INSTRUCTOR SOLUTIONS MANUAL

Hughes-Hallett Gleason McCallum et al.

CHAPTER ONE

Solutions for Section 1.1

Exercises

1. Since t represents the number of years since 1970, we see that $f(35)$ represents the population of the city in 2005. In 2005, the city's population was 12 million.

2. Since $T = f(P)$, we see that $f(200)$ is the value of T when $P = 200$; that is, the thickness of pelican eggs when the concentration of PCBs is 200 ppm.

3. If there are no workers, there is no productivity, so the graph goes through the origin. At first, as the number of workers increases, productivity also increases. As a result, the curve goes up initially. At a certain point the curve reaches its highest level, after which it goes downward; in other words, as the number of workers increases beyond that point, productivity decreases. This might, for example, be due either to the inefficiency inherent in large organizations or simply to workers getting in each other's way as too many are crammed on the same line. Many other reasons are possible.

4. The slope is $(1-0)/(1-0) = 1$. So the equation of the line is $y = x$.

5. The slope is $(3-2)/(2-0) = 1/2$. So the equation of the line is $y = (1/2)x + 2$.

6. Using the points $(-2, 1)$ and $(2, 3)$, we have

$$\text{Slope } = \frac{3-1}{2-(-2)} = \frac{2}{4} = \frac{1}{2}.$$

Now we know that $y = (1/2)x + b$. Using the point $(-2, 1)$, we have $1 = -2/2 + b$, which yields $b = 2$. Thus, the equation of the line is $y = (1/2)x + 2$.

7. Slope = $\dfrac{6-0}{2-(-1)} = 2$ so the equation is $y - 6 = 2(x-2)$ or $y = 2x + 2$.

8. Rewriting the equation as $y = -\frac{5}{2}x + 4$ shows that the slope is $-\frac{5}{2}$ and the vertical intercept is 4.

9. Rewriting the equation as

$$y = -\frac{12}{7}x + \frac{2}{7}$$

shows that the line has slope $-12/7$ and vertical intercept $2/7$.

10. Rewriting the equation of the line as

$$-y = \frac{-2}{4}x - 2$$
$$y = \frac{1}{2}x + 2,$$

we see the line has slope $1/2$ and vertical intercept 2.

11. Rewriting the equation of the line as

$$y = \frac{12}{6}x - \frac{4}{6}$$
$$y = 2x - \frac{2}{3},$$

we see that the line has slope 2 and vertical intercept $-2/3$.

12. (a) is (V), because slope is positive, vertical intercept is negative
(b) is (IV), because slope is negative, vertical intercept is positive
(c) is (I), because slope is 0, vertical intercept is positive
(d) is (VI), because slope and vertical intercept are both negative
(e) is (II), because slope and vertical intercept are both positive
(f) is (III), because slope is positive, vertical intercept is 0

13. (a) is (V), because slope is negative, vertical intercept is 0
(b) is (VI), because slope and vertical intercept are both positive
(c) is (I), because slope is negative, vertical intercept is positive
(d) is (IV), because slope is positive, vertical intercept is negative
(e) is (III), because slope and vertical intercept are both negative
(f) is (II), because slope is positive, vertical intercept is 0

14. The intercepts appear to be $(0, 3)$ and $(7.5, 0)$, giving

$$\text{Slope } = \frac{-3}{7.5} = -\frac{6}{15} = -\frac{2}{5}.$$

The y-intercept is at $(0, 3)$, so a possible equation for the line is

$$y = -\frac{2}{5}x + 3.$$

(Answers may vary.)

15. $y - c = m(x - a)$

16. Given that the function is linear, choose any two points, for example (5.2, 27.8) and (5.3, 29.2). Then

$$\text{Slope} = \frac{29.2 - 27.8}{5.3 - 5.2} = \frac{1.4}{0.1} = 14.$$

Using the point-slope formula, with the point $(5.2, 27.8)$, we get the equation

$$y - 27.8 = 14(x - 5.2)$$

which is equivalent to

$$y = 14x - 45.$$

17. $y = 5x - 3$. Since the slope of this line is 5, we want a line with slope $-\frac{1}{5}$ passing through the point $(2, 1)$. The equation is $(y - 1) = -\frac{1}{5}(x - 2)$, or $y = -\frac{1}{5}x + \frac{7}{5}$.

18. The line $y + 4x = 7$ has slope -4. Therefore the parallel line has slope -4 and equation $y - 5 = -4(x - 1)$ or $y = -4x + 9$. The perpendicular line has slope $\frac{-1}{(-4)} = \frac{1}{4}$ and equation $y - 5 = \frac{1}{4}(x - 1)$ or $y = 0.25x + 4.75$.

19. The line parallel to $y = mx + c$ also has slope m, so its equation is

$$y = m(x - a) + b.$$

The line perpendicular to $y = mx + c$ has slope $-1/m$, so its equation will be

$$y = -\frac{1}{m}(x - a) + b.$$

20. Since the function goes from $x = 0$ to $x = 4$ and between $y = 0$ and $y = 2$, the domain is $0 \le x \le 4$ and the range is $0 \le y \le 2$.

21. Since x goes from 1 to 5 and y goes from 1 to 6, the domain is $1 \le x \le 5$ and the range is $1 \le y \le 6$.

22. Since the function goes from $x = -2$ to $x = 2$ and from $y = -2$ to $y = 2$, the domain is $-2 \le x \le 2$ and the range is $-2 \le y \le 2$.

23. Since the function goes from $x = 0$ to $x = 5$ and between $y = 0$ and $y = 4$, the domain is $0 \le x \le 5$ and the range is $0 \le y \le 4$.

24. The domain is all numbers. The range is all numbers ≥ 2, since $x^2 \ge 0$ for all x.

25. The domain is all x-values, as the denominator is never zero. The range is $0 < y \le \frac{1}{2}$.

26. The value of $f(t)$ is real provided $t^2 - 16 \ge 0$ or $t^2 \ge 16$. This occurs when either $t \ge 4$, or $t \le -4$. Solving $f(t) = 3$, we have

$$\begin{aligned} \sqrt{t^2 - 16} &= 3 \\ t^2 - 16 &= 9 \\ t^2 &= 25 \end{aligned}$$

so

$$t = \pm 5.$$

27. We have $V = kr^3$. You may know that $V = \frac{4}{3}\pi r^3$.

28. If distance is d, then $v = \frac{d}{t}$.

29. For some constant k, we have $S = kh^2$.

30. We know that E is proportional to v^3, so $E = kv^3$, for some constant k.

31. We know that N is proportional to $1/l^2$, so

$$N = \frac{k}{l^2}, \quad \text{for some constant } k.$$

Problems

32. The year 1983 was 25 years before 2008 so 1983 corresponds to $t = 25$. Thus, an expression that represents the statement is:

$$f(25) = 7.019$$

33. The year 2008 was 0 years before 2008 so 2008 corresponds to $t = 0$. Thus, an expression that represents the statement is:

$$f(0) \text{ meters.}$$

34. The year 1965 was $2008 - 1865 = 143$ years before 2008 so 1965 corresponds to $t = 143$. Similarly, we see that the year 1911 corresponds to $t = 97$. Thus, an expression that represents the statement is:

$$f(143) = f(97)$$

35. Since $t = 1$ means one year before 2008, then $t = 1$ corresponds to the year 2007. Similarly, $t = 0$ corresponds to the year 2008. Thus, $f(1)$ and $f(0)$ are the average annual sea level values, in meters, in 2007 and 2008, respectively. Because 1 millimeter is the same as 0.001 meters, an expression that represents the statement is:

$$f(0) = f(1) + 0.001.$$

Note that there are other possible equivalent expressions, such as: $f(1) - f(0) = 0.001$.

36. (a) Each date, t, has a unique daily snowfall, S, associated with it. So snowfall is a function of date.
(b) On December 12, the snowfall was approximately 5 inches.
(c) On December 11, the snowfall was above 10 inches.
(d) Looking at the graph we see that the largest increase in the snowfall was between December 10 to December 11.

37. (a) When the car is 5 years old, it is worth \$6000.
(b) Since the value of the car decreases as the car gets older, this is a decreasing function. A possible graph is in Figure 1.1:

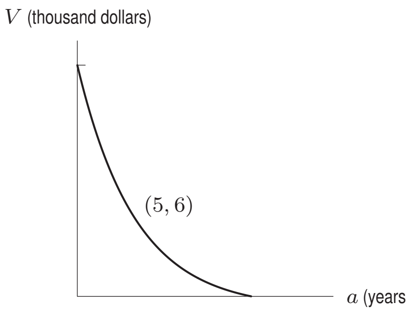

Figure 1.1

(c) The vertical intercept is the value of V when $a = 0$, or the value of the car when it is new. The horizontal intercept is the value of a when $V = 0$, or the age of the car when it is worth nothing.

38. (a) The story in (a) matches Graph (IV), in which the person forgot her books and had to return home.
(b) The story in (b) matches Graph (II), the flat tire story. Note the long period of time during which the distance from home did not change (the horizontal part).
(c) The story in (c) matches Graph (III), in which the person started calmly but sped up later.

The first graph (I) does not match any of the given stories. In this picture, the person keeps going away from home, but his speed decreases as time passes. So a story for this might be: *I started walking to school at a good pace, but since I stayed up all night studying calculus, I got more and more tired the farther I walked.*

39. (a) $f(30) = 10$ means that the value of f at $t = 30$ was 10. In other words, the temperature at time $t = 30$ minutes was 10°C. So, 30 minutes after the object was placed outside, it had cooled to 10 °C.
(b) The intercept a measures the value of $f(t)$ when $t = 0$. In other words, when the object was initially put outside, it had a temperature of a°C. The intercept b measures the value of t when $f(t) = 0$. In other words, at time b the object's temperature is 0 °C.

40. (a) The height of the rock decreases as time passes, so the graph falls as you move from left to right. One possibility is shown in Figure 1.2.

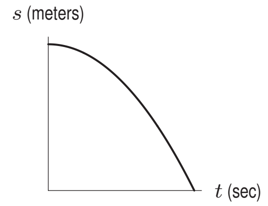

Figure 1.2

(b) The statement $f(7) = 12$ tells us that 7 seconds after the rock is dropped, it is 12 meters above the ground.
(c) The vertical intercept is the value of s when $t = 0$; that is, the height from which the rock is dropped. The horizontal intercept is the value of t when $s = 0$; that is, the time it takes for the rock to hit the ground.

41. (a) We find the slope m and intercept b in the linear equation $C = b + mw$. To find the slope m, we use

$$m = \frac{\Delta C}{\Delta w} = \frac{12.32 - 8}{68 - 32} = 0.12 \text{ dollars per gallon.}$$

We substitute to find b:

$$\begin{aligned} C &= b + mw \\ 8 &= b + (0.12)(32) \\ b &= 4.16 \text{ dollars.} \end{aligned}$$

The linear formula is $C = 4.16 + 0.12w$.
(b) The slope is 0.12 dollars per gallon. Each additional gallon of waste collected costs 12 cents.
(c) The intercept is \$4.16. The flat monthly fee to subscribe to the waste collection service is \$4.16. This is the amount charged even if there is no waste.

42. We are looking for a linear function $y = f(x)$ that, given a time x in years, gives a value y in dollars for the value of the refrigerator. We know that when $x = 0$, that is, when the refrigerator is new, $y = 950$, and when $x = 7$, the refrigerator is worthless, so $y = 0$. Thus $(0, 950)$ and $(7, 0)$ are on the line that we are looking for. The slope is then given by

$$m = \frac{950}{-7}$$

It is negative, indicating that the value decreases as time passes. Having found the slope, we can take the point $(7, 0)$ and use the point-slope formula:

$$y - y_1 = m(x - x_1).$$

So,

$$\begin{aligned} y - 0 &= -\frac{950}{7}(x - 7) \\ y &= -\frac{950}{7}x + 950. \end{aligned}$$

43. (a) The first company's price for a day's rental with m miles on it is $C_1(m) = 40 + 0.15m$. Its competitor's price for a day's rental with m miles on it is $C_2(m) = 50 + 0.10m$.

(b) See Figure 1.3.

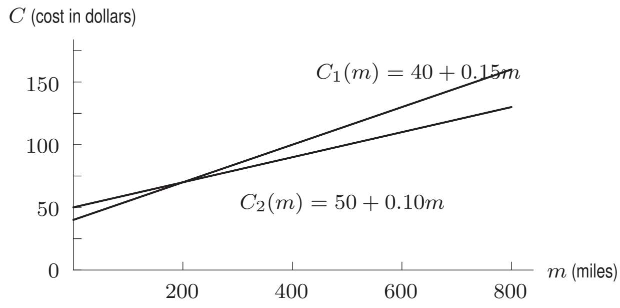

Figure 1.3

(c) To find which company is cheaper, we need to determine where the two lines intersect. We let $C_1 = C_2$, and thus

$$\begin{aligned} 40 + 0.15m &= 50 + 0.10m \\ 0.05m &= 10 \\ m &= 200. \end{aligned}$$

If you are going more than 200 miles a day, the competitor is cheaper. If you are going less than 200 miles a day, the first company is cheaper.

44. (a) Charge per cubic foot = $\dfrac{\Delta\$}{\Delta \text{ cu. ft.}} = \dfrac{55 - 40}{1600 - 1000} = \$0.025/\text{cu. ft.}$
Alternatively, if we let c = cost, w = cubic feet of water, b = fixed charge, and m = cost/cubic feet, we obtain $c = b + mw$. Substituting the information given in the problem, we have

$$\begin{aligned} 40 &= b + 1000m \\ 55 &= b + 1600m. \end{aligned}$$

Subtracting the first equation from the second yields $15 = 600m$, so $m = 0.025$.

(b) The equation is $c = b + 0.025w$, so $40 = b + 0.025(1000)$, which yields $b = 15$. Thus the equation is $c = 15 + 0.025w$.

(c) We need to solve the equation $100 = 15 + 0.025w$, which yields $w = 3400$. It costs \$100 to use 3400 cubic feet of water.

45. See Figure 1.4.

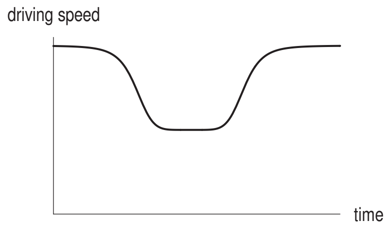

Figure 1.4

46. See Figure 1.5.

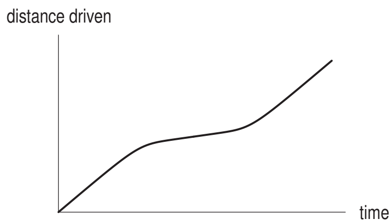

Figure 1.5

47. See Figure 1.6.

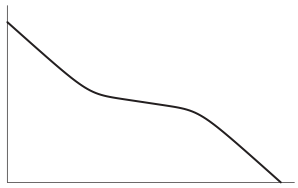

Figure 1.6

48. See Figure 1.7.

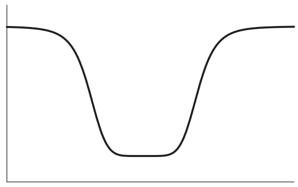

Figure 1.7

49. (a) (i) $f(1985) = 13$
(ii) $f(1990) = 99$

(b) The average yearly increase is the rate of change.

$$\text{Yearly increase} = \frac{f(1990) - f(1985)}{1990 - 1985} = \frac{99 - 13}{5} = 17.2 \text{ billionaires per year.}$$

(c) Since we assume the rate of increase remains constant, we use a linear function with slope 17.2 billionaires per year. The equation is

$$f(t) = b + 17.2t$$

where $f(1985) = 13$, so

$$13 = b + 17.2(1985)$$
$$b = -34{,}129.$$

Thus, $f(t) = 17.2t - 34{,}129$.

50. (a) The largest time interval was 2008–2009 since the percentage growth rate increased from -11.7 to 7.3 from 2008 to 2009. This means the US consumption of biofuels grew relatively more from 2008 to 2009 than from 2007 to 2008. (Note that the percentage growth rate was a decreasing function of time over 2005–2007.)

(b) The largest time interval was 2005–2007 since the percentage growth rates were positive for each of these three consecutive years. This means that the amount of biofuels consumed in the US steadily increased during the three year span from 2005 to 2007, then decreased in 2008.

51. (a) The largest time interval was 2005–2007 since the percentage growth rate decreased from -1.9 in 2005 to -45.4 in 2007. This means that from 2005 to 2007 the US consumption of hydroelectric power shrunk relatively more with each successive year.

(b) The largest time interval was 2004–2007 since the percentage growth rates were negative for each of these four consecutive years. This means that the amount of hydroelectric power consumed by the US industrial sector steadily decreased during the four year span from 2004 to 2007, then increased in 2008.

52. (a) The largest time interval was 2004–2006 since the percentage growth rate increased from -5.7 in 2004 to 9.7 in 2006. This means that from 2004 to 2006 the US price per watt of a solar panel grew relatively more with each successive year.

(b) The largest time interval was 2005–2006 since the percentage growth rates were positive for each of these two consecutive years. This means that the US price per watt of a solar panel steadily increased during the two year span from 2005 to 2006, then decreased in 2007.

53. (a) Since 2008 corresponds to $t = 0$, the average annual sea level in Aberdeen in 2008 was 7.094 meters.

(b) Looking at the table, we see that the average annual sea level was 7.019 fifty years before 2008, or in the year 1958. Similar reasoning shows that the average sea level was 6.957 meters 125 years before 2008, or in 1883.

(c) Because 125 years before 2008 the year was 1883, we see that the sea level value corresponding to the year 1883 is 6.957 (this is the sea level value corresponding to $t = 125$). Similar reasoning yields the table:

Year	1883	1908	1933	1958	1983	2008
S	6.957	6.938	6.965	6.992	7.019	7.094

54. (a) We find the slope m and intercept b in the linear equation $S = b + mt$. To find the slope m, we use

$$m = \frac{\Delta S}{\Delta t} = \frac{66 - 113}{50 - 0} = -0.94.$$

When $t = 0$, we have $S = 113$, so the intercept b is 113. The linear formula is

$$S = 113 - 0.94t.$$

(b) We use the formula $S = 113 - 0.94t$. When $S = 20$, we have $20 = 113 - 0.94t$ and so $t = 98.9$. If this linear model were correct, the average male sperm count would drop below the fertility level during the year 2038.

55. (a) This could be a linear function because w increases by 5 as h increases by 1.

(b) We find the slope m and the intercept b in the linear equation $w = b + mh$. We first find the slope m using the first two points in the table. Since we want w to be a function of h, we take

$$m = \frac{\Delta w}{\Delta h} = \frac{171 - 166}{69 - 68} = 5.$$

Substituting the first point and the slope $m = 5$ into the linear equation $w = b + mh$, we have $166 = b + (5)(68)$, so $b = -174$. The linear function is

$$w = 5h - 174.$$

The slope, $m = 5$, is in units of pounds per inch.

(c) We find the slope and intercept in the linear function $h = b + mw$ using $m = \Delta h/\Delta w$ to obtain the linear function

$$h = 0.2w + 34.8.$$

Alternatively, we could solve the linear equation found in part (b) for h. The slope, $m = 0.2$, has units inches per pound.

56. We will let

$$\begin{aligned} T &= \text{amount of fuel for take-off,} \\ L &= \text{amount of fuel for landing,} \\ P &= \text{amount of fuel per mile in the air,} \\ m &= \text{the length of the trip in miles.} \end{aligned}$$

Then Q, the total amount of fuel needed, is given by

$$Q(m) = T + L + Pm.$$

57. (a) The variable costs for x acres are $\$200x$, or $0.2x$ thousand dollars. The total cost, C (again in thousands of dollars), of planting x acres is:

$$C = f(x) = 10 + 0.2x.$$

This is a linear function. See Figure 1.8. Since $C = f(x)$ increases with x, f is an increasing function of x. Look at the values of C shown in the table; you will see that each time x increases by 1, C increases by 0.2. Because C increases at a constant rate as x increases, the graph of C against x is a line.

(b) See Figure 1.8 and Table 1.1.

Table 1.1
Cost of planting seed

x	C
0	10
2	10.4
3	10.6
4	10.8
5	11
6	11.2

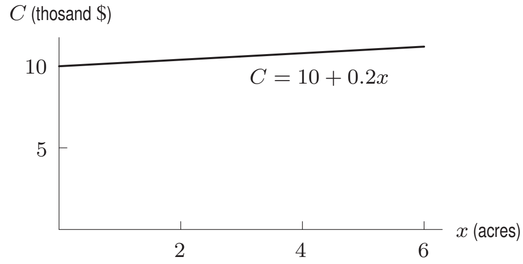

Figure 1.8

(c) The vertical intercept of 10 corresponds to the fixed costs. For $C = f(x) = 10 + 0.2x$, the intercept on the vertical axis is 10 because $C = f(0) = 10 + 0.2(0) = 10$. Since 10 is the value of C when $x = 0$, we recognize it as the initial outlay for equipment, or the fixed cost.

The slope 0.2 corresponds to the variable costs. The slope is telling us that for every additional acre planted, the costs go up by 0.2 thousand dollars. The rate at which the cost is increasing is 0.2 thousand dollars per acre. Thus the variable costs are represented by the slope of the line $f(x) = 10 + 0.2x$.

58. See Figure 1.9.

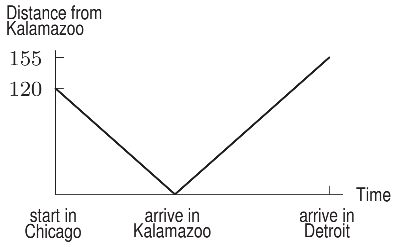

Figure 1.9

59. (a) The line given by $(0, 2)$ and $(1, 1)$ has slope $m = \frac{2-1}{-1} = -1$ and y-intercept 2, so its equation is

$$y = -x + 2.$$

The points of intersection of this line with the parabola $y = x^2$ are given by

$$\begin{aligned} x^2 &= -x + 2 \\ x^2 + x - 2 &= 0 \\ (x + 2)(x - 1) &= 0. \end{aligned}$$

The solution $x = 1$ corresponds to the point we are already given, so the other solution, $x = -2$, gives the x-coordinate of C. When we substitute back into either equation to get y, we get the coordinates for C, $(-2, 4)$.

(b) The line given by $(0, b)$ and $(1, 1)$ has slope $m = \frac{b-1}{-1} = 1 - b$, and y-intercept at $(0, b)$, so we can write the equation for the line as we did in part (a):

$$y = (1 - b)x + b.$$

We then solve for the points of intersection with $y = x^2$ the same way:

$$\begin{aligned} x^2 &= (1 - b)x + b \\ x^2 - (1 - b)x - b &= 0 \\ x^2 + (b - 1)x - b &= 0 \\ (x + b)(x - 1) &= 0 \end{aligned}$$

Again, we have the solution at the given point $(1, 1)$, and a new solution at $x = -b$, corresponding to the other point of intersection C. Substituting back into either equation, we can find the y-coordinate for C is b^2, and thus C is given by $(-b, b^2)$. This result agrees with the particular case of part (a) where $b = 2$.

60. Looking at the given data, it seems that Galileo's hypothesis was incorrect. The first table suggests that velocity is not a linear function of distance, since the increases in velocity for each foot of distance are themselves getting smaller. Moreover, the second table suggests that velocity is instead proportional to *time*, since for each second of time, the velocity increases by 32 ft/sec.

Strengthen Your Understanding

61. The line $y = 0.5 - 3x$ has a negative slope and is therefore a decreasing function.

62. If y is directly proportional to x we have $y = kx$. Adding the constant 1 to give $y = 2x + 1$ means that y is not proportional to x.

63. One possible answer is $f(x) = 2x + 3$.

64. One possible answer is $q = \dfrac{8}{p^{1/3}}$.

65. False. A line can be put through any two points in the plane. However, if the line is vertical, it is not the graph of a function.

66. True. Suppose we start at $x = x_1$ and increase x by 1 unit to $x_1 + 1$. If $y = b + mx$, the corresponding values of y are $b + mx_1$ and $b + m(x_1 + 1)$. Thus y increases by

$$\Delta y = b + m(x_1 + 1) - (b + mx_1) = m.$$

67. False. For example, let $y = x + 1$. Then the points $(1, 2)$ and $(2, 3)$ are on the line. However the ratios

$$\frac{2}{1} = 2 \qquad \text{and} \qquad \frac{3}{2} = 1.5$$

are different. The ratio y/x is constant for linear functions of the form $y = mx$, but not in general. (Other examples are possible.)

68. False. For example, if $y = 4x + 1$ (so $m = 4$) and $x = 1$, then $y = 5$. Increasing x by 2 units gives 3, so $y = 4(3) + 1 = 13$. Thus, y has increased by 8 units, not $4 + 2 = 6$. (Other examples are possible.)

69. (b) and (c). For $g(x) = \sqrt{x}$, the domain and range are all nonnegative numbers, and for $h(x) = x^3$, the domain and range are all real numbers.

Solutions for Section 1.2

Exercises

1. The graph shows a concave up function.

2. The graph shows a concave down function.

3. This graph is neither concave up or down.

4. The graph is concave up.

5. Initial quantity $= 5$; growth rate $= 0.07 = 7\%$.

6. Initial quantity $= 7.7$; growth rate $= -0.08 = -8\%$ (decay).

7. Initial quantity $= 3.2$; growth rate $= 0.03 = 3\%$ (continuous).

8. Initial quantity $= 15$; growth rate $= -0.06 = -6\%$ (continuous decay).

9. Since $e^{0.25t} = \left(e^{0.25}\right)^t \approx (1.2840)^t$, we have $P = 15(1.2840)^t$. This is exponential growth since 0.25 is positive. We can also see that this is growth because $1.2840 > 1$.

10. Since $e^{-0.5t} = (e^{-0.5})^t \approx (0.6065)^t$, we have $P = 2(0.6065)^t$. This is exponential decay since -0.5 is negative. We can also see that this is decay because $0.6065 < 1$.

11. $P = P_0(e^{0.2})^t = P_0(1.2214)^t$. Exponential growth because $0.2 > 0$ or $1.2214 > 1$.

12. $P = 7(e^{-\pi})^t = 7(0.0432)^t$. Exponential decay because $-\pi < 0$ or $0.0432 < 1$.

13. (a) Let $Q = Q_0 a^t$. Then $Q_0 a^5 = 75.94$ and $Q_0 a^7 = 170.86$. So

$$\frac{Q_0 a^7}{Q_0 a^5} = \frac{170.86}{75.94} = 2.25 = a^2.$$

So $a = 1.5$.

(b) Since $a = 1.5$, the growth rate is $r = 0.5 = 50\%$.

14. (a) Let $Q = Q_0 a^t$. Then $Q_0 a^{0.02} = 25.02$ and $Q_0 a^{0.05} = 25.06$. So

$$\frac{Q_0 a^{0.05}}{Q_0 a^{0.02}} = \frac{25.06}{25.02} = 1.001 = a^{0.03}.$$

So

$$a = (1.001)^{\frac{100}{3}} = 1.05.$$

(b) Since $a = 1.05$, the growth rate is $r = 0.05 = 5\%$.

15. (a) The function is linear with initial population of 1000 and slope of 50, so $P = 1000 + 50t$.

(b) This function is exponential with initial population of 1000 and growth rate of 5%, so $P = 1000(1.05)^t$.

16. (a) This is a linear function with slope -2 grams per day and intercept 30 grams. The function is $Q = 30 - 2t$, and the graph is shown in Figure 1.10.

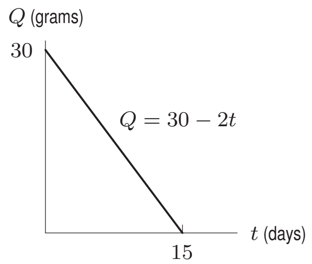

Figure 1.10

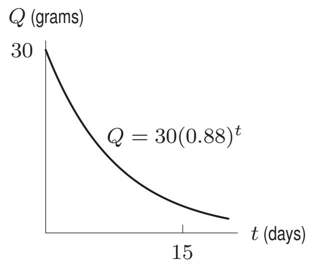

Figure 1.11

(b) Since the quantity is decreasing by a constant percent change, this is an exponential function with base $1 - 0.12 = 0.88$. The function is $Q = 30(0.88)^t$, and the graph is shown in Figure 1.11.

17. The function is increasing and concave up between D and E, and between H and I. It is increasing and concave down between A and B, and between E and F. It is decreasing and concave up between C and D, and between G and H. Finally, it is decreasing and concave down between B and C, and between F and G

18. (a) It was decreasing from March 2 to March 5 and increasing from March 5 to March 9.

(b) From March 5 to 8, the average temperature increased, but the rate of increase went down, from 12° between March 5 and 6 to 4° between March 6 and 7 to 2° between March 7 and 8.

From March 7 to 9, the average temperature increased, and the rate of increase went up, from 2° between March 7 and 8 to 9° between March 8 and 9.

Problems

19. (a) A linear function must change by exactly the same amount whenever x changes by some fixed quantity. While $h(x)$ decreases by 3 whenever x increases by 1, $f(x)$ and $g(x)$ fail this test, since both change by different amounts between $x = -2$ and $x = -1$ and between $x = -1$ and $x = 0$. So the only possible linear function is $h(x)$, so it will be given by a formula of the type: $h(x) = mx + b$. As noted, $m = -3$. Since the y-intercept of h is 31, the formula for $h(x)$ is $h(x) = 31 - 3x$.

(b) An exponential function must grow by exactly the same factor whenever x changes by some fixed quantity. Here, $g(x)$ increases by a factor of 1.5 whenever x increases by 1. Since the y-intercept of $g(x)$ is 36, $g(x)$ has the formula $g(x) = 36(1.5)^x$. The other two functions are not exponential; $h(x)$ is not because it is a linear function, and $f(x)$ is not because it both increases and decreases.

20. Table A and Table B could represent linear functions of x. Table A could represent the constant linear function $y = 2.2$ because all y values are the same. Table B could represent a linear function of x with slope equal to $11/4$. This is because x values that differ by 4 have corresponding y values that differ by 11, and x values that differ by 8 have corresponding y values that differ by 22. In Table C, y decreases and then increases as x increases, so the table cannot represent a linear function. Table D does not show a constant rate of change, so it cannot represent a linear function.

21. Table D is the only table that could represent an exponential function of x. This is because, in Table D, the ratio of y values is the same for all equally spaced x values. Thus, the y values in the table have a constant percent rate of decrease:

$$\frac{9}{18} = \frac{4.5}{9} = \frac{2.25}{4.5} = 0.5.$$

Table A represents a constant function of x, so it cannot represent an exponential function. In Table B, the ratio between y values corresponding to equally spaced x values is not the same. In Table C, y decreases and then increases as x increases. So neither Table B nor Table C can represent exponential functions.

22. (a) Let P represent the population of the world, and let t represent the number of years since 2010. Then we have $P = 6.91(1.011)^t$.

(b) According to this formula, the population of the world in the year 2020 (at $t = 10$) will be $P = 6.9(1.011)^{10} = 7.71$ billion people.

(c) The graph is shown in Figure 1.12. The population of the world has doubled when $P = 13.82$; we see on the graph that this occurs at approximately $t = 63.4$. Under these assumptions, the doubling time of the world's population is about 63.4 years.

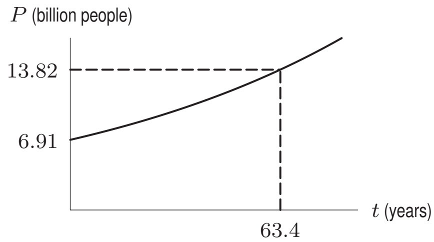

Figure 1.12

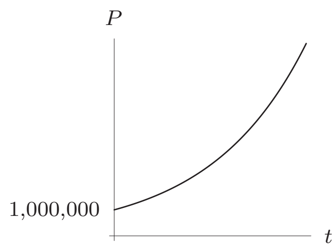
23. (a) We have $P_0 = 1$ million, and $k = 0.02$, so $P = (1{,}000{,}000)(e^{0.02t})$.

(b)



24. The doubling time t depends only on the growth rate; it is the solution to

$$2 = (1.02)^t,$$

since 1.02^t represents the factor by which the population has grown after time t. Trial and error shows that $(1.02)^{35} \approx 1.9999$ and $(1.02)^{36} \approx 2.0399$, so that the doubling time is about 35 years.

25. (a) We have

$$\text{Reduced size } = (0.80) \cdot \text{ Original size}$$

or

$$\text{Original size} = \frac{1}{(0.80)} \text{ Reduced size } = (1.25) \text{ Reduced size,}$$

so the copy must be enlarged by a factor of 1.25, which means it is enlarged to 125% of the reduced size.

(b) If a page is copied n times, then

$$\text{New size } = (0.80)^n \cdot \text{ Original.}$$

We want to solve for n so that

$$(0.80)^n = 0.15.$$

By trial and error, we find $(0.80)^8 = 0.168$ and $(0.80)^9 = 0.134$. So the page needs to be copied 9 times.

26. (a) See Figure 1.13.

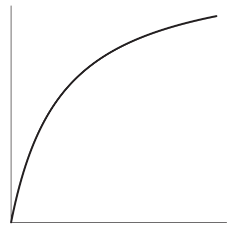


Figure 1.13

(b) "The rate at which new people try it" is the rate of change of the total number of people who have tried the product. Thus, the statement of the problem is telling you that the graph is concave down—the slope is positive but decreasing, as the graph shows.

27. (a) Advertising is generally cheaper in bulk; spending more money will give better and better marginal results initially, (Spending \$5,000 could give you a big newspaper ad reaching 200,000 people; spending \$100,000 could give you a series of TV spots reaching 50,000,000 people.) See Figure 1.14.

(b) The temperature of a hot object decreases at a rate proportional to the difference between its temperature and the temperature of the air around it. Thus, the temperature of a very hot object decreases more quickly than a cooler object. The graph is decreasing and concave up. See Figure 1.15 (We are assuming that the coffee is all at the same temperature.)

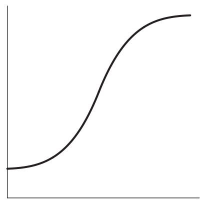

Figure 1.14

Figure 1.15

28. (a) This is the graph of a linear function, which increases at a constant rate, and thus corresponds to $k(t)$, which increases by 0.3 over each interval of 1.

(b) This graph is concave down, so it corresponds to a function whose increases are getting smaller, as is the case with $h(t)$, whose increases are 10, 9, 8, 7, and 6.

(c) This graph is concave up, so it corresponds to a function whose increases are getting bigger, as is the case with $g(t)$, whose increases are 1, 2, 3, 4, and 5.

29. (a) This is a linear function, corresponding to $g(x)$, whose rate of decrease is constant, 0.6.

(b) This graph is concave down, so it corresponds to a function whose rate of decrease is increasing, like $h(x)$. (The rates are -0.2, -0.3, -0.4, -0.5, -0.6.)

(c) This graph is concave up, so it corresponds to a function whose rate of decrease is decreasing, like $f(x)$. (The rates are -10, -9, -8, -7, -6.)

30. Since we are told that the rate of decay is *continuous*, we use the function $Q(t) = Q_0 e^{rt}$ to model the decay, where $Q(t)$ is the amount of strontium-90 which remains at time t, and Q_0 is the original amount. Then

$$Q(t) = Q_0 e^{-0.0247t}.$$

So after 100 years,

$$Q(100) = Q_0 e^{-0.0247 \cdot 100}$$

and

$$\frac{Q(100)}{Q_0} = e^{-2.47} \approx 0.0846$$

so about 8.46% of the strontium-90 remains.

31. We look for an equation of the form $y = y_0 a^x$ since the graph looks exponential. The points $(0, 3)$ and $(2, 12)$ are on the graph, so

$$3 = y_0 a^0 = y_0$$

and

$$12 = y_0 \cdot a^2 = 3 \cdot a^2, \quad \text{giving} \quad a = \pm 2.$$

Since $a > 0$, our equation is $y = 3(2^x)$.

32. We look for an equation of the form $y = y_0 a^x$ since the graph looks exponential. The points $(-1, 8)$ and $(1, 2)$ are on the graph, so

$$8 = y_0 a^{-1} \quad \text{and} \quad 2 = y_0 a^1$$

Therefore $\dfrac{8}{2} = \dfrac{y_0 a^{-1}}{y_0 a} = \dfrac{1}{a^2}$, giving $a = \frac{1}{2}$, and so $2 = y_0 a^1 = y_0 \cdot \frac{1}{2}$, so $y_0 = 4$.
Hence $y = 4\left(\frac{1}{2}\right)^x = 4(2^{-x})$.

33. We look for an equation of the form $y = y_0 a^x$ since the graph looks exponential. The points $(1, 6)$ and $(2, 18)$ are on the graph, so

$$6 = y_0 a^1 \quad \text{and} \quad 18 = y_0 a^2$$

Therefore $a = \frac{y_0 a^2}{y_0 a} = \dfrac{18}{6} = 3$, and so $6 = y_0 a = y_0 \cdot 3$; thus, $y_0 = 2$. Hence $y = 2(3^x)$.

34. The difference, D, between the horizontal asymptote and the graph appears to decrease exponentially, so we look for an equation of the form

$$D = D_0 a^x$$

where $D_0 = 4 =$ difference when $x = 0$. Since $D = 4 - y$, we have

$$4 - y = 4a^x \quad \text{or} \quad y = 4 - 4a^x = 4(1 - a^x)$$

The point $(1, 2)$ is on the graph, so $2 = 4(1 - a^1)$, giving $a = \frac{1}{2}$.
Therefore $y = 4(1 - (\frac{1}{2})^x) = 4(1 - 2^{-x})$.

35. Since f is linear, its slope is a constant

$$m = \frac{20 - 10}{2 - 0} = 5.$$

Thus f increases 5 units for unit increase in x, so

$$f(1) = 15, \quad f(3) = 25, \quad f(4) = 30.$$

Since g is exponential, its growth factor is constant. Writing $g(x) = ab^x$, we have $g(0) = a = 10$, so

$$g(x) = 10 \cdot b^x.$$

Since $g(2) = 10 \cdot b^2 = 20$, we have $b^2 = 2$ and since $b > 0$, we have

$$b = \sqrt{2}.$$

Thus g increases by a factor of $\sqrt{2}$ for unit increase in x, so

$$g(1) = 10\sqrt{2}, \quad g(3) = 10(\sqrt{2})^3 = 20\sqrt{2}, \quad g(4) = 10(\sqrt{2})^4 = 40.$$

Notice that the value of $g(x)$ doubles between $x = 0$ and $x = 2$ (from $g(0) = 10$ to $g(2) = 20$), so the doubling time of $g(x)$ is 2. Thus, $g(x)$ doubles again between $x = 2$ and $x = 4$, confirming that $g(4) = 40$.

36. We see that $\frac{1.09}{1.06} \approx 1.03$, and therefore $h(s) = c(1.03)^s$; c must be 1. Similarly $\frac{2.42}{2.20} = 1.1$, and so $f(s) = a(1.1)^s$; $a = 2$. Lastly, $\frac{3.65}{3.47} \approx 1.05$, so $g(s) = b(1.05)^s$; $b \approx 3$.

37. (a) Because the population is growing exponentially, the time it takes to double is the same, regardless of the population levels we are considering. For example, the population is 20,000 at time 3.7, and 40,000 at time 6.0. This represents a doubling of the population in a span of $6.0 - 3.7 = 2.3$ years.

How long does it take the population to double a second time, from 40,000 to 80,000? Looking at the graph once again, we see that the population reaches 80,000 at time $t = 8.3$. This second doubling has taken $8.3 - 6.0 = 2.3$ years, the same amount of time as the first doubling.

Further comparison of any two populations on this graph that differ by a factor of two will show that the time that separates them is 2.3 years. Similarly, during any 2.3 year period, the population will double. Thus, the doubling time is 2.3 years.

(b) Suppose $P = P_0 a^t$ doubles from time t to time $t + d$. We now have $P_0 a^{t+d} = 2P_0 a^t$, so $P_0 a^t a^d = 2P_0 a^t$. Thus, canceling P_0 and a^t, d must be the number such that $a^d = 2$, no matter what t is.

38. (a) After 50 years, the amount of money is

$$P = 2P_0.$$

After 100 years, the amount of money is

$$P = 2(2P_0) = 4P_0.$$

After 150 years, the amount of money is

$$P = 2(4P_0) = 8P_0.$$

(b) The amount of money in the account doubles every 50 years. Thus in t years, the balance doubles $t/50$ times, so

$$P = P_0 2^{t/50}.$$

39. (a) Since $162.5 = 325/2$, there are 162.5 mg remaining after H hours.
Since $81.25 = 162.5/2$, there are 81.25 mg remaining H hours after there were 162.5 mg, so $2H$ hours after there were 325 mg.
Since $40.625 = 81.25/2$, there are 41.625 mg remaining H hours after there were 81.25 mg, so $3H$ hours after there were 325 mg.

(b) Each additional H hours, the quantity is halved. Thus in t hours, the quantity was halved t/H times, so

$$A = 325\left(\frac{1}{2}\right)^{t/H}.$$

40. (a) The quantity of radium decays exponentially, so we know $Q = Q_0 a^t$. When $t = 1620$, we have $Q = Q_0/2$ so

$$\frac{Q_0}{2} = Q_0 a^{1620}.$$

Thus, canceling Q_0, we have

$$a^{1620} = \frac{1}{2}$$
$$a = \left(\frac{1}{2}\right)^{1/1620}.$$

Thus the formula is $Q = Q_0\left(\left(\frac{1}{2}\right)^{1/1620}\right)^t = Q_0\left(\frac{1}{2}\right)^{t/1620}$.

(b) After 500 years,

$$\text{Fraction remaining} = \frac{1}{Q_0}\cdot Q_0\left(\frac{1}{2}\right)^{500/1620} = 0.80740.$$

so 80.740% is left.

41. Let Q_0 be the initial quantity absorbed in 1960. Then the quantity, Q, of strontium-90 left after t years is

$$Q = Q_0\left(\frac{1}{2}\right)^{t/29}.$$

Since $2010 - 1960 = 50$ years, in 2010

$$\text{Fraction remaining} = \frac{1}{Q_0}\cdot Q_0\left(\frac{1}{2}\right)^{50/29} = \left(\frac{1}{2}\right)^{50/29} = 0.30268 = 30.268\%.$$

42. Direct calculation reveals that each 1000 foot increase in altitude results in a longer takeoff roll by a factor of about 1.096. Since the value of d when $h = 0$ (sea level) is $d = 670$, we are led to the formula

$$d = 670(1.096)^{h/1000},$$

where d is the takeoff roll, in feet, and h is the airport's elevation, in feet.

Alternatively, we can write

$$d = d_0 a^h,$$

where d_0 is the sea level value of d, $d_0 = 670$. In addition, when $h = 1000$, $d = 734$, so

$$734 = 670a^{1000}.$$

Solving for a gives

$$a = \left(\frac{734}{670}\right)^{1/1000} = 1.00009124,$$

so

$$d = 670(1.00009124)^h.$$

43. (a) Since the annual growth factor from 2005 to 2006 was $1 + 1.866 = 2.866$ and $91(1 + 1.866) = 260.806$, the US consumed approximately 261 million gallons of biodiesel in 2006. Since the annual growth factor from 2006 to 2007 was $1 + 0.372 = 1.372$ and $261(1 + 0.372) = 358.092$, the US consumed about 358 million gallons of biodiesel in 2007.

(b) Completing the table of annual consumption of biodiesel and plotting the data gives Figure 1.16.

Year	2005	2006	2007	2008	2009
Consumption of biodiesel (mn gal)	91	261	358	316	339

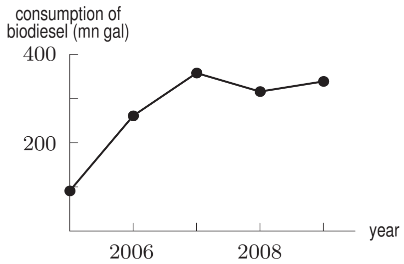

Figure 1.16

44. (a) False, because the annual percent growth is not constant over this interval.

(b) The US consumption of biodiesel more than doubled in 2005 and more than doubled again in 2006. This is because the annual percent growth was larger than 100% for both of these years.

(c) The US consumption of biodiesel more than tripled in 2005, since the annual percent growth in 2005 was over 200%

45. (a) Since the annual growth factor from 2006 to 2007 was $1 - 0.454 = 0.546$ and $29(1 - 0.454) = 15.834$, the US consumed approximately 16 trillion BTUs of hydroelectric power in 2007. Since the annual growth factor from 2005 to 2006 was $1 - 0.10 = 0.90$ and $\frac{29}{(1 - 0.10)} = 32.222$, the US consumed about 32 trillion BTUs of hydroelectric power in 2005.

(b) Completing the table of annual consumption of hydroelectric power and plotting the data gives Figure 1.17.

Year	2004	2005	2006	2007	2008	2009
Consumption of hydro. power (trillion BTU)	33	32	29	16	17	19

(c) The largest decrease in the US consumption of hydroelectric power occurred in 2007. In this year, the US consumption of hydroelectric power dropped by about 13 trillion BTUs to 16 trillion BTUs, down from 29 trillion BTUs in 2006.

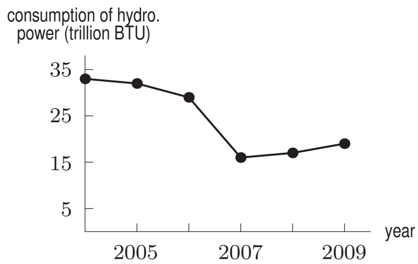

Figure 1.17

46. (a) From the figure we can read-off the approximate percent growth for each year over the previous year:

Year	2005	2006	2007	2008	2009
% growth over previous yr	25	50	30	60	29

Since the annual growth factor from 2006 to 2007 was $1 + 0.30 = 1.30$ and

$$\frac{341}{(1+0.30)} = 262.31,$$

the US consumed approximately 262 trillion BTUs of wind power energy in 2006. Since the annual growth factor from 2007 to 2008 was $1 + 0.60 = 1.60$ and $341(1 + 0.60) = 545.6$, the US consumed about 546 trillion BTUs of wind power energy in 2008.

(b) Completing the table of annual consumption of wind power and plotting the data gives Figure 1.18.

Year	2005	2006	2007	2008	2009
Consumption of wind power (trillion BTU)	175	262	341	546	704

(c) The largest increase in the US consumption of wind power energy occurred in 2008. In this year the US consumption of wind power energy rose by about 205 trillion BTUs to 546 trillion BTUs, up from 341 trillion BTUs in 2007.

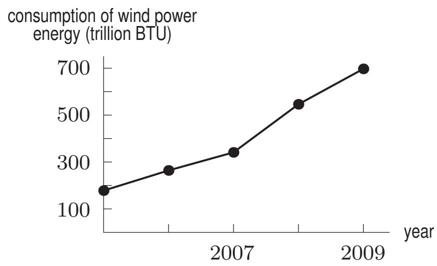

Figure 1.18

47. (a) The US consumption of wind power energy increased by at least 40% in 2006 and in 2008, relative to the previous year. In 2006 consumption increased by just under 50% over consumption in 2005, and in 2008 consumption increased by about 60% over consumption in 2007. Consumption did not decrease during the time period shown because all the annual percent growth values are positive, indicating a steady increase in the US consumption of wind power energy between 2005 and 2009.

(b) Yes. From 2006 to 2007 consumption increased by about 30%, which means $x(1+0.30)$ units of wind power energy were consumed in 2007 if x had been consumed in 2006. Similarly,

$$(x(1 + 0.30))(1 + 0.60)$$

units of wind power energy were consumed in 2008 if x had been consumed in 2006 (because consumption increased by about 60% from 2007 to 2008). Since

$$(x(1 + 0.30))(1 + 0.60) = x(2.08) = x(1 + 1.08),$$

the percent growth in wind power consumption was about 108%, or just over 100%, in 2008 relative to consumption in 2006.

Strengthen Your Understanding

48. The function $y = e^{-0.25x}$ is decreasing but its graph is concave up.

49. The graph of $y = 2x$ is a straight line and is neither concave up or concave down.

50. One possible answer is $q = 2.2(0.97)^t$.

51. One possible answer is $f(x) = 2(1.1)^x$.

52. One possibility is $y = e^{-x} - 5$.

53. False. The y-intercept is $y = 2 + 3e^{-0} = 5$.

54. True, since, as $t \to \infty$, we know $e^{-4t} \to 0$, so $y = 5 - 3e^{-4t} \to 5$.

55. False. Suppose $y = 5^x$. Then increasing x by 1 increases y by a factor of 5. However increasing x by 2 increases y by a factor of 25, not 10, since

$$y = 5^{x+2} = 5^x \cdot 5^2 = 25 \cdot 5^x.$$

(Other examples are possible.)

56. True. Suppose $y = Ab^x$ and we start at the point (x_1, y_1), so $y_1 = Ab^{x_1}$. Then increasing x_1 by 1 gives $x_1 + 1$, so the new y-value, y_2, is given by

$$y_2 = Ab^{x_1+1} = Ab^{x_1}b = (Ab^{x_1})b,$$

so

$$y_2 = by_1.$$

Thus, y has increased by a factor of b, so $b = 3$, and the function is $y = A3^x$.

However, if x_1 is increased by 2, giving $x_1 + 2$, then the new y-value, y_3, is given by

$$y_3 = A3^{x_1+2} = A3^{x_1}3^2 = 9A3^{x_1} = 9y_1.$$

Thus, y has increased by a factor of 9.

57. True. For example, $f(x) = (0.5)^x$ is an exponential function which decreases. (Other examples are possible.)

58. True. If $b > 1$, then $ab^x \to 0$ as $x \to -\infty$. If $0 < b < 1$, then $ab^x \to 0$ as $x \to \infty$. In either case, the function $y = a + ab^x$ has $y = a$ as the horizontal asymptote.

59. True, since $e^{-kt} \to 0$ as $t \to \infty$, so $y \to 20$ as $t \to \infty$.

(e) $f(t)g(t) = (\sqrt{t+4})t^2 = t^2\sqrt{t+4}$

10. (a) $f(g(1)) = f(1^2) = f(1) = e^1 = e$
(b) $g(f(1)) = g(e^1) = g(e) = e^2$
(c) $f(g(x)) = f(x^2) = e^{x^2}$
(d) $g(f(x)) = g(e^x) = (e^x)^2 = e^{2x}$
(e) $f(t)g(t) = e^t t^2$

11. (a) $f(g(1)) = f(3 \cdot 1 + 4) = f(7) = \frac{1}{7}$
(b) $g(f(1)) = g(1/1) = g(1) = 7$
(c) $f(g(x)) = f(3x+4) = \frac{1}{3x+4}$
(d) $g(f(x)) = g\left(\frac{1}{x}\right) = 3\left(\frac{1}{x}\right) + 4 = \frac{3}{x} + 4$
(e) $f(t)g(t) = \frac{1}{t}(3t+4) = 3 + \frac{4}{t}$

12. (a) $g(2+h) = (2+h)^2 + 2(2+h) + 3 = 4 + 4h + h^2 + 4 + 2h + 3 = h^2 + 6h + 11$.
(b) $g(2) = 2^2 + 2(2) + 3 = 4 + 4 + 3 = 11$, which agrees with what we get by substituting $h = 0$ into (a).
(c) $g(2+h) - g(2) = (h^2 + 6h + 11) - (11) = h^2 + 6h$.

13. (a) $f(t+1) = (t+1)^2 + 1 = t^2 + 2t + 1 + 1 = t^2 + 2t + 2$.
(b) $f(t^2+1) = (t^2+1)^2 + 1 = t^4 + 2t^2 + 1 + 1 = t^4 + 2t^2 + 2$.
(c) $f(2) = 2^2 + 1 = 5$.
(d) $2f(t) = 2(t^2+1) = 2t^2 + 2$.
(e) $(f(t))^2 + 1 = \left(t^2+1\right)^2 + 1 = t^4 + 2t^2 + 1 + 1 = t^4 + 2t^2 + 2$.

14. $m(z+1) - m(z) = (z+1)^2 - z^2 = 2z + 1$.

15. $m(z+h) - m(z) = (z+h)^2 - z^2 = 2zh + h^2$.

16. $m(z) - m(z-h) = z^2 - (z-h)^2 = 2zh - h^2$.

17. $m(z+h) - m(z-h) = (z+h)^2 - (z-h)^2 = z^2 + 2hz + h^2 - (z^2 - 2hz + h^2) = 4hz$.

18. (a) $f(25)$ is q corresponding to $p = 25$, or, in other words, the number of items sold when the price is 25.
(b) $f^{-1}(30)$ is p corresponding to $q = 30$, or the price at which 30 units will be sold.

19. (a) $f(10{,}000)$ represents the value of C corresponding to $A = 10{,}000$, or in other words the cost of building a 10,000 square-foot store.
(b) $f^{-1}(20{,}000)$ represents the value of A corresponding to $C = 20{,}000$, or the area in square feet of a store which would cost $20,000 to build.

20. $f^{-1}(75)$ is the length of the column of mercury in the thermometer when the temperature is 75°F.

21. (a) The equation is $y = 2x^2 + 1$. Note that its graph is narrower than the graph of $y = x^2$ which appears in gray. See Figure 1.23.

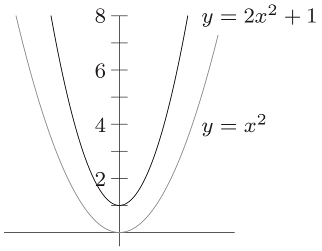

Figure 1.23

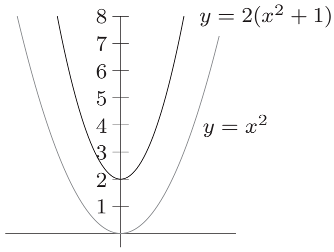

Figure 1.24

(b) $y = 2(x^2 + 1)$ moves the graph up one unit and *then* stretches it by a factor of two. See Figure 1.24.
(c) No, the graphs are not the same. Since $2(x^2 + 1) = (2x^2 + 1) + 1$, the second graph is always one unit higher than the first.

22. Figure 1.25 shows the appropriate graphs. Note that asymptotes are shown as dashed lines and x- or y-intercepts are shown as filled circles.

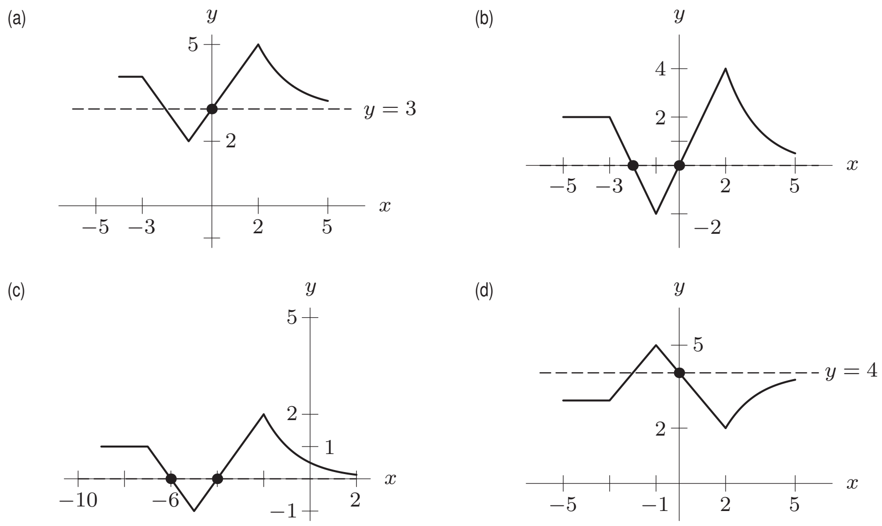

Figure 1.25

23. The function is not invertible since there are many horizontal lines which hit the function twice.

24. The function is not invertible since there are horizontal lines which hit the function more than once.

25. Since a horizontal line cuts the graph of $f(x) = x^2 + 3x + 2$ two times, f is not invertible. See Figure 1.26.

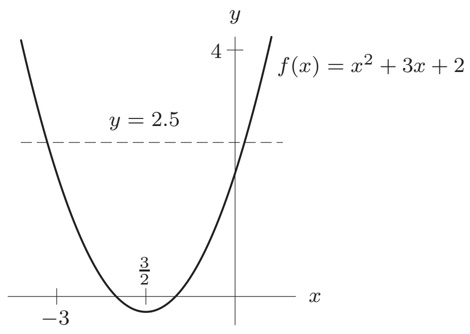

Figure 1.26

26. Since a horizontal line cuts the graph of $f(x) = x^3 - 5x + 10$ three times, f is not invertible. See Figure 1.27.

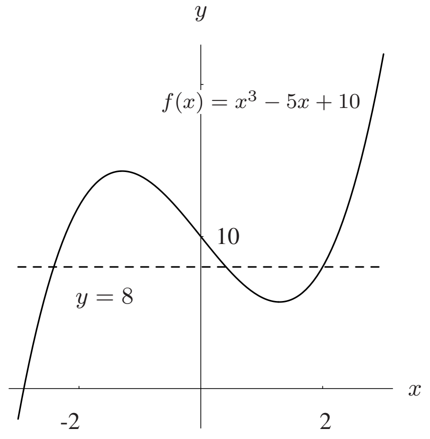

Figure 1.27

27. Since any horizontal line cuts the graph once, f is invertible. See Figure 1.28.

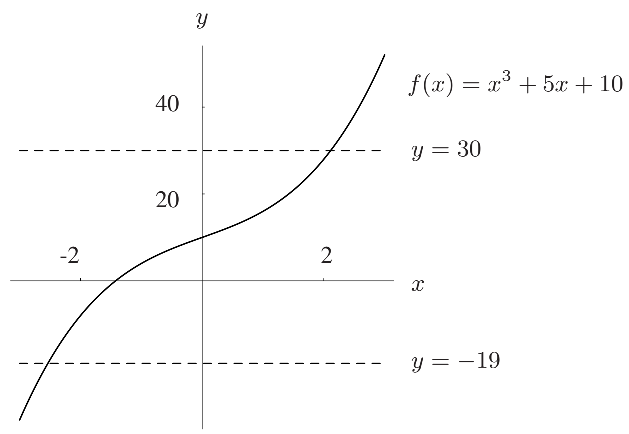

Figure 1.28

28.

$$f(-x) = (-x)^6 + (-x)^3 + 1 = x^6 - x^3 + 1.$$

Since $f(-x) \neq f(x)$ and $f(-x) \neq -f(x)$, this function is neither even nor odd.

29.

$$f(-x) = (-x)^3 + (-x)^2 + (-x) = -x^3 + x^2 - x.$$

Since $f(-x) \neq f(x)$ and $f(-x) \neq -f(x)$, this function is neither even nor odd.

30. Since

$$f(-x) = (-x)^4 - (-x)^2 + 3 = x^4 - x^2 + 3 = f(x),$$

we see f is even

31. Since

$$f(-x) = (-x)^3 + 1 = -x^3 + 1,$$

we see $f(-x) \neq f(x)$ and $f(-x) \neq -f(x)$, so f is neither even nor odd

32. Since

$$f(-x) = 2(-x) = -2x = -f(x),$$

we see f is odd.

33. Since

$$f(-x) = e^{(-x)^2-1} = e^{x^2-1} = f(x),$$

we see f is even.

34. Since

$$f(-x) = (-x)((-x)^2 - 1) = -x(x^2 - 1) = -f(x),$$

we see f is odd

35. Since

$$f(-x) = e^{-x} + x,$$

we see $f(-x) \neq f(x)$ and $f(-x) \neq -f(x)$, so f is neither even nor odd

Problems

36. $f(x) = x^3, \quad g(x) = x + 1.$

37. $f(x) = x + 1, \quad g(x) = x^3.$

38. $f(x) = \sqrt{x}, \quad g(x) = x^2 + 4$

39. $f(x) = e^x, \quad g(x) = 2x$

40. This looks like a shift of the graph $y = -x^2$. The graph is shifted to the left 1 unit and up 3 units, so a possible formula is $y = -(x + 1)^2 + 3$.

41. This looks like a shift of the graph $y = x^3$. The graph is shifted to the right 2 units and down 1 unit, so a possible formula is $y = (x - 2)^3 - 1$.

42. (a) We find $f^{-1}(2)$ by finding the x value corresponding to $f(x) = 2$. Looking at the graph, we see that $f^{-1}(2) = -1$.
(b) We construct the graph of $f^{-1}(x)$ by reflecting the graph of $f(x)$ over the line $y = x$. The graphs of $f^{-1}(x)$ and $f(x)$ are shown together in Figure 1.29.

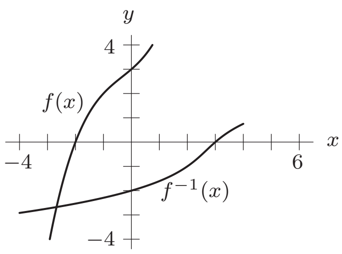

Figure 1.29

43. Values of f^{-1} are as follows

x	3	−7	19	4	178	2	1
$f^{-1}(x)$	1	2	3	4	5	6	7

The domain of f^{-1} is the set consisting of the integers $\{3, -7, 19, 4, 178, 2, 1\}$.

44. f is an increasing function since the amount of fuel used increases as flight time increases. Therefore f is invertible.

45. Not invertible. Given a certain number of customers, say $f(t) = 1500$, there could be many times, t, during the day at which that many people were in the store. So we don't know which time instant is the right one.

46. Probably not invertible. Since your calculus class probably has less than 363 students, there will be at least two days in the year, say a and b, with $f(a) = f(b) = 0$. Hence we don't know what to choose for $f^{-1}(0)$.

47. Not invertible, since it costs the same to mail a 50-gram letter as it does to mail a 51-gram letter.

48. The volume of the balloon t minutes after inflation began is: $g(f(t))$ ft^3.

49. The volume of the balloon if its radius were twice as big is: $g(2r)$ ft^3.

50. The time elapsed is: $f^{-1}(30)$ min.

51. The time elapsed is: $f^{-1}(g^{-1}(10{,}000))$ min.

52. We have $v(10) = 65$ but the graph of u only enables us to evaluate $u(x)$ for $0 \le x \le 50$. There is not enough information to evaluate $u(v(10))$.

53. We have approximately $v(40) = 15$ and $u(15) = 18$ so $u(v(40)) = 18$.

54. We have approximately $u(10) = 13$ and $v(13) = 60$ so $v(u(10)) = 60$.

55. We have $u(40) = 60$ but the graph of v only enables us to evaluate $v(x)$ for $0 \le x \le 50$. There is not enough information to evaluate $v(u(40))$.

56. (a) Yes, f is invertible, since f is increasing everywhere.
(b) The number $f^{-1}(400)$ is the year in which 400 million motor vehicles were registered in the world. From the picture, we see that $f^{-1}(400)$ is around 1979.
(c) Since the graph of f^{-1} is the reflection of the graph of f over the line $y = x$, we get Figure 1.30.

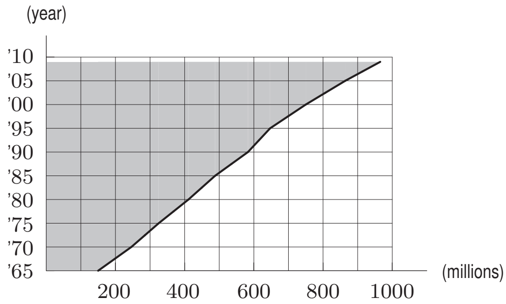

Figure 1.30: Graph of f^{-1}

57. $f(g(1)) = f(2) \approx 0.4$.

58. $g(f(2)) \approx g(0.4) \approx 1.1$.

59. $f(f(1)) \approx f(-0.4) \approx -0.9$.

60. Computing $f(g(x))$ as in Problem 57, we get Table 1.2. From it we graph $f(g(x))$ in Figure 1.31.

Table 1.2

2.5	0.9	-0.4
3	1.6	0

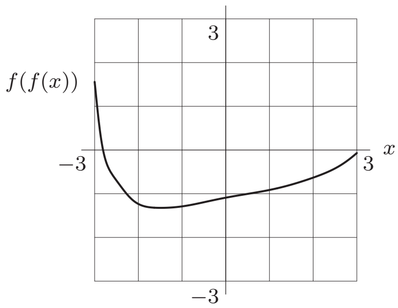

Figure 1.33

63. (a) The graph shows that $f(15)$ is approximately 48. So, the place to find find 15 million-year-old rock is about 48 meters below the Atlantic sea floor.

(b) Since f is increasing (not decreasing, since the depth axis is reversed!), f is invertible. To confirm, notice that the graph of f is cut by a horizontal line at most once.

(c) Look at where the horizontal line through 120 intersects the graph of f and read downward: $f^{-1}(120)$ is about 35. In practical terms, this means that at a depth of 120 meters down, the rock is 35 million years old.

(d) First, we standardize the graph of f so that time and depth are increasing from left to right and bottom to top. Points (t, d) on the graph of f correspond to points (d, t) on the graph of f^{-1}. We can graph f^{-1} by taking points from the original graph of f, reversing their coordinates, and connecting them. This amounts to interchanging the t and d axes, thereby reflecting the graph of f about the line bisecting the 90° angle at the origin. Figure 1.34 is the graph of f^{-1}. (Note that we cannot find the graph of f^{-1} by flipping the graph of f about the line $t = d$ in because t and d have different scales in this instance.)

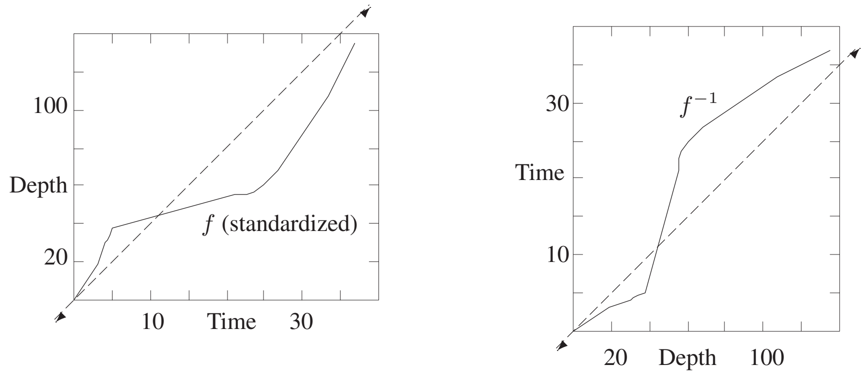

Figure 1.34: Graph of f, reflected to give that of f^{-1}

64. The tree has $B = y - 1$ branches on average and each branch has $n = 2B^2 - B = 2(y-1)^2 - (y-1)$ leaves on average. Therefore

$$\text{Average number of leaves } = Bn = (y-1)(2(y-1)^2 - (y-1)) = 2(y-1)^3 - (y-1)^2.$$

65. The volume, V, of the balloon is $V = \frac{4}{3}\pi r^3$. When $t = 3$, the radius is 10 cm. The volume is then

$$V = \frac{4}{3}\pi(10^3) = \frac{4000\pi}{3} \text{ cm}^3.$$

66. (a) The function f tells us C in terms of q. To get its inverse, we want q in terms of C, which we find by solving for q:

$$\begin{aligned} C &= 100 + 2q, \\ C - 100 &= 2q, \\ q &= \frac{C - 100}{2} = f^{-1}(C). \end{aligned}$$

(b) The inverse function tells us the number of articles that can be produced for a given cost.

67. Since $Q = S - Se^{-kt}$, the graph of Q is the reflection of y about the t-axis moved up by S units.

68.

x	$f(x)$	$g(x)$	$h(x)$
-3	0	0	0
-2	2	2	-2
-1	2	2	-2
0	0	0	0
1	2	-2	-2
2	2	-2	-2
3	0	0	0

Strengthen Your Understanding

69. The graph of $f(x) = -(x+1)^3$ is the graph of $g(x) = -x^3$ shifted left by 1 unit.

70. Since $f(g(x)) = 3(-3x - 5) + 5 = -9x - 10$, we see that f and g are not inverse functions.

71. While $y = 1/x$ is sometimes referred to as the *multiplicative* inverse of x, the inverse of f is $f^{-1}(x) = x$.

72. One possible answer is $g(x) = 3 + x$. (There are many answers.)

73. One possibility is $f(x) = x^2 + 2$.

74. Let $f(x) = 3x$, then $f^{-1}(x) = x/3$. Then for $x > 0$, we have $f(x) > f^{-1}(x)$.

75. We have

$$g(x) = f(x+2)$$

because the graph of g is obtained by moving the graph of f to the left by 2 units. We also have

$$g(x) = f(x) + 3$$

because the graph of g is obtained by moving the graph of f up by 3 units. Thus, we have $f(x+2) = f(x)+3$. The graph of f climbs 3 units whenever x increases by 2. The simplest choice for f is a linear function of slope $3/2$, for example $f(x) = 1.5x$, so $g(x) = 1.5x + 3$.

76. True. The graph of $y = 10^x$ is moved horizontally by h units if we replace x by $x - h$ for some number h. Writing $100 = 10^2$, we have $f(x) = 100(10^x) = 10^2 \cdot 10^x = 10^{x+2}$. The graph of $f(x) = 10^{x+2}$ is the graph of $g(x) = 10^x$ shifted two units to the left.

77. True. If f is increasing then its reflection about the line $y = x$ is also increasing. An example is shown in Figure 1.35. The statement is true.

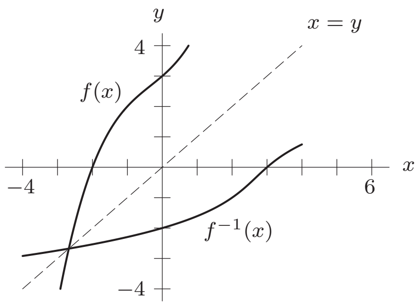

Figure 1.35

78. True. If $f(x)$ is even, we have $f(x) = f(-x)$ for all x. For example, $f(-2) = f(2)$. This means that the graph of $f(x)$ intersects the horizontal line $y = f(2)$ at two points, $x = 2$ and $x = -2$. Thus, f has no inverse function.

79. False. For example, $f(x) = x$ and $g(x) = x^3$ are both odd. Their inverses are $f^{-1}(x) = x$ and $g^{-1}(x) = x^{1/3}$.

80. False. For $x < 0$, as x increases, x^2 decreases, so e^{-x^2} increases.

81. True. We have $g(-x) = g(x)$ since g is even, and therefore $f(g(-x)) = f(g(x))$.

82. False. A counterexample is given by $f(x) = x^2$ and $g(x) = x + 1$. The function $f(g(x)) = (x+1)^2$ is not even because $f(g(1)) = 4$ and $f(g(-1)) = 0 \neq 4$.

83. True. The constant function $f(x) = 0$ is the only function that is both even and odd. This follows, since if f is both even and odd, then, for all x, $f(-x) = f(x)$ (if f is even) and $f(-x) = -f(x)$ (if f is odd). Thus, for all x, $f(x) = -f(x)$ i.e. $f(x) = 0$, for all x. So $f(x) = 0$ is both even and odd and is the only such function.

84. Let $f(x) = x$ and $g(x) = -2x$. Then $f(x) + g(x) = -x$, which is decreasing. Note f is increasing since it has positive slope, and g is decreasing since it has negative slope.

85. This is impossible. If $a < b$, then $f(a) < f(b)$, since f is increasing, and $g(a) > g(b)$, since g is decreasing, so $-g(a) < -g(b)$. Therefore, if $a < b$, then $f(a) - g(a) < f(b) - g(b)$, which means that $f(x) + g(x)$ is increasing.

86. Let $f(x) = e^x$ and let $g(x) = e^{-2x}$. Note f is increasing since it is an exponential growth function, and g is decreasing since it is an exponential decay function. Then $f(x)g(x) = e^{-x}$, which is decreasing.

87. This is impossible. As x increases, $g(x)$ decreases. As $g(x)$ decreases, so does $f(g(x))$ because f is increasing (an increasing function increases as its variable increases, so it decreases as its variable decreases).

Solutions for Section 1.4

Exercises

1. Using the identity $e^{\ln x} = x$, we have $e^{\ln(1/2)} = \frac{1}{2}$.

2. Using the identity $10^{\log x} = x$, we have

$$10^{\log(AB)} = AB$$

3. Using the identity $e^{\ln x} = x$, we have $5A^2$.

4. Using the identity $\ln(e^x) = x$, we have 2AB.

5. Using the rules for ln, we have

$$\begin{aligned} \ln\left(\frac{1}{e}\right) + \ln AB &= \ln 1 - \ln e + \ln A + \ln B \\ &= 0 - 1 + \ln A + \ln B \\ &= -1 + \ln A + \ln B. \end{aligned}$$

6. Using the rules for ln, we have $2A + 3e\ln B$.

7. Taking logs of both sides

$$\begin{aligned} \log 3^x &= x\log 3 = \log 11 \\ x &= \frac{\log 11}{\log 3} = 2.2. \end{aligned}$$

8. Taking logs of both sides

$$\begin{aligned} \log 17^x &= \log 2 \\ x\log 17 &= \log 2 \\ x &= \frac{\log 2}{\log 17} \approx 0.24. \end{aligned}$$

9. Isolating the exponential term

$$\begin{aligned} 20 &= 50(1.04)^x \\ \frac{20}{50} &= (1.04)^x. \end{aligned}$$

Taking logs of both sides

$$\begin{aligned} \log\frac{2}{5} &= \log(1.04)^x \\ \log\frac{2}{5} &= x\log(1.04) \\ x &= \frac{\log(2/5)}{\log(1.04)} = -23.4. \end{aligned}$$

10.

$$\begin{aligned} \frac{4}{7} &= \frac{5^x}{3^x} \\ \frac{4}{7} &= \left(\frac{5}{3}\right)^x \end{aligned}$$

Taking logs of both sides

$$\begin{aligned} \log\left(\frac{4}{7}\right) &= x\log\left(\frac{5}{3}\right) \\ x &= \frac{\log(4/7)}{\log(5/3)} \approx -1.1. \end{aligned}$$

11. To solve for x, we first divide both sides by 5 and then take the natural logarithm of both sides.

$$\begin{aligned}\frac{7}{5} &= e^{0.2x}\\ \ln(7/5) &= 0.2x\\ x &= \frac{\ln(7/5)}{0.2} \approx 1.68.\end{aligned}$$

12. $$\begin{aligned}\ln(2^x) &= \ln(e^{x+1})\\ x\ln 2 &= (x+1)\ln e\\ x\ln 2 &= x+1\\ 0.693x &= x+1\\ x &= \frac{1}{0.693-1} \approx -3.26\end{aligned}$$

13. To solve for x, we first divide both sides by 600 and then take the natural logarithm of both sides.

$$\begin{aligned}\frac{50}{600} &= e^{-0.4x}\\ \ln(50/600) &= -0.4x\\ x &= \frac{\ln(50/600)}{-0.4} \approx 6.212.\end{aligned}$$

14. $$\begin{aligned}\ln(2e^{3x}) &= \ln(4e^{5x})\\ \ln 2 + \ln(e^{3x}) &= \ln 4 + \ln(e^{5x})\\ 0.693 + 3x &= 1.386 + 5x\\ x &= -0.347\end{aligned}$$

15. Using the rules for ln, we get

$$\begin{aligned}\ln 7^{x+2} &= \ln e^{17x}\\ (x+2)\ln 7 &= 17x\\ x(\ln 7 - 17) &= -2\ln 7\\ x &= \frac{-2\ln 7}{\ln 7 - 17} \approx 0.26.\end{aligned}$$

16. $$\begin{aligned}\ln(10^{x+3}) &= \ln(5e^{7-x})\\ (x+3)\ln 10 &= \ln 5 + (7-x)\ln e\\ 2.303(x+3) &= 1.609 + (7-x)\\ 3.303x &= 1.609 + 7 - 2.303(3)\\ x &= 0.515\end{aligned}$$

17. Using the rules for ln, we have

$$\begin{aligned}2x - 1 &= x^2\\ x^2 - 2x + 1 &= 0\\ (x-1)^2 &= 0\\ x &= 1.\end{aligned}$$

18. $$\begin{aligned}4e^{2x-3} &= e+5\\ \ln 4 + \ln(e^{2x-3}) &= \ln(e+5)\\ 1.3863 + 2x - 3 &= 2.0436\\ x &= 1.839.\end{aligned}$$

19. $t = \dfrac{\log a}{\log b}$.

20. $t = \dfrac{\log\left(\frac{P}{P_0}\right)}{\log a} = \dfrac{\log P - \log P_0}{\log a}$.

21. Taking logs of both sides yields

$$nt = \frac{\log\left(\frac{Q}{Q_0}\right)}{\log a}.$$

Hence

$$t = \frac{\log\left(\frac{Q}{Q_0}\right)}{n \log a} = \frac{\log Q - \log Q_0}{n \log a}.$$

22. Collecting similar terms yields

$$\left(\frac{a}{b}\right)^t = \frac{Q_0}{P_0}.$$

Hence

$$t = \frac{\log\left(\frac{Q_0}{P_0}\right)}{\log\left(\frac{a}{b}\right)}.$$

23. $t = \ln \dfrac{a}{b}$.

24. $\ln \dfrac{P}{P_0} = kt$, so $t = \dfrac{\ln \frac{P}{P_0}}{k}$.

25. Since we want $(1.5)^t = e^{kt} = (e^k)^t$, so $1.5 = e^k$, and $k = \ln 1.5 = 0.4055$. Thus, $P = 15e^{0.4055t}$. Since 0.4055 is positive, this is exponential growth.

26. We want $1.7^t = e^{kt}$ so $1.7 = e^k$ and $k = \ln 1.7 = 0.5306$. Thus $P = 10e^{0.5306t}$.

27. We want $0.9^t = e^{kt}$ so $0.9 = e^k$ and $k = \ln 0.9 = -0.1054$. Thus $P = 174e^{-0.1054t}$.

28. Since we want $(0.55)^t = e^{kt} = (e^k)^t$, so $0.55 = e^k$, and $k = \ln 0.55 = -0.5978$. Thus $P = 4e^{-0.5978t}$. Since -0.5978 is negative, this represents exponential decay.

29. If $p(t) = (1.04)^t$, then, for p^{-1} the inverse of p, we should have

$$\begin{aligned}
(1.04)^{p^{-1}(t)} &= t, \\
p^{-1}(t)\log(1.04) &= \log t, \\
p^{-1}(t) &= \frac{\log t}{\log(1.04)} \approx 58.708 \log t.
\end{aligned}$$

30. Since f is increasing, f has an inverse. To find the inverse of $f(t) = 50e^{0.1t}$, we replace t with $f^{-1}(t)$, and, since $f(f^{-1}(t)) = t$, we have

$$t = 50e^{0.1f^{-1}(t)}.$$

We then solve for $f^{-1}(t)$:

$$\begin{aligned}
t &= 50e^{0.1f^{-1}(t)} \\
\frac{t}{50} &= e^{0.1f^{-1}(t)} \\
\ln\left(\frac{t}{50}\right) &= 0.1f^{-1}(t) \\
f^{-1}(t) &= \frac{1}{0.1}\ln\left(\frac{t}{50}\right) = 10\ln\left(\frac{t}{50}\right).
\end{aligned}$$

31. Using $f(f^{-1}(t)) = t$, we see

$$f(f^{-1}(t)) = 1 + \ln f^{-1}(t) = t.$$

So

$$\begin{aligned}
\ln f^{-1}(t) &= t - 1 \\
f^{-1}(t) &= e^{t-1}.
\end{aligned}$$

Problems

32. The population has increased by a factor of $48{,}000{,}000/40{,}000{,}000 = 1.2$ in 10 years. Thus we have the formula

$$P = 40{,}000{,}000(1.2)^{t/10},$$

and $t/10$ gives the number of 10-year periods that have passed since 2000.

In 2000, $t/10 = 0$, so we have $P = 40{,}000{,}000$.
In 2010, $t/10 = 1$, so $P = 40{,}000{,}000(1.2) = 48{,}000{,}000$.
In 2020, $t/10 = 2$, so $P = 40{,}000{,}000(1.2)^2 = 57{,}600{,}000$.
To find the doubling time, solve $80{,}000{,}000 = 40{,}000{,}000(1.2)^{t/10}$, to get $t = 38.02$ years.

33. In ten years, the substance has decayed to 40% of its original mass. In another ten years, it will decay by an additional factor of 40%, so the amount remaining after 20 years will be $100 \cdot 40\% \cdot 40\% = 16$ kg.

34. We can solve for the growth rate k of the bacteria using the formula $P = P_0 e^{kt}$:

$$\begin{aligned} 1500 &= 500e^{k(2)} \\ k &= \frac{\ln(1500/500)}{2}. \end{aligned}$$

Knowing the growth rate, we can find the population P at time $t = 6$:

$$\begin{aligned} P &= 500e^{(\frac{\ln 3}{2})6} \\ &\approx 13{,}500 \text{ bacteria.} \end{aligned}$$

35. (a) Assuming the US population grows exponentially, we have population $P(t) = 281.4e^{kt}$ at time t years after 2000. Using the 2010 population, we have

$$\begin{aligned} 308.7 &= 281.4e^{10k} \\ k &= \frac{\ln(308.7/281.4)}{10} = 0.00926. \end{aligned}$$

We want to find the time t in which

$$\begin{aligned} 350 &= 281.4e^{0.00926t} \\ t &= \frac{\ln(350/281.4)}{0.00926} = 23.56 \text{ years.} \end{aligned}$$

This model predicts the population to go over 350 million 23.56 years after 2000, in the year 2023.

(b) Evaluate $P = 281.4e^{0.00926t}$ for $t = 20$ to find $P = 338.65$ million people.

36. If C_0 is the concentration of NO_2 on the road, then the concentration x meters from the road is

$$C = C_0 e^{-0.0254x}.$$

We want to find the value of x making $C = C_0/2$, that is,

$$C_0 e^{-0.0254x} = \frac{C_0}{2}.$$

Dividing by C_0 and then taking natural logs yields

$$\ln\left(e^{-0.254x}\right) = -0.0254x = \ln\left(\frac{1}{2}\right) = -0.6931,$$

so

$$x = 27 \text{ meters.}$$

At 27 meters from the road the concentration of NO_2 in the air is half the concentration on the road.

37. (a) Since the percent increase in deaths during a year is constant for constant increase in pollution, the number of deaths per year is an exponential function of the quantity of pollution. If Q_0 is the number of deaths per year without pollution, then the number of deaths per year, Q, when the quantity of pollution is x micrograms per cu meter of air is

$$Q = Q_0(1.0033)^x.$$

(b) We want to find the value of x making $Q = 2Q_0$, that is,

$$Q_0(1.0033)^x = 2Q_0.$$

Dividing by Q_0 and then taking natural logs yields

$$\ln\left((1.0033)^x\right) = x\ln 1.0033 = \ln 2,$$

so

$$x = \frac{\ln 2}{\ln 1.0033} = 210.391.$$

When there are 210.391 micrograms of pollutants per cu meter of air, respiratory deaths per year are double what they would be in the absence of air pollution.

