you cannot administer digit absorption. |

## Extended Loop Range

This field appears only for a DID trunk group and is used only with the TN459A circuit pack. Enter **y** or **n** depending on the distance between the central office and the switch. If greater than the required distance, then the field should be **y**.

| Valid entries | Usage |
|---------------|-------|

## Group Name

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                    |                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 to 27 characters | Enter a unique name that provides information about the trunk group. Don't use the default entry or the group type (DID, WATS) here. For example, you might use names that identify the vendor and function of the trunk group: USWest Local; Sprint Toll, etc. |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Group Number

This field displays the group number assigned when the trunk group was added.

 **NOTE:**

For trunk groups connecting 2 switches in Distributed Communication System networks, Avaya recommends that you assign the same group number on both switches.

## Group Type

Enter the type of trunk group.

Busy-out the trunk group before you change the group type. Release the trunk group after you make the change. For more information about busying out and releasing trunk groups, see your system's Maintenance manual.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|               |                                                                                                                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Access</b> | Use access trunks to connect satellite switches to the main switch in Electronic Tandem Networks (ETN). Access trunks do not carry traveling class marks (TCM) and thus allow satellite callers unrestricted access to out-dial trunks on the main switch. Allows Inband ANI. |
| <b>APLT</b>   | Advanced Private Line Termination (APLT) trunks are used in private networks. APLT trunks allow inband ANI.                                                                                                                                                                   |
| <b>CAMA</b>   | CAMA trunks route emergency calls to the local community's Enhanced 911 systems.                                                                                                                                                                                              |

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CO</b>            | CO trunks typically connect your switch to the local central office, but they can also connect adjuncts such as external paging systems and data modules.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>CPE</b>           | Use CPE trunks to connect adjuncts, such as paging systems and announcement or music sources, to the switch.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>DID</b>           | Use DID trunks when you want people calling your organization to dial individual users directly without going through an attendant or some other central point. Allows Inband ANI.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DIOD</b>          | DIOD trunks are two-way trunks that transmit dialed digits in both directions. In North America, use tie trunks for applications that require two-way transmission of dialed digits. Allows Inband ANI.                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DMI-BOS</b>       | Digital Multiplexed Interface – Bit-Oriented Signaling (DMI-BOS) trunks allow communication with systems using DMI-BOS protocol. DMI-BOS trunks allow inband ANI.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>FX</b>            | An FX trunk is essentially a CO trunk that connects your switch directly to a central office outside your local exchange area. Use FX trunks to reduce long distance charges if your organization averages a high volume of long-distance calls to a specific area code.                                                                                                                                                                                                                                                                                                                 |
| <b>ISDN</b>          | <p>Use ISDN trunks when you need digital trunks that can integrate voice, data, and video signals and provide the bandwidth needed for applications such as high-speed data transfer and video conferencing. ISDN trunks can also efficiently combine multiple services on one trunk group.</p> <p>Use ISDN for Network Call Transfer. For more information, see <i>Avaya MultiVantage™ Network Call Redirection</i>.</p> <p>You cannot enter isdn unless the ISDN-PRI field, the ISDN-BRI Trunks field, or both have been enabled on the System-Parameters Customer-Options screen.</p> |
| <b>RLT</b>           | Release Link trunks work with Centralized Attendant Service in a private network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                           |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Tandem</b>        | Tandem trunks connect tandem nodes in a private network. Tandem trunks allow inband ANI.                                                                                                                                                                                                                                               |
| <b>Tie</b>           | Use tie trunks to connect a switch to a central office or to another switch in a private network. Tie trunks transmit dialed digits with both outgoing and incoming calls, and allow inband ANI.                                                                                                                                       |
| <b>WATS</b>          | Use WATS trunks to reduce long-distance bills when your organization regularly places many calls to a specific geographical area in North America. Outgoing WATS service allows calls to certain areas (“WATS bands”) for a flat monthly charge. Incoming WATS trunks allow you to offer toll-free calling to customers and employees. |

### Incoming Destination

Use this field to set the destination for all incoming calls on trunk groups such as CO, FX, and WATS that must terminate at a single destination. The destination you enter here is also the default night service destination unless you enter a different destination in the Night Service field. Appears when the Direction field is **incoming** or **two-way**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                       |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| blank                | Leave this field blank if the Trunk Type (in/out) field is not <b>auto/....</b>                                                                                                                                                                    |
| an extension number  | Calls go to the extension you enter. You may enter any type of extension, though typically the extension entered here identifies a VDN, a voice response unit, or a voice messaging system. Night service overrides this setting when it’s active. |
| <b>attd</b>          | Calls go to the attendant and are recorded as Listed Directory Number (LDN) calls on call detail records.                                                                                                                                          |

### Incoming Dial Tone

Indicates whether or not your switch will give dial tone in response to far-end seizures of the trunk group.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> if the incoming trunk group transmits digits. For example, you would enter <b>y</b> for two-way, dial-repeating tie trunks that users select by dialing a trunk access code. |
| <b>n</b>             | Enter <b>n</b> for trunks that aren’t sending digits, such as tandem or incoming CO trunks.                                                                                                 |

## Incoming Dial Type

Indicates the type of pulses required on an incoming trunk group. Usually, you should match what your central office provides. See [“Types of address transmission” on page 1911](#) for more information. This field appears for Access, APLT, DID, DIOD, DMI-BOS, FX, RLT, Tandem, and WATS trunk groups. It also appears for Tie trunk groups when the Trunk Signaling Type field is blank, **cont**, or **dis**.

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tone</b>   | Enter <b>tone</b> to use Dual Tone Multifrequency (DTMF) addressing, also known as “touch tone” in the U.S. Entering <b>tone</b> actually allows the trunk group to support both DTMF and rotary signals. Also, if you’re using the Inband ANI feature, enter <b>tone</b> .<br><br>For pulsed and continuous E&M signaling in Brazil and for discontinuous E&M signaling in Hungary, use <b>tone</b> .                                        |
| <b>rotary</b> | Enter <b>rotary</b> if you only want to allow the dial pulse addressing method used by non-touch tone phones. Though the tone entry supports rotary dialing as well, it’s inefficient to reserve touch tone registers for calls that don’t use DTMF.                                                                                                                                                                                          |
| <b>mf</b>     | Enter <b>mf</b> if the Trunk Signaling Type field is blank. The Multifrequency Signaling field must be enabled on the System-Parameters Customer-Options screen in order for you to enter <b>mf</b> here.<br><br>You may not enter <b>mf</b> if the Used for DCS field (Field descriptions for page 2) is <b>y</b> .<br><br>For pulsed and continuous E&M signaling in Brazil and for discontinuous E&M signaling in Hungary, use <b>mf</b> . |

## Incoming Rotary Timeout (sec)

Call setup at central offices that still use older switching equipment, such as step-by-step technology, is considerably longer than at central offices with more modern switches. If you’re receiving digits with incoming calls from a central office that uses less efficient switching technology, your switch needs to allow more time to ensure it receives all the incoming digits. When the Incoming Dial Type field is **rotary**, use this field to set the maximum time your switch will wait to receive all incoming digits from the far-end switch.

| Valid entries           | Usage                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>5 to 99</b> or blank | If the system is connected to a step-by-step central office, or any CO using older switching technology, enter at least <b>18</b> seconds; if not, enter at least <b>5</b> seconds. |

## ITC

The Generalized Route Selection feature, part of the automatic routing technology used in Avaya MultiVantage, compares the line coding of available digital facilities and selects appropriate routes for voice and data calls. The Information Transfer Capability field appears when the Comm Type field is **data**, **avd**, or **rbavd** and the BCC field is not **0**.

| Valid entries          | Usage                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rest</b> (stricted) | Restricted trunks use <b>ami-basic</b> or <b>ami-zcs</b> line coding and can carry only restricted calls.                                                                                                          |
| <b>unre</b> (stricted) | Unrestricted trunks use <b>b8zs</b> , <b>hdb3</b> , or <b>cmi</b> line coding and can carry restricted or unrestricted calls. A trunk group with an unrestricted ITC may have only unrestricted trunks as members. |

## Line Length

This field appears only when the Group Type field is **tie** and the Trunk Signaling Type field is **tge**, **tgi**, or **tgu**.

| Valid entries | Usage |
|---------------|-------|
| <b>short</b>  |       |
| <b>long</b>   |       |

### NOTE:

Unless one or more trunk members are administered, the administered value is not saved when you submit the screen (press ENTER).

## Night Service

This field sets the destination to which incoming calls go when Night Service is in operation. If a Night field on the Group Member Assignments page is administered with a different destination, that entry will override the group destination for that trunk. CPE, DID, and DIOD trunk groups do not support night service.

**Tip:**

*Whenever possible, use a night service destination on your switch: otherwise some features won't work correctly, even over a DCS network.*

| <b>Valid entries</b>                  | <b>Usage</b>                                                                                              |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------|
| blank                                 | Leave this field blank if the Trunk Type (in/out) field is not auto/....                                  |
| An extension number<br>(can be a VDN) | Enter the extension of your night service destination.                                                    |
| <b>attd</b>                           | Calls go to the attendant and are recorded as Listed Directory Number (LDN) calls on call detail records. |

## Outgoing Dial Type

This field sets the method used to transmit digits for an outgoing call. Usually, you should match what your central office provides. See [“Types of address transmission” on page 1911](#) for more information. This field appears for Access, APLT, CO, DIOD, DMI-BOS, FX, RLT, and WATS trunk groups. It also appears for Tie trunk groups when the Trunk Signaling Type field is blank, **cont**, or **dis**.

DIOD trunks support pulsed and continuous E&M signaling in Brazil and discontinuous E&M signaling in Hungary.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                      |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tone</b>          | Enter <b>tone</b> to use Dual Tone Multifrequency (DTMF) addressing, also known as “touch tone” in the U.S. Entering <b>tone</b> actually allows the trunk group to support both DTMF and rotary signals.<br><br>For pulsed and continuous E&M signaling in Brazil and for discontinuous E&M signaling in Hungary, use <b>tone</b> or <b>mf</b> . |
| <b>rotary</b>        | Enter <b>rotary</b> if you only want to allow the dial pulse addressing method used by non-touch tone phones. If you have a full touch tone system internally and a connection to a central office that only supports rotary dialing, for example, it would be appropriate to enter <b>rotary</b> .                                               |
| <b>r1mf</b>          | Enter <b>r1mf</b> for CAMA trunk groups. It is the only outgoing dial type allowed on CAMA trunk groups.<br><br>Enter <b>r1mf</b> to allow Russian MF Packet Signaling on outgoing trunks. Russian MF Packet Signaling carries calling party number and dialed number information. Group type field must be set to <b>co</b> .                    |

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mf</b>            | <p>Enter <b>mf</b> if the Trunk Signaling Type field is blank. The Multifrequency Signaling field must be enabled on the System-Parameters Customer-Options screen in order for you to enter <b>mf</b> here.</p> <p>You may not enter <b>mf</b> if the Used for DCS field (Field descriptions for page 2) is <b>y</b>.</p> <p>For pulsed and continuous E&amp;M signaling in Brazil and for discontinuous E&amp;M signaling in Hungary, use <b>tone</b> or <b>mf</b>.</p> |
| <b>automatic</b>     | <p>Enter <b>automatic</b> for tie trunks if the Trunk Signaling Type field is blank. This provides “cut-through” operation to outgoing callers who dial a trunk access code, connecting them directly to central office dial tone and bypassing any toll restrictions administered on your switch.</p>                                                                                                                                                                    |

### Outgoing Display

This field allows display phones to show the name and number of the trunk group used for an outgoing call before the call is connected. This information may be useful to you when you’re trying to diagnose trunking problems.

| <b>Valid entries</b> | <b>Usage</b>                              |
|----------------------|-------------------------------------------|
| <b>y</b>             | Displays the trunk group name and number. |
| <b>n</b>             | Displays the digits the caller dials.     |

### Prefix-1

Use this field for outgoing and two-way trunk groups handling long distance service. This field appears for CO, FX, and DIOD trunk groups.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to add the prefix “1” to the beginning of the digit string for outgoing calls. Do not enter <b>y</b> for trunk groups in AAR or ARS route patterns. |

## Protocol Type

This field specifies the type of line signaling protocol used for DID and DIOD trunk groups. This field appears when the Country field is **15** and is used only by trunk group members administered on a TN2199 or TN464D vintage 3 or later circuit pack.

| Valid entries                 | Usage                                                                                                      |
|-------------------------------|------------------------------------------------------------------------------------------------------------|
| <b>inloc</b> (Incoming local) | Enter the protocol the central office is using for this trunk group. Only the inloc protocol provides ANI. |
| <b>intol</b> (Incoming toll)  |                                                                                                            |

## Queue Length

Outgoing calls can wait in a queue, in the order in which they were made, when all trunks in a trunk group are busy. If you enter 0, callers receive a busy signal when no trunks are available. If you enter a higher number, a caller hears confirmation tone when no trunk is available for the outgoing call. The caller can then hang up and wait: when a trunk becomes available, the switch will call the extension that placed the original call. The caller will hear 3 short, quick rings. The caller doesn't need to do anything but pick up the handset and wait: the switch remembers the number the caller dialed and automatically completes the call.

This field appears when the Direction field is **outgoing** or **two-way**.

| Valid entries   | Usage                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------|
| <b>0 to 100</b> | Enter the number of outgoing calls that you want to be held waiting when all trunks are busy. |
| <b>0</b>        | Enter 0 for DCS trunks.                                                                       |

## Receive Answer Supervision

Use this field to specify whether the network provides answer supervision for a trunk group.

For Outbound Call Management applications, set this field to **y** for trunks supporting network answer supervision. For trunks that do not receive a real answer, this field determines when the CallVisor Adjunct-Switch Application Interface (ASAI) connect event is sent.

| Valid entries | Usage                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>      | Enter <b>y</b> if the network provides answer supervision. Set the Answer Supervision Timeout field to <b>0</b> .                                               |
| <b>n</b>      | Enter <b>n</b> if the network does not provide answer supervision, and set the Answer Supervision Timeout field. Also enter <b>n</b> for incoming trunk groups. |

**⇒ NOTE:**

When you set this field to **y**, the Outgoing End of Dial (sec) field is not displayed. The firmware timeout on circuit packs controlled by the Outgoing End of Dial (sec) field is automatically set to **0**.

**Receive Release Ack**

This field appears when the Trunk Signaling Type field is **cont** or **dis** and only applies to TN2140 ports (used for Italian and Hungarian tie trunks).

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|            |                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> if the switch will receive a release acknowledgment in response to a forward or backward release signal. |
|------------|-------------------------------------------------------------------------------------------------------------------------|

**Send Answer Supervision**

This field appears when the Trunk Signaling Type field is **cont** or **dis** and only applies to TN2140 ports.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|            |                                                                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to make your switch signal the calling switch when an incoming call is answered. You can only set this field to <b>y</b> if the Direction field is <b>incoming</b> or <b>two-way</b> . |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Send Release Ack**

This field appears when the Trunk Signaling Type field is **cont** or **dis** and only applies to TN2140 ports (used for Italian and Hungarian tie trunks).

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|            |                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to send a release acknowledgment in response to a forward or backward release signal. |
|------------|------------------------------------------------------------------------------------------------------|

**Sig Bit Inversion**

When transmission facilities use bit-oriented signaling (such as CAS), 2 bits are used to transmit seizure and release signals for calls. Called the A-bit and the B-bit, their meaning can vary. For example, in the A-bit a “1” might mean on-hook and a “0” might mean off-hook. The entry in the Country Protocol field on the DS1 Circuit Pack screen sets the default meaning of these bits.

For trunk ports on TN2242 and TN464B and later circuit packs, this field allows you to invert the A- and B-bits as necessary so that the far-end switch can understand your switch’s seizure and release signals. If the far-end switch, such as a central office, on this trunk group interprets the A- and B-bits differently from

the default, you may need to invert one or both bits — to change “1” to “0” and vice-versa in the A-bit, for example.

| <b>Valid entries</b> | <b>Usage</b>                                                                                |
|----------------------|---------------------------------------------------------------------------------------------|
| <b>A</b>             | For the TN464B and later circuit packs, indicate which bits, if any, should be inverted.    |
| <b>B</b>             |                                                                                             |
| <b>A&amp;B</b>       |                                                                                             |
| <b>none</b>          |                                                                                             |
| <b>A and none</b>    | For the Japanese 2Mbit trunk circuit pack, indicate which bits, if any, should be inverted. |

### Supplementary Service Protocol

Appears only when trunk group Type is ISDN.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                         |

### Synchronization

This field determines whether the trunk group will use synchronous or asynchronous communications. This field appears if:

- the Group Type field is **dmi-bos** or **isdn**, or
- the Group Type field is **access**, **co**, **fx**, **tandem**, **tie**, or **wats** and the Comm Type field is **avd** or **rbavd**, or
- the Group Type field is **access**, **co**, **fx**, **tandem**, **tie**, or **wats**, the Comm Type field is **data**, and the ISDN-PRI field or the ISDN-BRI Trunks field is **y** on the System-Parameters Customer-Options screen.

| Valid entries | Usage                                                                                      |
|---------------|--------------------------------------------------------------------------------------------|
| <b>async</b>  | Do not change this field without the assistance of Avaya or your network service provider. |
| <b>sync</b>   |                                                                                            |

### TAC

Enter the trunk access code (TAC) that must be dialed to access the trunk group. A different TAC must be assigned to each trunk group. CDR reports use the TAC to identify each trunk group.

| Valid entries    | Usage                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------|
| 1-4 digit number | Enter any number that fits the format for trunk access codes or dial access codes defined in your dial plan. |
| <b>*, #</b>      | * and # may be used as the first character in a TAC.                                                         |

## TN

| Valid entries                                                                                 | Usage                                                                                                                                                                      |
|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 20</b><br>(DEFINITY SI,<br>CSI)                                                       | Enter a Tenant Partition number to assign this trunk group to the partition.                                                                                               |
| <b>1 to 100</b><br>(DEFINITY R,<br>S8700<br>IP-Connect)                                       |                                                                                                                                                                            |
|  <b>Tip:</b> | <i>Double-check your entry. If you accidentally enter an unassigned tenant partition number, the system will accept the entry but no calls will go to the trunk group.</i> |

## Toll Restricted

| Valid entries                                                                                   | Usage                                                                                                                                                                               |
|-------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>                                                                                        | Enter <b>y</b> to prevent toll-restricted users from using a trunk access code to make restricted outgoing calls over this trunk group.                                             |
| <b>n</b>                                                                                        | Enter <b>n</b> if the field is automatic or if you don't want to restrict access.                                                                                                   |
|  <b>Tip:</b> | <i>To find out what kind of line coding a trunk group member uses, check the Line Coding field on the DS1 Circuit Pack screen for the DS1 port to which the member is assigned.</i> |

## Trunk Flash

Trunk Flash enables multifunction telephones located directly behind the DEFINITY System to access central office customized services that are provided by the far-end or Central Office (CO). These central office customized services are electronic features, such as conference and transfer, that are accessed by a sequence of flash signal and dial signals from the MultiVantage system telephone on an active trunk call.

| Valid entries | Usage                                |
|---------------|--------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to allow trunk flash. |

## Trunk Gain

This field specifies the amplification applied to the trunks in this group. With the values of the Trunk Termination and Country fields, the value in this field also determines the input and trans-hybrid balance impedance for TN465B, TN2146, TN2147, and TN2184 ports. All other CO and DID circuit packs are set automatically to high

| Valid entries | Usage                                                     |
|---------------|-----------------------------------------------------------|
| <b>high</b>   | Enter <b>high</b> if users complain of low volume.        |
| <b>low</b>    | Enter <b>low</b> if users complain of squeal or feedback. |

## Trunk Signaling Type

This field controls the signaling used by members in private network trunk groups, mainly in Italy, Brazil, and Hungary. This field also controls the signaling used by members in public network digital trunk groups. This field displays if the Group Type field is **access**, **aplt**, **rlt**, **tandem**, or **tie**. Entries in this field affect which timers appear on the Administrable Timers page.

| Valid entries                 | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cont</b><br>(continuous)   | E&M trunks in Italy, Brazil, and Hungary can use either continuous or discontinuous signaling. Each entry specifies a set of signals and available timers used in the process of setting up and releasing connections. The type of signaling you select on your switch must match the signaling type administered on the far-end switch. Use these values only when all trunk group members are assigned to ports on a TN464F, TN2464, or TN2140 circuit pack. Entering one of these values causes the Send Release Ack, Receive Release Ack, and Send Answer Supervision fields to appear. See <a href="#">“Trunk Type (in/out)” on page 1264</a> for more information. |
| <b>dis</b><br>(discontinuous) |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Use the following entries for tie trunks in Main-Satellite/Tributary networks. Each entry defines a function of the trunk group in the network. Use these values only when all trunk group members are assigned to a TN497 circuit pack.

|                                     |                                                                                                                                                                                 |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tgu</b><br>(for outgoing trunks) | Enter <b>tgu</b> at the main switch to administer a tie trunk group connected to a satellite switch. (This same group should be administered as <b>tge</b> at the satellite.)   |
| <b>tge</b><br>(for incoming trunks) | Enter <b>tge</b> at a satellite switch to administer a tie trunk group connected to the main switch. (This same group should be administered as <b>tgu</b> at the main switch.) |

| Valid entries                                                                                                                                                                                                                                                                                  | Usage                                                                                                                                                                                                  |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tgi</b><br>(for internal trunks)                                                                                                                                                                                                                                                            | Enter <b>tgi</b> at to administer a two-way tie trunk group between 2 satellites or between the main switch and a satellite. (This trunk group should be administered as <b>tgi</b> on both switches.) |
| <p>DIOD trunks support pulsed and continuous E&amp;M signaling in Brazil and discontinuous E&amp;M signaling in Hungary. Use the following entries for DIOD trunks. Use these values only when all trunk group members are assigned to a TN464F (or later version) or TN2464 circuit pack.</p> |                                                                                                                                                                                                        |
| <b>cont</b>                                                                                                                                                                                                                                                                                    | Enter <b>cont</b> for continuous E&M signaling.                                                                                                                                                        |
| <b>pulsed</b>                                                                                                                                                                                                                                                                                  | Enter <b>pulsed</b> for pulsed E&M signaling.                                                                                                                                                          |
| <b>discont</b>                                                                                                                                                                                                                                                                                 | <p>Leave blank for R2 signaling.</p> <p>Hungary uses discontinuous E&amp;M signaling when this field is <b>dis</b>. Brazil E&amp;M trunks use continuous and pulsed E&amp;M.</p>                       |

### Trunk Termination

This field adjusts the impedance of the trunk group for optimal transmission quality. Check with your service provider if you're not sure of the distance to your central office.

| Valid entries | Usage                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>600ohm</b> | Enter <b>600ohm</b> when the distance to the central office or the switch at the other end of the trunk is less than 3,000 feet. |
| <b>rc</b>     | Enter <b>rc</b> when the distance to the central office or the switch at the other end of the trunk is more than 3,000 feet.     |

### Trunk Type

Use this field to control the seizure and start-dial signaling used on this trunk group. Entries in this field vary according to the function of the trunk group and *must* match the corresponding setting on the far-end switch. This field appears for CO, DID, FX, and WATS trunk groups.

See “[Transmission and supervisory signaling](#)” on page 1908 for more information. Procedures in “[Managing trunks](#)” on page 411 give specific suggestions for signaling to use with different types of trunk groups.

| <b>Valid entries</b>                                                           | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ground-start</b>                                                            | Use ground-start signaling for two-way trunks whenever possible: ground-start signaling avoids glare and provides answer supervision from the far end.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>loop-start</b>                                                              | In general, try to use loop-start signaling only for one-way trunks. Loop-start signaling is susceptible to glare and does not provide answer supervision.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>auto/auto</b><br><b>auto/delay</b><br><b>auto/immed</b><br><b>auto/wink</b> | <p>The term before the slash tells the switch how and when it will receive incoming digits. The term after the slash tells the switch how and when it should send outgoing digits.</p> <ul style="list-style-type: none"><li>■ auto — Used for immediate connection to a single preset destination (incoming CO trunks, for example). No digits are sent, because all calls terminate at the same place.</li><li>■ delay — The sending switch does not send digits until it receives a delay dial signal (an off-hook signal followed by an on-hook signal) from the far-end switch, indicating that it’s ready to receive the digits.</li><li>■ wink — The sending switch does not send digits until it receives a a wink start (momentary off-hook) signal from the far-end switch, indicating that it’s ready to receive the digits.</li><li>■ immed — The sending switch sends digits without waiting for a signal from the far-end switch.</li></ul> |
| <b>2-wire-ac</b><br><b>2-wire-dc</b><br><b>3-wire</b>                          | These entries are used with CO trunks in Russia: enter the type of connection to your central office. Check with you network service provider if you don’t know what type of connection they’re using. To use these entries, the Country field must be <b>15</b> and the CO trunks must use ports on a TN2199 circuit board.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Trunk Type (in/out)

Use this field to control the seizure and start-dial signaling used on this trunk group. The setting of the Trunk Signaling Type field can affect the entries allowed in this field. In addition, settings may differ for incoming and outgoing trunks.

| Valid entries                                                              | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>auto</b><br>cont<br><b>delay</b><br>disc<br><b>immed</b><br><b>wink</b> | <p>There are numerous valid entries for this field: use the online help in the switch administration software to view all the possible combinations. Here are what the elements used in those combinations mean:</p> <ul style="list-style-type: none"> <li>■ auto — Used for immediate connection to a single preset destination (incoming CO trunks, for example). No digits are sent, because all calls terminate at the same place.</li> <li>■ cont — Continuous signaling is used with Italian E&amp;M tie trunks. The switch seizes a trunk by sending a continuous seizure signal for at least the duration specified by the Incoming Seizure Timer. See “<a href="#">Trunk Signaling Type</a>” on page 1261 for more information.</li> <li>■ delay — The sending switch does not send digits until it receives a delay dial signal (an off-hook signal followed by an on-hook signal) from the far-end switch, indicating that it’s ready to receive the digits.</li> <li>■ disc — Discontinuous signaling is used with Italian tie trunks that use E&amp;M signaling. The switch can seize a trunk by sending a single, short signal for the duration specified by the Normal Outgoing Seize Send field. However, with the Three-Way Seizure option the calling switch can also send routing information to the called switch by sending one or a series of brief seizure signals.</li> <li>■ wink — The sending switch does not send digits until it receives a wink start (momentary off-hook) signal from the far-end switch, indicating that it’s ready to receive the digits.</li> <li>■ immed — The sending switch sends digits without waiting for a signal from the far-end switch.</li> </ul> |
| <b>2-wire-ac</b>                                                           | <p>These entries are used with CO trunks in Russia: enter the type of connection to your central office. Check with you network service provider if you don’t know what type of connection they’re using. To use these entries, the Country field must be <b>15</b> and the CO trunks must use ports on a TN2199 circuit board.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>2-wire-dc</b>                                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>3-wire</b>                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### Tip:

*When incoming trunks use the setting immed/immed, the far-end switch seizes the trunk and sends digits without waiting for acknowledgment from the receiving switch. When traffic is heavy, the receiving switch may not immediately attach a Touch Tone Receiver to a call and therefore lose digits. Use wink-start trunks or increase the dial-guard timer value on the far-end switch to avoid this problem.*

**⇒ NOTE:**

The value in this field affects the appearance of the Incoming Partial Dial (sec) field on the Administrable Timer Page.

**Version**

Use this field to adjust the signaling on multi-country CO trunk circuit packs. Entries in this field adjust signaling characteristics on these circuit packs to match the signaling characteristics of the public network in a specific country. The field appears only for CO, FX, and WATS trunk groups when the Country field is **5**, **16**, or **23**.

**Valid entries      Usage**

---

If the Country field is **5**, the Version field only controls TN2147 ports.

- a**                      Enter **a** to use standard signaling for the Netherlands public network.
- b**                      Enter **b** to use country 1 (U.S.) signaling. The value **b** is appropriate if your switch is connected to a central office using an Ericsson AXE-10 switch.

If the Country field is **16** or **23**, the Version field sets the input impedance value and only controls TN465C (vintage 2 or later) ports.

- a**                      Enter **a** to set input impedance to 600 Ohms.
- b**                      Enter **b** to set input impedance to 900 Ohms. The value **b** is appropriate in Brazil.

**Wink Timer (msec)**

This field allows you to reduce the risk of glare by controlling part of call setup. Requirements for the United States domestic network specify that the wink signal for wink-start trunks must begin within 5 seconds after a trunk is seized. For trunks with a delay-dial start, the wink must not last longer than 5 seconds. While some circuit packs are hard-coded to allow the full 5 seconds in both cases, other circuit packs allow you reduce the allowed start time and duration, thus reducing the window in which glare could occur.

Unlike other fields on this screen, the Wink Timer field therefore controls 2 different variables. What your entry does depends on the outgoing value in the Trunk Type (in/out) field.

| Setting of the Trunk Type (in/out) field | What the Wink Timer field sets                                                      |
|------------------------------------------|-------------------------------------------------------------------------------------|
| <b>.../wink</b>                          | Maximum duration of the wink signal (wait-for-wink-to-end)                          |
| <b>.../delay</b>                         | Maximum interval after trunk seizure for the wink to begin (wait-for-wink-to-start) |

This field appears when the “out” side of the entry in the Trunk Type (in/out) field is **.../wink** or **.../delay** and the Group Type is **tie, access, aplt, dmi-bos, rlt, or tandem**. The setting in this field only affects trunks administered to ports on TN760C (vintage 4 or later), TN767, TN464C (or later), and TN2242 circuit packs. If the trunk group also contains trunks assigned to ports on other types of circuit packs, those trunks are unaffected.

| Valid entries                                | Usage                                                                                                                                                                |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>300 to 5000</b><br>in increments<br>of 50 | In general, Avaya recommends that you not change this field. If you do, remember that your switch’s timing must be compatible with the timing on the far-end switch. |

## Field descriptions for page 2

The figure below shows a common configuration for page 2 of the Trunk Group screen when the Group Type field is **co**. This screen is only an example, and the fields shown below may change or disappear according to specific field settings.

**Screen 296. CO Trunk Group**

**CAUTION:**

*Customers: Do not change fields on this page without assistance from Avaya or your network service provider.*

**Abandoned Call Search**

Use this field when the Trunk Type field is **ground-start**. Abandoned Call Search is designed to work with analog ground-start CO trunks that *do not* provide disconnect supervision. Your central office must support Abandoned Call Search for the feature to work properly. If your central office provides disconnect supervision, you do not need to use the Abandoned Call Search feature.

**Valid entries      Usage**

---

**y/n**                      Enter **y** if this trunk group will conduct an Abandoned Call Search to identify ghost calls.

## ACA Assignment

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> if you want Automatic Circuit Assurance (ACA) measurements to be taken for this trunk group. If <b>y</b> is entered, complete the Long Holding Time, Short Holding Time, and Short Holding Threshold fields. |

## Charge Conversion

Avaya MultiVantage multiplies the number of charge units by the value of this field and displays it as a currency amount. If there is no value in this field, Avaya MultiVantage displays the number of charge units without converting it to currency. This field appears for CO, DIOD, FX, and WATS trunk groups when the Direction field is **outgoing** or **two-way**. For ISDN trunk groups, it appears when the Charge Advice field is *not* **none**.

| <b>Valid entries</b> | <b>Usage</b>                                                       |
|----------------------|--------------------------------------------------------------------|
| <b>1 to 64,500</b>   | Enter the value of a charge unit in terms of the currency you use. |

## Charge Type

Entries in this field are text strings you use to describe charges related to a phone call. This field appears for CO, DIOD, FX, and WATS trunk groups when the Direction field is **outgoing** or **two-way**. For ISDN trunk groups, it appears when the Charge Advice field is *not* **none**.

| <b>Valid entries</b>                                                                     | <b>Usage</b>                                                                                                                                                                      |
|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1–7<br/>characters<br/>(embedded<br/>spaces count<br/>as characters)<br/>or blank</b> | Enter the words or characters you want to appear on phone displays after the charge amount. Most likely you will use either the currency symbol or the charge type, but not both. |

## Connected to CO

This field appears when the Group Type field is **tie**.

| <b>Valid entries</b> | <b>Usage</b>                                                 |
|----------------------|--------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to allow overlap sending to a Central Office. |

## Currency Symbol

This field appears for CO, DIOD, FX, and WATS trunk groups when the Direction field is **outgoing** or **two-way**. For ISDN trunk groups, it appears when the Charge Advice field is *not none*.

| <b>Valid entries</b>                                                                        | <b>Usage</b>                                                                    |
|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| 1–3<br>characters<br>(leading and<br>embedded<br>spaces count<br>as characters)<br>or blank | Enter the symbol you want to appear on phone displays before the charge amount. |

## Data Restriction

If **y**, whisper page is denied on this trunk.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                          |
|----------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to prevent features from generating tones on a data call that would cause erroneous data transmission. |

## Decimal Point

This field appears for CO, DIOD, FX, and WATS trunk groups when the Direction field is **outgoing** or **two-way**. For ISDN trunk groups, it appears when the Charge Advice field is *not none*.

| <b>Valid entries</b>                         | <b>Usage</b>                                                                                                                                                                        |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>comma</b><br><b>period</b><br><b>none</b> | Chose the appropriate representation for a decimal point as it will appear on phone displays. Entering <b>comma</b> or <b>period</b> in this field divides the charge value by 100. |

## DS1 Echo Cancellation

Reduces voice call echo.

| <b>Valid entries</b> | <b>Usage</b>                                                   |
|----------------------|----------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> to allow echo cancellation on a per port basis. |

## Glare Handling

This field determines what the switch will do when glare occurs. This field appears when the Direction field is **two-way** and the outgoing side of the Trunk Type field is either **.../wink** or **.../delay**.

If you enter **control** or **backoff**, and ports for the trunk group are not capable of detecting glare, warnings are generated. The following circuit packs can detect glare: TN767 (all releases), TN760C (or later releases), and TN464C (or later releases).

| Valid entries  | Usage                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------------|
| <b>control</b> | Your switch will seize the trunk and proceed with call setup. The other switch will find another trunk. |
| <b>backoff</b> | The other switch will seize the trunk proceed with call setup. Your switch will find another trunk.     |
| <b>none</b>    |                                                                                                         |

### Incoming Tone (DTMF) ANI

This field appears only when the Incoming Dial Type field is **tone**. Digits received through Automatic Number Identification (ANI) are printed on a CDR record, passed to the Intuity AUDIX and ASAI interfaces, and displayed on the phone (and on tandem calls if the outgoing trunk requires ANI). Then the digits are sent to the outgoing trunk.

| Valid entries     | Usage                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>*ANI*DNIS*</b> | If 555-3800 calls extension 81120, the trunk group receives *55538000*81120*. The phone displays Call from 555-3800. |
| <b>ANI*DNIS*</b>  | If 555-3800 calls extension 81120, the trunk group receives 55538000*81120*. The phone displays Call from 555-3800.  |
| <b>no</b>         |                                                                                                                      |

### Internal Alert

| Valid entries | Usage                                                                            |
|---------------|----------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> if internal ringing and coverage will be used for incoming calls. |

### Long Holding Time (hours)

This field appears only when the ACA Assignment field is **y**.

| Valid entries  | Usage                                                                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 10</b> | Enter the length of time (in hours) that the system will consider as being a long holding time. If you enter <b>0</b> , the system will not consider long holding calls. |

## Maintenance Tests

Appears when the Group Type field is **aplt** or **tie**.

| Valid entries | Usage                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> if hourly maintenance tests will be made on this trunk group. Your entry is not saved when the screen is submitted unless one or more trunk members are administered. |

## Measured

Indicates if the system will transmit data for this trunk group to the Call Management System (CMS). You cannot use **internal** and **both** unless either the BCMS (Basic) or the VuStats field is **y** on the System-Parameters Customer-Options screen. If the ATM field is set to **y** on the System-Parameters Customer-Option screen, this field accepts only **internal** or **none**. If this field contains a value other than **internal** or **none** when ATM is **y**, **none** appears.

| Valid entries   | Usage                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>internal</b> | Enter <b>internal</b> if the data can be sent to the Basic Call Management System (BCMS), the VuStats data display, or both. |
| <b>external</b> | Enter <b>external</b> to send the data to the CMS.                                                                           |
| <b>both</b>     | Enter <b>both</b> to collect data internally and to send it to the CMS.                                                      |
| <b>none</b>     | Enter <b>none</b> if trunk group measurement reports are not required.                                                       |

## MF Tariff Free

This field appears for Access, APLT, DID, DIOD, DMI-BOS, and Tandem trunk groups when the Incoming Dial Type field is **mf** or the Group Type field is **tie**, the Trunk Signaling Type field is blank, **cont**, or **dis**, and the Incoming Dial Type field is **mf**.

| Valid entries | Usage                                                                                                                                                                                                                                |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> to make the switch generate an MFC Tariff-Free Backward Signal (administered on the Multifrequency-Signaling-Related-System- Parameters screen) during call setup instead of the "free" signal. This aids CO billing. |

## Network Call Redirection

For more information, see *Avaya MultiVantage™ Network Call Redirection*.

| Valid entries          | Usage                                                                         |
|------------------------|-------------------------------------------------------------------------------|
| <b>deflect</b>         | Use to allow Network Call Deflection.                                         |
| <b>ANSI-transfer</b>   | Use to allow Network Call Transfer for MCI DEX 600 ISDN trunks.               |
| <b>Nortel-transfer</b> | Use to allow Network Call Transfer for MCI DMS 250 switches.                  |
| <b>telcordia-tbct</b>  | Use to allow Network Call Transfer for Lucent 5ESS or Nortel DMS100 switches. |

## Outgoing ANI

If this trunk group is used for an outgoing call with ANI, the entry in this field overrides the normal ANI. The ANI is sent exactly as administered, except for the normal truncation to 7 digits for Russian ANI. This ANI override works both for calls originated in Avaya MultiVantage and calls tandemed through it. This field appears for CO, DIOD, FX, and WATS trunk groups.

| Valid entries  | Usage                                                     |
|----------------|-----------------------------------------------------------|
| 1 to 15 digits | Enter the digit string to be sent in place of normal ANI. |
| blank          | Leave this field blank to allow ANI to work normally.     |

## Path Replacement Method

Appears when the following fields are set on the Trunk Group screen: trunk group Type is **ISDN**, Supplementary Service Protocol is **b** or **e**, the Path Replacement with Retention is **n**, and the Supplementary Services with Rerouting field or the DCS with Rerouting field on the System Parameters Customer Options screen is **y**.

| Valid entries        | Usage                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| always               | Use any QSIG (SSB) trunk group as the replacement trunk group. A new call is always originated, even when the original trunk group is determined to be the replacement trunk group.                                                                                                                 |
| BR<br>(better route) | Route pattern preferences help determine trunk group path replacement. The original trunk group is retained if the Path Replacement with Retention field is <b>y</b> . Path replacement fails (and the original trunk group is retained) if the Path Replacement with Retention field is <b>n</b> . |

### Path Replacement with Retention

Appears when the following fields are set on the Trunk Group screen: trunk group Type is **ISDN**, Supplementary Service Protocol is **b** or **e**, and the Supplementary Services with Rerouting field or the DCS with Rerouting field on the System Parameters Customer Options screen is **y**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|            |                                                                                                                                                         |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to retain the original trunk group. Set to <b>n</b> to allow path replacement according to setting on the Path Replacement Method field. |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|

### PBX ID

Appears when the Used for DCS field is **y**. This field identifies the remote switch in the network with which the trunk will communicate on a DCS signaling link.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                            |                                                            |
|----------------------------|------------------------------------------------------------|
| <b>1 to 63</b> or<br>blank | Enter the ID of the switch at the other end of this trunk. |
|----------------------------|------------------------------------------------------------|

### Per Call CPN Blocking Code

For Access, APLT, CO, DIOD, FX, tandem, tie, and WATS trunk groups only.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                                    |  |
|------------------------------------|--|
| 1 to 4 digit<br>number or<br>blank |  |
|------------------------------------|--|

|             |                                |
|-------------|--------------------------------|
| <b>*, #</b> | May be used as the first digit |
|-------------|--------------------------------|

### Per Call CPN Unblocking Code

For access, APLT, CO, DIOD, FX, tandem, tie, and WATS trunk groups only.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                                 |  |
|---------------------------------|--|
| 1 to 4 digit number or<br>blank |  |
|---------------------------------|--|

|             |                                |
|-------------|--------------------------------|
| <b>*, #</b> | May be used as the first digit |
|-------------|--------------------------------|

## Receive Analog Incoming Call ID

Your switch stores and displays 15 characters of name and number information associated with an incoming call on analog trunks (ICLID, or incoming call line identification information). This field appears for CO, DID, and DIOD trunk groups when the Analog Trunk Incoming Call ID field on the System-Parameters Customer-Options screen is **y** and the Direction field is **incoming** or **two-way**.

| <b>Valid entries</b> | <b>Usage</b>                                                |
|----------------------|-------------------------------------------------------------|
| <b>Bellcore</b>      | Used to collect ICLID information in the U.S.               |
| <b>NTT</b>           | Used to collect ICLID information in Japan.                 |
| <b>disabled</b>      | Stops the collection of ICLID information on analog trunks. |

## Request Category

This field appears when the Country field is **15** and the Shuttle field is **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                                         |
|----------------------|--------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> if the switch should request a call category from the central office. |

## Seize When Maintenance Busy

This field only affects ports on TN760C (or later release), TN767, and TN464C (or later release) circuit packs. It indicates whether this switch generates an outgoing seizure when a trunk in this trunk group is maintenance busied and whether the far-end switch is administered to do likewise. This supports the Electronic Tandem Network Busyout feature, which is intended to prevent a far-end switch from reporting problems with a trunk that has been removed from service on your switch. This field's setting does not affect the behavior of the far-end switch; it controls the behavior of this switch and defines the *expected* far-end behavior.

For DIOD trunks using TN464F (or later release) or TN2464, displays only when the Group Type field is **dioid** and the Trunk Signaling Type field is **pulsed, cont,** or **dis**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>near-end</b>      | Enter <b>near-end</b> if this switch generates an outgoing seizure when a trunk is maintenance busied but the far-end switch does not. The seizure is maintained until the maintenance busyout is released. |
| <b>far-end</b>       | Enter <b>far-end</b> if the far-end switch generates an outgoing seizure when a trunk is maintenance busied but this switch does not.                                                                       |
| <b>both-ends</b>     | Enter <b>both-ends</b> if both this switch and the far-end switch generate an outgoing seizure when a trunk is maintenance busied.                                                                          |

If a switch generates an outgoing seizure when a trunk is busied out, the seizure will probably cause alarms at the far-end switch, perhaps leading to a far-end maintenance busy out, unless the far-end switch is administered to expect this behavior.

If the administered value of this field is either **far-end** or **both-ends**, any abnormally long incoming seizure (including failure to drop from a completed call) is *assumed to be the result of a far-end maintenance busy condition*. Note that this assumption may be incorrect, since the abnormally long seizure may actually be due to failure of the trunk circuit. Regardless of the cause of the abnormally long seizure, your switch does the following things:

1. Generates a warning alarm indicating that the trunk is assumed to be maintenance busy at the far-end
2. Removes the trunk from service
3. Keeps the trunk out of service until a far-end disconnect is received

Allowable values depend on the entry in the Direction field: check the online help in the switch administration software.

## Short Holding Threshold

This field appears when the ACA Assignment field is **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                        |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 30</b>       | Enter the number of times the system will record a short holding call before alerting an attendant to the possibility of a faulty trunk. Enter <b>0</b> for no short holding calls. |

### Short Holding Time (seconds)

This field appears when the ACA Assignment field is **y**.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                 |                                                                                                                                                                          |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 160</b> | Enter the length of time (in seconds) that the system considers as being a short holding time. If <b>0</b> is entered, the system will not consider short holding calls. |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Shuttle

This field appears when the Group Type field is **co**, **fx**, or **wats**, the Country field is **15**, and the Outgoing Dial Type field is **rotary**. It can be administered on TN464D (or later release) or TN2199 circuit packs.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|            |                                                |
|------------|------------------------------------------------|
| <b>y/n</b> | Enter <b>y</b> to enable MF shuttle signaling. |
|------------|------------------------------------------------|

### Start B Signal

This field appears when the Country field is **15** and the Shuttle field is **y**. Enter **1–3** to indicate which B-signal should be used to start a call. The value administered in this field must be coordinated with your central office. See [“Start Position” on page 1276](#).

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|          |                                             |
|----------|---------------------------------------------|
| <b>1</b> | Start calls with signal B1 (first digit)    |
| <b>2</b> | Start calls with signal B2 (next digit)     |
| <b>3</b> | Start calls with signal B3 (previous digit) |

### Start Position

The value administered in this field must be coordinated with your central office. This field appears when the Country field is **15** and the Shuttle field is **y**.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|               |                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 9</b> | Indicate which digit in the digit string is considered to be the “previously sent” digit (see <a href="#">“Start B Signal” on page 1276</a> ). |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|

## Suppress # Outpulsing

| Valid entries | Usage                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> if end-to-end signaling begins with (and includes) “#”. The final “#” is suppressed in cases where the system would normally outpulse it. This field should be <b>y</b> when the Central Office (for example, rotary) or any other facility treats “#” as an error. |

## Time (sec) to Drop Call on No Answer

This field appears if the Group Type field is **co** or **diod** and the Outgoing Dial Type field is **mf**, or if the Group Type field is **co**, **diod**, **fx**, **wats**, and the Country field is **15**.

| Valid entries | Usage                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–1200        | Enter the duration (in seconds) the switch should wait for outgoing calls to be answered. If the call is not answered in the specified number of seconds, the call drops. If this field is <b>0</b> , the timer is not set and no calls drop. |

## Used for DCS

| Valid entries | Usage                                                                                      |
|---------------|--------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> if this trunk group will send and receive messages on a DCS signaling link. |

### NOTE:

This field cannot be activated if the trunk group number is greater than 255 or if the Trunk Access code is more than 3-digits long.

If this field is **y**, you can administer ISDN-BRI trunk groups unless the DCS Signaling field is **d-chan**. In that case, remove the BRI trunks or set the DCS Signaling field to **bx.25** before submitting the screen.

## Field descriptions for page 3

---

The figure below shows a common configuration for page 3 of the Trunk Group screen when the Group Type field is **co**. This screen is only an example, and the fields shown below may change or disappear according to specific field settings.

**Screen 297. Administrable Timers for Trunk Group**

**CAUTION:**

*Customers: Do not change fields on this page without assistance from Avaya or your network service provider.*

**Answer Send (msec)**

This field appears only if the Trunk Type field is **dis** and the trunk group Direction field is **incoming** or **two-way**. Only TN2140 and TN2199 ports receive this timer.

| Valid entries                  | Usage                                          |
|--------------------------------|------------------------------------------------|
| 10 to 2550 in increments of 10 | Enter the duration of the answer signal pulse. |

**Busy Tone Disconnect**

The field appears when Enable Busy Tone Disconnect for Analog loop-start Trunks is **y** on the System Parameters Country-Options screen.

| Valid entries | Usage                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to allow the switch to recognize a busy tone signal as a disconnect on this trunk group. |

### Cama Outgoing Dial Guard (msec)

This field appears when Group Type is **cama** (the trunk group type used for emergency 911 service).

| <b>Valid entries</b>                  | <b>Usage</b>                                                                                                                  |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>25 to 6375</b> in increments of 25 | Enter the minimum interval between the receiving switch's seizure acknowledgment and the outpulsing of digits by this switch. |

### Cama Wink Start Time (msec)

This field appears when Group Type is **cama**.

| <b>Valid entries</b>                  | <b>Usage</b>                                                                                                                                                |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>20 to 5100</b> in increments of 20 | Specifies the duration (the wait-for-wink-to-end time) for a wink-start CAMA trunk. The wink must begin before the Outgoing Seizure Response timer expires. |

### Disconnect Signal Error (sec)

This field appears for ground-start trunk groups.

| <b>Valid entries</b>               | <b>Usage</b>                                                                                                                                                                                                                                                                                        |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 255</b> in increments of 1 | Enter the maximum interval that the switch will wait to receive a disconnect signal from the far-end switch after the local party (a phone or tie trunk) goes on-hook. If the timer expires, the system assumes a disconnect failure and take appropriate action such as creating an error message. |

### Flash Length (msec)

This timer is sent to TN436B, TN459B, TN464C (or later), TN465B (or later), (TN753 if Country is **23**), TN2146, TN2147, TN2184, and TN2199 circuit boards.

| <b>Valid entries</b>                  | <b>Usage</b>                                                              |
|---------------------------------------|---------------------------------------------------------------------------|
| <b>10 to 2550</b> in increments of 10 | Enter the duration of a flash signal generated toward the central office. |

## Glare

This field is only administrable if the Trunk Type field is **cont** and the trunk group Direction field is **two-way** or **outgoing**. Only TN2140 ports receive this timer.

| Valid entries                        | Usage                                                                                                                                                                                                                                   |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>40 to 100</b> in increments of 10 | Enter the minimum acceptable interval (in msec) between the moment your switch sends an outgoing seizure and the moment it receives a seizure acknowledgment. If acknowledgment is received before the timer expires, glare is assumed. |

## Incoming Dial Guard (msec)

| Valid entries                         | Usage                                                                                                                                                                                  |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>10 to 2550</b> in increments of 10 | Enter the minimum acceptable interval between the detection of an incoming seizure and the acceptance of the first digit. The switch will not accept digits before this timer expires. |

### NOTE:

This timer is never sent to TN429 ports.

## Incoming Disconnect (msec)

The field appears only when the Direction field is **incoming** or **two-way** and the Trunk Type field is either blank or **cont**.

| Valid entries                         | Usage                                                                                                                                                                                                                 |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>50 to 2550</b> in increments of 10 | Enter the minimum valid duration of a disconnect signal for an incoming call. The switch will not recognize shorter disconnect signals. This field cannot be blank. For Brazil pulsed E&M signaling, use <b>600</b> . |

## Incoming Disconnect Send (msec)

This field is only administrable if the Trunk Type field is **dis** and the trunk group Direction field is **incoming** or **two-way**. Only TN2140 ports receive this timer.

| Valid entries                           | Usage                                                                                               |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------|
| <b>500 to 1200</b> in increments of 100 | Enter the duration of the backward release signal your switch sends at the end of an incoming call. |

### Incoming Glare Guard (msec)

This field only appears when the trunk group Direction field is **two-way**.

| Valid entries                                  | Usage                                                                                                                                                                                                                                                 |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>100 to 25500</b><br>in increments<br>of 100 | Enter the minimum interval that must elapse between a trunk's release from an incoming call and its seizure for an outgoing call. This field cannot be blank. This delay gives the far-end time to release all equipment after the trunk is released. |

### Incoming Incomplete Dial Alarm (sec)

Only the TN436 (all), TN459 (all), TN464C (or later), TN767, TN2140, TN2146, TN2184, TN2199, and TN2242 circuit packs use this timer.

| Valid entries                            | Usage                                                                                                                                                    |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 255</b> in<br>increments of<br>1 | Enter the maximum acceptable interval between an incoming seizure and receipt of all digits. Intervals greater than this limit generate an inline error. |

### Incoming Partial Dial (sec)

This timer appears only if the Incoming Dial Type field is **rotary**.

| Valid entries                            | Usage                                                          |
|------------------------------------------|----------------------------------------------------------------|
| <b>5 to 255</b> in<br>increments of<br>1 | Enter the maximum time allowed between incoming rotary digits. |

#### ⇒ NOTE:

This timer is never sent to TN429 ports.

### Incoming Seizure (msec)

This field appears when the Direction field is **incoming** or **two-way**, and, when applicable, the Trunk Type field is **cont**. Only TN429, TN438 (any release), TN447, TN464C (or later), TN465 (any release), TN767, TN2138, TN2140, TN2147, TN2184, and TN2199 ports receive this timer. For DID trunks, only TN2199 and TN429D (or later) receive this timer.

| Valid entries                               | Usage                                                                                                                                              |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>20 to 2550</b> in<br>increments of<br>10 | Enter the duration of the shortest incoming seizure signal your switch can recognize. For ICLID, set this field to 120. The field cannot be blank. |

### Normal Outgoing Seize Send (msec)

This field appears only if the Trunk Type field is **dis** and the trunk group Direction field is **two-way** or **outgoing**. Only TN2140 ports receive this timer.

| Valid entries                        | Usage                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------|
| <b>10 to 990</b> in increments of 10 | Enter the duration of the signal your switch sends for an outgoing seizure. |

### Outgoing Dial Guard (msec)

| Valid entries                            | Usage                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>100 to 25500</b> in increments of 100 | Enter the minimum interval between seizure acknowledgment of a trunk and the outpulsing of digits. This field cannot be blank. For trunks that do not provide seizure acknowledgment, the timer specifies the minimum time between seizure and the outpulsing of digits. Any digit the caller dials after they lift the receiver, but before the timer expires, is not outpulsed until the timer expires. |

### Outgoing Disconnect (msec)

| Valid entries                         | Usage                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>50 to 2550</b> in increments of 10 | Enter the minimum valid duration of a disconnect signal for an outgoing call. The switch will not recognize shorter disconnect signals. This field cannot be blank. This timer begins timing when a disconnect signal is detected on an outgoing call and resets when the signal is no longer detected. If the timer expires, the trunk drops. For Brazil pulsed E&M signaling, use <b>600</b> . |

### Outgoing Disconnect Send (msec)

This field is administrable only if the Trunk Type field is **dis** and the trunk group Direction field is **two-way** or **outgoing**. Only TN2140 ports receive this timer.

| Valid entries                           | Usage                                                                                            |
|-----------------------------------------|--------------------------------------------------------------------------------------------------|
| <b>100 to 9900</b> in increments of 100 | Enter the duration of the forward release signal your switch sends at the end of outgoing calls. |

## Outgoing End of Dial (sec)

This field controls firmware answer supervision timers on circuit packs that have them. It appears when the Direction field is **outgoing** or **two-way** and the Receive Answer Supervision field is **n**. If the Receive Answer Supervision field is **y**, this field does not appear and the firmware timer on the appropriate circuit pack is automatically disabled.

### NOTE:

The Answer Supervision Timeout field on the Trunk Group screen provides timed answer supervision for circuit packs without administrable timers. Since trunk groups may contain ports on more than one circuit pack, it's possible you may need to use both timers with the same trunk group. If so, set the Outgoing End of Dial field and the Answer Supervision Timeout field to the same value.

| <b>Valid entries</b>                      | <b>Usage</b>                                                                                                                                                                                                |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1</b> to <b>254</b> in increments of 1 | Enter the maximum time, in seconds, that the switch will wait to receive answer supervision for outgoing calls on the ports controlled by firmware timers. For Brazil pulsed E&M signaling, use <b>40</b> . |

During a cut-through operation, timing begins after the switch sends each outgoing digit and ceases when answer supervision is received. If the timer expires, the switch acts as if it has received answer supervision. On senderized operation, the timer begins after the switch sends the last digit collected. The timer ceases when answer supervision is received. If the timer expires, the switch acts as if it has received answer supervision.

## Outgoing Glare Guard (msec)

This field only appears for **outgoing** and **two-way** trunk groups.

| <b>Valid entries</b>                            | <b>Usage</b>                                                                                                                                                                                                                                                        |
|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>100</b> to <b>25500</b> in increments of 100 | Enter the minimum interval that must elapse between a trunk's release from an outgoing call and its seizure for another outgoing call. This field cannot be blank. This delay gives the far-end time to release all equipment after the outgoing trunk is released. |

### Outgoing Last Digit (sec)

This field is only administrable if the Trunk Type field is **dis** or **cont** and the trunk group Direction field is **two-way** or **outgoing**. Only TN497 and TN2140 ports receive this timer.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                                   |                                                                                                                                                       |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1 to 40</b> in increments of 1 | Enter the maximum time that the switch will wait for the next digit dialed. After the timer expires, no more digits are accepted by the circuit pack. |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

### Outgoing Rotary Dial Interdigit (msec)

This field only appears when:

1. the trunk group Group Type field is **access, ap1t, co, diod, dmi-bos, fx, rlt, tandem,** or **wats** and the Outgoing Dial Type field is **rotary**
2. the Group Type field is **tie**, the Trunk Type field is blank, **cont**, or **dis**, and the Outgoing Dial Type field is **rotary**
3. the Group Type field is **tie**, and the Trunk Type field is **tge, tgi,** or **tru** (the Outgoing Dial Type field does not appear but is implied to be **rotary**).

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                                        |                                                                            |
|----------------------------------------|----------------------------------------------------------------------------|
| <b>150 to 2550</b> in increments of 10 | Enter the minimum time between outpulsed digits on outgoing rotary trunks. |
|----------------------------------------|----------------------------------------------------------------------------|

### Outgoing Seizure (msec)

Appears when the Country field is **15**, the Direction field is **outgoing** or **two-way**, and the Trunk Type field is **2-wire-ac, 2-wire-dc,** or **3-wire**. This timer is sent only to the TN2199 circuit pack.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                                       |                                                    |
|---------------------------------------|----------------------------------------------------|
| <b>20 to 2550</b> in increments of 10 | Enter the duration of the outgoing seizure signal. |
|---------------------------------------|----------------------------------------------------|

### Outgoing Seizure Response (sec)

This timer is sent to the TN438B, TN439, TN447, TN458, TN464B (or later), TN465B (or later), TN767, TN2140, TN2147, TN2184, TN2199, and TN2242 circuit packs.

| <b>Valid entries</b>                      | <b>Usage</b>                                                                                                                                                                                                                                                                            |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1</b> to <b>255</b> in increments of 1 | Enter the maximum interval that the switch should wait after sending a seizure signal to receive seizure acknowledgment from the far-end. If the acknowledgment is not received in this time, a seizure failure response is uplinked. For Brazil pulsed E&M signaling, use <b>255</b> . |

### Programmed Dial Pause (msec)

This timer is administrable for all outgoing and two-way trunk groups. This timer works with the TN464B (or later), TN767, TN458, TN2140, and TN2242 tie circuit packs. All CO circuit packs that accept administrable timers accept this timer.

| <b>Valid entries</b>                            | <b>Usage</b>                                                                                                       |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>100</b> to <b>25500</b> in increments of 100 | Set the exact duration of pauses used during abbreviated dialing, ARS outpulsing, and terminal dialing operations. |

### Release Ack Send (msec)

After your switch receives a forward release signal, it must send a forward release acknowledgment signal. This field appears only if the Trunk Type field is **dis** and the trunk group Direction field is **incoming** or **two-way**. Only TN2140 ports receive this timer.

| <b>Valid entries</b>                           | <b>Usage</b>                                                                             |
|------------------------------------------------|------------------------------------------------------------------------------------------|
| <b>500</b> to <b>1200</b> in increments of 100 | Enter the duration of the signal your switch sends for a forward release acknowledgment. |

### Ringling Monitor (msec)

This timer is sent to TN464C (or later), TN767, TN438 (all), TN447, TN465 (all), TN2138, TN2147, TN2184, and TN2199 CO circuit packs.

| Valid entries                            | Usage                                                                                                                                                                                                                                                       |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>200 to 51000</b> in increments of 200 | Enter the minimum time the switch requires to determine if a trunk disconnects. The field cannot be blank. If the ringing signal disappears for a duration longer than the time specified in this field, the switch assumes the call has been disconnected. |

### Seize Ack Delay (msec)

This field appears only if the Trunk Type field is **dis** and the trunk group Direction field is **incoming** or **two-way**. Only TN2140 ports receive this timer.

| Valid entries                        | Usage                                                                                                                 |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>40 to 120</b> in increments of 10 | Enter the maximum interval your switch will wait after receipt of an incoming seizure to send seizure acknowledgment. |

### Seize Ack Send (msec)

This field appears only if the Trunk Type field is **dis** and the trunk group Direction field is **incoming** or **two-way**. Only TN2140 ports receive this timer.

| Valid entries                        | Usage                                                                                                         |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <b>10 to 990</b> in increments of 10 | Enter the duration of the seizure acknowledgment signal your switch sends in response to an incoming seizure. |

### Send Incoming/Outgoing Disconnect Timers to TN465 Ports

The field appears only for a co, fx, or wats trunk group.

| Valid entries | Usage                                                                                                                                               |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | Enter <b>y</b> if you want to send the incoming disconnect and outgoing disconnect timer values to the trunk group ports that are on a TN465 board. |

## END TO END SIGNALING

---

### Pause (msec)

This field is administrable only if the Trunk Type field is blank. All CO, DIOD, and tie circuit packs that accept administrable timers accept this timer. However, this timer is sent only to the following circuit packs: TN464B (or later), TN767, TN436B, TN459B, TN2146, TN2199, and TN2242, and TN429 and TN2184 ports in a DID trunk group.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                                       |                                                                                            |
|---------------------------------------|--------------------------------------------------------------------------------------------|
| <b>20 to 2550</b> in increments of 10 | Enter the minimum acceptable interval (pause) between DTMF tones sent from a hybrid phone. |
|---------------------------------------|--------------------------------------------------------------------------------------------|

### Tone (msec)

This field appears only if the Trunk Type field is blank. All CO, DIOD, and Tie circuit packs that accept administrable timers accept this timer. This timer is also sent to the following circuit packs: TN464B (or later), TN767, TN436B, TN459B, TN2146, TN2199, TN429, TN2184 ports in a DID trunk group.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|                                       |                                                                                    |
|---------------------------------------|------------------------------------------------------------------------------------|
| <b>20 to 2550</b> in increments of 10 | Enter the duration of a DTMF tone sent when a button on a hybrid phone is pressed. |
|---------------------------------------|------------------------------------------------------------------------------------|

## OUTPULSING INFORMATION

---

### Break (msec)

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

Enter the duration of the break interval (the pulse duration) while the system is outpulsing digits using dial pulse signaling. The field cannot be blank.

|                                    |                                                                                                |
|------------------------------------|------------------------------------------------------------------------------------------------|
| <b>20 to 80</b> in increments of 5 | If PPS field is <b>10</b> , the sum of the Make (msec) and Break (msec) fields must equal 100. |
|------------------------------------|------------------------------------------------------------------------------------------------|

|                                     |                                                                                                   |
|-------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>10 to 40</b> in increments of 5. | If the PPS field is <b>20</b> , the sum of the Make (msec) and Break (msec) fields must equal 50. |
|-------------------------------------|---------------------------------------------------------------------------------------------------|

## Frequency

This field identifies the PPM pulse frequency(ies) sent by the public network. It appears if the Direction field is **outgoing** or **two-way** and PPM is **y**. Circuit packs can detect up to three different frequencies, (12kHz, 16kHz, and 50Hz), plus two frequency combinations, (50Hz/12kHz and 50Hz/16kHz). This field controls TN465B, TN2138, and TN2184 circuit packs.

| Valid entries | Usage                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>12k</b>    | The TN465B (or later) and TN2184 can only detect 12k and 16kHz PPM. Therefore, if <b>12k</b> is administered, the circuit pack will be set to detect 12kHz.    |
| <b>16k</b>    | The TN465B (or later) and TN2184 can only detect 12k and 16kHz PPM. Therefore, if <b>16k</b> is administered, the circuit pack will be set to detect 16kHz.    |
| <b>50</b>     | The TN465B (or later) and TN2184 can only detect 12k and 16kHz PPM. Therefore, if <b>50</b> is administered, the circuit pack will be set to detect 16kHz.     |
| <b>50/12k</b> | The TN465B (or later) and TN2184 can only detect 12k and 16kHz PPM. Therefore, if <b>50/12k</b> is administered, the circuit pack will be set to detect 12kHz. |
| <b>50/16k</b> | The TN465B (or later) and TN2184 can only detect 12k and 16kHz PPM. Therefore, if <b>50/16k</b> is administered, the circuit pack will be set to detect 16kHz. |

## Make (msec)

| Valid entries                                                                                                                                                   | Usage                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------|
| Enter the duration of the make interval (the pause between pulses) while the system is outpulsing digits using dial pulse signaling. The field cannot be blank. |                                                                                                    |
| <b>20 to 80</b> in increments of 5                                                                                                                              | If the PPS field is <b>10</b> , the sum of the Make (msec) and Break (msec) fields must equal 100. |
| <b>10 to 40</b> in increments of 5                                                                                                                              | If the PPS field is <b>20</b> , the sum of the Make (msec) and Break (msec) fields must equal 50.  |

**PPM**

For CO, DIOD, FX, PCOL, and WATS trunks. This field appears when the Direction field is **outgoing** or **two-way**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                          |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>           | Enter <b>y</b> if Periodical Pulse Metering (PPM) pulses should be collected from the public network to determine call cost. If this field is <b>y</b> , the Frequency field appears. |

**PPS**

| <b>Valid entries</b> | <b>Usage</b>                                                                                       |
|----------------------|----------------------------------------------------------------------------------------------------|
| <b>10</b>            | Enter the rate (pulses per second) at which outgoing rotary pulses are sent over this trunk group. |
| <b>20</b>            |                                                                                                    |

**⇒ NOTE:**

The TN439, TN458, TN497, TN747Bv12 (or later), and TN767 circuit packs only send rotary pulses at 10 pps.

**Field descriptions for page 4**

This screen appears when the Direction field on Page 1 is **outgoing** or **two-way** and the ATMS field is **y** on the Feature-Related System Parameters screen.

The figure below shows a common configuration for page 4 of the Trunk Group screen when the Group Type field is **co**. This screen is only an example, and the fields shown below may change or disappear according to specific field settings.

| Valid entries  | Usage                                                                    |
|----------------|--------------------------------------------------------------------------|
| 1 to 16 digits | Enter the access number dialed to reach the terminating test line (TTL). |

## Trunk Contact

| Valid entries                   | Usage                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 25 alphanumeric characters | Enter the name and/or telephone number of someone from the trunk vendor who can be contacted in the event of problems with the trunks. |

## Trunk Length

This field is not required. Since noise on a trunk increases with the length of the trunk, however, this information may be useful,

| Valid entries                                                                  | Usage                           |
|--------------------------------------------------------------------------------|---------------------------------|
| Use this field to record the length of the trunk group in kilometers or miles. |                                 |
| 0–4 digits followed by <b>k</b>                                                | Shows the length in kilometers. |
| 0–4 digits followed <b>m</b>                                                   | Shows the length in miles.      |

## Trunk Vendor

| Valid entries                   | Usage                                                                                                                                                      |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 22 alphanumeric characters | Enter the name of the vendor providing service over this trunk group (the company to notify in the event of problems with the trunks in this trunk group). |

## TTL Contact

| Valid entries                   | Usage                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 25 alphanumeric characters | Enter the name and/or telephone number of someone from the TTL vendor who can be contacted in the event of problems with the terminating test line. |

## TTL Type

Specifies the type of terminating test line (TTL) selected for testing trunks. The TTL type determines what ATMS tests can be completed and thus which threshold values need to be administered.

| <b>105-wo-rl</b> | 105 without return loss |
| <b>high-lts</b>  | high-level tone source  |

| <b>Valid entries</b> | <b>Usage</b>          |
|----------------------|-----------------------|
| <b>low-lts</b>       | low-level tone source |
| <b>100</b>           | 100 type              |
| <b>102</b>           | 102 type              |

The following table explains the differences between types of terminating test lines:

| <b>Type TTL</b>        | <b>Description</b>                                                        | <b>Example</b>                                                    |
|------------------------|---------------------------------------------------------------------------|-------------------------------------------------------------------|
| <i>105-w-rl</i>        | Full range of 18 measurements or some defaults for return loss used (56A) | TN771B, ZLC12 and SN261B circuit packs and new 56A mini-responder |
| <i>105-wo-rl</i>       | Cannot return default values for far-end return loss                      | Older 56A mini-responder                                          |
| <i>high-level-tone</i> | Sends a fixed sequence of tones at 0 dBm                                  | ZLC12 and SN261B circuit packs                                    |
| <i>low-level-tone</i>  | Sends a fixed sequence of tones at -16dBm                                 | SN261B circuit pack                                               |
| <i>100</i>             | Up to 5 measurements that sends a 1004 Hz tone then a quiet termination   |                                                                   |
| <i>102</i>             | One measurement that sends a 1004 Hz tone                                 |                                                                   |

The far-end switch containing the TTL may be any of the following:

- System 85 R2 switch, equipped with the Maintenance/Test Board (TN771B)
- System 75 R1V2 and beyond, all of which contain the circuitry required to perform the TTL function
- System 85 R2 switch, equipped with the Analog/Digital Facility Test Circuit (ADFTC, SN261)
- DIMENSION FP8, equipped with the Analog Facility Test Circuit (AFTC, ZLC-12)
- Central Office switches, equipped with various TTL equipment that provide 100, 102, or 105 test line capabilities (56A)

Other vendors' switches *may* be supported if compatible test lines are provided by these switches.

Four different versions of the ATMS Threshold Administration page can appear depending upon the measurements allowed by the TTL type selected. The four possibilities are:

1. 105-w-rl and 105-wo-rl — All thresholds appear.
2. high-lts and low-lts — All thresholds (except maximum C-notched noise) appear.
3. 100 — All thresholds (except maximum c-notched noise, 404Hz loss, and 2804 Hz loss) appear.
4. 102 — Only 1004 Hz loss threshold appears.

### TTL Vendor

| Valid entries                         | Usage                                                                   |
|---------------------------------------|-------------------------------------------------------------------------|
| 0 to 22<br>alphanumeric<br>characters | Enter the name of the vendor supplying the terminating test line (TTL). |

### MARGINAL / UNACCEPTABLE

---

#### Allow ATMS Busyout, Error Logging and Alarming

| Valid entries | Usage                                                                                                                                          |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| y/n           | Enter <b>y</b> to allow ATMS error logging and alarming (subject to filtering depending on the service organization used to deal with alarms). |

#### Marginal Threshold - -Dev - 404 Hz Loss

| Valid entries | Usage                                                                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 9        | Enter the maximum negative deviation of measured loss at 404 Hz from the 1004 Hz test tone noise level (in dB) allowed before reporting a trunk as out of tolerance. Smaller dB values are more restrictive. |

**Marginal Threshold - +Dev - 404 Hz Loss**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 9</b>        | Enter the maximum positive deviation of measured loss at 404 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as out of tolerance. Smaller dB values are more restrictive. |

**Marginal Threshold - -Dev - 2804 Hz**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                 |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 9</b>        | Enter the maximum negative deviation of measured loss at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as out of tolerance. Smaller dB values are more restrictive. |

**Marginal Threshold - +Dev - 2804 Hz**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                 |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 9</b>        | Enter the maximum positive deviation of measured loss at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as out of tolerance. Smaller dB values are more restrictive. |

**Marginal Threshold - Max - 1004 Hz Loss**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                  |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 21</b>       | Enter the maximum signal loss allowed for a 1004 Hz test tone (in dB) before a trunk is reported as out of tolerance. A smaller dB value is more restrictive. |

**Marginal Threshold - Min -1004 Hz Loss**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                 |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-2 to 21</b>      | Enter the minimum signal loss allowed for a 1004 Hz test tone (in dB) before a trunk is reported as out of tolerance. A larger dB value is more restrictive. |

**Marginal Threshold - Minimum ERL**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                     |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 40</b>       | Enter the minimum low-frequency echo return loss in dB allowed before reporting a trunk as out of tolerance. Larger values are more restrictive. |

**Marginal Threshold - Maximum C Message Noise**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                          |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>15 to 55</b>      | Enter the maximum C-message noise phone as measured within the voice band frequency range (500 to 2500 Hz) allowed before reporting a trunk as out of tolerance. Smaller values are more restrictive. |

**Marginal Threshold - Maximum C Notched Noise**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                       |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>34 to 74</b>      | Enter the maximum C-notched signal dependent noise interference in dBmC allowed before reporting a trunk as out of tolerance. Smaller values are more restrictive. |

**Marginal Threshold - Minimum SRL-HI**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                           |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 40</b>       | Enter the minimum high-frequency signaling return loss in dB allowed before reporting a trunk as out of tolerance. Larger values are more restrictive. |

**Marginal Threshold - Minimum SRL-LO**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                          |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 40</b>       | Enter the minimum low-frequency signaling return loss in dB allowed before reporting a trunk as out of tolerance. Larger values are more restrictive. |

## Maximum Percentage of Trunks Which Can Be Removed From Service by ATMS

Appears when the Allow ATMS Busyout, Error Logging and Alarming field is **y**.

| Valid entries             | Usage                                                                                                                                                              |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0, 25, 50, 75, 100</b> | Enter the highest percentage of trunks from the trunk group that can be removed from service at one time because of unacceptable transmission measurement results. |

## Unacceptable Threshold - -Dev - 404 Hz

| Valid entries | Usage                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 9</b> | Enter the maximum negative deviation of measured loss at 404 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable. Smaller dB values are more restrictive. |

## Unacceptable Threshold - +Dev - 404 Hz

| Valid entries | Usage                                                                                                                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 9</b> | Enter the maximum positive deviation of measured loss at 404 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable. Smaller dB values are more restrictive. |

## Unacceptable Threshold - -Dev - 2804 Hz

| Valid entries | Usage                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 9</b> | Enter the maximum negative deviation of measured loss at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable. Smaller dB values are more restrictive. |

## Unacceptable Threshold - +Dev - 2804 Hz

| Valid entries | Usage                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 9</b> | Enter the maximum positive deviation of measured loss at 2804 Hz from the 1004 Hz test tone loss level (in dB) allowed before reporting a trunk as unacceptable. Smaller dB values are more restrictive. |

**Unacceptable Threshold - Max - 1004 Hz Loss**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                              |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 21</b>       | Enter the maximum signal loss allowed for a 1004 Hz test tone (in dB) before a trunk is reported as unacceptable. A smaller dB value is more restrictive. |

**Unacceptable Threshold - Min - 1004 Hz Loss**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                             |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-2 to 21</b>      | Enter the minimum signal loss allowed for a 1004 Hz test tone (in dB) before a trunk is reported as unacceptable. A larger dB value is more restrictive. |

**Unacceptable Threshold - Maximum C Message Noise**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                  |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>15 to 55</b>      | Enter the maximum C-message noise interference in dBmC above reference noise terminating on a phone as measured within the voice band frequency range (500 to 2500 Hz) allowed before reporting a trunk as unacceptable. Smaller values are more restrictive. |

**Unacceptable Threshold - Maximum C Notched Noise**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                   |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>34 to 74</b>      | Enter the maximum C-notched signal dependent noise interference in dBmC allowed before reporting a trunk as unacceptable. Smaller values are more restrictive. |

**Unacceptable Threshold - Minimum ERL**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                 |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0 to 40</b>       | Enter the minimum low-frequency echo return loss in dB allowed before reporting a trunk as unacceptable. Larger values are more restrictive. |

### Unacceptable Threshold - Minimum SRL-HI

| Valid entries | Usage                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 40       | Enter the minimum high-frequency signaling return loss in dB allowed before reporting a trunk as unacceptable. Larger values are more restrictive. |

### Unacceptable Threshold - Minimum SRL-LO

| Valid entries | Usage                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 to 40       | Enter the minimum low-frequency signaling return loss in dB allowed before reporting a trunk as unacceptable. Larger values are more restrictive. |

### Field descriptions for page 5

The total number of pages, and the first page of Group Member Assignments, vary depending on whether the Administrable Timers and ATMS Thresholds pages display.

### Screen 299. Group Member Assignments

#### Administered Members (min/max)

This display-only field shows the minimum and maximum member numbers that have been administered for this trunk group.

## Ans Delay

### CAUTION:

*Customers should not attempt to administer this field. Please contact your Avaya representative for assistance*

| Valid entries                  | Usage                                                                                                                                                                                                                                                  |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 20 to 5100 in increments of 20 | Specifies the length of time (in ms) your switch will wait before it sends answer supervision for incoming calls on tie trunks using the TN722A or later, TN760 (B, C, or D), TN767, TN464 (any suffix), TN437, TN439, TN458, or TN2140 circuit packs. |
| blank                          | Same as setting the field to zero.                                                                                                                                                                                                                     |

This delay serves two purposes:

- It ensures that the answer supervision signal is valid and not a secondary delay-dial or wink-start signal.
- It ignores momentary off-hook signals resulting from connections made off-network through certain No. 5 Crossbar CCSA switches as the connection is being established. Therefore, calls aren't dropped inappropriately.

## Code

This display-only field shows the type of circuit pack physically installed or logically administered at the location to which this member is assigned. If no circuit pack is installed or administered at the port address you enter, the field is blank.

## Mode

This field specifies the signaling mode used on tie trunks with TN722A or later, TN760B or later, TN767, TN464 (any suffix), TN437, TN439, TN458, or TN2140 circuit packs. This entry must correspond to associated dip switch settings on the circuit pack.

**CAUTION:**

*Customers should not attempt to administer this field. Please contact your Avaya representative for assistance.*

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                      |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>e&amp;m</b>       | Enter <b>e&amp;m</b> for 6-wire connections that pair 2 signaling wires with 4 voice wires. You'll use <b>e&amp;m</b> in the vast majority of systems in the U.S. |
| <b>simplex</b>       | Enter <b>simplex</b> for 4-wire connections that do not use an additional signaling pair. This configuration is very rare in the U.S.                             |
| <b>protected</b>     |                                                                                                                                                                   |

**Name**

Your vendor, as well as Avaya technical staff, sometimes need to identify specific trunks to work with your system. Therefore, the name you give to a trunk should identify the trunk unambiguously.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                  |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Up to 10 characters  | Examples of good names: <ul style="list-style-type: none"> <li>■ The phone number assigned to incoming trunks</li> <li>■ The Trunk Circuit Identification number assigned by your service provider</li> </ul> |

**Night**

Use this field only if you want to assign a night service destination to individual trunks that is different from the group destination entered in the Night Service field on page 1. Incoming calls are routed to this destination when the system is placed in night service mode.

| <b>Valid entries</b> | <b>Usage</b>                                                                             |
|----------------------|------------------------------------------------------------------------------------------|
| a valid extension    | Enter the extension of the night destination for the trunk.                              |
| <b>attd</b>          | Enter <b>attd</b> if you want calls to go to the attendant when night service is active. |
| blank                |                                                                                          |

**Port**

If this trunk is registered as an endpoint in an IP application, this field will display T00000.

| <b>Valid entries</b>                                                                                                                                                                       | <b>Usage</b>                                        |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| <b>01 through 44</b><br>(DEFINITY R) or<br><b>01 through 03</b><br>(DEFINITY CSI, SI) or<br><b>1 through 64</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server)     | First and second characters are the cabinet number. |
| <b>A through E</b>                                                                                                                                                                         | Third character is the carrier.                     |
| <b>0 through 20</b>                                                                                                                                                                        | Fourth and fifth characters are the slot number.    |
| <b>01 through 04</b><br>(Analog TIE trunks)<br><b>01 through 31</b> (R, CSI, SI,<br>S8700 IP-Connect, S8700<br>Multi-Connect)                                                              | Six and seventh characters are the circuit number.  |
| <b>1 through 80</b><br>(DEFINITY R, CSI) or<br><b>1 through 10</b> (DEFINITY<br>CSI, SI) or<br><b>1 through 250</b><br>(S8700 IP-Connect /<br>S8700 Multi-Connect /<br>S8300 Media Server) | Gateway                                             |
| <b>V1 through V9</b><br>(DEFINITY R, CSI, SI,<br>S8700 IP-Connect, S8700<br>Multi-Connect)                                                                                                 | Module                                              |
| <b>01 through 31</b><br>(DEFINITY R, CSI, SI,<br>S8700 IP-Connect, S8700<br>Multi-Connect)                                                                                                 | Circuit                                             |

**NOTE:**

In DCS networks, trunks must be assigned the same member number at both nodes.

 **NOTE:**

Members assigned to IP trunk groups will display a value of “T00001.”

**Sfx**

This display-only field shows the model suffix for the type of circuit pack physically installed at the location to which this member is assigned. If no circuit pack is installed at the port address you enter, the field is blank.

**Total Administered Members**

This display-only field shows the total number of members administered in the trunk group.

**Type**

The Type column appears when the Trunk Type field is blank or **cont**. The Type column does not display if the Trunk Type field is **dis**.

This field specifies the signaling type to be used with TN760B (or later release), TN722 (with any suffix), TN767, TN2140 (when the Trunk Type field is **cont**), TN437, TN439, TN464 with any suffix, or TN458 circuit packs.

 **CAUTION:**

*Customers should not attempt to administer this field. Please contact your Avaya representative for assistance.*

| Valid entries  | Usage                                                                                                                                                                  |

### Screen 300. Uniform Dial Plan Report screen

#### Matching Pattern

The number you want the switch to match to dialed numbers.

#### Len

The number of user-dialed digits the system collects to match to the dialed string.

#### Del

The number of digits deleted before routing the call.

#### Insert Digits

The digits that will be inserted at the beginning of the dialed number.

#### Net

The switch network used to analyze the converted number.

#### Conv

Indicates whether additional digit conversion is allowed.

**Node Num**

The Extension Number Portability (ENP) node number.

**Uniform Dial Plan Table**

The Uniform Dialing Plan field must be y on the System-Parameters Customer-Options screen before you can administer this table.

The UDP provides a common 3- to 7-digit dial plan length — or a combination of extension lengths — that can be shared among a group of switches. Additionally, UDP can be used alone to provide uniform dialing between two or more private switching systems without ETN, DCS, or Main/Satellite/Tributary configurations.

See “Uniform Dial Plan” on page 1913 for more information on Uniform Dial Plans.

|----------------------|----------------------------------------------|
| y/n                  | Enter y to allow additional digit conversion |

**Del**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                 |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 0–3                  | Enter the number of digits to delete before routing the call. This number must be less than or equal to the number entered in the Len field. |

**Insert Digits**

| <b>Valid entries</b>      | <b>Usage</b>                                                                                                                |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| 0 to 9<br>(1 to 4 digits) | Enter the digits that replace the deleted portion of the dialed number. Leave this field blank to simply delete the digits. |

**Len**

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                 |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3–7                  | Enter the number of user-dialed digits the system collects to match to this Matching Pattern. This number must be greater than or equal to the number entered in the Matching Pattern field. |

**Matching Pattern**

| <b>Valid entries</b>   | <b>Usage</b>                                                     |
|------------------------|------------------------------------------------------------------|
| 0–9<br>(1 to 7 digits) | Enter the number you want the switch to match to dialed numbers. |

## Net

Enter the switch network used to analyze the converted number.

| <b>Valid entries</b>      | <b>Usage</b>                                                                                                                                                                                                                                                                                                               |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>aar, ars, enp, ext</b> | The converted digit-string will be routed either as an extension number or via its converted AAR address, its converted ARS address, or its ENP node number.<br><br>If you enter <b>enp</b> , you must enter the ENP node number in the Node Num field. The Insert Digits field must be blank, and Conv must be <b>n</b> . |

## Node Num

This is the ENP (Extension Number Portability) Node Number.

| <b>Valid entries</b> | <b>Usage</b>               |
|----------------------|----------------------------|
| <b>1–999</b>         | Enter the ENP node number. |

## Percent Full

Displays the percentage (0 to 100) of the memory resources allocated for the uniform dial plan data that are currently being used.

## Vector Directory Number

This screen defines vector directory numbers (VDN) for the Call Vectoring feature. A VDN is an extension number used to access a call vector. Each VDN is mapped to one call vector.

VDNs are software extension numbers (that is, not assigned to physical equipment). A VDN is accessed via direct dial CO trunks mapped to the VDN (incoming destination or night service extension), DID trunks, and LDN calls. The VDN may be Night Destination for LDN.

See the *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide* for more information.

Page 1 of 1

**Screen 302. Vector Directory Number**

**1st/2nd/3rd Skill**

Only appears when, on the System-Parameters Customer-Options screen, the Expert Agent Selection (EAS) field is **y** and if, on this screen, the Meet-me Conferencing field is **n**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|                                 |                                                |
|---------------------------------|------------------------------------------------|
| <b>1</b> to <b>999</b> or blank | Enter the desired Skill numbers in each field. |
|---------------------------------|------------------------------------------------|

**Acceptable Service Level (sec)**

Only appears when, on the System-Parameters Customer-Options screen, the BCMS/VuStats Service Level field is **y** and the Measured field is **internal** or **both**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

|                                 |                                                                                                                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0</b> to <b>9999</b> seconds | Enter the number of seconds within which calls to this VDN should be answered. This will allow BCMS to print out a percentage of calls that were answered within the specified time. |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Allow VDN Override**

This field appears if the Meet-me Conferencing field is **n**. This entry affects the operation of an agent's display and certain options/data assigned to the VDN when a call is routed through several VDNs.

For Expert Agent Selection (EAS), if this field is **y** on the original VDN, the Skills of the new VDN will be used. If this field is **n** on the original VDN, the Skills of the original VDN will be used.

For Best Service Routing (BSR), if this field is **y** on the original VDN, the BSR Application and Available Agent Strategy of the new VDN will be used. If this field is **n** on the original VDN, the BSR Application and Available Agent Strategy of the original VDN will be used.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | The name of the VDN appearing on the terminating display depends on the administration and chaining of the subsequent VDNs and the AUDIX mail for the last VDN is accessed.                                                                                 |
| <b>n</b>             | The name of this VDN appears on the agent's display and the VDN's AUDIX mail is accessed. If any subsequent VDNs are used to process this call, their names will not appear on the terminating display and the AUDIX mail for the original VDN is accessed. |

## Attendant Vectoring

This field appears only if, on the System-Parameters Customer-Options screen, the Attendant Vectoring is **y** and if, on this screen, the Meet-me Conferencing field is **n**. This field identifies if the vector you are defining is an attendant vectoring VDN.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b>             | Enter <b>y</b> so the vector is an attendant vector. This entry will dynamically change the rest of the screen to eliminate field options available with other types of vectors. Default when, on the System-Parameters Customer-Options screen, both the Vectoring (Basic) and Vectoring (Prompting) fields are <b>n</b> . No changes allowed to this field. |
| <b>n</b>             | Default when, on the System-Parameters Customer-Options screen, the Vectoring (Basic) and/or Vectoring (Prompting) fields are <b>y</b> .                                                                                                                                                                                                                      |

## COR

Specifies the class of restriction (COR) of the VDN.

| <b>Valid entries</b> | <b>Usage</b>                                              |
|----------------------|-----------------------------------------------------------|
| <b>0 to 95</b>       | Enter a 1- or 2-digit number. This field cannot be blank. |

**Extension**

This is a display-only field when using an administration command such as **add** or **change** to access the screen. The extension is a 1- to 7-digit number that starts with a valid first digit and length as defined by the System's dial plan.

**Measured**

This field appears if the Meet-me Conferencing field is **n**. Used to collect measurement data for this VDN. Data may be collected for reporting by BCMS or CMS.

**NOTE:**

On the System-Parameters Customer-Options screen, the BCMS field must be **y** for the Measured field to be set to **internal** or **both**. In addition, the appropriate CMS release must be administered on the Feature-Related System Parameters screen if this field is being changed to **external** or **both**.

| <b>Valid entries</b> | <b>Usage</b>                                           |
|----------------------|--------------------------------------------------------|
| <b>internal</b>      | Data will be measured internally by BCMS.              |
| <b>external</b>      | Data will be measured internally by CMS.               |
| <b>both</b>          | Data will be measured internally by both BCMS and CMS. |
| <b>none</b>          | Data will not be measured.                             |

## Meet-me Conference

This field appears only if, on the System-Parameters Customer-Options screen, the Enhanced Conferencing field is **y**. This field determines if the VDN is a Meet-me Conference VDN.

### NOTE:

If the VDN extension is part of your DID block, external users will be able to access the conference VDN. If the VDN extension is not part of your DID block, only internal callers on the your network (including DCS or QSIG) or remote access callers can access the conference VDN.

| Valid entries | Usage                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y/n</b>    | <p>Enter <b>y</b> to enable Meet-me Conference for this VDN. If Meet-me Conference is <b>y</b>, only Extension, Name, Vector Number, Meet-me Conference, COR, and TN fields display and the fields for page 2 change.</p> <p>Both Attendant Vectoring and Meet-me Conference cannot be enabled at the same time.</p> <p>If Enhanced Conferencing is <b>y</b>, but no other vectoring options are enabled, only Meet-me Conference vectors can be assigned.</p> |

## Name

This is an optional field that need not contain any data. It is the name associated with the VDN.

| Valid entries                                                         | Usage                                                                                                                                                                     |
|-----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enter up to a 27-character alphanumeric name that identifies the VDN. | The name may be truncated on agents' displays depending on the application. When information is forwarded with an interflowed call, only the first 15 characters are sent |

## Service Objective

Appears when Skill and Centre Vu Advocate are **y** on the Feature Related System Parameters screen.

| Valid entries | Usage                        |
|---------------|------------------------------|
| <b>1-9999</b> | Enter the service objective. |

**TN**

Specifies the Tenant Partition number for this VDN.

| <b>Valid entries</b> | <b>Usage</b>          |
|----------------------|-----------------------|
| 1 to 20              | For R servers.        |
| 1 to 100             | For S8700 IP-Connect. |

**VDN of Origin Annc. Extension**

Data for this field appears only when, on the System-Parameters Customer-Options screen, the VDN of Origin Announcement field is **y** and, on this screen, the Meet-me Conferencing field is **n**.

| <b>Valid entries</b> | <b>Usage</b>                                                  |
|----------------------|---------------------------------------------------------------|
| VDN extension        | Enter the extension number of the VDN of Origin announcement. |

**Vector Number**

Identification number that specifies a particular call vector that is accessed through the VDN.

| <b>Valid entries</b> | <b>Usage</b>                                                     |
|----------------------|------------------------------------------------------------------|
| 1 to 999             | Enter a 1- to 3-digit vector number. This field cannot be blank. |