38. (a) Since there are 4 years between 2004 and 2008 we let t be the number of years since 2004 and get:

$$450{,}327 = 211{,}800e^{r4}.$$

Solving for r, we get

$$\begin{aligned} \frac{450{,}327}{211{,}800} &= e^{r4} \\ \ln\left(\frac{450{,}327}{211{,}800}\right) &= 4r \\ r &= 0.188583 \end{aligned}$$

Substituting $t = 1, 2, 3$ into

$$211{,}800\, e^{(0.188583)t},$$

we find the three remaining table values:

Year	2004	2005	2006	2007	2008
Number of E85 vehicles	211,800	255,756	308,835	372,930	450,327

(b) If N is the number of E85-powered vehicles in 2003, then

$$211{,}800 = Ne^{0.188583}$$

or

$$N = \frac{211{,}800}{e^{0.188583}} = 175{,}398 \text{ vehicles.}$$

(c) From the table, we can see that the number of E85 vehicles slightly more than doubled from 2004 to 2008, so the percent growth between these years should be slightly over 100%:

$$\begin{matrix}\text{Percent growth from} \\ \text{2004 to 2008}\end{matrix} = 100\left(\frac{450{,}327}{211{,}800} - 1\right) = 1.12619 = 112.619\%.$$

39. (a) The initial dose is 10 mg.
(b) Since $0.82 = 1 - 0.18$, the decay rate is 0.18, so 18% leaves the body each hour.
(c) When $t = 6$, we have $A = 10(0.82)^6 = 3.04$. The amount in the body after 6 hours is 3.04 mg.
(d) We want to find the value of t when $A = 1$. Using logarithms:

$$\begin{aligned} 1 &= 10(0.82)^t \\ 0.1 &= (0.82)^t \\ \ln(0.1) &= t\ln(0.82) \\ t &= 11.60 \text{ hours.} \end{aligned}$$

After 11.60 hours, the amount is 1 mg.

40. (a) Since the initial amount of caffeine is 100 mg and the exponential decay rate is -0.17, we have $A = 100e^{-0.17t}$.
(b) See Figure 1.36. We estimate the half-life by estimating t when the caffeine is reduced by half (so $A = 50$); this occurs at approximately $t = 4$ hours.

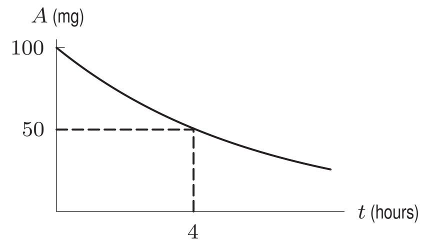

Figure 1.36

(c) We want to find the value of t when $A = 50$:

$$\begin{aligned} 50 &= 100e^{-0.17t} \\ 0.5 &= e^{-0.17t} \\ \ln 0.5 &= -0.17t \\ t &= 4.077. \end{aligned}$$

The half-life of caffeine is about 4.077 hours. This agrees with what we saw in Figure 1.36.

41. Since $y(0) = Ce^0 = C$ we have that $C = 2$. Similarly, substituting $x = 1$ gives $y(1) = 2e^{\alpha}$ so

$$2e^{\alpha} = 1.$$

Rearranging gives $e^{\alpha} = 1/2$. Taking logarithms we get $\alpha = \ln(1/2) = -\ln 2 = -0.693$. Finally,

$$y(2) = 2e^{2(-\ln 2)} = 2e^{-2\ln 2} = \frac{1}{2}.$$

42. The function e^x has a vertical intercept of 1, so must be A. The function $\ln x$ has an x-intercept of 1, so must be D. The graphs of x^2 and $x^{1/2}$ go through the origin. The graph of $x^{1/2}$ is concave down so it corresponds to graph C and the graph of x^2 is concave up so it corresponds to graph B.

43. (a) $B(t) = B_0 e^{0.067t}$
(b) $P(t) = P_0 e^{0.033t}$
(c) If the initial price is \$50, then

$$\begin{aligned} B(t) &= 50e^{0.067t} \\ P(t) &= 50e^{0.033t}. \end{aligned}$$

We want the value of t such that

$$\begin{aligned} B(t) &= 2P(t) \\ 50e^{0.067t} &= 2 \cdot 50e^{0.033t} \\ \frac{e^{0.067t}}{e^{0.033t}} &= e^{0.034t} = 2 \\ t = \frac{\ln 2}{0.034} &= 20.387 \text{ years}. \end{aligned}$$

Thus, when $t = 20.387$ the price of the textbook was predicted to be double what it would have been had the price risen by inflation only. This occurred in the year 2000.

44. (a) We assume $f(t) = Ae^{-kt}$, where A is the initial population, so $A = 100{,}000$. When $t = 110$, there were 3200 tigers, so

$$3200 = 100{,}000e^{-k \cdot 110}$$

Solving for k gives

$$\begin{aligned} e^{-k \cdot 110} &= \frac{3200}{100{,}000} = 0.0132 \\ k = -\frac{1}{110} \ln(0.0132) &= 0.0313 = 3.13\% \end{aligned}$$

so

$$f(t) = 100{,}000e^{-0.0313t}.$$

(b) In 2000, the predicted number of tigers was

$$f(100) = 100{,}000e^{-0.0313(100)} = 4372.$$

In 2010, we know the number of tigers was 3200. The predicted percent reduction is

$$\frac{3200 - 4372}{4372} = -0.268 = -26.8\%.$$

Thus the actual decrease is larger than the predicted decrease.

45. The population of China, C, in billions, is given by

$$C = 1.34(1.004)^t$$

where t is time measured from 2011, and the population of India, I, in billions, is given by

$$I = 1.19(1.0137)^t.$$

The two populations will be equal when $C = I$, thus, we must solve the equation:

$$1.34(1.004)^t = 1.19(1.0137)^t$$

for t, which leads to

$$\frac{1.34}{1.19} = \frac{(1.0137)^t}{(1.0004)^t} = \left(\frac{1.0137}{1.004}\right)^t.$$

Taking logs on both sides, we get

$$t \log \frac{1.0137}{1.004} = \log \frac{1.34}{1.19},$$

so

$$t = \frac{\log(1.34/1.19)}{\log(1.0137/1.004)} = 12.35 \text{ years.}$$

This model predicts the population of India will exceed that of China in 2023.

46. Let A represent the revenue (in billions of dollars) at Apple t years since 2005. Since $A = 3.68$ when $t = 0$ and we want the continuous growth rate, we write $A = 3.68e^{kt}$. We use the information from 2010, that $A = 15.68$ when $t = 5$, to find k:

$$\begin{aligned} 15.68 &= 3.68e^{k\cdot 5} \\ 4.26 &= e^{5k} \\ \ln(4.26) &= 5k \\ k &= 0.2899. \end{aligned}$$

We have $A = 3.68e^{0.2899t}$, which represents a continuous growth rate of 28.99% per year.

47. Let $P(t)$ be the world population in billions t years after 2010.

(a) Assuming exponential growth, we have

$$P(t) = 6.9e^{kt}.$$

In 2050, we have $t = 40$ and we expect the population then to be 9 billion, so

$$9 = 6.9e^{k\cdot 40}.$$

Solving for k, we have

$$e^{k\cdot 40} = \frac{9}{6.9}$$

$$k = \frac{1}{40}\ln\left(\frac{9}{6.9}\right) = 0.00664 = 0.664\% \text{ per year.}$$

(b) The "Day of 7 Billion" should occur when

$$7 = 6.9e^{0.00664t}.$$

Solving for t gives

$$e^{0.00664t} = \frac{7}{6.9}$$

$$t = \frac{\ln(7/6.9)}{0.00664} = 2.167 \text{ years.}$$

So the "Day of 7 Billion" should be 2.167 years after the end of 2010. This is 2 years and $0.167 \cdot 365 = 61$ days; so 61 days into 2013. That is, March 2, 2013.

48. If r was the average yearly inflation rate, in decimals, then $\frac{1}{4}(1+r)^3 = 2{,}400{,}000$, so $r = 211.53$, i.e. $r = 21{,}153\%$.

49. To find a half-life, we want to find at what t value $Q = \frac{1}{2}Q_0$. Plugging this into the equation of the decay of plutonium-240, we have

$$\begin{aligned}\frac{1}{2} &= e^{-0.00011t}\\ t &= \frac{\ln(1/2)}{-0.00011} \approx 6{,}301 \text{ years.}\end{aligned}$$

The only difference in the case of plutonium-242 is that the constant -0.00011 in the exponent is now -0.0000018. Thus, following the same procedure, the solution for t is

$$t = \frac{\ln(1/2)}{-0.0000018} \approx 385{,}081 \text{ years.}$$

50. Given the doubling time of 5 hours, we can solve for the bacteria's growth rate;

$$\begin{aligned}2P_0 &= P_0e^{k5}\\ k &= \frac{\ln 2}{5}.\end{aligned}$$

So the growth of the bacteria population is given by:

$$P = P_0e^{\ln(2)t/5}.$$

We want to find t such that

$$3P_0 = P_0e^{\ln(2)t/5}.$$

Therefore we cancel P_0 and apply ln. We get

$$t = \frac{5\ln(3)}{\ln(2)} = 7.925 \text{ hours.}$$

51. (a) The pressure P at 6194 meters is given in terms of the pressure P_0 at sea level to be

$$\begin{aligned}P &= P_0e^{-0.00012h}\\ &= P_0e^{(-0.00012)6194}\\ &= P_0e^{-0.74328}\\ &\approx 0.4756P_0 \quad \text{or about 47.6\% of sea level pressure.}\end{aligned}$$

(b) At $h = 12{,}000$ meters, we have

$$\begin{aligned}P &= P_0e^{-0.00012h}\\ &= P_0e^{(-0.00012)12{,}000}\\ &= P_0e^{-1.44}\\ &\approx 0.2369P_0 \quad \text{or about 23.7\% of sea level pressure.}\end{aligned}$$

52. We know that the y-intercept of the line is at (0,1), so we need one other point to determine the equation of the line. We observe that it intersects the graph of $f(x) = 10^x$ at the point $x = \log 2$. The y-coordinate of this point is then

$$y = 10^x = 10^{\log 2} = 2,$$

so $(\log 2, 2)$ is the point of intersection. We can now find the slope of the line:

$$m = \frac{2-1}{\log 2 - 0} = \frac{1}{\log 2}.$$

Plugging this into the point-slope formula for a line, we have

$$\begin{aligned}y - y_1 &= m(x - x_1)\\ y - 1 &= \frac{1}{\log 2}(x - 0)\\ y &= \frac{1}{\log 2}x + 1 \approx 3.3219x + 1.\end{aligned}$$

53. If t is time in decades, then the number of vehicles, V, in millions, is given by

$$V = 246(1.155)^t.$$

For time t in decades, the number of people, P, in millions, is given by

$$P = 308.7(1.097)^t.$$

There is an average of one vehicle per person when $\frac{V}{P} = 1$, or $V = P$. Thus, we solve for t in the equation:

$$246(1.155)^t = 308.7(1.097)^t,$$

which leads to

$$\left(\frac{1.155}{1.097}\right)^t = \frac{(1.155)^t}{(1.097)^t} = \frac{308.7}{246}$$

Taking logs on both sides, we get

$$t \log \frac{1.155}{1.097} = \log \frac{308.7}{246},$$

so

$$t = \frac{\log(308.7/246)}{\log(1.155/1.097)} = 4.41 \text{ decades.}$$

This model predicts one vehicle per person in 2054

54. We assume exponential decay and solve for k using the half-life:

$$e^{-k(5730)} = 0.5 \quad \text{so} \quad k = 1.21 \cdot 10^{-4}.$$

Now find t, the age of the painting:

$$e^{-1.21 \cdot 10^{-4} t} = 0.995, \quad \text{so} \quad t = \frac{\ln 0.995}{-1.21 \cdot 10^{-4}} = 41.43 \text{ years.}$$

Since Vermeer died in 1675, the painting is a fake.

55. Yes, $\ln(\ln(x))$ means take the ln of the value of the function $\ln x$. On the other hand, $\ln^2(x)$ means take the function $\ln x$ and square it. For example, consider each of these functions evaluated at e. Since $\ln e = 1$, $\ln^2 e = 1^2 = 1$, but $\ln(\ln(e)) = \ln(1) = 0$. See the graphs in Figure 1.37. (Note that $\ln(\ln(x))$ is only defined for $x > 1$.)

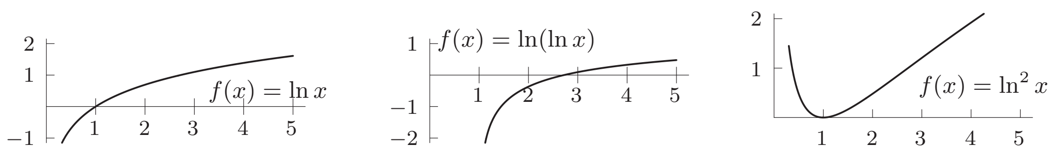

Figure 1.37

56. (a) The y-intercept of $h(x) = \ln(x + a)$ is $h(0) = \ln a$. Thus increasing a increases the y-intercept.
(b) The x-intercept of $h(x) = \ln(x+a)$ is where $h(x) = 0$. Since this occurs where $x+a = 1$, or $x = 1-a$, increasing a moves the x-intercept to the left.

57. The vertical asymptote is where $x + a = 0$, or $x = -a$. Thus increasing a moves the vertical asymptote to the left.

58. (a) The y-intercept of $g(x) = \ln(ax + 2)$ is $g(0) = \ln 2$. Thus increasing a does not effect the y-intercept.
(b) The x-intercept of $g(x) = \ln(ax + 2)$ is where $g(x) = 0$. Since this occurs where $ax + 2 = 1$, or $x = -1/a$, increasing a moves the x-intercept toward the origin. (The intercept is to the left of the origin if $a > 0$ and to the right if $a < 0$.)

59. The vertical asymptote is where $x + 2 = 0$, or $x = -2$, so increasing a does not effect the vertical asymptote.

60. The vertical asymptote is where $ax + 2 = 0$, or $x = -2/a$. Thus increasing a moves the vertical asymptote toward the origin. (The asymptote is to the left of the origin for $a > 0$ and to the right of the origin for $a < 0$.)

Strengthen Your Understanding

61. The function $-\log|x|$ is even, since $|-x| = |x|$, which means $-\log|-x| = -\log|x|$.

62. We have

$$\ln(100x) = \ln(100) + \ln x.$$

In general, $\ln(100x) \neq 100 \cdot \ln x$.

63. One possibility is $f(x) = -x$, because $\ln(-x)$ is only defined if $-x > 0$.

64. One possibility is $f(x) = \ln(x-3)$.

65. True, as seen from the graph.

66. False, since $\log(x-1) = 0$ if $x - 1 = 1$, so $x = 2$.

67. False. The inverse function is $y = 10^x$.

68. False, since $ax + b = 0$ if $x = -b/a$. Thus $y = \ln(ax+b)$ has a vertical asymptote at $x = -b/a$.

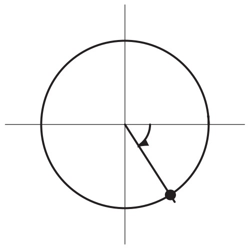

Figure 1.46

10. The period is $2\pi/3$, because when t varies from 0 to $2\pi/3$, the quantity $3t$ varies from 0 to 2π. The amplitude is 7, since the value of the function oscillates between -7 and 7.

11. The period is $2\pi/(1/4) = 8\pi$, because when u varies from 0 to 8π, the quantity $u/4$ varies from 0 to 2π. The amplitude is 3, since the function oscillates between 2 and 8.

12. The period is $2\pi/2 = \pi$, because as x varies from $-\pi/2$ to $\pi/2$, the quantity $2x + \pi$ varies from 0 to 2π. The amplitude is 4, since the function oscillates between 4 and 12.

13. The period is $2\pi/\pi = 2$, since when t increases from 0 to 2, the value of πt increases from 0 to 2π. The amplitude is 0.1, since the function oscillates between 1.9 and 2.1.

14. This graph is a sine curve with period 8π and amplitude 2, so it is given by $f(x) = 2\sin\left(\frac{x}{4}\right)$.

15. This graph is a cosine curve with period 6π and amplitude 5, so it is given by $f(x) = 5\cos\left(\frac{x}{3}\right)$.

16. This graph is an inverted sine curve with amplitude 4 and period π, so it is given by $f(x) = -4\sin(2x)$.

17. This graph is an inverted cosine curve with amplitude 8 and period 20π, so it is given by $f(x) = -8\cos\left(\frac{x}{10}\right)$.

18. This graph has period 6, amplitude 5 and no vertical or horizontal shift, so it is given by

$$f(x) = 5\sin\left(\frac{2\pi}{6}x\right) = 5\sin\left(\frac{\pi}{3}x\right).$$

19. The graph is a cosine curve with period $2\pi/5$ and amplitude 2, so it is given by $f(x) = 2\cos(5x)$.

20. The graph is an inverted sine curve with amplitude 1 and period 2π, shifted up by 2, so it is given by $f(x) = 2 - \sin x$.

21. This can be represented by a sine function of amplitude 3 and period 18. Thus,

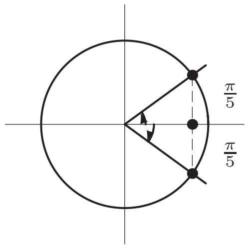
$$f(x) = 3\sin\left(\frac{\pi}{9}x\right).$$

22. This graph is the same as in Problem 14 but shifted up by 2, so it is given by $f(x) = 2\sin\left(\frac{x}{4}\right) + 2$.

23. This graph has period 8, amplitude 3, and a vertical shift of 3 with no horizontal shift. It is given by

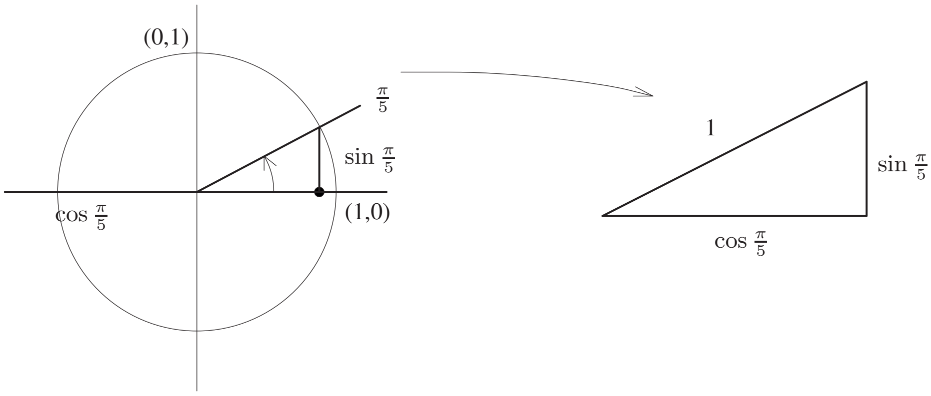
$$f(x) = 3 + 3\sin\left(\frac{2\pi}{8}x\right) = 3 + 3\sin\left(\frac{\pi}{4}x\right).$$

24.



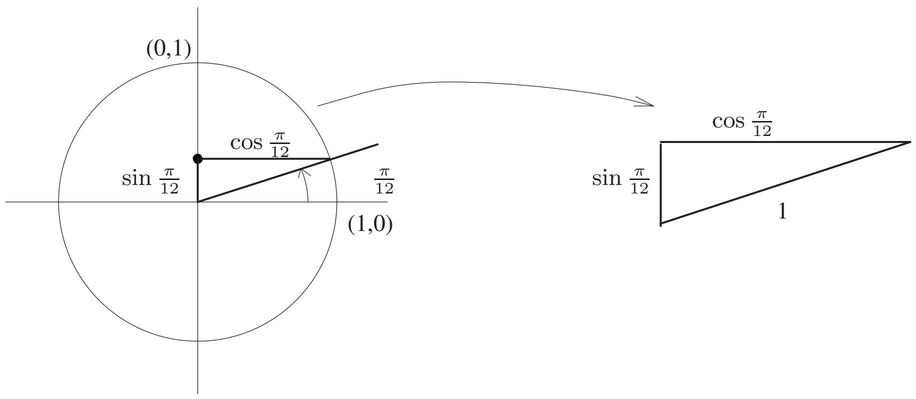
$$\cos\left(-\frac{\pi}{5}\right) = \cos\frac{\pi}{5} \quad \text{(by picture)}$$
$$= 0.809.$$

25.



By the Pythagorean Theorem, $(\cos\frac{\pi}{5})^2 + (\sin\frac{\pi}{5})^2 = 1^2$;
so $(\sin\frac{\pi}{5})^2 = 1 - (\cos\frac{\pi}{5})^2$, and $\sin\frac{\pi}{5} = \sqrt{1-(\cos\frac{\pi}{5})^2} = \sqrt{1-(0.809)^2} \approx 0.588$.
We take the positive square root since by the picture we know that $\sin\frac{\pi}{5}$ is positive.

26.



By the Pythagorean Theorem, $(\cos\frac{\pi}{12})^2+(\sin\frac{\pi}{12})^2 = 1^2$; so $(\cos\frac{\pi}{12})^2 = 1-(\sin\frac{\pi}{12})^2$ and $\cos\frac{\pi}{12} = \sqrt{1-(\sin\frac{\pi}{12})^2} = \sqrt{1-(0.259)^2} \approx 0.966$. We take the positive square root since by the picture we know that $\cos\frac{\pi}{12}$ is positive.

27. We first divide by 5 and then use inverse sine:

$$\frac{2}{5} = \sin(3x)$$
$$\sin^{-1}(2/5) = 3x$$
$$x = \frac{\sin^{-1}(2/5)}{3} \approx 0.1372.$$

There are infinitely many other possible solutions since the sine is periodic.

28. We first isolate $\cos(2x+1)$ and then use inverse cosine:

$$\begin{aligned}1 &= 8\cos(2x+1)-3\\ 4 &= 8\cos(2x+1)\\ 0.5 &= \cos(2x+1)\\ \cos^{-1}(0.5) &= 2x+1\\ x &= \frac{\cos^{-1}(0.5)-1}{2} \approx 0.0236.\end{aligned}$$

There are infinitely many other possible solutions since the cosine is periodic.

29. We first isolate $\tan(5x)$ and then use inverse tangent:

$$\begin{aligned}8 &= 4\tan(5x)\\ 2 &= \tan(5x)\\ \tan^{-1}2 &= 5x\\ x &= \frac{\tan^{-1}2}{5} = 0.221.\end{aligned}$$

There are infinitely many other possible solutions since the tangent is periodic.

30. We first isolate $(2x+1)$ and then use inverse tangent:

$$\begin{aligned}1 &= 8\tan(2x+1)-3\\ 4 &= 8\tan(2x+1)\\ 0.5 &= \tan(2x+1)\\ \arctan(0.5) &= 2x+1\\ x &= \frac{\arctan(0.5)-1}{2} = -0.268.\end{aligned}$$

There are infinitely many other possible solutions since the tangent is periodic.

31. We first isolate $\sin(5x)$ and then use inverse sine:

$$\begin{aligned}8 &= 4\sin(5x)\\ 2 &= \sin(5x).\end{aligned}$$

But this equation has no solution since $-1 \le \sin(5x) \le 1$.

Problems

32. (a) $h(t) = 2\cos(t-\pi/2)$
(b) $f(t) = 2\cos t$
(c) $g(t) = 2\cos(t+\pi/2)$

33. $\sin x^2$ is by convention $\sin(x^2)$, which means you square the x first and then take the sine.
$\sin^2 x = (\sin x)^2$ means find $\sin x$ and then square it.
$\sin(\sin x)$ means find $\sin x$ and then take the sine of that.
Expressing each as a composition: If $f(x) = \sin x$ and $g(x) = x^2$, then
$\sin x^2 = f(g(x))$
$\sin^2 x = g(f(x))$
$\sin(\sin x) = f(f(x))$.

34. Suppose P is at the point $(3\pi/2, -1)$ and Q is at the point $(5\pi/2, 1)$. Then

$$\text{Slope } = \frac{1-(-1)}{5\pi/2 - 3\pi/2} = \frac{2}{\pi}.$$

If P had been picked to the right of Q, the slope would have been $-2/\pi$.

35. (a) See Figure 1.47.

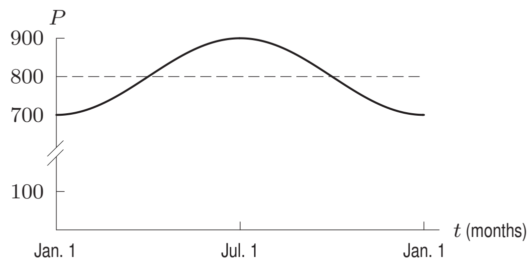


Figure 1.47

(b) Average value of population $= \frac{700+900}{2} = 800$, amplitude $= \frac{900-700}{2} = 100$, and period $= 12$ months, so $B = 2\pi/12 = \pi/6$. Since the population is at its minimum when $t = 0$, we use a negative cosine:

$$P = 800 - 100\cos\left(\frac{\pi t}{6}\right).$$

36. We use a cosine of the form

$$H = A\cos(Bt) + C$$

and choose B so that the period is 24 hours, so $2\pi/B = 24$ giving $B = \pi/12$.

The temperature oscillates around an average value of 60° F, so $C = 60$. The amplitude of the oscillation is 20° F. To arrange that the temperature be at its lowest when $t = 0$, we take A negative, so $A = -20$. Thus

$$A = 60 - 20\cos\left(\frac{\pi}{12}t\right).$$

37. (a) $f(t) = -0.5 + \sin t, \quad g(t) = 1.5 + \sin t, \quad h(t) = -1.5 + \sin t, \quad k(t) = 0.5 + \sin t.$

(b) The values of $g(t)$ are one more than the values of $k(t)$, so $g(t) = 1 + k(t)$. This happens because $g(t) = 1.5 + \sin t = 1 + 0.5 + \sin t = 1 + k(t)$.

(c) Since $-1 \le \sin t \le 1$, adding 1.5 everywhere we get $0.5 \le 1.5 + \sin t \le 2.5$ and since $1.5 + \sin t = g(t)$, we get $0.5 \le g(t) \le 2.5$. Similarly, $-2.5 \le -1.5 + \sin t = h(t) \le -0.5$.

38. Depth $= 7 + 1.5\sin\left(\frac{\pi}{3}t\right)$

39. (a) Beginning at time $t = 0$, the voltage will have oscillated through a complete cycle when $\cos(120\pi t) = \cos(2\pi)$, hence when $t = \frac{1}{60}$ second. The period is $\frac{1}{60}$ second.

(b) V_0 represents the amplitude of the oscillation.

(c) See Figure 1.48.

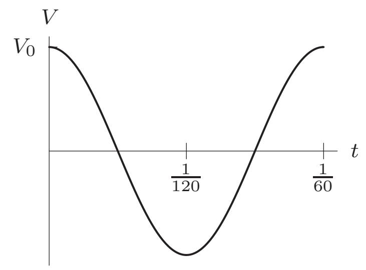

Figure 1.48

40. (a) When the time is t hours after 6 am, the solar panel outputs $f(t) = P(\theta(t))$ watts. So,

$$f(t) = 10\sin\left(\frac{\pi}{14}t\right)$$

where $0 \le t \le 14$ is the number of hours after 6 am.

(b) The graph of $f(t)$ is in Figure 1.49:

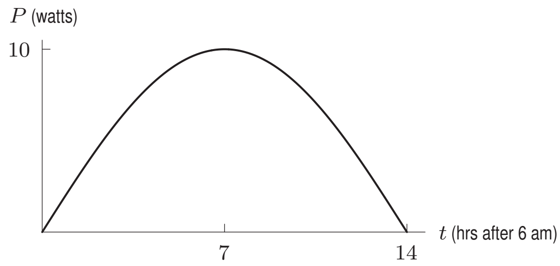

Figure 1.49

(c) The power output is greatest when $\sin(\pi t/14) = 1$. Since $0 \leq \pi t/14 \leq \pi$, the only point in the domain of f at which $\sin(\pi t/14) = 1$ is when $\pi t/14 = \pi/2$. Therefore, the power output is greatest when $t = 7$, that is, at 1 pm. The output at this time will be $f(7) = 10$ watts.

(d) On a typical winter day, there are 9 hours of sun instead of the 14 hours of sun. So, if t is the number of hours since 8 am, the angle between a solar panel and the sun is

$$\phi = \frac{14}{9}\theta = \frac{\pi}{9}t \quad \text{where } 0 \leq t \leq 9.$$

The solar panel outputs $g(t) = P(\phi(t))$ watts:

$$g(t) = 10\sin\left(\frac{\pi}{9}t\right)$$

where $0 \leq t \leq 9$ is the number of hours after 8 am.

41. The function R has period of π, so its graph is as shown in Figure 1.50. The maximum value of the range is v_0^2/g and occurs when $\theta = \pi/4$.

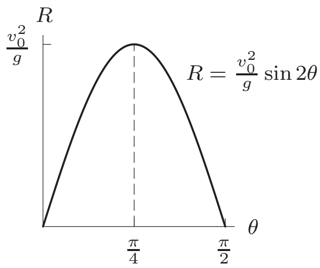

Figure 1.50

42. Over the one-year period, the average value is about 75° and the amplitude of the variation is about $\frac{90-60}{2} = 15°$. The function assumes its minimum value right at the beginning of the year, so we want a negative cosine function. Thus, for t in years, we have the function

$$f(t) = 75 - 15\cos\left(\frac{2\pi}{12}t\right).$$

(Many other answers are possible, depending on how you read the chart.)

43. (a) $D =$ the average depth of the water.
(b) $A =$ the amplitude $= 15/2 = 7.5$.
(c) Period = 12.4 hours. Thus $(B)(12.4) = 2\pi$ so $B = 2\pi/12.4 \approx 0.507$.
(d) C is the time of a high tide.

44. Using the fact that 1 revolution $= 2\pi$ radians and 1 minute = 60 seconds, we have

$$\begin{aligned} 200\frac{\text{rev}}{\text{min}} &= (200)\cdot 2\pi\frac{\text{rad}}{\text{min}} = 200\cdot 2\pi\frac{1}{60}\frac{\text{rad}}{\text{sec}} \\ &\approx \frac{(200)(6.283)}{60} \\ &\approx 20.94 \text{ radians per second.} \end{aligned}$$

Similarly, 500 rpm is equivalent to 52.36 radians per second.

45. 200 revolutions per minute is $\frac{1}{200}$ minutes per revolution, so the period is $\frac{1}{200}$ minutes, or 0.3 seconds.

46. The earth makes one revolution around the sun in one year, so its period is one year.

47. The moon makes one revolution around the earth in about 27.3 days, so its period is 27.3 days $\approx$ one month.

48. (a) The period of the tides is $2\pi/0.5 = 4\pi = 12.566$ hours.

(b) The boat is afloat provided the water is deeper than 2.5 meters, so we need

$$d(t) = 5 + 4.6\sin(0.5t) > 2.5.$$

Figure 1.51 is a graph of $d(t)$, with time t in hours since midnight, $0 \le t \le 24$. The boat leaves at $t = 12$ (midday). To find the latest time the boat can return, we need to solve the equation $d(t) = 5 + 4.6\sin(0.5t) = 2.5$.

A quick way to estimate the solution is to trace along the line $y = 2.5$ in Figure 1.51 until we get to the first point of intersection to the right of $t = 12$. The value we want is about $t = 20$. Thus the water remains deep enough until about 8 pm.

To find t analytically, we solve

$$\begin{aligned} 5 + 4.6\sin(0.5t) &= 2.5 \\ \sin(0.5t) &= -\frac{2.5}{4.6} = -0.5435 \\ t &= \frac{1}{0.5}\arcsin(-0.5435) = -1.149. \end{aligned}$$

This is the value of t immediately to the left of the vertical axis. The water is also 2.5 meters deep one period later at $t = -1.149 + 12.566 = 11.417$. This is shortly before the boat leaves, while the water is rising. We want the next time the time the water is this depth.

The water was at its deepest (that is, $d(t)$ was a maximum) when $t = 12.566/4 = 3.142$. From the figure, the time between when the water was 2.5 meters and when it was deepest was $3.142 + 1.149 = 4.291$ hours. Thus, the value of t that we want is

$$t = 11.417 + 2 \cdot 4.291 = 19.999.$$

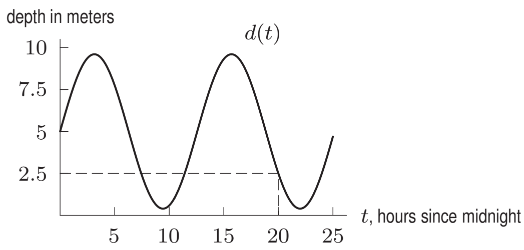

Figure 1.51

49. Since b is a positive constant, f is a vertical shift of $\sin t$ where the midline lies above the t-axis. So f matches Graph C.

Function g is the sum of $\sin t$ plus a linear function $at + b$. We suspect then that the graph of g might periodically oscillate about a line $at + b$, just like the graph of $\sin t$ oscillates about its midline. When adding $at + b$ to $\sin t$, we note that every zero of $\sin t$, $(t, 0)$, gets displaced to a corresponding point $(t, at + b)$ that lies both on the graph of g, and on the line $at + b$. See Figure 1.52. So g matches Graph B.

Function h is the sum of $\sin t$ plus an increasing exponential function $e^{ct} + d$. We suspect then that the graph of g might periodically oscillate about the graph of $e^{ct} + d$, just like the graph of $\sin t$ oscillates about its midline. When adding $e^{ct} + d$ to $\sin t$, we note that every zero of $\sin t$, $(t, 0)$, gets displaced to a corresponding point $(t, e^{ct} + d)$ that lies both on the graph of h, and on the graph of $e^{ct} + d$. See Figure 1.52. So h matches Graph A. Note that the oscillations on the graph of h may not be visible for all t values.

Function r is the sum of $\sin t$ plus an decreasing exponential function $-e^{ct} + b$. We suspect then that the graph of r might periodically oscillate about the graph of $-e^{ct} + b$, just like the graph of $\sin t$ oscillates about its midline. When adding $-e^{ct} + b$ to $\sin t$, we note that every zero of $\sin t$, $(t, 0)$, gets displaced to a corresponding point $(t, -e^{ct} + b)$ that lies both on the graph of r, and on the graph of $-e^{ct} + b$. See Figure 1.52. So r matches Graph D. Note that the oscillations on the graph of r may not be visible for all t values.

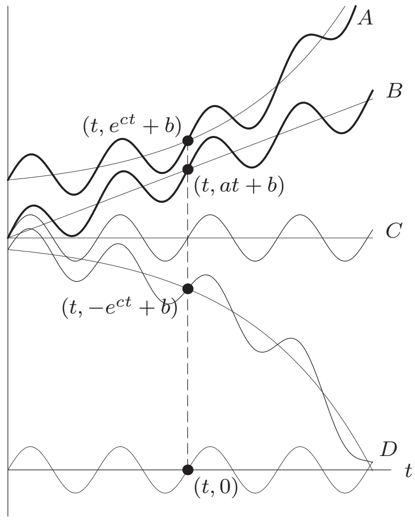

Figure 1.52

50. (a) The monthly mean CO_2 increased about 10 ppm between December 2005 and December 2010. This is because the black curve shows that the December 2005 monthly mean was about 381 ppm, while the December 2010 monthly mean was about 391 ppm. The difference between these two values, $391 - 381 = 10$, gives the overall increase.

(b) The average rate of increase is given by

$$\text{Average monthly increase of monthly mean} = \frac{391 - 381}{60 - 0} = \frac{1}{6} \text{ ppm/month.}$$

This tells us that the slope of a linear equation approximating the black curve is $1/6$. Since the vertical intercept is about 381, a possible equation for the approximately linear black curve is

$$y = \frac{1}{6}t + 381,$$

where t is measured in months since December 2005.

(c) The period of the seasonal CO_2 variation is about 12 months since this is approximately the time it takes for the function given by the blue curve to complete a full cycle. The amplitude is about 3.5 since, looking at the blue curve, the average distance between consecutive maximum and minimum values is about 7 ppm. So a possible sinusoidal function for the seasonal CO_2 cycle is

$$y = 3.5 \sin\left(\frac{\pi}{6}t\right).$$

(d) Taking $f(t) = 3.5 \sin\left(\frac{\pi}{6}t\right)$ and $g(t) = \frac{1}{6}t + 381$, we have

$$h(t) = 3.5 \sin\left(\frac{\pi}{6}t\right) + \frac{1}{6}t + 381.$$

See Figure 1.53.

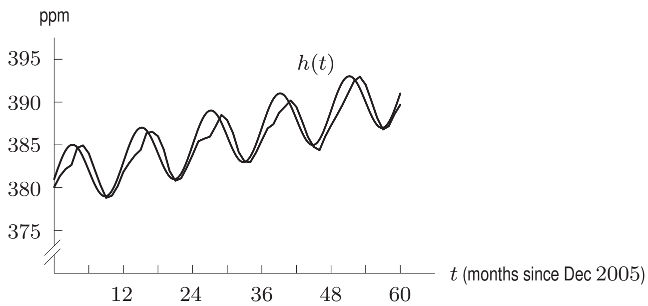

Figure 1.53

51. (a) The period is 2π.

(b) After π, the values of $\cos 2\theta$ repeat, but the values of $2\sin\theta$ do not (in fact, they repeat but flipped over the x-axis). After another π, that is after a total of 2π, the values of $\cos 2\theta$ repeat *again*, and now the values of $2\sin\theta$ repeat also, so the function $2\sin\theta + 3\cos 2\theta$ repeats at that point.

52. Figure 1.54 shows that the cross-sectional area is one rectangle of area hw and two triangles. Each triangle has height h and base x, where

$$\frac{h}{x} = \tan\theta \quad \text{so} \quad x = \frac{h}{\tan\theta}.$$

$$\text{Area of triangle} = \frac{1}{2}xh = \frac{h^2}{2\tan\theta}$$

$$\begin{aligned}\text{Total area} &= \text{Area of rectangle} + 2(\text{Area of triangle})\\ &= hw + 2\cdot\frac{h^2}{2\tan\theta} = hw + \frac{h^2}{\tan\theta}.\end{aligned}$$

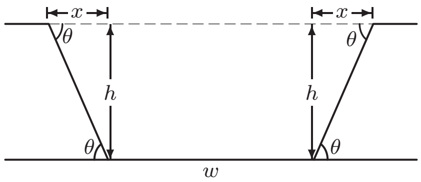

Figure 1.54

53. (a) Two solutions: 0.4 and 2.7. See Figure 1.55.

(b) $\arcsin(0.4)$ is the first solution approximated above; the second is an approximation to $\pi - \arcsin(0.4)$.

(c) By symmetry, there are two solutions: -0.4 and -2.7.

(d) $-0.4 \approx -\arcsin(0.4)$ and $-2.7 \approx -(\pi - \arcsin(0.4)) = \arcsin(0.4) - \pi$.

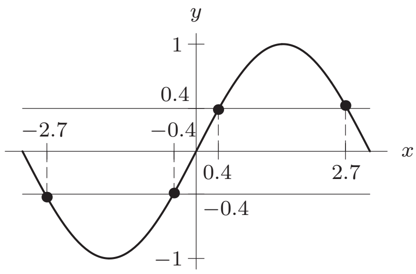

Figure 1.55

54. The ramp in Figure 1.56 rises 1 ft over a horizontal distance of x ft.

(a) For a 1 ft rise over 12 ft, the angle in radians is $\theta = \arctan(1/12) = 0.0831$. To find the angle in degrees, multiply by $180/\pi$. Hence

$$\theta = \frac{180}{\pi}\arctan\frac{1}{12} = 4.76^\circ.$$

(b) We have

$$\theta = \frac{180}{\pi}\arctan\frac{1}{8} = 7.13^\circ.$$

(c) We have

$$\theta = \frac{180}{\pi}\arctan\frac{1}{20} = 2.86^\circ.$$

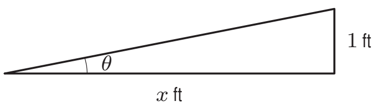

Figure 1.56

55. (a) A table of values for $g(x)$ is:

x	-1	-0.8	-0.6	-0.4	-0.2	0	0.2	0.4	0.6	0.8	1
$\arccos x$	3.14	2.50	2.21	1.98	1.77	1.57	1.37	1.16	0.93	0.64	0

(b) See Figure 1.57.

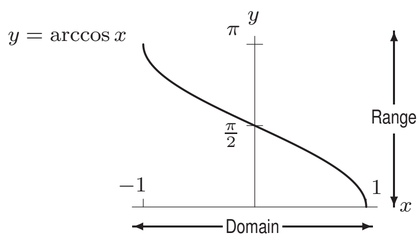

Figure 1.57

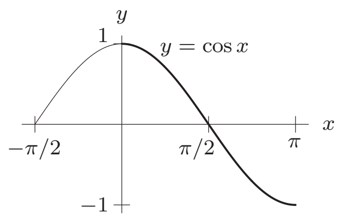

Figure 1.58

(c) The domain of arccos is $-1 \leq x \leq 1$, because its inverse, cosine, takes all values from -1 to 1. The domains of arccos and arcsin are the same because their inverses, sine and cosine, have the same range.
(d) Figure 1.57 shows that the range of $y = \arccos x$ is $0 \leq \theta \leq \pi$.
(e) The range of an inverse function is the domain of the original function. The arcsine is the inverse function to the piece of the sine having domain $[-\frac{\pi}{2}, \frac{\pi}{2}]$. Hence, the range of the arcsine is $[-\frac{\pi}{2}, \frac{\pi}{2}]$. But the piece of the cosine having domain $[-\frac{\pi}{2}, \frac{\pi}{2}]$ does not have an inverse, because there are horizontal lines that intersect its graph twice. Instead, we define arccosine to be the inverse of the piece of cosine having domain $[0, \pi]$, so the range of arccosine is $[0, \pi]$, which is different from the range of arcsine. See Figure 1.58.

Strengthen Your Understanding

56. Increasing the value of B decreases the period. For example, $f(x) = \sin x$ has period 2π, whereas $g(x) = \sin(2x)$ has period π.

57. The maximum value of $A\sin(Bx)$ is A, so the maximum value of $y = A\sin(Bx) + C$ is $y = A + C$.

58. For $B > 0$, the period of $y = \sin(Bx)$ is $2\pi/B$. Thus, we want

$$\frac{2\pi}{B} = 23 \quad \text{so} \quad B = \frac{2\pi}{23}.$$

The function is $f(x) = \sin(2\pi x/23)$

59. The midline is $y = (1200 + 2000)/2 = 1600$ and the amplitude is $y = (2000 - 1200)/2 = 400$, so a possible function is

$$f(x) = 400(\cos x) + 1600.$$

60. False, since $\cos\theta$ is decreasing and $\sin\theta$ is increasing.

61. False. The period is $2\pi/(0.05\pi) = 40$

62. True. The period is $2\pi/(200\pi) = 1/100$ seconds. Thus, the function executes 100 cycles in 1 second.

63. False. If $\theta = \pi/2, 3\pi/2, 5\pi/2\ldots$, then $\theta - \pi/2 = 0, \pi, 2\pi\ldots$, and the tangent is defined (it is zero) at these values.

64. False: When $x < 0$, we have $\sin|x| = \sin(-x) = -\sin x \neq \sin x$.

65. False: When $\pi < x < 2\pi$, we have $\sin|x| = \sin x < 0$ but $|\sin x| > 0$.

66. False: When $\pi/2 < x < 3\pi/2$, we have $\cos|x| = \cos x < 0$ but $|\cos x| > 0$.

67. True: Since $\cos(-x) = \cos x$, $\cos|x| = \cos x$.

68. False. For example, $\sin(0) \neq \sin((2\pi)^2)$, since $\sin(0) = 0$ but $\sin((2\pi)^2) = 0.98$.

69. True. Since $\sin(\theta + 2\pi) = \sin\theta$ for all θ, we have $g(\theta + 2\pi) = e^{\sin(\theta+2\pi)} = e^{\sin\theta} = g(\theta)$ for all θ.

70. False. A counterexample is given by $f(x) = \sin x$, which has period 2π, and $g(x) = x^2$. The graph of $f(g(x)) = \sin(x^2)$ in Figure 1.59 is not periodic with period 2π.

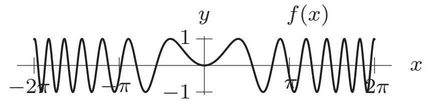

Figure 1.59

71. True. If $g(x)$ has period k, then $g(x + k) = g(x)$. Thus we have

$$f(g(x + k)) = f(g(x))$$

which shows that $f(g(x))$ is periodic with period k.

72. True, since $|\sin(-x)| = |-\sin x| = \sin x$.

Solutions for Section 1.6

Exercises

1. As $x \to \infty$, $y \to \infty$.
As $x \to -\infty$, $y \to -\infty$.

2. As $x \to \infty$, $y \to \infty$.
As $x \to -\infty$, $y \to 0$.

3. Since $f(x)$ is an even power function with a negative leading coefficient, it follows that $f(x) \to -\infty$ as $x \to +\infty$ and $f(x) \to -\infty$ as $x \to -\infty$.

4. Since $f(x)$ is an odd power function with a positive leading coefficient, it follows that $f(x) \to +\infty$ as $x \to +\infty$ and $f(x) \to -\infty$ as $x \to -\infty$.

5. As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree term of $5x^4$. Thus, as $x \to \pm\infty$, we see that $f(x) \to +\infty$.

6. As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree term of $-5x^3$. Thus, as $x \to +\infty$, we see that $f(x) \to -\infty$ and as $x \to -\infty$, we see that $f(x) \to +\infty$.

7. As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree terms in the numerator and denominator. Thus, as $x \to \pm\infty$, we see that $f(x)$ behaves like $\dfrac{3x^2}{x^2} = 3$. We have $f(x) \to 3$ as $x \to \pm\infty$.

8. As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree terms in the numerator and denominator. Thus, as $x \to \pm\infty$, we see that $f(x)$ behaves like $\dfrac{-3x^3}{2x^3} = -3/2$. We have $f(x) \to -3/2$ as $x \to \pm\infty$.

9. As $x \to \pm\infty$, we see that $3x^{-4}$ gets closer and closer to 0, so $f(x) \to 0$ as $x \to \pm\infty$.

10. As $x \to +\infty$, we have $f(x) \to +\infty$. As $x \to -\infty$, we have $f(x) \to 0$.

11. The power function with the higher power dominates as $x \to \infty$, so $0.2x^5$ is larger.

12. An exponential growth function always dominates a power function as $x \to \infty$, so $10e^{0.1x}$ is larger.

13. An exponential growth function always dominates a power function as $x \to \infty$, so 1.05^x is larger.

14. The lower-power terms in a polynomial become insignificant as $x \to \infty$, so we are comparing $2x^4$ to the leading term $10x^3$. In comparing two power functions, the higher power dominates as $x \to \infty$, so $2x^4$ is larger.

15. The lower-power terms in a polynomial become insignificant as $x \to \infty$, so we are comparing the leading term $20x^4$ to the leading term $3x^5$. In comparing two power functions, the higher power dominates as $x \to \infty$, so the polynomial with leading term $3x^5$ is larger. As $x \to \infty$, we see that $25 - 40x^2 + x^3 + 3x^5$ is larger.

16. A power function with positive exponent dominates a log function, so as $x \to \infty$, we see that $\sqrt{x}$ is larger.

17. (I) **(a)** Minimum degree is 3 because graph turns around twice.
(b) Leading coefficient is negative because $y \to -\infty$ as $x \to \infty$.
(II) **(a)** Minimum degree is 4 because graph turns around three times.
(b) Leading coefficient is positive because $y \to \infty$ as $x \to \infty$.
(III) **(a)** Minimum degree is 4 because graph turns around three times.
(b) Leading coefficient is negative because $y \to -\infty$ as $x \to \infty$.
(IV) **(a)** Minimum degree is 5 because graph turns around four times.
(b) Leading coefficient is negative because $y \to -\infty$ as $x \to \infty$.
(V) **(a)** Minimum degree is 5 because graph turns around four times.
(b) Leading coefficient is positive because $y \to \infty$ as $x \to \infty$.

18. (a) From the x-intercepts, we know the equation has the form

$$y = k(x+2)(x-1)(x-5).$$

Since $y = 2$ when $x = 0$,

$$\begin{aligned} 2 &= k(2)(-1)(-5) = k \cdot 10 \\ k &= \frac{1}{5}. \end{aligned}$$

Thus we have

$$y = \frac{1}{5}(x+2)(x-1)(x-5).$$

19. (a) Because our cubic has a root at 2 and a double root at -2, it has the form

$$y = k(x+2)(x+2)(x-2).$$

Since $y = 4$ when $x = 0$,

$$\begin{aligned} 4 &= k(2)(2)(-2) = -8k, \\ k &= -\frac{1}{2}. \end{aligned}$$

Thus our equation is

$$y = -\frac{1}{2}(x+2)^2(x-2).$$

20. $f(x) = k(x+3)(x-1)(x-4) = k(x^3 - 2x^2 - 11x + 12)$, where $k < 0$. ($k \approx -\frac{1}{6}$ if the horizontal and vertical scales are equal; otherwise one can't tell how large k is.)

21. $f(x) = kx(x+3)(x-4) = k(x^3 - x^2 - 12x)$, where $k < 0$. ($k \approx -\frac{2}{9}$ if the horizontal and vertical scales are equal; otherwise one can't tell how large k is.)

22. $f(x) = k(x+2)(x-1)(x-3)(x-5) = k(x^4 - 7x^3 + 5x^2 + 31x - 30)$, where $k > 0$. ($k \approx \frac{1}{15}$ if the horizontal and vertical scales are equal; otherwise one can't tell how large k is.)

23. $f(x) = k(x+2)(x-2)^2(x-5) = k(x^4 - 7x^3 + 6x^2 + 28x - 40)$, where $k < 0$. ($k \approx -\frac{1}{15}$ if the scales are equal; otherwise one can't tell how large k is.)

24. There are only two functions, h and p, which can be put in the form $y = Cb^x$, where C and b are constants:

$$p(x) = \frac{a^3 b^x}{c} = (a^3/c)b^x, \quad \text{where } C = a^3/c \text{ since } a, c \text{ are constants.}$$

$$h(x) = \frac{-1}{5^{x-2}} = -5^{-(x-2)} = -5^{-x+2} = (-25)5^{-x}.$$

Thus, h and p are the only exponential functions.

25. There is only one function, r, who can be put in the form $y = Ax^2 + Bx + C$:

$$r(x) = -x + b - \sqrt{cx^4} = -\sqrt{c}\,x^2 - x + b, \quad \text{where } A = -\sqrt{c}, \text{ since } c \text{ is a constant.}$$

Thus, r is the only quadratic function.

26. There is only one function, q, which is linear. Function q is a constant linear function whose vertical intercept is the constant ab^2/c, since a, b and c are constants.

Problems

27. Consider the end behavior of the graph; that is, as $x \to +\infty$ and $x \to -\infty$. The ends of a degree 5 polynomial are in Quadrants I and III if the leading coefficient is positive or in Quadrants II and IV if the leading coefficient is negative. Thus, there must be at least one root. Since the degree is 5, there can be no more than 5 roots. Thus, there may be 1, 2, 3, 4, or 5 roots. Graphs showing these five possibilities are shown in Figure 1.60.

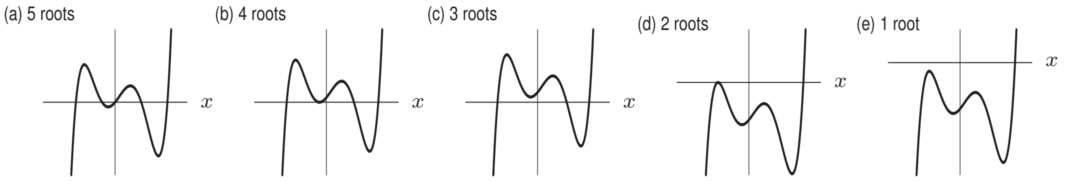

Figure 1.60

28. $g(x) = 2x^2$, $h(x) = x^2 + k$ for any $k > 0$. Notice that the graph is symmetric about the y-axis and $\lim_{x\to\infty} f(x) = 2$.

29. The graphs of both these functions will resemble that of x^3 on a large enough window. One way to tackle the problem is to graph them both (along with x^3 if you like) in successively larger windows until the graphs come together. In Figure 1.61, f, g and x^3 are graphed in four windows. In the largest of the four windows the graphs are indistinguishable, as required. Answers may vary.

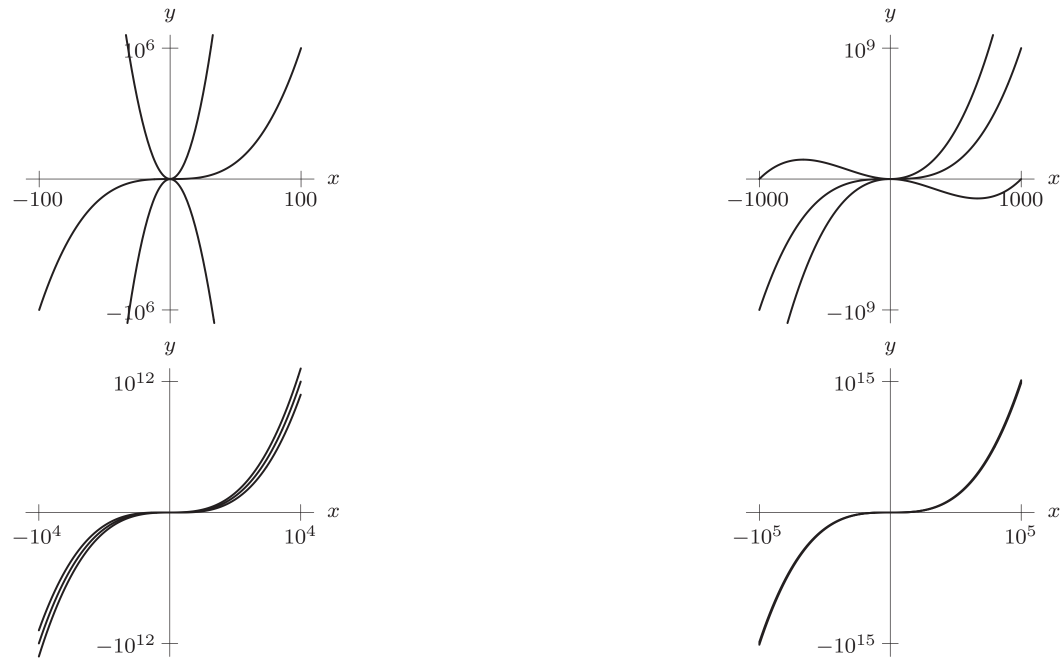

Figure 1.61

30. (a) A polynomial has the same end behavior as its leading term, so this polynomial behaves as $-5x^4$ globally. Thus we have:
$f(x) \to -\infty$ as $x \to -\infty$, and $f(x) \to -\infty$ as $x \to +\infty$.
(b) Polynomials behave globally as their leading term, so this rational function behaves globally as $(3x^2)/(2x^2)$, or $3/2$. Thus we have:
$f(x) \to 3/2$ as $x \to -\infty$, and $f(x) \to 3/2$ as $x \to +\infty$.
(c) We see from a graph of $y = e^x$ that
$f(x) \to 0$ as $x \to -\infty$, and $f(x) \to +\infty$ as $x \to +\infty$.

31. Substituting $w = 65$ and $h = 160$, we have

(a)
$$s = 0.01(65^{0.25})(160^{0.75}) = 1.3 \text{ m}^2.$$

(b) We substitute $s = 1.5$ and $h = 180$ and solve for w:
$$1.5 = 0.01w^{0.25}(180^{0.75}).$$
We have
$$w^{0.25} = \frac{1.5}{0.01(180^{0.75})} = 3.05.$$
Since $w^{0.25} = w^{1/4}$, we take the fourth power of both sides, giving
$$w = 86.8 \text{ kg}.$$

(c) We substitute $w = 70$ and solve for h in terms of s:
$$s = 0.01(70^{0.25})h^{0.75},$$
so
$$h^{0.75} = \frac{s}{0.01(70^{0.25})}.$$
Since $h^{0.75} = h^{3/4}$, we take the $4/3$ power of each side, giving
$$h = \left(\frac{s}{0.01(70^{0.25})}\right)^{4/3} = \frac{s^{4/3}}{(0.01^{4/3})(70^{1/3})}$$
so
$$h = 112.6s^{4/3}.$$

32. Let $D(v)$ be the stopping distance required by an Alpha Romeo as a function of its velocity. The assumption that stopping distance is proportional to the square of velocity is equivalent to the equation
$$D(v) = kv^2$$
where k is a constant of proportionality. To determine the value of k, we use the fact that $D(70) = 177$.
$$D(70) = k(70)^2 = 177.$$
Thus,
$$k = \frac{177}{70^2} \approx 0.0361.$$
It follows that
$$D(35) = \left(\frac{177}{70^2}\right)(35)^2 = \frac{177}{4} = 44.25 \text{ ft}$$
and
$$D(140) = \left(\frac{177}{70^2}\right)(140)^2 = 708 \text{ ft}.$$
Thus, at half the speed it requires one fourth the distance, whereas at twice the speed it requires four times the distance, as we would expect from the equation. (We could in fact have figured it out that way, without solving for k explicitly.)

33. (a) Since the rate R varies directly with the fourth power of the radius r, we have the formula
$$R = kr^4$$
where k is a constant.

(b) Given $R = 400$ for $r = 3$, we can determine the constant k.

$$400 = k(3)^4$$
$$400 = k(81)$$
$$k = \frac{400}{81} \approx 4.938.$$

So the formula is

$$R = 4.938r^4$$

(c) Evaluating the formula above at $r = 5$ yields

$$R = 4.928(5)^4 = 3086.42\frac{\text{cm}^3}{\text{sec}}.$$

34. Let us represent the height by h. Since the volume is V, we have

$$x^2h = V.$$

Solving for h gives

$$h = \frac{V}{x^2}.$$

The graph is in Figure 1.62. We are assuming V is a positive constant.

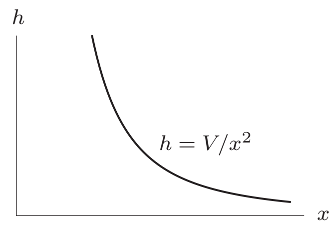

Figure 1.62

35. (a) Let the height of the can be h. Then

$$V = \pi r^2 h.$$

The surface area consists of the area of the ends (each is πr^2) and the curved sides (area $2\pi rh$), so

$$S = 2\pi r^2 + 2\pi rh.$$

Solving for h from the formula for V, we have

$$h = \frac{V}{\pi r^2}.$$

Substituting into the formula for S, we get

$$S = 2\pi r^2 + 2\pi r \cdot \frac{V}{\pi r^2} = 2\pi r^2 + \frac{2V}{r}.$$

(b) For large r, the $2V/r$ term becomes negligible, meaning $S \approx 2\pi r^2$, and thus $S \to \infty$ as $r \to \infty$.
(c) The graph is in Figure 1.63.

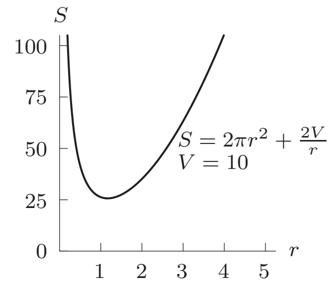

Figure 1.63

36. To find the horizontal asymptote, we look at end behavior. As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree term of the numerator and denominator. Thus, as $x \to \pm\infty$, we see that

$$f(x) \to \frac{5x}{2x} = \frac{5}{2}.$$

There is a horizontal asymptote at $y = 5/2$.
To find the vertical asymptotes, we set the denominator equal to zero. When $2x + 3 = 0$, we have $x = -3/2$ so there is a vertical asymptote at $x = -3/2$.

37. To find the horizontal asymptote, we look at end behavior. As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree term of the numerator and denominator. Thus, as $x \to \pm\infty$, we see that

$$f(x) \to \frac{x^2}{x^2} = 1.$$

There is a horizontal asymptote at $y = 1$.
To find the vertical asymptotes, we set the denominator equal to zero. When $x^2 - 4 = 0$, we have $x = \pm 2$ so there are vertical asymptotes at $x = -2$ and at $x = 2$.

38. To find the horizontal asymptote, we look at end behavior. As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree term of the numerator and denominator. Thus, as $x \to \pm\infty$, we see that

$$f(x) \to \frac{5x^3}{x^3} = 5.$$

There is a horizontal asymptote at $y = 5$.
To find the vertical asymptotes, we set the denominator equal to zero. When $x^3 - 27 = 0$, we have $x = 3$ so there is a vertical asymptote at $x = 3$.

39. (a) The object starts at $t = 0$, when $s = v_0(0) - g(0)^2/2 = 0$. Thus it starts on the ground, with zero height.

(b) The object hits the ground when $s = 0$. This is satisfied at $t = 0$, before it has left the ground, and at some later time t that we must solve for.

$$0 = v_0 t - gt^2/2 = t\,(v_0 - gt/2)$$

Thus $s = 0$ when $t = 0$ and when $v_0 - gt/2 = 0$, i.e., when $t = 2v_0/g$. The starting time is $t = 0$, so it must hit the ground at time $t = 2v_0/g$.

(c) The object reaches its maximum height halfway between when it is released and when it hits the ground, or at

$$t = (2v_0/g)/2 = v_0/g.$$

(d) Since we know the time at which the object reaches its maximum height, to find the height it actually reaches we just use the given formula, which tells us s at any given t. Substituting $t = v_0/g$,

$$\begin{aligned} s &= v_0\left(\frac{v_0}{g}\right) - \frac{1}{2}g\left(\frac{v_0^2}{g^2}\right) = \frac{v_0^2}{g} - \frac{v_0^2}{2g} \\ &= \frac{2v_0^2 - v_0^2}{2g} = \frac{v_0^2}{2g}. \end{aligned}$$

40. The pomegranate is at ground level when $f(t) = -16t^2 + 64t = -16t(t-4) = 0$, so when $t = 0$ or $t = 4$. At time $t = 0$ it is thrown, so it must hit the ground at $t = 4$ seconds. The symmetry of its path with respect to time may convince you that it reaches its maximum height after 2 seconds. Alternatively, we can think of the graph of $f(t) = -16t^2 + 64t = -16(t-2)^2 + 64$, which is a downward parabola with vertex (i.e., highest point) at $(2, 64)$. The maximum height is $f(2) = 64$ feet.

41. (a) (i) If $(1, 1)$ is on the graph, we know that

$$1 = a(1)^2 + b(1) + c = a + b + c.$$

(ii) If $(1, 1)$ is the vertex, then the axis of symmetry is $x = 1$, so

$$-\frac{b}{2a} = 1,$$

and thus

$$a = -\frac{b}{2}, \text{ so } b = -2a.$$

But to be the vertex, $(1, 1)$ must also be on the graph, so we know that $a + b + c = 1$. Substituting $b = -2a$, we get $-a + c = 1$, which we can rewrite as $a = c - 1$, or $c = 1 + a$.

(iii) For $(0, 6)$ to be on the graph, we must have $f(0) = 6$. But $f(0) = a(0^2) + b(0) + c = c$, so $c = 6$.

(b) To satisfy all the conditions, we must first, from (a)(iii), have $c = 6$. From (a)(ii), $a = c - 1$ so $a = 5$. Also from (a)(ii), $b = -2a$, so $b = -10$. Thus the completed equation is

$$y = f(x) = 5x^2 - 10x + 6,$$

which satisfies all the given conditions.

42. The function is a cubic polynomial with positive leading coefficient. Since the figure given in the text shows that the function turns around once, we know that the function has the shape shown in Figure 1.64. The function is below the x-axis for $x = 5$ in the given graph, and we know that it goes to $+\infty$ as $x \to +\infty$ because the leading coefficient is positive. Therefore, there are exactly three zeros. Two zeros are shown, and occur at approximately $x = -1$ and $x = 3$. The third zero must be to the right of $x = 10$ and so occurs for some $x > 10$.

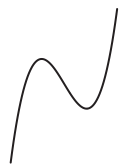

Figure 1.64

43. We use the fact that at a constant speed, Time = Distance/Speed. Thus,

$$\begin{aligned}\text{Total time} &= \text{Time running} + \text{Time walking}\\ &= \frac{3}{x} + \frac{6}{x-2}.\end{aligned}$$

Horizontal asymptote: x-axis.
Vertical asymptote: $x = 0$ and $x = 2$.

44. (a) II and III because in both cases, the numerator and denominator each have x^2 as the highest power, with coefficient $= 1$. Therefore,

$$y \to \frac{x^2}{x^2} = 1 \quad \text{as } x \to \pm\infty.$$

(b) I, since

$$y \to \frac{x}{x^2} = 0 \quad \text{as } x \to \pm\infty.$$

(c) II and III, since replacing x by $-x$ leaves the graph of the function unchanged.
(d) None
(e) III, since the denominator is zero and $f(x)$ tends to $\pm\infty$ when $x = \pm 1$.

45. $h(t)$ cannot be of the form ct^2 or kt^3 since $h(0.0) = 2.04$. Therefore $h(t)$ must be the exponential, and we see that the ratio of successive values of h is approximately 1.5. Therefore $h(t) = 2.04(1.5)^t$. If $g(t) = ct^2$, then $c = 3$ since $g(1.0) = 3.00$. However, $g(2.0) = 24.00 \neq 3 \cdot 2^2$. Therefore $g(t) = kt^3$, and using $g(1.0) = 3.00$, we obtain $g(t) = 3t^3$. Thus $f(t) = ct^2$, and since $f(2.0) = 4.40$, we have $f(t) = 1.1t^2$.

46. The graphs are shown in Figure 1.65.

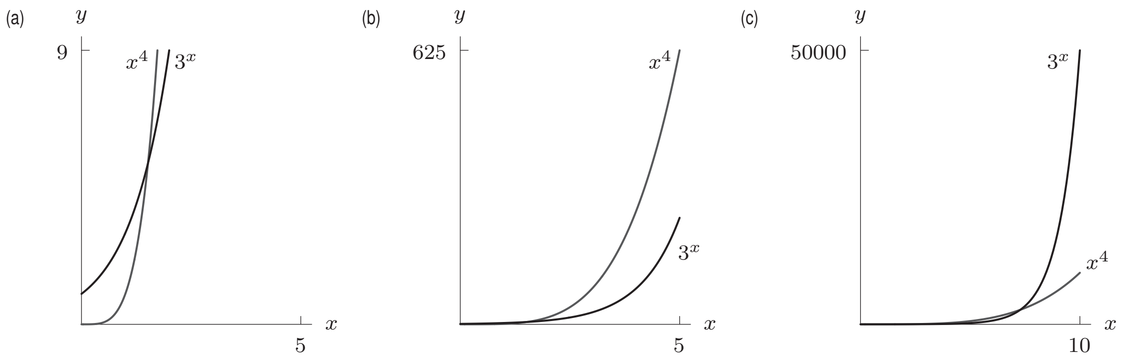

Figure 1.65

47. (a) $R(P) = kP(L - P)$, where k is a positive constant.
(b) A possible graph is in Figure 1.66.

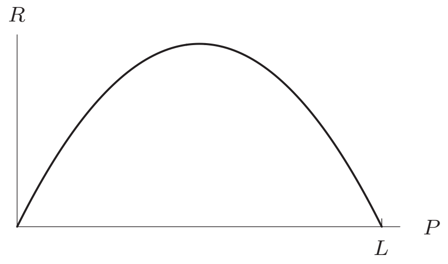

Figure 1.66

48. Since the parabola opens upward, we must have $a > 0$. To determine a relationship between x and y at the point of intersection P, we eliminate a from the parabola and circle equations. Since $y = x^2/a$, we have $a = x^2/y$. Putting this into the circle equation gives $x^2 + y^2 = 2x^4/y^2$. Rewrite this as

$$\begin{aligned} x^2y^2 + y^4 &= 2x^4 \\ y^4 + x^2y^2 - 2x^4 &= 0 \\ (y^2 + 2x^2)(y^2 - x^2) &= 0. \end{aligned}$$

This means $x^2 = y^2$ (since y^2 cannot equal $-2x^2$). Thus $x = y$ since P is in the first quadrant. So P moves out along the line $y = x$ through the origin.

49. (a) The graph is shown in Figure 1.67. The graph represented by the exact formula has a vertical asymptote where the denominator is undefined. This happens when

$$1 - \frac{v^2}{c^2} = 0, \text{ or at } v^2 = c^2.$$

Since $v > 0$, the graph of the exact formula has a vertical asymptote where

$$v = c = 3 \cdot 10^8 \text{m/sec.}$$

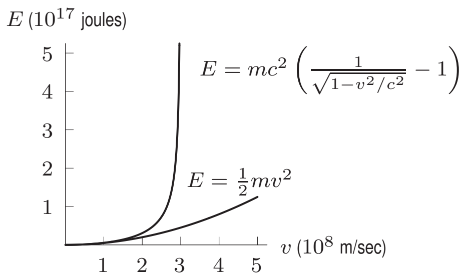

Figure 1.67

(b) The first formula does not give a good approximation to the exact formula when the graphs are not close together. This happens for $v > 1.5 \cdot 10^8$ m/sec. For $v < 1.5 \cdot 10^8$ m/sec, the graphs look close together. However, the vertical scale we are using is so large and the graphs are so close to the v-axis that a more careful analysis should be made. We should zoom in and redraw the graph.

Strengthen Your Understanding

50. The graph of a polynomial of degree 5 cuts the horizontal axis at most five times, but it could be fewer. For example, $f(x) = x^5$ cuts the x-axis only once.

51. The rational function $f(x) = (x^3 + 1)/x$ has no horizontal asymptotes. To see this, observe that

$$y = f(x) = \frac{x^3 + 1}{x} \approx \frac{x^3}{x} = x^2$$

for large x. Thus, $y \to \infty$ as $x \to \pm\infty$.

52. One possibility is $p(x) = (x - 1)(x - 2)(x - 3) = x^3 - 6x^2 + 11x - 6$.

53. A possible function is

$$f(x) = \frac{3x}{x - 10}.$$

54. One possibility is

$$f(x) = \frac{1}{x^2 + 1}.$$

55. Let $f(x) = \dfrac{1}{x + 7\pi}$. Other answers are possible.

56. Let $f(x) = \dfrac{1}{(x-1)(x-2)(x-3)\cdots(x-16)(x-17)}$. This function has an asymptote corresponding to every factor in the denominator. Other answers are possible.

57. The function $f(x) = \dfrac{x-1}{x-2}$ has $y = 1$ as the horizontal asymptote and $x = 2$ as the vertical asymptote. These lines cross at the point $(2, 1)$. Other answers are possible.

58. False. The polynomial $f(x) = x^2 + 1$, with degree 2, has no real zeros.

59. True. If the degree of the polynomial, $p(x)$, is n, then the leading term is $a_n x^n$ with $a_n \neq 0$.

If n is odd and a_n is positive, $p(x)$ tends toward ∞ as $x \to \infty$ and $p(x)$ tends toward $-\infty$ as $x \to -\infty$. Since the graph of $p(x)$ has no breaks in it, the graph must cross the x-axis at least once.

If n is odd and a_n is negative, a similar argument applies, with the signs reversed, but leading to the same conclusion.

60. (a), (c), (d), (e), (b). Notice that $f(x)$ and $h(x)$ are decreasing functions, with $f(x)$ being negative. Power functions grow slower than exponential growth functions, so $k(x)$ is next. Now order the remaining exponential functions, where functions with larger bases grow faster.

Solutions for Section 1.7

Exercises

1. Yes, because $x - 2$ is not zero on this interval.

2. No, because $x - 2 = 0$ at $x = 2$.

3. Yes, because $2x - 5$ is positive for $3 \leq x \leq 4$.

4. Yes, because the denominator is never zero.

5. Yes, because $2x + x^{2/3}$ is defined for all x.

6. No, because $2x + x^{-1}$ is undefined at $x = 0$.

7. No, because $\cos(\pi/2) = 0$.

8. No, because $\sin 0 = 0$.

9. No, because $e^x - 1 = 0$ at $x = 0$.

10. Yes, because $\cos\theta$ is not zero on this interval.

11. We have that $f(0) = -1 < 0$ and $f(1) = 1 > 0$ and that f is continuous. Thus, by the Intermediate Value Theorem applied to $k = 0$, there is a number c in $[0, 1]$ such that $f(c) = k = 0$.

12. We have that $f(0) = 1 > 0$ and $f(1) = e - 3 < 0$ and that f is continuous. Thus, by the Intermediate Value Theorem applied to $k = 0$, there is a number c in $[0, 1]$ such that $f(c) = k = 0$.

13. We have that $f(0) = -1 < 0$ and $f(1) = 1 - \cos 1 > 0$ and that f is continuous. Thus, by the Intermediate Value Theorem applied to $k = 0$, there is a number c in $[0, 1]$ such that $f(c) = k = 0$.

14. Since f is not continuous at $x = 0$, we consider instead the smaller interval $[0.01, 1]$. We have that $f(0.01) = 2^{0.01} - 100 < 0$ and $f(1) = 2 - 1/1 = 1 > 0$ and that f is continuous. Thus, by the Intermediate Value Theorem applied to $k = 0$, there is a number c in $[0.01, 1]$, and hence in $[0, 1]$, such that $f(c) = k = 0$.

15. (a) At $x = 1$, on the line $y = x$, we have $y = 1$. At $x = 1$, on the parabola $y = x^2$, we have $y = 1$. Thus, $f(x)$ is continuous. See Figure 1.68.

(b) At $x = 3$, on the line $y = x$, we have $y = 3$. At $x = 3$, on the parabola $y = x^2$, we have $y = 9$. Thus, $g(x)$ is not continuous. See Figure 1.69.

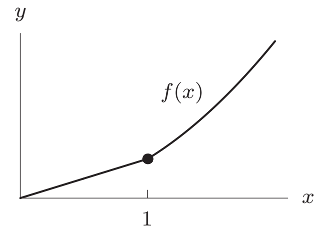

Figure 1.68

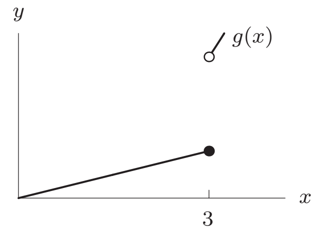

Figure 1.69

Problems

16. (a) Even if the car stops to refuel, the amount of fuel in the tank changes smoothly, so the fuel in the tank is a continuous function; the quantity of fuel cannot suddenly change from one value to another.

(b) Whenever a student joins or leaves the class the number jumps up or down immediately by 1 so this is not a continuous function, unless the enrollment does not change at all.

(c) Whenever the oldest person dies the value of the function jumps down to the age of the next oldest person, so this is not a continuous function.

17. Two possible graphs are shown in Figures 1.70 and 1.71.

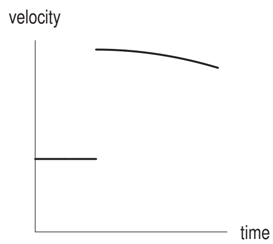

Figure 1.70: Velocity of the car

Figure 1.71: Distance

The distance moved by the car is continuous. (Figure 1.71 has no breaks in it.) In actual fact, the velocity of the car is also continuous; however, in this case, it is well-approximated by the function in Figure 1.70, which is not continuous on any interval containing the moment of impact.

18. The voltage $f(t)$ is graphed in Figure 1.72.

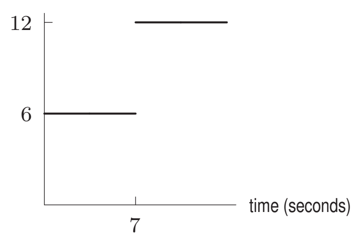

Figure 1.72: Voltage change from 6V to 12V

Using formulas, the voltage, $f(t)$, is represented by

$$f(t) = \begin{cases} 6, & 0 < t \le 7 \\ 12, & 7 < t \end{cases}$$

Although a real physical voltage is continuous, the voltage in this circuit is well-approximated by the function $f(t)$, which is not continuous on any interval around 7 seconds.

19. The value of y on the line $y = kx$ at $x = 3$ is $y = 3k$. To make $f(x)$ continuous, we need

$$3k = 5 \quad \text{so} \quad k = \frac{5}{3}.$$

See Figure 1.73.

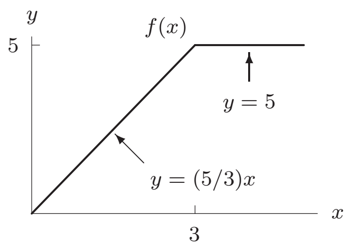

Figure 1.73

20. For any value of k, the function is continuous at every point except $x = 2$. We choose k to make the function continuous at $x = 2$.

Since $3x^2$ takes the value $3(2^2) = 12$ at $x = 2$, we choose k so that the graph of kx goes through the point $(2, 12)$. Thus $k = 6$.

21. If the graphs of $y = t + k$ and $y = kt$ meet at $t = 5$, we have

$$\begin{aligned} 5 + k &= 5k \\ k &= 5/4. \end{aligned}$$

See Figure 1.74.

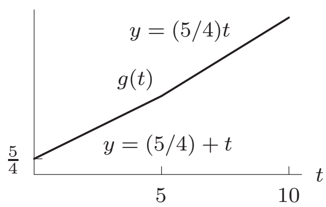

Figure 1.74

22. At $x = \pi$, the curve $y = k \cos x$ has $y = k \cos \pi = -k$. At $x = \pi$, the line $y = 12 - x$ has $y = 12 - \pi$. If $h(x)$ is continuous, we need

$$\begin{aligned} -k &= 12 - \pi \\ k &= \pi - 12. \end{aligned}$$

23. (a) See Figure 1.75.
(b) For any value of k, the function is continuous at every point except $x = 2$. We choose k to make the function continuous at $x = 2$.
Since $(x-2)^2 + 3$ takes on the value $(2-2)^2 + 3 = 3$ at $x = 2$, we choose k so that $kx = 3$ at $x = 2$, so $2k = 3$ and $k = 3/2$.
(c) See Figure 1.76.

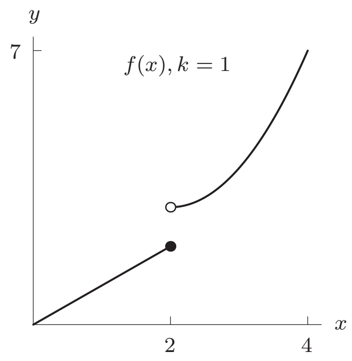

Figure 1.75

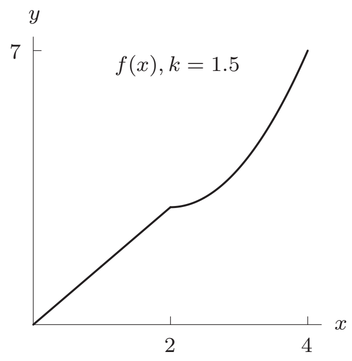

Figure 1.76

24. For any value of k, the function is continuous at every point except $x = 1$. We choose k to make the function continuous at $x = 1$.
Since $x + 3$ takes the value $1 + 3 = 4$ at $x = 1$, we choose k so that the graph of kx goes through the point $(1, 4)$. Thus $k = 4$.

25. For any value of k, the function is continuous at every point except $x = 1$. We choose k to make the function continuous at $x = 1$.
Since kx takes the value $k \cdot 1 = k$ at $x = 1$, we choose k so that the graph of $2kx + 3$ goes through the point $(1, k)$. This gives

$$2k \cdot 1 + 3 = k$$
$$k = -3.$$

26. For any value of k, the function is continuous at every point except $x = \pi$. We choose k to make the function continuous at $x = \pi$.
Since $k \sin x$ takes the value $k \sin \pi = 0$ at $x = \pi$, we cannot choose k so that the graph of $x + 4$ goes through the point $(\pi, 0)$. Thus, this function is discontinuous for all values of k.

27. For any value of k, the function is continuous at every point except $x = 2$. We choose k to make the function continuous at $x = 2$.
Since $x + 1$ takes the value $2 + 1 = 3$ at $x = 2$, we choose k so that the graph of e^{kx} goes through the point $(2, 3)$. This gives

$$e^{2k} = 3$$
$$2k = \ln 3$$
$$k = \frac{\ln 3}{2}$$

28. For any value of k, the function is continuous at every point except $x = 1$. We choose k to make the function continuous at $x = 1$.
Since $\sin(kx)$ takes the value $\sin k$ at $x = 1$, we choose k so that the graph of $0.5x$ goes through the point $(1, \sin k)$. This gives

$$\sin k = 0.5$$
$$k = \sin^{-1} 0.5 = \frac{\pi}{6}.$$

Other solutions are possible.

29. For any value of k, the function is continuous at every point except $x = 2$. We choose k to make the function continuous at $x = 2$.

Since $\ln(kx + 1)$ takes the value $\ln(2k + 1)$ at $x = 2$, we choose k so that the graph of $x + 4$ goes through the point $(2, \ln(2k + 1))$. This gives

$$\begin{aligned} \ln(2k+1) &= 2 + 4 = 6 \\ 2k + 1 &= e^6 \\ k &= \frac{e^6 - 1}{2}. \end{aligned}$$

30. (a) The initial value is when $t = 0$, and we see that $P(0) = e^{k \cdot 0} = e^0 = 1000$.
(b) Since the function is continuous, at $t = 12$, we have $e^{kt} = 100$ and we solve for k:

$$\begin{aligned} e^{12k} &= 100 \\ 12k &= \ln 100 \\ k &= \frac{\ln 100}{12} = 0.384. \end{aligned}$$

(c) The population is increasing exponentially for 12 months and then becoming constant.

31. For $x > 0$, we have $|x| = x$, so $f(x) = 1$. For $x < 0$, we have $|x| = -x$, so $f(x) = -1$. Thus, the function is given by

$$f(x) = \begin{cases} 1 & x > 0 \\ 0 & x = 0 \\ -1 & x < 1 \end{cases},$$

so f is not continuous on any interval containing $x = 0$.

32. The graph of g suggests that g is not continuous on any interval containing $\theta = 0$, since $g(0) = 1/2$.

33. The drug first increases linearly for half a second, at the end of which time there is 0.6 ml in the body. Thus, for $0 \le t \le 0.5$, the function is linear with slope $0.6/0.5 = 1.2$:

$$Q = 1.2t \quad \text{for} \quad 0 \le t \le 0.5.$$

At $t = 0.5$, we have $Q = 0.6$. For $t > 0.5$, the quantity decays exponentially at a continuous rate of 0.002, so Q has the form

$$Q = Ae^{-0.002t} \qquad 0.5 < t.$$

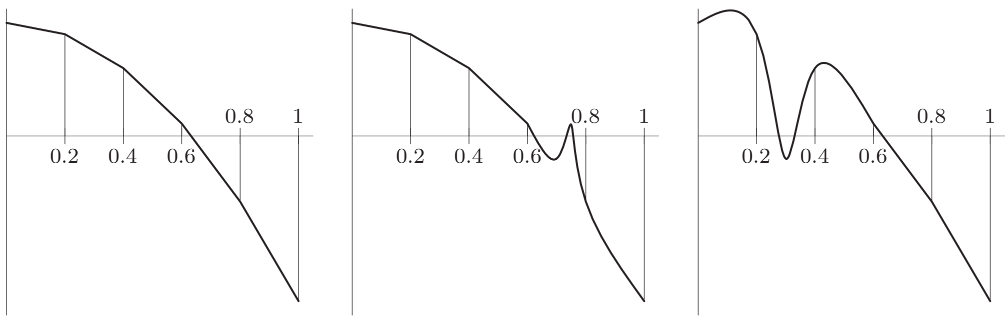
We choose A so that $Q = 0.6$ when $t = 0.5$:

$$\begin{aligned} 0.6 &= Ae^{-0.002(0.5)} = Ae^{-0.001} \\ A &= 0.6e^{0.001}. \end{aligned}$$

Thus

$$Q = \begin{cases} 1.2t & 0 \le t \le 0.5 \\ 0.6e^{0.001}e^{-.002t} & 0.5 < t. \end{cases}$$

34.