**Field descriptions for page 2**

 Display VDN for Route-To DAC?
 VDN Override for ISDN Trunk ASAI Messages?

```

**Screen 303. Vector Directory Number**

## AUDIX Name

Only appears for DEFINITY R and S8700 IP-Connect configurations. If this VDN is associated with the AUDIX vector, enter the name of the AUDIX machine as it appears in the Node Names screen.

## BSR Application

To use multi-site Best Service Routing with this VDN, specify an application plan for the VDN. This field appears if, on the System Parameters Customer-Options screen, the Lookahead Interflow (LAI) and Vectoring (Best Service Routing) fields are **y**.

| <b>Valid entries</b>  | <b>Usage</b>                                                                                     |
|-----------------------|--------------------------------------------------------------------------------------------------|
| <b>1-255</b> or blank | Enter a 1- to 3-digit number. For DEFINITY R, CSI, SI.                                           |
| <b>1-511</b> or blank | Enter a 1- to 3-digit number. For S8300 Media Server, S8700 IP-Connect, and S8700 Multi-Connect. |

## BSR Available Agent Strategy

The available agent strategy determines how Best Service Routing identifies the “best” split or skill to service a call in an agent surplus situation. To use Best Service Routing with this VDN, enter an agent selection strategy in this field.

This field only appears if, on the System Parameters Customer-Options screen, the Vectoring (Best Service Routing) field is **y**.

| <b>Valid entries</b> | <b>Usage</b>                                                                                                               |
|----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>1st-found</b>     |                                                                                                                            |
| <b>UCD-LOA</b>       | Can be set only if, on the System-Parameters Customer-Options screen, the Agent Allocation field is <b>y</b> .             |
| <b>UCD-MIA</b>       |                                                                                                                            |
| <b>EAD-LOA</b>       | Can be set only if, on the System-Parameters Customer-Options screen, the Agent Allocation field is <b>y</b> .             |
| <b>EAD-MIA</b>       | Can be set only if, on the System-Parameters Customer-Options screen, the Expert Agent Selection (EAS) field is <b>y</b> . |

## Display VDN for Route-To DAC

This field addresses situations where one of the following conditions is in effect:

- A **route-to number** or **route-to digits** vector command routes an EAS direct agent call, with coverage option set to **y**

- An adjunct routing step routes a direct agent call, with the coverage option set to **y**

For more information, see *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide*.

| <b>Valid entries</b> | <b>Usage</b> |

|----------------------|--------------|

---

|                        |                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| VDN extension or blank | Enter the VDN extension number to which an incoming trunk call will be routed if it returns to vector processing after the agent drops the call. |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

### **VDN Override for ISDN Trunk ASAI Messages**

This field appears if, on the System-Parameters Customer-Options screen, the ASAI Link Core Capabilities field is **y**. This field can be set to **y** only when the Allow VDN Override field on this screen is **y**.

| <b>Valid entries</b> | <b>Usage</b> |
|----------------------|--------------|
|----------------------|--------------|

---

|          |                                                                                                                                                                                                                                                    |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>y</b> | When an incoming call is routed, the “Called Number” information sent in the “Call Offered,” “Altering,” “Queued,” and “Connect” ASAI events and the “Adjunct Route Request” ASAI message, is the “active VDN” extension associated with the call. |
| <b>n</b> | The “Called Number” information sent for the ASAI event notification and adjunct-request messages does not change for a ISDN-PRI trunk. It is always the number in the Called Number IE sent in the incoming ISDN call’s SETUP message.            |

### VDN Timed ACW Interval

When a value is entered in this field, an agent in auto-in work mode who receives a call from this VDN is automatically placed into After Call Work (ACW) when the call drops. When the administered time is over, the agent automatically becomes available. This field has priority over the Timed ACW Interval field on the Hunt Group screen.

| Valid entries | Usage |
|---------------|-------|
|---------------|-------|

|                 |                                                                                |
|-----------------|--------------------------------------------------------------------------------|
| 1-9999 or blank | Enter the number of seconds the agent should remain in ACW following the call. |

|                         |                                                                                                                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6-digit number or blank | Enter a 6-digit access code for the Meet-me Conference VDN. If you do not want an access code, leave blank.<br><br>Once an access code is assigned, an asterisk displays in this field for subsequent change, display, or remove operations by all users except the “init” superuser login. |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Conference Controller

This field appears only if the Meet-me Conference field is **y**. This field controls which user is allowed to change the access code for a Meet-me Conference VDN using a feature access code. This can be a local user or someone dialing in via remote access trunks.

| <b>Valid entries</b>      | <b>Usage</b>                                                                                                                                                                                                                                                                                                |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| extension number or blank | <p>If an extension number is entered, only a user at that extension can change the access code for that VDN using a feature access code.</p> <p>If this field is blank, any station user that is assigned with console permissions can change the access code for that VDN using a feature access code.</p> |

## **Before you start**

---

MultiVantage software utilizes the following command syntax:

**action object qualifier**

Use the commands in the tables below to access each administration screen.

Brackets [ ] indicate the qualifier is optional. Single quotes ( ' ') indicate the text inside the quote must be entered exactly as shown or an abbreviated form of the word may be entered. MAX is the maximum number available in your system configuration. Some qualifiers aren't available on all systems.

The **display capacity** command is listed in the Maintenance Manual.

\*Partial string of a cell phone number followed by the wildcard “\*”.

This reference section describes many of the telephones and adjuncts that you can connect to Avaya MultiVantage systems.

Use this section to:

- determine where to connect a phone—is it analog, digital, hybrid, or IP? Is it designed for a 2-wire or 4-wire environment?
- determine whether a phone will fit your users' needs—does it accommodate enough feature buttons? does it include a display?
- understand how to assign the user's feature buttons—how do the buttons on the Station screen map to buttons on the physical phone.

Because you need to know how the physical buttons on the phone relate to your button assignments on the Station screen, this section includes figures for those phones to which you can assign feature buttons.

This section includes descriptions of the following telephones:

- 500 telephones (page [1388](#))
- 2420 telephones (page [1388](#))
- 2500-series telephones (page [1388](#))
- 4600-series telephones (digital IP telephones) (page [1389](#))
- 6200-series telephones (page [1391](#))
- 6400-series telephones (page [1395](#))
- 7100-series telephones (page [1399](#))
- 7300-series telephones (page [1399](#))

- 731x-series hybrid telephones (page [1403](#))
- 7400-series telephones (page [1408](#))
- ISDN telephones (7500-series & 8500-series) (page [1425](#))
- 8110 telephones (page [1430](#))
- 8400-series telephones (page [1430](#))
- CALLMASTER telephones (page [1437](#))
- Cordless telephones (page [1441](#))
- Internet Protocol (IP) SoftPhones (page [1444](#))

## **500 telephones**

---

The 500 telephones are single appearance analog rotary-dial telephones which provides cost-effective service wherever it is located. It provides limited access to features because the rotary dial has no \* or # positions.

## **2420 telephones**

---

The 2420 telephone is a digital phone with an optional feature expansion module and downloadable call appearance/feature buttons information. The 2420 Digital Communications Protocol (DCP) phone does not need paper labels. The button information appears on a screen on the phone. The firmware for the 2420 can be upgraded over its DCP connection to the switch. A new firmware image first must be downloaded into switch memory from a local trivial file transfer protocol (TFTP) server.

Avaya recommends that you administer call appears only on the first 8 call appearance/feature buttons on the 2420 phone.

## **2500-series telephones**

---

The 2500-series telephones consist of single appearance analog telephones with conventional touch-tone dialing. You can allow 2500-series phones users to access features by giving them the appropriate feature access codes. For more information about providing feature access codes to your users, see [“Changing feature access codes”](#) on page 74.

## **4600-series IP telephones**

---

The 4600-series telephones are DCP telephones that use Internet Protocol (IP) technology with Ethernet line interfaces. Firmware for these phones can be downloaded from the internet. The 4600 series includes a 2-button set, 6-button sets, a 12-button set, and a 24-button set.

Each of the 4600-series phones includes 6 standard feature buttons:

- SPEAKER button, which can access a 2-way speakerphone or allow group listen
- MUTE button, which mutes the handset or speakerphone microphone
- HOLD button
- REDIAL button
- TRANSFER/TEST button for transferring a call or testing the lights and display on the telephone
- CONF/RING button for setting up a conference call and for selecting a personalized ringing pattern.

The 4604, 4612, and 4624 phones do not have a standard Drop button, but you can assign a drop button to any feature button. The 4600-series display phones show the date and time in Normal mode, so you do not have to assign a Date/Time button to these phones.

### **4602 IP telephone**

---

The 4602 IP telephone has separate LEDs to indicate the on/off status of the speakerphone and mute buttons. The 4602 has a 2x24 display. The 4602 has no administrable feature buttons, 2 fixed call appearance buttons, one-way speakerphone or no speakerphone option, a fixed Drop button, a listen-only Speaker button, a redial button, and a fixed voice mail retrieval button that provides automatic access to voice mail.

### **4606 IP telephones**

---

The 4606 IP telephone is a multi-appearance digital telephone with six call appearance/feature buttons: a red Hold button, a Redial button, a Transfer button that can also be used for the Test feature, and a Conference button that can also be used to select a personalized ringing pattern, a red Message light, and a Volume control button.

## **4612 IP telephone**

---

The 4612 IP telephone is a multi-appearance digital telephone with 12 call appearance/feature buttons. With the 4612 IP telephone the end-user can access 12 features with the softkeys and display control buttons.

## **4620 IP telephone**

---

The 4620 IP telephone has an optional feature expansion module and downloadable call appearance/feature button information. It also includes features such as speed dial, call log, and Web browsing using the Wireless Markup Language (WML). The 4620 IP phone does not need paper labels. The button information appears on a screen on the phone.

The 4620 uses icons to indicate the status of call appearances, bridge call appearances and features. The phone maintains a call log with calling party and called party information. The 4620 has a local button for headset on/off. The button label information for the 4620 is downloaded automatically to the phone when a link is established between the switch and the phone. There are three speakerphone options on the 4620. Labels on the 4620 can be downloaded in English, French, Italian, Spanish, and user-defined languages.

## **4624 IP telephone**

---

The 4624 IP telephone is a multi-appearance digital telephone with 24 call appearance/feature buttons. With the 4624 telephone the end-user can access 12 features with the softkeys and display control buttons. These 12 features can be used in addition to the features you assign to the call appearance/feature buttons.

## **4630 IP screenphone**

---

The 4630 IP Screenphone uses a single connection. A large, color, touch-sensitive screen is used to operate the telephone functions. Avaya recommends that you use the default settings on the 4630 IP Screenphone administrable feature buttons with status indication.

---

Figure 18. The 4630 IP Screenphone

## 6200-series telephones

---

### 6210 telephone

---

The 6210 telephones are single-line analog models. They have fixed Flash, Redial, and Hold feature buttons and a message waiting light.

### 6218 telephone

---

The 6218 telephones are single-line analog models. They have 10 programmable dialing buttons. These phones also have fixed Flash, Redial, and Hold feature buttons and a message waiting light.

## 6220 telephone

The 6220 telephones are single-line analog models. These phones also have fixed Flash, Redial, Hold, Mute, and Speakerphone (Spkr) feature buttons and a message waiting light. They also have handset volume control, ringer volume control, timed switch-hook disconnect, 10 programmable dialing buttons, repertory keylock, set personalized ring, and system hold.

**Figure 21. The 6220 telephone**

## **6400-series telephones**

---

The 6400-series telephones are DCP 2-wire telephones that work with Avaya MultiVantage. The last two digits of the 6400-series model number identify the number of call appearances (2-lamp buttons) for that model. For example, the 6424D has 24 call appearances. The 6400 series includes two single-line sets (6402 and 6402D), 8-button sets, a 16-button set, a 24-button set, and a 24-button expansion module (for the 6416D+ and 6424D+ telephones).

Each of the 6400-series phones includes 6 standard feature buttons:

- **SPEAKER** button, which can access a 2-way speakerphone or allow group listen
- **MUTE** button, which mutes the handset or speakerphone microphone
- **HOLD** button
- **REDIAL** button
- **TRANSFER/TEST** button for transferring a call or testing the lights and display on the telephone
- **CONF/RING** button for setting up a conference call and for selecting a personalized ringing pattern.

These phones do not have a standard Drop button, but you can assign a drop button to any feature button. The 6400-series display phones show the date and time in Normal mode, so you do not have to assign a Date/Time button to these phones.

## **6402 telephones**

---

The 6402 is a single-line telephone with six fixed feature buttons: a listen-only Speaker button, a Feature button that allows you to use the dial pad keys for up to 12 features assigned by the system manager, a red Hold button, a Redial button, a Transfer button that can also be used for the Test feature, and a Conference button that can also be used to select a personalized ringing pattern, a red Message light, and a Volume control button.

The 6402D is the same as a 6402, but also has a 2-line by 16-character LCD display.

The 6402 and 6402D can be used in only a 2-wire environment.

## **6408 telephones**

---

The 6408 is a multi-appearance digital telephone with eight call appearance/feature buttons.

The 6408 telephone is available in the following four models:

- 6408 telephone—includes a 1-way, listen-only speaker, and no display
- 6408+ telephone—includes a 2-way speakerphone, and no display
- 6408D telephone—includes a 1-way, listen-only speaker, and a 2-line by 24-character display
- 6408D+ telephone—includes a 2-way speakerphone, and a 2-line by 24-character display.

With the 6408D and 6408D+ telephones, the end-user can access 12 features with the softkeys and display control buttons. These 12 features can be used in addition to the features you assign to the call appearance/feature buttons.

The 6408, 6408+, 6408D, and 6408D+ telephones can work only in 2-wire environments.

## **6416D+ telephone**

---

The 6416D+ telephone is a multi-appearance digital telephone with 16 call appearance/feature buttons.

With the 6416D+ telephone the end-user can access 12 features with the softkeys and display control buttons. These 12 features can be used in addition to the features you assign to the call appearance/feature buttons.

### **⇒ NOTE:**

You can connect an XM24 expansion module to the 6416D+ telephone to expand the number of buttons you can assign. However, when the expansion module is connected, you must connect an auxiliary power supply to the telephone.

## **6424D+ telephone**

---

The 6424D+ telephone is a multi-appearance digital telephone with 24 call appearance/feature buttons. With the 6424D+ telephone the end-user can access 12 features with the softkeys and display control buttons. These 12 features can be used in addition to the features you assign to the call appearance/feature buttons.

The 6424D+ telephone can work in both 4-wire and 2-wire environments.

**⇒ NOTE:**

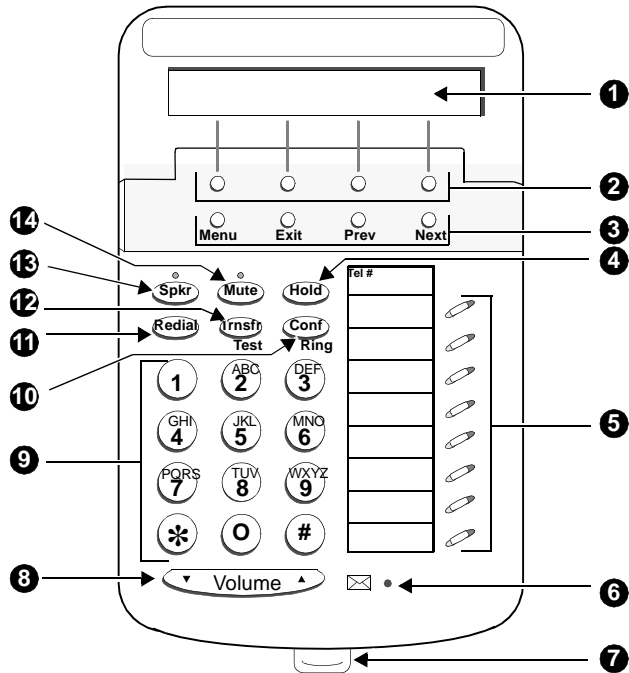

You can connect an XM24 expansion module to a 6424D+ phone to expand the number of buttons you can assign. However, when the expansion module is connected, you must connect an auxiliary power supply to the telephone.

**Figure 23. 6408D telephone**

## **7100-series telephones**

---

### **7101A telephone**

---

The 7101A telephone is a single-line analog model that is equipped with a Message Waiting light and a handy Recall button for activating the system's special features. It cannot be physically bridged to the same analog line port due to the message waiting and loop current circuitry.

### **7102A telephone**

---

The 7102A (7102A01A) and 7102+ (7102A01B), called the 7102 Plus. The front of the two sets is exactly the same in appearance. The only difference is that the 7102A01B is equipped with an adjunct jack. This jack allows speakerphone/headset capability.

### **7103A telephone**

---

The 7103A fixed feature phone is a single-line analog model which has been discontinued. The feature buttons on this phone must be programmed by the system manager. It cannot be physically bridged to the same analog line port due to the message waiting and loop current circuitry.

### **7104A telephone**

---

The 7104A telephone is a single-line analog model that is equipped with a display that is used to display stored numbers. It cannot be physically bridged to the same analog line port due to the message waiting and loop current circuitry.

## **7300-series telephones**

---

### **7302H MERLIN telephone**

---

The 7302H is a 5-button telephone that can be desk or wall mounted. This set can no longer be ordered.

Administer 7302H telephones (5-Button) as a 7303S model.

### **7303H MERLIN telephone**

---

The 7303H is a 10-button telephone that can be desk or wall mounted.

Administer 7303H telephones (10-Button) as a 7305S model. You can administer only the first 12 feature function buttons. Of these 12 buttons, 8 have two lamps and 4 have no lamps. However, the system treats the 8 double-lamp buttons as though they have a single (green) lamp. Administer the 4 buttons (with no lamps) with features that do not require status indications.

### **7303S telephone**

---

The 7303S is a multi-appearance hybrid telephone which provides access to 10 line appearances or selected programmable features. The 7303S telephone is also equipped with six fixed feature buttons. It requires 3-pair wiring for operation. One wire pair is used for analog voice, while the other two pairs are used for digital control and signaling.

### **7305H MERLIN telephone**

---

The 7305H series is a 34-button telephone. This telephone can be equipped with or without different features such as built-in speakerphone or display. Some versions of the 34-button series can be ordered using PEC code 3162 and the appropriate suffix.

Administer 7305H telephones (34-Button) as a 7305S model. The system treats the telephone's 24 feature function buttons (two lamps each) as single (green) lamp function buttons.

### **7305S telephone**

---

The 7305S telephone is a multi-appearance hybrid telephone which provides access to 10 line appearances. The 10 line appearance buttons can also be used as programmable feature buttons. The 7305S telephone is also equipped with 24 programmable feature buttons and six fixed feature buttons. It requires 3-pair wiring for operation. One wire pair is used for analog voice, while the other two pairs are used for digital control and signaling.

## **731x-series hybrid telephones**

---

You should note that the following restrictions apply to administering hybrid telephones in the system:

- Hybrid telephones equipped with displays cannot be used as Automatic Call Distribution (ACD) agents and do not allow your end-users to access the Directory.
- The following fixed feature buttons do not operate on Hybrid telephones: STOP, PAUSE, RECALL, MESSAGE, HFAI, and HFAI/MIC. If you want users to have Hands Free Automatic Answer on Intercom (HFAI), assign Internal Automatic Answer (IAA) to a lamp button.
- These telephones support Leave Word Calling (LWC), but users cannot retrieve messages with the display.

**7400-series telephones**

**7401D telephone**

The 7401D (7401D01A) and the 7401+ (7401D02A) are both single appearance digital phones which have no call appearance buttons or lights, but have two virtual call appearances. Depending on how the 7401D or the 7401+ telephone is administered, the second call appearance may be restricted to incoming priority calls and outgoing calls only.

### **7403D telephone**

---

The 7403D is a multi-appearance digital telephone which has 10 buttons available for line appearances, one-touch feature access, or Speed Dialing. In addition, the 7403D telephone may be equipped with a Digital Terminal Data Module (DTDM) which attaches to the right side and allows the connection of a EIA RS-232C data terminal.

### **7404D telephone**

---

The 7404D is a multi-appearance digital telephone which provides simultaneous voice/asynchronous data transmission. All the transmission is done over the same two pairs of wire.

### **7405D telephone**

---

The 7405D telephone is a multi-appearance digital telephone which allows features to be added as the user needs them. The Digital Display can be added to provide access to the Message Center. A Digital Terminal Data Module or 7400B can be added to enable the user of a 7405D telephone to transmit or receive data with an associated data terminal.

The basic 7405D provides 10 call appearance/feature buttons with lights that can be assigned to call appearances or system features. It has 24 programmable feature buttons and six fixed-feature buttons. The 7405D can also have a function key module which adds 24 feature buttons and a call coverage module (when no display module is used) which adds 20 call appearance/feature buttons.

### **7406 telephones**

---

The 7406D telephone (7406D01A, 7406D02A, 7406D03A, and 7406D04A models) has five call appearance/feature buttons, each with a red in-use light and a green status light, seven shiftable (2-level) programmable feature buttons with no lights, four programmable feature buttons with a green light, four fixed feature buttons (CONFERENCE, TRANSFER, DROP, and HOLD), a SHIFT button with a green light, a SPEAKER button, and a green Message light.

The 7406BIS telephone (7406D05A and 7406D06A models) has five call appearance/feature buttons, each with a red in-use light and a green status light, seven shiftable (2-level) programmable buttons with no lights, two programmable feature buttons with a green light, four fixed feature buttons (CONFERENCE, TRANSFER, DROP, and HOLD), a SHIFT button with a green light, a SPEAKER button with a green light, a MUTE button with a red light, a SPEAKER VOLUME “arrow” button, and a red Message light.

The 7406+ telephone (7406D07A and 7406D08A models) has five call appearance/feature buttons, each with a red in-use light and a green status light, three shiftable (2-level) programmable feature buttons with a green light, six shiftable (2-level) programmable feature buttons without lights, four fixed feature buttons (CONFERENCE, TRANSFER, DROP, and HOLD), a SELECT button with a green light, a SPEAKER/RESET SPKR button with a green light, a MUTE button with a red light, a VOLUME “arrow” button, and a red Message light.

## **7407+ telephone**

---

The 7407D, Enhanced 7407D, and 7407+ telephones are multi-appearance digital telephones which provide digital voice, display, and data capabilities (the latter with the 7400B+ Data Module).

There are three versions of the 7407D telephone:

- 7407+ (7407D02D) — offers 10 call appearance buttons, each with a red in-use light and a green status light, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), three fixed feature buttons with one light each (SELECT, SPEAKER/RESET SPKR, and MUTE), nine feature buttons with one light each (the uppermost two buttons can be used for voice or display features, the lower seven buttons for display features), 22 flexible feature buttons with no lights, a Message light, personalized ringing, a built-in speakerphone with a reset and listen-only option, and a built-in 2-line by 40-character display.
- The 7407D (the 7407D01B)—offers 10 call appearance/feature buttons, each with a red in-use light and a green status light, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), three fixed feature buttons with an associated light (CALCULATOR/SELECT RING, SPEAKERPHONE, and MICROPHONE), nine programmable feature buttons with lights (the two uppermost buttons can be used for voice or display features, the lower seven for display features), 11 dual-function buttons, 22 programmable feature-only buttons without lights, a Message light, a DISPLAY button that turns the display on and off, personalized ringing, a built-in speakerphone, a 2-line by 40-character liquid crystal display, and a built-in calculator. This set is AC powered.
- Enhanced 7407D (the 7407D02C)—offers 10 call appearance buttons, each with a red in-use light and green status light, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), three fixed feature buttons with an associated light (SELECT RING, SPEAKER, and MUTE), 22 programmable feature-only buttons without lights, nine programmable feature buttons with one light each (the uppermost two buttons can be used for voice or display features, the lower seven for display features), a Message light, personalized ringing, a built-in

speakerphone, a connection for an adjunct speakerphone or headset, a speakerphone with spokesman, and Mute option, and a 2-line by 40-character display.

### **7410D and 7410+ telephones**

---

The 7410D (7410D01A) and 7410+ (7410D02A) are both multi-appearance digital telephones with 10 line appearances, four standard fixed feature buttons and a Select Ring button. The 7410D and 7410+ telephones also provide a Message light, Ringer Volume control, a Speakerphone/headset adapter jack. You can activate a Self-Test feature to test the lights and tone ringer on the telephone. In addition, the 7410+ provides a Speaker for listening-only functions.

### **7434D telephone**

---

The 7434D is a multi-appearance digital telephone that offers 34 call appearance/feature buttons, each with a red in-use light and a green status light, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), three fixed feature buttons with one light each (SELECT, SPEAKER/RESET SPKR, and MUTE), seven display feature buttons with one light each, a Message light, personalized ringing, a built-in speakerphone with a reset option, and a built-in 2-line by 40-character display. You can connect this phone to a digital line port. The 7434D telephone supports an adjunct display module or a call coverage module.

### **7444D telephone**

---

The 7444 telephone is a multi-appearance digital telephone that offers 34 call appearance/feature buttons, each with a red in-use light and a green status light, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), three fixed feature buttons with one light each (SELECT, SPEAKER/RESET SPKR, and MUTE), seven display feature buttons with one light each, a Message light, personalized ringing, a built-in speakerphone with a reset option, and a built-in 2-line by 40-character display. You can connect this telephone to a digital line port. It is powered from the switch.

**⇒ NOTE:**

The 7444 is powered by the switch, however, to use the display, you must connect an auxiliary power supply to the telephone.

## **ISDN telephones (7500s & 8500s)**

---

The Integrated Services Digital Network (ISDN) phones include both the 7500-series and the 8500-series telephones. Each of these phones uses the ISDN communications through a 4-wire “T”-interface.

### **7505D ISDN-BRI telephone**

---

The 7505D telephone serves as a telephone if it is equipped with a Voice Only Module (VOM). As a telephone, it offers programmable buttons, fixed feature buttons, a Message light, touch-tone dialing, and a built-in, programmable speakerphone or SPOKESMAN loudspeaker.

The 7505 can be equipped with an optional Asynchronous Data Module (ADM) that provides the user with simultaneous voice and data capabilities. The 7505 equipped with the ADM offers the same voice capabilities as the 7505 equipped with the VOM, plus it allows you to attach data terminals or personal computers to send and receive data through the digital network.

### **7506D ISDN-BRI telephone**

---

The 7506D serves as a telephone if it is equipped with a VOM. As a telephone, it offers programmable buttons, fixed feature buttons, a Message light, touch-tone dialing, and a built-in, programmable speakerphone or SPOKESMAN loudspeaker.

The 7506 can be equipped with an optional Asynchronous Data Module that provides the user with simultaneous voice and data capabilities. The 7506 equipped with the ADM offers the same voice capabilities as the 7506 equipped with the VOM, plus it allows you to attach data terminals or personal computers to send and receive asynchronous data through the digital network.

### **7507D ISDN-BRI telephone**

---

The 7507D serves as a telephone if it is equipped with a VOM. As a telephone it offers programmable buttons, fixed feature buttons, Message light, touch-tone dialing, and a built-in, programmable speakerphone or SPOKESMAN loudspeaker.

The 7507 can be equipped with an optional Asynchronous Data Module that provides the user with simultaneous voice and data capabilities. The 7507 equipped with the ADM offers the same voice capabilities as the 7507 equipped with the VOM, plus it allows you to attach data terminals or personal computers to send and receive data through the digital network.

### **8503D ISDN-BRI telephones**

---

The 8503T telephone offers: four standard fixed feature buttons, a Message light, three call appearance/flexible feature buttons, each with a red and green light, 12 programmable memory-dialing locations on the dial pad keys, a PROGRAM button for storing numbers at the memory-dialing locations and a MEMORY button for dialing these programmed numbers or codes, the Redial feature, the Mute feature.

### **8510T ISDN-BRI telephone**

---

The 8510T voice/data telephone offers: 10 call appearance/feature buttons, each with a red and green status light, buttons for the Mute, Redial, Conference, Drop, Transfer, and Hold features (the MUTE, SPEAKER, CONF, and TRANSFER buttons have a red light next to them), a Speakerphone, a Volume control, and an Adjunct jack. You can administer the softkey buttons. Four softkeys and display control buttons below the a 2-line by 24-character display can be used to access such features as a personal Directory, a Call Log, the Self-Test feature, and a personalized ringing pattern for the telephone.

### **8520T ISDN-BRI telephones**

---

The 8520T voice/data telephone offers the following: 20 call appearance/feature buttons, each with a red and green status light, buttons for the Mute, Redial, Conference, Drop, Transfer, and Hold features (the MUTE, SPEAKER, CONF, and TRANSFER buttons have a red light next to them), a Speakerphone, a Volume control, and an Adjunct jack. Ten softkeys and four display control buttons located on either side of the 7-line by 24-character display can be used to access such features as a personal Directory, a Call Log, the Self-Test feature, and a personalized ringing pattern for the telephone.

- 3. 10 programmable buttons
- 4. 10 programmable buttons (11 to 20)

**Figure 46. 8520T telephone**

**NOTE:**

The 8520T telephone supports 20 call appearances. The system maximum of 10 call appearance buttons still applies. You can administer the buttons that are not used as call appearance buttons as bridged appearances.

## **8110 telephones**

---

The basic 8110 (8110A01A, 8110A01B, and 811A01C) and the modified 8110M (8110A01D) telephones are single-line analog telephones. These telephones are exactly the same in appearance: each contains 12 programmable dialing buttons with PROGRAM and PAUSE buttons, automatic redial, a flashing red Message light, and a Hold button. They also have built-in speakerphones with Mute capability and the Automatic Answer feature.

## **8400-series telephones**

---

### **8403B telephones**

---

The 8403 telephone is a multi-appearance digital telephone with three call appearance buttons, Conference, Transfer, Drop, and Hold buttons, a TEST button, a blue FEATURE button which allows you to access 12 system features assigned by the System Manager and to choose from among eight different ringing patterns, a MUTE button, a SPEAKER button which accesses a 1-way, listen-only speaker, a red Message light, and a Volume control button.

The 8403 can be used in either a 4-wire or 2-wire environment.

### **8405B telephone**

---

There are four varieties of the 8405 telephone: the 8405B and 8405B+, the 8405D and 8405D+. All four varieties are multi-appearance digital telephones with five call appearance/feature buttons. The 8405 telephones also have four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), a MUTE button, a SPEAKER button, a TEST button, and a Volume control button. The 8405D and 8405D+ allow you to administer 12 softkey feature buttons in addition to the call appearance and feature buttons.

The four 8405 variations have the following differences:

- The 8405B has a 1-way, listen-only speaker, with NO display.
- The 8405B+ has a 2-way speakerphone, without a display
- The 8405D has a 1-way, listen-only speaker and a 2-line by 24-character display.
- The 8405D+ has a 2-way speakerphone and a 2-line by 24-character display.

The 8405 telephones work in 4-wire or 2-wire environments.

## **8410B telephone**

---

The 8410 telephone is a multi-appearance digital telephone with 10 call appearance/feature buttons, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), a MUTE button, a SPEAKER button which can access either a 2-way speakerphone or a 1-way, listen-only speaker, a TEST button, and a Volume control button.

- The 8410B is the basic set, without a display.
- The 8410D (8410D03A) has a built-in 2-line by 24-character display. Those users who have an 8410D with display can access 12 features with the softkeys and display control buttons. These 12 features can be used *in addition to* the features on the call appearance/feature buttons.

The 8410 telephone can work in both 4-wire and 2-wire environments.

## **8411B and 8411D telephones**

---

The 8411 telephone is a multi-appearance digital telephone with 10 call appearance/feature buttons, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), a blue SHIFT button, a MUTE button, a SPEAKER button which can access either a 2-way speakerphone or a 1-way, listen-only speaker, a TEST button, and a Volume control button.

The rear of the 8411 telephone has two jacks: The Analog Adjunct jack can be used for connecting answering machines, fax machines, PC or laptop data/fax modem cards, data sets or modems, audio teleconferencing equipment, and TTY machines commonly used by the hearing impaired. The RS-232-D Jack can be used for connecting the telephone to a COM port on an IBM®-compatible personal computer on which you can load PassageWay Solution software.

There are two varieties of the 8411 telephone: the 8411B (8411D02A) is the basic set, without a display; the 8411D (8411D01A) has a built-in 2-line by 24-character display. Those users who have an 8411D with display can access 12 features with the softkeys and display control buttons. These 12 features can be used in addition to the features on the call appearance/feature buttons.

The 8411 telephone can work in both 4-wire and 2-wire environments.

## 8434D telephone

---

The basic 8434 (8434D01A) and the enhanced 8434DX (8434D02A) telephones are multi-appearance digital telephones which offer 34 call appearance/feature buttons, each with a red light and a green status light, four standard fixed feature buttons (CONFERENCE, DROP, HOLD, and TRANSFER), a MUTE button, a SPEAKER button which accesses either a 2-way speakerphone or a 1-way listen-only speaker, a TEST button, a SHIFT button (some 8434DX telephones will have a RING button instead), a red Message light, personalized ringing, a built-in speakerphone with a reset option, and a built-in 2-line by 40-character VFD display. The 8434 and 8434DX also have five softkeys and four display control buttons which allow the user to access 15 features. These softkey features can be used *in addition to* the features on the call appearance/feature buttons.

The 8434 and 8434DX telephones can be used in both a 4-wire and a 2-wire environment.

 **NOTE:**

In order to use the display on the 8434 or 8434DX telephone and to use an 801A expansion module connected to the 8434DX, you must connect an auxiliary power supply to the telephone.

You can connect an 801A Expansion Module to the 8434DX telephone to provide 24 additional call appearance/feature buttons.

## **CALLMASTER telephones**

---

There are several types of CALLMASTER telephones:

- **602A and 602D CALLMASTER**

The 602 CALLMASTER models have a display, a Message light, a Mute button, and four fixed feature buttons: Conference, Drop, Hold, and Transfer. You can administer its 10 call appearance/feature (2-lamp) buttons and its 17 feature-only (1-lamp) buttons.

- **603D (CALLMASTER II)**

The CALLMASTER II model has a display, a Message light, and the Mute, Select, Log In, and Release buttons. It also has four fixed features: Conference, Drop, Hold, and Transfer. You can administer its 6 call appearance/feature (2-lamp) buttons and its 15 feature-only (1-lamp) buttons.

- **603E (CALLMASTER III)**

The CALLMASTER III model has a display, a Message light, and the Select, Mute, Log In, and Release buttons. It also has four fixed features: Conference, Drop, Hold, and Transfer. You can administer its 6 call appearance/feature (2-lamp) buttons and its 15 feature-only (1-lamp) buttons. Note that you can assign any feature to the Log In and Release buttons.

You can connect the CALLMASTER III to either a standard 4-wire DCP or a 2-wire circuit pack.

- **603F (CALLMASTER IV)**

The CALLMASTER IV model has a display, a Message light, and the Select, Mute, Log In, and Release buttons. It also has four fixed features: Conference, Drop, Hold, and Transfer. You can administer its 6 call appearance/feature (2-lamp) buttons and its 15 feature-only (1-lamp) buttons. Note that you can assign any feature to the Log In and Release buttons.

You can connect the CALLMASTER IV to either a standard 4-wire DCP or a 2-wire circuit pack.

- **606A (CALLMASTER VI)**

The CALLMASTER VI model is a miniature, 8-button, 2-headset jack, digital telephone that is controlled by the user's personal computer (PC) through an RS-232 serial-port connection.

■ 607A (CALLMASTER V)

The CALLMASTER V model has a display, softkeys, and the display control buttons (Menu, Exit, Previous, and Next). This model does not have a standard handset, but you can connect a handset to one of its headset jacks. The CALLMASTER V has six fixed feature buttons: Speaker, Mute, Hold, Redial, Conference, and Transfer. You can administer its 16 call appearance/feature (2-lamp) buttons, however, one of these buttons must be administered as a Headset On/Off button and a second one must be administered as a Release button. You can also administer the 12 softkey buttons.

## **Cordless telephone**

---

### **MDC9000 cordless telephone**

---

The MDC 9000 Cordless Telephone has two basic parts, the handset and the charging base.

- The handset has line/programmable feature/intercom buttons, Conference, Drop, Hold, Transfer, Status, and Feature buttons, Headset On/Off and Handset On/Off buttons, a LCD display, an earpiece volume control switch, battery charging contacts, a directory card, and a headset jack.
- The charging base has a handset hook, ringer volume controls, battery charging contacts, a Talk indicator, a Charge indicator, a Message indicator, and a base ringer.

### **MDW9000 cordless telephone**

---

The MDW 9000 Wireless Telephone is part of the TransTalk™ 9000 Digital Wireless System family of telephones. This wireless telephone has three basic parts, the handset the charging cradle, and the radio module.

- The handset has line/programmable feature/intercom buttons, Drop, Mute, Hold, Conference, and Transfer buttons, a Headset On/Off button and a Handset On/Off button, a LCD display, a Volume control switch, battery charging contacts, a flexible antenna, and a Headset jack.
- The charging cradle has a handset hook, a spare battery cover, a spare battery.
- The radio module has Power, Pass, and Radio indicator lights, a top hook, card edge, and snap lock which connect the radio module to the carrier assembly/backplane, an antenna, and power plug and line connectors.

## **Internet Protocol (IP) Softphones**

---

IP Softphones extend the level of MultiVantage services. They turn a PC or a laptop into an advanced telephone. IP Softphones allow you to send voice and fax from the MultiVantage through an Internet Protocol (IP) network to other MultiVantage systems that have this feature. You can place calls, take calls, and handle multiple calls on your PC.

IP Softphones extend MultiVantage multifunction, multiline features support to IP-connected endpoints (typically user PCs). With certain exceptions, every feature available for wired-endpoint voice calling is available for IP-based calling; it supports full internetworking with conventional circuit-switched stations and trunks.

There are three IP Softphone applications available: the road-warrior, telecommuter, and the stand-alone H.323. Avaya IP Agent is a modified telecommuter configuration that uses the Avaya IP Agent interface, rather than the Avaya IP Softphone interface.

### **Road-warrior application**

---

The road-warrior application enables travelers to use MultiVantage features from temporary remote locations, such as a hotel room. The road-warrior configuration uses two separate software applications running on a user's PC that is connected to a MultiVantage system over an IP network. The single network connection carries two channels: one for call control signaling and one for voice. IP Softphone software handles the call signaling and an H.323 V2-compliant audio application (such as Microsoft® NetMeeting®) handles the voice communications.

### **Telecommuter application**

---

The telecommuter application enables remote workers to use MultiVantage features from a remote location, such while telecommuting from a home office. The telecommuter configuration uses two connections to the MultiVantage system: a connection to the PC over the IP network and a connection to the telephone over the public-switched telephone network (PSTN). The PC user places and takes calls with the IP Softphone interface and uses the telephone handset to speak and listen.

You can also use a variation of the telecommuter application for call center agents: Avaya IP Agent. This application uses the Avaya IP Agent interface instead of the IP Softphone interface to emulate a remote CallMaster phone.

## **Stand-alone H.323**

---

The stand-alone H.323 application enables travelers to use some MultiVantage features from a remote location. This application uses a PC running an H.323 v2-compliant audio application, such as Microsoft NetMeeting. The H.323 application controls the call signaling and the voice path. However, since it does not use the IP Softphone interface, this configuration is capable of operating only as a single-line telephone without any additional assigned features. You can provide stand-alone H.323 users only features that can they can activate with dial access codes.

## **Related topics**

---

For instructions on how to administer an IP Softphone on your system, see [“Adding an IP Softphone”](#) on page 115.

You can also find information on the IP Softphone CD (see *DEFINITY® IP Softphone Overview and Troubleshooting* and *DEFINITY® IP Softphone Getting Started*).

---

**AAR and ARS partitioning**

---

You can use Automatic Alternate Routing (AAR) and Automatic Route Selection (ARS) partitioning to change the call routing plan for up to 8 different user groups within a single MultiVantage system. You assign a Partition Group Number (PGN) to each user group and identify different call routing treatment for each PGN.

For example, you can partition hotel employees and guests into separate groups (PGN) and route the calls differently. When a guest makes a long-distance call, the guest's PGN and digit analysis tables route the call to a telephone-billing system that allocates long-distance charges. A similar call placed by an employee routes over a direct-distance dialing (DDD) trunk.

**Detailed description**

---

Partition user groups are used only with AAR, and ARS, and Uniform Dial Plan (UDP). You can assign AAR and ARS partitioning to phones, attendant consoles, remote-access users, data endpoints, and incoming trunks.

Use partitioning for:

- groups with different routing due to special billing needs
- groups that have dedicated use of a particular network facility
- groups in different businesses serviced by a single system
- data users who require special facility types on outgoing calls

You can assign a route pattern to just one partitioned user group or you can assign a route pattern to all your partitioned user groups.

You assign the PGN on the Class of Restriction (COR) screen, and then assign the COR on each station screen. When a user dials an AAR or ARS feature access code and a number, the switch uses the PGN of the caller's COR to determine the route pattern. The PGN field appears on the COR screen only if Time of Day Routing is **n** on the System Parameters Customer Options screen.

If Time of Day Routing is **y** on System Parameters Customer Options, you specify the PGN on the Time of Day Routing Plan screen. See [“Time of Day Routing” on page 1887](#) for more information.

## Interactions

---

- Bridged Call Appearance

If a Bridged Call Appearance is used for an AAR or ARS call, the system uses the bridged extension's PGN instead of the caller's PGN.

- Distributed Communications System (DCS)

When a call routes over DCS, the far-end switch uses the incoming trunk's PGN to route the call.

- Remote Access

When a remote-access user dials barrier code or authorization code and an ARS feature access code, the barrier code or authorization code's COR determines the PGN.

- Straightforward Outward Completion and Through Dialing

If the attendant assists or extends a call and dials an ARS feature access code, the attendant's COR determines the PGN if the individual extension is assigned. Otherwise, the COR set on the console parameter determines the PGN.

## Related topics

---

See [“Defining ARS Partitions” on page 265](#) to see how to set up an ARS partition group.

See [“Setting up time of day routing” on page 268](#) to see how to set up Time of day routing.

## Abbreviated dialing

---

Abbreviated Dialing (AD) provides easy access to selected numbers by reducing the number of digits users have to dial to place a call. Instead of dialing the entire number, the user dials a short code to access the number. The system then dials the stored number automatically. You can assign abbreviated dialing buttons to phones, so users can dial frequently-called numbers by pressing a single button.

You can also assign privileged numbers to abbreviated dialing lists, so you can allow a user to place calls to numbers that might otherwise be restricted.

### **SECURITY ALERT:**

*Privileged group-number, system-number, and enhanced-number lists provide access to numbers that typically would be restricted.*

## List types

---

You can store phone numbers in 4 different types of abbreviated dialing lists:

- personal
- group
- system
- enhanced

Your switch type and version determines which lists you have available and how many entries you can have on each list. You can assign up to 3 AD lists to each user (extension). The 3 lists can be made up of any combination of a system list, an enhanced list, up to 3 personal lists, or up to 3 group lists. Each abbreviated dialing entry can have up to 24 characters.

## Personal lists

You can provide personal lists to phone users who need their own set of stored numbers. You determine which users have access to a personal list and the size of each list. Either you or the user can assign phone numbers to personal lists. A personal list is created automatically when you assign the list to an individual phone. Each user can have up to 3 personal lists. Note that you cannot assign personal list to the attendant.

## Group lists

You can define group lists for groups or departments, such as purchasing or human resources, where members of the group have the need to frequently dial the same numbers. You determine which users have access to group lists and each user may have access to up to 3 group lists. You can program the list or you can designate a user in each group to program the list. You specify this designated user on the Abbreviated Dialing Group List screen.

## System lists

You can define one system list for the entire organization. Most administrators assign this list to every phone and allows everyone in the organization to use the list. If you choose to let everyone use the system list, you should only add numbers to the list that anyone in your organization may call. For example, you may want to add an emergency phone number or phone numbers for other office locations to this list.

The system list can contain up to 100 entries and can only be changed by a system administrator.

## Enhanced lists

Enhanced-number lists are used by telephone users, data-terminal users, and attendants who need more list entries than those allowed in group-number and system-number lists. One enhanced-number list is allowed per system in addition to the system-number list. The enhanced-number list can contain any number or dial-access code. You administer the enhanced-number lists and determine which users can access the list.

## Considerations

---

- You cannot remove a telephone or attendant if it is designated as the extension number that is permitted to program a group-number list.
- When using an AD button to access a messaging system, the user's login and password should not be assigned to the button. The system ignores button entries after the messaging access number.
- You can use an abbreviated dialing list at any time during incoming or outgoing calls.

## Interactions

---

- Last Number Dialed

The Last Number Dialed feature redials the same number a user just dialed, even if the user accessed an abbreviated dialing list for the previous call. However, if the last dialed string includes any special characters (such as indefinite wait, mark, pause, suppress, or wait) these characters are ignored by last-number-dialed call.

If the previously-called number was in an AD privileged list, and if the user is not normally allowed to dial the number because of his or her class of restriction, they cannot redial the number using Last Number Dialed. To redial the number, the user must again access the AD privileged list.

## Related topics

---

See [“Adding abbreviated dialing lists” on page 153](#) for instructions on creating abbreviated dialing lists.

See [“Abbreviated Dialing List” on page 585](#) for detailed descriptions of the fields on the abbreviated dialing screens.

## **Access Security Gateway**

---

Access Security Gateway (ASG) prevents unauthorized access by requiring the use of the ASG Key for logging into the system. The ASG Key can be:

- a hand-held device, or
- a software module you load on the PC you use for accessing the system.

### **Detailed Description**

---

Authentication is successful only when MultiVantage and ASG communicate with a compatible key. The challenge/response negotiation starts after establishing an RS-232 session and you enter a valid MultiVantage login ID. The authentication transaction consists of a challenge, issued by MultiVantage and based on the login ID entered by you, followed by the expected response, again entered by you. The core of this transaction is a secret key, which is information-possessed by both the lock (ASG) and the key. Interception of either the challenge or response during transmission does not compromise the security of the system. The relevance of the authentication token used to perform the challenge/response is limited to the current challenge/response exchange (session).

 **NOTE:**

ASG does not protect login access to a Multiple Application Platform for DEFINITY (MAPD).

The supported key consists of a hand-held encryption-generating device (ASG Key). The key (response generator) device is pre-programmed with the appropriate secret key to communicate with corresponding ASG protected login IDs on MultiVantage.

The *Avaya Products Security Handbook* contains information about:

- toll fraud and what you can do to prevent it.
- methods people use to gain access to your system, how to detect toll fraud, and what to do if you suspect that your system has been compromised.
- security information for many Avaya products, so you can be sure that all of your telecommunications equipment is secure.
- security checklists for each of these products. You should go through these with your Avaya representative for each piece of equipment you use.

## Interactions

---

- Customer Access to Initialization and Administration System (INADS) Port

If access to the INADS port is disabled on a system-wide basis, administering access to the SYSAM-RMT or INADS port, through ASG, does not override the INADS port restriction. Administration does not prohibit assignment of ASG to the SYSAM-RMT or INADS port. However, in a configuration where this method of access is blocked, you will be denied access to the system through the SYSAM-RMT or INADS port even if you attempt to access the port using a valid ASG login ID.

If access to the INADS port has been disabled on a login basis, administering access to the SYSAM-RMT or INADS port, via ASG, will not override the INADS port restriction.

- Login Administration

The standard user interface for MultiVantage login administration has not been modified by ASG. Also, the standard MultiVantage login user interface is maintained in cases where ASG parameters have not been administered for the login and/or port.

- Security Violation Notification (SVN)

ASG does not support an interface to SVN. Session rejection events do not appear in the monitor security-violations login report and referral calls are not spawned in the event that the number of rejected ASG sessions exceeds the threshold/time interval criteria imposed by SVN.

- Security Measurements

ASG session establishment or reject events do not increment the Successful Logins, Invalid Attempts, Invalid IDs, Forced Disconnects, Login Security Violations or Trivial Attempts counters maintained for the list measurements security-violations detail report. Additionally, login specific information maintained by the measurements security-violations summary report does not include ASG related data.

## Related topics

See [“Using access security gateway”](#) on page 393 for instructions.

## Administered connections

---

An Administered Connection (AC) is a connection between 2 access or data endpoints. MultiVantage automatically establishes the connection based on the attributes you administer. An AC provides the following capabilities:

- Support of both permanent and scheduled connections
- Auto Restoration (preserving the active session) for connections routed over Software Defined Data Network (SDDN) trunks
- Administrable retry interval (from 1 to 60 minutes) per AC
- Administrable alarm strategy per AC
- Establishment/retry/auto restoration order based on administered priority

### Detailed description

---

The SDDN provides virtual private-line connectivity using the AT&T Switched Network. Access to the service is provided via an Integrated Services Digital Network (ISDN) trunk group whose Service Type field is **SDDN**. The system uses the Destination field on the Administered Connection screen to route calls when AC is active, based on associated authorized time-of-day fields.

Establish an AC between the following:

- Two endpoints on the same switch
- Two endpoints in the same private network, but on different switches
- One endpoint on the controlling switch and another endpoint off the private network

In all configurations, administer the AC on the switch that has the originating endpoint. For an AC in a private network, if the two endpoints are on two different switches, normally the connection routes via AAR through tie trunks (ISDN, DS1, or analog tie trunks) and intermediate switches. If required, route the connection via ARS and Generalized Route Selection (GRS) through the public network. The call routes over associated ISDN trunks. When the far-end answers, a connection occurs between the far-end and the near-end extension in the Originator field on the Administered Connection screen.

### Access endpoints

Access endpoints are non-signaling trunk ports. They neither generate signaling to the far-end of the trunk nor respond to signaling from the far-end. Designate an access endpoint as the originating endpoint or destination endpoint in an AC.

## Typical AC applications

The following are typical AC applications:

- A local data endpoint connection to a local or remote-access endpoint. Examples: a modular processor data module (MPDM) ACCUNET digital service connecting to SDDN via an ISDN trunk-group DS1 port; an MPDM ACCUNET digital service connecting to an ACCUNET Switched 56 Service via a DS1 port.
- A local-access endpoint connecting to a local or remote-access endpoint. Examples: a DSO cross-connect and a 4-wire leased-line modem to a 4-wire modem connection via an analog tie trunk.
- A local data endpoint connecting to a local or remote data endpoint such as a connection between two 3270 data modules.

### NOTE:

The following guidelines do not include AAR and ARS, or GRS administration information for routing AC calls over trunk groups. See the respective feature elsewhere in this book for that information.

## Establishing Administered Connections

The originating switch attempts to establish an AC only if one of the following conditions exist:

- AC is active.
- AC is due to be active (either a permanent AC or time-of-day requirements are satisfied if it is a scheduled AC).
- Originating endpoint is in-service or idle state.

If the originating endpoint is not in service or is idle, no activity takes place for the AC until the endpoint transitions to the desired state. The originating switch uses the destination address to route the call to the desired endpoint. When the switch establishes 2 or more ACs at the same time, the switch arranges the connections in order of priority.

AC attempts can fail for the following reasons:

- Resources are unavailable to route to the destination.
- A required conversion resource is not available.
- Access is denied by COR, facilities restriction level (FRL), or Bearer Capability Class (BCC). Or, an attempt is made to route voice-band-data over SDDN trunks in the public switch network.
- Destination address is incorrect.
- Destination endpoint is busy.
- Other network or signaling failures occur.

In the event of a failure, an error is entered into the error log, which generates an alarm, if it is warranted by your alarming strategy. You can display AC failures via the **status administered-connection** command.

As long as an AC is due to be active, the originating switch continues to establish an AC unless the attempt fails because of an administrative error (for example, a wrong number) or service-blocking condition (for example, outgoing calls barred).

- The frequency with which failed attempts are retried is determined by the administered retry interval (1 to 60 minutes) for each AC.
- Retries are made after the retry interval has elapsed regardless of the restorable attribute of the AC.
- ACs are retried in priority order.
- When you change the time of day on the switch, an attempt is made to establish all ACs in the waiting-for-retry state.

## Dropping Administered Connections

An AC remains active until one of the following occurs:

- The AC is changed, disabled, or removed.
- The time-of-day requirements of a scheduled AC are no longer satisfied.
- One of the endpoints drops the connection. This could be because of user action (in the case of a data endpoint), maintenance activity resulting from an endpoint failure, busying out of the endpoint, or handshake failure. If the endpoints are incompatible, the connection is successful until handshake failure occurs.

### NOTE:

An AC between access endpoints remains connected even if the attached access equipment fails to handshake.

- An interruption (for example, facility failure) occurs between the endpoints.

If an AC drops because it was disabled/removed or is no longer due to be active, no action is taken. If an AC drops because of changed AC attributes, an immediate attempt is made to establish the connection with the changed attributes if it is still due to be active. Existing entries in the error/alarm log are resolved if they no longer apply. If handshake failure resulted in the dropping of the connection, in the case of an AC involving at least one data endpoint, no action is taken for that AC until the change administered-connection command is executed.

## Administered Connections failure: Auto Restoration and Fast Retry

When an active AC drops prematurely, you must invoke either auto restoration or fast retry to determine whether auto restoration is attempted for an active AC.

If you option AC for auto restoration and the connection was routed over SDDN trunks, auto restoration is attempted. During restoration, connections are maintained between the switch and both endpoints. In addition to allowing the active session to be maintained, AC also provides a high level of security by prohibiting other connections from intervening in active sessions. Auto restoration generally completes before the 60-second endpoint holdover interval. If auto restoration is successful, the call might be maintained (no guarantee). The restoration is transparent to the user with the exception of a temporary disruption of service while restoration is in progress. A successful restoration is reflected by the *restored* state on the status Administered Connection screen. Although the restoration was successful, the data session may not have been preserved.

If auto restoration is not active or if the AC is not routed over SDDN trunks, the switch immediately attempts to reestablish the connection (fast retry). The switch also attempts a retry if the originating endpoint initiated the drop. With fast retry, connections are not maintained on both ends. Fast retry is not attempted for an AC that was last established via fast retry, unless the AC is active for at least two minutes.

If auto restoration or fast retry fails to restore or reestablish the connection, the call drops and the AC goes into retry mode. Retry attempts continue, at the administered retry interval, as long as the AC is due to be active.

## Interactions

---

- Abbreviated Dialing  
Use Abbreviated Dialing entries in the Destination field on the Administered Connection screen. Entries must comply with restrictions.
- Busy Verification of Stations and Trunks  
This feature does not apply to access endpoints because they are used only for data.
- Call Detail Recording (CDR)  
For an AC that uses a trunk when CDR is active, the origination extension is the originator of the call.  
  
CDR is not available for access endpoints.

- **Class of Restriction**

Reserve a COR for AC endpoints and SDDN trunks. This restricts endpoints that are not involved in AC from connecting to SDDN trunks or endpoints involved in AC.
- **Class of Service/Call Forwarding**

Assign to an AC endpoint a COS that blocks Call Forwarding activation at the endpoint.
- **Data Call Setup**

Do not assign a default dialing destination to a data module when it is used in an AC.
- **Data Hotline**

Do not assign a hotline destination to a data module that is used in an AC.
- **Digital Multiplexed Interface (DMI)**

Use DMI endpoints as the destination in an AC. DMI endpoints do not have associated extensions, so do not use them as the originator in an AC.
- **Facility Test Calls**

The feature does not apply to access endpoints because an access endpoint acts as an endpoint rather than as a trunk.
- **Hunting**

Do not use a hunt-group extension as the origination extension of an AC.
- **Modem Pooling**

If you require a modem in an AC, one is inserted automatically. If no modem is available, the connection drops.
- **Non-Facility Associated Signaling (NFAS) and D-Channel Backup**

Auto restoration for an AC that initially is routed over an NFAS facility may fail if the only backup route is over the facility on which the backup D-channel is administered. The backup D-channel may not come into service in time to handle the restoration attempt.
- **Set Time Command**

When you change the system time via the set time command, all scheduled AC are examined. If the time change causes an active AC to be outside its scheduled period, the AC drops. If the time change causes an inactive AC to be within its scheduled period, the switch attempts to establish the AC.

If any AC (scheduled or continuous) is in retry mode and the system time changes, the switch attempts to establish the AC.

- System Measurements

Access endpoints are not measured. All other trunks in an AC are measured as usual.

- Terminal Dialing

Turn off terminal dialing for data modules involved in an AC. This prevents display of call-processing messages (INCOMING CALL,...) on the terminal.

- Trunk Groups

To invoke auto restoration, route an AC over SDDN trunks. Because a successful restoration depends on a SDDN path, keep some SDDN trunks idle.

## Administration change notification

---

You can use Administration Change Notification to notify adjunct systems when MultiVantage administration data is changed. This is intended to keep a client application running on an adjunct, such as Enterprise Directory Gateway, in sync with changes in the switch.

You can request notification of any changes to MultiVantage administration by entering the command **notify history** from the client application. MultiVantage will continue to send notification to the adjunct over the Operations Support System Interface (OSSI) link until the command is cancelled.

### Detailed description

---

Administration Change Notification tracks changes made via the System Access Terminal (SAT), INADS port, Property Management System (PMS), Call Management System (CMS), Avaya Site Administration (ASA), Avaya Network Administration, or Avaya Directory Gateway. It also tracks any changes made through a telephone interface, such as Terminal Translation Initialization (TTI), Personal Station Access (PSA), and Terminal Self Administration.

The MultiVantage System only notifies the adjunct that a data object has been changed, but does not provide details of the change. In order to obtain these details, the adjunct must request this information from the switch over a separate link.

## **Administrable language displays**

---

You can display messages in English, French, Italian, Spanish, or a user-defined language on attendant consoles and phones that have 40-character displays.

### **Detailed description**

---

You can select a language for messages that appear on phones and attendant consoles that have 40-character displays. You can choose one of five languages: English, French, Italian, Spanish, or “user-defined.” The meanings of the messages do not change, only the language.

If your company uses 32-character display phones, you cannot choose a display language. These phones, including the hybrid MERLIN 7315H and 7317H phones, default to English.

### **Related topics**

---

You can display the following types of information in English, French, Italian and Spanish:

- Automatic Wakeup
- ASAI
- Busy Verification of Terminals and Trunks
- Call Appearance buttons
- Call Detail Recording
- Call Progress Feedback Displays
- Class of Restriction
- Date-Time Mode - Time Not Available
- Days of the Week
- Months of the Year
- Do Not Disturb
- Enhanced Abbreviated Dialing
- Integrated Directory
- ISDN
- Leave Word Calling
- Malicious Call Trace
- Emergency Access to Attendant
- Queue Status

- Miscellaneous Call Identifiers
- Party Identifiers
- Property Management Interface
- Security Violation Notification
- Stored numbers
- Station hunting
- Time-of-day Routing
- Transfer messages

### **Alternate facility restriction levels**

Alternate Facility Restriction Levels (AFRL) allows a second set of facility restriction levels within a route pattern or for lines or trunks. Attendants and system administrators can activate the alternate FRLs and change users' access to lines and trunks. For example, a company can use AFRL to disable long-distance calling at night to prevent unauthorized staff from making long-distance calls.

AFRL alters the route patterns for originating phones, originating trunks, and dialed authorization codes. If AFRL is active, Travelling Class Mark (TCM) is also set to a new FRL value and the TCM information recorded in the billing data (CDR) is the AFRL value, not the original TCM.

#### **CAUTION:**

*AFRL impacts AAR and ARS call routing because it may change routing preferences. Using AFRL on tandem and tie-trunk applications affects entire networks. Calls that are part of a cross-country private network and may have to be routed further may be blocked.*

### **Detailed description**

You can administer an ALT-FRL button to any attendant console or any station to activate and deactivate the AFRL. Pressing the ALT-FRL button may affect the status of other buttons.

When AFRL is active, the user may notice a change in calling privileges. Consider notifying users of the changes, and prepare your telecommunications department to handle inquiries.

### Authorization codes

Authorization codes prevent unauthorized access to various facilities. When a user dials an authorization code, your system checks the code. If it is not valid, the call is intercepted. If the code is valid, the system determines an associated COR and FRL. If AFRL is activated, the AFRL level is used.

For example, a user whose FRL is 1 attempts a long-distance call. AFRL is active and maps to AFRL 3. The desired trunk has an FRL of 7, and the call is blocked. In the example below, an Authorization Code set to 1234567 has a COR of 3 with an FRL 5, which is still not high enough to access the desired trunk. However, AFRL is active and FRL 5 maps to FRL 7. The call is allowed.

| Authorization code to COR Table               |     | COR to FRL Table |     | FRL to AFRL Table |      |
|-----------------------------------------------|-----|------------------|-----|-------------------|------|
| Authorization Code                            | COR | COR              | FRL | FRL               | AFRL |
| 1234567                                       | 3   | 1                | 1   | 0                 | 3    |
| 1234568                                       | 2   | 2                | 3   | 1                 | 3    |
| 1234569                                       | 3   | 3                | 5   | 2                 | 3    |
| 2222222                                       | 3   | 4                | 7   | 3                 | 3    |
| Originator COR is 1<br>Trunk Desired COR is 4 |     |                  |     | 4                 | 7    |
|                                               |     |                  |     | 5                 | 7    |
|                                               |     |                  |     | 6                 | 7    |
|                                               |     |                  |     | 7                 | 7    |
|                                               |     |                  |     |                   |      |

**Figure 56. Example of authorization codes with AFRLs**

## **Analog busy automatic callback without flash**

---

This is an automatic callback for analog stations without flashing the hook. It will be applied only when the called station is busy and has no other coverage path or call forwarding. The caller can enable the automatic callback without flashing the hook or entering the feature access code.

### **Detailed description**

---

With Analog Busy Automatic Callback without Flash, when the caller places a call through an analog station, and the called station is busy and has no coverage path or forwarding, the caller hears an announcement and is presented with options. Depending on the caller's selection, the call is queued to Automatic Callback, routed to an extension, or dropped.

### **Configurations**

---

This feature will be available on the following platforms:

S8100 Media Server with a G600

S8100 Media Server with a CMC1

MultiVantage on a DEFINITY CSI

DEFINITY SI with an SCC1 Media Gateway

DEFINITY with an SCC1 Media Gateway

### **Related topics**

---

[“Automatic callback” on page 1486](#)

## Announcements

---

You can record announcements for people to hear when they call in to your office. For example, you can let callers know that their call cannot be completed as dialed, that their call is in queue, or that all the lines are busy.

Announcements can be integrated or external. Integrated announcements reside on a circuit pack in the switch carrier. Your system can store multiple announcements on each circuit pack up to the system capacity.

For MultiVantage software release R11 or later, multiple telephone sessions are allowed, with one session associated with each active integrated announcement circuit pack.

External announcements are stored and played back from adjunct equipment. For more information on external announcements, see *Avaya MultiVantage™ Call Center Software Guide to ACD Call Centers*.

Any announcement stored on a circuit pack can play through any port on the circuit pack. Any announcement (not administered for “barge-in”) can play simultaneously through multiple ports. All ports can play the same announcement at the same time, and the system can connect multiple users to each of these announcements.

Three types of announcements are:

- delay announcement — explains the reason for the delay and encourages caller to wait
- forced announcement — explains an emergency or service problem. Use when you anticipate a large number of calls about a specific issue.
- information announcement — gives the caller instructions on how to proceed, information about the number called, or information that the caller wants

### TN2501AP announcements

---

The TN2501AP is an integrated announcement circuit pack that allows you to store and manage announcements over a Local Area Network (LAN). For this reason, it is sometimes referred to as the Voice Announcements over the LAN (VAL) circuit pack.

The TN2501AP can make use of a separate announcement management tool, VAL Manager. VAL Manager provides a PC interface from which you can add, change, delete, save, and restore announcements. For more information, see [“VAL Manager” on page 466](#).

Despite the name, announcements are not actually played over the LAN, but can be transferred to and from the TN2501AP circuit pack over the LAN.

#### The TN2501AP

- is available with both Offer Category A (ECS and ProLogix Solutions) and Category B (BCS and GuestWorks).
- works with DEFINITY R, SI, CSI, S8100 Media Server with a CMC1, S8100 Media Server with a G600 platforms.
- can be updated with firmware files downloaded directly over the LAN. The files are downloaded through the TN2501AP's 10/100Mb ethernet interface, not through the TN799 C-LAN circuit pack.
- has a 10/100MB ethernet LAN connection through the Backplane Adapter.
- has up to 31 ports for announcement playback, with an additional port for recording announcements directly to the TN2501AP circuit pack through a system telephone.

You cannot save or restore announcements to a TN2501AP circuit pack to/from

- a TN750C circuit pack
- flash cards
- tape
- magneto optical disks

### **Administration options for TN2501AP announcements**

---

If you use the TN2501AP circuit pack, you can manage announcements through

- the System Access Terminal (SAT).
- Avaya Site Administration (ASA)
- a PC running the VAL Manager application. VAL Manager is the easiest way for you to manage your TN2501AP announcements. For more information, see your Avaya representative.

You can record VAL announcements

- from a system phone.
- on a computer or any device that supports recording .wav files in a VAL-compatible format (CCITT  $\mu$ -Law or A-Law, 8KHz, 8-bit mono).
- at a professional recording studio.

See [“Announcement file format requirements”](#) on page 455 for more information about recording parameters.

The following table shows the VAL administration tasks and which interface you can use to complete each task. The TN2501AP circuit pack was designed with your efficiency and flexibility in mind, so try combining methods to accommodate your particular installation. See [“Getting started with the TN2501AP or G700 Virtual VAL”](#) on page 451 and [“Managing VAL Announcements Using FTP”](#) on page 459 for instructions for performing these tasks.

**Table 18. VAL administration tasks**

| Tasks                                       | Methods                                             |     |             |
|---------------------------------------------|-----------------------------------------------------|-----|-------------|
|                                             | SAT                                                 | FTP | VAL Manager |
| Adding announcement extensions              | X                                                   |     | X           |
| Deleting VAL announcements                  | X                                                   | X   | X           |
| Saving or backing up announcements          |                                                     | X   | X           |
| Restoring an announcement                   |                                                     | X   | X           |
| Moving announcement files or administration | X                                                   | X   | X           |
| Recording announcements                     | Professional or computer recordings or system phone |     |             |

## System restarts - TN750

When someone powers up the system or inserts or resets an announcement circuit pack, the system checks the circuit pack for announcements. If the system finds no announcements on the circuit pack, and there are recorded announcements stored in system memory, the system restores the announcements from system memory to the announcement circuit pack.

### CAUTION:

*The announcements that are automatically restored are the last announcements saved to system memory. If multiple circuit packs are used, system memory might not contain the announcement for the B or A circuit pack.*

The system automatically restores announcements to only one announcement circuit pack. The system does not restore to announcement circuit packs that have built-in memory.

### About barge-in

---

You can allow callers to begin listening to an announcement after the system has begun playing the message. This is called “barge-in.” Use barge-in with auxiliary trunk announcements, DS1 announcements, and integrated announcements.

With barge-in, only one port plays the announcement at any one time. The system routes a call to the announcement, immediately connects the call to the port, and the caller hears the announcement as it is playing. You can set up barge-in announcements to repeat continually while callers are connected to the port. The caller listens until the system plays the entire announcement.

### Interactions

---

- Automatic Wakeup

Recorded Announcement allows Automatic Wakeup to use the built-in announcement circuit pack in place of an Audichron adjunct.

If you use an integrated, multiple-integrated, or external type of announcement for Automatic Wakeup, you can also administer the announcement to repeat and to allow “barge-in” as a queue type. The benefit of repeating announcements and “barge-in” queues is that you do not need a separate port for each wakeup announcement. When guests pick up an announcement at a particular time, they use only one port and the message repeats until the last guest hangs up and the message ends.

## Answer detection

---

For proper CDR and accurate billing, you need to know when your outgoing calls are answered. Answer detection means the method a switch uses to determine whether an outgoing call has been answered.

### Brief description

---

MultiVantage provides 3 ways to determine whether the called party has answered a call.

### Call classification

A call-classifier circuit pack detects tones and voice-frequency signals on the line to determine whether a call has been answered. This method is fairly accurate: calls that are answered normally are usually classified correctly. But there are exceptions:

- Miscellaneous tones, such as confirmation tones, may be classified as answers.
- Loud background noise may activate answer detection, causing a call to be classified as answered even if the call is not connected.
- Some calls that are answered may be incorrectly classified as fast busy signals.
- Call classifier circuit packs also don't recognize Special Information Tones (SIT) as answers.

Of course, the system generates a call record for any call that is classified as answered whether the classification is correct or not. If Call Classification incorrectly classifies a call as answered, and then the call is subsequently answered, the call duration reported by CDR includes the both time between the incorrect classification and the actual answer and the remaining duration of the call.

If you want to use call classification, on the System Parameter Customer-Options screen verify the Answer Supervision by Call Classifier field is **y**. If not, contact your Avaya representative. You also must have a call classifier circuit pack of the correct type. To find out what circuit packs you need, see *Avaya MultiVantage™ Solutions Hardware Guide*.

## Network answer supervision

The central office sends a signal to the originating switch to indicate that the far end has answered. If a call traveled over a private network before reaching the central office, the signal is transmitted back over the private network to the originating switch. This method is extremely accurate, but it is not available over most loop-start trunks (for example, central office (CO), foreign exchange (FX) and Wide Area Telecommunications Service (WATS) trunks in the US).

Network answer supervision does not override answer supervision by timeout.

## Answer supervision by timeout

You set a timer for each trunk group, using the Answer Supervision Timeout field on the Trunk Group screen. Or you set a circuit pack timer for the ports on that circuit pack, using the Outgoing End of Dial (sec) field on the Trunk Group screen. If the caller is off-hook when the timer expires, the system assumes that the outgoing call has been answered. This is the least accurate method. Calls that are shorter than the timer duration do not generate call records, and calls that ring for a long time produce call records whether they are answered.

If network answer supervision is received, it overrides answer supervision by timeout.

## Interactions

---

- Call Detail Recording  
Answer Detection provides more accurate call records where tone detection is possible and Network Answer Supervision is not received.
- Call Prompting  
Call classification competes with Call Prompting for ports on the call classifier circuit pack.
- CallVisor ASAI  
Call classification competes with CallVisor ASAI switch-classified calls for ports on the call classifier circuit pack. Answer Detection triggers reporting of a connect event to ASAI.

## Related topics

See [“Administering answer detection”](#) on page 436 for instructions.

See [“Trunk Group”](#) on page 1233 for definitions of the fields used to administer answer detection.

## Attendant Features

---

This section describes the following MultiVantage features that you may want to administer for your console operators:

- “Attendant Call Waiting” on page 1470
- “Attendant Control of Trunk Group Access” on page 1472
- “Attendant Direct Extension Selection” on page 1473
- “Attendant Intrusion” on page 1474
- “Attendant Override of Diversion Features” on page 1474
- “Attendant Serial Calling” on page 1475
- “Auto Start and Don’t Split” on page 1475
- “Attendant Timers” on page 1476
- “Visually Impaired Attendant Service” on page 1478

Each feature indicates how to administer the [Attendant Console](#) screen, [Console Parameters](#) screen, and other system-wide screens to enable the feature.

### Attendant Call Waiting

---

Attendant Call Waiting allows an attendant-originated or attendant-extended call to a busy single-line telephone to wait at the called telephone so that the attendant can handle other calls.

If you want the attendant to be able to send calls to busy single-line phones, set the Att. Call Waiting Indication field to Y on the [Station](#) screen for each single-line phone.

When the single-line phone receives a waiting call, the phone user hears a call-waiting signal. You can administer the number of bursts (1, 2, or 3) in the call-waiting signal by changing the Attendant Originated Calls field on the [Feature-Related System Parameters](#) screen.

If the attendant activates Attendant Call Waiting, and the Timed Reminder on Hold interval or the Return Call Timeout interval expires without the call being answered, the call returns to the console. You can modify these intervals on the [Console Parameters](#) screen.

## Interactions

- Automatic Callback

Activating Automatic Callback at the called telephone denies Attendant Call Waiting.

- Call Coverage

Attendant Call Waiting calls redirect to coverage if the called phone has Data Privacy or Data Restriction activated. If one of these conditions exists, and you assign call coverage to a telephone, and the user activates Send All Calls or coverage criteria is met, the call redirects to coverage.

- The Coverage Don't Answer interval specifies how long a call remains directed to the called telephone before redirecting to coverage. Attendant Call Waiting if applicable on the call, is active for the duration of the Don't Answer interval only. At the end of this interval, the call redirects to coverage.

- If the Return Call Timeout (Timed Reminder) interval expires before the Don't Answer interval expires, the call does not go to coverage, but returns to an attendant console. If the Don't Answer interval expires first, the call redirects to coverage, but can still return to the console if a coverage point does not answer the call before the Return Call Timeout.

- If the Station Hunting field is assigned and the called telephone is busy, the call redirects to the Hunt To Station Assignment.

- Data Privacy, Data Restriction

Activating Data Privacy or Data Restriction at the called telephone denies Attendant Call Waiting.

- Direct Department Calling (DDC) and Uniform Call Distribution (UCD)

Calls to a DDC or UCD group do not wait. However, they can enter the group queue, if provided.

- Loudspeaker Paging Access

Activating Loudspeaker Paging Access at the called telephone denies Attendant Call Waiting.

- Music-on-Hold Access

The calling party hears music if the call is a trunk-transferred call administered to receive Music-on-Hold. Otherwise, the calling party hears ringing.

- Recorded Telephone Dictation Access

Activating Recorded Telephone Dictation Access at the called telephone denies Attendant Call Waiting.

## **Attendant Control of Trunk Group Access**

---

Attendant Control of Trunk Group Access allows the attendant to control trunk groups, and prevents telephone users from directly accessing a controlled trunk group. The attendant gains direct access to an outgoing trunk group by pressing the button assigned to that trunk group.

Each attendant console has 12 designated Trunk Hundreds Select buttons that can be administered for Attendant Control of Trunk Group Access. You can also administer each console with up to 12 feature buttons for Trunk Hundreds Select buttons, which gives you up to a total of 24 buttons.

Each Trunk Hundreds Select button has busy lamps that light when all the members of the associated trunk group are busy. If you administer one of the 2-lamp feature buttons on a basic console as a Trunk Hundreds Select button, use the bottom lamp as the busy lamp. These buttons have 2 additional lamps for Attendant Control of Trunk Group Access. The 2 lamps are:

- Warn (warning) lamp  
Lights when the administered number of trunks are busy in the associated trunk group. You administer the Busy Threshold field on the associated [Trunk Group](#) screen to determine when to light this warning lamp.
- Cont (control) lamp  
Lights when the attendant activates Attendant Control of Trunk Group Access for the associated trunk group. Assign act-tr-grp and deact-tr-g buttons on the [Attendant Console](#) screen to allow the attendant to activate and deactivate control of the trunk group access.

### **Interactions**

- Authorization Codes  
Authorization codes do not collect when a trunk group has an incoming destination set to the attendant.
- Automatic Route Selection and Automatic Alternate Routing (ARS/AAR)  
Activating Attendant Control of Trunk Group Access removes the controlled trunk groups from the ARS and AAR patterns. Deactivating the feature reinserts the groups into the patterns. ARS calls do not route to the attendant.
- QSIG  
QSIG trunks do not support Attendant Control of Trunk Group Access.
- Uniform Dial Plan  
Activating Attendant Control of Trunk Group Access removes the controlled trunk groups from preferences. Deactivating the feature enables the UDP to access the trunk groups.

## **Attendant Direct Extension Selection**

---

Attendant Direct Extension Selection (DXS) with busy lamp field allows the attendant to track extension status (idle or busy) and to place or extend calls to extension numbers without having to dial the extension.

### **Standard DXS Tracking**

The basic selector console has 8 Hundreds Select buttons and 100 DXS buttons. The enhanced selector console has 20 Hundreds Select buttons and 100 DXS buttons. You can assign 12 additional Hundreds Select buttons to feature buttons on the attendant console.

However, as you assign these feature buttons, note that the total number of Hundreds Select buttons per attendant (including both attendant-console feature buttons and selector-console buttons) cannot exceed 20.

### **Enhanced DXS Tracking**

Enhanced DXS Tracking can help you if you have more than 100 telephones, but you use a console that does not have Hundreds Select buttons administered. It can also help if you have more telephones than you do Hundreds Select buttons (and thus have hundreds groups that are administered with Hundreds Select buttons).

To use Enhanced DXS, assign a Group Select button on the [Attendant Console](#) screen. This button allows the attendant to track and extend calls to telephones that do not have associated Hundreds Select buttons. You can not use Enhanced DXS Tracking if your extensions have fewer than three digits.

### **Group Display button**

You can administer a Group Display button on the [Attendant Console](#) screen to help the attendant track extension status. When the attendant presses this button, the system displays the range of extensions currently tracked by the selector console. Administer the Group Display button for either the feature area or the display area of the console.

If the attendant selects this button, the system identifies the digits associated with a Hundreds Select button — unless it finds no Hundreds Select button is lit, in which case it identifies the digits last entered with the Group Select button. The system continues to track the selected group of extensions until the attendant selects a new group of extensions.

## **Attendant Intrusion**

---

The attendant intrusion (Call Offer) button allows an attendant to intrude on an existing call to offer a new call or message to the intruded party.

When the attendant releases the intruded call, the source party waits at the intruded party's analog telephone or holds on an available line appearance on a digital telephone.

### **Interactions**

- Intrusion is denied in the following cases:
  - A telephone is on a conference call with administered maximum number of conferees
  - A call is established with Data Privacy activated
  - Establish a call with Data Restriction activated
  - A telephone is a forward-to point of another telephone
  - A telephone is busy talking to another attendant
- If a call is already call waiting for the intruded party, the source (split from attendant) party cannot wait for the intruded party using Call Waiting.
- The attendant display shows the character '1 wait' or '1 busy' if an intrusion is possible. Otherwise, the display shows 'wait' or 'busy'.
- The system provides Attendant Intrusion on remote telephones via TGU/TGE trunks (Italy only).

## **Attendant Override of Diversion Features**

---

Attendant Override of Diversion Features (override button) allows an attendant to bypass call-diversion features activated by a called extension. A diversion feature is any feature that, when activated, causes a call to redirect from the called telephone. Send All Calls, Call Coverage, and Call Forwarding are diversion features.

You should explain to your attendants that they can use this feature with the Attendant Intrusion to place an emergency or urgent call to a telephone user.

## Attendant Serial Calling

---

Attendant Serial Calling enables the attendant to transfer trunk calls that return to the same attendant after the called party hangs up. Once outside callers reach an attendant, they can use the same line into the switch for multiple calls. Attendant Serial Calling is useful if trunks are scarce and Direct Inward Dialing services are unavailable.

To allow your attendant to use serial calling, assign a serial-cal button on the [Attendant Console](#) screen. The Attendant Serial Calling feature is valid only on calls that have only one trunk on the connection.

You can define a priority queue for Serial Calls on the [Console Parameters](#) screen.

### Interactions

- Centralized Attendant Services  
Attendant Serial Calling does not work with Centralized Attendant Services.
- Distributed Communications System (DCS)  
Attendant Serial Calling works in a DCS environment only if the attendant activates it on the same node as the trunk to which the attendant is connected. Do not conference the incoming trunk call with a DCS party when activating. This would put two trunks on the connection.

## Attendant Vectoring

---

Attendant Vectoring allows you to establish an attendant vector directory number (VDN) and send attendant group calls through vector processing. This is useful when you want more flexibility with how calls are routed when the system is in Night Service mode. For more information, see *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide*.

## Auto Start and Don't Split

---

Auto Start allows the attendant to initiate a call by pressing any key on the keypad without having to first press the Start button.

If an attendant enables Auto Start and dials an AAR number where the min and max in the AAR analysis table are not equal, the attendant must dial a # after the digit string or the call cannot process.

You can assign a don't-split button on the [Attendant Console](#) screen which allows attendants to deactivate Auto Start. To deactivate auto start, the attendant presses the Don't Split button. When Don't Split is active, keys pressed on the keypad are heard by the parties on the call.

To reactivate Auto Start, and allow end-to-end signaling, the attendant again presses the Don't Split button, presses Cancel, or lets the current call terminate.

## Interactions

- CDR — Account Code Dialing  
If the system is using Call Detail Recording Account Code Dialing, Auto Start and Don't Split is not activated.
- Visually Impaired Attendant Service  
If VIAS is activated or deactivated while Don't Split is active, Don't Split deactivates.

## Attendant Timers

---

Attendant timers automatically alert the attendant after an administered time interval. The attendant can reenter the call and decide whether to terminate the call or permit the waiting to continue. You administer the timers on the [Console Parameters](#) screen.

Attendant Timers include:

- Unanswered DID Call Timer — Specifies how long a direct inward dialing (DID) call can go unanswered before it routes to the administered DID/TIE/ISDN Intercept Treatment.
- Attendant Return Call Timer — For unanswered calls that were extended by the attendant, they are returned to the same attendant who released them if the attendant is available. Otherwise they return to the attendant-group queue. The Attendant Return Call Timer is not set for calls extended from one attendant to another individual attendant. A transferred call that times out redirects to an attendant after an interval equal to the Attendant Return Call timer.
- Attendant Timed Reminder of Held Call Timer — Specifies how long a call is held. When the timer expires, the held call alerts the attendant. The message `hc` appears on the attendant display. You can administer either a high-pitched ring or a primary alert.

- **Attendant No-Answer Timer** — Specifies how long a call that terminates at an attendant console can ring with primary alerting. When the call reaches this interval setting, it rings with a secondary, higher-pitch ring. A disabled Attendant No Answer Timer's ringing pattern does not change over from the primary to the secondary pattern. If the call remains unanswered during this interval, it routes to the attendant group and console where the call was placed in a Position Busy state. This feature does not apply to calls placed to the attendant's extension or to calls originated by the attendant.
- **Attendant Alerting Interval (Timed Reminder)** — Specifies how long a call that terminates at an attendant console can ring with secondary alerting. When the call reaches this interval, the attendant console is placed into position busy mode and the call forwards to the attendant group. If the console where the alerting interval is reached is the last active day console, then the system goes into night service if night service is enabled. This feature does not apply to calls placed to the attendant's extension or to calls originated by the attendant.

You can disable the alerting interval. In this case, a call continues to ring at the original attendant's extension until the caller hangs up or another feature disconnects the call (for example, reaching the timeout limit for unanswered DID calls during night service.)

- **Line Intercept Tone Timer** — Specifies how long line intercept can be. For example: LITT:10 seconds means that line intercept stops after 10 seconds.

## Interactions

- **Call Coverage**

If a telephone user transfers a call to an on-premises telephone and the call remains unanswered at the expiration of the Timed Reminder Interval, the call redirects to an attendant. Redirection occurs even if the call redirects via Call Coverage or Call Forwarding from the transferred-to telephone.

An attendant-extended call redirects to coverage instead of returning to an attendant if the coverage criteria are met before the Timed Reminder Interval expires. However, unanswered calls return to an attendant at the expiration of the interval.

If a call alerts an attendant as a coverage call (unanswered station-to-station call with the "attd" (attendant) in the called telephone's coverage path screen), the secondary alerting tone does not sound.

- **Centralized Attendant Service**

If an attendant at the main location transfers a call from a branch location to an extension at the main location, the timed reminder does not apply and the call does not return to the attendant if unanswered.

## **Visually Impaired Attendant Service**

---

Visually Impaired Attendant Service (VIAS) allows a visually-impaired attendant to listen to an audio description of each feature button in Inspect mode. It provides the description in either British English or Italian.

The attendant presses the Inspect mode to locate each button and then presses a feature button to determine the feature assigned to the button without actually executing the feature.

The six VIAS attendant buttons are:

- Visually Impaired Service Activation/Deactivation button: activates or deactivates the feature. All ringers previously disabled (for example, recall and incoming calls) become reenabled.
- Console Status button: voices whether the console is in Position Available or Position Busy state, whether the console is a night console, the status of the attendant queue, and the status of system alarms.
- Display Status button: voices what is shown on the console display. VIAS support is not available for all display features (for example, class-of-restriction information, personal names, and some call purposes).
- Last Operation button: voices the last operation performed.
- Last Voiced Message button: repeats the last voiced message.
- Direct Trunk Group Selection Status button: voices the status of an attendant-monitored trunk group.

Some changes on the attendant console are automatically voiced (for example, alarms reported, night service activated, and call thresholds reached).

## **Audible message waiting**

---

Audible Message Waiting places a stutter at the beginning of a station dial tone on a station that has a message waiting. Audible Message Waiting is particularly useful for visually impaired people who may not be able to see a message light.

Messages for a station can be waiting in system memory (to be accessed via display or voice synthesizer), Property Management System (PMS) or AUDIX. When the system loses synchronization between telephones and message-status data, use Clear Message Waiting Indicators to turn off message-waiting indicators.

You typically assign Audible Message Waiting on phones without message-waiting lights, such as analog telephones.

Audible Message Waiting requires a separate software right-to-use fee. Audible Message Waiting may not be applicable in countries that restrict the characteristics of dial tones provided to users.

### Related topics

---

See [“Station” on page 1127](#) for information about and fields descriptions on the Station screen. Complete the Audible Message Waiting field on this screen to administer audible message waiting.

## Authorization codes

---

Authorization codes provide the means for extending control of system users' calling privileges. They extend calling-privilege control and enhance security for remote-access callers.

#### NOTE:

To maintain system security, Avaya recommends you use authorization codes.

Authorization codes may be used to:

- Override an FRL assigned to an originating station or trunk
- Restrict individual incoming tie trunks and remote-access trunks
- Track Call Detail Recording calls for cost-allocation purposes
- Provide additional security control

You can make authorization codes mandatory by setting, on the trunk group screen, the Auth Code field to **y**. See [“Trunk Group” on page 1233](#) for more information.

## More information

---

When you dial an authorization code, the FRL assigned to the extension number, attendant console, incoming trunk group, or remote access trunk group being used for the call is replaced by the FRL assigned to the authorization code. The new FRL functions the same as the one it replaces; however, the new FRL may represent greater or lesser calling privileges than the FRL that it replaces. Access to any given facility depends on the restrictions associated with the authorization code FRL.

## Example

A supervisor is at a desk of an employee and wants to make a call that is not normally allowed by the FRL assigned to that employee's extension. The supervisor, however, can still make the call by dialing an authorization code that is assigned an FRL that is not restricted from making that type of call.

For security reasons, authorization codes range from 4 to 13 digits. The number of digits in the codes must be a fixed length for a particular MultiVantage system.

### NOTE:

Once established, the number of digits (4 to 13) in the authorization code remains fixed unless all codes are removed and re-entered. All authorization codes used in the system must be the same length.

Incoming trunk groups within a system may be administered to always require an authorization code. The system applies recall dial tone to a call when the user must dial an authorization code. If the user dials a correct authorization code within 10 seconds (interdigit timeout), the call completes as dialed. If the user does not dial an authorization code or dials an incorrect authorization code, the call routes to the attendant, or routes to intercept tone, depending on system administration.

Normally, Direct Inward Dialing (DID) trunks should not require authorization codes. However, it can be done and care should be taken when administering DID trunks to require an authorization code, because different type calls could terminate at different endpoints, and requiring an authorization code could be confusing to the caller.

A Cancellation of Authorization Code Request (CACR) digit may be administered. The CACR digit cancels the 10-second interval between dialing. When the CACR digit is dialed, the call immediately routes according to system administration. (Incoming trunk calls receive intercept treatment or go to the attendant.) Other calls receive intercept treatment unless the user's FRL is high enough to route the call. A CACR digit from an off-premises extension over DID/Tie trunks use DID/Tie trunk intercept treatment. Internal calls receive intercept tone.

 **CAUTION:**

*Do not program passwords or authorization codes onto auto dial buttons. Display telephones display the programmed buttons, providing internal abusers access to the auto dial buttons to originate unauthorized calls. If passwords or authorization codes must be programmed onto auto dial buttons, use the ~s (suppress) character to prevent displaying the codes.*

For more information, see *BCS Products Security Handbook*.

## **AAR and ARS Calls**

Each authorization code is assigned a COR that contains an associated FRL. Within a system, access privileges are determined by the FRL assigned to the facility where the call is originated. When an AAR/ARS call is dialed, the system allows or denies the call based on the FRL of the originating station. COR is used to restrict internal or non-AAR/ARS calls.

Authorization codes are given to individual users and provide a method of specifying the level of calling privileges for that user regardless of the originating facility. Once an authorization code is required and dialed on an AAR/ARS call, the FRL assigned to the authorization code replaces the originating FRL and controls and defines the user's privileges.

An AAR or ARS call originated by a system user or routed over an incoming tie trunk may require a dialed authorization code to continue routing.

Extreme care should be taken when administering authorization codes, so that a user does not have to dial the authorization code more than once. For example, if a user makes an AAR or ARS call and the user's FRL is not high enough to access any of the trunks in the routing pattern, the system prompts the user for an authorization code. If the FRL assigned to the authorization code is high enough to access the next trunk group in the routing pattern, the user is not prompted to dial the code again. If the call is routed through another switch, the user may be required to dial an authorization code again. This type of situation can be avoided through careful administration.

When an authorization code is required on some, but not all, trunk groups, the system prompts for an authorization code when the originating FRL is not adequate to access the next available trunk group in the routing pattern.

## Considerations

---

- From remote locations users typically access authorization from touch-tone stations. However they can also do so from rotary dialing stations at specified authorization-code-forced locations that follow appropriate trunk administration practices. Rotary station users access attendants via Listed Directory Numbers (LDN) or remote access numbers and can experience a 10-second timeout.
- The use of Authorization Codes does not limit other call-control methods such as Toll Restriction, Miscellaneous Trunk Restriction, and Outward Restriction.
- For security reasons, do not assign authorization codes in sequential order. Assign random number barrier codes and authorization codes to users so if a hacker deciphers one code, it will not lead to the next code.
- If timeout to attendant does not occur or CACR digit codes are dialed instead of authorization codes, the system assumes that invalid authorization codes were dialed and the caller is given intercept tones.
- Authorization codes impact calling privileges by:
  - Changing an outgoing-call FRL when it is insufficient to access preferred routing patterns assigned by AAR/ARS. An FRL is assigned to a COR associated with user authorization codes. No additional COR data is assigned.
  - Overriding COR for remote access calls assigned to barrier codes, when required. For remote-access calls, if an authorization code is required, the user is assigned the COR of the dialed authorization code, with all connected data, such as the FRL. This COR overrides the COR assigned to any required barrier code.
- Incoming trunk calls that require authorization codes do not change user privileges.

## Interactions

---

- AAR/ARS Partitioning

Partitioned group numbers are assigned by COR and Authorization Codes can change Classes of Restriction. Therefore, Partitioned Group Numbers can be changed on incoming remote access calls by authorization codes. For originating calls, user Classes of Restrictions determine Partitioned Group Numbers.

- Cancellation of Authorization Code Request

| If                                  | Then                 |
|-------------------------------------|----------------------|
| CACR =1                             | ■ Authorization ≠ 1  |
| Network = DEFG1, DEFG3 or DEF ECSR5 | ■ CACR can be #      |
| Network - S85s, DIM switch          | ■ CACR = 1 (default) |

- COR and FRL

Authorization codes used for AAR/ARS calls override associated FRL. Associated Classes of Restriction determine remote-access user privileges.

- Forced Entry of Account Codes and Call Detail Recording

For 94A LSU (no longer supported) and 3B2 CDRU (no longer supported) 18-word records, authorization codes are output if administered account-code lengths are fewer than six digits. For 59-character records, authorization codes are never recorded.

Authorization codes are recorded after destination addresses are dialed. Invalidly-dialed authorization codes are recorded, and patterns can be traced using CDR printouts.

## Related topics

---

See [“Barrier codes” on page 1504](#) to use barrier codes to prevent unauthorized system access.

See [“Station” on page 1127](#) for setting a class of restriction on a station phone.

See [“Class of Restriction” on page 658](#) to set a facility restriction level on a phone.

See [“Route Pattern” on page 1096](#) for information concerning the sequence of trunk groups in which an attempt is made to route a call.

## **Automated attendant**

---

Automated Attendant uses vector commands to allow a caller to enter the extension of the party that he or she would like to reach. The call is routed by the vector to that extension.

See *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide* for a detailed description of Automated Attendant and for a sample vector that can be used for Automated Attendant. The guide contains information that is critical to the effective and efficient use of Automated Attendant.

You can administer any display-equipped phone or attendant console with a Caller Information CALLR-INFO button. The button displays digits collected for the last **collect digits** command.

Automated Attendant competes with several features for ports on the call classifier — detector circuit pack or equivalent.

## **Interactions**

---

- **AUDIX**

Automated Attendant gives the caller the option of leaving a message or waiting in queue for an attendant. See “Message Collection” in Chapter 5 of the *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide*.

- **Authorization Codes**

If authorization codes are enabled, and a *route-to* command in a prompting vector accesses AAR or ARS, if the Vector Directory Number’s (VDN’s) FRL does not have the permission to use the chosen routing preference, then the system does not prompt for an authorization code and the *route-to* command fails.

- CallVisor Adjunct-Switch Application Interface (ASAI)

ASAI-provided digits can be collected by the Call Vectoring feature via the *collect* vector command as dial-ahead digits. CINFO is passed to CallVisor ASAI.

- Hold

If a call is put on hold during the processing of a *collect* command, the command restarts, beginning with the announcement prompt, when the call is taken off hold. All dialed-ahead digits are lost. Similarly, if a call to a vector is put on hold, vector processing is suspended when a *collect* command is encountered. When the call becomes active, the *collect* command resumes.

- Inbound Call Management (ICM)

You can use Automated Attendant to collect information that may later be used by an adjunct to handle a call.

- Transfer

If a call to a VDN is transferred during a *collect* command, the *collect* command restarts when the transfer is complete, and all dialed-ahead digits are lost. Similarly, if a call to a vector is transferred, vector processing is suspended when a *collect* command is encountered. When the transfer is complete, the *collect* command resumes. Attendant extended calls do suspend vector processing in the same way as transferred calls.

## **Automatic callback**

---

Automatic Callback allows internal users who placed a call to a busy or unanswered internal telephone to be called back automatically when the called telephone becomes available.

When a user activates automatic callback, the system monitors the called telephone. When the called telephone becomes available to receive a call, the system originates the automatic callback call. The originating party receives priority ringing. The calling party then lifts the handset and the called party receives the same ringing provided on the original call.

A single-line telephone user activates this feature by pressing the Recall button or flashing the switchhook and then dialing the automatic callback access code. A single-line user can activate automatic callback for only one call at a time.

A multi-appearance telephone user can activate automatic callback for the number of automatic callback buttons assigned to the telephone. After placing a call to a telephone that is busy or that is not answered, the caller simply presses an idle automatic callback button and hangs up.

If the calling telephone user answers an automatic callback call, and for some reason the called extension cannot accept a new call, the calling user hears confirmation tone and then silence. The call is still queued.

Users cannot activate automatic callback for calls to:

- A telephone assigned Termination Restriction
- An extension with automatic callback already activated toward it
- A data terminal (or data module)
- An attendant console group
- A Terminating Extension Group
- An extension for a hunt group, split, or skill
- An EAS agent’s Login ID
- A VDN Extension

## **Automatic callback for busy trunks**

---

You can administer your system to call users back if they try to place an outgoing call over a trunk group where all trunks are busy. This is sometimes called Ringback Queueing.

If a multiappearance telephone user has an idle Automatic Callback button and tries to access an all-trunks-busy trunk group, the call is queued automatically. The lamp associated with the Automatic Callback button lights and confirmation tone is heard.

Ringback Queueing is automatic for a single-line telephone. After dialing is complete, the user hears confirmation tone if the queue is available. No action is required.

**The system will queue as many calls as allowed based on the Queue Length field on the each trunk group screen.** The system checks the busy/idle status of the trunk group just once. If all trunks are busy, the call queues, even if a trunk has become available by the time the caller has completed dialing. This occasionally results in the caller being called back immediately after receiving confirmation tone and going on-hook.

## **Considerations**

---

- The system cancels an automatic callback request for any of the following reasons:
  - The called party is not available within 30 minutes.
  - The calling party does not answer the callback call within the administered interval (2–9 ringing cycles set in the Automatic Callback-No Answer Timeout Interval field on the Feature-Related System Parameters screen).
  - The calling party decides not to wait and presses the same automatic callback button a second time (multi-appearance telephone) or dials the automatic callback cancellation code (single-line telephone).
- automatic callback is administered to individual telephones by their COS and cannot be assigned to the attendant(s). Multi-appearance telephones must have an automatic callback button to activate the feature.

- automatic callback works differently depending on if the called party was busy or did not answer the call. For a busy call, automatic callback takes place as soon as the called party hangs up. If the called party did not answer, the telephone must be used for another call and then hung up before automatic callback is activated.

 **NOTE:**

If the automatic callback originator has all line appearances occupied when the automatic callback call comes in, the user will hear priority ringing once, and the automatic callback lamp will blink. However, if the user presses the automatic callback button to answer the automatic callback call, one of the other calls will drop.

## **Interactions**

---

- **Attendant Call Waiting and Call Waiting Termination**  
If a user activates automatic callback to or from a single-line telephone, Call Waiting Termination is denied.
- **Attendant Intrusion**  
Attendant Intrusion does not work if a user has activated automatic callback.
- **Bridged Call Appearance**  
Users cannot activate automatic callback from a bridged call appearance. If a user activates automatic callback from a primary extension number, the return-call notification rings at all bridged call appearances.
- **Busy Verification**  
If a telephone has activated automatic callback, you cannot perform Busy Verification of that telephone.
- **Call Coverage**  
Automatic callback calls do not redirect to coverage.
- **Call Forwarding**  
If the called telephone has Call Forwarding activated, the calling party cannot activate automatic callback. However, if automatic callback was activated before the called telephone user activated Call Forwarding, the system redirects the callback call attempt toward the forwarded-to party.
- **Call Pickup**  
A group member cannot answer a callback call for another group member.
- **Class of Restriction**  
Telephones with origination restriction cannot activate automatic callback.

- Conference and Transfer

A single-line telephone user cannot activate conference or transfer if automatic callback is active.
- DCS

Automatic callback operates over a DCS network as if it were on a local switch.
- Expert Agent Selection

Users can't activate Automatic Callback to an EAS agent's Login ID. They can activate Automatic CallBack to the phone where the agent is logged in.
- Hold

A single-line telephone cannot receive automatic callback calls if the user has placed a call on hold.
- Hot Line Service

Telephones administered for Hot Line Service cannot activate automatic callback.
- Intercom - Automatic and Dial

Intercom calls are not eligible for automatic callback.
- Internal Automatic Answer (IAA)

IAA does not automatically answer automatic callback calls.
- Manual Originating Line Service

Telephones with Manual Originating Line Service cannot activate automatic callback.
- Ringback Queuing

Users can press an automatic callback button to activate Ringback Queuing.
- Telephone Display

When the system generates an automatic callback call, the display of the originating telephone displays *automatic callback* (or the equivalent for Administrable Language Displays).

## **Automatic circuit assurance**

---

Automatic circuit assurance (ACA) helps you identify possible trunk malfunctions. With ACA enabled, the system measures the holding time of each trunk call. If the measurements show calls with either extremely long or extremely short holding times, MultiVantage places a referral call to an attendant or telephone.

The system records holding time from when a trunk is accessed to when it is released. You set short-holding-time and long-holding-time limits for each trunk group. The system then compares the recorded holding times against these limits.

You enable ACA for the entire system, and administer thresholds for individual trunk groups. You can have all trunks or only certain trunks measured.

MultiVantage deals with long-holding and short-holding calls differently. For every call that is shorter than the administered short-holding time, the system increases the short-holding counter by 1. For calls over the same trunk that are within the normal range, it decreases the short-holding counter by 1. Thus, trunks that handle a normal variety of call lengths are not singled out as faulty. If the counter reaches the administered short-holding threshold, the system places a referral call.

If one long call exceeds the long-holding time, the system makes a referral call.

You cannot measure personal CO lines, out-of-service trunks, or trunks undergoing maintenance testing.

### **The referral call**

---

The display or voice-synthesized message that accompanies an ACA call contains the following information:

- The fact that this is an ACA call
- The trunk access code, trunk group number, and trunk group member number
- The type of referral (short or long holding time)

Once the referral call is answered, this information is displayed and remains displayed until the call is released. If the call is not answered within three minutes, the call stops. The system places the call again after one hour, and continues to place the call hourly until someone answers.

The attendant or telephone user who receives the referral call can stop further calls by pressing the aca-halt button, if one is provided. This is a toggle button, and turns off the feature until the user presses the button again.

## **The audit trail**

---

Each time a referral call is necessary, the system also adds a record to an audit trail. Audit trail records are available on the ACA Measurements Report. Each record contains the following information:

- Time and date of referral
- Trunk group number, trunk access code, and trunk group member
- The type of referral (short or long holding time)

## **Interactions**

---

- **Administrable Language Displays**  
You cannot administer languages for ACA messages.
- **AUDIX**  
Do not set the referral-call extension to a telephone that covers to AUDIX. AUDIX could potentially overload with the volume of calls, because ACA calls remain active for up to three minutes.
- **Busy Verification**  
Once you have identified a potentially defective trunk, you can use Busy Verification to check it.
- **Centralized Attendant Services (CAS)**  
When CAS is activated, the referral-call destination must be on the local switch. The system interprets a referral destination of 0 as the local attendant, if one exists. The CAS attendant cannot activate or deactivate ACA referral calls at a branch location.
- **Distributed Communications System (DCS)**  
Referral calls may be placed across a DCS network. One switch (the primary) is administered to receive ACA referred calls from remote nodes for all switches within the network. You must administer the ACA Remote PBX Identification field on the Feature-Related System Parameters screen with the PBX ID of the node that is designated as primary.  
  
If ACA referral calls are sent off the switch that generates the referral, the display and voicing information indicating the failed trunk is lost, even if the referral call is made over a DCS network.
- **Night Service**  
Referral calls to the attendant are not placed if the system is in Night Service mode.

- Visually Impaired Attendant Service (VIAS)

If the attendant presses the Display Status button and an ACA call has not been answered, then the words Automatic Circuit Assurance are voiced.

If a visually-impaired attendant presses the Display Status button and the ACA call has been answered, then the words Automatic Circuit Assurance and the extension assigned to the ACA call are voiced.

If your switch contains a voice-synthesis board, ACA referral calls are accompanied by an audible message identifying the type of ACA infraction encountered. The message is “Automatic circuit assurance <long> or <short> holding time threshold has been exceeded for trunk group <#> member number <#>.”

- Voice Message Retrieval

If you use Voice Message Retrieval, you can assign a nondisplay telephone as a referral destination.

- Wideband Switching

ACA treats wideband-trunk calls as a single-trunk call and therefore triggers a single referral call. The call information shows the lowest B-channel trunk member associated with the wideband channel.

## Automatic customer telephone rearrangement

---

Automatic Customer Telephone Rearrangement (ACTR) allows a phone to be unplugged from one location and moved to a new location without additional switch administration. The switch automatically associates the extension to the new port. ACTR works with 6400 Serialized phones. The 6400 Serialized phone is stamped with the word “Serialized” on the faceplate for easy identification. The 6400 Serialized phone memory electronically stores its own part ID (comcode) and serial number. ACTR uses the stored information and associates the phone with new port when the phone is moved.

ACTR is an enhancement to TTI, PSA, Customer Telephone Activation (CTA). ACTR makes it easy to identify and move phones.

 **CAUTION:**

*When a phone is unplugged and moved to another physical location, the Emergency Location Extension field must be changed for that extension or the USA Automatic Location Identification data base must be manually updated. If the Emergency Location Extension field is not changed or if the USA Automatic Location Identification data base is not updated, the DID number sent to the Public Safety Network could send emergency response personnel to the wrong location.*

## Detailed description

---

On the Feature-Related System Parameters screen, set the Terminal Translation Initialization (TTI) Enabled field to **y** and the TTI State field to **voice**.

### ⇒ NOTE:

When a phone is moved, if there is any local auxiliary power (a power supply plugged into a local AC outlet), the phone must be plugged into an AC outlet at the phone's new location. A phone with remote auxiliary power must be supplied remote auxiliary power at its new location. If you do not supply auxiliary power in either case after a phone is moved, some optional adjuncts (for example, an expansion module) do not operate.

When you enter **always** or **once** in the Automatic Moves field on the station screen, the switch adds the extension to its ACTR Move List database. When the phone is plugged in, the switch asks the phone for its serial number and records the serial number on the ACTR Move List. If you change the entry in the Automatic Moves field from **always** or **once** to **no**, the switch removes the extension from the Move List.

## Call processing

When a phone is unplugged while on a call, and a 6400 Serialized phone that is administered for automatic moves is plugged into the port within 60 seconds:

- both extensions are placed in idle state
- active calls on either extension are dropped, unless the call is active on a bridged appearance at some other phone
- held calls remain in a hold state
- any calls ringing on either extension instantly proceed to the next point in coverage or station hunting path, unless the call is ringing on a bridged appearance at some other phone
- user actions that were pending when the new phone was plugged in are aborted

## Design considerations

---

You can use the **list station movable** command to keep track of extensions on the move list. Once you reach the maximum number, the switch does not allow additional extensions.

## Considerations

Unless you are careful, ACTR can get in the way of your troubleshooting of phone problems. Here is how to prevent that.

You can unplug a movable 6400 Serialized phone and plug in a maintenance replacement that does not have move permission. If you are able to place and receive calls from the replacement phone, the problem could be with the original phone.

To troubleshoot phone problems with a 6400 Serialized phone using ACTR, one movable phone and one unassigned phone of the same model:

1. Type **change station nnnn**, where **nnnn** is the extension of the 6400 Serialized phone that is not working and press RETURN.  
The Station screen appears.
2. Set the Automatic Moves field to **always** or **no** and press ENTER.
3. Unplug the phone.
4. In the same jack, plug in a phone that does not have move permission of the same model and series into the same jack.  
The switch treats the new phone as a maintenance replacement and does not change the extension and move list administration.
5. Try to place and receive calls from the new phone.

The first phone is the problem if the replacement phone works properly.

The circuit pack is the problem if the replacement phone works incorrectly and experiences the same problems as the first phone.

If you do not have an unassigned phone:

- Change the Automatic Moves field on the Station screen to **no** for the suspect phone and plug it into a different jack.
- Change the Automatic Moves field on the Station screen to **no** for a different phone, then plug it into the suspect jack.

Remember to change the field back when you are done, and reassociate the phone with CTA, TTI, or at the switch. If you try either test without changing the field, the extensions move to the new port.

## Interactions

### **Attendant Console**

If the attendant console is unplugged and another Digital Communications Protocol (DCP) phone with move permissions is plugged into the port, the new DCP phone's extension do not move to the port. The port keeps the attendant console's extension.

### **Backup Console**

Queue threshold warning tone signals every 10 seconds to certain stations. If the set is ACTR moved while the extension is receiving warning tone, or if it becomes eligible to receive the tone by the time it is plugged in, the tone sounds within 10 seconds of the phone being plugged into new port.

### **Distributed Communications Systems, Uniform Dial Plan**

ACTR is not transparent across switches in DCS or UDP. The extension number is not carried along when a phone is moved from one switch and plugged into a different switch.

### **Emergency Access to the Attendant**

If the emergency access redirection extension phone is unplugged and another DCP phone with move permissions is plugged into the port, the new DCP phone does not have dial tone. The DCP phone's extension does not move to the port. The port keeps the emergency access redirection extension.

### **Expert Agent Selection (EAS)**

If an ACTR move takes place, a logged-in EAS agent is automatically logged off.

### **Night Service**

If the night service phone is unplugged and another DCP phone with move permissions is plugged into the port, the new DCP phone does not have dial tone. The DCP phone's extension does not move to the port. The port keeps night service extension.

### **Outgoing trunk Queuing (automatic callback, ringback queuing)**

If a station ACTR moves before the callback occurs, the callback rings at the new port. If the extension is in x-port (still being moved), the outgoing call attempt is removed from the queue.

### **Person Station Access (PSA)**

If you use PSA to disassociate an extension that is on the move list, the extension stays on the move list, but the serial number for that set is removed the port is X-port.

If you use PSA to associate an extension with a new set, and the extension is on the move list, the serial number on the move list changes to the serial number for the new set.

If you use PSA to associate an extension with a non-ACTR phone the extension is removed from the move list.

### **Survivable Remote EPN (SREPN)**

An ACTR move made under PPN control is recorded in switch translations, but not in the SREPN and vice versa. Do not use ACTR when the switch is running under control of SREPN. SREPN records need to be updated to reflect any ACTR moves made on the PPN.

### **Terminal Self Administration (TSA)**

If a phone in TSA mode is unplugged and another DCP phone with move permissions is plugged into the port, the new DCP phone is idle, not in TSA mode.

### **Terminal Translation Initialization (TTI)**

You can administer an extension, port, or X-port, and add them to the move list, without a port assignment, or a physical phone connected to the port. If a non-serialized 6400 phone is later plugged into the port or associated with that extension, the extension is removed from the move list and the “Automatic Moves” field is set to no. If a 6400 Serialized phone is later associated with that extension that phone’s serial number and port are added to the move list for that extension.

### **Wan Spare Processor (WSP)**

An ACTR move made under processor port network (PPN) control is recorded in switch translations, but not in the WSP, and vice versa. Do not use ACTR when the switch is running under control of WSP. WSP records need to be updated to reflect any ACTR moves made on the PPN.

## **Automatic number identification**

---

### **Inband Automatic Number Identification**

---

Your switch uses Inband Automatic Number Identification (ANI) to interpret calling party information, such as a calling party number or a billing number.

Inband signaling is when information such as the address digits for the called party is delivered over the same trunk circuit used for the voice or data connection. (Out-of-band or ISDN signaling is when signaling information passes through a different signaling path than the one used for the voice or data connection.)

When a call is made from 555-3800 to your display phone at 81120, and the Incoming Tone (DTMF) ANI field is set to **\*ANI\*DNIS\***, your trunk group receives **\*5553800\*81120\***. If the field is set to **ANI\*DNIS\***, your trunk group receives **5553800\*81120\***. In both cases, *Call From 555-3800* appears on your display.

If you do not use Inband ANI, the incoming trunk group name appears on your phone display.

### **Related topics**

---

See [“Trunk Group” on page 1233](#) for information about setting Inband ANI on the trunk group screen.

### **Outgoing Automatic Number Identification**

---

Outgoing ANI applies to outgoing Russian multi-frequency (MF) ANI, R2-MFC ANI and Spain Multi Frequency Espana (MFE) ANI trunks only.

Use Outgoing ANI to specify the type of ANI to send on outgoing calls. You can define MF ANI (the calling party number, sent via multi-frequency signaling) prefixes by COR. This allows a switch to send different ANIs to different central offices.

For a tandem call that uses different types of incoming and outgoing trunks, the switch uses:

- the incoming trunk's COR -assigned call type for Russian or R2-MFC outgoing trunks
- ARS call types for MFE outgoing trunks

## Interactions

---

- **Attendant Console**

If an attendant extends a call, the attendant's COR is used to select ANI.
- **Authorization Codes**

The authorization code COR is not used to select the ANI. The extension's ANI is used if an extension originates the call, and the ANI for the switch is used if the originating endpoint is an incoming trunk.
- **Bridged Call Appearance**

A call from a bridged call appearance uses the ANI of the primary extension.
- **Call Vectoring**

The ANI of the originating party is used, not the ANI of the call vector, when a call vectoring route-to command routes a call over an outgoing trunk.
- **Distributed Communications System (DCS)**

In a DCS, the ANI sent to the CO is determined by the ANI for PBX on PBX\_B, but the category sent to the CO is determined by the Category for MF ANI field on the Class of Restriction screen for the incoming DCS trunk or by the type of call.
- **Expert Agent Selection (EAS)**

The EAS agent's login extension and COR is used to determine ANI.
- **Hunt Groups and Automatic Call Distribution (ACD) Splits**

The phone's extension and COR is used to determine ANI for a hunt group or ACD split.
- **Multimedia Call Handling (MMCH)**

For call origination, multimedia complexes use the COR assigned to their phones.
- **Personal Station Access (PSA)**

For ANI, the PSA extension and COR overrides the phone's extension and COR.
- **Remote Access**

A remote access barrier code COR is not used for ANI. The extension's ANI is used if an extension originates the call, and the ANI for the switch is used if the originating endpoint is an incoming trunk.

## **Related topics**

---

See [“Displaying ANI calling party information” on page 181](#) for instructions on setting up ANI display in the U.S.

See [“Multifrequency signaling” on page 1772](#) for more information on signaling.

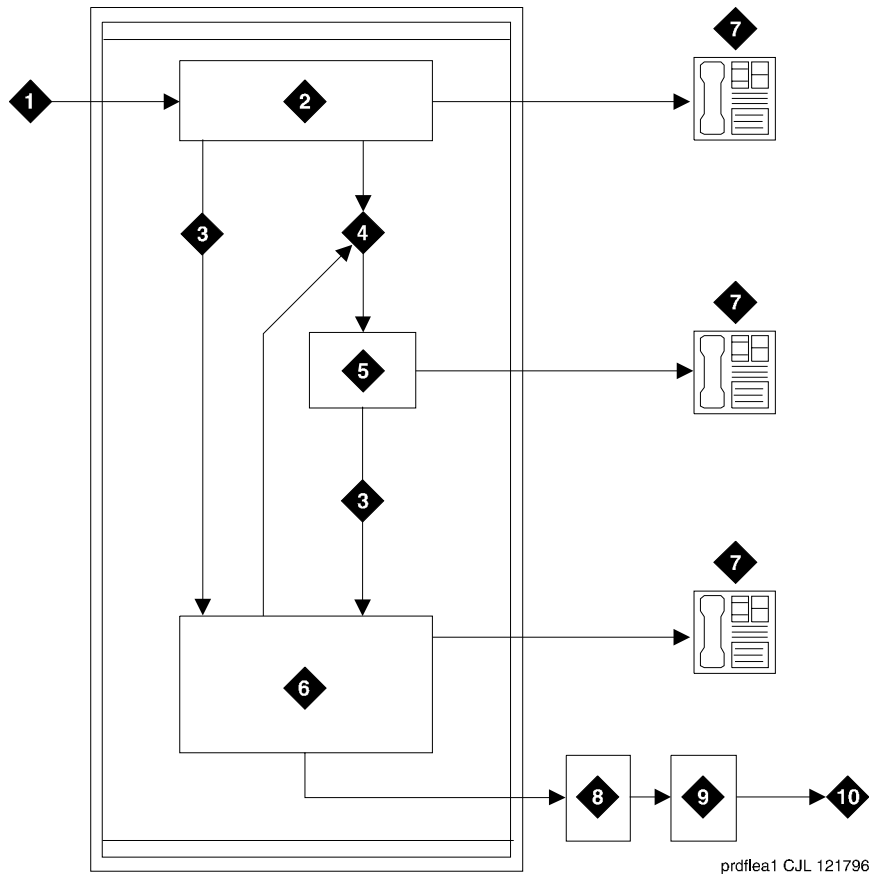

See [“CLAN and processor CLAN QoS and CIDR support” on page 1637](#) for more information on Class of Restriction.

## **Automatic routing — general**

---

MultiVantage automatically routes outgoing calls using the most preferred (normally the least expensive) route available at the time the call is placed. Generally, AAR routes calls over a private network and ARS routes calls using the public network numbering plan. However, both AAR and ARS support public and private networks.

[Figure 57](#) shows you an overview of automatic routing.

**Figure 57. Automatic Routing**

## AAR

---

AAR routes calls over private networks. When a user dials the AAR feature access code (normally 8 in North America) and phone number, AAR selects the least expensive route for the call in the private network and performs any digit conversion. If the first-choice route is not available, another route is chosen automatically.

AAR routes private-network numbers, public-network numbers, service codes, an international number, operator access code, or an operator-assisted dialing number. AAR routes calls route as far as possible over the private network, and then accesses the public network. This saves long-distance charges and allows you to use your private network as much as possible.

## ARS

---

ARS routes calls over the public network. When a user dials the ARS feature access code (normally 9 in the US and 0 outside of the US) and phone number, ARS selects the least expensive route for the call when there are one or more long-distance carriers or services.

ARS, like AAR, routes private-network numbers, public-network numbers, service codes, an international number, operator access code, or an operator-assisted dialing number, and also routes to Inter-exchange carriers (IXC). These are your long-distance providers.

You can route ARS calls to a variety of types of public-network and private-network trunk groups including CO, FX, ISDN, Tie, and WATS. See [“Managing trunks” on page 411](#) for more information.

### **AAR and ARS digit analysis default translations**

Your switch contains built-in AAR and ARS Digit Analysis Default Translations. These default translations are used for call processing whether or not AAR or ARS is enabled on your switch.

Any 7-digit dialed string that begins with any number 2 through 9 is processed as an AAR call. Exceptions are listed in the ARS Digit Analysis Default Translations Table. The translations shown on the [ARS digit analysis default translations](#) table are displayed in sorted order (including additions) on each of the 8 possible ARS Digit Analysis Tables.

**⇒ NOTE:**

For service outside of North America, these defaults should be deleted. You can delete the defaults by entering **change ARS analysis 0**. Then use spaces to blank out all of the Dialed String entries.

**Table 19. ARS digit analysis default translations**

| Total Digits  |      |      |               |           |
|---------------|------|------|---------------|-----------|
| Dialed String | Min. | Max. | Route Pattern | Call Type |
| 0             | 1    | 1    | deny          | op        |
| 0             | 8    | 8    | deny          | op        |
| 0             | 11   | 11   | deny          | op        |
| 00            | 2    | 2    | deny          | op        |
| 01            | 9    | 17   | deny          | iop       |

| 911           | 3    | 3    | 1             | svc       |
| 976           | 7    | 7    | deny          | hnpa      |
| N             | 7    | 7    | 2             | hnpa      |

*Continued on next page*

**Table 19. ARS digit analysis default translations (Continued)**

| Dialed String | Total Digits |      | Route Pattern | Call Type |
|---------------|--------------|------|---------------|-----------|
|               | Min.         | Max. |               |           |
| 1N00          | 11           | 11   | deny          | fnpa      |
| 1NX           | 11           | 11   | deny          | fnpa      |

Legend:

N - 2 through 9

X - any digit (0 - 9)

deny - deny

fnpa - foreign number plan area (10-digit call)

hnpa - home number plan area (7-digit call)

intl - international

iop - international operator

op - operator

svc - service

## Trunking facilities

MultiVantage can serve as an electronic tandem network (ETN). An ETN is a network of privately-owned trunk and switching facilities that provide a cost-effective alternative to long-distance calling between locations. Each switching facility in an ETN has a unique private-network office code consisting of 1–8 digits.

Traveling Class Marks (TCM) represent the caller's Facility Restriction Level (FRL) or the FRL of the caller's access trunk group, and are sent with AAR and ARS numbers sent on ETNs.

## Routing with ISDN and overlap sending

You can turn on overlap sending to work on AAR and ARS calls that are routed over ISDN trunk groups. Overlap sending sends ISDN call-address information one digit at a time instead of all the address information going out in one block. This significantly decreases call setup time in countries with complex public-network numbering plans, and is most useful for tandemed calls. See ISDN-PRI Trunk Group and ISDN-BRI Trunk group screens for information on how to set up overlap sending.

## Interactions

---

- Abbreviated Dialing

The switch does not check the FRL on an AAR or ARS call that uses a privileged Abbreviated Dialing Group List.

## Barrier codes

---

A barrier code is a security code used with Remote Access to prevent unauthorized access to your system.

## Brief description

---

Each barrier code must have a COR and Class of Service (COS) assigned. Remote Access has inherent risks; it can lead to large-scale unauthorized long-distance use. To increase your system's security use a 7-digit barrier code with Remote Access Barrier Code Aging. You can administer Remote Access Barrier Code Aging to:

- Limit the length of time an access code remains valid and/or
- Limit the number of times an access code can be used

A barrier code automatically expires if an expiration date or number of accesses has exceeded the limits you set. If both a time interval and access limits are administered for a barrier code, the barrier code expires when one of the conditions is satisfied.

You determine the barrier code length, the actual barrier code, and the barrier code expiration date on the Remote Access screen. You must administer expiration dates and access limits for each of the possible 10 barrier codes. If your system has more than 10 Remote Access users, they must share codes.

When you no longer need a barrier code, remove it from the system. Barrier codes should be safeguarded both by you and their users. If you use barrier codes for outside calls, change them often.

If barrier codes are administered, a special answer-back tone causes a calling modem to leave dial mode. A modem's dialer is sometimes used to gain access (this tone also cancels echo suppressors in the network, preventing dual-tone multifrequency (DTMF) tones from breaking dial tone from a switch). Barrier codes can be used alone or with authorization codes.

Use the **status remote-access** command to view the status of a Remote Access barrier code.

**⇒ NOTE:**

Barrier codes are *not* tracked by CDR. Barrier codes are incoming access codes, whereas, authorization codes are primarily outgoing access codes.

See [“Remote Access” on page 1800](#) for more information.

## **Bridged call appearance**

---

Bridged Call Appearance allows single-line and multiappearance telephone users to have an appearance of another user's primary extension number. The bridged call appearance can be used to originate, answer, and bridge onto calls to or from the other user's primary extension number.

An appearance of a telephone's primary extension number at another telephone is called a bridged call appearance. A bridged call appearance can be used to originate, answer, or bridge onto an existing call to or from the primary telephone user's extension number. A virtual extension cannot be a bridged call appearance.

On single-line telephones, Bridged Call Appearance is used by going off-hook. On multiappearance telephones, Bridged Call Appearance is used by going off-hook and pressing the bridged appearance button. In both cases, the user is then bridged onto the primary telephone's extension number and can handle calls on that extension number.

An incoming call rings the primary extension number's telephone and all telephones that have a bridged call appearance of the telephone's primary extension number. Each telephone is visually alerted for all bridged appearances on the telephone, but has the option of audible ringing.

On multiappearance telephones, a bridged call appearance can be assigned to any 2-lamp button. It does not require the use of a regular call appearance.

A bridged call appearance can be used just like a regular call appearance for most features. For example, Conference, Transfer, Hold, Drop, and Priority Calling can be used from a bridged appearance, just as they are used from a regular call appearance.

You can administer a telephone with zero call appearances of its primary extension. In this way, a telephone can be administered to have only bridged appearances.

### **Extension administrable buttons and lamps for multiappearance telephones**

You can administer the message lamp and some feature buttons to apply to a specified extension rather than the extension of the telephone they reside on.

- You can administer the message lamp to light when messages are waiting for the extension specified on the Station screen. In this way, the bridged user's telephone can be set up to indicate when messages are waiting for the primary extension.
- You can administer the call forwarding all calls and call forwarding busy/don't answer buttons to activate Call Forwarding for any extension that is on the telephone, even if this extension is a bridged appearance. In addition, you can administer the lamp associated with the call forwarding button to track the call forwarding status of any extension. In this way, a bridged user can activate or deactivate Call Forwarding for all primary and bridged appearances of the extension from the bridged appearance telephone, and the bridged appearance telephone shows the call forwarding status of the specified extension.
- You can administer the send all calls button to activate Send All Calls for any administered extension. The lamp associated with Send All Calls tracks the status of the administered extension. In this way, a bridged user can activate Send All Calls for the primary extension user.

## **Considerations for single-line telephones**

---

- The number of bridged call appearances allowed varies by system. See *Avaya MultiVantage™ Solutions Hardware Guide* for those numbers. A bridging user cannot have more than one bridged appearance for a particular primary telephone. However, a multiappearance bridging user can have appearances of more than one analog telephone on their telephone (a multiappearance bridging user, by use of different buttons, can bridge onto several different primary telephones).
- The number of bridged appearances allowed on a multiappearance bridging user's telephone is limited only by the number of 2-lamp buttons available on the telephone.
- If the primary single-line telephone is correctly administered, but not in service, calls can still be placed by the bridging users, and received on the bridged appearances of the telephone. The primary telephone can be out of service for several reasons, such as an unplugged telephone, a nonexistent telephone system technician busyout command, etc.
- If more than one user goes off-hook on a bridged appearance at the same time, only the user who was the first to go off-hook can dial.
- If a bridging user is not active on a call, and bridges onto the appearance of an active call, the user is bridged onto the active call. If a multiappearance bridging user is active on a call, and bridges onto the appearance of an active call, the previously selected call is dropped and the user is bridged onto the active call.
- The Privacy-Manual Exclusion feature can be activated by the bridging user only, while active on a call, to prevent accidental bridging of an active call.
- If a call terminates at a telephone on an extension number other than the primary extension number (for example, terminating extension group (TEG), UCD group, call coverage answer group, or DDC group extension number), a bridged call appearance is not maintained. Therefore, the primary telephone should not be made a member of such a group (even though administration of this is not prohibited).
- The Bridged Call Appearance feature should not be considered as a replacement for Call Coverage or any other similar features.
- If two parties are bridged together on an active call with a third party, and if the conference tone feature is enabled, conference tone is heard.

## **Considerations for multiappearance telephones**

- The number of bridged call appearances allowed at each telephone is limited only by the number of 2-lamp buttons available on the telephone. The number of appearances per primary extension varies by system. See *Avaya MultiVantage™ Solutions Hardware Guide* for this information.
- Up to six parties can be off-hook and involved in a conversation on a bridged appearance of an extension.
- A bridging telephone should have a bridged call appearance corresponding to each call appearance of the primary extension number at the bridged telephone. For example, if a primary telephone has three call appearances, a bridging telephone should have three bridged call appearances of that primary extension. This allows users to refer to the individual call appearances when talking about a specific call.
- Bridged call appearances may result in the reduction of available feature buttons, thereby reducing a user's capabilities. A Call Coverage module or expansion module can be used to provide up to 20 bridged call appearances. This leaves the other 2-lamp buttons as call appearances, or with other features such as Centralized Attendant Service (CAS).
- If a call terminates at a telephone on an extension number other than the primary extension number (for example, TEG, UCD group, call coverage answer group, or DDC group extension number), a bridged call appearance is not maintained. Therefore, the primary telephone should not be made a member of such a group (even though administration of this is not prohibited).
- Bridged Call Appearance should not be considered a replacement for Call Coverage.
- You can administer conference tone, which, when enabled, is heard when two parties are bridged together on an active call with a third party.

## **Interactions**

- **Abbreviated Dialing**

A user, accessing Abbreviated Dialing while on a bridged call appearance, accesses their own Abbreviated Dialing lists. The user does not access the Abbreviated Dialing lists of the primary extension associated with the bridged call appearance.

A user cannot use an abbreviated dialing feature access code (FAC) after using a priority calling FAC.

- Adjunct Switch Applications Interface (ASAI)

If you are using ASAI, do not administer more than 16 bridged appearances.

- Attendant Display and telephone Display

A call from the primary extension number or from a bridged call appearance of the primary extension number is displayed as a call from the primary extension number (the call is displayed as coming from the primary extension number regardless of which appearance placed the call).

On multiappearance telephones, the display at a principal shows the same information for a bridged call appearance as it does for a nonbridged call. For calls to the principal's extension number, the display at a zero call appearance bridging telephone shows a call from the originator to the principal with no "redirection reason" character. As telephones bridge onto the call, the display updates to show the number of parties in the conference.

- Automatic Call Distribution (ACD)

Bridged appearances cannot be accessed via non-ACD hunt groups (although administrable).

- Automatic Callback

Automatic Callback calls cannot originate from a bridged call appearance. However, when Automatic Callback is activated from the principal user's telephone, the callback call rings (with priority call distinctive ringing signal) at all bridged appearances of the extension as well as at the principal user's telephone. Displays at all telephones (principal and bridged users) show that it is a callback call.

- Busy Indicator (multiappearance telephones only)

The call is placed to the resource from the first available bridged call appearance for zero primary call appearance telephones.

- Call Coverage

- Single-line telephones

When an analog telephone is administered as a bridged call appearance, the telephone user cannot invoke Send All Calls for the extension of their telephone. The user does not have a send all calls button, and the call appearance is associated with another extension. When the user dials a FAC, Send All Calls is activated for the extension associated with the call appearance.

— Multiappearance telephones

Coverage criteria for bridged call appearances is based entirely on the criteria of the primary extension associated with bridged appearance. A call to the primary extension that requires call coverage treatment follows the coverage path of the primary extension and not the path of any of the bridged appearances. Bridged call appearances do not receive redirection notification.

A user with bridged call appearances can activate or deactivate Send All Calls for a principal's primary call appearance if they are on the bridged appearance.

The primary telephone should not be a member of a call coverage group, because calls to the primary telephone as a member of the group are not bridged.

You can administer the system so that a call can appear at a telephone as both a bridged call and a redirected call. In this way, if the bridged user is the first coverage point, the call redirects to that telephone when the coverage criteria are met.

If the principal is an analog telephone with a bridged call appearance on a multiappearance telephone, an incoming call to the analog telephone that goes to coverage terminates at a primary call appearance on the bridging user's telephone as a coverage call. If the bridging user is a zero primary call appearance telephone, the call cannot redirect to the bridging user since there are no primary call appearances. Therefore, the call redirects to the next available coverage point.

■ Call Detail Recording (CDR)

If a bridging user originates or answers a call on a bridged appearance, the extension of the bridge is recorded as the calling/called telephone. A conference or transfer by a bridging user also appears as though it was performed by the telephone user.

On multiappearance telephones, when a call originated from a bridged call appearance on a telephone administered for zero primary call appearance is recorded by CDR, the extension number associated with the appearance is recorded as the calling party. A conference or transfer by a bridged call appearance on a zero primary call appearances telephone also appears as though it were performed by the extension associated with the appearance.

- Call Forwarding All Calls, Call Forward Busy/Don't Answer

Call Forwarding can be activated or canceled for the primary extension number from any bridged call appearance of that number. When activated, calls to the primary extension number do not terminate at the bridged call appearances, but go to the designated forwarding destination. Bridged call appearances do not receive redirection notification of the call to the primary extension when it is forwarded unless Ringing — Abbreviated and Delayed is administered.

- Call Park

When a call is parked from a bridged call appearance, it is parked on the primary extension number.

- Call Pickup

- Single-line telephones

Calls to the primary telephone, alerting at bridged appearances of the primary telephone, can be picked up by member's of the bridging user's call pickup group. This causes all bridged appearances of the call to be dropped.

Calls ringing at a primary telephone can be picked up by members of the primary telephone's call pickup group. However, if the primary telephone and the bridging user's telephone are not in the same call pickup group, the bridging user cannot pick up calls to other members of the primary telephone's call pickup group.

Originating on a bridged appearance and dialing the call pickup FAC is interpreted as an attempt to pick up a call from the primary telephone's call pickup group.

A bridging user can use Call Pickup to pick up a call that is alerting at a bridged appearance, instead of selecting the bridged appearance button. This causes the call at the primary telephone and all bridged appearances of the call to be dropped.

If the bridging user has appearances of numerous single-line (primary) telephones (for example, sales, service, and warehouse), and it is not desired that the calls be answered by anyone other than the primary telephone user or the bridging users, the bridging user(s) should not be assigned to a pick up group.

— Multiappearance telephones

If a telephone receives ringing on a bridged call appearance, the incoming call can be picked up by members of that telephone's call pickup group. This causes all bridged call appearances to be dropped. Calls ringing at a primary telephone can be picked up by members of the telephone's call pickup group. However, if the primary telephone and the bridging user's primary telephone are not in the same call pickup group, the bridging user cannot pick up calls to other members of the primary telephone's call pickup group.

Originating on a bridged appearance and dialing the call pickup FAC is interpreted as an attempt to pick up a call from the primary telephone's call pickup group.

A bridging user can use Call Pickup to pick up a call that is alerting at a bridged appearance, instead of selecting the bridged appearance button. This causes the call to terminate on the bridging user's primary extension button, and the primary telephone and all bridged appearances of the call are dropped.

If the bridging user has appearances of numerous telephones (for example, sales, service, and warehouse), and it is not desired that the calls be answered by anyone other than the telephone user or the bridging users, the bridging users should not be assigned to a pickup group.

A telephone with zero primary call appearances can be assigned to a call pickup group.

- Call Waiting Termination (single-line telephones only)

Call Waiting Termination applies only to an active call on the primary telephone that has no one else bridged on. If one or more bridging users are active on a call, call waiting calls are denied whether or not the primary user is also off-hook on the call. A bridging user can bridge onto a call with the primary user if there is also a call waiting.

- Class of Restriction (multiappearance telephone users only)

The COR assigned to a telephone's primary extension also applies to calls originated from a bridged call appearance.

- Conference — Attendant, Conference

- Single-line telephones

A bridged call cannot be conferenced if more than one user is active on that call. This is because the bridging user has no access to the call after the primary telephone user places the call on soft hold, and the primary telephone user has no access to the bridging user's call appearance used for conference/transfer attempts.

If a bridging user is active on a bridged call and the primary analog telephone user attempts a conference, the attempt is ignored. The same is true if an analog bridging user attempts a conference when the primary telephone user and another bridging user is active on a call.

When the primary telephone user is active on a call, and no other bridging user is active on the call, that call can be placed on hold by the primary telephone user utilizing normal single-line conference procedures. Any attempt by a bridging user to bridge onto the call during a successful conference attempt is denied.

A bridging user, alone on a bridged call, can conference the call utilizing the normal multiappearance telephone conference procedures. Any attempt by the analog primary telephone user to bridge onto the call during a successful conference attempt is ignored. Any attempt by other bridging users is denied (standard denial response is returned to the bridged appearance).

If a conference is not allowed because of the preceding limitations, the user can accomplish a transfer by asking an internal nonbridged party in the connection to create the conference, or asking the remaining bridging users and primary user to disconnect so that the conference can be completed. At completion of the conference, the parties that left the call can reenter the call if control of the conference remains with the primary telephone. If control of the conference does not remain with the primary telephone, the bridging user must conference the primary telephone and the bridging user back into the call as required.

If the bridging user has no other available bridged appearances of the primary extension (other than the one he or she is currently on), the bridging user, after pressing the conference/transfer button, must select a call appearance to be used for the conference, before dialing the number.

— Multiappearance telephones

Call Waiting Termination applies only to an active call on the primary telephone that has no one else bridged on. If one or more bridging users are active on a call, Call Waiting calls are denied whether or not the primary user is also off-hook on the call. A bridging user cannot bridge onto a call with the primary user if there is also a call waiting.

Conferences can be set up on bridged appearances using the usual conference operations. Either a primary extension button or a bridged appearance button can be used to make the calls for adding to the conference.

You can administer the system to automatically select the first idle appearance if there is no idle appearance with an extension matching the extension that is conferencing the call.

When the user presses the conference button (the second time) to connect the parties together, the newly formed conference call appears on the primary or bridged appearance to which the user was connected at the time of that last conference button depression. The other appearance is disassociated from the conference call.

Therefore, if the original call is on a bridged appearance, and the conference is formed on an appearance of the bridged user's own primary extension, the bridged extension becomes disassociated from the conference call and the principal user of that bridged extension can no longer bridge onto the conference.

This disassociation of the conference from the bridged extension can be avoided by setting up the conference in the opposite order. To do this, the user:

1. Presses the hold button to hold the original call on the bridged appearance
2. Selects a call appearance and calls the party to be added
3. Presses the conference or transfer button
4. Selects the held bridged appearance
5. Presses the conference button (again)

When this procedure is used, the conference is formed on the bridged appearance so that the primary user of the bridged extension can still bridge onto the conference call.

If the primary user and the bridged user are both on the call when one user transfers the call, the user performing the transfer becomes the controlling user for the participation of both users on the conference. To disassociate the appearance from the call, the controlling user must be the latter of the two users to hang up from the call. If the controlling user hangs up first, the appearance goes on soft hold when the noncontrolling party hangs up. In this case, one of two things must occur to disassociate the appearance from the call: all other parties on the call hang up, or the controlling user rejoins the call and hangs up again.

The display shows the number of other active parties in a call, including active bridged appearances.

- Consult (multiappearance telephones only)

Bridged call appearances of the primary extension do not ring on a consult call to the primary extension.

- Coverage Answer Group

- Single-line telephones

The primary (analog) telephone is not a member of a call coverage answer group, because calls to the primary telephone as a member of the group *are not bridged*.

If the primary telephone is made a member of a coverage group, coverage criteria is based entirely on the criteria of the primary telephone. This means that a call to the primary telephone that requires call coverage treatment follows the path of the primary telephone and not the path of any of the telephones with bridged appearances of the primary telephones. In this case, it is desirable to have the bridging user in the coverage path of the primary telephone. Then, when a call to the primary telephone requires coverage treatment, it follows the coverage path to the bridging user's telephone, call appearances of the call are dropped, and the call terminates at the bridging user's telephone as a coverage call.

- Multiappearance telephones

Bridged call appearances of a primary extension do not ring when there is a Coverage Answer Group (CAG) call to the primary extension. Bridged call appearances cannot bridge onto the call.

- Data Privacy, Data Restriction

When Data Privacy is activated or Data Restriction is assigned to a telephone involved in a bridged call and the primary telephone and/or bridging user attempts to bridge onto the call, Data Privacy and Data Restriction are automatically overridden (or deactivated in the case of Data Privacy).

- Emergency calls

If a user dials an emergency call from a bridged appearance, the Calling Party Number that is sent to the public safety answering point for US E911 location is the bridged extension, not the extension of the physical phone from which the call is made. If the physical phone is located far from the phone to which it is bridged, the emergency response team may not be able to locate the caller. It is preferable to place E911 calls from an actual call appearance, rather than a bridged appearance.

- Hold — Automatic

- Single-line telephones

A call cannot be put on hold if more than one user is active on that call.

The primary telephone user, when no other bridges are active on the call, can put the call on hold, using normal single-line hold procedures. If the primary telephone user successfully soft holds the call, the status lamp at all of the bridged appearances shows the hold indication; and then the call can be put on hard hold by dialing the hard hold FAC. The hard held call is no longer accessible to the bridging users until it is taken off hold by the primary telephone user. After the call is put on hard hold, any new call to the primary telephone is tracked by the bridged appearances.

A bridging user can place an active call on hold (if the primary telephone or any other bridges are not active on the call) by using normal multiappearance hold procedures. Any attempt to enter the held call returns it to the status of an active call that can then be accessed using bridging procedures.

If hold is not allowed because of the preceding reasons, the user can just go on-hook and then reenter the call as required, because the call remains accessible as long as the primary telephone or any bridging user is active on it.

- Multiappearance telephones

Any user (primary or bridged appearance) can place an active call on hold. If only one user is active on a call and places that call on hold, the indicator lamp at both the principal's appearance button and the bridged party's appearance button shows that the call is on hold. If more than one user is bridged onto the active call, and one of the users activates Hold, the activator receives "hold" indication for the call and status lamp of all other bridged users remains active.

- **Hotline Service (single-line telephones)**

If a single-line telephone is administered for Hotline Service, bridged appearances of that telephone's extension also places a hot line call automatically when a user goes off-hook on that bridged appearance.

- **Hunt Group (DDC or UCD)**

Bridged call appearances cannot be used in conjunction with DDC or UCD hunt groups.

Although you can assign a bridged extension to a hunt group, Avaya does not recommend such assignment because DDC/UCD calls do not terminate at any bridged appearances of that extension on other telephones.

- **Intercom — Automatic and Intercom — Dial (multiappearance telephones only)**

Bridged appearances of a primary extension number are not rung for intercom calls. Furthermore, if a telephone has no primary call appearances it can never be rung for an intercom call. Therefore, if a secretary is screening all calls for the principal, and is indicating who is calling via intercom, the principal must have a call appearance on which to receive and send intercom calls.

- **Internal Automatic Answer (IAA)**

Calls terminating to a bridged appearance of an IAA-eligible telephone are not eligible for IAA.

- **Last Number Dialed (LND)**

Activation of the LND feature causes the last number dialed from the activating telephone to be redialed, regardless of the extension number used (primary or bridged call appearance).

- **Leave Word Calling (LWC)**

A LWC message left by a user on a bridged call appearance leaves a message for the called party to call the primary extension number assigned to the bridged call appearance.

When a user calls a primary extension, and activates LWC, the message is left for the primary extension, even if the call was answered at a bridged call appearance.

LWC messages left by the primary user can be canceled by a bridged appearance user (for example, a secretary can cancel a LWC message left by a boss).

- Personal Central Office Line

- Single-line telephones

- A single-line primary telephone cannot be a member of a Personal Central Office Line (PCOL) group.

- Multiappearance telephones

- If a user is active on his or her primary extension number on a PCOL call, bridged call appearances of that extension number cannot be used to bridge onto the call. The call can only be bridged onto the call if another telephone is a member of the same PCOL group and has a PCOL button.

- Preference

- Ring Line Preference selects an alerting bridged appearance; Idle Line Preference does not.

- Priority Calling

- The primary telephone user or the bridging user can make a priority call. If a priority call is made to an idle telephone, the primary telephone and all bridging users are alerted by priority alerting.

- A user cannot use an abbreviated dialing FAC after using a priority calling FAC.

- Privacy-Manual Exclusion

- Exclusion prevents any other user from bridging onto the call. Activation of exclusion by any user (primary or bridged appearance) before placing a call, prevents any other user from bridging onto the call. Activation of exclusion by any user active on a call, while the primary user and/or any other bridging users are active on the call, drops all other users from the call (including the primary user), leaving only the activator and the calling/called party on the call.

- Redirection Notification (multiappearance telephones only)

- Redirection Notification is not provided at telephones with a bridged appearance of a primary extension number unless Ringing — Abbreviated and Delayed is administered to give notification.

- Ringback Queuing

- Ringback Queuing is not provided on calls originated from a bridged call appearance. However, after the principal user of the bridged extension has activated Ringback Queuing, the resulting callback call alerts at bridged appearances as well as at the principal user's telephone. The call can be answered from the primary user's telephone or from any bridged appearance.

- Ringer Cutoff (multiappearance telephones only)

Ringer Cutoff prevents any nonpriority (or nonintercom) incoming call from ringing at that telephone. This is independent of whether the call is to the telephone's primary extension or to any of the bridged appearance's extensions.

- Ringing — Abbreviated and Delayed

See Ringing — Abbreviated and Delayed, for other bridged appearance alerting options.

- Service Observing

The telephone user or bridging user can bridge onto a service observed call at any time. If the telephone is being service observed and an incoming call is answered by the bridging user, the call is not observed unless or until the telephone user bridges onto the call. Conversely, if the bridging user is being service observed and an incoming call is answered by the telephone user, the call is not observed unless or until the bridging user bridges onto the call.

If the bridging user activates Service Observing using a bridged appearance, Service Observing is activated for the bridging user.

- Terminating Extension Group (TEG)

TEG calls to the primary extension do not ring at the associated bridged appearances. TEG calls cannot be answered or bridged onto from a bridged appearance of the TEG member's primary extension. The primary telephone should not be assigned to a TEG.

- Transfer

- Single-line telephones

A call cannot be transferred by an analog telephone if more than one user is active on that call.

The primary telephone user, when no other bridges are active on the call, can transfer the call using normal single-line transfer procedures. Any attempt by a bridging user to bridge onto this call during a successful transfer attempt is denied (a standard denial response is returned to the bridged appearance).

An analog bridging user, alone on a bridged call, can transfer the call, using normal transfer procedures. Any attempt by the primary telephone user to bridge onto this call during a successful transfer attempt is ignored; and any attempt to bridge on by a bridging user is denied.

If the bridging user has no other available bridged appearances of the primary extension (other than the one he or she is currently on), the bridging user, after pressing the conference/transfer button, must select a call appearance to be used for the transfer, before dialing the number.

- **Multiappearance telephones**

If the bridging user has at least one available bridged appearance of the primary extension (other than the one he or she is currently on), the system automatically selects a bridged call appearance for the transfer when the conference/transfer button is pressed.

You can administer the system to automatically select the first idle appearance if there is no idle appearance with an extension matching the extension that is transferring the call.

If the primary user and the bridged user are both on the call when one user transfers the call, the user performing the transfer becomes the controlling user for the participation of both users on the conference. The controlling user is immediately dropped from the call. When the noncontrolling user hangs up, the appearance goes on soft hold. In this case, one of two things must occur to disassociate the appearance from the call: all other parties on the call hang up, or the controlling user rejoins the call and hangs up again.

- **Videophone 2500 (single-line telephones)**

A user may not use an analog bridge to a Videophone 2500 principal that is on a video call.

- **Voice Message Retrieval**

A voice message to the primary extension can be retrieved on a bridged appearance by the bridged appearance user. If a security code is required to retrieve the message, the bridging user must use the security code of the primary telephone.

- **Voice Paging**

The use of Voice Paging automatically invokes exclusion. Therefore, interactions for this feature are the same as for Privacy-Manual Exclusion.

## **Busy indicator**

---

The Busy Indicator button provides multiappearance telephone users and attendants with a visual indicator of the busy or idle status of one of the following system resources:

- An extension number
- A trunk group
- A terminating extension group
- A hunt group—either DDC or UCD
- Any loudspeaker paging zone, including all zones

The Busy Indicator button provides the attendant or user with direct access to the extension number, trunk group, or paging zone.

You can assign extension numbers, trunk group access codes, and Loudspeaker Paging access codes to a Busy Indicator button.

The Facility Busy lamp indication for a VDN does not light when the VDN is being used. The associated button may be used to place a call to a VDN.

## **Busy tone disconnect**

---

In some regions of the world the CO sends a busy tone for the disconnect message. With Busy Tone Disconnect (BTD), the switch disconnects analog loop-start CO trunks when a busy tone is sent from the CO.

A call that is originated from or terminated to a phone using a BTD enabled trunk has a Call Classifier port connected to the trunk. The Classifier port connects, then the call is answered and stays connected on the trunk until the station hangs up or a BTD signal is received from the CO. If there is only one BTD trunk on a call when the BTD signal is received, the call is dropped. If it is a conference call, only the trunk is dropped and the rest of the parties stay connected.

## **Interactions**

---

- Answer supervision

If Answer supervision is enabled, set the Answer supervision timeout field to **0** (zero).

## Busy verification

---

Busy Verification (Verify button) allows attendants and specified multiappearance telephone users to make test calls to trunks, telephones, and hunt DDC and UCD groups. Attendants and multiappearance telephone users can distinguish between a telephone that is truly busy and one that only appears busy because of some trouble condition. They can also use this feature to quickly identify faulty trunks.

An attendant or multiappearance telephone user can activate Busy Verify by pressing the Verify button. If they want to verify a telephone or hunt group, they enter an extension number. If they want to verify a trunk, they dial a trunk-access code, followed by the 2- or 3-digit number of the trunk-group member to be verified. If the trunk-group member number is less than 10, the system requires a leading zero (01 or 001 rather than 1).

### NOTE:

For DEFINITY SI or DEFINITY CSI, the member number is a 2-digit number; for DEFINITY R, the member number is a 3-digit number.

After an attendant or multiappearance telephone user has activated Busy Verification, the system checks the validity of the extension or trunk-access code and member number. If the number is not a telephone extension, DDC/UCD group-extension, ACD split number, or trunk access code with a valid member number, the system denies Verify and returns intercept tone.

When you use Verify to check a valid telephone extension (one that is in the dial plan and assigned to a telephone), the system initiates a priority call to that extension. [Table 20 on page 1523](#) describes the process.

**Table 20. Verification of a telephone**

| Telephone Status                                                                  | System Response                                                                                                                                                                                                                           | Result                                                                                                                                                    |
|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Idle                                                                              | <ul style="list-style-type: none"> <li>■ Generates priority ringing at the telephone</li> <li>■ Processes the call as a normal telephone-originated or attendant-originated call</li> </ul>                                               | <ul style="list-style-type: none"> <li>■ Verification is complete.</li> <li>■ Anyone can place a call to the telephone.</li> </ul>                        |
| Active on a call and has an idle call appearance                                  | <ul style="list-style-type: none"> <li>■ Generates priority ringing at the first idle appearance</li> <li>■ Processes the call as a normal attendant-originated call</li> </ul>                                                           | <ul style="list-style-type: none"> <li>■ Verification is complete.</li> <li>■ Anyone can place a call to the telephone extension.</li> </ul>              |