35. Since polynomials are continuous, and since $p(5) < 0$ and $p(10) > 0$ and $p(12) < 0$, there are two zeros, one between $x = 5$ and $x = 10$, and another between $x = 10$ and $x = 12$. Thus, $p(x)$ is a cubic with at least two zeros.

If $p(x)$ has only two zeros, one would be a double zero (corresponding to a repeated factor). However, since a polynomial does not change sign at a repeated zero, $p(x)$ cannot have a double zero and have the signs it does.

Thus, $p(x)$ has three zeros. The third zero can be greater than 12 or less than 5. See Figures 1.77 and 1.78.

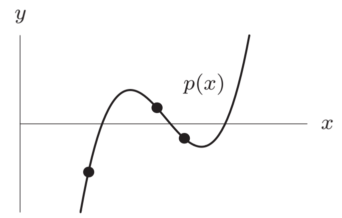


Figure 1.77

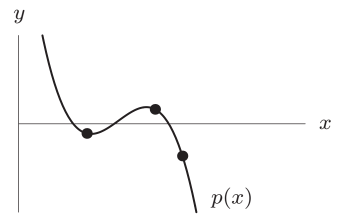

Figure 1.78

36. (a) The graphs of $y = e^x$ and $y = 4 - x^2$ cross twice in Figure 1.79. This tells us that the equation $e^x = 4 - x^2$ has two solutions.

Since $y = e^x$ increases for all x and $y = 4 - x^2$ increases for $x < 0$ and decreases for $x > 0$, these are only the two crossing points.

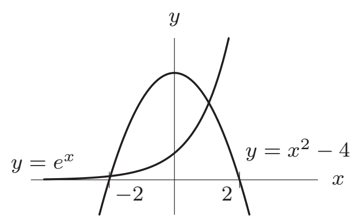

Figure 1.79

(b) Values of $f(x)$ are in Table 1.5. One solution is between $x = -2$ and $x = -1$; the second solution is between $x = 1$ and $x = 2$.

Table 1.5

x	-4	-3	-2	-1	0	1	2	3	4
$f(x)$	12.0	5.0	0.1	-2.6	-3	-0.3	7.4	25.1	66.6

37. (a) Figure 1.80 shows a possible graph of $f(x)$, yours may be different.

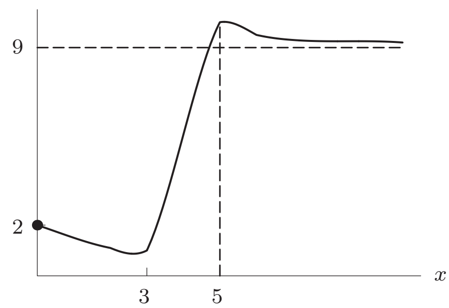

Figure 1.80

(b) In order for f to approach the horizontal asymptote at 9 from above it is necessary that f eventually become concave up. It is therefore not possible for f to be concave down for all $x > 6$.

38. (a) Since $f(x)$ is not continuous at $x = 1$, it does not satisfy the conditions of the Intermediate Value Theorem.

(b) We see that $f(0) = e^0 = 1$ and $f(2) = 4 + (2-1)^2 = 5$. Since e^x is increasing between $x = 0$ and $x = 1$, and since $4 + (x-1)^2$ is increasing between $x = 1$ and $x = 2$, any value of k between $e^1 = e$ and $4 + (1-1)^2 = 4$, such as $k = 3$, is a value such that $f(x) = k$ has no solution.

Strengthen Your Understanding

39. The Intermediate Value theorem only makes this guarantee for a *continuous* function, not for any function.

40. The Intermediate Value Theorem guarantees that for at least one value of x between 0 and 2, we have $f(x) = 5$, but it does not tell us which value(s) of x give $f(x) = 5$.

41. We want a function which has a value at every point but where the graph has a break at $x = 15$. One possibility is

$$f(x) = \begin{cases} 1 & x \geq 15 \\ -1 & x < 15 \end{cases}$$

42. One example is $f(x) = 1/x$, which is not continuous at $x = 0$. The Intermediate Value Theorem does not apply on an interval that contains a point where a function is not continuous.

43. Let $f(x) = \begin{cases} 1 & x \leq 2 \\ x & x > 2 \end{cases}$. Then $f(x)$ is continuous at every point in $[0, 3]$ except at $x = 2$. Other answers are possible.

44. Let $f(x) = \begin{cases} x & x \leq 3 \\ 2x & x > 3 \end{cases}$. Then $f(x)$ is increasing for all x but $f(x)$ is not continuous at $x = 3$. Other answers are possible.

45. False. For example, let $f(x) = \begin{cases} 1 & x \leq 3 \\ 2 & x > 3 \end{cases}$, then $f(x)$ is defined at $x = 3$ but it is not continuous at $x = 3$. (Other examples are possible.)

46. False. A counterexample is graphed in Figure 1.81, in which $f(5) < 0$.

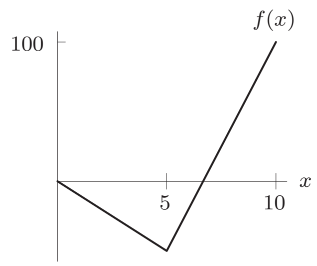

Figure 1.81

47. False. A counterexample is graphed in Figure 1.82.

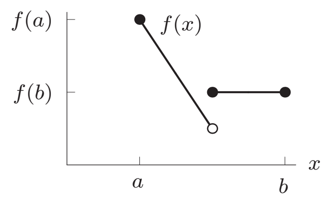

Figure 1.82

Solutions for Section 1.8

Exercises

1. (a) As x approaches -2 from either side, the values of $f(x)$ get closer and closer to 3, so the limit appears to be about 3.
(b) As x approaches 0 from either side, the values of $f(x)$ get closer and closer to 7. (Recall that to find a limit, we are interested in what happens to the function near x but not at x.) The limit appears to be about 7.
(c) As x approaches 2 from either side, the values of $f(x)$ get closer and closer to 3 on one side of $x = 2$ and get closer and closer to 2 on the other side of $x = 2$. Thus the limit does not exist.
(d) As x approaches 4 from either side, the values of $f(x)$ get closer and closer to 8. (Again, recall that we don't care what happens right at $x = 4$.) The limit appears to be about 8.

2. (a) $\lim_{x\to 1^-} f(x) = 1$.
(b) $\lim_{x\to 1^+} f(x)$ does not exist.
(c) $\lim_{x\to 1} f(x)$ does not exist.
(d) $\lim_{x\to 2^-} f(x) = 1$.
(e) $\lim_{x\to 2^+} f(x) = 1$.
(f) $\lim_{x\to 2} f(x) = 1$.

3. From the graphs of f and g, we estimate $\lim_{x\to 1^-} f(x) = 3$, $\lim_{x\to 1^-} g(x) = 5$,
$\lim_{x\to 1^+} f(x) = 4$, $\lim_{x\to 1^+} g(x) = 1$.
(a) $\lim_{x\to 1^-} (f(x) + g(x)) = 3 + 5 = 8$
(b) $\lim_{x\to 1^+} (f(x) + 2g(x)) = \lim_{x\to 1^+} f(x) + 2 \lim_{x\to 1^+} g(x) = 4 + 2(1) = 6$
(c) $\lim_{x\to 1^-} (f(x)g(x)) = (\lim_{x\to 1^-} f(x))(\lim_{x\to 1^-} g(x)) = (3)(5) = 15$
(d) $\lim_{x\to 1^+} (f(x)/g(x)) = \left(\lim_{x\to 1^+} f(x)\right) / \left(\lim_{x\to 1^+} g(x)\right) = 4/1 = 4$

4. We see that $f(x)$ goes to $-\infty$ on both ends, so one possible graph is shown in Figure 1.83. Other answers are possible.

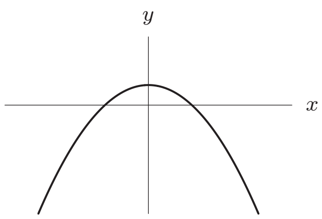

Figure 1.83

5. We see that $f(x)$ goes to $+\infty$ on the left and to $-\infty$ on the right. One possible graph is shown in Figure 1.84. Other answers are possible.

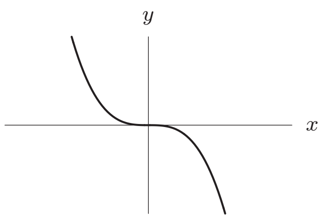

Figure 1.84

6. We see that $f(x)$ goes to $+\infty$ on the left and approaches a y-value of 1 on the right. One possible graph is shown in Figure 1.85. Other answers are possible.

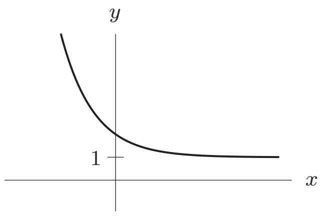

Figure 1.85

7. We see that $f(x)$ approaches a y-value of 3 on the left and goes to $-\infty$ on the right. One possible graph is shown in Figure 1.86. Other answers are possible.

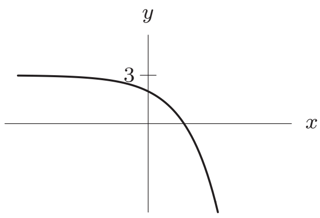

Figure 1.86

8. We see that $f(x)$ goes to $+\infty$ on the right and that it also passes through the point $(-1, 2)$. (Notice that this must be a point on the graph since the instructions require that $f(x)$ be defined and continuous.) One possible graph is shown in Figure 1.87. Other answers are possible.

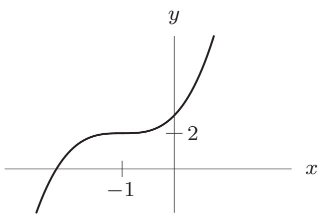

Figure 1.87

9. We see that $f(x)$ goes to $+\infty$ on the left and that it also passes through the point $(3, 5)$. (Notice that this must be a point on the graph since the instructions require that $f(x)$ be defined and continuous.) One possible graph is shown in Figure 1.88. Other answers are possible.

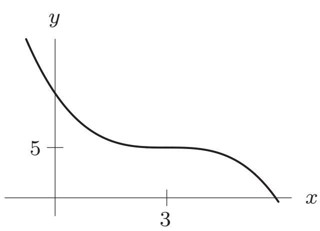

Figure 1.88

10. We see that $\lim_{x\to-\infty} f(x) = -\infty$ and $\lim_{x\to+\infty} f(x) = -\infty$.

11. As $x \to \pm\infty$, we know that $f(x)$ behaves like its leading term $-2x^3$. Thus, we have $\lim_{x\to-\infty} f(x) = +\infty$ and $\lim_{x\to+\infty} f(x) = -\infty$.

12. As $x \to \pm\infty$, we know that $f(x)$ behaves like its leading term x^5. Thus, we have $\lim_{x\to-\infty} f(x) = -\infty$ and $\lim_{x\to+\infty} f(x) = +\infty$.

13. As $x \to \pm\infty$, we know that $f(x)$ behaves like the quotient of the leading terms of its numerator and denominator. Since

$$f(x) \to \frac{3x^3}{5x^3} = \frac{3}{5},$$

we have $\lim_{x\to-\infty} f(x) = 3/5$ and $\lim_{x\to+\infty} f(x) = 3/5$.

14. As $x \to \pm\infty$, we know that x^{-3} gets closer and closer to zero, so we have $\lim_{x\to-\infty} f(x) = 0$ and $\lim_{x\to+\infty} f(x) = 0$.

15. We have $\lim_{x\to-\infty} f(x) = 0$ and $\lim_{x\to+\infty} f(x) = +\infty$.

16. The break in the graph at $x = 0$ suggests that $\lim_{x\to 0} \frac{|x|}{x}$ does not exist. See Figure 1.89.

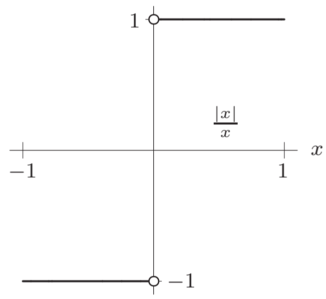

Figure 1.89

17. For $-1 \le x \le 1,\ -1 \le y \le 1$, the graph of $y = x\ln|x|$ is in Figure 1.90. The graph suggests that

$$\lim_{x\to 0} x\ln|x| = 0.$$

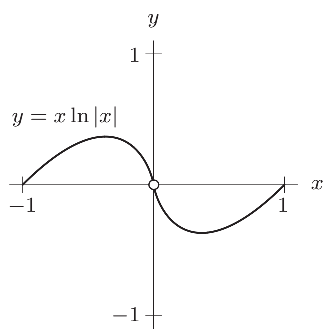

Figure 1.90

18. Since $\lim_{x\to 0^+} \frac{|x|}{x} = 1$ and $\lim_{x\to 0^-} \frac{|x|}{x} = -1$, we say that $\lim_{x\to 0} \frac{|x|}{x}$ does not exist. In addition $f(x)$ is not defined at 0. Therefore, $f(x)$ is not continuous on any interval containing 0.

19. For $-0.5 \le \theta \le 0.5$, $0 \le y \le 3$, the graph of $y = \dfrac{\sin(2\theta)}{\theta}$ is shown in Figure 1.91. Therefore, $\lim_{\theta\to 0} \dfrac{\sin(2\theta)}{\theta} = 2$.

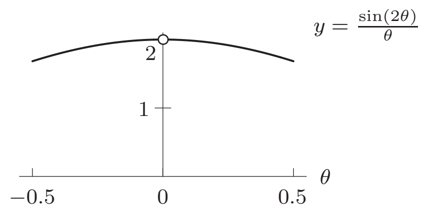

Figure 1.91

20. For $-1 \le \theta \le 1$, $-1 \le y \le 1$, the graph of $y = \dfrac{\cos\theta - 1}{\theta}$ is shown in Figure 1.92. Therefore, $\lim_{\theta\to 0} \dfrac{\cos\theta - 1}{\theta} = 0$.

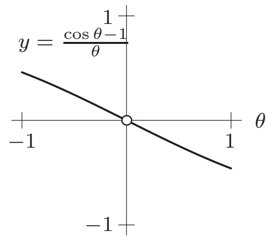

Figure 1.92

21. For $-90^\circ \le \theta \le 90^\circ$, $0 \le y \le 0.02$, the graph of $y = \dfrac{\sin\theta}{\theta}$ is shown in Figure 1.93. Therefore, by tracing along the curve, we see that in degrees, $\lim_{\theta\to 0} \dfrac{\sin\theta}{\theta} = 0.01745\ldots$.

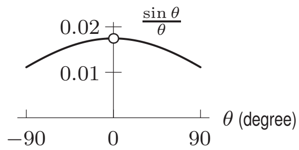

Figure 1.93

22. For $-0.5 \le \theta \le 0.5$, $0 \le y \le 0.5$, the graph of $y = \dfrac{\theta}{\tan(3\theta)}$ is shown in Figure 1.94. Therefore, by tracing along the curve, we see that $\lim_{\theta\to 0} \dfrac{\theta}{\tan(3\theta)} = 0.3333\ldots$.

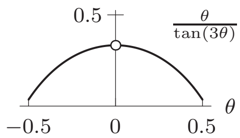

Figure 1.94

23. A graph of $y = \dfrac{e^h - 1}{h}$ in a window such as $-0.5 \le h \le 0.5$ and $0 \le y \le 3$ appears to indicate $y \to 1$ as $h \to 0$. Therefore, we estimate that $\lim_{h\to 0} \dfrac{e^h - 1}{h} = 1$.

24. A graph of $y = \dfrac{e^{5h}-1}{h}$ in a window such as $-0.5 \le h \le 0.5$ and $0 \le y \le 6$ appears to indicate $y \to 5$ as $h \to 0$. Therefore, we estimate that $\lim_{h\to 0} \dfrac{e^{5h}-1}{h} = 5$.

25. A graph of $y = \dfrac{2^h-1}{h}$ in a window such as $-0.5 \le h \le 0.5$ and $0 \le y \le 1$ appears to indicate $y \to 0.7$ as $h \to 0$. By zooming in on the graph, we can estimate the limit more accurately. Therefore, we estimate that

$$\lim_{h\to 0} \frac{2^h-1}{h} = 0.693.$$

26. A graph of $y = \dfrac{3^h-1}{h}$ in a window such as $-0.5 \le h \le 0.5$ and $0 \le y \le 1.5$ appears to indicate $y \to 1.1$ as $h \to 0$. By zooming in on the graph, we can estimate the limit more accurately. Therefore, we estimate that

$$\lim_{h\to 0} \frac{3^h-1}{h} = 1.098.$$

27. A graph of $y = \dfrac{\cos(3h)-1}{h}$ in a window such as $-0.5 \le h \le 0.5$ and $-1 \le y \le 1$ appears to indicate $y \to 0$ as $h \to 0$. Therefore, we estimate that

$$\lim_{h\to 0} \frac{\cos(3h)-1}{h} = 0.$$

28. A graph of $y = \dfrac{\sin(3h)}{h}$ in a window such as $-0.5 \le h \le 0.5$ and $0 \le y \le 4$ appears to indicate $y \to 3$ as $h \to 0$. Therefore, we estimate that

$$\lim_{h\to 0} \frac{\sin(3h)}{h} = 3.$$

29. $f(x) = \dfrac{|x-4|}{x-4} = \begin{cases} \dfrac{x-4}{x-4} & x > 4 \\ -\dfrac{x-4}{x-4} & x < 4 \end{cases} = \begin{cases} 1 & x > 4 \\ -1 & x < 4 \end{cases}$

Figure 1.95 confirms that $\lim_{x\to 4^+} f(x) = 1$, $\lim_{x\to 4^-} f(x) = -1$ so $\lim_{x\to 4} f(x)$ does not exist.

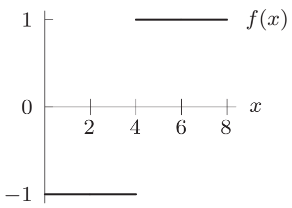

Figure 1.95

30. $f(x) = \dfrac{|x-2|}{x} = \begin{cases} \dfrac{x-2}{x}, & x > 2 \\ -\dfrac{x-2}{x}, & x < 2 \end{cases}$

Figure 1.96 confirms that $\lim_{x\to 2^+} f(x) = \lim_{x\to 2^-} f(x) = \lim_{x\to 2} f(x) = 0$.

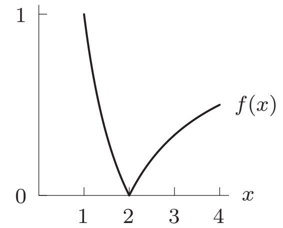

Figure 1.96

31. $f(x) = \begin{cases} x^2 - 2 & 0 < x < 3 \\ 2 & x = 3 \\ 2x+1 & 3 < x \end{cases}$

Figure 1.97 confirms that $\lim_{x\to 3^-} f(x) = \lim_{x\to 3^-} (x^2-2) = 7$ and that $\lim_{x\to 3+} f(x) = \lim_{x\to 3+} (2x+1) = 7$, so $\lim_{x\to 3} f(x) = 7$. Note, however, that $f(x)$ is not continuous at $x = 3$ since $f(3) = 2$.

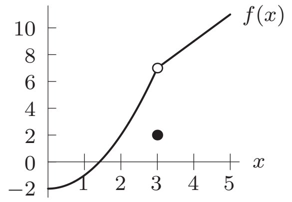

Figure 1.97

32. The graph in Figure 1.98 suggests that

$$\text{if } -0.05 < \theta < 0.05, \quad \text{then} \quad 0.999 < (\sin\theta)/\theta < 1.001.$$

Thus, if θ is within 0.05 of 0, we see that $(\sin\theta)/\theta$ is within 0.001 of 1.

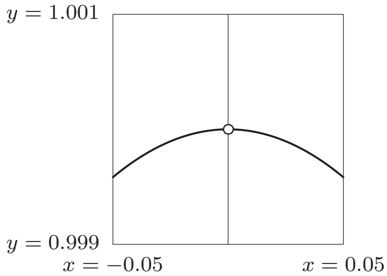

Figure 1.98: Graph of $(\sin\theta)/\theta$ with $-0.05 < \theta < 0.05$

33. The statement

$$\lim_{h\to a} g(h) = K$$

means that we can make the value of $g(h)$ as close to K as we want by choosing h sufficiently close to, but not equal to, a.

In symbols, for any $\epsilon > 0$, there is a $\delta > 0$ such that

$$|g(h) - K| < \epsilon \quad \text{for all } 0 < |h-a| < \delta.$$

Problems

34. At $x = 0$, the function is not defined. In addition, $\lim_{x\to 0} f(x)$ does not exist. Thus, $f(x)$ is not continuous at $x = 0$.

35. Since $\lim_{x\to 0^+} f(x) = 1$ and $\lim_{x\to 0^-} f(x) = -1$, we see that $\lim_{x\to 0} f(x)$ does not exist. Thus, $f(x)$ is not continuous at $x = 0$

36. Since $x/x = 1$ for $x \neq 0$, this function $f(x) = 1$ for all x. Thus, $f(x)$ is continuous for all x.

37. Since $2x/x = 2$ for $x \neq 0$, we have $\lim_{x\to 0} f(x) = 2$, so

$$\lim_{x\to 0} f(x) \neq f(0) = 3.$$

Thus, $f(x)$ is not continuous at $x = 0$.

38. The answer (see the graph in Figure 1.99) appears to be about 2.7; if we zoom in further, it appears to be about 2.72, which is close to the value of $e \approx 2.71828$.

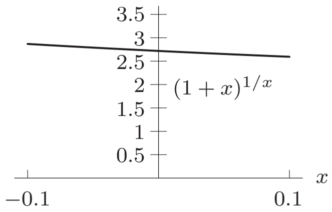

Figure 1.99

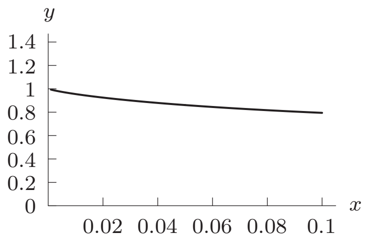
39. We use values of h approaching, but not equal to, zero. If we let $h = 0.01, 0.001, 0.0001, 0.00001$, we calculate the values 2.7048, 2.7169, 2.7181, and 2.7183. If we let $h = -0.01\ -0.001, -0.0001, -0.00001$, we get values 2.7320, 2.7196, 2.7184, and 2.7183. These numbers suggest that the limit is the number $e = 2.71828\ldots$. However, these calculations cannot tell us that the limit is exactly e; for that a proof is needed.

40. When $x = 0.1$, we find $xe^{1/x} \approx 2203$. When $x = 0.01$, we find $xe^{1/x} \approx 3 \times 10^{41}$. When $x = 0.001$, the value of $xe^{1/x}$ is too big for a calculator to compute. This suggests that $\lim_{x\to 0^+} xe^{1/x}$ does not exist (and in fact it does not).

41. If $x > 1$ and x approaches 1, then $p(x) = 55$. If $x < 1$ and x approaches 1, then $p(x) = 34$. There is not a single number that $p(x)$ approaches as x approaches 1, so we say that $\lim_{x\to 1} p(x)$ does not exist.

42. The limit appears to be 1; a graph and table of values is shown below.



x	x^x
0.1	0.7943
0.01	0.9550
0.001	0.9931
0.0001	0.9990
0.00001	0.9999

43. The only change is that, instead of considering all x near c, we only consider x near to and greater than c. Thus the phrase "$|x - c| < \delta$" must be replaced by "$c < x < c + \delta$." Thus, we define

$$\lim_{x\to c^+} f(x) = L$$

to mean that for any $\epsilon > 0$ (as small as we want), there is a $\delta > 0$ (sufficiently small) such that if $c < x < c + \delta$, then $|f(x) - L| < \epsilon$.

44. The only change is that, instead of considering all x near c, we only consider x near to and less than c. Thus the phrase "$|x - c| < \delta$" must be replaced by "$c - \delta < x < c$." Thus, we define

$$\lim_{x\to c^-} f(x) = L$$

to mean that for any $\epsilon > 0$ (as small as we want), there is a $\delta > 0$ (sufficiently small) such that if $c - \delta < x < c$, then $|f(x) - L| < \epsilon$.

45. Instead of being "sufficiently close to c," we want x to be "sufficiently large." Using N to measure how large x must be, we define

$$\lim_{x\to\infty} f(x) = L$$

to mean that for any $\epsilon > 0$ (as small as we want), there is a $N > 0$ (sufficiently large) such that if $x > N$, then $|f(x) - L| < \epsilon$.

46. From Table 1.6, it appears the limit is 1. This is confirmed by Figure 1.100. An appropriate window is $-0.0033 < x < 0.0033$, $0.99 < y < 1.01$.

Table 1.6

x	$f(x)$	x	$f(x)$
0.1	1.3	−0.0001	0.9997
0.01	1.03	−0.001	0.997
0.001	1.003	−0.01	0.97
0.0001	1.0003	−0.1	0.7

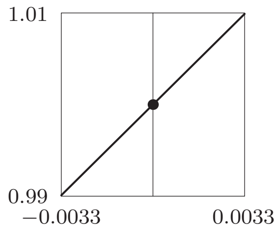


Figure 1.100

47. From Table 1.7, it appears the limit is −1. This is confirmed by Figure 1.101. An appropriate window is $-0.099 < x < 0.099$, $-1.01 < y < -0.99$.

Table 1.7

x	$f(x)$	x	$f(x)$
0.1	−0.99	−0.0001	−0.99999999
0.01	−0.9999	−0.001	−0.999999
0.001	−0.999999	−0.01	−0.9999
0.0001	−0.99999999	−0.1	−0.99

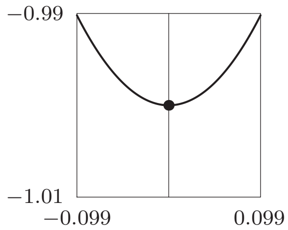

Figure 1.101

48. From Table 1.8, it appears the limit is 0. This is confirmed by Figure 1.102. An appropriate window is $-0.005 < x < 0.005$, $-0.01 < y < 0.01$.

Table 1.8

x	$f(x)$	x	$f(x)$
0.1	0.1987	−0.0001	−0.0002
0.01	0.0200	−0.001	−0.0020

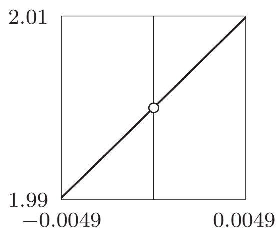

Figure 1.107

54. Divide numerator and denominator by x:

$$f(x) = \frac{x+3}{2-x} = \frac{1+3/x}{2/x-1},$$

so

$$\lim_{x\to\infty} f(x) = \lim_{x\to\infty} \frac{1+3/x}{2/x-1} = \frac{\lim_{x\to\infty}(1+3/x)}{\lim_{x\to\infty}(2/x-1)} = \frac{1}{-1} = -1.$$

55. Divide numerator and denominator by x:

$$f(x) = \frac{\pi+3x}{\pi x-3} = \frac{(\pi+3x)/x}{(\pi x-3)/x},$$

so

$$\lim_{x\to\infty} f(x) = \lim_{x\to\infty} \frac{\pi/x+3}{\pi-3/x} = \frac{\lim_{x\to\infty}(\pi/x+3)}{\lim_{x\to\infty}(\pi-3/x)} = \frac{3}{\pi}.$$

56. Divide numerator and denominator by x^2:

$$f(x) = \frac{x-5}{5+2x^2} = \frac{(1/x)-(5/x^2)}{(5/x^2)+2},$$

so

$$\lim_{x\to\infty} f(x) = \lim_{x\to\infty} \frac{(1/x)-(5/x^2)}{(5/x^2)+2} = \frac{\lim_{x\to\infty}((1/x)-(5/x^2))}{\lim_{x\to\infty}((5/x^2)+2)} = \frac{0}{2} = 0.$$

57. Divide numerator and denominator by x^2, giving

$$f(x) = \frac{x^2+2x-1}{3+3x^2} = \frac{1+2/x-1/x^2}{3/x^2+3},$$

so

$$\lim_{x\to\infty} f(x) = \lim_{x\to\infty} \frac{1+2/x-1/x^2}{3/x^2+3} = \frac{\lim_{x\to\infty}(1+2/x-1/x^2)}{\lim_{x\to\infty}(3/x^2+3)} = \frac{1}{3}.$$

58. Divide numerator and denominator by x, giving

$$f(x) = \frac{x^2+4}{x+3} = \frac{x+4/x}{1+3/x},$$

so

$$\lim_{x\to\infty} f(x) = +\infty.$$

59. Divide numerator and denominator by x^3, giving

$$f(x) = \frac{2x^3-16x^2}{4x^2+3x^3} = \frac{2-16/x}{4/x+3},$$

so

$$\lim_{x\to\infty} f(x) = \lim_{x\to\infty} \frac{2-16/x}{4/x+3} = \frac{\lim_{x\to\infty}(2-16/x)}{\lim_{x\to\infty}(4/x+3)} = \frac{2}{3}.$$

60. Divide numerator and denominator by x^5, giving

$$f(x) = \frac{x^4+3x}{x^4+2x^5} = \frac{1/x+3/x^4}{1/x+2},$$

so

$$\lim_{x\to\infty} f(x) = \frac{\lim_{x\to\infty}(1/x+3/x^4)}{\lim_{x\to\infty}(1/x+2)} = \frac{0}{2} = 0.$$

61. Divide numerator and denominator by e^x, giving

$$f(x) = \frac{3e^x + 2}{2e^x + 3} = \frac{3 + 2e^{-x}}{2 + 3e^{-x}},$$

so

$$\lim_{x\to\infty} f(x) = \frac{\lim_{x\to\infty}(3 + 2e^{-x})}{\lim_{x\to\infty}(2 + 3e^{-x})} = \frac{3}{2}.$$

62. Since $\lim_{x\to\infty} 2^{-x} = \lim_{x\to\infty} 3^{-x} = 0$, we have

$$\lim_{x\to\infty} f(x) = \lim_{x\to\infty} \frac{2^{-x} + 5}{3^{-x} + 7} = \frac{\lim_{x\to\infty}(2^{-x} + 5)}{\lim_{x\to\infty}(3^{-x} + 7)} = \frac{5}{7}.$$

63. $f(x) = \dfrac{2e^{-x} + 3}{3e^{-x} + 2}$, so $\lim\limits_{x\to\infty} f(x) = \dfrac{\lim_{x\to\infty}(2e^{-x} + 3)}{\lim_{x\to\infty}(3e^{-x} + 2)} = \dfrac{3}{2}$.

64. Because the denominator equals 0 when $x = 4$, so must the numerator. This means $k^2 = 16$ and the choices for k are 4 or -4.

65. Because the denominator equals 0 when $x = 1$, so must the numerator. So $1 - k + 4 = 0$. The only possible value of k is 5.

66. Because the denominator equals 0 when $x = -2$, so must the numerator. So $4 - 8 + k = 0$ and the only possible value of k is 4.

67. Division of numerator and denominator by x^2 yields

$$\frac{x^2 + 3x + 5}{4x + 1 + x^k} = \frac{1 + 3/x + 5/x^2}{4/x + 1/x^2 + x^{k-2}}.$$

As $x \to \infty$, the limit of the numerator is 1. The limit of the denominator depends upon k. If $k > 2$, the denominator approaches ∞ as $x \to \infty$, so the limit of the quotient is 0. If $k = 2$, the denominator approaches 1 as $x \to \infty$, so the limit of the quotient is 1. If $k < 2$ the denominator approaches 0^+ as $x \to \infty$, so the limit of the quotient is ∞. Therefore the values of k we are looking for are $k \geq 2$.

68. For the numerator, $\lim\limits_{x\to-\infty}\left(e^{2x} - 5\right) = -5$. If $k > 0$, $\lim\limits_{x\to-\infty}\left(e^{kx} + 3\right) = 3$, so the quotient has a limit of $-5/3$. If $k = 0$, $\lim\limits_{x\to-\infty}\left(e^{kx} + 3\right) = 4$, so the quotient has limit of $-5/4$. If $k < 0$, the limit of the quotient is given by $\lim\limits_{x\to-\infty}(e^{2x} - 5)/(e^{kx} + 3) = 0$.

69. Division of numerator and denominator by x^3 yields

$$\frac{x^3 - 6}{x^k + 3} = \frac{1 - 6/x^3}{x^{k-3} + 3/x^3}.$$

As $x \to \infty$, the limit of the numerator is 1. The limit of the denominator depends upon k. If $k > 3$, the denominator approaches ∞ as $x \to \infty$, so the limit of the quotient is 0. If $k = 3$, the denominator approaches 1 as $x \to \infty$, so the limit of the quotient is 1. If $k < 3$ the denominator approaches 0^+ as $x \to \infty$, so the limit of the quotient is ∞. Therefore the values of k we are looking for are $k \geq 3$.

70. We divide both the numerator and denominator by 3^{2x}, giving

$$\lim_{x\to\infty} \frac{3^{kx} + 6}{3^{2x} + 4} = \frac{3^{(k-2)x} + 6/3^{2x}}{1 + 4/3^{2x}}.$$

In the denominator, $\lim\limits_{x\to\infty} 1 + 4/3^{2x} = 1$. In the numerator, if $k < 2$, we have $\lim\limits_{x\to\infty} 3^{(k-2)x} + 6/3^{2x} = 0$, so the quotient has a limit of 0. If $k = 2$, we have $\lim\limits_{x\to\infty} 3^{(k-2)x} + 6/3^{2x} = 1$, so the quotient has a limit of 1. If $k > 2$, we have $\lim\limits_{x\to\infty} 3^{(k-2)x} + 6/3^{2x} = \infty$, so the quotient has a limit of ∞.

71. In the denominator, we have $\lim\limits_{x\to-\infty} 3^{2x} + 4 = 4$. In the numerator, if $k < 0$, we have $\lim\limits_{x\to-\infty} 3^{kx} + 6 = \infty$, so the quotient has a limit of ∞. If $k = 0$, we have $\lim\limits_{x\to-\infty} 3^{kx} + 6 = 7$, so the quotient has a limit of $7/4$. If $k > 0$, we have $\lim\limits_{x\to-\infty} 3^{kx} + 6 = 6$, so the quotient has a limit of $6/4$.

72. By tracing on a calculator or solving equations, we find the following values of δ:
For $\epsilon = 0.2$, $\delta \le 0.1$.
For $\epsilon = 0.1$, $\delta \le 0.05$.
For $\epsilon = 0.02$, $\delta \le 0.01$.
For $\epsilon = 0.01$, $\delta \le 0.005$.
For $\epsilon = 0.002$, $\delta \le 0.001$.
For $\epsilon = 0.001$, $\delta \le 0.0005$.

73. By tracing on a calculator or solving equations, we find the following values of δ:
For $\epsilon = 0.1$, $\delta \le 0.46$.
For $\epsilon = 0.01$, $\delta \le 0.21$.
For $\epsilon = 0.001$, $\delta < 0.1$. Thus, we can take $\delta \le 0.09$.

74. The results of Problem 72 suggest that we can choose $\delta = \epsilon/2$. For any $\epsilon > 0$, we want to find the δ such that

$$|f(x) - 3| = |-2x + 3 - 3| = |2x| < \epsilon.$$

Then if $|x| < \delta = \epsilon/2$, it follows that $|f(x) - 3| = |2x| < \epsilon$. So $\lim_{x\to 0}(-2x + 3) = 3$.

75. (a) Since $\sin(n\pi) = 0$ for $n = 1, 2, 3, \ldots$ the sequence of x-values

$$\frac{1}{\pi}, \frac{1}{2\pi}, \frac{1}{3\pi}, \ldots$$

works. These x-values $\to 0$ and are zeroes of $f(x)$.

(b) Since $\sin(n\pi/2) = 1$ for $n = 1, 5, 9 \ldots$ the sequence of x-values

$$\frac{2}{\pi}, \frac{2}{5\pi}, \frac{2}{9\pi}, \ldots$$

works.

(c) Since $\sin(n\pi)/2 = -1$ for $n = 3, 7, 11, \ldots$ the sequence of x-values

$$\frac{2}{3\pi}, \frac{2}{7\pi}, \frac{2}{11\pi} \ldots$$

works.

(d) Any two of these sequences of x-values show that if the limit were to exist, then it would have to have two (different) values: 0 and 1, or 0 and -1, or 1 and -1. Hence, the limit can not exist.

76. From Table 1.14, it appears the limit is 0. This is confirmed by Figure 1.108. An appropriate window is $-0.015 < x < 0.015$, $-0.01 < y < 0.01$.

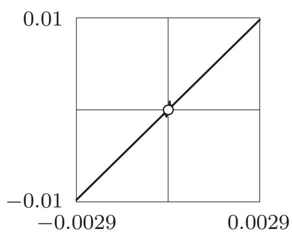

Figure 1.109

78. (a) If $b = 0$, then the property says $\lim_{x\to c} 0 = 0$, which is easy to see is true.

(b) If $|f(x) - L| < \frac{\epsilon}{|b|}$, then multiplying by $|b|$ gives

$$|b||f(x) - L| < \epsilon.$$

Since

$$|b||f(x) - L| = |b(f(x) - L)| = |bf(x) - bL|,$$

we have

$$|bf(x) - bL| < \epsilon.$$

(c) Suppose that $\lim_{x\to c} f(x) = L$. We want to show that $\lim_{x\to c} bf(x) = bL$. If we are to have

$$|bf(x) - bL| < \epsilon,$$

then we will need

$$|f(x) - L| < \frac{\epsilon}{|b|}.$$

We choose δ small enough that

$$|x - c| < \delta \quad \text{implies} \quad |f(x) - L| < \frac{\epsilon}{|b|}.$$

By part (b), this ensures that

$$|bf(x) - bL| < \epsilon,$$

as we wanted.

79. Suppose $\lim_{x\to c} f(x) = L_1$ and $\lim_{x\to c} g(x) = L_2$. Then we need to show that

$$\lim_{x\to c}(f(x) + g(x)) = L_1 + L_2.$$

Let $\epsilon > 0$ be given. We need to show that we can choose $\delta > 0$ so that whenever $|x - c| < \delta$, we will have $|(f(x) + g(x)) - (L_1 + L_2)| < \epsilon$. First choose $\delta_1 > 0$ so that $|x - c| < \delta_1$ implies $|f(x) - L_1| < \frac{\epsilon}{2}$; we can do this since $\lim_{x\to c} f(x) = L_1$. Similarly, choose $\delta_2 > 0$ so that $|x - c| < \delta_2$ implies $|g(x) - L_2| < \frac{\epsilon}{2}$. Now, set δ equal to the smaller of δ_1 and δ_2. Thus $|x - c| < \delta$ will make both $|x - c| < \delta_1$ and $|x - c| < \delta_2$. Then, for $|x - c| < \delta$, we have

$$\begin{aligned}|f(x) + g(x) - (L_1 + L_2)| &= |(f(x) - L_1) + (g(x) - L_2)|\\ &\le |(f(x) - L_1)| + |(g(x) - L_2)|\\ &\le \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.\end{aligned}$$

This proves $\lim_{x\to c}(f(x) + g(x)) = \lim_{x\to c} f(x) + \lim_{x\to c} g(x)$, which is the result we wanted to prove.

80. (a) We need to show that for any given $\epsilon > 0$, there is a $\delta > 0$ so that $|x - c| < \delta$ implies $|f(x)g(x)| < \epsilon$. If $\epsilon > 0$ is given, choose δ_1 so that when $|x - c| < \delta_1$, we have $|f(x)| < \sqrt{\epsilon}$. This can be done since $\lim_{x\to 0} f(x) = 0$. Similarly, choose δ_2 so that when $|x - c| < \delta_2$, we have $|g(x)| < \sqrt{\epsilon}$. Then, if we take δ to be the smaller of δ_1 and δ_2, we'll have that $|x - c| < \delta$ implies both $|f(x)| < \sqrt{\epsilon}$ and $|g(x)| < \sqrt{\epsilon}$. So when $|x - c| < \delta$, we have $|f(x)g(x)| = |f(x)|\,|g(x)| < \sqrt{\epsilon} \cdot \sqrt{\epsilon} = \epsilon$. Thus $\lim_{x\to c} f(x)g(x) = 0$.

(b) $(f(x) - L_1)(g(x) - L_2) + L_1 g(x) + L_2 f(x) - L_1 L_2$
$= f(x)g(x) - L_1 g(x) - L_2 f(x) + L_1 L_2 + L_1 g(x) + L_2 f(x) - L_1 L_2 = f(x)g(x).$

(c) $\lim_{x\to c}(f(x) - L_1) = \lim_{x\to c} f(x) - \lim_{x\to c} L_1 = L_1 - L_1 = 0$, using the second limit property. Similarly, $\lim_{x\to c}(g(x) - L_2) = 0$.

(d) Since $\lim_{x\to c}(f(x) - L_1) = \lim_{x\to c}(g(x) - L_2) = 0$, we have that $\lim_{x\to c}(f(x) - L_1)(g(x) - L_2) = 0$ by part (a).

(e) From part (b), we have

$$\begin{aligned}\lim_{x\to c} f(x)g(x) &= \lim_{x\to c}((f(x) - L_1)(g(x) - L_2) + L_1 g(x) + L_2 f(x) - L_1 L_2)\\ &= \lim_{x\to c}(f(x) - L_1)(g(x) - L_2) + \lim_{x\to c} L_1 g(x) + \lim_{x\to c} L_2 f(x) + \lim_{x\to c}(-L_1 L_2)\\ &\quad \text{(using limit property 2)}\\ &= 0 + L_1 \lim_{x\to c} g(x) + L_2 \lim_{x\to c} f(x) - L_1 L_2\\ &\quad \text{(using limit property 1 and part (d))}\\ &= L_1 L_2 + L_2 L_1 - L_1 L_2 = L_1 L_2.\end{aligned}$$

81. We will show $f(x) = x$ is continuous at $x = c$. Since $f(c) = c$, we need to show that

$$\lim_{x\to c} f(x) = c$$

that is, since $f(x) = x$, we need to show

$$\lim_{x\to c} x = c.$$

Pick any $\epsilon > 0$, then take $\delta = \epsilon$. Thus,

$$|f(x) - c| = |x - c| < \epsilon \quad \text{for all} \quad |x - c| < \delta = \epsilon.$$

82. Since $f(x) = x$ is continuous, Theorem 1.3 on page 64 shows that products of the form $f(x) \cdot f(x) = x^2$ and $f(x) \cdot x^2 = x^3$, etc., are continuous. By a similar argument, x^n is continuous for any $n > 0$.

83. If c is in the interval, we know $\lim_{x\to c} f(x) = f(c)$ and $\lim_{x\to c} g(x) = g(c)$. Then,

$$\begin{aligned}\lim_{x\to c} (f(x) + g(x)) &= \lim_{x\to c} f(x) + \lim_{x\to c} g(x) \quad \text{by limit property 2}\\ &= f(c) + g(c), \quad \text{so } f + g \text{ is continuous at } x = c.\end{aligned}$$

Also,

$$\begin{aligned}\lim_{x\to c} (f(x)g(x)) &= \lim_{x\to c} f(x) \lim_{x\to c} g(x) \quad \text{by limit property 3}\\ &= f(c)g(c) \quad \text{so } fg \text{ is continuous at } x = c.\end{aligned}$$

Finally,

$$\begin{aligned}\lim_{x\to c} \frac{f(x)}{g(x)} &= \frac{\lim_{x\to c} f(x)}{\lim_{x\to c} g(x)} \quad \text{by limit property 4}\\ &= \frac{f(c)}{g(c)}, \quad \text{so } \frac{f}{g} \text{ is continuous at } x = c.\end{aligned}$$

Strengthen Your Understanding

84. Though $P(x)$ and $Q(x)$ are both continuous for all x, it is possible for $Q(x)$ to be equal to zero for some x. For any such value of x, where $Q(x) = 0$, we see that $P(x)/Q(x)$ is undefined, and thus not continuous. For example,

$$\frac{P(x)}{Q(x)} = \frac{x}{x-1}$$

is not defined or continuous at $x = 1$.

85. The left- and right-hand limits are not the same:

$$\lim_{x\to 1^-} \frac{x-1}{|x-1|} = -1,$$

but

$$\lim_{x\to 1^+} \frac{x-1}{|x-1|} = 1.$$

Since the left- and right-hand limits are not the same, the limit does not exist and thus is not equal to 1.

86. For f to be continuous at $x = c$, we need $\lim_{x\to c} f(x)$ to exist and to be equal to $f(c)$.

87. One possibility is

$$f(x) = \frac{(x+3)(x-1)}{x-1}.$$

We have $\lim_{x\to 1} f(x) = 4$ but $f(1)$ is undefined.

88. One example is

$$f(x) = \frac{2|x|}{x}.$$

89. True, by Property 3 of limits in Theorem 1.2, since $\lim_{x\to 3} x = 3$.

90. False. If $\lim_{x\to 3} g(x)$ does not exist, then $\lim_{x\to 3} f(x)g(x)$ may not even exist. For example, let $f(x) = 2x + 1$ and define g by:

$$g(x) = \begin{cases} 1/(x-3) & \text{if } x \neq 3 \\ 4 & \text{if } x = 3 \end{cases}$$

Then $\lim_{x\to 3} f(x) = 7$ and $g(3) = 4$, but $\lim_{x\to 3} f(x)g(x) \neq 28$, since $\lim_{x\to 3}(2x+1)/(x-3)$ does not exist.

91. True, by Property 2 of limits in Theorem 1.2.

92. True, by Properties 2 and 3 of limits in Theorem 1.2.

$$\lim_{x\to 3} g(x) = \lim_{x\to 3}(f(x) + g(x) + (-1)f(x)) = \lim_{x\to 3}(f(x) + g(x)) + (-1)\lim_{x\to 3} f(x) = 12 + (-1)7 = 5.$$

93. False. For example, define f as follows:

$$f(x) = \begin{cases} 2x+1 & \text{if } x \neq 2.99 \\ 1000 & \text{if } x = 2.99. \end{cases}$$

Then $f(2.9) = 2(2.9) + 1 = 6.8$, whereas $f(2.99) = 1000$.

94. False. For example, define f as follows:

$$f(x) = \begin{cases} 2x+1 & \text{if } x \neq 3.01 \\ -1000 & \text{if } x = 3.01. \end{cases}$$

Then $f(3.1) = 2(3.1) + 1 = 7.2$, whereas $f(3.01) = -1000$.

95. True. Suppose instead that $\lim_{x\to 3} g(x)$ does not exist but $\lim_{x\to 3}(f(x)g(x))$ did exist. Since $\lim_{x\to 3} f(x)$ exists and is not zero, then $\lim_{x\to 3}((f(x)g(x))/f(x))$ exists, by Property 4 of limits in Theorem 1.2. Furthermore, $f(x) \neq 0$ for all x in some interval about 3, so $(f(x)g(x))/f(x) = g(x)$ for all x in that interval. Thus $\lim_{x\to 3} g(x)$ exists. This contradicts our assumption that $\lim_{x\to 3} g(x)$ does not exist.

96. False. For some functions we need to pick smaller values of δ. For example, if $f(x) = x^{1/3} + 2$ and $c = 0$ and $L = 2$, then $f(x)$ is within 10^{-3} of 2 if $|x^{1/3}| < 10^{-3}$. This only happens if x is within $(10^{-3})^3 = 10^{-9}$ of 0. If $x = 10^{-3}$ then $x^{1/3} = (10^{-3})^{1/3} = 10^{-1}$, which is too large.

97. False. The definition of a limit guarantees that, for any positive ϵ, there is a δ. This statement, which guarantees an ϵ for a specific $\delta = 10^{-3}$, is not equivalent to $\lim_{x\to c} f(x) = L$. For example, consider a function with a vertical asymptote within 10^{-3} of 0, such as $c = 0$, $L = 0$, $f(x) = x/(x - 10^{-4})$.

98. True. This is equivalent to the definition of a limit.

99. False. Although x may be far from c, the value of $f(x)$ could be close to L. For example, suppose $f(x) = L$, the constant function.

100. False. The definition of the limit says that if x is within δ of c, then $f(x)$ is within ϵ of L, not the other way round.

101. (a) This statement follows: if we interchange the roles of f and g in the original statement, we get this statement.
(b) This statement is true, but it does not follow directly from the original statement, which says nothing about the case $g(a) = 0$.
(c) This follows, since if $g(a) \neq 0$ the original statement would imply f/g is continuous at $x = a$, but we are told it is not.
(d) This does not follow. Given that f is continuous at $x = a$ and $g(a) \neq 0$, then the original statement says g continuous implies f/g continuous, not the other way around. In fact, statement (d) is not true: if $f(x) = 0$ for all x, then g could be any discontinuous, non-zero function, and f/g would be zero, and therefore continuous. Thus the conditions of the statement would be satisfied, but not the conclusion.

Solutions for Chapter 1 Review

Exercises

1. The line of slope m through the point (x_0, y_0) has equation

$$y - y_0 = m(x - x_0),$$

so the line we want is

$$\begin{aligned} y - 0 &= 2(x - 5) \\ y &= 2x - 10. \end{aligned}$$

2. We want a function of the form $y = a(x-h)^2 + k$, with $a < 0$ because the parabola opens downward. Since (h, k) is the vertex, we must take $h = 2$, $k = 5$, but we can take any negative value of a. Figure 1.110 shows the graph with $a = -1$, namely $y = -(x-2)^2 + 5$.

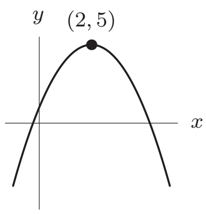

Figure 1.110: Graph of $y = -(x-2)^2 + 5$

3. A parabola with x-intercepts ± 1 has an equation of the form

$$y = k(x-1)(x+1).$$

Substituting the point $x = 0, y = 3$ gives

$$3 = k(-1)(1) \quad \text{so} \quad k = -3.$$

Thus, the equation we want is

$$\begin{aligned} y &= -3(x-1)(x+1) \\ y &= -3x^2 + 3. \end{aligned}$$

4. The equation of the whole circle is

$$x^2 + y^2 = (\sqrt{2})^2,$$

so the bottom half is

$$y = -\sqrt{2 - x^2}.$$

5. A circle with center (h, k) and radius r has equation $(x-h)^2 + (y-k)^2 = r^2$. Thus $h = -1$, $k = 2$, and $r = 3$, giving

$$(x+1)^2 + (y-2)^2 = 9.$$

Solving for y, and taking the positive square root gives the top half, so

$$\begin{aligned} (y-2)^2 &= 9 - (x+1)^2 \\ y &= 2 + \sqrt{9 - (x+1)^2}. \end{aligned}$$

See Figure 1.111.

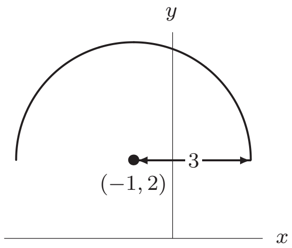

Figure 1.111: Graph of $y = 2 + \sqrt{9 - (x+1)^2}$

6. A cubic polynomial of the form $y = a(x-1)(x-5)(x-7)$ has the correct intercepts for any value of $a \neq 0$. Figure 1.112 shows the graph with $a = 1$, namely $y = (x-1)(x-5)(x-7)$.

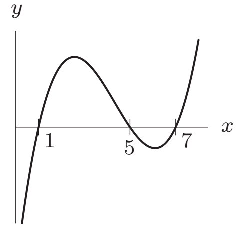

Figure 1.112: Graph of $y = (x-1)(x-5)(x-7)$

7. Since the vertical asymptote is $x = 2$, we have $b = -2$. The fact that the horizontal asymptote is $y = -5$ gives $a = -5$. So

$$y = \frac{-5x}{x-2}.$$

8. The amplitude of this function is 5, and its period is 2π, so $y = 5\cos x$.

9. See Figure 1.113.

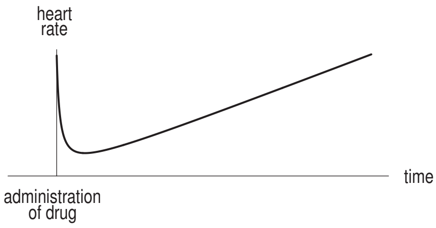

Figure 1.113

10. Factoring gives

$$g(x) = \frac{(2-x)(2+x)}{x(x+1)}.$$

The values of x which make $g(x)$ undefined are $x = 0$ and $x = -1$, when the denominator is 0. So the domain is all $x \neq 0, -1$. Solving $g(x) = 0$ means one of the numerator's factors is 0, so $x = \pm 2$.

11. (a) The domain of f is the set of values of x for which the function is defined. Since the function is defined by the graph and the graph goes from $x = 0$ to $x = 7$, the domain of f is $[0, 7]$.

(b) The range of f is the set of values of y attainable over the domain. Looking at the graph, we can see that y gets as high as 5 and as low as -2, so the range is $[-2, 5]$.

(c) Only at $x = 5$ does $f(x) = 0$. So 5 is the only zero of $f(x)$.

(d) Looking at the graph, we can see that $f(x)$ is decreasing on $(1, 7)$.

(e) The graph indicates that $f(x)$ is concave up at $x = 6$.

(f) The value $f(4)$ is the y-value that corresponds to $x = 4$. From the graph, we can see that $f(4)$ is approximately 1.

(g) This function is not invertible, since it fails the horizontal-line test. A horizontal line at $y = 3$ would cut the graph of $f(x)$ in two places, instead of the required one.

12. (a) $f(n) + g(n) = (3n^2 - 2) + (n + 1) = 3n^2 + n - 1$.
(b) $f(n)g(n) = (3n^2 - 2)(n + 1) = 3n^3 + 3n^2 - 2n - 2$.
(c) The domain of $f(n)/g(n)$ is defined everywhere where $g(n) \neq 0$, i.e. for all $n \neq -1$.
(d) $f(g(n)) = 3(n + 1)^2 - 2 = 3n^2 + 6n + 1$.
(e) $g(f(n)) = (3n^2 - 2) + 1 = 3n^2 - 1$.

13. (a) Since $m = f(A)$, we see that $f(100)$ represents the value of m when $A = 100$. Thus $f(100)$ is the minimum annual gross income needed (in thousands) to take out a 30-year mortgage loan of \$100,000 at an interest rate of 6%.
(b) Since $m = f(A)$, we have $A = f^{-1}(m)$. We see that $f^{-1}(75)$ represents the value of A when $m = 75$, or the size of a mortgage loan that could be obtained on an income of \$75,000.

14. Taking logs of both sides yields $t \log 5 = \log 7$, so $t = \dfrac{\log 7}{\log 5} = 1.209$.

15. $t = \dfrac{\log 2}{\log 1.02} \approx 35.003$.

16. Collecting similar factors yields $\left(\frac{3}{2}\right)^t = \frac{5}{7}$, so

$$t = \frac{\log\left(\frac{5}{7}\right)}{\log\left(\frac{3}{2}\right)} = -0.830.$$

17. Collecting similar factors yields $\left(\frac{1.04}{1.03}\right)^t = \frac{12.01}{5.02}$. Solving for t yields

$$t = \frac{\log\left(\frac{12.01}{5.02}\right)}{\log\left(\frac{1.04}{1.03}\right)} = 90.283.$$

18. We want $2^t = e^{kt}$ so $2 = e^k$ and $k = \ln 2 = 0.693$. Thus $P = P_0 e^{0.693t}$.

19. We want $0.2^t = e^{kt}$ so $0.2 = e^k$ and $k = \ln 0.2 = -1.6094$. Thus $P = 5.23e^{-1.6094t}$.

20. $f(x) = \ln x, \quad g(x) = x^3$. (Another possibility: $f(x) = 3x, \quad g(x) = \ln x$.)

21. $f(x) = x^3, \quad g(x) = \ln x$.

22. The amplitude is 5. The period is 6π. See Figure 1.114.

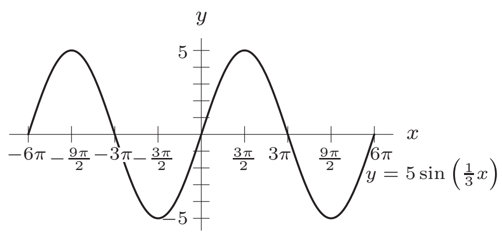

Figure 1.114

23. The amplitude is 2. The period is $2\pi/5$. See Figure 1.115.

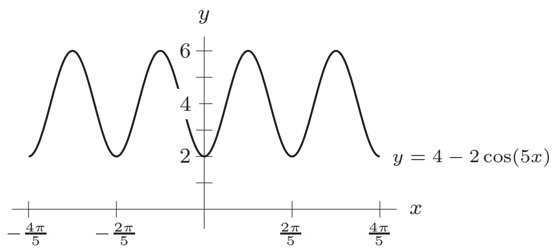

Figure 1.115

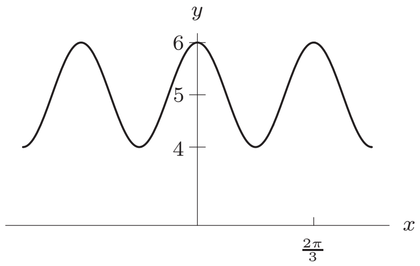
24. (a) We determine the amplitude of y by looking at the coefficient of the cosine term. Here, the coefficient is 1, so the amplitude of y is 1. Note that the constant term does not affect the amplitude.
(b) We know that the cosine function $\cos x$ repeats itself at $x = 2\pi$, so the function $\cos(3x)$ must repeat itself when $3x = 2\pi$, or at $x = 2\pi/3$. So the period of y is $2\pi/3$. Here as well the constant term has no effect.
(c) The graph of y is shown in the figure below.



25. (a) Since $f(x)$ is an odd polynomial with a positive leading coefficient, it follows that $f(x) \to \infty$ as $x \to \infty$ and $f(x) \to -\infty$ as $x \to -\infty$.
(b) Since $f(x)$ is an even polynomial with negative leading coefficient, it follows that $f(x) \to -\infty$ as $x \to \pm\infty$.
(c) As $x \to \pm\infty$, $x^4 \to \infty$, so $x^{-4} = 1/x^4 \to 0$.
(d) As $x \to \pm\infty$, the lower-degree terms of $f(x)$ become insignificant, and $f(x)$ becomes approximated by the highest degree terms in its numerator and denominator. So as $x \to \pm\infty$, $f(x) \to 6$.

26. Exponential growth dominates power growth as $x \to \infty$, so $10 \cdot 2^x$ is larger.

27. As $x \to \infty$, $0.25x^{1/2}$ is larger than $25{,}000x^{-3}$.

28. This is a line with slope $-3/7$ and y-intercept 3, so a possible formula is

$$y = -\frac{3}{7}x + 3.$$

29. Starting with the general exponential equation $y = Ae^{kx}$, we first find that for $(0, 1)$ to be on the graph, we must have $A = 1$. Then to make $(3, 4)$ lie on the graph, we require

$$\begin{aligned} 4 &= e^{3k} \\ \ln 4 &= 3k \\ k &= \frac{\ln 4}{3} \approx 0.4621. \end{aligned}$$

Thus the equation is

$$y = e^{0.4621x}.$$

Alternatively, we can use the form $y = a^x$, in which case we find $y = (1.5874)^x$.

30. This looks like an exponential function. The y-intercept is 3 and we use the form $y = 3e^{kt}$. We substitute the point $(5, 9)$ to solve for k:

$$\begin{aligned} 9 &= 3e^{k5} \\ 3 &= e^{5k} \\ \ln 3 &= 5k \\ k &= 0.2197. \end{aligned}$$

A possible formula is

$$y = 3e^{0.2197t}.$$

Alternatively, we can use the form $y = 3a^t$, in which case we find $y = 3(1.2457)^t$.

31. $y = -kx(x+5) = -k(x^2+5x)$, where $k > 0$ is any constant.

32. Since this function has a y-intercept at $(0,2)$, we expect it to have the form $y = 2e^{kx}$. Again, we find k by forcing the other point to lie on the graph:

$$\begin{aligned} 1 &= 2e^{2k} \\ \frac{1}{2} &= e^{2k} \\ \ln\left(\frac{1}{2}\right) &= 2k \\ k &= \frac{\ln(\frac{1}{2})}{2} \approx -0.34657. \end{aligned}$$

This value is negative, which makes sense since the graph shows exponential decay. The final equation, then, is

$$y = 2e^{-0.34657x}.$$

Alternatively, we can use the form $y = 2a^x$, in which case we find $y = 2(0.707)^x$.

33. $z = 1 - \cos\theta$

34. $y = k(x+2)(x+1)(x-1) = k(x^3+2x^2-x-2)$, where $k > 0$ is any constant.

35. $x = ky(y-4) = k(y^2-4y)$, where $k > 0$ is any constant.

36. $y = 5\sin\left(\frac{\pi t}{20}\right)$

37. This looks like a fourth degree polynomial with roots at -5 and -1 and a double root at 3. The leading coefficient is negative, and so a possible formula is

$$y = -(x+5)(x+1)(x-3)^2.$$

38. This looks like a rational function. There are vertical asymptotes at $x = -2$ and $x = 2$ and so one possibility for the denominator is $x^2 - 4$. There is a horizontal asymptote at $y = 3$ and so the numerator might be $3x^2$. In addition, $y(0) = 0$ which is the case with the numerator of $3x^2$. A possible formula is

$$y = \frac{3x^2}{x^2-4}.$$

39. There are many solutions for a graph like this one. The simplest is $y = 1 - e^{-x}$, which gives the graph of $y = e^x$, flipped over the x-axis and moved up by 1. The resulting graph passes through the origin and approaches $y = 1$ as an upper bound, the two features of the given graph.

40. The graph is a sine curve which has been shifted up by 2, so $f(x) = (\sin x) + 2$.

41. This graph has period 5, amplitude 1 and no vertical shift or horizontal shift from $\sin x$, so it is given by

$$f(x) = \sin\left(\frac{2\pi}{5}x\right).$$

42. Since the denominator, x^2+1, is continuous and never zero, $g(x)$ is continuous on $[-1,1]$.

43. Since

$$h(x) = \frac{1}{1-x^2} = \frac{1}{(1-x)(1+x)},$$

we see that $h(x)$ is not defined at $x = -1$ or at $x = 1$, so $h(x)$ is not continuous on $[-1,1]$.

44. (a) $\lim_{x\to 0} f(x) = 1$.
(b) $\lim_{x\to 1} f(x)$ does not exist.
(c) $\lim_{x\to 2} f(x) = 1$.
(d) $\lim_{x\to 3^-} f(x) = 0$.

45. $f(x) = \dfrac{x^3|2x-6|}{x-3} = \begin{cases} \dfrac{x^3(2x-6)}{x-3} = 2x^3, & x > 3 \\ \dfrac{x^3(-2x+6)}{x-3} = -2x^3, & x < 3 \end{cases}$

Figure 1.116 confirms that $\lim_{x\to 3^+} f(x) = 54$ while $\lim_{x\to 3^-} f(x) = -54$; thus $\lim_{x\to 3} f(x)$ does not exist.

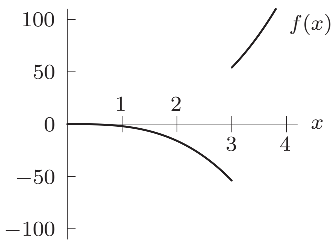


Figure 1.116

46. $f(x) = \begin{cases} e^x & -1 < x < 0 \\ 1 & x = 0 \\ \cos x & 0 < x < 1 \end{cases}$

Figure 1.117 confirms that $\lim_{x\to 0^-} f(x) = \lim_{x\to 0^-} e^x = e^0 = 1$, and that $\lim_{x\to 0+} f(x) = \lim_{x\to 0+} \cos x = \cos 0 = 1$, so $\lim_{x\to 0} f(x) = 1$.

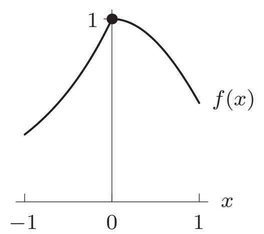

Figure 1.117

Problems

47. (a) More fertilizer increases the yield until about 40 lbs.; then it is too much and ruins crops, lowering yield.
(b) The vertical intercept is at $Y = 200$. If there is no fertilizer, then the yield is 200 bushels.
(c) The horizontal intercept is at $a = 80$. If you use 80 lbs. of fertilizer, then you will grow no apples at all.
(d) The range is the set of values of Y attainable over the domain $0 \le a \le 80$. Looking at the graph, we can see that Y goes as high as 550 and as low as 0. So the range is $0 \le Y \le 550$.
(e) Looking at the graph, we can see that Y is decreasing at $a = 60$.
(f) Looking at the graph, we can see that Y is concave down everywhere, so it is certainly concave down at $a = 40$.

48. (a) Given the two points $(0, 32)$ and $(100, 212)$, and assuming the graph in Figure 1.118 is a line,

$$\text{Slope} = \frac{212-32}{100} = \frac{180}{100} = 1.8.$$

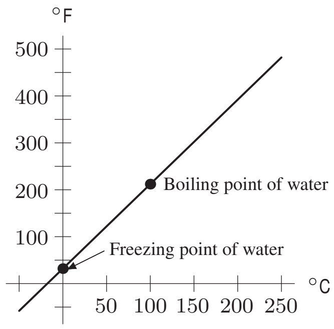

Figure 1.118

(b) The °F-intercept is $(0, 32)$, so

$$°\text{F} = 1.8(°\text{C}) + 32.$$

(c) If the temperature is 20°Celsius, then

$$°\text{F} = 1.8(20) + 32 = 68°\text{F}.$$

(d) If °F = °C, then

$$\begin{aligned} °\text{C} &= 1.8°\text{C} + 32 \\ -32 &= 0.8°\text{C} \\ °\text{C} &= -40° = °\text{F}. \end{aligned}$$

49. (a) We have the following functions.

(i) Since a change in p of \$5 results in a decrease in q of 2, the slope of $q = D(p)$ is $-2/5$ items per dollar. So

$$q = b - \frac{2}{5}p.$$

Now we know that when $p = 550$ we have $q = 100$, so

$$\begin{aligned} 100 &= b - \frac{2}{5} \cdot 550 \\ 100 &= b - 220 \\ b &= 320. \end{aligned}$$

Thus a formula is

$$q = 320 - \frac{2}{5}p.$$

(ii) We can solve $q = 320 - \frac{2}{5}p$ for p in terms of q:

$$\begin{aligned} 5q &= 1600 - 2p \\ 2p &= 1600 - 5q \\ p &= 800 - \frac{5}{2}q. \end{aligned}$$

The slope of this function is $-5/2$ dollars per item, as we would expect.

(b) A graph of $p = 800 - \dfrac{5}{2}q$ is given in Figure 1.119.

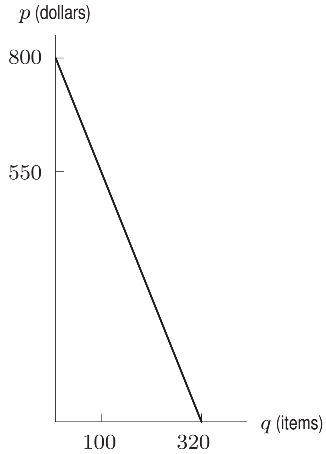

Figure 1.119

50. See Figure 1.120.

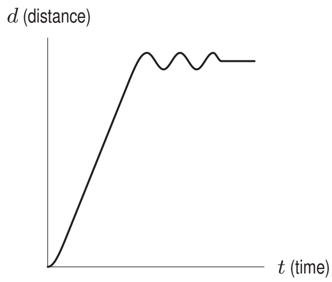

Figure 1.120

51. (a) (i) If the atoms are moved farther apart, then $r > a$ so, from the graph, F is negative, indicating an attractive force, which pulls the atoms back together.

(ii) If the atoms are moved closer together, then $r < a$ so, from the graph, F is positive, indicating an attractive force, which pushes the atoms apart again.

(b) At $r = a$, the force is zero. The answer to part (a)(i) tells us that if the atoms are pulled apart slightly, so $r > a$, the force tends to pull them back together; the answer to part (a)(ii) tells us that if the atoms are pushed together, so $r < a$, the force tends to push them back apart. Thus, $r = a$ is a stable equilibrium.

52. If the pressure at sea level is P_0, the pressure P at altitude h is given by

$$P = P_0\left(1 - \frac{0.4}{100}\right)^{h/100},$$

since we want the pressure to be multiplied by a factor of $(1 - 0.4/100) = 0.996$ for each 100 feet we go up to make it decrease by 0.4% over that interval. At Mexico City $h = 7340$, so the pressure is

$$P = P_0(0.996)^{7340/100} \approx 0.745P_0.$$

So the pressure is reduced from P_0 to approximately $0.745P_0$, a decrease of 25.5%.

53. Assuming the population of Ukraine is declining exponentially, we have population $P(t) = 45.7e^{kt}$ at time t years after 2009. Using the 2010 population, we have

$$\begin{aligned} 45.42 &= 45.7e^{-k\cdot 1} \\ k &= -\ln\left(\frac{45.42}{45.7}\right) = 0.0061. \end{aligned}$$

We want to find the time t at which

$$45 = 45.7e^{-0.0061t}$$
$$t = -\frac{\ln(45/45.7)}{0.0061} = 2.53 \text{ years.}$$

This model predicts the population to go below 45 million 2.53 years after 2009, in the year 2011.

54. (a) We compound the daily inflation rate 30 times to get the desired monthly rate r:

$$\left(1+\frac{r}{100}\right)^1 = \left(1+\frac{0.67}{100}\right)^{30} = 1.2218.$$

Solving for r, we get $r = 22.18$, so the inflation rate for April was 22.18%.

(b) We compound the daily inflation rate 365 times to get a yearly rate R for 2006:

$$\left(1+\frac{R}{100}\right)^1 = \left(1+\frac{0.67}{100}\right)^{365} = 11.4426.$$

Solving for R, we get $R = 1044.26$, so the yearly rate was 1044.26% during 2006. We could have obtained approximately the same result by compounding the monthly rate 12 times. Computing the annual rate from the monthly gives a lower result, because 12 months of 30 days each is only 360 days.

55. (a) The US consumption of hydroelectric power increased by at least 10% in 2009 and decreased by at least 10% in 2006 and in 2007, relative to each corresponding previous year. In 2009 consumption increased by 11% over consumption in 2008. In 2006 consumption decreased by 10% over consumption in 2005, and in 2007 consumption decreased by about 45% over consumption in 2006.

(b) False. In 2009 hydroelectric power consumption increased only by 11% over consumption in 2008.

(c) True. From 2006 to 2007 consumption decreased by 45.4%, which means $x(1 - 0.454)$ units of hydroelectric power were consumed in 2007 if x had been consumed in 2006. Similarly,

$$(x(1-0.454))(1+0.051)$$

units of hydroelectric power were consumed in 2008 if x had been consumed in 2006, and

$$(x(1-0.454)(1+0.051))(1+0.11)$$

units of hydroelectric power were consumed in 2009 if x had been consumed in 2006. Since

$$x(1-0.454)(1+0.051)(1+0.11) = x(0.637) = x(1-0.363),$$

the percent growth in hydroelectric power consumption was -36.3%, in 2009 relative to consumption in 2006. This amounts to about 36% decrease in hydroelectric power consumption from 2006 to 2009.

56. (a) For each 2.2 pounds of weight the object has, it has 1 kilogram of mass, so the conversion formula is

$$k = f(p) = \frac{1}{2.2}p.$$

(b) The inverse function is

$$p = 2.2k,$$

and it gives the weight of an object in pounds as a function of its mass in kilograms.

57. Since $f(x)$ is a parabola that opens upward, we have $f(x) = ax^2 + bx + c$ with $a > 0$. Since $g(x)$ is a line with negative slope, $g(x) = b + mx$, with slope $m < 0$. Therefore

$$g(f(x)) = b + m(ax^2 + bx + c) = max^2 + mbx + mc + b.$$

The coefficient of x^2 is ma, which is negative. Thus, the graph is a parabola opening downward.

58. (a) is $g(x)$ since it is linear. (b) is $f(x)$ since it has decreasing slope; the slope starts out about 1 and then decreases to about $\frac{1}{10}$. (c) is $h(x)$ since it has increasing slope; the slope starts out about $\frac{1}{10}$ and then increases to about 1.

59. Given the doubling time of 2 hours, $200 = 100e^{k(2)}$, we can solve for the growth rate k using the equation:

$$2P_0 = P_0e^{2k}$$
$$\ln 2 = 2k$$
$$k = \frac{\ln 2}{2}.$$

Using the growth rate, we wish to solve for the time t in the formula

$$P = 100e^{\frac{\ln 2}{2}t}$$

where $P = 3{,}200$, so

$$\begin{aligned} 3{,}200 &= 100e^{\frac{\ln 2}{2}t} \\ t &= 10 \text{ hours}. \end{aligned}$$

60. (a) The y-intercept of $f(x) = a\ln(x+2)$ is $f(0) = a\ln 2$. Since $\ln 2$ is positive, increasing a increases the y-intercept.
(b) The x-intercept of $f(x) = a\ln(x+2)$ is where $f(x) = 0$. Since this occurs where $x+2 = 1$, so $x = -1$, increasing a does not affect the x-intercept.

61. Since the factor by which the prices have increased after time t is given by $(1.05)^t$, the time after which the prices have doubled solves

$$\begin{aligned} 2 &= (1.05)^t \\ \log 2 &= \log(1.05^t) = t\log(1.05) \\ t &= \frac{\log 2}{\log 1.05} \approx 14.21 \text{ years}. \end{aligned}$$

62. Using the exponential decay equation $P = P_0e^{-kt}$, we can solve for the substance's decay constant k:

$$\begin{aligned} (P_0 - 0.3P_0) &= P_0e^{-20k} \\ k &= \frac{\ln(0.7)}{-20}. \end{aligned}$$

Knowing this decay constant, we can solve for the half-life t using the formula

$$\begin{aligned} 0.5P_0 &= P_0e^{\ln(0.7)t/20} \\ t &= \frac{20\ln(0.5)}{\ln(0.7)} \approx 38.87 \text{ hours}. \end{aligned}$$

63. (a) We know the decay follows the equation

$$P = P_0e^{-kt},$$

and that 10% of the pollution is removed after 5 hours (meaning that 90% is left). Therefore,

$$\begin{aligned} 0.90P_0 &= P_0e^{-5k} \\ k &= -\frac{1}{5}\ln(0.90). \end{aligned}$$

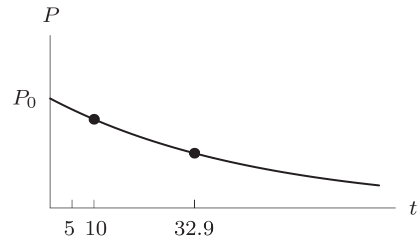
Thus, after 10 hours:

$$\begin{aligned} P &= P_0e^{-10((-0.2)\ln 0.90)} \\ P &= P_0(0.9)^2 = 0.81P_0 \end{aligned}$$

so 81% of the original amount is left.
(b) We want to solve for the time when $P = 0.50P_0$:

$$\begin{aligned} 0.50P_0 &= P_0e^{t((0.2)\ln 0.90)} \\ 0.50 &= e^{\ln(0.90^{0.2t})} \\ 0.50 &= 0.90^{0.2t} \\ t &= \frac{5\ln(0.50)}{\ln(0.90)} \approx 32.9 \text{ hours}. \end{aligned}$$

(c)



(d) When highly polluted air is filtered, there is more pollutant per liter of air to remove. If a fixed amount of air is cleaned every day, there is a higher amount of pollutant removed earlier in the process.

64. Since the amount of strontium-90 remaining halves every 29 years, we can solve for the decay constant;

$$0.5P_0 = P_0e^{-29k}$$
$$k = \frac{\ln(1/2)}{-29}.$$

Knowing this, we can look for the time t in which $P = 0.10P_0$, or

$$0.10P_0 = P_0e^{\ln(0.5)t/29}$$
$$t = \frac{29\ln(0.10)}{\ln(0.5)} = 96.336 \text{ years.}$$

65. One hour.

66. (a) V_0 represents the maximum voltage.
(b) The period is $2\pi/(120\pi) = 1/60$ second.
(c) Since each oscillation takes $1/60$ second, in 1 second there are 60 complete oscillations.

67. The US voltage has a maximum value of 156 volts and has a period of $1/60$ of a second, so it executes 60 cycles a second.
The European voltage has a higher maximum of 339 volts, and a slightly longer period of $1/50$ seconds, so it oscillates at 50 cycles per second.

68. (a) The amplitude of the sine curve is $|A|$. Thus, increasing $|A|$ stretches the curve vertically. See Figure 1.121.
(b) The period of the wave is $2\pi/|B|$. Thus, increasing $|B|$ makes the curve oscillate more rapidly—in other words, the function executes one complete oscillation in a smaller interval. See Figure 1.122.

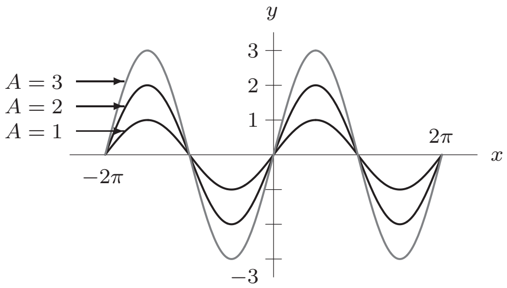


Figure 1.121

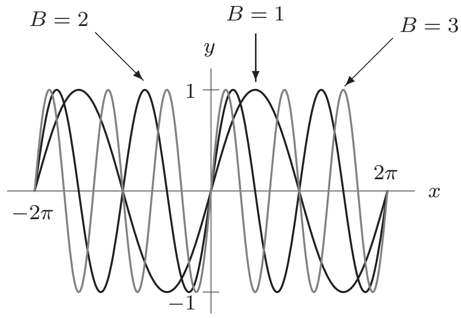

Figure 1.122

69. (a) (i) The water that has flowed out of the pipe in 1 second is a cylinder of radius r and length 3 cm. Its volume is

$$V = \pi r^2(3) = 3\pi r^2.$$

(ii) If the rate of flow is k cm/sec instead of 3 cm/sec, the volume is given by

$$V = \pi r^2(k) = \pi r^2 k.$$

(b) (i) The graph of V as a function of r is a quadratic. See Figure 1.123.

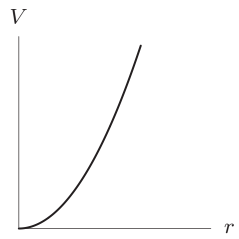

Figure 1.123

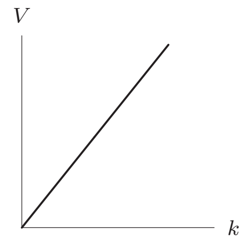

Figure 1.124

(ii) The graph of V as a function of k is a line. See Figure 1.124.

70. Looking at g, we see that the ratio of the values is:

$$\frac{3.12}{3.74} \approx \frac{3.74}{4.49} \approx \frac{4.49}{5.39} \approx \frac{5.39}{6.47} \approx \frac{6.47}{7.76} \approx 0.83.$$

Thus g is an exponential function, and so f and k are the power functions. Each is of the form ax^2 or ax^3, and since $k(1.0) = 9.01$ we see that for k, the constant coefficient is 9.01. Trial and error gives

$$k(x) = 9.01x^2,$$

since $k(2.2) = 43.61 \approx 9.01(4.84) = 9.01(2.2)^2$. Thus $f(x) = ax^3$ and we find a by noting that $f(9) = 7.29 = a(9^3)$ so

$$a = \frac{7.29}{9^3} = 0.01$$

and $f(x) = 0.01x^3$.

71. (a) See Figure 1.125.

(b) The graph is made of straight line segments, rising from the x-axis at the origin to height a at $x = 1$, b at $x = 2$, and c at $x = 3$ and then returning to the x-axis at $x = 4$. See Figure 1.126.

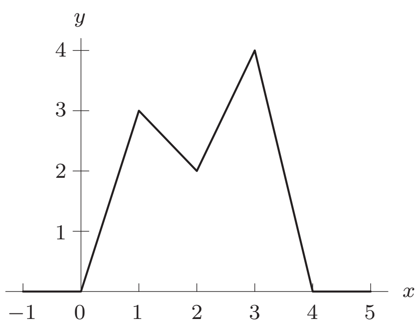

Figure 1.125

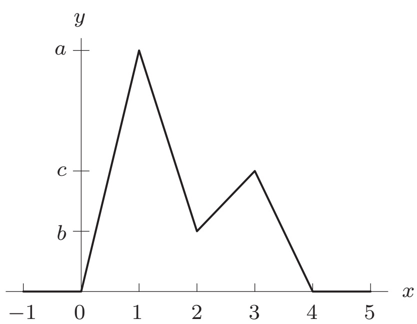

Figure 1.126

72. (a) Reading the graph of θ against t shows that $\theta \approx 5.2$ when $t = 1.5$. Since the coordinates of P are $x = 5\cos\theta$, $y = 5\sin\theta$, when $t = 1.5$ the coordinates are

$$(x, y) \approx (5\cos 5.2, 5\sin 5.2) = (2.3, -4.4).$$

(b) As t increases from 0 to 5, the angle θ increases from 0 to about 6.3 and then decreases to 0 again. Since $6.3 \approx 2\pi$, this means that P starts on the x-axis at the point $(5, 0)$, moves counterclockwise the whole way around the circle (at which time $\theta \approx 2\pi$), and then moves back clockwise to its starting point.

73. (a) III
(b) IV
(c) I
(d) II

74. The functions $y(x) = \sin x$ and $z_k(x) = ke^{-x}$ for $k = 1, 2, 4, 6, 8, 10$ are shown in Figure 1.127. The values of $f(k)$ for $k = 1, 2, 4, 6, 8, 10$ are given in Table 1.16. These values can be obtained using either tracing or a numerical root finder on a calculator or computer.

From Figure 1.127 it is clear that the smallest solution of $\sin x = ke^{-x}$ for $k = 1, 2, 4, 6$ occurs on the first period of the sine curve. For small changes in k, there are correspondingly small changes in the intersection point. For $k = 8$ and $k = 10$, the solution jumps to the second period because $\sin x < 0$ between π and 2π, but ke^{-x} is uniformly positive. Somewhere in the interval $6 \le k \le 8$, $f(k)$ has a discontinuity.

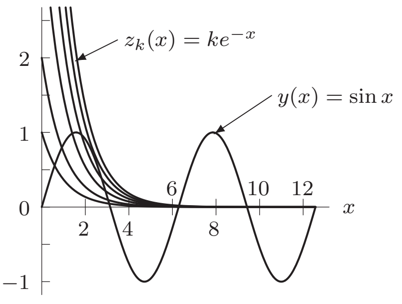

Figure 1.127

Table 1.16

k	$f(k)$
1	0.588
2	0.921
4	1.401
6	1.824
8	6.298
10	6.302

75. By tracing on a calculator or solving equations, we find the following values of δ:
For $\epsilon = 0.1$, $\delta \le 0.1$
For $\epsilon = 0.05$, $\delta \le 0.05$.
For $\epsilon = 0.0007$, $\delta \le 0.00007$.

76. By tracing on a calculator or solving equations, we find the following values of δ:
For $\epsilon = 0.1$, $\delta \le 0.45$.
For $\epsilon = 0.001$, $\delta \le 0.0447$.
For $\epsilon = 0.00001$, $\delta \le 0.00447$.

77. For any values of k, the function is continuous on any interval that does not contain $x = 2$.

Since $5x^3 - 10x^2 = 5x^2(x-2)$, we can cancel $(x-2)$ provided $x \ne 2$, giving

$$f(x) = \frac{5x^3 - 10x^2}{x-2} = 5x^2 \qquad x \ne 2.$$

Thus, if we pick $k = 5(2)^2 = 20$, the function is continuous.

78. At $x = 0$, the curve $y = k\cos x$ has $y = k\cos 0 = k$. At $x = 0$, the curve $y = e^x - k$ has $y = e^0 - k = 1 - k$. If $j(x)$ is continuous, we need

$$k = 1 - k, \quad \text{so} \quad k = \frac{1}{2}.$$

CAS Challenge Problems

79. (a) A CAS gives $f(x) = (x-a)(x+a)(x+b)(x-c)$.
(b) The graph of $f(x)$ crosses the x-axis at $x = a$, $x = -a$, $x = -b$, $x = c$; it crosses the y-axis at a^2bc. Since the coefficient of x^4 (namely 1) is positive, the graph of f looks like that shown in Figure 1.128.

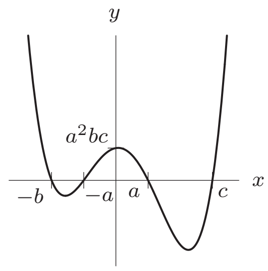

Figure 1.128: Graph of $f(x) = (x-a)(x+a)(x+b)(x-c)$

80. (a) A CAS gives $f(x) = -(x-1)^2(x-3)^3$.

(b) For large $|x|$, the graph of $f(x)$ looks like the graph of $y = -x^5$, so $f(x) \to \infty$ as $x \to -\infty$ and $f(x) \to -\infty$ as $x \to \infty$. The answer to part (a) shows that f has a double root at $x = 1$, so near $x = 1$, the graph of f looks like a parabola touching the x-axis at $x = 1$. Similarly, f has a triple root at $x = 3$. Near $x = 3$, the graph of f looks like the graph of $y = x^3$, flipped over the x-axis and shifted to the right by 3, so that the "seat" is at $x = 3$. See Figure 1.129.

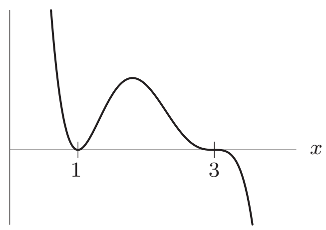

Figure 1.129: Graph of $f(x) = -(x-1)^2(x-3)^3$

81. (a) As $x \to \infty$, the term e^{6x} dominates and tends to ∞. Thus, $f(x) \to \infty$ as $x \to \infty$.
As $x \to -\infty$, the terms of the form e^{kx}, where $k = 6, 5, 4, 3, 2, 1$, all tend to zero. Thus, $f(x) \to 16$ as $x \to -\infty$.

(b) A CAS gives

$$f(x) = (e^x + 1)(e^{2x} - 2)(e^x - 2)(e^{2x} + 2e^x + 4).$$

Since e^x is always positive, the factors $(e^x + 1)$ and $(e^{2x} + 2e^x + 4)$ are never zero. The other factors each lead to a zero, so there are two zeros.

(c) The zeros are given by

$$e^{2x} = 2 \quad \text{so} \quad x = \frac{\ln 2}{2}$$
$$e^x = 2 \quad \text{so} \quad x = \ln 2.$$

Thus, one zero is twice the size of the other.

82. (a) Since $f(x) = x^2 - x$,

$$f(f(x)) = (f(x))^2 - f(x) = (x^2 - x)^2 - (x^2 - x) = x - 2\,x^3 + x^4.$$

Using the CAS to define the function $f(x)$, and then asking it to expand $f(f(f(x)))$, we get

$$f(f(f(x))) = -x + x^2 + 2\,x^3 - 5\,x^4 + 2\,x^5 + 4\,x^6 - 4\,x^7 + x^8.$$

(b) The degree of $f(f(x))$ (that is, f composed with itself 2 times) is $4 = 2^2$. The degree of $f(f(f(x)))$ (that is, f composed with itself 3 times), is $8 = 2^3$. Each time you substitute f into itself, the degree is multiplied by 2, because you are substituting in a degree 2 polynomial. So we expect the degree of $f(f(f(f(f(f(x))))))$ (that is, f composed with itself 6 times) to be $64 = 2^6$.

83. (a) A CAS or division gives

$$f(x) = \frac{x^3 - 30}{x - 3} = x^2 + 3x + 9 - \frac{3}{x-3},$$

so $p(x) = x^2 + 3x + 9$, and $r(x) = -3$, and $q(x) = x - 3$.

(b) The vertical asymptote is $x = 3$. Near $x = 3$, the values of $p(x)$ are much smaller than the values of $r(x)/q(x)$. Thus

$$f(x) \approx \frac{-3}{x-3} \qquad \text{for } x \text{ near 3.}$$

(c) For large x, the values of $p(x)$ are much larger than the value of $r(x)/q(x)$. Thus

$$f(x) \approx x^2 + 3x + 9 \qquad \text{as } x \to \infty, x \to -\infty.$$

(d) Figure 1.130 shows $f(x)$ and $y = -3/(x-3)$ for x near 3. Figure 1.131 shows $f(x)$ and $y = x^2 + 3x + 9$ for $-20 \le x \le 20$. Note that in each case the graphs of f and the approximating function are close.

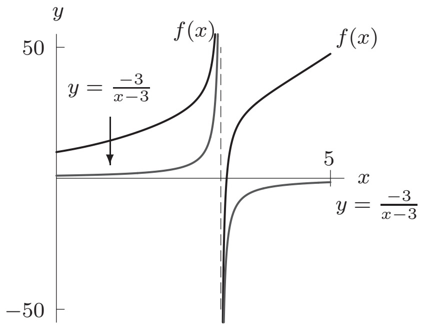

Figure 1.130: Close-up view of $f(x)$ and $y = -3/(x-3)$

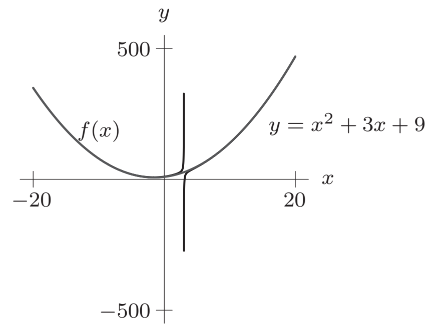

Figure 1.131: Far-away view of $f(x)$ and $y = x^2 + 3x + 9$

84. Using the trigonometric expansion capabilities of your CAS, you get something like

$$\sin(5x) = 5\cos^4(x)\,\sin(x) - 10\cos^2(x)\sin^3(x) + \sin^5(x).$$

Answers may vary. To get rid of the powers of cosine, use the identity $\cos^2(x) = 1 - \sin^2(x)$. This gives

$$\sin(5x) = 5\,\sin(x)\left(1 - \sin^2(x)\right)^2 - 10\sin^3(x)\,\left(1 - \sin^2(x)\right) + \sin^5(x).$$

Finally, using the CAS to simplify,

$$\sin(5x) = 5\,\sin(x) - 20\sin^3(x) + 16\sin^5(x).$$

85. Using the trigonometric expansion capabilities of your computer algebra system, you get something like

$$\cos(4x) = \cos^4(x) - 6\cos^2(x)\sin^2(x) + \sin^4(x).$$

Answers may vary.

(a) To get rid of the powers of cosine, use the identity $\cos^2(x) = 1 - \sin^2(x)$. This gives

$$\cos(4x) = \cos^4(x) - 6\cos^2(x)\,\left(1 - \cos^2(x)\right) + \left(1 - \cos^2(x)\right)^2.$$

Finally, using the CAS to simplify,

$$\cos(4x) = 1 - 8\cos^2(x) + 8\cos^4(x).$$

(b) This time we use $\sin^2(x) = 1 - \cos^2(x)$ to get rid of powers of sine. We get

$$\cos(4x) = \left(1 - \sin^2(x)\right)^2 - 6\sin^2(x)\,\left(1 - \sin^2(x)\right) + \sin^4(x) = 1 - 8\sin^2(x) + 8\sin^4(x).$$

PROJECTS FOR CHAPTER ONE

1. Notice that whenever x increases by 0.5, $f(x)$ increases by 1, indicating that $f(x)$ is linear. By inspection, we see that $f(x) = 2x$.

Similarly, $g(x)$ decreases by 1 each time x increases by 0.5. We know, therefore, that $g(x)$ is a linear function with slope $\frac{-1}{0.5} = -2$. The y-intercept is 10, so $g(x) = 10 - 2x$.

$h(x)$ is an even function which is always positive. Comparing the values of x and $h(x)$, it appears that $h(x) = x^2$.

$F(x)$ is an odd function that seems to vary between -1 and 1. We guess that $F(x) = \sin x$ and check with a calculator.

$G(x)$ is also an odd function that varies between -1 and 1. Notice that $G(x) = F(2x)$, and thus $G(x) = \sin 2x$.

Notice also that $H(x)$ is exactly 2 more than $F(x)$ for all x, so $H(x) = 2 + \sin x$.

2. (a) Begin by finding a table of correspondences between the mathematicians' and meteorologists' angles.

θ_{met} (in degrees)	0	45	90	135	180	225	270	315
θ_{math} (in degrees)	270	225	180	135	90	45	0	315

The table is linear for $0 \leq \theta_{\text{met}} \leq 270$, with θ_{math} decreasing by 45 every time θ_{met} increases by 45, giving slope $\Delta\theta_{\text{met}}/\Delta\theta_{\text{math}} = 45/(-45) = -1$.

The interval $270 < \theta_{\text{met}} < 360$ needs a closer look. We have the following more detailed table for that interval:

θ_{met}	280	290	300	310	320	330	340	350
θ_{math}	350	340	330	320	310	300	290	280

Again the table is linear, this time with θ_{math} decreasing by 10 every time θ_{met} increases by 10, again giving slope -1. The graph of θ_{math} against θ_{met} contains two straight line sections, both of slope -1. See Figure 1.132.

(b) See Figure 1.132.

$$\theta_{\text{math}} = \begin{cases} 270 - \theta_{\text{met}} & \text{if } 0 \leq \theta_{\text{met}} \leq 270 \\ 630 - \theta_{\text{met}} & \text{if } 270 < \theta_{\text{met}} < 360 \end{cases}.$$

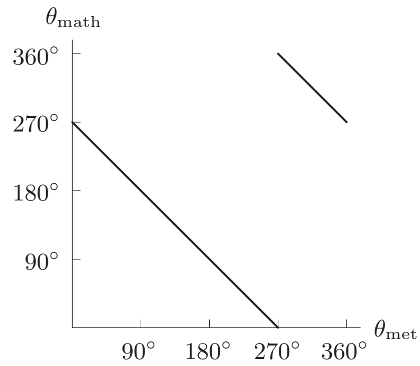

Figure 1.132

CHAPTER TWO

Solutions for Section 2.1

Exercises

1. For t between 2 and 5, we have

$$\text{Average velocity} = \frac{\Delta s}{\Delta t} = \frac{400-135}{5-2} = \frac{265}{3} \text{ km/hr.}$$

The average velocity on this part of the trip was $265/3$ km/hr.

2. The average velocity over a time period is the change in position divided by the change in time. Since the function $x(t)$ gives the position of the particle, we find the values of $x(0) = -2$ and $x(4) = -6$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta x(t)}{\Delta t} = \frac{x(4)-x(0)}{4-0} = \frac{-6-(-2)}{4} = -1 \text{ meters/sec.}$$

3. The average velocity over a time period is the change in position divided by the change in time. Since the function $x(t)$ gives the position of the particle, we find the values of $x(2) = 14$ and $x(8) = -4$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta x(t)}{\Delta t} = \frac{x(8)-x(2)}{8-2} = \frac{-4-14}{6} = -3 \text{ angstroms/sec.}$$

4. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the distance of the particle from a point, we read off the graph that $s(0) = 1$ and $s(3) = 4$. Thus,

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3)-s(0)}{3-0} = \frac{4-1}{3} = 1 \text{ meter/sec.}$$

5. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the distance of the particle from a point, we read off the graph that $s(1) = 2$ and $s(3) = 6$. Thus,

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3)-s(1)}{3-1} = \frac{6-2}{2} = 2 \text{ meters/sec.}$$

6. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the distance of the particle from a point, we find the values of $s(2) = e^2 - 1 = 6.389$ and $s(4) = e^4 - 1 = 53.598$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(4)-s(2)}{4-2} = \frac{53.598-6.389}{2} = 23.605\ \mu\text{m/sec.}$$

7. The average velocity over a time period is the change in the distance divided by the change in time. Since the function $s(t)$ gives the distance of the particle from a point, we find the values of $s(\pi/3) = 4 + 3\sqrt{3}/2$ and $s(7\pi/3) = 4 + 3\sqrt{3}/2$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(7\pi/3)-s(\pi/3)}{7\pi/3-\pi/3} = \frac{4+3\sqrt{3}/2-(4+3\sqrt{3}/2)}{2\pi} = 0 \text{ cm/sec.}$$

Though the particle moves, its average velocity is zero, since it is at the same position at $t = \pi/3$ and $t = 7\pi/3$.

8. (a) Let $s = f(t)$.

(i) We wish to find the average velocity between $t = 1$ and $t = 1.1$. We have

$$\text{Average velocity} = \frac{f(1.1) - f(1)}{1.1 - 1} = \frac{3.63 - 3}{0.1} = 6.3 \text{ m/sec.}$$

(ii) We have

$$\text{Average velocity} = \frac{f(1.01) - f(1)}{1.01 - 1} = \frac{3.0603 - 3}{0.01} = 6.03 \text{ m/sec.}$$

(iii) We have

$$\text{Average velocity} = \frac{f(1.001) - f(1)}{1.001 - 1} = \frac{3.006003 - 3}{0.001} = 6.003 \text{ m/sec.}$$

(b) We see in part (a) that as we choose a smaller and smaller interval around $t = 1$ the average velocity appears to be getting closer and closer to 6, so we estimate the instantaneous velocity at $t = 1$ to be 6 m/sec.

9. (a) Let $s = f(t)$.

(i) We wish to find the average velocity between $t = 0$ and $t = 0.1$. We have

$$\text{Average velocity} = \frac{f(0.1) - f(0)}{0.1 - 0} = \frac{0.004 - 0}{0.1} = 0.04 \text{ m/sec.}$$

(ii) We have

$$\text{Average velocity} = \frac{f(0.01) - f(0)}{0.01 - 0} = \frac{0.000004}{0.01} = 0.0004 \text{ m/sec.}$$

(iii) We have

$$\text{Average velocity} = \frac{f(0.001) - f(0)}{1.001 - 1} = \frac{4 \times 10^{-9} - 0}{0.001} = 4 \times 10^{-6} \text{ m/sec.}$$

(b) We see in part (a) that as we choose a smaller and smaller interval around $t = 0$ the average velocity appears to be getting closer and closer to 0, so we estimate the instantaneous velocity at $t = 0$ to be 0 m/sec.

Looking at a graph of $s = f(t)$ we see that a line tangent to the graph at $t = 0$ is horizontal, confirming our result.

10. (a) Let $s = f(t)$.

(i) We wish to find the average velocity between $t = 1$ and $t = 1.1$. We have

$$\text{Average velocity} = \frac{f(1.1) - f(1)}{1.1 - 1} = \frac{0.808496 - 0.909297}{0.1} = -1.00801 \text{ m/sec.}$$

(ii) We have

$$\text{Average velocity} = \frac{f(1.01) - f(1)}{1.01 - 1} = \frac{0.900793 - 0.909297}{0.01} = -0.8504 \text{ m/sec.}$$

(iii) We have

$$\text{Average velocity} = \frac{f(1.001) - f(1)}{1.001 - 1} = \frac{0.908463 - 0.909297}{0.001} = -0.834 \text{ m/sec.}$$

(b) We see in part (a) that as we choose a smaller and smaller interval around $t = 1$ the average velocity appears to be getting closer and closer to -0.83, so we estimate the instantaneous velocity at $t = 1$ to be -0.83 m/sec. In this case, more estimates with smaller values of h would be very helpful in making a better estimate.

11. See Figure 2.1.

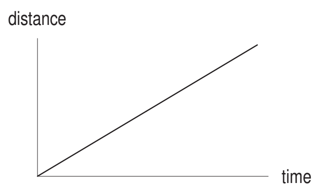

Figure 2.1

12. See Figure 2.2.

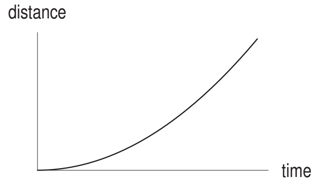

Figure 2.2

13. See Figure 2.3.

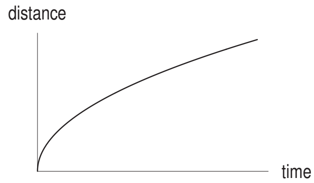

Figure 2.3

Problems

14. Using $h = 0.1, 0.01, 0.001$, we see

$$\frac{(3+0.1)^3-27}{0.1} = 27.91$$
$$\frac{(3+0.01)^3-27}{0.01} = 27.09$$
$$\frac{(3+0.001)^3-27}{0.001} = 27.009.$$

These calculations suggest that $\lim_{h\to 0} \frac{(3+h)^3-27}{h} = 27.$

15. Using radians,

h	$(\cos h - 1)/h$
0.01	-0.005
0.001	-0.0005
0.0001	-0.00005

These values suggest that $\lim_{h\to 0} \frac{\cos h - 1}{h} = 0.$

16. Using $h = 0.1, 0.01, 0.001$, we see

$$\frac{7^{0.1}-1}{0.1} = 2.148$$
$$\frac{7^{0.01}-1}{0.01} = 1.965$$
$$\frac{7^{0.001}-1}{0.001} = 1.948$$
$$\frac{7^{0.0001}-1}{0.0001} = 1.946.$$

This suggests that $\lim_{h\to 0} \frac{7^h-1}{h} \approx 1.9.$

17. Using $h = 0.1, 0.01, 0.001$, we see

h	$(e^{1+h} - e)/h$
0.01	2.7319
0.001	2.7196
0.0001	2.7184

These values suggest that $\lim_{h\to 0} \dfrac{e^{1+h} - e}{h} = 2.7$. In fact, this limit is e.

18.

Slope	-3	-1	0	$1/2$	1	2
Point	F	C	E	A	B	D

19. The slope is positive at A and D; negative at C and F. The slope is most positive at A; most negative at F.

20. $0 <$ slope at $C <$ slope at $B <$ slope of $AB < 1 <$ slope at A. (Note that the line $y = x$, has slope 1.)

21. Since $f(t)$ is concave down between $t = 1$ and $t = 3$, the average velocity between the two times should be less than the instantaneous velocity at $t = 1$ but greater than the instantaneous velocity at time $t = 3$, so $D < A < C$. For analogous reasons, $F < B < E$. Finally, note that f is decreasing at $t = 5$ so $E < 0$, but increasing at $t = 0$, so $D > 0$. Therefore, the ordering from smallest to greatest of the given quantities is

$$F < B < E < 0 < D < A < C.$$

22.

$$\begin{pmatrix}\text{Average velocity} \\ 0 < t < 0.2\end{pmatrix} = \frac{s(0.2) - s(0)}{0.2 - 0} = \frac{0.5}{0.2} = 2.5 \text{ ft/sec.}$$

$$\begin{pmatrix}\text{Average velocity} \\ 0.2 < t < 0.4\end{pmatrix} = \frac{s(0.4) - s(0.2)}{0.4 - 0.2} = \frac{1.3}{0.2} = 6.5 \text{ ft/sec.}$$

A reasonable estimate of the velocity at $t = 0.2$ is the average: $\frac{1}{2}(6.5 + 2.5) = 4.5$ ft/sec.

23. One possibility is shown in Figure 2.4.

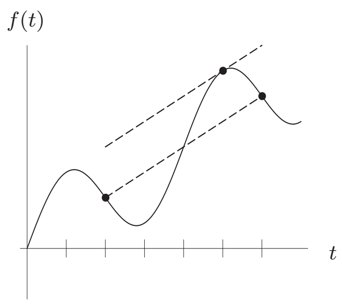

Figure 2.4

24. (a) When $t = 0$, the ball is on the bridge and its height is $f(0) = 36$, so the bridge is 36 feet above the ground.

(b) After 1 second, the ball's height is $f(1) = -16 + 50 + 36 = 70$ feet, so it traveled $70 - 36 = 34$ feet in 1 second, and its average velocity was 34 ft/sec.

(c) At $t = 1.001$, the ball's height is $f(1.001) = 70.017984$ feet, and its velocity about $\frac{70.017984-70}{1.001-1} = 17.984 \approx 18$ ft/sec.

(d) We complete the square:

$$\begin{aligned} f(t) &= -16t^2 + 50t + 36 \\ &= -16\left(t^2 - \frac{25}{8}t\right) + 36 \\ &= -16\left(t^2 - \frac{25}{8}t + \frac{625}{256}\right) + 36 + 16\left(\frac{625}{256}\right) \\ &= -16(t - \tfrac{25}{16})^2 + \tfrac{1201}{16} \end{aligned}$$

so the graph of f is a downward parabola with vertex at the point $(25/16, 1201/16) = (1.6, 75.1)$. We see from Figure 2.5 that the ball reaches a maximum height of about 75 feet. The velocity of the ball is zero when it is at the peak, since the tangent is horizontal there.

(e) The ball reaches its maximum height when $t = \frac{25}{16} = 1.6$.

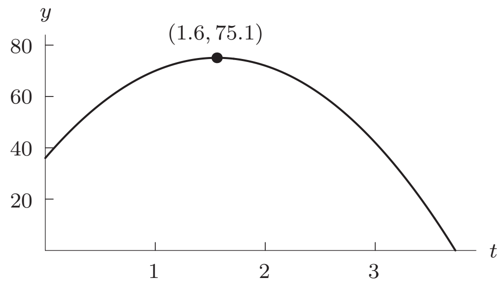

Figure 2.5

25. $\lim_{h\to 0} \frac{(2+h)^2 - 4}{h} = \lim_{h\to 0} \frac{4 + 4h + h^2 - 4}{h} = \lim_{h\to 0}(4 + h) = 4$

26. $\lim_{h\to 0} \frac{(1+h)^3 - 1}{h} = \lim_{h\to 0} \frac{1 + 3h + 3h^2 + h^3 - 1}{h} = \lim_{h\to 0} \frac{h(3 + 3h + h^2)}{h} = \lim_{h\to 0} 3 + 3h + h^2 = 3.$

27. $\lim_{h\to 0} \frac{3(2+h)^2 - 12}{h} = \lim_{h\to 0} \frac{12 + 12h + 3h^2 - 12}{h} = \lim_{h\to 0} \frac{h(12 + 3h)}{h} = \lim_{h\to 0} 12 + 3h = 12.$

28. $\lim_{h\to 0} \frac{(3+h)^2 - (3-h)^2}{2h} = \lim_{h\to 0} \frac{9 + 6h + h^2 - 9 + 6h - h^2}{2h} = \lim_{h\to 0} \frac{12h}{2h} = \lim_{h\to 0} 6 = 6.$

Strengthen Your Understanding

29. Speed is the magnitude of velocity, so it is always positive or zero; velocity has both magnitude and direction.

30. We expand and simplify first

$$\lim_{h\to 0} \frac{(2+h)^2 - 2^2}{h} = \lim_{h\to 0} \frac{(4 + 4h + h^2) - 4}{h} = \lim_{h\to 0} \frac{4h + h^2}{h} = \lim_{h\to 0}(4 + h) = 4.$$

31. Since the tangent line to the curve at $t = 4$ is almost horizontal, the instantaneous velocity is almost zero. At $t = 2$ the slope of the tangent line, and hence the instantaneous velocity, is relatively large and positive.

32. $f(t) = t^2$. The slope of the graph of $y = f(t)$ is negative for $t < 0$ and positive for $t > 0$.
Many other answers are possible.

33. One possibility is the position function $s(t) = t^2$. Any function that is symmetric about the line $t = 0$ works.
For $s(t) = t^2$, the slope of a tangent line (representing the velocity) is negative at $t = -1$ and positive at $t = 1$, and that the magnitude of the slopes (the speeds) are the same.

34. False. For example, the car could slow down or even stop at one minute after 2 pm, and then speed back up to 60 mph at one minute before 3 pm. In this case the car would travel only a few miles during the hour, much less than 50 miles.

35. False. Its average velocity for the time between 2 pm and 4 pm is 40 mph, but the car could change its speed a lot during that time period. For example, the car might be motionless for an hour then go 80 mph for the second hour. In that case the velocity at 2 pm would be 0 mph.

36. True. During a short enough time interval the car can not change its velocity very much, and so it velocity will be nearly constant. It will be nearly equal to the average velocity over the interval.

37. True. The instantaneous velocity is a limit of the average velocities. The limit of a constant equals that constant.

38. True. By definition, Average velocity = Distance traveled/Time.

39. False. Instantaneous velocity equals a *limit* of difference quotients.

Solutions for Section 2.2

Exercises

1. The derivative, $f'(2)$, is the rate of change of x^3 at $x = 2$. Notice that each time x changes by 0.001 in the table, the value of x^3 changes by 0.012. Therefore, we estimate

$$f'(2) = \begin{array}{c}\text{Rate of change}\\ \text{of } f \text{ at } x = 2\end{array} \approx \frac{0.012}{0.001} = 12.$$

The function values in the table look exactly linear because they have been rounded. For example, the exact value of x^3 when $x = 2.001$ is 8.012006001, not 8.012. Thus, the table can tell us only that the derivative is approximately 12. Example 5 on page 95 shows how to compute the derivative of $f(x)$ exactly.

2. With $h = 0.01$ and $h = -0.01$, we have the difference quotients

$$\frac{f(1.01) - f(1)}{0.01} = 3.0301 \quad \text{and} \quad \frac{f(0.99) - f(1)}{-0.01} = 2.9701.$$

With $h = 0.001$ and $h = -0.001$,

$$\frac{f(1.001) - f(1)}{0.001} = 3.003001 \quad \text{and} \quad \frac{f(0.999) - f(1)}{-0.001} = 2.997001.$$

The values of these difference quotients suggest that the limit is about 3.0. We say

$$f'(1) = \begin{array}{c}\text{Instantaneous rate of change of } f(x) = x^3\\ \text{with respect to } x \text{ at } x = 1\end{array} \approx 3.0.$$

3. (a) Using the formula for the average rate of change gives

$$\begin{array}{c}\text{Average rate of change}\\ \text{of revenue for } 1 \le q \le 2\end{array} = \frac{R(2) - R(1)}{1} = \frac{160 - 90}{1} = 70 \text{ dollars/kg}.$$

$$\begin{array}{c}\text{Average rate of change}\\ \text{of revenue for } 2 \le q \le 3\end{array} = \frac{R(3) - R(2)}{1} = \frac{210 - 160}{1} = 50 \text{ dollars/kg}.$$

So we see that the average rate decreases as the quantity sold in kilograms increases.

(b) With $h = 0.01$ and $h = -0.01$, we have the difference quotients

$$\frac{R(2.01) - R(2)}{0.01} = 59.9 \text{ dollars/kg} \quad \text{and} \quad \frac{R(1.99) - R(2)}{-0.01} = 60.1 \text{ dollars/kg}.$$

With $h = 0.001$ and $h = -0.001$,

$$\frac{R(2.001) - R(2)}{0.001} = 59.99 \text{ dollars/kg} \quad \text{and} \quad \frac{R(1.999) - R(2)}{-0.001} = 60.01 \text{ dollars/kg}.$$

The values of these difference quotients suggest that the instantaneous rate of change is about 60 dollars/kg. To confirm that the value is exactly 60, that is, that $R'(2) = 60$, we would need to take the limit as $h \to 0$.

4. (a) Using a calculator we obtain the values found in the table below:

x	1	1.5	2	2.5	3
e^x	2.72	4.48	7.39	12.18	20.09

(b) The average rate of change of $f(x) = e^x$ between $x = 1$ and $x = 3$ is

$$\text{Average rate of change} = \frac{f(3) - f(1)}{3 - 1} = \frac{e^3 - e}{3 - 1} \approx \frac{20.09 - 2.72}{2} = 8.69.$$

(c) First we find the average rates of change of $f(x) = e^x$ between $x = 1.5$ and $x = 2$, and between $x = 2$ and $x = 2.5$:

$$\text{Average rate of change} = \frac{f(2) - f(1.5)}{2 - 1.5} = \frac{e^2 - e^{1.5}}{2 - 1.5} \approx \frac{7.39 - 4.48}{0.5} = 5.82$$

$$\text{Average rate of change} = \frac{f(2.5) - f(2)}{2.5 - 2} = \frac{e^{2.5} - e^2}{2.5 - 2} \approx \frac{12.18 - 7.39}{0.5} = 9.58.$$

Now we approximate the instantaneous rate of change at $x = 2$ by averaging these two rates:

$$\text{Instantaneous rate of change} \approx \frac{5.82 + 9.58}{2} = 7.7.$$

5. (a)

Table 2.1

x	1	1.5	2	2.5	3
$\log x$	0	0.18	0.30	0.40	0.48

(b) The average rate of change of $f(x) = \log x$ between $x = 1$ and $x = 3$ is

$$\frac{f(3) - f(1)}{3 - 1} = \frac{\log 3 - \log 1}{3 - 1} \approx \frac{0.48 - 0}{2} = 0.24$$

(c) First we find the average rates of change of $f(x) = \log x$ between $x = 1.5$ and $x = 2$, and between $x = 2$ and $x = 2.5$.

$$\frac{\log 2 - \log 1.5}{2 - 1.5} = \frac{0.30 - 0.18}{0.5} \approx 0.24$$

$$\frac{\log 2.5 - \log 2}{2.5 - 2} = \frac{0.40 - 0.30}{0.5} \approx 0.20$$

Now we approximate the instantaneous rate of change at $x = 2$ by finding the average of the above rates, i.e.

$$\begin{pmatrix} \text{the instantaneous rate of change} \\ \text{of } f(x) = \log x \text{ at } x = 2 \end{pmatrix} \approx \frac{0.24 + 0.20}{2} = 0.22.$$

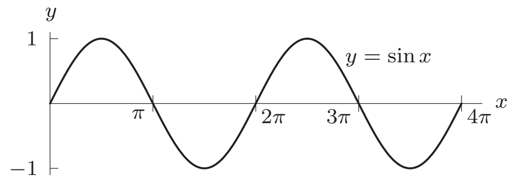
6. In Table 2.2, each x increase of 0.001 leads to an increase in $f(x)$ by about 0.031, so

$$f'(3) \approx \frac{0.031}{0.001} = 31.$$

Table 2.2

x	2.998	2.999	3.000	3.001	3.002
$x^3 + 4x$	38.938	38.969	39.000	39.031	39.062

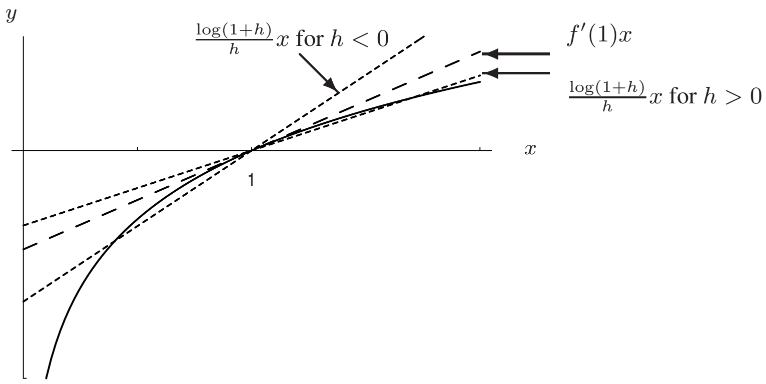
7.



Since $\sin x$ is decreasing for values near $x = 3\pi$, its derivative at $x = 3\pi$ is negative.

8. $f'(1) = \lim_{h\to 0} \dfrac{\log(1+h) - \log 1}{h} = \lim_{h\to 0} \dfrac{\log(1+h)}{h}$

Evaluating $\frac{\log(1+h)}{h}$ for $h = 0.01, 0.001$, and 0.0001, we get $0.43214, 0.43408, 0.43427$, so $f'(1) \approx 0.43427$. The corresponding secant lines are getting steeper, because the graph of $\log x$ is concave down. We thus expect the limit to be more than 0.43427 . If we consider negative values of h, the estimates are too large. We can also see this from the graph below:



9. We estimate $f'(2)$ using the average rate of change formula on a small interval around 2. We use the interval $x = 2$ to $x = 2.001$. (Any small interval around 2 gives a reasonable answer.) We have

$$f'(2) \approx \frac{f(2.001) - f(2)}{2.001 - 2} = \frac{3^{2.001} - 3^2}{2.001 - 2} = \frac{9.00989 - 9}{0.001} = 9.89.$$

10. (a) The average rate of change from $x = a$ to $x = b$ is the slope of the line between the points on the curve with $x = a$ and $x = b$. Since the curve is concave down, the line from $x = 1$ to $x = 3$ has a greater slope than the line from $x = 3$ to $x = 5$, and so the average rate of change between $x = 1$ and $x = 3$ is greater than that between $x = 3$ and $x = 5$.

(b) Since f is increasing, $f(5)$ is the greater.

(c) As in part (a), f is concave down and f' is decreasing throughout so $f'(1)$ is the greater.

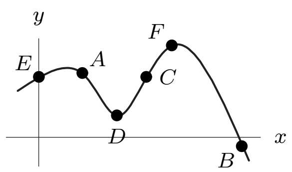
11. Since $f'(x) = 0$ where the graph is horizontal, $f'(x) = 0$ at $x = d$. The derivative is positive at points b and c, but the graph is steeper at $x = c$. Thus $f'(x) = 0.5$ at $x = b$ and $f'(x) = 2$ at $x = c$. Finally, the derivative is negative at points a and e but the graph is steeper at $x = e$. Thus, $f'(x) = -0.5$ at $x = a$ and $f'(x) = -2$ at $x = e$. See Table 2.3.

Thus, we have $f'(d) = 0, f'(b) = 0.5, f'(c) = 2, f'(a) = -0.5, f'(e) = -2$.

Table 2.3

x	$f'(x)$
d	0
b	0.5
c	2
a	−0.5
e	−2

12. One possible choice of points is shown below.



Problems

13. The statements $f(100) = 35$ and $f'(100) = 3$ tell us that at $x = 100$, the value of the function is 35 and the function is increasing at a rate of 3 units for a unit increase in x. Since we increase x by 2 units in going from 100 to 102, the value of the function goes up by approximately $2 \cdot 3 = 6$ units, so

$$f(102) \approx 35 + 2 \cdot 3 = 35 + 6 = 41.$$

14. The answers to parts (a)–(d) are shown in Figure 2.6.

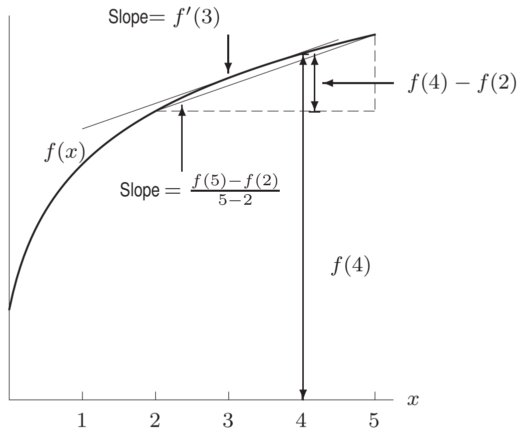


Figure 2.6

15. (a) Since f is increasing, $f(4) > f(3)$.

(b) From Figure 2.7, it appears that $f(2) - f(1) > f(3) - f(2)$.

(c) The quantity $\dfrac{f(2) - f(1)}{2 - 1}$ represents the slope of the secant line connecting the points on the graph at $x = 1$ and $x = 2$. This is greater than the slope of the secant line connecting the points at $x = 1$ and $x = 3$ which is $\dfrac{f(3) - f(1)}{3 - 1}$.

(d) The function is steeper at $x = 1$ than at $x = 4$ so $f'(1) > f'(4)$.

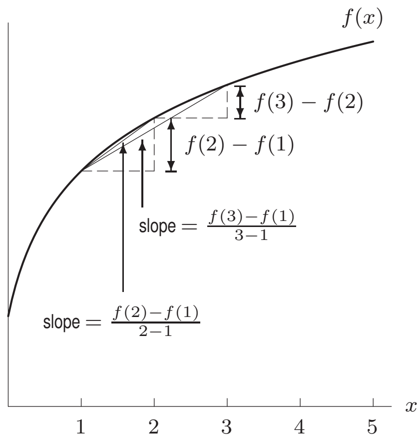

Figure 2.7

16. Figure 2.8 shows the quantities in which we are interested.

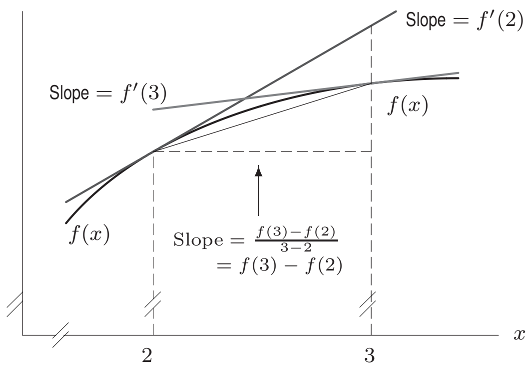

Figure 2.8

The quantities $f'(2)$, $f'(3)$ and $f(3) - f(2)$ have the following interpretations:

- $f'(2)$ = slope of the tangent line at $x = 2$
- $f'(3)$ = slope of the tangent line at $x = 3$
- $f(3) - f(2) = \frac{f(3)-f(2)}{3-2}$ = slope of the secant line from $f(2)$ to $f(3)$.

From Figure 2.8, it is clear that $0 < f(3) - f(2) < f'(2)$. By extending the secant line past the point $(3, f(3))$, we can see that it lies above the tangent line at $x = 3$.

Thus

$$0 < f'(3) < f(3) - f(2) < f'(2).$$

17. The coordinates of A are $(4, 25)$. See Figure 2.9. The coordinates of B and C are obtained using the slope of the tangent line. Since $f'(4) = 1.5$, the slope is 1.5

From A to B, $\Delta x = 0.2$, so $\Delta y = 1.5(0.2) = 0.3$. Thus, at C we have $y = 25 + 0.3 = 25.3$. The coordinates of B are $(4.2, 25.3)$.

From A to C, $\Delta x = -0.1$, so $\Delta y = 1.5(-0.1) = -0.15$. Thus, at C we have $y = 25 - 0.15 = 24.85$. The coordinates of C are $(3.9, 24.85)$.

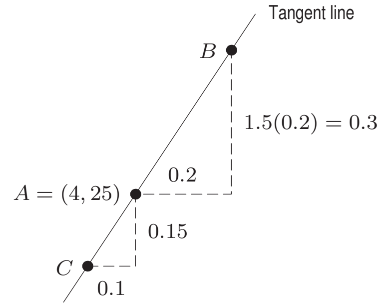

Figure 2.9

18. (a) Since the point $B = (2, 5)$ is on the graph of g, we have $g(2) = 5$.
(b) The slope of the tangent line touching the graph at $x = 2$ is given by

$$\text{Slope} = \frac{\text{Rise}}{\text{Run}} = \frac{5 - 5.02}{2 - 1.95} = \frac{-0.02}{0.05} = -0.4.$$

Thus, $g'(2) = -0.4$.

19. See Figure 2.10.

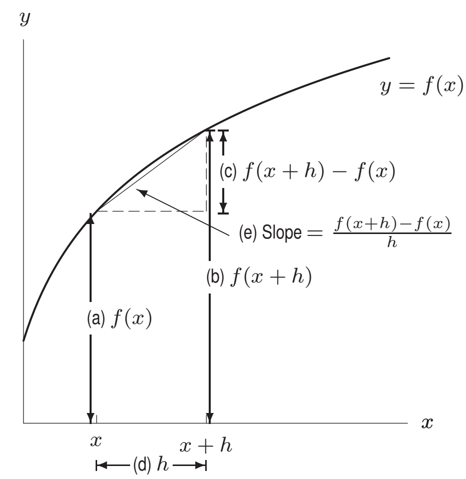

Figure 2.10

20. See Figure 2.11.

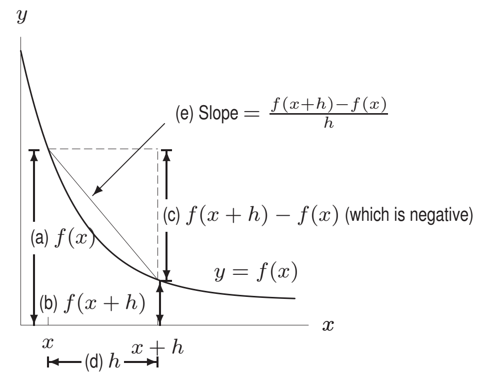

Figure 2.11

21. (a) For the line from A to B,

$$\text{Slope} = \frac{f(b) - f(a)}{b - a}.$$

(b) The tangent line at point C appears to be parallel to the line from A to B. Assuming this to be the case, the lines have the same slope.

(c) There is only one other point, labeled D in Figure 2.12, at which the tangent line is parallel to the line joining A and B.

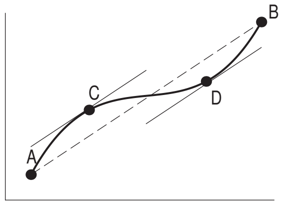

Figure 2.12

22. (a) Figure 2.13 shows the graph of an even function. We see that since f is symmetric about the y-axis, the tangent line at $x = -10$ is just the tangent line at $x = 10$ flipped about the y-axis, so the slope of one tangent is the negative of that of the other. Therefore, $f'(-10) = -f'(10) = -6$.

(b) From part (a) we can see that if f is even, then for any x, we have $f'(-x) = -f'(x)$. Thus $f'(-0) = -f'(0)$, so $f'(0) = 0$.

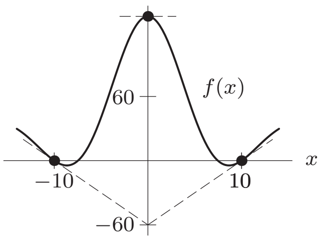

Figure 2.13

23. Figure 2.14 shows the graph of an odd function. We see that since g is symmetric about the origin, its tangent line at $x = -4$ is just the tangent line at $x = 4$ flipped about the origin, so they have the same slope. Thus, $g'(-4) = 5$.

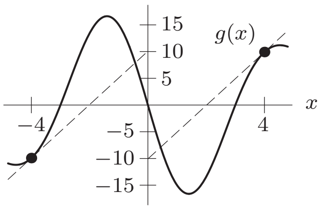

Figure 2.14

24. (a)

$$f'(0) = \lim_{h\to 0} \frac{\overbrace{\sin h}^{h \text{ in degrees}} - \overbrace{\sin 0}^{0}}{h} = \frac{\sin h}{h}.$$

To four decimal places,

$$\frac{\sin 0.2}{0.2} \approx \frac{\sin 0.1}{0.1} \approx \frac{\sin 0.01}{0.01} \approx \frac{\sin 0.001}{0.001} \approx 0.01745$$

so $f'(0) \approx 0.01745$.

(b) Consider the ratio $\frac{\sin h}{h}$. As we approach 0, the numerator, $\sin h$, will be much smaller in magnitude if h is in degrees than it would be if h were in radians. For example, if $h = 1^\circ$ radian, $\sin h = 0.8415$, but if $h = 1$ degree, $\sin h = 0.01745$. Thus, since the numerator is smaller for h measured in degrees while the denominator is the same, we expect the ratio $\frac{\sin h}{h}$ to be smaller.

25. We find the derivative using a difference quotient:

$$f'(3) = \lim_{h\to 0} \frac{f(3+h)-f(3)}{h} = \lim_{h\to 0} \frac{(3+h)^2+3+h-(3^2+3)}{h}$$
$$= \lim_{h\to 0} \frac{9+6h+h^2+3+h-9-3}{h} = \lim_{h\to 0} \frac{7h+h^2}{h} = \lim_{h\to 0}(7+h) = 7.$$

Thus at $x = 3$, the slope of the tangent line is 7. Since $f(3) = 3^2 + 3 = 12$, the line goes through the point $(3, 12)$, and therefore its equation is

$$y - 12 = 7(x-3) \quad \text{or} \quad y = 7x - 9.$$

The graph is in Figure 2.15.

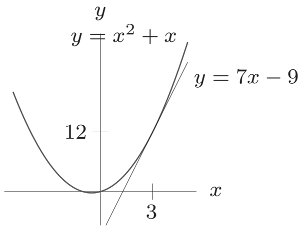

Figure 2.15

26. Using a difference quotient with $h = 0.001$, say, we find

$$f'(1) \approx \frac{1.001\ln(1.001) - 1\ln(1)}{1.001 - 1} = 1.0005$$
$$f'(2) \approx \frac{2.001\ln(2.001) - 2\ln(2)}{2.001 - 2} = 1.6934$$

The fact that f' is larger at $x = 2$ than at $x = 1$ suggests that f is concave up between $x = 1$ and $x = 2$.

27. We want $f'(2)$. The exact answer is

$$f'(2) = \lim_{h\to 0} \frac{f(2+h)-f(2)}{h} = \lim_{h\to 0} \frac{(2+h)^{2+h}-4}{h},$$

but we can approximate this. If $h = 0.001$, then

$$\frac{(2.001)^{2.001}-4}{0.001} \approx 6.779$$

and if $h = 0.0001$ then

$$\frac{(2.0001)^{2.0001}-4}{0.0001} \approx 6.773,$$

so $f'(2) \approx 6.77$.

28. Notice that we can't get all the information we want just from the graph of f for $0 \le x \le 2$, shown on the left in Figure 2.16. Looking at this graph, it looks as if the slope at $x = 0$ is 0. But if we zoom in on the graph near $x = 0$, we get the graph of f for $0 \le x \le 0.05$, shown on the right in Figure 2.16. We see that f does dip down quite a bit between $x = 0$ and $x \approx 0.11$. In fact, it now looks like $f'(0)$ is around -1. Note that since $f(x)$ is undefined for $x < 0$, this derivative only makes sense as we approach zero from the right.

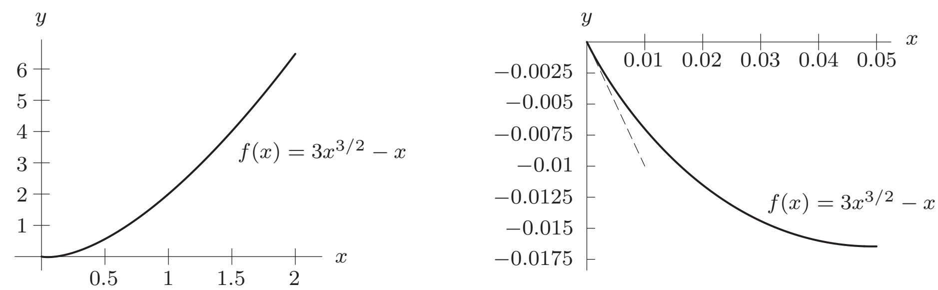

Figure 2.16

We zoom in on the graph of f near $x = 1$ to get a more accurate picture from which to estimate $f'(1)$. A graph of f for $0.7 \leq x \leq 1.3$ is shown in Figure 2.17. [Keep in mind that the axes shown in this graph don't cross at the origin!] Here we see that $f'(1) \approx 3.5$.

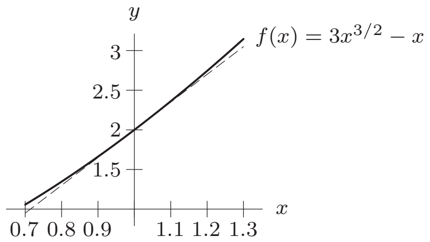

Figure 2.17

29.

$$f'(1) = \lim_{h\to 0} \frac{f(1+h) - f(1)}{h} = \lim_{h\to 0} \frac{\ln(\cos(1+h)) - \ln(\cos 1)}{h}$$

For $h = 0.001$, the difference quotient $= -1.55912$; for $h = 0.0001$, the difference quotient $= -1.55758$. The instantaneous rate of change of f therefore appears to be about -1.558 at $x = 1$.
At $x = \frac{\pi}{4}$, if we try $h = 0.0001$, then

$$\text{difference quotient} = \frac{\ln[\cos(\frac{\pi}{4} + 0.0001)] - \ln(\cos\frac{\pi}{4})}{0.0001} \approx -1.0001.$$

The instantaneous rate of change of f appears to be about -1 at $x = \frac{\pi}{4}$.

30. The quantity $f(0)$ represents the population on October 17, 2006, so $f(0) = 300$ million.

The quantity $f'(0)$ represents the rate of change of the population (in millions per year). Since

$$\frac{1 \text{ person}}{11 \text{ seconds}} = \frac{1/10^6 \text{ million people}}{11/(60 \cdot 60 \cdot 24 \cdot 365) \text{ years}} = 2.867 \text{ million people/year},$$

so we have $f'(0) = 2.867$.

31. We want to approximate $P'(0)$ and $P'(7)$. Since for small h

$$P'(0) \approx \frac{P(h) - P(0)}{h},$$

if we take $h = 0.01$, we get

$$\begin{aligned} P'(0) &\approx \frac{1.267(1.007)^{0.01} - 1.267}{0.01} = 0.00884 \text{ billion/year} \\ &= 8.84 \text{ million people/year in 2000}, \\ P'(7) &\approx \frac{1.267(1.007)^{7.01} - 1.267(1.007)^{7}}{0.01} = 0.00928 \text{ billion/year} \\ &= 9.28 \text{ million people/year in 2007} \end{aligned}$$

32. (a) From Figure 2.18, it appears that the slopes of the tangent lines to the two graphs are the same at each x. For $x = 0$, the slopes of the tangents to the graphs of $f(x)$ and $g(x)$ at 0 are

$$\begin{aligned} f'(0) &= \lim_{h\to 0} \frac{f(0+h)-f(0)}{h} \\ &= \lim_{h\to 0} \frac{f(h)-0}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}h^2}{h} \\ &= \lim_{h\to 0} \frac{1}{2}h \\ &= 0, \end{aligned}$$

$$\begin{aligned} g'(0) &= \lim_{h\to 0} \frac{g(0+h)-g(0)}{h} \\ &= \lim_{h\to 0} \frac{g(h)-g(0)}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}h^2+3-3}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}h^2}{h} \\ &= \lim_{h\to 0} \frac{1}{2}h \\ &= 0. \end{aligned}$$

For $x = 2$, the slopes of the tangents to the graphs of $f(x)$ and $g(x)$ are

$$\begin{aligned} f'(2) &= \lim_{h\to 0} \frac{f(2+h)-f(2)}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(2+h)^2-\frac{1}{2}(2)^2}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(4+4h+h^2)-2}{h} \\ &= \lim_{h\to 0} \frac{2+2h+\frac{1}{2}h^2-2}{h} \\ &= \lim_{h\to 0} \frac{2h+\frac{1}{2}h^2}{h} \\ &= \lim_{h\to 0} \left(2+\frac{1}{2}h\right) \\ &= 2, \end{aligned}$$

$$\begin{aligned} g'(2) &= \lim_{h\to 0} \frac{g(2+h)-g(2)}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(2+h)^2+3-(\frac{1}{2}(2)^2+3)}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(2+h)^2-\frac{1}{2}(2)^2}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(4+4h+h^2)-2}{h} \\ &= \lim_{h\to 0} \frac{2+2h+\frac{1}{2}(h^2)-2}{h} \\ &= \lim_{h\to 0} \frac{2h+\frac{1}{2}(h^2)}{h} \\ &= \lim_{h\to 0} \left(2+\frac{1}{2}h\right) \\ &= 2. \end{aligned}$$

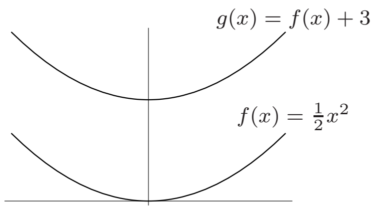

Figure 2.18

For $x = x_0$, the slopes of the tangents to the graphs of $f(x)$ and $g(x)$ are

$$\begin{aligned} f'(x_0) &= \lim_{h\to 0} \frac{f(x_0+h)-f(x_0)}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(x_0+h)^2 - \frac{1}{2}x_0^2}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(x_0^2+2x_0h+h^2) - \frac{1}{2}x_0^2}{h} \\ &= \lim_{h\to 0} \frac{x_0h+\frac{1}{2}h^2}{h} \\ &= \lim_{h\to 0} \left(x_0 + \frac{1}{2}h\right) \\ &= x_0, \end{aligned}$$

$$\begin{aligned} g'(x_0) &= \lim_{h\to 0} \frac{g(x_0+h)-g(x_0)}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(x_0+h)^2 + 3 - (\frac{1}{2}(x_0)^2+3)}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(x_0+h)^2 - \frac{1}{2}(x_0)^2}{h} \\ &= \lim_{h\to 0} \frac{\frac{1}{2}(x_0^2+2x_0h+h^2) - \frac{1}{2}x_0^2}{h} \\ &= \lim_{h\to 0} \frac{x_0h+\frac{1}{2}h^2}{h} \\ &= \lim_{h\to 0} \left(x_0 + \frac{1}{2}h\right) \\ &= x_0. \end{aligned}$$

(b)

$$\begin{aligned} g'(x) &= \lim_{h\to 0} \frac{g(x+h)-g(x)}{h} \\ &= \lim_{h\to 0} \frac{f(x+h)+C-(f(x)+C)}{h} \\ &= \lim_{h\to 0} \frac{f(x+h)-f(x)}{h} \\ &= f'(x). \end{aligned}$$

33. As h gets smaller, round-off error becomes important. When $h = 10^{-12}$, the quantity $2^h - 1$ is so close to 0 that the calculator rounds off the difference to 0, making the difference quotient 0. The same thing will happen when $h = 10^{-20}$.

34. (a) Table 2.4 shows that near $x = 1$, every time the value of x increases by 0.001, the value of x^2 increases by approximately 0.002. This suggests that

$$f'(1) \approx \frac{0.002}{0.001} = 2.$$

Table 2.4 *Values of $f(x) = x^2$ near $x = 1$*

x	x^2	Difference in successive x^2 values
0.998	0.996004	
		0.001997
0.999	0.998001	
		0.001999
1.000	1.000000	
		0.002001
1.001	1.002001

1.002	1.004004	
↑ x increments of 0.001		↑ All approximately 0.002

(b) The derivative is the limit of the difference quotient, so we look at

$$f'(1) = \lim_{h\to 0} \frac{f(1+h)-f(1)}{h}.$$

Using the formula for f, we have

$$f'(1) = \lim_{h\to 0} \frac{(1+h)^2 - 1^2}{h} = \lim_{h\to 0} \frac{(1+2h+h^2)-1}{h} = \lim_{h\to 0} \frac{2h+h^2}{h}.$$

Since the limit only examines values of h close to, but not equal to zero, we can cancel h in the expression $(2h + h^2)/h$. We get

$$f'(1) = \lim_{h\to 0} \frac{h(2+h)}{h} = \lim_{h\to 0}(2+h).$$

This limit is 2, so $f'(1) = 2$. At $x = 1$ the rate of change of x^2 is 2.

(c) Since the derivative is the rate of change, $f'(1) = 2$ means that for small changes in x near $x = 1$, the change in $f(x) = x^2$ is about twice as big as the change in x. As an example, if x changes from 1 to 1.1, a net change of 0.1, then $f(x)$ changes by about 0.2. Figure 2.19 shows this geometrically. Near $x = 1$ the function is approximately linear with slope of 2.

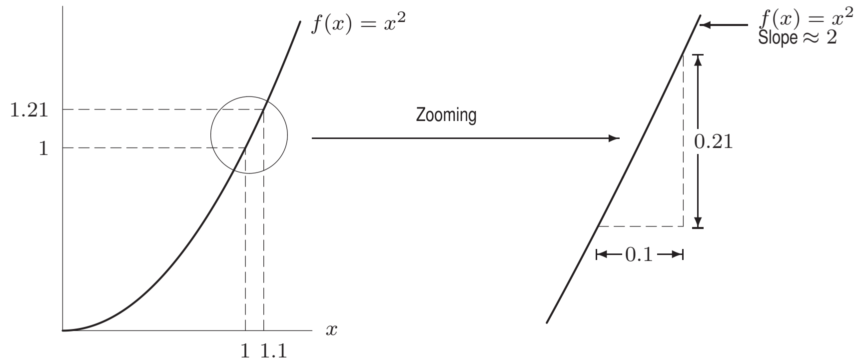

Figure 2.19: Graph of $f(x) = x^2$ near $x = 1$ has slope ≈ 2

35. $\lim_{h\to 0} \frac{(-3+h)^2 - 9}{h} = \lim_{h\to 0} \frac{9 - 6h + h^2 - 9}{h} = \lim_{h\to 0} \frac{h(-6+h)}{h} = \lim_{h\to 0} -6 + h = -6.$

36. $\lim_{h\to 0} \frac{(2-h)^3 - 8}{h} = \lim_{h\to 0} \frac{8 - 12h + 6h^2 - h^3 - 8}{h} = \lim_{h\to 0} \frac{h(-12 + 6h - h^2)}{h} = \lim_{h\to 0} -12 + 6h - h^2 = -12.$

37. $\lim_{h\to 0} \frac{1}{h}\left(\frac{1}{1+h} - 1\right) = \lim_{h\to 0} \frac{1-(1+h)}{(1+h)h} = \lim_{h\to 0} \frac{-1}{1+h} = -1$

38. $\lim_{h\to 0} \frac{1}{h}\left(\frac{1}{(1+h)^2} - 1\right) = \lim_{h\to 0} \frac{1-(1+2h+h^2)}{h(1+h)^2} = \lim_{h\to 0} \frac{-2-h}{(1+h)^2} = -2$

39. $\sqrt{4+h} - 2 = \frac{(\sqrt{4+h}-2)(\sqrt{4+h}+2)}{\sqrt{4+h}+2} = \frac{4+h-4}{\sqrt{4+h}+2} = \frac{h}{\sqrt{4+h}+2}.$

Therefore $\lim_{h\to 0} \frac{\sqrt{4+h}-2}{h} = \lim_{h\to 0} \frac{1}{\sqrt{4+h}+2} = \frac{1}{4}$

40. $\frac{1}{\sqrt{4+h}} - \frac{1}{2} = \frac{2-\sqrt{4+h}}{2\sqrt{4+h}} = \frac{(2-\sqrt{4+h})(2+\sqrt{4+h})}{2\sqrt{4+h}(2+\sqrt{4+h})} = \frac{4-(4+h)}{2\sqrt{4+h}(2+\sqrt{4+h})}.$

Therefore $\lim_{h\to 0} \frac{1}{h}\left(\frac{1}{\sqrt{4+h}} - \frac{1}{2}\right) = \lim_{h\to 0} \frac{-1}{2\sqrt{4+h}(2+\sqrt{4+h})} = -\frac{1}{16}$

41. Using the definition of the derivative, we have

$$\begin{aligned} f'(10) &= \lim_{h\to 0} \frac{f(10+h) - f(10)}{h} \\ &= \lim_{h\to 0} \frac{5(10+h)^2 - 5(10)^2}{h} \\ &= \lim_{h\to 0} \frac{500 + 100h + 5h^2 - 500}{h} \\ &= \lim_{h\to 0} \frac{100h + 5h^2}{h} \\ &= \lim_{h\to 0} \frac{h(100+5h)}{h} \\ &= \lim_{h\to 0} 100 + 5h \\ &= 100. \end{aligned}$$

42. Using the definition of the derivative, we have

$$\begin{aligned}
f'(-2) &= \lim_{h\to 0} \frac{f(-2+h)-f(-2)}{h} \\
&= \lim_{h\to 0} \frac{(-2+h)^3-(-2)^3}{h} \\
&= \lim_{h\to 0} \frac{(-8+12h-6h^2+h^3)-(-8)}{h} \\
&= \lim_{h\to 0} \frac{12h-6h^2+h^3}{h} \\
&= \lim_{h\to 0} \frac{h(12-6h+h^2)}{h} \\
&= \lim_{h\to 0} (12-6h+h^2),
\end{aligned}$$

which goes to 12 as $h \to 0$. So $f'(-2) = 12$.

43. Using the definition of the derivative

$$\begin{aligned}
g'(-1) &= \lim_{h\to 0} \frac{g(-1+h)-g(-1)}{h} \\
&= \lim_{h\to 0} \frac{((-1+h)^2+(-1+h))-((-1)^2+(-1))}{h} \\
&= \lim_{h\to 0} \frac{(1-2h+h^2-1+h)-(0)}{h} \\
&= \lim_{h\to 0} \frac{-h+h^2}{h} = \lim_{h\to 0}(-1+h) = -1.
\end{aligned}$$

44.

$$\begin{aligned}
f'(1) &= \lim_{h\to 0} \frac{f(1+h)-f(1)}{h} = \lim_{h\to 0} \frac{((1+h)^3+5)-(1^3+5)}{h} \\
&= \lim_{h\to 0} \frac{1+3h+3h^2+h^3+5-1-5}{h} = \lim_{h\to 0} \frac{3h+3h^2+h^3}{h} \\
&= \lim_{h\to 0}(3+3h+h^2) = 3.
\end{aligned}$$

45.

$$\begin{aligned}
g'(2) &= \lim_{h\to 0} \frac{g(2+h)-g(2)}{h} = \lim_{h\to 0} \frac{\frac{1}{2+h}-\frac{1}{2}}{h} \\
&= \lim_{h\to 0} \frac{2-(2+h)}{h(2+h)2} = \lim_{h\to 0} \frac{-h}{h(2+h)2} \\
&= \lim_{h\to 0} \frac{-1}{(2+h)2} = -\frac{1}{4}
\end{aligned}$$

46.

$$\begin{aligned}
g'(2) &= \lim_{h\to 0} \frac{g(2+h)-g(2)}{h} = \lim_{h\to 0} \frac{\frac{1}{(2+h)^2}-\frac{1}{2^2}}{h} \\
&= \lim_{h\to 0} \frac{2^2-(2+h)^2}{2^2(2+h)^2h} = \lim_{h\to 0} \frac{4-4-4h-h^2}{4h(2+h)^2} \\
&= \lim_{h\to 0} \frac{-4h-h^2}{4h(2+h)^2} = \lim_{h\to 0} \frac{-4-h}{4(2+h)^2} \\
&= \frac{-4}{4(2)^2} = -\frac{1}{4}.
\end{aligned}$$

47. As we saw in the answer to Problem 41, the slope of the tangent line to $f(x) = 5x^2$ at $x = 10$ is 100. When $x = 10$, $f(x) = 500$ so $(10, 500)$ is a point on the tangent line. Thus $y = 100(x - 10) + 500 = 100x - 500$.

48. As we saw in the answer to Problem 42, the slope of the tangent line to $f(x) = x^3$ at $x = -2$ is 12. When $x = -2$, $f(x) = -8$ so we know the point $(-2, -8)$ is on the tangent line. Thus the equation of the tangent line is $y = 12(x + 2) - 8 = 12x + 16$.

49. We know that the slope of the tangent line to $f(x) = x$ when $x = 20$ is 1. When $x = 20$, $f(x) = 20$ so $(20, 20)$ is on the tangent line. Thus the equation of the tangent line is $y = 1(x - 20) + 20 = x$.

50. First find the derivative of $f(x) = 1/x^2$ at $x = 1$.

$$\begin{aligned} f'(1) &= \lim_{h\to 0} \frac{f(1+h) - f(1)}{h} = \lim_{h\to 0} \frac{\frac{1}{(1+h)^2} - \frac{1}{1^2}}{h} \\ &= \lim_{h\to 0} \frac{1^2 - (1+h)^2}{h(1+h)^2} = \lim_{h\to 0} \frac{1 - (1 + 2h + h^2)}{h(1+h)^2} \\ &= \lim_{h\to 0} \frac{-2h - h^2}{h(1+h)^2} = \lim_{h\to 0} \frac{-2 - h}{(1+h)^2} = -2 \end{aligned}$$

Thus the tangent line has a slope of -2 and goes through the point $(1, 1)$, and so its equation is

$$y - 1 = -2(x - 1) \quad \text{or} \quad y = -2x + 3.$$

Strengthen Your Understanding

51. The graph of $f(x) = \log x$ is increasing, so $f'(0.5) > 0$.

52. The derivative of a function at a point is the slope of the tangent line, not the tangent line itself.

53. $f(x) = e^x$.

Many other answers are possible.

54. A linear function is of the form $f(x) = ax + b$. The derivative of this function is the slope of the line $y = ax + b$, so $f'(x) = a$, so $a = 2$. One such function is $f(x) = 2x + 1$.

55. True. The derivative of a function is the limit of difference quotients. A few difference quotients can be computed from the table, but the limit can not be computed from the table.

56. True. The derivative $f'(10)$ is the slope of the tangent line to the graph of $y = f(x)$ at the point where $x = 10$. When you zoom in on $y = f(x)$ close enough it is not possible to see the difference between the tangent line and the graph of f on the calculator screen. The line you see on the calculator is a little piece of the tangent line, so its slope is the derivative $f'(10)$.

57. True. This is seen graphically. The derivative $f'(a)$ is the slope of the line tangent to the graph of f at the point P where $x = a$. The difference quotient $(f(b) - f(a))/(b - a)$ is the slope of the secant line with endpoints on the graph of f at the points where $x = a$ and $x = b$. The tangent and secant lines cross at the point P. The secant line goes above the tangent line for $x > a$ because f is concave up, and so the secant line has higher slope.

58. (a). This is best observed graphically.

Solutions for Section 2.3

Exercises

1. (a) We use the interval to the right of $x = 2$ to estimate the derivative. (Alternately, we could use the interval to the left of 2, or we could use both and average the results.) We have

$$f'(2) \approx \frac{f(4) - f(2)}{4 - 2} = \frac{24 - 18}{4 - 2} = \frac{6}{2} = 3.$$

We estimate $f'(2) \approx 3$.

(b) We know that $f'(x)$ is positive when $f(x)$ is increasing and negative when $f(x)$ is decreasing, so it appears that $f'(x)$ is positive for $0 < x < 4$ and is negative for $4 < x < 12$.

2. For $x = 0$, 5, 10, and 15, we use the interval to the right to estimate the derivative. For $x = 20$, we use the interval to the left. For $x = 0$, we have

$$f'(0) \approx \frac{f(5) - f(0)}{5 - 0} = \frac{70 - 100}{5 - 0} = \frac{-30}{5} = -6.$$

Similarly, we find the other estimates in Table 2.5.

Table 2.5

x	0	5	10	15	20
$f'(x)$	-6	-3	-1.8	-1.2	-1.2

3. The graph is that of the line $y = -2x + 2$. The slope, and hence the derivative, is -2. See Figure 2.20.

19. Since $1/x = x^{-1}$, using the power rule gives

$$k'(x) = (-1)x^{-2} = -\frac{1}{x^2}.$$

Using the definition of the derivative, we have

$$\begin{aligned} k'(x) &= \lim_{h\to 0}\frac{k(x+h)-k(x)}{h} = \lim_{h\to 0}\frac{\frac{1}{x+h}-\frac{1}{x}}{h} = \lim_{h\to 0}\frac{x-(x+h)}{h(x+h)x} \\ &= \lim_{h\to 0}\frac{-h}{h(x+h)x} = \lim_{h\to 0}\frac{-1}{(x+h)x} = -\frac{1}{x^2}. \end{aligned}$$

20. Since $1/x^2 = x^{-2}$, using the power rule gives

$$l'(x) = -2x^{-3} = -\frac{2}{x^3}.$$

Using the definition of the derivative, we have

$$\begin{aligned} l'(x) &= \lim_{h\to 0}\frac{\frac{1}{(x+h)^2}-\frac{1}{x^2}}{h} = \lim_{h\to 0}\frac{x^2-(x+h)^2}{h(x+h)^2x^2} \\ &= \lim_{h\to 0}\frac{x^2-(x^2+2xh+h^2)}{h(x+h)^2x^2} = \lim_{h\to 0}\frac{-2xh-h^2}{h(x+h)^2x^2} \\ &= \lim_{h\to 0}\frac{-2x-h}{(x+h)^2x^2} = \frac{-2x}{x^2x^2} = -\frac{2}{x^3}. \end{aligned}$$

21. Using the definition of the derivative,

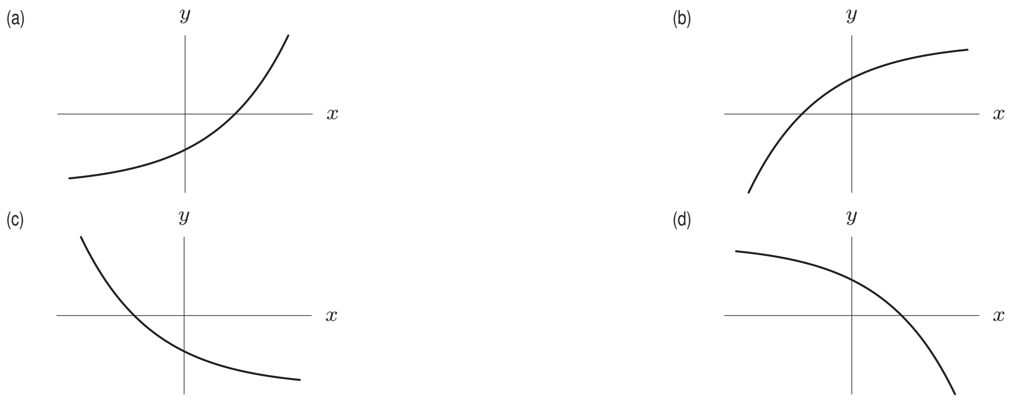
$$\begin{aligned} g'(x) &= \lim_{h\to 0}\frac{g(x+h)-g(x)}{h} = \lim_{h\to 0}\frac{2(x+h)^2-3-(2x^2-3)}{h} \\ &= \lim_{h\to 0}\frac{2(x^2+2xh+h^2)-3-2x^2+3}{h} = \lim_{h\to 0}\frac{4xh+2h^2}{h} \\ &= \lim_{h\to 0}(4x+2h) = 4x. \end{aligned}$$

22. Using the definition of the derivative, we have

$$\begin{aligned} m'(x) &= \lim_{h\to 0}\frac{m(x+h)-m(x)}{h} = \lim_{h\to 0}\frac{1}{h}\left(\frac{1}{x+h+1}-\frac{1}{x+1}\right) \\ &= \lim_{h\to 0}\frac{1}{h}\left(\frac{x+1-x-h-1}{(x+1)(x+h+1)}\right) = \lim_{h\to 0}\frac{-h}{h(x+1)(x+h+1)} \\ &= \lim_{h\to 0}\frac{-1}{(x+1)(x+h+1)} \\ &= \frac{-1}{(x+1)^2}. \end{aligned}$$

Problems

23.



24. Since $f'(x) > 0$ for $x < -1$, $f(x)$ is increasing on this interval.
Since $f'(x) < 0$ for $x > -1$, $f(x)$ is decreasing on this interval.
Since $f'(x) = 0$ at $x = -1$, the tangent to $f(x)$ is horizontal at $x = -1$.
One possible shape for $y = f(x)$ is shown in Figure 2.42.

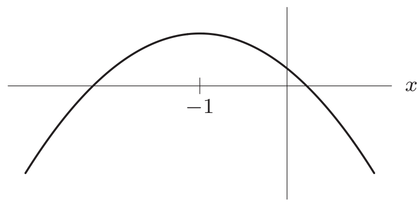


Figure 2.42

25.

x	$\ln x$
0.998	−0.0020
0.999	−0.0010
1.000	0.0000
1.001	0.0010
1.002	0.0020

x	$\ln x$
1.998	0.6921
1.999	0.6926
2.000	0.6931
2.001	0.6936
2.002	0.6941

x	$\ln x$
4.998	1.6090
4.999	1.6092
5.000	1.6094
5.001	1.6096
5.002	1.6098

x	$\ln x$
9.998	2.3024
9.999	2.3025
10.000	2.3026
10.001	2.3027
10.002	2.3028

At $x = 1$, the values of $\ln x$ are increasing by 0.001 for each increase in x of 0.001, so the derivative appears to be 1. At $x = 2$, the increase is 0.0005 for each increase of 0.001, so the derivative appears to be 0.5. At $x = 5$, $\ln x$ increases by 0.0002 for each increase of 0.001 in x, so the derivative appears to be 0.2. And at $x = 10$, the increase is 0.0001 over intervals of 0.001, so the derivative appears to be 0.1. These values suggest an inverse relationship between x and $f'(x)$, namely $f'(x) = \frac{1}{x}$.

26. We know that $f'(x) \approx \dfrac{f(x+h) - f(x)}{h}$. For this problem, we'll take the average of the values obtained for $h = 1$ and $h = -1$; that's the average of $f(x+1) - f(x)$ and $f(x) - f(x-1)$ which equals $\dfrac{f(x+1) - f(x-1)}{2}$. Thus,
$f'(0) \approx f(1) - f(0) = 13 - 18 = -5$.
$f'(1) \approx (f(2) - f(0))/2 = (10 - 18)/2 = -4$.
$f'(2) \approx (f(3) - f(1))/2 = (9 - 13)/2 = -2$.
$f'(3) \approx (f(4) - f(2))/2 = (9 - 10)/2 = -0.5$.
$f'(4) \approx (f(5) - f(3))/2 = (11 - 9)/2 = 1$.
$f'(5) \approx (f(6) - f(4))/2 = (15 - 9)/2 = 3$.
$f'(6) \approx (f(7) - f(5))/2 = (21 - 11)/2 = 5$.

$f'(7) \approx (f(8) - f(6))/2 = (30 - 15)/2 = 7.5.$
$f'(8) \approx f(8) - f(7) = 30 - 21 = 9.$
The rate of change of $f(x)$ is positive for $4 \leq x \leq 8$, negative for $0 \leq x \leq 3$. The rate of change is greatest at about $x = 8$.

27. The value of $g(x)$ is increasing at a decreasing rate for $2.7 < x < 4.2$ and increasing at an increasing rate for $x > 4.2$.

$$\frac{\Delta y}{\Delta x} = \frac{7.4 - 6.0}{5.2 - 4.7} = 2.8 \qquad \text{between } x = 4.7 \text{ and } x = 5.2$$
$$\frac{\Delta y}{\Delta x} = \frac{9.0 - 7.4}{5.7 - 5.2} = 3.2 \qquad \text{between } x = 5.2 \text{ and } x = 5.7$$

Thus $g'(x)$ should be close to 3 near $x = 5.2$.

28. (a) x_3 (b) x_4 (c) x_5 (d) x_3

29. This is a line with slope 1, so the derivative is the constant function $f'(x) = 1$. The graph is the horizontal line $y = 1$. See Figure 2.43.

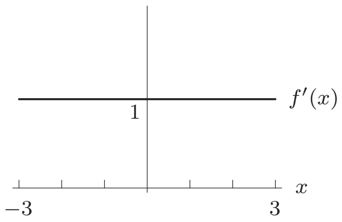

Figure 2.43

30. This is a line with slope -2, so the derivative is the constant function $f'(x) = -2$. The graph is a horizontal line at $y = -2$. See Figure 2.44.

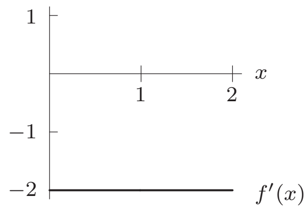

Figure 2.44

31. See Figure 2.45.

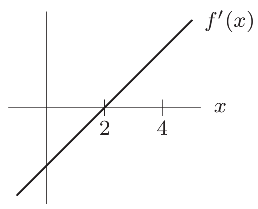

Figure 2.45

32. See Figure 2.46.

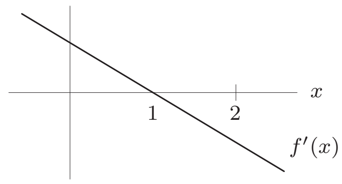

Figure 2.46

33. See Figure 2.47.

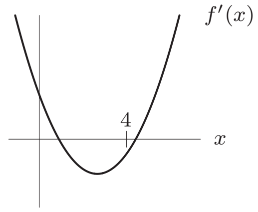

Figure 2.47

34. See Figure 2.48.

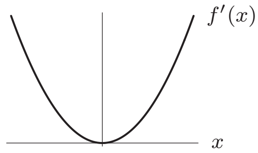

Figure 2.48

35. See Figure 2.49.

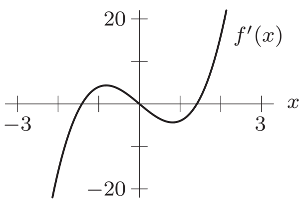

Figure 2.49

36. One possible graph is shown in Figure 2.50. Notice that as x gets large, the graph of $f(x)$ gets more and more horizontal. Thus, as x gets large, $f'(x)$ gets closer and closer to 0.

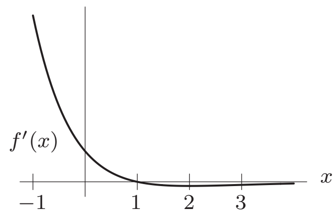

Figure 2.50

37. See Figure 2.51.

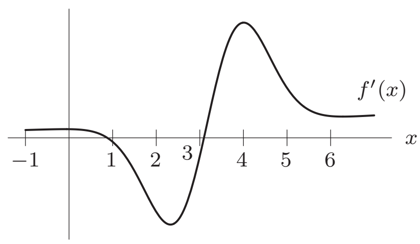

Figure 2.51

38. See Figure 2.52.

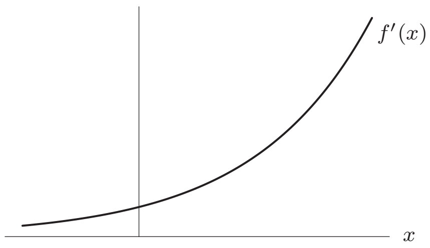

Figure 2.52

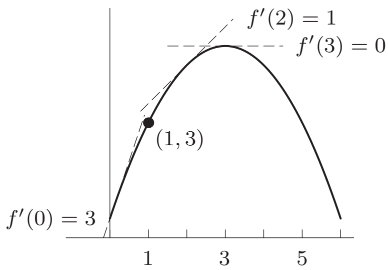

Figure 2.53

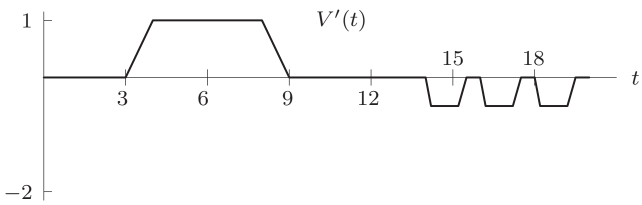
40. (a) Graph II
(b) Graph I
(c) Graph III

41. (a) $t = 3$
(b) $t = 9$
(c) $t = 14$
(d)



42. The derivative is zero whenever the graph of the original function is horizontal. Since the current is proportional to the derivative of the voltage, segments where the current is zero alternate with positive segments where the voltage is increasing and negative segments where the voltage is decreasing. See Figure 2.54. Note that the derivative does not exist where the graph has a corner.

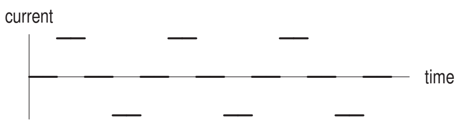


Figure 2.54

43. (a) The function f is increasing where f' is positive, so for $x_1 < x < x_3$.
(b) The function f is decreasing where f' is negative, so for $0 < x < x_1$ or $x_3 < x < x_5$.

44. On intervals where $f' = 0$, f is not changing at all, and is therefore constant. On the small interval where $f' > 0$, f is increasing; at the point where f' hits the top of its spike, f is increasing quite sharply. So f should be constant for a while, have a sudden increase, and then be constant again. A possible graph for f is shown in Figure 2.55.

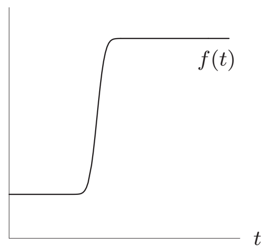

Figure 2.55: Step function

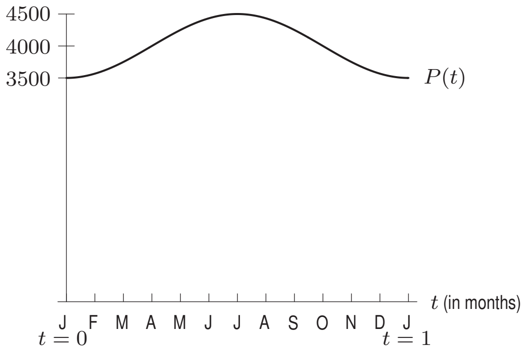
45. (a) The population varies periodically with a period of 1 year. See below.



(b) The population is at a maximum on July 1^{st}. At this time $\sin(2\pi t - \frac{\pi}{2}) = 1$, so the actual maximum population is $4000 + 500(1) = 4500$. Similarly, the population is at a minimum on January 1^{st}. At this time, $\sin(2\pi t - \frac{\pi}{2}) = -1$, so the minimum population is $4000 + 500(-1) = 3500$.
(c) The rate of change is most positive about April 1^{st} and most negative around October 1^{st}.
(d) Since the population is at its maximum around July 1^{st}, its rate of change is about 0 then.

46. The derivative of the accumulated federal debt with respect to time is shown in Figure 2.56. The derivative represents the rate of change of the federal debt with respect to time and is measured in trillions of dollars per year.

Figure 2.56

47. From the given information we know that f is increasing for values of x less than -2, is decreasing between $x = -2$ and $x = 2$, and is constant for $x > 2$. Figure 2.57 shows a possible graph—yours may be different.

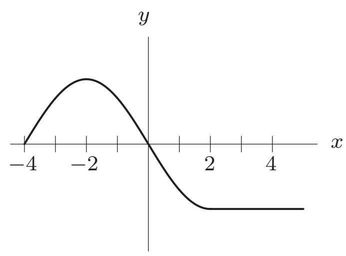


Figure 2.57

48. Since $f'(x) > 0$ for $1 < x < 3$, we see that $f(x)$ is increasing on this interval.
Since $f'(x) < 0$ for $x < 1$ and for $x > 3$, we see that $f(x)$ is decreasing on these intervals.
Since $f'(x) = 0$ for $x = 1$ and $x = 3$, the tangent to $f(x)$ will be horizontal at these x's.
One of many possible shapes of $y = f(x)$ is shown in Figure 2.58.

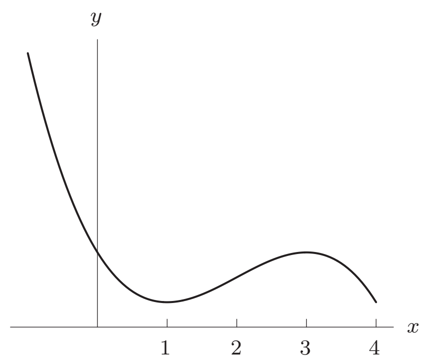

Figure 2.58

49. If $\lim_{x\to\infty} f(x) = 50$ and $f'(x)$ is positive for all x, then $f(x)$ increases to 50, but never rises above it. A possible graph of $f(x)$ is shown in Figure 2.59. If $\lim_{x\to\infty} f'(x)$ exists, it must be zero, since f looks more and more like a horizontal line. If $f'(x)$ approached another positive value c, then f would look more and more like a line with positive slope c, which would eventually go above $y = 50$.