| Active on a call and has no idle call appearances or has only one line appearance | <ul style="list-style-type: none"> <li>■ Bridges the attendant onto the call</li> <li>■ Generates a warning tone to all active parties and repeats the tone every 15 seconds while the attendant remains bridged onto the call</li> </ul> | <ul style="list-style-type: none"> <li>■ Verification is complete.</li> <li>■ The attendant can determine if the telephone is actually in use.</li> </ul> |
| Out of service                                                                    | <ul style="list-style-type: none"> <li>■ Generates reorder tone</li> </ul>                                                                                                                                                                | <ul style="list-style-type: none"> <li>■ Verification is denied.</li> </ul>                                                                               |

When you use Verify to check a valid ACD split, UCD group, or DDC group, the system initiates a priority call to that group. (Valid in this case means the split or group is translated and at least one member is logged in.) [Table 21 on page 1524](#) describes the process.

**Table 21. Verification of an ACD Split, UCD Group, or DDC Group**

| <b>Split or Group Member Status</b> | <b>System Response</b>                                                                                                                                                       | <b>Result</b>                                                                                                                               |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Available for an incoming call      | <ul style="list-style-type: none"> <li>■ Generates priority ringing at the member's telephone</li> <li>■ Processes the call as a normal attendant-originated call</li> </ul> | <ul style="list-style-type: none"> <li>■ Verification is complete.</li> <li>■ Anyone can place a call to the member's telephone.</li> </ul> |
| All activated Make Busy             | <ul style="list-style-type: none"> <li>■ Generates reorder tone</li> </ul>                                                                                                   | <ul style="list-style-type: none"> <li>■ Verification is denied.</li> </ul>                                                                 |
| Not available for incoming calls    | <ul style="list-style-type: none"> <li>■ The system does not queue the call even if a queue is available.</li> <li>■ Generates reorder tone</li> </ul>                       | <ul style="list-style-type: none"> <li>■ Verification is denied.</li> </ul>                                                                 |

When you use Verify to check a valid trunk, the system checks the status of that trunk. (Valid in this case means the trunk is translated with members and is not in an out-of-service state.) [Table 22](#) describes the process.

**Table 22. Verification of a Trunk**

| <b>Trunk Status</b>                    | <b>System Response</b>                                                                                                                                                                                                                                                            | <b>Result</b>                                                                                                      |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| The trunk is idle and incoming.        | <ul style="list-style-type: none"> <li>■ The system generates confirmation tone.</li> </ul>                                                                                                                                                                                       | <ul style="list-style-type: none"> <li>■ Verification is complete.</li> <li>■ Anyone can use the trunk.</li> </ul> |
| The trunk is idle and outgoing.        | <ul style="list-style-type: none"> <li>■ The system generates dial tone.</li> </ul>                                                                                                                                                                                               | <ul style="list-style-type: none"> <li>■ Verification is complete.</li> <li>■ Anyone can use the trunk.</li> </ul> |
| The trunk is busy with an active call. | <ul style="list-style-type: none"> <li>■ The system bridges the Verify originator onto the call.</li> <li>■ The system generates a warning tone to all active parties and repeats the tone every 15 seconds while the Verify originator remains bridged onto the call.</li> </ul> | <ul style="list-style-type: none"> <li>■ Verification is complete.</li> <li>■ The trunk is in use.</li> </ul>      |
| The trunk is out of service.           | <ul style="list-style-type: none"> <li>■ The system generates reorder tone.</li> </ul>                                                                                                                                                                                            | <ul style="list-style-type: none"> <li>■ Verification is denied.</li> </ul>                                        |

## Considerations

---

- A busy verification cannot be made to an analog extension that is waiting to be answered at another extension. A call must be answered before it can be verified.
- If your country requires a tone other than 440 Hz, use the Intrusion feature rather than Verify to verify telephones.
- The system does not provide bridging when you verify UCD and DDC groups or RLTs.
- You cannot make outgoing test calls on DID trunks.
- You can verify an extension that is administered without hardware (X-ported). In this case, the system generates reorder tone.

## Interactions

---

- Automatic Callback

Once the called party in an Automatic Callback call hangs up, neither extension can be busy-verified until both the calling and called parties are connected or the callback attempt is canceled (by the activating party or by time-out of the callback interval).
- Call Coverage

Since the busy-verification call to an extension is originated as a priority call, the call does not go to coverage.
- Call Forwarding

Busy verification made to an extension with call forwarding activated, does not busy verify the forwarded-to extension. Only the called extension is busy verified.
- Call Waiting Termination

You cannot verify an extension that called an active telephone and is receiving call-waiting ringback tone unless the extension has an idle call appearance.
- Conference

The system denies busy verification of any extension involved in a conference call of more than five people. However, the system does allow a busy verification of any extension involved in a conference call of 5 or fewer parties. The system also denies busy verification of a trunk on a 6-party call.

- Data Privacy  
Busy verification is denied if it would cause a bridging attempt on a telephone that has activated Data Privacy.
- Data Restriction  
The system denies Verify if Data Restriction is active on a call, and a busy verification bridging attempt is made on that call.
- Hold  
Busy verification of a multiappearance telephone is denied if all call appearances have calls on hold.
- Individual Attendant Access  
An attendant cannot make a busy verification of another individual attendant console or of the attendant group.
- Loudspeaker Paging Access  
The system denies busy verification if the telephone or trunk to be verified is connected to paging equipment.
- Transfer  
Once the originator of busy verification has bridged onto a call, any attempt to transfer the call is denied until the originator drops from the call.
- telephone Origination Restriction  
A telephone that is origination restricted can be assigned a Busy Verify button. However, the button cannot be used.
- telephone Termination Restriction  
The system denies busy verification of telephones that are termination restricted.

## Call charge information

---

Avaya MultiVantage provides two ways to know the approximate charge for calls made on outgoing trunks:

- Advice of Charge — for ISDN trunks  
Advice of Charge (AOC) collects charge information from the public network for each outgoing call. Charge advice is a number representing the cost of a call; it is recorded as either a charging or currency unit.
- Periodic Pulse Metering — for non-ISDN trunks  
Periodic Pulse Metering (PPM) accumulates pulses transmitted from the public network at periodic intervals during an outgoing trunk call. At the end of the call, the number of pulses collected is the basis for determining charges.

Call-charge information helps you to account for the cost of outgoing calls without waiting for the next bill from your network provider. This is especially important in countries where telephone bills are not itemized. You can also use this information to let employees know the cost of their phone calls, and so encourage them to help manage the company's telecommunications expenses. Note, however, that you cannot necessarily use this information to dispute telephone bills with the network provider.

You need to request either AOC or PPM service from your network provider. In some areas, your choice may be limited. Your Avaya representative can help you determine the type of service you need.

 **NOTE:**

This service is not offered by the public network in some countries, including the US.

### Detailed description

---

The availability of AOC and PPM varies from one country to the next. In some countries, AOC information is received automatically for each call. In others, the system must request AOC information for each call.

In some countries, the public network sends call-charge information only at the end of a call. In others, the public network sends information during a call as well. PPM is available over the following trunk types:

- Central Office (CO)
- Direct Inward and Outward Dialing (DIOD)
- Foreign Exchange (FX)
- Personal Central Office Line (PCOL)
- Wide Area Telecommunication Service (WATS)

## CDR Output

The ISDN Call Charge or PPM field contains the last cumulative charge received from the network. If Call Splitting or Attendant Call Recording is enabled, and a call has been transferred for the first time, the ISDN Call Charge field contains the cumulative charge most recently received from the network.

For all subsequent transfers, the ISDN Call Charge field contains the difference between the cumulative charge most recently received and the value generated in the previous CDR record for the same call.

A zero appears in the Call Charge field when: no AOC information is received; a value of zero is the last charge information received; or the outgoing trunk group is not administered for AOC or PPM.

## Charge Display and CDR

Avaya MultiVantage provides two ways for you to view call-charge information: on a display or as part of the CDR report.

From a display, you can see the cost of an outgoing call, both while the call is in progress and at the end of the call. If you want end users to control when they view this information, you can assign a display button that they can press to see the current call charges. If you want call charges to display automatically whenever a user places an outgoing call, you can set the Automatic Charge Display field to **y** on the user's COR screen.

You can administer the system so that call charges appear on CDR reports. You can also allow users to view call charges on phone displays. For information on how to set this up, see [“Viewing call charge information” on page 547](#).

## Considerations

---

The Primary (or Secondary) Output Format for the CDR report must be one of the following types.

- Customized — You must also include either the ISDN-CC or PPM fields in your record design. If you use both types of call-charge information, you need both fields.
- Expanded (Enhanced 24-word standard ASCII)
- Int-direct
- Int-ISDN (International ISDN expanded)
- Int-process
- Unformatted (Enhanced 24-word standard ASCII)
- If you want call charges to restart at 0 for calls that are forwarded or transferred, administer Outg Trk Call Splitting.

## Attendant consoles

Automatic Charge Display Mode does not apply to attendant consoles. The attendant must always press a button to enter display mode.

## Performance impact

Call Charge Information can impact system performance in several ways. The information coming in over ISDN trunks takes up bandwidth, and reduces the maximum amount of traffic the ISDN D-channel can handle. This is especially true in countries such as Germany and France, where the network sends charging information updates as often as every 3 to 10 seconds for each active international call.

The number of sets that display charge information and the frequency of updates also affect performance. Normally, the update frequency should match the average rate at which call charge updates are received from the public network.

### **CAUTION:**

*Updating displays too frequently can cause unnecessary system performance degradation. If performance slows to an unacceptable rate, you may need to lengthen the amount of time between updates.*

## Button operations

If you administer a button for charge display, the display-set user can press the disp-chnr button at any time during the call to see the current charges. If your public network sends charge information only at the end of a call, display-set users must have this button and press it just before they hang up. After the call drops, the charge will appear.

## Other display functions

If a user invokes the elapsed-timer display, the timer may overwrite part of the charge display. If the user has a local directory (Dir button), and presses this button while a call is in charge display mode, the call-charge information will overwrite the directory any time an update comes in. To avoid this, the user must press Exit or Normal.

## Interactions

---

- **Attendant Features**

Attendant consoles cannot have automatic charge display. If you want the attendant to see call charges, you must assign a disp-chnrg button to the attendant console. If the attendant moves to transfer an outgoing call, the display returns to normal mode. If the transfer does not complete, or the call remains at the attendant console for whatever reason, the attendant must press the disp-chnrg button again to view call charges.

- **Automatic Incoming Call Display**

If a user has charges displayed for an existing call and a second call rings on another line appearance, the display returns to normal mode for a short time to show the identity of the caller. The user must press disp-chnrg again to view call charges, or if automatic charge display is enabled, must wait for the Charge Update Frequency Timer to expire.

- **Bridged Appearance**

If a user makes a call using a bridged appearance, the call charges display on the telephone from which the call is made. If that telephone has Automatic Charge Display as part of its COR, the charges will appear automatically. The actual charge for the call appears on the CDR report as if the call had been made from the principal's extension, not the bridged appearance.

- **Call Coverage or Forwarding — Off Net**

Call charges for a call to an extension whose calls are redirected over a public-network trunk are charged to the called extension, not the calling extension. However, if the call is placed from an internal phone that has charge display capability, the caller will see the charges for the redirected call.

- **Call Park**

When a user parks a call, the display mode returns to Normal. If a user retrieves a parked, outgoing call from another display telephone, the display on that set shows the current call charges if the user presses a disp-chnrg button, or if the user's COR allows Automatic Charge Display. If call splitting is enabled, the display shows the charges accumulated since the user unparked the call.

- **Call Transfer**

For Advice of Charge, if a transferred call is routed over a public-network ISDN-PRI trunk group, AOC administration for the outgoing trunk group controls whether AOC information is requested or recorded for the call. If two or more outgoing trunks are connected together via trunk-to-trunk transfer, the Avaya MultiVantage may receive AOC information from the network for each outgoing trunk involved in the call.

- **CDR Adjuncts**

Avaya MultiVantage does not tandem AOC information through a private network to other switches. Therefore, the CDR adjunct that records AOC information must receive its input from Avaya MultiVantage directly connected to the public network.

- **CDR Call Splitting**

If you use CDR Call Splitting for outgoing trunks, each time a call is transferred, the system generates a separate record. Attendant Call Recording, a form of Call Splitting, generates a CDR record when an attendant drops from a call. Incoming Trunk Call Splitting has no effect on charge information.

If you rely on Call Splitting or Attendant Call Recording, you should request call charge information during the call. However, for AOC, this increases message activity on the signaling channel and reduces Busy Hour Call Capacity of the MultiVantage System.

In some countries, or with specific protocols, AOC information during a call is not available. In this case, you can use the Elapsed Time in the CDR records to allocate the charges among the parties on the call.

You must use CDR Call Splitting if you want the charge display to restart at 0 when a call is transferred.

- **Centralized Attendant Services**

In any configuration where a branch system has no direct connection to the public network, the private network does not pass call-charge information to these branches.

- **Conference**

If a user adds a third party to a call in charge-display mode, the display returns to normal. Call charges will not appear as long as there are more than two parties on the call.

- **Distributed Communications System (DCS)**

In any configuration where a branch system has no direct connection to the public network, the private network does not pass call-charge information to these branches.

- **Electronic Tandem Network (ETN)**

In any configuration where a branch system has no direct connection to the public network, the private network does not pass call-charge information to these branches.
- **Hold**

If a user places a call on hold, the display returns to normal mode. The user must press disp-chnrg again to view call charges, or if automatic charge display is enabled, must wait for the display to refresh.
- **Last Number Dialed**

Users can view the dialed number while active on a call by pressing the stored-numb button, then the last-numb button. To view call charges again, the user must then press the disp-chnrg button, or (if Automatic Charge Display is part of the user's COR) the Normal button.
- **QSIG**

In any configuration where a branch system has no direct connection to the public network, the private network does not pass call charge information to these branches.
- **System Resets**

If you perform a warm reset while calls are active with charge display, the charge display will freeze. To resume call charge updates, users must press the Normal button.

## **Call coverage**

---

Call Coverage provides automatic redirection of calls to alternate answering positions in a Call Coverage path. Call Coverage allows you to:

- Establish coverage paths with up to 6 alternate answering positions
- Establish redirection criteria that govern when a call redirects
- Redirect calls to a local switch location
- Redirect calls to a remote (off-net) location
- Redirect calls based on time-of-day
- Allow users to change back and forth between two coverage choices (either specific lead coverage paths or time-of-day tables). See [“Extended user administration of redirected calls”](#) on page 1673 for more information.

## **Hardware requirement**

---

The Coverage of Calls Redirected Off-Net (CCRON) generally requires call classification hardware. Both the Call Classifier - Detector and Tone Clock/Call Classifier - Detector circuit packs provide tone detection ports including the capability to do call classification. There are 8 ports on each circuit pack.

For countries using the USA tone plan, a Call Classifier - Detector or Tone Clock/Call Classifier - Detector circuit pack is sufficient to provide call classification.

For countries not using the USA tone plan, the Call Classifier - Detector and Tone Clock with Call Classifier - Tone Detector circuit packs must be configured appropriately to provide call classification.

The number of simultaneous monitored calls depends on the:

- total amount of outbound call traffic,
- number of call classification ports available, and
- use of other switch applications that make use of call classification ports.

Coverage of Calls Redirected Off-Net competes with the following switch applications for ports on the Call Classifier - Detector and Tone Clock with Call Classifier - Tone Detector circuit packs:

- Answer Detection
- Call Prompting
- CallVisor ASAI
- Multifrequency Compelled (MFC) signaling

Serious degradation of switch performance, including the inability to launch new calls, can result from an insufficient resource of call classifier ports.

## **Detailed description**

---

When a call meets the redirection criteria of the principal, the call attempts to route to one of up to 6 points in the coverage path. If no coverage points are available, the call may revert to the called principal or group. If any point in the path is available, the call either rings the individual phone or member of a group specified for that point or queues on the group. Once a call is ringing or queued at any point in a coverage path, the call never reverts to the called principal or group, or to the previous point. A call remains at a coverage point for the Coverage Subsequent Redirection interval. At the end of this interval, the call attempts to route to any remaining points in the coverage path. If no other point is available to accept the call, the call remains queued or continues ringing the current coverage point.

## Call Classification

Classifying a call means determining the state of the call at its final destination. That means whether the call was answered, received busy, reorder, intercept, special information tone (SIT), or other treatment.

Call classification is accomplished by the Integrated Services Digital Network (ISDN) protocol or ports on the:

- Tone Clock with Call Classifier - Tone Detector circuit pack
- Call Classifier - Detector circuit pack

## Coverage Path

A Call Coverage path is a list of up to six alternate answering positions (covering users/points) that are accessed, in sequence, when the called party or group is not available to answer the call.

You can assign any of the following entities a coverage path so they are eligible to have calls redirected to coverage:

- ACD split
- Agent LoginID
- PCOL group
- TEG
- Hunt group
- Phone (on-net or off-net)

You establish the coverage paths and set the redirection criteria. If a coverage path is not assigned to a particular facility, calls are not redirected from that facility, unless another feature is assigned. A coverage path can include any of the following:

- Announcement
- Attendant group
- AUDIX
- Coverage answer group
- Hunt group
- Public network number (off-net)
- VDN
- Phone (on-net or off-net)

Avaya MultiVantage allows for multiple coverage paths. However, for any particular call only one coverage path is used. The “lead” coverage path is the first coverage path in a chain that is considered when a call redirects to coverage. The chain is defined in the Next Path Name field on the Coverage Path screen.

When a call redirects to coverage, the lead coverage path at that time is checked to determine whether its coverage redirection criteria match the call status. If there is a match the lead coverage path is used. If the lead coverage path’s redirection criteria does not match, the system moves down the path chain until it finds a coverage path with redirection criteria that matches the call status. If the chain is exhausted before the system finds a match, the call does not redirect to coverage. Once a coverage path is selected, it is used exclusively through the duration of the call.

You can assign lead coverage paths directly in the Coverage Path 1 or Coverage Path 2 fields on the appropriate screens. For example, to assign a lead path for a TEG, set the Coverage Path field on the Terminating Extension Group screen. You can also assign the lead paths indirectly by assigning a Time-of-Day Coverage Table to the Coverage Path 1 and Coverage Path 2 fields. Then, the system selects the lead path according to the time of day.

**Subsequent redirection interval**

The number of times a call rings at a particular coverage point before the switch moves the call to the next coverage point depends on the type of ringing coverage point (for example, local, DCS, CCRON, and so forth). For each type of coverage point, the following table shows which subsequent redirection interval on the System-Parameters Call Coverage/Call Forwarding screen is used.

| Type of Coverage | Subsequent Redirection Interval |
|------------------|---------------------------------|
| local            | local                           |
| remote           | *                               |
| CCRON            | off-net                         |
| DCS              | local                           |

- Local — On the System-Parameters Coverage/Forwarding screen, the Local Subsequent Redirection/CFWD Don’t Answer Interval field.
- Off-net — On the System-Parameters Coverage/Forwarding screen, the Offnet Subsequent Redirection/CFWD Don’t Answer Interval field.
- \* — The call is left off-net.

## Call redirection criteria

Redirection criteria determine the conditions under which a call redirects from the principal (called) extension to the first position in the coverage path. The criteria and conditions that apply are as follows:

- **Active**

Redirects calls to coverage immediately when the principal is active on at least one call appearance. For a phone with only one appearance or a single-line extension, assign the Busy criterion (discussed below) instead of the Active criterion.

- **Busy**

Redirects calls to coverage when all available call appearances at the principal extension are in use. For multiappearance phones, one call appearance can be reserved for outgoing calls or incoming priority calls (discussed later). The remaining assigned call appearances are available for other incoming calls. An incoming call (other than a priority call) redirects to coverage only when all of these unreserved call appearances are in use. If at least one unreserved call appearance is idle at the principal extension, the call remains at that idle appearance.

A TEG is considered busy if any phone in the group is active on a call.

Each phone in a UCD or DDC group must be active on at least one call appearance for the call to redirect to coverage. If any phone in the group is idle the call directs to that phone. If no phone is available, the call can queue if queuing is provided. If queuing is not provided, then the call routes to coverage. If the queue is full or all agents are in an auxiliary state, the group is considered busy and the call routes to coverage. Queued calls remain in queue for the Don't Answer Interval.

A call will not cover to a hunt group if no agents are logged in, or if all agents are in AuxWork mode.

- **Don't Answer**

Redirects calls to coverage if unanswered during the assigned Don't Answer Interval. A call rings for the Don't Answer Interval and then redirects to coverage.

- **Cover All Calls**

Redirects all incoming calls to coverage. This criterion has precedence over any other criterion previously assigned.

- **Send All Calls/Go to Cover**

Allows users to activate Send All Calls or Go to Cover as an overriding coverage criteria. This redirection criteria must be assigned before a user can activate Send All Calls or Go to Cover (discussed later).

- No Coverage

Occurs when none of the above criteria are assigned. Calls redirect to coverage only when the principal has activated Send All Calls or the caller has activated Go to Cover. Both of these overriding criteria are discussed later.

Redirection criteria can be assigned in combinations. For example, you can combine Active/Don't Answer and Busy/Don't Answer. Other combinations are not possible or do not provide any useful function. For example, Active/Busy does not accomplish anything. A busy phone is always active.

Redirection criteria are assigned separately for internal and external calls. By linking the coverage paths, Busy/Don't Answer can be assigned for internal calls and Active can be assigned for external calls. Similarly, Busy/Don't Answer can apply for external calls and No Coverage can apply for internal calls. In the latter case, internal calls remain directed to the called phone or group.

All calls extended by the attendant are treated as external.

## **Warning users if their calls are redirected**

You can warn analog phone users if they have features active that may redirect calls. For example, if the user has activated send all calls or call forwarding, you can administer a setting to play a special dial tone when the user goes off-hook. See [“DISTINCTIVE AUDIBLE ALERTING” on page 826](#) for more information.

## **Features that override Call Coverage**

Some system features override Call Coverage criteria; they are checked before the redirection criteria are checked. These features are:

- Call Forwarding All Calls

Call Forwarding provides a temporary override of the redirection criteria, if Send All Calls is not active. The call attempts to complete to the forwarded-to extension before redirecting to coverage. If the principal's redirection criteria are met at the forwarded-to extension, the call redirects to the principal's coverage path.

- Go to Cover

Go to Cover allows users, when calling to another internal extension, to send the call directly to coverage. This is optionally assigned to a button on a phone and is activated by the internal calling party. Use of Go to Cover is discussed later.

- Send All Calls

Send All Calls allows principals to temporarily direct all incoming calls to coverage regardless of the assigned redirection criteria. For example, if the redirection criteria are administered so that no calls redirect, all incoming calls terminate at the principal's phone unless Send All Calls is activated. Also, Send All Calls allows covering users to temporarily remove their phones from another user's coverage path.

Send All Calls is activated by pressing the Send All Calls button or by dialing the Send All Calls access code. It is deactivated by pressing the button a second time or by dialing the deactivate code.

A user who is not assigned a coverage path with Send All Calls or Cover All Calls redirection criteria, cannot activate Send All Calls.

Any attempt to activate Send All Calls is denied if the currently active coverage path does not allow it in its coverage criteria. However, if the user activates Send All Calls for a coverage path that does allow it, and then the user's coverage path is changed by the system to a coverage path that does *not* allow Send All Calls:

- The Send All Calls button remains lit.
- Send All Calls automatically resumes when the user is changed back to a coverage path that does allow it.

If a user has activated Send All Calls and has only one coverage point, and receives a call from that coverage point, the call rings silently at the user's phone, because the coverage point is already on the call.

Send All Calls is similar to Cover All Calls, discussed previously. However, you set Cover All Calls and it is used for screening the principal's call. The principal may or may not be rung on an incoming call, depending on how this function is assigned. Send All Calls is controlled by the principal and is normally used when the principal is away temporarily.

TEG calls are not affected by Send All Calls.

- Send Term

Send Term is the Send All Calls equivalent for TEG. Since a TEG cannot be in a coverage path, Send Term applies only to a directly called TEG.

## Conditions that override Call Coverage

Call Coverage provides redirection of calls from the called principal or group to alternate answering positions when certain criteria are met. Certain provisions allow calls to direct to and/or be answered by the principal even though the redirection or overriding criteria are met. These provisions are:

- If no answering positions are available in the Coverage Path, the call rings the called phone, if possible; otherwise, the calling party receives busy tone. This applies even if the Cover All Calls redirection criterion or the Send All Calls overriding criterion is active.
- Similarly, calls directed to a UCD or DDC group are queued, if queuing is available, when no group members are available to answer the call. The call remains in queue for the Don't Answer Interval before routing according to the coverage path. If no points on the path are available, the call remains in queue. The worst case is when group queuing and the coverage points both are unavailable. In this case, the caller receives busy tone or ringback, depending on the type of trunk carrying the call.
- If the redirection criterion is Active or Cover All Calls, a called principal can receive a redirection notification signal (a short burst of ringing) when the call routes to coverage. (Redirection Notification is optional on a per-phone basis.) Note that in the Active, Cover All Calls, and Don't Answer cases, the principal could answer the call. Busy means no call appearances are available to answer the call. Redirected calls maintain an appearance on the called phone, if possible. The call appearance status lamp flashes to indicate an incoming call before the call redirects. When the call does redirect, the status lamp continues to flash (when redirecting to AUDIX, the lamp goes out). The user can answer the call by pressing the call appearance button. If the call has already been answered by a covering user, the principal may bridge onto the call. This provision is called Simulated Bridged Appearance. If a covering user answers the call, the status lamp on the principal's phone lights steadily.
- A phone user can use Directed Call Pickup to pick up a principal's call or a call alerting at a coverage point. Directed Call Pickup allows a phone user to answer an alerting call from any station on the Avaya MultiVantage. That is, the alerting and answering stations do not need to be members of the same Call Pickup group. You enable and disable Directed Call Pickup on a system-wide base. However, permission to use the feature can be allowed or disallowed based on COR.
- Priority Calling, Dial Intercom, and Automatic Intercom Calls always route directly to the principal's phone until the calling party activates Go to Cover. These calls take precedence over the redirection criteria and can seize the call appearance normally reserved for outgoing calls, if no other call appearances are available.

An internal calling party is informed that a call is redirecting to coverage by a single, short burst of ringing, called a Call Coverage tone. This tone is followed by an optional period of silence, called a Caller Response Interval (administered on the System-Parameters Call Coverage/Call Forwarding screen). This interval allows the calling party time to decide what to do: hang up or activate Leave Word Calling, Automatic Callback, or Go to Cover. Activating Go to Cover cancels the remaining interval.

## Covering-user options

For specific Call Coverage needs, the following options are available to phone users:

- Consult

Allows the covering user, by first pressing the Transfer button and then the Consult button, to call the principal (called party) for private consultation. These two actions place the caller on hold and establish a connection between the principal and the covering user. If the principal wishes, the covering user can complete the conference and add the calling party to the conversation. Similarly, the call can be transferred to the principal. Consult calls use the Simulated Bridged Appearance maintained on the call, if there is one. If not, the Consult call seizes any idle call appearance. If there is no idle call appearance, the Consult call is denied.

- Coverage Callback

Allows a covering user, by pressing the Cover Callback button, to leave a message for the principal to call the calling party. Coverage Callback uses Implied Principal Addressing to infer both extensions so that the covering user does not have to dial either the principal's or the caller's number. The caller must be an internal caller. The principal receives no indication that the covering user handled the call.

Alternatively, if the covering user presses the Leave Word Calling button, a "call me" message is left for the principal. The principal calls the covering user to get the message. This method is used when an external call is received or when an internal caller wants to leave a message but is not available for a return call.

- Coverage Answer Group

A Coverage Answer Group can have up to eight members. When a call is redirected to a Coverage Answer Group, all phones in the group ring simultaneously. Anyone in the group can answer the call. Note that a bridged appearance of a coverage answer group member does not ring when calls cover to the group. A Coverage Answer Group member already handling a group call is rung when another call is redirected to that Coverage Answer Group. If a Coverage Answer Group member is also a member of another Coverage Answer Group, he or she can also receive calls for the other group. A second call directed to a Coverage Answer Group lights a Coverage Incoming Call Identification (ICI) lamp, if administered.

- Coverage Incoming Call Identification

A Coverage ICI button can be assigned to multiappearance phone users without a display in a Coverage Answer Group.

The Coverage ICI status lamp identifies a call incoming to that Coverage Answer Group. If a Coverage Answer Group is assigned to more than one Call Coverage path, the path number cannot be identified. Likewise, if a given path is assigned to more than one principal, the individual principals cannot be identified. To provide unique path and principal identification, you must establish a unique path for each principal and a unique Coverage Answer Group to be included in the path. A second coverage call takes control of the Coverage ICI lamp and does not return control to the previous call when the second call is released.

## Time-of-Day Coverage

The Time-of-Day Coverage Table allows you to redirect calls to different lead-coverage paths at different times of the day and on different days of the week.

For example, an employee may want incoming calls to cover to a co-worker (office) during normal business hours, to cover to an off-net destination (home) in the early evening, and to cover to AUDIX at all other times. By specifying the appropriate lead-coverage paths in the Time-of-Day Coverage Table, the employee can have the call redirection flexibility shown in the following table. (If you were actually administering a Time-of-Day Coverage Table, you would provide the lead-coverage path numbers that redirect the calls to the employee's office, to their home, and to AUDIX.

| Day of the Week | Time 1 Directed To           | Time 2 Directed To            | Time 3 Directed To          | Time 4 Directed To           |
|-----------------|------------------------------|-------------------------------|-----------------------------|------------------------------|
| Monday          | 00:00<br>CovPath3<br>(AUDIX) | 08:00<br>CovPath1<br>(Office) | 17:30<br>CovPath2<br>(Home) | 20:00<br>CovPath3<br>(AUDIX) |
| Tuesday         | 00:00<br>CovPath3<br>(AUDIX) | 08:00<br>CovPath1<br>(Office) | 17:30<br>CovPath2<br>(Home) | 20:00<br>CovPath3<br>(AUDIX) |
| Wednesday       | 00:00<br>CovPath3<br>(AUDIX) | 08:00<br>CovPath1<br>(Office) | 17:30<br>CovPath2<br>(Home) | 20:00<br>CovPath3<br>(AUDIX) |
| Thursday        | 00:00<br>CovPath3<br>(AUDIX) | 08:00<br>CovPath1<br>(Office) | 17:30<br>CovPath2<br>(Home) | 20:00<br>CovPath3<br>(AUDIX) |
| Friday          | 00:00<br>CovPath3<br>(AUDIX) | 08:00<br>CovPath1<br>(Office) | 17:30<br>CovPath2<br>(Home) |                              |
| Saturday        | 00:00<br>CovPath3<br>(AUDIX) |                               |                             |                              |
| Sunday          | 00:00<br>CovPath3<br>(AUDIX) |                               |                             |                              |

Time is represented in 24-hour format and activation times are ascending from the earliest to the latest. There are no gaps in the activation times; the entire day is covered. If you do not assign a lead-coverage path to a specific time interval, there is no coverage from that time until the next activation time with an assigned lead-coverage path.

When a call arrives at a principal, the system queries for the lead coverage path in effect at that time and uses that information to determine call redirection. If call coverage is changed via administration *while the call is in progress*, the administration changes do not affect that call.

## Off-Net Call Coverage

Call Coverage allows a call to be redirected to a destination on the public network. The remote (off-net) number is administered on the Remote Call Coverage Table screen and may have up to 16 digits including either the outgoing trunk access code (TAC) or the FAC specifying ARS or AAR. Any coverage point can be an off-net destination.

Whenever an incoming trunk call is redirected off-net (coverage or forwarded), a timer is set that precludes any other incoming trunk call from redirecting off-net until the timer either expires or is cancelled. The rationale for this mechanism is to prevent calls that were redirected off-net from being re-routed back to the original principal from the off-net destination, effectively creating a round-robin loop that continuously seizes trunks until they are exhausted.

Avaya MultiVantage provides the means of performing call classification on an off-net coverage call to determine its disposition. If the off-net call is carried completely over ISDN facilities to its final destination, then ISDN trunk signaling is used to monitor the call. Otherwise, the system uses a call classifier port.

When the Avaya MultiVantage tries to classify an off-net coverage call (CCRON) using a call classifier port, the system introduces an unavoidable cut-through delay while the call classifier port attempts to identify an answered call. Neither the originating nor the answering party can hear each other during this delay of up to 1 second. A call classifier is attached to all off-net coverage calls made over analog facilities and also over ISDN facilities if the call is interworked to non-ISDN facilities on the public network.

When the Coverage of Calls Redirected Off-Net Enabled field on the System-Parameters Coverage-Forwarding screen is **y**:

- The system monitors off-net calls (call classification) and brings them back to the switch if they are not answered within the defined time interval. (Set this interval in the Off-Net Cvg Subsequent Redirection/CFWD No Ans Interval field on the System-Parameters Coverage-Forwarding screen.) Calls also return to the switch if the system detects a call progress tone, such as busy or reorder.
- A simulated bridge appearance (SBA) is put on the principal and the green lamp is put in flashing mode; the principal can pick up the call at any time. You have the option of dispensing with call classification (and consequently the SBA) on a final CCRON coverage point.
- When a call classifier port is used to classify the call, the switch plays local ringback tone to the caller while the off-net call is being classified, concealing from the caller what is happening on the public network. When the call is answered off-net, it is likely that the first few syllables spoken by the answering party will not be heard by the calling party.
- If any party on the call is on HOLD when the call routes off net, the call classifier is removed from the call. The call behaves in the same manner as off-net calls when the Coverage of Calls Redirected Off-Net field is **n**.

- While an off-net call is undergoing call classification, any party who is not already on the call will be unable to bridge onto the call. Also, the originating party cannot release the call, conference anyone else onto the call, or transfer the call to a new party. Once the call is answered off-net or the call is returned to the switch for further call processing, then these restrictions are removed.
- If the last point in a coverage path is an off-net destination and no trunks are available to route the call, the switch attempts to re-terminate the call to the principal.
- Avaya MultiVantage has no control over any redirection of the call that may take place at an off-net destination. However, further coverage treatment will be provided if the Off-Net Cvg Subsequent Redirection/CFWD No Ans Interval field expires before the call is answered off-net.

If the Coverage of Calls Redirected Off-Net field is not activated, the system does not monitor off-net calls and bring them back for additional call-coverage processing. In this case, once a call is directed to the remote call-coverage point, the principal is dropped from the call. Effectively, the off-net coverage point is the last coverage point in the coverage path.

### **VDN in a Call Coverage path**

Assigning a VDN extension as the last point in a Call Coverage path allows the functionality of Call Vectoring to be applied to a coverage point. The programmable vector associated with the VDN effectively can provide great flexibility in call handling. The integration of the Call Vectoring and Call Coverage features can drive powerful AUDIX and Message Server applications.

For example, you can program the vector assigned to the VDN in the coverage path to queue a redirected call to a messaging split for call answer operation and to allow the caller to leave a message for the called principal. The same VDN also can be used to retrieve messages. The vector program may also be varied by time of day or split status to provide different types of coverage.

When a redirected call covers to a VDN, the principal's simulated bridged appearance is removed when vector processing begins.

When covered or direct calls are connected to AUDIX or a messaging split via call vectoring, the original reason for redirection and the called principal must be passed to the adjunct over the Switch Communication Interface (SCI) link.

Use of a VDN as a coverage point provides integration to Centralized Messaging. That is, the DCS message sent to the remote switch with AUDIX includes the original reason for redirection and called principal.

An administration change is required to allow an extension that is assigned as a VDN to be entered as the last point in the coverage path. See *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide* for more information.

### **Extended User Administration of Redirected Calls**

The Extended User Administration of Redirected Calls feature (also called telecommuting access) allows system users to change their lead-coverage path (or time of day table) or their call-forwarding designated destination from any on-site or off-site location. See [“Extended user administration of redirected calls” on page 1673](#) for more information.

### **Measurements and reports**

---

Three reports provide measurement information about Call Coverage:

- The Coverage Path Measurement Report describes coverage activity as it relates to the coverage paths.
- The Principal Coverage Measurement Report describes coverage activity as it relates to the principal extensions.
- The CDR shows the outgoing trunk calls.

For each report, a selection form lists the specific coverage paths or principal extensions to be measured. For more detailed information on these reports and their associated commands, see *Reports for Avaya MultiVantage™ Software*.

### **Considerations**

---

- Incoming tie-trunk calls can be administered as either internal or external and are redirected to Call Coverage accordingly.

## **Guidelines and examples of Call Coverage**

Call Coverage is an extremely flexible feature and allows several combinations of coverage points. To illustrate the usefulness of Call Coverage, three typical coverage arrangements are given below.

- **Executive Coverage**

Provides a principal with call redirection to covering users having a close working relationship with the principal. Because of the status of the principal, personalized answering should be provided. Also, the principal may or may not choose to answer his or her own calls.

Redirection of a principal's calls to a secretary is a typical example of this form of coverage. The secretary would be informed of the principal's daily schedule and other useful information such as the importance of certain calls. The secretary could provide personalized answering by answering calls with the principal's name.

If the secretary is unavailable to answer the coverage call for the principal, the call redirects to a backup answering position. Personalized answering should also be provided at the backup position.

- **Middle Manager Coverage**

Provides a group of principals with call redirection to one or more covering users (such as a secretary). The secretary should have some knowledge of the principal's daily schedule. A backup answering position should be provided in case the secretary is unavailable.

- **General User Coverage**

Provides less-personal coverage for a broader spectrum of users. Covering users typically consist of a group or pooled answering arrangement. Coverage calls may be distributed among the members of the answering group.

Following is an example of how to provide an Executive Coverage arrangement.

1. Establish a unique Call Coverage Path for the executive.
  - If the secretary screens calls, specify Cover All Calls as the redirection criteria.
  - If the executive answers calls, specify Active, Busy, Don't Answer, Active/Don't Answer, or Busy/Don't Answer as desired.
  - Specify the secretary and the backup position (or the Coverage Answer Groups containing the secretary's and backup position's extensions) as the coverage points in the path.

2. If a Coverage Answer Group has been chosen as a coverage point, expect the following behavior:
  - Note that, if the secretary and/or backup answering position are in a Coverage Answer Group, each receives only one redirected call for the executive at any given time.
  - Only one call may cover and ring at a time.
  - Calls do ring a Coverage Answer Group member already busy on a call to the group.
3. Optionally, specify a Send All Calls button on the executive's phone. If someone else answers the executive's calls via bridging, the button is not needed.
4. Specify a Send All Calls button and a Consult button on the secretary's phone. Specify a Coverage ICI button if the secretary does not have a call display. Send All Calls is needed if the secretary is unavailable for a period of time. Consult is needed to enable private consultation with the executive during an established call. Coverage ICI is needed to identify the call as a call to the executive rather than a personal call to the secretary.
5. Specify a Consult button and a Coverage ICI button on the backup position's phone for the same reasons that these buttons were specified for the secretary.

## **Interactions**

---

- **Agent Call Handling**

Do not assign Cover All Calls to agents with the Automatic Answer option. Any call (ACD or non-ACD), to an extension that has Automatic Answer enabled and has its coverage redirection criteria administered as Cover All Calls does not go to coverage but to the called extension. Cover All Calls redirection criteria have no effect on an incoming call when a user is in the Auto-Answer mode.
- **Answer Detection**

Coverage of Calls Redirected Off-Net competes with Answer Detection for call classifier ports.
- **Automatic Callback and Ringback Queuing**

Callback calls do not redirect to coverage. The caller can activate Automatic Callback when ringing, redirection notification signal, or busy signal is heard.

- Automatic Intercom, Dial Intercom, and Priority Calling

Calls using these features are not redirected to coverage unless the caller presses the Go to Cover button.

- Bridged Call Appearance

Coverage criteria for bridged call appearances are based entirely on the criteria of the primary extension associated with the bridged call appearance.

If a phone user has activated Send All Calls on the primary extension, incoming calls still ring bridged call appearances of that extension as long as a simulated bridged appearance of the call is maintained at the primary extension.

The switch blocks a user from bridging onto a call that has routed off-net while the call is undergoing call classification.

- Call Detail Recording

When the Coverage of Calls Redirected Off-Net field is **y**, a CDR record is generated only after the call has actually been answered off-net. The dialed number in the record is the off-net number to which the call covers. The calling number is the station that is covered to the off-net location.

- Call Forwarding

Call Forwarding provides a temporary override of the redirection criteria. Normally, calls forward instead of redirecting to coverage. When a forwarding extension's redirection criteria are met at the designated (forwarded-to) extension, the call redirects to the forwarding extension's coverage path.

The system allows calls forwarded off-net to be tracked for busy or no-answer conditions and to return for further call-coverage processing under those conditions. However, if the principal does not have a coverage path, the system does not track the call and it is left at the off-net destination regardless of whether it is answered or busy.

If an extension has both Send All Calls and Call Forwarding activated, most calls to that extension are immediately redirected to coverage. However, Priority Calls, are forwarded to the designated forwarding destination.

If Cover All Calls is part of the coverage redirection criteria and if Call Forwarding is active at an extension, most calls to that extension are immediately redirected to coverage. However, Priority Calls, are forwarded to the designated forwarding destination.

Activation of Send All Calls at the forwarded-to extension does not affect calls forwarded to that extension.

- **Call Pickup**

Any call redirected to a covering user who is a member of a Call Pickup group can be answered by other members of the group.
- **Call Prompting**

Coverage of Calls Redirected Off-Net competes with the Call Prompting feature for call classifier ports.
- **CallVisor ASAI**

Coverage of Calls Redirected Off-Net competes with CallVisor for call classifier ports.
- **Centralized Attendant Service (CAS)**

If an incoming CAS call is directed to a hunt group, the call is not redirected to the hunt group's coverage path.
- **Class of Restriction and Controlled Restrictions**

Users who normally may be restricted from receiving calls still can receive calls directed to them via Call Coverage.
- **Conference**

The switch blocks users from conferencing another party onto a call which has routed off-net while that call is undergoing call classification. If any party on the call is on hold, the call routes off-net, but without undergoing call classification, even when the Coverage of Calls Redirected Off-Net field is **y**.

A call that covers to a VDN cannot be added to a conference while the call is in vector processing. For example, say user A calls user B. B wants to have a three-way conference call and calls C. C doesn't answer, the call covers to a VDN, and from there enters a vector. Until vector processing has completed this call to some destination, the conference cannot be established.
- **Direct Department Calling (DDC), Uniform Call Distribution (UCD), and Automatic Call Distribution (ACD)**

If a user has an Auxiliary Work button, and activates or deactivates Send All Calls, the Auxiliary Work function associated with DDC or UCD is activated or deactivated simultaneously.

If a user has no Auxiliary Work button, activating or deactivating Send All Calls still makes the user unavailable or available, respectively, for DDC and UCD calls, but Auxiliary Work is not activated or deactivated. The Auxiliary Work mode may be activated or deactivated using a feature access code.

Activating or deactivating the Auxiliary Work function does not activate or deactivate Send All Calls.

- Direct Outward Dialing (DOD)

Coverage of Calls Redirected Off-Net competes with DOD for call classifier ports when DOD uses MFC signaling. The Call Classifier - Detector port provides the MFC tones. Non-MFC DOD calls do not need the Call Classifier - Detector port for this purpose.

- Global Call Classification

To classify tones in countries not using the USA tone plan, time cadences and frequencies must be administered so they can be downloaded to the call classification circuit packs. You need a Call Classifier - Detector or Tone Clock with Call Classifier - Tone Detector circuit pack.

- Hold

If a covering user puts a call on hold, and the principal picks up on the call, the coverage appearance may or may not be dropped, depending on administration.

If any party is on hold when a coverage call routes off-net, that call does not undergo call classification, even when the Coverage of Calls Redirected Off-Net field is **y**.

- Internal Automatic Answer (IAA)

If an internal call is redirected to another phone by a Call Coverage redirection criteria, then that call is eligible for IAA at that phone.

IAA does not apply to calls to the original called extension when:

- The called phone has activated Do Not Disturb, Send All Calls, or Cover All Calls
- The calling phone has selected Go To Cover before placing the call

Calls directed to a Coverage Answering Group are not eligible for IAA.

- ISDN End-to-End Calls

When ISDN facilities carry an off-net coverage call entirely (end-to-end), call classification is accomplished through the ISDN protocol rather than by a call classifier port.

- Leave Word Calling (LWC)

Call Coverage can be used with or without LWC. However, the two features complement each other. When a covering user activates LWC during a coverage call, a message is left for the principal to call the covering user. When a covering user activates Coverage Callback during a coverage call, a message is left for the principal to call the internal caller.

- Night Service

Calls routed to the night station via Night Service follow the coverage path of the night extension under all coverage criteria except Send All Calls.

- Privacy — Manual Exclusion

When the primary or principal user bridges onto a call that went to coverage and has been answered at the coverage point, the user is not dropped when Privacy — Manual Exclusion is activated.

- R2-MFC Signaling

Coverage of Calls Redirected Off-Net competes with the R2-MFC Signaling feature for Call Classifier - Detector ports.

- Simulated Bridged Appearance (SBA)

Calls redirected to coverage maintain an appearance on the called phone if a call appearance is available to handle the call. The called party can bridge onto the call at any time. The system can be administered to allow an SBA of the call to either remain at or be removed from the covering phone after the principal bridges onto the call.

An SBA is maintained for calls covered by an off-net coverage point if the Coverage of Calls Redirected Off-Net feature is enabled. An SBA cannot be maintained for calls if the coverage point is linked to AUDIX.

Consult calls use the SBA maintained on the call. At the conclusion of a consult call, the bridged appearance is no longer maintained. If the principal chooses not to talk with the calling party, the principal cannot bridge onto the call later.

If a call that has, or has had, an SBA is conferenced or transferred, and redirects to coverage again, an SBA is not maintained at the conferenced-to or transferred-to extension.

- Tenant Partitioning

The caller and called party must be able to access a coverage point. The caller is considered to be the covering user and the called party is considered to be the covered user. Both parties must be able to access the coverage point.

- Transfer

The switch blocks a user from transferring a call which has routed off-net to another party while that call is undergoing call classification. If any party on a call that has routed off-net is on hold, the call does route off-net without undergoing call classification, even when the Coverage of Calls Redirected Off-Net field is **y**.

Transfers with Call Coverage as listed in the following table.

| Source   | Transfer initiator | Destination    | Coverage type |
|----------|--------------------|----------------|---------------|
| External | Local station      | Local station  | External      |
|          | Local station      | Remote station | External      |
|          | Remote station     | Local station  | Internal      |
|          | Remote station     | Remote station | Internal      |
|          | Attendant          | Local station  | External      |
|          | Attendant          | Remote station | External      |
| Internal | Local station      | Local station  | Internal      |
|          | Local station      | Remote station | Internal      |
|          | Remote station     | Local station  | Internal      |
|          | Remote station     | Remote station | Internal      |
|          | Attendant          | Local station  | External      |
|          | Attendant          | Remote station | External      |

**NOTE:**

The coverage criteria for transferred DID calls depends upon the External Treatment For Transferred Incoming Calls field on the [Feature-Related System Parameters](#) screen.

## Call detail recording

---

Call Detail Recording (CDR) tracks call information on a per-trunk-group or station-to-station basis. For every trunk group (including auxiliary trunks) that you administer for CDR reports, the system keeps track of incoming, outgoing and tandem calls. You can also receive reports on temporary signaling connections (TSCs) that involve trunks, and calls made using loudspeaker paging or code calling access.

### Detailed description

---

You can also ask the system to report on ineffective call attempts. This may greatly increase the number of calls recorded, but may also help you to increase security, since the system records call attempts that are blocked because of insufficient calling privileges. This can also let you know if your users are not able to make calls because all trunks are busy.

CDR tracks the audio service link calls that the switch uses for IP softphones set up as telecommuter. An IP softphone may use one audio service link to make many short calls, but this appears as one long call on the CDR reports.

Some call accounting systems do not support all of the information offered by CDR. See your Avaya representative for details.

## Account Code Dialing

Account Code Dialing allows certain calls to be associated with a particular project or account number. To do this, users enter account codes when they place certain types of outgoing calls. These account codes then appear on the call record, which you can use for accounting or billing purposes. Account code dialing can be optional or mandatory (forced).

To associate an account code with a particular call, a user first dials the CDR account code access code that you have established, then dials the desired account code. Next, the user dials the desired trunk access code, or ARS access code, followed by the phone number.

The call record contains the account code, Trunk Access Code (TAC) or Automatic Route Selection (ARS) access code, and the phone number. It does not contain the account code feature access code (FAC).

## Forced Entry of Account Codes

You can force your users to enter account codes on a system-wide, per-trunk or per-user basis, or on the basis of the digit string the user dials. If you have this feature in place, the system rejects any call that requires an account code where one is not supplied. To maximize system security, Avaya recommends that you use Forced Entry of Account Codes (FEAC).

### **SECURITY ALERT:**

*Avaya MultiVantage does not verify account codes. As long as the user enters a digit string of the appropriate length, the system allows the call. You must use Authorization Codes if you want the system to determine if the user is authorized to make the call.*

You can assign FEAC in the following ways:

- All calls marked for FEAC on the Toll Analysis table

If you activate this CDR system parameter, all users must dial an account code when the digits dialed match a digit string with FEAC=y. This includes calls made by ARS or TAC.

- Toll calls made by users with a specific COR

If FEAC is assigned to a specific COR, any telephone user assigned that COR must dial an account code before making calls that are administered forced entry of account codes.

- All calls made over a trunk group with FEAC in COR (TAC calls)  
Users cannot access a trunk group that is assigned a COR with FEAC until they dial an account code. If a call is routed via ARS, the system does not check for FEAC in the trunk group's COR. Therefore, if you want your users to enter account codes for ARS calls, you must administer this in the Toll Analysis table.

If an account code is required for a call and the user does not enter one, the system responds with intercept tone.

The following types of calls never require an account code:

- Attendant originated call
- Busy verification of a trunk by an attendant or telephone user
- DCS (unless required by the trunk group's COR)
- PCOL
- Remote access without barrier codes
- Trunk-to-trunk connections

## **Call Splitting**

Call splitting keeps track of calls where more than two parties are involved. These can be calls that are transferred, conferenced, or where an attendant becomes involved. If you have call splitting activated and any of these situations arise, CDR produces a separate record for each new party on the call.

You can administer call splitting for both incoming and outgoing trunks, and both can have attendant calls recorded separately.

### **Incoming trunk call splitting**

If incoming trunk call splitting is enabled, CDR starts a new record whenever an incoming trunk call is conferenced or transferred. Whenever a user drops from the call or the call is successfully transferred, CDR produces a record relevant to this user's participation. These call records show the amount of time each party was on the call, the incoming trunk access code, the dialed number and the condition code, as well as the other fields specified in the record format.

For incoming trunk calls that are conferenced, CDR creates a new record whenever a new party comes on the call. The duration field in these records shows how long each party participated on the call. Conference calls produce records with duration fields that overlap. The duration of a transferred call begins when the transferring party presses the TRANSFER button for the second time, so there is no overlap.

If ITCS is enabled and an incoming trunk call is conferenced or transferred to a local extension that is optioned for Intraswitch CDR, the call produces an incoming trunk call record. It does not produce an Intraswitch record.

To enable this option, set the Incoming Call Splitting field to **y** on the CDR System Parameters screen, and make sure that Record Outgoing Calls Only = **n**.

**ITCS examples**

The following scenarios depict calls made with ITCS active. The tables that follow do not show all fields, only those that may change due to call splitting. Call durations are approximate.

Caller A (TAC 123) makes an incoming trunk call to switch party B (5657890). They talk for 2 minutes. B then conferences in C (ext. 54321), and D (ext. 59876). The entire group talks for another 8 minutes, at which point B drops off the call. This produces a record for segment A–B.

A, C and D continue to talk for another 5 minutes. All remaining parties drop, producing two more records; A–C and A–D. Note that each record shows the incoming trunk ID as the calling number.

**Table 23. ITCS conference**

| Segment | Duration | Condition Code | Access Code Used | Calling Number | Dialed Number |
|---------|----------|----------------|------------------|----------------|---------------|
| A–B     | 0:10:0   | C              |                  | 123            | 5657890       |
| A–C     | 0:13:0   | C              |                  | 123            | 54321         |
| A–D     | 0:13:0   | C              |                  | 123            | 59876         |

A (TAC 123) calls Station B (5657890). They talk for 1 minute, then B transfers the call to C (54321). CDR generates a record for segment A–B. A and C talk for 5 minutes. CDR generates a record for segment A–C.

**Table 24. ITCS transfer**

| Segment | Duration | Condition Code | Access Code Used | Calling Number | Dialed Number |
|---------|----------|----------------|------------------|----------------|---------------|
| A–B     | 0:01:0   | 9              |                  | 123            | 5657890       |
| A–C     | 0:05:0   | 9              |                  | 123            | 54321         |

A (TAC 123) calls switch party B (5657890), they talk for one minute. B transfers the call to public-network party C (5665555), they talk for 4 minutes. Note that the duration of the original incoming trunk call includes the time after the call was transferred to an outgoing trunk, until all trunk parties drop.

**Table 25. ITCS transfer to outgoing trunk**

| Segment | Duration | Condition Code | Access Code Used | Calling Number | Dialed Number |
|---------|----------|----------------|------------------|----------------|---------------|
| A-B     | 0:05:0   | 9              |                  | 123            | 5657890       |
| A-C     | 0:04:0   | 9              | 345              | 123            | 5665555       |

### Outgoing trunk call splitting

If outgoing trunk call splitting is active, CDR creates records of transferred outgoing calls as described above for incoming trunk call splitting. For conferenced calls, the originator of the conference will be charged until he or she drops from the call, at which point CDR begins a second record for the conferenced user. Records for parties on a conference do not overlap; they are split. To enable this option, set the Outgoing Call Splitting field to **y** on the CDR System Parameters screen.

### OTCS examples

In the next example, switch party A (57890) calls B(7771234), talks for 5 minutes, then conferences in C (7775678). They all talk for another 5 minutes, at which point all parties drop.

**Table 26. OTCS conference**

| Segment | Duration | Condition Code | Access Code Used | Calling Number | Dialed Number |
|---------|----------|----------------|------------------|----------------|---------------|
| A-B     | 0:10:0   | C              | 345              | 57890          | 7771234       |
| A-C     | 0:05:0   | C              | 345              | 57890          | 7775678       |

Switch party A (51234) calls public-network party B (5659999). They talk for 5 minutes. A then transfers the call to switch party C (54444).

**Table 27. OTCS transfer**

| Segment | Duration | Condition Code | Access Code Used | Calling Number | Dialed Number |
|---------|----------|----------------|------------------|----------------|---------------|
| A-B     | 0:01:0   | A              | 345              | 51234          | 5659999       |
| C-B     | 0:05:0   | A              | 345              | 54444          | 5659999       |

### Attendant call recording

Both incoming and outgoing call splitting give you the option of recording the attendant portion of calls that are transferred. To enable this option, set the Incoming and/or Outgoing Attendant Call Record field to **y**.

If either incoming or outgoing trunk call splitting is enabled, the attendant portion of a conference call always produces a separate record.

### Attendant call recording examples

Public-network party A (TAC 123) calls the attendant (Attd), and asks to be transferred to switch party B (58888).

**Table 28. Attendant transfer incoming trunk**

| Segment | Duration | Condition Code | Access Code Used | Calling Number | Dialed Number |
|---------|----------|----------------|------------------|----------------|---------------|
| A-Attd  | 0:01:0   | 9              |                  | 123            | Attd          |
| A-B     | 0:05:0   | 9              |                  | 123            | 58888         |

The attendant (Attd) dials switch party A (59999), then transfers the call to public-network party B (4445678).

**Table 29. Attendant transfer outgoing trunk**

| Segment | Duration | Condition Code | Access Code Used | Calling Number | Dialed Number |
|---------|----------|----------------|------------------|----------------|---------------|
| Attd-B  | 0:01:0   | A              | 345              | Attd           | 4445678       |
| A-B     | 0:05:0   | A              | 345              | 59999          | 4445678       |

## Intrawitch CDR

Intrawitch CDR generates call records for calls to and from users on the local switch. For the system to generate an intrawitch CDR record, one of the extensions involved in a call must have intrawitch CDR assigned.

If a station is optioned for Intrawitch CDR, and ITCS is also enabled, ITCS overrides Intrawitch CDR. That is, incoming trunk calls involving the station produce trunk call records, not Intrawitch CDR records.

The output for intrawitch CDR follows the same format you have established for other call records. Certain fields do not appear on intrawitch call records, because they do not pertain to internal calls. For example, an intrawitch record does not contain trunk access codes or circuit IDs, since these do not apply.

Some calls may seem to be intrawitch CDR calls, but actually result in trunk calls. For example, a station-to-station call to an extension that is forwarded to an outgoing trunk produces only a trunk CDR record, regardless of whether or not either station has intrawitch CDR assigned.

You can assign intrawitch CDR to TEGs, stations, data modules, VDNs, Primary Rate Interface (PRI) endpoints, access endpoints, or hunt groups. The number that appears in the dialed number field depends on whether you have administered CDR System Parameters to record hunt group/member or VDN information. You *cannot* assign intrawitch CDR to attendant consoles or CallVisor ASAI stations.

### NOTE:

If an extension with intrawitch CDR is neither the originator of the call nor the dialed number of the call, the system does not produce a call record, even though the extension might be a party on the call (via Call Pickup, Call Forwarding, etc.).

## Privacy

CDR Privacy allows you to administer the system to blank a given number of dialed digits from a CDR report. This is useful when it is necessary to know details of a person's calls for accounting purposes, but it is not necessary or desirable to know the exact number called.

You can administer the number of digits to hide, up to 7. The value in Privacy Digits to Hide determines how many digits do not appear on the call record. This parameter is system-wide. Whether or not an individual's calls receive Privacy treatment is determined by the CDR Privacy field on the Station screen.

When an adjunct-originated call is made on behalf of a hunt group and the CDR system parameter option is set to **group-ext**, then CDR privacy does not apply. If this field is set to **member-ext**, privacy does apply.

**⇒ NOTE:**

Certain countries have requirements that a certain number of digits must be blanked from every call. Also, certain report processors do not support this option.

## CDR output

If your system uses two CDR output formats, one is administered as the primary CDR output format; the other is administered as the secondary CDR output format. The secondary output format is typically used for a local storage format (CDRU) to provide CDR data to NCOSS for assessing network performance or helping to find network problems.

The primary and secondary ports work independently. Each port will work even if the link to the other port is down. If a link is down for more than a minute, some data may be lost. However, the most recent 500 (Release 5vs/si/csi and later), or 1,900 (Release 5r and later) records are stored for the primary port even when a loss of records occurs. When the link comes back up, these records are output on a first-in, first-out basis.

If the CDR buffer is full, you can select a call record handling option to determine which of the following occurs:

- Calls are blocked with a reorder tone
- Overwrite old CDR records with new ones
- Calls are routed to an attendant as non-CDR calls

The following information applies to the port used for the secondary CDR output device:

- Data going to the secondary port should be the same as that going to the primary port. You can use the following record types for secondary output: LSU, Int-Direct, Int-Process, and Unformatted.
- If the system experiences problems in sending records to the primary CDR Output Device, the system discontinues sending records to the secondary port for 2 minutes. The secondary port should be run at the highest possible speed in order to prevent loss of information.
- If the output buffer is full, the system busies out the secondary port for 2 minutes. This makes system resources available to send data to the primary CDR port before the data is lost. The system continues to busy out the secondary port for 2-minute intervals until less than 400 records (1800 for Release 5r and later) remain in the buffer.

## CDR Record formats

Two types of formats are sent to the CDR output device, date record and call detail formats.

### Date record format

CDR sends date information to the CDR device once a day (at midnight), or when the device is connected. This is a non-call record, and contains only the information shown in the date record formats below.

Several formats are available for date records: one for CDRUs, one for the printer, and one for the TELESEER. The records sent to the TELESEER and printer contain the date only while the records sent to the CDRU contain time. See [Table 30](#), [Table 31](#), and [Table 32](#).

#### NOTE:

The date can be in month/day *or* day/month format, as selected on the CDR System Parameters screen. The date/time may also be reversed for international standards.

**Table 30. Date record format to LSU, LSU-Expand, Unformatted, and Customized**

| Position | Data Field Description               |
|----------|--------------------------------------|
| 1–2      | Hour (leading 0 added if needed)     |
| 3        | Colon (:)                            |
| 4–5      | Minute (leading 0 added if needed)   |
| 6        | Blank                                |
| 7–8      | Month (Leading Zero Added if Needed) |
| 9        | Slash (/)                            |
| 10–11    | Day (leading 0 added if needed)      |
| 12       | Carriage return                      |
| 13       | Line feed                            |
| 14–16    | Null                                 |

**Table 31. Date record format for Printer and Expanded**

| <b>Position</b> | <b>Data Field Description</b>     |
|-----------------|-----------------------------------|
| 1–2             | Month (leading 0 added if needed) |
| 3               | Space                             |
| 4–5             | Day (leading 0 added if needed)   |
| 6               | Carriage return                   |
| 7               | Line feed                         |
| 8–10            | Null                              |

**Table 32. Date record format for TELESEER 59 Character, Int-Proc, Int-Direct, and Int-ISDN**

| <b>Position</b> | <b>Data Field Description</b>     |
|-----------------|-----------------------------------|
| 1–2             | Month (leading 0 added if needed) |
| 3–4             | Day                               |
| 5               | Carriage return                   |
| 6               | Line feed                         |
| 7–9             | Null                              |

## Call Detail Record formats

### Customized format

You can use the customized record format to make up your own call record. You can determine the data elements you want and their positions in the record. This method may be necessary if you want to include certain data elements that are not available on the standard formats.

However, whatever device you use to interpret the CDR data needs to be programmed to accept these formats. Consult your Avaya representative before using a custom record format.

**Table 33. CDR data format — TELESEER**

| <b>Position</b> | <b>Data Field Description</b> |
|-----------------|-------------------------------|
| 1–3             | Space                         |
| 4–5             | Time of day-hours             |
| 6–7             | Time of day-minutes           |
| 8               | Duration-hours                |
| 9–10            | Duration-minutes              |
| 11              | Duration-tenths of minutes    |
| 12              | Condition code                |
| 13–15           | Access code dialed            |
| 16–18           | Access code used              |
| 19–33           | Dialed number                 |
| 34–38           | Calling number                |
| 39–53           | Account code                  |
| 54              | FRL                           |
| 55              | IXC                           |
| 56–58           | Incoming circuit ID           |

| 134–136  | Null                   |

### **Call detail record field descriptions**

The following list describes the CDR data collected for each call and the number of digits in each field. All information is right adjusted in the respective field, unless otherwise indicated. Where the field name for customized records is different from the standard, the custom field name appears in parentheses.

- **Access Code Dialed** (code-dial) — 3 or 4 digits

The access code the user dialed to place an outgoing call. This can be the ARS access code, AAR access code, or the access code of a specific trunk group. This field is also used to record the X.25 Feature Access Code of an outgoing X.25-addressed call.

- **Access Code Used** (code-used) — 3 or 4 digits

This field is used only for outgoing calls when the trunk group used is different from the access code dialed. It is not used when a TAC is dialed. For example, your system may use a feature access code for ARS. This field contains the access code of the actual trunk group that the call was routed over. When the dialed and used access code are the same, this field will be blank.

If you use ISDN or enhanced formats with TELESEER, LSU, or Printer record types, this field always shows the access code of the trunk group, even if it is the same as the access code dialed.

- **Account Code** (acct-code) — up to 15 digits

This field may contain a number to associate call information with projects or account numbers. For some formats, a long account code overwrites spaces on the record that are assigned to other fields.

- **Attendant Console** (attd-console) — 2 digits

This field contains the attendant console number of the attendant that handled the call in a record that is marked as being attendant handled.

- **Authorization Code** (auth-code) — 4–13 digits

This field contains the authorization code used to make the call. For all formats except the custom format, codes longer than 7 digits are truncated, keeping only the first 7 digits. For non-ISDN and ISDN LSU formats, the authorization code is fewer than 6 digits in length. It is 5 for Enhanced LSU. On the 59-character record, the authorization code is never recorded.

- **Bandwidth** — 2 digits

Used to capture the bandwidth of the wideband calls to support H0, H11, H12, and N x 64 kbps data rates. For Enhanced Expanded, Enhanced Unformatted and customized record formats, this value is expressed as the number of DSOs of 64 Kbps channels comprising a call.

- **Bearer Capability Class** (bcc) — 1 digit

This field contains the BCC for ISDN calls, identifying the type of an ISDN call. It will distinguish between voice and different types of data. The BCC is a single digit. Any one of the following may appear in this field.

- 0 = Voice Grade Data and Voice
- 1 = Mode 1 (56 kbps synchronous data)
- 2 = Mode 2 (less than 19.2 kbps synchronous or asynchronous data)
- 3 = Mode 3 (64 kbps data for LAPD protocol)
- 4 = Mode 0 (64 kbps data clear)
- w = Wideband

Intrastwitch CDR outputs a value in this field for Wideband calls only.

- **Calling Number** (calling-num) — up to 10 digits (15 for customized records)

For outgoing or intraswitch calls, this field contains the extension number of the originating telephone user. For incoming and tandem calls, this field contains the TAC in standard formats. The fifth digit is the first digit of a 5-digit dialing plan. In formats where the field is less than 7 digits, this also shows the TAC of the incoming call.

This field shows the calling party number in Unformatted or Expanded records. If the CPN is not available, this field is blank for both formats.

This field contains the local extension of the noncall-associated/temporary-signaling connection (NCA-TSC) endpoint when the CDR record is for an outgoing (or originating) NCA-TSC. This field is blank for other NCA-TSC CDR records (that is, terminating, tandem, or unsuccessful).

- **Calling Number/Incoming TAC** (clg-num/in-tac)

You can use this field on a customized record to display the calling number if it is available. If calling party number is not available, this field contains the Incoming TAC. For outgoing calls, this field contains the calling extension.

- **Carriage Return** (return)

The ASCII carriage return character followed by a line feed indicates the end of a call record.

- **Condition Code** — 1 character

The condition code indicates what type of call this record describes. For example, condition code C indicates a conference call, 7 indicates an ARS call, etc.

[Table 51](#) shows condition codes for most record formats. The 59-character format uses different condition codes from those used for other record types. The codes that apply to 59-character records appear in parentheses in the table.

**Table 51. Condition codes**

| <b>Condition Codes</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                      | Identifies an intraswitch call (a call that originates and terminates on the switch).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 1 (A)                  | Identifies an attendant-handled call or an attendant-assisted call (except conference calls).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 4 (D)                  | Identifies an extremely long call (10 hours or more) or an extremely high message count TSC (9999 messages or more). On a call exceeding 10 hours, a call record with this condition code and a duration entry of 9 hours, 59 minutes, and 1–9 tenths of a minute is produced after the first period. A similar call record with this condition code is produced after each succeeding 10-hour period. When the call does terminate, a final call record with a different condition code identifying the call type is produced.                                                                                                                                         |
| 6 (E)                  | Identifies calls that are not recorded because of resource exhaustion. A record with this condition code is generated for calls that are routed to the attendant or calls that require CDR to overwrite records. This also includes ISDN calls that did not complete at the far end, for which the Q.931 message included a cause value. It does not include ISDN calls that receive inband tones.<br><br>The record includes the time and duration of the outage.                                                                                                                                                                                                      |
| 7 (G)                  | Identifies calls served by the AAR or ARS Selection feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 8 (H)                  | Identifies calls which have been served on a delayed basis via the Ringback Queuing feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 9 (I)                  | Identifies an incoming or tandem call, or an incoming or tandem NCA-TSC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| A                      | Identifies an outgoing call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| B                      | Identifies an adjunct-placed outgoing call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| C (L)                  | Identifies a conference call. For trunk CDR, a separate call record with this condition code is produced for each incoming or outgoing trunk serving the conference connection. The only extension recorded for a conference call is the conference call originator, provided ITCS and OTCS are disabled. For intraswitch CDR, if the originator is optioned for intraswitch, each time the originator dials a non-trunk party a separate call record is produced with this condition code, provided ITCS is disabled. If the originator is not optioned for intraswitch CDR, a separate record with this condition code is produced for each intraswitch party dialed. |

**Table 51. Condition codes (Continued)**

| Condition Codes | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E (N)           | An ineffective call attempt due to facilities not being available, such as all trunks are busy and either no queuing exists or the queue is full on an outgoing call, or the called extension is busy or unassigned for an incoming call attempt. This also means an ISDN Call By Call Service Selection call was unsuccessful because of an administered trunk usage allocation plan. Incoming trunk calls to a busy terminal do <i>not</i> generate a CDR record. |
| F               | Identifies an ineffective call attempt because of either insufficient calling privileges of the originator (assigned per FRL), ISDN calls rejected by the switch due to an NSF mismatch, or an authorization mismatch which prevents the completion of a data call.                                                                                                                                                                                                 |
| G               | Indicates a call terminating to a ringing station.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| H               | Indicates that a ringing call has been abandoned.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| I               | Indicates a call terminated to a busy station.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| J               | Indicates an incoming trunk call that is a new connection using ANF-PR (Additional Network Feature–Path Replacement, see QSIG) or DCS with Rerouting.                                                                                                                                                                                                                                                                                                               |
| K               | Indicates an outgoing trunk call that is a new connection using ANF-PR (Additional Network Feature–Path Replacement, see QSIG) or DCS with Rerouting.                                                                                                                                                                                                                                                                                                               |

If the trunk-group CDR Reports field is set to **ring**, CDR records the ring time to answer or abandon for incoming calls originated by the trunk group. In addition, CDR indicates if the incoming destination is busy. This record is separate from the normal call duration record printed for an answered call. This information is indicated by the condition code.

When an incoming call originated by a trunk group with this option set is terminated to an internal destination, the call is tracked from the time ringing feedback is given to the originator. If the call is answered, a CDR record is printed with the condition code “G” and the duration reflects the time between the start of ringing and the answer of the call. If the call is abandoned before being answered, the system prints a record with the condition code “H” and the duration reflects the time between the start of ringing and the time the call was abandoned. If the destination is busy, a CDR record is printed with the condition code “I” and a duration of 0.

■ Condition Code overrides

If two condition codes apply to the same call, one code overrides the other. The matrix below, [Table 52 on page 1592](#), defines the overrides. To use this matrix, assume that condition codes 7 and A apply to the same call. To find the condition code that overrides, look at the point of where row 7 intersects column A (or where row A intersects column 7). In this case, condition code 7 overrides.

**Table 52. Condition code override matrix**

| CONDITION CODE |        |        |        |        |        |        |        |        |        |        |        |        |        |        |
|----------------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
|                | 0      | 1      | 4      | 6      | 7      | 8      | 9      | A      | B      | C      | E      | F      | J      | K      |
| 0              | N<br>A | 0      | 4      | 6      | 0      | N<br>A | N<br>A | N<br>A | B      | C      | N<br>A | N<br>A | N<br>A | N<br>A |
| 1              | 0      | N<br>A | 4      | 6      | 1      | N<br>A | 9      | 1      | B      | C      | E      | N<br>A | J      | K      |
| 4              | 4      | 4      | N<br>A | 6      | 4      | 4      | 4      | 4      | 4      | 4      | N<br>A | N<br>A | J      | K      |
| 6              | 6      | 6      | 6      | N<br>A | 6      | 6      | 6      | 6      | 6      | 6      | 6      | 6      | 6      | 6      |
| 7              | 0      | 1      | 4      | 6      | N<br>A | 7      | 9      | 7      | B      | C      | E      | F      | J      | K      |

- **Date**

You can include the date in customized records only. The format is based on the value of the CDR Date Format field on the CDR System Parameters screen.

- **Dialed Number** (dialed-num) — up to 23 digits

This field contains the number dialed. If it is an outgoing call, the field contains the number dialed by a system user. If it is an incoming call, the field contains the extension that was dialed (or implied, as in Dialed Number Identification System). If more than 18 digits are dialed, the least significant digits (starting from the right) are truncated.

If CDR Privacy is active for the calling number and this is an outgoing call, the trailing digits of the dialed number are blank in the call record. If more than 18 digits are dialed, the system truncates the dialed number to 18 digits, then blanks the administered number of digits.

For an outgoing (or originating) NCA-TSC or tandem NCA-TSC, this field contains the dialed digits used to establish a route to a far-end switch. It contains the extension of the local extension used as the NCA-TSC endpoint when it is for a terminating NCA-TSC. For an unsuccessful NCA-TSC, this field is blank.

The # sign (or E for some formats) may appear in this field in the following cases for both ARS and TAC calls.

- When the user dials # at the end of digit dialing
- If an outgoing call experiences an interdigit-timeout interaction with the ARS Analysis table
- When a user dials a TAC for a Look Ahead Interflow (LAI). For example: A successful LAI to <TAC> 1001 where 1001 is the remote VDN extension will yield **1001E** or **1001#** in the Dialed Number field. The # or E is used by the vector processing software to indicate the end of dialing.

You can eliminate the # or E as the last digit of the CDR record using the CDR System Parameters screen.

- **Duration** (duration or sec-dur) — 4 digits

This is the duration of the call, recorded in hours (0–9), minutes (00–59), and to tenths of minutes (0–9). Calls are rounded down in 6-second increments. Therefore, a call of 5-second duration will be indicated as 0 duration. If 9999 appears in this field, this call was in progress when a time change was made in the switch.

You can use the customized record format to have the duration reported in hours/minutes/seconds. This field is called sec\_dur.

- **Feature Flag** (feat-flag) — 1 digit

The feature flag indicates whether a call received network answer supervision, and if the call was interworked in the network. The call duration starts at the point of receiving the network answer.

You can administer the feature flag (on the CDR System Parameters screen) to reflect whether an outgoing ISDN call was reported as interworked by the network.

- A 0 in this field indicates a voice call without network answer supervision, or NCA-TSC not established.
- A 1 in this field indicates a data call without network answer supervision.
- A 2 in this field indicates a voice call with network answer supervision, but interworked.
- A 3 in this field indicates a data call with network answer supervision, but interworked.
- A 4 in this field indicates a voice call with network answer supervision.
- A 5 in this field indicates a data call with network answer supervision.

If the feature flag indicates that the call received network answer supervision, then the time of answer is accurate, and the recorded duration is also accurate. If a call does not receive network answer supervision, or receives answer supervision but is interworked with non-ISDN trunks, the time of answer is not necessarily accurate. Therefore the recorded duration for these calls may also not be entirely accurate.

Calls are considered data calls if they use a conversion resource (such as a modem) and/or originate or terminate on a data module.

- **Format Code** — 2 digits

This field contains 2 values: 00 is no PPM; 03 denotes a PPM count in the digits record.

- **FRL** — 1 digit

FRLs, numbered 0–7, are associated with the AAR and ARS features and define calling privileges. The information contained in this field is as follows:

- If the call is an outgoing call and an authorization code is not used to make the call, this field contains the originating telephone user's FRL.

- If the call is an outgoing call and an authorization code is used to make the call, this field contains the FRL associated with the dialed authorization code.
- If the call is an incoming or tandem call, this field contains the FRL assigned to the incoming trunk group.
- If the call is an incoming tandem tie trunk call, this field contains either the FRL assigned to the tandem tie trunk or the TCM sent with the tandem tie trunk call, depending on which was used to complete the call. On ISDN calls, this field always contains the TCM, if it was received.

You can administer CDR so that disconnect information appears in this field in place of the FRL. If you do this, for trunk CDR, the following disconnect information appears:

| Data | Meaning                            |
|------|------------------------------------|
| 0    | Cannot determine who dropped first |
| 1    | Switch party dropped first         |
| 2    | CO dropped first                   |
| 3    | Maintenance seized the trunk       |

For intraswitch CDR, the following call disconnect data appears in this field in place of the FRL data:

| Data | Meaning                            |
|------|------------------------------------|
| 0    | Cannot determine who dropped first |
| 1    | Calling number dropped first       |
| 2    | Dialed number dropped first        |

■ **Incoming Circuit Identification** (in-crt-id) — 3 digits

This field contains the member number of a trunk within a trunk group used for an incoming call. For outgoing calls, this field is blank. Tandem calls contain both incoming and outgoing circuit id-numbers.

The format of this field varies from record to record. For printer, Teleseer and 59-character formats, the numbers appear inverted on the record. For example, the circuit ID 123 appears as 231 (tens, units, hundreds). If you want to change this to appear in hundreds, tens, units format (123), use the Modified Circuit ID Display field on the CDR System Parameters screen.

■ **Incoming TAC** (in-trk-code) — 4 digits

This field contains the access code of the incoming trunk group.

- **INS** (3 digits)

This field specifies the ISDN Network Service requested for a call. This field applies only to ISDN calls. Each Network Specific Facility has a corresponding INS value, shown in [Table 53](#).

This field also appears as ISDN NSV (Network Service Value).

**Table 53. Network specific facility to INS mapping**

| Network Specific Facility             | INS Value |
|---------------------------------------|-----------|
| OUTWATS Band 0                        | 33        |
| OUTWATS Band 1–255                    | 34–288    |
| Network Operator                      | 324       |
| Presubscribed Common Carrier Operator | 325       |
| Software Defined Network (SDN)        | 352       |
| MEGACOM 800                           | 353       |
| MEGACOM                               | 354       |
| INWATS                                | 355       |
| Maximum Banded WATS                   | 356       |
| ACCUNET Digital Service               | 357       |
| AT&T Long Distance Service            | 358       |
| International 800                     | 359       |
| Multiquest                            | 367       |

- **ISDN CC**

The call charge supplied by the ISDN advice of charge function (see [“Receiving call-charge information” on page 544](#)).

- **ISDN NSV**

See INS.

- **IXC Code**

— Non-ISDN Formats — 1 digit hexadecimal

Interexchange Carrier (IXC) codes, 1–F hexadecimal, indicate the carrier used on the call. This information is sent to the CDR output device in ASCII code as a hexadecimal representation (for example, ASCII “F” equals “15”).

Users must dial an IXC access number to access a specific common carrier for a call. In the US, this number is in the form 10XXX, 950 — 1XXX, or any 8–11 digit number. The IXC access numbers applicable at a given location are associated with an IXC code on the Inter-Exchange Carrier Codes screen.

When ARS is used, and a route pattern inserts one of the administered IXC codes, the report contains the associated IXC code. If no IXC access number is used, or the carrier is selected at the CO, the report contains a 0.

— ISDN formats — 3 or 4 digits

With an ISDN record format, this field is a 3 or 4-digit field that identifies the actual IXC used on an ISDN call. This information is determined from the route pattern administration. For AAR and ARS calls, the 3-digit IXC value is administered in the route pattern for all ISDN calls. If a user dials an IXC code with a 10XXX format as administered on the Inter-Exchange Carrier Codes screen, the CDR record contains only the last 3 digits (4 for Enhanced). If a user dials a 7-digit IXC code, this field contains a 0.

- **Line Feed** — 1 character

The ASCII line feed character follows a carriage return to terminate CDR records.

- **MA-UUI** — 1 digit

Message Associated User-to-User Signaling shows the number of ISDN messages containing user data sent on an outgoing call. Data in this field can range from 0 to 9.

- **Node Number** (node-num) — 2 digits

This field identifies the DCS node number of a switch within a DCS arrangement. The number output is the same as the node number on the Dial Plan screen (the local id).

- **Null** — 1 character

The NULL is used to terminate and divide CDR Records (usually in triplets) when needed by the receiving adjunct.

- **Outgoing Circuit Identification** (out-crt-id) — 3 digits

For outgoing calls, this field contains the member number of the trunk within a trunk group used. This field is blank for incoming calls. Tandem calls include both incoming and outgoing circuit id numbers. For outgoing and tandem NCA-TSCs, this field contains the signaling group used to carry the NCA-TSC.

The format of this field varies from record to record. For printer, Teleseer and 59-character formats, and the ISDN and enhanced forms of those records, the numbers appear inverted on the record. For example, the circuit ID 123 appears as 231 (tens, units, hundreds). If you want to change this to appear in hundreds, tens, units format (123), use the Modified Circuit ID Display field on the CDR System Parameters screen.

- **Packet Count** (tsc\_ct) — 4 digits

For ISDN TSCs, this field contains the number of ISDN-PRI USER INFO messages sent, received, or (for tandem TSCs) passing through the switch.

- **PPM**

Periodic Pulse Metering (PPM) contains pulse counts transmitted over the trunk line from the serving CO. These are used to determine call charges.

- **Resource Flag** (res\_flag) — 1 digit

Indicates whether the call was circuit switched or packet switched, whether a conversion resource was used, or if the call involved a MASI terminal or trunk.

- 0 — circuit switched, no conversion device used
- 1 — packet switched, no conversion device used
- 2 — circuit switched, conversion device used
- 3 — packet switched, conversion device used
- 8 — MASI call

- **Sec-dur**

For customized records only, this field allows you to set the duration field to display seconds instead of tenths of minutes.

- **Space** — up to 40 characters

The ASCII space character separates other CDR fields or fills unused record locations.

- **TSC-Count** (tsc\_ct)

This is the customized name for Packet Count. See Packet Count.

- **TSC Flag** (tsc\_flag) — 1 digit

This field describes call records that pertain to temporary signalling connections. When not equal to 0, this field will indicate the status of the TSC. [Table 54 on page 1599](#) presents the TSC Flag encoding.

**Table 54. Encoding for TSC flag**

| <b>Encoding</b> | <b>Meaning</b>                                                                                                                                                                                                                        |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0               | Circuit-switched call without TSC requests                                                                                                                                                                                            |
| 1–3             | Reserved                                                                                                                                                                                                                              |
| 4               | Call Associated TSC requested and accepted in response to SETUP, no congestion control (applicable to originating node). Call Associated TSC received and accepted via SETUP, no congestion control (applicable to terminating node). |
| 5               | Call Associated TSC received and accepted via SETUP, congestion control (applicable to terminating node).                                                                                                                             |
| 6               | Call Associated TSC requested, accepted after SETUP, no congestion control (applicable to originating node). Call Associated TSC received and accepted after SETUP, no congestion control (applicable to terminating node).           |
| 7               | Call Associated TSC received and accepted after SETUP, congestion control (applicable to terminating node).                                                                                                                           |
| 8               | Call Associated TSC requested, rejected (rejection came from outside the local switch).                                                                                                                                               |
| 9               | Call Associated TSC requested, rejected (rejection came from the local switch, that is, lack of resource).                                                                                                                            |
| A               | Non Call Associated TSC received, accepted, no congestion control (applicable to terminating node). Non Call Associated TSC received, accepted, no congestion control (applicable to terminating node).                               |
| B               | Non Call Associated TSC requested, accepted, congestion control (applicable to originating node). Non Call Associated TSC received, accepted, congestion control (applicable to terminating node).                                    |
| C               | Non Call Associated TSC requested, rejected (rejection came from outside the local switch).                                                                                                                                           |
| D               | Non Call Associated TSC requested, rejected (rejection came from the local switch, that is, lack of resource).                                                                                                                        |
| E               | Reserved for future use.                                                                                                                                                                                                              |
| F               | Reserved for future use.                                                                                                                                                                                                              |

- **Time**

This field contains the time that the call ended, or the time that a user dropped from a multiparty call, if Call Splitting is active.

- **VDN (vdn)** — 5 digits

This field is only available on customized records. The call record contains the VDN extension number. If VDN Return Destination is active, this field contains the first VDN the caller accessed.

## **Security**

---

Monitor call detail records daily for unusual calling patterns, long calls, international calls, calls outside of normal business hours, and other indications of toll fraud. Call accounting systems are available that automatically monitor CDR output for fraudulent calling patterns.

## **Considerations**

---

- **Date and Time**

If a time of day is not administered in the system, Avaya MultiVantage does not generate CDR records. If the time is changed while a call is in progress, the actual duration for that call is not reflected in the CDR record. Instead, a special sequence of 9999 is recorded in the CDR record to indicate that the call was in progress during a time change.

- **Dial plan**

If the dial plan supports 6/7 digit extensions, only the formats that already support Calling Numbers longer than 7 digits (expanded, Unformatted, customized, and international ISDN) support 6 or 7 digits. All other formats send only 5 digits and when a 6 or 7 digit extension is involved, the last 5 digits are sent.

## **Interactions**

---

- **Abbreviated Dialing**

When a user places a call using Abbreviated Dialing or a Facility Busy Indicator button, all outpulsed digits appear on the record.

- **Answer Detection**

The Avaya MultiVantage provides Answer Detection using a Call Classifier circuit pack. This feature is an option for your system and requires an 8-port call classifier circuit pack. CDR starts recording call duration at the time the answer is detected by the circuit pack.

- **Attendant Console**

If an attendant-assisted call involves an outgoing trunk, the primary extension of the user who requests attendant service is recorded as the calling number, even if the attendant dialed the outside number. Condition Code 1 indicates the call was assisted by the attendant.

If the attendant allows through dialing, the primary extension of the user who dialed the number is recorded as the calling party. Condition Code 1 indicates that a trunk access code was extended by the attendant. Condition Code 7 indicates that a feature access code was extended by the attendant.

If Incoming or Outgoing Attendant Call Record is enabled, the system produces a separate record for the attendant portion of incoming or outgoing calls that are transferred.

On attendant-assisted calls that require an account code, the account code must be entered before the trunk access code.

If the attendant is redirecting an incoming call to an extension, the attendant may dial an account code before dialing the extension number.

It is not possible to option the attendant for intraswitch calls. Intraswitch records are produced for an intraswitch-optioned extension calling the attendant or for a call from the attendant to an intraswitch-optioned extension. In the case of an attendant-assisted call involving an intraswitch extension, the calling number recorded is the extension of the party who called the attendant, and the dialed number recorded is the extension that the attendant extended the call to. The record has a Condition Code 0.

- **AUDIX**

For remote AUDIX over DCS, if station A on node 1 forwards its calls to AUDIX on node 2, each switch produces a call record. The record from node 1 contains A as the dialed number. The record from node 2 contains AUDIX as the dialed number.

If the calling number is on a different switch within the DCS network, or the call comes in over ISDN, the actual calling number is recorded in the Calling Number field, and the TAC of the trunk bringing the call into the local switch is recorded in the Incoming Trunk Access Code field of 24-word records.

If the forwarded call is an incoming call, then, as in all cases (other than vectoring) in which an incoming call is forwarded, transferred, or conferenced using an outgoing trunk, two separate CDR records are produced, one for incoming and one for outgoing trunk usage. The outgoing trunk usage record lists AUDIX as the Calling Number.

- **AUDIX - Transfer out of**

If Incoming Trunk Call Splitting is enabled, and Transfer out of AUDIX is used, CDR generates two records. The first contains the AUDIX, the second contains the transferred-to party.

- **Authorization Codes**

Authorization codes are recorded on CDR records provided account codes do not exceed 5 digits for non-ISDN and ISDN LSU formats, or 4 digits for Enhanced LSU formats. On the 59-character CDR International Processing and International Direct records, the authorization code is never recorded. When account codes are dialed, for the non-ISDN and the ISDN LSU formats, authorization codes are recorded on CDR printouts if the account code length does not exceed 6 digits. For Enhanced LSU, the account code length must not exceed 6 digits.

- **Automatic Selection of DID Numbers**

Incoming calls, if recorded at all, are recorded for the DID extension number, not the room extension number.

- **Automatic Alternate Routing (AAR) and ARS**

CDR records contain the following information for ARS:

- Fact that an ARS call was made
- Calling extension number
- FRL of the calling extension
- Called number
- TAC of trunk group used for the ARS call
- Time of call completion
- Call duration (how long the parties talked)
- IXC code, if any

If CDR is suppressed for the trunk group actually used on an ARS call, a CDR record is not generated; otherwise, Condition Code 7 applies. The ARS access code is recorded in the Access Code Dialed field and the trunk access code for the trunk group actually used is recorded in the Access Code Used field.

If an AAR call is placed to a busy trunk group and CDR is suppressed for that trunk group, the user hears reorder tone and the CDR output shows an ineffective call attempt.

If an ARS call is an attendant-assisted call, the CDR record shows the call with a Condition Code of 7 (ARS call) instead of a Condition Code of 1 (attendant-assisted call). This occurs because CDR is not notified until after the trunk is seized and, in this case, the trunk is not seized until the user dials the number.

For FEAC, if a trunk group is accessed via ARS, the trunk group's COR is not used to determine if an account code needs to be entered.

- Automatic Callback

When the Automatic Callback feature is used for an intraswitch call, no CDR record is generated for the first call attempt or the ringback. However, if the caller or extension being called is optioned for intraswitch CDR, a record of the actual call is output provided the call is answered and completed.

- Automatic Circuit Assurance

ACA calls generate intraswitch CDR if the terminating extension is monitored by CDR. The originating extension for ACA calls cannot be administered for intraswitch monitoring.

- Automatic Wakeup

No CDR intraswitch records are generated for wakeup calls.

- Bridged Call Appearance

CDR does not record any information on the party who bridges onto a call. Instead, the number that was called appears in the Dialed Number field of the CDR record. The duration of the call is recorded when the last party drops off the call. This also applies for intraswitch calls.

If the user originates a call over a bridged appearance, the call record contains the calling number of the bridged appearance extension and not the extension number of the original, calling station.

- Busy Verification of Terminals and Trunks

An attendant or user is never required to enter an account code when making a busy verification.

- Call-by-Call Service Selection

When a successful call is made on a Call-by-Call Service Selection trunk, the network specific facility used on the call is translated into an INS number and recorded in the INS field of the call record. If a Call-by-Call Service Selection call is unsuccessful because of an administered trunk usage allocation plan, the INS number is recorded in the INS field of the report with a condition code of "E."

- Call Coverage

When an incoming or intraswitch call is answered by a covering extension, the extension number dialed by the originating party is recorded as the dialed number. If a call is covered to an off-net location, the dialed number is the number of the off-net location, the calling number is the number of the station that is covered to the remote location.

- Call Forwarding All Calls

When a call is forwarded to another extension, the extension number dialed by the calling party is recorded as the dialed number. If a call is forwarded to an off-net location, the dialed number is the number of the off-net location, the calling number is the number of the station that is forwarded to the remote location.

CDR generates one record for a forwarded intraswitch call. In this record, the dialed number is the same as the extension dialed by the originating party.

For a trunk call to a station that is forwarded to a trunk, CDR generates two records. The first record shows an incoming trunk call to the station. The second record shows an outgoing trunk call from the station.

For FEAC, calls cannot be forwarded to a destination where a user is required to enter an account code.

- Call Park

When a user parks an incoming or intraswitch call, that user's extension is recorded as the dialed number in the CDR record. Call duration in CDR reflects the entire time the incoming trunk is busy (incoming) or until the call ends (intraswitch).

- Call Pickup

When an incoming or intraswitch call is answered by another user in the pickup group, the extension number dialed by the calling party is recorded as the dialed number.

- Call Vectoring

The CDR System Parameters screen can be administered so that the VDN extension is used in place of the Hunt Group or Member extension. If administered to do so, this overrides the Calls to Hunt Group - Record option of CDR for incoming Call Vectoring calls.

Outgoing vector calls generate ordinary outgoing CDR records with the originating extension as the calling number.

For incoming calls to a VDN, the duration of the call is recorded from the time answer supervision is returned.

- If answer supervision is returned by the vector (via an announcement, collect, disconnect, or wait with music command), and the call never goes to another extension, the VDN extension is recorded as the called number in the CDR record.
- If the call terminates to a hunt group, the VDN, hunt group, or agent extension is recorded as the called number as per the administration discussed above.
- If the call terminates to a trunk, CDR generates the following two records:
  - An incoming record with the incoming TAC as the dialed number.
  - An outgoing record with the incoming TAC as the calling number and the digits dialed through the vector step as the dialed number.

If “member extensions” is administered on the CDR System Parameters screen and the call successfully completes to a station via the “route-to” command, the call record shows an incoming call to that station.

Call Vectoring “route to” commands that are unsuccessful do not generate ineffective call attempt records.

If a vector interacts with an extension or group that has Call Forwarding All Calls active, normal Call Forwarding/CDR interactions apply.

Some calls may originally look like intraswitch calls, but result in trunk calls (for example, a call from a station administered for intraswitch CDR to a VDN, which ends up an outgoing call on an outgoing trunk). Such calls will not generate intraswitch CDR records; the CDR record will have a condition code A - outgoing.

- **Call Waiting Termination**

Call duration timing starts when the user answers an incoming call.

- **Centralized Attendant Services**

If a CAS attendant extends a call for a user, and CDR is not assigned to the RLT trunk group, the user’s extension is recorded as the originator of the call. If the RLT trunk group does have CDR administered, the RLT trunk is recorded. If a CAS attendant answers a call but does not extend the call, no CDR records are made.

- CO Trunks

All incoming and outgoing calls on a CO trunk group are recorded, if CDR is assigned to the trunk group and CDR is administered to record incoming calls.

- Conference

For the purpose of CDR, a call is considered a conference call if it contains at least one trunk that is eligible for CDR plus two or more parties, or if it contains at least one party optioned for intraswitch CDR. Condition Code C applies to each CDR record made for a conference call.

For a conference call, a separate CDR record is produced for each outgoing/incoming trunk serving the conference call. If ITCS or OTCS is enabled, CDR produces a separate record for each internal party on the call as well.

For the outgoing portion of a conference call involving multiple extensions, the extension that requested outside dial tone to bring an outside party into the conference is recorded as the calling party.

For the outgoing/incoming portion of a conference call, the call duration in CDR reflects the entire time the trunk is on the conference call.

A separate CDR record is produced for each trunk used in a trunk-to-trunk transfer. If ITCS is active, the incoming trunk record shows the duration of the entire call.

If the originator of the conference call is optioned for intraswitch CDR, each time the originator dials a non-trunk party, a new CDR record is started. For example, Station A is optioned for intraswitch CDR and calls Station B. Station A conferences in Station C. Station A drops from the call. Station B or C drops from the call. Two CDR records are output with Condition Code C: one for the A to B call and one for the A to C call.

If the originator is not optioned for intraswitch CDR, but one or more parties brought into the conference are, one record with Condition Code C is generated for each dialed intraswitch party. For example, Station A calls Station B, which is optioned for intraswitch CDR. Station A conferences Station C. Station A drops from the call. Station B or C drops from the call. One CDR record is output with condition code C for the A to B call.

Intraswitch conference call CDR records are output when both the calling number (originator) and dialed number (terminator) of the call drop. The duration of the call will be from the time the terminator answers until both the originator and terminator drop from the call.

If the attendant originates the conference, only the dialed numbers corresponding to intraswitch optioned extensions stimulate the creation of CDR records.

- DCS  
Station information is not passed throughout the DCS network for CDR purposes.
- DID trunks  
All incoming calls on the DID trunk group will be recorded if administered to record incoming CDR and if CDR is administered for this trunk group.
- Emergency Access to the Attendant  
CDR does not generate intraswitch records for Emergency Access calls.
- Expert Agent Selection  
A logical extension can be assigned to an agent who can log into a phone using that extension number. On the CDR System Parameters screen, you can chose to record the agent's logical extension as the called number rather than the hunt-group extension or hunt-group-member extension.
- Foreign Exchange (FX) Trunks  
All calls made on an FX trunk group are recorded if administered to record CDR and if CDR is administered for this trunk group.
- Hotline Service  
The stored number used on an outgoing or intraswitch Hotline call is recorded by CDR the same as if it was manually dialed.
- Hunt Groups  
Either the hunt group extension number or individual hunt group member extension number is recorded as the called number. This is administrable on the CDR System Parameters screen.
- Intercept Treatment  
If an outgoing or tandem call is routed to Intercept Treatment, the number dialed by the calling party is recorded as the dialed number, and Condition Code F is recorded.
- Inter-PBX Attendant Calls  
If a user calls an Inter-PBX attendant and the trunk group used has CDR assigned, call records contain the following information:
  - Condition Code — A
  - Access Code Dialed — Blank
  - Access Code Used — Trunk access code of trunk used
  - Dialed Digits — Inter-PBX attendant access code

- ISDN

When true answer supervision is received from the network, an indication is sent to the CDR device to this effect. If an ISDN call has been interworked, the call record shows this, and answer supervision may or may not be accurate. If you use unformatted or expanded record formats, the SID/ANI appears in the record, if sent.

- Last Number Dialed

The CDR access code and account code dialed are stored as part of the Last Number Dialed. However, some digits may be lost due to the limit on the number of digits stored for this feature.

- Manual Originating Line Service

If an attendant establishes an outgoing call for a user, designated as a Manual Originating Line, the CDR record for the call is the same as for any attendant-assisted outgoing call. The calling extension is recorded as the calling number, and Condition Code 1 applies.

- Multiple Listed Directory Numbers (LDNs)

If incoming call information is recorded, the called number recorded for LDN calls is the extension number or trunk group access code to which the attendant completes the call. If the call terminates at the attendant console only, the dialed number is the attendant extension. The attendant extension number is administrable (the default is 0).

LDNs cannot be administered for intraswitch CDR. However, a call from an intraswitch optioned extension to a LDN produces an intraswitch CDR.

- Night Service

The extension number assigned to the attendants is recorded as the dialed number. The attendant extension number is administrable (the default is 0).

- Off-Premises Station

CDR data is recorded if the extension is involved in an outgoing/incoming trunk call or it (or the other terminal involved in the call) is optioned for intraswitch CDR.

- PCOL trunks

An outgoing PCOL call shows the dialed number in the `Dialed Number` field of the CDR record rather than a TAC. An outgoing PCOL call is recorded as a call from the originating extension number via the trunk group associated with the PCOL. On incoming PCOL calls the answering extension's primary extension is recorded as the called number if incoming calls are recorded.

- **Planned Interchange**

When a planned interchange occurs (either demand or scheduled), it is possible for the CDR records on calls ending within 10–20 seconds after the interchange to report as “invalid long duration calls” (duration of 9:59:9 and Condition Code other than 4). This is caused by deviations in the clocks between the two processors and the short duration of the calls. Consider these records invalid.

- **Private Network Access**

Private Network Access calls are recorded if CDR is assigned for incoming or outgoing tie trunks.

- **Remote Access**

Remote Access calls are recorded if Remote Access is provided on a per trunk group basis (incoming destination is the remote access number), and those trunks are administered for CDR. The call record gives no indication that this is a remote access call, other than the trunk group access code.

- **Ringback Queuing**

Condition Code 8 is recorded for an outgoing call which is queued for a trunk before completion. The length of time the call is queued is not recorded.

When an outgoing call is queued for a trunk and is unsuccessful (the queue times out or the calling party does not answer the callback) a CDR record is not generated for the call.

- **Security Violation Notification (SVN)**

SVN calls generate intraswitch CDR if the terminating extension is monitored. You cannot administer the originating extension for intraswitch monitoring.

- **Service Observing**

No CDR records are generated for Service Observing calls. Tandem Tie-Trunk Switching

The calling party on an incoming trunk can dial the CDR account code. The `Calling Number` field in CDR is the trunk access code for the incoming trunk group, the called number is the number dialed.

- **Temporary Bridged Appearance**

A CDR record is not affected by any second or subsequent use bridging a call.

- Temporary Signaling Connections (TSCs)

Call-associated TSCs and TSC requests appear in the call record, provided the switch is administered to use ISDN layouts. Non-call-associated TSCs and TSC requests generate separate CDR records if the switch is administered to record them. In either case, the `TSC Flag` and `Packet Count` fields of the call record contain TSC data.

- Tie Trunk Access

Tie-trunk calls are recorded if CDR is administered to record the trunk group and to record incoming calls.

- Transfer

If a user *originates* a call on an outgoing trunk and then transfers the call to another extension, the originating extension is recorded as the calling party.

If a user *receives* a call on an incoming trunk and then transfers the call to another extension, the extension that originally received the call is recorded as the dialed number.

If a user *receives an intraswitch call* and then transfers it to another extension, the extension that originally received the call is recorded as the dialed number.

If call splitting is active, when a user receives or originates a trunk call and then transfers the call to another extension, two records are generated.

Intraswitch CDR records are generated for each call to or from an intraswitch optioned extension. For example, Station A, which is intraswitch optioned, calls Station B. Station A then transfers the call to Station C. When either Station B or C drops, two CDR records with Condition Code 0 are output: one for the A to B call, and the second for the A to C call.

Intraswitch CDR transfer records are output when both the calling number (originator) and dialed number (terminator) drop from the call. The duration of the call is from the time the terminator answers until both the originator and terminator have dropped from the call.

If ITCS is enabled and an incoming trunk call is transferred to a local extension that is optioned for Intraswitch CDR, the call produces an incoming trunk call record. It does not produce an Intraswitch record.

Users cannot dial an account code when transferring a call to another extension, unless they have console permissions. However, a user transferring a call to a trunk can dial an account code before dialing the ARS or TAC.

- **Trunk-to-Trunk Transfer**

Although they are not really conference calls, Trunk-to-Trunk Transfer connections are treated as such for CDR purposes. A separate CDR record is generated for each trunk in the connection.

Unanswered Trunk Calls may or may not be recorded depending on administration. You can administer each trunk group so that unanswered calls are recorded if they remain unanswered for a specified period of time.

If Incoming Trunk Call Splitting is active, a trunk-to-trunk transfer produces a record of the incoming call, and a record of the outgoing call. The outgoing call record shows the duration from the time the call was transferred until both parties drop. The incoming call record shows the duration from the time the station receives the incoming trunk call until both parties drop.

- **Uniform Dial Plan (UDP)**

If one user calls another user via a UDP extension number, and the trunk group used has CDR assigned, CDR records the following information:

- Condition Code — 7
- Access Code Dialed — blank
- Access Code Used — trunk access code of trunk used
- Dialed Digits — Uniform Dial Plan extension

- **VDN Return Destination**

An incoming call does not generate a CDR record until the originator drops from the call. CDR creates a record when a call goes to the return destination VDN, the originator has not dropped, and vector processing — that is, the return destination VDN — routes the call to an outgoing trunk. CDR does not create a record if vector processing routes a call from the return destination VDN to an internal call. The call record shows only the first VDN that the caller accessed, no matter how many other extensions are involved in the call.

If an incoming VDN call is routed to a station, CDR includes the station in the record. If an incoming VDN call is routed to an outgoing trunk, CDR includes the VDN in the record.

## Call forwarding

---

Call Forwarding allows users to redirect calls to designated destinations. The forwarded-to destination can be an internal extension, external (off-net) number, an attendant group, or a specific attendant.

Call Forwarding provides five functions:

- Call Forwarding-All Calls — Allows a user to redirect every incoming call to the forwarded-to destination.
- Call Forward Busy/Don't Answer — Allows a user to redirect incoming calls to a forwarded-to destination only when the user is busy or when the call is not answered after an administrable interval. If the extension is busy, the call forwards immediately. If the extension is not busy, the incoming call rings the called extension, then forwards only if it remains unanswered longer than the administered interval.
- Call Forwarding Off Net— Allows a user to forward calls to an off-net destination.
- When the Coverage of Calls Redirected Off-Net field is activated, calls can be monitored for call progress tones, and if a call is not answered, it returns to the Avaya MultiVantage for call coverage processing in some circumstances.
- Call Forwarding Override — Allows the user at the forwarded-to extension to override Call Forwarding at the forwarded-from extension on a per-call basis so the user can initiate a call or transfer a call back to the forwarded-from extension.

### Detailed description

---

You assign Call Forwarding All Calls and Call Forwarding Busy/Don't Answer to extensions on a Class of Service basis. You assign Call Forwarding Override and Call Forwarding Off-Net on a system-wide basis. You can also restrict Call Forwarding Off-Net with the Class of Service.

### Call Forwarding All Calls

Phone users and data-terminal users can activate or deactivate Call Forwarding All Calls for their own terminals with a feature-access code or Call Forward-All feature button. Virtual extension users cannot activate or deactivate Call Forwarding All Calls. An attendant or phone user with console permission can activate or deactivate the feature for another extension, virtual extensions, TEG, DDC, UCD group, or ACD split (but not vector-controlled splits).

## Call Forwarding Busy/Don't Answer

The feature is activated or deactivated with a feature-access code or Call Forward Busy/Don't Answer feature button. An attendant or phone with console permission can also activate or deactivate the feature for another extension by using a feature-access code. Virtual extension users cannot activate or deactivate Call Forwarding Busy/Don't Answer.

Call Forward Busy/Don't Answer cannot be activated for hunt groups, data extensions, or TEG. Calls to an attendant or Expert Agent Selection (EAS) agent cannot be forwarded.

## Call Forwarding Off Net

When a call is forwarded off net, the forwarded-to number can have up to 18 digits. When counting the 18-digit limit, count the digits in the Trunk Access Code or Automatic Alternate Routing/Automatic Route Selection (AAR/ARS) feature access code. Do not count the “#” used to terminate a forwarded-to number if the “#” is used.

If the Coverage of Calls Redirected Off-Net field on the System Parameters Customer-Options screen and the Coverage of Calls Redirected Off-Net Enabled field on the System Parameters - Call Coverage/Call Forwarding screen are both set to **y**, the system allows calls forwarded off-net to be monitored for busy or no-answer conditions. The system may bring the call back for call-coverage processing if the principal's coverage criteria are satisfied at the forwarded-to destination. However, if the principal does not have a coverage path, the system does not monitor the call. It is left at the off-net destination regardless of whether it is answered or busy.

Calls forwarding off net require an available outgoing trunk. Additionally, when the Coverage of Calls Redirected Off-Net field is **y**, a call-classifier port may be required. If there are no call-classifier ports available when needed, the call still routes off net, but it is not monitored for call progress tones and cannot be returned to the switch for further call coverage processing.

Whenever an incoming trunk call is redirected off-net, a timer is set that precludes any other incoming trunk call from redirecting off-net until the timer either expires or is cancelled. The rationale for this mechanism is to prevent calls that were redirected off-net from being re-routed back to the original principal from the off-net destination, effectively creating a round-robin loop that continuously seizes trunks until they are exhausted. The blocked call receives busy tone or redirects to coverage.

 **NOTE:**

If you send calls off-net and use the Call Classifier - Detector or the Tone-Clock (with Call Classifier-Tone Detector) circuit pack (the international version) for call classification and do not use the American tone plan, use the System-Parameters Country-Options screen to define specific country tones. If you use the Call Classifier - Detector or the Tone-Clock (with Call Classifier-Tone Detector) circuit pack (the international version) and do not use the System-Parameters Country-Options screen, your system will download the American tone plan regardless of your geographical location.

## Call Forwarding — Override

You can administer Call Forwarding Override on a system-wide basis to allow a forwarded-to party to override Call Forwarding when placing a call to the forwarded-from party. Call Forwarding Override is invoked automatically if the system-wide override option is set.

Call Forwarding Override cannot be used when calls forward to an external number. Call Forwarding All Calls from a data user or a hunt group cannot be overridden with Call Forwarding Override.

## Warning users if their calls are redirected

You can warn analog phone users if they have features active that may redirect calls. For example, if the user has activated call forwarding, you can administer a setting to play a special dial tone when the user goes off-hook. See [“DISTINCTIVE AUDIBLE ALERTING” on page 826](#) for more information.

## Security

---

Use the **list call-forwarding** command to get general information and to identify unauthorized Call Forwarding feature activation. The list shows the station name, station number, and forwarded-to destination number.

 **SECURITY ALERT:**

*Users who do not have permission to call out of the building may not do so with Call Forwarding.*

## Considerations

---

Calls can be forwarded only once. Consider the following scenario. Extension A forwards its calls to extension B. Extension B forwards its calls to extension C. Calls made to extension A:

- Ring at A, if possible
- Ring at B, if possible
- Redirect to extension A's coverage path, if available and A's coverage criteria are satisfied when applied at B
- Are not forwarded to extension C

There is no maximum number of calls that can be forwarded simultaneously.

You can administer a phone to receive a redirection notification signal when a call is forwarded.

The system restricts users from forwarding calls to a number that they are not allowed to call.

If **save translation** is run after call forwarding is activated for a phone, forwarding status and destination number are saved to tape.

## Attendant

Calls to attendants cannot be forwarded. However, calls can be forwarded to the attendant *group*.

The attendant cannot have a Call Forwarding button.

Only the attendant or phone user with console permission can activate Call Forwarding All Calls for TEGs, UCD groups, DDC, and data modules.

## Number of rings provided to a forwarded call

The following table shows the field used to specify the number of rings provided a forwarded call before the call redirects to coverage.

| Type of Forwarding | Forwarding All | Forwarding Busy/Don't Answer |
|--------------------|----------------|------------------------------|
| local              | coverage path  | local                        |
| remote             | *              | *                            |

| Type of Forwarding | Forwarding All | Forwarding Busy/Don't Answer |
|--------------------|----------------|------------------------------|
| CCRON              | off-net        | off-net                      |
| DCS (CCRON off)    | coverage path  | local                        |
| DCS (CCRON on)     | off-net        | off-net                      |

- Coverage path — On the Coverage Path screen, the Number of Rings field.
- Local — On the System-Parameters Coverage/Forwarding screen, the Local Subsequent Redirection/CFWD Don't Answer Interval field.
- Off-net — On the System-Parameters Coverage/Forwarding screen, the Offnet Subsequent Redirection/CFWD Don't Answer Interval field.
- \* — No coverage treatment applied (rings until answered).

## Example

---

If you forward all calls to a local site, the switch checks the Number of Rings field on the [“Coverage Path”](#) screen.

If you forward busy/don't answer calls to a local site, the switch checks the Local Subsequent Redirection/CFWD Don't Answer Interval field on the [“System Parameters Call Coverage / Call Forwarding”](#) screen.

## Interactions

---

- Answer Detection
 

This feature shares call-classifier resources with the Coverage of Calls Redirected Off-Net feature.
- Attendant Override of Diversion Features
 

If an attendant uses redirection override to call a user who has Call Forwarding active, the call does not forward and remains at the user's phone.
- Automatic Callback and Ringback Queuing
 

Automatic Callback cannot be activated toward a phone that has Call Forwarding active. If Automatic Callback was activated first, the callback call attempt is redirected to the forwarded-to party.

- Bridging

Calls do not terminate to bridged appearances when Call Forward Busy/Don't Answer is active.

The switch blocks users from bridging onto a call that has routed off net while the call is undergoing call classification.

- Call Coverage

If the principal's (forwarding extension) redirection criteria are met at the designated (forwarded-to) destination, the forwarded call redirects to the principal's coverage path; the designated destination gets a temporary bridged appearance (except when it is off net), which remains active after the call is answered so that the designated extension can bridge onto the call if desired. The temporary bridge appearance remains until the caller hangs up.

If Cover All Calls is part of the coverage redirection criteria and if Call Forwarding or Call Forwarding Off-Net is active at a phone, incoming priority calls forward to the designated destination; all other calls redirect according to the Call Coverage path. Non-priority calls are not directed off net.

When a covering user has activated Call Forwarding, a coverage redirected call does not forward to the designated extension number. Instead, the call is redirected to the next point in the principal's coverage path, if available. If no other coverage point is available, the call remains at the principal's phone.

- Call Detail Recording (CDR)

When a call is forwarded to an off-net number, the call is recorded in CDR records as a call from the forwarding station. When the Coverage of Calls Redirected Off-Net field is **y**, a CDR record is generated only after the call has actually been answered off net.

If forced entry of account codes is required, calls cannot be forwarded to off-net destinations.

- Call Forwarding All Calls and Call Forward Busy/Don't Answer

Call Forwarding All Calls and Call Forward Busy/Don't Answer cannot be active for the same phone at the same time.

- Call Park

Calls can be parked on a forwarded-from extension even though Call Forwarding is active for that extension. If a forwarded-to extension user parks a call that had been forwarded to that extension, the call is normally parked on the forwarded-to extension, not the forwarded-from extension.

- **Call Pickup/Directed Call Pickup**

If the Temporary Bridged Appearance on Call Pickup field is set to **y** on the Feature-Related System Parameters screen, a Temporary Bridged Appearance is maintained if the forwarded-to destination is a member of the same call pickup group as that of the forwarded from station. If the Temporary Bridged Appearance on Call Pickup field is set to **n**, a Temporary Bridged Appearance is not maintained.
- **Call Prompting**

This feature shares call-classifier resources with the Coverage of Calls Redirected Off-Net feature.
- **Call Visor ASAI**

This feature shares call-classifier resources with the Coverage of Calls Redirected Off-Net feature.
- **Conference**

The switch blocks users from conferencing another party onto a call which has routed off net while the call is undergoing call classification. If any party on a call that has forwarded off net is on hold (due to the initiation of a conference), the call routes off net without undergoing call classification. This occurs even when the Coverage of Calls Redirected Off-Net field is **y**.
- **Expert Agent Selection (EAS)**

Agents logged in with EAS enabled cannot activate or deactivate Call Forwarding. The physical extension where the EAS agent is logged in can be forwarded, but the EAS agent must first log out. Then, the phone can be forwarded.
- **Hold**

If any party is on hold when a forwarded-to call routes off net, that call does not undergo call classification, even when the Coverage of Calls Redirected Off-Net field is **y**.
- **Intercom—Automatic**

When a phone with Intercom—Automatic is call forwarded to another phone, the auto-icom feature also forwards. Intercom—Automatic is not forwarded if a call forwards off-net.
- **Interflow**

The Interflow feature allows ACD calls to be redirected from one split to a split on another switch or to another external location. This is accomplished by forwarding calls that are directed to the split extension to an off-notify-net location via the Call Forwarding All Calls feature.

- **Intraflow**

Call forwarding can be used to unconditionally redirect ACD calls from a split to another destination on the same switch.
- **Leave Word Calling (LWC)**

LWC cannot be activated toward a phone that has Call Forwarding activated. If LWC was activated before the called phone user activated Call Forwarding, the callback call attempt is redirected to the forwarded-to party.
- **Multifrequency Compelled (MFC) Signaling**

This feature shares call classification resources with the Coverage of Calls Redirected Off-Net feature.
- **Personal Central Office Line (PCOL)**

PCOL calls cannot be forwarded.
- **QSIG**

If a call is forwarded over an ISDN-PRI trunk administered with supplementary service protocol “b” (QSIG), then additional call information may be displayed.
- **Send All Calls**

If an extension has both Send All Calls and Call Forwarding All Calls activated, calls to that extension that can immediately be redirected to coverage are redirected. However, other calls, such as Priority Calls, are forwarded to the designated extension.

Activation of Send All Calls at the forwarded-to extension does not affect calls forwarded to that extension.
- **Temporary Bridged Appearance**

The system maintains a Temporary Bridged Appearance for on-net calls after the call is answered or until the caller hangs up. However, for calls forwarded off-net, the system cannot maintain a Temporary Bridged Appearance. Once the call is redirected to the principal’s coverage path, the trunk to the off-net, forwarded-to, number is released.
- **Traffic Reports Removed**

The list measurement tone-receiver traffic reports provide port usage for this feature.
- **Transfer**

The switch blocks a user from transferring a call which has routed off net to another party while the call is undergoing call classification. If any party on a call that has routed off net is on hold (due to the initiation of a transfer), the call routes off net without undergoing call classification. This occurs even when the Coverage of Calls Redirected Off-Net field is **y**.

---

See [“System Parameters Call Coverage / Call Forwarding” on page 1167](#) for information on setting the number of times an extension rings before the system redirects the call or to determine whether the forwarded-to phone can override call forwarding to allow calls to the forwarded-from phone.

See [“Feature Access Code” on page 781](#) for information on forwarding calls to an administered number.

See [“Class of Service” on page 672](#) for information about assigning extensions a Class of Service (COS) that allows call forwarding.

See [“Station” on page 1127](#) for information about button assignments.

See [“Setting up call forwarding” on page 199](#) for instructions on administering various types of automatic call forwarding.

## Call park

---

Call Park allows users to put a call on hold and then retrieve the call from any other telephone within the system.

You can set a system-wide expiration interval for parked calls. If a call is not answered within the interval, the parked call redirects to an attendant or to the user who activated Call Park (the parking user). Calls redirect to the attendant if the default “Loudspeaker Paging” option is assigned and to the parking user if the Deluxe Paging and Call Park Timeout to Originator option is assigned.

If no attendant or night service extension is administered, and if Night Service — Trunk Answer from Any Station is not administered, the expiration interval is ignored and the call remains parked.

If two parties are connected on a parked call, a third party can also answer the call before the interval expires, creating a 3-way conference.

The attendant console group can have common, shared extensions used exclusively for Call Park. These extensions are not assigned to a telephone, but are stored in system translations and used to park a call. The extensions are particularly useful when one party is paged at the request of another party. The caller is parked on a common shared extension and the extension is announced. The status lamp associated with the extension identifies “call parked” or “no call parked” (instead of active or idle status).

Call Park allows telephone users to answer a call at one extension, but complete the call at another extension. Call Park also allows users to answer a call at any telephone after being paged by a telephone user or an attendant.

To retrieve parked calls, either:

- Depress the lit **Call Park** button on the user's extension, or
- If other than the user's extension, type the FAC for the Answer Back Access Code field assigned the Feature Access Code screen

### **Considerations**

---

- Only one call per extension can be parked at a time, even if the extension has multiple call appearances. Conference calls with up to five parties can be parked; the sixth position must remain open for the retrieving party.
- Calls cannot be parked on a group extension. If a group member places a call in Call Park, the call is parked on the member's extension. Group members can belong to the following:
  - A coverage answer group
  - A DDC group
  - A TEG
  - A UCD group
- If all appearances on a parked telephone are busy and no attendant or night-service extensions are configured when the call park timeout expires:
  - A parked call is dropped if no coverage path is assigned
  - A parked call is not dropped if a coverage path is assigned.

### **Interactions**

---

- **Abbreviated Dialing**

This button allows users to park calls or retrieve parked calls by pressing a button, instead of using the buttons and access codes separately.
- **Automatic Wakeup**

Automatic Wakeup calls cannot be parked.
- **Bridged Call Appearance**

If a user, active on a bridged call appearance, activates Call Park, the call is parked on the primary extension associated with the bridged call appearance.

- **Call Vectoring**

A call cannot be parked on a vector directory number (VDN) extension. Also, a call that is undergoing vector processing cannot be parked.
- **Code Calling Access**

When a paging party dials the Code Calling Access code and the paged user's extension, the paging party is automatically parked on the paged party's extension.
- **Common Shared Extensions**

If an attendant parks a call on a shared extension and tenant partitioning is not active, then when the call park timeout occurs, the call returns to the attendant group.

If an attendant parks a call on a shared extension and tenant partitioning is active, then when call park timeout occurs, the call returns to the attendant who parked the call.

The setting of the Deluxe Paging and Call Park Timeout to Originator field of the Feature-Related System-Parameters screen does not effect this behavior.
- **Conference**

Conference calls can be parked.
- **Data Privacy and Data Restriction**

These features are automatically deactivated when a call is parked.
- **Drop**

If a digital-telephone user parks a call and then pushes the drop button, the call is unparked. If the parked call is from an internal digital-telephone user, pushing the drop button does not drop the call. The parking user must hang up to drop the call.
- **Loudspeaker Paging Access**

Calls to paging zones cannot be parked.
- **Music-on-Hold**

If a parked call involves only one party, the parked user hears music-on-hold. The parking user also hears music after first parking the call and hearing confirmation tone.
- **Remote Access**

A Remote Access caller cannot park a call. However, the Code Calling Access feature, an answering attendant, or a telephone user can park an incoming Remote Access call.

## Call Pickup

---

Call Pickup and Directed Call Pickup allow a telephone user to answer calls that alert at other extension numbers within the user's specified call pickup group. Directed Call Pickup allows telephone users to pick up any call on the Avaya MultiVantage system.

### Call Pickup

Establish a call pickup group so that when one member of a group is away, other members can answer the absent member's calls. A call pickup group usually consists of users who are located in the same area or who have similar functions.

To pick up another user's call, a user goes off-hook and dials the Call Pickup access code or presses a Call Pickup button.

If a user's telephone has a Call Pickup button and status lamp, then:

- The status lamp lights steadily when Call Pickup is used.
- If Call Pickup Alerting is activated, members' status lamps flash when a call comes in to any extension in the call pickup group. Group members other than the called party, can answer using Call Pickup. The called party can answer on the ringing call or bridged appearance.

**NOTE:**

Call Pickup Alerting for a telephone takes effect only when the Call Pickup status lamp is not lit. If Call Pickup is used to answer a call, the status lamp lights steadily and does not flash if there are additional calls to the call pickup group.

Both Call Pickup and Call Appearance status buttons flash at the called party's telephone.

If calls ring at 2 or more telephones in a call pickup group and a group member presses the Call Pickup button, a distribution algorithm determines which call is answered. Thus, all call pickup group members are treated equally. Specifically, when a Call Pickup button is pressed, the system searches the group extension numbers until reaching an extension with a call eligible for Call Pickup. The next time a Call Pickup button is pressed, the system searches from the *next* extension number.

For example, if extension A has 2 calls ringing and extension B has 1 call ringing, and one of extension A's calls is answered with Call Pickup, then extension B's call is answered the next time Call Pickup is used. After extension B's call is answered, a user can answer the second call to extension A.

When multiple calls ring on a telephone and a group member activates Call Pickup, the call with the lowest call-appearance number is answered. For example, if calls ring on the second and fourth call-appearance button on a telephone and a user at another telephone activates Call Pickup, the call on the second call-appearance button is answered.

## Directed Call Pickup

Directed Call Pickup functions like Call Pickup, except for the following:

- A user can answer an alerting call at any telephone on the system — the alerting and answering telephones need not be members of the same call pickup group.
- You grant users permission to have their calls answered or to answer others' calls with Directed Call Pickup on a per-telephone basis on the Class of Restriction screen.

## Considerations

---

- A telephone can be a member of only one call pickup group.
- When a call pickup group member is away from his or her telephone and receives a call, other call pickup group members' telephones do not ring. Therefore Call Pickup is only useful if either:
  - Call Pickup Alerting is enabled and call pickup group members have telephones with Call Pickup buttons and status lamps.
  - Call pickup group members are in close proximity and can hear each other's telephones ring.
- Exclusion is not supported for pickup calls.

## Interactions

---

- **Abbreviated Dialing**

A user can store:

- The Directed Call Pickup feature access code (FAC) plus a telephone address in an Abbreviated Dial button
- The Directed Call Pickup FAC. (The user then dials each extension.)

- **Attendant**

Attendant can use Directed Call Pickup, but other users cannot use the feature to answer a call alerting at an attendant's telephone.

- **Automatic Callback and Ringback Queuing**

Neither call pickup group members or Directed Call Pickup users can answer Callback calls.

- **Bridged Call Appearance**

- If Call Pickup Alerting is activated and a bridged call appearance rings on a call pickup group member's telephone, other group members cannot pick up the call.
- If Call Pickup Alerting is not activated and a telephone rings on a bridged call appearance, group members can pick up the call.
- If Temporary Bridged Appearance on Call Pickup is enabled, a temporary-bridged appearance is maintained at the called telephone. This allows the called party to bridge onto the call after it has been picked up by another call pickup group member.
- Directed Call Pickup cannot be used to pick up a call alerting at a bridged call appearance.

- **Call Coverage**

You can use Directed Call Pickup to answer a redirected call alerting at a covering user's telephone if there is a call-coverage temporary bridged appearance.

- **Call Detail Recording (CDR)**

The extension number dialed by the caller is recorded as the dialed number in CDR.

- Call Forwarding

If Temporary Bridged Appearance on Call Pickup is enabled, a temporary bridged appearance is maintained if the forwarded-to telephone belongs to the same call pickup group as the forwarded-from telephone. If Temporary Bridged Appearance on Call Pickup is not enabled, a temporary bridged appearance is not maintained.

- Call Pickup Alerting

If a user who is a member of a ringing telephone's pickup group uses the Direct Call Pickup to answer a call and the call is the only call ringing for any member of the pickup group, the Call Pickup Alerting lamp goes dark when the user picks up the call.

If a user who is not a member of a pickup group uses Direct Call Pickup to answer a call, then Call Pickup Alerting does not apply.

- Call Waiting Termination

You cannot use Call Pickup to pick up a Call Waiting call.

- Conference

If the Call Pickup Alerting field is enabled and a call is picked up and conferenced into a conference call, the Call Pickup status lamp flashes if additional calls are available for Call Pickup.

- Consult

If the Temporary Bridged Appearance on Call Pickup field is not enabled, the consult call from the covering user appears as an idle-call appearance.

- Expert Agent Selection (EAS)

EAS agents can use Directed Call Pickup to pick up a call or have their calls picked up. The agent's COR overrides the class of restriction (COR) of the telephone where the agent is logged in.

If both the telephone's COR and the logged-in agent's COR allow Directed Call Pickup, the user picking up the call can use either the telephone's extension or the agent's loginID.

- **Hold**

If the Temporary Bridged Appearance on Call Pickup field is not enabled and a user puts a call answered with Directed Call Pickup on hold, the called party cannot answer the call because a temporary bridged appearance is maintained. If the Temporary Bridged Appearance on Call Pickup field is enabled, then:

- A call picked up and placed on hold at an extension remains on that extension, even if the called party answers the call.
- If the Call Pickup Alerting field is enabled and a call is picked up and placed on hold, the Call Pickup status lamp flashes if additional calls are available for Call Pickup.

- **Hot Line Service and Manual Originating Line Service**

Telephones assigned these features can be members of a call pickup group and have calls picked up, but they cannot answer calls for other pickup group members.

- **Intercom — Automatic/Dial**

If Call Pickup on Intercom Calls is activated, you can use Call Pickup and Directed Call Pickup to pick up Automatic Intercom calls. If it is not activated, Automatic Intercom calls cannot be picked up and the calls are not included in the call-pickup-alerting-count.

- **Internal Automatic Answer (IAA)**

Internal calls to a telephone in a call pickup group are eligible for IAA. If the called extension in a call pickup group has IAA activated, the call is answered automatically. An extension that has IAA cannot automatically answer calls to other telephones in its call pickup group.

IAA-eligible calls to an IAA extension cannot be answered with Call Pickup because they are automatically answered at the called telephone. Any non-IAA-eligible calls, such as external calls that ring the IAA-active telephone, can be answered by members of that telephone's call pickup group.

- **Malicious Call Trace (MCT)**

You cannot use Directed Call Pickup to pick up an alerting MCT call at the MCT-Controller telephone.

- **Multimedia Call Handling**

Do not use Call Pickup or Directed Call Pickup with a Multimedia data endpoint. However, calls alerting at the voice component of a multimedia complex can be picked up with Call Pickup or Directed Call Pickup.

- Privacy — Manual Exclusion

In the following case, the called party is not dropped when Privacy — Manual Exclusion is activated.

A call is made to Station A and Station B picks it up using Call Pickup. Station A bridges onto the call by going off-hook on its call appearance. Station B activates Privacy — Manual Exclusion.

- Tenant Partitioning

Directed Call Pickup follows existing Tenant Partitioning. The feature does not function across tenant partitions unless specifically administered to do so.

- Terminating Extension (TEG)

You cannot use Directed Call Pickup to pick up a call alerting at a TEG extension number.

- Transfer

If the Call Pickup Alerting field is enabled and a call is picked up and transferred, the Call Pickup status lamp flashes if additional calls are available for Call Pickup.

## **Call waiting termination**

---

Call Waiting Termination notifies a user with a single-line telephone who is active on one call that a second call is waiting. Single-line telephone users can place a call on hold to answer a waiting call. After answering the waiting call, they can return to the held call or toggle back and forth between the two calls. A single-line, telephone user can connect to only one call at a time.

Generally, the single-line telephone user hears one quick burst of tone when a call from another telephone user is waiting, 2 quick bursts of tone when an attendant-handled or an outside call is waiting, and 3 quick bursts of tone when a Priority Call is waiting.

**⇒ NOTE:**

Special ring tones are not supported over DID facilities.

A priority call can wait for the telephone to become idle even if Call Waiting Termination is not activated. However, an attendant-handled call receives busy tone unless the Attendant Call Waiting Indication field is set to **y**.

You assign Call Waiting Termination on a per-telephone basis. For a virtual extension, call waiting is assigned on the physical station.

## Considerations

---

- An analog telephone user must place the active call on soft hold and dial the Answer Hold-Unhold feature access code to answer the waiting call.
- If an analog single-line telephone has Call Waiting enabled and has initiated a conference call, Call Waiting is denied. For example, caller A (on an analog telephone) is talking to caller B, then flashes and is talking to caller C, and then flashes to conference B and C. Then, if caller D attempts to call caller A, Call Wait is denied.

## Interactions

---

Call Waiting is denied when the following features are activated at the single-line telephone:

- Another Call Waiting Call
- Automatic Callback (to or from the telephone)
- Data Privacy
- Data Restriction

A Call Waiting call cannot be picked up by a Call Pickup group member or by directed call pick-up.

## Call-by-call service selection

---

Call-by-Call Service Selection enables a single ISDN trunk group to carry calls to a variety of services. It does not require that each trunk group be dedicated to a specific service. It allows you to set up various voice and data services and features for a particular call.

Call-by-Call Service Selection provides the following benefits:

- Cost reduction — Since many services share the same trunks, the total number of trunks can be reduced.
- Improved service — Features and services are less likely to be blocked.
- Simplified Networking — Network engineering is simplified because analysis of trunking needs can be done based on total traffic instead of on a per-service basis.
- Timely response to changes — With Usage Allocation Plans (UAPs), the network does not have to be consulted.
- Measurement of Call-by-Call Service Selection calls

**Brief description**

Call-by-Call Service Selection uses the same route patterns and route preferences that are used by AAR, ARS, and GRS. The service or facility used on an outgoing Call-by-Call Service Selection call is determined by information assigned in the AAR/ARS/GRS route patterns.

You can allow a variety of services to use a single trunk group. The system obtains trunking efficiency by distributing traffic over all the available trunks. Then you can assign services that are used on incoming and outgoing Call-by-Call Service Selection calls. The system provides traffic measurements for each individual service administered for an ISDN Call-by-Call Service Selection trunk group.

A Call-by-Call Service Selection example is shown below.

i773197 C.JL 060396

**Figure Notes**

- |                            |                                               |
|----------------------------|-----------------------------------------------|
| 1. Avaya Media Server      | 6. Call-by-Call Service Selection trunk group |
| 2. Megacom trunk group     | 7. Public-switched network                    |
| 3. Megacom 800 trunk group | 8. Without Call-by-Call Service Selection     |
| 4. SDN trunk group         | 9. With Call-by-Call Service Selection        |
| 5. OUTWATS trunk group     |                                               |

Using Country Protocol 1, you integrate services and features such as MEGACOM, ACCUNET, and INWATS onto a single ISDN-PRI trunk group with flexible assignment of trunks to each service or feature. Calls such as an incoming 800 Service call that requires through-switching as an Outgoing WATS call can be routed via the same facility. See the ISDN trunk group screen on page [“ISDN trunk group” on page 936](#) for a listing of available services.

 **NOTE:**

When the Avaya Media Server is connected to 5ESS, all of the services supported under the Avaya and NI-2 country options are available.

## **Screens used to administer Call-by-Call Service Selection**

You administer Call-by-Call Service Selection on a per trunk group basis. The following list shows the required screens and the fields you must use on each screen:

- [System-Parameters Customer-Options](#)
  - Version
  - ISDN-PRI
  - ISDN-BRI Trunks
  - Usage Allocation Enhancements
- [ISDN trunk group](#)
  - Service Type
  - Usage Alloc
  - all fields on the Incoming Call Handling Treatment (ICHT) Table
- [Route Pattern](#)
  - IXC
  - Service/Feature
  - Band

You can administer trunk Usage Allocation for multiple called numbers within a given Service/Feature, or you can administer trunk Usage Allocation for incoming or outgoing calls independent of Service/Feature.

- [System-Parameters Customer-Options](#)
  - Version
  - ISDN-PRI Trunks
  - ISDN-BRI Trunks
  - Usage Allocation Enhancements

- Network-Facilities (See the DEFINTY services documentation for information about the Network Facilities screen.)
  - All

## ISDN messages and information elements for usage allocation

Understanding the technical details of ISDN messages and information elements may help you implement ISDN.

Call-by-Call Service Selection allows the system to specify one of the preceding service types on a call-by-call basis. You can specify service types by classifying incoming calls to an ISDN Call-By-Call trunk group using the called-party's number.

You can also specify service types with a SETUP message that indicates the intent of the originating system to initiate a call using the specified service or facility. The SETUP message may contain units called information elements (IE) that specify call-related information. The IE used with Call-by-Call Service Selection are:

- Network-Specific Facility (NSF) — Indicates which facilities or services are to be used to complete the call (typically not used outside the US and Canada).

The system also checks all incoming ISDN trunk calls for the presence of an NSF IE. If an NSF IE is present, the system makes sure that the requested service is compatible with the trunk administration before it accepts a call.

For an outgoing call on a Call-By-Call trunk group, the NSF IE is constructed using the Service/Feature specified on the routing-pattern preference selected for the call.

If the Service/Feature specified does not have an associated NSF, an NSF IE is not sent. For example, SETUP messages for incoming and outgoing calls classified only by a called-party number do not contain an NSF IE.

- Transit Network Selection — Indicates which interexchange carrier is to be used on an inter-LATA call.

If a call requires both the Service/Feature and the interexchange carrier to be specified, the interexchange carrier information is sent in the NSF IE rather than the Transit Network Selection IE.

## Usage allocation plans

Optional UAPs may be assigned to provide more control over a Call-by-Call Service Selection trunk group. You can allocate a minimum and maximum number of channels for incoming and outgoing called numbers, privileged users, and voice and data calls.

A UAP allows the customer to set the following options:

- Maximum number of trunks that each service can use at any given time. The sum for all services may exceed the total number of trunk-group members. For example, for a 15-member trunk group, you could administer a maximum of seven MEGACOM service calls, six MEGACOM 800 service calls, and eight SDN calls. This ensures that all trunk-group members are not dominated by a specific service, yet allows for fluctuations in demand.
- Minimum number of trunks that always must be available for each service. The sum for all services may not exceed the total number of trunk-group members. For example, for a 10-member trunk group that provides access to MEGACOM service, MEGACOM 800 service, and SDN, the minimum number of trunks to be used for each of these services cannot add up to more than 10.

When these UAP limits are exceeded, the system rejects the call, even if a trunk is available. On outgoing calls, the calling party receives a reorder tone unless other preferences are available.

You can assign either fixed or scheduled UAP for each Call-by-Call Service Selection trunk group.

- With a fixed UAP, one plan applies at all times.
- With a scheduled UAP, different plans can be administered to apply at different times of day and different days of the week. As many as 6 activation times and associated plans can be assigned for each day of the week.

You can have anything from a simple fixed UAP to a very flexible UAP with many scheduling options. You can even start out with no UAP and build one as the need arises.

## Incoming call-handling treatment

Call-by-Call Service Selection provides special incoming call-handling treatment for ISDN trunk groups. An incoming call on an ISDN trunk is handled according to a treatment table administered for the trunk group. Depending on the platform you use, the table allows for a different number of combinations of call treatments.

The treatment for an incoming call is selected based on the first 3 columns in the ICHT on the ISDN Trunk Group screen. When the attributes of an incoming call match these specifications, the call is treated according to the corresponding following 4 columns. If an incoming call matches more than one set of specifications, the most restrictive case applies. The following table lists the possible cases from most restrictive to least restrictive.

|                   | <b>Service / Feature</b> | <b>Called Len</b> | <b>Called Number</b>                      |
|-------------------|--------------------------|-------------------|-------------------------------------------|
| Most restrictive  | Specified                | Specified         | x leading digits specified                |
|                   | Specified                | Specified         | y leading digits specified, where $y < x$ |
|                   | Specified                | Specified         | not specified                             |
|                   | Specified                | Not specified     | not specified                             |
|                   | “other”                  | Specified         | x leading digits specified                |
|                   | “other”                  | Specified         | y leading digits specified, where $y < x$ |
|                   | “other”                  | Specified         | Not specified                             |
| Least restrictive | “other”                  | Not specified     | Not specified                             |

### Call detail recording

On successful call attempts using ISDN Call-By-Call trunk groups, CDR records the NSF specified by the call’s NSF IE. CDR refers to this information as the ISDN Network Service (INS). The value passed to CDR is the 3-digit equivalent of NSF IE. NSF information for Facility Type 2 calls (used with ISDN-Pri Call-by-Call trunk groups) also is recorded if the NSF is available in the incoming SETUP message.

If an outgoing Call-by-Call Service Selection call uses an interexchange carrier other than the presubscribed common carrier, CDR records the 3-digit or 4-digit Interexchange Carrier Code (IXC). CDR may not record the IXC properly if the dialed-code format differs from the US IXC formats.

When a Call-by-Call Service Selection call is rejected because of a UAP, CDR records the cause as an ineffective call attempt. The NSF recording takes place also for the user-defined Facility Type 2. However, the NSF recording takes place only if the NSF is available in the incoming SETUP message.

## Interactions

---

- **Multiquest Flexible Billing**  
Do not use a Service/Facility with the Facility Type field set to 2 or 3. NSF processing is not performed for Facility Type 2. An NSF is not included in the outgoing SETUP message for Facility Type 3.
- **Time-of-Day Routing**  
Any Time-of-Day Routing administration that affects routing preference also affects Call-by-Call Service Selection. Use Time-of-Day Routing to vary the IXC based on the time of day and day of the week.

## Calling party/billing number

---

Calling Party Number/Billing Number (CPN/BN) allows the system to request CPN/BN information from an AT&T network. The CPN is the calling party's telephone number. BN is the calling party's billing number. The CPN/BN may contain international country codes. CPN/BN can be used with an adjunct application.

## Brief Description

---

The following list shows the screens used to administer CPN/BN and the fields you must use on each screen:

- **ISDN trunk group**
  - All fields including Per Call CPN/BN
- **ISDN Numbering — Public/ Unknown or ISDN Numbering — Private**
  - All
- **Processor Channel Assignment** (See the DEFINTY services documentation for information about this screen.)
  - All

On the Integrated Services Digital Network (ISDN) Trunk Group screen, assign all fields needed to provide an ISDN-PRI link between the system and the adjunct. Set the Per Call CPN/BN field to **can-only**, **can-pref**, **bn-only**, or **bn-pref** as required to make sure that CPN/BN information is sent with a call-offered event report to the adjunct.

On the Processor Channel screen, assign all fields for one data link. The system can support only one interface.

## Related topics

---

See “[ISDN service](#)” on page 1730 for an overview of ISDN capabilities.

See the *Avaya MultiVantage™ Call Center Software Guide to ACD Call Centers* for information on using Calling Party Number and Billing Number with Automatic Call Distribution (ACD) and Inbound Call Management. Complete all screens required to administer ACD.

See the DEFINTY services documentation for information about the Multifrequency-Signaling-Related System parameters screen.

## Calling party number restriction

---

With Calling Party Number (CPN) Restriction, you can administer individual phones to restrict sending CPN information on outgoing calls (per call restriction). Also, phone users can use a phone button or a FAC to restrict CPN information on individual outgoing calls (per line restriction). CPN Restriction works on any trunk that supports MFC signaling.

Per Line CPN Restriction overrides any outgoing trunk group CPN administration. Per Call CPN Restriction overrides any Per Line CPN Restriction for the phone, and it also overrides any Trunk Group administration for sending the calling number. For a tandemed ISDN call, only the Tandem Trunk Group’s “sending calling number” administration applies.

## Interactions

---

CPN Restriction is not supported on:

- local switch station-to-station calls
- calls originated from attendant console or data module
- DCS calls (DCS CPN information is not affected by CPN Restriction)
- UDP calls
- TAC calls where the Per Line CPN Restriction field on the \* screen is **y** or **r**, or when the Per Call CPN Restriction FAC is dialed before the TAC
- non-ISDN calls that must be tandemed
- Per Call CPN Restriction over ASAI and CTI interfaces

## **CLAN and processor CLAN QoS and CIDR support**

---

Previous IP packet addressing and routing procedures for the TN799 Control-LAN circuit pack have not always been compatible with Avaya MultiVantage customers' evolved networks. Quality of Service (QoS) features are necessary to provide superior call quality for voice-over-IP (VoIP) signaling.

Although classful IP addressing structures were used in the beginning of VoIP development, enhancing C-LAN support of Classless Inter-Domain Routing (CIDR) and the closely-related Variable Length Subnet Mask (VLSM) paradigms provide the Avaya MultiVantage platforms with enhanced IP addressing and routing flexibility, while ensuring customer-network compatibility.

### **Configurations/Platforms**

---

To use CIDR and IP QoS, the TN799DP Control-LAN circuit pack is required for:

- Avaya Media gateways (DEFINITY CSI, DEFINITY SI, DEFINITY R, S8700 Media Server, and S8700 Media Server)
- Avaya™ S8100 Media Servers

To use CIDR and IP QoS, the TN799DP C-LAN circuit pack is not required for:

- S8300 Media Server

The S8300 Media Server uses the its processor CLAN feature. The S8100 Media Server with a CMC1 and S8100 Media Server with a G600 can use either its processor CLAN feature or a TN799DP Control-LAN circuit pack.

## Windows Operating System

---

Whether the TN799 Control-LAN circuit pack tags frames with VLAN and user-priority values is administered on the IP Network Region screen. However, for the processor CLAN function on S8100 Media Server with a CMC1 and S8100 Media Server with a G600, the operating system also controls tagging.

- If the IP Network Region screen is administered to tag, but the Windows operating system is set to not tag, then the processor CLAN function will not tag.
- If the Windows operating system is set to tag, but the IP Network Region screen is administered to not tag, then the S8100 Media Server with a CMC1 or S8100 Media Server with a G600 fill in the VLAN\_ID and 802.1p fields of the extended ethernet header, but with the VLAN\_ID to 0, and the priority to 0.

Tagging is administered on S8100 Media Server with a CMC1 and S8100 Media Server with a G600 as follows:

1. Log on to S8100 Media Server with a G600 Media Gateway/ S8100 Media Server with a CMC1 using the Windows log-in.
2. Double-click the Intel PROSet icon in the Control Panel or in the system tray.
3. Select the first adapter from the list and right click on it.

There are three adapters; PCLAN uses the first one.

4. In the menu that appears, click **Add VLAN**.

You may see a dialog regarding 802.1 tagging. This tagging must be enabled for VLAN support.

5. Enter the VLAN ID and VLAN Name.

The VLAN Name is for information only and does not have to match the name on the switch.

6. Click **OK**.

## Linux Operating System

---

Whether the TN799 Control-LAN circuit pack tags frames with VLAN and user-priority values is administered on the IP Network Region screen. However, for the processor CLAN function on the S8300 Media Server with a G700, the operating system also controls tagging. The IP Network Region screen and the bash command under the Linux operating system both set the same entries in a configuration file. There is no difference between setting them through one user interface versus the other.

Tagging is administered through the bash command line as follows:

```
vlanconfig -c -d device -v vlan_id [-i ip_address] [-g gw_address] [-m netmask] [-e on|off] [-f]
```

```
vlanconfig -r -d device -v vlan_id [-nf]
```

```
vlanconfig -q [-d device] [-v vlan_id]
```

- |           |                                                                                        |
|-----------|----------------------------------------------------------------------------------------|
| -c        | will create/change an interface                                                        |
| -r        | will remove an interface                                                               |
| -q        | will query an interface                                                                |
| -d device | create/change, remove, or query this device<br>(valid with the -c, -r, and -q options) |
| -e on off | enable or disable the interface<br>(valid only with the -c option)                     |
| -f        | force the command to execute<br>(valid only with the -c and -r options)                |

## Interactions

---

Signaling to other switches or adjuncts can be done through the CLAN and the processor CLAN function.

If you have an R11 connected to an older system that does not support 802.1p and 802.1Q VLANs on their signaling channels, you can administer it to be in a network region where these things are administered to **no**.

If you decide to ignore the above advice and attempt signaling from a new system that is using 802.1p and 802.1Q VLANs on their signaling channels to an older system that does not support these protocols, then whether signaling information would:

- Reach the destination, with the network using the frames' VLAN and priority information, or
- Reach the destination, but without having been given VLAN or priority treatment, or
- Be dropped, either by the destination or by an intermediate device, depends on the capabilities of the switches or hubs used in the data network and how they are configured.

The third possibility, “all frames dropped,” means no signals get through between the MultiVantage switch and the other device.

## **Class of restriction**

---

You use COR to define the types of calls your users can place and receive. Your system may have only a single COR, a COR with no restrictions, or as many CORs as necessary to effect the desired restrictions.

You will see the COR field in many different places throughout the MultiVantage System - when administering phones, trunks, agent logins, and data modules, to name a few. You must enter a COR on these screens, although you control the level of restriction the COR provides. You must administer a COR for the following objects:

- Agent LoginID
- Access Endpoint
- Announcements/Audio Sources
- Attendant Console
- Authorization Code — COR Mapping
- Console-Parameters
- Hunt Groups
- Loudspeaker Paging
- Data Modules
- Remote Access (each barrier code has a COR)
- Station
- Terminating Extension Group
- Trunk Groups
- Vector Directory Number

## **Called-party and calling-party restrictions**

---

Called-party and calling-party restrictions are the basis for all CORs. When no restrictions are needed, assign a single COR with called-party and calling-party restrictions set to none. You can use this COR for unrestricted telephones, trunk groups, TEGs, UCD groups, DDC groups, data modules, attendant groups, and individual attendant extensions.

The called-party restriction is checked only at the called terminal, module, attendant console, zone, or group, even if a call redirects from one telephone to another. For example, if a called terminal (with no terminal restrictions) has Call Forwarding active to a restricted terminal, the call still completes.

### **Inward restrictions**

You can use inward restrictions to permit users to receive only internal calls. Inward restrictions prohibit users at assigned telephones from receiving public-network, attendant-originated, and attendant-extended calls.

The COR of the originally-called extension is the only one checked unless you administer 3-way COR check on conference and transfer calls. Denied calls are routed to intercept tone, a recorded announcement, or the attendant for Direct Inward Dialing (DID) calls.

### **Manual terminating line restrictions**

You can use manual terminating line restrictions to allow users to receive calls only from an attendant or that were extended by an attendant. Calls can redirect to a manual terminating line-restricted telephone. The COR of the originally-called extension is the only one checked.

Local Central Office (CO), foreign exchange (FX), and Wide Area Telecommunications Service (WATS) calls are routed to the attendant. DID calls are routed to an announcement or the attendant. Telephone calls are routed to intercept treatment.

### **Origination restrictions**

You can use origination restrictions to prohibit users from originating calls. These users can still receive calls.

### **Outward restrictions**

You can use outward restrictions to prevent users from placing calls to the public network. These users can still place calls to other telephone users, to the attendant, and over tie trunks. If necessary, an attendant or an unrestricted telephone user can extend a call to an outside number for an outward-restricted telephone user.

When outward restriction is applied to the Calling Party Restriction field on the Class of Restriction screen, calls coming into a trunk with that COR will be denied if they make use of the AAR/ARS feature.

### **Public restrictions**

Public restrictions prohibit users from receiving public-network calls. Denied calls are routed to an intercept tone, a recorded announcement, or the attendant. Public restrictions still allow users to receive internal calls from other telephones or calls that were extended from the attendant.

### **Termination restrictions**

You can use termination restrictions to prohibit users from receiving any calls. These users can still originate calls. DID or Advanced Private-Line Termination calls route to a recorded announcement or the attendant.

## **Fully restricted service**

Fully restricted service prevents specific users from making or receiving public-network calls. Fully-restricted users cannot use authorization codes to deactivate this feature.

Calls from the public network to a fully-restricted extension redirect to intercept treatment or to the attendant. If the call redirects to the attendant, the attendant's display indicates the call was redirected because of fully restricted service (FULL).

There are circumstances where an extension with fully restricted service can access or be accessed by the public network.

## **Miscellaneous terminal restrictions**

You can use miscellaneous terminal restrictions to prohibit users from accessing other specific terminals. Restricted calls are routed to intercept tone. Miscellaneous restriction groups apply on a per-COR basis. However, you can assign the same COR to more than one facility. Facilities with the same COR may be like facilities (such as two telephones) or different facilities (such as a telephone and a trunk group)

## Miscellaneous trunk restrictions

You can use miscellaneous trunk restrictions to prohibit users from accessing specific trunk groups, such as WATS or CO trunk groups. Any or all trunk groups can be in a miscellaneous-trunk-restriction group. Restricted calls are routed to intercept tone.

## Toll and TAC-Toll restrictions

Toll restrictions prevent users from placing public-network calls to certain toll-call numbers. Toll restriction is *not* a COR; you assign Toll restrictions to outgoing trunk groups on the Trunk Group screen. You disable TAC-toll restrictions for specific outgoing trunk groups on the Trunk Group screen.

## Interactions

---

- **AAR/ARS**  
Originating FRLs are assigned via a COR. Termination and Miscellaneous Restrictions do not apply to ARS/AAR calls.
- **AAR/ARS Partitioning**  
Partition Group Numbers are assigned via a COR.
- **Bridged Call Appearance**  
The COR assigned to a telephone's primary extension also applies to calls originated from a bridged call appearance of that extension on another terminal.
- **Call Coverage**  
Users who normally are restricted from calls can still receive calls directed to them via Call Coverage. When a call goes to coverage, the called party's (not the covering party's) restrictions are used.
- **Call Forwarding All Calls**  
If a call is restricted between the forwarding and forwarded-to extensions, Call Forwarding is denied. Restrictions are always checked when Call Forwarding is activated, but not when a call is forwarded.
- **Call Vectoring**  
When a call is directed to a VDN extension, the COR of the caller and the VDN are compared to determine if the caller can access the associated call vector.

- Class of Service (COS)

In some cases, the COR can be overridden by the COS. See the Trk-to-Trk Restriction Override field documented with the “Class of Service” on [page 672](#).

- Controlled Restriction

Restrictions assigned via Controlled Restriction override COR restriction.

- Emergency Access to Attendant

Emergency Access to Attendant calls are not restricted by COR.

### **Interactions for called-party and calling-party restrictions**

- Night Service

Night Service and Night Station — Trunk Answer From Any Station override Inward, Manual Terminating Line, and Public Restrictions.

- Tie-Trunk Access

Incoming dial-repeating tie-trunk calls can be completed directly to an inward-restricted or public-restricted extension but cannot be extended by an attendant to an inward-restricted telephone.

- Transfer

Incoming trunk calls cannot be transferred to an inward-restricted extension when a 3-way COR check is made.

Incoming trunk calls can be transferred from an unrestricted extension to an inward-restricted or public-restricted extension if the 3-way COR check on Conference is overridden.

### **Interactions for fully restricted service restrictions**

- Centralized Attendant Service (CAS)

Since COR information is not passed over Release Link Trunks (RLT), fully restricted service allows all CAS calls. Therefore, CAS allows a public network call to complete to a fully-restricted station.

- Distributed Communications System (DCS)

Fully Restricted Service allows all DCS calls because COR information is not transparent for DCS. DCS can allow a public network call to be completed to a Fully Restricted station.

- Power Failure Transfer

All authorization features are bypassed when the switch is in Emergency Transfer Mode.

- Hunt Group

The COR assigned to the Hunt Group is checked on calls redirected by the DDC or UCD of the hunt group. Extensions in the hunt group that have Fully Restricted Service can receive calls from the public network (via the hunt group) if the COR of the Hunt Group does not have Fully Restricted Service.

- Personal Central Office Line

Do not assign fully restricted service to users who have a personal CO line. If you do, you will be paying for a CO line that no one can use!

- Remote Access

If a barrier code is entered during connection to remote access, the code's associated COR is used for authorization checks. If remote access does not require a barrier code, then the default barrier code's COR is used. Remote Access can require an authorization code instead of or in addition to the barrier code. If an authorization code is required, the authorization code's associated COR overrides the barrier code's COR.

Do not assign fully restricted service to a station with the following features or conditions:

- Abbreviated Dialing
- Bridged Call Appearance
- Attendant stations
- Night Service stations
- Stations that are Call Coverage or Send All Calls points
- Stations that are Call Forward destinations
- Stations that are Call Pickup points

### **Interactions for miscellaneous terminal and trunk restrictions**

- AAR/ARS

AAR or ARS access to a trunk group overrides miscellaneous trunk restrictions.

- Abbreviated Dialing Privileged Group Number List

A telephone user with authorization to access an Abbreviated Dialing Privileged Group Number List can place calls to any number on that list. COR assignments are not checked.

- Privileged System Number List

A telephone user with authorization to access a Privileged System Number List can place calls to any number on that list. COR assignments are not checked.

## Conference

---

The Conference button allows multiappearance telephone users to make up to six party conference calls without attendant assistance. This button also allows single-line telephone users to make up to three party conference calls without attendant assistance.

### Considerations

---

- A single-line telephone can have up to 6 parties on a conference call, if each conferee adds another conferee. For example, one user can add a party, who then adds a third party, and so on.
- If you do not allow trunk-to-trunk connections and a telephone releases from a conference call (where all of the other parties were connected to the conference via trunks), then all parties are disconnected.
- If an analog single-line set has Call Wait active and creates a conference call, Call Wait is rendered inactive as long as the single-line set is on the call. For example, caller A on an analog set talks to caller B, flashes to talk to caller C, and flashes to conference B and C. Then, if caller D calls caller A, Call Wait is denied.
- Users of Digital Communications Protocol (DCP), Hybrid, and wireless phones can conference a call on hold. If there is only one call on hold, no active call appearances, and an available call appearance for the conference, a user can initiate the conference process without taking the call out of hold. When the Conference button is pressed, Avaya MultiVantage assumes the conference is for the call on hold, and the conference feature works as usual.

If there is more than one call on hold, the user must make a call active in order to include it in a conference. If the user presses the Conference button with two or more calls on hold, Avaya MultiVantage will ignore the conference attempt since it will not know which call the user wants to conference. If there are calls on hold and an active call, pressing the Conference button will start the conference process for the active call.

- You can allow users to abort a conference operation that is in progress by hanging up the phone. You set this parameter with the Abort Conference on Hang-Up field on the [Feature-Related System Parameters](#) screen. When a user hangs up the phone while trying to conference a call, the existing call is placed on hold, and the conference operation is aborted.

## **Conference/Transfer Toggle/Swap**

---

Conference/Transfer Toggle/Swap allows users to toggle between two parties in the middle of setting up a conference prior to connecting all parties together or to consult with both parties prior to transferring a call. The display also toggles between the two parties. This is not available on attendant consoles.

## **Selective Conference Party Display, Drop, and Mute**

---

Selective Conference Party Display, Drop, and Mute allows any user on a digital station with display or on an attendant console to use the display to identify all of the other parties on a two-party or conference call. The user presses a feature button while on the call that puts the station or console into conference display mode. The user then can scroll through the display of each party currently on the call by repeatedly pressing the feature button. The display shows the party's number and name (when available).

The user then could do either of the following:

- The user can selectively drop the party currently shown on the display with a single button push. This can be useful during conference calls when adding a party that does not answer and the call goes to voice mail.
- The user can selectively mute the party currently shown on the display with a single button push. This puts the selected party in "listen-only" mode. This can be useful during conference calls when a party puts the conference call on hold and everyone on the call is forced to listen to music-on-hold. The user can mute that party so the conference call can continue without interruption. The muted party can then rejoin the call by pressing the # key on their telephone.

## **Meet-me Conference**

---

Meet-me Conference allows users to set up a dial-in conference of up to six parties. Meet-me Conference uses Call Vectoring to process the setup of the conference call. Meet-me Conference can be assigned optionally to require an access code. If an access code is assigned, and if the vector is programmed to expect an access code, each user dialing in to the conference call must enter the correct access code to be added to the call. The Meet-me Conference extension can be dialed by any internal or remote access users, and by external parties if the extension number is part of the customer's Direct Inward Dialing (DID) block.

## **No Hold Conference**

---

No Hold Conference allows a user that is actively on a call to call another party and set up a conference call without interrupting the current call. The called party is added to the conference call as soon as they answer. Once the conference call is established, the call proceeds like a normal conference call. This feature can be used on a multiple-line digital telephones.

## **Interactions**

---

- **Bridged Call Appearance**

A bridged call appearance can be used to make conference calls. A bridged appearance can bridge onto a conference call only if there were never 6 parties on the conference.

- **Call Vectoring**

A call to a VDN can be included as a party in a conference call only after vector processing terminates for that call (for example, after a successful route-to command).

- **Class of Restriction (COR)**

If the Restriction Override field is set to **all**, the COR of the party being added is always checked against the COR of the party controlling the add-on, but the new party's COR is not checked against any other conferee's CORs.

- **Trunk-to-Trunk Transfer**

When a multifunction telephone (BRI/Digital/Hybrid) dials sufficient digits to route a call, but could route differently if additional digits were dialed, the telephone does not recognize the Conference or Transfer buttons. The user must delay dialing for 3 seconds or dial # to indicate that the call can be routed based on the digits already dialed. The Conference or Transfer buttons are then recognized and the switch completes the call.

- **VDN in a Coverage Path**

Calls in an established conference will not cover to a VDN.

Once a call covers to a VDN, a conference cannot be established until the call is delivered to an extension and vector processing ends.

## Related Topics

---

See the [“Feature-Related System Parameters” on page 795](#) screen for the following conference-related fields:

- Public Network Trunks on Conference Call

- Abort Conference Upon Hang-Up

## Co-Resident DEFINITY Local Area Network Gateway

---

Co-Resident DEFINITY Local Area Network (LAN) Gateway (DLG) is application software that is part of the MultiVantage software on the MultiVantage server. It provides the functionality of the Adjunct/Switch Application Interface (ASAI) using an Ethernet transport instead of a Basic Rate Interface (BRI) transport. In the S8300 Media Server with a G700, connectivity is provided through the processor's Ethernet.

## How it works

---

DLG listens for client connections over a well-known TCP port (5678) at a specified IP address.

The client receives the DLG's services by connecting to TCP port 5678 at the IP address.

The client then exchanges TCP Tunnel Protocol messages with the DLG to request a connection to a specific CTI link.

DLG authenticates the client based on its administration and then establishes or refuses the connection.

Once the connection is established, the actual ASAI layer 3 messages are passed transparently through the DLG. Each TCP connection to the DLG has a one-to-one correspondence with a CTI link.

## Hardware specifications

---

### CallVisor ASAI

The CallVisor ASAI CTI link requires the following hardware components:

- An Ethernet interface for connectivity to adjunct. The platform configuration determines the Ethernet interface.
  - The following platforms rely on the TN801B MAPD-based DEFINITY LAN Gateway (DLG) as the Ethernet interface.
    - DEFINITY CSI
    - DEFINITY SI
    - DEFINITY R
    - S8100 Media Server configurations use the MAPD for CVLAN applications only
  - For S8100 Media Server configurations, the Co-Resident DLG can use the C-LAN (TN799), the Processor Card (TN2314) or both the C-LAN and Processor Card as its Ethernet interfaces.
  - For S8300 Media Server with a G700 (with an Internal Communications Controller, or ICC) the Co-Resident DLG relies on the S8300 Media Server as its Ethernet interface.
- Packet Controller circuit pack (for internal communications)
- Packet Maintenance circuit pack

### Co-Resident DLG

Supported by the following platforms:

- S8300 Media Server with a G700
- S8100 Media Servers

The Co-Resident DLG is not available for any of the following platforms:

- DEFINITY CSI
- DEFINITY SI
- DEFINITY R
- S8700 IP-Connect
- S8700 Multi-Connect

## **Restriction — controlled**

---

Controlled Restrictions allow a telephone user with console permission to activate or deactivate specific restrictions.

### **Detailed description**

---

Use Controlled Restriction to administer the following restrictions:

- **Outward** — The telephone cannot place calls to the public network.
- **Total** — The telephone cannot place or receive calls. (Allowed calls include calls to a remote-access extension, terminating-trunk transmission tests, and Emergency Access to Attendant calls.)

Direct Inward Dialing (DID) calls are routed to the attendant or a recorded announcement. All other calls receive intercept tone.

- **Termination** — The telephone cannot receive any calls. Incoming calls are routed to the attendant, are redirected via Call Coverage, or receive intercept treatment.
- **Station-to-Station** — The telephone cannot place or receive station-to-station calls.
- **Toll** — The telephone cannot place toll calls but can place free local calls.

**NOTE:**

Toll Restriction may be substituted for either the outward or station-to-station restrictions. Administer this option on the [“Feature-Related System Parameters”](#) on page 795.

To activate Controlled Restriction:

1. Dial the group or extension feature access code.
2. Dial the number for the type of restriction desired:
  - 1 for outward/toll
  - 2 for total
  - 3 for termination
  - 4 for station-to-station/toll
3. Dial the extension (Attendant Control — Extension) or the Class of Restriction (COR) for a group of telephones (Attendant Control — COR).

## Interactions

---

- Call Coverage  
Controlled Restrictions are not checked for covering users.
- Call Forwarding  
Controlled Restrictions for the forwarded-to extension are checked when Call Forwarding All Calls is active.
- Class of Restriction  
All telephones with the same COR are affected by a group restriction. When a call is placed, both individual and group restrictions are checked.
- Priority Call  
If a station user or a Station-to-Station Restricted user activates priority calling before they dial another station, they receive intercept tone. They receive this tone whether you set Controlled Station to Station Restriction on the Feature-Related System Parameters screen to **y** or to **n**.
- Uniform Call Distribution  
Calls dialed through the UDP are not restricted by Outward Restriction.

## Crisis Alert

---

Crisis Alert notifies designated extensions when an emergency call is made, and indicates the origin of the emergency call. This information allows the attendant or other user to direct emergency-service response to the caller.

When a user places an emergency call, the system notifies the designated extensions with audible and visual alerting. Audible alerting sounds like an ambulance siren. Visual alerting consists of flashing of the CRSS-ALERT button lamp and display of the caller name and extension.

When crisis alerting is active at the attendant console, the console is in position-busy mode so that no other incoming calls interfere with the emergency call. The console can still originate calls. The attendant must press the POSITION-BUSY button to unbusy the console and then the CRSS-ALERT button to deactivate audible and visual alerting.

## **Multiple emergency calls**

---

If an emergency call is made while another crisis alert is still active, the call will be placed in queue. If you have administered the system so that all users must respond, then every user must respond to every call. The calls may not necessarily queue in the order in which they were made.

If you have administered the system so that only one user must respond, the first crisis alert remains active at the phone where it was acknowledged. Any subsequent calls are queued to the next available station in the order in which they were made.

## **Alerting a digital pager**

---

Crisis Alert to a Digital Pager allows users to receive crisis alert messages on a pager. When a crisis alert call is originated in an emergency situation, a message of 7 to 22 digits is sent to the pager and displays a crisis alert code, an extension or room number, and a main number (if one is entered) so the pager knows the location from which the emergency call originated. At the same time, an emergency call connects over a Centralized Automatic Message Accounting (CAMA) trunk.

To receive a crisis alert message, you need to administer at least one attendant or digital set with a CRSS-ALRT button. With the Alert Pager field set to **y**, any station with a CRSS-ALRT button and a pager receives the correct alert.

### **NOTE:**

The crisis alert call uses 2-4 trunks; 1 trunk for the actual call and 1-3 trunks to notify the pager(s) depending on the number of administered pagers.

Information about the alert can be viewed on the history report printed at the journal printer and the emergency log.

## **Considerations**

---

- Only one crss-alert button is allowed per attendant console or digital station.
- Consoles without a crss-alert button do not receive emergency notification.
- If a user attempts to make an emergency call, but all trunks are busy, this call will not generate an alert. If Outgoing Trunk Queuing is enabled for a trunk group, the call will queue, but will not generate an alert.

## Interactions

---

- Centralized Attendant Service (CAS)

If CAS is enabled, the alert still goes to the local attendant.

- Phone Display

When an emergency call is made and a crisis alert station with a 27-character display is notified, only 17 characters of the name field appear on the first display line, followed by the extension. The second line contains the last 3 characters of the name field, followed by the word "EMERGENCY." Characters 18 through 24 of the name field do not appear at all.

Avaya recommends that you consider the display for emergency notification when you complete the name field on the station screen. Put the most important identifying information at the beginning of the field.

- Tenant Partitioning

If tenant partitioning is active, attendants only receive emergency notification from callers within their partition. If there is no attendant assigned to a partition from which an emergency call originates, the switch still sends a record of the call to the journal printer.

- Terminal Self Administration

Those users who have the ability to administer their own phones do not have the ability to disable a crisis alert button.

## Dial plan

---

The dial plan provides information to the switch on what to do with dialed digits. A table defines the intended use of a code beginning with a specific first digit or pair of digits. These digits tell the system how many digits to collect before processing the full digit string. For example, a digit string beginning with 8 may tell the system to wait for 4 more digits because this is the first digit of a 5-digit internal extension.

All feature access codes, extensions and trunk access codes must be consistent with the dial plan.

### Detailed description

---

The dial plan provides information to the switch on what to do with dialed digits. A table defines the intended use of a code beginning with a specific first digit or pair of digits. These digits tell the system how many digits to collect before processing the full digit string. For example, a digit string beginning with 8 may tell the system to wait for 4 more digits because this is the first digit of a 5-digit internal extension. For more information about the tables that define the dial plan, see:

- [Dial Plan Analysis Table](#)
- [Dial Plan Parameters](#)

You can also administer a UDP as part of the dial plan to be shared among a group of switches. For more information, see [Uniform Dial Plan](#). So that calls route to the desired switch, a UDP requires the following information:

- A PBX code, which represents the first 1 to 5 digits of an extension and can range from 0 to 9xxxxxx with a maximum of 50,000 PBX codes on DEFINITY R or 20,000 PBX codes on DEFINITY SI/DEFINITY CSI.
- An RNX, which is associated with the PBX code and is used to select an AAR pattern for the call. This information is required for each PBX code. The 3-digit RNX can be an AAR location code or, for ENP calls, an ENP code.
- A PBX ID (1 to 63), which represents a specific switch (optional).
- Whether or not the PBX code is local to this system (optional).

## Considerations

---

- You cannot assign prefixed extensions longer than five digits (including prefix) to intercom lists.
- A TAC and an extension can share a first digit only if the extension is shorter than the TAC.
- Although extensions with the same first digit can have different lengths, data-channel extensions must have the maximum number of digits to avoid timeout problems for data calls that the switch automatically sets up, for example, the CDR link.
- An extension and a FAC can share the same first digit only if the extension is longer as long as they are not used for AAR/ARS faxes. These extensions work only within the switch; they do not work as remote UDP extensions.
- When you design your dial plan or add new information to your dial plan, be careful if you assign the same first digit to more than one FAC. Your system may need to distinguish between FACs with the same first digit by using the Short Interdigit Timer field on the Feature Related System Parameters screen.

## Interactions

---

All dial-access features and services provided by the system require the dial plan.

- **Attendant Display and Telephone (Voice Terminal) Display**  
Prefixed extensions display without the prefix. The return call button causes the prefix to dial, even though it does not display.
- **Integrated Services Digital Network-Basic Rate Interface (ISDN-BRI)**  
When an ISDN-BRI station dials sufficient digits to route a call, but the call could route differently if additional digits were dialed, the station does not recognize the Conference or Transfer buttons. The user must delay dialing for 3 seconds or dial # to indicate that the call can be routed based on the digits already dialed. The Conference or Transfer buttons then are recognized and the switch completes the operation.
- **Multifrequency (MF) Signaling**  
Flexible numbering is supported in countries using R2-MFC trunk signaling without Group II tones. Different-length extensions can exist as long as the extensions have different first digits.

- Property Management System (PMS)

PMS products accept only extensions of 5 digits or shorter. Therefore, a customer using PMS cannot use 6/7-digit extensions.

- Uniform Dial Plan

The following limitations apply to a DCS environment:

- Extensions that differ in length from the UDP do not distribute to other switches.
- You can use only a single length in your UDP.

- Single-Digit Dialing

- A prefixed extension is still made up of a prefix and an extension of up to five digits.
- Mixed station numbering extensions can have 1 - 7 digits.

## **Distinctive ringing**

---

Distinctive Ringing provides several ringing cycles to help telephone users and attendants distinguish between incoming call types. Administer Distinctive Audible Alerting on Feature-Related System Parameters for internal, external, priority, and attendant originated calls. If the phone is a single-line analog, you have to set this on the Station screen for each user.

### **Detailed description**

---

You can administer system-wide distinctive-ringing cycles for the three basic call types. Most installations use 1-burst for internal calls, 2-burst for external calls, and 3-burst for priority calls. There are also non-administrable ringing signals for Automatic and Dial Intercom calls, Manual Signaling, and Redirect Notification.

Normally if an internal phone user transfers an external call, the call rings as internal. You can set a feature parameter (Update Transferred Ringing Pattern) to make the call ring as an external call.

## Considerations

---

- If Distinctive Ringing is disabled, the system generates a 1-burst repetitive tone for all incoming calls. This is useful for equipment interfaced by analog lines, especially if you use off-premises station.
- A single distinctive ring cycle is used for each new incoming call to an off-hook telephone or headset. The system alerts a CALLMASTER terminal with a single ring cycle whenever either the headset or the handset is plugged into the headset jack.

## Interactions

---

- Personalized Ringing  
The called party hears the user-selected ringing pattern for the distinctive ring cycles.

## DS1 trunk service

---

Digital Signal Level 1 (DS1) trunk service uses bit-oriented signaling (BOS) and multiplexes 24 channels (T1 service) or 32 channels (E1 service) into a single data stream. DS1 can be used for voice or voice-grade data and for data-transmission protocols. T1 trunk service multiplexes 24 channels into a single 1.544-Mbps data stream. E1 trunk service multiplexes 32 channels into a single 2.048-Mbps stream. Both T1 and E1 provide a digital interface for trunk groups.

For information about how to administer DS1 with enhanced administration, see [“Signaling modes” on page 1662](#).

## Brief description

---

DS1 trunk service provides a digital interface for the following trunks.

- Voice-grade DS1 tie trunks
- Alternate voice/data (AVD) DS1 tie trunks
- Robbed-bit AVD (RBAVD) DS1 tie trunks
- Digital Multiplexed Interface (DMI) tie trunks
- Integrated Services Digital Network-Primary Rate Interface (ISDN-PRI) trunks
- Central Office (CO) trunks
- Foreign Exchange (FX) trunks
- Remote-access trunks

- Wide Area Telecommunications Service (WATS) trunks
- Direct Inward Dialing (DID) trunks
- Main/Satellite tie trunks
- Tie trunks that link Common-Control Switching Arrangement (CCSA) or Enhanced Private Switched Communications Service (EPSCS) networks
- Release-link trunks for Centralized Attendant Service (CAS)
- Access trunks
- Off-premises stations (also known as station-side DS1)
- Access endpoints

DS1 also provides the following functions in public and private networks:

- Electronic tandem networks (ETN) or tandem tie-trunk networks (TTTN)
- Direct access to local exchange carriers

### DS1 operational and signaling parameters

The table below provides the recommended combination of parameters for each DS1 interface.

| DS1 Circuit Packs      | # Trunk Members       | Bit Rate Mbps | Companding | Signaling Mode        | Trunk Type <sup>1</sup>       |
|------------------------|-----------------------|---------------|------------|-----------------------|-------------------------------|
| TN722                  | 1-23                  | 1.544         | mulaw      | common-chan           | Tie, DMI-BOS, CO <sup>2</sup> |
|                        | 1-24                  |               |            | robbed-bit            | Tie                           |
| TN722B                 | 1-23                  | 1.544         | mulaw      | common-chan           | Tie, DMI-BOS, CO <sup>2</sup> |
|                        | 1-24                  |               |            | robbed-bit            | CO/DID/Tie                    |
| TN767D, E <sup>3</sup> | 1-23                  | 1.544         | mulaw      | common-chan           | Tie, DMI-BOS, CO <sup>2</sup> |
|                        | 1-24                  |               |            | robbed-bit            | CO/DID/Tie                    |
|                        | 1-23 (24th is D-chan) |               |            | isdn-pri <sup>4</sup> | ISDN                          |
|                        | 1-24                  |               |            | isdn-ext <sup>4</sup> | ISDN                          |

*Continued on next page*

| DS1 Circuit Packs                                  | # Trunk Members       | Bit Rate Mbps      | Companding              | Signaling Mode        | Trunk Type <sup>1</sup>             |
|----------------------------------------------------|-----------------------|--------------------|-------------------------|-----------------------|-------------------------------------|
| TN464B <sup>5</sup>                                | 1-30                  | 2.048              | alaw/mulaw <sup>6</sup> | CAS                   | CO/DID/Tie                          |
|                                                    | 1-31                  |                    | alaw                    | isdn-pri <sup>4</sup> | ISDN                                |

- CO is any of the following trunk types: CO, FX, WATS.  
Tie is any of the following trunk types: access, tie, tandem, RLT, APLT.
- Common-channel DS1 circuit packs used in CO trunk groups must have a trunk type of auto.
- Integrated CSU functionality is available only with the TN767D and TN464E or later-suffix DS1 circuit packs. Enhanced ICSU functionality is available only with TN767E, TN464F, and later-suffix DS1 circuit packs.
- Mixed-mode signaling is allowed. This means that if the signaling mode is isdn-ext or isdn-pri, a port from that circuit pack may be used in any trunk group that allows robbed-bit signaling.
- The TN464B's companding is based upon the system companding that you administer.
- ISDN-PRI calls are not guaranteed to work for the TN464B if the system's companding is set to mu-law.
- The administered D-channel on the DS1 screen for ISDN-PRI cannot be a trunk group member.

## Signaling modes

Common-channel signaling (CCS) is an industry-standard technique where any one of a group of channels carries the signals for the other channels. Avaya uses the 24th channel of a group for signaling. This signaling technique differs from 24-channel signaling. When the system is configured for Facility-Associated Signaling, 24-channel signaling uses the 24th channel in a DS1 facility to carry signals. This technique also is called clear channel, out-of-band, or alternate voice data (AVD) signaling.

Channel Associated Signaling (CAS) is similar to common-channel signaling and is used only when the Bit Rate is 2.048 Mbps (the trunk is used with an E1 interface). Signaling is carried on the 16th channel.

Common-channel signaling and channel associated signaling provide a maximum transmission rate of 64 Kbps for bearer channels.

Robbed-bit signaling is a per-channel signaling technique for transmitting signaling bits on each channel in a DS1 facility. The least-significant bit in every 6th transmitted information frame is removed and replaced by a signaling bit. This technique is also called in-band signaling. The maximum transmission rate for each bearer channel with robbed-bit signaling is 56 Kbps.

ISDN-PRI signaling is carried on the 24th channel for a 1.544 Mbps connection and on the 16th channel for a 2.048 Mbps connection.

### Public network signaling administration for ISDN-PRI Layer 3

The table below shows Avaya MultiVantage public network access connections for ISDN-PRI Layer 3.

## **EC500 Extension to Cellular**

---

EC500 is an integrated mobility solution that offers users the freedom to work anywhere, anytime, using any type of cellular or wireless phone. With EC500, calls to an office number are extended to a cellular phone, allowing users to receive work-related calls wherever they are and whenever needed. Additionally, the cellular phone can be administered so that when an individual calls into the office, the individual's name and office phone number appear in the caller ID display of the phone being called.

## **Capabilities of EC500**

---

### **Office Caller ID**

Depending on the XMOBILE Station administration, the EC500 cell phone gains the identity of the user's office extension when calling into the office switch. When the EC500 user is administered to send the office caller ID and calls into the office, the person receiving the call sees the office name and number of the caller, not the cell phone caller ID. This type of administration provides both in-house Caller Identification at the destination phone and allows the user to bridge onto the office phone.

When the EC500 cell phone is administered to send office caller ID, this behavior is in effect whether the EC500 extensions are enabled or disabled. However, while someone else is using the line appearance on the office phone that is the same as that administered for the EC500 cell phone call to send office caller ID, the office caller ID is temporarily not available.

## Call Waiting, Call Identification, and Voice Mail

EC500 allows use of standard cellular features such as incoming call waiting and caller identification.

- If the cell phone (and network) supports calling number identification, the Avaya Communications Server delivers the calling number to it. For internally originated calls, the calling number may be presented in either the national numbering plan format (i.e. 10 digits) or as a less than 10 digit extension, depending upon how it is administered. Some cellular phone networks only pass calling number information in the national format while others are more flexible.
- If the cell phone (and network) supports call waiting, EC500 can be administered to deliver a second call to the cell phone while it is busy on another call. The cell phone features (i.e. swapping calls, conferencing the calls) may then be used to answer the second call and manipulate the two calls at the cell phone.

Since the cell phone is treated as a local extension on the Avaya Communications Server, it can be completely integrated with the Corporate voice mail system while retaining its own Cellular Service Provider voice mail. The office number retains the primary extension on the Avaya Communications Server. Calls to the office number simultaneously ring the office number and the cell phone. If neither answer then standard coverage arrangements take effect. As needed, EC500 can be disabled when not in use in order to ensure the use of the Corporate voice mail.

The System Administrator can control in-service and out-of-service status of the bridged extensions through a busy out and release maintenance capability.

## Receiving Calls

EC500 is a solution for delivering office calls to a cell phone through the Avaya Communications Server.

With EC500, when a call is made to an office number with a mapped XMOBILE bridge, the call is extended out of the Avaya Communications Server to alert a cell phone. If the Avaya Communications Server is administered to send calling number information, then it is presented to the cell phone. When the cell phone answers the call, the Avaya Communications Server treats it like a local answer of a physically connected station, and the following is true:

- Status station of the XMOBILE station shows it off-hook. It shows both the port used on the outbound loop back trunk group and the other connected port.
- Any office number busy indicators tracking the XMOBILE station light up to show that it is busy.

- Any other station linked to the call as part of a bridge or temporary bridge is able to bridge on to that call.

## **Making Calls**

Calls can be made to any number from the EC500 cell phone. Depending on how the EC500 XMOBILE stations are administered, the EC500 cell phone can function both as a standard cell phone and as an office extension when the calls are made into the user's office switch. Administering an EC500 cell phone to send office caller ID allows the EC500 cell phone call to the switch to appear as a local extension on the switch.

## **Feature Interactions**

---

Generally, an XMOBILE station may be administered (and used) like an analog station. The following are exceptions:

### **Cellular Service Provider Voice Mail**

While XMOBILE stations may have standard Avaya Communications Server voice mail coverage (i.e. AUDIX®), cell phones usually have voice mail coverage from the Service Provider. Although there is no way to indicate a preference for use of a specific system, there is a way to coordinate the two systems.

It is generally possible to set up the number of don't answer rings so that one or the other always answer first. However, there are coverage options in both the Avaya Communications Server (busy, active, send-all-calls) and the network (cell phone unavailable, network congested) that causes a call to immediately go to the respective voice mail. Users should realize that an unanswered call might result in a voice mail message in either mailbox.

### **Distinctive Alerting**

Cell phones do not receive distinct rings for different types of calls.

### **Feature Access Codes**

The cell phone can activate Avaya Communications Server features accessible via the Avaya EC500 Access Number (Avaya Communications Server Telecommuting Access number).

### **Message Waiting Indication**

The cell phones cannot receive any form of message waiting indication directly from the Avaya Communications Server.

## **Additional information**

---

For additional information, see the EC500 documentation:

1. Access the Avaya website at <http://avaya.com>
2. Click **Support**.
3. Click **Online Services**.
4. Click **Documentation**.
5. Click **Recent Documents**.
6. Scroll down to the Wireless section.
7. Select **EC500 Extension to Cellular**.

You now can select from:

## **Emergency Access to the Attendant**

---

Emergency Access to the Attendant alerts an attendant if a telephone remains off-hook for more than the administered period of time. It also enables a user to place an emergency call to an attendant.

### **Detailed description**

---

Emergency calls can be placed automatically by the system or dialed by system users. Such calls can receive priority handling by the attendant.

Place emergency calls to the attendant in the following ways:

- Automatically by the system

Assign a telephone the Off-Hook Alert option via COS. If the terminal is left off-hook until intercept timeout, the (administrable) off-hook alerting timer starts. If the terminal is still off-hook when the timer expires, an emergency call is automatically placed to the attendant.

- Dial access by a system user

A user can place an emergency call to the attendant by dialing the Emergency Access to the Attendant feature-access code.

When an emergency call is placed, one of the available attendants receives visual and audible notification of the call. If all attendants are busy, the call enters a queue for emergency calls. Calls can be administered to redirect to another extension if the queue is full.

An emergency call causes the following to occur:

1. The system selects the first available attendant to receive the call.
2. The attendant hears the emergency tone and sees the lamp associated with the Emergency button, if assigned, light. If the console does not have emergency-tone capability, the attendant hears normal ringing and sees the display flash.
3. The attendant display shows:
  - Calling-party identification
  - Calling-party extension
  - How many emergency calls remain in queue

An audit record is created for each emergency call. This record includes:

- Extension where the call originated
- The attendant or attendant group that answered the call

- Time of the call
- The following known call results:
  - Call Completed — Call answered at attendant or listed directory number (LDN) night extension.
  - Queue Full — Emergency-access queue is full; tries to redirect the call to an emergency-access redirection extension.
  - No Attd — No active attendants are available to receive the call; tries to redirect the call to an emergency-access redirection extension.
  - Redirected Answered — Call is answered by the emergency-access redirection extension.
  - No Redirection Ext. — Could not redirect the call to the emergency-access redirection extension because none are administered.
  - Attd Night Service — System is in night service. Will try to redirect the call to attendant night service.
  - Failed — Caller drops the call before it can be answered. Call was either waiting in the attendant emergency queue, ringing at an attendant console, or ringing at the LDN night extension.
  - Redirected Abandoned — Caller drops the call before it can be answered. Call had been redirected to the emergency-access redirection extension.

You can generate an Emergency Access Summary Report of the emergency audit records. Schedule the report for printing once a day at a designated printer. If the switch has a journal printer Emergency Access to the Attendant audit records print as the calls occur.

You can monitor emergency-access calls by displaying them at the administration terminal. The command for listing emergency call events is **list emergency**. You can use a from and to time option with the command. For example, if you enter the command **list emergency 8:00am 12:00pm**, the report shows emergency call events that occurred during that interval.

### Considerations

---

- The emergency tone cannot be silenced except by answering the emergency call.
- The system should have at least one day and one night attendant (or night service station) for this feature to be useful at all times.

## Interactions

---

- **Centralized Attendant Service (CAS)**

For a branch with CAS in effect, an emergency call reroutes to the branch attendant group. If the branch does not have an attendant or if the branch is not in CAS Backup Service, the call is denied.

If the branch PBX is in CAS Backup Service, an emergency call routes to the backup position and is handled as any other non-emergency call.
- **Class of Restriction (COR)**

An emergency call to the Attendant overrides all restrictions on the COR.
- **Individual Attendant Access**

An emergency call cannot be placed to an individual attendant.

Emergency calls have priority over other calls to an individual attendant, only if they are assigned a higher priority on the Console Parameters screen.
- **Inter-PBX Attendant Service**

For branches with Inter-PBX Attendant Service in effect, an emergency call reroutes to the local attendant group. If the branch does not have an attendant or if the attendant is not on duty, the call is denied.
- **Night Service**

When Night Service is in effect, emergency calls route to the night destination. Such calls are included on the Emergency Audit Record, and the call is designated as Emergency Night in the audit trail.

When an attendant is in night service, you must assign either a night station or a redirect extension. Otherwise emergency calls to the night attendant hear a busy tone.
- **Off-Hook Alerting automatically places an emergency call to the attendant.**
- **Priority Queue**

You can change the priority of emergency calls to equal or lower than that of other types of calls.
- **Remote Access**

An emergency call cannot be placed through Remote Access.
- **Restriction — Controlled**

An emergency call overrides any controlled restriction.

## Emergency calls

---

Enhancement to E911 includes the ability to report the Emergency Location Extension as the CPN by manually correlating the CPN with the phone location, even if the phone is moved.

### Detailed description

---

If the IP Emergency Calls field on the Station screen is set to extension, the MultiVantage system uses the Emergency Location Extension as the E911 CPN instead of the IP phone's extension.

The Enhanced 911 (E911) systems installed in many jurisdictions in the U.S. are equipped so that by dialing a service code (911 in the U.S.), a victim of a fire, accident, crime, or medical emergency may quickly access a public safety agency that will dispatch the appropriate response. The public E911 system maintains a database that stores location and background information to aid public safety agencies in responding quickly with the appropriate assistance. Information about the calling party can be triggered by the transmission of a Caller's Emergency Service Identification (CESID) number over Centralized Automatic Message Accounting (CAMA) trunks when the call originates from behind a PBX. 911

calls from a station on a PBX not equipped with CAMA trunks (or an adjunct computer system associated with CAMA trunks) will not provide the E911 system with the information required to identify the location of the person placing the call. Instead, the E911 system will only be able to identify the location of the trunk termination at the PBX.

This feature allows transmission of identifying information in the form of the CESID over CAMA trunks as to the extension number of a DID station associated with the calling party. The calling party may be at or near a station on a remote port network, or may be at a remote location served by an off-premises station.

## **Considerations**

---

- Emergency response personnel might go to the wrong location when extensions and IP phones are moved without notifying the system administrator.
- The ANI that is sent to the CO might not be the same extension as that of the phone used to dial emergency personnel. If the call is disconnected and emergency personnel call back they will call the ANI and may not be able to reach the person who placed the call. However, if the emergency location phone had a crisis alert button, the return call would be answered by someone who was notified of the extension making the emergency call. That person could forward the return call from the emergency personnel to the extension that made the emergency call. See “Crisis Alert”.
- Emergency response personnel can be sent to the wrong location during the time between an IP phone registering after a move and the time that the system administrator updates the emergency location extension field.
- Enhancements to E911 only applies to emergency calls on CAMA and ISDN trunks.
- Several call appearances should be provided on the last phone in the Emergency Location Extension’s coverage path and station hunting path.
- Emergency Location Extensions should not include voice mail, automated attendant or announcement extensions.

## **Emergency Transfer**

---

Emergency Transfer provides service to and from the local telephone company CO during a power failure or when service is impaired. Emergency Transfer is also called Power Failure Transfer; the terms are synonymous.

## Detailed description

---

Emergency Transfer allows analog telephones (500- or 2500-type) to access the local CO and to answer incoming calls during a power failure.

Each DEFINITY server cabinet supports Emergency Transfer panels via the AUX connectors on the rear panel. The transfer is initiated when:

- a transfer panel or associated cabinet loses power.
- someone manually activates the Emergency Transfer switch on the associated maintenance circuit pack
- the software determines that service for that cabinet is severely impaired

You cannot activate any other system features during a complete system power failure.

Emergency Transfer panels are available in multiples of five telephones, which may be pulse-dialing or touch-tone phones. You must use pulse dialing if the CO accepts dial pulses only. Each telephone can be connected to a separate CO.

When your system is not in Emergency Transfer mode, transfer phones can be used as regular telephone.

## Interactions

---

- Night Service

If a power failure occurs when the system is in night service, the system automatically returns to night service when power returns.

## Extended user administration of redirected calls

---

Extended User Administration of Redirected Calls allows you to change your lead-coverage path or your call forwarding from any local (on-site) or remote (off-site) location.

### SECURITY ALERT:

*Invalid extensions and invalid station security codes are logged as security violations. The extension or incoming trunk from which the command sequence was dialed, the FAC, and the dialed command string appear on the Monitor Security-Violations Station Security Codes screen or report if Security Violation Notification is enabled.*

For administration information about tracking security violations, see [“Setting up security violations notification” on page 401](#).

## Detailed description

This feature does not change Call Coverage, nor does it change Call Forwarding All Calls or the Call Forwarding Busy/Don't Answer. It merely allows you to select between one of two previously administered coverage paths or to change your forwarding from any on-site or off-site location.

## Telecommuting access extension

The telecommuting access extension allows you to use Extended User Administration of Redirected Calls from off-site. If you want to quickly disable the feature for all users, change the Telecommuting Access Extension to blank.

If you are operating in a DCS environment, you need to assign a different telecommuting-access extension to each switch and tell your users which extension they should use. You can use Extended User Administration of Redirected Calls from any of the DCS nodes, but you need to dial the telecommuting-access extension of the node on which your station is defined before using the feature access code.

## Extended User Administration of Redirected Calls and COS

The following table shows the relationship between COS and a your ability to use call forwarding at the your station without a security code or from any on-site or off-site location with a security code.

**Table 55. COS and Extended User Administration of Redirected Calls of Call Forwarding**

| If the user's COS are set to these values |                   |                                    |                                         | Then the user's call forwarding capability is                      |                                                                                          |
|-------------------------------------------|-------------------|------------------------------------|-----------------------------------------|--------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| Call Fwd All COS                          | Call Fwd B/DA COS | Extended Call Fwd Activate All COS | Extended Call Fwd Activate Busy D/A COS | Users can forward calls from their station without a security code | Users can forward calls from their station or from another location with a security code |
| Yes                                       | Yes               | Yes                                | Yes                                     | Yes                                                                | Yes                                                                                      |
| No                                        | No                | Yes                                | Yes                                     | No                                                                 | Yes                                                                                      |
| Yes                                       | Yes               | No                                 | No                                      | Yes                                                                | No                                                                                       |

## COR

The COR controls the use of the change coverage option of Extended User Administration of Redirected Calls. This means that, if the Can Change Coverage field on the COR screen is set to **y**, you can use the Change Coverage FAC to change your coverage option.

### How to use from an attendant or console-permissions station

To use Extended User Administration of Redirected Calls from an attendant or console-permissions station is the same as that described for a user, except console-permissions stations and attendants do not need to enter a station security code, nor do they need to press the pound key (#).

### How to use from an off-site location

To use Extended User Administration of Redirected Calls from off-site, you must first access the telecommuting-access extension. If you make the request via Direct Inward Dialing (DID), you must precede the extension with the correct public-network prefix. If you make the request via a trunk group dedicated to remote access of this feature, you must dial the public-network number for the trunk group.

The system provides dial tone after you access the telecommuting access extension. At that point you can enter only one of the four FACs associated with this feature. The 4 FACs associated with Extended User Administration of Redirected Calls are:

- Extended Call Fwd All Activate
- Extended Call Fwd Busy D/A Activate
- Extended Call Fwd Deactivation
- Change Coverage

When the system provides dial tone, you can proceed with the steps outlined for on-site use of the feature in [“Training users” on page 373](#).

### How to interrupt the command sequence

To interrupt the command sequence and begin again, you can enter an asterisk (\*) at any point before the second pound sign. The system provides dial tone, and you can begin the command sequence at the point of entering your extension. (You should not enter the FAC again.) The interrupted command sequence is not recorded as an invalid attempt.

## Interactions

---

- **Bridged Appearance**

When the pound key (#) is pressed from a bridged appearance immediately following any of this feature's four FACs, the system assumes the currently active bridged extension will be administered. The station security code of the currently active bridged extension must be entered after the initial # to successfully complete the command sequence.

If the station has only bridged appearances, the station's extension must be dialed after the FAC to successfully complete the command sequence, since the station's extension is not associated with any appearances.

- **Call Coverage**

Extended User Administration of Redirected Calls interacts with this feature only in that system users can change their lead-coverage path.

An attempt to activate Send All Calls is denied if the currently active coverage path does not allow Send All Calls in its coverage criteria. However, if you activate Send All Calls when it is allowed, and then change your coverage path to one that does not allow Send All Calls, the Send All Calls button remains lit and Send All Calls automatically resumes if you change back to the coverage path that allows it.

- **Call Forwarding**

When Call Forwarding is active, the status lamps for the active features for that extension are lit. When Call Forwarding is deactivated, the status lamps for both Call Forward All and Call Forward Busy/DA buttons for that extension are extinguished. Off-net forward destinations are not allowed.

- **Distributed Communications System (DCS)**

Assign a different telecommuting access extension for each switch. You can use Extended User Administration of Redirected Calls from any of the DCS nodes, but you must dial the extension of the node on which your station is defined before dialing the FAC.

- **Security Violation Notification (SVN)**

Extended User Administration of Redirected Calls security violations are tracked and reported by SVN for station security codes, if it is enabled.

- Tenant Partitioning

The telecommuting access extension is always automatically assigned to Tenant Partition 1, so it can be accessed by all tenants.

The tenant number of the extension administered must be accessible by the tenant number from which the Extended User Administration of Redirected Calls FAC is dialed or the request is denied. If the FAC is being dialed on site, the tenant number of the station or attendant must have access to the tenant number of the extension administered. If the FAC is dialed off site, the tenant number of the incoming trunk must have access to the tenant number of the extension administered.

## Facility and Non-Facility Associated Signaling

---

Facility Associated Signaling (FAS) allows an ISDN-PRI T1/E1 interface D-channel to carry signaling information for all the bearer (B) channels on its associated span.

Non-Facility Associated Signaling (NFAS) allows 1 ISDN-PRI T1/E1 interface D-channel to carry signaling information for up to 300 bearer (B) channels on its associated spans. In other words, a D-channel can carry signaling information for numerous B-channels located on different DS1 circuit packs.

### NOTE:

NFAS is only valid for T1/E1 Country Protocol 1. Digital T1 service is also sometimes called “DS1” to distinguish it from analog T1 service.

ISDN-BRI trunks don't support Non-Facility Associated Signaling.

## Brief Description

---

### D-Channel Backup with NFAS

When NFAS is used, a backup D-channel can be administered to improve reliability. The system switches to the backup D-channel if a signaling link failure occurs on the primary D-channel span.

One D-channel is administered as the Primary D-channel and another D-channel is administered as the Secondary D-channel. These assignments ensure that both D-channels are in the same state at the same time and neither can be used to carry B-channel traffic at any time. The Primary D-channel is given precedence over the Secondary D-channel.

When D-Channel Backup is activated, all calls that have been answered are preserved. However, some call-related information may be lost. Calls that are not answered when D-channels are switched also may lose call-related information.

The figure below shows a possible configuration involving 3 ISDN-PRIs between a DEFINITY Server and another DEFINITY Server or the public network.

**Figure Notes**

- |                        |                                           |
|------------------------|-------------------------------------------|
| 1. Avaya Media Server  | 4. ISDN-PRI controlled by D-Channel       |
| 2. Secondary D-Channel | 5. Network Far-End Switch DEFINITY Server |
| 3. Primary D-Channel   |                                           |

**Figure 58. ISDN-PRI Configuration**

With T1 (24 channel) interfaces, 2 of the ISDN-PRIs contain a D-channel and 23 B-channels, while the other ISDN-PRI contains 24 B-channels. One of the D-channels is the Primary D-channel, and the other is the Secondary D-channel. Together, this pair of D-channels signals for all 70 (23+24+23) B-channels in the 3 Primary Rate Interfaces.

Since the D-channels are signaling for more than one ISDN-PRI facility, D-Channel Backup requires the use of NFAS. At any given time, one of the two D-channels is carrying Layer 3 signaling messages, while the other D-channel is active at layer 2, but in standby mode only. Any layer 3 messages received over the standby D-channel are ignored. Since only one of the D-channels can be active at a time, load sharing between the two D-channels is not possible. The two D-channels can provide signaling for only a predefined set of B-channels and cannot dynamically backup other D-channels on other interfaces.

## D-Channel Backup activation

- D-Channel Failure

If the signaling link fails on the active D-channel (D1) or the hardware carrying D1 fails, the system sends a message over the standby D-channel (D2). D2 then becomes the active D-channel and carries all subsequent signaling messages. When the signaling link or hardware on D1 recovers from the failure, D1 becomes the standby D-channel.

- System Technician Commands

If a system technician commands that a D-channel switchover take place, the first action taken by the system is to tear down the signaling link on D1. After this is completed, a message is sent on D2 to request that D2 become the active D-channel. D2 then becomes the active D-channel and the switchover is complete.

## Screens used to administer FAS and NFAS

The following list shows the required screens and the fields you must use on each screen:

- [Signaling Group](#) (Also see the DEFINTY services documentation for information about this screen.)
  - all
- [ISDN trunk group](#)
  - Port
  - Sig Grp
- [DS1 Circuit Pack](#)
  - Signaling Mode

## Guidelines for administering FAS and NFAS

Coordinate the following when implementing FAS and NFAS:

- Decide which T1/E1 facilities will use FAS.
- Decide which of the remaining T1/E1 facilities carries D-channel signaling information on the 16th (E1) or 24th (T1) channel. For those channels that have a D-Channel Backup, D-channel pairs must be allocated.

- Define Signaling Groups. A Signaling Group is a group of B-channels for which a given D-channel (or D-channel pair) carries the signaling information. Each Signaling Group must be designated as either a FAS or NFAS Signaling Group.
  - A FAS Signaling Group must contain all the ISDN B-Channels on the T1/E1 interface associated with the group's D-channel, and cannot contain B-channels from any other DS1 circuit pack. For 24-channel DS1 boards, some of the DS1 ports may use in-band (robbed-bit) signaling and be members in a tie trunk group rather than an ISDN trunk group. These tie trunks cannot be members of a Signaling Group.
  - There is no restriction on which T1/E1 ports can belong to an NFAS Signaling Group. Normally, an NFAS Signaling Group consists of one or two D-channels and several complete T1/E1 interfaces.
  - If a Signaling Group contains only a subset of a T1/E1's B-channels (ports 1–12, for example), it is considered an NFAS Signaling Group, not a FAS Signaling Group. The remaining B-channels on the T1/E1 are then assigned as members of another NFAS Signaling Group.
- An Interface ID must be assigned to each T1/E1 facility in an NFAS Signaling Group. For example, if the B-channels in a Signaling Group span 3 T1/E1 facilities, a unique Interface ID must be assigned to each of the 3 facilities. This designation is required to uniquely identify the same B-channel (port) number on each of the T1/E1 facilities in the Signaling Group. Therefore, this interface must be agreed upon by both sides of the interface and administered prior to initialization.
- Primary and Secondary D-Channel Backup must be agreed upon by both sides of the interface and administered prior to initialization. If the IDs do not match, the signaling group will come up but calls will fail.

The following screens show the DS1 interface configuration for NFAS. When implementing FAS and NFAS, the DS1 screen must be submitted first, followed by the Interface Link and associated forms, followed by the ISDN-PRI trunk group, Signaling Group, and Trunk Group Members screens.

The Interface Link and associated screens may be administered at any time after the DS1 screens have been administered, with the following restrictions:

- A D-channel cannot be assigned on a Signaling Group screen unless the associated link is disabled.
- A trunk member cannot be assigned unless its associated Signaling Group has been administered.

The Signaling Mode field must be specified for each DS1 circuit pack. Because this circuit pack has the Signaling Mode field set to isdn-ext, all trunks on this circuit pack are signaled using either inband robbed-bit signaling or a D-channel on another DS1 circuit pack.