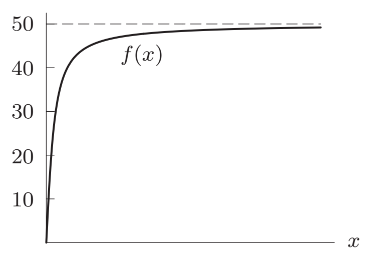

Figure 2.59

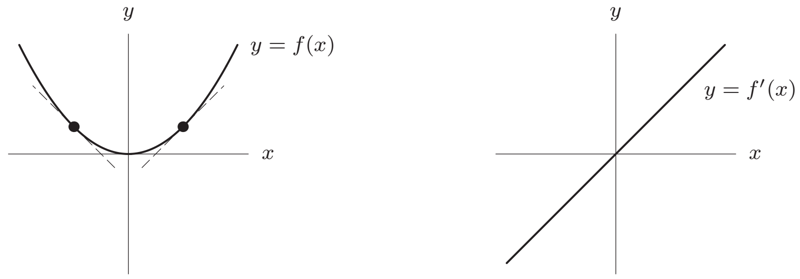
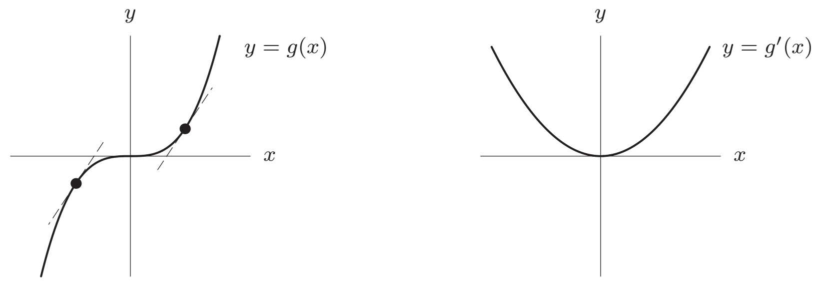
50. If $f(x)$ is even, its graph is symmetric about the y-axis. So the tangent line to f at $x = x_0$ is the same as that at $x = -x_0$ reflected about the y-axis.



So the slopes of these two tangent lines are opposite in sign, so $f'(x_0) = -f'(-x_0)$, and f' is odd.

51. If $g(x)$ is odd, its graph remains the same if you rotate it 180° about the origin. So the tangent line to g at $x = x_0$ is the tangent line to g at $x = -x_0$, rotated 180°.



But the slope of a line stays constant if you rotate it 180°. So $g'(x_0) = g'(-x_0)$; g' is even.

Strengthen Your Understanding

52. Since $f(x) = \cos x$ is decreasing on some intervals, its derivative $f'(x)$ is negative on those intervals, and the graph of $f'(x)$ is below the x-axis where $\cos x$ is decreasing.

53. In order for $f'(x)$ to be greater than zero, the slope of $f(x)$ has to be greater than zero. For example, $f(x) = e^{-x}$ is positive for all x but since the graph is decreasing everywhere, $f(x)$ has negative derivative for all x.

54. Two different functions can have the same rate of change. For example, $f(x) = 1, g(x) = 2$ both are constant, so $f'(x) = g'(x) = 0$ but $f(x) \neq g(x)$.

55. $f(t) = t(1-t)$. We have $f(t) = t - t^2$, so $f'(t) = 1 - 2t$ so the velocity is positive for $0 < t < 0.5$ and negative for $0.5 < t < 1$.

Many other answers are possible.

56. Every linear function is of the form $f(x) = b + mx$ and has derivative $f'(x) = m$. One family of functions with the same derivative is $f(x) = b + 2x$.

57. True. The graph of a linear function $f(x) = mx + b$ is a straight line with the same slope m at every point. Thus $f'(x) = m$ for all x.

58. True. Shifting a graph vertically does not change the shape of the graph and so it does not change the slopes of the tangent lines to the graph.

59. False. If $f'(x)$ is increasing then $f(x)$ is concave up. However, $f(x)$ may be either increasing or decreasing. For example, the exponential decay function $f(x) = e^{-x}$ is decreasing but $f'(x)$ is increasing because the graph of f is concave up.

60. False. A counterexample is given by $f(x) = 5$ and $g(x) = 10$, two different functions with the same derivatives: $f'(x) = g'(x) = 0$.

Solutions for Section 2.4

Exercises

1. (a) The statement $f(200) = 1300$ means that it costs \$1300 to produce 200 gallons of the chemical.

(b) The statement $f'(200) = 6$ means that when the number of gallons produced is 200, costs are increasing at a rate of \$6 per gallon. In other words, it costs about \$6 to produce the next (the 201^{st}) gallon of the chemical.

2. (a) The statement $f(5) = 18$ means that when 5 milliliters of catalyst are present, the reaction will take 18 minutes. Thus, the units for 5 are ml while the units for 18 are minutes.

(b) As in part (a), 5 is measured in ml. Since f' tells how fast T changes per unit a, we have f' measured in minutes/ml. If the amount of catalyst increases by 1 ml (from 5 to 6 ml), the reaction time decreases by about 3 minutes.

3. (Note that we are considering the average temperature of the yam, since its temperature is different at different points inside it.)

(a) It is positive, because the temperature of the yam increases the longer it sits in the oven.

(b) The units of $f'(20)$ are °F/min. The statement $f'(20) = 2$ means that at time $t = 20$ minutes, the temperature T would increase by approximately $2°$F if the yam is in the oven an additional minute.

4. (a) As the cup of coffee cools, the temperature decreases, so $f'(t)$ is negative.

(b) Since $f'(t) = dH/dt$, the units are degrees Celsius per minute. The quantity $f'(20)$ represents the rate at which the coffee is cooling, in degrees per minute, 20 minutes after the cup is put on the counter.

5. (a) The function f takes quarts of ice cream to cost in dollars, so 200 is the amount of ice cream, in quarts, and \$600 is the corresponding cost, in dollars. It costs \$600 to produce 200 quarts of ice cream.

(b) Here, 200 is in quarts, but the 2 is in dollars/quart. After producing 200 quarts of ice cream, the cost to produce one additional quart is about \$2.

6. (a) If the price is \$150, then 2000 items will be sold.

(b) If the price goes up from \$150 by \$1 per item, about 25 fewer items will be sold. Equivalently, if the price is decreased from \$150 by \$1 per item, about 25 more items will be sold.

7. Units of $C'(r)$ are dollars/percent. Approximately, $C'(r)$ means the additional amount needed to pay off the loan when the interest rate is increased by 1%. The sign of $C'(r)$ is positive, because increasing the interest rate will increase the amount it costs to pay off a loan.

8. The units of $f'(x)$ are feet/mile. The derivative, $f'(x)$, represents the rate of change of elevation with distance from the source, so if the river is flowing downhill everywhere, the elevation is always decreasing and $f'(x)$ is always negative. (In fact, there may be some stretches where the elevation is more or less constant, so $f'(x) = 0$.)

9. Units of $P'(t)$ are dollars/year. The practical meaning of $P'(t)$ is the rate at which the monthly payments change as the duration of the mortgage increases. Approximately, $P'(t)$ represents the change in the monthly payment if the duration is increased by one year. $P'(t)$ is negative because increasing the duration of a mortgage decreases the monthly payments.

10. Since B is measured in dollars and t is measured in years, dB/dt is measured in dollars per year. We can interpret dB as the extra money added to your balance in dt years. Therefore dB/dt represents how fast your balance is growing, in units of dollars/year.

11. (a) This means that investing the \$1000 at 5% would yield \$1649 after 10 years.

(b) Writing $g'(r)$ as dB/dr, we see that the units of dB/dr are dollars per percent (interest). We can interpret dB as the extra money earned if interest rate is increased by dr percent. Therefore $g'(5) = \frac{dB}{dr}|_{r=5} \approx 165$ means that the balance, at 5% interest, would increase by about \$165 if the interest rate were increased by 1%. In other words, $g(6) \approx g(5) + 165 = 1649 + 165 = 1814$.

12. (a) The units of lapse rate are the same as for the derivative dT/dz, namely (units of T)/(units of z) $=$ $°C$/km.

(b) Since the lapse rate is 6.5, the derivative of T with respect to z is $dT/dz = -6.5°C$/km. The air temperature drops about $6.5°$ for every kilometer you go up.

Problems

13. (a) Since $W = f(c)$ where W is weight in pounds and c is the number of Calories consumed per day:

$f(1800) = 155$	means that	consuming 1800 Calories per day results in a weight of 155 pounds.
$f'(2000) = 0$	means that	consuming 2000 Calories per day causes neither weight gain nor loss.
$f^{-1}(162) = 2200$	means that	a weight of 162 pounds is caused by a consumption of 2200 Calories per day.

(b) The units of dW/dc are pounds/(Calories/day).

14. (a) Let $f(t)$ be the volume, in cubic km, of the Greenland Ice Sheet t years since 2011 (Alternatively, in year t). We are given information about $f'(t)$, which has unit km^3 per year.
(b) If t is in years since 2011, we know $f'(0)$ is between -224 and -82 cubic km/year. (Alternatively, $f'(2011)$ is between -224 and -82.)

15. The graph is increasing for $0 < t < 15$ and is decreasing for $15 < t < 30$. One possible graph is shown in Figure 2.60. The units on the horizontal axis are years and the units on the vertical axis are people.

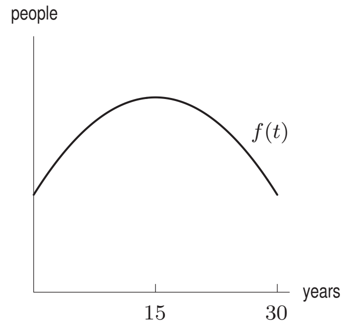


Figure 2.60

The derivative is positive for $0 < t < 15$ and negative for $15 < t < 30$. Two possible graphs are shown in Figure 2.61. The units on the horizontal axes are years and the units on the vertical axes are people per year.

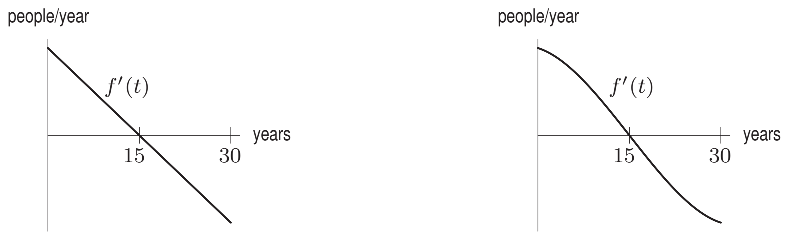

Figure 2.61

16. Since $f(t) = 1.34(1.004)^t$, we have

$$f(9) = 1.34(1.004)^9 = 1.389.$$

To estimate $f'(9)$, we use a small interval around 9:

$$f'(9) \approx \frac{f(9.001) - f(9)}{9.001 - 9} = \frac{1.34(1.004)^{9.001} - 1.34(1.004)^9}{0.001} = 0.0055.$$

We see that $f(9) = 1.389$ billion people and $f'(9) = 0.0055$ billion (that is, 5.5 million) people per year. Since $t = 9$ in 2020, this model predicts that the population of China will be about 1,389,000,000 people in 2009 and growing at a rate of about 5,500,000 people per year at that time.

17. $f(10) = 240{,}000$ means that if the commodity costs \$10, then 240,000 units of it will be sold. $f'(10) = -29{,}000$ means that if the commodity costs \$10 now, each \$1 increase in price will cause a decline in sales of 29,000 units.

18. Let p be the rating points earned by the CBS Evening News, let R be the revenue earned in millions of dollars, and let $R = f(p)$. When $p = 4.3$,

$$\text{Rate of change of revenue} \approx \frac{\$5.5 \text{ million}}{0.1 \text{ point}} = 55 \text{ million dollars/point.}$$

Thus

$$f'(4.3) \approx 55.$$

19. (a) The units of P are millions of people, the units of t are years, so the units of $f'(t)$ are millions of people per year. Therefore the statement $f'(6) = 2$ tells us that at $t = 6$ (that is, in 1986), the population of Mexico was increasing at 2 million people per year.
(b) The statement $f^{-1}(95.5) = 16$ tells us that the year when the population was 95.5 million was $t = 16$ (that is, in 1996).
(c) The units of $(f^{-1})'(P)$ are years per million of population. The statement $(f^{-1})'(95.5) = 0.46$ tells us that when the population was 95.5 million, it took about 0.46 years for the population to increase by 1 million.

20. (a) When $t = 10$, that is, at 10 am, 3.1 cm of rain has fallen.
(b) We are told that when 5 cm of rain has fallen, 16 hours have passed ($t = 16$); that is, 5 cm of rain has fallen by 4 pm.
(c) The rate at which rain is falling is 0.4 cm/hr at $t = 10$, that is, at 10 am.
(d) The units of $(f^{-1})'(5)$ are hours/cm. Thus, we are being told that when 5 cm of rain has fallen, rain is falling at a rate such that it will take 2 additional hours for another centimeter to fall.

21. (a) The depth of the water is 3 feet at time $t = 5$ hours.
(b) The depth of the water is increasing at 0.7 feet/hour at time $t = 5$ hours.
(c) When the depth of the water is 5 feet, the time is $t = 7$ hours.
(d) Since 5 is the depth in feet and $h^{-1}(5)$ is time in hours, the units of $(h^{-1})'$ are hours/feet. Thus, $(h^{-1})'(5) = 1.2$ tells us that when the water depth is 5 feet, the rate of change of time with depth is 1.2 hours per foot. In other words, when the depth is 5 feet, water is entering at a rate such that it takes 1.2 hours to add an extra foot of water.

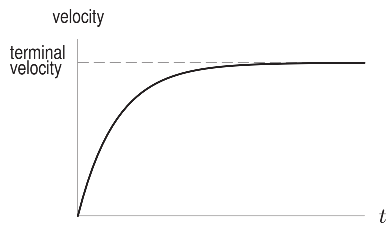
22. (a) The pressure in dynes/cm^2 at a depth of 100 meters.
(b) The depth of water in meters giving a pressure of $1.2 \cdot 10^6$ dynes/cm^2.
(c) The pressure at a depth of h meters plus a pressure of 20 dynes/cm^2.
(d) The pressure at a depth of 20 meters below the diver.
(e) The rate of increase of pressure with respect to depth, at 100 meters, in units of dynes/cm^2 per meter. Approximately, $p'(100)$ represents the increase in pressure in going from 100 meters to 101 meters.
(f) The depth, in meters, at which the rate of change of pressure with respect to depth is 100,000 dynes/cm^2 per meter.

23. The units of $g'(t)$ are inches/year. The quantity $g'(10)$ represents how fast Amelia Earhart was growing at age 10, so we expect $g'(10) > 0$. The quantity $g'(30)$ represents how fast she was growing at age 30, so we expect $g'(30) = 0$ because she was probably not growing taller at that age.

24. Units of $g'(55)$ are mpg/mph. The statement $g'(55) = -0.54$ means that at 55 miles per hour the fuel efficiency (in miles per gallon, or mpg) of the car decreases at a rate of approximately one half mpg as the velocity increases by one mph.

25. Units of dP/dt are barrels/year. dP/dt is the change in quantity of petroleum per change in time (a year). This is negative. We could estimate it by finding the amount of petroleum used worldwide over a short period of time.

26. (a)



(b) The graph should be concave down because air resistance decreases your acceleration as you speed up, and so the slope of the graph of velocity is decreasing.
(c) The slope represents the acceleration due to gravity.

27. (a) The derivative, dW/dt, measures the rate of change of water in the bathtub in gallons per minute.
(b) (i) The interval $t_0 < t < t_p$ represents the time before the plug is pulled. At that time, the rate of change of W is 0 since the amount of water in the tub is not changing.
(ii) Since dW/dt represents the rate at which the amount of water in the tub is changing, after the plug is pulled and water is leaving the tub, the sign of dW/dt is negative.
(iii) Once all the water has drained from the tub, the amount of water in the tub is not changing, so $dW/dt = 0$.

28. (a) The company hopes that increased advertising always brings in more customers instead of turning them away. Therefore, it hopes $f'(a)$ is always positive.
(b) If $f'(100) = 2$, it means that if the advertising budget is \$100,000, each extra dollar spent on advertising will bring in about \$2 worth of sales. If $f'(100) = 0.5$, each dollar above \$100 thousand spent on advertising will bring in about \$0.50 worth of sales.

(c) If $f'(100) = 2$, then as we saw in part (b), spending slightly more than \$100,000 will increase revenue by an amount greater than the additional expense, and thus more should be spent on advertising. If $f'(100) = 0.5$, then the increase in revenue is less than the additional expense, hence too much is being spent on advertising. The optimum amount to spend is an amount that makes $f'(a) = 1$. At this point, the increases in advertising expenditures just pay for themselves. If $f'(a) < 1$, too much is being spent; if $f'(a) > 1$, more should be spent.

29. (a) The derivative has units of people/second, so we find the rate of births, deaths, and migrations per second and combine them.

$$\begin{aligned}\text{Birth rate } &= \frac{1}{8} \text{ people per second}\\ \text{Death rate } &= \frac{1}{13} \text{ people per second}\\ \text{Migration rate } &= \frac{1}{27} \text{ people per second}\end{aligned}$$

Thus

$$f'(0) = \text{ Rate of change of population } = \frac{1}{8} - \frac{1}{13} + \frac{1}{27} = 0.0851 \text{ people/second.}$$

In other words, the population is increasing at 0.0851 people per second.

(b) From the answer to part (a), we see that it took $1/0.0851 = 11.75 \approx 12$ seconds to add one person.

30. Since $O'(2000) = -1,25$, we know the ODGI is decreasing at 1.25 units per year. To reduce the ODGI from 95 to 0 will take $95/1.25 = 76$ years. Thus the ozone hole is predicted to recover by 2076.

31. Since

$$\frac{P(67) - P(66)}{67 - 66} \approx P'(66),$$

we may think of $P'(66)$ as an estimate of $P(67) - P(66)$, and the latter is the number of people between 66 and 67 inches tall. Alternatively, since

$$\frac{P(66.5) - P(65.5)}{66.5 - 65.5} \text{ is a better estimate of } P'(66),$$

we may regard $P'(66)$ as an estimate of the number of people of height between 65.5 and 66.5 inches. The units for $P'(x)$ are people per inch. Since there are about 300 million people in the US, we guess that there are about 250 million full-grown persons in the US whose heights are distributed between 60 inches (5 ft) and 75 inches (6 ft 3 in). There are probably quite a few people of height 66 inches—between one and two times what we would expect from an even, or uniform, distribution— because 66 inches is nearly average. An even distribution would yield

$$P'(66) = \frac{250 \text{ million}}{15 \text{ ins}} \approx 17 \text{ million people per inch,}$$

so we expect $P'(66)$ to be between 17 and 34 million people per inch.

The value of $P'(x)$ is never negative because $P(x)$ is never decreasing. To see this, let's look at an example involving a particular value of x, say $x = 70$. The value $P(70)$ represents the number of people whose height is less than or equal to 70 inches, and $P(71)$ represents the number of people whose height is less than or equal to 71 inches. Since everyone shorter than 70 inches is also shorter than 71 inches, $P(70) \leq P(71)$. In general, $P(x)$ is 0 for small x, and increases as x increases, and is eventually constant (for large enough x).

32. (a) The units of compliance are units of volume per units of pressure, or liters per centimeter of water.

(b) The increase in volume for a 5 cm reduction in pressure is largest between 10 and 15 cm. Thus, the compliance appears maximum between 10 and 15 cm of pressure reduction. The derivative is given by the slope, so

$$\text{Compliance } \approx \frac{0.70 - 0.49}{15 - 10} = 0.042 \text{ liters per centimeter.}$$

(c) When the lung is nearly full, it cannot expand much more to accommodate more air.

33. Solving for $dp/d\delta$, we get

$$\frac{dp}{d\delta} = \left(\frac{p}{\delta + (p/c^2)}\right)\gamma.$$

(a) For $\delta \approx 10$ g/cm^3, we have $\log \delta \approx 1$, so, from Figure 2.38 in the text, we have $\gamma \approx 2.6$ and $\log p \approx 13$.

Thus $p \approx 10^{13}$, so $p/c^2 \approx 10^{13}/(9 \cdot 10^{20}) \approx 10^{-8}$, and

$$\frac{dp}{d\delta} \approx \frac{10^{13}}{10 + 10^{-8}} 2.6 \approx 2.6 \cdot 10^{12}.$$

The derivative can be interpreted as the ratio between a change in pressure and the corresponding change in density. The fact that it is so large says that a very large change in pressure brings about a very small change in density. This says that cold iron is not a very compressible material.

(b) For $\delta \approx 10^6$, we have $\log \delta \approx 6$, so, from Figure 2.38 in the text, $\gamma \approx 1.5$ and $\log p \approx 23$.
Thus $p \approx 10^{23}$, so $p/c^2 \approx 10^{23}/(9 \cdot 10^{20}) \approx 10^2$, and

$$\frac{dp}{d\delta} \approx \frac{10^{23}}{10^6 + 10^2} 1.5 \approx 1.5 \cdot 10^{17}.$$

This tells us that the matter in a white dwarf is even less compressible than cold iron.

Strengthen Your Understanding

34. Since we are not given the units of either t or s we cannot conclude that the units of the derivative are meters/second.

35. Since air is leaking from the balloon, the radius of the balloon must be decreasing, so $r'(t) < 0$.

36. Since T has units of minutes, its derivative with respect to P will have units of minutes/page.

37. Let $T(P)$ be the time, in years, to repay a loan of P dollars, then the derivative dT/dP is given in years/dollar.
There are many other possible answers.

38. Let $m = f(t)$ be the total distance, in miles, driven in a car, t days since it was purchased. Then the derivative dm/dt is given in miles/day.
There are many other possible answers.

39. True. The two sides of the equation are different frequently used notations for the very same quantity, the derivative of f at the point a.

40. True. The derivatives $f'(t)$ and $g'(t)$ measure the same thing, the rate of chemical production at the same time t, but they measure it in different units. The units of $f'(t)$ are grams per minute, and the units of $g'(t)$ are kilograms per minute. To convert from kg/min to g/min, multiply by 1000.

41. False. The derivatives $f'(t)$ and $g'(t)$ measure different things because they measure the rate of chemical production at different times. There is no conversion possible from one to the other.

42. (b) and (e) (b), (e)

43. (b) and (d) are equivalent, with (d) containing the most information. Notice that (a) and (c) are wrong.

Solutions for Section 2.5

Exercises

1. (a) Increasing, concave up
(b) Decreasing, concave down

2. (a) Since the graph is below the x-axis at $x = 2$, the value of $f(2)$ is negative.
(b) Since $f(x)$ is decreasing at $x = 2$, the value of $f'(2)$ is negative.
(c) Since $f(x)$ is concave up at $x = 2$, the value of $f''(2)$ is positive.

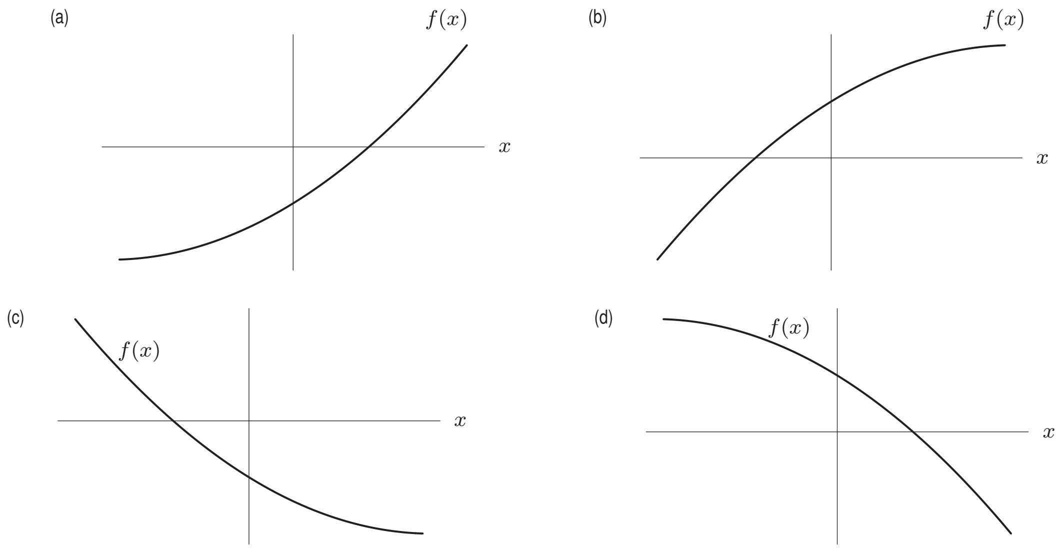
3. At B both dy/dx and d^2y/dx^2 could be positive because y is increasing and the graph is concave up there. At all the other points one or both of the derivatives could not be positive.

4. The two points at which $f' = 0$ are A and B. Since f' is nonzero at C and D and f'' is nonzero at all four points, we get the completed Table 2.6:

Table 2.6

Point	f	f'	f''
A	$-$	0	$+$
B	$+$	0	$-$
C	$+$	$-$	$-$
D	$-$	$+$	$+$

5.



6. The graph must be everywhere decreasing and concave up on some intervals and concave down on other intervals. One possibility is shown in Figure 2.62.

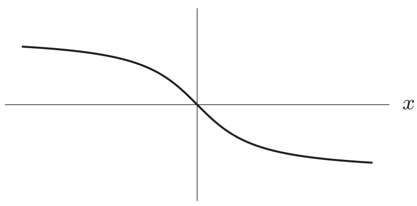


Figure 2.62

7. Since velocity is positive and acceleration is negative, we have $f' > 0$ and $f'' < 0$, and so the graph is increasing and concave down. See Figure 2.63.

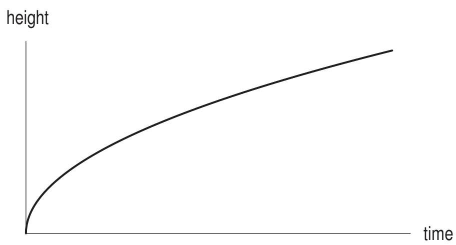

Figure 2.63

8. $f'(x) = 0$
$f''(x) = 0$

9. $f'(x) < 0$
$f''(x) = 0$

10. $f'(x) > 0$
$f''(x) > 0$

11. $f'(x) < 0$
$f''(x) > 0$

12. $f'(x) > 0$
$f''(x) < 0$

13. $f'(x) < 0$
$f''(x) < 0$

14. The velocity is the derivative of the distance, that is, $v(t) = s'(t)$. Therefore, we have

$$\begin{aligned} v(t) &= \lim_{h\to 0} \frac{s(t+h) - s(t)}{h} \\ &= \lim_{h\to 0} \frac{(5(t+h)^2 + 3) - (5t^2 + 3)}{h} \\ &= \lim_{h\to 0} \frac{10th + 5h^2}{h} \\ &= \lim_{h\to 0} \frac{h(10t + 5h)}{h} = \lim_{h\to 0} (10t + 5h) = 10t \end{aligned}$$

The acceleration is the derivative of velocity, so $a(t) = v'(t)$:

$$\begin{aligned} a(t) &= \lim_{h\to 0} \frac{10(t+h) - 10t}{h} \\ &= \lim_{h\to 0} \frac{10h}{h} = 10. \end{aligned}$$

Problems

15. (a) The derivative, $f'(t)$, appears to be positive since the number of cars is increasing. The second derivative, $f''(t)$, appears to be negative during the period 1975–1990 because the rate of change is increasing. For example, between 1975 and 1980, the rate of change is $(121.6 - 106.7)/5 = 2.98$ million cars per year, while between 1985 and 1990, the rate of change is 1.16 million cars per year.

(b) The derivative, $f'(t)$, appears to be negative between 1990 and 1995 since the number of cars is decreasing, but increasing between 1995 and 2000. The second derivative, $f''(t)$, appears to be positive during the period 1990–2000 because the rate of change is increasing. For example, between 1990 and 1995, the rate of change is $(128.4 - 133.7)/5 = -1.06$ million cars per year, while between 1995 and 2000, the rate of change is 1.04 million cars per year.

(c) To estimate $f'(2000)$ we consider the interval 2000–2005

$$f'(2005) \approx \frac{f(2005) - f(2000)}{2005 - 2000} \approx \frac{136.6 - 133.6}{5} = \frac{3}{5} = 0.6.$$

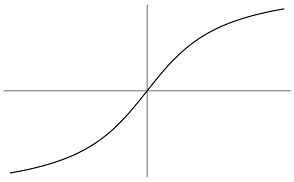
We estimate that $f'(2005) \approx 0.6$ million cars per year. The number of passenger cars in the US was increasing at a rate of about 600,000 cars per year in 2005.

16. To measure the average acceleration over an interval, we calculate the average rate of change of velocity over the interval. The units of acceleration are ft/sec per second, or (ft/sec)/sec, written ft/sec^2.

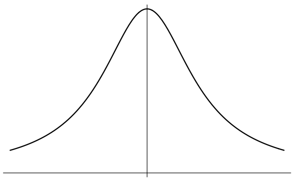
$$\begin{array}{c}\text{Average acceleration}\\ \text{for } 0 \le t \le 1\end{array} = \frac{\text{Change in velocity}}{\text{Time}} = \frac{v(1) - v(0)}{1} = \frac{30 - 0}{1} = 30 \text{ ft/sec}^2$$

$$\begin{array}{c}\text{Average acceleration}\\ \text{for } 1 \le t \le 2\end{array} = \frac{52 - 30}{2 - 1} = 22 \text{ ft/sec}^2$$

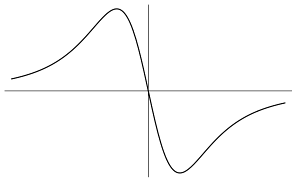
17. (a)



(b)



(c)



18. Since the graph of this function is a line, the second derivative (of any linear function) is 0. See Figure 2.64.

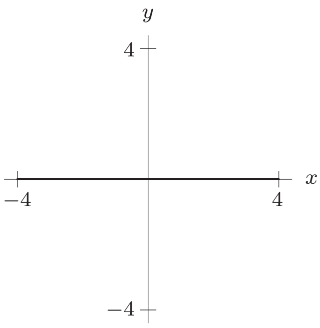


Figure 2.64

19. See Figure 2.65.

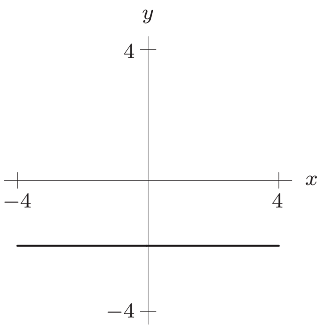

Figure 2.65

20. See Figure 2.66.

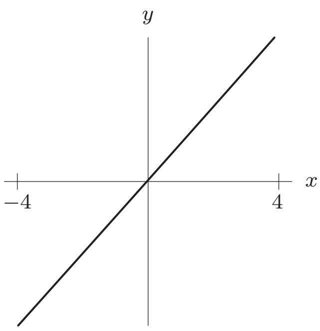

Figure 2.66

21. See Figure 2.67.

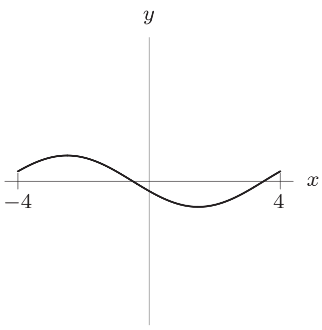

Figure 2.67

22. See Figure 2.68.

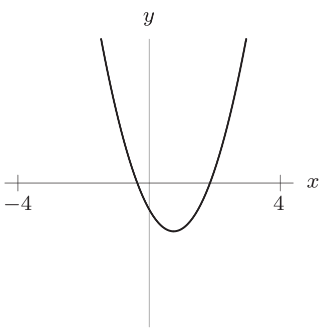

Figure 2.68

23. See Figure 2.69.

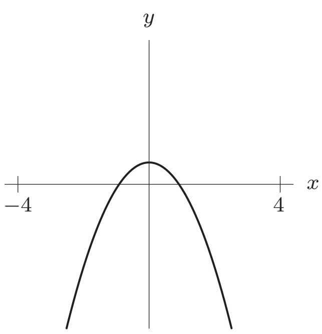

Figure 2.69

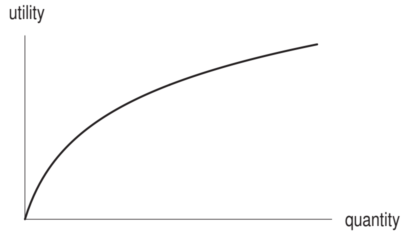
24. (a) $dP/dt > 0$ and $d^2P/dt^2 > 0$.

(b) $dP/dt < 0$ and $d^2P/dt^2 > 0$ (but dP/dt is close to zero).

25. (a)



(b) As a function of quantity, utility is increasing but at a decreasing rate; the graph is increasing but concave down. So the derivative of utility is positive, but the second derivative of utility is negative.

26. (a) Let $N(t)$ be the number of people below the poverty line. See Figure 2.70.

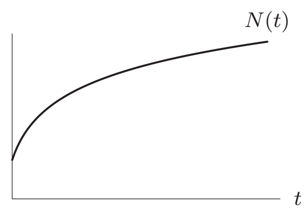


Figure 2.70

(b) dN/dt is positive, since people are still slipping below the poverty line. d^2N/dt^2 is negative, since the rate at which people are slipping below the poverty line, dN/dt, is decreasing.

27. (a) The EPA will say that the rate of discharge is still rising. The industry will say that the rate of discharge is increasing less quickly, and may soon level off or even start to fall.

(b) The EPA will say that the rate at which pollutants are being discharged is leveling off, but not to zero—so pollutants will continue to be dumped in the lake. The industry will say that the rate of discharge has decreased significantly.

28. (a) At x_4 and x_5, because the graph is below the x-axis there.
(b) At x_3 and x_4, because the graph is sloping down there.
(c) At x_3 and x_4, because the graph is sloping down there. This is the same condition as part (b).
(d) At x_2 and x_3, because the graph is bending downward there.
(e) At x_1, x_2, and x_5, because the graph is sloping upward there.
(f) At x_1, x_4, and x_5, because the graph is bending upward there.

29. (a) At t_3, t_4, and t_5, because the graph is above the t-axis there.
(b) At t_2 and t_3, because the graph is sloping up there.
(c) At t_1, t_2, and t_5, because the graph is concave up there
(d) At t_1, t_4, and t_5, because the graph is sloping down there.
(e) At t_3 and t_4, because the graph is concave down there.

30. Since f' is everywhere positive, f is everywhere increasing. Hence the greatest value of f is at x_6 and the least value of f is at x_1. Directly from the graph, we see that f' is greatest at x_3 and least at x_2. Since f'' gives the slope of the graph of f', f'' is greatest where f' is rising most rapidly, namely at x_6, and f'' is least where f' is falling most rapidly, namely at x_1.

31. To the right of $x = 5$, the function starts by increasing, since $f'(5) = 2 > 0$ (though f may subsequently decrease) and is concave down, so its graph looks like the graph shown in Figure 2.71. Also, the tangent line to the curve at $x = 5$ has slope 2 and lies above the curve for $x > 5$. If we follow the tangent line until $x = 7$, we reach a height of 24. Therefore, $f(7)$ must be smaller than 24, meaning 22 is the only possible value for $f(7)$ from among the choices given.

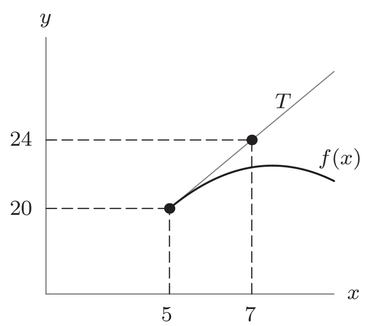

Figure 2.71

32. (a) From the information given, $C(1994) = 3200$ ppt and $C(2010) = 2750$ ppt.
(b) Since the change has been approximately linear, the rate of change is constant:

$$C'(1994) = C'(2010) = \frac{2750 - 3200}{2010 - 1994} = -28.125 \text{ ppt per year}.$$

(c) The slope is -28.125 and $C(1994) = 3200$.
If t is the year, we have

$$C(t) = 3200 - 28.125(t - 1994).$$

(d) We solve

$$\begin{aligned} 1850 &= 3200 - 28.125(t - 1994) \\ 28.125(t - 1994) &= 3200 - 1850 \\ t &= 1994 + \frac{3200 - 1850}{28.125} = 2042. \end{aligned}$$

The CFC level in the atmosphere above the US is predicted to return to the original level in 2042.
(e) Since $C''(t) > 0$, the graph bends upward, so the answer to part (d) is too early. The CFCs are expected to reach their original level later than 2042.

Strengthen Your Understanding

33. A linear function is neither concave up nor concave down.

34. When the acceleration of a car is zero, the car is not speeding up or slowing down. This happens whenever the velocity is constant. The car does not have to be stationary for this to happen.

35. One possibility is $f(x) = b + ax$, $a \neq 0$.

36. One possibility is $f(x) = x^2$. We have $f'(x) = 2x$, which is zero at $x = 0$ but $f''(x) = 2$.
There are many other possible answers.

37. True. The second derivative $f''(x)$ is the derivative of $f'(x)$. Thus the derivative of $f'(x)$ is positive, and so $f'(x)$ is increasing.

38. True. Instantaneous acceleration is a derivative, and all derivatives are limits of difference quotients. More precisely, instantaneous acceleration $a(t)$ is the derivative of the velocity $v(t)$, so

$$a(t) = \lim_{h \to 0} \frac{v(t+h) - v(t)}{h}.$$

39. True.

40. True; $f(x) = x^3$ is increasing over any interval.

41. False; $f(x) = x^2$ is monotonic on intervals which do not contain the origin (unless the origin is an endpoint).

Solutions for Section 2.6

Exercises

1. (a) Function f is not continuous at $x = 1$.
(b) Function f appears not differentiable at $x = 1, 2, 3$.

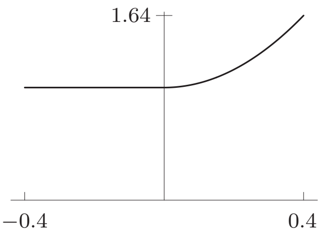
2. (a) Function g appears continuous at all x-values shown.
(b) Function g appears not differentiable at $x = 2, 4$. At $x = 2$, the curve is vertical, so the derivative does not exist. At $x = 4$, the graph has a corner, so the derivative does not exist.

3. No, there are sharp turning points.

4. Yes.

Problems

5. Yes, f is differentiable at $x = 0$, since its graph does not have a "corner" at $x = 0$. See below.



Another way to see this is by computing:

$$\lim_{h\to 0}\frac{f(h)-f(0)}{h} = \lim_{h\to 0}\frac{(h+|h|)^2}{h} = \lim_{h\to 0}\frac{h^2+2h|h|+|h|^2}{h}.$$

Since $|h|^2 = h^2$, we have:

$$\lim_{h\to 0}\frac{f(h)-f(0)}{h} = \lim_{h\to 0}\frac{2h^2+2h|h|}{h} = \lim_{h\to 0} 2(h+|h|) = 0.$$

So f is differentiable at 0 and $f'(0) = 0$.

6. As we can see in Figure 2.72, f oscillates infinitely often between the x-axis and the line $y = 2x$ near the origin. This means a line from $(0, 0)$ to a point $(h, f(h))$ on the graph of f alternates between slope 0 (when $f(h) = 0$) and slope 2 (when $f(h) = 2h$) infinitely often as h tends to zero. Therefore, there is no limit of the slope of this line as h tends to zero, and thus there is no derivative at the origin. Another way to see this is by noting that

$$\lim_{h\to 0}\frac{f(h)-f(0)}{h} = \lim_{h\to 0}\frac{h\sin(\frac{1}{h})+h}{h} = \lim_{h\to 0}\left(\sin\left(\frac{1}{h}\right)+1\right)$$

does not exist, since $\sin(\frac{1}{h})$ does not have a limit as h tends to zero. Thus, f is not differentiable at $x = 0$.

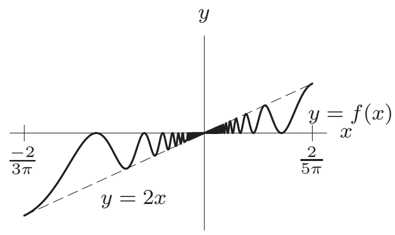


Figure 2.72

7. We can see from Figure 2.73 that the graph of f oscillates infinitely often between the curves $y = x^2$ and $y = -x^2$ near the origin. Thus the slope of the line from $(0, 0)$ to $(h, f(h))$ oscillates between h (when $f(h) = h^2$ and $\frac{f(h)-0}{h-0} = h$) and $-h$ (when $f(h) = -h^2$ and $\frac{f(h)-0}{h-0} = -h$) as h tends to zero. So, the limit of the slope as h tends to zero is 0, which is the derivative of f at the origin. Another way to see this is to observe that

$$\begin{aligned}\lim_{h\to 0}\frac{f(h)-f(0)}{h} &= \lim_{h\to 0}\left(\frac{h^2\sin(\frac{1}{h})}{h}\right)\\ &= \lim_{h\to 0} h\sin(\frac{1}{h})\\ &= 0,\end{aligned}$$

since $\lim_{h\to 0} h = 0$ and $-1 \le \sin(\frac{1}{h}) \le 1$ for any h. Thus f is differentiable at $x = 0$, and $f'(0) = 0$.

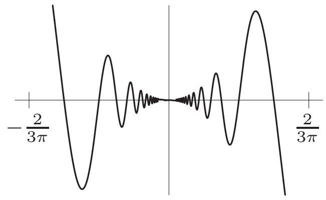

Figure 2.73

8. (a) The graph is concave up everywhere, except at $x = 2$ where the derivative is undefined. This is the case if the graph has a corner at $x = 2$. One possible graph is shown in Figure 2.74.
(b) The graph is concave up for $x < 2$ and concave down for $x > 2$, and the derivative is undefined at $x = 2$. This is the case if the graph is vertical at $x = 2$. One possible graph is shown in Figure 2.75.

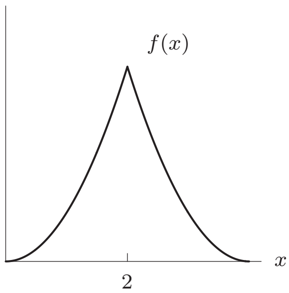

Figure 2.74

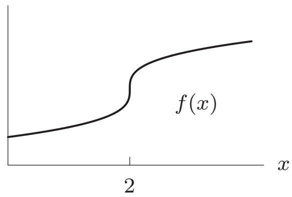

Figure 2.75

9. We want to look at

$$\lim_{h\to 0} \frac{(h^2 + 0.0001)^{1/2} - (0.0001)^{1/2}}{h}.$$

As $h \to 0$ from positive or negative numbers, the difference quotient approaches 0. (Try evaluating it for $h = 0.001$, 0.0001, etc.) So it appears there is a derivative at $x = 0$ and that this derivative is zero. How can this be if f has a corner at $x = 0$?

The answer lies in the fact that what appears to be a corner is in fact smooth—when you zoom in, the graph of f looks like a straight line with slope 0! See Figure 2.76.

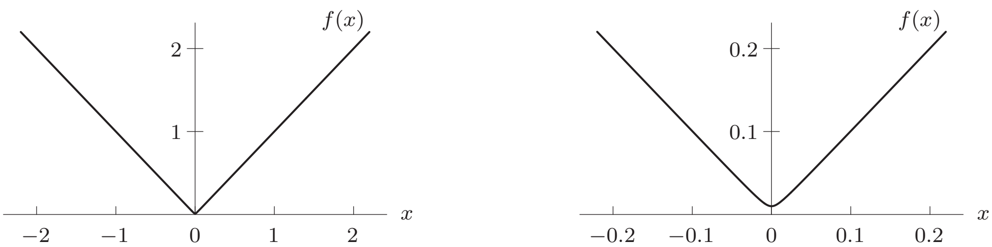

Figure 2.76: Close-ups of $f(x) = (x^2 + 0.0001)^{1/2}$ showing differentiability at $x = 0$

10. (a)

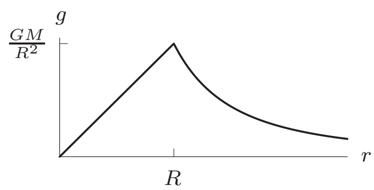

Figure 2.77

(b) The graph certainly looks continuous. The only point in question is $r = R$. Using the second formula with $r = R$ gives

$$g = \frac{GM}{R^2}.$$

Then, using the first formula with r approaching R from below, we see that as we get close to the surface of the earth

$$g \approx \frac{GMR}{R^3} = \frac{GM}{R^2}.$$

Since we get the same value for g from both formulas, g is continuous.

(c) For $r < R$, the graph of g is a line with a positive slope of $= \frac{GM}{R^3}$. For $r > R$, the graph of g looks like $1/x^2$, and so has a negative slope. Therefore the graph has a "corner" at $r = R$ and so is not differentiable there.

11. (a) The graph of Q against t does not have a break at $t = 0$, so Q appears to be continuous at $t = 0$. See Figure 2.78.

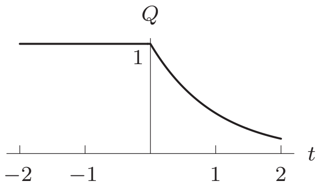

Figure 2.78

(b) The slope dQ/dt is zero for $t < 0$, and negative for all $t > 0$. At $t = 0$, there appears to be a corner, which does not disappear as you zoom in, suggesting that I is defined for all times t except $t = 0$.

12. (a) Notice that B is a linear function of r for $r \leq r_0$ and a reciprocal for $r > r_0$. The constant B_0 is the value of B at $r = r_0$ and the maximum value of B. See Figure 2.79.

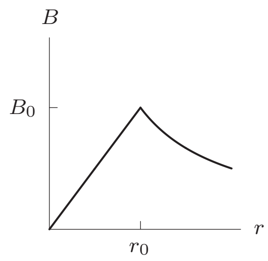

Figure 2.79

(b) B is continuous at $r = r_0$ because there is no break in the graph there. Using the formula for B, we have

$$\lim_{r \to r_0^-} B = \frac{r_0}{r_0} B_0 = B_0 \quad \text{and} \quad \lim_{r \to r_0^+} B = \frac{r_0}{r_0} B_0 = B_0.$$

(c) The function B is not differentiable at $r = r_0$ because the graph has a corner there. The slope is positive for $r < r_0$ and the slope is negative for $r > r_0$.

13. (a) Since

$$\lim_{r \to r_0^-} E = kr_0$$

and

$$\lim_{r \to r_0^+} E = \frac{kr_0^2}{r_0} = kr_0$$

and

$$E(r_0) = kr_0,$$

we see that E is continuous at r_0.

(b) The function E is not differentiable at $r = r_0$ because the graph has a corner there. The slope is positive for $r < r_0$ and the slope is negative for $r > r_0$.
(c) See Figure 2.80.

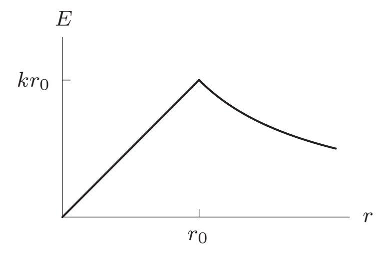

Figure 2.80

14. (a) The graph of $g(r)$ does not have a break or jump at $r = 2$, and so $g(r)$ is continuous there. See Figure 2.81. This is confirmed by the fact that

$$g(2) = 1 + \cos(\pi 2/2) = 1 + (-1) = 0$$

so the value of $g(r)$ as you approach $r = 2$ from the left is the same as the value when you approach $r = 2$ from the right.

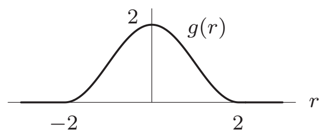

Figure 2.81

(b) The graph of $g(r)$ does not have a corner at $r = 2$, even after zooming in, so $g(r)$ appears to be differentiable at $r = 0$. This is confirmed by the fact that $\cos(\pi r/2)$ is at the bottom of a trough at $r = 2$, and so its slope is 0 there. Thus the slope to the left of $r = 2$ is the same as the slope to the right of $r = 2$.

15. (a) The graph of ϕ does not have a break at $y = 0$, and so ϕ appears to be continuous there. See figure Figure 2.82.

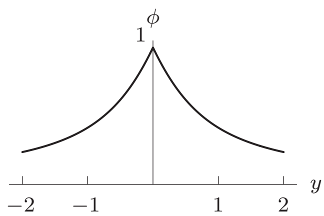

Figure 2.82

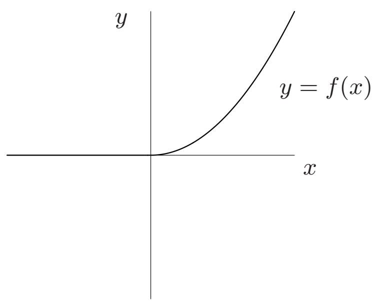
(b) The graph of ϕ has a corner at $y = 0$ which does not disappear as you zoom in. Therefore ϕ appears not be differentiable at $y = 0$.

16. (a) The graph of

$$f(x) = \begin{cases} 0 & \text{if } x < 0. \\ x^2 & \text{if } x \geq 0. \end{cases}$$

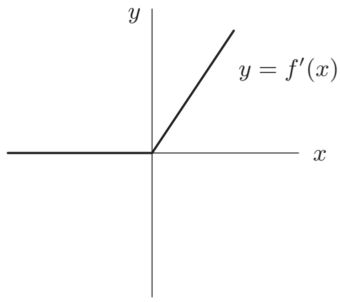
is shown to the right. The graph is continuous and has no vertical segments or corners, so $f(x)$ is differentiable everywhere.



By Example 4 on page 94,

$$f'(x) = \begin{cases} 0 & \text{if } x < 0 \\ 2x & \text{if } x \geq 0 \end{cases}$$

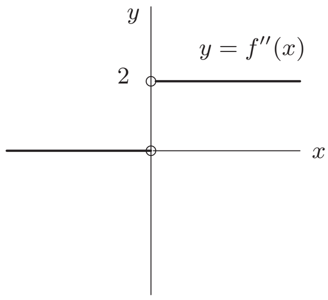
So its graph is shown to the right.



(b) The graph of the derivative has a corner at $x = 0$ so $f'(x)$ is not differentiable at $x = 0$. The graph of

$$f''(x) = \begin{cases} 0 \text{ if } x < 0 \\ 2 \text{ if } x > 0 \end{cases}$$

looks like:



The second derivative is not defined at $x = 0$. So it is certainly neither differentiable nor continuous at $x = 0$.

Strengthen Your Understanding

17. There are several ways in which a function can fail to be differentiable at a point, one of which is because the graph has a sharp corner at the point. Other cases are when the function is not continuous at a point or if the graph has a vertical tangent line.

18. The converse of this statement is true. However, a function can be continuous and not differentiable at a point; for example, $f(x) = |x|$ is continuous but not differentiable at $x = 0$.

19. $f(x) = |x - 2|$. This is continuous but not differentiable at $x = 2$.

20. $f(x) = \sqrt{x}$, $x \geq 0$. This is invertible but $f'(x) = 1/(2\sqrt{x})$, which is not defined at $x = 0$.

21. Let

$$f(x) = \frac{x^2 - 1}{x^2 - 4}.$$

Since $x^2 - 1 = (x - 1)(x + 1)$, this function has zeros at $x = \pm 1$. However, at $x = \pm 2$, the denominator $x^2 - 4 = 0$, so $f(x)$ is undefined and not differentiable.

22. True. Let $f(x) = |x - 3|$. Then $f(x)$ is continuous for all x but not differentiable at $x = 3$ because its graph has a corner there. Other answers are possible.

23. True. If a function is differentiable at a point, then it is continuous at that point. For example, $f(x) = x^2$ is both differentiable and continuous on any interval. However, *one* example does not establish the truth of this statement; it merely illustrates the statement.

24. False. Being continuous does not imply differentiability. For example, $f(x) = |x|$ is continuous but not differentiable at $x = 0$.

25. True. If a function were differentiable, then it would be continuous. For example,
$f(x) = \begin{cases} 1 & x \geq 0 \\ -1 & x < 0 \end{cases}$ is neither differentiable nor continuous at $x = 0$. However, *one* example does not establish the truth of this statement; it merely illustrates the statement.

26. False. For example, $f(x) = |x|$ is not differentiable at $x = 0$, but it is continuous at $x = 0$.

27. (a) This is not a counterexample, since it does not satisfy the conditions of the statement, and therefore does not have the potential to contradict the statement.

(b) This contradicts the statement, because it satisfies its conditions but not its conclusion. Hence it is a counterexample. Notice that this counterexample could not actually exist, since the statement is true.

(c) This is an example illustrating the statement; it is not a counterexample.

(d) This is not a counterexample, for the same reason as in part (a).

Solutions for Chapter 2 Review

Exercises

1. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the distance of the particle from a point, we find the values of $s(3) = 72$ and $s(10) = 144$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(10) - s(3)}{10 - 3} = \frac{144 - 72}{7} = \frac{72}{7} = 10.286 \text{ cm/sec.}$$

2. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the position of the particle, we find the values of $s(3) = 12 \cdot 3 - 3^2 = 27$ and $s(1) = 12 \cdot 1 - 1^2 = 11$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3) - s(1)}{3 - 1} = \frac{27 - 11}{2} = 8 \text{ mm/sec.}$$

3. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the position of the particle, we find the values of $s(3) = \ln 3$ and $s(1) = \ln 1$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3) - s(1)}{3 - 1} = \frac{\ln 3 - \ln 1}{2} = \frac{\ln 3}{2} = 0.549 \text{ mm/sec.}$$

4. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the position of the particle, we find the values of $s(3) = 11$ and $s(1) = 3$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3) - s(1)}{3 - 1} = \frac{11 - 3}{2} = 4 \text{ mm/sec.}$$

5. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the position of the particle, we find the values of $s(3) = 4$ and $s(1) = 4$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3) - s(1)}{3 - 1} = \frac{4 - 4}{2} = 0 \text{ mm/sec.}$$

Though the particle moves, its average velocity over the interval is zero, since it is at the same position at $t = 1$ and $t = 3$.

6. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the position of the particle, we find the values on the graph of $s(3) = 2$ and $s(1) = 3$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3) - s(1)}{3 - 1} = \frac{2 - 3}{2} = -\frac{1}{2} \text{ mm/sec.}$$

7. The average velocity over a time period is the change in position divided by the change in time. Since the function $s(t)$ gives the position of the particle, we find the values on the graph of $s(3) = 2$ and $s(1) = 2$. Using these values, we find

$$\text{Average velocity } = \frac{\Delta s(t)}{\Delta t} = \frac{s(3) - s(1)}{3 - 1} = \frac{2 - 2}{2} = 0 \text{ mm/sec.}$$

Though the particle moves, its average velocity over the interval is zero, since it is at the same position at $t = 1$ and $t = 3$.

8. (a) Let $s = f(t)$.

(i) We wish to find the average velocity between $t = 1$ and $t = 1.1$. We have

$$\text{Average velocity} = \frac{f(1.1) - f(1)}{1.1 - 1} = \frac{7.84 - 7}{0.1} = 8.4 \text{ m/sec.}$$

(ii) We have

$$\text{Average velocity} = \frac{f(1.01) - f(1)}{1.01 - 1} = \frac{7.0804 - 7}{0.01} = 8.04 \text{ m/sec.}$$

(iii) We have

$$\text{Average velocity} = \frac{f(1.001) - f(1)}{1.001 - 1} = \frac{7.008004 - 7}{0.001} = 8.004 \text{ m/sec.}$$

(b) We see in part (a) that as we choose a smaller and smaller interval around $t = 1$ the average velocity appears to be getting closer and closer to 8, so we estimate the instantaneous velocity at $t = 1$ to be 8 m/sec.

9. See Figure 2.83.

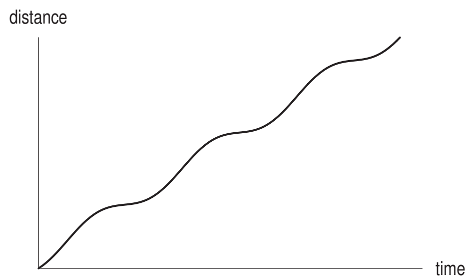


Figure 2.83

10. See Figure 2.84.

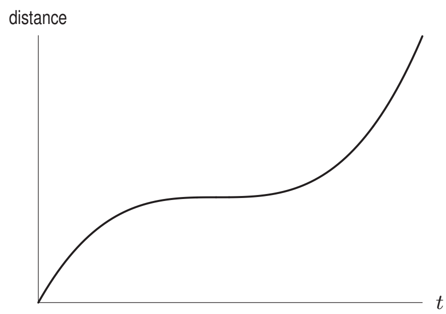

Figure 2.84

11. (a) Figure 2.85 shows a graph of $f(x) = x \sin x$.

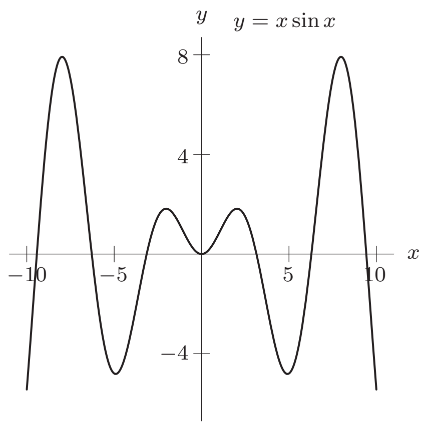

Figure 2.85

(b) Seven, since $x \sin x = 0$ at $x = 0, \pm\pi, \pm 2\pi, \pm 3\pi$.
(c) From the graph, we see $x \sin x$ is increasing at $x = 1$, decreasing at $x = 4$.
(d) We calculate both average rates of change

$$\frac{f(2) - f(0)}{(2-0)} = \frac{2\sin 2 - 0}{2} = \sin 2 \approx 0.91$$
$$\frac{f(8) - f(6)}{(8-6)} = \frac{8\sin 8 - 6\sin 6}{2} \approx 4.80.$$

So the average rate of change over $6 \leq x \leq 8$ is greater.
(e) From the graph, we see the slope is greater at $x = -9$.

12. (a) Using the difference quotient

$$f'(0.6) \approx \frac{f(0.8) - f(0.4)}{0.8 - 0.4} = \frac{0.5}{0.4} = 1.25.$$

Substituting $x = 0.6$, we have $y = 3.9$, so the tangent line is $y - 3.9 = 1.25(x - 0.6)$, that is $y = 1.25x + 3.15$.
(b) The equation from part (a) gives

$$f(0.7) \approx 1.25(0.7) + 3.15 = 4.025$$
$$f(1.2) \approx 1.25(1.2) + 3.15 = 4.65$$
$$f(1.4) \approx 1.25(1.4) + 3.15 = 4.9$$

The estimate for $f(0.7)$ is likely to be reliable as 0.7 is close to 0.6 (and $f(0.8) = 4$, which is not too far off). The estimate for $f(1.2)$ is less reliable as 1.2 is outside the given data (from 0 to 1.0). The estimate for $f(1.4)$ less reliable still.

13. See Figure 2.86.

Figure 2.86

14. See Figure 2.87.

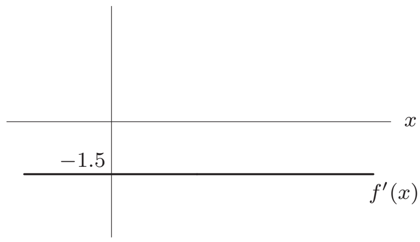

Figure 2.87

15. See Figure 2.88.

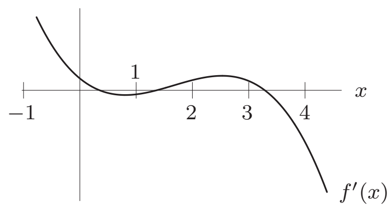

Figure 2.88

16. See Figure 2.89.

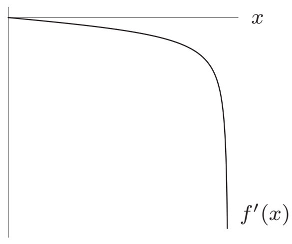

Figure 2.89

17. See Figure 2.90.

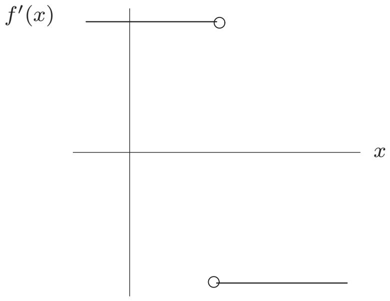

Figure 2.90

18. See Figure 2.91.

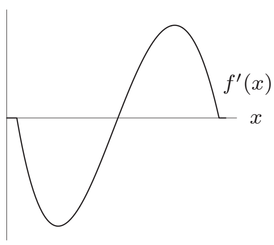

Figure 2.91

19. See Figure 2.92.

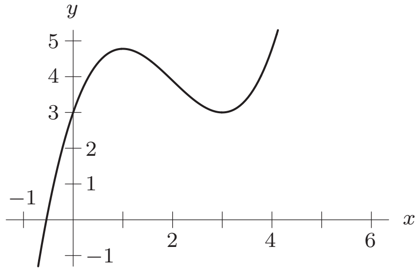

Figure 2.92

20. See Figure 2.93.

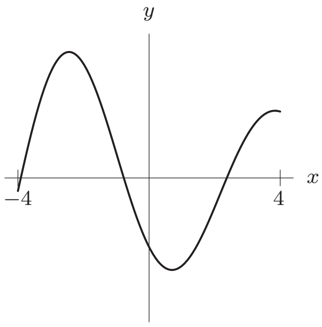

Figure 2.93

21. See Figure 2.94.

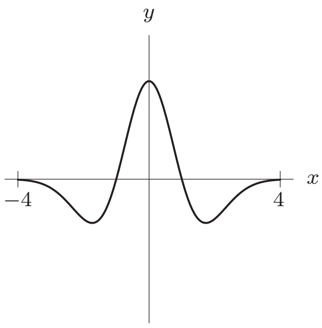

Figure 2.94

22. Using the definition of the derivative

$$\begin{aligned}
f'(x) &= \lim_{h\to 0} \frac{f(x+h)-f(x)}{h} \\
&= \lim_{h\to 0} \frac{5(x+h)^2+x+h-(5x^2+x)}{h} \\
&= \lim_{h\to 0} \frac{5(x^2+2xh+h^2)+x+h-5x^2-x}{h} \\
&= \lim_{h\to 0} \frac{10xh+5h^2+h}{h} \\
&= \lim_{h\to 0} (10x+5h+1) = 10x+1
\end{aligned}$$

23. Using the definition of the derivative, we have

$$\begin{aligned}
n'(x) &= \lim_{h\to 0} \frac{n(x+h)-n(x)}{h} \\
&= \lim_{h\to 0} \frac{1}{h}\left[\left(\frac{1}{x+h}+1\right)-\left(\frac{1}{x}+1\right)\right] \\
&= \lim_{h\to 0} \frac{1}{h}\left(\frac{1}{x+h}-\frac{1}{x}\right) \\
&= \lim_{h\to 0} \frac{x-(x+h)}{hx(x+h)} \\
&= \lim_{h\to 0} \frac{-h}{hx(x+h)} \\
&= \lim_{h\to 0} \frac{-1}{x(x+h)} = \frac{-1}{x^2}.
\end{aligned}$$

24. We need to look at the difference quotient and take the limit as h approaches zero. The difference quotient is

$$\frac{f(3+h)-f(3)}{h} = \frac{[(3+h)^2+1]-10}{h} = \frac{9+6h+h^2+1-10}{h} = \frac{6h+h^2}{h} = \frac{h(6+h)}{h}.$$

Since $h \neq 0$, we can divide by h in the last expression to get $6+h$. Now the limit as h goes to 0 of $6+h$ is 6, so

$$f'(3) = \lim_{h\to 0} \frac{h(6+h)}{h} = \lim_{h\to 0}(6+h) = 6.$$

So at $x = 3$, the slope of the tangent line is 6. Since $f(3) = 3^2 + 1 = 10$, the tangent line passes through $(3, 10)$, so its equation is

$$y - 10 = 6(x-3), \quad \text{or} \quad y = 6x - 8.$$

25. By joining consecutive points we get a line whose slope is the average rate of change. The steeper this line, the greater the average rate of change. See Figure 2.95.

(a) (i) C and D. Steepest slope.
(ii) B and C. Slope closest to 0.

(b) A and B, and C and D. The two slopes are closest to each other.

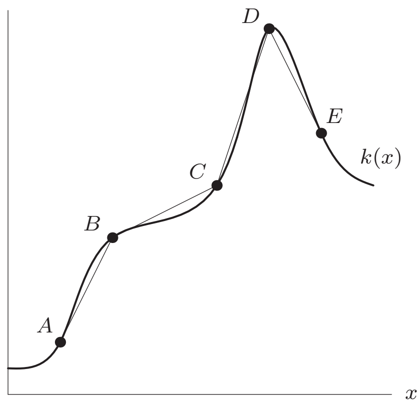

Figure 2.95

26. Using the definition of the derivative,

$$\begin{aligned} f'(x) &= \lim_{h\to 0} \frac{f(x+h)-f(x)}{h} \\ &= \lim_{h\to 0} \frac{(3(x+h)-1)-(3x-1)}{h} \\ &= \lim_{h\to 0} \frac{3x+3h-1-3x+1}{h} \\ &= \lim_{h\to 0} \frac{3h}{h} \\ &= \lim_{h\to 0} 3 \\ &= 3. \end{aligned}$$

27. Using the definition of the derivative,

$$\begin{aligned} f'(x) &= \lim_{h\to 0} \frac{f(x+h)-f(x)}{h} \\ &= \lim_{h\to 0} \frac{(5(x+h)^2)-(5x^2)}{h} \\ &= \lim_{h\to 0} \frac{5(x^2+2xh+h^2)-5x^2}{h} \end{aligned}$$

$$
\begin{aligned}
&= \lim_{h\to 0} \frac{5x^2+10xh+5h^2-5x^2}{h} \\
&= \lim_{h\to 0} \frac{10xh+5h^2}{h} \\
&= \lim_{h\to 0} (10x+5h) \\
&= 10x.
\end{aligned}
$$

28. Using the definition of the derivative,

$$
\begin{aligned}
f'(x) &= \lim_{h\to 0} \frac{f(x+h)-f(x)}{h} \\
&= \lim_{h\to 0} \frac{((x+h)^2+4)-(x^2+4)}{h} \\
&= \lim_{h\to 0} \frac{x^2+2xh+h^2+4-x^2-4}{h} \\
&= \lim_{h\to 0} \frac{2xh+h^2}{h} \\
&= \lim_{h\to 0} (2x+h) \\
&= 2x.
\end{aligned}
$$

29. Using the definition of the derivative,

$$
\begin{aligned}
f'(x) &= \lim_{h\to 0} \frac{f(x+h)-f(x)}{h} \\
&= \lim_{h\to 0} \frac{(3(x+h)^2-7)-(3x^2-7)}{h} \\
&= \lim_{h\to 0} \frac{(3(x^2+2xh+h^2)-7)-(3x^2-7)}{h} \\
&= \lim_{h\to 0} \frac{3x^2+6xh+3h^2-7-3x^2+7}{h} \\
&= \lim_{h\to 0} \frac{6xh+3h^2}{h} \\
&= \lim_{h\to 0} (6x+3h) \\
&= 6x.
\end{aligned}
$$

30. Using the definition of the derivative,

$$
\begin{aligned}
f'(x) &= \lim_{h\to 0} \frac{f(x+h)-f(x)}{h} \\
&= \lim_{h\to 0} \frac{(x+h)^3-x^3}{h} \\
&= \lim_{h\to 0} \frac{x^3+3x^2h+3xh^2+h^3-x^3}{h} \\
&= \lim_{h\to 0} \frac{3x^2h+3xh^2+h^3}{h} \\
&= \lim_{h\to 0} (3x^2+3xh+h^2) \\
&= 3x^2.
\end{aligned}
$$

31. $\displaystyle \lim_{h\to 0} \frac{(a+h)^2-a^2}{h} = \lim_{h\to 0} \frac{a^2+2ah+h^2-a^2}{h} = \lim_{h\to 0} (2a+h) = 2a$

32. $\displaystyle \lim_{h\to 0} \frac{1}{h}\left(\frac{1}{a+h}-\frac{1}{a}\right) = \lim_{h\to 0} \frac{a-(a+h)}{(a+h)ah} = \lim_{h\to 0} \frac{-1}{(a+h)a} = \frac{-1}{a^2}$

33. $\displaystyle \lim_{h\to 0} \frac{1}{h}\left(\frac{1}{(a+h)^2}-\frac{1}{a^2}\right) = \lim_{h\to 0} \frac{a^2-(a^2+2ah+h^2)}{(a+h)^2a^2h} = \lim_{h\to 0} \frac{(-2a-h)}{(a+h)^2a^2} = \frac{-2}{a^3}$

34. $\sqrt{a+h}-\sqrt{a} = \dfrac{(\sqrt{a+h}-\sqrt{a})(\sqrt{a+h}+\sqrt{a})}{\sqrt{a+h}+\sqrt{a}} = \dfrac{a+h-a}{\sqrt{a+h}+\sqrt{a}} = \dfrac{h}{\sqrt{a+h}+\sqrt{a}}.$

Therefore $\lim\limits_{h\to 0}\dfrac{\sqrt{a+h}-\sqrt{a}}{h} = \lim\limits_{h\to 0}\dfrac{1}{\sqrt{a+h}+\sqrt{a}} = \dfrac{1}{2\sqrt{a}}$

35. We combine terms in the numerator and multiply top and bottom by $\sqrt{a}+\sqrt{a+h}$.

$$\frac{1}{\sqrt{a+h}}-\frac{1}{\sqrt{a}} = \frac{\sqrt{a}-\sqrt{a+h}}{\sqrt{a+h}\sqrt{a}} = \frac{(\sqrt{a}-\sqrt{a+h})(\sqrt{a}+\sqrt{a+h})}{\sqrt{a+h}\sqrt{a}(\sqrt{a}+\sqrt{a+h})}$$
$$= \frac{a-(a+h)}{\sqrt{a+h}\sqrt{a}(\sqrt{a}+\sqrt{a+h})}$$

Therefore $\lim\limits_{h\to 0}\dfrac{1}{h}\left(\dfrac{1}{\sqrt{a+h}}-\dfrac{1}{\sqrt{a}}\right) = \lim\limits_{h\to 0}\dfrac{-1}{\sqrt{a+h}\sqrt{a}(\sqrt{a}+\sqrt{a+h})} = \dfrac{-1}{2(\sqrt{a})^3}$

Problems

36. The function is everywhere increasing and concave up. One possible graph is shown in Figure 2.96.

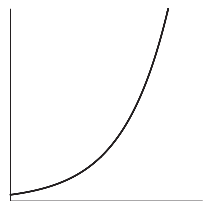

Figure 2.96

37. First note that the line $y = t$ has slope 1. From the graph, we see that

$$0 < \text{Slope at } C < \text{Slope at } B < \text{Slope between } A \text{ and } B < 1 < \text{Slope at } A.$$

Since instantaneous velocity is represented by the slope at a point and average velocity is represented by the slope between two points, we have

$$0 < \text{ Inst. vel. at } C < \text{ Inst. vel. at } B < \text{ Av. vel. between } A \text{ and } B < 1 < \text{ Inst. vel. at } A.$$

38. (a) The only graph in which the slope is 1 for all x is Graph (III).
(b) The only graph in which the slope is positive for all x is Graph (III).
(c) Graphs where the slope is 1 at $x = 2$ are Graphs (III) and (IV).
(d) Graphs where the slope is 2 at $x = 1$ are Graphs (II) and (IV).

39. (a) Velocity is zero at points A, C, F, and H.
(b) These are points where the acceleration is zero, at which the particle switches from speeding up to slowing down or vice versa.

40. (a) The derivative, $f'(t)$, appears to be positive between 2003–2005 and 2006–2007, since the number of cars increased in these intervals. The derivative, $f'(t)$, appears to be negative from 2005–2006, since the number of cars decreased then.
(b) We use the average rate of change formula on the interval 2005 to 2007 to estimate $f'(2006)$:

$$f'(2006) \approx \frac{135.9-136.6}{2007-2005} = \frac{-0.7}{2} = -0.35.$$

We see that $f'(2006) \approx -0.35$ million cars per year. The number of passenger cars in the US was decreasing at a rate of about 0.35 million, or 350,000, cars per year in 2006.

41. (a) If $f'(t) > 0$, the depth of the water is increasing. If $f'(t) < 0$, the depth of the water is decreasing.
(b) The depth of the water is increasing at 20 cm/min when $t = 30$ minutes.
(c) We use 1 meter $= 100$ cm, 1 hour $= 60$ min. At time $t = 30$ minutes

$$\text{Rate of change of depth} = 20\frac{\text{cm}}{\text{min}} = 20\frac{\text{cm}}{\text{min}}\cdot\frac{60 \text{ min}}{1 \text{ hr}}\cdot\frac{1 \text{ m}}{100 \text{ cm}} = 12 \text{ meters/hour}.$$

42. Since $f(t) = 45.7e^{-0.0061t}$, we have
$$f(6) = 45.7e^{-0.0061\cdot 6} = 44.058.$$
To estimate $f'(6)$, we use a small interval around 6:
$$f'(6) \approx \frac{f(6.001) - f(6)}{6.001 - 6} = \frac{45.7e^{-0.0061\cdot 6.001} - 45.7e^{-0.0061\cdot 6}}{0.001} = -0.269.$$
We see that $f(6) = 44.058$ million people and $f'(6) = -0.269$ million (that is, $-269{,}000$) people per year. Since $t = 6$ in 2015, this model predicts that the population of Ukraine will be about $44{,}058{,}000$ people in 2015 and declining at a rate of about 269,000 people per year at that time.

43. (a) The units of $R'(3)$ are thousands of dollars per (dollar per gallon).
The derivative $R'(3)$ tells us the rate of change of revenue with price. That is, $R'(3)$ gives approximately how much the revenue changes if the gas price increases by \$1 per gallon from \$3 per gallon.

(b) The units of $R^{-1}(5)$ are dollars per gallon. Thus, the units of $(R^{-1})'(5)$ are dollars/gallon per thousand dollars.
The derivative $(R^{-1})'(5)$ tells us the rate of change of price with revenue. That is, $(R^{-1})'(5)$ gives approximately how much the price of gas changes if the revenue increases by \$1000 from \$5000 to \$6000.

44. (a) A possible example is $f(x) = 1/|x-2|$ as $\lim_{x\to 2} 1/|x-2| = \infty$.

(b) A possible example is $f(x) = -1/(x-2)^2$ as $\lim_{x\to 2} -1/(x-2)^2 = -\infty$.

45. For $x < -2$, f is increasing and concave up. For $-2 < x < 1$, f is increasing and concave down. At $x = 1$, f has a maximum. For $x > 1$, f is decreasing and concave down. One such possible f is in Figure 2.97.

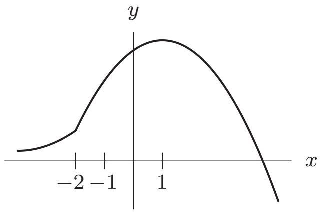

Figure 2.97

46. Since $f(2) = 3$ and $f'(2) = 1$, near $x = 2$ the graph looks like the segment shown in Figure 2.98.

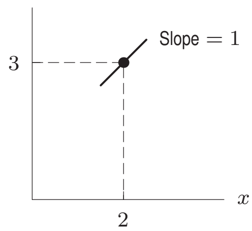

Figure 2.98

(a) If $f(x)$ is even, then the graph of $f(x)$ near $x = 2$ and $x = -2$ looks like Figure 2.99. Thus $f(-2) = 3$ and $f'(-2) = -1$.

(b) If $f(x)$ is odd, then the graph of $f(x)$ near $x = 2$ and $x = -2$ looks like Figure 2.100. Thus $f(-2) = -3$ and $f'(-2) = 1$.

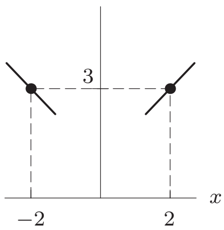

Figure 2.99: For f even

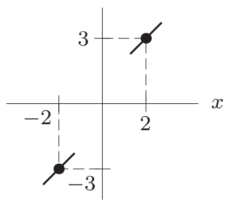

Figure 2.100: For f odd

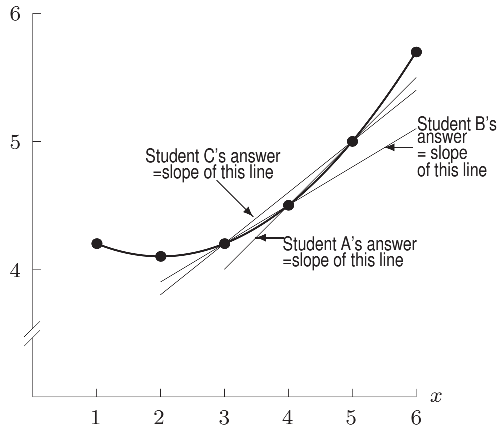
47. The slopes of the lines drawn through successive pairs of points are negative but increasing, suggesting that $f''(x) > 0$ for $1 \le x \le 3.3$ and that the graph of $f(x)$ is concave up.

48. Using the approximation $\Delta y \approx f'(x)\Delta x$ with $\Delta x = 2$, we have $\Delta y \approx f'(20) \cdot 2 = 6 \cdot 2$, so

$$f(22) \approx f(20) + f'(20) \cdot 2 = 345 + 6 \cdot 2 = 357.$$

49. (a)

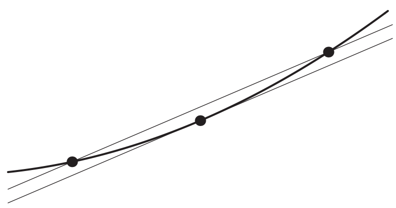


(b) The slope of f appears to be somewhere between student A's answer and student B's, so student C's answer, halfway in between, is probably the most accurate.

(c) Student A's estimate is $f'(x) \approx \frac{f(x+h)-f(x)}{h}$, while student B's estimate is $f'(x) \approx \frac{f(x)-f(x-h)}{h}$. Student C's estimate is the average of these two, or

$$f'(x) \approx \frac{1}{2}\left[\frac{f(x+h)-f(x)}{h} + \frac{f(x)-f(x-h)}{h}\right] = \frac{f(x+h)-f(x-h)}{2h}.$$

This estimate is the slope of the chord connecting $(x-h, f(x-h))$ to $(x+h, f(x+h))$. Thus, we estimate that the tangent to a curve is nearly parallel to a chord connecting points h units to the right and left, as shown below.



50. (a) Since the point $A = (7, 3)$ is on the graph of f, we have $f(7) = 3$.

(b) The slope of the tangent line touching the curve at $x = 7$ is given by

$$\text{Slope} = \frac{\text{Rise}}{\text{Run}} = \frac{3.8 - 3}{7.2 - 7} = \frac{0.8}{0.2} = 4.$$

Thus, $f'(7) = 4$.

51. At point A, we are told that $x = 1$ and $f(1) = 3$. Since $A = (x_2, y_2)$, we have $x_2 = 1$ and $y_2 = 3$. Since $h = 0.1$, we know $x_1 = 1 - 0.1 = 0.9$ and $x_3 = 1 + 0.1 = 1.1$.

Now consider Figure 2.101. Since $f'(1) = 2$, the slope of the tangent line AD is 2. Since $AB = 0.1$,

$$\frac{\text{Rise}}{\text{Run}} = \frac{BD}{0.1} = 2,$$

so $BD = 2(0.1) = 0.2$. Therefore $y_1 = 3 - 0.2 = 2.8$ and $y_3 = 3 + 0.2 = 3.2$.

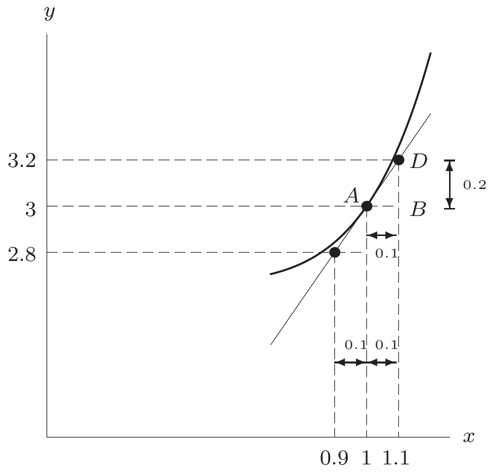


Figure 2.101

52. A possible graph of $y = f(x)$ is shown in Figure 2.102.

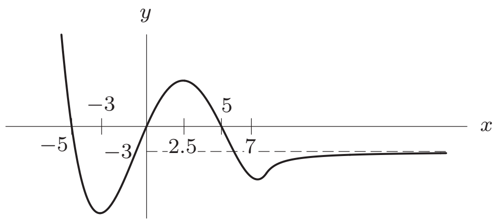

Figure 2.102

53. (a) Negative.
(b) $dw/dt = 0$ for t bigger than some t_0 (the time when the fire stops burning).
(c) $|dw/dt|$ increases, so dw/dt decreases since it is negative.

54. (a) The yam is cooling off so T is decreasing and $f'(t)$ is negative.
(b) Since $f(t)$ is measured in degrees Fahrenheit and t is measured in minutes, df/dt must be measured in units of $^\circ\text{F/min}$.

55. (a) The statement $f(140) = 120$ means that a patient weighing 140 pounds should receive a dose of 120 mg of the painkiller. The statement $f'(140) = 3$ tells us that if the weight of a patient increases by one pound (from 140 pounds), the dose should be increased by about 3 mg.
(b) Since the dose for a weight of 140 lbs is 120 mg and at this weight the dose goes up by about 3 mg for one pound, a 145 lb patient should get about an additional $3(5) = 15$ mg. Thus, for a 145 lb patient, the correct dose is approximately

$$f(145) \approx 120 + 3(5) = 135 \text{ mg}.$$

56. Suppose $p(t)$ is the average price level at time t. Then, if $t_0 =$ April 1991,
"Prices are still rising" means $p'(t_0) > 0$.
"Prices rising less fast than they were" means $p''(t_0) < 0$.
"Prices rising not as much less fast as everybody had hoped" means $H < p''(t_0)$, where H is the rate of change in rate of change of prices that people had hoped for.

57. The rate of change of the US population is $P'(t)$, so

$$P'(t) = 0.8\% \cdot \text{ Current population } = 0.008P(t).$$

58. (a) See Figure 2.103.

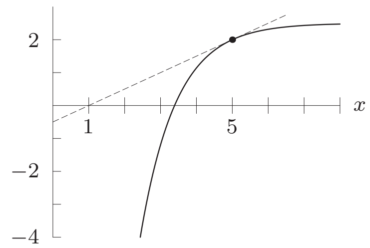

Figure 2.103

(b) Exactly one. There can't be more than one zero because f is increasing everywhere. There does have to be one zero because f stays below its tangent line (dotted line in above graph), and therefore f must cross the x-axis.