```

 DS1 CIRCUIT PACK

```

**Screen 308. Signaling Group screen (Group 3) — Facility Associated Signaling**

Note the following details in the Signaling Group screens shown above:

- Signaling Group 1 B-channels on DS1 circuit packs (boards) B0 and B1 are signaled by D-channel pair B1524 (see the Primary D-channel field) and B1624 (see the Secondary D-channel field).
- Signaling Group 2 B-channels on board B1 are signaled by D-channel B1824.
- Board B0 has no D-channel. The B-channels on board B0 can be signaled by either D-channel pair B1524/B1624 (Signaling Group 1) or D-channel B1824 (Signaling Group 2).
- The DS1 interface on board B19 (Signaling Group 3) is a Facility Associated Signaling case. Note that the Secondary D-channel and Trunk Board/Interface ID fields are not displayed when the Associated Signaling field is **y**.

The following 2 communications-interface screens must be completed for the ISDN-PRI interface on DEFINITY SI configurations if the D-channel is switched through the TN765 Processor Interface (PI) circuit pack:

- Interface Links screen — Used to create an association between the D-channel on a DSI circuit pack and the port on a TN765 Processor Interface circuit pack used for this link.
- Processor Channels screen — Used to assign processor channels to the link administered on the Interface Links screen.

Finally, trunk ports are added to the ISDN-PRI trunk group and to Signaling Groups.

| TRUNK GROUP                             |        |     |      |       |         |
|-----------------------------------------|--------|-----|------|-------|---------|
| Page Y of X                             |        |     |      |       |         |
| Administered Members (min/max): xxx/yyy |        |     |      |       |         |
| Total Administered Members: xxx         |        |     |      |       |         |
| GROUP MEMBER ASSIGNMENTS                |        |     |      |       |         |
| Port                                    | Code   | Sfx | Name | Night | Sig Grp |
| 1:                                      | 1B1501 |     |      |       | -       |
| 2:                                      | 1B1523 |     |      |       | -       |
| 3:                                      | 1B1601 |     |      |       | -       |
| 4:                                      | 1B1623 |     |      |       | -       |
| 5:                                      | 1B1701 |     |      |       | 1       |
| 6:                                      | 1B1709 |     |      |       | 1       |
| 7:                                      | 1B1716 |     |      |       | 2       |
| 8:                                      | 1B1724 |     |      |       | 2       |
| 9:                                      | 1B1801 |     |      |       | -       |
| 10:                                     | 1B1823 |     |      |       | -       |
| 11:                                     | 1B1901 |     |      |       | -       |
| 12:                                     | 1B1923 |     |      |       | -       |
| 13:                                     |        |     |      |       | -       |
| 14:                                     |        |     |      |       | -       |
| 15:                                     |        |     |      |       | -       |

**Screen 309. ISDN-PRI Trunk Group screen — Trunk Members with Required Signaling Group**

The Sig Grp column on the above trunk group screen is completed as follows:

- If a DS1 interface appears in one and only one Signaling Group, then Sig Grp may be left blank because the system automatically populates the field with the correct Signaling Group.
- If a DS1 circuit pack appears in more than one Signaling Group, then the Signaling Group numbers must be entered in the appropriate fields before submitting the screen.

**Related topics**

See [“ISDN service” on page 1730](#) for an overview of ISDN capabilities.

**Facility restriction levels and traveling class marks**

Facility Restriction Levels (FRL) and Travelling Class Marks (TCM) allow certain calls to specific users, and deny the same calls to other users. For example, you can give certain users access to CO trunks to other corporate locations, and you can restrict other users to less expensive, private-network lines.

## Detailed Description

---

### FRL

The switch compares the FRL of the outgoing phone to the FRL of either the terminating trunk group or, for AAR and ARS, the routing preference specified on the Routing Pattern Table. If the FRL of the originator is equal to or greater than the terminating or route pattern FRL, the call continues. Otherwise, the call is blocked.

### TCM

If an intertandem tie-trunk group is used for a call, then a TCM is outpulsed as the last digit. If the intertandem tie-trunk FRL is equal to or greater than the terminating FRL, the call continues. If the originating FRL is less than the terminating FRL, the TCM is compared with the tie-trunk's FRL. If the TCM is greater than or equal to the FRL, the call continues.

### Call-originating facilities

Any of the following can originate an AAR or ARS call. Each is assigned an FRL via an associated COR.

- attendant
- data terminal capable of keyboard dialing
- incoming tie-trunk group from a subtending location
- incoming intertandem tie-trunk group (at a tandem switch)
- incoming access tie-trunk group (links a remote main switch to a tandem switch)
- phone
- remote access user

Phones and all incoming tie-trunk groups use the FRL of their COR. On attendant-extended calls, the attendant-group FRL is used. If Individual Attendant Access assigned, the individual attendant's COR FRL is used. Data terminals use the FRL of the COR assigned to the associated data module.

A remote access call uses the FRL of the COR assigned to the dialed barrier code. If a barrier code is not required on remote access calls, there is no FRL.

## Call terminating facilities

Any of the following trunk types can serve as the termination point for an AAR or ARS call:

- Tie trunk — excluding RLT, but including CCSA and Enhanced Private Switched Communications Services (EPSCS) access trunks
- WATS
- CO
- FX
- ISDN-PRI

Each of these outgoing trunk groups has an assigned COR that contains an FRL. However, this FRL is never used in an AAR or ARS call. A terminating-side FRL for AAR/ARS calls is assigned in the route pattern, not to the outgoing trunk group.

## FRL guidelines

You assign the FRL to the trunk group within the route pattern. You can use the same trunk group in more than one route pattern, and the same trunk group can have a different FRL in a different pattern. You can assign the same FRL to more than one trunk group.

Be consistent in FRL assignments. For ease of assignments, always use FRL 0 or 1 for a trunk group that everyone can access. If you use a range of 0–5 in one pattern, use the same range in another pattern if all users can access the first-choice route.

Assign a COR with an FRL of 0 to a group of users to restrict them from making outgoing calls. Use any other number for the FRL on your first choice route pattern. This denies access to any trunk group for the users, because all trunk-group FRLs are greater than 0.

You assign FRLs for remote access users through the remote-access barrier codes. You can assign up to 10 barrier codes, each with its own COR and FRL. The simplest way to assign these FRLs is to duplicate the on-premises FRLs, then relate the appropriate barrier code to users who need remote access.

## Example

---

The following is an example of how FRLs can be assigned in a COR:

- FRL0 — 911 access only
- FRL1 — Local calls only
- FRL2 — FRL1 plus home area-code calls using WATS
- FRL3 — FRL2 plus use of local lines for all calls in the home area code
- FRL4 — FRL3 plus calls to all the USA, using WATS only
- FRL5 — FRL4 plus calls to all the USA, using local lines
- FRL6 — FRL5 plus international calls
- FRL7 — Reserved

## Interactions

---

- Call Detail Recording

If 15-digit CDR account codes are used, the FRL field in the CDR record is overwritten with the account code.

## Related topics

---

See [“Route Pattern” on page 1096](#) to find more information on fields on the route pattern screen.

## Generalized route selection

---

Generalized Route Selection (GRS) is built into AAR and ARS. This switch uses GRS to look at various route patterns and preferences and decide which preference is most appropriate at the time. With GRS, voice and data calls can be sent along separate routes or be integrated on the same trunk group. If the type of transmission is incompatible with the endpoint (for example, a digital data call is sent to an analog phone), GRS provides a conversion resource such as a modem from a modem pool to complete the call.

## Detailed description

GRS recognizes one or more BCC for each trunk group preference in the route pattern. BCC defines the type of information being sent as voice or data. The switch checks the BCC for all trunk groups to see if the route selected and type of call are compatible. The BCC is assigned to the route preference on the Route Pattern screen.

GRS chooses a preference with BCC set to yes in this order: BCC 2, BCC 1, BCC 3, BCC 4.

When an exact match is not found in any route-pattern preference, calls with originating BCCs listed are treated as follows:

- BCC of 0 (such as voice or analog modem)

GRS routes a BCC 0-originated call with no match. This allows voice transfer to data when making a data call.

Since BCC 0 (voice) has no Information Transfer Capability (ITC), the switch selects an ITC from the route pattern when a BCC 0 call is routed as a data call. [Table 56](#) shows how the ITC codepoint in the Bearer Capability IE is determined.

**Table 56. Determination of ITC codepoint**

| Originating Endpoint's ITC | Routing Preference's ITC |               |               |                    | ITC codepoint in BC IE |
|----------------------------|--------------------------|---------------|---------------|--------------------|------------------------|
|                            | restricted               | un-restricted | both endpoint | both un-restricted |                        |
| voice                      | x                        |               |               |                    | restricted             |
| voice                      |                          | x             |               |                    | unrestricted           |
| voice                      |                          |               | x             |                    | unrestricted           |
| voice                      |                          |               |               | x                  | unrestricted           |

- BCC 2

If there is no preference with BCC 2 yes, GRS chooses a preference with BCC 0 yes. If BCC 0 yes does not exist, the call is blocked.

- BCC 1, 3, or 4

BCC 4 (DCP/DMI Mode 0), BCC 1 (Mode 1), and BCC 3 (Mode 3) calls requires an exact match in order for the call to complete. ITCs must also match.

## Example

Assume a route pattern is set up with BCC 0 and BCC 2 set to yes in preference 1, and BCC 1, BCC 3, and BCC 4 set to yes in preference 2.

A voice or Mode 2 data call accessing this pattern uses preference 1. A Mode 1, Mode 3, or Mode 0 data call uses preference 2, regardless of what trunks are available in the first preference.

## Data modules and GRS

For all endpoints, the switch automatically determines its current operating mode when a data module begins operations. The default is Mode 2.

Because call origination from a data module determines the mode used on the call, you should press the Originate/Disconnect button if you change data options. This way, the right mode is assigned to the next call.

[Table 57](#) lists the BCC for different types of information and endpoints.

**Table 57. BCC assignment**

| Endpoint                                                                   | Voice/Data Mode | BCC   |
|----------------------------------------------------------------------------|-----------------|-------|
| Phone                                                                      | Voice           | 0     |
| Data Line Circuit Pack                                                     | 2               | 2     |
| Voice Data Set                                                             | 2               | 2     |
| Modular Processor Data Module                                              | 0,1,2           | 1,2,4 |
| Modular Processor Data Module-M1<br>(For ACCUNET Switched 56 kbps Service) | 1               | 1     |
| Modular Trunk /Data Module                                                 | 2               | 2     |
| Digital Terminal/ Data Module                                              | 2               | 2     |
| 510D Personal Terminal                                                     | 2               | 2     |
| Digital Communications Protocol Interface                                  | 0,2,3           | 2,3,4 |
| 7400A Data Module                                                          | 2               | 2     |
| 3270T Data Module                                                          | 3               | 3     |
| 3270C Data Module                                                          | 3               | 3     |
| 3270A Data Module                                                          | 2,3             | 2,3   |

**Legend**

| <b>BCC</b> | <b>Type</b>                | <b>DCP/DM I Mode</b> |

**Related topics**

---

See [“Route Pattern” on page 1096](#) for information on how to set up route patterns.

**Group paging**

---

Group paging allows users to make an announcement over a group of digital speakerphones.

- You can create up to 32 paging groups on one DEFINITY server.
- Each group can have up to 32 extensions in it.
- It's OK to assign the same extension to different groups.

**Brief description**

---

You, the switch administrator, create paging groups and assign extensions as members to the appropriate groups. Each group is assigned its own identifying extension, and users page the group by dialing this extension. When a user dials the group's extension, the switch activates the speakers on all the phones in the group. Speakerphone paging is one-way communication: group members hear the person placing the page but cannot respond directly.

**Restrictions**

Pages aren't always heard on every phone in a group. An extension does not transmit a group page if it has an active or ringing call or if it is off-hook. Listeners may drop a page by disconnecting. See [“Interactions” on page 1691](#) for features that block group pages.

## Controlling access to paging groups

Each paging group is assigned a class of restriction, so you can provide or deny access to different classes of users by setting calling permissions appropriately. Note that you can administer classes of restriction so remote callers can make speakerphone pages. If you don't want to allow remote users to page, you may want to set calling permissions (on the Class of Restriction screen) for VDNs and trunk groups so that neither can initiate pages.

## Interactions

---

- **Attendant Intrusion**

Attendants cannot intrude on group pages. If the attendant tries to intrude on the paging originator, the intrusion attempt succeeds. However, all group page members are able to hear both the paging originator and the attendant.
- **Auto Exclusion and Manual Exclusion**

Bridged appearances are not allowed on the page. Therefore, the Auto Exclusion and Manual Exclusion features are disabled. Auto Exclusion is not activated because there are no bridged appearances to alert when the page terminates.
- **Auto Hold**

Auto Hold does not put a group page on hold. The page is dropped and the incoming call is answered.
- **Automatic Callback**

Automatic Callback is disabled when calling an active page group.
- **Bridging**

Bridging is disabled on this feature. A bridged appearance of a group member does not receive any indication of a call when the page arrives. The bridged appearance cannot bridge onto the page.
- **Call Coverage**

Pages do not follow group members' coverage paths. A page group cannot be a coverage point.
- **Call Park**

Group members who receive a page cannot park the call.
- **Call Pickup/Direct Call Pickup**

Other extensions cannot pick up a group page.

- Call Forwarding  
Group pages cannot be forwarded.
- Conference  
Neither group members receiving a page nor the originator of the page can conference the page to other extensions.
- Distributed Communications System (DCS)  
Page groups cannot be administered across DCS switches. DCS is not supported.
- Do Not Disturb  
If a member of a page group activates Do Not Disturb, that member does not receive pages.
- Go to Cover  
The Go to Cover feature is ignored because group pages do not follow coverage.
- Hold  
The originator of a group page can put the page on hold, but group members cannot.
- Leave Word Calling  
Leave Word Calling (LWC) is disabled. A page group cannot receive messages.
- Manual Signaling  
The Manual Signaling feature cannot be assigned to a page group.
- Send All Calls  
If a member of a page group activates Send All Calls (SAC), that member does not receive pages.
- Service Observing  
Group page members and page originators cannot be observed while active on a page.
- Transfer  
Group members cannot transfer a page.
- Trunks  
Trunks cannot be added to a page group.

- Vectoring

Paging groups cannot be explicitly added to a vector path.

 **NOTE:**

If a vector has a collect digits step and a route-to digits step, a person who uses the vector can enter a page group extension. Ensure that the COR of the vector restricts the vector from calling the page group if this action is not desired.

### Related topics

See [“Paging over speakerphones” on page 479](#) to administer group paging.

## Hospitality features

This section describes the following Avaya MultiVantage features that are tailored to hospitality applications:

- [“Attendant Room Status” on page 1693](#)
- [“Automatic Selection of DID Numbers to Guest Rooms” on page 1694](#)
- [“Automatic Wakeup” on page 1695](#)
- [“Custom Selection of VIP DID Numbers” on page 1701](#)
- [“Do Not Disturb” on page 1701](#)
- [“Names Registration” on page 1704](#)
- [“Property Management System Interface” on page 1707](#)
- [“Suite Check-in” on page 1714](#)

Each feature indicates how to administer the [Attendant Console](#) screen and [Hospitality](#) screen to enable the hospitality features.

### Attendant Room Status

Attendant Room Status allows the attendant to see whether a room is occupied and each room’s housekeeping status.

 **NOTE:**

This feature is available only if you have Enhanced Hospitality enabled on the System-Parameters Customer-Options screen and you have the DXS lamp field on the console. (Contact your Avaya account representative for information.)

## Check In/Check Out Status

You can allow the attendant to review the check-in/check-out status by assigning an occ-rooms (occupied rooms) button on the [Attendant Console](#) screen.

When the attendant activates check-in/check-out mode, the DXS lamps light for every occupied room.

## Maid Status

You can allow the attendant to review the maid status by assigning a maid-stat button on the [Attendant Console](#) screen.

When the attendant activates the maid status mode, the system prompts the attendant to enter the room status number (1 to 6) that they want to review. You can define these six room states on the [Hospitality](#) screen. Once they enter a room state, the display shows the definition of the room state and lights the DXS lamps for every room in that state.

While the console is in maid status mode, the attendant can review another room state by entering the room status number.

### NOTE:

The attendant cannot make outgoing calls via the keypad while the console is in maid status mode; they must return to normal mode.

## Automatic Selection of DID Numbers to Guest Rooms

---

Automatic Selection of DID Numbers for Guest Rooms allows you to give guests, upon check-in, phone numbers that provide direct dial access to their room. The switch automatically chooses a number from a rotating list of available DID numbers to be assigned to a guest's room. This provides a measure of privacy to your guests because providing the phone number does not give away the room number.

Callers would use a 7- to 10-digit number from outside of the hotel. For calls from inside the hotel, callers would use either the room/extension number or the 2- to 5-digit DID number.

For example, when a check-in is done from the switch (via the CHECK-IN button on the console) or remotely via a Property Management System (PMS) system, the switch assigns a DID number to the checked-in room from a list that is assigned at the switch. All calls made to the DID number are directed to the room as if the room was called directly.

### NOTE:

The following process presumes you have established a dial plan and administered all DID numbers to their extensions (on the Station screen) as XDID station types.

## Interactions

- Coverage

XDID ports perform hunt-to before coverage. After hunting, coverage criteria for these calls is based upon the DID, but the coverage points are based upon the hunted-to phone (room).
- Coverage

Do not assign a Class of Service (COS) with Client Room enabled for the XDID station types.

## Automatic Wakeup

---

Automatic Wakeup allows attendants, front desk users, and guests to request an automatic wakeup call at a later time.

If the Dual Wakeup field on the [Hospitality](#) screen is **y**, each extension is allowed two wakeup call requests within one 24-hour time period. If the Room Activated Wakeup with Tones field is **y**, wakeup calls can be activated via tones that prompt users for the time they want to be called.

## Detailed description

Wakeup requests may be placed from 5 minutes to 23 hours and 55 minutes in advance of a wakeup call.

Depending on how automatic wakeup is administered, when a user answers a wakeup call, the system can provide:

- a recorded announcement
- a speech-synthesis announcement
- music
- silence

All wakeup times entered into the system round to the nearest five minutes. For example, a requested time of 6:58 am stores in the system as 7:00 am. The switch bases time-validity checks on the rounded figure.

Wakeup calls are placed within two and one-half minutes of the requested time, and never reroute, forward, or go to coverage. Before placing the wakeup call, the system overrides Do Not Disturb for the extension.

If a wakeup-call attempt is not answered or if the extension is busy, the system tries two more times at 5-minute intervals. If the call does not complete after 3 attempts, the switch leaves an LWC message for a designated extension (usually assigned to a button on the attendant console or backup phone). The system maintains a complete record of all wakeup-call activity for the past 24 hours.

Users with touch-tone dialing can enter a wakeup request (if they have a speech synthesizer circuit pack and no display set or if Wakeup Activation via Tone is enabled) or can have the front desk set a wakeup time. Users with rotary-dial phones call the front desk to request a wakeup call.

Activate Automatic Wakeup either by dialing the FAC or by pressing the automatic wakeup entry button. If the system has a speech synthesizer circuit pack, the system provides voice prompting. If the user has a display set, the system provides display prompting.

- **Voice Prompting with Room Activated with Tones Off**

A guest enters his or her own wakeup-call request. The request is entered only for the extension where the call originates.

After the user dials the Automatic Wakeup FAC, the system generates voice prompts (the system must have a voice synthesizer circuit pack). These prompts tell the user when to enter information and what information is needed. Use touch-tone buttons to enter the information. The system accepts 24-hour or standard time. The user dials the automatic wakeup FAC again to change or delete a wakeup request.

If the user makes invalid entries, a standard message generates that notifies the user of the error. The system then repeats the original prompt for input. If invalid entries occur on the second try, the system informs the user to dial the attendant for assistance.

- **Voice Prompting with Room Activated with Tones On**

A guest enters his or her own wakeup-call request. The request is entered only for the extension where the call originates.

After the user dials the Automatic Wakeup FAC, the system generates recall dial tone (the system does not need a voice synthesizer). This dial tone prompts the user to enter the time in a 24-hour, 4-digit format. Confirmation tone means that the wakeup request is successful.

- **Display Prompting with Dual Wakeup Off**

Display prompting is provided to attendants, front-desk users, and other users with display-equipped phones. Administer front-desk users (or any other phones you want to grant permissions to) with a console permission COS to perform the same actions as the attendant. Other users can enter a wakeup request only for the extension where the call originates.

The attendant presses the automatic wakeup entry button to activate the feature. If the attendant is on an active call with a system user, the user's extension displays as the default extension after pressing the pound sign (#). If the displayed extension is not the extension of the user requesting the wakeup call, the attendant can change it. Display prompting continues until the attendant enters all necessary information and the request for the wakeup call is confirmed.

If a condition exists that does not allow the system to accept the wakeup request, the system displays the reason for denial. Wakeup requests are denied for one of the following reasons:

- Too Soon — Indicates that the requested wakeup time is within the current five-minute wakeup interval
- System Full — Indicates that the maximum number of wakeup calls is reached
- Interval Full — Indicates that the maximum number of wakeup calls in any 15-minute interval is reached

The attendant can change or cancel a wakeup call request at any time.

■ Display Prompting with Dual Wakeup On

Display prompting with Dual Wakeup works the same as Display Prompting with Dual Wakeup off (described in the previous text), except that after the first wakeup request is entered, the user is prompted for the second wakeup request.

When the system places a wakeup call, one of the following occurs:

- Extension Is Busy — The wakeup call is placed again later.
- No Answer — The extension rings for 30 seconds. If the call is not answered, the system tries again later.
- Ringing Blockage — If four or more ports on the same analog-circuit pack are already ringing, the system waits 16 seconds and tries again. If the second attempt is blocked, the call has failed and the system waits 5 minutes before trying again.
- Call Is Answered — The guest answers the wakeup call and hears either music, a recorded announcement, the speech-synthesizer announcement, or silence.
- System Reset — indicates that a system reset level 1 or system reset level 2 occurred while the system attempted to place the wakeup call. Calls affected by these conditions are treated as other wakeup attempts.

If a wakeup call is incomplete because of a busy, no answer, ringing blockage, or system reset, the system attempts to place the call 2 more times at 5-minute intervals. If the call is not completed after 3 attempts, the system leaves an LWC message to account for the failed attempt.

A special extension, called the Extension to Receive Failed Wakeup LWC Messages, is administered exclusively for receiving failed wakeup-call LWC messages. When a failed message is retrieved, the display shows the date, time, and extension for the failed wakeup-call attempt.

Assign an automatic-message waiting (AMW) button and associated lamp to attendant consoles or front-desk terminals. The number associated with the button can be the wakeup-messages extension. The AMW lamp lights when a failed wakeup message is waiting. The user retrieves the message by invoking coverage-message retrieval on the wakeup-message extension. The user presses the AMW button to place the console or phone in coverage-retrieval mode. The user then retrieves the failed wakeup-call attempt messages. Only attendants and specified phone users can retrieve and delete failed wakeup messages.

The system maintains an audit-trail record of wakeup-call activity for the past 24 hours. The wakeup-call buffer can only hold a number of records equal to the maximum number of stations administrable on the switch. For example, if a maximum of 200 stations is administrable, only 200 automatic-wakeup records are stored.

You can display wakeup events at the management terminal, or print to a designated printer. If the system has a journal printer, wakeup events print as they occur.

The audit trail record contains the following information:

- Type of event:
  - Request — A new wakeup-call request is made.
  - Change — The time is changed on an existing wakeup-call request.
  - Cancel — A wakeup request is canceled.
  - Move To — The wakeup request for this room moves to another room.
  - Move From — The wakeup request for another room moves from the old room to the new room.
  - Move-Cancel — A wakeup request from another room replaces the request for this room.

- Swap — A room swap occurs and at least one of the rooms has a wakeup request. Wakeup calls swap when a room swap is performed. A journal entry is made for each room. If the room receives a wakeup call as the result of the swap, the time of the call is provided in the entry. If the room loses a wakeup call as the result of the swap (and has not received another), the time is not present in the entry.
  - Completed — The wakeup call completes successfully.
  - Not Completed — The wakeup call failed.
  - Skip — The wakeup call is skipped. This event occurs if the system time advances past the requested time of a wakeup call.
- Time of the event
  - Extension number receiving the call
  - Time of the wakeup request
  - Extension (or 0 for the attendant) where the event took place
  - Number of call attempts that were placed
  - An indication of why a wakeup-call attempt failed

In addition, all wakeup-time changes are recorded. This record shows the original time requested and the changed time. The audit-trail record is not backed up and all wakeup data is lost if a system failure occurs.

Schedule the following reports for printing on a daily basis:

- Wakeup Activity report – summarizes wakeup activity for each extension that had any wakeup activity over the past 24 hours.
- Wakeup Summary report — gives an hour-by-hour summary of the number of scheduled wakeup calls, the number of wakeup calls completed, and a list of extensions. The report covers all automatic-wakeup events for each hour over a 24-hour period.

With VDNs and multiple announcements, you can choose as the announcement extension a VDN that reaches one announcement if the system clock is less than 12:00 and another if the system clock is greater than 12:00. The hotel guest hears “good morning” before noon and “good evening” after noon. Or, a business customer can choose as the announcement extension a VDN that points to an extension assigned to a quorum bridge, with the wakeup time as a scheduled teleconference time. When the wakeup call is completed, the customer automatically connects to the teleconference bridge.

You can administer a multiple announcement to repeat. To enable repeating announcements, enter announcement type **integ-rep** command on the Recorded Announcement screen. With repeating integrated-message functionality, the announcement keeps repeating from when the first guest (of a group of guests receiving the same wakeup announcement at the same time) goes off-hook until the last guest goes on-hook.

If the announcement type is either an externally-recorded announcement or is integrated-repeating, you can administer the wakeup-call queue for barge-in. Barge-in means that the guest receiving the wakeup call hears the announcement as soon as he or she is off-hook, even if the announcement is not at the beginning. This provides the capability of many users being bridged onto the same announcement port, eliminating the need for a separate port for each wakeup call. See [“Recording announcements” on page 442](#) for additional information.

## Considerations

- Up to 10 attendant consoles and/or front desk terminals may be in the wakeup display mode at any one time.
- Wakeup call attempts are not rerouted, forwarded, or sent to coverage.

## Interactions

- **Attendant or Phone Display**  
If the console or phone is in automatic-wakeup mode and the user presses another display-mode button, wakeup mode aborts and the wakeup request is not entered, changed, or deleted.
- **Do Not Disturb**  
If Do Not Disturb is active at a phone, Automatic Wakeup deactivates Do Not Disturb for that terminal, and the system places the wakeup call.
- **PMS Interface**  
A Check-Out request cancels an active-wakeup call request for the guest room. Room Change/Room Swap requests through PMS cause a wakeup request to change or swap.
- **Speech Synthesizer Circuit Pack**  
Auto Wakeup competes with the following features for use of the speech-synthesizer circuit pack.
  - Do Not Disturb
  - Leave Word Calling Message Retrieval
  - Visually Impaired Attendant Service

If the Wakeup Activation via Tone is enabled, the auto wakeup interface from the Speech Synthesizer circuit pack is disabled. The Do Not Disturb interface still operates.

## **Custom Selection of VIP DID Numbers**

---

Custom Selection of VIP DID numbers allows you to select the DID number assigned to a room when a guest checks in. It also provides buttons on display sets that allow you to check-in a VIP (the vip-chkin button), to view and change XDID and XDIDVIP numbers (the did-view button), and to disassociate XDID and XDIDVIP numbers outside of the normal guest check-out procedure (the did-remove button).

Make sure the following fields are administered in order to use Custom Selection of VIP DID Numbers:

- the Basic Hospitality field on the Feature Related System Parameters Customer Options screen is **y**
- the Custom Selection of VIP DID Numbers field on the Feature Related System Parameters Hospitality screen is **y**
- the Automatic Selection of DID Numbers field on the Feature Related System Parameters Hospitality screen is **y**

You also need to set up a number of stations as xdidvip (enter **xdidvip** in the Type field on the Station screen).

When you use the vip-chkin button on a display phone to check in a guest, you receive prompts to enter the room extension number and the VIP DID number. Use the did-view button to change a DID number that is automatically assigned by the switch (XDID), or one you select yourself (XDIDVIP).

Use **list station** to see which VIP DID numbers are administered. Check the hunt-to station field to see if an XDIDVIP number is available or is assigned to a guest room.

## **Do Not Disturb**

---

Do Not Disturb allows guests, attendants, and authorized front-desk phone users (those with console permission) to request that no calls, other than priority calls, terminate at a particular extension until a specified time. At the specified time, the system automatically deactivates the feature and allows calls to terminate normally at the extension.

Do Not Disturb is a form of termination restriction associated with an automatic deactivate time. When Do Not Disturb is active, the user receives only those calls associated with Automatic Callback, Automatic Wakeup, and Priority Calling, and those calls that are redirected to that extension via the Call Coverage and Call Forwarding All Calls. All other calls redirect to a recorded announcement, an attendant, or intercept tone. You can administer the switch to provide a special dial tone whenever an analog set goes off-hook when Do Not Disturb is active.

Phone users with touch-tone dialing can activate this feature themselves or ask the front desk to do it for them. Users with rotary-dial phones must call the attendant or front-desk user to request Do Not Disturb.

### **Activation by phone users**

Phone users can activate Do Not Disturb by dial access or by button access. If users have a speech-synthesizer circuit pack, they can activate Do Not Disturb themselves, without attendant assistance.

- **Dial Access**

When a user dials a Do Not Disturb FAC, the system prompts the user to enter a deactivate time. The user may later change or delete the request by dialing the Do Not Disturb FAC again and entering the required information.

If the user makes invalid entries or if system conditions prevent entry of the request, the system informs the user to dial the attendant or front desk for assistance, if the user has a speech-synthesizer circuit pack.

- **Button Access**

If a phone has a Do Not Disturb button, the user can press the button to activate the feature. The handset may be on-hook or off-hook. The user presses the button a second time to deactivate the feature.

The lamp associated with the Do Not Disturb button lights until the feature is deactivated with the button. An automatic-deactivate time is not provided.

### **Activation by Attendant**

The attendant can activate the feature for a user or a group of users. (The assigned COR determines which users are in the group.) The attendant presses the Do Not Disturb — Extension button followed by the extension, or the Do Not Disturb — Group button. The extension followed by the appropriate COR number.

The attendant can cancel a Do Not Disturb request by activating the feature, entering the desired extension or group COR number, and pressing the delete button.

### **Activation via a PMS**

The system provides an interface to a PMS. This interface allows activation and deactivation of controlled restrictions. Activation of Do Not Disturb through a PMS is similar to activation of termination restriction. A scheduled deactivate time cannot be specified.

## Audit Trail Reports

The system keeps a record of all phones that are in Do Not Disturb mode. You can display or print this information.

Administer the following reports for printing on a daily basis:

- Do Not Disturb Status Report — This report lists all extensions with Do Not Disturb active and the specified deactivate time for each.
- Do Not Disturb Plus COR Status Report — This report lists all extensions, plus those whose controlled-restriction level is termination restriction. (The attendant activates termination restriction for a specific extension or COR. A deactivate time is not associated with termination restriction.)

Records do not include Do Not Disturb information for extensions that are both termination and outward restricted.

## Considerations

- Do Not Disturb lessens the attendant's workload when phone users with speech-synthesizer circuit packs activate the feature themselves.
- A front-desk user must have a console-permission COS to activate this feature.
- The number of available speech-synthesis ports is the only limit on the number of users receiving voice prompting.

## Interactions

- Automatic Callback

Do Not Disturb does not block an Automatic Callback call. Return calls terminate at a phone in the normal way.

- Automatic Wakeup

An Automatic Wakeup call deactivates Do Not Disturb and alerts the guest at the specified time.

If the Wakeup Activation via Tone is enabled, the auto wakeup interface from the Speech Synthesizer circuit pack is disabled. The Do Not Disturb interface still operates.

- Call Coverage

If a point in a coverage path has Do Not Disturb active, calls covering to that extension alert the extension unless the extension has controlled-restriction termination active. When Do Not Disturb is active and a phone does not have a coverage path, calls are routed to the attendant.

- **Call Forwarding All Calls**

If Do Not Disturb is active at the forwarding extension, the caller receives intercept treatment. If Do Not Disturb is active at the forwarded-to extension, the call alerts the forwarded-to extension.

- **Controlled Restriction**

When a phone has total-controlled restriction, it cannot receive or place any calls. However, it can receive a call if another station has an auto-icom button pointing to the controlled-restriction station.

- **Internal Automatic Answer (IAA)**

Activation of Do Not Disturb at the called phone preempts IAA.

- **PC Console**

You cannot implement Do Not Disturb at a PC Console.

- **PMS Interface**

Checkout from either a PMS or the switch automatically deactivates Do Not Disturb for the specified extension.

## **Names Registration**

---

Names Registration automatically sends a guest's name and room extension from the PMS to the switch at check-in, and automatically removes this information at checkout.

### **Detailed description**

The information provided by Names Registration displays on any attendant console or display-equipped phone (as might be used for example, by Room Service, Security, and others). The information allows hotel personnel to provide personalized greetings to calling guests. For example, if John Smith calls room service, personnel with a display-equipped phone, see John's name and room extension and can answer with a personalized greeting.

The name of the calling or called party can display on display-equipped phones. To maintain necessary guest security, hotels do not divulge guests' room numbers to other guests or callers. For this reason, do not assign display-equipped phones to guest rooms.

### **Check In**

The switch performs the following procedures at check-in:

1. Information about the guest is obtained and stored in the hotel's PMS.
2. The PMS sends a check-in message to the switch.

3. The switch stores the guest's name and coverage path.
4. The switch removes the outward restriction on the telephone in the guest room. The switch removes all LWC messages.
5. The switch changes the status of the room from unoccupied to occupied.

At check-in, update the PBX names internal table and the call-coverage path for the guest phone. Name Registration automatically sends a guest's name, extension (room), and preferred call-coverage path to the switch.

### **Check Out**

1. The switch clears any previous wakeup calls.
2. The switch clears message-waiting lamp indications.
3. The switch activates controlled outward restriction, removes the guest's name, and identifies any unopened messages.

At checkout, Name Registration automatically changes the call-coverage path to the administered Default Coverage Path for Client Rooms.

### **Guest Information Input/Change**

Use Guest Information Input/Change to change the guest name associated with an extension, input a guest name after check-in, or change a call-coverage path. For example, hotel may check in airline personnel before their arrival to guarantee their reservation. However, hotel personnel may be unaware of the guests' names and so wait until their arrival to update the names.

### **Name Registration Information Format**

For both Name Registration and Guest Information Input/Change, a guest name may consist of as many as 15 characters, including spaces and commas. Do not use periods.

The name may be in all upper case letters, all lower case letters, or a mixture of upper case and lower case letters. To use Integrated Directory, enter the name using one of the following methods.

- Last name, comma, first name (for example, Jones, Fred)
- Last name, comma, first name, space, title/middle initial/name (for example, Jones, Fred Mr)
- Last name only (for example, Jones)

## Call Coverage

Both Names Registration and Guest Information Input/Change messages contain call-coverage path numbers. These numbers do not display but are used to configure the appropriate call-coverage arrangements for guest extensions. Arrangements can be for voice mail, text messages, any available coverage point, or no coverage at all.

Administer call-coverage paths on the switch, and use the associated path numbers to establish coverage arrangements at check-in. For suites, administer paths to allow one room in the suite to be the coverage point for the other. To make customized arrangements at time of check-in (such as coverage from one guest room to another), manually administer the path attributes at the switch.

## Considerations

- Call-coverage path numbers sent by PMS to the switch for automatic reconfiguration are limited to those administered in the switch and stored in PMS.
- A guest room extension can have a maximum of 5 digits.
- An input in PMS of the name displayed on display-equipped phones updates the switch.
- The Name and Room Number/Extension is not overwritten with a redirection reason unless the call is an emergency call or the station always is administered to have redirection. Also, certain redirection displays will not be shown (for example, priority, intercom dialing).

## Interactions

- Call Coverage  
Call-coverage arrangements are not limited to automatic update during check-in messages sent from PMS. Hotel personnel require coverage points other than those designated for guests. Call-coverage paths can be manually administered at the switch via the management terminal.
- COS  
If an extension has a client room COS, the save translation operation clears the station name and sets the coverage path to the default coverage path for client room when stored on tape. This does not affect the existing information in memory. However, if the translations are read in, it affects existing extensions until a database swap synchronizes the switch and PMS.
- Name Character Length  
The switch supports 27-character names, but the PMS interface supports only 15-character names.

- PMS Interface

During a Room Change/Room Swap, the name originally associated with the first terminal is changed or swapped to the second terminal along with call-coverage path, automatic wake-up entries, message-waiting status, and controlled restrictions.

## Property Management System Interface

Property Management System (PMS) Interface provides a communications link between the switch and a customer-owned PMS. The PMS allows a customer to control certain features in a hospital and hotel/motel environments. See *GuestWorks® and Avaya® MultiVantage Enterprise Communications Server Property Management Interface Specifications*.

### Detailed description

[Table 58](#) summarizes how the hospitality features are activated when you use only the switch and when you use the PMS.

**Table 58. PMS/Switch links**

| Feature                | Switch Only                  | With PMS                                                        |
|------------------------|------------------------------|-----------------------------------------------------------------|
| Automatic Wakeup       | Activated via console button | N/A                                                             |
| Call Coverage          | Activated via administration | Activated via PMS terminal — Transparent or ASCII mode          |
| Check-In/Check-out     | Activated via console button | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Controlled Restriction | Activated via console button | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Do Not Disturb         | Activated via console button | Activated via PMS terminal — Normal, Transparent, or ASCII mode |

*Continued on next page*

**Table 58. PMS/Switch links (Continued)**

| <b>Feature</b>                                      | <b>Switch Only</b>           | <b>With PMS</b>                                                 |
|-----------------------------------------------------|------------------------------|-----------------------------------------------------------------|
| Emergency Access to Attendant                       | Activated by guest action    | N/A                                                             |
| Housekeeping Status                                 | Activated via console button | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Message Waiting Notification                        | Activated via console button | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Names Registration                                  | Activated via administration | Activated via PMS terminal — Transparent or ASCII mode          |
| Room Change/Swap and Guest Information Input/Change | Activated via administration | Activated via PMS terminal — Normal, Transparent, or ASCII mode |
| Room Occupancy                                      | Activated via console button | Activated via PMS terminal — Normal, Transparent, or ASCII mode |

The PMS Interface provides the following:

- A communications protocol for controlling message exchange between the switch and a PMS
- An application module for controlling the operation of PMS features
- Status data on all guest/patient rooms for selected features

The protocol is full-duplex asynchronous and provides the mechanisms for setting up a data session with PMS, message-exchange control, error identification, and recovery. The interface supports standard data rates.

Two protocol modes are provided: the normal-protocol mode as described above, and transparent-protocol mode. Normal-protocol mode supports a character set that has a combination of Binary Coded Decimal (BCD) characters and ASCII characters. Transparent-protocol mode supports a complete ASCII-character set.

The application module of the PMS Interface implements requested features and provides backup if the PMS link is down. Whether or not the link is down, the switch always maintains the following data for each room:

- Whether the room is vacant or occupied
- Whether the phone's message lamp is on or off
- Whether a controlled restriction is active at the phone and, if so, which one
- The guest's name and coverage path

When the PMS link is down, the switch automatically activates Check-In/Check-Out for the attendant console and front-desk terminal with display capability, and continues to support PMS features activated from guest/patient-room phones.

When the PMS link is up again, the switch sends one of the following messages to PMS:

- No room-status changes occurred during loss of communications.
- Room-status changes did occur during loss of communications; therefore, a data exchange is needed to synchronize the switch and the PMS databases.
- The system failed momentarily, destroying its record of room status; therefore, a data exchange is needed to synchronize the switch and the PMS databases.

When the PMS link is down or not used, the switch maintains an audit-trail report of all events that are normally sent to the PMS. The audit-trail report (accessed via the management terminal) is a sequential listing of all PMS transactions executed by the switch when the PMS link is down. Included are error events that occur when the link is up or down.

If you have a PMS printer and the PMS link is down, the following status changes print as changes occur:

- Room number
- FAC dialed
- Any additional information digits that were dialed
- Reason for the entry (error message)
- Time that the error occurred

Additional reports print to the PMS Journal/Schedule printer. These include Automatic Wakeup activity, Emergency Access to the Attendant activity, and scheduled reports.

A supporting function called Room Data Image synchronizes the switch and PMS databases after a PMS link goes down and comes back up. Information exchanged includes:

- Room extension
- Whether the room is occupied or vacant
- Message Waiting lamp status
- Controlled Restriction status
- Guest's name
- Call Coverage path

### **Message Waiting Notification**

Message Waiting Notification requests originate from attendant consoles, front-desk terminals, or PMS terminals. When a request is entered, PMS sends a message to the switch to change the state of the Message Waiting lamp. If the lamp is activated by AUDIX, INTUITY Lodging, or LWC, the PMS cannot deactivate the lamp. PMS cannot turn LWC or AUDIX messages on or off; these are controlled by the switch.

Assign a console permissions COS to any console or terminal as part of the "System Wide Retrieval Stations" to retrieve requests for another station. Assign a client room COS to the extensions for which Message Notification is to be made.

### **Controlled Restriction**

When Controlled Restriction is activated through the PMS, the PMS sends a message to the switch to assign one of the following restrictions to the phone in a guest/patient room:

- No restriction
- Outward restriction
- Total restriction
- Station-to-station restriction
- Termination restriction
- Combined outward and termination restriction
- Combined outward and station-to-station restriction
- Combined termination and station-to-station restriction

The attendant can still set Controlled Restriction for a phone whether the PMS link is up or down.

## **PMS-Down Log**

The pms-down log records only those User Controller Restriction events that are for stations having a COS where:

- the Client Room field is **y**
- the Controlled Restriction Configuration field is **act-pms**
- the pms link is not up
- the pms log extension is valid

## **Housekeeping Status**

Your housekeeping staff enters status information from phones in guest/patient rooms or from designated terminals. You can assign up to 10 Housekeeping Status access codes within two different types:

- Room phone access code type  
Staff members dial up to six access codes that represent room status plus up to six additional digits for items such as maid identification.
- Designated phone access code type  
Staff members dial up to four access codes that represent room status plus the room extension and then up to six additional digits for items such as maid identification.

The switch notifies PMS when Housekeeping Status information is entered. If the PMS is unavailable, the switch writes this information to a log. The log is accessible at the switch management terminal, and is sent to the log printer, if administered.

## **Check In/Check Out**

A Check-In request deactivates the outward-controlled restriction on the phone in a guest/patient room. A Check-Out request deactivates any controlled restrictions and changes the controlled-restriction level to outward restriction, checks for any messages, clears the wakeup request, and deactivates Do Not Disturb.

If you do not use PMS or if the PMS link is down, the attendant can activate Check-In and Check-Out from an attendant console or a front-desk phone with display capability and console permission. This requires two buttons, Check-In and Check-Out. Pressing either button places the display in the respective mode and allows use of the touch-tone or DTMF buttons for entering data (rather than for placing calls).

The attendant exits Check-In or Check-Out mode by pressing any other button associated with the display (for example, the Normal Mode button). This restores the display and the touch-tone or DTMF buttons to normal operation.

A Check-In/Check-Out request sends information for Names Registration to the switch. This information includes the guest's name, room extension, and call-coverage path. If the PMS link is down and check-in is done from an attendant console or display-equipped front-desk phone, the guest's name and coverage-path information is not automatically updated.

If a guest/patient room has both a voice and a data extension, the checkout request applies only to the voice extension.

### **Room Change/Room Swap**

Room Change/Room Swap is provided only through PMS and activated from a PMS terminal. With Room Change, data pertaining to the old room — including a pending wakeup request, the guest's name (transparent/ASCII mode), and the guest's call-coverage path (transparent/ASCII mode) — moves to the new room. With Room Swap, data pertaining to the two rooms swap. With either feature, if the occupancy status is inconsistent, the system sends an error message to PMS.

### **Names Registration**

Names Registration automatically sends a guest's name and room extension from PMS to the switch at check-in, and removes this information at checkout. The guest's call-coverage path is sent to the switch during check-in and set to the administered Default Call Coverage Path for Client Rooms at checkout.

### **Guest Information Input/Change**

Guest Information Input/Change allows the attendant to enter or alter guest information (name or coverage path). Information changed at the PMS is sent automatically to the switch.

### **PMS/INTUITY Link Integration**

PMS/INTUITY Link Integration allows the following PMS administrative messages to tandem through the switch to the INTUITY Lodging adjunct. This eliminates the need for the INTUITY-to-PMS voice messaging link. This does not remove the need for the INTUITY-to-PMS call accounting link.

- Check-in
- Check-out
- Room-data-image (database synchronization)
- Modify (guest-information)
- Add/Remote Text/Fax Notification Message (message-waiting status)
- Transfer/Merge Mailbox (room change/swap)

When the messaging link is down and the PMS/MultiVantage link is up, the switch buffer holds up to 100 PMS messages. The switch updates the Intuity Lodging adjunct once the link is up. If the buffer overflows before the link is up, the database resync among PMS/MultiVantage/Intuity initiates by demand or by a routine database update from PMS.

### Considerations

- You can use Leave Word Calling (LWC) or Integrated Message Center Service for the hospital or hotel/motel staff and Message Waiting Notification for guests/patients. However, if you do not use Message Waiting Notification, Integrated Message Center Service is used for both.
- Do not remove an extension while the PMS link is active.
- Normal-protocol mode allows extensions of up to four digits. Transparent/ASCII-protocol mode allows extensions of up to five digits.
- When save translations is done when transparent/ASCII-protocol mode is active, station names with client-room COS save as blank and coverage paths save as the default coverage path for client rooms.
- The PMS link may not work correctly when multiple p-extensions have the same leading digit and adjacent lengths. For example, 3 and 4 p-extensions with the same leading digit may cause problems. The same applies to 4 and 5, and 5 and 6.
- A room extension may begin with 0 only if the PMS sends a prefix digit or a fixed number of digits.

### Interactions

- Attendant Console or Front Desk Terminal  
Activate Controlled Restriction, Check-In/Check-Out, and Message Waiting Notification at an attendant console or a front-desk phone with console permission. The attendant console receives visual notification of the status of the PMS link between the system and the PMS.
- AUDIX Interface  
Message lamps activated by this feature cannot deactivate with feature buttons or with feature messages from the PMS.
- Automatic Wakeup  
Set or cancel an Automatic Wakeup request for a guest room as a result of Room Change/Room Swap or Check-Out.

- Do Not Disturb

Set or cancel a Do Not Disturb request for a guest room as a result of a different Controlled Restriction, Room Change/Room Swap, or Check-Out.

- Leave Word Calling (LWC)

Message lamps activated by this feature cannot deactivate with Manual Message Waiting feature buttons.

If Room Change is active, LWC messages for the old room do not move to the new room. If Room Swap is active, LWC messages for the two rooms do not swap. Therefore, do not encourage use of LWC in guest rooms.

- Restriction — Controlled

Controlled Restriction for a group of user extensions, when activated from the switch, is not conveyed to the PMS. The PMS is not able to add or remove such restrictions by sending feature messages.

## Suite Check-in

---

Suite Check-in allows you to have the switch automatically check in more than one phone with one check-in command (whether from your PMS or from the switch).

When a room phone is checked in, the switch looks for a hunt-to extension associated with that station. If it finds one, the switch also checks in the station found in the hunt-to field. The switch also:

- removes controlled outward restriction
- adds the guest's name to the station record for that extension
- stores the call coverage path
- removes any Leave Word Calling (LWC) messages
- marks the room as "occupied"

If the hunt-to (second or subsequent) station has an extension in its hunt-to field, that station also is checked in. The switch continues checking in stations until it meets a station in the chain with a blank hunt-to field.

### Interactions

- Automatic Selection of DID Numbers for Guest Rooms

If Automatic Selection of DID numbers is active, then a DID number is assigned only to the initial extension (the one that appears in the check-in message), not to all of the hunt-to extensions.

- Dial By Name

Since the secondary phones that are checked-in insert a "\*" before the name, they do not appear when Dial By Name is used. However, the name (with the "\*" in front of it) appears when the phone dials the attendant or another display set.

- Do Not Disturb

When Do Not Disturb is activated for a phone, it is active for just that phone and not other phones in the hunt-to chain.

- Housekeeping Status Change

When a room status feature access code is dialed, the room status is updated only for the extension from which the code was dialed (not the hunt-to phones as well). Housekeeping should be instructed to dial the room status changes from the primary phone.

## Hunt groups

---

A hunt group is a group of extensions that can handle multiple calls simultaneously to a single phone number. For each call to the phone number, the system hunts for an available extension in the group and connects the call to that extension.

A hunt group is especially useful when you expect a high number of calls to a particular phone number. A hunt group might consist of people trained to handle calls on specific topics. For example, the group might be:

- A benefits department within your company
- A service department for products you sell
- A travel reservations service
- A pool of attendants

In addition, a hunt group might consist of a group of shared telecommunications facilities. For example, the group might be:

- A modem pool
- A group of data-line circuit ports
- A group of data modules

**NOTE:**

You may also assign ACD to a hunt group. In this case, the hunt group is known as an ACD split. See *Avaya MultiVantage™ Call Center Software Guide to ACD Call Centers* for more details about ACD splits.

### Detailed description

---

The following sections describe how a hunt group works.

### Hunting methods

The system uses one of two types of hunting method to distribute calls:

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Direct department calling | The system hunts for an available extension in the hunt group, always starting with the first extension in the group. If the first extension is busy, the system checks the second extension. If the second extension is busy, the system checks the third, and so on. When an extension is available, the system rings that extension to connect the call.                                                                                                                                              |
| Uniform call distribution | The system hunts for the extension that has been available for the longest time. The system then rings that extension to connect the call. This type of hunting provides the most equitable distribution of calls. <i>Also, this type of hunting is required for a modem pool, data-line circuit ports, and data modules.</i>                                                                                                                                                                            |
| Circular                  | Enter <b>circ</b> when the call should be routed in a “round-robin” order. The order in which the participating extensions are administered is the order in which calls are directed. The switch keeps track of the last extension in the hunt group to which a call was connected. The next call terminating on the hunt group is offered to the next station in the circular list independent of how long that station has been idle. The switch does not start searching at the same place each time. |

**NOTE:**

Expert Agent Selection uses uniform call distribution and expert agent distribution. See *Avaya MultiVantage™ Call Center Software Guide to ACD Call Centers*.

### Hunt group queues

You can set up a queue for a hunt group. When all extensions in the group are busy, calls wait in queue for the next available extension. You determine how many calls can wait in queue by setting the queue length.

If all hunt-group members are unavailable or the queue is full, the system treats the call as follows:

- If the call is internal or is carried on a DID, DS1, or tie trunk, the caller hears busy tone.
- If the call is on a central office trunk, the caller hears ringing, but gets no answer.
- If the hunt group has call coverage, the system sends the call to a coverage point.

See [“How hunt group extensions become unavailable”](#) on page 1719.

### Queue warning level

You can set up a queue warning level and an associated queue warning indicator lamp. When the queue reaches this level, the lamp lights and remains lit until the queue drops below this level. You can have one lamp for each hunt-group queue. Install the lamp so the members of the hunt group can see it.

### Call coverage

You can set up call coverage for a hunt group. Then, if a hunt-group queue is full, the system sends new calls to the coverage point.

If a call goes into a hunt group queue, it stays in queue for the Coverage Don't Answer interval, then redirects to the coverage point. A call coverage point can be another hunt group.

### Announcements

You can record and assign one delay announcement to each hunt-group queue. An announcement can be shared among hunt groups. Normally, the announcement should tell the caller to wait and say the call will be answered in the order in which it was received.

A call that connects to a delay announcement remains in queue while the announcement plays. If the call has not been answered by the time the announcement completes, the caller hears music (if provided) or silence. When the call begins ringing a member of the hunt group, the caller hears ringing.

## Delay announcement interval

You also define for each hunt group a delay announcement interval. When a call enters the queue, the interval starts. This interval (0 to 99 seconds) indicates how long a call remains in queue before the call connects to a recorded announcement. If Call Coverage is provided, the Don't Answer interval (one to 99 ringing cycles) may also begin when the call enters the queue. After these intervals begin, one of the following occurs:

- If the Don't Answer interval expires before the delay announcement interval expires, the call redirects to coverage.
- If no coverage point is available to handle the call, the call remains in queue and may connect to the delay announcement.
- If the delay announcement interval expires before the Don't Answer interval, the call connects to a delay announcement. If the announcement is already in use, the delay announcement interval is reset.

This process continues until the call is answered, goes to coverage, connects to an announcement, or ends because the caller hangs up.

If you set the delay announcement interval to 0 seconds, a call automatically connects to the announcement. The result is a “forced first announcement.” In this case, the call does not connect to a hunt-group member until after the announcement. The caller does not hear music.

If a call redirects to another hunt group via Call Coverage, the caller does not hear either hunt group's forced first announcement. However, the caller may hear the first or second announcement of the covering hunt group.

## Analog, aux-trunk, or integrated announcements

Delay announcements may be analog, aux-trunk, or integrated (digital). For an analog or aux-trunk announcement, callers who enter the queue hear the associated announcement the next time the system plays it. Callers who enter the queue after the announcement begins do not hear it until it starts again. For an integrated announcement, multiple callers can be connected to the same announcement at different times, depending on the availability of ports. See [“Recording announcements” on page 442](#) for more information.

## Example

Assume that a hunt group has the following parameters.

- Queue length is 10 calls.
- Queue warning level is 5 calls.
- Recorded announcement delay is 20 seconds.

All hunt-group members are busy. A call enters the queue as the fifth call, which causes the queue warning level lamp to light. Hunt-group members see the lamp and try to quickly complete their present calls. Meanwhile, the call waits in the queue for 20 seconds and hears the recorded announcement. When a hunt-group member becomes available, the first call in queue connects to that group member. The queue warning-level lamp turns off because the number of calls in queue fell to four.

### How hunt group extensions become unavailable

An extension in a hunt group becomes unavailable to receive calls if the hunt group member is already handling a call. This rule is true even if the call is not a hunt-group call and even if the extension's phone is a multiappearance phone.

An extension also becomes unavailable if the member presses one of the following buttons:

- Hunt Group Busy
- Send All Calls
- Call Forwarding All Calls

#### NOTE:

If a member is also an ACD agent, pressing the AUX work button also makes the member unavailable. On the other hand, if an agent presses the ACW (after call work) button, the system considers the agent to be available and still will queue calls.

- Hunt Group member dials the Hunt Group Busy Activate feature access code

### Hunt Group Busy

If you turn on the Hunt Group Busy option, a hunt group member can dial the Hunt Group Busy code followed by the hunt group number. The extension is unavailable for calls until the group member dials the Hunt Group Busy deactivation code or presses the button again.

If the last available member of a hunt group tries to activate the Hunt Group Busy option, the following occurs:

- New calls to the hunt group receive busy tone or go to coverage.
- Calls already in the queue continue to route to the last available extension.

- When the queue is empty, Hunt Group Busy activates. At the last available extension, the status lamp associated with the AUXILIARY WORK button, if provided, flashes until the queue is empty. When no more calls remain in the queue, Hunt Group Busy activates and the status lamp, if provided, lights steadily.

 **NOTE:**

If an extension is an ACD split agent as well as a hunt-group member, the split agent normally has an AUX-WORK button that also activates/deactivates Hunt Group Busy. If an agent is the last available member and they push AUX-WORK, the button's light flashes until the queue is empty. This means the agent is still available. When the queue finally empties, the button lights steadily and Hunt Group Busy takes effect.

### Send All Calls

If a station activates Send All Calls with the Send All Calls button, then calls to the hunt group extension go in queue if there is a queue, otherwise callers get a busy treatment if all the agents have their Send All Calls pushed.

 **NOTE:**

If an extension is an ACD split agent as well as a hunt-group member, the split agent normally has an AUX-WORK button that also activates/deactivates Hunt Group Busy. If an agent presses the SEND ALL CALLS button, the agent becomes unavailable for hunt-group calls. The agent then can become available for calls again by pressing the SEND ALL CALLS button again.

### Call Forwarding All Calls

With Call Forwarding All Calls active, an extension within a hunt group is unavailable for hunt-group calls. Callers hear the hunt group's forced first announcement, if administered, before the system forwards the call.

## Considerations

---

- Members assigned to multiple hunt groups

An extension can be a member of more than one hunt-group. However, a phone, even a multiappearance phone, can receive only one hunt group call at a time. On a multiappearance phone, all appearances must be idle to receive a hunt-group call.

You can assign a COVERAGE INCOMING CALL INDICATOR (ICI) button to a multiappearance phone or attendant console. When a member receives a call for the hunt group associated with the ICI button, the button's status lamp lights.

- ACD agents as hunt group members

Do not include ACD split agents in non-ACD hunt groups if they also receive ACD split calls. The system distributes all ACD calls to split agents before it distributes hunt-group calls.

When you change an ACD split to a non-ACD hunt group, each split agent must enter the Hunt Group Busy deactivation code in order to receive calls in that hunt group. If the agent has an AUX-WORK button, the button lamp lights when you make the change. The agent can then press the button to become available for hunt-group calls.

- Hunt group for communications devices

Members of a hunt group used for shared data communications must be of the same type. Thus, you can put data modules or analog modems in a hunt group, but not both. Option settings must be the same for all group members.

A caller can still use the DATA EXTENSION button to access the associated data module, even if the module is in a hunt group. Individual data modules or modems can originate and receive calls.

- Access restrictions

You can restrict, via the Class of Restrictions (COR), any extension in a hunt group from receiving calls other than those to its assigned hunt group. You can also restrict extensions on your switch from calling the hunt group's extension.

- System limits

The size of your system determines how many hunt groups you can set up and how many extensions you can assign to each group.

- Trunk signaling

A hunt group always has its own extension. Therefore, a caller with a phone on the switch can call the hunt group by dialing only that extension. If a trunk group has the ability to pass digits from the CO to the switch (for example, a DS1 trunk group), a caller can also call the hunt group by dialing a 7-digit phone number that consists of a specified prefix and the hunt group's extension.

If a trunk group cannot pass digits from the Central Office (CO) to the switch, incoming calls on that trunk group can connect to a hunt group only if the trunk group has the hunt-group extension as its primary destination. This includes trunk groups for incoming listed directory number (LDN) calls, international exchange calls, 800 service calls, and automatic tie-trunk calls.

- Answer supervision

The switch sends answer supervision to the central office when a call connects to an extension in the hunt group or an announcement. Charging for the call, if applicable, then begins.

## **Interactions**

---

- Attendant Call Waiting

Attendant Call Waiting does not work for calls that the attendant sends to a hunt group. It does work for calls to individual hunt-group members.

- Attendant Return Call

Attendant Return Call does not work for calls that the attendant sends to a hunt group.

- Automatic Callback

Automatic Callback does not work on calls to a hunt group.

- Automatic Call Distribution

ACD does not work with circular station hunting.

- Call Detail Recording

For each call, the system can record the associated hunt-group extension or member extension that answered.

- Internal Automatic Answer

Internal calls to a hunt-group member are eligible for IAA.

- Leave Word Calling

- A hunt group can receive and store LWC messages. The following people can retrieve LWC messages:

- One member of the hunt group
- A covering user of the group
- A system-wide message retriever

The message retriever must have a phone display and proper authorization. If the message retriever is a member of the hunt group, you can assign to that member a remote Automatic Message Waiting lamp to indicate when the hunt group has an LWC message.

Night Service — Hunt Group

When Night Service is active for a hunt group and the night service destination is another hunt group, the caller hears the forced announcement of the first hunt group, if administered. The system then redirects the call to the night-service hunt group.

- **Priority Calling**

The system treats a priority call to a hunt group the same as a nonpriority call, except that the extension receives a distinctive 3-burst ring.

- **Queuing**

Queuing does not work with circular station hunting.

- **Terminating Extension Group**

A Terminating Extension Group cannot be a member of a hunt group.

- **Vectoring**

Call vectoring does not work with circular station hunting.

### **Related topics**

---

See [“Announcements/Audio Sources” on page 606](#) to assign analog, DS1, auxiliary trunk, or integrated announcements, audio/music sources, or any desired combination of announcements and audio sources.

See [“Data modules” on page 707](#) for information about and field descriptions on the Announcement circuit pack.

See [“Coverage Path” on page 696](#) for information on automatic redirection of calls to answering positions.

See [“Trunk Group” on page 1233](#) for information about where incoming calls terminate or assigning an extension number to night service.

See [“Setting up hunt groups” on page 224](#) for information on how to set up hunt groups.

## **Incoming Call Line Identification**

---

Your switch collects the calling party name and number (Incoming Call Line Identification, or ICLID) received from the CO on analog trunks.

## Detailed description

---

Your switch stores and displays up to 15 characters of ICLID information received on analog trunks. If the information is longer than 15 characters, it truncates to 15 characters. If the caller ID information is not received, the trunk group name and trunk access code appear on the display.

Calling party information appears on all Avaya MultiVantage digital phones with 40-character or 32-character displays. In the US, the CO sends both calling party name and number, if they are available. In Japan, the CO sends only the calling party number.

## Interactions

---

- Distributed Communications System (DCS)

If the Avaya MultiVantage has both DCS and Integrated Services Digital Network (ISDN) displays, the ICLID information displays in DCS formats.

## Intercom

---

If you have users who call each other frequently, you can help them communicate more quickly. With the intercom feature, you can allow one user to call another user in a predefined group just by pressing a couple of buttons. You can even administer a button that always calls a predefined extension when pressed.

## Brief description

---

You control which phones can make intercom calls to each other by putting them in groups called “intercom groups.” Once a set of phones have been added to the group, you allow users to make intercom calls by administering one or both of the following feature buttons on their phones:

|                    |                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Automatic Intercom | This button always calls one predefined phone in the same intercom group when pressed. You specify the destination extension for this button.                                                                               |
| Dial Intercom      | This button allows users in an intercom group to call anyone else in the same group. The caller lifts the handset, presses the Dial Intercom button, then dials a 1- or 2- digit code for the extension they want to reach. |

Phones with one or both of these features can belong to the same group.

## Intercom groups

- You can create up to 32 intercom groups on one DEFINITY server.
- Each group can have up to 32 extensions in it.
- It's OK to assign the same extension to different groups.
- Intercom calls are only possible between extensions in the same group.
- Any group member with a feature button for dial intercom can make an intercom call to any other member in the group.

## Phones

- You can assign any type of phone to an intercom group. However, only multiappearance phones can make and receive intercom calls. Single-line phones can only receive intercom calls. Multiappearance phones must have at least one open or available call appearance to receive intercom calls.
- Phones receiving an intercom call make a unique alerting sound. If the phone has an intercom button with a status lamp, the lamp flashes.
- You can administer an automatic intercom connection between 2 phones even if their classes of restriction don't allow other calls between them.

## Interactions

---

- Bridged Appearances  
Bridged appearances can't receive intercom calls.
- Call Coverage  
Intercom calls do not follow a coverage path unless the caller activates Go To Cover.
- Call Forwarding  
Intercom calls cannot be forwarded off-net.
- Call Pickup/Directed Call Pickup  
Intercom calls are not included in the call pickup alerting count.
- Data Privacy and Data Restriction  
Extensions with either of these features active cannot originate intercom calls.

## Related topics

---

See [“Using phones as intercoms” on page 483](#) to administer intercom capabilities on phones.

## Internal Automatic Answer

---

Internal Automatic Answer (IAA) provides convenient hands-free answering of internal calls to users on multifunction stations with a speakerphone or a headphone.

### Detailed description

---

An eligible call can be answered automatically via IAA if the user activates IAA at the answering telephone and the user is able to accept an incoming call. A telephone is unable to accept an incoming call if it is off-hook, is in the process of dialing digits, or has a call on hold.

The following internal calls are eligible for IAA, depending on how you administer the Internal Auto-Answer of Attd-Extended/Transferred Calls field on the Feature-Related System Parameters screen:

- Station-to-station voice calls, with both telephones on the same switch (includes redirected intraswitch calls). Set the Internal Auto-Answer of Attd-Extended/Transferred Calls field to **transferred** or **both**.
- Internal call from another switch node in a Distributed Communications System (DCS) configuration when the origin of the call is known to be an internal, non-attendant telephone on that switch (includes redirected inter-DCS calls). Set the Internal Auto-Answer of Attd-Extended/Transferred Calls field to **transferred** or **both**.
- Attendant-extended external calls. Set the Internal Auto-Answer of Attd-Extended/Transferred Calls field to **attd-extended** or **both**.

The following calls are *not* eligible for IAA:

- Calls from public-network trunks (including PCOL)
- Calls from non-DCS tie trunks
- Automatic Callback calls
- Automatic Circuit Assurance calls
- Data calls
- Attendant-extended external calls if the Internal Auto-Answer for Attd Extended/Transferred Calls field is set to **transferred** or **none**
- Calls that the system redirects because of a queue overflow of Emergency Access to the Attendant calls
- Calls when the receiving station's Active Station Ringing field is set to **continuous**

## IAA Feature Operations

With IAA, you can assign a single programmable feature button (IAA) to telephones. When the user presses the IAA feature button, the button lamp lights and the system activates IAA. Pressing the same button again deactivates IAA and turns off the status lamp. (Pressing the feature button has no effect on a currently-active call or a ringing call.) The IAA button may be toggled on or off at any time, regardless of the state of the telephone. Using the speakerphone to place calls does not affect the state of IAA.

The calling telephone receives a tone when its call is answered automatically by a telephone with IAA. The called telephone receives a tone (a ring ping) and then goes off-hook when automatically answering an IAA-eligible call. The answering telephone's speaker and microphone are both turned on.

If a user has IAA active and is currently busy on a call or is in the process of dialing digits, subsequent incoming calls are treated as if IAA were not activated.

## Considerations

---

- Users should always deactivate IAA when leaving the work area. Otherwise, incoming calls are unintentionally answered by the unattended station, and do not go to coverage.
- A 602A terminal is off-hook when the headset or speakerphone is connected. Therefore IAA answers a call if all other call appearances are idle.

## Interactions

---

- Attendant Console  
IAA is not available with Attendant Console.
- Automatic Answer  
You cannot administer both IAA and Automatic Answer simultaneously on the same telephone.
- Automatic Call Distribution (ACD)  
Calls directed to an ACD split are eligible for IAA.
- Automatic Callback  
Callback calls via Automatic Callback are not answered automatically by IAA.
- Automatic Circuit Assurance (ACA)  
Calls generated by ACA are not eligible for IAA.

- Bridged Call Appearance — Multiappearance Telephone

Calls terminating on a bridged call appearance are not eligible for IAA at the bridged station, even if the bridged station has IAA active. (IAA can be used by the principal station to answer the call.)

- Bridged Call Appearance — Single-Line Telephone

Calls terminating to a bridged call appearance are not eligible for IAA at the bridged station, even if the bridged station has IAA active.

- Call Coverage

If an internal call is redirected to another telephone by Call Coverage redirection criteria, then that call is eligible for IAA at the redirected telephone.

IAA does not apply to calls to the original called extension when:

- The called telephone has activated Send All Calls
- The calling telephone has selected Go to Cover before placing the call

Calls directed to a coverage answering group are not eligible for IAA.

 **NOTE:**

If you set the coverage path for a station to All Calls and that station activates IAA, the first coverage point hears a ring, the principal station automatically answers, and the coverage-simulated bridge is dropped. The coverage station rings, but is not able to answer the call because the coverage-simulated bridge has been dropped.

- Call Forwarding

Calls to a station with IAA and Call Forwarding active are forwarded and are not answered by the station dialed.

 **NOTE:**

If the forwarded-to station is internal and has IAA active, it automatically answers the redirected call.

- Call Park

If you are using Deluxe Paging and Call Park times out, the call returns to the originating station that parked the call and is eligible for IAA.

- Call Pickup

Internal calls to a telephone in a Call Pickup group are eligible for IAA. If the called extension in a Call Pickup group has IAA-active, the call is automatically answered. A telephone with IAA active is not able to automatically answer calls to other telephones in its Call Pickup group.

- Conference

Internal conference calls can be answered automatically via IAA. If more than one party has joined a conference call through automatic answer, the parties remain connected until they disconnect or the controlling party drops the call.
- Data Call Setup

Data calls are not eligible for IAA.
- Direct Department Calling (DDC) and Uniform Call Distribution (UCD)

Internal calls to a DDC or UCD group member are eligible for IAA.
- Distributed Communications System (DCS)

If a call is from an internal telephone on another switch in a DCS configuration, then that call is considered internal and is eligible for automatic answer.
- Do Not Disturb

Do Not Disturb preempts IAA at the called telephone.
- Go to Cover

IAA does not apply to calls to the original called extension when the calling telephone has selected Go to Cover before placing a call.
- ISDN-BRI

IAA is not available with ISDN-BRI terminals.
- Loudspeaker Paging — Deluxe Paging

When you are using Deluxe Paging and Call Park times out, the call returns to the originating station that parked the call and is eligible for IAA.
- Ringback Queuing

Automatic calls generated by Ringback Queuing are not eligible for IAA.
- Send All Calls

IAA does not apply to calls to extensions with Send All Calls is active.
- Terminating Extension Group

Calls to a Terminating Extension Group extension are not eligible for IAA. However, calls placed to an individual extension are eligible.

## ISDN service

---

The Integrated Services Digital Network (ISDN) provides a message-oriented signaling method that allows information to be sent along with a call and gives you access to a variety of public and private network services and facilities. The ISDN standard consists of layers 1, 2, and 3 of the Open System Interconnect (OSI) model. Avaya MultiVantage can be connected to an Integrated Services Digital Network using standard frame formats: the Basic Rate Interface (BRI) and the Primary Rate Interface (PRI).

An Integrated Services Digital Network provides end-to-end digital connections and uses a high-speed interface that provides service-independent access to switched services. Through internationally accepted standard interfaces, an Integrated Services Digital Network provides circuit or packet-switched connections within a network and can link to other ISDN-supported interfaces to provide national and international digital connections.

### NOTE:

This manual does not contain procedures for working with ISDN trunk groups. Due to the complexity of ISDN technology and the potential consequences of errors, ask your Avaya representative to assist you in planning, installing, and administering ISDN trunks.

## Brief description

---

ISDN supports the following:

- Call-by-Call Service Selection (CBC)
- Distributed Communications System (DCS). (Only ISDN-PRI supports DCS+ and DCS with Rerouting)
- Electronic Tandem Networks (ETN)
- Facility Associated Signaling (FAS) and Non-Facility Associated Signaling (NFAS) (Only ISDN-PRI supports this.)
- Generalized Route Selection (GRS)
- Call Identification Display — Calling Party Number (CPN) and Billing Number (BN)
- Administered Connections and Access Endpoints
- Interworking (a mixture of ISDN and non-ISDN trunks and stations)
- Wideband Switching (H0, H11, H12, and NxDS0 — only ISDN-PRI supports this.)
- QSIG Multivendor Connectivity

- Lookahead Inteflow
- Lookahead Routing
- Usage Allocation

## Screens used to administer ISDN

See [Access Endpoint](#) to administer Access Endpoints and Wideband Access endpoints.

See [ISDN trunk group](#) for detailed information on the fields used to administer:

- Supplementary Service Protocol (supports public network connection)
- Calling Number (supports CPN)
- Incoming Call Handling Treatment Table (supports digit manipulation, CPN or BN requests, and night service destinations)
- CBC Trunk Group Usage Allocation screen (supports Call-by-Call Service Selection Usage Allocation Plans)
- CBC Trunk Group Allocation Plan Assignment Schedule (supports Call-by-Call Service Selection Usage Allocation Plans)
- Wideband Support Options (supports Wideband Switching)

See [“ISDN Numbering — Private”](#) to administer private numbering plans.

See [“ISDN Numbering — Public/ Unknown”](#) to administer ISDN call identification displays.

See the DEFINTY services documentation for information about the following screens: ISDN TSC Gateway Channel Assignments, Network Facilities (supports usage allocation used in Call-by-Call Service Selection), and Signaling Group (used to define a group of B-channels for which a given D-channel or D-channel pair carries signaling information).

## Transmission rate and protocols

In ISDN-PRI, the transmission standard for layer 1 (the physical layer) is either DS1 T1 or E1. The DS1 T1 (used in North America and Japan) is a digital-transmission standard that carries traffic at the rate of 1.544 Mbps, and the E1 (used in Europe) carries traffic at a rate of 2.048 Mbps. The “D” (data) channel multiplexes signaling messages for the “B” (bearer) channels carrying voice or data. In a T1, when a D-channel is present, it occupies Channel 24. In an E1, when a D-channel is present, it occupies channel 16.

Avaya MultiVantage offers several administrable protocols, each of which provides a different set of ISDN services. See [“DS1 trunk service” on page 1659](#) for more information. These protocols are discussed in detail later in this section. The following combination of services, including but not limited to Basic Call, Basic Supplementary Services, Supplementary Services with Rerouting, Display, and QSIG Networking are supported on the ISDN-PRI interface. Available services outside the United States vary from country to country.

With ISDN, Avaya MultiVantage interfaces with a wide range of other products including switches, network switches, and host computers. These products include earlier MultiVantage systems, public network switches (for example, 4ESS, 5ESS, and Northern Telecom DMS250), and other products that adhere to the ISDN signaling protocol.

As an example of how ISDN is used in private- and public-network configurations, see the following figures. For example, ISDN can be used to connect a switch to a public-switched network, to other switches, and to computers:

r773199 PDH 061096

**Figure Notes**

- 1. Avaya Media Server
- 2. ISDN trunk
- 3. Public switched network
- 4. Host computer

**Figure 59. ISDN network configuration**

## AT&T Switched Network Protocol

Avaya MultiVantage supports the AT&T Switched Network Protocol described in the TR41449 (for 4ESS to common carrier) and TR41459 (for 5ESS to CO) ISDN protocol standards as defined by AT&T. This protocol is used when the DS1 circuit pack is administered for Country Code 1, Protocol Version a. The AT&T Switched Network provides you with the following services.

### Access to AT&T Switched Network Services

ISDN provides access to AT&T Switched Network Services. The definition of the Service Type field on the ISDN Trunk Group screen includes a table that outlines these switched-network services. An ISDN trunk group may be dedicated to a particular feature. Alternately, an ISDN call-by-call trunk group may provide access to several features. For a description of the services accessible via ISDN (either via dedicated or call-by-call trunk groups), see [“Call-by-call service selection” on page 1629](#).

### Call Identification Display

ISDN Call Identification Display provides a transparent name and number display for all display-equipped telephones within an ISDN network. The feature is transparent in that the same information can be provided at all ISDN facilities. Telephones using this feature should be digital telephones with a 40-character alphanumeric display. The Merlin hybrid sets with 32-character displays (7315H and 7317H) also support this feature.

ISDN Call Identification Display is provided in addition to the normal Telephone Display and Attendant Display features when the network supports end-to-end ISDN connectivity. When both ISDN and DCS display information are received, the switch can display either the DCS or ISDN call identification information. If only ISDN display information is received, information displays in ISDN format.

The display fields that may be used for ISDN are: Name, Number, Miscellaneous Call Identification, and Reason for Call Redirection. The display information varies, depending on the type of call, how the call is handled (for example, whether it is redirected or not), and the information is available on the call.

### CPN/BN to Host Call Identification

The CPN/BN to Host Call Identification enables CPN and BN information to be passed from the switch to the ISDN Gateway, so that the ISDN Gateway can forward the information to a host for data-screen delivery to agents in an ACD split.

By delivering call-identification information such as CPN/BN and switch information such as the answering-agent's extension to an adjunct network (ISDN Gateway), the adjunct automatically delivers data screens to agents for new calls and call transfers.

The figure below shows a simplified diagram of a CPN- and BN-to-host arrangement. The ISDN Gateway is a UNIX or MSDOS computer connected to the switch on one side and to a host computer on the other side. The connection to the switch is over a synchronous interface with BX.25 protocol.

**Figure Notes**

**Figure 60. CPN- and BN-to-host configuration**

**Private network services**

In addition to providing access to switched-public networks, ISDN provides private-network services by connecting Avaya MultiVantage in an ETN, DCS, or QSIG Network. This gives you more efficient private networks that support new integrated voice and data services. ETN, DCS, and QSIG networking services are provided as follows.

**ETN services**

Avaya Media Servers that function as tandem nodes in an ETN can be interconnected using DS1 trunking facilities with ISDN. All signaling between the tandem switches is done with ISDN D-channel and normal ISDN protocol.

The ISDN can also be used to connect ETN tandem and main switches. In this case, the main switch collects all of the address digits from local users as well as users at other satellite and tributary switches, and originates a call over ISDN to the tandem switch.

Automatic Alternate Routing (AAR) and Automatic Route Selection (ARS) are used with ISDN and DS1 trunking facilities to access ETN facilities. AAR and ARS are used to collect the dialing information for the call that is originated from the main switch.

### **DCS services**

ISDN-PRI facilities can be used in a DCS arrangement whenever tie trunks are used to connect the DCS nodes. Most DCS features are not affected by ISDN-PRI. However, there is a minor impact on a few of the DCS features, as far as the functions that the local and remote switches perform.

### **QSIG services**

QSIG networking provides compliance to the International Organization for Standardization (ISO) ISDN private-networking specifications. The QSIG Networking platform is supported over the ISDN Basic Call setup protocol. Avaya MultiVantage supports QSIG Supplementary Services.

### **Wideband Switching (ISDN-PRI only)**

Wideband Switching provides support for services that require large bandwidth, such as high-speed video conferencing. Wideband also supports multiple channel calls end-to-end. These services have traditionally been handled by dedicated facilities. With Wideband Switching, dedicated facilities are no longer a requirement for these large bandwidth services.

### **Call-by-Call Service Selection**

Call-by-Call Service Selection allows the same ISDN trunk group to carry calls to a variety of services or facilities. Embodied in this feature is the ability to allocate usage. It provides significant flexibility for creating user-defined incoming and outgoing services and is used on any ISDN trunk group.

### **Access to Software Defined Data Network**

With ISDN, the SDDN service may be accessed. SDDN provides virtual private-line connectivity via the switched public network. The services provided by SDDN include voice, data, and video applications. SDDN services complement the ISDN voice services.

## **Access to Switched Digital International**

Switched Digital International (SDI) provides 64 kbps of unrestricted connectivity to international locations via the AT&T Switched Network. It is also the backbone for the AT&T International ISDN network. SDI complements the ACCUNET digital service already available to United States locations. This service can be accessed using Call-by-Call Service Selection. SDI provides economical high-speed data transfer to international locations.

## **National ISDN-2 Services**

Avaya MultiVantage supports National ISDN-2 (NI-2), which offers many of the same services as the AT&T Switched Network protocol. The NI-2 protocol is used when the DS1 circuit pack is administered for Country Code 1, Protocol Version b.

NI-2 provides users with the following services:

- Calling Line Identification
- Non-Facility Associated Signaling (ISDN-PRI only)
- D-Channel Backup (ISDN-PRI only)
- Wideband Switching (ISDN-PRI only)
- Call-by-Call Service Selection

### **Calling Line Identification**

Calling Line Identification for NI-2 is essentially CPN identification, as previously described.

### **Non-Facility Associated Signaling (ISDN-PRI only)**

NFAS allows an ISDN-PRI T1 or E1 Interface D-channel (signaling channel) to convey signaling information for B-channels (voice and data) on ISDN-PRI T1 or E1 facilities other than the one containing the D-channel. See [“Facility and Non-Facility Associated Signaling” on page 1678](#) for more information.

### **D-Channel Backup (ISDN-PRI only)**

D-Channel Backup is provided to improve reliability in the event of a signaling-link failure. See [“Facility and Non-Facility Associated Signaling” on page 1678](#) for more information.

### **Wideband Switching (ISDN-PRI only)**

Wideband Switching for NI-2 is essentially the same as that of the AT&T Switched Network ISDN-PRI protocol.

## Call-by-Call Service Selection

Call-by-Call Service Selection for NI-2 is essentially the same as that for the AT&T Switched Network ISDN-PRI protocol.

## ISDN interworking

ISDN interworking allows calls to use a combination of both ISDN and non-ISDN trunking and station facilities. A non-ISDN trunking facility is any trunk facility supported by the system that does not use the ITU-T recommended Q.931 message set for signaling. Non-ISDN trunking facilities include facilities such as analog trunks, AVD DS1 trunks, and DS1 trunks with bit-oriented signaling (robbed-bit or common channel).

Avaya MultiVantage supports the conversion of ISDN signaling to non-ISDN in-band signaling and the conversion of non-ISDN in-band signaling to ISDN signaling for interworking purposes.

A mixture of ISDN and non-ISDN signaling is required in order to provide end-to-end signaling when using different types of trunk or station facilities on a call. See the figure below for an example of interworking.

### Figure Notes

- |                                  |                   |
|----------------------------------|-------------------|
| 1. Call from network to Switch B | 4. Non-ISDN trunk |
| 2. ISDN trunk                    | 5. Switch B       |
| 3. Switch A                      |                   |

### Figure 61. ISDN and non-ISDN interworking

In this example, a call for someone at Switch B comes into Switch A. Interworking allows the ISDN signaling of the call to be converted at Switch A to non-ISDN in-band signaling before the call forwards to Switch B. Even though the call comes into Switch A on an ISDN trunk, Switch A can send the call to Switch B over a non-ISDN trunk by converting the signaling information.

The system provides accurate CDR billing information on calls that are not interworked. Accuracy of CDR billing information on interworked calls is equivalent to the accuracy provided by the public network.

Avaya MultiVantage supports sending a non-ISDN trunk name as the connected name. Therefore, a non-ISDN trunk name can be sent as the connected name even when a call starts out as an ISDN call but is interworked over non-ISDN trunks.

## Call Identification Display

Two types of identification numbers are provided with ISDN and may be used in the various types of displays used with ISDN. The two types of identification numbers are as follows:

- **Calling Party Number (CPN):** A 0–15 digit DDD number associated with a specific station. When a system user makes a call that uses ISDN, that user's CPN is provided by the system for ISDN. ISDN public-unknown numbering or ISDN private numbering screens are administered to create a 0–15 digit CPN from a local station number.
- **Billing Number (BN):** The calling party's billing number, which is provided to an inter-exchange network via Equal Access or CAMA. This number is stored at either a local or network switch. If a customer is connected directly to the AT&T Switched Network, the BN is the customer's billing number stored in that network. If the CPN is not provided on an incoming ISDN call, the network uses the BN for the station identification number.

The following types of display information are provided with ISDN:

- **Calling Party's Number**

The calling party's number appears on the called party's display. This number is provided only if the outgoing ISDN trunk group is administered to send the CPN, and if ISDN public-unknown numbering or ISDN private numbering screens are administered to create a CPN. On calls incoming to a system, the network may provide either the CPN or BN as the calling party's number. Extensions and 12-digit international numbers display without dashes. Dashes are only used for 7-digit and 10-digit numbers when North American Area Code is enabled on the Dial Plan screen.

- Calling Party's Name

The calling party's name appears on the called party's display. On calls generated from a DEFINITY server, the caller's name is provided if the ISDN trunk group is administered to send the name to the network. On calls incoming to a DEFINITY server, the (public or private) network may provide the caller's name. If the caller's name is not available, the called party's display shows "CALL FROM" instead, followed by the calling party's number (if available).

- Connected Party's Number

The connected party's number appears on the caller's display. On calls generated from a DEFINITY server, callers' displays may show the digits dialed as the call is made. If the (public or private) ISDN network provides the connected party's number, the calling party's display is updated to show the connected party's number. The format of the connected party's number is the same as that of the calling party's number described previously on calls incoming to a DEFINITY server. The 0–15 digit number of the party who answers the call is provided to the ISDN network only if the incoming ISDN trunk group is administered to send connected number to the network and ISDN public-unknown numbering or ISDN private numbering screens are administered to create a CPN.

**NOTE:**

The connected party may be the party actually called, in the event the call is transferred before the connected party answers the call.

- Connected Party's Name

The connected party's name appears on the calling party's display. On calls generated from a DEFINITY server, the (public or private) ISDN network may provide the connected party's name to the Avaya MultiVantage, when the call is answered. If the connected party's name is not available, the calling party's display shows *ANSWERED BY*, followed by the connected party's number (if available).

On calls incoming to a DEFINITY server, the connected party's name is provided if the incoming ISDN trunk group is administered to send the name to the network.

Depending on how the switches involved in a call are configured, parties may see none, some, or all the information described above.

## Displays for redirected calls

Features such as Call Coverage, Call Forwarding All Calls, Bridged Call Appearance, or Call Pickup redirect calls from the called party's extension to some other destination. Once the redirected call has been connected at its new destination, the displays for the calling, called, and connected parties are as follows:

- Calling Party Display

a= CONNECTED NAME CONNECTED NUM MISCID

- Called Party Display

This is the display of the party the caller originally dialed. If this party bridges onto the redirected call after it has been answered, they see:

a= CONFERENCE 2

In this situation, the connected party's display (see below) shows the same information. The calling party's display is also updated if the calling and called parties are on the same switch.

- Connected Party Display

The connected party is the party who answers the redirected call.

a= CALLING ID to CALLED ID R

The R indicates the reason for redirection. The CALLING ID and the CALLED ID may be the name or the number, depending on the information received from the far end.

## Displays for conference calls

Both terminal and attendant conference calls are identified as calls with "n" number of conferees. This display information generates locally and does not change the display on another switch. If the conference call eventually drops back to a two-party call, the original display information is restored. However, when two DCS and/or ISDN calls (or any possible combination of each) are conferenced and revert to a two-party call, the trunk group of the remaining call displays.

## Displays for calls to hunt groups

On ISDN calls to a hunt group extension, the caller's display identifies either the name of the hunt group or the name of the group member who answers the call, depending on hunt group administration.

## Displays for calls to Terminating Extension Groups (TEG)

On ISDN calls to a TEG, the caller's display identifies either the group or the group member who answers the call, depending on administration.

## **Caller Information Forwarding**

With CINFO you can use a vector *collect digits* step to retrieve caller entered digits (ced) and customer database-provided digits (cdpd) supplied by the network in an incoming call's ISDN SET UP message. ISDN is required if the CINFO comes from the network.

## **Facility Restriction Level (FRL) and Traveling Class Mark (TCM)**

The TCM used to pass on the originating facility's FRL is sent by ISDN facilities in the SETUP message only if the trunk services type is tandem.

## **Information Indicator Digits (II-digits)**

With II-digits you can make vector-routing decisions based on the type of the originating line. II-digits are provided for an incoming call by ISDN-PRI. It is a generally available ISDN AT&T Network service.

## **Malicious Call Trace (MCT)**

ISDN calling number identification is sent when MCT notification is activated on an ISDN trunk.

## **Multiple Subscriber Number (MSN) - Limited**

The ISDN standard MSN feature lets you assign multiple extensions to a single BRI endpoint. A side effect of supporting the NT interface is the MSN feature works with BRI endpoints allowing the Channel ID IE to be encoded as "preferred." The endpoint must be administered as the far end of an NT-side ISDN-BRI trunk group. Also, you must use the Uniform Dial Plan (UDP) feature to assign the desired extensions to the "node" at the far end of the trunk group.

## **Overlap Sending**

You can administer overlap sending on AAR and ARS calls routed over ISDN trunk groups. This allows you to send and receive digits one digit at a time instead of enbloc. (With enbloc, digits are not sent until the entire group of digits is received).

## **Interworking between TGU/TGE trunks and ISDN (Italy)**

---

This feature modifies ISDN messaging operations in systems that use TGE/TGU trunks to network satellite switches. Messaging from the Avaya MultiVantage provides appropriate ringback or busy tone to the calling party.

## Interactions

---

- **Australia Malicious Call Trace**

Avaya MultiVantage with a BRI connection to the Australian public network is able to notify the network if a user in a private network invokes the Malicious Call Trace feature. This works on Australian national connections.
- **Direct Inward Dialing**

Some public network operators may not offer full DID service on BRI trunks, but instead may offer the BRI equivalent, which typically is called MSN. This is the case if the public network treats the BRI as an endpoint interface rather than a trunk group interface.

In such a case, the network only routes up to 10 public numbers to a particular pair of BRI trunks. Furthermore, the network may not let calls overflow from one BRI trunk to another.
- **D-Channel Backup**

D-Channel Backup is not supported on BRI connections.
- **Distributed Communications System**

If both DCS and ISDN features are provided over the same facility with a DEFINITY server, DCS displays generally override ISDN displays. However, with Avaya MultiVantage, the ISDN connected name and number can override the DCS called name and number if the Display Connected Name/Number for ISDN DCS Calls field is y on the Feature-Related System Parameters screen.

BRI trunks support DCS if using a BX.25 link to transport the DCS messages. DCS+, also known as DCS Over ISDN D-Channel, according to the AT&T protocol, is not supported on BRI trunks.
- **Facility Test Calls**

Neither BRI or PRI trunks support Facility Test Calls.
- **France VN4 Protocol**

The France national VN4 protocol is supported on BRI trunks as ETSI.
- **Generalized Route Selection**

BRI trunks are capable of carrying 56Kbps or 64Kbps data calls. The link coding that restricts certain PRI trunks to 56Kbps only does not apply to BRI trunks.
- **German ITR6 Protocol**

The German national ITR6 protocol is not supported over BRI trunks.

- Message Sequence Tracer

ISDN-BRI trunks support Message Sequence Tracer. However, certain filtering capabilities available for PRI trunks are not available. Specifically, it is not possible to filter BRI trunk messages based on incoming/outgoing calling/called number.

- Network Access - Public (LEC/AT&T/Other Carriers)

Public-network access using BRI trunks is available but only in those countries that support point-to-point BRI connections. In the U.S., BRI access is offered only by the Local Exchange Carriers and not by Interexchange Carriers such as AT&T.

- Network Access - Private Premises Based

Full support for private-network connections using BRI trunks is available.

- Non-Facility Associated Signaling

Non-Facility Associated Signaling is not supported on BRI connections.

- Temporary Signaling Connections

Avaya MultiVantage does not support Temporary Signaling Connections according to the AT&T protocol on BRI trunk interfaces. Only the QSIG NCA TSC protocol is supported on these interfaces

- Wideband Switching (NxDS0)

Avaya MultiVantage does not support wideband switching on BRI connections.

## **Leave Word Calling**

---

Leave Word Calling (LWC) allows internal system users to leave a short preprogrammed message for other internal users. When the message is stored, the Automatic Message Waiting lamp on the called telephone lights. Users can retrieve LWC messages using a telephone display, Voice Messaging Retrieval, or AUDIX. Messages may be retrieved in English, French, Italian, Spanish, or a user-defined language.

Avaya MultiVantage also provides voice synthesis (either English or Italian) for LWC, depending on which voice-synthesis circuit pack is installed in the system.

The system can indicate that one telephone received a LWC message on a second telephone. The system lights a remote Automatic Message Waiting lamp at the remote telephone and the Automatic Message Waiting lamp lights at the called telephone. The Remote Automatic Message Waiting lamp is a status lamp associated with a button assigned for this purpose. Thus, an assistant's telephone could light when an executive receives a LWC message. If the executive calls to retrieve messages, the assistant knows at a glance if any messages have been left.

Users without telephone Display can have their messages retrieved by a system-wide message retriever or by covering users in their Call Coverage path. They can also use Voice Message Retrieval.

The system restricts unauthorized users from displaying, canceling, or deleting messages. The Lock function restricts a telephone and the Unlock function releases the restriction. Users activate Lock by dialing a system-wide access code. They cancel Lock by first dialing a system-wide access code and then an Unlock security code unique to the telephone. These functions apply only to the telephone where the function is active. You can assign a status lamp to show the lock status of the telephone.

Leave Word Calling Log External Calls allows the switch to monitor when an external call is not answered. The switch keeps a record of up to 15 calls, provided information on the caller identification is available, and the phone's message lamp lights. The phone set displays the names and numbers of unsuccessful callers.

### Considerations

---

- You can administer up to 10 telephones (or nine telephones and the attendant console group) as system-wide message retrievers.
- If the stored-message level reaches 95 percent of capacity, the status lamps associated with all Coverage Message Retrieval buttons in the system flash. These lamps continue to flash until the stored-message level falls below 85 percent. Authorized retrievers can selectively delete messages to gain storage space. Old messages are not purged automatically by the system.
- LWC messages cannot be stored, canceled, or retrieved for Vector Directory Number extensions.

### Interactions

---

- **AUDIX Interface**  
LWC Cancel cannot be used to cancel an AUDIX message.
- **Bridged Call Appearance**  
A LWC message left by a user on a bridged call appearance leaves a message for the called party to call the primary extension for the bridged call appearance. When a user calls a primary extension and activates LWC, the message is left for the primary extension, even if the call was answered at a bridged call appearance.
- **Call Coverage**  
You can use LWC with or without Call Coverage. However, the two features complement each other. The Coverage Callback option of Call Coverage is provided by LWC. Also, a caller can activate LWC for the called party even if the call has been answered by a covering user.
- **Centralized Attendant Service (CAS)**  
LWC Message Retrieval does not work with CAS.

- Conference

A member of a conference call cannot activate LWC because the user cannot be uniquely identified. After LWC has been activated for a party on a conference or transfer, the conference or transfer originator cannot press Conference/Transfer a second time to return to the original call. The originator must select the call appearance button to return to the previously-held call.

- Expert Agent Selection (EAS)

When an EAS agent is logged into a telephone, the agent can only retrieve LWC messages left for that agent's login ID. To retrieve LWC messages left for that telephone, the agent must log out.

When an EAS agent is logged into a telephone, its Message lamp defaults to tracking the status of LWC messages waiting for the telephone. However, you can assign the Message lamp to track the status of LWC messages waiting for the agent's login ID.

- Vector Directory Number (VDN)

LWC messages cannot be stored, cancelled, or retrieved through VDN.

## Line Lockout

---

Line Lockout removes single-line extensions from service when users do not hang up after receiving dial tone or intercept tone for an administered length of time.

You can administer the system to play a special “howler” tone before locking an analog extension by setting the Station Tone Forward Disconnect field to **busy** on the “[Feature-Related System Parameters](#)” screen. For the howler tone to play, an Avaya representative must also enable the Howler After Busy field on the “[System Parameters Country-Options](#)” screen.

If you want the system to disconnect and optionally lock out users who have let an outgoing public network trunk call ring for an extended period of time, you can have Avaya enable the Disconnect on No Answer by Call Type field, also on the “[System Parameters Country-Options](#)” screen.

Line Lockout occurs when:

- A user does not hang up after the other party on a call is disconnected.  
The user receives the dial tone for 10 seconds and then receives the intercept tone for the length of time administered in Line Intercept Tone Timer on the Feature-Related System Parameters screen. If the handset remains off-hook, the telephone is taken out of service.
- A user pauses for 10 seconds between digits while dialing.  
The user receives intercept tone for 30 seconds. If the handset remains off-hook, the telephone is taken out of service.

The out-of-service condition remains in effect until the user hangs up.

### **Considerations**

---

- The out-of-service condition provided by Line Lockout does not tie up switching facilities.
- Line Lockout does not apply to multiappearance telephones.

### **Related topics**

---

See [“Feature-Related System Parameters” on page 795](#), Time Before Off-hook Alert for more information.

## **Listed Directory Numbers**

---

Listed Directory Numbers (LDN) has two capabilities that allow outside callers to access your attendant group, depending on the type of trunk used for the incoming call. You use one capability to allow attendant group access via incoming DID trunks. You use another capability to allow attendant group access via incoming CO and FX trunks.

### **Brief description**

---

The system routes both incoming DID calls and incoming FX and CO calls to an attendant group, depending on how you administer the trunks.

## How the system routes incoming DID trunk calls to the attendant group

Incoming DID calls route only to an extension. The LDN feature allows you to assign one or more extensions to an attendant group. The system uses the LDN extension, or extensions, to route calls to an attendant group.

## How the system routes incoming FX and CO trunk calls to the attendant group

Incoming FX and CO trunks can terminate at an attendant group, although you administer your system to terminate the calls elsewhere. You can administer the system to terminate an incoming FX or CO trunk to one of the following:

- Attendant group
- Extension (This could be a VDN, an ACD split, a DDC group, a UCD group, a remote access extension, or any system extension.)

If you decide to terminate the call at the attendant group, *the system treats the call as an LDN call.*

## Considerations

The number of listed directory numbers that you can assign depends on your system's configuration.

## Interactions

---

- Night Service

If you activate night-service capability and a night console is not assigned or is not operational, incoming LDN calls route as follows:

- DID LDN calls route to a designated DID LDN night extension. If no DID LDN night extension is designated, DID LDN calls route to the attendant.
- Incoming CO or FX trunk calls route to the night destination specified for the trunk group. If no night destination is specified for the trunk group, the calls route to the normal incoming destination for that trunk group.
- Internal calls and coverage calls to the attendant route to the DID LDN night extension during night service.

## **Location by region**

---

Location by Region provides a way to administer location by IP network region. This allows for the correct date and time information and trunk routing based on the IP network region.

### **Detailed description**

---

Location by Region allows you the ability to have an IP phone registered with a DEFINITY server, but located at a site with a S8300 Media Server with a G700 or Remote Office endpoints, to display the correct time and date worldwide. The IP phone can be administered in a different network region from other Avaya MultiVantage endpoints, and in the same “location” as the S8300 Media Server or Remote Office users. It allows IP endpoint users the ability to move from location to location and always have correct display information. Remote users are identified in a network region and location that routes them to correct 911 services or notifies them via announcements, that they are in a different 911 jurisdiction than the DEFINITY they are registered to.

### **Alerts/Interactions**

---

#### **911 Call Handling**

Location by Region attempts to overcome a limitation in the emergency response system - USA Public Safety Answering Points (PSAPs) currently have no good way to contact each other. Even if you are able to speak, and you explain to a PSAP in one part of the country that you need help in another part of the country, the 911 staff that you are talking to have no fast way to relay your comments to a PSAP near where you are located. If you describe your location as out-of-state, you likely will be told to hang up and find a local phone.

Earlier 911 call handling features were unable to handle IP telephones because there was no way to pop up a window on an IP telephone to let the IP telephone user know why their 911 call was blocked and advise them on the right thing to do. Now, you can choose to dedicate one location to handle such roaming IP telephones. That special location could have corresponding ARS routing tables that route all 911 calls to a repeating announcement saying something like “You are too far away from the switch for the [name of the home location]’s public safety office to be able to help you. Please call 911 from a local circuit switched phone.”

## Look-ahead routing

---

Look-Ahead Routing (LAR) allows the switch to reroute an outgoing ISDN call that is not completing. The switch attempts to complete the call along a different routing preference, or it tries the current routing preference a second time. If the current preference fails twice, the next routing preference is tried.

LAR can be administered at an origination switch or a tandem switch. It can be turned off at different points in the network to reduce network load. You use LAR with AAR and ARS, GRS, and UDP) You can also use it with a FAC ISDN Access Code. A LAR field is administered on the Route Pattern screen.

### NOTE:

When LAR is used in a mixed network of Avaya MultiVantage Systems and DEFINITY ECS switches, LAR ends at the DEFINITY ECS switch and calls are rejected the normal way. However, if a LAR-triggering cause value is passed back in the network to a DEFINITY server that is enabled for LAR, LAR is attempted from that switch again.

## Detailed description

---

LAR can be administered for each ISDN route preference in each Pattern Number. The maximum number of LAR attempts per call per switch is 2 times the number of route preferences in the route pattern. LAR can be administered at each intermediate node that the call may be tandemed through to allow the attempt of all possible routes.

You can control LAR by:

- administering it on a per route-preference basis
- partitioning trunks
- limiting the number of hop counts

## LAR activation

LAR is active when a call is rejected with a cause value in the range of #34–#47 and #3 (no route to destination). The range of #34–#47 indicates congestion and that resources are unavailable. The following cause values activate LAR:

| <b>Cause Value</b> | <b>Cause Description</b>                   |
|--------------------|--------------------------------------------|
| 3                  | no route to destination                    |
| 34                 | no circuit/channel available               |
| 38                 | network out of order                       |
| 41                 | temporary failure                          |
| 42                 | switching equipment congestion             |
| 43                 | access information discarded               |
| 44                 | requested circuit or channel not available |
| 47                 | resources unavailable                      |

### NOTE:

When country code 13, protocol version a, is administered on the DS1 Circuit Pack screen, only the cause values #10 and #89 activate LAR.

LAR terminates when:

- call is successfully routed
- call is rejected with a non-LAR-triggering cause value
- no further route preference can be used to route the call

## LAR measurement

You can measure the number of attempted and successful LAR reroutes. The Measurements LAR Route Pattern screen displays LAR measurements for a particular route pattern. See *Avaya MultiVantage™ System Monitoring and Reporting* for more information.

## Interactions

---

- Automatic Circuit Assurance

LAR rerouting attempts are recorded as short holding time calls.

- Distributed Communications Systems (DCS)

If a non-DCS trunk preference is selected for rerouting a DCS call, DCS feature transparency is lost. If LAR for a DCS call is done within the same DCS trunk group, feature transparency is not lost.

- QSIG Networks

If a non-Supplementary Services B (SSB) trunk preference is selected for rerouting a SSB call, QSIG feature transparency is lost. If LAR for a QSIG call is done through either the same or another SS B trunk group, feature transparency is not lost.

- Ringback Queuing

When a call originates and queues at the trunk group queue, the call can be placed in queue multiple times if LAR is active. The call originator can be called back each time the call is continued automatically.

- Satellite Hop Limit

Satellite Hop Limit always takes precedence over LAR. When the maximum hop limit is reached for a route preference, the last call routing attempt is denied and the call is rejected with a cause value of #28 — invalid number format. This value does not activate LAR.

- System Measurements

System resource use during LAR attempts are included in existing system measurements and performance reports. For more information about LAR system measurements, see *Reports for Avaya MultiVantage™ Software*.

---

See [Route Pattern](#) for information on the Route Pattern screen.

## Loss plans

---

Loss plans determine the amount of loss (quieter) or gain (louder) applied on calls. Usually, your system uses a pre-defined loss plan that is based on the administered country code. In some circumstances, you may be able to change the loss plan used by your system on a per trunk or per phone basis.

### CAUTION:

*The values in the loss plan can significantly affect the quality of service that your users experience. Therefore, in order to change the loss plan you must thoroughly understand loss plans and your particular configuration. Avaya recommends that you seek technical assistance from Avaya before making any modifications to the loss plan.*

In order to be able to modify your loss plan, the Digital Loss Plan Modification field must be set to **y** on the [System-Parameters Customer-Options](#) screen, and the Customize field must also be **y** on the [System Parameters Country-Options](#) screen. An Avaya representative must enable these fields for you.

The 2 Party Loss Plan page of the [System Parameters Country-Options](#) screen allows you to set the gain or loss levels (in dB) between two parties on a call. Each row on this screen is considered a different loss group. You can assign a loss group to a particular phone or trunk by administering a value for the Loss Group fields on the [Station](#) and [Trunk Group](#) screens. This allows you to use different loss plans for different types of phones or different trunk groups.

The Tone and Conference Loss Plans page of the [System Parameters Country-Options](#) screen allows you to set the gain or loss levels (in dB) between all parties on a conference call, as well as the total gain or loss in a conference based on the number of parties.

IP endpoints connected via hairpinning or direct IP-IP are not under the control of the administrable loss plan.

## Loudspeaker paging

---

You can connect Avaya MultiVantage to loudspeaker systems and allow users to page from their phones. You can administer up to 9 separate zones (sets of loudspeakers) on Avaya MultiVantage, so an announcement can be made to one group or location without disturbing people who don't need to hear the announcement. Auxiliary trunks connect the speakers in each zone to ports on an auxiliary trunk circuit pack.

## Brief description

Avaya MultiVantage offers 2 types of loudspeaker paging. You can use each separately, and you can also use both together.

|              |                                                                                                                                                                                                                                                                                              |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Voice paging | Voice paging allows users to make announcements over a loudspeaker system from their phones. You can integrate voice paging and Call Park by enabling deluxe paging.                                                                                                                         |
| Chime paging | If frequent voice pages are undesirable, you can assign a unique series of chimes (a <i>chime code</i> ) to each extension. The chime code assigned to that extension plays over the speakers whenever that extension is paged.<br><br>Chime paging is sometimes called Code Calling Access. |

## How users place voice pages

With standard voice paging, users page by dialing the trunk access code assigned to the zone they wish to page. If users have an active call, they must manually put the call on hold or park it before they dial the trunk access code.

When deluxe paging is enabled, users can automatically park an active call when they page, as described below.

### Users with multi-appearance phones

The following description only applies to systems with deluxe paging. To page and park an active call simultaneously, users with a multi-appearance phone press Transfer, dial the trunk access code + an extension number where the call will be parked, make the announcement, and press Transfer again. The paged party dials the answer back feature access code + the extension number and is connected directly to the parked call. If the paging user ends the page by pressing Conference instead of Transfer, they are conferenced with the parked caller and both are connected in a 3-way conference with the paged user when he or she responds. This is called “Meet-Me Conferencing.”

If the paging user doesn't want to park the active call, deluxe paging also allows “Meet-Me Paging.” Paging users can put an active call on hold and make their page, announcing their own extension. When the paged party calls, the paging user can conference the call on hold or transfer it to the paged party.

### **Users with single-line phones**

This description only applies to systems with deluxe paging. To page and park an active call simultaneously, users with a single-line phone press Recall or flash the switch hook, dial the trunk access code + an extension where the call will be parked, and press Recall again. The paging user is conferenced with the parked caller and both are connected in a 3-way conference with the paged user when he or she responds. In other words, Meet-Me conferencing is standard operation for users with single-line phones. The paged party dials the answer back feature access code + the extension number and is connected directly to the parked call.

If the paging user does not press Recall until the loudspeaker paging time-out interval expires, they hear confirmation tone and the active call is automatically parked on their extension. When the paged party answers the call, they are connected to the paging party who can then transfer the call to the calling party.

### **How users place chime pages**

Users page by dialing the trunk access code for a zone followed by the extension of the person they want to page. The system matches the extension dialed to its assigned code and plays the code over the loudspeakers. If users have an active call when they start to page, the call is automatically parked on the extension dialed in the page. Paged parties may retrieve the parked call normally.

### **Auxiliary paging systems**

Avaya MultiVantage requires a separate port for each paging zone and supports a maximum of 9 zones. If you have more than 9 zones or don't want to allot that many ports for paging, Avaya can provide auxiliary paging systems. These systems can support many zones from 1 port. They can also provide additional capabilities such as two-way communication through the loudspeaker system (the person paged can speak directly to the pager over the loudspeaker).

For more information, contact your Avaya representative.

## Restrictions on loudspeaker paging

These restrictions apply to both voice, deluxe voice, and chime paging:

- A paging call can't be placed on hold, included in a conference call, or transferred. Ringback queuing doesn't work with loudspeaker paging calls either.
- Users with any of the following restrictions cannot page:
  - Controlled restriction
  - Manual originating line service
  - Origination restriction
  - Miscellaneous trunk restriction
- A user with a single-line phone will not hear a call-waiting tone if they get a call while they're paging.
- Listed directory number and direct inward dialing calls cannot access the paging system. However, attendants can park incoming calls and page.
- Remote users (such as remote access users and tie-trunk users) who are paging cannot use # to park calls on their own extensions.

## Interactions

---

- Bridged Call Appearance

If a parked call includes a shared terminating extension group, a shared PCOL, or a redirected call with a temporary bridged appearance, the maximum number of off-hook parties on the call is five, instead of six. The sixth position is reserved for the answer-back call.
- Call Coverage

If a coverage call is parked by deluxe paging, the temporary bridged appearance at the principal extension is maintained as long as the covering user remains off-hook or places the call on hold.
- Call Park

If a call is parked by deluxe paging and the time-out interval expires, the call normally returns to the paging user. However, with remote access and tie trunk access, the call returns to the attendant. If unanswered, the call follows the coverage path of the paging user.
- Call Pickup

If you use call pickup or directed call pickup to answer a call and then park it by deluxe paging, a temporary bridged appearance at the principal extension is maintained if you remain off-hook or place the call on hold.

- **Conference — Attendant and Terminal**

Paging calls cannot be conferenced.
- **Data Call Setup**

If the Data button has been pressed for modem pooling, access to paging is denied.
- **Data Privacy**

If a call has Data Privacy activated and you park it by deluxe paging, Data Privacy for that call is automatically deactivated.
- **Hunt Groups**

If a hunt-group member parks a call using deluxe paging, the call is parked on the member's own extension, not the hunt-group extension. You cannot park calls on a group extension by dialing the extension as a call-park destination.
- **Night Service**

If a night-station user parks a Night Service call with deluxe paging, the call is parked on the night station's primary extension.
- **Personal Central Office Line (PCOL)**

If a PCOL call is parked by deluxe paging, the temporary bridged appearance of the call is maintained at the PCOL extension until the call is disconnected.
- **Terminating Extension Group (TEG)**

If a TEG member parks a call using deluxe paging, the call is parked on the member's extension, not the group extension. You cannot park calls on a group extension by dialing the extension as a call-park destination.
- **Transfer**

Paging calls can't be transferred.

### **Chime paging**

- **Abbreviated Dialing**

Don't use special characters in abbreviated dialing lists used with chime paging.
- **Conference — Attendant**

A call cannot be conference while the attendant is accessing paging equipment. The attendant can, however, release the call after paging the called party.

- Conference — Terminal

A call cannot be conferenced while the user is accessing paging equipment.

- PagePac Paging Systems

If you use chime code paging with a PagePac system, you can only page one zone at a time. PagePac systems expect a 2-digit code to access a particular zone. The system, however, immediately plays the chime code once a connection is established.

- Transfer

A call cannot be transferred while the attendant is accessing paging equipment.

## **Related topics**

---

See [“Setting up voice paging over loudspeakers” on page 473](#) to administer voice paging.

See [“Setting up chime paging over loudspeakers” on page 476](#) to administer chime paging.

## Malicious Call Trace

---

Malicious Call Trace (MCT) allows you to trace malicious calls. MCT allows you to define a group of telephone users who can notify others in the group when they receive a malicious call. These users then can retrieve information related to the call. Using this information, you can identify the malicious call source or provide information to personnel at an adjacent switch to complete the trace. MCT also allows you to record the malicious call.

You allow users in the group to activate MCT and/or to control malicious call trace. The controlling telephone user, or controller, receives the information that MCT collects on the call.

### NOTE:

MCT does not work with the S8300 Media Server at this time.

## MCT Voice Recorder

---

The MCT Voice Recorder is any type of audio recorder (for example, a standard audio cassette player) that you can control via the Avaya Auxiliary Trunk board.

To record the call, manually place the MCT Voice Recorder in Record mode. The telephone user then activates the MCT feature which applies power to the recorder (via the connected Auxiliary Trunk's control signal interface).

## Activating MCT

---

To activate MCT while on an active malicious call, perform one of the following:

- Push an MCT-Activate feature button
- Place the call on hold, get a second call appearance, and dial an MCT-Activate FAC. After the dial tone, the user then dials their own extension, presses #, or waits for a 10-second time-out.
- Signal another user in the defined group to activate MCT. The co-worker activates MCT, waits for the dial tone, and dials the call recipient's extension.
- Inform a controller, who can request that another switch continue tracing the call.

The switches must be tandemed. The controller on the first switch supplies the trunk member port id to be traced. The controller on the second switch activates MCT and presses \*, followed by the trunk port id. The letters A through E of a port id are entered as 1 through 5 on the station keypad. For example, trunk port id 01C0401 would be entered as 0130401.

Once MCT is activated, information on the call is collected and alerts users in the group. The alert is not a call, so it is not affected by queues at the user's terminal. If an MCT Voice Recorder is connected, it begins recording the conversation.

**⇒ NOTE:**

Any Bridging, Conference, or Intrusion tone connected to parties on the connection are temporarily removed while the MCT Voice Recorder connects.

## **Controlling MCT**

---

The first controlling terminal to respond to an MCT alert becomes the controller for the call. Alerting on any other controlling terminals stops.

To begin trace of an incoming call using the Malicious Call Trace feature, the controller dials the 3-digit equipment location of the incoming trunk.

During alerting, the controller's display shows the message "MALICIOUS CALL TRACE REQUEST." While this message displays, no information on incoming calls displays.

When the controller pushes the MCT-Control button, information displays identifying the called party. When the controller pushes the button again the remaining MCT information displays.

MCT collects and displays three types of information, calling information as follows:

- If the call originated inside the system or on the same node within a DCS network, the calling number displays.
- If the call originates outside the system and an Integrated Services Digital Network (ISDN) calling number identification is available on the incoming trunk, then the calling number displays. Otherwise, the incoming trunk-equipment location displays. In this case, the user must call the connecting switch.

For all calls, the system displays the called number, the activating number, whether the call is active, and identification of any other parties on the call.

## **Deactivating MCT**

---

The controller deactivates MCT by dialing the MCT-Deactivate FAC. Deactivation frees resources involved in the trace that were blocked. When all parties hang up, the MCT Voice Recorder disconnects.

## Administering MCT for ISDN notification

The following describes how to administer the ISDN MCT notification for an ISDN trunk group (public-ntwrk, tandem, tie, or access).

Display the System-Parameter Customer-Options screen and ensure that ISDN is enabled.

One of the following must be set on the DS1 screen:

- If the DS1 is connected to the public network in Australia, set `Country Protocol` field to **2**.
- For a private network of MultiVantage systems, set `Country Protocol` to **1** and `Protocol Version` to **a**. Avaya recommends this if DCS features are used in the private network.
- For a private network of MultiVantage systems, set `Peer Protocol` to **q-sig**. (`Peer Protocol` appears on the DS1 screen when `Signaling Mode` field is **isdn-pri**, `Connect field` is **pbx**, and `Interface` field is **peer-master** or **peer-slave**.)

One of the following must be set on the ISDN-BRI Trunk Circuit Pack screen:

- If the ISDN-BRI is connected to the public network in Australia, set `Country Protocol` field to **2**.
- For a private network of MultiVantage systems, set `Interface` to **peer-master** or **peer-slave**.

## Considerations

- If the originator of the call disconnects, MCT drops; if the recipient of the call disconnects, MCT does not drop.
- Except for Emergency Access to the Attendant, features that normally display information do not do so on a controlling telephone. Otherwise, these features function normally until MCT deactivates.
- Do not use FACs to activate MCT because the process takes users too long.
- Visually Impaired Attendant Service (VIAS) voices-out display information for MCT activation, but not for MCT control.
- MCT information on an active malicious call is lost during a switch failure.
- When directing a trace to an adjacent switch, consider the following:
  - The malicious caller may hear a warning tone as a result of the intrusion.
  - You may lose continuity on the trace because the person activating MCT on the second switch may not be the MCT controller.

- If a malicious call comes in on a non-ISDN trunk, the controller needs the telephone number for the connecting switch and a cross-reference of system-trunk port numbers (including DS1 channel number, if appropriate) not the trunk equipment locations at the connecting switch. Be sure that they have this information.
- The following are the system initiated operations for MCT:
  - Conversation Recording — After the user activates MCT, the system attaches a MCT Voice Recorder, if available, to record the conversation, if available.
  - Historical Recording — After the user activates MCT, the system records the MCT-information that you can subsequently retrieve via the MCT History report.

## Interactions

---

- Bridged Call Appearance

If a user at a primary extension receives an indication call, then a telephone with a bridged call appearance of this extension can bridge on to the call. For an MCT-Activate button push, if the currently active extension is a bridged appearance, the system records the primary extension as the MCT recipient.

For an MCT-Activate FAC, the user dials the number of the telephone with the bridged call appearance that is actually on the call, instead of the bridged number. However, the system logs the primary extension as the recipient. Likewise, for self-originated MCT activations via FAC, the system logs the primary extension as the MCT recipient provided that the recently held appearance is a bridged call appearance. When you activate MCT for yourself, dial # or wait for interdigit time-out.

- Conference

A user can use conferencing to place a malicious caller on hold. The user can initiate conferencing and enter the MCT-Activate FAC, then stop conferencing and return to the malicious caller's appearance.

MCT-Activate can be generated for a member of a conference and is not affected by the number of parties on the conference.

- Centralized Attendant Service

MCT-Activate, MCT-Control, and MCT-Deactivate must be performed by telephones within the same PBX.

- Distributed Communications System (DCS)

If a telephone in a DCS network is involved in a malicious call, the extension is recorded and displayed with the MCT information. MCT notification passes over ISDN-PRI DCS trunks but MCT-Activate, MCT-Control, and MCT-Deactivate must be performed by telephones within the same DCS node.

- Emergency Access to the Attendant

Ordinarily, during MCT-Control no other feature can access the controlling telephone's display. However, MCT gives up control of the display until the Emergency Access call has completed.

- ISDN

ISDN notification of an MCT activation takes place if either the originator of the call is an ISDN trunk group with Country Protocol 2 or any trunk on the call is an ISDN private network trunk with Country Protocol 1 and Protocol Version "a" or Peer Protocol q-sig. When the ISDN trunk group is Country Protocol 2, notification is sent only to the public network.

- Make-Busy/Position-Busy/Send All Calls

The switch attempts to activate Make-Busy or Position-Busy for telephones or consoles that activate MCT-Control. If a user has a SAC button administered but not active for the primary extension on the phone, SAC activates when the user activates MCT-Control. When the user deactivates MCT, SAC stays active until it is deactivated by the user.

- Music-On-Hold

If an agent places a malicious call on hold that is being recorded and the call goes to music-on-hold, the music-on-hold port and the MCT Voice Recorder port can lock. In this case, the MCT Voice Recorder continues to record the music-on-hold and is unavailable for recording subsequent malicious calls. You must perform a busy-out/release on the MCT Voice Recorder port to drop the connection.

- Priority Calling

A priority call to an MCT recipient is denied.

- QSIG Global Networking

MCT notification passes over the following ISDN QSIG trunk groups: tandem, tie, access, and DMI-BOS. QSIG supplementary services name and number ID provide a malicious caller's name and telephone number.

- Transfer

If a user transfers a malicious call, the MCT information displayed on the controlling telephone identifies the transferring party as the MCT recipient.

A user transfers a malicious caller to hold. The user initiates a Transfer, receives the second dial tone, enters the MCT-Activate FAC, then halts the remainder of the Transfer operation and returns to the malicious caller's appearance.

- Trunk Access Code

To activate MCT for a TAC, a user must have an MCT-Control button administered. The user hears a dial tone and enters the trunk-member number for the trunk group that the TAC identified. The user then becomes the MCT controller for a call involving the identified trunk member. This TAC operation is useful when users need to trace a call that has tandemed through their switch to terminate on another switch.

- Trunk Groups

If a PCOL is involved in an MCT, then the switch may hold up the trunk until the MCT deactivates.

## **Misoperation Handling**

---

Misoperation Handling defines how calls are handled when a misoperation occurs. A misoperation can occur either:

- When a user with a call on hold goes on-hook before an operation completes. In some cases, going on-hook completes the operation, as in call transfer.
- When the system enters Night Service while attendant consoles have calls on hold.

You can alter standard Misoperation Handling to ensure that callers are not left on hold indefinitely with no way to reach someone for assistance or that callers are not dropped by the system. See Misoperation Alerting and Intercept Treatment on Failed Trunk Transfers on the Feature-Related System Parameters screen for more information.

Contact an Avaya representative for instructions on administering Misoperation Handling for use in France.

### **Detailed description**

---

Misoperation handling varies considerably, depending on how it is administered and what conditions are in effect when a call is placed on hold.

## Standard operation

Standard misoperation handling is in effect when you set the Intercept Treatment on Failed Trunk Transfers field to **y** and set the Misoperation Alerting field to **n**.

The type of telephone that is in use when the misoperation occurs (analog single-line or digital multiappearance) affects standard misoperation handling.

The following scenario describes a typical misoperation on an analog terminal.

1. While connected to an incoming external call, an analog-terminal user flashes with the intent of transferring the call to another terminal.
2. The user hears dial tone, dials an invalid extension, and hangs up.
3. A misoperation occurs. The analog-terminal user receives priority ringback indefinitely.

The following scenario describes a typical misoperation on a digital terminal.

1. While connected to an incoming external call, a digital-terminal user with a call on hold goes on-hook during another feature operation before completing the operation.
2. The user hears dial tone, dials an invalid extension, and hangs up.
3. A misoperation occurs unless going on-hook completes the operation (for example, call transfer). The held call remains on hold indefinitely with a flashing call-appearance lamp.

## Enhanced operation

Once you enable Misoperation Alerting, calls are handled depending upon the type of call placed on hold and the type of telephone (digital multiappearance, analog single-line, or attendant console) in use when the misoperation occurs. The following list describes the 3 call types that determine misoperation handling.

- Call Type 1 — An outgoing public-network call is classified as Type 1 when answer supervision is received or when the trunk group's Answer Supervision Timer expires, even if the trunk is still ringing. An incoming call is classified as Type 1 when it is answered.
- Call Type 2 — An incoming external-public-network call is classified as Type 2 before it is answered. A misoperation cannot occur with a Type 2 call because an unanswered incoming call cannot be placed on hold without first being answered.
- Call Type 3 — All internal calls, conference calls, and tie-trunk calls are classified as Type 3.

## **Analog terminal misoperation**

The following 2 scenarios describe typical misoperations on an analog terminal.

### **Scenario 1.**

1. While connected to an incoming external call (Type 1), an analog-terminal user flashes to transfer the call to another terminal.
2. The user hears dial tone, dials an invalid extension, then hears intercept tone.
3. When the user hangs up, the call re-alerts the user for 15 seconds and eventually routes to the attendant.

### **Scenario 2.**

1. While connected to an incoming external call (Type 1), an analog station user flashes to place the call on hold while calling another extension.
2. The user hears dial tone and dials the CAS Remote Hold/Answer Hold/unhold access code.
3. The user dials an extension and talks with the user at the extension and hangs up.
4. A misoperation occurs because the first call is still left on hold.
5. The terminal is alerted for 15 seconds and the call routes to an attendant.
6. If the first call is not answered before the timer expires, the call drops.

## **Digital terminal misoperation**

The following scenario describes a typical misoperation on a digital terminal.

1. While connected to an incoming external call (Type 1), a digital-terminal user places the call on hold to transfer the call to another terminal.
2. The user hears dial tone, dials an invalid extension, and hangs up.
3. A misoperation occurs. The call on hold rings the terminal again (not priority ringing) for the number of rings administered for call coverage.
4. The call then routes to the terminal's coverage path, which directs the call to an announcement and/or disconnects.

## **Attendant console misoperation**

A misoperation occurs on an attendant console with calls on hold only when the system enters Night Service.

1. The system enters Night Service with calls on hold at an attendant console.
2. All calls on hold re-alert (as if the Held-Call Timed-Reminder had expired).

3. When the calls start re-alerting, a timer starts. The timer is set to the value assigned in the Alerting (sec) field on the Console-Parameters screen.
4. If the attendant does not answer the calls before the timer expires, calls route to the system Night Service destination. Calls that are not answered at the night service destination before the night-service-disconnect timer expires are dropped.

### Interactions

---

- Attendant Lockout  
Attendant Lockout is temporarily disabled on calls that re-alert the attendant console following a misoperation. This allows an attendant to answer the calls.
- Bridged Appearances  
Misoperation Alerting calls do not re-alert on bridged call appearances.
- Voice Response Integration  
Do not use Misoperations Handling with this feature if you are using analog boards with Conversant.

## Modem pooling

---

(Not available with Offer B) Modem Pooling allows switched connections between digital-data endpoints (data modules) and analog-data endpoints via pods of acoustic-coupled modems. The analog-data endpoint is either a trunk or a line circuit.

### Detailed description

---

Data transmission between a digital data endpoint and an analog endpoint requires conversion via a modem, because the DCP format used by the data module is not compatible with the modulated signals of an analog modem. A modem translates DCP format into modulated signals and vice versa.

Modem Pooling feature provides pools of integrated-conversion modems and combined-conversion modems.

Integrated-conversion modem pools have functionality integrated on the Pooled Modem circuit pack, providing two modems. Each one emulates a time-division multiplexing (TDM) cabled to a 212 modem. Integrated are modem pools not available in countries that use A-law companding.

Combined-conversion modem pools are TDMs cabled to any TDM-compatible modem. Combined-conversion modem pools can be used with all systems.

When the system needs a modem, it queries the digital-data module associated with the call to determine if the module's options are compatible with those supported by the modem pools. If the options are not compatible, the originating user receives intercept treatment. If the options are compatible, the system obtains a modem from the appropriate pool. If a modem is not available, the user receives reorder treatment.

The system can detect the needs for a modem. Data calls from an analog-data endpoint require that the user indicate the need for a modem, because the system considers such calls to be voice calls. Users indicate this need by dialing the data-origination access code before dialing the digital-data endpoint.

The system provides a Hold Time parameter to specify the maximum time any modem can be held but not used (while a data call is in queue).

The integrated-conversion modems support the following options:

- Receiver responds to remote loop
- Loss of carrier disconnect
- Send space disconnect
- Receive space disconnect
- CF-CB common
- Speed, duplex, and synch (administered)

Combined-conversion modems support the following:

- IBM bisynchronous protocols typically used in 3270 and 2780/3780 applications. Both require 2400 or 4800 bps, half-duplex, synchronous transmission.
- Interactive IBM-TSO applications using 1200 bps, half-duplex, asynchronous transmissions
- DATAPHONE II switched-network modems supporting asynchronous and synchronous communications, and autobaud at 300, 1200, or 2400 bps
- The Avaya MultiVantage system operating at up to 19.2 kbps
- Different pools with different data-transmission characteristics

## Considerations

---

- On data calls between a data module and an analog-data endpoint, Return-to-Voice releases the modem and returns it to the pool. The phone user connects to the analog-data endpoint.
- For traffic purposes, the system accumulates data on modem-pooling calls separate from voice calls. Measurements on the pools also accumulate.
- When a phone user places a data call to a digital-data endpoint, does not transfer the call to another digital-data endpoint, and uses a modem or acoustically-coupled modem, the user dials the data-origination access code before dialing the distant endpoint.
- Modem Pooling is not restricted. Queuing for modems is not provided, although calls queued on a hunt group retain reserved modems.
- Avoid mixing modems from different vendors within a combined pool because such modems may differ in transmission characteristics.
- When you administer data-transmission characteristics (speed, duplex, and synchronization mode), they must be identical to the TDM and optional modem selections made by the customer.
- Each data call that uses Modem Pooling uses four time slots (not just two). As a result, heavy usage of Modem Pooling could affect TDM bus-blocking characteristics.
- Tandem switches do not insert a pooled modem. The originating switch inserts a pooled modem.

## Interactions

---

- Call Detail Recording (CDR)  
Data call CDR records the use of modem pools on trunk calls.
- Data Call Setup  
Data calls to or from a TDM cannot use Modem Pooling.
- Data Privacy and Data Restriction  
The insertion of a modem pool does not turn off Data Privacy or Data Restriction.
- Data-Only Off-Premises Extensions  
Calls to or from a Data-Only Off-Premises Extension cannot use Modem Pooling, when this type of digital-data endpoint uses a TDM.

- Digital-multiplexed Interface Trunks

If you place a data call from a local analog-data endpoint to a DMI trunk, you must dial the data-origination access code to obtain a modem. Data calls on DMI trunks to local analog-data endpoints automatically obtain modems.

- DS1 Tie Trunk Service

Connect modems used for Modem Pooling to AVD DS1 tie trunks via Data Terminal Dialing or by dialing the feature-access code for data origination.

## Multiappearance Preselection and Preference

---

Multiappearance Preselection and Preference selects the call appearances you use to connect to when you lift the handset.

Multiappearance Preselection and Preference provides multiappearance telephone users with the following options for placing or answering calls on selected call appearances.

- Ringing Appearance Preference

When a user lifts the handset to answer a call, the system automatically connects them to the ringing call appearance. If there is more than one call, the user automatically connects to the oldest (first-in) ringing call appearance. The in-use (red) lamp tracks the ringing appearance and the answered appearance.

- **Idle Appearance Preference**

When a user lifts the handset to place a call, the system automatically connects them to an idle appearance even if an incoming call is ringing at another appearance. The in-use (red) lamp tracks an idle appearance when the user lifts the handset.

- **Last Appearance Preference**

When a user lifts the handset, they connect to the call appearance or bridged appearance last used for a call, unless an audibly ringing call on a different appearance caused the line selection to move. If the line selection moves, a call may be originated, answered, or unheld, depending on the state of that appearance.

- **Preselection**

Before lifting the handset to place or answer a call, the user can press a call appearance button or a feature button to select an appearance when the in-use lamp is dark. Preselection reenters a held call or activates a feature or the speakerphone if the telephone is so equipped.

Preselection overrides both Preference options. If the user does not lift the handset within 5 seconds after using Preselection, the selected appearance returns to idle.

You can assign a preselection feature button. For example, if a user presses an Abbreviated Dialing button, a call appearance is automatically selected. If the user lifts the handset within 5 seconds, the system automatically places the call.

Preference dictates whether a user connects to the ringing call appearance or to an idle call appearance. If there is no call, users automatically connect to an idle call appearance when they lift the handset, regardless of which Preference option is assigned.

### **Considerations**

---

- Multiappearance telephones can have from 2 to 10 call appearances. One of these call appearances is reserved for placing calls or for receiving a Priority Calling call. If a telephone has 2 call appearances and one of them is active, a nonpriority call cannot access the other call appearance, even if the call appearance is idle. The default number of call appearances is 3.
- The reserved call appearance is not a fixed-position button; it is just the last-idle call appearance. For example, if a telephone has 10 call appearances, any 9 can be in use, but the tenth (last) is reserved.

## Interactions

---

- Automatic Incoming Call Display  
Incoming calls are not displayed if Idle Appearance Preference is activated.
- Call Coverage  
If you administer Cover All Calls as the redirection criterion for a telephone, administer Idle Appearance Preference for the telephone. The called party can then lift the handset without accidentally connecting to a call that should be screened.
- Integrated Services Digital Network — Basic Rate Interface  
When an Integrated Services Digital Network-Basic Rate Interface (ISDN-BRI) telephone (with Select Last Used Appearance enabled) transfers a call while off-hook by using the handset, the user hears dial tone on the last-used call appearance. Users of other telephone types hear silence in this case.

## Related Topics

---

For more information, see [“Station” on page 1127](#). You administer this feature with the following two fields:

- Idle Appearance Preference
- Select Last Used Appearance

## Multifrequency signaling

---

Multifrequency (MF) signaling is a form of address signaling used between switches and the CO. It is similar to DTMF signaling in that tones convey the dialed number.

With MF signaling, the signal is typically a combination of two frequencies from a group of 5 or 6 frequencies (2/5 or 2/6). The origination switch and destination switch exchange tones that have specific meanings according to the MF protocol.

## Detailed description

---

Avaya MultiVantage supports two frequency groups:

- R2-multifrequency compelled signaling (R2-MFC) frequency
- R1 frequency (for Spain and Russia)

R2-MFC is a version of MFC recommended by the International Telecommunication Union (ITU). It provides signaling between a CO and a switch over analog or digital CO, DID, or DIOD trunks. It also provides signaling between 2 MultiVantage switches.

Avaya MultiVantage provides MF signaling that complies with ITU regulations and national regulations for specific countries. It provides these types of MF signaling: MFE) MF Shuttle, and multifrequency compelled (R2-MFC). These protocols signal the called number, the calling party's number (ANI), and information about the type of call or type of caller (category).

Avaya MultiVantage allows prefix digits for ANI sent on outgoing calls to be defined per PBX or per the originator's class of restriction.

If a call is a tandem call and the incoming and outgoing trunk use different protocols, the switch makes no attempt to convert between the various protocol's meanings for category. Instead,

- the PBX uses the incoming trunk's COR assigned category if the outgoing trunk is Russian or R2-MFC, and
- the PBX uses ARS call types if the outgoing trunk is MFE.

Avaya MultiVantage provides the incoming ANI to all features on the switch that need to identify the calling party.

### **MFE**

MFE, for Country code 11 (Spain), uses R1 frequency and compelled signaling. It is available on CO and DID trunk groups. There are four kinds of MFE signaling:

- Public 2/5
- Public 2/6
- Ibercom 2/5
- Ibercom 2/6

### **MF Shuttle**

MF shuttle signaling, for country code 15 (Russia), uses R1 frequency and noncompelled signaling. With MF shuttle signaling, it is possible to change to decadic rotary pulse in the middle of address signal exchange. MF shuttle signaling is available on CO, DID, and DIOD trunk groups.

Also, ANI transmission, for Country code 15, uses a gapless R1 MF signal and is completed within 800ms. This is available on an outgoing CO trunk group.

## R2-MFC

R2-MFC permits each country to define the meanings of the R2 frequency combinations.

### R2-MFC Considerations

- Both non-group II signaling and group II signaling are supported on incoming MF signaling calls. The group II signaling protocol has an extra signal that provides caller-category information. Only group II signaling is supported on outgoing MF signaling calls.
- MF signaling also can be used in tandem trunk groups. After address signals are collected from an incoming group II MF signaling call, the call can route to a group II MF signaling trunk.
- Both incoming and outgoing MF signaling calls support ANI. The terminal displays ANI information and the CDR record records it.
- When Avaya MultiVantage uses an open numbering plan, the end-of-dial signal must be defined in the incoming Group I signal administration. After sending all address digits, the CO sends the end-of-dial signal to Avaya MultiVantage.
- If Avaya MultiVantage makes an outgoing call to the CO that uses an open numbering plan, the CO should send the signal A.1 to Avaya MultiVantage after sending the last address digit to the CO. Then, the CO should time-out and send a pulsed signal A.3 to Avaya MultiVantage requesting the Group II signal.
- Avaya MultiVantage offers the option to record the Calling Party Category in the CDR. For incoming external calls, this comes from the Group II signal. For internal calls and station-originated external calls, this comes from the COR of the originating station. For tandem calls, this value comes from the Group II signal, determined by the COR of the originating trunk group. The CDR device must be capable of receiving this information. See [“CDR System Parameters” on page 646](#) for more information.
- You can assign Calling Party Category and Called Party Category on a trunk-by-trunk basis. See [“Multifrequency-Signaling-Related System Parameters” on page 1045](#) for more information.
- You can record an announcement to play when outgoing R2-MFC trunk calls do not complete. This applies when Avaya MultiVantage receives either group A or B signals from the called Central Office or other switch. See [“Multifrequency-Signaling-Related System Parameters” on page 1045](#) for more information.

**Guidelines for administering MF signaling**

To administer MF signaling, first you identify the origination switch and the destination switch. (The switch making the call is the origination switch; the switch answering the call is the destination switch.)

- The origination switch creates *forward* signals, classified as group I and group II signals.
- The destination switch creates *backward* signals, classified as group A and group B signals.

Group I and group A signals comprise the basic signaling for the dialed number. More elaborate signaling requires Group II and group B signals. Signal meanings and timer values can be administered.

The sequence below shows a typical interaction between the origination (forward group I and group II signals) and destination switch (backward group A and group B signals).

| <b>Forward</b> |           | <b>Backward</b> |
|----------------|-----------|-----------------|
| Group I        | digit --> |                 |
|                | <-- A.1   | Group A         |
|                | digit --> |                 |
|                | <-- A.1   |                 |
|                | digit --> |                 |
|                | <-- A.1   |                 |
|                | digit --> |                 |
|                | <-- A.1   |                 |
|                | digit --> |                 |
|                | <-- A.3   | End of dial     |
| Group II       | II.2 -->  |                 |
|                | <-- B.x   | Group B         |

Second, you assign the correlation between signal codes and their meanings.

1. Assign a code to every message. The code consists of a group category, like group II or A, and a number.
  - For example, you might assign code A.1 to the message “next-digit.”
2. Assign a signal to each identifying code.
  - In every country, the frequencies (levels may differ by country) assigned to the identifying codes are the same. However, the messages assigned to the identifying codes may be different.

For example, in Switzerland the B.6 code and its associated signal convey the *free* message, while in Thailand, *free* is conveyed by the B.1 code and its associated signal. But in both Switzerland and Thailand, the frequency associated with the B.1 code is the same.

As another example, you might assign the signal “busy” to the B.1 code.

To receive Russian incoming ANI:

- On the DID or DIOD trunk group screen, set the Country field to **15** and the Protocol Type field to **inloc**.
- On AAR and ARS Digit Analysis Table screen, set the ANI Req field to **y** or on AAR and ARS Digit Conversion Table screen, set the ANI Req field to **y**.

## Interactions

---

- ASAI

ANI collected from incoming R2-MFC signaling can be used with ASAI.
- Abbreviated Dialing

Although calls dialed automatically from an abbreviated dialing privileged list complete without COR checking, ANI prefix and ANI truncation still apply.
- Attendant Console

If the attendant assists or extends a call for a station via Straightforward Outward Completion and Through Dialing, and if the attendant has not yet released the call when the request for ANI comes in from the far end, the attendant’s COR is used to select the ANI for the call. If the attendant has already released the call when the request for ANI comes in from the far end, the attendant’s COR is used to select the ANI for the call.

- Authorization Codes

The COR of the authorization code as administered on the authorization-code screen is not used for ANI prefix determination, even if the originating endpoint enters an authorization code before call processing for an outgoing call seizes an outgoing trunk. If the originating endpoint is an extension, the extension's ANI is used. If the originating endpoint is an incoming trunk, the ANI for PBX is used.

- Bridging

The ANI of a telephone's primary extension also applies to calls originated from a bridged call appearance of that extension on another terminal. ANI prefix and ANI truncation will still apply to the primary extension number of bridged call appearances.

- Call Detail Recording (CDR)

CDR records ANI collected from incoming MF signaling.

**For India** MFC, on incoming calls, ANI digits may be appended with zeroes if the actual ANI digits are less than the administered ANI-length; in those cases, the zero-digits appear on CDR.

- Call Redirection

A call is redirected if any of the following are active: Call Forwarding, Call Coverage, Send All Calls, or Night Service.

- Call Vectoring

Call Vectoring can now use ANI collected from incoming MFC signaling.

The ANI of a call vector is not used when a call vectoring route-to-command routes a call over an outgoing trunk. Instead, the ANI of the originating party is sent.

- DID No Answer Timer

DID No Answer Timer is applied to MF signaling DID calls.

- Distributed Communications System (DCS)

In a DCS arrangement, the ANI sent to the CO is determined by the ANI for PBX on PBX\_B, but the category sent to the CO is determined by the Category for MF ANI field on the Class of Restriction screen for the incoming DCS trunk or by the type of call.

- Expert Agent Select (EAS)

For ANI, the EAS agent's login extension number and COR overrides the extension number and COR of the physical terminal where the agent is logged in. ANI prefix and ANI truncation apply to logged in EAS agents.

- **Hunt Groups and Automatic Call Distribution (ACD) Splits**

For ANI, a physical terminal's extension number and COR overrides the extension number and COR of the hunt group or ACD split that the terminal is a member of or logged into. ANI prefix and ANI truncation apply to terminals that are members of hunt groups or logged into ACD splits.

- **Intercept treatment**

For DID MF signaling calls that are denied, you can administer whether the corresponding B.x signal or intercept tone should be sent to the CO. The default is to send the administered DID/TIE/ISDN Intercept Treatment. If the option to send the B.x signal is set, then:

- For Group II calls, the B.x signal for the intercept is sent to the CO.
- For non-Group II calls, if the CO dials an invalid number, the trunk is locked (regardless of this option). If the CO dials a number that is valid but not assigned, intercept tone is sent to the CO.

- **Multimedia Call Handling (MMCH)**

For call origination, multimedia complexes use the COR assigned to their telephones. ANI prefix and ANI truncation will apply to the telephones assigned to multimedia complexes.

- **Off-Net Call Coverage or Call Forwarding**

If the originating endpoint is an extension, the extension's ANI is used. If the originating endpoint is an incoming trunk that can supply ANI, the ANI received from the incoming trunk is used. If the originating endpoint is neither of the above, the ANI for PBX is used.

- **Personal Station Access (PSA)**

For ANI, the PSA extension number and COR overrides the extension number and COR of the physical terminal where the PSA extension number is associated. ANI prefix and ANI truncation will apply to associated PSA extension numbers.

- **Remote Access**

The COR of a remote access barrier code is not used for ANI prefix determination when the originating end point dials a remote access extension and then places a call. If the originating endpoint is an extension, the extension's ANI is used. If the originating endpoint is an incoming trunk, the ANI for PBX is used.

- Station Set Displays

When no ANI is possible, if station sets are equipped with display option, they do not display the ANI digits. Instead, the trunk group name displays. When ANI is possible, ANI displays on the station set.

**For India Only.** If ANI digits are padded with “zero,” then zeroes also are displayed along with ANI digits.

- Tandem / Offnet Calls

If ANI digits are received on incoming MFC calls, the ANI digits are sent to outgoing tandem/off-net calls.

**For Russia Only.** The ANI is requested on incoming trunks only when all the address digits have been collected. When the incoming trunk on a tandem call is a Russian incoming local trunk administered to collect ANI, the PBX collects all ANI digits before seizing the outgoing tandem trunk. This happens even if ARS is administered with a “min” value low enough that it would be possible to determine an outgoing route through digit analysis.

**For India Only.** On an outgoing tandem-call, the default operation is to send the ANI-Not-Available forward signal if ANI is not available from the incoming trunk. However, in order to support this operation, leave the ANI for PBX field blank, and define the ANI-Not-Available signal.

### Related topics

---

For administration settings, see [“Multifrequency-Signaling-Related System Parameters”](#) on page 1045.

To establish MF Signaling for a trunk group, see [“Trunk Group”](#) on page 1233, (CO, DID, DIOC, TIE) - Incoming and Outgoing Dial Type.

To set up MFC ANI, see [“AAR and ARS Digit Analysis Table”](#) on page 577, [“AAR and ARS Digit Conversion Table”](#) on page 582, and [“Class of Restriction”](#) on page 658.

## Night Service

---

Avaya MultiVantage provides the following Night Service features:

- Hunt Group Night Service
- Night Console Service
- Night Station Service
- Trunk Answer from Any Station
- Trunk Group Night Service

## **Hunt Group Night Service**

---

Hunt Group Night Service allows an attendant or a split supervisor to assign a hunt group or split to Night Service mode. All calls for the hunt group then are redirected to the hunt group's designated Night Service extension (NSE). When a user activates Hunt Group Night Service, the associated button lamp lights.

## **Night Console Service**

---

Night Console Service directs all calls for primary and daytime attendant consoles to a night console. When a user activates Night Console Service, the Night Service button for each attendant lights and all attendant-seeking calls (and calls waiting) in the queue are directed to the night console.

To activate and deactivate this feature, the attendant typically presses the Night button on the principal attendant console or designated console.

## **Night Station Service**

---

Night Station Service directs incoming calls for the attendant to designated extensions. Attendants can activate Night Station Service by pressing the Night button on the principle console if there is not an active night console. If the night station is busy, calls (including emergency attendant calls) receive busy tone. They do not queue for the attendant.

When Night Station Service is active, incoming calls to the attendant route as follows:

- DID Listed Directory Number (LDN) calls route to a designated DID-LDN night extension.
- Internal calls route to the DID-LDN night extension (unless you administer the system so only DID-LDN calls can route to the LDN night extension).
- Non-DID calls route to the night destination that you specify for the trunk group or for the individual trunk. If you do not specify a night destination, the calls route to the DID-LDN night extension.

You can assign a unique extension as the night destination for each incoming central-office, foreign-exchange, or 800-Service trunk group. Both the extension assigned as a trunk group's night destination and the DID-LDN night extension can be phones or answering groups (such as DDC group, UCD group, or TEG).

## **Trunk Answer from Any Station**

---

Trunk Answer from Any Station (TAAS) allows phone users to answer all incoming calls to the attendant when the attendant is not on duty and when other phones have not been designated to answer the calls. The incoming call activates a gong, bell, or chime and a phone user dials an access code to answer the call.

Users can activate TAAS if each of the following conditions is met:

- The attendant has pressed the Night button on the primary console or a user (if the switch has no attendant) pressed the Night Service button on the designated Night Service phone.
- A night console is not assigned or is not operational.
- Night Station Service is not active.

## **Trunk Group Night Service**

---

Trunk Group Night Service allows an attendant or a designated Night Service phone user to assign one or all trunk groups to Night Service mode. When a user activates Night Service, trunk groups that are assigned a Trunk Group Night Service termination change to Individual Trunk Night Service mode so that calls coming into the trunk group are redirected to the group's designated NSE. Incoming calls on trunk groups that are not assigned to Trunk Group Night Service are queued in the attendant queue. If the call remains unanswered during the Night Service Disconnect Timer interval, the incoming trunk disconnects.

In addition, a user can assign all the trunk groups to the night service mode at the same time. Then all the trunk groups are in the System Night Service mode. Any incoming calls made on the trunk groups are redirected to their designated NSE. To assign all the trunk groups to System Night Service, the user presses the System Night Service button on the principal attendant console or the Night Service button on a designated phone. You can assign a Night Service button to only one phone.

You can activate Night Service for specific trunk groups (Trunk Group Night Service) by pressing the individual Trunk Night Service buttons on the attendant console or on a phone. You can assign Trunk Night Service buttons on more than one phone.

## Considerations

---

### Considerations for Hunt Group Night Service

- Both Hunt Group Night Service and Trunk Group Night Service can be active at the same time. An incoming trunk call is redirected to the trunk group's designated NSE. If this NSE is a hunt group or split that is in Hunt Group Night Service mode, the call is redirected to the Hunt Group NSE.
- Calls in progress (such as talking, on hold, or waiting in queue) on the hunt group or split are not affected when the hunt group or split is put in Hunt Group Night Service mode.
- When a hunt-group queue becomes empty, all idle members are placed in a busy condition.
- If Night Service is activated for a hunt group or split and a power failure occurs, the hunt group or split automatically returns to the Night Service mode.

### Considerations for Night Console Service

- The night console must be identical to and have the same features as the primary console. A daytime console can double as the night console.
- Night Console Service calls to the attendant group are still handled by an attendant, even though the primary and daytime attendant consoles are out of service.
- Only one night console is allowed in the system. The night console can be activated only when the primary and daytime consoles have been deactivated.
- If Night Console Service is active and a power failure occurs, the system automatically returns to Night Console Service mode when it is powered up.

### Considerations for Night Station Service

- When Night Station Service is active but you have not established Night Station extensions, a user can activate TAAS.
- You can assign a Night-Serv button to either an attendant extension or a phone extension. An individual trunk group or hunt group can be put into night service by either an attendant extension or a phone extension with the necessary button. When a user presses this button to activate Night Station Service, all calls to that particular trunk group or hunt group are routed to the Night Service extension assigned to that group.

- If a trunk without disconnect supervision goes to Night Service, the system drops the trunk after a period of time to avoid locking up the trunk. The call is not routed to the DID-LDN night extension.

### **Considerations for TAAS**

- If Night Service is active and a power failure occurs, the system, when brought back up, automatically returns to Night Service mode.

### **Considerations for Trunk Group Night Service**

- All incoming calls on Night Service trunk groups go to the trunk group's NSE unless the trunk group member has its own Trunk Group Member Night Destination, in which case the calls are redirected to that destination instead of the trunk group's NSE.
- Calls already in progress on a trunk group (such as talking, on hold, or waiting in queue), are not affected when the individual Trunk Group Night Service or System Night Service is activated.
- Trunk Group Night Service and System Night Service work independently of one another.
  - When a user activates System Night Service, any trunks that are controlled by individual Trunk Group Night Service buttons remain in day service. Trunk groups that are not currently assigned to Trunk Group Night Service are assigned to System Night Service.
  - Trunks with individual Trunk Group Night Service can be removed from Night Service even though the rest of the system remains in Night Service.
  - When a user deactivates System Night Service, any trunks that have individual Trunk Group Night Service still active remain in night service.
  - Trunks with individual Trunk Group Night Service can be placed into Night Service even though the rest of the system remains in day service.
- If a trunk is added to a trunk group while that trunk group is in Trunk Group Night Service, the trunk is brought up in night service.
- Individual Trunk Group Night Service does not apply to DID trunk groups.
- If Night Service is activated for a trunk group, and a power failure occurs, the trunk group automatically returns to the Night Service mode.

- If for some reason, a phone with a trunk-ns button remains out-of-service after a system reboot and later comes back in service, the trunk-ns lamp shows the trunk status within 10 seconds of coming back in service. For example, a phone with a trunk-ns button may be unplugged when the system is rebooted. If the phone is plugged back in later, the trunk status is shown on the trunk-ns button within 10 seconds.

## **Interactions**

---

### **Interactions for Hunt Group Night Service**

- **ACD**

When Hunt Group Night Service is active for a split and the night-service destination is a hunt group, the caller hears the first forced announcement for the original split. The system then redirects the call to the Night Service destination hunt group. When an agent in the Night Service hunt group becomes available, the call goes to that agent. If all agents in the hunt group are busy, the caller hears the following: forced or delayed first announcement, ringback, music-on-hold or silence, and a second announcement.

- **Call Coverage**

Coverage takes precedence over Night Service. When Hunt Group Night Service is active, the NSE's normal coverage criteria and path apply. If the coverage path destination is AUDIX, AUDIX answers with the mail of the original hunt group. If the NSE is a hunt group or split of any type, the hunt group or split's call coverage criteria and coverage path apply. The coverage criteria and path can be different from that assigned to the phones that are members of that hunt group or split.

If a coverage point is a hunt group or split in Night Service, the system considers the point to be unavailable and does not forward the call to the coverage point's NSE.

- **Call Forwarding All Calls**

If a hunt group or split is in Hunt Group Night Service mode and the hunt group or split's NSE has Call Forwarding — All Calls active, the system forwards night-service calls terminating to that NSE to its designated call-forward extension.

If the forwarded-to destination is a hunt group or split in Night Service mode, the system terminates the call at the forwarding extension.

## Interactions for Night Console Service

- Trunk Group Night Service

Activation of Night Console Service for the attendant consoles also puts trunk groups into night service, except those trunk groups for which you administered a Trunk Group Night Service button.

## Interactions for Night Station Service

- Call Coverage

Calls routed to the night extension via Night Station Service follow the coverage path of the night extension under all coverage criteria except Send All Calls.

If a night extension has a coverage path in which Cover All Calls is administered, all attendant-seeking calls redirect to coverage. Changes to the protocol for handling DID-LDN calls (that is, forwarding attendant-seeking calls on or off premise from the night extension) do not work.

- Call Forwarding All Calls

Calls redirected to the attendant via Call Forwarding All Calls do not route to the DID-LDN extension.

- Inward Restriction

Inward-restricted phones can be administered for Night Station Service. Night Service features override Inward Restriction.

- Night Console Service

Do not provide Night Console Service with this Night Station Service.

- Remote Access

A Remote Access extension can be specified as the Night Station extension on an incoming, non-DID, trunk group.

- Tenant Partitioning

Each tenant may have a designated night-service station. The system directs calls to an attendant group in night service to the night-service station of the appropriate tenant (when a night attendant is not available). When someone places an attendant group into night service, all trunk groups and hunt groups that belong to tenants served by that attendant group go into night service. In this case, the system routes incoming calls to the night-service destination of the appropriate tenant.

Each tenant can have its own LDN night destination, TAAS port, or night attendant.

- **Timed Reminder**

Timed Reminder calls returning to a console that has been placed in Night Service and has an assigned DID-LDN night extension are not redirected to the DID-LDN night extension. Rather, they are dropped.

- **Trunk Answer from Any Station**

TAAS and Night Station Service can both be assigned within the same system, but cannot be assigned to the same trunk group.

## **Interactions for TAAS**

- **Call Coverage**

If Night Station Service is active, calls that are redirected to the attendant via Call Coverage can be answered via TAAS.

- **Call Forwarding All Calls**

If Night Station Service is active, calls that are redirected to the attendant via Call Forwarding All Calls can be answered via TAAS.

- **Inward Restriction**

Inward-restricted phones can activate TAAS for incoming trunk calls. Night Service features override Inward Restriction.

- **Night Console Service**

Do not provide a Night Console Service with TAAS.

- **Night Station Service**

TAAS and Night Station Service can both be assigned within the same system, but cannot be assigned to the same trunk group. Activating Night Station Service also activates Night Service — Trunk Group for any trunk group without an individual trunk-group Night Service button.

- **Tenant Partitioning**

Each tenant can have its own LDN night destination, TAAS port, or night attendant.

## Interactions for Trunk Group Night Service

- Call Forwarding All Calls

If the individual Trunk Group Night Service mode and the trunk group's NSE have Call Forwarding All Calls activated, the night service calls terminating to that NSE are forwarded to the designated extension.

- Forced First Announcements

An interaction occurs with System Night Service and Forced First Announcement. For example, if hunt group A has a forced first announcement, assign the incoming CO trunk to terminate at hunt group A. Assign the incoming trunk's night-service destination to be another hunt group (hunt group B). Assign a Night Service button to the attendant.

With night service active on the attendant, the incoming CO call routes to the night-service destination hunt group B and does not play the Forced First Announcement of the incoming destination's hunt group A.

- Listed Directory Number

In System Night Service mode, all incoming LDN calls (except those using DID trunks) which have activated night service are redirected to their corresponding trunk group's NSE. Incoming LDN calls using DID trunks are directed to the Night Console Service, Night Station Service, or Trunk Answer From Any Station, respectively, whichever applies first. Non-LDN DID trunk calls terminate at the dialed extension.

## Off-Premises Station

---

Off-Premises Station allows a phone located outside of the building where the switch is located to be connected to the system. If CO trunk circuits are used, the voice terminal must be analog and must be FCC-registered or, outside the US, registered by the appropriate governmental agency. Digital communications protocol (DCP) sets can be used as off-premises terminals with the addition of the DEFINITY extender. IP stations can be set up off-premises using PPP connections. DS1 trunk service provides a digital interface for off-premises stations (also known as station-side DS1).

Off-premises stations are useful when it is necessary to have a voice terminal located away from the main location. The maximum loop distance for analog off-premises stations is 20,000 feet (6093.34 meters) without repeaters. For cabling distance information for the various voice terminal types, see the user guide for the appropriate telephone.

### Detailed description

---

Off-Premises Station requires cross-connecting capabilities and one port on a Analog Line or DS1 Tie Trunk circuit pack for each interface to be provided. Not all analog lines can support an off-premises station. For information about user guide for the appropriate telephone.

#### NOTE:

The use of a message waiting indicator lamp on an off-premises station is not supported.

### Interactions

---

The Distinctive Ringing feature might function improperly at an off-premises station due to the distance. However, the Distinctive Ringing feature can be disabled when the Off-Premises Station field is administered. If the Distinctive Ringing feature is not used with an off-premises station, the terminal receives 1-burst ringing for all calls.

## PC Interface

---

The PC Interface consists of the PC/ISDN Platform product family. These products are used with Avaya MultiVantage to provide users of IBM-compatible PCs fully-integrated voice and data workstation capabilities.

### Detailed description

---

Two groups of different configurations are available for PC Interface: group 1 uses DCP and group 2 uses the ISDN-BRI (Basic Rate Interface) protocol.

The group 1 configurations consist of DCP configurations that use a PC/PBX Interface card (formerly DCP expansion card) in the PC to link to the switch. Group 1 (shown in [Figure 62 on page 1791](#)) uses the following connections:

- The PC Interface card plugs into an expansion slot on the PC. The card has 2 standard 8-pin modular jacks (line and phone).
- The digital phone plugs into the phone jack on the PC Interface card.
- The line jack on the card provides a digital port connection to Avaya MultiVantage.
- The distance between the PC Interface card and the PBX should be no more than 1524m for 24-gauge wire or 1219m for 26-gauge wire.

- 3. DCP
- 4. DCP phone
- 5. Avaya Media Server (Digital Line circuit pack)
- 6. Host

**Figure 62. DCP PC interface configuration (Group 1)**

The group 2 configurations link to the switch using a PC/ISDN Interface card installed in the PC. This group can include a stand-alone PC terminal, or up to 4 phones, handsets, or headsets. Group 2 (shown in [Figure 63 on page 1792](#)) uses PC/ISDN Interface cards (up to four cards) which plug into expansion slots on the PC. These cards each provide 2 standard 8-pin modular-jack connections for both line connections (to the switch) and phone connections. A standard 4-pin modular jack is also available for use with a handset or headset.

| 6. ISDN-BRI Line, 4-wire S/T-NT,<br>interface circuit pack | 12. Switch features   |

**Figure 63. ISDN—BRI PC interface configuration (Group 2)**

PC Interface users have multiple appearances (depending on the software application used) for their assigned extension. Designate one or more of these appearances for use with data calls. With the ISDN-BRI version, you can use up to 4 separate PC/ISDN Interface cards on the same PC. Assign each card a separate extension, and assign each extension one or more appearances. The availability of specific features depends on the COS of the extension and the COS for the switch. Modem Pooling is provided to ensure general availability of off-net data-calling services.

## Security

---

There are two areas where unauthorized use may occur with this feature: unauthorized local use and remote access.

### **SECURITY ALERT:**

*Unauthorized local use involves unauthorized users who attempt to make calls from a PC. The PC software has a security setting so users can place the PC in Security Mode when it is unattended. You can also assign Automatic Security so that the administration program on the PC is always active and runs in Security Mode. This mode is password-protected.*

### **SECURITY ALERT:**

*Remote access involves remote access to the PC over a data extension. Remote users can delete or copy PC files with this feature. You can password-protect this feature. Consult the Avaya Products Security Handbook for additional steps to secure your system and to find out about obtaining information regularly about security developments.*

## Considerations

---

- Use the Function Key Module of the 7405D with PC Interface.
- BRI terminals normally are initializing terminals and require you to assign an Service Profile Identifier (SPID). The PC/ISDN Platform (Group 2), in a stand-alone configuration, is a noninitializing BRI terminal and does not require you to assign a SPID.
  - Set a locally-defined terminal type with General Terminal Administration
  - Define the terminal type as a noninitializing terminal that does not support Management Information Messages (MIM).
  - Assign the PC/ISDN Platform with an associated (initializing) ISDN-BRI phone (such as an ISDN 7505) using a SPID.
  - Assign the station (using a locally-defined terminal type) to take full advantage of the capabilities of the PC Interface. This terminal type is also noninitializing with no support of MIMs.
- Do not use phones with data modules with the PC Interface. (You can still use 3270 Data Modules if you also use 3270 emulation). If you attach a DCP data module or ISDN data module to a phone that is connected to a PC Interface card, the data module is bypassed (not used). All the interface functions are performed by the interface card even if a data module is present.

- The 7404D phone with messaging cartridge cannot be used with PC Interface. However, the 7404D with PC cartridge can be used, but only with Group 1 configurations.

## Interactions

---

- **Data Communications Access**  
PC Interface uses a digital interface and is not directly compatible with Data Communications Access, which uses an analog interface. Apply Modem Pooling conversion if you use these features together.
- **Data Protection**  
Assign Data Protection—Permanent for use with PC Interface for data communications.
- **Host Computer Access**  
Both PC Interface and Host Computer Access use digital interfaces. These features are compatible and Modem Pooling conversion is unnecessary.
- **ISDN-BRI**  
Each card can have its own separate phone or voice-calling device. A phone does not require special application software on the PC. However, a handset or headset alone requires special application software.
- **Modem Pooling**  
Use Modem Pooling if you use PC Interface to place calls to, or receive calls from, off-premises stations over analog trunks.

## Personal Station Access

---

Personal Station Access (PSA) allows users to associate the preferences and permissions of their telephone with any other telephone of the same type.

PSA makes it convenient for different users to use the same bank of phones at different times. For example, several telecommuting or hoteling employees can use the same office on different days of the week. The employees use PSA to “associate” with the office phone — that is, make the terminal “theirs” for the day. Calls an employee originates from the station are recognized and displayed as the employee’s calls, and calls routed to the employee’s extension route to the voice terminal “associated” with that extension.

A telecommuting or hoteling employee can also use PSA when working at home. For example, the employee installs a DCP terminal and a DEFINITY Extender at home, calls into the system, and uses PSA to associate the remote phone with their extension. The system associates the home terminal — that is, recognizes the home terminal as having the employee's preferences and permissions. When someone calls the employee's extension, the call rings at the employee's home. When the employee no longer needs to use the office, they "dissociate" from the terminal.

PSA requires users to enter a security code and can be used on-site or off-site. PSA-invalid attempts generate referral calls and are recorded by SVN software, if that feature is enabled. If a user interrupts the PSA dialing sequence by pressing the release button or by hanging up, the system does not log the action as an invalid attempt.

### **Detailed description**

---

The preferences and permissions that are retained with PSA include the definition of terminal buttons, abbreviated dial lists, and COS and COR permissions assigned to the your station. Extensions that do not have a COS, such as EAS agents or hunt groups, cannot use PSA.

PSA functions only on analog, hybrid, and DCP terminals. Many types of DCP terminals exist, and these terminals have different types and numbers of buttons. If you attempt to associate DCP stations with DCP terminals that have incompatible buttons, button mapping is unpredictable. This is also true of hybrid terminals. If you want a user to be able to use the terminal buttons and to have consistent displays, associate stations with terminals of the same type.

Stations and ports on different switches cannot be PSA associated. This includes stations on different switches (or nodes) within Distributed Communications. The system does not limit the number of stations that can use PSA. However, heavy use of the associate and dissociate functions may temporarily impact system performance.

When a call that goes to coverage from a PSA-disassociated extension, the switch sends a message to the coverage point indicating that the call was not answered. If the coverage point is a display phone, the display shows "da" for "don't answer." If the coverage point is a voice messaging system, the VM system receives an indication from the switch that this call was not answered, and treats the call accordingly.

## Dissociated telephones

When a user requests to associate a telephone with PSA, any other telephone using that extension is automatically dissociated. It is possible to place emergency calls from a dissociated telephone, provided a COR has been assigned to dissociated phones on the Feature-Related System Parameters screen.

PSA allows a dissociate request from a bridged appearance. However, when you execute a dissociate command from Terminal B, even if you are on a bridged appearance of an extension belonging to Terminal A, you dissociate the station belonging to Terminal B.

The dissociate function within PSA allows a user to restrict the features available to a phone. When a phone has been dissociated using PSA, it can be used only to call an attendant, to place an emergency call, or to accept a TTI or PSA request. To enable users to make other types of calls from dissociated sets, you must establish a class of restriction for these phones. See [“Setting up Personal Station Access” on page 360](#) for more information.

### NOTE:

Once a station has been associated with a terminal, anyone using the terminal has the capabilities of the associated station. Be sure to execute a dissociate request if the terminal can be accessed by unauthorized users. This is particularly important if you use PSA and DCP extenders to permit remote DCP access.

## Interactions

---

- Adjunct/Switch Application Interface

An ASAI link cannot use this feature because ASAI uses a BRI port. Do not assign to an ASAI link a Class of Service that allows PSA.

- Bridged Appearance

When you execute a PSA dissociate request for the principal station, its bridged appearances remain active if the stations on which they appear have not been dissociated. When a call is made to the principal extension, any of its bridged appearances that can be alerted are alerted. Otherwise, the call follows the principal extension's coverage path.

PSA dissociate requests executed at a bridged appearance dissociates the station that the bridged appearance is on.

- Call Management

PSA dissociate automatically logs out an ACD agent.

- Coverage

PSA does not change coverage path operations. If a station is dissociated, its calls still go to coverage unless they are forwarded.
- Property Management System

A station assigned to a room, rather than to a person who needs to work in multiple locations, should not use PSA. Such a station should not have PSA in its COS.
- Save Translations

PSA commands cannot be successfully executed during a save translations. When a reset 3 or greater (reset 4, reset 5, and so on) occurs on the system, all associations revert to their state as of the last save translations.
- Security Violation Notification (SVN)

PSA security violations are tracked and reported by SVN, if it is active.
- Tenant Partitioning

If a terminal is already associated, a user attempting a PSA associate request at that terminal must specify a station in the same partition as the station already associated with the terminal.

However, anyone, in any partition, can execute a PSA dissociate request at the terminal (if the associated station has PSA in its COS) and then execute a PSA associate request for a station in any tenant partition.

## Priority Calling

---

Priority Calling provides a special type of call alerting between internal telephone users, including the attendant. The called party receives a distinctive ring when the calling party uses Priority Calling.

You administer the priority-calling ringing-pattern system wide. Default is a 3-burst alerting signal. You allow feature use for each telephone user by administering the user's class of service.

The following types of calls are always priority-calling calls:

- Call coverage consult
- Automatic callback
- Ringback queuing
- Attendant intrusion
- Security violation notification

The system generates the call waiting ringback tone that a single-line telephone user hears even if the user is active on a call. In contrast, the system *does not* generate the pattern for a multiappearance telephone if there are no idle call appearances. In this case the caller hears busy tone. However, the system does generate the pattern if the telephone has an idle call appearance, including the one reserved for call origination.

## Interactions

---

- Abbreviated Dialing

If a user wants to make a priority call to a number in an abbreviated dial list, the Priority Calling access code and the AD code must be programmed on one button. If a user attempts to use Abbreviated Dialing (either by button or FAC after dialing the Priority Access Code, the system denies the call.
- Call Coverage

Priority Calling calls do not redirect to coverage unless the caller activates Go to Cover. If the call redirects, it remains a priority call, and the covering user receives a distinctive (default is three-burst) ringing signal.
- Call Forwarding All Calls

Priority Calling calls (except callback calls) are forwarded, and the forwarded call remains a priority call.

- **Call Vectoring**

The system generates intercept tone when someone attempts to activate Priority Calling toward a VDN.
- **Call Waiting**

A Priority Calling call waits on an active single-line telephone even if Call Waiting is not assigned to the telephone. The active, single-line telephone user receiving the call hears a distinctive (default is three-burst) priority Call Waiting tone.
- **Consult**

A Consult call acts as a priority call and waits at a single-line telephone, even if the telephone does not have Call Waiting Indication assigned.
- **Distributed Communications System (DCS)**

On a DCS tandem call to a single-line telephone, the called party does not receive priority ringing if the caller activates Priority Calling by pressing the priority button *after making a call*.
- **Last Number Dialed**

If a priority call is to be made to the last number dialed, the Last Number Dialed button must be used. The Last Number Dialed feature access code is not valid after Priority Calling has been activated.

Single-line telephones (2500 series) can be administered so that distinctive signals are not provided. In this case, 1-burst ringing is provided for priority calls.

### **Related topics**

---

To administer Distinctive Audible Alerting settings, see [“Feature-Related System Parameters” on page 795](#).

To allow Priority Calling, see [“Class of Service” on page 672](#).

## Recorded Telephone Dictation Access

---

Recorded Telephone Dictation Access permits phone users, including Remote Access and incoming tie-trunk users, to access dictation equipment.

Users start by dialing an access code or extension. Start/stop is controlled by voice or dialing. Initial activation and playback are controlled by dial codes.

Recorded Telephone Dictation Access cannot be used with the following features:

- Automatic Route Selection
- Conference

## Remote Access

---

Remote Access permits authorized callers to access the system via the public network from remote locations and then use its features and services. The Remote Access caller must use a touch-tone phone or equivalent equipment. Since the system does not have access to the calling (outside) number, Ringback Queuing and Automatic Callback cannot be used on a Remote Access call. Also, any feature requiring recall dial tone (for example, Hold and Transfer) cannot be accessed remotely.

Read the information in [“Security” on page 1802](#) before administering this feature.

 **SECURITY ALERT:**

*Avaya has designed the Remote Access feature incorporated in this product that, when properly administered by the customer, enables the customer to minimize the ability of unauthorized persons to gain access to the network. It is the customer's responsibility to take the appropriate steps to properly implement the features, evaluate and administer the various restriction levels, protect access codes, and distribute them only to individuals who have been advised of the sensitive nature of the access information. Each authorized user should be instructed on the proper use and handling of access codes.*

*In rare instances, unauthorized individuals make connections to the telecommunications network through use of remote-access features. In such an event, applicable tariffs require that the customer pay all network charges for traffic. Avaya cannot be responsible for such charges, and does not make any allowance or give any credit for charges that result from unauthorized access.*

## **Detailed description**

---

Remote Access provides you with access to the system and its features from the public network. This allows you to make business calls from home or use Recorded Telephone Dictation Access to dictate a letter. If authorized, you can also access system features from any on-site extension.

With Remote Access, you can dial into the system using DID, CO, FX, or 800 Service trunks. When a call comes in on a trunk group dedicated to Remote Access, the system routes the call to the Remote Access extension you have assigned. If DID is provided and the Remote Access extension is within the range of numbers that can be accessed by DID, Remote Access is accessed through DID.

Upon access to the feature, you hear system dial tone. If you have administered your system to require a barrier code or authorization code, the system requires you to enter it now. When you enter the required codes, the system generates dial tone. You can now place local or long-distance calls as allowed.

Barrier codes provide your system security and define calling privileges through the administered COR. You can administer up to 10 barrier codes, each with a different COR and COS. Barrier codes can be from 4 to 7 digits, *but all codes must be the same length*. You can also require that users enter an authorization code to use this feature. Both barrier codes and authorization codes are described under [“Security” on page 1802](#).

The destination of incoming non-DID trunk calls can be an attendant or an extension. The destination is specified on each individual trunk group. When the trunk group is dedicated to Remote Access, the Remote Access extension is specified. In this case, you do all dialing. If an attendant is needed on a call, you dial the public network telephone number assigned, the barrier code, and the attendant access code. You can administer your system to provide attendant-assisted calling during the day but Remote Access after normal business hours. You do this by setting the trunk group Incoming Destination field to the attendant (attd), and specifying the Remote Access extension as the Night Service extension .

After a Digital Terminal Data Module's (DTDM) baud rate is changed from 9600 to 1200, the DTDM cannot be accessed by Remote Access until an internal call is made to the DTDM.

## Security

---

The system provides the ability to check the status of the remote access feature and barrier codes. The **status remote-access** command displays information that can help in determining why and when use of Remote Access or a particular barrier code was denied. The display indicates if Remote Access is:

- Not administered
- Enabled
- Disabled
- Disabled following detection of a security violation

It also gives the date and time Remote Access was last modified.

For each barrier code, the command displays:

- Date the code was administered, reactivated, or modified
- Expiration date
- Number of calls that can be placed with the code
- Number of calls that have been placed using the code
- Whether the code is active or expired
- Date and reason a code expired

For a detailed description of the status remote-access command and display, see *BCS Products Security Handbook*.

## Barrier Codes

Remote Access has inherent risks; it can lead to large-scale unauthorized long-distance use. To increase your system's security, use a 7-digit barrier code with Remote Access Barrier Code Aging. You can administer the Remote Access Barrier Code Aging feature to:

- Limit the length of time an access code remains valid
- Limit the number of times an access code can be used
- Both of the above

You must administer expiration dates and access limits for each of the possible 10 barrier codes. If your system has more than 10 Remote Access users, they must share codes. A barrier code automatically expires if an expiration date or number of accesses has exceeded the limits you set. If both a time interval and access limits are administered for a barrier code, the barrier code expires when one of the conditions is satisfied.

If barrier codes are administered, a special answer-back tone causes a calling modem to leave dial mode. A modem's dialer is sometimes used to gain access (this tone also cancels echo suppressors in the network, preventing DTMF tones from breaking dial tone from a switch). Barrier codes can be used alone or with authorization codes.

To view the status of a Remote Access barrier code, use the status remote-access command.

### NOTE:

Barrier codes are *not* tracked by Call Detail Recording (CDR). Barrier codes are incoming access codes, whereas, authorization codes are primarily outgoing access codes.

When you no longer need a barrier code, remove it from the system. Barrier codes should be safeguarded both by you and their users.

## Authorization Codes

You can also administer authorization codes to manage access to your system. You can then use CDR to track this code use. Use these guidelines to manage your system's authorization codes.

- Assigning codes — Create random codes; do not allow them to follow a predictable pattern. Use the maximum code length allowed and assign a unique code to each person responsible for protecting the code.
- Changing codes — Change codes often.
- Deleting codes — Delete codes when they are no longer needed.
- Monitoring codes — Use CDR reports to analyze code use.

## Alternate Facility Restriction Levels

Consider changing FRLs with AFRLs after normal business hours to restrict where calls can be made over your facilities. Take care not to restrict callers from summoning emergency services after hours.

## Class of Restriction

The COR of an authorization code supersedes that of a barrier code.

- Time of Day Routing — Controlled by the time-of-day entries in COR or by the partition.
- Toll Restriction and Analysis — Controlled by COR.
- Trunk Access Code — Interacts with toll restriction. You can translate your switch so users can make toll calls via ARS without using a trunk access code.
- Trunk Administration — Remote Access trunks can be restricted.

For additional steps to secure your system and to find out about obtaining security information on a regular basis, see the *BCS Products Security Handbook*.

## Logoff Notification

Use Logoff Notification when Remote Access is enabled, but not actively used. Logoff Notification notifies you at logoff that Remote Access is enabled. It guards against inadvertently leaving Remote Access active and can also alert you to unauthorized feature activation. Logoff Notification is administered by login ID.

## Interactions

---

- Authorization Codes  
When a Remote Access caller dials the assigned Remote Access extension and connects to the system, the system may request the caller to dial an authorization code in addition to a barrier code. Dial Tone between the barrier code and authorization code is optional. Calling privileges associated with the COR assigned to the authorization code supersede those assigned to the barrier code.
- Class of Restriction  
COR restrictions do not block access to the Remote Access feature.
- Night Service  
The Remote Access extension can be specified as the Night Service extension on an incoming, non-DID, trunk group.

## Reset Shift Call

---

Reset Shift Call allows users to redial a local or private network call by pressing a single digit. The switch plays reset shift dial tone on busy calls if:

- A station or attendant originates a call
- The dialed endpoint is in the dial plan and is one of the following types:
  - Extension (local or UDP)
  - Prefixed extension (local or UDP)
  - AAR
- The destination is on the same switch as the originator, or is connected via an ISDN trunk to the originating switch

When the caller hears reset shift dial tone, they can press a single digit that replaces the last digit of the originally-dialed destination and the call transfers to the new destination. This feature is useful, for example, where extensions are assigned sequentially to functional organizations.

The originator and destination of the call both must be connected to Avaya MultiVantage. In DCS or QSIG environments, both must be on the same DCS or QSIG networks, but do not need to be connected to the same Avaya MultiVantage.

## Interactions

---

- Automatic Alternate Routing (AAR)

If a user dials the AAR feature access code followed by destination digits to place a call and the destination is busy, reset shift dial tones is heard. If the user then dials a new destination last digit, a new call is placed and the display updates as if the AAR feature access code, followed by the new destination, was dialed originally.

- Bridged Call Appearance

If set A has a bridged appearance on set B, and both users A and B are off-hook on that bridged appearance, and set A calls set C, and set C is busy, both A and B hear reset shift dial tone. If set B then presses a single digit, the digit is ignored and both A and B continue to hear reset shift dial tone. Set A must dial the new destination last digit.

- Distributed Communications System (DCS)

Reset shift call works in a DCS network over ISDN trunks. DCS+ and QSIG networks always support reset shift calls.

- Forwarding

If the called destination is forwarded to station A and station A is busy, the switch applies reset shift dial tone.

If a user dials to a forwarded set and then gets reset shift dial tone, and enters a digit, the number dialed by the reset shift call feature is 1 digit off from the original user-dialed number, not the forwarded-to number.

- Hot Line Service

If a station set user with hot line service reaches a busy endpoint, the user hears busy tone and not reset shift dial tone.

- Intercom

- Dial

If a user lifts the handset, presses the DIAL INTERCOM button, dials the 1-digit or 2-digit intercom code assigned to another set, and reaches a busy set, the switch plays busy tone, not reset shift dial tone.

- Automatic

If a user lifts the handset, presses the AUTOMATIC INTERCOM button, and reaches a busy set, the switch plays busy tone, not reset shift dial tone.

- **Last Number Dialed**

If a user hits a LAST NUMBER DIALED button while listening to reset shift dial tone, the button press is denied.

If a user uses last number dialed after having used reset shift call on the last call, the switch re-attempts the last special-dialed call.

- **Line Lockout**

An analog user listening to reset shift dial tone is not subject to the line intercept tone timer.

- **Line Side DS1**

A call originated from a line side DS1 station (ds1fd, ds1sa, ops, vrufd, vrusa) is considered a station originated call.

- **Multimedia Call Handling**

If a user at a multimedia complex presses the MM-CALL button or dials the multimedia-origination feature access code after receiving dial tone, and then reaches a busy set and uses the reset shift call feature, the resulting new call attempt will be a multimedia call attempt.

- **Priority Calling**

If a user dials the priority calling feature access code or presses a priority call button, dials a busy station, and then uses the reset shift call feature, the switch makes a priority call to the substituted destination.

- **QSIG**

Reset shift call does work in a QSIG network if the QSIG network configuration allows the ISDN busy signaling to always propagate back to the originating switch, which may not be the case if the network includes non-Avaya trunks and/or switches.

- **Remote Access**

A call originated from a remote access extension does not receive reset shift dial tone.

## **Remotely readable electronic phone IDs**

---

Remotely readable electronic identification allows the switch to read a serialized DCP telephone's part number (comcode) and serial number. Avaya can use this information to determine the proper maintenance replacement unit or the date of manufacture for warranty or QPPCN status.

The remotely readable electronic identification is currently only available with the 6400 Serialized DCP telephones. The 6400 Serialized phone is stamped with the word “Serialized” on the faceplate for easy identification.

The remotely readable electronic ID allows both you and Avaya service personnel to obtain more accurate information about the phone, thus simplifying the repair process. With this new functionality, the serial numbers for phones can be entered into trouble tickets manually so that Avaya can identify the problem more easily. In addition, this feature enables the switch to read the model number of DCP phone types whose electronic IDs are not remotely readable.

Phones with remotely readable IDs show whatever information is available for phones connected to a DEFINITY Extender, provided that the Extender has an active connection with the switch.

## Ringer Cutoff

Ringer Cutoff allows multiappearance telephone users to turn audible ringing signals on and off. This feature does not affect visual alerting.

When this feature is enabled, only Priority ring (by default 3-burst), Redirect Notification, Intercom ring, and manual signaling ring at the telephone. Internal and external calls do not ring.

The following table summarizes which calls are affected by Ringer Cutoff.

| Call Type                  | Redirect notification is |           |
|----------------------------|--------------------------|-----------|
|                            | Inactive                 | Active    |
| telephone to telephone     | no                       | ring ping |
| Attendant to telephone     | no                       | ring ping |
| Internal tie to telephone  | no                       | ring ping |
| APLT trunk to telephone    | no                       | ring ping |
| Trunk to telephone         | no                       | ring ping |
| Priority call to telephone | yes                      | yes       |
| Intercom call to telephone | yes                      | yes       |
| Manual signaling           | yes                      | yes       |

**⇒ NOTE:**

If Call Coverage is set to Cover All and Ringer Cutoff and Redirect Notification are both active, then Redirect Notification is received. If Redirect Notification is not active, no audible alerting is received.

A user may not wish to be disturbed by the arrival of incoming calls, yet not want calls to be redirected immediately to coverage. For example, an executive may want a secretary to answer calls before they redirect to coverage. The bridging user (the secretary) is not affected by the executive's activation of Ringer Cutoff.

If a primary extension and all other users with bridged appearances of the primary extension activate Ringer Cutoff, an incoming call silently alerts all of the telephones and then redirects to coverage.

### Interactions

---

- **Automatic Callback**

If Ringer Cutoff is active, an Automatic Callback call returns to the user's telephone with the normal 3-burst ring.

- **Bridging**

A bridging user is not affected by a primary extension's activation of Ringer Cutoff. Nor is the primary extension affected by the bridging user's activation of Ringer Cutoff.

- **Call Forwarding All Calls**

If Ringer Cutoff and Call Forwarding All Calls are active, the user receives redirect notification, if you set Redirection Notification to **y** for the extension.

- **Distinctive Ringing**

Ringer Cutoff turns off only the distinctive ringing of internal and external calls. Intercom ringing, priority ringing, redirect notification, and manual signaling are not turned off.

- **Intercom**

If Ringer Cutoff is active, intercom calls still ring the user's telephone.

- **Manual Signaling**

If Ringer Cutoff is active, Manual Signaling still rings the user's telephone.

- **Ringback Queuing**

If Ringer Cutoff is active, the return call for Ringback Queuing still rings the user's telephone with a 3-burst alerting signal.

- **Priority Calling**

If Ringer Cutoff is active, priority calls still ring at the user's telephone.

- **Send All Calls**

When Ringer Cutoff and Send All Calls are both active, the user receives redirect notification, when Redirection Notification is set to **y** for that extension.

## **Ringling — Abbreviated and Delayed**

---

Ringling — Abbreviated and Delayed allows you to assign one of four ring types to each call appearance on a telephone. Whatever treatment is assigned to a call appearance is automatically assigned to each of its bridged call appearances.

### **Detailed description**

---

Ring types fall into two categories:

- Those that alert consistently and don't change:
  - Ringing, in which the lamp flashes and audible ringing occurs
  - Silent ringing, in which the lamp flashes and audible ringing does not occur
- Those that transition from one ringing state to another:
  - Abbreviated ringing, in which ringing continues for as many cycles as specified by the automatic abbreviated/delayed transition interval and then changes to silent alerting
  - Delayed ringing, in which visual alerting continues for as many cycles as specified by the automatic abbreviated/delayed transition interval and then changes to ringing

For a station with call appearances that have either abbreviated or delayed ringing, an abbreviated-ring button associated with that station's extension can be assigned on a different station. When one of those call appearances is being alerted, pressing the button forces immediate transition of the alerting — that is, from ringing to silence or from silence to ringing.

This feature is most useful in bridging situations in which some users want to be:

- Audibly alerted to a call immediately upon its arrival
- Audibly notified if the call has not been answered within a specified number of rings or if they have indicated.
- Able to stop the audible alerting if the call is not being answered by the principal and the user is not able to answer the call.

Because ring type can be specified on a per-station basis, mixing ring-type specifications within a station's access to a particular extension is possible.

For Ringling — Abbreviated and Delayed, each call appearance must be:

- Assigned a ring type
- Administered to transition when the:
  - Abbreviated/delayed transition interval is reached or when the user presses the abbreviated ring button
  - user presses the abbreviated ring button, regardless of the abbreviated/delayed transition interval

## **Considerations**

---

- You cannot assign Ringling — Abbreviated and Delayed to an attendant console.
- You can assign Abbreviated and Delayed Ringling to analog stations. However, because analog stations cannot visually alert, a user may unexpectedly answer an incoming call while intending to originate a call.

## **Interactions**

---

- Call Coverage

If the number-of-rings interval for coverage is shorter than the automatic transition interval, a call redirects to coverage before audibly alerting a call appearance that has delayed ringing. However, timing continues for the automatic transition interval in case no coverage point is available and the call continues to alert at the station.

When a call is immediately redirected to coverage, the Abbreviated and Delayed ringing has no effect.

- Call Forwarding — Busy/Don't Answer

When a call is forwarded because it is not answered in the specified time, the call stops alerting the station and is not affected by the Ringling — Abbreviated and Delayed feature. However, timing continues for the automatic transition interval in case forwarding fails and the call continues to alert at the station.

If the call forward don't answer interval is shorter than the automatic transition interval, the call redirects to the forwarded-to extension before ringing a station with a ring type of delayed ringing.

- Call Vectoring — Expert Agent Selection — Logical Agents

Calls routed to a logical agent use the translations for the Ringling — Abbreviated and Delayed feature of the station being used by the agent.

- Data Extension Calls

Data Extension calls are not affected by the ring values, but continue to be directed by the bridged call alerting administration.

- Hospitality Features — Do Not Disturb

The Do Not Disturb feature takes precedence over the Ringing — Abbreviated and Delayed feature in blocking ringing to the station.

- Integrated Services Digital Network (ISDN) — World Class Basic Rate Interface

Several of the protocol variations supported by the World Class BRI feature do not permit the messaging required for control of the station's ringer by Ringing — Abbreviated and Delayed. In this case, ring type is forced to a value of ring.

- Multiappearance Preselection and Preference

The system automatically selects any alerting call on a station whether or not it is ringing if the Per Button Ring Control field is set to **n**. If the field is set to **y**, it selects only audibly ringing calls.

- Off-Premises Station and Off-Premises Extension Lines

You must use ring type of “ring” for OPS and OPX lines.

- Personal Central Office Line (PCOL) Calls

PCOL calls are not affected by the ring values, but continue to be directed by the bridged call alerting administration.

- Redirection Notification

If Redirection Notification is enabled, terminals only receive redirection notification if the alerting button or the first call appearance has an assigned ring value of ring or abbreviated ring.

- Terminating Extension Group (TEG) Calls

TEG calls are not affected by the ring values, but continue to be directed by the bridged call alerting administration.

- Voice Mail Systems

Voice mail systems may look for ringing applied to a port to trigger call answer. Undesirable adjunct operation may result if ring-type translations are inappropriately set for ports serving these adjuncts.

## Security violations notification

---

When a security violation occurs, security violations notification (SVN) notifies a designated referral point. This can be an attendant console, a display-equipped phone, or a phone without display for SVN referral calls with announcements.

The system monitors and reports on the following types of security violations:

- Login violations
- Remote access barrier code violations
- Authorization code violations
- Station security code violations

Avaya MultiVantage provides the option to log a major alarm if a security violation occurs involving an Avaya services login ID. Avaya is responsible for retiring the alarm.

See *Reports for Avaya MultiVantage™ Software* for more information on how to run reports, and respond to security violations.

To effectively monitor the security of your system, you need to know how often both valid and invalid attempts at system entry are normally made. Then you will know if the number of invalid attempts is unusually high. A significant increase in such attempts can mean the system is being compromised.

### NOTE:

Avaya recommends that you print and clear the security-violation measurement reports at least once a month. In a busy system, once a week is not too frequent.

## Security violation thresholds and notification

As an example, you may determine that during a forty-hour week, it's normal for users to submit about 1,000 valid barrier codes and 150 invalid barrier codes; that is, about 3.75 invalid barrier codes are submitted per hour.

With this information, you may decide to declare that a security violation occurs during any hour in which 8 invalid barrier codes are submitted. If you know that during an 8-hour period, about 30 invalid codes are submitted, you might set the threshold to count a security violation when 40 invalid codes are submitted within eight hours.

You can administer SVN to place a referral call to the location of your choice whenever the established thresholds are reached. All SVN referral calls are priority calls.

Invalid attempts accumulate at different rates in the various security arenas (login, authorization code, remote access, and station security code), depending on feature usage and the number of users on a server. For this reason, you administer thresholds separately for each type of violation.

## Sequence of events

The following is the sequence of events that occur when an SVN is enabled and a detects a security violation:

1. SVN parameters are exceeded (the number of invalid attempts permitted in a specified time interval is exceeded).
2. An SVN referral call (with announcements, if assigned) is placed to a designated point, and SVN provides an audit trail containing information about each attempt to access the switch.
3. SVN disables a login ID or Remote Access following the security violation.
4. The login ID or Remote Access remains disabled until re-enabled by an authorized login ID, with the correct permissions.

## Reporting

The system reports information about security violations in the following ways:

- **In real time** — you can use the **monitor security-violations** command to monitor security violations as they may be occurring. Enter this command, followed by the type of security violation you want to monitor (logins, remote-access, authorization-codes, or station-security-codes).
- **On an immediate basis** — when a security violation occurs, the system sends a priority call to a designated referral point (attendant console or phone). Thus, there is some chance of apprehending the violator during the attempted violation.

Upon notification, you can request the Security Violations Status Reports , which show details of the last 16 security violations of each type. The Barrier Code and Authorization Code reports also include the calling party number from which the attempt was made, where available.

- **On a historical basis** — the number of security violations of each type, as well as other security measurements, are collected and displayed in the Security Violations Summary and Detail reports. These reports show summary information since the counters were reset by the **clear measurements security-violations** command or since system initialization. They do not show all aspects of the individual security violations.

## SVN- halt buttons

You can administer buttons for the notification extension to stop notification calls. However, this may pose a security risk. Do not use these buttons if you do not really need them.

To find out what svn-halt buttons exist in the system, type **display svn-button-location** and press RETURN.

The SVN Button Locations screen appears.

## SVN Referral Call With Announcement

The SVN Referral Call with Announcement option has the capacity to provide a recorded message identifying the type of violation accompanying the SVN referral call. Using Call Forwarding, Call Coverage, or Call Vector Time-of-Day Routing (to route to an extension or a number off the switch), SVN referral calls with announcements can terminate to a point on or off the switch.

Use of other means to route SVN referral calls to alternate destinations are not supported at this time. An attempt to use an alternate method to route SVN referral calls may result in a failure to receive the call or to hear the announcement.

## Considerations

---

- You may only administer one referral destination per system for each type of violation.
- Exercise caution when administering bridged appearances for stations that are used as SVN referral destinations. SVN referral calls terminating to bridged appearances *must* be accompanied by an announcement message or *must* route to bridge appearances equipped with a display module. SVN referral calls that do not have an announcement and terminate to a bridged appearance not having a display will not provide an indication of the nature of the call.
- An authorization code violation with remote access generates two SVNs -- one displaying “authorization code violation” and one displaying “barrier code violation,” even though the correct barrier code was input. These two displays help you determine that the violation took place in the context of a remote access attempt, not an attempt to place an outgoing call to an ARS trunk.

## Interactions

---

- Call Coverage, Call Forwarding, and Call Pickup  
These items are supported for SVN only if you use recorded announcements.
- Centralized Attendant Services (CAS)  
CAS attendants cannot receive referral calls from branch locations.
- Distributed Communications System (DCS)  
SVN does not support referral calls across a DCS network.

## Service observing

---

Designated users, normally supervisors, can listen to other users' calls. This capability is often used to train agents and monitor service quality in call centers and other environments where employees serve customers over the phone. On MultiVantage, this is called "service observing" and the user observing calls is the "observer."

This section describes service observing in environments without ACD or call vectoring. See *Avaya MultiVantage™ Call Center Software Guide to ACD Call Centers* to use service observing in those environments.

### Brief description

---

Observers can monitor calls to any of the following:

- an extension
- a VDN (on systems with call vectoring)
- a logical agent ID (on systems with Expert Agent Selection)

Note that service observing allows you to observe calls to one particular extension, not all calls to all extensions at a terminal.

Observers can monitor calls in one of two modes: "listen-only" or "listen-and-talk." The latter permits an observer to hear and speak with all parties on a call. The person being monitored doesn't know an observer is listening to the call unless you administer Avaya MultiVantage to provide a monitoring tone.

 **WARNING:**

*Listening to someone else's calls may be subject to federal, state, or local laws, rules, or regulations. It may require the consent of one or both of the parties on the call. Familiarize yourself with all applicable laws, rules, and regulations and comply with them when you use this feature.*

Observers can use remote access to monitor calls when they're off-site. In systems with call vectoring, a vector can control access to service observing.

## How to observe calls

Observers press the service observing button on their phone or dial a feature access code, and then dial the extension they want to observe. When using a service observing button, observers start in listen-only mode and can toggle between listen-only and listen/talk mode by pressing the button. The button lamp indicates which mode the observer is in.

If a service observer is in the wait state (waiting for an eligible call), the only visual indication the station/agent is observing is if the observing station has a Service Observe button administered. When this happens, the Service Observe button flutters while the observer is waiting, and the button is lit steady when the observer is actively observing a call.

If service observing is activated via the Service Observing feature access code, and there is no Service Observe button administered on the set, there will be no call appearance reserved while the call remains in the wait state. An idle call appearance must be available for the user to go to the observing state when a new eligible call arrives.

By contrast, there are different feature access codes for listen-only and listen-and-talk modes. When observers initiate sessions with a feature access code, they must choose one of the two modes at the start of the session. They cannot switch to the other mode without ending the session and beginning another. The feature access codes for service observing are:

- Service Observing Listen Only Access Code
- Service Observing Listen/Talk Access Code

### NOTE:

Feature access codes are required for remote observing.

An observer can observe an agent who is not active on a call. The observer is in wait state until the agent receives a call, and then the observer is bridged onto the call.

To deactivate Service Observing, the observer hangs up, selects another call appearance, or presses the disconnect or release button.

## Restrictions

Two observers can't monitor the same extension or the same call simultaneously. If user A is observing an extension and user B tries to observe it, B gets a busy signal. If 2 extensions are being observed independently and one calls the other, only the observer of the calling extension observes the call. The observer of the called extension goes into wait state until the call is over.

## Phone displays

A local observer's phone display shows exactly what is displayed on the observed phone's display, followed by the letters "so".

## Trunk calls

If a user makes a trunk-call, observation starts after the user finishes dialing. On central office (CO) trunks, dialing is considered complete when answer supervision is returned or when answer supervision timeout occurs.

Service observing cannot be activated over trunks without disconnect supervision. Any attempt is denied.

## Warning and conference tones

If you administer a tone to notify the parties on a call when they are being observed, you can choose between a warning tone and conference tone. If you select warning tone, a unique 2-second, 440-Hz warning tone plays before an observer connects to the call. While the call is observed, a shorter version of this tone repeats every 12 seconds. If you select conference tone, all parties will hear conference tone before an observer connects to the call. However, unlike warning tone the conference tone is not repeated.

## Interactions

---

- Attendants  
An attendant can be observed but cannot be an observer.
- Bridged Appearances  
You can only observe calls on primary extensions, not on bridged appearances. For example, let's say you're observing extension 3082 and this phone also has a bridged appearance for extension 3282. You can't observe calls to 3282.
- Busy-Verification  
You can't observe an extension that's being busy-verified. You can't busy-verify an extension that's being observed.
- Call Coverage/Call Pickup  
An observer cannot observe a call answered by a covering agent or a member of a pickup group unless the called agent bridges onto the call.
- Call Park  
An observer cannot park the call they are observing.

- **Call Waiting**

Incoming calls cannot wait on a single-line phone that is being observed.
- **Conference**

Observers cannot initiate a conference while observing.

If an observed user starts a conference or enters a conference with fewer than 6 parties, the observer is placed in wait state until the call is connected. Then the observer observes the conference and is counted as one party in the conference. (Conference members are observed during a conference regardless of their Class of Restriction (COR) setting.) In addition, the observer is bridged onto any calls the user makes or receives before the conference is complete. When the user leaves the conference, the observer also leaves and returns to observing the original call.
- **Data Privacy**

You can't observe an extension on which Data Privacy is active. You also can't observe an extension while it's on a conference call with another extension using Data Privacy.
- **Data Restriction**

You can't observe an extension on which Data Restriction is active. You also can't observe an extension while it's on a conference call with another extension using Data Restriction.
- **Integrated Directory**

Observers do not hear users dialing when the latter use this feature.
- **Distributed Communications System (DCS)**

To observe stations on another node (a DCS station extension), you must set up remote-access service observing. Service observing displays are not transmitted across DCS networks.
- **Hold**

Observers cannot place calls on hold while they're observing. If a user places a call on hold, the observer enters wait state.
- **IP Solutions**

If you service observe into an ip-ip direct call, the people on the call may hear a break in conversation of about 200 ms.
- **Leave Word Calling (LWC)**

Parties on an observed call cannot use LWC.
- **Music-on-Delay/Music-on-Hold**

If an observer is in listen/talk mode, neither caller nor observer hears music-on-hold. If an observer is in listen-only mode, the caller hears music-on-hold but the observer does not.

- Privacy — Manual Exclusion

You can't observe an extension on which Privacy — Manual Exclusion is active. You also can't observe an extension while it's on a conference call with another extension using Privacy — Manual Exclusion.

- Transfer

Observers cannot initiate a transfer while observing.

If a user transfers a call, the observer is placed in wait state. The observer is bridged onto the call when the transfer is complete.

### Related topics

---

See [“Setting up automatic answer intercom calls” on page 486](#) to administer service observing.

## Single-Digit Dialing and Mixed Station Numbering

---

Single-Digit Dialing and Mixed Station Numbering allows easy guest access to internal hotel/motel services and provides the capability to associate room numbers with guest-room telephones.

### Detailed description

---

You must create a dial plan for hotel/motel services and room numbers. (See [“Dial Plan Analysis Table” on page 748](#) for more information about creating a dial plan.)

Some suggestions follow.

- Assign a single-digit extension to internal hotel/motel services such as room service. Assign single-digit extensions to individual-telephones or to a group of telephones (for example, to service the front desk).
- Assign a prefixed extension to guest rooms.

A prefixed extension is still made up of a prefix and an extension up to **five** digits. The prefix identifies the call type. The switch collects dialed digits, removes the prefix digit, and uses the extension for further processing.

- Mixed station numbering extensions can have from one to seven digits and can begin with any digit from 0 to 9.

The first digit, in combination with the number of digits dialed, defines the call type. To differentiate between two numbers with the same leading digit but different lengths, the system monitors the interval after a digit is dialed and before the next digit is dialed. If the interval extends past the administered interdigit timeout, the system assumes that dialing is complete and calculates the number of digits dialed up to that point.

### Examples

```
change dialplan analysis Page 1 of 3 SPE A

| 8             | 1            | dac       |               |              |           |               |              |           |
| 9             | 1            | dac       |               |              |           |               |              |           |
| *             | 2            | fac       |               |              |           |               |              |           |
| #             | 2            | fac       |               |              |           |               |              |           |

Dial plan 1 allows the following dial access:

- Single-digit access to the hotel/motel attendant (0)
- Ten dial-access codes (DACs) beginning with the digit 1 (10 through 19)
- Single-digit access to five hotel/motel services (2, 3, 4, 6 and 7)
- Nonprefixed access to as many as 100 hotel/motel staff extensions (500 through 599)
- Guest room extensions for as many as 100 floors
  - Access to floors 1 through 9 (prefix digit 6 + [100 through 999])
  - Access to floors 10 through 99 (prefix digit 7 + [1000 through 9999])
- Toll-call access via DAC 8

- Local calling via ARS DAC 9
- 2-digit feature-access codes (FACs) [\* or # plus another digit]

```

3 3 ext 9 1 dac
4 1 ext * 2 fac
4 2 ext # 2 fac
4 3 ext
5 1 ext

```

Dial plan 2 allows the following dial access:

- Single-digit access to the hotel/motel attendant (0)
- Single-digit access to seven hotel/motel services (extensions 1 through 7)
- 2-digit access to 70 hotel/motel services (extensions 10 through 79)
- Guest-room extensions for floors 1 through 7 (extensions 100 through 799)
- Toll-calling access via DAC 8
- Toll-calling access via ARS feature access code 9
- 2-digit FACs (\* or # plus another digit)

Cancel timeout intervals if the user dials # after dialing all required digits.

When using prefixed extension numbers, it is not necessary to include an entry for the "real" extension number in the dial plan. The server is able to complete a call using the prefixed extension number. When dialing 7345 (where 7 is the prefix), the communications server will ring extension 345.

When using a dial plan like the one above, which includes both prefixed and non-prefixed extensions, dialing 567 instead of 4567 will ring an administrative extension instead of a room.

The dialing delays, which may not be perceived by hotel guests, will occur when dialing 6 and 7. The server must wait for the 3- to 9-second interdigit timeout to expire before the call will be sent. The user can preempt the timer by pressing the # key after the number has been dialed.

**NOTE:**

When using prefixed extensions, the extension that shows up on a display phone does not show the prefix. The prefix will not show up on CDR reports. If extension number 3315 is prefixed with a 6 and the dial plan shows 3xxx for extensions, it is possible to dial either 3315 or 63315 to reach extension 3315. If the dial plan was changed to remove the entry for extensions in the 3xxx block, then 3315 could be reached only by dialing 63315.

## Considerations

---

- Mixed Station Numbering allows guest room numbers and room extensions to be the same.
- You cannot assign prefixed extensions longer than seven digits (including prefix) to intercom lists.
- A TAC and an extension can share a first digit only if the extension is shorter than the TAC.
- Although extensions with the same first digit can have different lengths, data-channel extensions must have the maximum number of digits to avoid timeout problems for data calls that the switch automatically sets up, for example, via the CDR link.
- An extension and a FAC can share the same first digit only if the extension is longer as long as they are not used for AAR/ARS faxes. These extensions work only within the switch; they do not work as remote UDP extensions.
- You should administer the Short Interdigit Timeout on the [Feature-Related System Parameters](#) screen to ensure that the delay between the end of dialing and call completion is not too long.

## Interactions

---

- Attendant Display and Telephone Display  
Prefixed extensions display without the prefix. The return call button causes the prefix to dial, even though it does not display.
- Property Management System (PMS)

- PMS products accept only extensions of 5 digits or shorter. Therefore, a customer using PMS cannot use 6/7-digit extensions
- .Uniform Dial Plan (UDP)

The following limitations apply to a DCS environment:

- Extensions that differ in length from the UDP do not distribute to other switches.
- If the first two digits of an extension correspond to the floor number, floors cannot be serviced by more than one switch.

## Station Hunting

---

Station Hunting routes calls made to a busy station down a chain of stations until one is found that is not active.

### Detailed description

---

To use Station Hunting, you create a station hunting chain that governs the order in which a call routes from one station to the next when the called station is busy. Each station in the chain links to only one subsequent station. However, any number of stations may link to one station.

The system updates the calling party’s display with “h” when the system begins checking the station-hunting chain. Likewise, the system updates the display of the station that is hunted-to (the station that takes the call) with an “h.”

Calls route through the chain as follows.

**Table 59. Station hunting characteristics**

| Condition                                                         | Response                                 |
|-------------------------------------------------------------------|------------------------------------------|
| Encounters an idle extension                                      | Rings extension                          |
| Encounters an active extension                                    | Routes to next extension in chain        |
| Encounters an extension with a blank hunt-to station field        | Returns busy tone if no station was idle |
| Encounters any station a second time                              | Returns busy tone                        |
| Has checked 30 stations in the chain, without finding an idle one | Returns busy tone                        |

There is no limit to the number of extensions that can be in a station-hunting chain.

## Station Hunting examples

In this example (Table 60), extension 2 is the called extension. Because extension 2 is busy, the system follows the station-hunting chain to find an idle extension. The system cannot find an idle extension so it returns busy tone to the caller. Note that the chain terminates with extension 5. This means that the system cannot route the call to extension 1 even though it is an idle extension in the chain.

**Table 60. Station-Hunting chain — Example 1**

| Extension | State  | Rings on extension |
|-----------|--------|--------------------|
| 1         | Idle   | 2                  |
| 2         | Busy   | 3                  |
| 3         | Active | 4                  |
| 4         | Active | 5                  |
| 5         | Busy   |                    |

In this example (Table 61), extension 2 is the called extension. Because extension 2 is busy, the system follows the station-hunting chain to find an idle extension. The call is answered at extension 1.

**Table 61. Station-Hunting chain — Example 2**

| Extension | State  | Rings on extension |
|-----------|--------|--------------------|
| 1         | Idle   | 2                  |
| 2         | Busy   | 3                  |
| 3         | Busy   | 4                  |
| 4         | Active | 5                  |
| 5         | Active | 1                  |

In this example (Table 62), extension 2 is the called extension. Because extension 2 is busy, the system follows the station-hunting chain to find an idle extension. The system encounters extension 3 a second time without finding an idle station. The system stops checking the station-hunting chain and returns busy tone to the caller. Notice that both extensions 5 and 2 link to extension 3.

**Table 62. Station-Hunting chain — Example 3**

| Extension | State | Rings on extension |
|-----------|-------|--------------------|
| 1         | Idle  | 2                  |
| 2         | Busy  | 3                  |
| 3         | Busy  | 4                  |
| 4         | Busy  | 5                  |
| 5         | Busy  | 3                  |

### Station hunting options

You can administer the system to perform station hunting prior to sending calls to coverage. The Station Hunt Before Coverage option on the System-Parameters Call Coverage/Call Forwarding screen provides that when a call is made to a busy station, the switch checks to see if there is a hunt-to station assigned to the busy station. If there is, the switch tries to connect to the hunt-to station before going to coverage. If the hunt-to station is also busy, the switch continues hunting down the hunt-to chain. If all stations in the hunt-to chain are busy, the call goes to the dialed station's coverage.

### Administration commands

When you remove a station, the system attempts to maintain a station-hunting chain. Consider the following examples:

- Station 1 links to 2 and 2 links to 3. If you remove station 2, the system links 1 to 3.
- Station 1 links to 2. Station 2 does not link to another extension. If you remove station 2, 1 no longer links to another extension.

When you duplicate a station, the extension in the hunt-to station field is not copied into the duplicated station.

When you execute "**list usage extension xxxxx**," the system displays all stations that contain the station's extension as their hunt-to station.

## Interactions

---

Remember that the system checks the station-hunting chain only for idle and available extensions.

- Adjunct Switch Applications Interface (ASAI)

The system attempts Station Hunting when ASAI routes to an extension with a hunt-to station.

- Automatic Call Distribution (ACD)

An agent extension can be part of a station-hunting chain. The system hunts the agent's chain only when the call is made directly to the agent's extension. Calls distributed through hunt groups to an ACD agent do not hunt the agent's station-hunting chain. Calls made to an extension for logical agents do not hunt the agent's station-hunting chain.

- Automatic Callback

The system does not hunt the chain of the called extension when the call is a callback-return call.

- Bridged Appearance

The system hunts the extension's station-hunting chain if the principal station has no call appearance at which the call can terminate, even though it may have available bridged appearances on other stations.

- Busy Verification

The system does not attempt Station Hunting for busy-verify calls.

- Call Coverage

Call Coverage has precedence over Station Hunting.

Station Hunting is applied to the final coverage point following the final coverage point's hunt-to chain when the following conditions occur:

- The Call Coverage screen's Hunt After Coverage field is **y**.
- The last coverage point is unavailable (busy or no answer).
- The last coverage point is a station with an assigned hunt-to station.
- No one in the coverage path answered the call.

Coverage — Don't Answer will cover the call after hunt if the call can terminate, but no one answers.

If Station Hunt Before Coverage is active, a call to a busy station tries to terminate to the hunt-to phone before going to coverage. If the call does go to coverage, it is the coverage of the dialed extension (unless the phone is an XDID, and then the call goes to the coverage of the non-XDID phone found in the XDID's hunt-to field).

- Call Detail Recording (CDR)

CDR records the called extension, not the answering extension.
- Call Forwarding

Call Forwarding has precedence over Station Hunting.

If an idle station has Call Forwarding active, the system forwards the call. If a busy station has Call Forwarding active, a call to the station forwards. If the forwarded-to station is busy, the call follows that forwarded-to station's hunting chain.

If the system finds Call Forwarding active at one of the stations in a station-hunting chain, it considers the station busy and bypasses it. The call goes to the next station in the chain.
- Call Park

The system does not attempt Station Hunting on callpark-return calls.
- Call Pickup

Call Pickup functions the same for calls terminating at a point in a station-hunting chain as it does for a regular calls.
- Call Vectoring

You cannot assign a VDN as a hunt-to station.

If a **route-to** command's **with cov y** directs a call to a busy station, the call follows the station's hunt-to chain and not its coverage path. See *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide* for more information.
- Call Waiting/Attendant Call Waiting

Station Hunting has precedence over Call Waiting.

If a called extension has Call Waiting active, and the extension is already busy on a call, the system hunts the station-hunting chain. If the system cannot terminate the call to a member of the chain, then the call waits at the called extension.

If the system finds Call Waiting active at an extension in a station-hunting chain, it considers the extension busy and bypasses it.
- Class of Restriction (COR)

The system checks the COR of the called extension; it does not check the COR of the hunt-to stations in the chain.
- Distributed Communications System (DCS)

Station Hunting is not a DCS feature. All members of a station-hunting chain must be on the same switch.

- Do Not Disturb  
When a phone has Do Not Disturb activated, a call to that phone goes to intercept treatment and not to station hunting.
- Extension Number Portability (ENP)  
You cannot assign a remote ENP extension as a hunt-to station.
- Hunting/Hunting Group  
You cannot assign a direct departmental calling or Uniform Call Distribution extension as a hunt-to station.
- Intercom Call  
The system denies Station Hunting for intercom calls to a busy extension.
- Leave Word Calling (LWC)  
If a caller initiates LWC, the LWC message is left at the called extension even if the system uses Station Hunting in an attempt to complete the call.
- Multimedia  
Calls to multimedia endpoints must convert to voice before station hunting.
- Night Service  
The system denies Station Hunting when a night service call is made to a busy night-console extension.
- Outgoing Trunk Queueing  
The system does not attempt Station Hunting for an OTQ callback-return call.
- Personal Central Office Line (PCOL)  
The system does not attempt Station Hunting for a PCOL call.
- Personal Station Access (PSA)  
The system considers a station with PSA dissociated as busy and bypasses it in the station-hunting chain.
- Priority Call  
The system denies Station Hunting for priority calls.
- Restriction  
The system applies proper intercept treatment to a restricted, called extension. However, the system *does not check restrictions on hunt-to stations*.
- Send All Calls  
Send All Calls coverage takes precedence over Station Hunting.

- Tenant Partitioning  
The system applies normal tenant restrictions to a call to the called extension. However, the system *does not check tenant restrictions on hunt-to stations*.
- Terminal Translation Initialization (TTI)  
The system considers a station with TTI separation as busy and bypasses it in the station-hunting chain.
- Terminating Extension Group (TEG)  
You cannot assign a TEG as a hunt-to station.
- Uniform Dial Plan (UDP)  
You cannot assign a remote UDP extension as a hunt-to station.
- X-port extension  
You can assign a hunt-to station to a station administered with X in the port field. It is treated as unavailable and skipped.

---

See [“Station” on page 1127](#) for information to administer a Hunt-to-Station button.

See [“Coverage Path” on page 696](#) for information about station hunting after coverage.

## **Station Lock**

---

Station Lock provides users with the capability to manually lock their stations, using a button or feature access code, in order to prevent unauthorized external calls from being placed.

Station Lock can prevent unauthorized external calls. Phones can be remotely locked and unlocked. Station Lock allows users to:

- lock their phones to prevent unauthorized outgoing calls.
- block outgoing calls and still receive incoming calls.
- block all outgoing calls except for emergency calls.

Station Lock is activated by pressing a phone button, which lights the button indicator, or dialing a FAC.

Analog and XMOBILE stations must dial a FAC to activate the feature. The user hears a special dial tone on subsequent origination attempts from the telephone to indicate that the lock feature is active.

Digital stations (including DCP, BRI, IP hardphones and softphones) access Station Lock with a feature button or via a FAC. If a digital station has a Station Lock button but activates the feature with the FAC, the LED for the button lights and no special dial tone is provided. However, if a digital station does not have a Station Lock button and activates the feature with the FAC, a special dial tone is provided.

A station can be locked or unlocked from any other station if the FAC is used and the Station Security Code is known. The attendant console can never be locked but can be used to lock or unlock other stations. A station also can be locked or unlocked via a remote access trunk.

## Interactions

---

- Attendant Console

Station Lock cannot be used for attendant consoles but it can be assigned to regular digital stations that might also have console permissions. The FAC cannot be used to activate Station Lock for the attendant console, but the FAC can be dialed from the attendant console in an attempt to remotely activate or deactivate Station Lock for another station.

- Personal Station Access (PSA)

Station Lock can be used for PSA stations as long as they are associated with an extension. When stations are disassociated, Station Lock cannot be activated.

- Remote Access

After a remote user dials a valid barrier code, the user receives system dial tone. To activate/deactivate Station Lock, the user must dial the FAC, then the extension number, then the security code number.

## Station security codes

---

Station security codes (SSC) provide security to you by preventing other users from accessing functions associated with your station. Each station user can change their own SSC if they know the station's current settings.