(c) The equation of the (dotted) tangent line is $y = \frac{1}{2}x - \frac{1}{2}$, and so it crosses the x-axis at $x = 1$. Therefore the zero of f must be between $x = 1$ and $x = 5$.

(d) $\lim_{x\to-\infty} f(x) = -\infty$, because f is increasing and concave down. Thus, as $x \to -\infty$, $f(x)$ decreases, at a faster and faster rate.

(e) Yes.

(f) No. The slope is decreasing since f is concave down, so $f'(1) > f'(5)$, i.e. $f'(1) > \frac{1}{2}$.

59. (a) $f'(0.6) \approx \dfrac{f(0.8) - f(0.6)}{0.8 - 0.6} = \dfrac{4.0 - 3.9}{0.2} = 0.5.$ $\quad f'(0.5) \approx \dfrac{f(0.6) - f(0.4)}{0.6 - 0.4} = \dfrac{0.4}{0.2} = 2.$

(b) Using the values of f' from part (a), we get $f''(0.6) \approx \dfrac{f'(0.6) - f'(0.5)}{0.6 - 0.5} = \dfrac{0.5 - 2}{0.1} = \dfrac{-1.5}{0.1} = -15.$

(c) The maximum value of f is probably near $x = 0.8$. The minimum value of f is probably near $x = 0.3$.

60. (a) Slope of tangent line $= \lim_{h\to 0} \frac{\sqrt{4+h}-\sqrt{4}}{h}$. Using $h = 0.001$, $\frac{\sqrt{4.001}-\sqrt{4}}{0.001} = 0.249984$. Hence the slope of the tangent line is about 0.25.

(b)

$$\begin{aligned} y - y_1 &= m(x - x_1) \\ y - 2 &= 0.25(x - 4) \\ y - 2 &= 0.25x - 1 \\ y &= 0.25x + 1 \end{aligned}$$

(c) $f(x) = kx^2$
If $(4, 2)$ is on the graph of f, then $f(4) = 2$, so $k \cdot 4^2 = 2$. Thus $k = \frac{1}{8}$, and $f(x) = \frac{1}{8}x^2$.

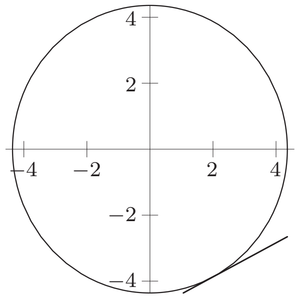
(d) To find where the graph of f crosses then line $y = 0.25x + 1$, we solve:

$$\begin{aligned} \frac{1}{8}x^2 &= 0.25x + 1 \\ x^2 &= 2x + 8 \\ x^2 - 2x - 8 &= 0 \\ (x - 4)(x + 2) &= 0 \\ x = 4 &\text{ or } x = -2 \\ f(-2) &= \frac{1}{8}(4) = 0.5 \end{aligned}$$

Therefore, $(-2, 0.5)$ is the other point of intersection. (Of course, $(4, 2)$ is a point of intersection; we know that from the start.)

61. (a) The slope of the tangent line at $(0, \sqrt{19})$ is zero: it is horizontal.
The slope of the tangent line at $(\sqrt{19}, 0)$ is undefined: it is vertical.

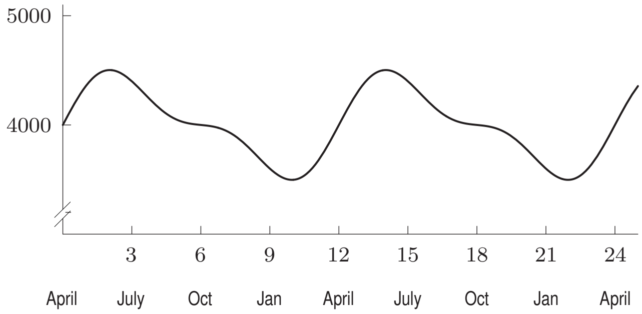
(b) The slope appears to be about $\frac{1}{2}$. (Note that when x is 2, y is about -4, but when x is 4, y is approximately -3.)



(c) Using symmetry we can determine: Slope at $(-2, \sqrt{15})$: about $\frac{1}{2}$. Slope at $(-2, -\sqrt{15})$: about $-\frac{1}{2}$. Slope at $(2, \sqrt{15})$: about $-\frac{1}{2}$.

62. (a) IV, (b) III, (c) II, (d) I, (e) IV, (f) II

63. (a) The population varies periodically with a period of 12 months (i.e. one year).



(b) The herd is largest about June 1^{st} when there are about 4500 deer.
(c) The herd is smallest about February 1^{st} when there are about 3500 deer.
(d) The herd grows the fastest about April 1^{st}. The herd shrinks the fastest about July 15 and again about December 15.
(e) It grows the fastest about April 1^{st} when the rate of growth is about 400 deer/month, i.e about 13 new fawns per day.

64. (a) The graph looks straight because the graph shows only a small part of the curve magnified greatly.
(b) The month is March: We see that about the 21^{st} of the month there are twelve hours of daylight and hence twelve hours of night. This phenomenon (the length of the day equaling the length of the night) occurs at the equinox, midway between winter and summer. Since the length of the days is increasing, and Madrid is in the northern hemisphere, we are looking at March, not September.
(c) The slope of the curve is found from the graph to be about 0.04 (the rise is about 0.8 hours in 20 days or 0.04 hours/day). This means that the amount of daylight is increasing by about 0.04 hours (about $2\frac{1}{2}$ minutes) per calendar day, or that each day is $2\frac{1}{2}$ minutes longer than its predecessor.

65. (a) A possible graph is shown in Figure 2.104. At first, the yam heats up very quickly, since the difference in temperature between it and its surroundings is so large. As time goes by, the yam gets hotter and hotter, its rate of temperature increase slows down, and its temperature approaches the temperature of the oven as an asymptote. The graph is thus concave down. (We are considering the average temperature of the yam, since the temperature in its center and on its surface will vary in different ways.)

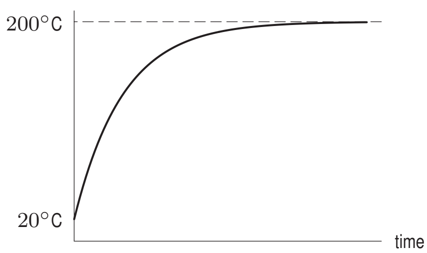


Figure 2.104

(b) If the rate of temperature increase were to remain 2°/min, in ten minutes the yam's temperature would increase $20°$, from $120°$ to $140°$. Since we know the graph is not linear, but concave down, the actual temperature is between $120°$ and $140°$.

(c) In 30 minutes, we know the yam increases in temperature by $45°$ at an average rate of $45/30 = 1.5°$/min. Since the graph is concave down, the temperature at $t = 40$ is therefore between $120 + 1.5(10) = 135°$ and $140°$.

(d) If the temperature increases at 2°/minute, it reaches $150°$ after 15 minutes, at $t = 45$. If the temperature increases at $1.5°$/minute, it reaches $150°$ after 20 minutes, at $t = 50$. So t is between 45 and 50 mins.

66. (a) We construct the difference quotient using $\text{erf}(0)$ and each of the other given values:

$$\begin{aligned} \text{erf}'(0) &\approx \frac{\text{erf}(1) - \text{erf}(0)}{1-0} = 0.84270079 \\ \text{erf}'(0) &\approx \frac{\text{erf}(0.1) - \text{erf}(0)}{0.1-0} = 1.1246292 \\ \text{erf}'(0) &\approx \frac{\text{erf}(0.01) - \text{erf}(0)}{0.01-0} = 1.128342. \end{aligned}$$

Based on these estimates, the best estimate is $\text{erf}'(0) \approx 1.12$; the subsequent digits have not yet stabilized.

(b) Using $\text{erf}(0.001)$, we have

$$\text{erf}'(0) \approx \frac{\text{erf}(0.001) - \text{erf}(0)}{0.001-0} = 1.12838$$

and so the best estimate is now 1.1283.

67. (a)

Table 2.7

x	$\frac{\sinh(x+0.001)-\sinh(x)}{0.001}$	$\frac{\sinh(x+0.0001)-\sinh(x)}{0.0001}$	so $f'(0) \approx$	$\cosh(x)$
0	1.00000	1.00000	1.00000	1.00000
0.3	1.04549	1.04535	1.04535	1.04534
0.7	1.25555	1.25521	1.25521	1.25517
1	1.54367	1.54314	1.54314	1.54308

(b) It seems that they are approximately the same, i.e. the derivative of $\sinh(x) = \cosh(x)$ for x = 0, 0.3, 0.7, and 1.

68. (a) Since the sea level is rising, we know that $a'(t) > 0$ and $m'(t) > 0$. Since the rate is accelerating, we know that $a''(t) > 0$ and $m''(t) > 0$.

(b) The rate of change of sea level for the mid-Atlantic states is between 2 and 4, we know $2 < a'(t) < 4$. (Possibly also $a'(t) = 2$ or $a'(t) = 4$.)
Similarly, $2 < m'(t) < 10$. (Possibly also $m'(t) = 2$ or $m'(t) = 10$.)

(c) (i) If $a'(t) = 2$, then sea level rise $= 2 \cdot 100 = 200$ mm.
If $a'(t) = 4$, then sea level rise $= 4 \cdot 100 = 400$ mm.
So sea level rise is between 200 mm and 400 mm.

(ii) The shortest amount of time for the sea level in the Gulf of Mexico to rise 1 meter occurs when the rate is largest, 10 mm per year. Since 1 meter $=$ 1000 mm,
shortest time to rise 1 meter $= 1000/10 = 100$ years.

CAS Challenge Problems

69. The CAS says the derivative is zero. This can be explained by the fact that $f(x) = \sin^2 x + \cos^2 x = 1$, so $f'(x)$ is the derivative of the constant function 1. The derivative of a constant function is zero.

70. (a) The CAS gives $f'(x) = 2\cos^2 x - 2\sin^2 x$. Form of answers may vary.

(b) Using the double angle formulas for sine and cosine, we have

$$\begin{aligned} f(x) &= 2\sin x \cos x = \sin(2x) \\ f'(x) &= 2\cos^2 x - 2\sin^2 x = 2(\cos^2 x - \sin^2 x) = 2\cos(2x). \end{aligned}$$

Thus we get

$$\frac{d}{dx}\sin(2x) = 2\cos(2x).$$

71. (a) The first derivative is $g'(x) = -2axe^{-ax^2}$, so the second derivative is

$$g''(x) = \frac{d^2}{dx^2}e^{-ax^2} = \frac{-2\,a}{e^{ax^2}} + \frac{4a^2x^2}{e^{ax^2}}.$$

Form of answers may vary.

(b) Both graphs get narrow as a gets larger; the graph of g'' is below the x-axis along the interval where g is concave down, and is above the x-axis where g is concave up. See Figure 2.105.

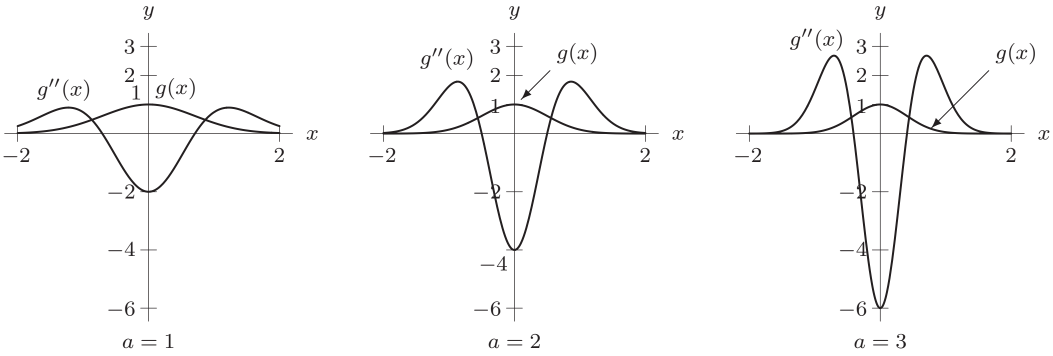

Figure 2.105

(c) The second derivative of a function is positive when the graph of the function is concave up and negative when it is concave down.

72. (a) The CAS gives the same derivative, $1/x$, in all three cases.

(b) From the properties of logarithms, $g(x) = \ln(2x) = \ln 2 + \ln x = f(x) + \ln 2$. So the graph of g is the same shape as the graph of f, only shifted up by $\ln 2$. So the graphs have the same slope everywhere, and therefore the two functions have the same derivative. By the same reasoning, $h(x) = f(x) + \ln 3$, so h and f have the same derivative as well.

73. (a) The computer algebra system gives

$$\frac{d}{dx}(x^2+1)^2 = 4x(x^2+1)$$
$$\frac{d}{dx}(x^2+1)^3 = 6x(x^2+1)^2$$
$$\frac{d}{dx}(x^2+1)^4 = 8x(x^2+1)^3$$

(b) The pattern suggests that

$$\frac{d}{dx}(x^2+1)^n = 2nx(x^2+1)^{n-1}.$$

Taking the derivative of $(x^2+1)^n$ with a CAS confirms this.

74. (a) Using a CAS, we find

$$\frac{d}{dx}\sin x = \cos x$$
$$\frac{d}{dx}\cos x = -\sin x$$
$$\frac{d}{dx}(\sin x\cos x) = \cos^2 x - \sin^2 x = 2\cos^2 x - 1.$$

(b) The product of the derivatives of $\sin x$ and $\cos x$ is $\cos x(-\sin x) = -\cos x\sin x$. On the other hand, the derivative of the product is $\cos^2 x - \sin^2 x$, which is not the same. So no, the derivative of a product is not always equal to the product of the derivatives.

PROJECTS FOR CHAPTER TWO

1. (a) $S(0) = 12$ since the days are always 12 hours long at the equator.

(b) Since $S(0) = 12$ from part (a) and the formula gives $S(0) = a$, we have $a = 12$. Since $S(x)$ must be continuous at $x = x_0$, and the formula gives $S(x_0) = a + b\arcsin(1) = 12 + b\left(\frac{\pi}{2}\right)$ and also $S(x_0) = 24$, we must have $12 + b\left(\frac{\pi}{2}\right) = 24$ so $b\left(\frac{\pi}{2}\right) = 12$ and $b = \frac{24}{\pi} \approx 7.64$.

(c) $S(32°13') \approx 14.12$ and $S(46°4') \approx 15.58$.

(d)

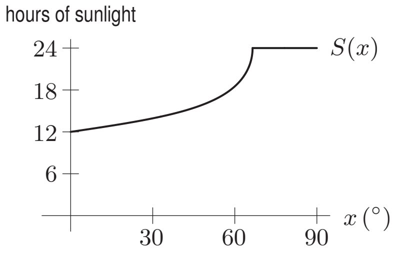

Figure 2.106

(e) The graph in Figure 2.106 appears to have a corner at $x_0 = 66°30'$. We compare the slope to the right of x_0 and to the left of x_0. To the right of S_0, the function is constant, so $S'(x) = 0$ for $x > 66°30'$.

We estimate the slope immediately to the left of x_0. We want to calculate the following:

$$\lim_{h\to 0^-} \frac{S(x_0+h) - S(x_0)}{h}.$$

We approximate it by taking $x_0 = 66.5$ and $h = -0.1,\ -0.01,\ -0.001$:

$$\frac{S(66.49) - S(66.5)}{-0.1} \approx \frac{22.3633 - 24}{-0.1} = 16.38,$$

$$\frac{S(66.499) - S(66.5)}{-0.01} \approx \frac{23.4826 - 24}{-0.01} = 51.83,$$

$$\frac{S(66.4999) - S(66.5)}{-0.001} \approx \frac{23.8370 - 24}{-0.001} = 163.9.$$

These approximations suggest that, for $x_0 = 66.5$,

$$\lim_{h\to 0^-} \frac{S(x_0+h) - S(x_0)}{h} \quad \text{does not exist.}$$

This evidence suggests that $S(x)$ is not differentiable at x_0. A proof requires the techniques found in Chapter 3.

2. (a) (i) Estimating derivatives using difference quotients (but other answers are possible):

$$P'(1900) \approx \frac{P(1910) - P(1900)}{10} = \frac{92.0 - 76.0}{10} = 1.6 \text{ million people per year}$$

$$P'(1945) \approx \frac{P(1950) - P(1940)}{10} = \frac{150.7 - 131.7}{10} = 1.9 \text{ million people per year}$$

$$P'(2000) \approx \frac{P(2000) - P(1990)}{10} = \frac{281.4 - 248.7}{10} = 3.27 \text{ million people per year}$$

(ii) The population growth rate was at its greatest at some time between 1950 and 1960.

(iii) $P'(1950) \approx \dfrac{P(1960) - P(1950)}{10} = \dfrac{179.0 - 150.7}{10} = 2.83$ million people per year,
so $P(1956) \approx P(1950) + P'(1950)(1956 - 1950) = 150.7 + 2.83(6) \approx 167.7$ million people.

(iv) If the growth rate between 2000 and 2010 was the same as the growth rate from 1990 to 2000, then the total population should be about 314 million people in 2010.

(b) (i) $f^{-1}(100)$ is the point in time when the population of the US was 100 million people (somewhere between 1910 and 1920).

(ii) The derivative of $f^{-1}(P)$ at $P = 100$ represents the ratio of change in time to change in population, and its units are years per million people. In other words, this derivative represents about how long it took for the population to increase by 1 million, when the population was 100 million.

(iii) Since the population increased by $105.7 - 92.0 = 13.7$ million people in 10 years, the average rate of increase is 1.37 million people per year. If the rate is fairly constant in that period, the amount of time it would take for an increase of 8 million people (100 million $-$ 92.0 million) would be

$$\frac{8 \text{ million people}}{1.37 \text{ million people/year}} \approx 5.8 \text{ years} \approx 6 \text{ years}$$

Adding this to our starting point of 1910, we estimate that the population of the US reached 100 million around 1916, i.e. $f^{-1}(100) \approx 1916$.

(iv) Since it took 10 years between 1910 and 1920 for the population to increase by $105.7 - 92.0 = 13.7$ million people, the derivative of $f^{-1}(P)$ at $P = 100$ is approximately

$$\frac{10 \text{ years}}{13.7 \text{ million people}} = 0.73 \text{ years/million people}$$

(c) (i) Clearly the population of the US at any instant is an integer that varies up and down every few seconds as a child is born, a person dies, or a new immigrant arrives. So $f(t)$ has "jumps;" it is not a smooth function. But these jumps are small relative to the values of f, so f appears smooth unless we zoom in very closely on its graph (to within a few seconds).

Major land acquisitions such as the Louisiana Purchase caused larger jumps in the population, but since the census is taken only every ten years and the territories acquired were rather sparsely populated, we cannot see these jumps in the census data.

(ii) We can regard rate of change of the population for a particular time t as representing an estimate of how much the population will increase during the year after time t.

(iii) Many economic indicators are treated as smooth, such as the Gross National Product, the Dow Jones Industrial Average, volumes of trading, and the price of commodities like gold. But these figures only change in increments, not continuously.

CHAPTER THREE

Solutions for Section 3.1

Exercises

1. The derivative, $f'(x)$, is defined as
$$f'(x) = \lim_{h\to 0} \frac{f(x+h) - f(x)}{h}.$$
If $f(x) = 7$, then
$$f'(x) = \lim_{h\to 0} \frac{7-7}{h} = \lim_{h\to 0} \frac{0}{h} = 0.$$

2. The definition of the derivative says that
$$f'(x) = \lim_{h\to 0} \frac{f(x+h) - f(x)}{h}.$$
Therefore,
$$f'(x) = \lim_{h\to 0} \frac{[17(x+h)+11] - [17x+11]}{h} = \lim_{h\to 0} \frac{17h}{h} = 17.$$

3. The x is in the exponent and we haven't learned how to handle that yet.

4. $y' = 3x^2$. (power rule)

5. $y' = \pi x^{\pi-1}$. (power rule)

6. $y' = 12x^{11}$.

7. $y' = 11x^{10}$.

8. $y' = 11x^{-12}$.

9. $y' = -12x^{-13}$.

10. $y' = 3.2x^{2.2}$.

11. $y' = -\frac{3}{4}x^{-7/4}$.

12. $y' = \frac{4}{3}x^{1/3}$.

13. $y' = \frac{3}{4}x^{-1/4}$.

14. $\dfrac{dy}{dx} = 2x + 5$.

15. $f'(t) = 3t^2 - 6t + 8$.

16. $f'(x) = -4x^{-5}$.

17. Since $g(t) = \dfrac{1}{t^5} = t^{-5}$, we have $g'(t) = -5t^{-6}$.

18. Since $f(z) = -\dfrac{1}{z^{6.1}} = -z^{-6.1}$, we have $f'(z) = -(-6.1)z^{-7.1} = 6.1z^{-7.1}$.

19. Since $y = \dfrac{1}{r^{7/2}} = r^{-7/2}$, we have $\dfrac{dy}{dx} = -\dfrac{7}{2}r^{-9/2}$.

20. Since $y = \sqrt{x} = x^{1/2}$, we have $\dfrac{dy}{dx} = \dfrac{1}{2}x^{-1/2}$.

21. $f'(x) = \frac{1}{4}x^{-3/4}$.

22. Since $h(\theta) = \dfrac{1}{\sqrt[3]{\theta}} = \theta^{-1/3}$, we have $h'(\theta) = -\dfrac{1}{3}\theta^{-4/3}$.

23. Since $f(x) = \sqrt{\dfrac{1}{x^3}} = \dfrac{1}{x^{3/2}} = x^{-3/2}$, we have $f'(x) = -\dfrac{3}{2}x^{-5/2}$.

24. $h(x) = ax \cdot \ln e = ax$, so $h'(x) = a$.

25. $y' = 6x^{1/2} - \frac{5}{2}x^{-1/2}$.

26. $f'(t) = 6t - 4$.

27. $y' = 17 + 12x^{-1/2}$.

28. $y' = 2z - \frac{1}{2z^2}$.

29. The power rule gives $f'(x) = 20x^3 - \dfrac{2}{x^3}$.

30. $h'(w) = 6w^{-4} + \dfrac{3}{2}w^{-1/2}$

31. $y' = -12x^3 - 12x^2 - 6$.

32. $y' = 15t^4 - \frac{5}{2}t^{-1/2} - \frac{7}{t^2}$.

33. $y' = 6t - \frac{6}{t^{3/2}} + \frac{2}{t^3}$.

34. Since $y = \sqrt{x}(x+1) = x^{1/2}x + x^{1/2} \cdot 1 = x^{3/2} + x^{1/2}$, we have $\dfrac{dy}{dx} = \dfrac{3}{2}x^{1/2} + \dfrac{1}{2}x^{-1/2}$.

35. Since $y = t^{3/2}(2 + \sqrt{t}) = 2t^{3/2} + t^{3/2}t^{1/2} = 2t^{3/2} + t^2$, we have $\frac{dy}{dx} = 3t^{1/2} + 2t$.

36. Since $h(t) = \dfrac{3}{t} + \dfrac{4}{t^2} = 3t^{-1} + 4t^{-2}$, we have $h'(t) = -3t^{-2} - 8t^{-3}$.

37. Since $h(\theta) = \theta(\theta^{-1/2} - \theta^{-2}) = \theta\theta^{-1/2} - \theta\theta^{-2} = \theta^{1/2} - \theta^{-1}$, we have $h'(\theta) = \dfrac{1}{2}\theta^{-1/2} + \theta^{-2}$.

38. $y = x + \frac{1}{x}$, so $y' = 1 - \frac{1}{x^2}$.

39. $f(z) = \dfrac{z}{3} + \dfrac{1}{3}z^{-1} = \dfrac{1}{3}\left(z + z^{-1}\right)$, so $f'(z) = \dfrac{1}{3}\left(1 - z^{-2}\right) = \dfrac{1}{3}\left(\dfrac{z^2-1}{z^2}\right)$.

40. $g'(x) = \dfrac{d}{dx}\left(x^{\frac{1}{2}} + x^{-1} + x^{-\frac{3}{2}}\right) = \dfrac{1}{2}x^{-\frac{1}{2}} - x^{-2} - \dfrac{3}{2}x^{-\frac{5}{2}}$.

41. $y = \frac{\theta}{\sqrt{\theta}} - \frac{1}{\sqrt{\theta}} = \sqrt{\theta} - \frac{1}{\sqrt{\theta}}$
$y' = \frac{1}{2\sqrt{\theta}} + \frac{1}{2\theta^{3/2}}$.

42. Since $g(t) = \dfrac{\sqrt{t}(1+t)}{t^2} = \dfrac{t^{1/2} \cdot 1 + t^{1/2}t}{t^2} = \dfrac{t^{1/2}}{t^2} + \dfrac{t^{3/2}}{t^2} = t^{-3/2} + t^{-1/2}$, we have $g'(t) = -\dfrac{3}{2}t^{-5/2} - \dfrac{1}{2}t^{-3/2}$.

43. $j'(x) = \dfrac{3x^2}{a} + \dfrac{2ax}{b} - c$

44. Since $f(x) = \dfrac{ax+b}{x} = \dfrac{ax}{x} + \dfrac{b}{x} = a + bx^{-1}$, we have $f'(x) = -bx^{-2}$.

45. Since $h(x) = \dfrac{ax+b}{c} = \dfrac{a}{c}x + \dfrac{b}{c}$, we have $h'(x) = \dfrac{a}{c}$.

46. Since $4/3$, π, and b are all constants, we have

$$\frac{dV}{dr} = \frac{4}{3}\pi(2r)b = \frac{8}{3}\pi rb.$$

47. Since w is a constant times q, we have $dw/dq = 3ab^2$.

48. Since a, b, and c are all constants, we have

$$\frac{dy}{dx} = a(2x) + b(1) + 0 = 2ax + b.$$

49. Since a and b are constants, we have

$$\frac{dP}{dt} = 0 + b\frac{1}{2}t^{-1/2} = \frac{b}{2\sqrt{t}}.$$

Problems

50. So far, we can only take the derivative of powers of x and the sums of constant multiples of powers of x. Since we cannot write $\sqrt{x+3}$ in this form, we cannot yet take its derivative.

51. The x is in the exponent and we have not learned how to handle that yet.

52. $g'(x) = \pi x^{(\pi-1)} + \pi x^{-(\pi+1)}$, by the power and sum rules.

53. $y' = 6x$. (power rule and sum rule)

54. We cannot write $\frac{1}{3x^2+4}$ as the sum of powers of x multiplied by constants.

55. $y' = -2/3z^3$. (power rule and sum rule)

56.

$$\begin{aligned} y' &= 3x^2 - 18x - 16 \\ 5 &= 3x^2 - 18x - 16 \\ 0 &= 3x^2 - 18x - 21 \\ 0 &= x^2 - 6x - 7 \\ 0 &= (x+1)(x-7) \\ x &= -1 \text{ or } x = 7. \end{aligned}$$

When $x = -1$, $y = 7$; when $x = 7$, $y = -209$.
Thus, the two points are $(-1, 7)$ and $(7, -209)$.

57. Differentiating gives

$$f'(x) = 6x^2 - 4x \quad \text{so} \quad f'(1) = 6 - 4 = 2.$$

Thus the equation of the tangent line is $(y - 1) = 2(x - 1)$ or $y = 2x - 1$.

58. (a) We have $f(2) = 8$, so a point on the tangent line is $(2, 8)$. Since $f'(x) = 3x^2$, the slope of the tangent is given by

$$m = f'(2) = 3(2)^2 = 12.$$

Thus, the equation is

$$y - 8 = 12(x - 2) \quad \text{or} \quad y = 12x - 16.$$

(b) See Figure 3.1. The tangent line lies below the function $f(x) = x^3$, so estimates made using the tangent line are underestimates.

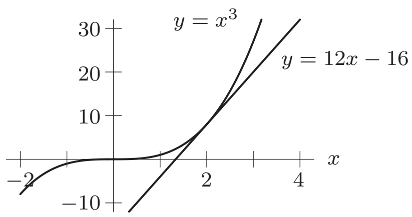

Figure 3.1

59. To calculate the equation of the tangent line to $y = f(x) = x^2 + 3x - 5$ at $x = 2$, we need to find the y-coordinate and the slope at $x = 2$. The y-coordinate is

$$y = f(2) = 2^2 + 3(2) - 5 = 5,$$

so a point on the line is $(2, 5)$. The slope is found using the derivative: $f'(x) = 2x + 3$. At the point $x = 2$, we have

$$\text{Slope} = f'(2) = 2(2) + 3 = 7.$$

The equation of the line is

$$\begin{aligned} y - 5 &= 7(x - 2) \\ y &= 7x - 9. \end{aligned}$$

When we graph the function and the line together, the line $y = 7x - 9$ appears to lie tangent to the curve $y = x^2 + 3x - 5$ at the point $x = 2$ as we expect.

60. The slope of the tangent line is the value of the first derivative at $x = 2$. Differentiating gives

$$\begin{aligned}\frac{d}{dx}\left(\frac{x^3}{2} - \frac{4}{3x}\right) &= \frac{d}{dx}\left(\frac{1}{2}x^3 - \frac{4}{3}x^{-1}\right)\\ &= \frac{1}{2}\cdot 3x^2 - \frac{4}{3}(-1)x^{-2}\\ &= \frac{3}{2}x^2 + \frac{4}{3x^2}.\end{aligned}$$

For $x = 2$,

$$f'(2) = \frac{3}{2}(2)^2 + \frac{4}{3(2)^2} = 6 + \frac{1}{3} = 6.333$$

and

$$f(2) = \frac{2^3}{2} - \frac{4}{3(2)} = 4 - \frac{2}{3} = 3.333.$$

To find the y-intercept for the tangent line equation at the point $(2, 3.333)$, we substitute in the general equation, $y = b + mx$, and solve for b.

$$\begin{aligned}3.333 &= b + 6.333(2)\\ -9.333 &= b.\end{aligned}$$

The tangent line has the equation

$$y = -9.333 + 6.333x.$$

61. The slopes of the tangent lines to $y = x^2 - 2x + 4$ are given by $y' = 2x - 2$. A line through the origin has equation $y = mx$. So, at the tangent point, $x^2 - 2x + 4 = mx$ where $m = y' = 2x - 2$.

$$\begin{aligned}x^2 - 2x + 4 &= (2x - 2)x\\ x^2 - 2x + 4 &= 2x^2 - 2x\\ -x^2 + 4 &= 0\\ -(x + 2)(x - 2) &= 0\\ x &= 2, -2.\end{aligned}$$

Thus, the points of tangency are $(2, 4)$ and $(-2, 12)$. The lines through these points and the origin are $y = 2x$ and $y = -6x$, respectively. Graphically, this can be seen in Figure 3.2.

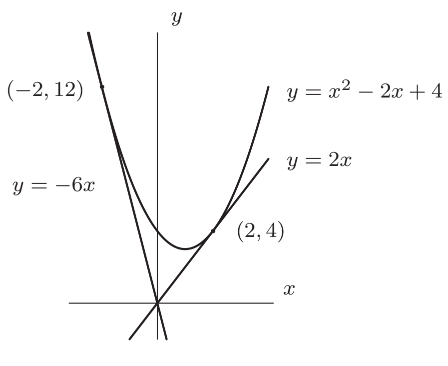

Figure 3.2

62. Decreasing means $f'(x) < 0$:

$$f'(x) = 4x^3 - 12x^2 = 4x^2(x - 3),$$

so $f'(x) < 0$ when $x < 3$ and $x \neq 0$. Concave up means $f''(x) > 0$:

$$f''(x) = 12x^2 - 24x = 12x(x - 2)$$

so $f''(x) > 0$ when

$$\begin{aligned}12x(x - 2) &> 0\\ x < 0 \quad \text{or} \quad x &> 2.\end{aligned}$$

So, both conditions hold for $x < 0$ or $2 < x < 3$.

63. The graph increases when $dy/dx > 0$:

$$\frac{dy}{dx} = 5x^4 - 5 > 0$$
$$5(x^4 - 1) > 0 \quad \text{so} \quad x^4 > 1 \quad \text{so} \quad x > 1 \text{ or } x < -1.$$

The graph is concave up when $d^2y/dx^2 > 0$:

$$\frac{d^2y}{dx^2} = 20x^3 > 0 \quad \text{so} \quad x > 0.$$

We need values of x where $\{x > 1 \text{ or } x < -1\}$ AND $\{x > 0\}$, which implies $x > 1$. Thus, both conditions hold for all values of x larger than 1.

64.

$$\begin{aligned} f'(x) = 12x^2 + 12x - 23 &\geq 1 \\ 12x^2 + 12x - 24 &\geq 0 \\ 12(x^2 + x - 2) &\geq 0 \\ 12(x + 2)(x - 1) &\geq 0. \end{aligned}$$

Hence $x \geq 1$ or $x \leq -2$.

65.

$$\begin{aligned} f'(x) &= 3(2x - 5) + 2(3x + 8) = 12x + 1 \\ f''(x) &= 12. \end{aligned}$$

66. (a) We have $p(x) = x^2 - x$. We see that $p'(x) = 2x - 1 < 0$ when $x < \frac{1}{2}$. So p is decreasing when $x < \frac{1}{2}$.

(b) We have $p(x) = x^{1/2} - x$, so

$$\begin{aligned} p'(x) = \frac{1}{2}x^{-1/2} - 1 &< 0 \\ \frac{1}{2}x^{-1/2} &< 1 \\ x^{-1/2} &< 2 \\ x^{1/2} &> \frac{1}{2} \\ x &> \frac{1}{4}. \end{aligned}$$

Thus $p(x)$ is decreasing when $x > \frac{1}{4}$.

(c) We have $p(x) = x^{-1} - x$, so

$$\begin{aligned} p'(x) = -1x^{-2} - 1 &< 0 \\ -x^{-2} &< 1 \\ x^{-2} &> -1, \end{aligned}$$

which is always true where x^{-2} is defined since $x^{-2} = 1/x^2$ is always positive. Thus $p(x)$ is decreasing for $x < 0$ and for $x > 0$.

67. Since W is proportional to r^3, we have $W = kr^3$ for some constant k. Thus, $dW/dr = k(3r^2) = 3kr^2$. Thus, dW/dr is proportional to r^2.

68. Since $f(t) = 700 - 3t^2$, we have $f(5) = 700 - 3(25) = 625$ cm. Since $f'(t) = -6t$, we have $f'(5) = -30$ cm/year. In the year 2010, the sand dune will be 625 cm high and eroding at a rate of 30 centimeters per year.

69. (a) Velocity $v(t) = \frac{dy}{dt} = \frac{d}{dt}(1250 - 16t^2) = -32t$.
Since $t \geq 0$, the ball's velocity is negative. This is reasonable, since its height y is decreasing.

(b) Acceleration $a(t) = \frac{dv}{dt} = \frac{d}{dt}(-32t) = -32$.
So its acceleration is the negative constant -32.

(c) The ball hits the ground when its height $y = 0$. This gives

$$1250 - 16t^2 = 0$$
$$t = \pm 8.84 \text{ seconds}$$

We discard $t = -8.84$ because time t is nonnegative. So the ball hits the ground 8.84 seconds after its release, at which time its velocity is

$$v(8.84) = -32(8.84) = -282.88 \text{ feet/sec} = -192.84 \text{ mph}.$$

70. (a) The average velocity between $t = 0$ and $t = 2$ is given by

$$\text{Average velocity} = \frac{f(2) - f(0)}{2 - 0} = \frac{-4.9(2^2) + 25(2) + 3 - 3}{2 - 0} = \frac{33.4 - 3}{2} = 15.2 \text{ m/sec}.$$

(b) Since $f'(t) = -9.8t + 25$, we have

$$\text{Instantaneous velocity} = f'(2) = -9.8(2) + 25 = 5.4 \text{ m/sec}.$$

(c) Acceleration is given $f''(t) = -9.8$. The acceleration at $t = 2$ (and all other times) is the acceleration due to gravity, which is -9.8 m/sec^2.

(d) We can use a graph of height against time to estimate the maximum height of the tomato. See Figure 3.3. Alternately, we can find the answer analytically. The maximum height occurs when the velocity is zero and $v(t) = -9.8t + 25 = 0$ when $t = 2.6$ sec. At this time the tomato is at a height of $f(2.6) = 34.9$. The maximum height is 34.9 meters.

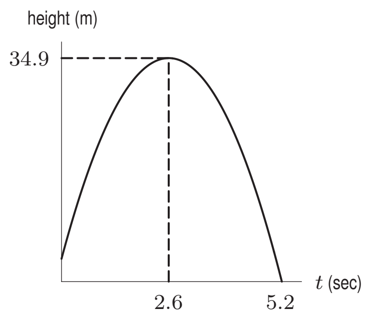

Figure 3.3

(e) We see in Figure 3.3 that the tomato hits ground at about $t = 5.2$ seconds. Alternately, we can find the answer analytically. The tomato hits the ground when

$$f(t) = -4.9t^2 + 25t + 3 = 0.$$

We solve for t using the quadratic formula:

$$t = \frac{-25 \pm \sqrt{(25)^2 - 4(-4.9)(3)}}{2(-4.9)}$$
$$t = \frac{-25 \pm \sqrt{683.8}}{-9.8}$$
$$t = -0.12 \quad \text{and} \quad t = 5.2.$$

We use the positive values, so the tomato hits the ground at $t = 5.2$ seconds.

71. Recall that $v = dx/dt$. We want to find the acceleration, dv/dt, when $x = 2$. Differentiating the expression for v with respect to t using the chain rule and substituting for v gives

$$\frac{dv}{dt} = \frac{d}{dx}(x^2 + 3x - 2) \cdot \frac{dx}{dt} = (2x + 3)v = (2x + 3)(x^2 + 3x - 2).$$

Substituting $x = 2$ gives

$$\text{Acceleration} = \left.\frac{dv}{dt}\right|_{x=2} = (2(2) + 3)(2^2 + 3 \cdot 2 - 2) = 56 \text{ cm/sec}^2.$$

72. (a) Given $h(t) = f(t) - g(t)$, this means $h'(t) = f'(t) - g'(t)$, so

$$\begin{aligned} h(0) &= f(0) - g(0) &&= 2000 - 1500 = 500 \\ h'(0) &= f'(0) - g'(0) = 11 - 13.5 &&= -2.5. \end{aligned}$$

This tells us that initially there are 500 more acre-feet of water in the first reservoir than the second, but that this difference drops at an initial rate of 2.5 acre-feet per day.

(b) Assume h' is constant, this means $h'(t) = -2.5$. It also means that h is a linear function:

$$\begin{aligned} h(t) &= \underbrace{\text{Starting value}}_{h(0)} + \underbrace{\text{Rate of change}}_{h'(0)} \times \underbrace{\text{Time}}_{t} \\ &= 500 - 2.5t. \end{aligned}$$

To find zeros of h, we write:

$$\begin{aligned} h(t) &= 0 \\ 500 - 2.5t &= 0 \\ t &= 200. \end{aligned}$$

This tells us the difference in water level will be zero—that is, the water levels will be equal—after 200 days.

73. (a) We have

$$\frac{dg}{dr} = GM\frac{d}{dr}\left(\frac{1}{r^2}\right) = GM\frac{d}{dr}\left(r^{-2}\right) = GM(-2)r^{-3} = -\frac{2GM}{r^3}.$$

(b) The derivative dg/dr is the rate of change of acceleration due to the pull of gravity with respect to distance. The further away from the center of the earth, the weaker the pull of gravity is. So g is decreasing and therefore its derivative, dg/dr, is negative.

(c) By part (a),

$$\left.\frac{dg}{dr}\right|_{r=6400} = -\left.\frac{2GM}{r^3}\right|_{r=6400} = -\frac{2(6.67 \times 10^{-20})(6 \times 10^{24})}{(6400)^3} \approx -3.05 \times 10^{-6}.$$

(d) Since the magnitude of dg/dr is small, the value of g is not changing much near $r = 6400$. It is reasonable to assume that g is a constant near the surface of the earth.

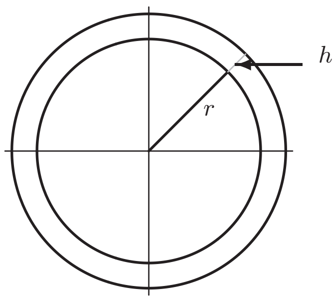
74. (a) $T = 2\pi\sqrt{\dfrac{l}{g}} = \dfrac{2\pi}{\sqrt{g}}\left(l^{\frac{1}{2}}\right)$, so $\dfrac{dT}{dl} = \dfrac{2\pi}{\sqrt{g}}\left(\dfrac{1}{2}l^{-\frac{1}{2}}\right) = \dfrac{\pi}{\sqrt{gl}}$.

(b) Since $\dfrac{dT}{dl}$ is positive, the period T increases as the length l increases.

75. (a) $A = \pi r^2$
$\frac{dA}{dr} = 2\pi r$.

(b) This is the formula for the circumference of a circle.

(c) $A'(r) \approx \frac{A(r+h)-A(r)}{h}$ for small h. When $h > 0$, the numerator of the difference quotient denotes the area of the region contained between the inner circle (radius r) and the outer circle (radius $r + h$). See figure below. As h approaches 0, this area can be approximated by the product of the circumference of the inner circle and the "width" of the region, i.e., h. Dividing this by the denominator, h, we get A' = the circumference of the circle with radius r.



We can also think about the derivative of A as the rate of change of area for a small change in radius. If the radius increases by a tiny amount, the area will increase by a thin ring whose area is simply the circumference at that radius times the small amount. To get the rate of change, we divide by the small amount and obtain the circumference.

76. $V = \frac{4}{3}\pi r^3$. Differentiating gives $\frac{dV}{dr} = 4\pi r^2 =$ surface area of a sphere.

The difference quotient $\frac{V(r+h)-V(r)}{h}$ is the volume between two spheres divided by the change in radius. Furthermore, when h is very small, the difference between volumes, $V(r+h) - V(r)$, is like a coating of paint of depth h applied to the surface of the sphere. The volume of the paint is about $h \cdot$ (Surface Area) for small h: dividing by h gives back the surface area.

Thinking about the derivative as the rate of change of the function for a small change in the variable gives another way of seeing the result. If you increase the radius of a sphere a small amount, the volume increases by a very thin layer whose volume is the surface area at that radius multiplied by that small amount.

77. If $f(x) = x^n$, then $f'(x) = nx^{n-1}$. This means $f'(1) = n \cdot 1^{n-1} = n \cdot 1 = n$, because any power of 1 equals 1.

78. Since $f(x) = ax^n$, $f'(x) = anx^{n-1}$. We know that $f'(2) = (an)2^{n-1} = 3$, and $f'(4) = (an)4^{n-1} = 24$. Therefore,

$$\frac{f'(4)}{f'(2)} = \frac{24}{3}$$
$$\frac{(an)4^{n-1}}{(an)2^{n-1}} = \left(\frac{4}{2}\right)^{n-1} = 8$$
$$2^{n-1} = 8, \text{ and thus } n = 4.$$

Substituting $n = 4$ into the expression for $f'(2)$, we get $3 = a(4)(8)$, or $a = 3/32$.

79. Yes. To see why, we substitute $y = x^n$ into the equation $13x\dfrac{dy}{dx} = y$. We first calculate $\dfrac{dy}{dx} = \dfrac{d}{dx}(x^n) = nx^{n-1}$. The differential equation becomes

$$13x(nx^{n-1}) = x^n$$

But $13x(nx^{n-1}) = 13n(x \cdot x^{n-1}) = 13nx^n$, so we have

$$13n(x^n) = x^n$$

This equality must hold for all x, so we get $13n = 1$, so $n = 1/13$. Thus, $y = x^{1/13}$ is a solution.

80. (a)

$$\begin{aligned}
\frac{d(x^{-1})}{dx} &= \lim_{h\to 0} \frac{(x+h)^{-1} - x^{-1}}{h} = \lim_{h\to 0} \frac{1}{h}\left[\frac{1}{x+h} - \frac{1}{x}\right] \\
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{x-(x+h)}{x(x+h)}\right] = \lim_{h\to 0} \frac{1}{h}\left[\frac{-h}{x(x+h)}\right] \\
&= \lim_{h\to 0} \frac{-1}{x(x+h)} = \frac{-1}{x^2} = -1x^{-2}.
\end{aligned}$$

$$\begin{aligned}
\frac{d(x^{-3})}{dx} &= \lim_{h\to 0} \frac{(x+h)^{-3} - x^{-3}}{h} \\
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{1}{(x+h)^3} - \frac{1}{x^3}\right] \\
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{x^3 - (x+h)^3}{x^3(x+h)^3}\right] \\
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{x^3 - (x^3 + 3hx^2 + 3h^2x + h^3)}{x^3(x+h)^3}\right] \\
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{-3hx^2 - 3xh^2 - h^3}{x^3(x+h)^3}\right] \\
&= \lim_{h\to 0} \frac{-3x^2 - 3xh - h^2}{x^3(x+h)^3} \\
&= \frac{-3x^2}{x^6} = -3x^{-4}.
\end{aligned}$$

(b) For clarity, let $n = -k$, where k is a positive integer. So $x^n = x^{-k}$.

$$\frac{d(x^{-k})}{dx} = \lim_{h\to 0} \frac{(x+h)^{-k} - x^{-k}}{h}$$

$$
\begin{aligned}
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{1}{(x+h)^k} - \frac{1}{x^k}\right] \\
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{x^k - (x+h)^k}{x^k(x+h)^k}\right] \\
&= \lim_{h\to 0} \frac{1}{h}\left[\frac{x^k - x^k - khx^{k-1} - \overbrace{\ldots - h^k}^{\text{terms involving } h^2 \text{ and higher powers of } h}}{x^k(x+h)^k}\right] \\
&= \frac{-kx^{k-1}}{x^k(x)^k} = \frac{-k}{x^{k+1}} = -kx^{-(k+1)} = -kx^{-k-1}.
\end{aligned}
$$

81. (a) We see that $f(1) = a \cdot 1 = a$, and the graph of $x^2 + 3$ goes through the point $(1, 4)$, so $f(x)$ is continuous when $a = 4$.

(b) No, $f(x)$ does not have a derivative at $(1, 4)$. There is a corner there. We can see this without a graph by noticing that

$$\frac{d}{dx}(x^2 + 3) = 2x$$

has a value of 2 at $x = 1$, but

$$\frac{d}{dx}(4x) = 4$$

has a value of 4 at $x = 1$.

82. Since $ax + b$ and $x^2 + 3$ are each differentiable for all x, the function is differentiable on $0 < x < 2$ except at $x = 1$. For continuity, we must have $a \cdot 1 + b = 1^2 + 3$.

For differentiability, the derivatives at $x = 1$ of the two pieces must be the same. Since

$$\frac{d}{dx}(ax + b) = a \quad \text{and} \quad \frac{d}{dx}(x^2 + 3) = 2x,$$

at $x = 1$, we have $a = 2 \cdot 1 = 2$. We can then solve for b:

$$2 \cdot 1 + b = 4, \text{ so } b = 2.$$

Strengthen Your Understanding

83. Since the derivative of a constant is zero, $\frac{d}{dx}(x^2 + a) = 2x$ for any constant a.

84. The function can be written as $f(x) = x^{-2}$ so the power rule gives $f'(x) = -2x^{-3} = -2/x^3$.

85. One possible example is $f(x) = x^2$ and $g(x) = 3x$. More generally, $f(x) = x^2 + c$ and $g(x) = 3x + k$ work for any c and k.

86. Any function of the form $g(x) = x^2 + c$, where c is a positive constant works. One possibility is $g(x) = x^2 + 1$.

87. If $f(x) = 3x^2$, we have $f'(x) = 6x$ and $f''(x) = 6$. Other answers are possible.

88. True. Since $d(x^n)/dx = nx^{n-1}$, the derivative of a power function is a power function, so the derivative of a polynomial is a polynomial.

89. False, since

$$\frac{d}{dx}\left(\frac{\pi}{x^2}\right) = \frac{d}{dx}\left(\pi x^{-2}\right) = -2\pi x^{-3} = \frac{-2\pi}{x^3}.$$

90. True. The slope of $f(x) + g(x)$ at $x = 2$ is the sum of the derivatives, $f'(2) + g'(2) = 3.1 + 7.3 = 10.4$.

91. True. Since $f''(x) > 0$ and $g''(x) > 0$ for all x, we have $f''(x) + g''(x) > 0$ for all x, which means that $f(x) + g(x)$ is concave up.

92. False. Let $f(x) = 2x^2$ and $g(x) = x^2$. Then $f(x) - g(x) = x^2$, which is concave up for all x.

Solutions for Section 3.2

Exercises

1. $f'(x) = 2e^x + 2x$.
2. $y' = 10t + 4e^t$.
3. Using the chain rule gives $f'(x) = 5\ln(a)a^{5x}$.
4. $f'(x) = 12e^x + (\ln 11)11^x$.
5. $y' = 10x + (\ln 2)2^x$.
6. $f'(x) = (\ln 2)2^x + 2(\ln 3)3^x$.
7. $\dfrac{dy}{dx} = 4(\ln 10)10^x - 3x^2$.
8. $z' = (\ln 4)e^x$.
9. $\dfrac{dy}{dx} = \dfrac{1}{3}(\ln 3)3^x - \dfrac{33}{2}(x^{-\frac{3}{2}})$.
10. Since $y = 2^x + \dfrac{2}{x^3} = 2^x + 2x^{-3}$, we have $\dfrac{dy}{dx} = (\ln 2)2^x - 6x^{-4}$.
11. $z' = (\ln 4)^2 4^x$.
12. $f'(t) = (\ln(\ln 3))(\ln 3)^t$.
13. $\dfrac{dy}{dx} = 5 \cdot 5^t \ln 5 + 6 \cdot 6^t \ln 6$
14. $h'(z) = (\ln(\ln 2))(\ln 2)^z$.
15. $f'(x) = ex^{e-1}$.
16. $\dfrac{dy}{dx} = \pi^x \ln \pi$
17. $f'(x) = (\ln \pi)\pi^x$.
18. This is the sum of an exponential function and a power function, so $f'(x) = \ln(\pi)\pi^x + \pi x^{\pi-1}$.
19. Since e and k are constants, e^k is constant, so we have $f'(x) = (\ln k)k^x$.
20. $f(x) = e^{1+x} = e^1 \cdot e^x$. Then, since e^1 is just a constant,
    $f'(x) = e \cdot e^x = e^{1+x}$.
21. $f(t) = e^t \cdot e^2$. Then, since e^2 is just a constant, $f'(t) = \frac{d}{dt}(e^t e^2) = e^2 \frac{d}{dt} e^t = e^2 e^t = e^{t+2}$.
22. $f'(\theta) = ke^{k\theta}$
23. $y'(x) = a^x \ln a + ax^{a-1}$
24. $f'(x) = \pi^2 x^{(\pi^2-1)} + (\pi^2)^x \ln(\pi^2)$
25. $g'(x) = \dfrac{d}{dx}(2x - x^{-1/3} + 3^x - e) = 2 + \dfrac{1}{3x^{\frac{4}{3}}} + 3^x \ln 3$.
26. $f'(x) = 6x(e^x - 4) + (3x^2 + \pi)e^x = 6xe^x - 24x + 3x^2 e^x + \pi e^x$.

Problems

27. $y' = 2x + (\ln 2)2^x$.
28. $y' = \frac{1}{2}x^{-\frac{1}{2}} - \ln \frac{1}{2}(\frac{1}{2})^x = \frac{1}{2\sqrt{x}} + \ln 2(\frac{1}{2})^x$.
29. We can take the derivative of the sum $x^2 + 2^x$, but not the product.
30. $f(s) = 5^s e^s = (5e)^s$, so $f'(s) = \ln(5e) \cdot (5e)^s = (1 + \ln 5)5^s e^s$.
31. Since $y = e^5 e^x$, $y' = e^5 e^x = e^{x+5}$.
32. $y = e^{5x} = (e^5)^x$, so $y' = \ln(e^5) \cdot (e^5)^x = 5e^{5x}$.
33. The exponent is x^2, and we haven't learned what to do about that yet.
34. $f'(z) = (\ln \sqrt{4})(\sqrt{4})^z = (\ln 2)2^z$.

35. We can't use our rules if the exponent is $\sqrt{\theta}$.

36. This is the composition of two functions each of which we can take the derivative of, but we don't know how to take the derivative of the composition.

37. Once again, this is a product of two functions, 2^x and $\frac{1}{x}$, each of which we can take the derivative of; but we don't know how to take the derivative of the product.

38. The derivative is

$$P'(t) = 300(\ln 1.044)(1.044)^t$$

so

$$P'(5) = 300(\ln 1.044)(1.044)^5 = 16.021.$$

The value

$$P'(5) = 16.021$$

means that when $t = 5$, the population is increasing by approximately 16 animals per year.

39. Since $P = 1 \cdot (1.05)^t$, $\frac{dP}{dt} = \ln(1.05)1.05^t$. When $t = 10$,

$$\frac{dP}{dt} = (\ln 1.05)(1.05)^{10} \approx \$0.07947/\text{year} \approx 7.95¢/\text{year}.$$

40. (a) Substituting $t = 4$ gives $V(4) = 25(0.85)^4 = 25(0.522) = 13.050$. Thus the value of the car after 4 years is \$13,050.

(b) We have a function of the form $f(t) = Ca^t$. We know that such functions have a derivative of the form $(C \ln a) \cdot a^t$. Thus, $V'(t) = (25 \ln 0.85) \cdot (0.85)^t = -4.063(0.85)^t$. The units are the change in value (in thousands of dollars) with respect to time (in years), or thousands of dollars/year.

(c) Substituting $t = 4$ gives $V'(4) = -4.063(0.85)^4 = -4.063(0.522) = -2.121$. This means that at the end of the fourth year, the value of the car is decreasing by \$2121 per year.

(d) The function $V(t)$ is positive and decreasing, so that the value of the automobile is positive and decreasing. The function $V'(t)$ is negative, and its magnitude is decreasing, meaning the value of the automobile is always dropping, but the yearly loss of value decreases as time goes on. The graphs of $V(t)$ and $V'(t)$ confirm that the value of the car decreases with time. What they do not take into account are the *costs* associated with owning the vehicle. At some time, t, it is likely that the yearly costs of owning the vehicle will outweigh its value. At that time, it may no longer be worthwhile to keep the car.

41. For t in years since 2009, the population of Mexico is given by the formula

$$M = 111(1 + 0.0113)^t = 111(1.0113)^t \text{ million}$$

and that of the US by

$$U = 307(1 + 0.00975)^t = 307(1.00975)^t \text{ million},$$

The rate of change of each population, in people/year is given by

$$\left.\frac{dM}{dt}\right|_{t=0} = 111\left.\frac{d}{dt}(1.0113)^t\right|_{t=0} = \left.111(1.0113)^t \ln(1.0113)\right|_{t=0} = 1.247 \text{ million people per year}$$

$$\text{and} \quad \left.\frac{dU}{dt}\right|_{t=0} = 307\left.\frac{d}{dt}(1.00975)^t\right|_{t=0} = \left.307(1.00975)^t \ln(1.00975)\right|_{t=0} = 2.979 \text{ million people per year.}$$

Since $\left.\frac{dU}{dt}\right|_{t=0} > \left.\frac{dM}{dt}\right|_{t=0}$, the population of the US was growing faster in 2009.

42. Differentiating gives

$$\text{Rate of change of price} = \frac{dV}{dt} = 75(1.35)^t \ln 1.35 \approx 22.5(1.35)^t \text{ dollar/yr.}$$

43. (a) $f(x) = 1 - e^x$ crosses the x-axis where $0 = 1 - e^x$, which happens when $e^x = 1$, so $x = 0$. Since $f'(x) = -e^x$, $f'(0) = -e^0 = -1$.

(b) $y = -x$

(c) The negative of the reciprocal of -1 is 1, so the equation of the normal line is $y = x$.

44. Since $y = 2^x$, $y' = (\ln 2)2^x$. At $(0, 1)$, the tangent line has slope $\ln 2$ so its equation is $y = (\ln 2)x + 1$. At c, $y = 0$, so $0 = (\ln 2)c + 1$, thus $c = -\frac{1}{\ln 2}$.

45.

$$g(x) = ax^2 + bx + c \qquad f(x) = e^x$$
$$g'(x) = 2ax + b \qquad f'(x) = e^x$$
$$g''(x) = 2a \qquad f''(x) = e^x$$

So, using $g''(0) = f''(0)$, etc., we have $2a = 1$, $b = 1$, and $c = 1$, and thus $g(x) = \frac{1}{2}x^2 + x + 1$, as shown in Figure 3.4.

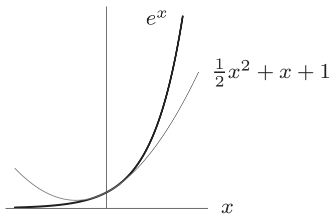


Figure 3.4

The two functions do look very much alike near $x = 0$. They both increase for large values of x, but e^x increases much more quickly. For very negative values of x, the quadratic goes to ∞ whereas the exponential goes to 0. By choosing a function whose first few derivatives agreed with the exponential when $x = 0$, we got a function which looks like the exponential for x-values near 0.

46. The first and second derivatives of e^x are e^x. Thus, the graph of $y = e^x$ is concave up. The tangent line at $x = 0$ has slope $e^0 = 1$ and equation $y = x + 1$. A graph that is always concave up is always above any of its tangent lines. Thus $e^x \geq x + 1$ for all x, as shown in Figure 3.5.

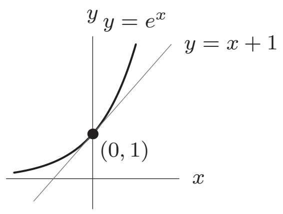

Figure 3.5

47. For $x = 0$, we have $y = a^0 = 1$ and $y = 1 + 0 = 1$, so both curves go through the point $(0, 1)$ for all values of a.

Differentiating gives

$$\left.\frac{d(a^x)}{dx}\right|_{x=0} = \left. a^x \ln a\right|_{x=0} = a^0 \ln a = \ln a$$
$$\left.\frac{d(1+x)}{dx}\right|_{x=0} = 1.$$

The graphs are tangent at $x = 0$ if

$$\ln a = 1 \qquad \text{so} \qquad a = e.$$

48. We are interested in when the derivative $\frac{d(a^x)}{dx}$ is positive and when it is negative. The quantity a^x is always positive. However $\ln a > 0$ for $a > 1$ and $\ln a < 0$ for $0 < a < 1$. Thus the function a^x is increasing for $a > 1$ and decreasing for $a < 1$.

Strengthen Your Understanding

49. The function is an exponential function so the power rule does not apply. The derivative of f is $f'(x) = (\ln 2)2^x$.

50. Since π and e are constants, f is a constant function, so $f'(x) = 0$.

51. The derivative of $f(x) = a^x$ is $f'(x) = (\ln a)a^x$ which is negative when $\ln a < 0$. Since $\ln a < 0$ when $0 < a < 1$, we see that 0.5^x is such a function. There are many other possible examples.

52. A possibility is $f(x) = e^x$. Then $f'(x) = e^x$, $f''(x) = e^x$, and $f'''(x) = e^x$, so $f'''(x) = f(x)$.

53. False. If $f(x) = \ln x$, then $f'(x) = 1/x$, which is decreasing for $x > 0$.

54. False, since $f'(x) = f(x) = e^x$ for all x.

55. False. If $f(x) = |x|$, then $f(x)$ is not differentiable at $x = 0$ and $f'(x)$ does not exist at $x = 0$.

Solutions for Section 3.3

Exercises

1. By the product rule, $f'(x) = 2x(x^3 + 5) + x^2(3x^2) = 2x^4 + 3x^4 + 10x = 5x^4 + 10x$. Alternatively, $f'(x) = (x^5 + 5x^2)' = 5x^4 + 10x$. The two answers should, and do, match.

2. Using the product rule,

$$f'(x) = (\ln 2)2^x 3^x + (\ln 3)2^x 3^x = (\ln 2 + \ln 3)(2^x \cdot 3^x) = \ln(2\cdot 3)(2\cdot 3)^x = (\ln 6)6^x$$

or, since $2^x \cdot 3^x = (2\cdot 3)^x = 6^x$,

$$f'(x) = (6^x)' = (\ln 6)(6^x).$$

The two answers should, and do, match.

3. $f'(x) = x \cdot e^x + e^x \cdot 1 = e^x(x + 1)$.

4. $y' = 2^x + x(\ln 2)2^x = 2^x(1 + x\ln 2)$.

5. $y' = \frac{1}{2\sqrt{x}}2^x + \sqrt{x}(\ln 2)2^x$.

6. $\dfrac{dy}{dt} = 2te^t + (t^2 + 3)e^t = e^t(t^2 + 2t + 3)$.

7. $f'(x) = (x^2 - x^{\frac{1}{2}}) \cdot 3^x(\ln 3) + 3^x\left(2x - \dfrac{1}{2}x^{-\frac{1}{2}}\right) = 3^x\left[(\ln 3)(x^2 - x^{\frac{1}{2}}) + \left(2x - \dfrac{1}{2\sqrt{x}}\right)\right]$.

8. $y' = (3t^2 - 14t)e^t + (t^3 - 7t^2 + 1)e^t = (t^3 - 4t^2 - 14t + 1)e^t$.

9. $f'(x) = \dfrac{e^x \cdot 1 - x \cdot e^x}{(e^x)^2} = \dfrac{e^x(1 - x)}{(e^x)^2} = \dfrac{1 - x}{e^x}$.

10. $g'(x) = \dfrac{50xe^x - 25x^2e^x}{e^{2x}} = \dfrac{50x - 25x^2}{e^x}$.

11. $\dfrac{dy}{dx} = \dfrac{1 \cdot 2^t - (t + 1)(\ln 2)2^t}{(2^t)^2} = \dfrac{2^t(1 - (t + 1)\ln 2)}{(2^t)^2} = \dfrac{1 - (t + 1)\ln 2}{2^t}$

12. $g'(w) = \dfrac{3.2w^{2.2}(5^w) - (\ln 5)(w^{3.2})5^w}{5^{2w}} = \dfrac{3.2w^{2.2} - w^{3.2}(\ln 5)}{5^w}$.

13. $q'(r) = \dfrac{3(5r + 2) - 3r(5)}{(5r + 2)^2} = \dfrac{15r + 6 - 15r}{(5r + 2)^2} = \dfrac{6}{(5r + 2)^2}$

14. $g'(t) = \dfrac{(t + 4) - (t - 4)}{(t + 4)^2} = \dfrac{8}{(t + 4)^2}$.

15. $\dfrac{dz}{dt} = \dfrac{3(5t + 2) - (3t + 1)5}{(5t + 2)^2} = \dfrac{15t + 6 - 15t - 5}{(5t + 2)^2} = \dfrac{1}{(5t + 2)^2}$.

16. $z' = \dfrac{(2t + 5)(t + 3) - (t^2 + 5t + 2)}{(t + 3)^2} = \dfrac{t^2 + 6t + 13}{(t + 3)^2}$.

17. $f'(t) = \dfrac{d}{dt}\left(2te^t - \dfrac{1}{\sqrt{t}}\right) = 2e^t + 2te^t + \dfrac{1}{2t^{3/2}}$.

18. Divide and then differentiate

$$f(x) = x + \frac{3}{x}$$
$$f'(x) = 1 - \frac{3}{x^2}.$$

19. $w = y^2 - 6y + 7.\quad w' = 2y - 6, y \neq 0.$

20. $g'(t) = -4(3+\sqrt{t})^{-2}\left(\frac{1}{2}t^{-1/2}\right) = \dfrac{-2}{\sqrt{t}(3+\sqrt{t})^2}$

21. $\dfrac{d}{dz}\left(\dfrac{z^2+1}{\sqrt{z}}\right) = \dfrac{d}{dz}(z^{\frac{3}{2}} + z^{-\frac{1}{2}}) = \dfrac{3}{2}z^{\frac{1}{2}} - \dfrac{1}{2}z^{-\frac{3}{2}} = \dfrac{\sqrt{z}}{2}(3 - z^{-2}).$

22.

$$\frac{dw}{dz} = \frac{(-3)(5+3z) - (5-3z)(3)}{(5+3z)^2}$$
$$= \frac{-15 - 9z - 15 + 9z}{(5+3z)^2} = \frac{-30}{(5+3z)^2}$$

23. $h'(r) = \dfrac{d}{dr}\left(\dfrac{r^2}{2r+1}\right) = \dfrac{(2r)(2r+1) - 2r^2}{(2r+1)^2} = \dfrac{2r(r+1)}{(2r+1)^2}.$

24. Notice that you can cancel a z out of the numerator and denominator to get

$$f(z) = \frac{3z}{5z+7}, \qquad z \neq 0$$

Then

$$f'(z) = \frac{(5z+7)3 - 3z(5)}{(5z+7)^2}$$
$$= \frac{15z + 21 - 15z}{(5z+7)^2}$$
$$= \frac{21}{(5z+7)^2}, z \neq 0.$$

[If you used the quotient rule correctly without canceling the z out first, your answer should simplify to this one, but it is usually a good idea to simplify as much as possible before differentiating.]

25. $w'(x) = \dfrac{17e^x(2^x) - (\ln 2)(17e^x)2^x}{2^{2x}} = \dfrac{17e^x(2^x)(1-\ln 2)}{2^{2x}} = \dfrac{17e^x(1-\ln 2)}{2^x}.$

26. $h'(p) = \dfrac{2p(3+2p^2) - 4p(1+p^2)}{(3+2p^2)^2} = \dfrac{6p + 4p^3 - 4p - 4p^3}{(3+2p^2)^2} = \dfrac{2p}{(3+2p^2)^2}.$

27. Either notice that $f(x) = \dfrac{x^2+3x+2}{x+1}$ can be written as $f(x) = \dfrac{(x+2)(x+1)}{x+1}$ which reduces to $f(x) = x+2$, giving $f'(x) = 1$, or use the quotient rule which gives

$$f'(x) = \frac{(x+1)(2x+3) - (x^2+3x+2)}{(x+1)^2}$$
$$= \frac{2x^2 + 5x + 3 - x^2 - 3x - 2}{(x+1)^2}$$
$$= \frac{x^2 + 2x + 1}{(x+1)^2}$$
$$= \frac{(x+1)^2}{(x+1)^2}$$
$$= 1.$$

28. We use the quotient rule. We have

$$f'(x) = \frac{(cx+k)(a) - (ax+b)(c)}{(cx+k)^2} = \frac{acx + ak - acx - bc}{(cx+k)^2} = \frac{ak - bc}{(cx+k)^2}.$$

29. Using the product and chain rules, we have

$$\begin{aligned}\frac{dy}{dx} &= 3(x^2+5)^2(2x)(3x^3-2)^2 + (x^2+5)^3[2(3x^3-2)(9x^2)] \\ &= 3(2x)(x^2+5)^2(3x^3-2)[(3x^3-2) + (x^2+5)(3x)] \\ &= 6x(x^2+5)^2(3x^3-2)[6x^3+15x-2].\end{aligned}$$

30. $f'(x) = \frac{d}{dx}(2-4x-3x^2)(6x^e - 3\pi) = (-4-6x)(6x^e - 3\pi) + (2-4x-3x^2)(6ex^{e-1})$.

Problems

31. Using the product rule, we know that $h'(x) = f'(x)\cdot g(x) + f(x)\cdot g'(x)$. We use slope to compute the derivatives. Since $f(x)$ is linear on the interval $0 < x < 2$, we compute the slope of the line to see that $f'(x) = 2$ on this interval. Similarly, we compute the slope on the interval $2 < x < 4$ to see that $f'(x) = -2$ on the interval $2 < x < 4$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist.

Similarly, $g(x)$ is linear on the interval shown, and we see that the slope of $g(x)$ on this interval is -1 so we have $g'(x) = -1$ on this interval.

(a) We have $h'(1) = f'(1)\cdot g(1) + f(1)\cdot g'(1) = 2\cdot 3 + 2(-1) = 6 - 2 = 4$.
(b) Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist. Therefore, we cannot use the product rule (and, in this case, $h'(2)$ does not exist).
(c) We have $h'(3) = f'(3)\cdot g(3) + f(3)\cdot g'(3) = (-2)1 + 2(-1) = -2 - 2 = -4$.

32. Using the quotient rule, we know that $k'(x) = (f'(x)\cdot g(x) - f(x)\cdot g'(x))/(g(x))^2$, when f and g are differentiable. We use slope to compute the derivatives. Since $f(x)$ is linear on the interval $0 < x < 2$, we compute the slope of the line to see that $f'(x) = 2$ on this interval. Similarly, we compute the slope on the interval $2 < x < 4$ to see that $f'(x) = -2$ on the interval $2 < x < 4$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist.

Similarly, $g(x)$ is linear on the interval shown, and we see that the slope of $g(x)$ on this interval is -1 so we have $g'(x) = -1$ on this interval.

(a) We have
$$k'(1) = \frac{f'(1)\cdot g(1) - f(1)\cdot g'(1)}{(g(1))^2} = \frac{2\cdot 3 - 2(-1)}{3^2} = \frac{6+2}{9} = \frac{8}{9}.$$
(b) Since $f(x)$ has a corner at $x = 2$, we know that the quotient rule does not apply. We know that $f'(2)$ does not exist, and k is not differentiable at $x = 2$.
(c) We have
$$k'(3) = \frac{f'(3)\cdot g(3) - f(3)\cdot g'(3)}{(g(3))^2} = \frac{(-2)1 - 2(-1)}{1^2} = \frac{-2+2}{1} = 0.$$

33. Using the quotient rule, we know that $j'(x) = (g'(x)\cdot f(x) - g(x)\cdot f'(x))/(f(x))^2$. We use slope to compute the derivatives. Since $f(x)$ is linear on the interval $0 < x < 2$, we compute the slope of the line to see that $f'(x) = 2$ on this interval. Similarly, we compute the slope on the interval $2 < x < 4$ to see that $f'(x) = -2$ on the interval $2 < x < 4$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist.

Similarly, $g(x)$ is linear on the interval shown, and we see that the slope of $g(x)$ on this interval is -1 so we have $g'(x) = -1$ on this interval.

(a) We have
$$j'(1) = \frac{g'(1)\cdot f(1) - g(1)\cdot f'(1)}{(f(1))^2} = \frac{(-1)2 - 3\cdot 2}{2^2} = \frac{-2-6}{4} = \frac{-8}{4} = -2.$$
(b) Since $f(x)$ has a corner at $x = 2$, so the quotient rule does not apply. We know that $f'(2)$ does not exist, so $j'(2)$ does not exist.
(c) We have
$$j'(3) = \frac{g'(3)\cdot f(3) - g(3)\cdot f'(3)}{(f(3))^2} = \frac{(-1)2 - 1(-2)}{2^2} = \frac{-2+2}{4} = 0.$$

34. Estimates may vary. From the graphs, we estimate $f(1) \approx -0.4$, $f'(1) \approx 0.5$, $g(1) \approx 2$, and $g'(1) \approx 1$. By the product rule,
$$h'(1) = f'(1) \cdot g(1) + f(1) \cdot g'(1) \approx (0.5)2 + (-0.4)1 = 0.6.$$

35. Estimates may vary. From the graphs, we estimate $f(1) \approx -0.4$, $f'(1) \approx 0.5$, $g(1) \approx 2$, and $g'(1) \approx 1$. By the quotient rule, to one decimal place
$$k'(1) = \frac{f'(1) \cdot g(1) - f(1) \cdot g'(1)}{(g(1))^2} \approx \frac{(0.5)2 - (-0.4)1}{2^2} = 0.4.$$

36. Estimates may vary. From the graphs, we estimate $f(2) \approx 0.3$, $f'(2) \approx 1.1$, $g(2) \approx 1.6$, and $g'(2) \approx -0.5$. By the product rule, to one decimal place
$$h'(2) = f'(2) \cdot g(2) + f(2) \cdot g'(2) \approx 1.1(1.6) + 0.3(-0.5) = 1.6.$$

37. Estimates may vary. From the graphs, we estimate $f(2) \approx 0.3$, $f'(2) \approx 1.1$, $g(2) \approx 1.6$, and $g'(2) \approx -0.5$. By the quotient rule, to one decimal place
$$k'(2) = \frac{f'(2) \cdot g(2) - f(2) \cdot g'(2)}{(g(2))^2} \approx \frac{1.1(1.6) - 0.3(-0.5)}{(1.6)^2} = 0.7.$$

38. Estimates may vary. From the graphs, we estimate $f(1) \approx -0.4$, $f'(1) \approx 0.5$, $g(1) \approx 2$, and $g'(1) \approx 1$. By the quotient rule, to one decimal place
$$l'(1) = \frac{g'(1) \cdot f(1) - g(1) \cdot f'(1)}{(f(1))^2} \approx \frac{1(-0.4) - 2(0.5)}{(-0.4)^2} = -8.8.$$

39. Estimates may vary. From the graphs, we estimate $f(2) \approx 0.3$, $f'(2) \approx 1.1$, $g(2) \approx 1.6$, and $g'(2) \approx -0.5$. By the quotient rule, to one decimal place
$$l'(2) = \frac{g'(2) \cdot f(2) - g(2) \cdot f'(2)}{(f(2))^2} \approx \frac{(-0.5)0.3 - 1.6(1.1)}{(0.3)^2} = -21.2.$$

40.
$$\begin{aligned} f(t) &= \frac{1}{e^t} \\ f'(t) &= \frac{e^t \cdot 0 - e^t \cdot 1}{(e^t)^2} \\ &= \frac{-1}{e^t} = -e^{-t}. \end{aligned}$$

41. $f(x) = e^x \cdot e^x$
$f'(x) = e^x \cdot e^x + e^x \cdot e^x = 2e^{2x}$.

42.
$$\begin{aligned} f(x) &= e^x e^{2x} \\ f'(x) &= e^x (e^{2x})' + (e^x)' e^{2x} \\ &= 2e^x e^{2x} + e^x e^{2x} \text{ (from Problem 41)} \\ &= 3e^{3x}. \end{aligned}$$

43. We have
$$\begin{aligned} f'(x) &= e^x + xe^x \\ f''(x) &= e^x + e^x + xe^x = (2 + x)e^x. \end{aligned}$$
Since $f(x)$ is concave up when $f''(x) > 0$, we see that $f(x)$ is concave up when $x > -2$.

44. Using the quotient rule, we have

$$\begin{aligned} g'(x) &= \frac{0-1(2x)}{(x^2+1)^2} = \frac{-2x}{(x^2+1)^2} \\ g''(x) &= \frac{-2(x^2+1)^2 + 2x(4x^3+4x)}{(x^2+1)^4} \\ &= \frac{-2(x^2+1)^2 + 8x^2(x^2+1)}{(x^2+1)^4} \\ &= \frac{-2(x^2+1)+8x^2}{(x^2+1)^3} \\ &= \frac{2(3x^2-1)}{(x^2+1)^3}. \end{aligned}$$

Since $(x^2+1)^3 > 0$ for all x, we have $g''(x) < 0$ if $(3x^2-1) < 0$, or when

$$\begin{aligned} 3x^2 &< 1 \\ -\frac{1}{\sqrt{3}} < x &< \frac{1}{\sqrt{3}}. \end{aligned}$$

45. Since $f(0) = -5/1 = -5$, the tangent line passes through the point $(0,-5)$, so its vertical intercept is -5. To find the slope of the tangent line, we find the derivative of $f(x)$ using the quotient rule:

$$f'(x) = \frac{(x+1)\cdot 2 - (2x-5)\cdot 1}{(x+1)^2} = \frac{7}{(x+1)^2}.$$

At $x=0$, the slope of the tangent line is $m = f'(0) = 7$. The equation of the tangent line is $y = 7x-5$.

46. This is the same function we were asked to differentiate in Problem 24, so we know that, if $x \neq 0$,

$$f'(x) = \frac{21}{(5x+7)^2}.$$

So at $x = 1$,

$$\begin{aligned} y = f(1) &= \frac{3}{12} = \frac{1}{4}, \\ y' &= \frac{21}{144} = \frac{7}{48}. \end{aligned}$$

So,

$$\begin{aligned} y - \frac{1}{4} &= \frac{7}{48}(x-1). \\ y &= \frac{7}{48}x + \frac{5}{48}. \end{aligned}$$

47. (a) Although the answer you would get by using the quotient rule is equivalent, the answer looks simpler in this case if you just use the product rule:

$$\begin{aligned} \frac{d}{dx}\left(\frac{e^x}{x}\right) &= \frac{d}{dx}\left(e^x \cdot \frac{1}{x}\right) = \frac{e^x}{x} - \frac{e^x}{x^2} \\ \frac{d}{dx}\left(\frac{e^x}{x^2}\right) &= \frac{d}{dx}\left(e^x \cdot \frac{1}{x^2}\right) = \frac{e^x}{x^2} - \frac{2e^x}{x^3} \\ \frac{d}{dx}\left(\frac{e^x}{x^3}\right) &= \frac{d}{dx}\left(e^x \cdot \frac{1}{x^3}\right) = \frac{e^x}{x^3} - \frac{3e^x}{x^4}. \end{aligned}$$

(b) $\dfrac{d}{dx}\dfrac{e^x}{x^n} = \dfrac{e^x}{x^n} - \dfrac{ne^x}{x^{n+1}}.$

48. By the product rule, we have

$$\frac{d}{dx}(x^2 f(x)) = \frac{d}{dx}(x^2)\cdot f(x) + x^2 \cdot f'(x) = 2xf(x) + x^2 f'(x).$$

49. By the product rule, we have

$$\begin{aligned}\frac{d}{dx}(4^x(f(x)+g(x))) &= \frac{d}{dx}(4^x)\cdot(f(x)+g(x))+4^x\cdot\frac{d}{dx}(f(x)+g(x))\\ &= (\ln 4\cdot 4^x)(f(x)+g(x))+4^x(f'(x)+g'(x))\\ &= 4^x(\ln 4\cdot f(x)+\ln 4\cdot g(x)+f'(x)+g'(x)).\end{aligned}$$

50. By the quotient rule, we have

$$\frac{d}{dx}\left(\frac{f(x)}{g(x)+1}\right)=\frac{f'(x)(g(x)+1)-f(x)\cdot\frac{d}{dx}(g(x)+1)}{(g(x)+1)^2}=\frac{f'(x)g(x)+f'(x)-f(x)g'(x)}{(g(x)+1)^2}.$$

51. By the quotient rule, we have

$$\begin{aligned}\frac{d}{dx}\left(\frac{f(x)g(x)}{h(x)}\right) &= \frac{\frac{d}{dx}(f(x)g(x))\cdot h(x)-(f(x)g(x))\cdot h'(x)}{(h(x))^2}\\ &= \frac{(f'(x)g(x)+f(x)g'(x))\cdot h(x)-f(x)g(x)h'(x)}{(h(x))^2}\\ &= \frac{f'(x)g(x)h(x)+f(x)g'(x)h(x)-f(x)g(x)h'(x)}{(h(x))^2}.\end{aligned}$$

52. (a) We have $h'(2)=f'(2)+g'(2)=5-2=3$.
(b) We have $h'(2)=f'(2)g(2)+f(2)g'(2)=5(4)+3(-2)=14$.
(c) We have $h'(2)=\dfrac{f'(2)g(2)-f(2)g'(2)}{(g(2))^2}=\dfrac{5(4)-3(-2)}{4^2}=\dfrac{26}{16}=\dfrac{13}{8}$.

53. (a) $G'(z)=F'(z)H(z)+H'(z)F(z)$, so
$G'(3)=F'(3)H(3)+H'(3)F(3)=4\cdot 1+3\cdot 5=19$.
(b) $G'(w)=\dfrac{F'(w)H(w)-H'(w)F(w)}{[H(w)]^2}$, so $G'(3)=\dfrac{4(1)-3(5)}{1^2}=-11$.

54. Use the product rule and rewrite the expression as

$$f'(x)g(x)+f(x)g'(x)-g(x)+4f'(x).$$

At $x=3$, we have

$$f'(3)g(3)+f(3)g'(3)-g(3)+4f'(3).$$

Using the given values,

$$\frac{1}{2}\cdot 12+6\cdot\frac{4}{3}-12+4\cdot\frac{1}{2}=6+8-12+2=4.$$

55. $f'(x)=10x^9e^x+x^{10}e^x$ is of the form $g'h+h'g$, where

$$g(x)=x^{10},\ g'(x)=10x^9$$

and

$$h(x)=e^x,\ h'(x)=e^x.$$

Therefore, using the product rule, let $f=g\cdot h$, with $g(x)=x^{10}$ and $h(x)=e^x$. Thus

$$f(x)=x^{10}e^x.$$

56. (a) $f(140)=15{,}000$ says that 15,000 skateboards are sold when the cost is \$140 per board.
$f'(140)=-100$ means that if the price is increased from \$140, roughly speaking, every dollar of increase will decrease the total sales by 100 boards.

(b) $\dfrac{dR}{dp} = \dfrac{d}{dp}(p \cdot q) = \dfrac{d}{dp}\left(p \cdot f(p)\right) = f(p) + pf'(p)$.
So,

$$\begin{aligned}\left.\frac{dR}{dp}\right|_{p=140} &= f(140) + 140f'(140) \\ &= 15{,}000 + 140(-100) = 1000.\end{aligned}$$

(c) From (b) we see that $\left.\dfrac{dR}{dp}\right|_{p=140} = 1000 > 0$. This means that the revenue will increase by about \$1000 if the price is raised by \$1.

57. We want dR/dr_1. Solving for R:

$$\frac{1}{R} = \frac{1}{r_1} + \frac{1}{r_2} = \frac{r_2 + r_1}{r_1 r_2}, \text{ which gives } R = \frac{r_1 r_2}{r_2 + r_1}.$$

So, thinking of r_2 as a constant and using the quotient rule,

$$\frac{dR}{dr_1} = \frac{r_2(r_2 + r_1) - r_1 r_2(1)}{(r_2 + r_1)^2} = \frac{r_2^2}{(r_1 + r_2)^2}.$$

58. (a) If the museum sells the painting and invests the proceeds $P(t)$ at time t, then t years have elapsed since 2000, and the time span up to 2020 is $20 - t$. This is how long the proceeds $P(t)$ are earning interest in the bank. Each year the money is in the bank it earns 5% interest, which means the amount in the bank is multiplied by a factor of 1.05. So, at the end of $(20 - t)$ years, the balance is given by

$$B(t) = P(t)(1 + 0.05)^{20-t} = P(t)(1.05)^{20-t}.$$

(b)

$$B(t) = P(t)(1.05)^{20}(1.05)^{-t} = (1.05)^{20}\frac{P(t)}{(1.05)^t}.$$

(c) By the quotient rule,

$$B'(t) = (1.05)^{20}\left[\frac{P'(t)(1.05)^t - P(t)(1.05)^t \ln 1.05}{(1.05)^{2t}}\right].$$

So,

$$\begin{aligned}B'(10) &= (1.05)^{20}\left[\frac{5000(1.05)^{10} - 150{,}000(1.05)^{10}\ln 1.05}{(1.05)^{20}}\right] \\ &= (1.05)^{10}(5000 - 150{,}000 \ln 1.05) \\ &\approx -3776.63.\end{aligned}$$

59. Note first that $f(v)$ is in $\frac{\text{liters}}{\text{km}}$, and v is in $\frac{\text{km}}{\text{hour}}$.

(a) $g(v) = \frac{1}{f(v)}$. (This is in $\frac{\text{km}}{\text{liter}}$.) Differentiating gives

$$g'(v) = \frac{-f'(v)}{(f(v))^2}.$$

So,

$$\begin{aligned}g(80) &= \frac{1}{0.05} = 20\tfrac{\text{km}}{\text{liter}}. \\ g'(80) &= \frac{-0.0005}{(0.05)^2} = -\frac{1}{5}\tfrac{\text{km}}{\text{liter}} \text{ for each } 1\tfrac{\text{km}}{\text{hr}} \text{ increase in speed.}\end{aligned}$$

(b) $h(v) = v \cdot f(v)$. (This is in $\frac{\text{km}}{\text{hour}} \cdot \frac{\text{liters}}{\text{km}} = \frac{\text{liters}}{\text{hour}}$.) Differentiating gives

$$h'(v) = f(v) + v \cdot f'(v),$$

so

$$\begin{aligned}h(80) &= 80(0.05) = 4\tfrac{\text{liters}}{\text{hr}}. \\ h'(80) &= 0.05 + 80(0.0005) = 0.09\tfrac{\text{liters}}{\text{hr}} \text{ for each } 1\tfrac{\text{km}}{\text{hr}} \text{ increase in speed.}\end{aligned}$$

(c) Part (a) tells us that at 80 km/hr, the car can go 20 km on 1 liter. Since the first derivative evaluated at this velocity is negative, this implies that as velocity increases, fuel efficiency decreases, i.e., at higher velocities the car will not go as far on 1 liter of gas. Part (b) tells us that at 80 km/hr, the car uses 4 liters in an hour. Since the first derivative evaluated at this velocity is positive, this means that at higher velocities, the car will use more gas per hour.

60. Assume for $g(x) \neq f(x)$, $g'(x) = g(x)$ and $g(0) = 1$. Then for

$$h(x) = \frac{g(x)}{e^x}$$

$$h'(x) = \frac{g'(x)e^x - g(x)e^x}{(e^x)^2} = \frac{e^x(g'(x) - g(x))}{(e^x)^2} = \frac{g'(x) - g(x)}{e^x}.$$

But, since $g(x) = g'(x)$, $h'(x) = 0$, so $h(x)$ is constant. Thus, the ratio of $g(x)$ to e^x is constant. Since $\frac{g(0)}{e^0} = \frac{1}{1} = 1$, $\frac{g(x)}{e^x}$ must equal 1 for all x. Thus $g(x) = e^x = f(x)$ for all x, so f and g are the same function.

61. (a) $f'(x) = (x-2) + (x-1)$.

(b) Think of f as the product of two factors, with the first as $(x-1)(x-2)$. (The reason for this is that we have already differentiated $(x-1)(x-2)$).

$$f(x) = [(x-1)(x-2)](x-3).$$

Now $f'(x) = [(x-1)(x-2)]'(x-3) + [(x-1)(x-2)](x-3)'$
Using the result of a):

$$\begin{aligned} f'(x) &= [(x-2)+(x-1)](x-3) + [(x-1)(x-2)] \cdot 1 \\ &= (x-2)(x-3) + (x-1)(x-3) + (x-1)(x-2). \end{aligned}$$

(c) Because we have already differentiated $(x-1)(x-2)(x-3)$, rewrite f as the product of two factors, the first being $(x-1)(x-2)(x-3)$:

$$f(x) = [(x-1)(x-2)(x-3)](x-4)$$

$$\text{Now } f'(x) = [(x-1)(x-2)(x-3)]'(x-4) + [(x-1)(x-2)(x-3)](x-4)'.$$

$$\begin{aligned} f'(x) &= [(x-2)(x-3) + (x-1)(x-3) + (x-1)(x-2)](x-4) \\ &\quad + [(x-1)(x-2)(x-3)] \cdot 1 \\ &= (x-2)(x-3)(x-4) + (x-1)(x-3)(x-4) \\ &\quad + (x-1)(x-2)(x-4) + (x-1)(x-2)(x-3). \end{aligned}$$

From the solutions above, we can observe that when f is a product, its derivative is obtained by differentiating each factor in turn (leaving the other factors alone), and adding the results.

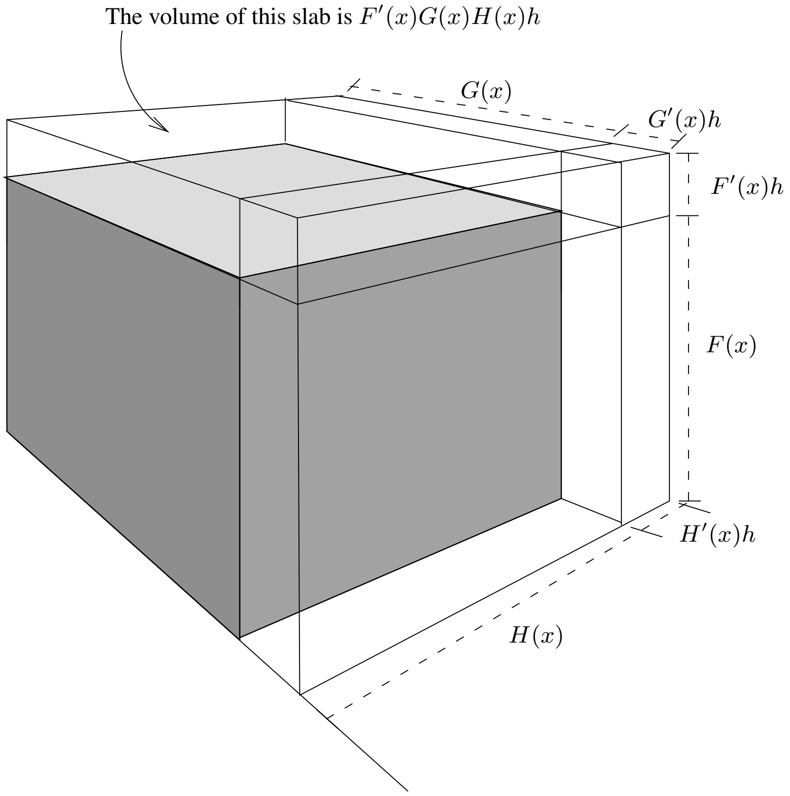
62. From the answer to Problem 61, we find that

$$\begin{aligned} f'(x) &= (x-r_1)(x-r_2)\cdots(x-r_{n-1}) \cdot 1 \\ &\quad + (x-r_1)(x-r_2)\cdots(x-r_{n-2}) \cdot 1 \cdot (x-r_n) \\ &\quad + (x-r_1)(x-r_2)\cdots(x-r_{n-3}) \cdot 1 \cdot (x-r_{n-1})(x-r_n) \\ &\quad + \cdots + 1 \cdot (x-r_2)(x-r_3)\cdots(x-r_n) \\ &= f(x)\left(\frac{1}{x-r_1} + \frac{1}{x-r_2} + \cdots + \frac{1}{x-r_n}\right). \end{aligned}$$

63. (a) We can approximate $\frac{d}{dx}[F(x)G(x)H(x)]$ using the large rectangular solids by which our original cube is increased:

Volume of whole − volume of original solid = change in volume.

$F(x+h)G(x+h)H(x+h) - F(x)G(x)H(x)$ = change in volume.



As in the book, we will ignore the smaller regions which are added (the long, thin rectangular boxes and the small cube in the corner.) This can be justified by recognizing that as $h \to 0$, these volumes will shrink much faster than the volumes of the big slabs and will therefore be insignificant. (Note that these smaller regions have an h^2 or h^3 in the formulas of their volumes.) Then we can approximate the change in volume above by:

$$\begin{aligned} F(x+h)G(x+h)H(x+h) - F(x)G(x)H(x) \approx & F'(x)G(x)H(x)h \quad \text{(top slab)} \\ & + F(x)G'(x)H(x)h \quad \text{(front slab)} \\ & + F(x)G(x)H'(x)h \quad \text{(other slab).} \end{aligned}$$

Dividing by h gives

$$\begin{aligned} & \frac{F(x+h)G(x+h)H(x+h) - F(x)G(x)H(x)}{h} \\ & \approx F'(x)G(x)H(x) + F(x)G'(x)H(x) + F(x)G(x)H'(x). \end{aligned}$$

Letting $h \to 0$

$$(FGH)' = F'GH + FG'H + FGH'.$$

(b) Verifying,

$$\begin{aligned} \frac{d}{dx}[(F(x) \cdot G(x)) \cdot H(x)] &= (F \cdot G)'(H) + (F \cdot G)(H)' \\ &= [F'G + FG']H + FGH' \\ &= F'GH + FG'H + FGH' \end{aligned}$$

as before.

(c) From the answer to (b), we observe that the derivative of a product is obtained by differentiating each factor in turn (leaving the other factors alone), and adding the results. So, in general,

$$(f_1 \cdot f_2 \cdot f_3 \cdot \ldots \cdot f_n)' = f_1' f_2 f_3 \cdots f_n + f_1 f_2' f_3 \cdots f_n + \cdots + f_1 \cdots f_{n-1} f_n'.$$

64. (a) Since $x = a$ is a double zero of a polynomial $P(x)$, we can write $P(x) = (x-a)^2Q(x)$, so $P(a) = 0$. Using the product rule, we have

$$P'(x) = 2(x-a)Q(x) + (x-a)^2Q'(x).$$

Substituting in $x = a$, we see $P'(a) = 0$ also.

(b) Since $P(a) = 0$, we know $x = a$ is a zero of P, so that $x - a$ is a factor of P and we can write

$$P(x) = (x-a)Q(x),$$

where Q is some polynomial. Differentiating this expression for P using the product rule, we get

$$P'(x) = Q(x) + (x-a)Q'(x).$$

Since we are told that $P'(a) = 0$, we have

$$P'(a) = Q(a) + (a-a)Q'(a) = 0$$

and so $Q(a) = 0$. Therefore $x = a$ is a zero of Q, so again we can write

$$Q(x) = (x-a)R(x),$$

where R is some other polynomial. As a result,

$$P(x) = (x-a)Q(x) = (x-a)^2R(x),$$

so that $x = a$ is a double zero of P.

65. Using the product rule

$$\begin{aligned}\frac{d^2}{dx^2}\left(f(x)g(x)\right) &= \frac{d}{dx}\left(\frac{d}{dx}\left(f(x)g(x)\right)\right) = \frac{d}{dx}\left(f'(x)g(x) + f(x)g'(x)\right)\\ &= f''(x)g(x) + f'(x)g'(x) + f'(x)g'(x) + f(x)g''(x)\\ &= f''(x)g(x) + 2f'(x)g'(x) + f(x)g''(x).\end{aligned}$$

Strengthen Your Understanding

66. The derivative of x^2e^x is not the product of the derivatives of the factors. Applying the product rule gives

$$\frac{df}{dx} = \frac{d}{dx}(x^2)e^x + x^2\frac{d}{dx}(e^x) = (2x + x^2)e^x.$$

67. The terms in the numerator of $f'(x)$ are transposed. Applying the quotient rule with $u(x) = x$ and $v(x) = x + 1$ we get

$$\frac{d}{dx}\left(\frac{u}{v}\right) = \frac{\frac{du}{dx}\cdot v - u\cdot\frac{dv}{dx}}{v^2}$$

so

$$f'(x) = \frac{(x+1)\frac{d}{dx}(x) - x\frac{d}{dx}(x+1)}{(x+1)^2}.$$

68. Rewrite $f(x)$ as $f(x) = e^x(x+1)$ then the product rule gives $f'(x) = e^x(x+1) + e^x\cdot 1 = (x+2)e^x$.

69. One possibility is $f(x) = e^x\sin x$. More complicated examples include $g(x) = 10^x\sin(3x)$.

70. Functions like $f(x) = x^2$ can be differentiated using the power rule. However, we can also view it as $f(x) = x\cdot x$ and apply the product rule.

71. False. The product rule gives

$$(fg)' = fg' + f'g.$$

Differentiating this and using the product rule again, we get

$$(fg)'' = f'g' + fg'' + f'g' + f''g = fg'' + 2f'g' + f''g.$$

Thus, the right hand side is not equal to $fg'' + f''g$ in general.

72. True; looking at the statement from the other direction, if both $f(x)$ and $g(x)$ are differentiable at $x = 1$, then so is their quotient, $f(x)/g(x)$, as long as it is defined there, which requires that $g(1) \neq 0$. So the only way in which $f(x)/g(x)$ can be defined but not differentiable at $x = 1$ is if either $f(x)$ or $g(x)$, or both, is not differentiable there.

73. False. Let $f(x) = x^2$ and $g(x) = x^2 - 1$. Let $h(x) = f(x)g(x)$. Then $h''(x) = 12x^2 - 2$. Since $h''(0) < 0$, clearly h is not concave up for all x.

74. (a) This is not a counterexample. Although the product rule says that $(fg)' = f'g + fg'$, that does not rule out the possibility that also $(fg)' = f'g'$. In fact, if f and g are both constant functions, then both $f'g + fg'$ and $f'g'$ are zero, so they are equal to each other.

(b) This is not a counterexample. In fact, it agrees with the product rule:

$$\frac{d}{dx}(xf(x)) = \left(\frac{d}{dx}(x)\right) f(x) + x\frac{d}{dx}f(x) = f(x) + xf'(x) = xf'(x) + f(x).$$

(c) This is not a counterexample. Although the product rule says that

$$\frac{d}{dx}(f(x)^2) = \frac{d}{dx}f(x) \cdot f(x) = f'(x)f(x) + f(x)f'(x) = 2f(x)f'(x),$$

it could be true that $f'(x) = 1$, so that the derivative is also just $2f(x)$. In fact, $f(x) = x$ is an example where this happens.

(d) This would be a counterexample. If $f'(a) = g'(a) = 0$, then

$$\frac{d}{dx}(f(x)g(x))\Big|_{x=a} = f'(a)g(a) + f(a)g'(a) = 0.$$

So fg cannot have positive slope at $x = a$. Of course such a counterexample could not exist, since the product rule is true.

Solutions for Section 3.4

Exercises

1. $f'(x) = 99(x+1)^{98} \cdot 1 = 99(x+1)^{98}$.

2. $w' = 100(t^3+1)^{99}(3t^2) = 300t^2(t^3+1)^{99}$.

3. $g'(x) = \frac{d}{dx}\left((4x^2+1)^7\right) = 7(4x^2+1)^6 \frac{d}{dx}(4x^2+1) = 7(4x^2+1)^6 \cdot 8x = 56x(4x^2+1)^6$.

4. $f'(x) = \frac{1}{2}(1-x^2)^{-\frac{1}{2}}(-2x) = \frac{-x}{\sqrt{1-x^2}}$.

5. $\frac{dy}{dx} = \frac{d}{dx}(\sqrt{e^x+1}) = \frac{d}{dx}(e^x+1)^{1/2} = \frac{1}{2}(e^x+1)^{-1/2}\frac{d}{dx}(e^x+1) = \frac{e^x}{2\sqrt{e^x+1}}$.

6. $w' = 100(\sqrt{t}+1)^{99}\left(\frac{1}{2\sqrt{t}}\right) = \frac{50}{\sqrt{t}}(\sqrt{t}+1)^{99}$.

7. $h'(w) = 5(w^4 - 2w)^4(4w^3 - 2)$

8. $s'(t) = 3(3t^2+4t+1)^2 \cdot (6t+4) = 3(6t+4)(3t^2+4t+1)^2$.

9. We can write $w(r) = (r^4+1)^{1/2}$, so

$$w'(r) = \frac{1}{2}(r^4+1)^{-1/2}(4r^3) = \frac{2r^3}{\sqrt{r^4+1}}.$$

10. $k'(x) = 4(x^3+e^x)^3(3x^2+e^x)$.

11. $f'(x) = 2e^{2x}[x^2+5^x] + e^{2x}[2x+(\ln 5)5^x] = e^{2x}[2x^2+2x+(\ln 5+2)5^x]$.

12. $y' = \frac{3}{2}e^{\frac{3}{2}w}$.

13. $g(x) = \pi e^{\pi x}$.

14. $\frac{dB}{dt} = 15e^{0.20t} \cdot 0.20 = 3e^{0.20t}$.

15. $\frac{dw}{dx} = 100e^{-x^2} \cdot (-2x) = -200xe^{-x^2}$.

16. $f(\theta) = (2^{-1})^\theta = (\frac{1}{2})^\theta$ so $f'(\theta) = (\ln \frac{1}{2})2^{-\theta}$.

17. $y' = (\ln \pi)\pi^{(x+2)}$.

18. $g'(x) = 2(\ln 3)3^{(2x+7)}$.

19. $f'(t) = 1 \cdot e^{5-2t} + te^{5-2t}(-2) = e^{5-2t}(1-2t)$.

20. $p'(t) = 4e^{4t+2}$.

21. Using the product rule gives $v'(t) = 2te^{-ct} - ce^{-ct}t^2 = (2t - ct^2)e^{-ct}$.

22. $\frac{d}{dt}e^{(1+3t)^2} = e^{(1+3t)^2}\frac{d}{dt}(1+3t)^2 = e^{(1+3t)^2} \cdot 2(1+3t) \cdot 3 = 6(1+3t)e^{(1+3t)^2}$.

23. $w' = \frac{1}{2\sqrt{s}}e^{\sqrt{s}}$.

24. $y' = -4e^{-4t}$.

25. $y' = \frac{3s^2}{2\sqrt{s^3+1}}$.

26. $y' = 1 \cdot e^{-t^2} + te^{-t^2}(-2t)$

27. $f'(z) = \frac{1}{2\sqrt{z}}e^{-z} - \sqrt{z}e^{-z}$.

28. $z'(x) = \frac{(\ln 2)2^x}{3\sqrt[3]{(2^x+5)^2}}$.

29. $z' = 5 \cdot \ln 2 \cdot 2^{5t-3}$.

30. $w' = \frac{3}{2}\sqrt{x^2 \cdot 5^x}[2x(5^x) + (\ln 5)(x^2)(5^x)] = \frac{3}{2}x^2\sqrt{5^{3x}}(2 + x\ln 5)$.

31. $f(y) = \left[10^{(5-y)}\right]^{\frac{1}{2}} = 10^{\frac{5}{2}-\frac{1}{2}y}$

$f'(y) = (\ln 10)\left(10^{\frac{5}{2}-\frac{1}{2}y}\right)\left(-\frac{1}{2}\right) = -\frac{1}{2}(\ln 10)(10^{\frac{5}{2}-\frac{1}{2}y})$.

32. We can write this as $f(z) = \sqrt{z}e^{-z}$, in which case it is the same as problem 27. So $f'(z) = \frac{1}{2\sqrt{z}}e^{-z} - \sqrt{z}e^{-z}$.

33. $y' = \frac{\frac{2^z}{2\sqrt{z}} - (\sqrt{z})(\ln 2)(2^z)}{2^{2z}} = \frac{1 - 2z\ln 2}{2^{z+1}\sqrt{z}}$.

34. $y' = 2\left(\frac{x^2+2}{3}\right)\left(\frac{2x}{3}\right) = \frac{4}{9}x\left(x^2+2\right)$

35. We can write $h(x) = \left(\frac{x^2+9}{x+3}\right)^{1/2}$, so

$$h'(x) = \frac{1}{2}\left(\frac{x^2+9}{x+3}\right)^{-1/2}\left[\frac{2x(x+3) - (x^2+9)}{(x+3)^2}\right] = \frac{1}{2}\sqrt{\frac{x+3}{x^2+9}}\left[\frac{x^2+6x-9}{(x+3)^2}\right].$$

36.

$$\begin{aligned}\frac{dy}{dx} &= \frac{(e^x+e^{-x})(e^x+e^{-x}) - (e^x-e^{-x})(e^x-e^{-x})}{(e^x+e^{-x})^2} \\ &= \frac{(e^x+e^{-x})^2 - (e^x-e^{-x})^2}{(e^x+e^{-x})^2} = \frac{(e^{2x}+2+e^{-2x}) - (e^{2x}-2+e^{-2x})}{(e^x+e^{-x})^2} \\ &= \frac{4}{(e^x+e^{-x})^2}\end{aligned}$$

37. $y' = \frac{-(3e^{3x}+2x)}{(e^{3x}+x^2)^2}$.

38. $h'(z) = \frac{-8b^4z}{(a+z^2)^5}$

39. $f'(x) = -\frac{1}{2}(x^3+1)^{-\frac{3}{2}} \cdot (3x^2) = -1.5x^2(x^3+1)^{-1.5}$.

40. $f'(z) = -2(e^z+1)^{-3} \cdot e^z = \dfrac{-2e^z}{(e^z+1)^3}$.

41. $w' = (2t+3)(1-e^{-2t}) + (t^2+3t)(2e^{-2t})$.

42. $h'(x) = (\ln 2)(3e^{3x})2^{e^{3x}} = 3e^{3x}2^{e^{3x}} \ln 2$.

43. $f'(x) = 6(e^{5x})(5) + (e^{-x^2})(-2x) = 30e^{5x} - 2xe^{-x^2}$.

44. $f'(x) = e^{-(x-1)^2} \cdot (-2)(x-1)$.

45.

$$\begin{aligned} f'(w) &= (e^{w^2})(10w) + (5w^2+3)(e^{w^2})(2w) \\ &= 2we^{w^2}(5+5w^2+3) \\ &= 2we^{w^2}(5w^2+8). \end{aligned}$$

46. The power and chain rules give

$$f'(\theta) = -1(e^\theta + e^{-\theta})^{-2} \cdot \frac{d}{d\theta}(e^\theta + e^{-\theta}) = -(e^\theta + e^{-\theta})^{-2}(e^\theta + e^{-\theta}(-1)) = -\left(\frac{e^\theta - e^{-\theta}}{(e^\theta + e^{-\theta})^2}\right).$$

47. We write $y = (e^{-3t^2}+5)^{1/2}$, so

$$\begin{aligned} \frac{dy}{dt} = \frac{1}{2}(e^{-3t^2}+5)^{-1/2} \cdot \frac{d}{dt}(e^{-3t^2}+5) &= \frac{1}{2}(e^{-3t^2}+5)^{-1/2} \cdot e^{-3t^2} \cdot \frac{d}{dt}(-3t^2) \\ &= \frac{1}{2}(e^{-3t^2}+5)^{-1/2} \cdot e^{-3t^2} \cdot (-6t) = -\frac{3te^{-3t^2}}{\sqrt{e^{-3t^2}+5}}. \end{aligned}$$

48. Using the product and chain rules, we have

$$\begin{aligned} \frac{dz}{dt} &= 9(te^{3t}+e^{5t})^8 \cdot \frac{d}{dt}(te^{3t}+e^{5t}) = 9(te^{3t}+e^{5t})^8(1 \cdot e^{3t} + t \cdot e^{3t} \cdot 3 + e^{5t} \cdot 5) \\ &= 9(te^{3t}+e^{5t})^8(e^{3t} + 3te^{3t} + 5e^{5t}). \end{aligned}$$

49. $f'(y) = e^{e^{(y^2)}}\left[(e^{y^2})(2y)\right] = 2ye^{[e^{(y^2)}+y^2]}$.

50. $f'(t) = 2(e^{-2e^{2t}})(-2e^{2t})2 = -8(e^{-2e^{2t}+2t})$.

51. Since a and b are constants, we have $f'(x) = 3(ax^2+b)^2(2ax) = 6ax(ax^2+b)^2$.

52. Since a and b are constants, we have $f'(t) = ae^{bt}(b) = abe^{bt}$.

53. We use the product rule. We have

$$f'(x) = (ax)(e^{-bx}(-b)) + (a)(e^{-bx}) = -abxe^{-bx} + ae^{-bx}.$$

54. Using the product and chain rules, we have

$$\begin{aligned} g'(\alpha) &= e^{\alpha e^{-2\alpha}} \cdot \frac{d}{dx}(\alpha e^{-2\alpha}) = e^{\alpha e^{-2\alpha}}(1 \cdot e^{-2\alpha} + \alpha e^{-2\alpha}(-2)) \\ &= e^{\alpha e^{-2\alpha}}(e^{-2\alpha} - 2\alpha e^{-2\alpha}) \\ &= (1-2\alpha)e^{-2\alpha}e^{\alpha e^{-2\alpha}}. \end{aligned}$$

55. We have

$$\begin{aligned} \frac{dy}{dx} &= \left(ae^{-be^{-cx}}\right)' \\ &= \left(-be^{-cx}\right)'\left(ae^{-be^{-cx}}\right) \quad \text{chain rule} \end{aligned}$$

$$= -ab\left(-ce^{-cx}\right)e^{-be^{-cx}}$$
$$= abce^{-cx}e^{-be^{-cx}}.$$

This can also be written $\frac{dy}{dx} = abce^{-be^{-cx}-cx}$.

56. One approach is to expand this at the outset:

$$\begin{aligned} y &= \left(e^x - e^{-x}\right)^2 \\ &= \left(e^x - e^{-x}\right)\left(e^x - e^{-x}\right) \\ &= \underbrace{(e^x)^2}_{e^{2x}} - \underbrace{e^x e^{-x}}_{1} - \underbrace{e^{-x}e^x}_{1} + \underbrace{\left(e^{-x}\right)^2}_{e^{-2x}} \\ &= e^{2x} + e^{-2x} - 2, \\ \text{so} \quad \frac{dy}{dx} &= \left(e^{2x} + e^{-2x} - 2\right)' \\ &= 2e^{2x} - 2e^{-2x}. \end{aligned}$$

Another approach is to use the Chain Rule:

$$\begin{aligned} \frac{dy}{dx} &= \left(\left(e^x - e^{-x}\right)^2\right)' \\ &= 2\left(e^x - e^{-x}\right)\cdot\left(e^x - e^{-x}\right)' \\ &= 2\left(e^x - e^{-x}\right)\cdot\left(e^x + e^{-x}\right) \\ &= 2\left((e^x)^2 + e^x e^{-x} - e^{-x}e^x - \left(e^{-x}\right)^2\right) \\ &= 2\left(e^{2x} - e^{-2x}\right), \end{aligned}$$

which is equivalent to our first answer.

Problems

57. When f and g are differentiable, the chain rule gives $h'(x) = f'(g(x)) \cdot g'(x)$. We use slope to compute the derivatives. Since $f(x)$ is linear on the interval $0 < x < 2$, we compute the slope of the line to see that $f'(x) = 2$ on this interval. Similarly, we compute the slope on the interval $2 < x < 4$ to see that $f'(x) = -2$ on the interval $2 < x < 4$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist.

Similarly, $g(x)$ is linear on the interval shown, and we see that the slope of $g(x)$ on this interval is -1 so we have $g'(x) = -1$ on this interval.

(a) We have $h'(1) = f'(g(1)) \cdot g'(1) = (f'(3))(-1) = (-2)(-1) = 2$.
(b) Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist. Therefore, the chain rule does not apply.
(c) We have $h'(3) = f'(g(3)) \cdot g'(3) = (f'(1))(-1) = 2(-1) = -2$.

58. When f and g are differentiable, the chain rule gives $u'(x) = g'(f(x)) \cdot f'(x)$. We use slope to compute the derivatives. Since $f(x)$ is linear on the interval $0 < x < 2$, we compute the slope of the line to see that $f'(x) = 2$ on this interval. Similarly, we compute the slope on the interval $2 < x < 4$ to see that $f'(x) = -2$ on the interval $2 < x < 4$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist.

Similarly, $g(x)$ is linear on the interval shown, and we see that the slope of $g(x)$ on this interval is -1 so we have $g'(x) = -1$ on this interval.

(a) We have $u'(1) = g'(f(1)) \cdot f'(1) = (g'(2))2 = (-1)2 = -2$.
(b) Since $f(x)$ has a corner at $x = 2$, the chain rule is not applicable.
(c) We have $u'(3) = g'(f(3)) \cdot f'(3) = (g'(2))(-2) = (-1)(-2) = 2$.

59. When f and g are differentiable, the chain rule gives $v'(x) = f'(f(x)) \cdot f'(x)$. We use slope to compute the derivatives. Since $f(x)$ is linear on the interval $0 < x < 2$, we compute the slope of the line to see that $f'(x) = 2$ on this interval. Similarly, we compute the slope on the interval $2 < x < 4$ to see that $f'(x) = -2$ on the interval $2 < x < 4$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist.

(a) To use the chain rule, we need $f'(f(1)) = f'(2)$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist. Therefore, the chain rule does not apply.
(b) Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist. Therefore, the chain rule does not apply.

(c) To use the chain rule, we need $f'(f(3)) = f'(2)$. Since $f(x)$ has a corner at $x = 2$, we know that $f'(2)$ does not exist. Therefore, the chain rule does not apply.

60. When f and g are differentiable, the chain rule gives $w'(x) = g'(g(x)) \cdot g'(x)$. We use slope to compute the derivatives. Since $g(x)$ is linear on the interval shown, with slope equal to -1, we have $g'(x) = -1$ on this interval.

(a) We have $w'(1) = g'(g(1)) \cdot g'(1) = (g'(3))(-1) = (-1)(-1) = 1$.
(b) We have $w'(2) = g'(g(2)) \cdot g'(2) = (g'(2))(-1) = (-1)(-1) = 1$.
(c) We have $w'(3) = g'(g(3)) \cdot g'(3) = (g'(1))(-1) = (-1)(-1) = 1$.

61. The chain rule gives

$$\left.\frac{d}{dx}f(g(x))\right|_{x=30} = f'(g(30))g'(30) = f'(55)g'(30) = (1)(\frac{1}{2}) = \frac{1}{2}.$$

62. The chain rule gives

$$\left.\frac{d}{dx}f(g(x))\right|_{x=70} = f'(g(70))g'(70) = f'(60)g'(70) = (1)(0) = 0.$$

63. The chain rule gives

$$\left.\frac{d}{dx}g(f(x))\right|_{x=30} = g'(f(30))f'(30) = g'(20)f'(30) = (1/2)(-2) = -1.$$

64. The chain rule gives

$$\left.\frac{d}{dx}g(f(x))\right|_{x=70} = g'(f(70))f'(70) = g'(30)f'(70) = (1)(\frac{1}{2}) = \frac{1}{2}.$$

65. We have $f(2) = (2-1)^3 = 1$, so $(2, 1)$ is a point on the tangent line. Since $f'(x) = 3(x-1)^2$, the slope of the tangent line is

$$m = f'(2) = 3(2-1)^2 = 3.$$

The equation of the line is

$$y - 1 = 3(x - 2) \quad \text{or} \quad y = 3x - 5.$$

66.

$$f(x) = 6e^{5x} + e^{-x^2} \qquad f'(x) = 30e^{5x} - 2xe^{-x^2}$$
$$f(1) = 6e^5 + e^{-1} \qquad f'(1) = 30e^5 - 2(1)e^{-1}$$

$$\begin{aligned} y - y_1 &= m(x - x_1) \\ y - (6e^5 + e^{-1}) &= (30e^5 - 2e^{-1})(x - 1) \\ y - (6e^5 + e^{-1}) &= (30e^5 - 2e^{-1})x - (30e^5 - 2e^{-1}) \\ y &= (30e^5 - 2e^{-1})x - 30e^5 + 2e^{-1} + 6e^5 + e^{-1} \\ &\approx 4451.66x - 3560.81. \end{aligned}$$

67. To calculate the equation of the tangent line, we need to find the function value and the slope at $t = 2$. The function value is

$$f(2) = 100e^{-0.3(2)} = 54.8812,$$

so a point on the line is $(2, 54.8812)$.

The slope is found using the derivative: $f'(t) = 100e^{-0.3t}(-0.3)$. At the point $t = 2$, we have

$$\text{Slope} = f'(2) = 100e^{-0.3(2)}(-0.3) = -16.4643.$$

The equation of the line is

$$\begin{aligned} y - 54.8812 &= -16.4643(t - 2) \\ y &= -16.464t + 87.810. \end{aligned}$$

68. The graph is concave down when $f''(x) < 0$.

$$\begin{aligned} f'(x) &= e^{-x^2}(-2x) \\ f''(x) &= \left[e^{-x^2}(-2x)\right](-2x) + e^{-x^2}(-2) \\ &= \frac{4x^2}{e^{x^2}} - \frac{2}{e^{x^2}} \\ &= \frac{4x^2-2}{e^{x^2}} < 0 \end{aligned}$$

The graph is concave down when $4x^2 < 2$. This occurs when $x^2 < \frac{1}{2}$, or $-\frac{1}{\sqrt{2}} < x < \frac{1}{\sqrt{2}}$.

69. We rewrite $e^{-x} = 1/e^x$ so that we can use the quotient rule, then

$$\begin{aligned} f(x) &= \frac{x}{e^x}, \\ f'(x) &= \frac{1\cdot e^x - x\cdot e^x}{(e^x)^2} = \frac{(1-x)e^x}{(e^x)^2} = \frac{1-x}{e^x}, \\ f''(x) &= \frac{-1\cdot e^x - (1-x)e^x}{(e^x)^2} = \frac{-e^x - e^x + xe^x}{(e^x)^2} = \frac{(-2+x)e^x}{(e^x)^2} = \frac{x-2}{e^x}. \end{aligned}$$

Since $e^{-x} > 0$, for all x, we have $f''(x) < 0$ if $x - 2 < 0$, that is, $x < 2$.

70.

$$\begin{aligned} f'(x) &= [10(2x+1)^9(2)][(3x-1)^7] + [(2x+1)^{10}][7(3x-1)^6(3)] \\ &= (2x+1)^9(3x-1)^6[20(3x-1) + 21(2x+1)] \\ &= [(2x+1)^9(3x-1)^6](102x+1) \end{aligned}$$

$$\begin{aligned} f''(x) = \; & [9(2x+1)^8(2)(3x-1)^6 + (2x+1)^9(6)(3x-1)^5(3)](102x+1) \\ & + (2x+1)^9(3x-1)^6(102). \end{aligned}$$

71. (a) $P(12) = 10e^{0.6(12)} = 10e^{7.2} \approx 13{,}394$ fish. There are 13,394 fish in the area after 12 months.

(b) We differentiate to find $P'(t)$, and then substitute in to find $P'(12)$:

$$\begin{aligned} P'(t) &= 10(e^{0.6t})(0.6) = 6e^{0.6t} \\ P'(12) &= 6e^{0.6(12)} \approx 8037 \text{ fish/month.} \end{aligned}$$

The population is growing at a rate of approximately 8037 fish per month.

72. (a) With μ and σ constant, differentiating $m(t) = e^{\mu t + \sigma^2 t^2/2}$ with respect to t gives

$$m'(t) = e^{ut+\sigma^2 t^2/2} \cdot \left(\mu + \frac{2\sigma^2 t}{2}\right) = e^{\mu t + \sigma^2 t^2/2}(\mu + \sigma^2 t).$$

Thus,

$$\text{Mean } = m'(0) = e^0(\mu + 0) = \mu.$$

(b) Differentiating $m'(t) = e^{\mu t + \sigma^2 t^2/2}(\mu + \sigma^2 t)$, we have

$$m''(t) = e^{\mu t + \sigma^2 t^2/2}(\mu + \sigma^2 t)^2 + e^{\mu t + \sigma^2 t^2/2}\sigma^2.$$

Thus

$$\text{Variance } = m''(0) - (m'(0))^2 = e^0\mu^2 + e^0\sigma^2 - \mu^2 = \sigma^2.$$

73. (a) If

$$p(x) = k(2x),$$

then

$$p'(x) = k'(2x)\cdot 2.$$

When $x = \frac{1}{2}$,

$$p'\left(\frac{1}{2}\right) = k'\left(2\cdot\frac{1}{2}\right)(2) = 2\cdot 2 = 4.$$

(b) If

$$q(x) = k(x+1),$$

then

$$q'(x) = k'(x+1)\cdot 1.$$

When $x = 0$,

$$q'(0) = k'(0+1)(1) = 2\cdot 1 = 2.$$

(c) If

$$r(x) = k\left(\frac{1}{4}x\right),$$

then

$$r'(x) = k'\left(\frac{1}{4}x\right)\cdot\frac{1}{4}.$$

When $x = 4$,

$$r'(4) = k'\left(\frac{1}{4}4\right)\frac{1}{4} = 2\cdot\frac{1}{4} = \frac{1}{2}.$$

74. Yes. To see why, simply plug $x = \sqrt[3]{2t+5}$ into the expression $3x^2\dfrac{dx}{dt}$ and evaluate it. To do this, first we calculate $\dfrac{dx}{dt}$. By the chain rule,

$$\frac{dx}{dt} = \frac{d}{dt}(2t+5)^{\frac{1}{3}} = \frac{2}{3}(2t+5)^{-\frac{2}{3}} = \frac{2}{3}[(2t+5)^{\frac{1}{3}}]^{-2}.$$

But since $x = (2t+5)^{\frac{1}{3}}$, we have (by substitution)

$$\frac{dx}{dt} = \frac{2}{3}x^{-2}.$$

It follows that $3x^2\dfrac{dx}{dt} = 3x^2\left(\dfrac{2}{3}x^{-2}\right) = 2.$

75. We see that $m'(x)$ is nearly of the form $f'(g(x))\cdot g'(x)$ where

$$f(g) = e^g \quad\text{and}\quad g(x) = x^6,$$

but $g'(x)$ is off by a multiple of 6. Therefore, using the chain rule, let

$$m(x) = \frac{f(g(x))}{6} = \frac{e^{(x^6)}}{6}.$$

76. (a) $H(x) = F(G(x))$
$H(4) = F(G(4)) = F(2) = 1$

(b) $H(x) = F(G(x))$
$H'(x) = F'(G(x))\cdot G'(x)$
$H'(4) = F'(G(4))\cdot G'(4) = F'(2)\cdot 6 = 5\cdot 6 = 30$

(c) $H(x) = G(F(x))$
$H(4) = G(F(4)) = G(3) = 4$

(d) $H(x) = G(F(x))$
$H'(x) = G'(F(x))\cdot F'(x)$
$H'(4) = G'(F(4))\cdot F'(4) = G'(3)\cdot 7 = 8\cdot 7 = 56$

(e) $H(x) = \frac{F(x)}{G(x)}$
$H'(x) = \frac{G(x)\cdot F'(x) - F(x)\cdot G'(x)}{[G(x)]^2}$
$H'(4) = \frac{G(4)\cdot F'(4) - F(4)\cdot G'(4)}{[G(4)]^2} = \frac{2\cdot 7 - 3\cdot 6}{2^2} = \frac{14-18}{4} = \frac{-4}{4} = -1$

77. (a) Differentiating $g(x) = \sqrt{f(x)} = (f(x))^{1/2}$, we have

$$g'(x) = \frac{1}{2}(f(x))^{-1/2}\cdot f'(x) = \frac{f'(x)}{2\sqrt{f(x)}}$$

$$g'(1) = \frac{f'(1)}{2\sqrt{f(1)}} = \frac{3}{2\sqrt{4}} = \frac{3}{4}.$$

(b) Differentiating $h(x) = f(\sqrt{x})$, we have

$$h'(x) = f'(\sqrt{x}) \cdot \frac{1}{2\sqrt{x}}$$
$$h'(1) = f'(\sqrt{1}) \cdot \frac{1}{2\sqrt{1}} = \frac{f'(1)}{2} = \frac{3}{2}.$$

78. (a) Using the chain rule, $h'(x) = e^{f(x)} \cdot f'(x)$. Since $e^{f(x)} \neq 0$ for all values of x, the derivative $h'(x)$ is zero when $f'(x) = 0$ and only then.

From the graph we see that $f'(x) = 0$ occurs when $x \approx -2.5$ and $x \approx 1.5$.

(b) Taking the derivative of p, we have $p'(x) = f'(e^x) \cdot e^x$. Since $e^x \neq 0$ for any value of x, the derivative $p'(x)$ is zero only when $f'(e^x) = 0$.

From the graph we see that $f'(y) = 0$ for $y \approx 1.5$ and $y \approx -2.5$. Thus, $f'(e^x)$ equals zero when $e^x = 1.5$ or $e^x = -2.5$. Since e^x never equals -2.5, the only solution to $f'(e^x) = 0$ is $x = \ln(1.5)$.

79. We have $h(0) = f(g(0)) = f(d) = d$. From the chain rule, $h'(0) = f'(g(0))g'(0)$. From the graph of g, we see that $g'(0) = 0$, so $h'(0) = f'(g(0)) \cdot 0 = 0$.

80. We have $h(-c) = f(g(-c)) = f(-b) = 0$. From the chain rule,

$$h'(-c) = f'(g(-c))g'(-c).$$

Since g is increasing at $x = -c$, we know that $g'(-c) > 0$. We have

$$f'(g(-c)) = f'(-b),$$

and since f is decreasing at $x = -b$, we have $f'(g(-c)) < 0$. Thus,

$$h'(-c) = \underbrace{f'(g(-c))}_{-} \cdot \underbrace{g'(-c)}_{+} < 0,$$

so h is decreasing at $x = -c$.

81. We have

$$h'(a) = f'(g(a))g'(a).$$

From the graph of g, we see that g is decreasing at $x = a$, so $g'(a) < 0$. We have

$$f'(g(a)) = f'(b),$$

and from the graph of f, we see that f is increasing at $x = b$, so $f'(b) > 0$. Thus,

$$h'(a) = \underbrace{f'(g(a))}_{+} \cdot \underbrace{g'(a)}_{-} < 0,$$

so h is decreasing at $x = a$.

82. We have $h(d) = f(g(d)) = f(-d) = d$ so $h(d)$ is positive. From the chain rule,

$$h'(d) = f'(g(d))g'(d).$$

We have

$$f'(g(d)) = f'(-d).$$

From the graph of f, we see that $f'(-d) < 0$, and from the graph of g, we see that $g'(d) < 0$. This means the sign of $h'(d)$ is the product of two negative numbers, so $h'(d) > 0$.

83. On the interval $-d < x < -b$, we see that the value of $g(x)$ increases from $-d$ to 0. On the interval $-d < x < 0$, the value of $f(x)$ decreases from d to $-d$. Thus, the value of $h(x) = f(g(x))$ decreases on the interval $-d < x < -b$ from

$$h(-d) = f(g(-d)) = f(-d) = d \quad \text{to} \quad h(-b) = f(g(-b)) = f(0) - d.$$

Confirming this using derivatives and the chain rule, we see

$$h'(x) = f'(g(x)) \cdot g'(x),$$

and since $g'(x)$ is negative on $-d < x < -b$ and $f'(g(x))$ is positive on this interval, the value of $h(x)$ is decreasing.

84. We have $f(0) = 6.91$ and $f(10) = 6.91e^{0.011(10)} = 7.713$. The derivative of $f(t)$ is

$$f'(t) = 6.91e^{0.011t} \cdot 0.011 = 0.0760e^{0.011t},$$

and so $f'(0) = 0.0760$ and $f'(10) = 0.0848$.

These values tell us that in 2010 (at $t = 0$), the population of the world was 6.91 billion people and the population was growing at a rate of 0.0760 billion people per year. In the year 2020 (at $t = 10$), this model predicts that the population of the world will be 7.71 billion people and growing at a rate of 0.0848 billion people per year.

85. Since the population is 308.75 million on April 1, 2010 and growing exponentially, $P = 308.75e^{kt}$, where P is the population in millions and t is time in years since the census in 2010. Then

$$\frac{dP}{dt} = 308.75ke^{kt},$$

so, since the population is growing at 2.85 million/year on April 1, 2010,

$$\left.\frac{dP}{dt}\right|_{t=0} = 308.75ke^{k\cdot 0} = 308.75k = 2.85$$

$$k = \frac{2.85}{308.75} = 0.00923,$$

so $P = 308.75e^{0.00923t}$.

86. (a) The function $f(t)$ is linear; $g(t)$ is exponential; $h(t)$ is quadratic (polynomial of degree 2.)

(b) In 2010, we have $t = 60$. For $f(t)$, the rate of change is

$$f'(t) = 1.3,$$

$$f'(60) = 1.3 \text{ ppm per year.}$$

For $g(t)$, the rate of change is

$$g'(t) = 304(0.0038)e^{0.0038t} = 1.1552e^{0.0038t},$$

$$g'(60) = 1.1552e^{0.0038(60)} = 1.451 \text{ ppm per year .}$$

For $h(t)$, the rate of change is

$$h'(t) = 0.0135 \cdot 2t + 0.5133 = 0.027t + 0.5135,$$

$$h'(60) = 0.027(60) + 0.5133 = 2.133 \text{ ppm per year .}$$

(c) Since $1.3 < 1.451 < 2.133$, we see
Linear prediction < Exponential < Quadratic.

(d) The linear growth rate remains constant and will always be the smallest. The other two growth rates increase with time, and eventually the exponential growth rate will overtake the quadratic growth rate.
For example, if $t = 1000$, we have

$$f'(1000) = 1.3$$

$$g'(1000) = 1.1552e^{0.0038(1000)} = 51.639$$

$$h'(1000) = 0.027(1000) + 0.5133 = 27.513.$$

Thus, at $t = 1000$, the exponential growth rate is largest.

87. We have $f(5) = 5.1e^{0.043(5)} = 6.3$ billion dollars. Since $f'(t) = 5.1e^{0.043t} \cdot 0.043$, we have

$$f'(5) = 5.1e^{0.043(5)}(0.043) = 0.272 \text{ billion dollars per year.}$$

In 2013, net sales at Hershey are predicted to be 6.3 billion dollars and to be increasing at a rate of 0.272 billion dollars per year.

88. Since we're given that the instantaneous rate of change of T at $t = 30$ is 2, we want to choose a and b so that the derivative of T agrees with this value. Differentiating, $T'(t) = ab \cdot e^{-bt}$. Then we have

$$2 = T'(30) = abe^{-30b} \text{ or } e^{-30b} = \frac{2}{ab}.$$

We also know that at $t = 30$, $T = 120$, so

$$120 = T(30) = 200 - ae^{-30b} \text{ or } e^{-30b} = \frac{80}{a}.$$

Thus

$$\frac{80}{a} = e^{-30b} = \frac{2}{ab},$$

so

$$b = \frac{1}{40} = 0.025 \quad \text{and} \quad a = 169.36.$$

89. (a) $\dfrac{dB}{dt} = P\left(1+\dfrac{r}{100}\right)^t \ln\left(1+\dfrac{r}{100}\right)$. The expression $\dfrac{dB}{dt}$ tells us how fast the amount of money in the bank is changing with respect to time for fixed initial investment P and interest rate r.

(b) $\dfrac{dB}{dr} = Pt\left(1+\dfrac{r}{100}\right)^{t-1}\dfrac{1}{100}$. The expression $\dfrac{dB}{dr}$ indicates how fast the amount of money changes with respect to the interest rate r , assuming fixed initial investment P and time t.

90. (a) We see from the formula that \$1000 was deposited initially, and that the money is earning interest at 8% compounded continuously.

(b) We have $f(10) = 1000e^{0.08(10)} = 2225.54$ dollars. Since $f'(t) = 1000e^{0.08t} \cdot 0.08$, we have

$$f'(10) = 1000e^{0.08(10)}(0.08) = 178.04 \text{ dollars per year.}$$

Ten years after the money was deposited, the balance is \$2225.54 and is growing at a rate of \$178.04 per year.

91. (a)

$$\begin{aligned}\frac{dm}{dv} &= \frac{d}{dv}\left[m_0\left(1-\frac{v^2}{c^2}\right)^{-1/2}\right]\\ &= m_0\left(-\frac{1}{2}\right)\left(1-\frac{v^2}{c^2}\right)^{-3/2}\left(-\frac{2v}{c^2}\right)\\ &= \frac{m_0 v}{c^2}\frac{1}{\sqrt{\left(1-\frac{v^2}{c^2}\right)^3}}.\end{aligned}$$

(b) $\dfrac{dm}{dv}$ represents the rate of change of mass with respect to the speed v.

92. (a) For $t < 0$, $I = \dfrac{dQ}{dt} = 0$.

For $t > 0$, $I = \dfrac{dQ}{dt} = -\dfrac{Q_0}{RC}e^{-t/RC}$.

(b) For $t > 0$, $t \to 0$ (that is, as $t \to 0^+$),

$$I = -\frac{Q_0}{RC}e^{-t/RC} \to -\frac{Q_0}{RC}.$$

Since $I = 0$ just to the left of $t = 0$ and $I = -Q_0/RC$ just to the right of $t = 0$, it is not possible to define I at $t = 0$.

(c) Q is not differentiable at $t = 0$ because there is no tangent line at $t = 0$.

93. Let f have a zero of multiplicity m at $x = a$ so that

$$f(x) = (x-a)^m h(x), \quad h(a) \neq 0.$$

Differentiating this expression gives

$$f'(x) = (x-a)^m h'(x) + m(x-a)^{(m-1)}h(x)$$

and both terms in the sum are zero when $x = a$ so $f'(a) = 0$. Taking another derivative gives

$$f''(x) = (x-a)^m h''(x) + 2m(x-a)^{(m-1)} h'(x) + m(m-1)(x-a)^{(m-2)} h(x).$$

Again, each term in the sum contains a factor of $(x-a)$ to some positive power, so at $x = a$ this will evaluate to 0. Differentiating repeatedly, all derivatives will have positive integer powers of $(x-a)$ until the m^{th} and will therefore vanish. However,

$$f^{(m)}(a) = m!h(a) \neq 0.$$

94. Using the chain and product rule:

$$\begin{aligned}\frac{d^2}{dx^2}\left(f(g(x))\right) &= \frac{d}{dx}\left(\frac{d}{dx}\left(f(g(x))\right)\right) = \frac{d}{dx}\left(f'(g(x))\cdot g'(x)\right)\\ &= f''(g(x))\cdot g'(x)\cdot g'(x) + f'(g(x))\cdot g''(x)\\ &= f''(g(x))\cdot\left(g'(x)\right)^2 + f'(g(x))\cdot g''(x).\end{aligned}$$

95. Using the chain and product rules:

$$\begin{aligned}\frac{d^2}{dx^2}\left(\frac{f(x)}{g(x)}\right) &= \frac{d}{dx}\left(\frac{d}{dx}\left(f(x)(g(x))^{-1}\right)\right) = \frac{d}{dx}\left(f'(x)(g(x))^{-1} - f(x)(g(x))^{-2}g'(x)\right)\\ &= f''(x)(g(x))^{-1} - f'(x)(g(x))^{-2}g'(x) - f'(x)(g(x))^{-2}g'(x)\\ &\qquad + 2f(x)(g(x))^{-3}(g'(x))^2 - f(x)(g(x))^{-2}g''(x)\\ &= f''(x)(g(x))^{-1} - 2f'(x)(g(x))^{-2}g'(x) + 2f(x)(g(x))^{-3}(g'(x))^2 - f(x)(g(x))^{-2}g''(x).\end{aligned}$$

Strengthen Your Understanding

96. The derivative of the inside function, e^x, is missing.
Let $z = h(x) = e^x + 2$, so $g(z) = z^5$ and $g'(z) = 5z^4 \cdot h'(x)$. Taking the derivative of h, we have $h'(x) = e^x$, so

$$g'(x) = 5(e^x+2)^4 e^x = 5e^x(e^x+2)^4.$$

97. To calculate the derivative of e^{x^2} we need to apply the chain rule. Take $z = g(x) = x^2$ as the inside function and $f(z) = e^z$ as the outside function. Since $g'(x) = 2x$ and $f'(z) = e^z$, the chain rule gives

$$w'(x) = e^z \cdot 2x = 2xe^{x^2}.$$

98. Two possibilities are

$$f(x) = \sin(e^x) \qquad \text{and} \qquad g(x) = e^{\sin x}.$$

More complicated examples include

$$f(x) = \sin(3\cdot 10^x) \qquad \text{and} \qquad g(x) = 5\cdot 7^{3\sin 2x}.$$

99. One possibility is $f(x) = (x^2+1)^2$, which can be differentiated using the chain rule with x^2+1 as the inside function and x^2 as the outside function:

$$f'(x) = 2(x^2+1)^1 \cdot 2x.$$

In addition, we can expand the function into a polynomial: $f(x) = x^4 + 2x^2 + 1$, and now differentiate term-by-term:

$$f'(x) = 4x^3 + 4x.$$

100. False; for example, if both $f(x)$ and $g(x)$ are constant functions, such as $f(x) = 6$, $g(x) = 10$, then $(fg)'(x) = 0$, and $f'(x) = 0$ and $g'(x) = 0$.

101. False; for example, if both f and g are constant functions, then the derivative of $f(g(x))$ is zero, as is the derivative of $f(x)$. Another example is $f(x) = 5x + 7$ and $g(x) = x + 2$.

102. False. Let $f(x) = e^{-x}$ and $g(x) = x^2$. Let $h(x) = f(g(x)) = e^{-x^2}$. Then $h'(x) = -2xe^{-x^2}$ and $h''(x) = (-2 + 4x^2)e^{-x^2}$. Since $h''(0) < 0$, clearly h is not concave up for all x.

Solutions for Section 3.5

2. $r'(\theta) = \cos\theta - \sin\theta$.

3. $s'(\theta) = -\sin\theta\sin\theta + \cos\theta\cos\theta = \cos^2\theta - \sin^2\theta = \cos 2\theta$.

4. $z' = -4\sin(4\theta)$.

5. $f'(x) = \cos(3x)\cdot 3 = 3\cos(3x)$.

6. $\dfrac{dy}{dt} = 5\cos(3t)\cdot 3 = 15\cos(3t)$.

7. $\dfrac{dP}{dt} = 4(-\sin(2t))\cdot 2 = -8\sin(2t)$.

8. $\dfrac{d}{dx}\sin(2-3x) = \cos(2-3x)\dfrac{d}{dx}(2-3x) = -3\cos(2-3x)$.

9. Using the chain rule gives $R'(x) = 3\pi\sin(\pi x)$.

10. $g'(\theta) = 2\sin(2\theta)\cos(2\theta)\cdot 2 - \pi = 4\sin(2\theta)\cos(2\theta) - \pi$

11. $g'(t) = 3(2+\sin(\pi t))^2\cdot(\cos(\pi t)\cdot\pi) = 3\pi\cos(\pi t)(2+\sin(\pi t))^2$.

12. $f'(x) = (2x)(\cos x) + x^2(-\sin x) = 2x\cos x - x^2\sin x$.

13. $w' = e^t\cos(e^t)$.

14. $f'(x) = (e^{\cos x})(-\sin x) = -\sin x e^{\cos x}$.

15. $f'(y) = (\cos y)e^{\sin y}$.

16. $z' = e^{\cos\theta} - \theta(\sin\theta)e^{\cos\theta}$.

17. Using the chain rule gives $R'(\theta) = 3\cos(3\theta)e^{\sin(3\theta)}$.

18. $g'(\theta) = \dfrac{\cos(\tan\theta)}{\cos^2\theta}$

19. $w'(x) = \dfrac{2x}{\cos^2(x^2)}$

20.

$$\begin{aligned} f(x) &= (1-\cos x)^{\frac{1}{2}} \\ f'(x) &= \frac{1}{2}(1-\cos x)^{-\frac{1}{2}}(-(-\sin x)) \\ &= \frac{\sin x}{2\sqrt{1-\cos x}}. \end{aligned}$$

21. $f'(x) = \frac{1}{2}(3+\sin(8x))^{-\frac{1}{2}} \cdot (\cos(8x)\cdot 8) = 4\cos(8x)(3+\sin(8x))^{-0.5}$.

22. $f'(x) = [-\sin(\sin x)](\cos x)$.

23. $f'(x) = \dfrac{\cos x}{\cos^2(\sin x)}$.

24. $k'(x) = \frac{3}{2}\sqrt{\sin(2x)}(2\cos(2x)) = 3\cos(2x)\sqrt{\sin(2x)}$.

25. $f'(x) = 2\cdot[\sin(3x)] + 2x[\cos(3x)]\cdot 3 = 2\sin(3x) + 6x\cos(3x)$

26. $y' = e^{\theta}\sin(2\theta) + 2e^{\theta}\cos(2\theta)$.

27. $f'(x) = (e^{-2x})(-2)(\sin x) + (e^{-2x})(\cos x) = -2\sin x(e^{-2x}) + (e^{-2x})(\cos x) = e^{-2x}[\cos x - 2\sin x]$.

28. $z' = \dfrac{\cos t}{2\sqrt{\sin t}}$.

29. $y' = 5\sin^4\theta\cos\theta$.

30. $g'(z) = \dfrac{e^z}{\cos^2(e^z)}$.

31. $z' = \dfrac{-3e^{-3\theta}}{\cos^2(e^{-3\theta})}$.

32. $w' = (-\cos\theta)e^{-\sin\theta}$.

33. $\dfrac{dQ}{dx} = -\sin(e^{2x})\cdot(e^{2x}\cdot 2) = -2e^{2x}\sin(e^{2x})$.

34. $h'(t) = 1\cdot(\cos t) + t(-\sin t) + \frac{1}{\cos^2 t} = \cos t - t\sin t + \frac{1}{\cos^2 t}$.

35. $f'(\alpha) = -\sin\alpha + 3\cos\alpha$

36. $k'(\alpha) = (5\sin^4\alpha\cos\alpha)\cos^3\alpha + \sin^5\alpha(3\cos^2\alpha(-\sin\alpha)) = 5\sin^4\alpha\cos^4\alpha - 3\sin^6\alpha\cos^2\alpha$

37. $f'(\theta) = 3\theta^2\cos\theta - \theta^3\sin\theta$.

38. $y' = -2\cos w\sin w - \sin(w^2)(2w) = -2(\cos w\sin w + w\sin(w^2))$

39. $y' = \cos(\cos x + \sin x)(\cos x - \sin x)$

40. $y' = 2\cos(2x)\sin(3x) + 3\sin(2x)\cos(3x)$.

41. We use the quotient rule. We have

$$\frac{dP}{dt} = \frac{(-\sin t)\cdot t^3 - (3t^2)\cdot\cos t}{(t^3)^2} = \frac{-t^3\sin t - 3t^2\cos t}{t^6} = \frac{-t\sin t - 3\cos t}{t^4}.$$

42. $t'(\theta) = \dfrac{-\sin\theta\sin\theta - \cos\theta\cos\theta}{\sin^2\theta} = -\dfrac{(\sin^2\theta + \cos^2\theta)}{\sin^2\theta} = -\dfrac{1}{\sin^2\theta}$.

43. Using the power and quotient rules gives

$$\begin{aligned} f'(x) &= \frac{1}{2}\left(\frac{1-\sin x}{1-\cos x}\right)^{-1/2}\left[\frac{-\cos x(1-\cos x) - (1-\sin x)\sin x}{(1-\cos x)^2}\right] \\ &= \frac{1}{2}\sqrt{\frac{1-\cos x}{1-\sin x}}\left[\frac{-\cos x(1-\cos x) - (1-\sin x)\sin x}{(1-\cos x)^2}\right] \\ &= \frac{1}{2}\sqrt{\frac{1-\cos x}{1-\sin x}}\left[\frac{1-\cos x-\sin x}{(1-\cos x)^2}\right]. \end{aligned}$$

44. $\dfrac{d}{dy}\left(\dfrac{y}{\cos y + a}\right) = \dfrac{\cos y + a - y(-\sin y)}{(\cos y + a)^2} = \dfrac{\cos y + a + y\sin y}{(\cos y + a)^2}$.

45. The quotient rule gives $G'(x) = \dfrac{2\sin x\cos x(\cos^2 x + 1) + 2\sin x\cos x(\sin^2 x + 1)}{(\cos^2 x + 1)^2}$

or, using $\sin^2 x + \cos^2 x = 1$,

$G'(x) = \dfrac{6\sin x\cos x}{(\cos^2 x + 1)^2}$.

46. $\dfrac{dy}{dt} = a\cos(bt)\cdot b = ab\cos(bt)$.

47. $\dfrac{dP}{dt} = a(-\sin(bt + c) \cdot b) = -ab\sin(bt + c).$

Problems

48. We begin by taking the derivative of $y = \sin(x^4)$ and evaluating at $x = 10$:

$$\frac{dy}{dx} = \cos(x^4) \cdot 4x^3.$$

Evaluating $\cos(10{,}000)$ on a calculator (in radians) we see $\cos(10{,}000) < 0$, so we know that $dy/dx < 0$, and therefore the function is decreasing.
Next, we take the second derivative and evaluate it at $x = 10$, giving $\sin(10{,}000) < 0$:

$$\frac{d^2y}{dx^2} = \underbrace{\cos(x^4) \cdot (12x^2)}_{\text{negative}} + \underbrace{4x^3 \cdot (-\sin(x^4))(4x^3)}_{\substack{\text{positive, but much} \\ \text{larger in magnitude}}}.$$

From this we can see that $d^2y/dx^2 > 0$, thus the graph is concave up.

49. To calculate the equation of the tangent line, we need to find the y-coordinate and the slope at $t = \pi$. The y-coordinate is

$$y = f(\pi) = 3\sin(2\pi) + 5 = 5,$$

so a point on the line is $(\pi, 5)$.
The slope is found using the derivative: $f'(t) = 3\cos(2t) \cdot 2 = 6\cos(2t)$. At the point $t = \pi$, we have

$$\text{Slope} = f'(\pi) = 6\cos(2\pi) = 6.$$

The equation of the line is

$$\begin{aligned} y - 5 &= 6(t - \pi) \\ y &= 6t - 13.850. \end{aligned}$$

50. The pattern in the table below allows us to generalize and say that the $(4n)^{\text{th}}$ derivative of $\cos x$ is $\cos x$, i.e.,

$$\frac{d^4y}{dx^4} = \frac{d^8y}{dx^8} = \cdots = \frac{d^{4n}y}{dx^{4n}} = \cos x.$$

Thus we can say that $d^{48}y/dx^{48} = \cos x$. From there we differentiate twice more to obtain $d^{50}y/dx^{50} = -\cos x$.

n	1	2	3	4	$\cdots$	48	49	50
n^{th} derivative	$-\sin x$	$-\cos x$	$\sin x$	$\cos x$		$\cos x$	$-\sin x$	$-\cos x$

51. Differentiating with respect to t using the chain rule and substituting for dx/dt gives

$$\frac{d^2x}{dt^2} = \frac{d}{dt}\left(\frac{dx}{dt}\right) = \frac{d}{dx}(x\sin x) \cdot \frac{dx}{dt} = (\sin x + x\cos x)x\sin x.$$

52. We see that $q'(x)$ is of the form

$$\frac{g(x) \cdot f'(x) - f(x) \cdot g'(x)}{(g(x))^2},$$

with $f(x) = e^x$ and $g(x) = \sin x$. Therefore, using the quotient rule, let

$$q(x) = \frac{f(x)}{g(x)} = \frac{e^x}{\sin x}.$$

53. Since $F'(x)$ is of the form $\sin u$, we can make an initial guess that

$$F(x) = \cos(4x),$$

then

$$F'(x) = -4\sin(4x)$$

so we're off by a factor of -4. To fix this problem, we modify our guess by a factor of -4, so the next try is

$$F(x) = -(1/4)\cos(4x),$$

which has

$$F'(x) = \sin(4x).$$

54. (a) We have

$$f'(x) = 2(\sin x)^1(\cos x) + 2(\cos x)^1(-\sin x) = 2\sin x\cos x - 2\sin x\cos x = 0.$$

(b) Since $\sin^2 x + \cos^2 x = 1$, we see that $f(x) = 1$ so $f'(x) = 0$.

55. We have

$$\begin{aligned} h'(x) &= \left(f\left(x^2\right)\right)' \\ &= f'\left(x^2\right)\left(x^2\right)' && \text{Chain rule} \\ &= \sin\left(\left(x^2\right)^2\right)\cdot 2x && \text{since } f'(x) = \sin\left(x^2\right) \\ &= 2x\sin\left(x^4\right) \\ \text{so}\quad h''(x) &= \left(2x\sin\left(x^4\right)\right)' \\ &= (2x)'\sin\left(x^4\right) + 2x\left(\sin\left(x^4\right)\right)' && \text{Product rule} \\ &= 2\sin\left(x^4\right) + 2x\cos\left(x^4\right)\left(x^4\right)' \\ &= 2\sin\left(x^4\right) + 2x\cos\left(x^4\right)4x^3 \\ &= 2\sin\left(x^4\right) + 8x^4\cos\left(x^4\right). \end{aligned}$$

56. (a) Differentiating gives

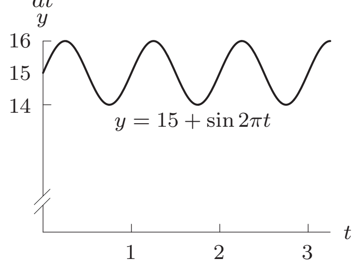
$$\frac{dy}{dt} = -\frac{4.9\pi}{6}\sin\left(\frac{\pi}{6}t\right).$$

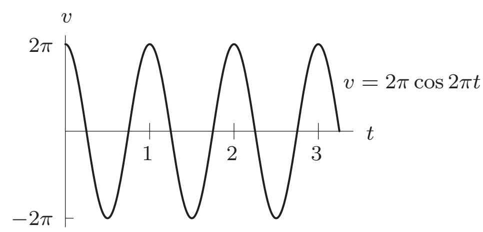
The derivative represents the rate of change of the depth of the water in feet/hour.

(b) The derivative, dy/dt, is zero where the tangent line to the curve y is horizontal. This occurs when $dy/dt = \sin(\frac{\pi}{6}t) = 0$, or at $t = 6$, 12, 18 and 24 (6 am, noon, 6 pm, and midnight). When $dy/dt = 0$, the depth of the water is no longer changing. Therefore, it has either just finished rising or just finished falling, and we know that the harbor's level is at a maximum or a minimum.

57. (a) $v(t) = \dfrac{dy}{dt} = \dfrac{d}{dt}(15 + \sin(2\pi t)) = 2\pi\cos(2\pi t)$.

(b)





58. (a) Differentiating, we find

$$\begin{aligned} \text{Rate of change of voltage with time} = \frac{dV}{dt} &= -120\pi\cdot 156\sin(120\pi t) \\ &= -18720\pi\sin(120\pi t)\ \text{volts per second.} \end{aligned}$$

(b) The rate of change of voltage with time is zero when $\sin(120\pi t) = 0$. This occurs when $120\pi t$ equals any multiple of π. For example, $\sin(120\pi t) = 0$ when $120\pi t = \pi$, or at $t = 1/120$ seconds. Since there are an infinite number of multiples of π, there are many times when the rate of change dV/dt is zero.

(c) The maximum value of the rate of change is $18720\pi = 58810.6$ volts/sec.

59. (a) When $\sqrt{\frac{k}{m}}t = \frac{\pi}{2}$ the spring is farthest from the equilibrium position. This occurs at time $t = \frac{\pi}{2}\sqrt{\frac{m}{k}}$

$v = A\sqrt{\frac{k}{m}}\cos\left(\sqrt{\frac{k}{m}}t\right)$, so the maximum velocity occurs when $t = 0$

$a = -A\frac{k}{m}\sin\left(\sqrt{\frac{k}{m}}t\right)$, so the maximum acceleration occurs when $\sqrt{\frac{k}{m}}t = \frac{3\pi}{2}$, which is at time $t = \frac{3\pi}{2}\sqrt{\frac{m}{k}}$

(b) $T = \frac{2\pi}{\sqrt{k/m}} = 2\pi\sqrt{\frac{m}{k}}$

(c) $\dfrac{dT}{dm} = \dfrac{2\pi}{\sqrt{k}} \cdot \dfrac{1}{2}m^{-\frac{1}{2}} = \dfrac{\pi}{\sqrt{km}}$

Since $\dfrac{dT}{dm} > 0$, an increase in the mass causes the period to increase.

60. (a) The population varies periodically with a period of 1 year. See Figure 3.6.

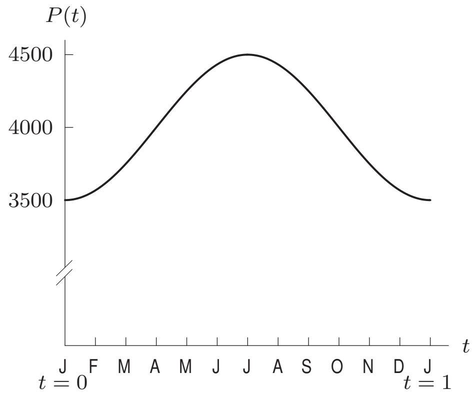


Figure 3.6

(b) The population is at a maximum on July 1st. At this time $\sin(2\pi t - \frac{\pi}{2}) = 1$, so the actual maximum population is $4000 + 500(1) = 4500$. Similarly, the population is at a minimum on January 1st. At this time, $\sin(2\pi t - \frac{\pi}{2}) = -1$, so the minimum population is $4000 + 500(-1) = 3500$.

(c) The rate of change is most positive about April 1st and most negative around October 1st.

(d) Since the population is at its maximum around July 1st, its rate of change is about 0 then.

61. (a) The function $d(t)$ is increasing at a constant rate for the period $0 \le t \le 2$, when the derivative of $d(t)$ is k.

(b) The functions $d(t)$ must be continuous, since the depth of water cannot shift suddenly and instantly (even the fastest change takes some amount of time), so we know that

$$2k = 50 + \sin(0.2), \quad \text{so} \quad k = 25.099.$$

This means that the derivative for $0 < t < 2$ is 25.099, whereas the derivative for $t > 2$ is $0.1\cos(0.1t)$. In other words

$$d(t) = \begin{cases} 25.099t & 0 \le t \le 2 \\ 50 + \sin(0.1t) & t > 2, \end{cases}$$

so

$$d'(t) = \begin{cases} 25.099 & 0 \le t < 2 \\ 0.1\cos(0.1t) & t > 2, \end{cases}$$

At $t = 2$, the derivative is undefined, since $0.1\cos(0.1 \cdot 2) \ne 25.099$.

62. (a) Using triangle OPD in Figure 3.7, we see

$$\frac{OD}{a} = \cos\theta \quad \text{so} \quad OD = a\cos\theta$$
$$\frac{PD}{a} = \sin\theta \quad \text{so} \quad PD = a\sin\theta.$$

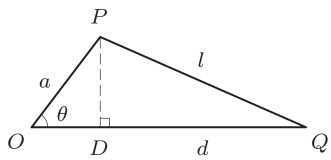

Figure 3.7

Using triangle PQD, we have

$$(PD)^2 + d^2 = l^2$$

so

$$a^2 \sin^2\theta + d^2 = l^2, \quad d = \sqrt{l^2 - a^2\sin^2\theta}.$$

Thus,

$$\begin{aligned} x &= OD + DQ \\ &= a\cos\theta + \sqrt{l^2 - a^2\sin^2\theta}. \end{aligned}$$

(b) Differentiating, regarding a and l as constants,

$$\begin{aligned} \frac{dx}{d\theta} &= -a\sin\theta + \frac{1}{2}\frac{(-2a^2\sin\theta\cos\theta)}{\sqrt{l^2 - a^2\sin^2\theta}} \\ &= -a\sin\theta - \frac{a^2\sin\theta\cos\theta}{\sqrt{l^2 - a^2\sin^2\theta}}. \end{aligned}$$

We want to find dx/dt. Using the chain rule and the fact that $d\theta/dt = 2$, we have

$$\frac{dx}{dt} = \frac{dx}{d\theta}\cdot\frac{d\theta}{dt} = 2\frac{dx}{d\theta}.$$

(i) Substituting $\theta = \pi/2$, we have

$$\begin{aligned} \frac{dx}{dt} = 2\frac{dx}{d\theta}\bigg|_{\theta=\pi/2} &= -2a\sin\left(\frac{\pi}{2}\right) - 2\frac{a^2\sin(\frac{\pi}{2})\cos(\frac{\pi}{2})}{\sqrt{l^2 - a^2\sin^2(\frac{\pi}{2})}} \\ &= -2a \text{ cm/sec.} \end{aligned}$$

(ii) Substituting $\theta = \pi/4$, we have

$$\begin{aligned} \frac{dx}{dt} = 2\frac{dx}{d\theta}\bigg|_{\theta=\pi/4} &= -2a\sin\left(\frac{\pi}{4}\right) - 2\frac{a^2\sin(\frac{\pi}{4})\cos(\frac{\pi}{4})}{\sqrt{l^2 - a^2\sin^2(\frac{\pi}{4})}} \\ &= -a\sqrt{2} - \frac{a^2}{\sqrt{l^2 - a^2/2}} \text{ cm/sec.} \end{aligned}$$

63. The tangent lines to $f(x) = \sin x$ have slope $\frac{d}{dx}(\sin x) = \cos x$. The tangent line at $x = 0$ has slope $f'(0) = \cos 0 = 1$ and goes through the point $(0, 0)$. Consequently, its equation is $y = g(x) = x$. The approximate value of $\sin(\pi/6)$ given by this equation is $g(\pi/6) = \pi/6 \approx 0.524$.

Similarly, the tangent line at $x = \frac{\pi}{3}$ has slope

$$f'\left(\frac{\pi}{3}\right) = \cos\frac{\pi}{3} = \frac{1}{2}$$

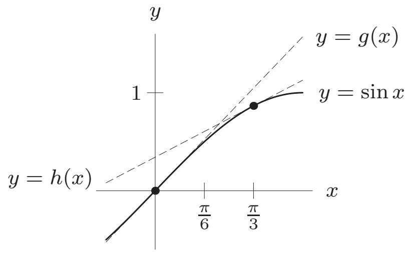
and goes through the point $(\pi/3, \sqrt{3}/2)$. Consequently, its equation is

$$y = h(x) = \frac{1}{2}x + \frac{3\sqrt{3} - \pi}{6}.$$

The approximate value of $\sin(\pi/6)$ given by this equation is then

$$h\left(\frac{\pi}{6}\right) = \frac{6\sqrt{3} - \pi}{12} \approx 0.604.$$

The actual value of $\sin(\pi/6)$ is $\frac{1}{2}$, so the approximation from 0 is better than that from $\pi/3$. This is because the slope of the function changes less between $x = 0$ and $x = \pi/6$ than it does between $x = \pi/6$ and $x = \pi/3$. This is illustrated by the following figure.



64. If the graphs of $y = \sin x$ and $y = ke^{-x}$ are tangent, then the y-values and the derivatives, $\frac{dy}{dx} = \cos x$ and $\frac{dy}{dx} = -ke^{-x}$, are equal at that point, so

$$\sin x = ke^{-x} \qquad \text{and} \qquad \cos x = -ke^{-x}.$$

Thus $\sin x = -\cos x$ so $\tan x = -1$. The smallest x-value is $x = 3\pi/4$, which leads to the smallest k value

$$k = \frac{\sin(3\pi/4)}{e^{-3\pi/4}} = 7.46.$$

When $x = \frac{3\pi}{4}$, we have $y = \sin\left(\frac{3\pi}{4}\right) = \frac{1}{\sqrt{2}}$ so the point is $\left(\frac{3\pi}{4}, \frac{1}{\sqrt{2}}\right)$.

65. For $f(x)$ and $g(x)$ to be tangent at $x = 0$ we must have $f(0) = g(0)$ and $f'(0) = g'(0)$.

From $f(0) = g(0)$ we have

$$(1 + R)\cos(-wt) = T\cos(-wt)$$

and thus

$$1 + R = T.$$

Since

$$f'(x) = -k_1 \sin(k_1 x - wt) + k_1 R \sin(-k_1 x - wt)$$
$$g'(x) = -k_2 T \sin(k_2 x - wt)$$

the condition $f'(0) = g'(0)$ gives

$$-k_1 \sin(-wt) + k_1 R \sin(-wt) = -k_2 T \sin(-wt)$$

and thus

$$-k_1 + k_1 R = -k_2 T.$$

Substituting $T = 1 + R$ and solving for R yields

$$-k_1 + k_1 R = -k_2(1 + R)$$
$$(k_1 + k_2)R = k_1 - k_2$$
$$R = \frac{k_1 - k_2}{k_1 + k_2}.$$

Finally

$$T = 1 + R = 1 + \frac{k_1 - k_2}{k_1 + k_2} = \frac{2k_1}{k_1 + k_2}.$$

66. (a) If $f(x) = \sin x$, then

$$\begin{aligned} f'(x) &= \lim_{h\to 0} \frac{\sin(x+h) - \sin x}{h} \\ &= \lim_{h\to 0} \frac{(\sin x \cos h + \sin h \cos x) - \sin x}{h} \\ &= \lim_{h\to 0} \frac{\sin x(\cos h - 1) + \sin h \cos x}{h} \\ &= \sin x \lim_{h\to 0} \frac{\cos h - 1}{h} + \cos x \lim_{h\to 0} \frac{\sin h}{h}. \end{aligned}$$

(b) $\frac{\cos h-1}{h} \to 0$ and $\frac{\sin h}{h} \to 1$, as $h \to 0$. Thus, $f'(x) = \sin x \cdot 0 + \cos x \cdot 1 = \cos x$.

(c) Similarly,

$$\begin{aligned} g'(x) &= \lim_{h\to 0} \frac{\cos(x+h) - \cos x}{h} \\ &= \lim_{h\to 0} \frac{(\cos x \cos h - \sin x \sin h) - \cos x}{h} \\ &= \lim_{h\to 0} \frac{\cos x(\cos h - 1) - \sin x \sin h}{h} \\ &= \cos x \lim_{h\to 0} \frac{\cos h - 1}{h} - \sin x \lim_{h\to 0} \frac{\sin h}{h} \\ &= -\sin x. \end{aligned}$$

67. (a) Sector OAQ is a sector of a circle with radius $\frac{1}{\cos\theta}$ and angle $\Delta\theta$. Thus its area is the left side of the inequality. Similarly, the area of Sector OBR is the right side of the equality. The area of the triangle OQR is $\frac{1}{2}\Delta\tan\theta$ since it is a triangle with base $\Delta\tan\theta$ (the segment QR) and height 1 (if you turn it sideways, it is easier to see this). Thus, using the given fact about areas (which is also clear from looking at the picture), we have

$$\frac{\Delta\theta}{2\pi} \cdot \pi \left(\frac{1}{\cos\theta}\right)^2 \le \frac{1}{2} \cdot \Delta(\tan\theta) \le \frac{\Delta\theta}{2\pi} \cdot \pi \left(\frac{1}{\cos(\theta+\Delta\theta)}\right)^2.$$

(b) Dividing the inequality through by $\frac{\Delta\theta}{2}$ and canceling the π's gives:

$$\left(\frac{1}{\cos\theta}\right)^2 \le \frac{\Delta\tan\theta}{\Delta\theta} \le \left(\frac{1}{\cos(\theta+\Delta\theta)}\right)^2$$

Then as $\Delta\theta \to 0$, the right and left sides both tend toward $\left(\frac{1}{\cos\theta}\right)^2$ while the middle (which is the difference quotient for tangent) tends to $(\tan\theta)'$. Thus, the derivative of tangent is "squeezed" between two values heading toward the same thing and must, itself, also tend to that value. Therefore, $(\tan\theta)' = \left(\frac{1}{\cos\theta}\right)^2$.

(c) Take the identity $\sin^2\theta + \cos^2\theta = 1$ and divide through by $\cos^2\theta$ to get $(\tan\theta)^2 + 1 = (\frac{1}{\cos\theta})^2$. Differentiating with respect to θ yields:

$$\begin{aligned} 2(\tan\theta)\cdot(\tan\theta)' &= 2\left(\frac{1}{\cos\theta}\right)\cdot\left(\frac{1}{\cos\theta}\right)' \\ 2\left(\frac{\sin\theta}{\cos\theta}\right)\cdot\left(\frac{1}{\cos\theta}\right)^2 &= 2\left(\frac{1}{\cos\theta}\right)\cdot(-1)\left(\frac{1}{\cos\theta}\right)^2(\cos\theta)' \\ 2\frac{\sin\theta}{\cos^3\theta} &= (-1)2\frac{1}{\cos^3\theta}(\cos\theta)' \\ -\sin\theta &= (\cos\theta)'. \end{aligned}$$

(d)

$$\begin{aligned} \frac{d}{d\theta}\left(\sin^2\theta + \cos^2\theta\right) &= \frac{d}{d\theta}(1) \\ 2\sin\theta\cdot(\sin\theta)' + 2\cos\theta\cdot(\cos\theta)' &= 0 \\ 2\sin\theta\cdot(\sin\theta)' + 2\cos\theta\cdot(-\sin\theta) &= 0 \\ (\sin\theta)' - \cos\theta &= 0 \\ (\sin\theta)' &= \cos\theta. \end{aligned}$$

Strengthen Your Understanding

68. The function $\sin(\cos x)$ is a composition of two functions and requires the chain rule to differentiate. The correct derivative computation is

$$\frac{d}{dx}\sin(\cos x) = \cos(\cos x)\cdot(-\sin x).$$

69. The function f is not a product; it is a composition. We need to use the chain rule. Let $z = g(x) = \sin x$, so $f(z) = \sin z$. Then, using the chain rule, $f'(x) = \cos z \cdot g'(x) = \cos(\sin x)\cos x$.

70. One possibility is $f(x) = \cos(x^2)$ whose derivative is $f'(x) = -\sin(x^2) \cdot 2x = -2x\sin(x^2)$.

71. The function $f(x) = \sin x$ satisfies this condition because

$$f'(x) = \frac{d}{dx}\sin x = \cos x$$
$$f''(x) = \frac{d}{dx}\cos x = -\sin x = -f(x).$$

There are many other possibilities, including $f(x) = \cos x$.

72. True, since $\cos\theta$ and therefore $\cos^2\theta$ are periodic, and

$$\frac{d}{d\theta}(\tan\theta) = \frac{1}{\cos^2\theta}.$$

73. True. If $f(x)$ is periodic with period c, then $f(x+c) = f(x)$ for all x. By the definition of the derivative, we have

$$f'(x) = \lim_{h\to 0}\frac{f(x+h) - f(x)}{h}$$

and

$$f'(x+c) = \lim_{h\to 0}\frac{f(x+c+h) - f(x+c)}{h}.$$

Since f is periodic, for any $h \neq 0$, we have

$$\frac{f(x+h) - f(x)}{h} = \frac{f(x+c+h) - f(x+c)}{h}.$$

Taking the limit as $h \to 0$, we get that $f'(x) = f'(x+c)$, so f' is periodic with the same period as $f(x)$.

74. False; the fourth derivative of $\cos t + C$, where C is any constant, is indeed $\cos t$. But any function of the form $\cos t + p(t)$, where $p(t)$ is a polynomial of degree less than or equal to 3, also has its fourth derivative equal to $\cos t$. So $\cos t + t^2$ will work.

Solutions for Section 3.6

Exercises

1. $f'(t) = \dfrac{2t}{t^2+1}$.

2. $f'(x) = \dfrac{-1}{1-x} = \dfrac{1}{x-1}$.

3. $f'(x) = \dfrac{1}{5x^2+3}\cdot(10x) = \dfrac{10x}{5x^2+3}$.

4. $f'(x) = 4x + 3\dfrac{1}{x} = 4x + \dfrac{3}{x}$.

5. $\dfrac{dy}{dx} = \dfrac{1}{\sqrt{1-(x+1)^2}}$.

6. $f'(x) = \dfrac{1}{1+(3x)^2}\cdot 3 = \dfrac{3}{1+9x^2}$.

7. $\dfrac{dP}{dt} = 3\dfrac{1}{x^2+5x+3}\cdot(2x+5) = \dfrac{6x+15}{x^2+5x+3}$.

8. $\dfrac{dQ}{dx} = a\dfrac{1}{bx+c}\cdot b = \dfrac{ab}{bx+c}$.