You must create a system-wide SSC change FAC before users can change their SSC. You must also provide users with their individual SSC. A user cannot change a blank SSC.

## Interactions

---

Users need a station security code to use the following system capabilities:

- Demand printing
- Extended User Administration of Redirected Calls
- Leave Word Calling
- Personal Station Access
- Voice Message Retrieval

## Related topics

---

See [“Assigning an extender password” on page 366](#) for information about creating a station security code.

See [“Training users” on page 373](#) for information about changing your station security code.

See [“Station” on page 1127](#) for information about and field descriptions on the Station screen.

See [“Security-Related System Parameters” on page 1105](#) for information about and field descriptions on the Security-Related System Parameters screen.

## Telephone displays

---

Telephone displays provide multi-appearance phone users with current call and message information. The information that appears depends on the type of display the user selects with the buttons on the phone.

Retrieving stored information, such as messages and directory information, is easy and convenient. Users can select English, French, Italian, Spanish, or a user-defined language for their display.

With [Enhanced Telephone Display](#), you can choose the types of characters that appear on user’s phone displays. You can administer the switch to display standard Roman (European) characters, or Cyrillic (Russian), Katakana (Japanese), or Ukrainian characters. The character set displayed is determined by the phones your company uses.

## Button display modes

You can assign several display modes to phone buttons. Users access these modes by pressing the assigned button on the phone. All the buttons are administrable.

| Button Mode          | Displays                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <p>Message Retrieval</p>               | <p>Retrieves messages for phone users. If no messages are stored, display shows NO MESSAGES. Messages can be retrieved even if the retriever is active on a call.</p> <p>Message Retrieval can use 3 additional related buttons:</p> <ul style="list-style-type: none"> <li>■ Next Message - retrieves the next message or displays END OF FILE, PUSH Next TO REPEAT when in Retrieval mode.</li> <li>■ Delete - deletes the currently displayed message.</li> <li>■ Call-Disp - automatically returns the call requested by the currently-displayed message or the currently-displayed name and extension.</li> </ul>                                                                                                                                                                                       |
| <p>Coverage Message Retrieval Mode</p> | <p>Retrieves messages for phone users who do not have a display module assigned to their phone. You must administer retrieval permission for a user to be able to retrieve another user's messages. The retriever does not need to lift the handset to retrieve messages. Messages can be retrieved even if the retriever is active on a call.</p> <p>Coverage Message Retrieval can use 3 additional related buttons:</p> <ul style="list-style-type: none"> <li>■ Next Message - retrieves the next message or displays END OF FILE, PUSH Next TO REPEAT when in Retrieval mode.</li> <li>■ Delete - deletes the currently displayed message.</li> <li>■ Call-Disp - automatically returns the call requested by the currently-displayed message or the currently-displayed name and extension.</li> </ul> |

**Information on the display**

Avaya MultiVantage provides the following call-related information:

- Call Appearance Identification

The call appearance buttons are designated on the display by a lowercase letter. The display shows a= for a call incoming on the first button, b= for a call incoming on the second button, and so on.

The system may omit the call-appearance information so that the Call Log find capability in the PC/PBX Connection software works properly.

- Calling Party Identification

When a call is from inside the system, the display shows the caller's name or a unique identification administered for the phone being used, along with the calling party's extension. When the call is from outside the system, the display shows the trunk group name (such as CHICAGO) and the trunk access code assigned to the trunk group used for the call. If a user is active on a call and receives a subsequent call, the display automatically shows the identification of the subsequent caller for a few seconds, then automatically restores the display associated with the active call appearance.

For example:

Outgoing trunk call

b=87843541

8 is the trunk access code and 784-3541 is the number dialed

then

b=OUTSIDE CALL 8

or

b=WATS 101

**⇒ NOTE:**

Due to space limitations, some name displays are shortened to 15 characters. These include displays for transferred or covered calls, non-DCS, ISDN-PRI call displays, VDN service observing displays, and LWC messages or the queue status of an agent.

- Called Party Identification

On calls to a system user, the digits appear on the display as they are dialed. After dialing is complete, the called party's name and extension appears. If no name is accessed, the dialed digits remain on the display.

On outgoing calls, the digits appear on the display as they are dialed. After dialing is complete, the display shows the name and trunk access code assigned to the trunk group being called. Optionally on a trunk-group basis, the display can show only the dialed digits, not the trunk group name and trunk access code.

For example:

dialed digits

a=3602

then

a=TOM BROWN 3062

or, if no name is available

a=EXT 3602 3062

■ Call Purpose

This identifies the reason for an incoming call or a redirected call. (A normal incoming call is not identified by a call purpose.) The following identifiers sometimes appear on the display:

| Display                        | Meaning                                                                                                                                                |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| b — (Busy)                     | The called user is active on a call, and has a temporary bridged appearance of the call.                                                               |
| c — (Cover All)                | The called user has Cover All assigned.                                                                                                                |
| callback                       | The call is an Automatic Callback call from the system.                                                                                                |
| d — (Coverage on Don't Answer) | The call was redirected because the called phone was not answered. Also indicates that the called user has a temporary bridged appearance of the call. |
| f — (Call Forwarding)          | Another user has forwarded calls to this phone.                                                                                                        |
| h — (Station hunt)             | The called user is active on a call and station hunt was used to route the call.                                                                       |
| ICOM                           | The call is an Intercom call.                                                                                                                          |
| p — (Pickup)                   | The user answered a Call Pickup group member's call.                                                                                                   |
| park                           | The user parked a call.                                                                                                                                |
| priority                       | The call has priority status.                                                                                                                          |
| s — (Send All Calls)           | The called user is temporarily sending all calls to coverage and the call has been redirected to this phone.                                           |

## Message retrieval

Certain phones and the attendant groups can be designated for system-wide message retrieval. Users of these phones or consoles can retrieve LWC and Call Coverage messages for other phone users, including DDC groups, UCD groups, and TEG. They can also retrieve external call logs. You can assign system-wide retrieving phones or consoles on the Feature-Related System Parameters screen.

Messages for a phone user can be retrieved at selected phones or any attendant console if the retriever is in the user's Call Coverage path and if permission to retrieve messages is assigned for the user's phone.

## Enhanced Telephone Display

With Enhanced Telephone Display, you can choose the types of characters that appear on your phone displays. You can choose standard Roman characters, or Cyrillic, Katakana, or Ukrainian characters. Your Avaya representative sets the character type on the System Parameters Country-Options screen. The character set displayed is also determined by the phones your company uses.

You can choose one of the following character sets for messages on your display phones:

- Cyrillic contains the characters required to display the Russian language. All Russian characters appear in capital letters.
- Katakana contains the characters to display the Japanese language as well as some European characters and other symbols. All Japanese characters appear in capital letters.
- Roman contains two character sets:
  - US English contains the Roman alphabet, numerals, and special characters found on the standard US English keyboard. US English characters appear in capital and lowercase letters.
  - European contains characters for many European languages. All European characters appear in capital letters.
- Ukrainian contains the characters required to display the Ukrainian language. All Ukrainian characters appear in capital letters.

The type of phones your company uses must support the characters you want to display. Each character set requires specific firmware in the phone. Make sure you use phones with the same firmware type across your entire system, or the displays do not appear as expected. Your Avaya representative can make sure that you have the correct phone types for the characters you want to display.

## **Interactions**

---

- **Distributed Communications System (DCS)**

Trunk group and attendant information associated with a DCS call can be translated. If the displays are not associated with a DCS call, the name that appears is the name administered on the form used to administer the trunk group.

- **Single-Digit Dialing and Mixed-Station Numbering**

If prefixed extensions are used in the system's dial plan, the prefix is not displayed when the extension is displayed. The Return Call button can be used to dial prefixed extensions, because the system dials the prefix, even though it is not displayed.

## **Interactions (Enhanced)**

---

- **ASAI and related adjuncts**

Information sent from the switch to any adjunct is the literal value of the field, not the enhanced characters. The display appears as a string of random characters — for example, as “2<@^.”

- **AUDIX Voice Power/Audix Voice Power Lodging**

Not supported.

- **Data Call Setup**

Not supported.

- **DCS**

All switches in a DCS network must have the same software load installed on each server, must have the enhanced characters enabled, and must have phones with the same firmware type.

- **ECMA and QSIG Networking**

Information must be sent between Avaya MultiVantage systems.

- **Leave Word Calling - Adjunct**

Not supported.

- **Message Retrieval - Print Messages (Demand Print)**

Not supported.

- **Monitor 1 and OneVision**

Monitor 1 and OneVision receive ASCII characters.

- OSSI  
OSSI displays the literal value of the display field, not the enhanced characters.
- Passageway Direct Connect  
Not supported.
- VUStats  
Use phones that support enhanced characters or screens may clear and displays will be incorrect.

### Feature information displays

Phone displays provide information about the activity on individual phones and consoles, including confirmation that a certain feature is being used. The language used for messages is administered on the station screen for each phone.

This section shows the English, French, Italian, and Spanish message for each feature. When time is displayed, the English language uses AM and PM. All other languages use 24-hour time.

**Table 63. Automatic Wakeup**

**Table 66. Call Appearance**

For each language, the active call appearance appears as:

“a =” (English)

Call-appearance buttons are shown on the display by a lower-case letter (a through z for the first 26 call appearances), followed by “=.” Lower-case letters A through Z, followed by “=” are used for additional call appearances.

## **Temporary Bridged Appearance**

---

Temporary Bridged Appearance allows multiappearance telephone users in a TEG or PCOL group to bridge onto an existing group call. If a call has been answered using the Call Pickup feature, the originally called party can bridge onto the call. This feature also allows a called party to bridge onto a call that redirects to coverage before the called party can answer it.

### **Detailed description**

---

An incoming call to a TEG or PCOL group is not a call to an individual, although one particular member of the group can be the most qualified person to handle the given call. If this individual did not answer the call originally, this individual can bridge onto the call; the call does not have to be transferred.

A call to an individual can be answered by a call pickup group member. If the called party returns while the call is still connected, the called party bridges onto the call and the answering party hangs up.

Call Coverage provides redirection of calls to alternate answering positions (covering users). A temporary bridged appearance is maintained at the called telephone.

The called party can answer the call at any time, even if it is already answered by a covering user. If the called party does not bridge onto the call, the covering user can use the Consult function of Call Coverage to determine if the called party wants to accept the call. The Consult function uses the temporary bridged appearance maintained on the call. When the consult call is finished, the temporary bridged appearance is removed.

Stations that normally have a temporary bridged appearance with their coverage point do not have a temporary bridged appearance if the coverage point is AUDIX.

## Considerations

---

- Temporary Bridged Appearance allows the desired party to bridge onto a call without manually transferring the call, providing convenience of operation and saving time.
- Temporary Bridged Appearance does not provide any call originating capability or the capability to answer another party's calls. These capabilities are provided by the Bridged Call Appearance feature.
- If two parties are bridged together on an active call with a third party, and if the Conference Tone feature is enabled, conference tone is heard.
- The Bridged Call Appearance feature enhances Temporary Bridged Appearance by allowing more than one call to an extension to be bridged and by allowing calls to be originated from bridged appearances.

## Interactions

---

- Call Coverage

Calls redirected to Call Coverage maintain a temporary bridged appearance on the called telephone if a call appearance is available to handle the call. The called party can bridge onto the call at any time. The system can be administered to allow a temporary bridged appearance of the call to either remain at or be removed from the covering telephone after the principal bridges onto the call. If two parties are bridged together on an active call with a third party, and the bridging tone is administered to yes, all three parties hear the bridging tone.
- Consult

Consult calls use the temporary bridged appearance maintained on the call. At the conclusion of a consult call, the bridged appearance is no longer maintained. If the principal chooses not to talk with the calling party, the principal cannot bridge onto the call later.
- Conference and Transfer

If a call has, or has had, a temporary bridged appearance; is conferenced or transferred; and redirects to coverage again; a temporary bridged appearance is not maintained at the conferenced-to or transferred-to extension.
- Privacy — Manual Exclusion

When Privacy — Manual Exclusion is activated, other users are prevented from bridging onto a call. A user who attempts to bridge onto a call when this feature is active is dropped.

## Tenant Partitioning

---

(Not available with Offer B) Tenant Partitioning provides telecommunications services to multiple independent groups of users through a single Avaya MultiVantage. Most commonly, Tenant Partitioning provides these services from a single provider to multiple tenants of an office complex. This eliminates the need for each tenant to purchase services separately, while still giving each tenant the appearance of a dedicated Avaya MultiVantage. You can also use this feature to provide group services, such as departmental attendants, on a single-customer Avaya MultiVantage. Tenant Partitioning also allows you to assign a unique music source for each tenant partition for callers who are put on hold.

### NOTE:

If you use equipment that rebroadcasts music or other copyrighted materials, you may be required to obtain a copyright license from, or pay fees to, a third party such as the American Society of Composers, Artists, and Producers (ASCAP) or Broadcast Music Incorporated (BMI). You can purchase a Magic-on-Hold<sup>®</sup> system, which does not require such a license.

### Detailed description

---

Tenants are defined and assigned by you, the system administrator. You must have the same authorization as that required for COR administration.

Because some features are not partitioned, you must take care to administer these features to prevent inter-tenant access. See [“Interactions” on page 1876](#) for a list of these features.

You must ensure that:

- All tenants can call and be called by partition 1. This is the system default. If you change this default some call types fail. For example, *dial 0 fails*, as do SVN calls, ACA calls, etc.
- All stations in a call-pickup group are under control of the same tenant
- All stations with bridged appearances are under control of the same tenant
- Stations in different departments (for the purposes of attendant services) can call each other

You must assign a tenant partition number to each object (endpoint, virtual endpoint, or other entity) that has an assigned COR. The exceptions are authorization codes and fixed-assignment virtual endpoints.

You administer Tenant Partitioning via the Tenant Partitioning screen; you need to administer one screen for each tenant partition. Begin the initial administration of the Tenant Partitioning feature by completing the tenant partitioning screen. Keep in mind that you must specify an attendant group for each tenant that you define, even if there are no consoles assigned to the attendant group. You must also assign an attendant console to a tenant partition and you must assign a group number to the Attendant Console screen.

### Tenant Partitioning capabilities

Tenant Partitioning can provide the following services to tenants: telephone equipment, building wiring, public and private network access, and attendant services. In addition, the feature can provide a full range of Avaya MultiVantage capabilities to even the smallest tenant office, including Call Coverage, Remote Access, Night Service Routing, and others. Tenants can also purchase Avaya MultiVantage adjuncts available on the switch, such as CMS activity reporting.

Tenant Partitioning provides advantages to both the telecommunications service provider and individual tenants:

- Shared resources offer enhanced services at lower cost to the tenant, with increased profit for the service provider.
- The tenant has the appearance of a dedicated Avaya MultiVantage without the expense.
- All tenants can have attendant services.
- A trained, full-time system administrator can install, administer, and maintain the switch.

With proper administration, tenant resources, including trunking facilities, and all other switch endpoints can be protected from access by other tenants.

### Partitioning tenants

The default for Tenant Partitioning is one universal tenant for the system. This tenant, partition 1, is usually reserved for the service provider. By default it has access to all facilities and any other tenant can access it.

The service provider creates additional partitions based on tenant requirements. When deciding which tenant partitions to create, remember:

- You can assign each switch endpoint to one and only one tenant partition. And, you must pass each switch endpoint to a partition. For example, you must assign each telephone, attendant console, trunk, and virtual endpoint, such as an LDN or VDN, to a tenant partition.

- Most tenant partitions are discrete, separate units. By default, the system prevents all tenants, except partition 1, from accessing stations or trunking facilities belonging to other tenants. However, you can change this default. You can give explicit permission for one tenant to access another. For example, you can allow tenant 6 to call tenants 9 and 16 only.

 **NOTE:**

If a tenant has permission to call another tenant, it has access to every endpoint belonging to that tenant. For example, if tenant 6 has permission to call tenant 9, tenant 6 can also use any trunking facilities present in tenant partition 9.

- Even if two extensions are blocked from calling each other by Tenant Partitioning restrictions, either extension can still reach the other by dialing the extension's Direct Inward Dialing (DID) number via the public network.
- If any facilities are to be shared among tenants who do not want complete access to each other's facilities, you must group the shared facilities in a separate partition. For example, if two tenants share a trunk, but do not have direct access to each other's telephones, that trunk will need to be placed in its own partition so that both tenants can access it.

It is also important to consider the following constraints and requirements of access control, attendant services, music sources on hold, and network route selection when you establish or assign partitions.

### **Access control**

Features such as call coverage are limited by tenant-to-tenant access restrictions. For example, suppose tenant 1 includes a telephone from tenant 2 in its coverage path. If tenant 3 has permission to call tenant 1 but not tenant 2, a call from tenant 3 to tenant 1 skips the tenant 2 coverage point.

You may also want to set up tenants with special access privileges. For example, you might give a restaurant in an office complex permission to be called by any other tenant. Likewise, permission to call or be called by other tenants is helpful for building security or Avaya MultiVantage administration or troubleshooting.

You can also assign all CO trunks to one tenant partition that can then be accessed by all other tenants.

### **Attendant services**

Tenant Partitioning allows you to provide personalized attendant services to each tenant.

The system provides one principal and one night or day/night attendant per attendant group. You assign each tenant an attendant group for service. Each attendant group has a separate queue. Queue warning lamps remain dark when Tenant Partitioning is active. However, information displayed when someone presses a queue-status button reflects the status of the attendant-group queue. The total number of calls queued for all tenants cannot exceed the system limit.

Attendant groups may serve more than one tenant. In this case, the attendant group cannot extend a call from one tenant via facilities belonging to another tenant, unless the former tenant has permission to access the other's facilities.

Each tenant may have a designated night-service station. The system directs calls to an attendant group in night service to the night-service station of the appropriate tenant (when a night attendant is not available). When someone places an attendant group into night service, all trunk groups and hunt groups that belong to tenants served by that attendant group go into night service. In this case, the system routes incoming calls to the night-service destination of the appropriate tenant. Each tenant can have its own LDN night destination, trunk answer on any station (TAAS) port, or night attendant.

An attendant can specify that access to a trunk group is under attendant control if the trunk group is assigned to a tenant served by that attendant's group. The system directs any valid user attempt to access the trunk group to the attendant group serving the tenant.

### **Network route selection**

You can place trunk groups belonging to different tenants in the same route pattern. Calls routing to that pattern select the first trunk group in the pattern with access permission by the calling tenant (subject to normal constraints).

### **Tenant partitioning examples**

The following is a simple example of how you might administer Tenant Partitioning in an office complex.

You assign tenant partition 1, the universal tenant, as the service provider. All other tenants can call and be called by the service provider.

You assign tenant partitions 2–15 to individual businesses in the complex. You maintain the system-default restrictions for these tenants. That is, tenants cannot access telephones, trunking facilities, or other switch endpoints belonging to other tenants.

You assign tenant partition 16 to the restaurant in the building complex. You give all tenants permission to call this tenant. However, to prevent the restaurant from accessing trunks and other facilities belonging to tenants, you do not permit the restaurant to call any other tenants.

You assign tenant partition 17 to all CO trunk groups. You give all tenants permission to call this tenant.

You assign tenant partition 18 to a trunk group that tenants 3 and 7 want to share. You give Tenants 3 and 7 access to this partition; you deny all other tenants access. To prevent toll fraud, you do not allow tenant 18 to call itself.

The Automatic Route Selection (ARS) route pattern can be the same for all tenants. In this example, the trunk for tenant partition 18 (the private trunk shared by tenants 3 and 7) is first in the route pattern. Tenant partition 17 is second. Tenants 3 and 7 route first to partition 18 and then as a second choice to partition 17. You deny all other tenants access to partition 18 and so the system routes them directly to partition 17.

All facilities that are not shared, including trunk groups, VDNs, telephones, attendant consoles, and other endpoints, are assigned to the tenant partition that they serve.

[Table 98 on page 1874](#) summarizes the calling permissions for the different partitions. Yes indicates that the partitions have permission to call and be called by each other; no indicates that partitions cannot call or be called by each other.

**Table 98. Calling permissions for partitions**

| Calling tenant partition number | Called tenant partition number |                                                   |                                                   |     |     |     |
|---------------------------------|--------------------------------|---------------------------------------------------|---------------------------------------------------|-----|-----|-----|
|                                 | 1                              | 2, 4—6, 8—15                                      | 3,7                                               | 16  | 17  | 18  |
| 1                               | yes                            | yes                                               | yes                                               | yes | yes | yes |
| 2, 4-6, 8-15                    | yes                            | Each partition can call itself but not the others | no                                                | yes | yes | no  |
| 3,7                             | yes                            | no                                                | Each partition can call itself but not the others | yes | yes | yes |

*Continued on next page*

**Table 98. Calling permissions for partitions (Continued)**

| Calling tenant partition number | Called tenant partition number |              |     |     |     |    |
|---------------------------------|--------------------------------|--------------|-----|-----|-----|----|
|                                 | 1                              | 2, 4—6, 8—15 | 3,7 | 16  | 17  | 18 |
| 16                              | yes                            | no           | no  | yes | yes | no |
| 17                              | yes                            | yes          | yes | yes | yes | no |
| 18                              | yes                            | no           | yes | no  | no  | no |

**Detailed description of Multiple Music-on-Hold**

Tenant Partitioning allows you to assign each tenant a music source, unique to each tenant partition, to be heard when a call is placed on hold. The tenant number assigned to the destination extension usually determines which music source is heard. This capability allows you to tailor the music or messages for the business needs of each tenant partition.

If the COR of the extension that places the call on hold permits music-on-hold, a caller on hold hears the music source assigned to the partition at which the call initially terminates. For example, if calls coming into the Avaya MultiVantage route first to an INTUITY automated attendant that then routes the call to the appropriate tenant partition, the caller on hold hears the music source of the INTUITY automated attendant, not the tenant partition to which it is routed. Likewise, if a caller in tenant partition 2 makes an out-going call using tenant partition 1’s trunk groups, the caller will hear the music source assigned to tenant partition 1. If the COR of the called extension does not permit music on hold, however, the caller hears nothing.

The maximum number of music sources allowed is the same as the maximum number of tenant partitions allowed; each music source can be used by one or more tenant partitions.

You can assign one of the following music-on-hold types to each tenant partition.

**Table 99. Music-on-Hold types**

| Type  | System Response for a caller placed on hold                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none  | silence                                                                                                                                                                              |
| tone  | system-wide administered tone                                                                                                                                                        |
| music | the music associated with the administered port. The number of possible music sources equals the number of possible tenant partitions. Each partition can have its own music source. |

## Interactions

Tenant-partition identification is not passed between switches. A network of Avaya MultiVantage systems does not enforce Tenant Partitioning restrictions without special administration. For example, Tenant Partitioning on a network of Avaya MultiVantage systems does not enforce tenant-specific tie trunks.

Administration of the following features requires special care to avoid undesired intertenant access.

- Bridging
- Call Pickup
- Call Vectoring
- Controlled Restriction
- Facility Busy Indication
- Facility Test Calls
- Integrated Directory
- Inter-PBX Attendant Calls
- Main/Satellite/Tributary
- Malicious Call Trace
- Personal CO line
- Private Networking (AAR)
- Service Observing
- Uniform Dial Plan

The function of any feature that specifies a tenant partition is affected by tenant-to-tenant restrictions, as follows.

- **Automatic Alternate Routing (AAR)/ARS**

Do not confuse tenant partitions with Time-of-Day Plan Numbers and Partition Groups in AAR/ARS. You can still use Time-of-Day Plan Numbers and Partition Groups can still be used to select one of eight route patterns for AAR/ARS routing when Tenant Partitioning is in effect.

- **Attendant and Attendant Group Features**

Tenant Partitioning creates multiple attendant groups. Attendant operations such as direct-station or trunk-group select (DCS/DTGS) are subject to tenant-to-tenant restrictions, both at selection time and at split time.

All calls put on hold by an attendant from the attendant group hear the music source from the attendant group.

- **Attendant Control of Trunk-Group Access**

An attendant group controls access only to trunk groups that belong to tenants that are served by that attendant group.

- **AUDIX, embedded AUDIX, and AUDIX Voice Power**

AUDIX voice and data ports are subject to the same tenant-to-tenant restrictions as any other endpoint.

AUDIX can restrict one group of subscribers from sending voice mail to another group. The tenant-partitioning provider can create up to 10 different communities within each AUDIX that either have or do not have permission to send voice messages across community boundaries.

- **Authorization Codes**

Authorization codes are associated with classes of restriction. If you want to have a set of authorization codes that is unique to a given tenant, you could select a group of CORs for a that tenant and only assign those CORs to objects in that partition.

- **Automatic Wakeup**

Wakeup music will be the music source assigned to the wakeup station's tenant partition.

- **Bridged Call Appearance**

All stations with bridged call appearances should be administered to be under control of the same tenant.

- Call Coverage

Tenant-to-Tenant access restrictions apply to coverage paths. If a tenant cannot access a particular tenant, it cannot access that tenant as part of another tenant's coverage point.

When an attendant is specified as part of a coverage path, the attendant group of the called tenant, not the calling tenant, is accessed.

When a call goes to coverage, is answered, and is put on hold, the music on hold is the music source assigned to the tenant partition of the terminal that was originally called.

- Call Detail Record (CDR)

CDR does not report the tenant partition number of the extension or trunk group used. You must infer the tenant partition number from the extension or trunk-group number.

- Call Pickup

Administer all stations in a call-pickup group to be under control of the same tenant. The system supports Call Pickup only if the caller and the called party can both call the pickup user. The caller and the called party do not need to be in the same pickup group.

- Call Vectoring/VDN

A caller routed to a new destination by a vector step hears the music assigned to the last active VDN. While a call is in vector processing, the tenant number (TN) assigned to the active VDN (as determined by VDN Override) determines the music source heard by callers on hold in most circumstances. Note the following exception, however.

If you use a *wait-time <time> hearing <extension> then <treatment 2>* command where the *<extension>* is a music source (assigned on the Announcements/Audios Sources screen), that music source will play instead of the music source associated with the active VDN.

The COR assigned to the VDN must permit music-on-hold.

- CMS

You can administer CMS to provide CMS reports to each tenant. You can restrict each CMS login to control, on a permission basis, only those entities that are assigned to a particular tenant. Outputs to separate printers allow any tenant to print their own CMS reports. The tenant-partitioning provider must administer CMS to provide this separation of tenant permissions.

- Dial Access to Attendant

When a tenant dials an attendant, it accesses its own assigned attendant group.

- **Emergency Access to the Attendant**

When a tenant dials emergency access, it accesses its own assigned attendant group.
- **Expert Agent Selection (EAS)**

For agents in an EAS system, the COR assigned to the logical agent ID (not the physical extension) determines whether callers on hold can hear music.
- **Hunt groups**

The tenant number assigned to the hunt group extension determines the music source callers to the hunt group hear while they're in queue or on hold.
- **Intercept Treatment**

When access to the attendant is designated as intercept treatment, the caller accesses their assigned attendant group.
- **Malicious Call Trace (MCT)**

By default, MCT extensions are assigned to tenant partition 1. Therefore, if Malicious Call Trace is enabled, any telephone with permission to call tenant partition 1 can use it.
- **Multiple Listed Directory Numbers**

Each Listed Directory Number is assigned to a tenant partition.
- **Multiple Audio/Music Sources for Vector Delay**

When an audio source is specified by a *wait-time <time> hearing <treatment>* vector step, the audio source assigned to the tenant number of the active VDN is the one that plays.

If you use a *wait-time <time> hearing <extension> then <treatment 2>* command where the *<extension>* is an audio source (assigned on the Announcements/Audios Sources screen), that audio source will play instead of the one associated with the active VDN. For information on administering multiple audio sources see the *Avaya MultiVantage™ Call Center Software Call Vectoring and Expert Agent Selection (EAS) Guide*.
- **Music-on-Hold Access**

When Tenant Partitioning is enabled, you can assign a unique source for music to each tenant. If Tenant Partitioning on the System-Parameters Customer-Options screen is set to **y**, you must use the Music Sources screen to administer music-on-hold.

- **Night Service**

Each tenant can have its own LDN night destination, TAAS port, or night attendant.
- **PC Interfaces**

You must assign each PC interface to a tenant partition.
- **PC/PBX Connections**

You must assign each PC/PBX Connection to a tenant partition.
- **PC/(ISDN**

You must assign each PC/ISDN to a tenant partition.
- **Remote Access**

You must assign each Remote Access barrier code to a tenant.
- **Traffic Studies**

Traffic studies do not report the tenant partition number of the extension or trunk group used. You must infer the tenant partition number must be inferred from the extension or trunk-group number.
- **Uniform Dial Plan**

If a Uniform Dial Plan is in place between switches, tenant partition identification is not passed between the switches, and so tenant-partition restrictions are not enforced between the switches without special administration.

**NOTE:**

Tenant Partitioning restrictions do not override COR restrictions. COR restrictions are independent of tenant partitions.

## **Terminal Translation Initialization**

---

Terminal Translation Initialization (TTI) allows you to merge an x-port extension to a valid port by dialing a system-wide TTI security code and the extension from a telephone connected to that port. TTI also allows you to separate an extension from its port by dialing a similar separate digit sequence. This action causes the extension to be administered as an X port.

When TTI is enabled for voice, all voice ports (except BRI ports) become TTI ports or ports from which a TTI merge sequence can occur.

TTI is usually used to move phones, however, it also supports connecting and moving attendants, data modules, voice/data telephones, and ISDN-BRI telephones.

## Attendants

---

In order for attendants to use TTI, you must assign an extension to the attendant console. TTI port translations are the same for digital telephones and attendant consoles. To merge a digital TTI voice port and an attendant, you must first administer the attendant as an X port. Then a digital telephone must be plugged into the jack assigned to the attendant console, and the TTI merge digit sequence must be entered on the digital telephone. Once the TTI merge has been completed for the attendant console, the digital telephone must be unplugged and the attendant plugged into the jack.

An attendant console can be separated from its port only through administration. A TTI separate request from an attendant console gives the user intercept treatment.

## Data modules

---

Data modules have different tones and digit sequences.

In the merge and separate control flow, different tones are given to the telephone user to give the current status of the TTI operation. Instead of audible tones, status messages are displayed on a telephone connected to a data module when activating the TTI sequence through keyboard dialing. If the TTI State field is set to **data**, you see the data display messages. If the TTI State field is set to **voice**, you hear the tones.

For a stand alone data module, the TTI merge/separate digit sequence is entered in one line at a dial prompt:

- DIAL: <TTI feature access code><TTI security code><ext>

Separate prompts are not given for the TTI security code and extension.

## Voice/data telephones

---

A telephone with a data terminal (DTDM) is treated as a telephone in the TTI merge and separation sequence. The DTDM is merged with and separated from its hardware translation at the same time the telephone is merged or separated. The TTI merge and separate sequence can only be initiated through the telephone for DTDMs; it cannot be initiated through the data port.

## ISDN BRI telephones

---

The TTI separation sequence for Automatic-TEI SPID-initializing BRI telephones is identical to the sequence used for telephones. However, the merge sequence is different.

- Separation sequence
  1. Feature Access Code
  2. Security Code
  3. Extension
- Merge sequence
  1. Connect the telephone to any port to get power.
  2. Program the service profile identifier (SPID) to the extension with which it will be merged.
  3. Unplug the telephone (this is necessary even if the telephone is connected to its intended port).
  4. Connect the telephone to its intended port (this port should indicate Equipment Type: TTI Port).
  5. Receive dial tone.
    - If there is dial tone, the merge is complete.
    - If there is no dial tone, the telephone's SPID is not an available extension.

You can dial the TTI merge sequence for BRI sets only if a user separates a BRI extension from its set and then wants to undo the process by reassociating the set to the same extension. Note that you cannot use the SAT to put an X in the port field of a BRI set that is still connected to the switch. You must use the TTI separation sequence from the set.

## Analog Queue Warning Ports and External Alert Ports

---

The analog queue warning port (used for hunt groups) and the external alert port may be administered with an X in the Port field. These extensions can be merged to an analog port via TTI. The merge must be done by an analog set, and then the analog set is unplugged from the port. These extensions cannot be separated from their port location with the TTI feature. A TTI separate request from one of these ports gives you intercept treatment.

## Security measures

---

### **SECURITY ALERT:**

*If you do not manage this feature carefully, its unauthorized use may cause you security problems. For example, someone who knows the TTI security code could disrupt normal business functions by separating telephones or data terminals. You can help protect against this action by frequently changing the TTI security code. You can further enhance system security by removing the FAC from the system when it does not need to be used (for example, there are no moves going on at present). Consult the Avaya Products Security Handbook for additional steps to secure your system and find out about obtaining information regularly about security developments.*

## Interactions

---

- **Attendant**

It is possible to have the attendant in Position Available Mode and still separate. Any calls queued, held, or seen as active for the attendant prevent separation.
- **Attendant Night Service**

The night service station cannot be separated while in night service.
- **Attendant Release Loop Operation**

If the attendant separates before the attendant-timed reminder-interval expires, all calls held with the release loop operation by the attendant are reclassified as attendant group calls.
- **Automatic Callback**

If a telephone has Automatic Callback active for another telephone, executing TTI separate for either telephone breaks the automatic callback sequence.
- **Call Coverage**

If a telephone separates while Send All Calls or Goto Coverage is active, these features remain active while the telephone has no associated hardware.

You can separate a telephone that is the target of Send All Calls or Goto Coverage; the features function as if the telephone were busy.

- **Call Coverage Answer Group**

If a extension was an X port, then rejoins the group as a result of a TTI merge, a PSA associate, or a port assignment, that telephone is excluded from all transactions already active in the call coverage answer group.

- **Call Forwarding**

A telephone can separate while Call Forwarding is active. If a destination extension for call forwarding separates, Call Forwarding to that extension remains active. Calls forwarded while the telephone is separated hear a busy signal.

- **Call Pickup**

If a line appearance is available, a member of a call pickup group may separate at any time. If a call is attempting to terminate, and a member of a group associates, that member does not join the group for the call that is currently in progress, but is available for all subsequent calls to that group.

- **Expert Agent Selection (EAS)**

Station user records cannot be shared between TTI ports and EAS login ID extensions. This reduces the number of possible TTI ports your system provides, depending on the number of administered EAS login IDs. For example, if you administer 2,000 EAS login IDs, the maximum number of TTI ports that the system can provide is reduced by 2,000.

- **Hunt Group Uniform Call Distribution/Direct Department Calling**

The system excludes telephones previously X-ported as a result of a TTI separate, a PSA dissociate, or administration from all transactions already active in the hunt group when the telephone is merged.

- **Site Data**

If Terminal Translation Initialization is enabled, a warning message displays when you tab off the Site Data fields.

If Terminal Translation Initialization is enabled, and you change the Port field on the Station screen from “x” to a real port number and change the Room, Jack, or Cable fields in the Site Data section, a warning message displays when you tab off the fields.

- **Terminating Extension Group (TEG)**

If any member of the TEG (that was previously an X port as a result of TTI, PSA or telephone administration) is merged, that member is excluded from all transactions already taking place in the TEG when that member is merged. The member is able to join in all subsequent calls to the group.

## Related topics

---

For more information about configuring the TTI system-wide fields, see [“Feature-Related System Parameters” on page 795](#).

For more information about setting the TTI feature access codes, see [“Feature Access Code” on page 781](#).

## Terminating Extension Group

---

A TEG allows an incoming call to ring as many as 4 phones at one time. Any user in the group can answer the call.

### Detailed description

---

You can administer any phone as a TEG member; however, only a multiappearance phone can be assigned a TEG button with merged-status lamp. The TEG button allows the user to select a TEG call appearance for answering or bridging onto an existing call but not for call origination.

When a TEG member answers an incoming call, a temporary bridged appearance is maintained at the multiappearance phones in the group. However, this appearance is not visible. Any TEG members can bridge onto the call by pressing the TEG button.

### Considerations

---

- A phone user can be a member of more than one TEG, but can have only one TEG button for each group.
- A TEG can handle only one TEG call at a time. Additional calls do not reach the TEG. If a coverage path is assigned to the TEG, the additional calls route accordingly.

### Interactions

---

- Automatic Callback  
This feature cannot be active for a TEG.
- Bridged Call Appearance  
Calls to a TEG cannot be bridged, except via a Temporary Bridged Appearance.

- Call Coverage

A TEG can have a Call Coverage path assigned, but cannot be a point in a Call Coverage path.

A Send Term button for the TEG can be assigned to group members who have multiappearance phones. When a user presses Send Term, calls to the TEG redirect to coverage. The merged status lamp lights on all phones with a Send Term button. Any member with a Send Term button can deactivate Send Term by pressing the button. Incoming calls are directed to the group.

- Call Park

A TEG call cannot be parked on the group extension. However, a group member answering a call can park a TEG call on their own extension.

- Direct Department Calling (DDC) and Uniform Call Distribution (UCD)

A TEG cannot be a member of a DDC or UCD group.

- Internal Automatic Answer

TEG calls are not eligible for Internal Automatic Answer; however, calls placed to an individual extension are eligible.

- Leave Word Calling

Leave Word Calling messages can be stored for a TEG and can be retrieved by a member of the group, a covering user of the group, or a system-wide message retriever. Phone Display and proper authorization can be assigned to the message retriever. Also, a remote Automatic Message Waiting lamp can be assigned to a group member to provide a visual indication that a message has been stored for the group. One indicator is allowed per TEG.

- Privacy — Manual Exclusion

Privacy — Manual Exclusion can be assigned to any of the phones in a TEG to prohibit bridging by other group members. A TEG member who attempts to bridge onto a call with Privacy — Manual Exclusion active is dropped.

- Temporary Bridged Appearance

At multiappearance phones in the TEG, a temporary bridged appearance is maintained after a call is answered. Thus, other members of the group can bridge onto the call.

## Time of Day Routing

---

You can use Time of Day Routing to select route patterns for calls according to the time of day and day of the week. You need to define the route pattern you want to use before you set up time of day routing.

You can route calls based on the least expensive route, and you can deny outgoing long-distance calls after business hours to help prevent toll fraud. You can use partition groups to assign different time of day route plans for different groups of users.

Automatic Alternate Routing (AAR) or Automatic Route Selection (ARS) must be administered on your switch before you use Time of Day Routing. Time of Day Routing applies to all AAR or ARS outgoing calls and trunks used for call forwarding to external numbers.

### Interactions

---

- Distributed Communications System (DCS)

Be careful when you make Time of Day Routing assignments in a DCS environment. The user's COR Time of Day Plan Number determines whether or not the call is routed to a DCS trunk group. The call loses feature transparency if it is not routed to a DCS trunk group.

When a call routes over a DCS trunk, the switch at the far end routes the call according to the COR Time of Day Plan Number of the incoming trunk.

- Remote Access

When remote access is used and an authorization code or barrier code is dialed for an AAR or ARS call, the COR Time of Day Plan Number of the barrier code or authorization code is used to route the call.

### Related topics

---

- See [“Setting up time of day routing” on page 268](#) for information on setting up Time of Day routing.
- See [“Defining ARS Partitions” on page 265](#) if you want to set up different Time of Day routing for different partition groups.
- See [“Automatic routing — general” on page 1499](#) for information on AAR and ARS

## **Time of Day Clock Synchronization**

---

Time of Day Clock Synchronization provides you with the capability of synchronizing your MultiVantage system clock(s) with Internet servers providing Coordinated Universal Time (UTC).

Time of Day Clock Synchronization enables a switch to synchronize its internal clock to UTC time provided by Internet time servers. The LINUX or Windows 2000 platforms, running NTP or SNTP software, poll the time servers for the UTC time. UTC time is then converted to the local time of the switch. The platform system clock then provides the synchronized time to MultiVantage.

### **Detailed description**

---

UTC time is received from time servers connected to the Internet. LINUX/Windows 2000 connect, through an Ethernet port, to these time servers using NTP or SNTP software. UTC time then is converted to the local time of the switch.

### **ORYX/PECOS and Legacy DEFINITY**

The existing design of legacy DEFINITY uses a software clock to keep track of the time of day. A MultiVantage SAT command is used to set and display this time. A hardware clock also is provided to maintain the system when power is lost.

The software and hardware clocks are set whenever a manual change is made on the Set Time SAT screen or when local time changes because of daylight savings time adjustment. These adjustments can have significant delays (more than a minute) in a heavily loaded system because of process priorities so the accuracy of the time actually can be compromised by a manual set of the time.

The software clock is not synchronized with an external timing source so this time will drift over time. Corrections for the drift of the software and hardware clocks can be made by software on LINUX but not on Oryx/Pecos.

### **S8100 Media Server and Windows 2000**

The system time is maintained by the operating system at UTC. Library functions are provided to obtain local time. The time zone and use of daylight savings time are set from the time/date dialog box on the desktop.

SNTP compliant software is available on Windows 2000. This software runs a system service that can be started up at system boot time. Windows 2000 uses Registry entries to set SNTP parameters. Avaya will not support the optional use of a Microsoft network domain controller as the primary time server.

## Use of Time of Day information by MultiVantage

MultiVantage features use the time of day information for a variety of reasons.

- Time stamp data elements (CDR records, error logs, Message Sequence Trace data, MCT records, BCMS, and CMS data)
- Set time-out intervals (Automatic wakeup messages, Do no disturb intervals)
- Schedule tasks (scheduled maintenance, moving CDR data to the output file)
- Synchronize time of day information with other processors (periodic TOD messages sent to the 860 processor on the S8100 Media Server processor circuit pack)

The time of day value used for the MultiVantage system time is essentially local time with or without daylight savings time adjustments.

S8100 Media Server uses the Windows 2000 and S8700 Multi-Connect uses LINUX as the platform operating system. The use of the system clock from the platform OS is transparent. Both Windows and LINUX use UTC for the system (software) clock. Library functions and APIs are used to express the time in local time. MultiVantage code still uses local time. However, the daylight savings rule for system time is controlled by the OS. This is accounted for by using the time adjustments from the OS for Daylight Savings Rule 1. The display of this rule on the System Access Terminal Daylight Savings Rules screen is display-only. The values displayed for the time adjustments are read from the operating system.

In legacy DEFINITY when a change is made to the system time because of a manual change on the Set Time SAT screen or because of an adjustment for daylight savings time, certain DEFINITY applications that need to know about the change are notified before the change is made to the system clock.

If you do not have Internet access, you can continue to manually set the time of day.

### **CAUTION:**

*Avoid setting the time manually while the TOD clock sync feature is enabled. Manually setting the time, while NTP/SNTP is running, defeats the purpose of syncing the UTC time and could cause problems depending on the difference between the system time and UTC.*

## **Setting time of day clock synchronization**

The recommended configuration for ASA PC and time synchronization:

1. The PC clock is to be set to the local time including applying the local daylight savings time (DST) rule.
2. The offset for each switch is to be set based on the difference between the local ASA PC standard time and the switch standard time (for example, use offset of “plus 1 hour” if ASA PC standard time is 02:00 when the switch standard time is 03:00 per existing operation).
3. Schedule the task to occur no more often than every 24 hours at a low traffic time period based on the local time at the switch and in the middle of a BCMS/CMS interval being used at the switch (for example, 11:07 PM or 3:07 AM). Also the time picked should not be set to a time period when MultiVantage nightly maintenance is scheduled to be run or the BCMS next day period starts. Note that the time ASA uses to decide when to send the time change is based on the local PC time including DST when applicable. Therefore the start time and interval entered for a switch must be based on the switch local time converted to the PC local time.

Running the task more frequently (for example, every 12 hours) makes it more difficult to have it run during a low traffic period or it could cause the scheduled time to occur at different times during the day as time goes on (for example, picking any entry other than Every 24 hours or 12 hours will make the scheduled time “creep” over the day by the selected time interval since only the start date-time and repeat interval can be specified). The use of the Weekly or Monthly Recurrence Patterns does not have the “creep” problem.

4. Note that ASA must be running and OSSI connectivity to the switches must be available (via LAN or dialup) during the scheduled times for synchronizing the MultiVantage switches that it manages.

The recommended configuration for each MultiVantage switch time synchronization:

1. The system clock may be set to either local time using automatic DST changes, local standard time (without DST changes - DST Rule set to 0) or GMT time (without DST changes). In the case where automatic DST changes is not assigned to the system clock (that is, the DST rule is set to 0 on the Date and Time screen), you can use the Multiple Locations feature to display DST (and local time in the case where the system time is set to GMT) on the station sets homed on the local port networks. However, all switch reports (including BCMS), CMS/Supervisor reports, TOD routing and scheduled events will be based on the system clock time not the location time. It is expected that in most cases the system clock will be set to local time with DST change. In each case, the ASA assigned offset for the switch will provide the proper conversion from PC time to the desired system clock standard time.
2. In all cases the Multiple Locations feature provides local time display on station sets based on the local time zone and DST rule in effect at the remote port network (EPN) site. The time determined by the location assignments also applies to do-not-disturb, Automatic Wakeup programming and execution (however, the announced time is the system time). Use the Locations screen to define the time zone offset from the standard time local to the switch location (the PPN location) and the DST rule to be used for any remote EPNs that are located in different time zones. The location numbers established in the Locations screen then are assigned to the appropriate EPN cabinets using the cabinet description screen. The same location number can be assigned to more than one cabinet that are in the same time zone. Note that only DEFINITY R (Mips) configurations can be assigned locations other than 1 (the DEFINITY CSI/SI configuration defaults to location 1).
3. Each of the configuration possibilities is summarized as follows:
  - a. **System time set to local time with automatic DST changes** (when observed in that area) - Use the Date and Time screen to set the time for the local time zone and the DST rule defined on the [“Daylight Savings Rules”](#) screen. The time initially can be set manually to the local standard time during fall/winter/spring or to the local DST time in the summer. If DST is not observed then the following configuration b would be used. All reports and display station sets will show the local time with the DST rule applied. TOD routing/scheduled events occur based on the system clock (which will be in the local standard time or local DST depending on the time of the year). Use the Multiple Locations feature to display local time on station sets at remote sites.

- b. **System time set to local time without DST rules** - the Date and Time screen has the standard time for the local time zone set and the DST rule field is set to **0**. All reports and TOD routing/scheduled events are all based on local standard time regardless of whether DST is being observed or not. Display station sets at the local PPN and remote EPN sites can have actual local time (with DST applied) via the Multiple Locations feature.
- c. **System time set to GMT (UTC)** - the Date and Time screen has GMT standard time set with the DST rule set to 0. All reports and TOD routing/scheduled events are all based on GMT time. Display station sets at the local PPN and remote EPN sites can have actual local time (with DST applied) via the Multiple Locations feature. The ASA offset for this MultiVantage switch will be the offset of the ASA PC local standard time from GMT/UTC time (for example if the ASA PC is in Denver, the offset for any switch using GMT time is +7).

**⇒ NOTE:**

When NTP starts up, there will be a gap of possibly several minutes between MultiVantage time and the time provided by NTP. NTP reduces this gap to milliseconds over a period of hours.

## **Transfer**

---

Transfer allows telephone users to transfer trunk or internal calls to other telephones or trunks without attendant assistance.

### **Considerations**

---

- You can administer transferred-trunk calls to receive either music or silence if the first part of the transfer places the call on hold.
- Multi-appearance telephones must have an idle appearance to transfer a call.
- Single-line telephone users momentarily flash the switchhook or press the RECALL button, dial the desired extension, and hang up. Multi-appearance telephone users press the TRANSFER button, dial the desired extension, and press the TRANSFER button again.
- If, on the Feature-Related System Parameters screen, the Transfer Upon Hang-up field is **y**, users can transfer a call by pressing the TRANSFER button, dialing the desired extension, and then hanging up. The user can hang up while the desired extension is ringing or after the party has picked up. The user also can still press the TRANSFER button a second time to complete the transfer process.

- If, on the Feature-Related System Parameters screen, the Abort Transfer field is **y**, users can abort the transfer a call by pressing the TRANSFER button, dialing the desired extension, and then hanging up or selecting any non-idle call appearance. The user must press the Transfer button again to complete the process (see Note). If the user selects an idle call appearance, the transfer still is active.

 **NOTE:**

If both the Abort Transfer and Transfer Upon Hang-Up fields are **y** and you press the TRANSFER button and then dial the complete transfer-to number, hanging up the phone transfers the call.

- Users of Digital Communications Protocol (DCP), Hybrid, and wireless phones can transfer a call on hold without removing the call from hold. If there is only one call on hold, no active call appearances, and an available call appearance for the transfer, the user can transfer the call simply by pressing the Transfer button. Avaya MultiVantage assumes the transfer is for the call on hold, and the transfer feature works as usual.

If there is more than one call on hold, the user must make a call active in order to transfer it. If the user presses the Transfer button with two or more calls on hold, Avaya MultiVantage will ignore the transfer attempt since it will not know which call the user wants to transfer. If there are calls on hold and an active call, pressing the Transfer button will start the transfer process for the active call.

- Avaya MultiVantage can be administered to display a confirmation message to users upon successful call transfers. The confirmation message will only be visible to users with DCP, Hybrid, wireless (except for 9601), or Integrated Services Digital Network-Basic Rate Interface (ISDN-BRI) display phones. All of these phones, except for the Hybrids, can display the confirmation message in English, Spanish, French, Italian, or a language you define. Hybrid phones only display the message in English.
- You can administer the system to return a transferred call to the originator if the transferred-to party does not answer within a set time limit. To do this, enter a value in the Station Call Transfer Recall Timer field on the [Feature-Related System Parameters](#) screen.

## Interactions

---

- **Attendant Conference**

This may not operate properly if the CO does not provide answer supervision. In that case, the Answer Supervision Timeout and Outgoing End of Dial fields (on the CO Trunk Group screen) must be set to the same non-zero number. The Receive Answer Supervision field must be set to **n**.

If the CO does provide answer supervision, the Answer Supervision Timeout and Outgoing End of Dial field must be set to **0** and the Receive Answer Supervision field must be set to **y**.

- **Bridged Call Appearance**

A bridged call appearance can be used to transfer calls.

- **CentreVu Agent**

CentreVu Agent supports the conference and transfer of calls on hold, but it does not display the confirmation message for transferred calls.

- **Class of Restriction (COR)**

Set the Block Transfer Display field on the COR screen to **y** if you do *not* want users to receive a confirmation message for call transfers.

- **Integrated Services Digital Network Basic Rate Interface (ISDN-BRI)**

When an ISDN-BRI telephone, assigned with the Select Last Used Appearance field set to **y**, completes a transfer while off-hook using the handset, the user is left listening to dial tone on the last-used appearance.

- **Internal Automatic Answer**

Transferred calls can be answered automatically via IAA.

- **QSIG Networking**

If calls over an ISDN-PRI trunk are administered for Supplementary QSIG, then additional call information may display.

- **Station**

When a multifunction telephone dials enough digits to route a call, but the call could route differently if additional digits were dialed, the telephone does not recognize the Conference or Transfer buttons. The user must delay dialing for 3 seconds or dial # to indicate that the call can be routed based on the digits already dialed. The Conference or Transfer buttons then are recognized and the switch completes the operation.

## **Pull Transfer**

---

Pull Transfer allows either the transferring or transferred-to party to press the Transfer button to complete the transfer operation.

When attendants control calls, called parties cannot use Pull Transfer. Attendants who are called parties cannot use Pull Transfer. When attendants have parties on hold they are transferred with the standard transfer process.

To use Pull Transfer, calling parties and called parties must be on the same switch, or called parties must be reached via Italian TGU/TGE tie trunks.

Called parties using analog telephones flash the switchhook or press the flash key or recall button to transfer calls. Called parties using digital phones press the transfer key to complete transfers.

## **Interactions**

---

- **Analog Station Recall Operation and Feature Activation**

When called parties initiate either analog-telephone recall or feature activation, callers are not put on hold for transfer, they are transferred via Pull Transfer.

- **BRI telephones**

Callers using BRI Stations reach desired parties through an intermediate step by calling a party who calls a final destination. Intermediate parties activate pull transfer to complete transfers. Final called parties go off hook as if a new transfer was originated.

- **Call Detail Recording**

The switch checks to ensure that calls are correctly recorded with CDR when Pull Transfer is completed.

- **Digital Station Transfer Operation**

When called parties initiate transfer operations, callers are not put on hold for transfer; they are transferred via Pull Transfer.

- **Non-BRI telephones:**

Callers using Non-BRI telephones reach desired parties through an intermediate step by calling a party who calls a final destination. Each called party activates pull transfer.

## Transfer — Outgoing Trunk to Outgoing Trunk

---

Outgoing Trunk to Outgoing Trunk Transfer (OTTOTT) permits a controlling party (such as a station user or attendant) to initiate two or more outgoing trunk calls and then connect the trunks. This operation removes the controlling party from the connection and conferences the outgoing trunks. Alternatively, the controlling party can establish a conference call with the outgoing trunks and then drop out of the conference, leaving only the outgoing trunks on the conference.

### NOTE:

This is an optional enhancement to Trunk-to-Trunk Transfer and requires careful administration and use. The DCS Trunk Turnaround may be an acceptable and safer alternative to this feature.

OTTOTT allows calls to be established in which the only parties involved are external to the switch and are on outgoing trunks. This type of call can result in locked-up trunks, such as trunks that cannot be disconnected except by busying-out and releasing the affected trunk circuit. To clear the lockup, a service technician must reseat the trunk board, or busy-out and release the affected trunk.

## Detailed description

---

This feature is enabled by administering the Disconnect Supervision Out field to **y** on at least one outgoing trunk group screen, and enabling Trunk-to-trunk transfer on the Feature Related System Parameters screen. In addition, the network must provide answer supervision. The answer supervision test increases the probability, but does not guarantee, that a disconnect signal is received from the remote end of the trunk. To mitigate problems associated with its accidental use, this feature is administrable only on trunk groups on the Trunk Group screen. It is not a system option.

DCS networks provide a similar but more restrictive version of this feature, called DCS Trunk Turnaround, which permits two outgoing trunks to be connected when the switch at the remote end of one of the trunks agrees to turn around the logical direction of the trunk. DCS trunk turnaround is permitted, when some other party involved in the call (at the remote switch) can provide disconnect supervision.

Without OTTOTT or DCS, a conference involving two or more outgoing trunks is permitted only when at least one remaining conference party is an attendant, incoming trunk, or station.

## Considerations

---

- OTTOTT is not intended for use in DCS networks, since DCS Trunk Turnaround provides comparable capabilities much more safely. However, use of OTTOTT with DCS is not prohibited, and may be useful when one or more of the trunks goes off the DCS network.

## Security Measures

---

### SECURITY ALERT:

*This feature can be used to transfer an outside party to a trunk over which toll calls might be made, and enabling it poses significant security risks. Since trunks have to be specifically administered for OTTOTT, you should examine the COR and FRL of that trunk group to determine if they are appropriate.*

### SECURITY ALERT:

*OTTOTT is not a system-wide parameter. It is administered on a trunk-group basis. You must enable the Trunk-to-Trunk Transfer field on the Feature-Related System Parameters screen for this feature to work. If you deem that the feature is not relevant to your business practices, do not enable it. Alternately, if a temporary need presents itself, you can temporarily enable this feature and then turn it off.*

## Interactions

---

- DCS Trunk Turnaround

OTTOTT increases the set of cases in which DCS Trunk Turnaround may be accepted. However, use of OTTOTT in combination with a DCS network is strongly discouraged. The following algorithm describes the DCS Trunk Turnaround request process.

- a. If any party on the call receives a local-dial, busy, intercept, or reorder tone, deny turnaround.
- b. If any remaining party is an answered station or attendant, accept turnaround.
- c. If any remaining party is on an incoming trunk, accept turnaround. For the purposes of this check, an outgoing DCS trunk that has been turned around an odd number of times via a DCS trunk turnaround is considered an incoming trunk with disconnect supervision. Similarly, an incoming DCS trunk that has been turned around an odd number of times is considered an outgoing trunk.
- d. If any remaining party is an outgoing trunk administered for OTTOTT that has received answer supervision, accept turnaround.
- e. If any remaining party is an outgoing DCS trunk, forward the turnaround request.
- f. Otherwise, deny turnaround.

- Incoming Disconnect Supervision

Outside of the U.S., incoming disconnect supervision is a switch capability that restricts transfers or conferences for certain incoming trunks. In the U.S., all incoming trunks are assumed to provide disconnect supervision. In some countries this assumption is not valid, so administer whether or not an incoming trunk provides disconnect supervision for each trunk group.

- Personal Central Office Lines (PCOLs)

Transfer of PCOLs is not subject to the normal restrictions applied to transfer of other trunks. These transfers are allowed since the PCOL appearance remains on one or more stations as a feature button. System users must be aware that the DROP button cannot be used to disconnect the transferred-to party from the call. Hence, if an outgoing PCOL is transferred to an outgoing trunk and neither of the trunks can supply a disconnect signal, the two trunks lock up.

- QSIG Global Networking

If either call is over an ISDN-PRI trunk administered with Supplementary Service Protocol b (QSIG), additional call information may display.

- Release Link Trunks (RLT)

RLTs are used by CAS. An outgoing RLT at a remote branch is used to access an attendant at the main. The attendant at the main can transfer the incoming caller to a station or trunk at the branch. The RLT is typically used only for a short period of time and is usually idled after the transfer is established.

A station at a branch can transfer an outgoing trunk to the attendant at the main. This transfer could be viewed as an OTTOTT (the attendant is accessed via an outgoing RLT). Since administering outgoing disconnect supervision for RLT trunks provides no additional capability, this administration is not provided for RLT trunks.

- Restriction

Restrictions on the transferring party may block a transfer or drop operation even when Outgoing Disconnect Supervision is provided.

- Trunk-to-Trunk Transfer

If this feature-related system parameter is set to restricted, all trunk-to-trunk transfer/release/drop operations for public trunks (CO, CPE, CAS, DID, DIOD, FX, and WATS) have calls terminated or receive denial. If the parameter is set to none, all trunk-to-trunk transfers (except CAS and DCS) have calls terminated or receive denial.

Hence, this option must be set to all to enable OTTOTT operation for these types of trunks. The number of public-network trunks allowed on a conference call is administrable. This number defaults to 1, so if OTTOTT is being used to connect two or more public network trunks, you must increase this limit on the Feature-Related System Parameters screen.

- Trunks (CO, FX, and WATS)

You cannot have two CO, FX, or WATS trunks in a OTTOTT connection, even if the Disconnect Supervision - Out field is set to **y**.

## Transfer — Trunk-to-Trunk

---

Trunk-to-Trunk Transfer allows the attendant or user to connect an incoming trunk call to an outgoing trunk.

 **SECURITY ALERT:**

*Trunk-to-trunk transfer poses a significant security risk. Use this feature only with extreme caution.*

The system provides three levels of administration for this feature: system-wide, COR-to-COR, and COS.

To administer Trunk-to-Trunk Transfer system-wide, complete the Feature-Related System Parameters screen. To restrict Trunk-to-Trunk Transfer on a trunk-group basis, assign COR-to-COR calling-party restrictions on the Class of Restriction screen. To allow individual users to control Trunk-to-Trunk Transfers, assign capabilities on the Class of Service screen.

## Considerations

---

- Trunk-to-Trunk Transfer is particularly useful when a caller outside the system calls a user or attendant and requests a transfer to another outside number. For example, a worker, away on business, can call in and have the call transferred elsewhere.
- Transferred trunk calls can be administered to receive either music or silence.
- Some CO trunks do not signal the PBX when the CO user disconnects from a call. The system ensures that incoming CO trunks without Disconnect Supervision are not transferred to outgoing trunks or to other incoming CO trunks without Disconnect Supervision.
- An attendant-assisted call connecting an outgoing trunk or incoming trunk without Disconnect Supervision to an outgoing trunk must be held on the console. The system does not allow the attendant to release the call. The attendant can, however, use the Forced Release button and disconnect all parties associated with the call.
- If a user has connected two outgoing trunks or an outgoing call and an incoming call without Disconnect Supervision, the user must remain on the call. Otherwise, the call is dropped. An incoming trunk with Disconnect Supervision can be connected to an outgoing trunk without the user remaining on the call. An incoming trunk can also be connected to another incoming trunk without the user remaining on the call if one of the incoming trunks has Disconnect Supervision.

## Interactions

---

- Attendant Lockout  
Attendant Lockout does not function on Trunk-to-Trunk Transfer.
- Call Vectoring  
Station control of Trunk-to-Trunk Transfer does not affect routing of incoming trunks to a vector directory number (VDN) that ultimately routes to a destination off-net.  
  
A route to a number off the switch does *not* require you to enable trunk-to-trunk transfer.

- Tenant Partitioning

Station control of Trunk-to-Trunk Transfer is prohibited between trunks in different tenant partitions if those partitions are restricted.

## Trunk Flash

---

Trunk Flash allows a feature or function button on a multifunction telephone or attendant console to be assigned as a Flash button. Pressing this button while connected to a trunk (which must have been administered to allow trunk flash) causes the System to send a flash signal out over the connected trunk.

Trunk Flash enables multifunction telephones to access central office customized services that are provided by the far-end or CO located directly behind the MultiVantage System. These central office customized services are electronic features, such as conference and transfer, that are accessed by a sequence of flash signal and dial signals from the MultiVantage system telephone on an active trunk call. The Trunk Flash feature can help to reduce the number of trunk lines connected to the MultiVantage switch by:

- Performing trunk-to-trunk call transfers at the far-end or CO, which eliminates the use of a second trunk line for the duration of the call and frees the original trunk line for the duration of the call.
- Performing a conference call with a second outside call party, which eliminates the need for a second trunk line for the duration of the call.

 **NOTE:**

Some analog DTMF telephone sets used in Italy and the United Kingdom are equipped with a FLASH button that, when pressed, generates a rotary digit 1. When an analog telephone which is administered as a DTMF telephone (for example, as a 2500 or 71nn-type telephone) transmits a rotary digit 1, the system treats the signal as a recall signal from the telephone set to the Avaya MultiVantage.

When used by a CAS attendant connected to an RLT, the flash controls certain CAS features at the branch. When used by a multifunction telephone or non-CAS attendant connected to a CO, FX, or WATS trunk, the flash controls certain features (such as add-on) at the connected CO.

Trunk Flash is not available on PCOL groups.

The system supports the Trunk Flash signal for incoming, outgoing, or 2-way call directions on selected 2-wire analog (ground-start or loop-start) or digital (DS1) trunks or Tie trunks on DS1.

If the trunk group is a DS1 trunk in Italy, the Trunk Flash feature applies only to outgoing calls.

If the trunk is not directly connected to the far end or CO providing the customized services, use of the Trunk Flash signal may cause the call to be disconnected by the far end or CO.

Calls made after the Flash are not recorded in CDR records.

## Considerations

---

### NOTE:

The Trunk Flash feature allows the telephone user to receive central office dial tone, and place a call that is not monitored by the MultiVantage system, and is not subject to restrictions (toll, facilities restriction level (FRL), class of restriction (COR), etc.). Therefore you should enable this feature with caution.

- A Trunk Flash button can be assigned on CAS attendant consoles, non-CAS attendant consoles, and multifunction telephones. For CAS attendants, use of this button is limited to certain CAS features via RLT trunks. For multifunction and non-CAS attendant consoles, this button is used for the Trunk Flash feature.
- FAC activation of the trunk flash feature is allowed.
- The Flash button is used by the Trunk Flash and CAS features.
- System features (such as internal conference call, transfer, and call park) may be combined with custom services (that is, CO-based features that are activated/controlled by sending a flash signal over the trunk to the CO). However, mixing Avaya MultiVantage features with custom services causes complications for the user when tracking a call. MultiVantage Systems cannot give the local telephone user status information on the custom services.
- The Trunk Flash feature may only be accessed if the call has only one trunk, the trunk must be outgoing from the PBX's perspective, and the trunk group of that trunk has Trunk Flash enabled. The Trunk Flash feature is disabled when the call involves more than one trunk, even if all the trunks have Trunk Flash enabled.
- Any Avaya MultiVantage telephone can flash and dial a FAC to access the Trunk Flash feature; any Avaya MultiVantage telephone with a flash button can access the Trunk Flash feature by hitting the flash button. The system allows as many as five telephones to participate in a conference call with the trunk line party. However, to access the Trunk Flash feature, at least one of the telephones must have a Flash button.

- In a call involving more than one telephone, one of the telephones may press the Flash button, and another telephone may dial the phone number. The telephone that dials the phone number is not required to have a Flash button.
- If the far-end/CO does not support custom services, the call may be dropped by the far-end/CO on sending the flash signal or the signal may be ignored and a click-click sound is heard.

## Trunks and trunk groups

---

Trunks connect Avaya MultiVantage to other pieces of equipment (adjuncts) and to other switches. In general, trunks connect your switch to one of four things:

- the public telephone network
- a private telephone network
- the Internet or a private intranet
- switch adjuncts, such as a loudspeaker paging system or a source for music or announcements

When trunks of the same type are used for the same application, assign them to the same trunk group. A trunk group allows you to assign service characteristics to the group rather than administering each trunk individually.

### NOTE:

Trunks and access endpoints consume the same resource. The sum of trunks and access endpoints cannot exceed the total number of trunks allowed on your system.

This chapter contains information about the most common analog and digital trunks. Specialized trunks such as Advanced Private-Line Termination (APLT), tandem, release-link, and DMI-BOS trunks are not covered in this manual. See *Overview for Avaya MultiVantage™ Software* and *Administration for Network Connectivity for Avaya MultiVantage™ Software* for information on these trunks.

### **Brief description**

---

Avaya MultiVantage supports the following basic trunk types.

### **Access**

Used in ETN, access trunks connect satellite switches to the main switch. Unlike tandem trunks, access trunks do not carry TCMs and thus allow satellite callers unrestricted access to out-dial trunks on the main switch.

## **CAMA — Centralized Automatic Message Accounting (E911)**

CAMA trunks route emergency calls to the local community's Enhanced 911 systems and provide CESID information to the system. Public Service Answering Points (PSAP) use CAMA trunks to determine the caller's physical address.

### **⇒ NOTE:**

Avaya does not recommend tandeming 911 calls.

When the CAMA feature is administered and a 911 call is placed from an Avaya MultiVantage station, MultiVantage software searches for the proper CAMA Touch-Tone Receiver (TTR) resource in the port network (PN) where the CAMA trunk group is located. If the proper CAMA TTR resource is not available in that port network, the software checks any other available port networks for the CAMA TTR. If none is found in the entire system, a busy tone is returned to the calling party. However, if another trunk group is in the same routing pattern as the CAMA trunk group, the call routes to the next available trunk group in the pattern. For example, if a CO trunk group is used, then any available TTR resource can be used and the call routes as a normal call over the CO trunk and the public switched telephone network.

E911 systems use CESID information to identify the location of the calling phone. The following features can cause incorrect CESID information to be sent with a 911 call.

### **Bridged stations**

911 calls from a bridged extension will report the CESID of the principle station.

### **EAS agents**

911 calls from an agent in an EAS skill will report the CESID of the physical station, not the logical agent.

### **Personal Station Access/Terminal Translation Initialization**

When you use PSA or TTI to associate a phone with another extension, the switch will report the CESID of the extension — not the physical phone associated with it.

## **CO — Central Office**

CO trunks transmit dialed digits for outgoing calls but not for incoming calls. Use CO trunks when you want all incoming calls go to the same destination, such as an attendant or a voice menu system. Individual users can place outgoing calls without attendant assistance. CO trunks typically connect your switch to the local central office, but they can also connect adjuncts such as external paging systems and data modules.

## **CPE — Customer-Provided Equipment**

Use CPE trunks to connect adjuncts, such as paging systems and announcement or music sources, to the switch.

### **⇒ NOTE:**

You can connect some types of equipment to the switch by trunks without administering a CPE trunk group. For example, trunk port interfaces can be assigned on system screens for Music-on-Hold Access (Feature-Related System Parameters screen) or voice and chime paging (Loudspeaker Paging and Code Calling Access screen).

## **DID — Direct Inward Dialing**

DID trunks carry incoming calls directly from the local central office to your switch. These trunks transmit the digits your switch needs to route incoming calls to specific extensions. Use DID trunks when you want people calling your organization to dial individual users directly without going through an attendant or some other central point.

## **DIOD — Direct Inward/Outward Dialing**

DIOD trunks are two-way trunks that transmit dialed digits in both directions. Thus, use DIOD trunks when you want a two-way trunk group with the convenience of direct inward dialing for incoming calls. DIOD trunks are used mostly outside North America, and typically they connect the switch to a local central office.

In North America, use tie trunks for applications that require two-way transmission of dialed digits. In the U.S., trunks that transmit digits in both directions are sometimes called “smart trunks” and are administered as T1 tie trunks.

## **FX — Foreign Exchange**

An FX trunk is essentially a CO trunk that connects your switch directly to a central office outside your local exchange area. Use FX trunks to reduce long distance charges if your organization averages a high volume of long-distance calls to a specific area code.

## **IP Trunks — Internet Protocol Trunks**

IP trunks allow Avaya MultiVantage to route voice calls and faxes over a local- or wide-area TCP/IP network. Use IP trunks to reduce long-distance charges by routing calls over the Internet or your intranet.

### **NOTE:**

The origin and destination switches must both have the special hardware and software needed to route telephone calls over IP networks. See the *Administration for Network Connectivity for Avaya MultiVantage™ Software* for more information.

## **ISDN — Integrated Services Digital Network**

ISDN trunks are digital trunks that can integrate voice, data, and video signals and provide the bandwidth needed for applications such as high-speed data transfer and video conferencing. ISDN provides end-to-end digital connectivity and uses a high-speed interface that provides service-independent access to switched services. Through internationally accepted standard interfaces, an ISDN provides circuit or packet-switched connectivity within a network and can link to other ISDN-supported interfaces to provide national and international digital communications. ISDN trunks can also efficiently combine multiple services on one trunk group.

## **PCOL — Personal Central Office Line**

A personal central office line is one dedicated trunk that links a group of phones to the local central office or to another switch in a private network. A PCOL group can have 1–16 phones, and each phone can have one or more appearances for the personal central office line. You may administer a PCOL group as a CO, FX, or WATS trunk group. Use a PCOL line when one or more users need a direct, dedicated connection to the public network or to another switch.

### Tie

Tie trunks connect a switch to a central office or to another switch in a private network. These trunks transmit dialed digits with both outgoing and incoming calls. Thus, incoming calls over a tie trunk can be routed directly to the extension the caller dialed. Tie trunks are frequently used in private networks; in addition, use tie trunks when you want a two-way trunk group with the convenience of direct inward dialing for incoming calls.

Tie trunks that connect private network switches are “universal. “This means that the trunks can be administered with a variety of translation encodes. The originating switch can recognize any start dial signal (precise dial tone, wink start, or delay dial) that the terminating switch sends. If the originating switch does not receive one of these start dial signals, it can be administered to send digits after an administered interval. (This time-out interval is the amount of time that the originating switch waits before sending digits.)

#### **Analog tie trunks**

The number of tie trunks in a connection and the technology of any multiplex systems used in the facilities affect the maximum data transfer rate. Generally, for transfer rates up to 300 bps, a connection can have 5 tie trunks in tandem. For data rates of 301–2,400 bps, a connection can have up to 3 tie trunks in tandem. For data rates of 2,401–4,800 bps, a connection can have up to 2 tie trunks in tandem.

Analog tie trunks used in unswitched connections can support up to 9,600 bps.

#### **Digital tie trunks**

The digital tie trunk is a high-speed and high-volume trunk interface to a T1 or E1 carrier. It uses a digital signal level 1 (DS1) protocol. By multiplexing 24 64-kbps digital channels onto a single 1.544-Mbps T1 carrier, or 32 64-kbps digital channels onto a single 2.048-Mbps E1 carrier, DS1 offers an economical alternative to the analog tie trunk as well as a high-speed fully digital (without modems) connection between the switches.

The maximum per-channel data rate for DS1 is 64 Kbps, and DS1 trunks can carry voice, voiceband data, or high-speed data communications.

### **WATS — Wide Area Telecommunications Service**

Outgoing WATS service allows calls to certain areas (“WATS bands”) for a flat monthly charge. Incoming WATS trunks allow you to offer toll-free calling to customers and employees.

## Applications for different trunk types

To help you select the right type of trunk for a specific application, the following table gives you an overview of key characteristics of different trunk groups. Remember that all analog trunks can carry only voice and voice-grade data.

| Type of trunk | Direction                       | Analog or Digital? | Traffic supported                  | Transmits digits?       |
|---------------|---------------------------------|--------------------|------------------------------------|-------------------------|
| CO, FX, WATS  | Incoming<br>Outgoing<br>Two-way | Either             | Any kind of voice or data traffic. | No                      |
| CPE           | N.A.                            | Either             | Any kind of voice or data traffic. | No                      |
| DID           | Incoming                        | Either             | Only voice and voice-grade data.   | Yes                     |
| DIOD          | Incoming<br>Outgoing<br>Two-way | Either             | Any kind of voice or data traffic. | Only for incoming calls |
| PCOL          | Incoming<br>Outgoing<br>Two-way | Analog only        | Only voice and voice-grade data.   | No                      |
| Tie, Access   | Incoming<br>Outgoing<br>Two-way | Either             | Any kind of voice or data traffic. | Yes                     |

## Transmission and supervisory signaling

A trunk is named for its transmission characteristics. For example, trunks are always classified by the direction of the traffic they allow:

- One-way incoming trunk — A local trunk that can be selected (seized) by the far-end connected switch.
- One-way outgoing trunk — A trunk that can be seized by the local switch to call the far-end switch.
- Two-way trunk — A trunk that can be seized by either of the connected switches.

Another transmission characteristic is signaling, which is the transmission of supervision, address, alerting, or other switching information. Supervisory signaling establishes or sets up the connection of the local switch to the distant switch. In general, supervisory signaling has 2 phases:

- Seizure signal — The originating office's signal for a request for service from the distant office.
- Start-dial signal — The distant office's acknowledgment that it is ready to accept dialing from the originating office.

## Seizure signals

### Ear & Mouth (E&M) supervision

E&M supervision is a symmetric signaling scheme used on private network trunks. DC voltage levels are sent over E&M leads, which are separate from the transmission path. E & M signals indicate on-hook and off-hook states for each end of the connection path.

### Ear & Mouth (E&M) supervision on digital trunks

DIOD trunk groups support Continuous and Pulsed E&M Signaling that allows you to make and receive calls over Brazil pulsed or continuous E&M signaling trunks and Hungarian pulsed E&M signaling trunks.

### Ground-start (GS) supervision

Ground-start signaling is a supervisory signaling scheme used on public network trunks in which ground is applied on the tip (T) lead by the CO and on the ring (R) lead by the switch. For example, the calling switch on a call to a CO seizes the outgoing trunk by placing a ground on the trunk interface R lead. The CO recognizes the trunk seizure as a request for service and grounds the trunk T lead to indicate to the calling switch that the CO is ready to receive digits. Ground-start signaling is superior to loop-start signaling (described below) for the following reasons:

- The switch can make trunks busy to outgoing calls almost immediately, because the tip ground seizure by the distant switch minimizes the interval during which a two-way trunk can be seized from both ends (called glare).

- Ground-start signaling allows answer supervision, a positive indication that a distant switch has disconnected from a call. Answer supervision has 2 benefits:
  - Callers who remain off-hook after completing a call won't be connected to central office dial tone. For example, this prevents a restricted station from making an unauthorized call after placing an authorized call using the attendant.
  - By holding the trunk busy until the central office disconnects, another switch cannot seize the trunk and be connected to the CO party of the previous call.
- **Loop-start (LS) supervision** — A supervisory signaling scheme used between a telephone and a switch in which the telephone or far-end office completes the current path formed by the trunk wires. The circuit provides one signaling state when it is open and another when it is closed. A third signaling state is achieved by changing the direction or magnitude of current in the loop. The preferred method of loop-start signaling is reverse battery signaling. Disconnect times when using loop-start signaling can result in delays of up to 10–20 seconds. Glare, as described in ground-start, is possible.

Loop-start signaling does not provide answer supervision. This lack can open a potential for toll fraud in some situations, especially when incoming calls are forwarded off-net. Loop-start is used with analog DIOD trunks, but in general try to use loop start only with one-way trunks.
- **Reverse Battery (RB) supervision** — A supervisory technique on one-way trunks that uses open and closure signals from the originating end and reversals of battery and ground from the terminating end (normally used on direct inward dialing trunks).

## Start-dial signals

Network trunks operate as automatic, immediate start, dial tone, wink start, or delay dial according to the type of start-dial signal (alerting) the switch sends out or expects to receive. The different transmissions of alerting are:

- **Automatic** — The originating switch sends no digits or start dial signal and expects the terminating switch to complete the call. The call usually is completed by the attendant or other service such as Centralized Attendant Service (CAS).
- **Immediate start** — The originating switch sends digits immediately without waiting for a start dial signal from the terminating switch.
- **Dial tone** — The terminating switch sends precise dial tone to the originating switch. This indicates that the terminating switch is ready to receive digits.

- **Wink start** — The terminating switch sends a wink start (momentary off-hook) signal to the originating switch. This indicates that the terminating switch is ready to receive digits.
- **Delay dial** — The terminating switch sends a delay dial signal (an off-hook signal followed by an on-hook signal) to the originating switch. This indicates that the terminating switch is ready to receive digits.

### Types of address transmission

In addition to seizure and start dial signals, switches have to transmit the digits and characters for telephone numbers. This is called address transmission. Three types of signaling are available:

- **Dial Pulse (DP) addressing** — A method of signaling that consists of regular momentary interruptions of a direct or alternating current at the sending end. The number of interruptions corresponds to the value of a digit or character (alternating current is not used by switches). The interruptions usually are produced by a rotary telephone dial, or may be produced by a sender in a switching system.
- **Dual Tone Multifrequency (DTMF) addressing** — Signaling arrangements (commonly known as touch-tone) that consist of two, simultaneous, dialing signals. One tone is from a low group of four frequencies. The other tone is from a high group of four frequencies. Both tones correspond to digits, letters, or characters (0–9, A–Y, or \* and #). One of the tones (1,633 Hz) from the high group is a spare.
- **Multifrequency (MF) addressing** — Signaling arrangements that make use of only 2 frequencies out of 6 to represent 10 decimal digits (0–9) and 5 auxiliary signals. MF signals are used for called number addressing, calling number identification. They also report whether the far end is ringing or busy.

### Analog vs. digital trunks

Analog trunks carry voice and voiceband data communication. “Voice” means that sound of any kind is transformed into electrical waveforms and transmitted within an approximate bandwidth of 300 Hz to 3,400 Hz. “Voiceband data” means that data is transmitted within the voiceband and requires a conversion resource (modem) at both ends of the connection. The data-transmission rate for analog trunks depends on the data-handling capability of the modems in the connection.

Digital trunks represent both sound and data as 0's and 1's and can be configured to carry any kind of voice or data traffic. Digital trunks connect to a DS1 circuit pack and provide a T1 or E1 carrier. DS1 service provides an interface for CO, FX, DID, tie, and WATS trunks. The DS1 interface supports incoming and outgoing dial types of ground-start, loop-start, auto/auto, auto/delay, auto/immed, and auto/wink. Signaling may be robbed-bit or common-channel depending on the trunk type and whether the dial-type is incoming or outgoing. The interface may be used to connect the switch to a toll office directly using wink-start tie trunks for two-way access to the toll network.

Supervision, addressing, and alerting methods have been carried over to digital trunks, which use basically the same signaling scheme as analog trunks when establishing a call. These schemes are handled in a variety of ways to indicate particular calling states, such as on-hook, off-hook, ringing, not ringing, and so on, by using A and B bit-timed signaling. A and B bits carry a 0 or 1 depending on the type of trunk, the near-end channel unit type, far-end channel type, the condition of the trunk (open loop, loop closure, reverse battery, and so on), and whether it is transmit or receive signaling. In addition to the above, see [“DS1 Circuit Pack” on page 757](#) for trunk-related terms associated with DS1 trunk interfaces.

## **Interactions**

---

- **Brazil Block Collect Call**  
In both continuous and pulsed E&M signaling, Block Collect Call is not included.
- **Personal Central Office Line (PCOL)**  
PCOL trunks cannot use continuous, pulsed, or discontinuous E&M.

## Uniform Dial Plan

---

Uniform Dial Plan (UDP) provides a common 3, 4, 5, 6, or 7-digit dial plan - or even a combination of these - that can be shared among a group of switches. The UDP applies interswitch dialing and intraswitch dialing. UDP can be used with an ETN; main, satellite, and tributary switches; and DCS. In a nutshell, UDP provides extension-to-extension dialing among 2 or more private-switching systems. Note that for DCS, a uniform 4 or 5-digit dialing plan must be used.

### Administering UDP

---

Following is a list of the forms and fields you need to consider when administering UDP

| Screen                                      | Field                        |
|---------------------------------------------|------------------------------|
| Dial Plan Analysis Table                    | ■ All                        |

### Detailed description

---

UDP routes calls off the local switch by converting the extension number into a private-network or public-network number. The extension initially dialed by the user can be 3, 4, 5, 6, or 7 digits. The private-network or public-network number is formed by deleting digits from and then inserting digits to the front of the extension. Three types of conversion are supported: AAR, ARS, extension number portability (ENP) and EXT.

- For AAR and ARS, the resulting number is analyzed and routed as a private-network (AAR) or public-network (ARS) number. If you wish to block further digit conversion by AAR or ARS, you can enter n(o) in the Conv(ersion) column.

- For ENP, a node number must be entered. Node-number routing uses this number to determine which route pattern should be used to route the call. If the original extension is 4, 5, or 6 digits, an ENP code is chosen based on the first 1 or 2 digits of the dialed string. Because it is not used for routing, the ENP code can be independent of location.
- If EXT is entered, the resulting number (which may be unchanged from the dialed extensions) is routed over again as an extension. If you wish to block further digit conversion by UDP, you can enter n(o) in the Conv(ersion) column.
- If no UDP entry exists for a particular extension or range of extensions, those extensions are considered local.

UDP conversion is specified for individual extensions or groups of extensions sharing the same leading digits, via the UDP screen and the matching pattern. A matching pattern is the desired leading digits of an extension. For example, with a 5-digit UDP “123” is the matching pattern for all 100 possible 5-digit extensions beginning with “123”. By contrast, “12345” would be a matching pattern specifying a single extension.

Each extension code can be assigned to 1 of 6 possible treatments.

- UDPCode — Conversion to AAR with given location code, further conversion suppressed
- AARCode — Conversion to AAR with given location code, further conversion allowed
- ENPCode — Conversion to private network number (via ENP screen), route to given node number routing
- TempOOS — Temporarily out of service, give reorder
- Local — Local range of extensions
- blank — Similar to local; however, this extension is not chosen when the system is asked to “add a station”

When a user at a switch that is included in a UDP dials an extension, Avaya MultiVantage first checks to see if the extension is assigned to a local station on that switch. If so, the call is routed to the station, and UDP is not invoked. If the extension is not found locally, the system checks to see if the extension matches an assigned extension code. If the extension matches an assigned extension code, the system performs the specified conversion into a private network number and routes the call as specified. If more than one extension code matches, the “best” match (most explicit digits) is used. For example, 1234 is chosen over 123 if 12345 is dialed. However, 123 is chosen if 12355 is dialed. If no matching extension code is found, the user receives intercept treatment. Or, if Extended Trunk Access (ETA) is enabled, the call routes via ETA.

## Example of how UDP works

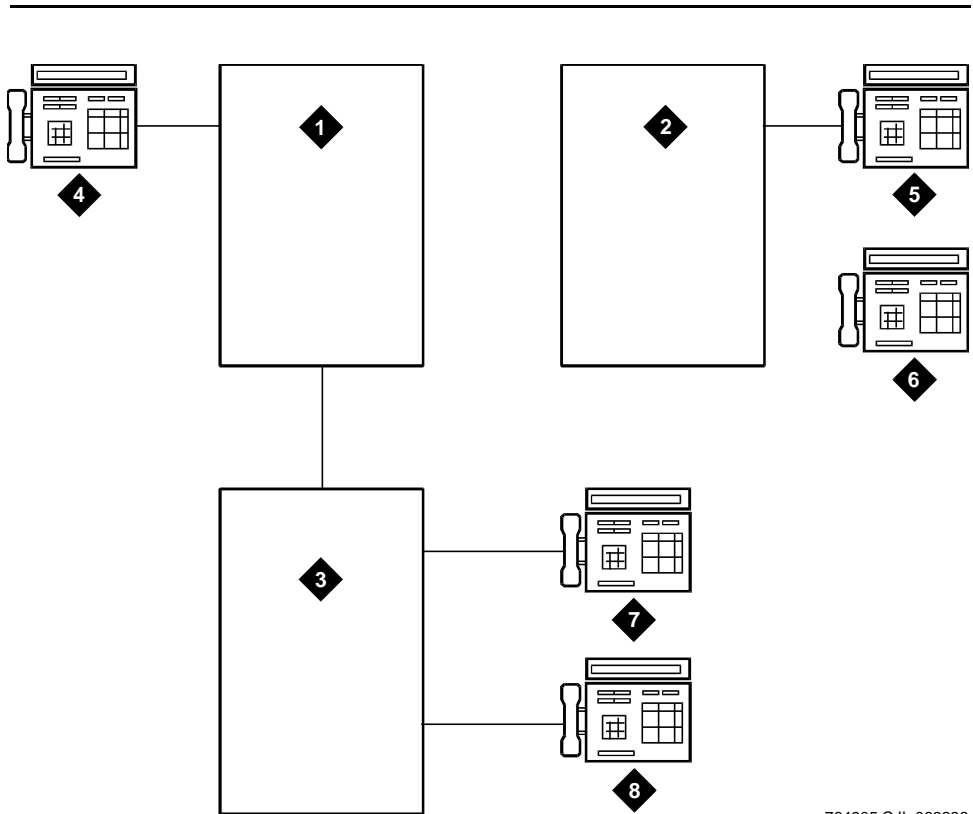

To administer, assign each UDP code:

- To a private network location code (RNX) or node number. (The RNX is equivalent to an office code of a central office in a public network. This RNX determines how a UDP call is routed.)
- Assign each UDP code as either local or remote to the switch.

To understand the function of a UDP, review the following example.

A given station is called using the same 5-digit extension regardless of where in the ETN the call originates. Three switches are included in the example. Each has been assigned a list of RNX and UDP codes. See [Figure 64 on page 1916](#).

| SWITCH | RNX | UDP CODE |
|--------|-----|----------|
| A      | 224 | 41       |
| C      | 223 | 51       |
| C      | 223 | 52       |
| B      | 222 | 60       |
| B      | 222 | 61       |

r764905 CJL 062296

- |                                                                                                                                             |                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>1. Switch A<br/>Dial Plan for extensions is 41<br/>RNX=224</p> <p>2. Switch B:<br/>Dial Plan for Extensions is 60<br/>and 61 RNX=222</p> | <p>3. Switch C:<br/>Dial Plan for extensions is 51<br/>and 52 RNX=223</p> <p>4. Extension 41000</p> <p>5. Extension 61234</p> <p>6. Extension 60123</p> <p>7. Extension 51234</p> |
|---------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Figure 64. UDP Example**

If a user at extension 41000 wants to call extension 61234, there are two choices:

- Dial 61234
- Dial the AAR access code followed by 222-1234

If 61234 is dialed, the system recognizes 61 as a remote UDP, determines the associated RNX (222), and uses AAR to route the call to 222-1234.

If the AAR access code and 222-1234 are dialed, the system finds the route pattern for RNX 222 and routes the call to the switch associated with that RNX.

Whenever UDP is used to route a call to another switch, the correct digit deletion and insertion must be specified within the route pattern so that the receiving switch gets digits in the format it expects. Avaya MultiVantage can be configured in several different ways.

- If AAR is available on the receiving switch, Subnet Trunking can be used to insert the AAR feature access code on the originating switch or digit insertion may be used to insert it on the receiving switch. The receiving switch then uses AAR digit conversion to convert 222 with 7 digits to an extension by deleting 3 digits and inserting a 6.
- If AAR is not available on the receiving switch, Subnet Trunking must be used on the originating switch to delete the 222 and insert the digit 6 at the beginning of the extension number so that the receiving switch can continue to route correctly.

If the user at extension 51234 on Switch C dials extension 61234, the call must first go through Switch A before proceeding to Switch B. When 61234 is dialed, the system recognizes 61 as a UDP code, determines the associated RNX (222), and uses AAR to route the call. The AAR feature access code plus 222-1234 are outpulsed to Switch A. Switch A then recognizes the RNX 222 as a remote switch and routes the call to Switch B and extension 61234. This same type of call routing occurs when an extension at Switch B calls an extension at Switch C.

If extension 61234 on Switch B calls extension 61235, the system recognizes 61 as a local UDP code and routes the call directly to extension 61235.

## **Considerations**

---

- In North American network environments, extensions beginning with 0 may route to an attendant. You are encouraged to use another number as the leading digit when assigning extensions.
- When you call an extension on another switch, there may be a slight delay before call-progress tones are applied. This delay is due to the trunk signaling necessary to complete the call to the remote switch.
- When you select the option to look at the UDP table first, calls that might otherwise terminate at a local extension route over the network. This is easily reversed. When you remove the extensions from the UDP table, the local extension can be dialed again.

- If AAR is active, facility restriction levels (FRLs) and Traveling Class Marks (TCMs) can be sent along with the private network number. UDPCode and AARCode conversions use the FRL assigned to the caller. ENPNode conversion always raises the FRL to the maximum (7).

If an FRL is insufficient to access the facility, access is denied. There is no prompt for an authorization code even if authorization codes are enabled and administered.

- If AAR is not active, tandem-tie trunks should not be used to transport UDP numbers. The TCM is not recognized at the terminating switch.

 **NOTE:**

Never use tandem-tie trunks to transport UDP numbers (the TCM and Hop count will not be recognized as such following the extension received at the receiving switch).

## Interactions

---

- Automatic Alternate Routing (AAR)

AAR routes UDP calls. (Included with UDP is the required AAR subset.) If AAR is enabled in addition to UDP, then the 7-digit AAR number provides the same routing as UDP.

- Dial Plan

- All of the extension numbers on a switch are not necessarily part of UDP. Any that do not belong to UDP are handled by a regular, non-UDP Dial Plan associated with the switch.
- When administering the Dial Plan screen and designating a group of extensions as UDP non-local, you can specify whether you want to search for local extensions first or last. This allows flexibility to change extensions from local to non-local and vice-versa.

- DID Trunk Group

DID calls to a UDP extension number may require that the DID trunk group insert enough digits to create the full extension number. For example, if the DID trunk provides 4 digits, but a 5-digit UDP is in place, then the appropriate leading digit must be inserted.

- Distributed Communications System (DCS)

UDP is required when DCS is provided. The necessary UDP software is provided with the DCS software.

- Extension Number Portability (ENP)

If an extension code is administered to use ENP node routing, ENP routes the call to the correct switch. If AAR is enabled in addition to UDP, the 7-digit AAR number provides the same routing as UDP (that is, via ENP).

## Voice Message Retrieval

---

Voice Message Retrieval allows attendants, phone users, and remote-access users to retrieve Leave Word Calling (LWC) and Call Coverage messages.

### Detailed description

---

Voice Message Retrieval is only used for the retrieval of messages. When a terminal is in Voice Message Retrieval mode, it cannot be used to make calls or access other features. Voice Message Retrieval can be used to retrieve your own messages or messages for another user. However, a different user's messages can only be retrieved by a user at a phone or attendant console in the coverage path, by an administered system-wide message retriever, or by a remote-access user when the extension and associated security code are known. The number of simultaneous Voice Message Retrieval users possible depends on the number of speech-synthesizer circuit packs used in the system.

Certain phones and attendants can be designated for system-wide message retrieval. These system-wide retrievers are the same as those used for Display Message Retrieval and have the same privileges. Voice Message Retrieval cannot be accessed from rotary phones.

You can use the system to restrict unauthorized users from retrieving messages. Use the Lock function to restrict a phone and the Unlock function to release the restriction. Users activate Lock by dialing a system-wide access code. They cancel Lock by dialing a system-wide access code and then an Unlock security code unique to the phone. These functions only apply to the phone where the function is active. The system-wide access codes and security code used for the Lock and Unlock functions are the same as those used for LWC message retrieval by display. You can assign a status lamp to show the lock status of the phone.

### Interactions

---

- AUDIX Interface

Retrieval of LWC messages via Voice Message Retrieval is separate and distinct from retrieval of messages via INTUITY. LWC messages left for a principal on AUDIX cannot be accessed via Voice Message Retrieval. However, the caller of Voice Message Retrieval is informed of any new messages for the principal on AUDIX:

- The Voice Message Retrieval voices that there are AUDIX messages.
- The Display Message Retrieval displays "Message Center AUDIX Call."

If your system has a voice-synthesizer circuit pack and LWC Activation is active, users can retrieve messages from two locations:

- Users can retrieve LWC messages with Voice Message Retrieval.
- Users can retrieve all other messages with AUDIX.

If you do not have a TN725B speech-synthesizer board, non-display phone users cannot retrieve LWC messages sent via the LWC button on a phone.

- **Bridged Call Appearance**

Voice Message Retrieval on a Bridged Call Appearance functions the same as if it were activated by the primary extension associated with the bridged call appearance.

- **Leave Word Calling**

Voice Message Retrieval enhances LWC by allowing any authorized touch-tone phone user to retrieve messages.

## Voice messaging systems

---

Avaya MultiVantage supports several Avaya voice or multimedia messaging systems. These systems allow users to send, retrieve, store, and forward messages, as well as perform many other tasks associated with messages. In addition to supporting multiple AUDIX systems, MultiVantage can have multiple hunt groups associated with a single AUDIX system. This allows partitioning of the voice ports into different hunt groups and different coverage paths to cover different voice ports. Thus voice ports can be reserved for particular users or groups of users (for example, those that use unique coverage paths).

The following features do not use coverage paths:

- Transfer into AUDIX with the feature access code or the GOTO COVER button
- Last Call

If a local AUDIX and a remote AUDIX use the same hunt-group numbers, calls route to the local hunt group.

Avaya MultiVantage supports the following systems:

**INTUITY  
AUDIX** INTUITY AUDIX runs on a separate MAP/5, MAP/40, or MAP/100 PC. The switch communicates with INTUITY AUDIX via analog voice ports and a data link. The switch can also communicate with INTUITY AUDIX without the data link. In this case, the switch and INTUITY AUDIX communicate by sending and receiving special strings of touch-tone codes (dual tone multifrequency tones) via analog voice ports. These touch-tone codes are called *mode codes* and carry data such as calling party ID, called party ID, and type of call.

INTUITY AUDIX allows up to 64 ports. This means up to 64 people can be simultaneously retrieving or leaving messages. INTUITY AUDIX also supports fax and e-mail messaging.

For more information, see *INTUITY AUDIX System Description* or *INTUITY AUDIX Administration*, and *INTUITY Messaging Solutions Integration with System 75, Generic 1 and 3, and R5/6*.

**Embedded AUDIX** (Not available with GuestWorks) Embedded AUDIX runs on a multifunction circuit pack assembly. This assembly fits into 2 contiguous slots in the MultiVantage switch. Embedded AUDIX communicates with the switch via analog voice ports with a data link. Embedded AUDIX can also communicate exclusively via analog voice ports when set up to emulate a digital phone set.

Embedded AUDIX allows up to 16 ports.

For more information, see *DEFINITY AUDIX System Feature Descriptions*, *DEFINITY AUDIX System Administration*, *Switch Administration for DEFINITY AUDIX System*, or *DEFINITY AUDIX System Forms Reference*.

**Octel Serenade** Octel Serenade is a voice messaging system that supports MultiVantage systems via QSIG signaling protocols.

**Octel 100** Octel 100 runs on personal computer running the OS2 operating system.

Other non-Avaya messaging systems may also use mode codes to work with Avaya MultiVantage.

## Centralized Voice Mail

---

You can use a single voice mail system to support multiple MultiVantage systems in a DCS network. In addition, you can use a voice mail system to support multiple MultiVantage systems and Merlin Legend in a network via mode code. For more information, see *Administration for Network Connectivity for Avaya MultiVantage™ Software*.

## Security Measures

---

### **SECURITY ALERT:**

*Fraudulent long-distance calls can be placed through INTUITY AUDIX, embedded AUDIX, and AUDIX R1 if proper security precautions are not implemented.*

The following actions help secure your system from unauthorized use.

- For Intuity AUDIX, embedded AUDIX, and AUDIX R1
  - Remove any unused or unassigned mail to help prevent exchange of information through unassigned Voice Mail.
  - Secure system lines that serve AUDIX and control where calls can be placed.

- Assign a restrictive COR, COS, and FRL to the station lines and trunks serving AUDIX.
  - Use switch CDR reports to determine if the lines are being used for calls that are normally not within your sphere of business.
  - Change default passwords on voice mailboxes immediately after installation and use random numbers for passwords.
  - Require passwords with at least 5 digits.
  - Change system administration passwords to alphanumeric codes.
  - INTUITY AUDIX, AUDIX R1, and embedded AUDIX provide a maintenance/administration port. A remote port security device provides an added layer of security to prevent unauthorized access to this port.
- For INTUITY AUDIX and embedded AUDIX
    - Determine whether to only allow transfers to other AUDIX subscribers or to any extension of the correct length. The most secure approach is to only allow transfers to other AUDIX subscribers. If you decide to allow transfers to any extension, administer the COR on the AUDIX ports to prevent calls outside the PBX or immediate Distributed Communications System (DCS) site network.
  - For AUDIX only
    - Activate Enhanced Call Transfer (ECT) to help prevent having billable calls placed from unauthorized transfers outside of the system. ECT performs call transfer over the data link between AUDIX and the Avaya MultiVantage. (The destination extensions must be administered on the switch dial plan.)

## **Interactions**

---

- Attendant Conference

An attendant who has split a call can conference the call with AUDIX by dialing the Transfer Into AUDIX access code. The attendant presses Release to drop out of the conference call.
- Automatic Call Distribution (ACD) (external AUDIX only)

You can administer a hunt group as an AUDIX ACD split. You can then obtain AUDIX traffic measurements with the ACD Call Management System (CMS). Login occurs when AUDIX signals the switch to make a voice port available for AUDIX service. Logout occurs when AUDIX signals the switch to disable the port.

AUDIX and ACD CMS must be connected to the same switch. If AUDIX in the DCS feature is active, a CMS located on a switch other than the host switch (AUDIX location) does not provide measurements for the AUDIX ports.

Because AUDIX frequently takes voice ports in and out of service for maintenance testing, high login activity may be seen for the AUDIX split in the measurement reports.

On CMS reports that display an agent's login ID, AUDIX voice ports always show a login ID that is the same as the extension, even if you have not administered login IDs on the switch.

- **Call Coverage**

When a coverage call successfully completes to AUDIX or routes from a remote switch to the host switch because of coverage, the principal is dropped from the call (no temporary bridge appearance is maintained).

Coverage calls from a remote switch that fail to reach AUDIX as a coverage point cannot be returned to the original coverage path on the remote switch.

- **Call Forwarding**

An AUDIX user can forward calls to a remote AUDIX hunt group or to the host AUDIX hunt group. You must correctly administer the AUDIX destination for the remote AUDIX hunt group.

- **Call Monitoring**

Call Monitoring allows users to pick up the handset after the call goes to AUDIX to listen to the message being left by the caller. This allows the user to determine whether they want to talk to the caller or let them complete their message.

- **Call Transfer**

A call transfer out of AUDIX can be to a UDP extension. If the UDP extension is on a remote switch, the call is treated as a direct call. Additional trunks are used for calls transferred between DCS nodes.

Calls may be transferred into AUDIX by users handling redirected calls for principals who are AUDIX subscribers.

- **Class of Restriction (COR)**

A high FRL assigned in the COR allows callers to transfer to long-distance numbers.

To prevent toll fraud, assign a low FRL to the AUDIX system ports.

- DCS — Leave Word Calling (external only)

In a DCS network, the called party may be on a different switch than the calling party. If the DCS link is down, attempts to store Leave Word Cancel messages are denied and intercept tone is returned. LWC requests are always denied for principals with AUDIX LWC; in some instances, the request to cancel LWC may appear to be active when it actually is not.

When the local switch communicates with INTUITY AUDIX via mode codes, INTUITY AUDIX cannot support remote DCS switches.

- Facility Test Call

Unauthorized calls can be placed using the facility test-call access code.

To prevent toll fraud, remove the facility test call access code.

- Leave Word Calling (LWC)

You can have a principal's LWC messages kept by AUDIX. The principal can retrieve a message by calling AUDIX. The principal cannot retrieve the message using other retrieval methods, but is notified of its existence by AUDIX.

For other messaging services, you can have AUDIX report the existence of waiting LWC messages for the principal, but not the message content. The principal can retrieve the message using other retrieval methods, but is still notified of the existence of AUDIX messages.

If the data link between the system and AUDIX is down, attempts to activate LWC for an AUDIX-covered principal are denied and reorder tone is returned.

If a caller attempts to cancel a LWC message sent to AUDIX, the caller receives intercept tone if the called party is on the same switch. The caller receives confirmation tone if the called party is on another switch in the DCS network as long as the DCS data link to the called party's switch is operational, *even though the message is not actually canceled*.

When the local switch communicates with INTUITY AUDIX via mode codes, INTUITY AUDIX does not accept or store LWC messages in user mailboxes.

- Ringback Queueing

Ringback Queueing does not apply to AUDIX calls. On direct calls to a remote AUDIX, if all trunks to the host AUDIX are busy, busy tone is returned. On coverage calls, if all trunks are busy, AUDIX is treated as a busy coverage point. If there are coverage points after AUDIX, then the call terminates at those points.

- **Single-Digit Dialing and Mixed-Station Numbering**

AUDIX is designed for use with a Uniform Dial Plan. It supports only one extension length (3-, 4-, or 5-digit) that is used by AUDIX subscribers. Single-Digit and Mixed Station Numbering cannot be used. However, nothing prohibits connecting a switch to AUDIX that provides these features, as long as all AUDIX subscribers have the same extension length.

- **Temporary Bridged Appearance**

Stations that normally have a temporary bridged appearance with their coverage point do not have that appearance if the coverage point is AUDIX.

## Whisper paging

---

Whisper paging allows one user to interrupt or “barge in” on another user’s call and make an announcement. The paging user dials a feature access code or presses a feature button, then dials the extension they want to call.

Only the person on the paged extension can hear the page; other parties on the call cannot hear it, and the person making the page cannot hear anyone on the call. If the paged user has a display phone, he or she can see who is making the whisper page.

For example, let’s say users A and B are on a call. C has an urgent message for A and makes a whisper page. All 3 users hear the tone that signals the page, but only A hears the page itself. The person making the page, C, cannot hear A or B.

## Brief description

---

### Allowing users to make whisper pages

To make a whisper page users dial a feature access code or press a feature button, then dial the extension of the user they are trying to reach.

- To assign a feature access code, enter a code in the Whisper Page Activation Access Code field on the Feature Access Code screen.
- To give users a feature button for making a whisper page, use the Station screen and administer a Whisper Page Activation button on users’ phones.

## Allowing users to answer whisper pages quickly

To give users a feature button for answering a whisper page, use the Station screen and administer an Answerback button on users' phones.

### NOTE:

You cannot administer an Answerback button on an attendant console. Attendants can make whisper pages but cannot receive them.

Normally, before a paged user can answer a whisper page he or she must complete the active call or put it on hold. However, you can give users the ability to put an active call on hold and speak directly to the person making a whisper page simply by pushing a feature button. Once the Answerback button is pressed, the user can treat both the paging call and the original call as separate calls and all call-related features (conference, transfer, etc.) operate normally.

## Allowing users to block whisper pages

To give users a feature button to block incoming whisper pages, use the Station screen and administer a Whisper Page Off button on users' phones.

Administer this function on a feature button with a lamp so that users can tell whether or not blocking is active. Users can activate blocking even when they're on a call.

### NOTE:

You cannot administer a Whisper Page Off button on a soft key.

Two features, Do Not Disturb and Privacy — Attendant Lockout, also block incoming whisper pages.

## Call redirection overrides

If a paged user is not on an active call, a whisper page is converted to a priority call that overrides any of the following call redirection features:

- Call Forward All Calls
- Call Forward Busy
- Call Forward Don't Answer
- Send All Calls
- Go To Cover
- Call Coverage

For example, let's say Call Forwarding — All Calls is activated on a phone. If there are no active calls, a whisper page to that phone will ring at that phone as a priority call. For information on blocking incoming whisper pages, see [“Allowing users to block whisper pages”](#).

### Group answering environments

Whisper paging does not work with extensions assigned to a group answering environment. You cannot place a whisper page to the main extension assigned to a hunt group, split, skill, or terminating extension group. You cannot place a whisper page to any extension that is a member of one of these groups.

### Network restrictions

Whisper paging does not work across networks (such as Distributed Communication System networks or Electronic Tandem Networks): both the paging user and paged user must be on the same switch.

### Speakerphones

When a call is on the speaker, an incoming whisper page is heard over the speaker too. When the group listening feature on a 6400-series phone is active, an incoming whisper page is heard on both the handset and the speaker.

### Interactions

---

- Attendant

Attendants cannot intrude on a whisper page. If an attendant is using intrusion to talk to a user, that user cannot receive a whisper page.

An attendant may initiate a whisper page while a call is split away using auto-manual splitting. However, they cannot use Release, Hold, or Split after the page is made.

- Bridged Call Appearances

Whisper pages are designed to reach a specific user associated with a specific extension.

- When an extension and one or more of its bridged appearances are in use, parties on the bridged appearances hear the tone that signals an incoming whisper page but only the user on the principle extension hears the announcement. Only the display on the principle extension shows the whisper page message.

- When all appearances are idle or only a bridged appearance is in use, a whisper page rings the principal extension with priority ringing.

— If a user makes a whisper page on a call appearance that is a member of a bridge group, then no other users in the bridge group can connect to the call while the whisper page intrusion is active.

- **Busy Verification**

You can't make a whisper page to an extension while it's being busy-verified. You can't busy-verify an extension while it's making or receiving a whisper page.

- **Calling Restrictions — Origination**

Phones with this restriction cannot make whisper pages.

- **Calling Restrictions — Termination**

Phones with this restriction cannot receive whisper pages.

- **Class of Restriction (COR)**

A station user must have a COR that allows for station-to-station calling in order to perform Whisper Paging to a member outside of their own COR. Calling and called party restrictions also determine which extensions can make and receive whisper pages.

- **Conference**

Everyone on a conference call hears the tone that signals an incoming whisper page. But only the owner of the paged extension hears the page, and only the display on that phone shows the whisper page message.

If a conference call already has the maximum number of parties and trunks allowed, you cannot make a whisper page to any of the participants. Parties cannot be added to a conference call if an active whisper page is on the call.

- **Data Privacy — Permanent or Temporary**

Any station that has Data Privacy activated cannot make a whisper page.

- **Data Restriction**

A whisper page to a station is denied when Data Restriction is enabled on a station or trunk.

- **Expert Agent Selection**

You can't make a whisper page by dialing an agent's Logical Agent ID. Pages must be made to a physical extension.

- **Go to Cover**

If you make a whisper page and then press your Go To Cover button while the page is in progress, the Go To Cover button doesn't work. The opposite is true as well. If you activate Go to Cover and then press the whisper page activation button, you aren't able to make a whisper page.

- Last Number Dialed

When you make a whisper page, it's tracked as the last number dialed.

- QSIG

This feature does not operate in a QSIG environment.

- Remote access

You can't make a whisper page by remote access. Both the paging party and paged party must be on the same switch or the attempt is denied.

- Tenant Partitioning

Whisper paging is permitted across tenant partitions if the assigned classes of restriction allow for intercom calling between members of different partitions. This feature is especially useful to attendants who serve multiple partitions.

 **NOTE:**

It is important for system administrators to ensure that this feature is managed appropriately in systems with tenant partitioning. Some tenants may not want other tenants to interrupt their calls.

- Transfer

A call cannot be transferred during an active whisper page.

- Vector Directory Number (VDN)

You can't make a whisper page to a VDN. Pages must be made to a physical extension.

### Related topics

---

See [“Paging users who are on active calls” on page 481](#) to administer whisper paging.

## Wideband Switching

---

(Not available with Offer B) Wideband Switching provides the ability to dedicate 2 or more ISDN-PRI B-channels or DS0 endpoints for applications that require large bandwidth. It provides high-speed end-to-end connectivity between endpoints where dedicated facilities are not economic or appropriate. ISDN-BRI trunks do not support wideband switching.

## Brief description

---

ISDN-PRI (and the emulation of it by Asynchronous Transfer Mode-Circuit Emulation Service (ATM-CES)) divides a T1 or E1 trunk into 24 (31 for E1) information channels and one signaling channel for standard narrowband communication. Certain applications, like video conferencing, require greater bandwidth. You can combine several narrowband channels into one wideband channel to accommodate the extra bandwidth requirement. Avaya MultiVantage serves as a gateway to many types of high-bandwidth traffic. Wideband switching is also supported by the Expansion Interface (EI) circuit pack and the DS1 Converter circuit pack (for Center Stage Switching or directly connected port networks) and the ATM-EI circuit pack (for Asynchronous Transfer Mode connected port networks). ATM-CES supports wideband switching only for access, tie, and tandem trunks, not for line-side connections.

Wideband Switching supports:

- High-speed video conferencing
- WAN disaster recovery
- Scheduled batch processing (for example, nightly file transfers)
- LAN interconnections and imaging
- Other high bandwidth applications involving high-speed data transmission, video transmission, etc.

## How to administer Wideband Switching

The following list shows the required screens you must to set up Wideband Switching:

- [Access Endpoint](#)
- [PRI Endpoint](#)
- [ISDN trunk group](#)
- [Route Pattern](#)
- Fiber Link Administration (Optional: see the DEFINTY services documentation for information about this screen.)

## Channel allocation

For standard narrowband communication, ISDN-PRI divides a T1 or E1 trunk as follows:

- T1 trunks are divided into 23 information channels and 1 signaling channel
- E1 trunks are divided into 30 information channels, 1 signaling channel, and 1 framing channel

Certain applications, like video conferencing, require greater bandwidth. You can combine several narrowband channels into one wideband channel to accommodate the extra bandwidth requirement. Avaya MultiVantage serves as a gateway to many types of high-bandwidth traffic. In addition, DS1 converters are used for wideband switching at remote locations.

The following table provides information on Wideband Switching channel types.

| Channel Type | Number of Channels | Data Rate     |
|--------------|--------------------|---------------|
| H0           | 6                  | 384 Kbps      |
| H11          | 24                 | 1536 Kbps     |
| H12          | 30                 | 1920 Kbps     |
| NXDS0 (T1)   | 2-24               | 128–1536 Kbps |
| NXDS0 (E1)   | 2-31               | 128–1984 Kbps |

Perform wideband line-side channel allocation using one of three allocation algorithms: fixed, flexible, or floating.

- Fixed allocation — Provides contiguous-channel aggregation. The starting channel is constrained to a predetermined starting point. (Used only for H0, H11, and H12 calls.)
- Flexible allocation — Allows a wideband call to occupy noncontiguous positions within a single T1 or E1 facility.
- Floating allocation — Enforces contiguous-channel aggregation. The starting channel is not constrained to a predetermined starting point.

## Typical uses

A typical video application uses an ISDN-PRI interface to DS0 1 through 6 of the line-side facility. See the following figure.

wdbndex CJL 061996

### Figure Notes

- |                          |                           |
|--------------------------|---------------------------|
| 1. Video application     | 8. Network                |
| 2. Port 1                | 9. DS0 24 D-channel       |
| 3. Port 2                | 10. DS0 23 unused         |
| 4. ISDN terminal adaptor | 11. DS0 1-6 wideband      |
| 5. Line-side ISDN-PRI    | 12. DS0 24 D-channel      |
| 6. Avaya Media Server    | 13. DS0 7-23 narrow bands |
| 7. ISDN or ATM-CES trunk | 14. DS0 1-6 wideband      |

**Figure 65. Typical video broadband application**

## Endpoint applications with signaling

An endpoint application is the origination or destination point of a wideband call. Endpoint applications can be any number of data applications based on the customer's particular needs.

## **ISDN-PRI terminal adapters**

For wideband switching with non-ISDN-PRI equipment, you can use an ISDN-PRI terminal adapter. ISDN-PRI terminal adapters translate standard ISDN signaling into a form that can be used by the endpoint application and vice versa. The terminal adapter also must adhere to the PRI-endpoint boundaries as administered on the Avaya MultiVantage switch when handling both incoming (to the endpoint) applications and outgoing calls.

The terminal adapter passes calls to and receives calls from the line-side ISDN-SETUP messages indicating the data rate and specific B-channels (DS0) to be used and communicates all other call status information via standard ISDN messages. See *DEFINITY Line-Side ISDN Primary Rate Interface Technical Reference* for more information.

## **Line-side (T1 or E1) ISDN-PRI facility**

A line-side ISDN-PRI (T1 or E1) facility is comprised of a group of DS0s (24 for a T1 facility and 32 for an E1 facility). In this context, these DS0s are also called channels. T1 facilities have 23 B-channels and a single D-channel. E1 facilities have 30 B-channels, 1 D-channel, and a framing channel. Data flows bi-directionally across the facility between the switch and the ISDN-PRI terminal adapter.

## **PRI-endpoints**

A PRI-endpoint (PE) is a combination of DS0 B-channels on a line-side ISDN-PRI facility that has been assigned an extension.

A PRI-endpoint can support calls of lower bandwidth. In other words, a PE having a width 6 (six DS0s) can handle a call of one channel (64 Kbps) up to and including six channels (384 Kbps). Also, a PE can support calls on non-adjacent channels. For example, an endpoint application connected to a PE defined as using B-channels 1 through 6 of an ISDN-PRI facility could originate a call using B-channels 1, 3, and 5 successfully. If the PE has been administered to use flexible channel allocation, the algorithm for offering a call to the PE starts from the first DS0 administered to the PE. Since only one active call is permitted on a PE, contiguous B-channels are always selected unless one or more B-channels are not in service.

A PE remains in service unless all of its B-channels are out of service. In other words, if B-channel 1 is out of service and the PE is five B-channels wide, the PE could still handle a wideband call of up to four B-channels in width. A PE can only be active on a single call at any given time; that is, it is either considered idle, active (busy), or out of service.

One facility can support multiple separate and distinct PRI-endpoints (several extensions) within a single facility. Non-overlapping contiguous sets of DS0s (B-channels) are associated with each PE.

### **Universal digital signal level 1 board**

The UDS1 board is the interface for line-side and network facilities carrying wideband calls.

## **Non-signaling endpoint applications**

Wideband can also support configurations using non-signaling (non-ISDN-PRI) line-side T1 or E1 facilities. The endpoint applications are the same as those defined for configurations with signaling.

### **Data service unit/channel service unit**

This unit simply passes the call to the endpoint application. Unlike terminal adapters, the device service unit (DSU)/channel service unit (CSU) does not have signaling capability.

#### **⇒ NOTE:**

No DSU/CSU is needed if the endpoint application has a fractional T1 interface.

### **Line-side (T1 or E1) facility**

This facility, like the ISDN-PRI facility, is composed of a group of DS0s (23 for a T1 facility and 30 for an E1 facility). Line-side facilities are controlled solely from the switch. Through the access-endpoint command, a specific DS0 or group of DS0s is assigned an extension. This individual DS0 or group, along with the extension, is known as a wideband access endpoint (WAE).

### **Wideband access endpoint**

WAEs have no signaling interface to the switch. These endpoints simply transmit and receive wideband data when the connection is active.

#### **⇒ NOTE:**

The switch can determine if the connection is active, but this does not necessarily mean that data is actually coming across the connection.

A WAE is treated as a single endpoint and can support only one call. If all DS0s comprising a wideband access endpoint are in service, then the wideband access endpoint is considered in service. Otherwise, the wideband access endpoint is considered out of service. If an in-service wideband access endpoint has no active calls on its DS0s, it is considered idle. Otherwise, the wideband access endpoint is considered busy.

Multiple WAEs are separate and distinct within the facility and endpoint applications must be administered to send and receive the correct data rate over the correct DS0s. An incoming call at the incorrect data rate is blocked.

## Guidelines and examples

This section examines wideband and its components in relation to the following specific customer usage scenarios:

- High-speed video conferencing
- Data backup connection
- Scheduled batch processing
- Primary data connectivity
- Networking

### High-speed video conferencing

All data rates are multiples of 64 Kbps; from 128 Kbps to 1,536 Kbps (T1) and 1,984 Kbps (E1) are supported. Key customer data rates are listed below.

| Channel Type | Number of Channels | Data Rate     |
|--------------|--------------------|---------------|
| H0           | 6                  | 384 Kbps      |
| H11          | 24                 | 1536 Kbps     |
| H12          | 30                 | 1920 Kbps     |
| NXDS0 (T1)   | 2-24               | 128–1536 Kbps |
| NXDS0 (E1)   | 2-31               | 128–1984 Kbps |

### Data backup connection

Using wideband for data transmission backup provides customers with alternate transmission paths for critical data in the event of primary transmission path failure.

**Scheduled batch processing.** Scheduled batch processing applications are used for periodic database updates (for example, retail inventory) or distributions (for example, airline fare schedules). These updates are primarily done after business hours and are often referred to as nightly file transfers. Wideband meets the high bandwidth requirements at low cost for scheduled batch processing. In addition, wideband allows the dedicated-access bandwidth for busy-hour switch traffic to be used for these applications after business hours; no additional bandwidth costs are incurred.

The non-ISDN backup data connection is also appropriate for scheduled batch processing applications. Administered Connections are used to schedule daily or weekly sessions originating from this application.

**Primary data connectivity.** Permanent data connections (those always active during business hours), such as interconnections between local area networks (LANs), are well suited for Avaya MultiVantage when ISDN-PRI endpoints are used. The ISDN end-to-end monitoring and the endpoint's ability to react to failures provide for critical data availability needs. With ISDN, endpoints can detect network failures and initiate backup connections through the switch; ISDN endpoints can also establish additional calls when extra bandwidth is needed.

Any failures not automatically restored by Avaya MultiVantage are signaled to the endpoint application, which can initiate backup data connections over the same PRI endpoint. Avaya MultiVantage routes the backup data connections over alternate facilities if necessary.

## **Networking**

All of the wideband networking is over ISDN-PRI facilities (and the emulation of them by ATM-CES) but may connect to a variety of networks, other domestic interexchange carriers' services, private line, RBOC services, and services in other countries.

## **ISDN-PRI trunk groups and channel allocation**

Only ISDN-PRI trunks (and the emulation of them by ATM-CES) support wideband calls to the network. Wideband's bandwidth requirements have necessitated modification of the algorithms by which trunks look for clear channels. The following section describes the search methods and their relationship to the available wideband data services.

### **Facility lists**

A wideband call accessing the network must reside on a single ISDN-PRI facility. Trunks within a trunk group must be organized based on the facility on which they reside. This is accomplished by compiling a facility list as trunks are administered to a trunk group; if a trunk is added to a trunk group from a facility not already on that trunk group's list, that facility is added to the list in an order based on the facility's signaling group number and interface identifier. In other words, the facility list is compiled in an ascending order based first on signaling group number and second on the interface identifier assigned to the facility within the signaling group. For example, if three facilities having signaling group/interface identifier combinations of 1/1, 1/2, and 2/1 were associated with a trunk group, then a call offered to that trunk group would search those facilities in the order as they were just listed. Also note that since trunks within a given facility can span several trunk groups, a single facility can be associated with several different trunk groups.

Given this facility list concept, the algorithms have the ability to search for trunks, by facility, in an attempt to satisfy the bandwidth requirements of a given wideband call. If one facility does not have enough available bandwidth to support a given call, or it is not used for a given call due to the constraints presented in the following section, then the algorithm searches the next facility in the trunk group for the required bandwidth (if there is more than one facility in the trunk group).

In addition to searching for channels based on facilities and required bandwidth, Port Network (PN) preferential trunk routing is also employed. This PN routing applies within each algorithm at a higher priority than the constraints put on the algorithm by the parameters listed later in this section. In short, all facilities that reside on the same PN as the originating endpoint are searched in an attempt to satisfy the bandwidth of a given call, prior to searching any facilities on another PN.

### **Direction of trunk/hunting within facilities**

The algorithms have the ability to select trunks from low B-channel to high B-channel or from high B-channel to low B-channel with an ISDN facility. This is a per ISDN trunk group option, but infers the direction of search within all ISDN facilities (or portions of those facilities) administered within that trunk group. This is necessary so the selection of trunks are not prone to as much glare as they otherwise would be if trunks were chosen in the same direction by both user and network sides of the ISDN interface. Note that in previous Avaya MultiVantage releases, the order in which trunks were selected, whether through linear or circular hunting, would always be with respect to the order in which trunks were administered within the trunk group. Now, with the support of wideband services, all trunks within an ISDN trunk group optioned for wideband are ordered based on this new “direction of trunk/hunt with facilities” parameter, and without regard to the order in which trunks are administered within the trunk group. If an ISDN trunk group is not optioned for wideband, then a cyclical trunk hunt based on the administration of trunks within the trunk group is still available.

### **H11**

When a trunk group is administered to support H11, the algorithm to satisfy a call requiring 1,536 Kbps of bandwidth uses a fixed allocation scheme. That is, the algorithm searches for an available facility using the following facility-specific channel definitions.

- T1: H11 can only be carried on a facility without a D-channel being signaled in a nonfacility-associated signaling (NFAS) arrangement (B-channels 1-24 are used).
- E1: Although the 1,536-kbps bandwidth could be satisfied using a number of fixed starting points (for example, 1, 2, 3, etc.) the only fixed starting point being supported is 1. Hence, B-channels 1–15 and 17–25 are always used to carry an H11 call on an E1 facility.

If the algorithm cannot find an available facility within the trunk group that meets these constraints, then the call is blocked from using this trunk group. In this case, the call may be routed to a different trunk group preference via Generalized Route Selection (GRS), at which time, based on the wideband options administered on that trunk group, the call would be subject to another hunt algorithm (that is, either the same H11 algorithm or perhaps an N x DS0 algorithm described in a later paragraph).

This same hunt algorithm, when offered any other call (other than a 1,920-kbps call) attempts to preserve idle facilities by selecting trunk(s) in a partially contaminated facility if one exists. If the bandwidth required by this call cannot be satisfied by any partially contaminated facility, then the call is placed on available trunk(s) within an idle facility, thus contaminating the facility. Again, facilities are selected via the trunk group's facility list and with PN preference, and trunk(s) within a facility are selected based on the direction of channel search administered. Note that on a T1 facility, a D-channel is not considered a busy trunk and results in a facility with a D-channel always being partially contaminated. On an E1 facility, however, a D-channel is not considered a busy trunk because H11 and H12 calls may still be placed on that facility; an E1 facility with a D-channel and idle B-channels is considered an idle facility.

## H12

Since H12 is 1,920 Kbps which is comprised of 30 B-channels, a 1,920-kbps call can only be carried on an E1 facility. As with H11, the hunt algorithm uses a fixed allocation scheme with channel 1 being the fixed starting point. Hence, an H12 call always is carried on B-channels 1 to 15 and 17 to 31 on an E1 facility (as illustrated in the following table). When offered any other call (other than a 1,536-kbps call), the algorithm behaves as it does when H11 is optioned.

| Facility | ISDN Interface | DS0s Comprising Each Channel |             |
|----------|----------------|------------------------------|-------------|
|          |                | H11                          | H12         |
| T1       | 23B + D        | -                            | -           |
| T1       | 24B (NFAS)     | 1-24                         | -           |
| E1       | 30B + D        | 1-15, 17-25                  | 1-15, 17-31 |
| E1       | 31B (NFAS)     | 1-15, 17-25                  | 1-15, 17-31 |

## H0

When a trunk group is administered to support H0, the algorithm to satisfy a call requiring 384 Kbps of bandwidth also uses a fixed allocation scheme. Unlike the H11 fixed scheme which only supports a single fixed starting point, the H0 fixed scheme supports four (T1) or five (E1) fixed starting points. The H0 algorithm searches for an available quadrant within a facility based on the direction of trunk or hunt administered. If the algorithm cannot find an available quadrant within any facility allocated to this trunk group, then the call is blocked from using this trunk group. Again, based on GRS administration, the call may route to a different trunk group preference and be subject to another algorithm based on the wideband options administered.

This same trunk or hunt algorithm, when offered any narrowband or N x DS0 call, attempts to preserve idle quadrants by choosing a trunk(s) in a partially contaminated quadrant if one exists. If a partially contaminated quadrant capable of carrying the call does not exist, then the call is placed on available trunk(s) within an idle quadrant, thus contaminating the quadrant. Again, facilities are selected via the trunk group's facility list and with PN preference, and a trunk(s) within a facility is selected based on the direction administered. Note that a D-channel is considered a busy trunk and results in the top most quadrant of a T1, B-channels 19 to 24, always being partially contaminated. This is *not true* for NFAS.

If this H0 optioned trunk group is also administered to support H11, H12, or N x DS0, then this algorithm also attempts to preserve idle facilities. In other words, when offered a narrowband, H0, or N x DS0 call, the algorithm searches partially-contaminated facilities before it searches to idle facilities.

## N x DS0

For the N x DS0 multi-rate service, a trunk group parameter determines whether a floating or a flexible trunk allocation scheme is to be used. The algorithm to satisfy an N x DS0 call is either floating or flexible.

- Floating (Contiguous) — In the floating scheme, an N x DS0 call is placed on a contiguous group of B-channels large enough to satisfy the requested bandwidth without any constraint being put on the starting channel (that is, no fixed starting point trunk).
- Flexible — In the flexible scheme, an N x DS0 call is placed on any set of B-channels as long as the requested bandwidth is satisfied. There is absolutely no constraint such as contiguity of B-channels or fixed starting points. Of course, as with all wideband calls, all the B-channels comprising the wideband call must reside on the same ISDN facility.

Regardless of the allocation scheme employed, the  $N \times$  DS0 algorithm, like the H11 and H12 algorithms, attempts to preserve idle facilities when offered B, H0, and  $N \times$  DS0 calls. This is important so that  $N \times$  DS0 calls, for large values of  $N$ , have a better chance of being satisfied by a given trunk group. However, if one of these calls cannot be satisfied by a partially-contaminated facility and an idle facility exists, a trunk on that idle facility is selected, thus contaminating that facility.

There are additional factors to note regarding specific values of  $N$  and the  $N \times$  DS0 service:

- $N = 1$  — this is considered a narrowband call and is treated as any other voice or narrowband-data (B-channel) call.
- $N = 6$  — if a trunk group is optioned for both H0 and  $N \times$  DS0 service, a 384-kbps call offered to that trunk group is treated as an H0 call and the H0 constraints apply. If the H0 constraints cannot be met, then the call is blocked.
- $N = 24$  — if a trunk group is optioned for both H11 and  $N \times$  DS0 service, a 384-kbps call offered to that trunk group is treated as an H0 call and the H0 constraints apply. If the H0 constraints cannot be met, then the call is blocked.
- $N = 24$  — if a trunk group is optioned for both H11 and  $N \times$  DS0 service, a 1,536-kbps call offered to that trunk group is treated as an H11 call and the H11 trunk allocation constraints apply.
- $N = 30$  — if a trunk group is optioned for both H12 and  $N \times$  DS0 service, a 1,920-kbps call offered to that trunk group is treated as an H12 call and the H12 trunk allocation constraints apply.

### **Glare prevention**

Glare occurs when both sides of an ISDN interface select the same B-channel for call initiation. For example, a user side of an interface selects the B-channel for an outgoing call and, before the switch receives and processes the SETUP message, the switch selects the same B-channel for call origination. Since wideband calls use more channels, the chances of glare are greater. Glare conditions can be limited with proper channel administration, but they may never be eliminated and some calls may still be dropped.

Some glare situations might not be resolvable. In one case, the network and the user side may send SETUP messages simultaneously or nearly simultaneously. Another glare scenario can occur in the brief window after the SETUP message has been sent but before the first response is received from the switch at the other side of the interface. If an incoming SETUP arrive during this window, the incoming SETUP message is allowed to proceed and the outgoing call is dropped. Various glare situations and their resolution are described in the following table.

Avaya MultiVantage does not negotiate channels for wideband calls.

### GLARE RESOLUTION

| Outgoing Call Type | Incoming Call Type | Switch-Supporting User Protocol                                                                                                                                               | Switch-Supporting Network Protocol                                                                                                                          |
|--------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| B-channel          | B-channel          | No negotiation<br>Incoming call (from network) wins                                                                                                                           | Negotiation is attempted<br>Incoming call (from user) dropped if negotiation is unsuccessful                                                                |
|                    |                    | Outgoing call (to network) retried on another trunk                                                                                                                           | Outgoing call (to user) stays up                                                                                                                            |
| B-channel(s)       | Wide               | No negotiation                                                                                                                                                                | No negotiation                                                                                                                                              |
|                    |                    | Incoming call (from network) dropped                                                                                                                                          | Incoming call (from user) dropped                                                                                                                           |
|                    |                    | Outgoing calls (to network) stay up but likely are dropped by network because channels are in use, although there is a possibility some switches might negotiate these calls. | Outgoing calls (to user) stay up and possibly stay up if other side lets the network call win.                                                              |
| Wide               | B-channel(s)       | No negotiation                                                                                                                                                                | Negotiation is attempted                                                                                                                                    |
|                    |                    | Incoming call (from network) wins                                                                                                                                             | Incoming call (from user) dropped if negotiation is unsuccessful                                                                                            |
|                    |                    | Outgoing call (to network) retried on another trunk                                                                                                                           | Outgoing call (to user) stays up                                                                                                                            |
| Wide               | Wide               | No negotiation                                                                                                                                                                | No negotiation                                                                                                                                              |
|                    |                    | Incoming call (from network) dropped                                                                                                                                          | Incoming call (from user) dropped                                                                                                                           |
|                    |                    | Outgoing call (to network) stays up but likely are dropped by network because channels are in use.                                                                            | Outgoing call (to user) stays up and may not be dropped by other side because other side, if it is not an Avaya MultiVantage, may let the network call win. |

To reduce glare probability, the network needs to be administered so both sides of the interface select channels from opposite ends of facilities. For example, on a 23B+D trunk group, the user side could be administered to select B-channels starting at channel 23 while the network side would be administered to start selecting at channel 1. Using the same example, if channel 22 is active but channel 23 is idle, the user side should select channel 23 for re-use. This is known as linear trunk hunt and is the hunt option used by Avaya MultiVantage for wideband.

### Blocking prevention

Blocking occurs when insufficient B-channels required to make a call are available. Narrowband calls require only one channel so blocking is less likely than with wideband calls that require multiple B-channels. Blocking also occurs for wideband calls when bandwidth is not available in the appropriate format (that is, fixed, floating, or flexible).

To reduce blocking, the switch selects trunks for both wideband and narrowband calls to maximize availability of idle fixed channels for H0, H11, and H12 calls and idle floating channels for N x DS0 calls that require a contiguous bandwidth. The strategy for preserving idle channels depends on the channel type. The chances for blocking are reduced if you use a flexible algorithm, assuming it is supported on the other end.

| Channel Type   | Blocking Minimization Strategy             |
|----------------|--------------------------------------------|
| H0             | Preserve idle quadrants                    |
| H11            | Preserve idle facilities                   |
| H12            | Preserve idle facilities                   |
| Flexible NxDS0 | Preserve idle facilities                   |
| Floating NxDS0 | Preserve idle facilities as first priority |

### Considerations

---

- For example, if the user side is provisioned to start at the high side (DS0 23) and DS0 22 is idle but DS0 23 is active, reselect DS0 22 for the next call. This is known as linear trunk hunting. Only the direction of hunt is administrable.

## Interactions

---

- **Administered Connections**

Provides call initiation for WAEs. All Administered Connections that originate from WAEs use the entire bandwidth administered for WAE. The destination of an Administered Connection can be a PRI endpoint.
- **Automatic Circuit Assurance (ACA)**

Treats wideband calls as single-trunk calls so that a single ACA-referral call is made if an ACA-referral call is required. The call is on the lowest B-channel associated with the wideband call.
- **Call Coverage**

A wideband endpoint extension cannot be administered as a coverage point in a call-coverage path.
- **Call Detail Recording (CDR)**

When CDR is active for the trunk group, all wideband calls generate CDR records. The feature flag indicates a data call and CDR records contain bandwidth and Bearer Capability Class (BCC).
- **Call Forwarding**

You must block Call Forwarding through Class of Service.
- **Call Management System (CMS) and Basic Call Management System (BCMS)**

Wideband calls can be carried over trunks that are measured by CMS and BCMS. Wideband endpoints are not measured by CMS and BCMS.
- **Call Vectoring**

PRI endpoints use a vector-directory number when dialing. For example, PRI endpoint 1001 dials VDN 500. VDN 500 points to Vector 1. Vector 1 can point to other PRI endpoints such as route-to 1002, or route-to 1003, or busy.

Call Vectoring is used by certain applications. When an incoming wideband call hunts for an available wideband endpoint, the call can route to a VDN, that sends the call to the first available PRI endpoint.
- **Class of Restriction (COR)**

COR identifies caller and called-party privileges for PRI endpoints. Administer the COR so that account codes are not required. Forced entry of account codes is turned off for wideband endpoints.

- **Class of Service (COS)**

COS determines the class of features that a wideband endpoint can activate.
- **Facility Associated Signaling (FAS) and Non-Facility Associated Signaling (NFAS)**

FAS and NFAS with or without D-Channel Backup requires administration via signaling groups for trunk-side wideband interfaces.
- **Facility Busy Indication**

You can administer a busy-indicator button for a wideband-endpoint extension, but the button does not accurately track endpoint status.
- **Facility Test Calls**

Use Facility Test Calls to perform loop-back testing of the wideband call facility.
- **Generalized Route Selection (GRS)**

GRS supports wideband BCC to identify wideband calls. GRS searches a route pattern for a preference that has wideband BCC. Route preferences that support wideband BCC also support other BCCs to allow different call types to share the same trunk group.
- **CO Trunk (TTC - Japan) Circuit Pack**

The CO Trunk (TTC - Japan) circuit pack cannot perform wideband switching. No member of the circuit pack should be a member of a wideband group.

## **World-Class Tone Detection and Generation**

---

World-Class Tone Detection allows Avaya MultiVantage to identify and handle different types of call-progress tones. The tone detector and identification is used to display on Data Terminal Dialing and for deciding when to send digits on trunk calls through Abbreviated Dialing, ARS, AAR, and Data Terminal Dialing.

World-Class Tone Generation allows you to define call-progress tones. You can select values for frequency and cadence. If you do not define a call-progress tone, Avaya MultiVantage sends silence. Brief call-waiting tones are optimal because, while a tone is sounding, speech cannot be heard.

An Avaya representative must administer tone detection and tone generation when establishing country-specific system parameters.

## Interactions

---

- Data Modules

Multiline Data Terminal Dialing is disabled if the Multiple-line Level of Tone Detection field is **medium** or **broadband**. It is enabled if the Level of Tone Detection field is **precise**.

---

# Glossary and abbreviations

---

## Numerics

---

### 800 service

A service in the United States that allows incoming calls from certain areas to an assigned number for a flat-rate charge based on usage.

---

## A

### AA

Archangel. See [angel](#).

### AAC

ATM access concentrator

### AAR

Automatic Alternate Routing

### abandoned call

An incoming call in which the caller hangs up before the call is answered.

### Abbreviated Dialing (AD)

A feature that allows callers to place calls by dialing just one or two digits.

### AC

1. Alternating current.
2. See [Administered Connection \(AC\)](#).

### ACA

See [Automatic Circuit Assurance \(ACA\)](#).

### ACB

See [Automatic Callback \(ACB\)](#).

### ACD

See [Automatic Call Distribution \(ACD\)](#).

### ACD agent

See [agent](#).

### ACU

See [Automatic calling unit \(ACU\)](#)

### ACW

See [after-call work \(ACW\) mode](#).

### access code

A 1-, 2-, or 3-digit dial code used to activate or cancel a feature, or access an outgoing trunk.

**access endpoint**

Either a nonsignaling channel on a DS1 interface or a nonsignaling port on an analog tie-trunk circuit pack that is assigned a unique extension.

**access tie trunk**

A trunk that connects a main communications system with a tandem communications system in an electronic tandem network (ETN). An access tie trunk can also be used to connect a system or tandem to a serving office or service node. Also called access trunk.

**access trunk**

See [access tie trunk](#).

**ACCUNET**

A trademarked name for a family of digital services offered by AT&T in the United States.

**ACD**

See [Automatic Call Distribution \(ACD\)](#). ACD also refers to a work state in which an agent is on an ACD call.

**ACD work mode**

See [work mode](#).

**active-notification association**

A link that is initiated by an adjunct, allowing it to receive event reports for a specific switch entity, such as an outgoing call.

**active-notification call**

A call for which event reports are sent over an active-notification association (communication channel) to the adjunct. Sometimes referred to as a monitored call.

**active notification domain**

VDN or ACD split extension for which event notification has been requested.

**ACTR**

Automatic Customer Telephone Rearrangement

**ACU**

See [Automatic calling unit \(ACU\)](#).

**AD**

See [Abbreviated Dialing \(AD\)](#).

**ADAP**

AUDIX Data Acquisition Package

**ADC**

See [analog-to-digital converter \(ADC\)](#).

**adjunct**

A processor that does one or more tasks for another processor and that is optional in the configuration of the other processor. See also [application](#).

**adjunct-control association**

A relationship initiated by an application via *Third Party Make Call*, the *Third Party Take Control*, or *Domain (Station) Control* capabilities to set up calls and control calls already in progress.

**adjunct-controlled call**

Call that can be controlled using an adjunct-control association. Call must have been originated via *Third Party Make Call* or *Domain (Station) Control* capabilities or must have been taken control of via *Third Party Take Control* or *Domain (Station) Control* capabilities.

**adjunct-controlled split**

An ACD split that is administered to be under adjunct control. Agents logged into such splits must do all telephony work, ACD login/ logout, and changes of work mode through the adjunct (except for auto-available adjunct-controlled splits, whose agents may not log in/out or change work mode).

**adjunct-monitored call**

An adjunct-controlled call, active-notification call, or call that provides event reporting over a domain-control association.

**Adjunct-Switch Application Interface (ASAI)**

A recommendation for interfacing adjuncts and communications systems, based on the CCITT Q.932 specification for layer 3.

**ADM**

Asynchronous data module

**administer**

To access and change parameters associated with the services or features of a system.

**Administered Connection (AC)**

A feature that allows the switch to automatically establish and maintain end-to-end connections between access endpoints (trunks) and/or data endpoints (data modules).

**administration group**

See [capability group](#).

**administration terminal**

A terminal that is used to administer and maintain a system. See also [terminal](#).

**Administration Without Hardware (AWOH)**

A feature that allows administration of ports without associated terminals or other hardware.

**ADU**

See [asynchronous data unit \(ADU\)](#).

**AE**

See [access endpoint](#).

**AFRL**

Alternate Facility Restriction Levels

**after-call work (ACW) mode**

A mode in which agents are unavailable to receive ACD calls. Agents enter the ACW mode to perform ACD-related activities such as filling out a form after an ACD call.

**AG**

ASAI Gateway

**agent**

A person who receives calls directed to a split. A member of an ACD hunt group or ACD split. Also called an ACD agent.

**agent report**

A report that provides historical traffic information for internally measured agents.

**AIM**

Asynchronous interface module

**AIOD**

Automatic Identification of Outward Dialing

**ALBO**

Automatic Line Build Out

**All trunks busy (ATB)**

The state in which no trunks are available for call handling.

**ALM-ACK**

Alarm acknowledge

**American Standard Code for Information Interchange**

See [ASCII \(American Standard Code for Information Interchange\)](#).

**AMW**

Automatic Message Waiting

**AN**

Analog

**analog**

The representation of information by continuously variable physical quantities such as amplitude, frequency, and phase. See also [digital](#).

**analog data**

Data that is transmitted over a digital facility in analog (PCM) form. The data must pass through a modem either at both ends or at a modem pool at the distant end.

**analog telephone**

A telephone that receives acoustic voice signals and sends analog electrical signals along the telephone line. Analog telephones are usually served by a single wire pair (tip and ring). The model-2500 telephone set is a typical example of an analog telephone.

**analog-to-digital converter (ADC)**

A device that converts an analog signal to digital form. See also [digital-to-analog converter \(DAC\)](#).

**angel**

A microprocessor located on each port card in a processor port network (PPN). The angel uses the control-channel message set (CCMS) to manage communications between the port card and the archangel on the controlling switch-processing element (SPE). The angel also monitors the status of other microprocessors on a port card and maintains error counters and thresholds.

**ANI**

See [Automatic Number Identification \(ANI\)](#).

**ANSI**

American National Standards Institute. A United States professional/technical association supporting a variety of standards.

**answerback code**

A number used to respond to a page from a code-calling or loudspeaker-paging system, or to retrieve a parked call.

**AOC**

Advice of Charge

**AOL**

Attendant-offered load

**AP**

Applications processor

**API**

Application programming interface

**APLT**

Advanced Private-Line Termination

**appearance**

A software process that is associated with an extension and whose purpose is to supervise a call. An extension can have multiple appearances. Also called call appearance, line appearance, and occurrence. See also [call appearance](#).

**application**

An adjunct that requests and receives ASAI services or capabilities. One or more applications can reside on a single adjunct. However, the switch cannot distinguish among several applications residing on the same adjunct and treats the adjunct, and all resident applications, as a single application. The terms application and adjunct are used interchangeably throughout this document.

**applications processor**

A micro-computer based, program controlled computer providing application services for the DEFINITY switch. The processor is used with several user-controlled applications such as traffic analysis and electronic documentation.

**application service element**

See [capability group](#).

**architecture**

The organizational structure of a system, including hardware and software.

**ARS**

See [Automatic Route Selection \(ARS\)](#).

**ASA**

Avaya Site Administration.

**ASAI**

See [Adjunct-Switch Application Interface \(ASAI\)](#)

**ASCII (American Standard Code for Information Interchange)**

The standard code for representing characters in digital form. Each character is represented by an 8-bit code (including parity bit).

**ASG**

Access Security Gateway.

**association**

A communication channel between adjunct and switch for messaging purposes. An active association is one that applies to an existing call on the switch or to an extension on the call.

**asynchronous data transmission**

A method of transmitting data in which each character is preceded by a start bit and followed by a stop bit, thus permitting data characters to be transmitted at irregular intervals. This type transmission is advantageous when transmission is not regular (characters typed at a keyboard). Also called asynchronous transmission. See also [synchronous data transmission](#).

**asynchronous data unit (ADU)**

A device that allows direct connection between RS-232C equipment and a digital switch.

**Asynchronous Transfer Mode (ATM)**

A packet-like switching technology in which data is transmitted in fixed-size (53-byte) cells. ATM provides high-speed access for data communication in LAN, campus, and WAN environments.

**ATB**

See [All trunks busy \(ATB\)](#).

**ATD**

See [Attention dial \(ATD\)](#).

**attendant**

A person at a console who provides personalized service for incoming callers and voice-services users by performing switching and signaling operations. See also [ATM-CES](#).

**ATM**

See [Asynchronous Transfer Mode \(ATM\)](#).

**ATM-CES**

Asynchronous Transfer Mode-Circuit Emulation Service

**attendant console**

The workstation used by an attendant. The attendant console allows the attendant to originate a call, answer an incoming call, transfer a call to another extension or trunk, put a call on hold, and remove a call from hold. Attendants using the console can also manage and monitor some system operations. Also called console. See also [attendant](#).

**Attention dial (ATD)**

A command in the Hayes modem command set for asynchronous modems.

**Audio Information Exchange (AUDIX)**

A fully integrated voice-mail system. Can be used with a variety of communications systems to provide call-history data, such as subscriber identification and reason for redirection.

**AUDIX**

See [Audio Information Exchange \(AUDIX\)](#).

**auto-in trunk group**

Trunk group for which the CO processes all of the digits for an incoming call. When a CO seizes a trunk from an auto-in trunk group, the switch automatically connects the trunk to the destination — typically an ACD split where, if no agents are available, the call goes into a queue in which callers are answered in the order in which they arrive.

**Auto-In Work mode**

One of four agent work modes: the mode in which an agent is ready to process another call as soon as the current call is completed.

**Automatic Alternate Routing (AAR)**

A feature that routes calls to other than the first-choice route when facilities are unavailable.

**Automatic Callback (ACB)**

A feature that enables internal callers, upon reaching a busy extension, to have the system automatically connect and ring both parties when the called party becomes available.

**Automatic Call Distribution (ACD)**

A feature that answers calls, and then, depending on administered instructions, delivers messages appropriate for the caller and routes the call to an agent when one becomes available.

**Automatic Call Distribution (ACD) split**

A method of routing calls of a similar type among agents in a call center. Also, a group of extensions that are staffed by agents trained to handle a certain type of incoming call.

**Automatic calling unit (ACU)**

A device that places a telephone call.

**Automatic Circuit Assurance (ACA)**

A feature that tracks calls of unusual duration to facilitate troubleshooting. A high number of very short calls or a low number of very long calls may signify a faulty trunk.

**Automatic Number Identification (ANI)**

Representation of the calling number, for display or for further use to access information about the caller.

**automatic restoration**

A service that restores disrupted connections between access endpoints (nonsignaling trunks) and data endpoints (devices that connect the switch to data terminal and/or communications equipment). Restoration is done within seconds of a service disruption so that critical data applications can remain operational.

**Automatic Route Selection (ARS)**

A feature that allows the system to automatically choose the least-cost way to send a toll call.

**automatic trunk**

A trunk that does not require addressing information because the destination is predetermined. A request for service on the trunk, called a seizure, is sufficient to route the call. The normal destination of an automatic trunk is the communications-system attendant group. Also called automatic incoming trunk and automatic tie trunk.

**AUX**

Auxiliary

**auxiliary equipment**

Equipment used for optional system features, such as Loudspeaker Paging and Music-on-Hold.

**auxiliary trunk**

A trunk used to connect auxiliary equipment, such as radio-paging equipment, to a communications system.

**Aux-Work mode**

A work mode in which agents are unavailable to receive ACD calls. Agents enter Aux-Work mode when involved in non-ACD activities such as taking a break, going to lunch, or placing an outgoing call.

**AVD**

Alternate voice/data

**AWOH**

See [Administration Without Hardware \(AWOH\)](#).

**AWG**

American Wire Gauge

**AWT**

Average work time

## B

### B8ZS

Bipolar Eight Zero Substitution.

### bandwidth

The difference, expressed in hertz, between the defined highest and lowest frequencies in a range.

### barrier code

A security code used with the Remote Access feature to prevent unauthorized access to the system.

### Basic Rate Interface (BRI)

A standard ISDN frame format that specifies the protocol used between two or more communications systems. BRI runs at 192 Mbps and provides two 64-kbps B-channels (voice and data) and one 16-kbps D-channel (signaling). The D-channel connects, monitors, and disconnects all calls. It also can carry low-speed packet data at 9.6 kbps.

### baud

A unit of transmission rate equal to the number of signal events per second. See also [bit rate](#) and [bits per second \(bps\)](#).

### BCC

See [Bearer capability class \(BCC\)](#).

### BCD

Binary coded decimal

### BCMS

Basic Call Management System

### BCT

See [business communications terminal \(BCT\)](#).

### Bearer capability class (BCC)

Code that identifies the type of a call (for example, voice and different types of data). Determination of BCC is based on the caller's characteristics for non-ISDN endpoints and on the Bearer Capability and Low-Layer Compatibility Information Elements of an ISDN endpoint. Current BCCs are 0 (voice-grade data and voice), 1 (DMI mode 1, 56 kbps data transmission), 2 (DMI mode 2, synchronous/asynchronous data transmission up to 19.2 kbps) 3 (DMI mode 3, 64 kbps circuit/packet data transmission), 4 (DMI mode 0, 64 kbps synchronous data), 5 (temporary signaling connection, and 6 (wideband call, 128–1984 kbps synchronous data).

### BER

Bit error rate

### BHCC

Busy-hour call completions

### bit (binary digit)

One unit of information in binary notation, having two possible values: 0 or 1.

### bits per second (bps)

The number of binary units of information that are transmitted or received per second. See also [baud](#) and [bit rate](#).

### bit rate

The speed at which bits are transmitted, usually expressed in bits per second. Also called data rate. See also [baud](#) and [bits per second \(bps\)](#).

**BLF**

Busy Lamp Field

**BN**

Billing number

**BOS**

Bit-oriented signaling

**BPN**

Billed-party number

**bps**

See [bits per second \(bps\)](#).

**bridge (bridging)**

The appearance of a voice terminal's extension at one or more other voice terminals.

**BRI**

The ISDN Basic Rate Interface specification.

**bridged appearance**

A call appearance on a voice terminal that matches a call appearance on another voice terminal for the duration of a call.

**BTD**

Busy Tone Disconnect

**BTU**

British Thermal Unit

**buffer**

1. In hardware, a circuit or component that isolates one electrical circuit from another. Typically, a buffer holds data from one circuit or process until another circuit or process is ready to accept the data.
2. In software, an area of memory that is used for temporary storage.

**bus**

A multiconductor electrical path used to transfer information over a common connection from any of several sources to any of several destinations.

**business communications terminal (BCT)**

A digital data terminal used for business applications. A BCT can function via a data module as a special-purpose terminal for services provided by a processor or as a terminal for data entry and retrieval.

**BX.25**

A version of the CCITT X.25 protocol for data communications. BX.25 adds a fourth level to the standard X.25 interface. This uppermost level combines levels 4, 5, and 6 of the ISO reference model.

**bypass tie trunks**

A 1-way, outgoing tie trunk from a tandem switch to a main switch in an ETN. Bypass tie trunks, provided in limited quantities, are used as a last-choice route when all trunks to another tandem switch are busy. Bypass tie trunks are used only if all applicable intertandem trunks are busy.

**byte**

A sequence of (usually eight) bits processed together.

## C

### **cabinet**

Housing for racks, shelves, or carriers that hold electronic equipment.

### **cable**

Physical connection between two pieces of equipment (for example, data terminal and modem) or between a piece of equipment and a termination field.

### **cable connector**

A jack (female) or plug (male) on the end of a cable. A cable connector connects wires on a cable to specific leads on telephone or data equipment.

### **CACR**

Cancellation of Authorization Code Request

### **CAG**

Coverage answer group

### **call appearance**

1. For the attendant console, six buttons, labeled a–f, used to originate, receive, and hold calls. Two lights next to the button show the status of the call appearance.
2. For the voice terminal, a button labeled with an extension and used to place outgoing calls, receive incoming calls, or hold calls. Two lights next to the button show the status of the call appearance.

### **call-control capabilities**

Capabilities (*Third Party Selective Hold*, *Third Party Reconnect*, *Third Party Merge*) that can be used in either of the Third Party Call Control ASE (cluster) subsets (Call Control and Domain Control).

### **Call Detail Recording (CDR)**

A feature that uses software and hardware to record call data (same as CDRU).

### **Call Detail Recording utility (CDRU)**

Software that collects, stores, optionally filters, and outputs call-detail records.

### **Call Management System (CMS)**

An application, running on an adjunct processor, that collects information from an ACD unit. CMS enables customers to monitor and manage telemarketing centers by generating reports on the status of agents, splits, trunks, trunk groups, vectors, and VDNs, and enables customers to partially administer the ACD feature for a communications system.

### **call-reference value (CRV)**

An identifier present in ISDN messages that associates a related sequence of messages. In ASAI, CRVs distinguish between associations.

### **call vector**

A set of up to 15 vector commands to be performed for an incoming or internal call.

### **callback call**

A call that automatically returns to a voice-terminal user who activated the Automatic Callback or Ringback Queuing feature.

### **call-waiting ringback tone**

A low-pitched tone identical to ringback tone except that the tone decreases in the last 0.2 seconds (in the United States). Call-waiting ringback tone notifies the attendant that the Attendant Call Waiting feature is activated and that the called party is aware of the waiting call. Tones in international countries may sound different.

**call work code**

A number, up to 16 digits, entered by ACD agents to record the occurrence of customer-defined events (such as account codes, social security numbers, or phone numbers) on ACD calls.

**CAMA**

Centralized Automatic Message Accounting

**carrier**

An enclosed shelf containing vertical slots that hold circuit packs.

**carried load**

The amount of traffic served by traffic-sensitive facilities during a given interval.

**CARR-POW**

Carrier Port and Power Unit for AC Powered Systems

**CAS**

Centralized Attendant Service or Call Accounting System

**capability**

A request or indication of an operation. For example, *Third Party Make Call* is a request for setting up a call; *event report* is an indication that an event has occurred.

**capability group**

Set of capabilities, determined by switch administration, that can be requested by an application. Capability groups denote association types. For example, *Call Control* is a type of association that allows certain functions (the ones in the capability group) to be performed over this type of association. Also referred to as administration groups or application service elements (ASEs).

**CA-TSC**

Call-Associated Temporary Signaling Connection

**cause value**

A value is returned in response to requests or in event reports when a denial or unexpected condition occurs. ASAI cause values fall into two coding standards: Coding Standard 0 includes any cause values that are part of AT&T and CCITT ISDN specifications; Coding standard 3 includes any other ASAI cause values. This document uses a notation for cause value where the coding standard for the cause is given first, then a slash, then the cause value. Example: CS0/100 is coding standard 0, cause value 100.

**CBC**

Call-by-call or coupled bonding conductor

**CC**

Country code

**CCIS**

Common-Channel Interoffice Signaling

**CCITT**

CCITT (Comite Consultatif International Telephonique et Telegraphique), now called *International Telecommunications Union* (ITU). See [International Telecommunications Union \(ITU\)](#).

**CCMS**

Control-Channel Message Set

**CCRON**

Coverage of Calls Redirected Off-Net

**CCS**

See [capability](#).

**CCS or hundred call seconds**

A unit of call traffic. Call traffic for a facility is scanned every 100 seconds. If the facility is busy, it is assumed to have been busy for the entire scan interval. There are 3600 seconds per hour. The Roman numeral for 100 is the capital letter C. The abbreviation for call seconds is CS. Therefore, 100 call seconds is abbreviated CCS. If a facility is busy for an entire hour, then it is said to have been busy for 36 CCS. See also [Erlang](#).

**CCSA**

Common-Control Switching Arrangement

**CDM**

Channel-division multiplexing

**CDOS**

Customer-dialed and operator serviced

**CDPD**

Customer database-provided digits

**CDR**

See [Call Detail Recording \(CDR\)](#).

**CDRP**

Call Detail Record Poller

**CDRR**

Call Detail Recording and Reporting

**CDRU**

See [Call Detail Recording utility \(CDRU\)](#).

**CED**

Caller entered digits

**CEM**

Channel-expansion multiplexing

**center-stage switch (CSS)**

The central interface between the processor port network and expansion port networks in a CSS-connected system.

**central office (CO)**

The location housing telephone switching equipment that provides local telephone service and access to toll facilities for long-distance calling.

**central office (CO) codes**

The first three digits of a 7-digit public-network telephone number in the United States.

**central office (CO) trunk**

A telecommunications channel that provides access from the system to the public network through the local CO.

**CEPT**

European Conference of Postal and Telecommunications Rate 1

**CESID**

Caller's Emergency Service Identification

**channel**

1. A circuit-switched call.
2. A communications path for transmitting voice and data.
3. In wideband, all of the time slots (contiguous or noncontiguous) necessary to support a call. Example: an H0-channel uses six 64-kbps time slots.
4. A DS0 on a T1 or E1 facility not specifically associated with a logical circuit-switched call; analogous to a single trunk.

**channel negotiation**

The process by which the channel offered in the Channel Identification Information Element (CIIE) in the SETUP message is negotiated to be another channel acceptable to the switch that receives the SETUP message and ultimately to the switch that sent the SETUP. Negotiation is attempted only if the CIIE is encoded as *Preferred*. Channel negotiation is not attempted for wideband calls.

**CI**

Clock input

**circuit**

1. An arrangement of electrical elements through which electric current flows.
2. A channel or transmission path between two or more points.

**circuit pack**

A card on which electrical circuits are printed, and IC chips and electrical components are installed. A circuit pack is installed in a switch carrier.

**CISPR**

International Special Committee on Radio Interference

**Class of Restriction (COR)**

A feature that allows up to 96 classes of call-origination and call-termination restrictions for voice terminals, voice-terminal groups, data modules, and trunk groups. See also [Class of Service \(COS\)](#).

**Class of Service (COS)**

A feature that uses a number to specify if voice-terminal users can activate the Automatic Callback, Call Forwarding All Calls, Data Privacy, or Priority Calling features. See also [Class of Restriction \(COR\)](#).

**CLI**

command-line interface

**cm**

Centimeter

**CM**

Connection Manager

**CMC**

Compact Modular Cabinet

**CMDR**

Centralized Message Detail Recording

**CMS**

Call Management System

**CO**

See [central office \(CO\)](#).

**common-control switching arrangement (CCSA)**

A private telecommunications network using dedicated trunks and a shared switching center for interconnecting company locations.

**communications system**

The software-controlled processor complex that interprets dialing pulses, tones, and keyboard characters and makes the proper connections both within the system and external to the system. The communications system itself consists of a digital computer, software, storage device, and carriers with special hardware to perform the connections. A communications system provides voice and data communications services, including access to public and private networks, for telephones and data terminals on a customer's premises. See also [switch](#).

**confirmation tone**

A tone confirming that feature activation, deactivation, or cancellation has been accepted.

**connectivity**

The connection of disparate devices within a single system.

**console**

See [ATM-CES](#).

**contiguous**

Adjacent DS0s within one T1 or E1 facility or adjacent TDM or fiber time slots. The first and last TDM bus, DS0, or fiber time slots are not considered contiguous (no wraparound). For an E1 facility with a D-channel, DS0s 15 and 17 are considered contiguous.

**control cabinet**

See [control carrier](#).

**control carrier**

A carrier in a multi-carrier cabinet that contains the SPE circuit packs and, unlike an G3r control carrier, port circuit packs. Also called control cabinet in a single-carrier cabinet. See also [switch-processing element \(SPE\)](#).

**controlled station**

A station that is monitored and controlled via a domain-control association.

**COR**

See [Class of Restriction \(COR\)](#).

**COS**

See [Class of Service \(COS\)](#).

**coverage answer group**

A group of up to eight voice terminals that ring simultaneously when a call is redirected to it by Call Coverage. Any one of the group can answer the call.

**coverage call**

A call that is automatically redirected from the called party's extension to an alternate answering position when certain coverage criteria are met.

**coverage path**

The order in which calls are redirected to alternate answering positions.

**coverage point**

An extension or attendant group, VDN, or ACD split designated as an alternate answering position in a coverage path.

**covering user**

A person at a coverage point who answers a redirected call.

**CP**

Circuit pack

**CPE**

Customer-premises equipment

**CPN**

Called-party number

**CPN/BN**

Calling-party number/billing number

**CPTR**

Call-progress-tone receiver

**CRC**

Cyclical Redundancy Checking

**critical-reliability system**

A system that has the following duplicated items: control carriers, tone clocks, EI circuit packs, and cabling between port networks and center-stage switch in a CSS-connected system. See also [duplicated common control](#), and [duplication](#).

**CSA**

Canadian Safety Association or Customer Software Administrator

**CSCC**

Compact single-carrier cabinet

**CSCN**

Center-stage control network

**CSD**

Customer-service document

**CSM**

Centralized System Management

**CSS**

See [center-stage switch \(CSS\)](#).

**CSSO**

Customer Services Support Organization

**CSU**

Channel service unit

**CTA**

Customer Telephone Activation

**CTI Station**

CTI Stations are AWOH stations that allow applications to originate and receive calls. CTI Stations support ASAI call control features such as hold, answer, drop, conference etc. Calls on a CTI station operate the same way as they would on a real phone. CTI Stations can also be used to originate phantom calls.

**CTS**

Clear to Send

**CWC**

See [call work code](#).

---

**D**

**DAC**

1. Dial access code or Direct Agent Calling
2. See [digital-to-analog converter \(DAC\)](#).

**data channel**

A communications path between two points used to transmit digital signals.

**data-communications equipment (DCE)**

The equipment (usually a modem, data module, or packet assembler/disassembler) on the network side of a communications link that makes the binary serial data from the source or transmitter compatible with the communications channel.

**data link**

The configuration of physical facilities enabling end terminals to communicate directly with each other.

**data module**

An interconnection device between a BRI or DCP interface of the switch and data terminal equipment or data communications equipment.

**data path**

The end-to-end connection used for a data communications link. A data path is the combination of all elements of an interprocessor communication in a DCS.

**data port**

A point of access to a computer that uses trunks or lines for transmitting or receiving data.

**data rate**

See [bit rate](#).

**data service unit (DSU)**

A device that transmits digital data on transmission facilities.

**data terminal**

An input/output (I/O) device that has either switched or direct access to a host computer or to a processor interface.

**data terminal equipment (DTE)**

Equipment consisting of the endpoints in a connection over a data circuit. In a connection between a data terminal and host, the terminal, the host, and their associated modems or data modules make up the DTE.

**dB**

Decibel

**dBa**

Decibels in reference to amperes.

**dBrnC**

Decibels above reference noise with C filter.

**DC**

Direct current

**DCE**

Data-communications equipment

**D-channel backup**

Type of backup used with Non-Facility Associated Signaling (NFAS). A primary D-channel provides signaling for an NFAS D-channel group (two or more PRI facilities). A second D-channel, on a separate PRI facility of the NFAS D-channel group, is designated as backup for the D-channel. Failure of the primary D-channel causes automatic transfer of call-control signaling to the backup D-channel. The backup becomes the primary D-channel. When the failed channel returns to service, it becomes the backup D-channel.

**DCO**

Digital central office

**DCP**

Digital Communications Protocol

**DCS**

Distributed Communications System

**DDC**

Direct Department Calling

**DDD**

Direct Distance Dialing

**delay-dial trunk**

A trunk that allows dialing directly into a communications system (digits are received as they are dialed).

**denying a request**

Sending a negative acknowledgment (NAK), done by sending an FIE with a *return error* component (and a cause value). It should not be confused with the denial event report that applies to calls.

**designated voice terminal**

The specific voice terminal to which calls, originally directed to a certain extension, are redirected. Commonly used to mean the forwarded-to terminal when Call Forwarding All Calls is active.

**dial-repeating trunks**

A PBX tie trunk that is capable of handling PBX station-signaling information without attendant assistance.

**dial-repeating tie trunk**

A tie trunk that transmits called-party addressing information between two communications systems.

**DID**

Direct Inward Dialing

**digit conversion**

A process used to convert specific dialed numbers into other dialed numbers.

**digital**

The representation of information by discrete steps. See also [analog](#).

### **digital communications protocol (DCP)**

A proprietary protocol used to transmit both digitized voice and digitized data over the same communications link. A DCP link is made up of two 64-kbps information (I-) channels and one 8-kbps signaling (S-) channel. The DCP protocol supports two information-bearing channels, and thus two telephones/data modules. The I1 channel is the DCP channel assigned on the first page of the 8411 station form. The I2 channel is the DCP channel assigned on the analog adjunct page of the 8411 station form or on the data module page.

Digital Communications Protocol. The DCP protocol supports two information-bearing channels, and thus two telephones/data modules. The I1 channel is the DCP channel assigned on the first page of the 8411 station form. The I2 channel is the DCP channel assigned on the analog adjunct page of the 8411 station form or on the data module page.

### **digital data endpoints**

In DEFINITY ECS, devices such as the 510D terminal or the 515-type business communications terminal (BCT).

### **digital multiplexed interface (DMI)**

An interface that provides connectivity between a communications system and a host computer or between two communications systems using DS1 24th-channel signaling. DMI provides 23 64-kbps data channels and 1 common-signaling channel over a twisted-pair connection. DMI is offered through two capabilities: bit-oriented signaling (DMI-BOS) and message-oriented signaling (DMI-MOS).

### **digital signal level 0 (DS0)**

A single 64-kbps voice channel. A DS0 is a single 64-kbps channel in a T1 or E1 facility and consists of eight bits in a T1 or E1 frame every 125 microseconds.

### **digital signal level 1 (DS1)**

A single 1.544-Mbps (United States) or 2.048-Mbps (outside the United States) digital signal carried on a T1 transmission facility. A DS1 converter complex consists of a pair, one at each end, of DS1 converter circuit packs and the associated T1/E1 facilities.

### **digital terminal data module (DTDM)**

An integrated or adjunct data module that shares with a digital telephone the same physical port for connection to a communications system. The function of a DTDM is similar to that of a PDM and MPDM in that it converts RS-232C signals to DCP signals.

### **digital-to-analog converter (DAC)**

A device that converts data in digital form to the corresponding analog signals. See also [analog-to-digital converter \(ADC\)](#).

### **digital transmission**

A mode of transmission in which information to be transmitted is first converted to digital form and then transmitted as a serial stream of pulses.

### **digital trunk**

A circuit that carries digital voice and/or digital data in a telecommunications channel.

### **DIOD**

Direct Inward and Outward Dialing

### **direct agent**

A feature, accessed only via ASAI, that allows a call to be placed in a split queue but routed only to a specific agent in that split. The call receives normal ACD call treatment (for example, announcements) and is measured as an ACD call while ensuring that a particular agent answers.

### **Direct Extension Selection (DXS)**

A feature on an attendant console that allows an attendant direct access to voice terminals by pressing a group-select button and a DXS button.

**Direct Inward Dialing (DID)**

A feature that allows an incoming call from the public network (not FX or WATS) to reach a specific telephone without attendant assistance.

**Direct Inward Dialing (DID) trunk**

An incoming trunk used for dialing directly from the public network into a communications system without help from the attendant.

**disk drive**

An electromechanical device that stores data on and retrieves data from one or more disks.

**distributed communications system (DCS)**

A network configuration linking two or more communications systems in such a way that selected features appear to operate as if the network were one system.

**DIVA**

Data In/Voice Answer

**DLC**

Data line circuit

**DLDM**

Data-line data module

**DMI**

Digital-multiplexed interface

**DND**

Do not disturb

**DNIS**

Dialed-Number Identification Service

**DNS**

Domain name service

**DOD**

Direct Outward Dialing

**domain**

VDNs, ACD splits, and stations. The VDN domain is used for active-notification associations. The ACD-split domain is for active-notification associations and domain-control associations. The station domain is used for the domain-control associations.

**domain-control association**

A *Third Party Domain Control Request* capability initiates a unique CRV/link number combination, which is referred to as a domain-control association.

**domain-controlled split**

A split for which *Third Party Domain Control* request has been accepted. A domain-controlled split provides an event report for logout.

**domain-controlled station**

A station for which a *Third Party Domain Control* request has been accepted. A domain-controlled station provides event reports for calls that are alerting, connected, or held at the station.

**domain-controlled station on a call**

A station that is active on a call, and which provides event reports over one or two domain-control associations.

**DOSS**

Delivery Operations Support System

**DOT**

Duplication Option Terminal

**DPM**

Dial Plan Manager

**DPR**

Dual-port RAM

**DS1**

Digital Signal Level 1

**DS1C**

Digital Signal Level-1 protocol C

**DS1 CONV**

Digital Signal Level-1 converter

**DSI**

Digital signal interface

**DSU**

Data service unit

**DTDM**

Digital-terminal data module

**DTE**

Data-terminal equipment

**DTGS**

Direct Trunk Group Select

**DTMF**

Dual-tone multifrequency

**DTS**

Disk-tape system

**duplicated common control**

Two processors ensuring continuous operation of a communications system. While one processor is online, the other functions as a backup. The backup processor goes online periodically or when a problem occurs.

**duplication**

The use of redundant components to improve availability. When a duplicated subsystem fails, its backup redundant system automatically takes over.

**duplication option**

A system option that duplicates the following: control carrier containing the SPE, EI circuit packs in carriers, fiber-optic cabling between port networks, and center-stage switch in a CSS-connected system.

**DWBS**

DEFINITY Wireless Business System

**DXS**

Direct extension selection

**E****E1**

A digital transmission standard that carries traffic at 2.048 Mbps. The E1 facility is divided into 32 channels (DSOs) of 64 kbps information. Channel 0 is reserved for framing and synchronization information. A D-channel occupies channel 16.

**E & M**

Ear and mouth (receive and transmit)

**EA**

Expansion archangel

**EAL**

Expansion archangel link

**ear and mouth (E & M) signaling**

Trunk supervisory signaling, used between two communications systems, whereby signaling information is transferred through 2-state voltage conditions (on the E and M leads) for analog applications and through a single bit for digital applications.

**EAS**

See "Expert Agent Selection".

**ECC**

Error Correct Code

**ECMA**

European Computer Manufacturers Association

**ECT**

Enhanced Call Transfer

**EEBCDIC**

Extended Binary-Coded Decimal Interexchange Code

**EPF**

Electronic power feed

**EI**

Expansion interface

**EIA**

Electronic Industries Association

**EIA-232**

A physical interface specified by the EIA. EIA-232 transmits and receives asynchronous data at speeds of up to 19.2 kbps over cable distances of up to 50 feet. EIA-232 replaces RS-232 protocol in some DEFINITY applications.

**electronic tandem network (ETN)**

A tandem tie-trunk network that has automatic call-routing capabilities based on the number dialed and the most preferred route available. Each switch in the network is assigned a unique private network office code (RNX), and each voice terminal is assigned a unique extension.

**Electronics Industries Association (EIA)**

A trade association of the electronics industry that establishes electrical and functional standards.

**emergency transfer**

If a major system failure occurs, automatic transfer is initiated to a group of telephones capable of making outgoing calls. The system operates in this mode until the failure is repaired and the system automatically returns to normal operation. Also called power-failure transfer.

**EMI**

Electromagnetic interference

**end-to-end signaling**

The transmission of touch-tone signals generated by dialing from a voice terminal to remote computer equipment. These digits are sent over the trunk as DTMF digits whether the trunk signaling type is marked as tone or rotary and whether the originating station is tone or rotary. Example: a call to a voice-mail machine or automated-attendant service. A connection is first established over an outgoing trunk. Then additional digits are dialed to transmit information to be processed by the computer equipment.

**enhanced private-switched communications service (EPSCS)**

An analog private telecommunications network based on the No. 5 crossbar and 1A ESS that provides advanced voice and data telecommunications services to companies with many locations.

**ENP**

Extension number portability

**EPN**

Expansion-port network

**EPROM**

Erasable programmable read-only memory

**EPSCS**

Enhanced Private Switched Communications Services

**ERL**

Echo return loss

**Erlang**

A unit of traffic intensity, or load, used to express the amount of traffic needed to keep one facility busy for one hour. One Erlang is equal to 36 CCS. See also [capability](#).

**ESF**

Extended superframe format

**ESPA**

European Standard Paging Access

**ETA**

Extended Trunk Access; also Enhanced Terminal Administration

**ETN**

Electronic tandem network

**ETSI**

European Telecommunications Standards Institute

**expansion archangel (EAA)**

A network-control microprocessor located on an expansion interface (EI) port circuit pack in an expansion port network. The EA provides an interface between the EPN and its controlling switch-processing element.

**expansion-archangel link (EAL)**

A link-access function on the D-channel (LAPD) logical link that exists between a switch-processing element and an expansion archangel (EA). The EAL carries control messages from the SPE to the EA and to port circuit packs in an expansion port network.

**expansion control cabinet**

See [expansion control carrier](#).

**expansion control carrier**

A carrier in a multicarrier cabinet that contains extra port circuit packs and a maintenance interface. Also called expansion control cabinet in a single-carrier cabinet.

**expansion interface (EI)**

A port circuit pack in a port network that provides the interface between a PN's TDM bus/ packet bus and a fiber-optic link. The EI carries circuit-switched data, packet-switched data, network control, timing control, and DS1 control. In addition, an EI in an expansion port network communicates with the master maintenance circuit pack to provide the EPN's environmental and alarm status to the switch-processing element.

**expansion port network (EPN)**

A port network (PN) that is connected to the TDM bus and packet bus of a processor port network (PPN). Control is achieved by indirect connection of the EPN to the PPN via a port-network link (PNL). See also [port network \(PN\)](#).

**Expert Agent Selection**

A feature allowing incoming calls to be routed to specialized groups of agents within a larger pool of agents.

**extension-in**

Extension-In (ExtIn) is the work state agents go into when they answer (receive) a non-ACD call. If the agent is in Manual-In or Auto-In and receives an extension-in call, it is recorded by CMS as an AUX-In call.

**extension-out**

The work state that agents go into when they place (originate) a non-ACD call.

**external measurements**

Those ACD measurements that are made by the External CMS adjunct.

**extension**

A 1- to 5-digit number by which calls are routed through a communications system or, with a Uniform Dial Plan (UDP) or main-satellite dialing plan, through a private network.

**external call**

A connection between a communications system user and a party on the public network or on another communications system in a private network.

---

**F****FAC**

Feature Access Code

**facility**

A telecommunications transmission pathway and associated equipment.

**facility-associated signaling (FAS)**

Signaling for which a D-channel carries signaling only for those channels on the same physical interface.

**FAS**

Facility-associated signaling

**FAT**

Facility access trunk

**FAX**

Facsimile

**FCC**

Federal Communications Commission

**FEAC**

Forced Entry of Account Codes

**feature**

A specifically defined function or service provided by the system.

**feature button**

A labeled button on a telephone or attendant console used to access a specific feature.

**FEP**

Front-end processor

**fiber optics**

A technology using materials that transmit ultra wideband electromagnetic light-frequency ranges for high-capacity carrier systems.

**FIC**

Facility interface codes

**FIE**

Facility Information Element

**fixed**

A trunk allocation term. In the fixed allocation scheme, the time slots necessary to support a wideband call are contiguous, and the first time slot is constrained to certain starting points.

**flexible**

A trunk allocation term. In the flexible allocation scheme, the time slots of a wideband call can occupy non-contiguous positions within a single T1 or E1 facility.

**floating**

A trunk allocation term. In the floating allocation scheme, the time slots of a wideband call are contiguous, but the position of the first time slot is not fixed.

**FNPA**

Foreign Numbering-Plan Area

**foreign-exchange (FX)**

A CO other than the one providing local access to the public telephone network.

**foreign-exchange trunk**

A telecommunications channel that directly connects the system to a CO other than its local CO.

**foreign numbering-plan area code (FNPAC)**

An area code other than the local area code, that must be dialed to call outside the local geographical area.

**FRL**

Facilities Restriction Level

**FTC**

Facility Test Call

**FTP**

File Transfer Protocol

**FX**

Foreign exchange

---

**G**

**G3-MA**

Generic 3 Management Applications

**G3-MT**

Generic 3 Management Terminal

**G3r**

Generic 3, RISC (Reduced Instruction Set Computer)

**generalized route selection (GRS)**

An enhancement to Automatic Alternate Routing/Automatic Route Selection (AAR/ARS) that performs routing based on call attributes, such as Bearer Capability Classes (BCCs), in addition to the address and facilities restriction level (FRL), thus facilitating a Uniform Dial Plan (UDP) that is independent of the type of call being placed.

**glare**

The simultaneous seizure of a 2-way trunk by two communications systems, resulting in a standoff.

**GM**

Group manager

**GPTR**

General-purpose tone receiver

**grade of service**

The number of call attempts that fail to receive service immediately. Grade of service is also expressed as the quantity of all calls that are blocked or delayed.

**ground-start trunk**

A trunk on which, for outgoing calls, the system transmits a request for services to a distant switching system by grounding the trunk ring lead. To receive the digits of the called number, that system grounds the trunk tip lead. When the system detects this ground, the digits are sent.

**GRS**

Generalized Route Selection

**GUI**

graphical user interface

---

## H

### H0

An ISDN information transfer rate for 384-kbps data defined by CCITT and ANSI standards.

### H11

An ISDN information transfer rate for 1536-kbps data defined by CCITT and ANSI standards.

### H12

An ISDN information transfer rate for 1920-kbps data defined by CCITT and ANSI standards.

### handshaking logic

A format used to initiate a data connection between two data module devices.

### hertz (Hz)

A unit of frequency equal to one cycle per second.

### HFAI

Hands Free Automatic Answer on Intercom

### high-reliability system

A system having the following: two control carriers, duplicate expansion interface (EI) circuit packs in the PPN (in G3r with CSS), and duplicate switch node clock circuit packs in the switch node (SN) carriers. See also [duplicated common control](#), [duplication](#), [duplication option](#), and [critical-reliability system](#).

### HNPA

See [home numbering-plan area code \(HNPA\)](#).

### holding time

The total length of time in minutes and seconds that a facility is used during a call.

### home numbering-plan area code (HNPA)

The local area code. The area code does not have to be dialed to call numbers within the local geographical area.

### hop

Nondirect communication between two switch communications interfaces (SCI) where the SCI message passes automatically without intermediate processing through one or more intermediate SCIs.

### host computer

A computer, connected to a network, that processes data from data-entry devices.

### hunt group

A group of extensions that are assigned the Station Hunting feature so that a call to a busy extension reroutes to an idle extension in the group. See also [ACD work mode](#).

### Hz

See [hertz \(Hz\)](#).

---

## I

### I1

The first information channel of DCP.

**I2**

The second information channel of DCP.

**I2 Interface**

A proprietary interface used for the DEFINITY Wireless Business System for the radio-controller circuit packs. Each interface provides communication between the radio-controller circuit pack and up to two wireless fixed bases.

**I3 Interface**

A proprietary interface used for the DEFINITY Wireless Business System for the cell antenna units. Each wireless fixed base can communicate to up to four cell antenna units.

**IAA**

Internal Automatic Answer

**IAS**

Inter-PBX Attendant Service

**ICC**

Intercabinet cable or intercarrier cable

**ICD**

Inbound Call Director

**ICDOS**

International Customer-Dialed Operator Service

**ICHT**

Incoming call-handling table

**ICI**

Incoming call identifier

**ICLID**

Incoming Call Line Identification

**ICM**

Inbound Call Management

**IDDD**

International Direct Distance Dialing

**IDF**

Intermediate distribution frame

**IE**

Information element

**immediate-start tie trunk**

A trunk on which, after making a connection with a distant switching system for an outgoing call, the system waits a nominal 65 ms before sending the digits of the called number. This allows time for the distant system to prepare to receive digits. On an incoming call, the system has less than 65 ms to prepare to receive the digits.

**IMT**

Intermachine trunk

**in**

Inch

**INADS**

Initialization and Administration System

**ICLID**

Incoming Caller ID

**incoming gateway**

A PBX that routes an incoming call on a trunk *not* administered for Supplementary Services Protocol B to a trunk *not* administered for Supplementary Services Protocol B.

**information exchange**

The exchange of data between users of two different systems, such as the switch and a host computer, over a LAN.

**Information Systems Network (ISN)**

A WAN and LAN with an open architecture combining host computers, minicomputers, word processors, storage devices, PCs, high-speed printers, and nonintelligent terminals into a single packet-switching system.

**INS**

ISDN Network Service

**inside call**

A call placed from one telephone to another within the local communications system.

**Integrated Services Digital Network (ISDN)**

A public or private network that provides end-to-end digital communications for all services to which users have access by a limited set of standard multipurpose user-network interfaces defined by the CCITT. Through internationally accepted standard interfaces, ISDN provides digital circuit-switched or packet-switched communications within the network and links to other ISDNs to provide national and international digital communications. See also [Integrated Services Digital Network Basic Rate Interface \(ISDN-BRI\)](#) and [Integrated Services Digital Network Primary Rate Interface \(ISDN-PRI\)](#).

**Integrated Services Digital Network Basic Rate Interface (ISDN-BRI)**

The interface between a communications system and terminal that includes two 64-kbps B-channels for transmitting voice or data and one 16-kbps D-channel for transmitting associated B-channel call control and out-of-band signaling information. ISDN-BRI also includes 48 kbps for transmitting framing and D-channel contention information, for a total interface speed of 192 kbps. ISDN-BRI serves ISDN terminals and digital terminals fitted with ISDN terminal adapters. See also [Integrated Services Digital Network \(ISDN\)](#) and [Integrated Services Digital Network Primary Rate Interface \(ISDN-PRI\)](#).

**Integrated Services Digital Network Primary Rate Interface (ISDN-PRI)**

The interface between multiple communications systems that in North America includes 24 64-kbps channels, corresponding to the North American digital signal level-1 (DS1) standard rate of 1.544 Mbps. The most common arrangement of channels in ISDN-PRI is 23 64-kbps B-channels for transmitting voice and data and 1 64-kbps D-channel for transmitting associated B-channel call control and out-of-band signaling information. With nonfacility-associated signaling (NFAS), ISDN-PRI can include 24 B-channels and no D-channel. See also [Integrated Services Digital Network \(ISDN\)](#) and [Integrated Services Digital Network Basic Rate Interface \(ISDN-BRI\)](#).

**intercept tone**

A tone that indicates a dialing error or denial of the service requested.

**interface**

A common boundary between two systems or pieces of equipment.

**internal call**

A connection between two users within a system.

**International Telecommunications Union (ITU)**

Formerly known as International Telegraph and Telephone Consultative Committee (CCITT), ITU is an international organization that sets universal standards for data communications, including ISDN. ITU members are from telecommunications companies and organizations around the world. See also [BX.25](#).

**International Telegraph and Telephone Consultative Committee**

See [International Telecommunications Union \(ITU\)](#).

**interflow**

The ability for calls to forward to other splits on the same PBX or a different PBX using the Call Forward All Calls feature.

**intraflow**

The ability for calls to redirect to other splits on the same PBX on a conditional or unconditional basis using call coverage busy, don't answer, or all criteria.

**internal measurements**

BCMS measurements that are made by the system. ACD measurements that are made external to the system (via External CMS) are referred to as external measurements.

**in-use lamp**

A red light on a multiappearance voice terminal that lights to show which call appearance will be selected when the handset is lifted or which call appearance is active when a user is off-hook.

**INWATS**

Inward Wide Area Telephone Service

**IO**

Information outlet

**IP**

Internet Protocol

**ISDN**

See [Integrated Services Digital Network \(ISDN\)](#).

**ISDN-BRI**

Integrated Services Digital Network-Basic Rate Interface

**ISDN Gateway (IG)**

A feature allowing integration of the switch and a host-based telemarketing application via a link to a gateway adjunct. The gateway adjunct is a 3B-based product that notifies the host-based telemarketing application of call events.

**ISDN-PRI**

Integrated Services Digital Network-Primary Rate Interface

**ISDN trunk**

A trunk administered for use with ISDN-PRI. Also called ISDN facility.

**ISDN-PRI terminal adapter**

An interface between endpoint applications and an ISDN PRI facility. ISDN-PRI terminal adapters are currently available from other vendors and are primarily designed for video conferencing applications. Accordingly, currently available terminal adapters adapt the two pairs of video codec data (V.35) and dialing (RS-366) ports to an ISDN PRI facility.

**IS/DTT**

Integrated Services/digital tie trunk

**ISN**

Information Systems Network

**ISO**

International Standards Organization

**ISV**

Independent software vendor

**ITC**

Information transfer capability

**ITP**

Installation test procedure

**ITU**

International Telecommunications Union

**IXC**

Interexchange carrier code

---

**K**

**kHz**

Kilohertz

**kbps**

Kilobits per second

**kbyte**

Kilobyte

**kg**

Kilogram

---

**L**

**LAN**

Local area network

**LAP-D**

Link Access Procedure on the D-channel

**LAPD**

Link Access Procedure data

**LATA**

Local access and transport area

**lb**

Pound

**LBO**

Line buildout

**LDN**

Listed directory number

**LDS**

Long-distance service

**LEC**

Local exchange carrier

**LED**

See [light-emitting diode \(LED\)](#).

**light-emitting diode (LED)**

A semiconductor device that produces light when voltage is applied. LEDs provide a visual indication of the operational status of hardware components, the results of maintenance tests, the alarm status of circuit packs, and the activation of telephone features.

**lightwave transceiver**

Hardware that provides an interface to fiber-optic cable from port circuit packs and DS1 converter circuit packs. Lightwave transceivers convert electrical signals to light signals and vice versa.

**line**

A transmission path between a communications system or CO switching system and a voice terminal or other terminal.

**line appearance**

See [appearance](#).

**line buildout**

A selectable output attenuation is generally required of DTE equipment because T1 circuits require the last span to lose 15–22.5 dB.

**line port**

Hardware that provides the access point to a communications system for each circuit associated with a telephone or data terminal.

**link**

A transmitter-receiver channel that connects two systems.

**link-access procedure on the D-channel (LAPD)**

A link-layer protocol on the ISDN-BRI and ISDN-PRI data-link layer (level 2). LAPD provides data transfer between two devices, and error and flow control on multiple logical links. LAPD is used for signaling and low-speed packet data (X.25 and mode 3) on the signaling (D-) channel and for mode-3 data communications on a bearer (B-) channel.

**LINL**

Local indirect neighbor link

**local area network (LAN)**

A networking arrangement designed for a limited geographical area. Generally, a LAN is limited in range to a maximum of 6.2 miles and provides high-speed carrier service with low error rates. Common configurations include daisy chain, star (including circuit-switched), ring, and bus.

**logical link**

The communications path between a processor and a BRI terminal.

**loop-start trunk**

A trunk on which, after establishing a connection with a distant switching system for an outgoing call, the system waits for a signal on the loop formed by the trunk leads before sending the digits of the called number.

**loss plan**

The overall plan, used in network design and management, for creating and maintaining consistent signal strength across the network. The term also applies to local management of signal strength to achieve appropriate levels for specific applications.

**LSP**

Local Survivable Processor

**LSU**

Local storage unit

**LWC**

Leave Word Calling

---

## M

**MAC**

Medium access

**MADU**

Modular asynchronous data unit

**main distribution frame (MDF)**

A device that mounts to the wall inside the system equipment room. The MDF provides a connection point from outside telephone lines to the PBX switch and to the inside telephone stations.

**main-satellite-tributary**

A private network configuration that can either stand alone or access an ETN. A main switch provides interconnection, via tie trunks, with one or more subtending switches, called satellites; all attendant positions for the main/satellite configuration; and access to and from the public network. To a user outside the complex, a main/satellite configuration appears as one switch, with one listed directory number (LDN). A tributary switch is connected to the main switch via tie trunks, but has its own attendant positions and LDN.

**maintenance**

Activities involved in keeping a telecommunications system in proper working condition: the detection and isolation of software and hardware faults, and automatic and manual recovery from these faults.

**management terminal**

The terminal that is used by the system administrator to administer the switch. The terminal may also be used to access the BCMS feature.

**major alarm**

An indication of a failure that has caused critical degradation of service and requires immediate attention. Major alarms are automatically displayed on LEDs on the attendant console and maintenance or alarming circuit pack, logged to the alarm log, and reported to a remote maintenance facility, if applicable.

**Manual-In work mode**

One of four agent work modes: the mode in which an agent is ready to process another call manually. *See* [Auto-In Work mode](#) for a contrast.

**MAP**

Maintenance action process

**MAPD**

Multiapplication platform for DEFINITY

**MASI**

Multimedia Applications Server Interface

**MA-UUI**

Message-Associated User-to-User Signaling

**Mbps**

Megabits per second

**M-Bus**

Memory bus

**Mbyte**

Megabyte

**MCC**

Multicarrier cabinet

**MCS**

Message Center Service

**MCT**

Malicious Call Trace

**MCU**

Multipoint control unit

**MDF**

Main distribution frame

**MDM**

Modular data module

**MDR**

Message detail record

**MEM**

Memory

**memory**

A device into which information can be copied and held, and from which information can later be obtained.

**memory shadowing link**

An operating-system condition that provides a method for memory-resident programs to be more quickly accessed, allowing a system to reboot faster.

**message center**

An answering service that supplies agents to and stores messages for later retrieval.

**message center agent**

A member of a message-center hunt group who takes and retrieves messages for voice-terminal users.

**MF**

Multifrequency

**MFB**

Multifunction board

**MFC**

1. Multifrequency code
2. Multi-Frequency Compelled

**MFE**

Multifrequency Espana

**MGP**

Media Gateway Processor

**MHz**

Megahertz

**MIM**

Management information message

**minor alarm**

An indication of a failure that could affect customer service. Minor alarms are automatically displayed on LEDs on the attendant console and maintenance or alarming circuit pack, sent to the alarm log, and reported to a remote maintenance facility, if applicable.

**MIPS**

Million instructions per second

**MIS**

Management information system

**MISCID**

Miscellaneous identification

**MMCS**

Multimedia Call Server

**MMCH**

Multimedia call handling

**MMCX**

Multimedia Communications Exchange

**MMI**

Multimedia interface

**MMS**

Material Management Services

**MO**

Maintenance object

**modem**

A device that converts digital data signals to analog signals for transmission over telephone circuits. The analog signals are converted back to the original digital data signals by another modem at the other end of the circuit.

**modem pooling**

A capability that provides shared conversion resources (modems and data modules) for cost-effective access to analog facilities by data terminals. When needed, modem pooling inserts a conversion resource into the path of a data call. Modem pooling serves both outgoing and incoming calls.

**modular processor data module (MPDM)**

A processor data module (PDM) that can be configured to provide several kinds of interfaces (RS-232C, RS-449, and V.35) to customer-provided data terminal equipment (DTE). See also [processor data module \(PDM\)](#).

**modular trunk data module (MTDM)**

A trunk data module that can be configured to provide several kinds of interfaces (RS-232, RS-449, and V.35) to customer-provided data terminal equipment.

**modulator-demodulator**

See [modem](#).

**monitored call**

See [active-notification call](#).

**MOS**

Message-oriented signaling

**MPDM**

Modular processor data module

**MS**

Message server

**ms**

Millisecond

**MS/T**

Main satellite/tributary

**MSG**

Message service

**MSI**

Manufacturer Specific Information allows for vendor-specific messages to be passed in the QSIG enterprise network.

**MSL**

Material stocking location

**MSM**

Modular System Management

**MSS**

Mass storage system

**MSSNET**

Mass storage/network control

**MT**

Management terminal

**MTDM**

Modular trunk data module

**MTP**

Maintenance tape processor

**MTT**

Multitasking terminal

**multiappearance voice terminal**

A terminal equipped with several call-appearance buttons for the same extension, allowing the user to handle more than one call on that same extension at the same time.

**Multicarrier cabinet**

A structure that holds one to five carriers. See also [single-carrier cabinet](#).

**Multifrequency Compelled (MFC) Release 2 (R2) signaling**

A signal consisting of two frequency components, such that when a signal is transmitted from a switch, another signal acknowledging the transmitted signal is received by the switch. R2 designates signaling used in the United States and in countries outside the United States.

**multiplexer**

A device used to combine a number of individual channels into a single common bit stream for transmission.

**multiplexing**

A process whereby a transmission facility is divided into two or more channels, either by splitting the frequency band into a number of narrower bands or by dividing the transmission channel into successive time slots. See also [time-division multiplexing \(TDM\)](#).

**multirate**

The new N x DS0 service (see N x DS0).

**MWL**

Message-waiting lamp

---

## N

**N+1**

Method of determining redundant backup requirements. Example: if four rectifier modules are required for a DC-powered single-carrier cabinet, a fifth rectifier module is installed for backup.

**N x DS0**

N x DS0, equivalently referred to as N x 64 kbps, is an emerging standard for wideband calls separate from H0, H11, and H12 ISDN channels. The emerging N x DS0 ISDN multirate circuit mode bearer service will provide circuit-switched calls with data-rate multiples of 64 kbps up to 1536 kbps on a T1 facility or up to 1920 kbps on an E1 facility. In the switch, N x DS0 channels will range up to 1984 kbps using NFAS E1 interfaces.

**NANP**

North American Numbering Plan

**narrowband**

A circuit-switched call at a data rate up to and including 64 kbps. All nonwideband switch calls are considered narrowband.

**native terminal support**

A predefined terminal type exists in switch software, eliminating the need to alias the terminal (that is, manually map call appearances and feature buttons onto some other natively supported terminal type).

**NAU**

Network access unit

**NCA/TSC**

Noncall-associated/temporary-signaling connection

**NCOSS**

Network Control Operations Support Center

**NCSO**

National Customer Support Organization

**NEC**

National Engineering Center

**NEMA**

National Electrical Manufacturer's Association

**NETCON**

Network-control circuit pack

**network**

A series of points, nodes, or stations connected by communications channels.

**network-specific facility (NSF)**

An information element in an ISDN-PRI message that specifies which public-network service is used. NSF applies only when Call-by-Call Service Selection is used to access a public-network service.

**network interface**

A common boundary between two systems in an interconnected group of systems.

**NFAS**

See [Nonfacility-associated signaling \(NFAS\)](#).

**NI**

Network interface

**NID**

Network Inward Dialing

**NM**

Network management

**NMS**

Network Management System

**NN**

National number

**node**

A switching or control point for a network. Nodes are either tandem (they receive signals and pass them on) or terminal (they originate or terminate a transmission path).

**Nonfacility-associated signaling (NFAS)**

A method that allows multiple T1 and/or E1 facilities to share a single D-channel to form an ISDN-PRI. If D-channel backup is not used, one facility is configured with a D-channel, and the other facilities that share the D-channel are configured without D-channels. If D-channel backup is used, two facilities are configured to have D-channels (one D-channel on each facility), and the other facilities that share the D-channels are configured without D-channels.

**NPA**

Numbering-plan area

**NPE**

Network processing element

**NQC**

Number of queued calls

**NSE**

Night-service extension

**NSF**

Network-specific facility

**NSU**

Network sharing unit

**null modem cable**

Special wiring of an RS-232-C cable such that a computer can talk to another computer (or to a printer) without a modem.

**NXX**

Public-network office code

---

**O**

**OA**

Operator assisted

**occurrence**

See [appearance](#).

**OCM**

Outbound Call Management

**offered load**

The traffic that would be generated by all the requests for service occurring within a monitored interval, usually one hour.

**ONS**

On-premises station

**OPS**

Off-premises station

**OPX**

Off-premises extension

**OQT**

Oldest queued time

**OSHA**

Occupational Safety and Health Act

**OSI**

Open Systems Interconnect

**OSS**

Operations Support System

**OSSI**

Operational Support System Interface

**OTDR**

Optical time-domain reflectometer

**othersplit**

The work state that indicates that an agent is currently active on another split's call, or in ACW for another split.

**OTL**

Originating Test Line

**OTQ**

Outgoing trunk queuing

**OTTOTT**

Outgoing Trunk to Outgoing Trunk Transfer

**outgoing gateway**

A PBX that routes an incoming call on a trunk administered for Supplementary Services Protocol B to a trunk *not* administered for Supplementary Services Protocol B.

---

**P**

**PACCON**

Packet control

**packet**

A group of bits (including a message element, which is the data, and a control information element (IE), which is the header) used in packet switching and transmitted as a discrete unit. In each packet, the message element and control IE are arranged in a specified format. See also [packet bus](#) and [packet switching](#).

**packet bus**

A wide-bandwidth bus that transmits packets.

**packet switching**

A data-transmission technique whereby user information is segmented and routed in discrete data envelopes called packets, each with its own appended control information, for routing, sequencing, and error checking. Packet switching allows a channel to be occupied only during the transmission of a packet. On completion of the transmission, the channel is made available for the transfer of other packets. See also [BX.25](#) and [packet](#).

**PAD**

Packet assembly/disassembly

**paging trunk**

A telecommunications channel used to access an amplifier for loudspeaker paging.

**party/extension active on call**

A party is on the call if he or she is actually connected to the call (in active talk or in held state). An originator of a call is always a party on the call. Alerting parties, busy parties, and tones are not parties on the call.

**PBX**

Private branch exchange

**PC**

See [personal computer \(PC\)](#).

**PCM**

See [pulse-code modulation \(PCM\)](#).

**PCOL**

Personal central-office line

**PCOLG**

Personal central-office line group

**PCS**

Permanent switched calls

**PDM**

See [processor data module \(PDM\)](#).

**PDS**

Premises Distribution System

**PE**

Processing element

**PEC**

Price element code

**PEI**

Processor element interchange

**personal computer (PC)**

A personally controllable microcomputer.

**PGATE**

Packet gateway

**PGN**

Partitioned group number

**Phantom Calls**

A feature that allows a call to originate either from a station AWOH or from a non-hunt group made up of AWOH stations.

**PI**

Processor interface

**PIB**

Processor interface board

**pickup group**

A group of individuals authorized to answer any call directed to an extension within the group.

**PIDB**

Product image database

**PKTINT**

Packet interface

**PL**

Private line

**PLS**

Premises Lightwave System

**PMS**

Property Management System

**PN**

Port network

**PNA**

Private network access

**POE**

Processor occupancy evaluation

**POP**

Point of presence

**port**

A data- or voice-transmission access point on a device that is used for communicating with other devices.

**port carrier**

A carrier in a multicarrier cabinet or a single-carrier cabinet containing port circuit packs, power units, and service circuits. Also called a port cabinet in a single-carrier cabinet.

**port network (PN)**

A cabinet containing a TDM bus and packet bus to which the following components are connected: port circuit packs, one or two tone-clock circuit packs, a maintenance circuit pack, service circuit packs, and (optionally) up to four expansion interface (EI) circuit packs in DEFINITY ECS. Each PN is controlled either locally or remotely by a switch processing element (SPE). See also [expansion port network \(EPN\)](#) and [processor port network \(PPN\)](#).

**port-network connectivity**

The interconnection of port networks (PNs), regardless of whether the configuration uses direct or switched connectivity.

**PPM**

1. Parts per million
2. Periodic pulse metering

**PPN**

See [processor port network \(PPN\)](#).

**PPP**

Point-to-Point Protocol

**PRI**

See [Primary Rate Interface \(PRI\)](#).

**primary extension**

The main extension associated with the physical voice or data terminal.

**Primary Rate Interface (PRI)**

A standard ISDN frame format that specifies the protocol used between two or more communications systems. PRI runs at 1.544 Mbps and, as used in North America, provides 23 64-kbps B-channels (voice or data) and one 64-kbps D-channel (signaling). The D-channel is the 24th channel of the interface and contains multiplexed signaling information for the other 23 channels.

**PRI endpoint (PE)**

The wideband switching capability introduces PRI endpoints on switch line-side interfaces. A PRI endpoint consists of one or more contiguous B-channels on a line-side T1 or E1 ISDN PRI facility and has an extension. Endpoint applications have call-control capabilities over PRI endpoints.

**principal**

A terminal that has its primary extension bridged on one or more other terminals.

**principal (user)**

A person to whom a telephone is assigned and who has message-center coverage.

**private network**

A network used exclusively for the telecommunications needs of a particular customer.

**private network office code (RNX)**

The first three digits of a 7-digit private network number.

**processor carrier**

See [control carrier](#).

**processor data module (PDM)**

A device that provides an RS-232C DCE interface for connecting to data terminals, applications processors (APs), and host computers, and provides a DCP interface for connection to a communications system. See also [modular processor data module \(MPDM\)](#).

**processor port network (PPN)**

A port network controlled by a switch-processing element that is directly connected to that PN's TDM bus and LAN bus. See also [port network \(PN\)](#).

**processor port network (PPN) control carrier**

A carrier containing the maintenance circuit pack, tone/clock circuit pack, and SPE circuit packs for a processor port network (PPN) and, optionally, port circuit packs.

**PROCR**

Processor

**Property Management System (PMS)**

A stand-alone computer used by lodging and health-services organizations for services such as reservations, housekeeping, and billing.

**protocol**

A set of conventions or rules governing the format and timing of message exchanges to control data movement and correction of errors.

**PSA**

Personal Station Access

**PSAP**

Public Safety Answering Points

**PSC**

Premises service consultant

**PSDN**

Packet-switch public data network

**PSTN**

Public switched telephone network

## Q

---

### PT

Personal terminal

### PTC

Positive temperature coefficient

### PTT

Postal Telephone and Telegraph

### public network

The network that can be openly accessed by all customers for local and long-distance calling.

### pulse-code modulation (PCM)

An extension of pulse-amplitude modulation (PAM) in which carrier-signal pulses modulated by an analog signal, such as speech, are quantized and encoded to a digital, usually binary, format.

---

## Q

### QoS

Quality of Service

### QPPCN

Quality Protection Plan Change Notice

### quadrant

A group of six contiguous DS0s in fixed locations on an ISDN-PRI facility. Note that this term comes from T1 terminology (one-fourth of a T1), but there are five quadrants on an E1 ISDN-PRI facility (30B + D).

### queue

An ordered sequence of calls waiting to be processed.

### queuing

The process of holding calls in order of their arrival to await connection to an attendant, to an answering group, or to an idle trunk. Calls are automatically connected in first-in, first-out sequence.

---

## R

### RAM

See [random-access memory \(RAM\)](#).

### random-access memory (RAM)

A storage arrangement whereby information can be retrieved at a speed independent of the location of the stored information.

### RBS

Robbed-bit signaling

### RBVD

Robbed-bit AVD

### RC

Radio controller

**RCL**

Restricted call list

**read-only memory (ROM)**

A storage arrangement primarily for information-retrieval applications.

**recall dial tone**

Tones signalling that the system has completed a function (such as holding a call) and is ready to accept dialing.

**redirection criteria**

Information administered for each voice terminal's coverage path that determines when an incoming call is redirected to coverage.

**Redirection on No Answer**

An optional feature that redirects an unanswered ringing ACD call after an administered number of rings. The call is then redirected back to the agent.

**release**

To release a call is to initiate its disconnection.

**release signal**

The signal one switch sends to another to disconnect a call. If the calling switch ends the call, it sends a "forward" release signal. If the receiving switch ends the call, it sends a "backward" release signal.

**remote home numbering-plan area code (RHNPA)**

A foreign numbering-plan area code that is treated as a home area code by the Automatic Route Selection (ARS) feature. Calls can be allowed or denied based on the area code and the dialed CO code rather than just the area code. If the call is allowed, the ARS pattern used for the call is determined by these six digits.

**Remote Operations Service Element (ROSE)**

A CCITT and ISO standard that defines a notation and services that support interactions between the various entities that make up a distributed application.

**REN**

Ringer equivalency number

**reorder tone**

A tone to signal that at least one of the facilities, such as a trunk or a digit transmitter, needed for the call was not available.

**report scheduler**

Software that is used in conjunction with the system printer to schedule the days of the week and time of day that the desired reports are to be printed.

**RFP**

Request for proposal

**RHNPA**

See [remote home numbering-plan area code \(RHNPA\)](#).

**RINL**

Remote indirect neighbor link

**RISC**

Reduced-instruction-set computer

**RLT**

Release-link trunk

**RMATS**

Remote Maintenance, Administration, and Traffic System

**RNX**

Route-number index (private network office code)

**ROM**

See [read-only memory \(ROM\)](#).

**ROSE**

See [Remote Operations Service Element \(ROSE\)](#).

**RPN**

Routing-plan number

**RS-232C**

A physical interface specified by the Electronic Industries Association (EIA). RS-232C transmits and receives asynchronous data at speeds of up to 19.2 kbps over cable distances of up to 50 feet.

**RS-449**

Recommended Standard 449

**RSC**

Regional Support Center

**RTCP**

Real-time control protocol

---

**S****S1**

The first logical signalling channel of DCP. The channel is used to provide signaling information for DCP's I1 channel.

**S2**

The second logical signaling channel of DCP. The channel is used to provide signaling information for DCP's I2 channel.

**SABM**

Set Asynchronous Balance Mode

**SAC**

Send All Calls

**SAKI**

See [sanity and control interface \(SAKI\)](#).

**sanity and control interface (SAKI)**

A custom VLSI microchip located on each port circuit pack. The SAKI provides address recognition, buffering, and synchronization between the angel and the five control time slots that make up the control channel. The SAKI also scans and collects status information for the angel on its port circuit pack and, when polled, transmits this information to the archangel.

**SAT**

System access terminal

**SBA**

Simulated bridged appearance

**SCC**

1. See [single-carrier cabinet](#).
2. Serial communications controller

**SCD**

Switch-control driver

**SCI**

Switch communications interface

**SCO**

System control office

**SCOTCH**

Switch Conferencing for TDM Bus in Concentration Highway

**SCSI**

See [small computer system interface \(SCSI\)](#).

**SDDN**

Software-Defined Data Network

**SDI**

Switched Digital International

**SDLC**

Synchronous data-link control

**SDN**

Software-defined network

**SFRL**

Single-frequency return loss

**SID**

Station-identification number

**simplex system**

A system that has no redundant hardware.

**simulated bridged appearance**

The same as a temporary bridged appearance; allows the terminal user (usually the principal) to bridge onto a call that had been answered by another party on his or her behalf.

**single-carrier cabinet**

A combined cabinet and carrier unit that contains one carrier. See also [Multicarrier cabinet](#).

**single-line voice terminal**

A voice terminal served by a single-line tip and ring circuit (models 500, 2500, 7101A, 7103A).

**SIT**

Special-information tones

**SLS**

Service Level Supervisor

**small computer system interface (SCSI)**

An ANSI bus standard that provides a high-level command interface between host computers and peripheral devices.

**SMDR**

Station Message Detail Recording

**SN**

Switch Node

**SNA**

Systems Network Architecture

**SNC**

Switch Node Clock

**SNI**

Switch Node Interface

**SNMP**

Simple Network Management Protocol

**software**

A set of computer programs that perform one or more tasks.

**SPE**

Switch Processing Element

**SPID**

Service Profile Identifier

**split**

See [ACD work mode](#).

**split condition**

A condition whereby a caller is temporarily separated from a connection with an attendant. A split condition automatically occurs when the attendant, active on a call, presses the start button.

**split number**

The split's identity to the switch and BCMS.

**split report**

A report that provides historical traffic information for internally measured splits.

**split (agent) status report**

A report that provides real-time status and measurement data for internally measured agents and the split to which they are assigned.

**SREPN**

Survivable Remote EPN

**SSC**

Station Security Code

**SSI**

Standard serial interface

**SSM**

Single-site management

**SSV**

Station service

**ST3**

Stratum 3 clock board

**staffed**

Indicates that an agent position is logged in. A staffed agent functions in one of four work modes: Auto-In, Manual-In, ACW, or AUX-Work.

**STARLAN**

Star-Based Local Area Network

**Station Message Detail Recording (SMDR)**

An obsolete term now called CDR — a switch feature that uses software and hardware to record call data. See [Call Detail Recording \(CDR\)](#).

**standard serial interface (SSI)**

A communications protocol developed for use with 500-type business communications terminals (BCTs) and 400-series printers.

**status lamp**

A green light that shows the status of a call appearance or a feature button by the state of the light (lit, flashing, fluttering, broken flutter, or unlit).

**stroke counts**

A method used by ACD agents to record up to nine customer-defined events per call when CMS is active.

**SVN**

Security-violation notification

**switch**

Any kind of telephone switching system. See also [communications system](#).

**switchhook**

The buttons located under the receiver on a voice terminal.

**switch-node (SN) carrier**

A carrier containing a single switch node, power units, and, optionally, one or two DS1 converter circuit packs. An SN carrier is located in a center-stage switch.

**switch-node (SN) clock**

The circuit pack in an SN carrier that provides clock and maintenance alarm functions and environmental monitors.

**switch-node interface (SNI)**

The basic building block of a switch node. An SNI circuit pack controls the routing of circuit, packet, and control messages.

**switch-node link (SNL)**

The hardware that provides a bridge between two or more switch nodes. The SNL consists of the two SNI circuit packs residing on the switch nodes and the hardware connecting the SNIs. This hardware can include lightwave transceivers that convert the SNI's electrical signals to light signals, the copper wire that connects the SNIs to the lightwave transceivers, a full-duplex fiber-optic cable, DS1 converter circuit cards and DS1 facilities if a company does not have rights to lay cable, and appropriate connectors.

**switch-processing element (SPE)**

A complex of circuit packs (processor, memory, disk controller, and bus-interface cards) mounted in a PPN control carrier. The SPE serves as the control element for that PPN and, optionally, for one or more EPNs.

## **SXS**

Step-by-step

## **synchronous data transmission**

A method of sending data in which discrete signal elements are sent at a fixed and continuous rate and specified times. See also [association](#).

## **SYSAM**

System Access and Administration

## **system administrator**

The person who maintains overall customer responsibility for system administration. Generally, all administration functions are performed from the Management Terminal. The switch requires a special login, referred to as the system administrator login, to gain access to system-administration capabilities.

## **system printer**

An optional printer that may be used to print scheduled reports via the report scheduler.

## **system report**

A report that provides historical traffic information for internally measured splits.

## **system-status report**

A report that provides real-time status information for internally measured splits.

## **system manager**

A person responsible for specifying and administering features and services for a system.

## **system reload**

A process that allows stored data to be written from a tape into the system memory (normally after a power outage).

---

# T

## **T1**

A digital transmission standard that in North America carries traffic at the DS1 rate of 1.544 Mbps. A T1 facility is divided into 24 channels (DS0s) of 64 kbps. These 24 channels, with an overall digital rate of 1.536 Mbps, and an 8-kbps framing and synchronization channel make up the 1.544-Mbps transmission. When a D-channel is present, it occupies channel 24. T1 facilities are also used in Japan and some Middle-Eastern countries.

## **TAAS**

Trunk Answer from Any Station

## **TABS**

Telemetry asynchronous block serial

## **TAC**

Trunk-access code

## **tandem switch**

A switch within an electronic tandem network (ETN) that provides the logic to determine the best route for a network call, possibly modifies the digits outpulsed, and allows or denies certain calls to certain users.

## **tandem through**

The switched connection of an incoming trunk to an outgoing trunk without human intervention.

**tandem tie-trunk network (TTTN)**

A private network that interconnects several customer switching systems.

**TC**

Technical consultant

**TCM**

Traveling class mark

**TDM**

See [time-division multiplexing \(TDM\)](#).

**TDR**

Time-of-day routing

**TEG**

Terminating extension group

**terminal**

A device that sends and receives data within a system. See also [administration terminal](#).

**TFTP**

Trivial file transfer protocol

**tie trunk**

A telecommunications channel that directly connects two private switching systems.

**time-division multiplex (TDM) bus**

A bus that is time-shared regularly by preallocating short time slots to each transmitter. In a PBX, all port circuits are connected to the TDM bus, permitting any port to send a signal to any other port.

**time-division multiplexing (TDM)**

Multiplexing that divides a transmission channel into successive time slots. See also [multiplexing](#).

**time interval**

The period of time, either one hour or one-half hour, that BCMS measurements are collected for a reports.

**time slice**

See [time interval](#).

**time slot**

64 kbps of digital information structured as eight bits every 125 microseconds. In the switch, a time slot refers to either a DS0 on a T1 or E1 facility or a 64-kbps unit on the TDM bus or fiber connection between port networks.

**time slot sequence integrity**

The situation whereby the N octets of a wideband call that are transmitted in one T1 or E1 frame arrive at the output in the same order that they were introduced.

**to control**

An application can invoke *Third Party Call Control* capabilities using either an adjunct-control or domain-control association.

**to monitor**

An application can receive *event reports* on an active-notification, adjunct-control, or domain-control association.

**TOD**

Time of day

## U

---

### **tone ringer**

A device with a speaker, used in electronic voice terminals to alert the user.

### **TOP**

Task-oriented protocol

### **trunk**

A dedicated telecommunications channel between two communications systems or COs.

### **trunk allocation**

The manner in which trunks are selected to form wideband channels.

### **trunk-data module**

A device that connects off-premises private-line trunk facilities and DEFINITY ECS. The trunk-data module converts between the RS-232C and the DCP, and can connect to DDD modems as the DCP member of a modem pool.

### **trunk group**

Telecommunications channels assigned as a group for certain functions that can be used interchangeably between two communications systems or COs.

### **TSA**

Terminal Self-Administration

### **TSAPI**

Telephony Services Application Programming Interface

### **TSC**

Technical Service Center

### **TTI**

Terminal translation initialization

### **TTR**

Touch-tone receiver

### **TTT**

Terminating trunk transmission

### **TTTN**

See [tandem tie-trunk network \(TTTN\)](#).

### **TTY**

Teletypewriter

---

## U

### **UAP**

Usage-allocation plan

### **UART**

Universal asynchronous transmitter

### **UCD**

Uniform call distribution

**UCL**

Unrestricted call list

**UDP**

1. User Datagram Protocol - Transport layer; connectionless, unreliable, fast.
2. Uniform Dial Plan -A feature that allows a unique 4- or 5-digit number assignment for each terminal in a multiswitch configuration such as a DCS or main-satellite-tributary system.

**UL**

Underwriter Laboratories

**UM**

User manager

**UNMA**

Unified Network Management Architecture

**UNP**

Uniform numbering plan

**UPS**

Uninterruptible power supply

**USOP**

User service-order profile

**UUCP**

UNIX-to-UNIX Communications Protocol

**UUI**

User-to-user information

**V**

**VAL**

Voice Announcements over the LAN

**VAR**

Value-added reseller

**VDN**

See [vector directory number \(VDN\)](#).

**vector directory number (VDN)**

An extension that provides access to the Vectoring feature on the switch. Vectoring allows a customer to specify the treatment of incoming calls based on the dialed number.

**vector-controlled split**

A hunt group or ACD split administered with the vector field enabled. Access to such a split is possible only by dialing a VDN extension.

**VIAS**

Visually Impaired Attendant Service

## W

---

### **Virtual Private Network**

Private network functionality supported in the PSTN.

### **VIS**

Voice Information System

### **VLAN**

Virtual local area network

### **VLSI**

Very-large-scale integration

### **VLSM**

Variable Length Subnet Mask

### **VM**

Voltmeter

### **VMON**

Voice over Internet Protocol Monitoring Manager

### **VNI**

Virtual nodepoint identifier

### **VOA**

VDN of origin announcement

### **voice terminal**

A single-line or multiappearance telephone.

### **VOM**

Voice Only Module

### **VPN**

See [Virtual Private Network](#).

---

## W

### **WAE**

Wideband Access Endpoint

### **WATS**

See [Wide Area Telecommunications Service \(WATS\)](#).

### **WCC**

World-Class Core

### **WCR**

World-Class Routing

### **WCTD**

World-Class Tone Detection

### **WFB**

Wireless fixed base

**Wide Area Telecommunications Service (WATS)**

A service in the United States that allows calls to certain areas for a flat-rate charge based on expected usage.

**wideband**

A circuit-switched call at a data rate greater than 64 kbps. A circuit-switched call on a single T1 or E1 facility with a bandwidth between 128 and 1536 (T1) or 1984 (E1) kbps in multiples of 64 kbps. H0, H11, H12, and N x DS0 calls are wideband.

**wideband access endpoint**

Access endpoints, extended with wideband switching to include wideband access endpoints. A wideband access endpoint consists of one or more contiguous DS0s on a line-side T1 or E1 facility and has an extension. The Administered Connections feature provides call control for calls originating from wideband access endpoints.

**wink-start tie trunk**

A trunk with which, after making a connection with a distant switching system for an outgoing call, the system waits for a momentary signal (wink) before sending the digits of the called number. Similarly, on an incoming call, the system sends the wink signal when ready to receive digits.

**WML**

Wireless Makeup Language

**work mode**

One of four states (Auto-In, Manual-In, ACW, AUX-Work) that an ACD agent can be in. Upon logging in, an agent enters AUX-Work mode. To become available to receive ACD calls, the agent enters Auto-In or Manual-In mode. To do work associated with a completed ACD call, an agent enters ACW mode.

**work state**

An ACD agent may be a member of up to three different splits. Each ACD agent continuously exhibits a work state for every split of which it is a member. Valid work states are Avail, Unstaffed, AUX-Work, ACW, ACD (answering an ACD call), ExtIn, ExtOut, and OtherSpl. An agent's work state for a particular split may change for a variety of reasons (example: when a call is answered or abandoned, or the agent changes work modes). The BCMS feature monitors work states and uses this information to provide BCMS reports.

**write operation**

The process of putting information onto a storage medium, such as a hard disk.

**WSA**

Waiting session accept

**WSP**

WAN spare processor

**WSS**

Wireless Subscriber System

---