9. Since $\ln(e^{2x}) = 2x$, the derivative $f'(x) = 2$.

10. Since $e^{\ln(e^{2x^2+3})} = e^{2x^2+3}$, the derivative $f'(x) = 4xe^{2x^2+3}$.

11. $f'(x) = \dfrac{1}{1-e^{-x}} \cdot (-e^{-x})(-1) = \dfrac{e^{-x}}{1-e^{-x}}.$

12. $f'(\alpha) = \dfrac{1}{\sin\alpha} \cdot \cos\alpha = \dfrac{\cos\alpha}{\sin\alpha}.$

13. $f'(x) = \dfrac{1}{e^x+1} \cdot e^x.$

14. $\dfrac{dy}{dx} = \ln x + x\left(\dfrac{1}{x}\right) - 1 = \ln x$

15. $j'(x) = \dfrac{ae^{ax}}{(e^{ax}+b)}$

16. We use the product rule. We have

$$\frac{dy}{dx} = 3x^2 \cdot \ln x + x^3 \cdot \frac{1}{x} = 3x^2 \ln x + x^2.$$

17. Using the product and chain rules gives $h'(w) = 3w^2\ln(10w) + w^3\dfrac{10}{10w} = 3w^2\ln(10w) + w^2.$

18. $f'(x) = \dfrac{1}{e^{7x}} \cdot (e^{7x})7 = 7.$

(Note also that $\ln(e^{7x}) = 7x$ implies $f'(x) = 7$.)

19. Note that $f(x) = e^{\ln x} \cdot e^1 = x \cdot e = ex$. So $f'(x) = e$. (Remember, e is just a constant.) You might also use the chain rule to get:

$f'(x) = e^{(\ln x)+1} \cdot \frac{1}{x}$.

[Are the two answers the same? Of course they are, since

$$e^{(\ln x)+1}\left(\frac{1}{x}\right) = e^{\ln x} \cdot e\left(\frac{1}{x}\right) = xe\left(\frac{1}{x}\right) = e.]$$

20. $f'(\theta) = \frac{-\sin\theta}{\cos\theta} = -\tan\theta.$

21. $f(t) = \ln t$ (because $\ln e^x = x$ *or* because $e^{\ln t} = t$), so $f'(t) = \frac{1}{t}$.

22. $f'(y) = \dfrac{2y}{\sqrt{1-y^4}}.$

23. $s'(x) = \dfrac{d}{dx}(\arctan(2-x)) = \dfrac{-1}{1+(2-x)^2}.$

24. $g(\alpha) = \alpha$, so $g'(\alpha) = 1$.

25. $g'(t) = e^{\arctan(3t^2)}\left(\dfrac{1}{1+(3t^2)^2}\right)(6t) = e^{\arctan(3t^2)}\left(\dfrac{6t}{1+9t^4}\right).$

26. $g'(t) = \dfrac{-\sin(\ln t)}{t}.$

27. $h'(z) = (\ln 2)z^{(\ln 2 - 1)}.$

28. $h'(w) = \arcsin w + \dfrac{w}{\sqrt{1-w^2}}.$

29. Note that $f(x) = kx$ so, $f'(x) = k$.

30. Using the chain rule gives $r'(t) = \dfrac{2}{\sqrt{1-4t^2}}.$

31. $j'(x) = -\sin\left(\sin^{-1} x\right) \cdot \left[\dfrac{1}{\sqrt{1-x^2}}\right] = -\dfrac{x}{\sqrt{1-x^2}}$

32. $f'(x) = -\sin(\arctan 3x)\left(\dfrac{1}{1+(3x)^2}\right)(3) = \dfrac{-3\sin(\arctan 3x)}{1+9x^2}.$

33. $f'(z) = -1(\ln z)^{-2} \cdot \dfrac{1}{z} = \dfrac{-1}{z(\ln z)^2}.$

34. Using the quotient rule gives

$$g'(t) = \frac{\left(\frac{k}{kt}+1\right)(\ln(kt)-t) - (\ln(kt)+t)\left(\frac{k}{kt}-1\right)}{(\ln(kt)-t)^2}$$

$$g'(t) = \frac{\left(\frac{1}{t}+1\right)(\ln(kt)-t) - (\ln(kt)+t)\left(\frac{1}{t}-1\right)}{(\ln(kt)-t)^2}$$
$$g'(t) = \frac{\ln(kt)/t - 1 + \ln(kt) - t - \ln(kt)/t - 1 + \ln(kt) + t}{(\ln(kt)-t)^2}$$
$$g'(t) = \frac{2\ln(kt)-2}{(\ln(kt)-t)^2}.$$

35. $f'(w) = 3w^{-1/2} - 2w^{-3} + 5\frac{1}{w} = \frac{3}{\sqrt{w}} - \frac{2}{w^3} + \frac{5}{w}.$

36. $\frac{dy}{dx} = 2(\ln x + \ln 2) + 2x\left(\frac{1}{x}\right) - 2 = 2(\ln x + \ln 2) = 2\ln(2x)$

37. Using the chain rule gives $f'(x) = \frac{\cos x - \sin x}{\sin x + \cos x}.$

38. $f'(t) = \frac{1}{\ln t} \cdot \frac{1}{t} = \frac{1}{t\ln t}$

39. Using the chain rule gives

$$\begin{aligned} T'(u) &= \left[\frac{1}{1+\left(\frac{u}{1+u}\right)^2}\right]\left[\frac{(1+u)-u}{(1+u)^2}\right] \\ &= \frac{(1+u)^2}{(1+u)^2+u^2}\left[\frac{1}{(1+u)^2}\right] \\ &= \frac{1}{1+2u+2u^2}. \end{aligned}$$

40. Since $\ln\left[\left(\frac{1-\cos t}{1+\cos t}\right)^4\right] = 4\ln\left[\left(\frac{1-\cos t}{1+\cos t}\right)\right]$ we have

$$\begin{aligned} a'(t) &= 4\left(\frac{1+\cos t}{1-\cos t}\right)\left[\frac{\sin t(1+\cos t) + \sin t(1-\cos t)}{(1+\cos t)^2}\right] \\ &= \left[\frac{1+\cos t}{1-\cos t}\right]\left[\frac{8\sin t}{(1+\cos t)^2}\right] \\ &= \frac{8\sin t}{1-\cos^2 t} \\ &= \frac{8}{\sin t}. \end{aligned}$$

41. $f'(x) = -\sin(\arcsin(x+1))\left(\frac{1}{\sqrt{1-(x+1)^2}}\right) = \frac{-(x+1)}{\sqrt{1-(x+1)^2}}.$

Problems

42. (a) We have
$$f'(x) = \frac{1}{3x}\cdot 3 = \frac{3}{3x} = \frac{1}{x}.$$
(b) Using properties of logs, we have $f(x) = \ln 3 + \ln x$.
(c) Since $\ln 3$ is a constant, the derivative of $f(x) = \ln 3 + \ln x$ is
$$f'(x) = 0 + \frac{1}{x} = \frac{1}{x}.$$
Yes, the answer is the same as that obtained in part (a), as it should be.

43. Differentiating

$$f'(x) = \frac{1}{x^2+1}\cdot 2x = 2x(x^2+1)^{-1}$$

$$\begin{aligned} f''(x) &= 2(x^2+1)^{-1} - 2x(x^2+1)^{-2}\cdot 2x \\ &= \frac{2}{(x^2+1)} - \frac{4x^2}{(x^2+1)^2} = \frac{2x^2+2}{(x^2+1)^2} - \frac{4x^2}{(x^2+1)^2} \\ &= \frac{2(1-x^2)}{(x^2+1)^2}. \end{aligned}$$

Since $(x^2+1)^2 > 0$ for all x, we see that $f''(0) > 0$ for $1-x^2 > 0$ or $x^2 < 1$. That is, $\ln(x^2+1)$ is concave up on the interval $-1 < x < 1$.

44. Let

$$g(x) = \arcsin x$$

so

$$\sin[g(x)] = x.$$

Differentiating,

$$\begin{aligned} \cos[g(x)]\cdot g'(x) &= 1 \\ g'(x) &= \frac{1}{\cos[g(x)]} \end{aligned}$$

Using the fact that $\sin^2\theta + \cos^2\theta = 1$, and $\cos[g(x)] \geq 0$, since $-\frac{\pi}{2} \leq g(x) \leq \frac{\pi}{2}$, we get

$$\cos[g(x)] = \sqrt{1-(\sin[g(x)])^2}.$$

Therefore,

$$g'(x) = \frac{1}{\sqrt{1-(\sin[g(x)])^2}}$$

Since $\sin[g(x)] = x$, we have

$$g'(x) = \frac{1}{\sqrt{1-x^2}}, -1 < x < 1.$$

45. Let

$$g(x) = \log x.$$

Then

$$10^{g(x)} = x.$$

Differentiating,

$$\begin{aligned} (\ln 10)[10^{g(x)}]g'(x) &= 1 \\ g'(x) &= \frac{1}{(\ln 10)[10^{g(x)}]} \\ g'(x) &= \frac{1}{(\ln 10)x}. \end{aligned}$$

46. $\text{pH} = 2 = -\log x$ means $\log x = -2$ so $x = 10^{-2}$. Rate of change of pH with hydrogen ion concentration is

$$\frac{d}{dx}\text{pH} = -\frac{d}{dx}(\log x) = \frac{-1}{x(\ln 10)} = -\frac{1}{(10^{-2})\ln 10} = -43.4$$

47. We have $g(5000) = 20\ln(0.001(5000)) = 32.189$ years. Since

$$g'(F) = 20\cdot\frac{1}{0.001F}\cdot 0.001 = \frac{20}{F},$$

we have

$$g'(5000) = \frac{20}{5000} = 0.004$$

years per dollar. It takes about 32.189 years for the investment to grow to \$5000, and it takes about 0.004 years (or about 1.5 days) for the investment to grow by one more dollar.

48. The marginal revenue, MR, is obtained by differentiating the total revenue function, R. We use the chain rule so

$$MR = \frac{dR}{dq} = \frac{1}{1+1000q^2} \cdot \frac{d}{dq}\left(1000q^2\right) = \frac{1}{1+1000q^2} \cdot 2000q.$$

When $q = 10$,

$$\text{Marginal revenue} = \frac{2000 \cdot 10}{1 + 1000 \cdot 10^2} = \$0.2\text{/unit}.$$

49. (a) For $y = \ln x$, we have $y' = 1/x$, so the slope of the tangent line is $f'(1) = 1/1 = 1$. The equation of the tangent line is $y - 0 = 1(x-1)$, so, on the tangent line, $y = g(x) = x - 1$.

(b) Using a value on the tangent line to approximate $\ln(1,1)$, we have

$$\ln(1.1) \approx g(1.1) = 1.1 - 1 = 0.1.$$

Similarly, $\ln(2)$ is approximated by

$$\ln(2) \approx g(2) = 2 - 1 = 1.$$

(c) From Figure 3.8, we see that $f(1.1)$ and $f(2)$ are below $g(x) = x - 1$. Similarly, $f(0.9)$ and $f(0.5)$ are also below $g(x)$. This is true for any approximation of this function by a tangent line since f is concave down ($f''(x) = -\frac{1}{x^2} < 0$ for all $x > 0$). Thus, for a given x-value, the y-value given by the function is always below the value given by the tangent line.

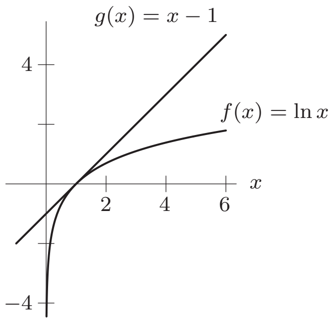


Figure 3.8

50. (a) Let $g(x) = ax^2 + bx + c$ be our quadratic and $f(x) = \ln x$. For the best approximation, we want to find a quadratic with the same value as $\ln x$ at $x = 1$ and the same first and second derivatives as $\ln x$ at $x = 1$. $g'(x) = 2ax + b$, $g''(x) = 2a$, $f'(x) = \frac{1}{x}$, $f''(x) = -\frac{1}{x^2}$.

$$\begin{aligned} g(1) &= a(1)^2 + b(1) + c \quad f(1) = 0 \\ g'(1) &= 2a(1) + b \quad f'(1) = 1 \\ g''(1) &= 2a \quad f''(1) = -1 \end{aligned}$$

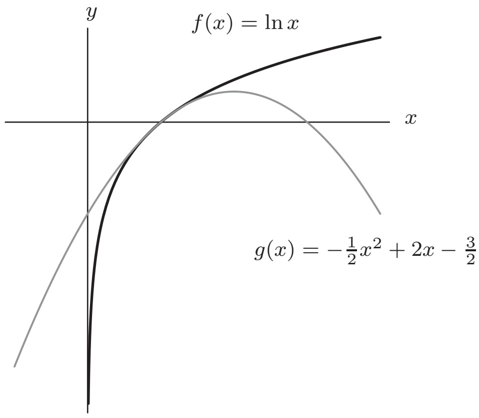
Thus, we obtain the equations

$$\begin{aligned} a + b + c &= 0 \\ 2a + b &= 1 \\ 2a &= -1 \end{aligned}$$

We find $a = -\frac{1}{2}$, $b = 2$ and $c = -\frac{3}{2}$. Thus our approximation is:

$$g(x) = -\frac{1}{2}x^2 + 2x - \frac{3}{2}$$

(b) From the graph below, we notice that around $x = 1$, the value of $f(x) = \ln x$ and the value of $g(x) = -\frac{1}{2}x^2 + 2x - \frac{3}{2}$ are very close.



(c) $g(1.1) = 0.095 \quad g(2) = 0.5$
Compare with $f(1.1) = 0.0953$, $f(2) = 0.693$.

51. (a)

$$\begin{aligned} f'(x) &= \frac{1}{1+x^2} + \frac{1}{1+\frac{1}{x^2}} \cdot (-\frac{1}{x^2}) \\ &= \frac{1}{1+x^2} + \left(-\frac{1}{x^2+1}\right) \\ &= \frac{1}{1+x^2} - \frac{1}{1+x^2} \\ &= 0 \end{aligned}$$

(b) f is a constant function. Checking at a few values of x,

Table 3.2

x	$\arctan x$	$\arctan x^{-1}$	$f(x) = \arctan x + \arctan x^{-1}$
1	0.785392	0.7853982	1.5707963
2	1.1071487	0.4636476	1.5707963
3	1.2490458	0.3217506	1.5707963

52. The closer you look at the function, the more it begins to look like a line with slope equal to the derivative of the function at $x = 0$. Hence, functions whose derivatives at $x = 0$ are equal will look the same there.

The following functions look like the line $y = x$ since, in all cases, $y' = 1$ at $x = 0$.

$y = x$ $\quad y' = 1$
$y = \sin x$ $\quad y' = \cos x$
$y = \tan x$ $\quad y' = \frac{1}{\cos^2 x}$
$y = \ln(x+1)$ $\quad y' = \frac{1}{x+1}$

The following functions look like the line $y = 0$ since, in all cases, $y' = 0$ at $x = 0$.

$y = x^2$ $\quad y' = 2x$
$y = x \sin x$ $\quad y' = x\cos x + \sin x$
$y = x^3$ $\quad y' = 3x^2$
$y = \frac{1}{2}\ln(x^2+1)$ $\quad y' = 2x \cdot \frac{1}{2} \cdot \frac{1}{x^2+1} = \frac{x}{x^2+1}$
$y = 1 - \cos x$ $\quad y' = \sin x$

The following functions look like the line $x = 0$ since, in all cases, as $x \to 0^+$, the slope $y' \to \infty$.

$y = \sqrt{x}$ $\quad y' = \frac{1}{2\sqrt{x}}$
$y = \sqrt{\frac{x}{x+1}}$ $\quad y' = \frac{(x+1)-x}{(x+1)^2} \cdot \frac{1}{2} \cdot \frac{1}{\sqrt{\frac{x}{x+1}}} = \frac{1}{2(x+1)^2} \cdot \sqrt{\frac{x+1}{x}}$
$y = \sqrt{2x - x^2}$ $\quad y' = (2-2x)\frac{1}{2} \cdot \frac{1}{\sqrt{2x-x^2}} = \frac{1-x}{\sqrt{2x-x^2}}$

53. Since the chain rule gives $h'(x) = n'(m(x))m'(x) = -2$ we must find values a and x such that $a = m(x)$ and $n'(a)m'(x) = -2$.

Calculating slopes from the graph of n gives

$$n'(a) = \begin{cases} 1 & \text{if} \quad 0 < a < 50 \\ 1/2 & \text{if} \quad 50 < a < 100. \end{cases}$$

Calculating slopes from the graph of m gives

$$m'(x) = \begin{cases} -2 & \text{if} \quad 0 < x < 50 \\ 2 & \text{if} \quad 50 < x < 100. \end{cases}$$

The only values of the derivative n' are 1 and $1/2$ and the only values of the derivative m' are 2 and -2. In order to have $n'(a)m'(x) = -2$ we must therefore have $n'(a) = 1$ and $m'(x) = -2$. Thus $0 < a < 50$ and $0 < x < 50$.

Now $a = m(x)$ and from the graph of m we see that $0 < m(x) < 50$ for $25 < x < 75$.

The two conditions on x we have found are both satisfied when $25 < x < 50$. Thus $h'(x) = -2$ for all x in the interval $25 < x < 50$. The question asks for just one of these x values, for example $x = 40$.

54. Since the chain rule gives $h'(x) = n'(m(x))m'(x) = 2$ we must find values a and x such that $a = m(x)$ and $n'(a)m'(x) = 2$.

Calculating slopes from the graph of n gives

$$n'(a) = \begin{cases} 1 & \text{if} \quad 0 < a < 50 \\ 1/2 & \text{if} \quad 50 < a < 100. \end{cases}$$

Calculating slopes from the graph of m gives

$$m'(x) = \begin{cases} -2 & \text{if} \quad 0 < x < 50 \\ 2 & \text{if} \quad 50 < x < 100. \end{cases}$$

The only values of the derivative n' are 1 and $1/2$ and the only values of the derivative m' are 2 and -2. In order to have $n'(a)m'(x) = 2$ we must therefore have $n'(a) = 1$ and $m'(x) = 2$. Thus $0 < a < 50$ and $50 < x < 100$.

Now $a = m(x)$ and from the graph of m we see that $0 < m(x) < 50$ for $25 < x < 75$.

The two conditions on x we have found are both satisfied when $50 < x < 75$. Thus $h'(x) = 2$ for all x in the interval $50 < x < 75$. The question asks for just one of these x values, for example $x = 60$.

55. Since the chain rule gives $h'(x) = n'(m(x))m'(x) = 1$ we must find values a and x such that $a = m(x)$ and $n'(a)m'(x) = 1$.

Calculating slopes from the graph of n gives

$$n'(a) = \begin{cases} 1 & \text{if} \quad 0 < a < 50 \\ 1/2 & \text{if} \quad 50 < a < 100. \end{cases}$$

Calculating slopes from the graph of m gives

$$m'(x) = \begin{cases} -2 & \text{if} \quad 0 < x < 50 \\ 2 & \text{if} \quad 50 < x < 100. \end{cases}$$

The only values of the derivative n' are 1 and $1/2$ and the only values of the derivative m' are 2 and -2. In order to have $n'(a)m'(x) = 1$ we must therefore have $n'(a) = 1/2$ and $m'(x) = 2$. Thus $50 < a < 100$ and $50 < x < 100$.

Now $a = m(x)$ and from the graph of m we see that $50 < m(x) < 100$ for $0 < x < 25$ or $75 < x < 100$.

The two conditions on x we have found are both satisfied when $75 < x < 100$. Thus $h'(x) = 1$ for all x in the interval $75 < x < 100$. The question asks for just one of these x values, for example $x = 80$.

56. Since the chain rule gives $h'(x) = n'(m(x))m'(x) = -1$ we must find values a and x such that $a = m(x)$ and $n'(a)m'(x) = -1$.

Calculating slopes from the graph of n gives

$$n'(a) = \begin{cases} 1 & \text{if} \quad 0 < a < 50 \\ 1/2 & \text{if} \quad 50 < a < 100. \end{cases}$$

Calculating slopes from the graph of m gives

$$m'(x) = \begin{cases} -2 & \text{if} \quad 0 < x < 50 \\ 2 & \text{if} \quad 50 < x < 100. \end{cases}$$

The only values of the derivative n' are 1 and $1/2$ and the only values of the derivative m' are 2 and -2. In order to have $n'(a)m'(x) = -1$ we must therefore have $n'(a) = 1/2$ and $m'(x) = -2$. Thus $50 < a < 100$ and $0 < x < 50$.

Now $a = m(x)$ and from the graph of m we see that $50 < m(x) < 100$ for $0 < x < 25$ or $75 < x < 100$.

The two conditions on x we have found are both satisfied when $0 < x < 25$. Thus $h'(x) = -1$ for all x in the interval $0 < x < 25$. The question asks for just one of these x values, for example $x = 10$.

57. We have

$$(f^{-1})'(5) = \frac{1}{f'(f^{-1}(5))}.$$

From the graph of $f(x)$ we see that $f^{-1}(5) = 13$. From the graph of $f'(x)$ we see that $f'(13) = 0.36$. Thus $(f^{-1})'(5) = 1/0.36 = 2.8$.

58. We have

$$(f^{-1})'(10) = \frac{1}{f'(f^{-1}(10))}.$$

From the graph of $f(x)$ we see that $f^{-1}(10) = 23$. From the graph of $f'(x)$ we see that $f'(23) = 0.62$. Thus $(f^{-1})'(10) = 1/0.62 = 1.6$.

59. We have

$$(f^{-1})'(15) = \frac{1}{f'(f^{-1}(15))}.$$

From the graph of $f(x)$ we see that $f^{-1}(15) = 30$. From the graph of $f'(x)$ we see that $f'(30) = 0.73$. Thus $(f^{-1})'(15) = 1/0.73 = 1.4$.

60. Since the point $(2, 5)$ is on the curve, we know $f(2) = 5$. The point $(2.1, 5.3)$ is on the tangent line, so

$$\text{Slope tangent } = \frac{5.3 - 5}{2.1 - 2} = \frac{0.3}{0.1} = 3.$$

Thus, $f'(2) = 3$.

By the chain rule

$$h'(2) = 3(f(2))^2 \cdot f'(2) = 3 \cdot 5^2 \cdot 3 = 225.$$

61. Since the point $(2, 5)$ is on the curve, we know $f(2) = 5$. The point $(2.1, 5.3)$ is on the tangent line, so

$$\text{Slope tangent } = \frac{5.3 - 5}{2.1 - 2} = \frac{0.3}{0.1} = 3.$$

Thus, $f'(2) = 3$.

By the chain rule

$$k'(2) = -(f(2))^{-2} \cdot f'(2) = -5^{-2} \cdot 3 = -0.12.$$

62. Since the point $(2, 5)$ is on the curve, we know $f(2) = 5$. The point $(2.1, 5.3)$ is on the tangent line, so

$$\text{Slope tangent } = \frac{5.3 - 5}{2.1 - 2} = \frac{0.3}{0.1} = 3.$$

Thus, $f'(2) = 3$. Since g is the inverse function of f and $f(2) = 5$, we know $f^{-1}(5) = 2$, so $g(5) = 2$.

Differentiating, we have

$$g'(2) = \frac{1}{f'(g(5))} = \frac{1}{f'(2)} = \frac{1}{3}.$$

63. (a) Since $f(x) = x^3$, we have $f'(x) = 3x^2$. Thus, $f'(2) = 3(2)^2 = 12$.

(b) To find $f^{-1}(x)$, we switch xs and ys and solve for y.

Since $y = x^3$, we get $x = y^3$.

Solving for y gives $y = \sqrt[3]{x}$.

Thus, $f^{-1}(x) = \sqrt[3]{x}$.

(c) To find $(f^{-1})'(x)$, we differentiate. Since $f^{-1}(x) = \sqrt[3]{x} = x^{1/3}$, we get

$$(f^{-1})'(x) = \frac{1}{3}x^{-2/3}.$$

Thus,

$$(f^{-1})'(8) = \frac{1}{3}(8)^{-2/3} = \frac{1}{3 \cdot 8^{2/3}} = \frac{1}{3 \cdot 4} = \frac{1}{12}.$$

(d) The point $(2, 8)$ is on the graph of f. Thus the point $(8, 2)$ is on the graph of f^{-1}, so $f^{-1}(8) = 2$. Therefore,

$$(f^{-1})'(8) = \frac{1}{f'(f^{-1}(8))} = \frac{1}{f'(2)} = \frac{1}{12}.$$

64. (a) Since $f(x) = 2x^5 + 3x^3 + x$, we differentiate to get $f'(x) = 10x^4 + 9x^2 + 1$.
(b) Because $f'(x)$ is always positive, we know that $f(x)$ is increasing everywhere. Thus, $f(x)$ is a one-to-one function and is invertible.
(c) To find $f(1)$, substitute 1 for x into $f(x)$. We get $f(1) = 2(1)^5 + 3(1)^3 + 1 = 2 + 3 + 1 = 6$.
(d) To find $f'(1)$, substitute 1 for x into $f'(x)$. We get $f'(1) = 10(1)^4 + 9(1)^2 + 1 = 20$.
(e) Since $f(1) = 6$, we have $f^{-1}(6) = 1$, so

$$(f^{-1})'(6) = \frac{1}{f'(f^{-1}(6))} = \frac{1}{f'(1)} = \frac{1}{20}.$$

65. To find $(f^{-1})'(3)$, we first look in the table to find that $3 = f(9)$, so $f^{-1}(3) = 9$. Thus,

$$(f^{-1})'(3) = \frac{1}{f'(f^{-1}(3))} = \frac{1}{f'(9)} = \frac{1}{5}.$$

66. (a) The statement $f(2) = 4023$ tells us that when the price is \$2 per gallon, 4023 gallons of gas are sold.
(b) Since $f(2) = 4023$, we have $f^{-1}(4023) = 2$. Thus, 4023 gallons are sold when the price is \$2 per gallon.
(c) The statement $f'(2) = -1250$ tells us that if the price increases from \$2 per gallon, the sales decrease at a rate of 1250 gallons per \$1 increase in price.
(d) The units of $(f^{-1})'(4023)$ are dollars per gallon. We have

$$(f^{-1})'(4023) = \frac{1}{f'(f^{-1}(4023))} = \frac{1}{f'(2)} = -\frac{1}{1250} = -0.0008.$$

Thus, when 4023 gallons are already sold, sales decrease at the rate of one gallon per price increase of 0.0008 dollars. In others words, an additional gallon is sold if the price drops by 0.0008 dollars.

67. (a) Knowing $f(2005) = 296$ tells us that the US population was 296 million in the year 2005.
(b) Since $f(2005) = 296$, we have $f^{-1}(296) = 2005$. This tells us that the year in which the US population was 296 million was 2005.
(c) Knowing $f'(2005) = 2.65$ tells us that in the year 2005, the US population was growing at a rate of 2.65 million people per year.
(d) Using parts (b) and (c), we have

$$(f^{-1})'(296) = \frac{1}{f'(f^{-1}(296))} = \frac{1}{f'(2005)} = \frac{1}{2.65} = 0.377.$$

The units of the derivative of f^{-1} are years per million people (the reciprocal of the units of f'). The statement $(f^{-1})'(296) = 0.377$ tells us that when the US population was 296 million, it took 0.377 of a year (between 4 and 5 months) for the population to increase by another million.

68. Each grid mark on the horizontal axis represents 5 years and each grid mark on the vertical axis represents 100 million vehicles.

(a) When $t = 20$, the year is 1985. Reading from the graph, we find that in 1985

$$f(20) \approx 500 \text{ million vehicles.}$$

This tells us that 20 years after 1965, in 1985, there were 500 million registered vehicles.

(b) Drawing a tangent line to the curve at $t = 20$, we have

$$\text{Slope } = f'(20) \approx \frac{175}{10} = 17.5 \text{ million vehicles/year.}$$

Thus, 20 years after 1965, in 1985, the number of registered vehicles was increasing at 17.5 million vehicles per year.

(c) From the graph or part (a)

$$f^{-1}(500) = 20 \text{ years.}$$

Thus, there were 500 million cars registered when $t = 20$, that is, in 1985.

(d) We have

$$(f^{-1})'(500) = \frac{1}{f'(f^{-1}(500))} = \frac{1}{f'(20)} = \frac{1}{17.5} = 0.0571 \text{ years/million vehicles.}$$

Thus, when 500 million vehicles were already registered, it took 0.0571 year, or about 21 days, for another million to be registered.

69. We have $(f^{-1})'(8) = 1/f'(f^{-1}(8))$. From the graph we see $f^{-1}(8) = 4$. Thus $(f^{-1})'(8) = \dfrac{1}{f'(4)} = \dfrac{1}{3.0}$.

70. Since $f(20) = 10$, we have $f^{-1}(10) = 20$, so $(f^{-1})'(10) = \dfrac{1}{f'(f^{-1}(10))} = \dfrac{1}{f'(20)}$. Therefore $(f^{-1})'(10)f'(20) = 1$.

Option (b) is wrong.

71. All three values equal 1.

(a) We have $f^{-1}(A) = a$, so $(f^{-1})'(A) = \frac{1}{f'(f^{-1}(A))} = \frac{1}{f'(a)}$. Thus $f'(a)(f^{-1})'(A) = 1$.
(b) We have $f^{-1}(B) = b$, so $(f^{-1})'(B) = \frac{1}{f'(f^{-1}(B))} = \frac{1}{f'(b)}$. Thus $f'(b)(f^{-1})'(B) = 1$.
(c) We have $f^{-1}(C) = c$, so $(f^{-1})'(C) = \frac{1}{f'(f^{-1}(C))} = \frac{1}{f'(c)}$. Thus $f'(c)(f^{-1})'(C) = 1$.

72. A continuous invertible function $f(x)$ cannot be increasing on one interval and decreasing on another because it would fail the horizontal line test. The same is true of the inverse function $f^{-1}(x)$. Either $f^{-1}(x)$ is increasing and $(f^{-1})'(x) \geq 0$ for all x, or $f^{-1}(x)$ is decreasing and $(f^{-1})'(x) \leq 0$ for all x. We can not have both $(f^{-1})'(10) = 8$ and $(f^{-1})'(20) = -6$.

73. (a) The definition of the derivative of $\ln(1 + x)$ at $x = 0$ is

$$\lim_{h\to 0} \frac{\ln(1+h) - \ln 1}{h} = \lim_{h\to 0} \frac{\ln(1+h)}{h} = \left.\frac{1}{1+x}\right|_{x=0} = 1.$$

(b) The rules of logarithms give

$$\lim_{h\to 0} \frac{\ln(1+h)}{h} = \lim_{h\to 0} \frac{1}{h} \ln(1+h) = \lim_{h\to 0} \ln(1+h)^{1/h} = 1.$$

Thus, taking e to both sides and using the fact that $e^{\ln A} = A$, we have

$$\begin{aligned} e^{\lim_{h\to 0} \ln(1+h)^{1/h}} &= \lim_{h\to 0} e^{\ln(1+h)^{1/h}} = e^1 \\ \lim_{h\to 0} (1+h)^{1/h} &= e. \end{aligned}$$

This limit is sometimes used as the definition of e.

(c) Let $n = 1/h$. Then as $h \to 0^+$, we have $n \to \infty$. Since

$$\lim_{h\to 0^+} (1+h)^{1/h} = \lim_{h\to 0} (1+h)^{1/h} = e,$$

we have

$$\lim_{n\to\infty} \left(1 + \frac{1}{n}\right)^n = e.$$

This limit is also sometimes used as the definition of e.

Strengthen Your Understanding

74. To calculate the derivative of $\ln(1+x^4)$ we need to apply the chain rule. Take $z = g(x) = 1 + x^4$ as the inside function and $f(z) = \ln z$ as the outside function. Since $g'(x) = 4x^3$ and $f'(z) = 1/z$, the chain rule gives

$$\frac{dw}{dx} = \frac{1}{z} \cdot 4x^3 = \frac{4x^3}{1+x^4}.$$

75. The function f is not a product. We need the chain rule, so $f'(x) = \dfrac{1}{\ln x} \cdot \dfrac{1}{x} = \dfrac{1}{x \ln x}$.

76. The formula for $(f^{-1})'(2)$ is wrong. We need $f'(f^{-1}(2))$, and we are not given $f^{-1}(2)$.

77. Any exponential function of the form $c \cdot a^x$ with $c \neq 0$, $a > 0$ and $a \neq e$ is a constant multiple of its derivative but it is not equal to its derivative: $\frac{d}{dx}(c \cdot a^x) = (\ln a)(c \cdot a^x)$. One example is $f(x) = 2^x$.

78. Since

$$\frac{d}{dx} \ln(x) = \frac{1}{x},$$

any function of the form $y = c \ln x$ for some constant c will have derivative c/x. A particular example is $y = 2 \ln x$.

79. $f(x) = \ln x$ is a possible answer since

$$\frac{d}{dx} \ln x = \frac{1}{x} \quad \text{and} \quad \frac{d}{dx} f(cx) = \frac{d}{dx} \ln(cx) = \frac{c}{cx} = \frac{1}{x}$$

by the chain rule.

80. For the statement to be true, we need $f'(x) = 1$, so $f(x) = x$ is a function to try. Then $f^{-1}(x) = x$, so

$$(f^{-1})'(x) = \frac{1}{f'(f^{-1}(x))} = \frac{1}{f'(x)} = \frac{1}{1} = 1.$$

81. False. Since

$$\frac{d}{dx} \ln(x^2) = \frac{1}{x^2} \cdot 2x = \frac{2}{x} \quad \text{and} \quad \frac{d^2}{dx^2} \ln(x^2) = \frac{d}{dx}\left(\frac{2}{x}\right) = -\frac{2}{x^2},$$

we see that the second derivative of $\ln(x^2)$ is negative for $x > 0$. Thus, the graph is concave down.

82. False; For example, the inverse function of $f(x) = x^3$ is $x^{1/3}$, and the derivative of $x^{1/3}$ is $(1/3)x^{-2/3}$, which is not $1/f'(x) = 1/(3x^2)$.

Solutions for Section 3.7

Exercises

1. We differentiate implicitly both sides of the equation with respect to x.

$$2x + 2y\frac{dy}{dx} = 0\,,$$

$$\frac{dy}{dx} = -\frac{2x}{2y} = -\frac{x}{y}.$$

2. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned} 2x + 3y^2\frac{dy}{dx} &= 0 \\ 3y^2\frac{dy}{dx} &= -2x \\ \frac{dy}{dx} &= \frac{-2x}{3y^2}. \end{aligned}$$

3. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned} 2x + \left(y + x\frac{dy}{dx}\right) - 3y^2\frac{dy}{dx} &= y^2 + x(2y)\frac{dy}{dx}\ , \\ x\frac{dy}{dx} - 3y^2\frac{dy}{dx} - 2xy\frac{dy}{dx} &= y^2 - y - 2x\ , \\ \frac{dy}{dx} &= \frac{y^2 - y - 2x}{x - 3y^2 - 2xy}. \end{aligned}$$

4. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned} 2x + 2y\frac{dy}{dx} + 3 - 5\frac{dy}{dx} &= 0 \\ 2y\frac{dy}{dx} - 5\frac{dy}{dx} &= -2x - 3 \\ (2y - 5)\frac{dy}{dx} &= -2x - 3 \\ \frac{dy}{dx} &= \frac{-2x - 3}{2y - 5}. \end{aligned}$$

5. Implicit differentiation gives

$$1 \cdot y + x \cdot \frac{dy}{dx} + 1 + \frac{dy}{dx} = 0.$$

Solving for dy/dx, we have

$$\frac{dy}{dx} = -\frac{1 + y}{1 + x}.$$

6.

$$\begin{aligned} 2xy + x^2\frac{dy}{dx} - 2\frac{dy}{dx} &= 0 \\ (x^2 - 2)\frac{dy}{dx} &= -2xy \\ \frac{dy}{dx} &= \frac{-2xy}{(x^2 - 2)} \end{aligned}$$

7. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned} (x^2 \cdot 3y^2\frac{dy}{dx} + 2x \cdot y^3) - (x \cdot \frac{dy}{dx} + 1 \cdot y) &= 0 \\ 3x^2y^2\frac{dy}{dx} + 2xy^3 - x\frac{dy}{dx} - y &= 0 \\ 3x^2y^2\frac{dy}{dx} - x\frac{dy}{dx} &= y - 2xy^3 \\ (3x^2y^2 - x)\frac{dy}{dx} &= y - 2xy^3 \\ \frac{dy}{dx} &= \frac{y - 2xy^3}{3x^2y^2 - x}. \end{aligned}$$

8. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned} x^{1/2} &= 5y^{1/2} \\ \frac{1}{2}x^{-1/2} &= \frac{5}{2}y^{-1/2}\frac{dy}{dx} \\ \frac{dy}{dx} &= \frac{\frac{1}{2}x^{-1/2}}{\frac{5}{2}y^{-1/2}} = \frac{1}{5}\sqrt{\frac{y}{x}} = \frac{1}{25}. \end{aligned}$$

We can also obtain this answer by realizing that the original equation represents part of the line $x = 25y$ which has slope $1/25$.

9. We differentiate implicitly both sides of the equation with respect to x.

$$x^{\frac{1}{2}} + y^{\frac{1}{2}} = 25\,,$$
$$\frac{1}{2}x^{-\frac{1}{2}} + \frac{1}{2}y^{-\frac{1}{2}}\frac{dy}{dx} = 0\,,$$
$$\frac{dy}{dx} = -\frac{\frac{1}{2}x^{-\frac{1}{2}}}{\frac{1}{2}y^{-\frac{1}{2}}} = -\frac{x^{-\frac{1}{2}}}{y^{-\frac{1}{2}}} = -\frac{\sqrt{y}}{\sqrt{x}} = -\sqrt{\frac{y}{x}}.$$

10. We differentiate implicitly with respect to x.

$$y + x\frac{dy}{dx} - 1 - \frac{3dy}{dx} = 0$$
$$(x-3)\frac{dy}{dx} = 1 - y$$
$$\frac{dy}{dx} = \frac{1-y}{x-3}$$

11.

$$12x + 8y\frac{dy}{dx} = 0$$
$$\frac{dy}{dx} = \frac{-12x}{8y} = \frac{-3x}{2y}$$

12.

$$2ax - 2by\frac{dy}{dx} = 0$$
$$\frac{dy}{dx} = \frac{-2ax}{-2by} = \frac{ax}{by}$$

13. We differentiate implicitly both sides of the equation with respect to x.

$$\ln x + \ln(y^2) = 3$$
$$\frac{1}{x} + \frac{1}{y^2}(2y)\frac{dy}{dx} = 0$$
$$\frac{dy}{dx} = \frac{-1/x}{2y/y^2} = -\frac{y}{2x}.$$

14. We differentiate implicitly both sides of the equation with respect to x.

$$\ln y + x\frac{1}{y}\frac{dy}{dx} + 3y^2\frac{dy}{dx} = \frac{1}{x}$$
$$\frac{x}{y}\frac{dy}{dx} + 3y^2\frac{dy}{dx} = \frac{1}{x} - \ln y$$
$$\frac{dy}{dx}\left(\frac{x}{y} + 3y^2\right) = \frac{1 - x\ln y}{x}$$
$$\frac{dy}{dx}\left(\frac{x + 3y^3}{y}\right) = \frac{1 - x\ln y}{x}$$
$$\frac{dy}{dx} = \frac{(1 - x\ln y)}{x} \cdot \frac{y}{(x + 3y^3)}$$

15. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned}\cos(xy)\left(y+x\frac{dy}{dx}\right)&=2\\ y\cos(xy)+x\cos(xy)\frac{dy}{dx}&=2\\ \frac{dy}{dx}&=\frac{2-y\cos(xy)}{x\cos(xy)}.\end{aligned}$$

16. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned}e^{\cos y}(-\sin y)\frac{dy}{dx}&=3x^2\arctan y+x^3\frac{1}{1+y^2}\frac{dy}{dx}\\ \frac{dy}{dx}\left(-e^{\cos y}\sin y-\frac{x^3}{1+y^2}\right)&=3x^2\arctan y\\ \frac{dy}{dx}&=\frac{3x^2\arctan y}{-e^{\cos y}\sin y-x^3(1+y^2)^{-1}}.\end{aligned}$$

17. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned}\arctan(x^2y)&=xy^2\\ \frac{1}{1+x^4y^2}(2xy+x^2\frac{dy}{dx})&=y^2+2xy\frac{dy}{dx}\\ 2xy+x^2\frac{dy}{dx}&=[1+x^4y^2][y^2+2xy\frac{dy}{dx}]\\ \frac{dy}{dx}[x^2-(1+x^4y^2)(2xy)]&=(1+x^4y^2)y^2-2xy\\ \frac{dy}{dx}&=\frac{y^2+x^4y^4-2xy}{x^2-2xy-2x^5y^3}.\end{aligned}$$

18. We differentiate implicitly both sides of the equation with respect to x.

$$\begin{aligned}e^{x^2}+\ln y&=0\\ 2xe^{x^2}+\frac{1}{y}\frac{dy}{dx}&=0\\ \frac{dy}{dx}&=-2xye^{x^2}.\end{aligned}$$

19. We differentiate implicitly both sides of the equation with respect to x.

$$(x-a)^2+y^2=a^2$$

$$\begin{aligned}2(x-a)+2y\frac{dy}{dx}&=0\\ 2y\frac{dy}{dx}&=2a-2x\\ \frac{dy}{dx}&=\frac{2a-2x}{2y}=\frac{a-x}{y}.\end{aligned}$$

20. $\frac{2}{3}x^{-1/3}+\frac{2}{3}y^{-1/3}\cdot\frac{dy}{dx}=0,\ \frac{dy}{dx}=-\frac{x^{-1/3}}{y^{-1/3}}=-\frac{y^{1/3}}{x^{1/3}}.$

21. Differentiating implicitly on both sides with respect to x,

$$\begin{aligned} a\cos(ay)\frac{dy}{dx} - b\sin(bx) &= y + x\frac{dy}{dx} \\ (a\cos(ay) - x)\frac{dy}{dx} &= y + b\sin(bx) \\ \frac{dy}{dx} &= \frac{y + b\sin(bx)}{a\cos(ay) - x}. \end{aligned}$$

22. Differentiating $x^2 + y^2 = 1$ with respect to x gives

$$2x + 2yy' = 0$$

so that

$$y' = -\frac{x}{y}$$

At the point $(0, 1)$ the slope is 0.

23. Differentiating $\sin(xy) = x$ with respect to x gives

$$(y + xy')\cos(xy) = 1$$

or

$$xy'\cos(xy) = 1 - y\cos(xy)$$

so that

$$y' = \frac{1 - y\cos(xy)}{x\cos(xy)}.$$

As we move along the curve to the point $(1, \frac{\pi}{2})$, the value of $dy/dx \to \infty$, which tells us the tangent to the curve at $(1, \frac{\pi}{2})$ has infinite slope; the tangent is the vertical line $x = 1$.

24. Differentiating with respect to x gives

$$3x^2 + 2xy' + 2y + 2yy' = 0$$

so that

$$y' = -\frac{3x^2 + 2y}{2x + 2y}$$

At the point $(1, 1)$ the slope is $-\frac{5}{4}$.

25. The slope is given by dy/dx, which we find using implicit differentiation. Notice that the product rule is needed for the second term. We differentiate to obtain:

$$\begin{aligned} 3x^2 + 5x^2\frac{dy}{dx} + 10xy + 4y\frac{dy}{dx} &= 4\frac{dy}{dx} \\ (5x^2 + 4y - 4)\frac{dy}{dx} &= -3x^2 - 10xy \\ \frac{dy}{dx} &= \frac{-3x^2 - 10xy}{5x^2 + 4y - 4}. \end{aligned}$$

At the point $(1, 2)$, we have $dy/dx = (-3 - 20)/(5 + 8 - 4) = -23/9$. The slope of this curve at the point $(1, 2)$ is $-23/9$.

26. First, we must find the slope of the tangent, i.e. $\left.\frac{dy}{dx}\right|_{(1,-1)}$. Differentiating implicitly, we have:

$$\begin{aligned} y^2 + x(2y)\frac{dy}{dx} &= 0, \\ \frac{dy}{dx} = -\frac{y^2}{2xy} &= -\frac{y}{2x}. \end{aligned}$$

Substitution yields $\left.\frac{dy}{dx}\right|_{(1,-1)} = -\frac{-1}{2} = \frac{1}{2}$. Using the point-slope formula for a line, we have that the equation for the tangent line is $y + 1 = \frac{1}{2}(x - 1)$ or $y = \frac{1}{2}x - \frac{3}{2}$.

27. First we must find the slope of the tangent, $\frac{dy}{dx}$, at $(1, e^2)$. Differentiating implicitly, we have:

$$\frac{1}{xy}\left(x\frac{dy}{dx}+y\right) = 2$$
$$\frac{dy}{dx} = \frac{2xy-y}{x}.$$

Evaluating dy/dx at $(1, e^2)$ yields $(2(1)e^2 - e^2)/1 = e^2$. Using the point-slope formula for the equation of the line, we have:

$$y - e^2 = e^2(x-1),$$

or

$$y = e^2 x.$$

28. First, we must find the slope of the tangent, $\left.\frac{dy}{dx}\right|_{(4,2)}$. Implicit differentiation yields:

$$2y\frac{dy}{dx} = \frac{2x(xy-4) - x^2\left(x\frac{dy}{dx}+y\right)}{(xy-4)^2}.$$

Given the complexity of the above equation, we first want to substitute 4 for x and 2 for y (the coordinates of the point where we are constructing our tangent line), then solve for $\frac{dy}{dx}$. Substitution yields:

$$2\cdot 2\frac{dy}{dx} = \frac{(2\cdot 4)(4\cdot 2-4) - 4^2\left(4\frac{dy}{dx}+2\right)}{(4\cdot 2-4)^2} = \frac{8(4) - 16(4\frac{dy}{dx}+2)}{16} = -4\frac{dy}{dx}.$$

$$4\frac{dy}{dx} = -4\frac{dy}{dx},$$

Solving for $\frac{dy}{dx}$, we have:

$$\frac{dy}{dx} = 0.$$

The tangent is a horizontal line through $(4, 2)$, hence its equation is $y = 2$.

29. First, we must find the slope of the tangent at the origin, that is $\left.\frac{dy}{dx}\right|_{(0,0)}$. Rewriting $y = \frac{x}{y+a}$ as $y(y+a) = x$ so that we have

$$y^2 + ay = x$$

and differentiating implicitly gives

$$2y\frac{dy}{dx} + a\frac{dy}{dx} = 1$$
$$\frac{dy}{dx}(2y+a) = 1$$
$$\frac{dy}{dx} = \frac{1}{2y+a}.$$

Substituting $x = 0,\ y = 0$ yields $\left.\frac{dy}{dx}\right|_{(0,0)} = \frac{1}{a}$. Using the point-slope formula for a line, we have that the equation for the tangent line is

$$y - 0 = \frac{1}{a}(x-0) \quad \text{or} \quad y = \frac{x}{a}.$$

30. First, we must find the slope of the tangent, $\left.\frac{dy}{dx}\right|_{(a,0)}$. We differentiate implicitly, obtaining:

$$\frac{2}{3}x^{-\frac{1}{3}} + \frac{2}{3}y^{-\frac{1}{3}}\frac{dy}{dx} = 0\,,$$

$$\frac{dy}{dx} = -\frac{\frac{2}{3}x^{-\frac{1}{3}}}{\frac{2}{3}y^{-\frac{1}{3}}} = -\frac{\sqrt[3]{y}}{\sqrt[3]{x}}.$$

Substitution yields, $\left.\frac{dy}{dx}\right|_{(a,0)} = \frac{\sqrt[3]{0}}{\sqrt[3]{a}} = 0$. The tangent is a horizontal line through $(a, 0)$, hence its equation is $y = 0$.

Problems

31. (a) By implicit differentiation, we have:

$$\begin{aligned} 2x + 2y\frac{dy}{dx} - 4 + 7\frac{dy}{dx} &= 0 \\ (2y+7)\frac{dy}{dx} &= 4 - 2x \\ \frac{dy}{dx} &= \frac{4-2x}{2y+7}. \end{aligned}$$

(b) The curve has a horizontal tangent line when $dy/dx = 0$, which occurs when $4 - 2x = 0$ or $x = 2$. The curve has a horizontal tangent line at all points where $x = 2$.
The curve has a vertical tangent line when dy/dx is undefined, which occurs when $2y + 7 = 0$ or when $y = -7/2$. The curve has a vertical tangent line at all points where $y = -7/2$.

32. (a) Taking derivatives implicitly, we get

$$\begin{aligned} \frac{2}{25}x + \frac{2}{9}y\frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \frac{-9x}{25y}. \end{aligned}$$

(b) The slope is not defined anywhere along the line $y = 0$. This ellipse intersects that line in two places, $(-5, 0)$ and $(5, 0)$. (These are the "ends" of the ellipse where the tangent is vertical.)

33. Differentiating implicitly with respect to x, gives

$$\frac{d}{dx}\left(\frac{(x-2)^2}{16} + \frac{y^2}{4}\right) = \frac{d}{dx}(1).$$

Treating y as a function of x and using the chain rule, we get

$$\begin{aligned} \frac{x-2}{8} + \frac{y}{2}\cdot\frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= \frac{-\left(\frac{x-2}{8}\right)}{\frac{y}{2}} = \frac{2-x}{4y}. \end{aligned}$$

At $x = 2$, the value of dy/dx is 0 and the tangent lines are horizontal. The corresponding y-values satisfy

$$\begin{aligned} \frac{0^2}{16^2} + \frac{y^2}{4} &= 1 \\ y^2 &= 4 \\ y &= \pm 2. \end{aligned}$$

Thus the tangent line equations at $(2, 2)$ and $(2, -2)$ are the horizontal lines $y = 2$ and $y = -2$, respectively.

34. (a) If $x = 4$ then $16 + y^2 = 25$, so $y = \pm 3$. We find $\frac{dy}{dx}$ implicitly:

$$\begin{aligned} 2x + 2y\frac{dy}{dx} &= 0 \\ \frac{dy}{dx} &= -\frac{x}{y} \end{aligned}$$

So the slope at $(4,3)$ is $-\frac{4}{3}$ and at $(4,-3)$ is $\frac{4}{3}$. The tangent lines are:

$$(y-3) = -\frac{4}{3}(x-4) \quad \text{and} \quad (y+3) = \frac{4}{3}(x-4)$$

(b) The normal lines have slopes that are the negative of the reciprocal of the slopes of the tangent lines. Thus,

$$(y-3) = \frac{3}{4}(x-4) \quad \text{so} \quad y = \frac{3}{4}x$$

and

$$(y+3) = -\frac{3}{4}(x-4) \quad \text{so} \quad y = -\frac{3}{4}x$$

are the normal lines.

(c) These lines meet at the origin, which is the center of the circle.

35. (a) Solving for $\frac{dy}{dx}$ by implicit differentiation yields

$$3x^2 + 3y^2\frac{dy}{dx} - y^2 - 2xy\frac{dy}{dx} = 0$$
$$\frac{dy}{dx} = \frac{y^2 - 3x^2}{3y^2 - 2xy}.$$

(b) We can approximate the curve near $x = 1$, $y = 2$ by its tangent line. The tangent line will have slope $\frac{(2)^2-3(1)^2}{3(2)^2-2(1)(2)} = \frac{1}{8} = 0.125$. Thus its equation is

$$y = 0.125x + 1.875$$

Using the y-values of the tangent line to approximate the y-values of the curve, we get:

x	0.96	0.98	1	1.02	1.04
approximate y	1.995	1.9975	2.000	2.0025	2.005

(c) When $x = 0.96$, we get the equation $0.96^3 + y^3 - 0.96y^2 = 5$, whose solution by numerical methods is 1.9945, which is close to the one above.

(d) The tangent line is horizontal when $\frac{dy}{dx}$ is zero and vertical when $\frac{dy}{dx}$ is undefined. These will occur when the numerator is zero and when the denominator is zero, respectively.

Thus, we know that the tangent is horizontal when $y^2 - 3x^2 = 0 \Rightarrow y = \pm\sqrt{3}x$. To find the points that satisfy this condition, we substitute back into the original equation for the curve:

$$x^3 + y^3 - xy^2 = 5$$
$$x^3 \pm 3\sqrt{3}x^3 - 3x^3 = 5$$
$$x^3 = \frac{5}{\pm 3\sqrt{3} - 2}$$

So $x \approx 1.1609$ or $x \approx -0.8857$.

Substituting,

$$y = \pm\sqrt{3}x \quad \text{so} \quad y \approx 2.0107 \quad \text{or} \quad y \approx 1.5341.$$

Thus, the tangent line is horizontal at $(1.1609, 2.0107)$ and $(-0.8857, 1.5341)$.

Also, we know that the tangent is vertical whenever $3y^2 - 2xy = 0$, that is, when $y = \frac{2}{3}x$ or $y = 0$. Substituting into the original equation for the curve gives us $x^3 + (\frac{2}{3}x)^3 - (\frac{2}{3})^2x^3 = 5$. This means $x^3 \approx 5.8696$, so $x \approx 1.8039$, $y \approx 1.2026$. The other vertical tangent is at $y = 0$, $x = \sqrt[3]{5}$.

36. The slope of the tangent to the curve $y = x^2$ at $x = 1$ is 2 so the equation of such a tangent will be of the form $y = 2x + c$. As the tangent must pass through $(1,1)$, $c = -1$ and so the required tangent is $y = 2x - 1$.

Any circle centered at $(8,0)$ will be of the form

$$(x-8)^2 + y^2 = R^2.$$

The slope of this curve at (x,y) is given by implicit differentiation:

$$2(x-8) + 2yy' = 0$$

or

$$y' = \frac{8-x}{y}$$

For the tangent to the parabola to be tangential to the circle we need

$$\frac{8-x}{y} = 2$$

so that at the point of contact of the circle and the line the coordinates are given by (x, y) when $y = 4 - x/2$. Substituting into the equation of the tangent line gives $x = 2$ and $y = 3$. From this we conclude that $R^2 = 45$ so that the equation of the circle is

$$(x-8)^2 + y^2 = 45.$$

37. (a) Differentiating both sides of the equation with respect to P gives

$$\frac{d}{dP}\left(\frac{4f^2P}{1-f^2}\right) = \frac{dK}{dP} = 0.$$

By the product rule

$$\begin{aligned}\frac{d}{dP}\left(\frac{4f^2P}{1-f^2}\right) &= \frac{d}{dP}\left(\frac{4f^2}{1-f^2}\right)P + \left(\frac{4f^2}{1-f^2}\right)\cdot 1\\ &= \left(\frac{(1-f^2)(8f) - 4f^2(-2f)}{(1-f^2)^2}\right)\frac{df}{dP}P + \left(\frac{4f^2}{1-f^2}\right)\\ &= \left(\frac{8f}{(1-f^2)^2}\right)\frac{df}{dP}P + \left(\frac{4f^2}{1-f^2}\right) = 0.\end{aligned}$$

So

$$\frac{df}{dP} = \frac{-4f^2/(1-f^2)}{8fP/(1-f^2)^2} = \frac{-1}{2P}f(1-f^2).$$

(b) Since f is a fraction of a gas, $0 \le f \le 1$. Also, in the equation relating f and P we can't have $f = 0$, since that would imply $K = 0$, and we can't have $f = 1$, since the left side is undefined there. So $0 < f < 1$. Thus $1 - f^2 > 0$. Also, pressure can't be negative, and from the equation relating f and P, we see that P can't be zero either, so $P > 0$. Therefore $df/dP = -(1/2P)f(1-f^2) < 0$ always. This means that at larger pressures less of the gas decomposes.

38. Let the point of intersection of the tangent line with the smaller circle be (x_1, y_1) and the point of intersection with the larger be (x_2, y_2). Let the tangent line be $y = mx + c$. Then at (x_1, y_1) and (x_2, y_2) the slopes of $x^2 + y^2 = 1$ and $y^2 + (x-3)^2 = 4$ are also m. The slope of $x^2 + y^2 = 1$ is found by implicit differentiation: $2x + 2yy' = 0$ so $y' = -x/y$. Similarly, the slope of $y^2 + (x-3)^2 = 4$ is $y' = -(x-3)/y$. Thus,

$$m = \frac{y_2 - y_1}{x_2 - x_1} = -\frac{x_1}{y_1} = -\frac{(x_2-3)}{y_2},$$

where $y_1 = \sqrt{1 - x_1^2}$ and $y_2 = \sqrt{4 - (x_2-3)^2}$. The positive values for y_1 and y_2 follow from Figure 3.9 and from our choice of $m > 0$. We obtain

$$\begin{aligned}\frac{x_1}{\sqrt{1-x_1^2}} &= \frac{x_2-3}{\sqrt{4-(x_2-3)^2}}\\ \frac{x_1^2}{1-x_1^2} &= \frac{(x_2-3)^2}{4-(x_2-3)^2}\\ x_1^2[4-(x_2-3)^2] &= (1-x_1^2)(x_2-3)^2\\ 4x_1^2 - (x_1^2)(x_2-3)^2 &= (x_2-3)^2 - x_1^2(x_2-3)^2\\ 4x_1^2 &= (x_2-3)^2\\ 2|x_1| &= |x_2-3|.\end{aligned}$$

From the picture $x_1 < 0$ and $x_2 < 3$. This gives $x_2 = 2x_1 + 3$ and $y_2 = 2y_1$. From

$$\frac{y_2-y_1}{x_2-x_1} = -\frac{x_1}{y_1},$$

substituting $y_1 = \sqrt{1 - x_1^2}$, $y_2 = 2y_1$ and $x_2 = 2x_1 + 3$ gives

$$x_1 = -\frac{1}{3}.$$

From $x_2 = 2x_1 + 3$ we get $x_2 = 7/3$. In addition, $y_1 = \sqrt{1 - x_1^2}$ gives $y_1 = 2\sqrt{2}/3$, and finally $y_2 = 2y_1$ gives $y_2 = 4\sqrt{2}/3$.

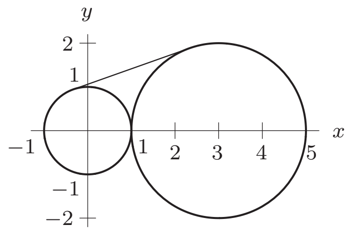


Figure 3.9

39. Using implicit differentiation we have

$$1 = (\cos y)\frac{dy}{dx}.$$

Therefore,

$$\frac{dy}{dx} = \frac{1}{\cos y}.$$

Solving the trig identity $\sin^2 y + \cos^2 y = 1$ for $\cos y$ and substituting $x = \sin y$ gives $\cos y = \pm\sqrt{1 - x^2}$. However, because $y = \arcsin x$, we have $-\pi/2 \le y \le \pi/2$, so $\cos y \ge 0$ and thus we take the positive root:

$$\frac{dy}{dx} = \frac{1}{\cos y} = \frac{1}{\sqrt{1 - \sin^2 y}} = \frac{1}{\sqrt{1 - x^2}}.$$

40. $y = x^{\frac{m}{n}}$. Taking n^{th} powers of both sides of this expression yields $(y)^n = (x^{\frac{m}{n}})^n$, or $y^n = x^m$.

$$\begin{aligned}
\frac{d}{dx}(y^n) &= \frac{d}{dx}(x^m) \\
ny^{n-1}\frac{dy}{dx} &= mx^{m-1} \\
\frac{dy}{dx} &= \frac{m}{n}\frac{x^{m-1}}{y^{n-1}} \\
&= \frac{m}{n}\frac{x^{m-1}}{(x^{m/n})^{n-1}} \\
&= \frac{m}{n}\frac{x^{m-1}}{x^{m-\frac{m}{n}}} \\
&= \frac{m}{n}x^{(m-1)-(m-\frac{m}{n})} = \frac{m}{n}x^{\frac{m}{n}-1}.
\end{aligned}$$

41. Implicit differentiation gives

$$\begin{aligned}
\left(1 - \frac{2n^2a}{V^3}\frac{dV}{dP}\right)(V - nb) + \left(P + \frac{n^2a}{V^2}\right)\frac{dV}{dP} &= 0 \\
\frac{dV}{dP}\left(-\frac{2n^2a}{V^3}(V - nb) + \left(P + \frac{n^2a}{V^2}\right)\right) &= nb - V \\
\frac{dV}{dP}\left(P - \frac{n^2a}{V^2} + \frac{2n^3ab}{V^3}\right) &= nb - V \\
\frac{dV}{dP} &= \frac{nb - V}{P - n^2a/V^2 + 2n^3ab/V^3}.
\end{aligned}$$

Strengthen Your Understanding

42. Since we cannot solve for y in terms of x, we need to differentiate implicitly. This gives

$$\frac{d}{dx}(y) = \frac{d}{dx}\left(\sin(xy)\right),$$

so

$$\frac{dy}{dx} = \cos(xy)\left(1 \cdot y + x \cdot \frac{dy}{dx}\right).$$

Solving for dy/dx gives

$$\frac{dy}{dx} = \frac{y\cos(xy)}{1 - x\cos(xy)}.$$

43. The formula applies only when the point (x, y) is on the circle.

44. One possible format for the slope is

$$\frac{dy}{dx} = \frac{x^2 - 4}{y - 2}.$$

To confirm that the tangents exist, we would need to have the formula for the implicit function and check that there are points satisfying it with $y = 2$ and $x = \pm 2$.

45. A hyperbola opening up and down works here.

For example, $-x^2 + y^2 = 1$. Note that $\dfrac{dy}{dx} = \dfrac{x}{y}$. Although the denominator is zero when $y = 0$, the original equation is not satisfied by $y = 0$. Thus, there are no vertical tangents to the curve. Horizontal tangents occur when $x = 0$ and $y = \pm\sqrt{1}$.

46. True; differentiating the equation with respect to x, we get

$$2y\frac{dy}{dx} + y + x\frac{dy}{dx} = 0.$$

Solving for dy/dx, we get that

$$\frac{dy}{dx} = \frac{-y}{2y + x}.$$

Thus dy/dx exists where $2y + x \neq 0$. Now if $2y + x = 0$, then $x = -2y$. Substituting for x in the original equation, $y^2 + xy - 1 = 0$, we get

$$y^2 - 2y^2 - 1 = 0.$$

This simplifies to $y^2 + 1 = 0$, which has no solutions. Thus dy/dx exists everywhere.

Solutions for Section 3.8

Exercises

1. Using the chain rule, $\dfrac{d}{dz}\left(\sinh(3z + 5)\right) = \cosh(3z + 5) \cdot 3 = 3\cosh(3z + 5)$.

2. Using the chain rule, $\dfrac{d}{dx}\left(\cosh(2x)\right) = \left(\sinh(2x)\right) \cdot 2 = 2\sinh(2x)$.

3. Using the chain rule,

$$\frac{d}{dt}\left(\cosh^2 t\right) = 2\cosh t \cdot \sinh t.$$

.

4. Using the chain rule,

$$\frac{d}{dt}\left(\cosh(\sinh t)\right) = \sinh(\sinh t) \cdot \cosh t$$

.

5. Using the product rule,

$$\frac{d}{dt}\left(t^3 \sinh t\right) = 3t^2 \sinh t + t^3 \cosh t.$$

6. Using the product and chain rules, $\frac{d}{dt}(\cosh(3t)\sinh(4t)) = 3\sinh(3t)\sinh(4t) + 4\cosh(3t)\cosh(4t)$.

7. Using the chain rule, $\frac{d}{dx}(\tanh(3+\sinh x)) = \frac{1}{\cosh^2(3+\sinh x)} \cdot \cosh x$.

8. Using the chain rule twice, $\frac{d}{dt}\left(\cosh(e^{t^2})\right) = \sinh(e^{t^2}) \cdot e^{t^2} \cdot 2t = 2te^{t^2}\sinh(e^{t^2})$.

9. Using the chain rule,

$$\frac{d}{d\theta}(\ln(\cosh(1+\theta))) = \frac{1}{\cosh(1+\theta)} \cdot \sinh(1+\theta) = \frac{\sinh(1+\theta)}{\cosh(1+\theta)} = \tanh(1+\theta).$$

10. Using the chain rule twice,

$$\begin{aligned}\frac{d}{dy}(\sinh(\sinh(3y))) &= \cosh(\sinh(3y)) \cdot \cosh(3y) \cdot 3 \\ &= 3\cosh(3y) \cdot \cosh(\sinh(3y)).\end{aligned}$$

11. Using the chain rule, $f'(t) = 2\cosh t \sinh t - 2\sinh t \cosh t = 0$. This is to be expected since $\cosh^2 t - \sinh^2 t = 1$.

12. Using the formula for $\sinh x$ and the fact that $d(e^{-x})/dx = -e^{-x}$, we see that

$$\frac{d}{dx}\left(\frac{e^x - e^{-x}}{2}\right) = \frac{e^x + e^{-x}}{2} = \cosh x.$$

13. Substitute $x = 0$ into the formula for $\sinh x$. This yields

$$\sinh 0 = \frac{e^0 - e^{-0}}{2} = \frac{1-1}{2} = 0.$$

14. Substituting $-x$ for x in the formula for $\sinh x$ gives

$$\sinh(-x) = \frac{e^{-x} - e^{-(-x)}}{2} = \frac{e^{-x} - e^x}{2} = -\frac{e^x - e^{-x}}{2} = -\sinh x.$$

15. By definition $\cosh x = (e^x + e^{-x})/2$ so, since $e^{\ln t} = t$ and $e^{-\ln t} = 1/e^{\ln t} = 1/t$, we have

$$\cosh(\ln t) = \frac{e^{\ln t} + e^{-\ln t}}{2} = \frac{t + 1/t}{2} = \frac{t^2+1}{2t}.$$

16. By definition $\sinh x = (e^x - e^{-x})/2$ so, since $e^{\ln t} = t$ and $e^{-\ln t} = 1/e^{\ln t} = 1/t$, we have

$$\sinh(\ln t) = \frac{e^{\ln t} - e^{-\ln t}}{2} = \frac{t - 1/t}{2} = \frac{t^2-1}{2t}.$$

Problems

17. The graph of $\sinh x$ in the text suggests that

$$\text{As } x \to \infty, \quad \sinh x \to \frac{1}{2}e^x.$$
$$\text{As } x \to -\infty, \quad \sinh x \to -\frac{1}{2}e^{-x}.$$

Using the facts that

$$\text{As } x \to \infty, \quad e^{-x} \to 0,$$
$$\text{As } x \to -\infty, \quad e^{x} \to 0,$$

we can obtain the same results analytically:

$$\text{As } x \to \infty, \quad \sinh x = \frac{e^x - e^{-x}}{2} \to \frac{1}{2}e^x.$$
$$\text{As } x \to -\infty, \quad \sinh x = \frac{e^x - e^{-x}}{2} \to -\frac{1}{2}e^{-x}.$$

18. Using the identity

$$\cosh^2 t - \sinh^2 t = 1,$$

we see

$$x^2 - y^2 = 1.$$

19. First we observe that

$$\sinh(2x) = \frac{e^{2x} - e^{-2x}}{2}.$$

Now let's calculate

$$\begin{aligned}(\sinh x)(\cosh x) &= \left(\frac{e^x - e^{-x}}{2}\right)\left(\frac{e^x + e^{-x}}{2}\right)\\ &= \frac{(e^x)^2 - (e^{-x})^2}{4}\\ &= \frac{e^{2x} - e^{-2x}}{4}\\ &= \frac{1}{2}\sinh(2x).\end{aligned}$$

Thus, we see that

$$\sinh(2x) = 2\sinh x \cosh x.$$

20. First, we observe that

$$\cosh(2x) = \frac{e^{2x} + e^{-2x}}{2}.$$

Now let's use the fact that $e^x \cdot e^{-x} = 1$ to calculate

$$\begin{aligned}\cosh^2 x &= \left(\frac{e^x + e^{-x}}{2}\right)^2\\ &= \frac{(e^x)^2 + 2e^x \cdot e^{-x} + (e^{-x})^2}{4}\\ &= \frac{e^{2x} + 2 + e^{-2x}}{4}.\end{aligned}$$

Similarly, we have

$$\begin{aligned}\sinh^2 x &= \left(\frac{e^x - e^{-x}}{2}\right)^2\\ &= \frac{(e^x)^2 - 2e^x \cdot e^{-x} + (e^{-x})^2}{4}\\ &= \frac{e^{2x} - 2 + e^{-2x}}{4}.\end{aligned}$$

Thus, to obtain $\cosh(2x)$, we need to add (rather than subtract) $\cosh^2 x$ and $\sinh^2 x$, giving

$$\begin{aligned}\cosh^2 x + \sinh^2 x &= \frac{e^{2x} + 2 + e^{-2x} + e^{2x} - 2 + e^{-2x}}{4} \\ &= \frac{2e^{2x} + 2e^{-2x}}{4} \\ &= \frac{e^{2x} + e^{-2x}}{2} \\ &= \cosh(2x).\end{aligned}$$

Thus, we see that the identity relating $\cosh(2x)$ to $\cosh x$ and $\sinh x$ is

$$\cosh(2x) = \cosh^2 x + \sinh^2 x.$$

21. Recall that

$$\sinh A = \frac{1}{2}(e^A - e^{-A}) \quad \text{and} \quad \cosh A = \frac{1}{2}(e^A + e^{-A}).$$

Now substitute, expand and collect terms:

$$\begin{aligned}\cosh A \cosh B + \sinh A \sinh B &= \frac{1}{2}(e^A + e^{-A}) \cdot \frac{1}{2}(e^B + e^{-B}) + \frac{1}{2}(e^A - e^{-A}) \cdot \frac{1}{2}(e^B - e^{-B}) \\ &= \frac{1}{4}\left(e^{A+B} + e^{A-B} + e^{-A+B} + e^{-(A+B)}\right. \\ &\qquad \left. + e^{B+A} - e^{B-A} - e^{-B+A} + e^{-A-B}\right) \\ &= \frac{1}{2}\left(e^{A+B} + e^{-(A+B)}\right) \\ &= \cosh(A+B).\end{aligned}$$

22. Recall that

$$\sinh A = \frac{1}{2}(e^A - e^{-A}) \quad \text{and} \quad \cosh A = \frac{1}{2}(e^A + e^{-A}).$$

Now substitute, expand and collect terms:

$$\begin{aligned}\sinh A \cosh B + \cosh A \sinh B &= \frac{1}{2}(e^A - e^{-A}) \cdot \frac{1}{2}(e^B + e^{-B}) + \frac{1}{2}(e^A + e^{-A}) \cdot \frac{1}{2}(e^B - e^{-B}) \\ &= \frac{1}{4}\left(e^{A+B} + e^{A-B} - e^{-A+B} - e^{-(A+B)}\right. \\ &\qquad \left. + e^{B+A} + e^{B-A} - e^{-B+A} - e^{-A-B}\right) \\ &= \frac{1}{2}\left(e^{A+B} - e^{-(A+B)}\right) \\ &= \sinh(A+B).\end{aligned}$$

23. $\lim_{x\to\infty} \sinh(2x)/\cosh(3x) = \lim_{x\to\infty}(e^{2x} - e^{-2x})/(e^{3x} + e^{-3x}) = \lim_{x\to\infty}(1 - e^{-4x})/(e^x + e^{-5x}) = 0.$

24. Using the definition of $\sinh x$, we have $\sinh 2x = \dfrac{e^{2x} - e^{-2x}}{2}$. Therefore

$$\begin{aligned}\lim_{x\to\infty} \frac{e^{2x}}{\sinh(2x)} &= \lim_{x\to\infty} \frac{2e^{2x}}{e^{2x} - e^{-2x}} \\ &= \lim_{x\to\infty} \frac{2}{1 - e^{-4x}} \\ &= 2.\end{aligned}$$

25. Using the definition of $\cosh x$ and $\sinh x$, we have $\cosh x^2 = \dfrac{e^{x^2}+e^{-x^2}}{2}$ and $\sinh x^2 = \dfrac{e^{x^2}-e^{-x^2}}{2}$. Therefore

$$\begin{aligned}\lim_{x\to\infty}\frac{\sinh(x^2)}{\cosh(x^2)} &= \lim_{x\to\infty}\frac{e^{x^2}-e^{-x^2}}{e^{x^2}+e^{-x^2}}\\ &= \lim_{x\to\infty}\frac{e^{x^2}(1-e^{-2x^2})}{e^{x^2}(1+e^{-2x^2})}\\ &= \lim_{x\to\infty}\frac{1-e^{-2x^2}}{1+e^{-2x^2}}\\ &= 1.\end{aligned}$$

26. Using the definition of $\cosh x$ and $\sinh x$, we have $\cosh 2x = \dfrac{e^{2x}+e^{-2x}}{2}$ and $\sinh 3x = \dfrac{e^{3x}-e^{-3x}}{2}$. Therefore

$$\begin{aligned}\lim_{x\to\infty}\frac{\cosh(2x)}{\sinh(3x)} &= \lim_{x\to\infty}\frac{e^{2x}+e^{-2x}}{e^{3x}-e^{-3x}}\\ &= \lim_{x\to\infty}\frac{e^{2x}(1+e^{-4x})}{e^{2x}(e^{x}-e^{-5x})}\\ &= \lim_{x\to\infty}\frac{1+e^{-4x}}{e^{x}-e^{-5x}}\\ &= 0.\end{aligned}$$

27. Note that

$$\begin{aligned}e^{-3x}\cosh kx &= e^{-3x}\frac{e^{kx}+e^{-kx}}{2}\\ &= \frac{e^{(k-3)x}+e^{-(k+3)x}}{2}.\end{aligned}$$

If $|k| = 3$, then the limit as $x\to\infty$ is 1/2.
If $|k| > 3$, then the limit as $x\to\infty$ does not exist.
If $|k| < 3$, then the limit as $x\to\infty$ is 0.

28. Note that

$$\begin{aligned}\frac{\sinh kx}{\cosh 2x} &= \frac{e^{kx}-e^{-kx}}{e^{2x}+e^{-2x}}\\ &= \frac{e^{2x}(e^{(k-2)x}-e^{-(k+2)x})}{e^{2x}(1+e^{-4x})}\\ &= \frac{e^{(k-2)x}-e^{-(k+2)x}}{1+e^{-4x}}.\end{aligned}$$

If $k = 2$, then the limit as $x\to\infty$ is 1.
If $|k| > 2$, then the limit as $x\to\infty$ does not exist.
If $|k| < 2$, then the limit as $x\to\infty$ is 0.

29. (a) Since the cosh function is even, the height, y, is the same at $x = -T/w$ and $x = T/w$. The height at these endpoints is

$$y = \frac{T}{w}\cosh\left(\frac{w}{T}\cdot\frac{T}{w}\right) = \frac{T}{w}\cosh 1 = \frac{T}{w}\left(\frac{e^1+e^{-1}}{2}\right).$$

At the lowest point, $x = 0$, and the height is

$$y = \frac{T}{w}\cosh 0 = \frac{T}{w}.$$

Thus the "sag" in the cable is given by

$$\text{Sag} = \frac{T}{w}\left(\frac{e+e^{-1}}{2}\right) - \frac{T}{w} = \frac{T}{w}\left(\frac{e+e^{-1}}{2}-1\right) \approx 0.54\frac{T}{w}.$$

(b) To show that the differential equation is satisfied, take derivatives

$$\frac{dy}{dx} = \frac{T}{w} \cdot \frac{w}{T} \sinh\left(\frac{wx}{T}\right) = \sinh\left(\frac{wx}{T}\right)$$
$$\frac{d^2y}{dx^2} = \frac{w}{T} \cosh\left(\frac{wx}{T}\right).$$

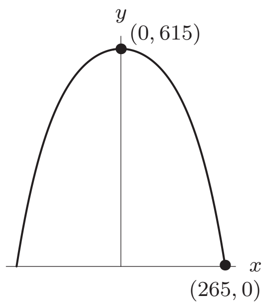
Therefore, using the fact that $1 + \sinh^2 a = \cosh^2 a$ and that cosh is always positive, we have:

$$\frac{w}{T}\sqrt{1 + \left(\frac{dy}{dx}\right)^2} = \frac{w}{T}\sqrt{1 + \sinh^2\left(\frac{wx}{T}\right)} = \frac{w}{T}\sqrt{\cosh^2\left(\frac{wx}{T}\right)}$$
$$= \frac{w}{T}\cosh\left(\frac{wx}{T}\right).$$

So

$$\frac{w}{T}\sqrt{1 + \left(\frac{dy}{dx}\right)^2} = \frac{d^2y}{dx^2}.$$

30.



We know $x = 0$ and $y = 615$ at the top of the arch, so

$$615 = b - a\cosh(0/a) = b - a.$$

This means $b = a + 615$. We also know that $x = 265$ and $y = 0$ where the arch hits the ground, so

$$0 = b - a\cosh(265/a) = a + 615 - a\cosh(265/a).$$

We can solve this equation numerically on a calculator and get $a \approx 100$, which means $b \approx 715$. This results in the equation

$$y \approx 715 - 100\cosh\left(\frac{x}{100}\right).$$

31. (a) The graph in Figure 3.10 looks like the graph of $y = \cosh x$, with the minimum at about $(0.5, 6.3)$.

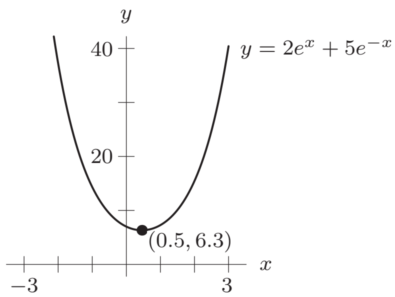


Figure 3.10

(b) We want to write

$$\begin{aligned} y = 2e^x + 5e^{-x} = A\cosh(x-c) &= \frac{A}{2}e^{x-c} + \frac{A}{2}e^{-(x-c)} \\ &= \frac{A}{2}e^x e^{-c} + \frac{A}{2}e^{-x}e^c \\ &= \left(\frac{Ae^{-c}}{2}\right)e^x + \left(\frac{Ae^c}{2}\right)e^{-x}. \end{aligned}$$

Thus, we need to choose A and c so that

$$\frac{Ae^{-c}}{2} = 2 \quad \text{and} \quad \frac{Ae^c}{2} = 5.$$

Dividing gives

$$\begin{aligned} \frac{Ae^c}{Ae^{-c}} &= \frac{5}{2} \\ e^{2c} &= 2.5 \\ c &= \frac{1}{2}\ln 2.5 \approx 0.458. \end{aligned}$$

Solving for A gives

$$A = \frac{4}{e^{-c}} = 4e^c \approx 6.325.$$

Thus,

$$y = 6.325\cosh(x - 0.458).$$

Rewriting the function in this way shows that the graph in part (a) is the graph of $\cosh x$ shifted to the right by 0.458 and stretched vertically by a factor of 6.325.

32. We want to show that for any $A,\ B$ with $A > 0,\ B > 0$, we can find K and c such that

$$\begin{aligned} y = Ae^x + Be^{-x} &= \frac{Ke^{(x-c)} + Ke^{-(x-c)}}{2} \\ &= \frac{K}{2}e^x e^{-c} + \frac{K}{2}e^{-x}e^c \\ &= \left(\frac{Ke^{-c}}{2}\right)e^x + \left(\frac{Ke^c}{2}\right)e^{-x}. \end{aligned}$$

Thus, we want to find K and c such that

$$\frac{Ke^{-c}}{2} = A \quad \text{and} \quad \frac{Ke^c}{2} = B.$$

Dividing, we have

$$\begin{aligned} \frac{Ke^c}{Ke^{-c}} &= \frac{B}{A} \\ e^{2c} &= \frac{B}{A} \\ c &= \frac{1}{2}\ln\left(\frac{B}{A}\right). \end{aligned}$$

If $A > 0,\ B > 0$, then there is a solution for c. Substituting to find K, we have

$$\begin{aligned} \frac{Ke^{-c}}{2} &= A \\ K &= 2Ae^c = 2Ae^{(\ln(B/A))/2} \\ &= 2Ae^{\ln\sqrt{B/A}} = 2A\sqrt{\frac{B}{A}} = 2\sqrt{AB}. \end{aligned}$$

Thus, if $A > 0,\ B > 0$, there is a solution for K also.

The fact that $y = Ae^x + Be^{-x}$ can be rewritten in this way shows that the graph of $y = Ae^x + Be^{-x}$ is the graph of $\cosh x$, shifted over by c and stretched (or shrunk) vertically by a factor of K.

33. (a) Substituting $x = 0$ gives
$$\tanh 0 = \frac{e^0 - e^{-0}}{e^0 + e^{-0}} = \frac{1-1}{2} = 0.$$

(b) Since $\tanh x = \dfrac{e^x - e^{-x}}{e^x + e^{-x}}$ and $e^x + e^{-x}$ is always positive, $\tanh x$ has the same sign as $e^x - e^{-x}$. For $x > 0$, we have $e^x > 1$ and $e^{-x} < 1$, so $e^x - e^{-x} > 0$. For $x < 0$, we have $e^x < 1$ and $e^{-x} > 1$, so $e^x - e^{-x} < 0$. For $x = 0$, we have $e^x = 1$ and $e^{-x} = 1$, so $e^x - e^{-x} = 0$. Thus, $\tanh x$ is positive for $x > 0$, negative for $x < 0$, and zero for $x = 0$.

(c) Taking the derivative, we have
$$\frac{d}{dx}(\tanh x) = \frac{1}{\cosh^2 x}.$$
Thus, for all x,
$$\frac{d}{dx}(\tanh x) > 0.$$
Thus, $\tanh x$ is increasing everywhere.

(d) As $x \to \infty$ we have $e^{-x} \to 0$; as $x \to -\infty$, we have $e^x \to 0$. Thus
$$\lim_{x\to\infty} \tanh x = \lim_{x\to\infty} \left(\frac{e^x - e^{-x}}{e^x + e^{-x}}\right) = 1,$$
$$\lim_{x\to-\infty} \tanh x = \lim_{x\to-\infty} \left(\frac{e^x - e^{-x}}{e^x + e^{-x}}\right) = -1.$$
Thus, $y = 1$ and $y = -1$ are horizontal asymptotes to the graph of $\tanh x$. See Figure 3.11.

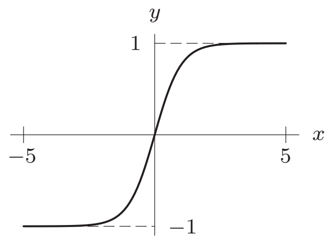

Figure 3.11: Graph of $y = \tanh x$

(e) The graph of $\tanh x$ suggests that $\tanh x$ is increasing everywhere; the fact that the derivative of $\tanh x$ is positive for all x confirms this. Since $\tanh x$ is increasing for all x, different values of x lead to different values of y, and therefore $\tanh x$ does have an inverse.

Strengthen Your Understanding

34. Since $f(x) = \cosh x = (e^x + e^{-x})/2$, the function is not periodic.

35. Since $f(x) = \cosh x = (e^x + e^{-x})/2$ we have
$$f'(x) = \frac{d}{dx}\left(\frac{e^x + e^{-x}}{2}\right) = \frac{e^x - e^{-x}}{2} = \sinh x.$$

36. The required identity for hyperbolic functions is $\cosh^2 x - \sinh^2 x = 1$.

37. Since $\cosh x$ and $\sinh x$ behave like $e^x/2$ as $x \to \infty$ then $\tanh x = \sinh x/\cosh x \to 1$ as $x \to \infty$.

38. $f(x) = \cosh x$ is concave up. Other answers are possible.

39. We have
$$\lim_{x\to\infty} e^{kx}\cosh x = \lim_{x\to\infty} e^{kx}\left(\frac{e^x + e^{-x}}{2}\right) = \lim_{x\to\infty} \frac{e^{(k+1)x} + e^{(k-1)x}}{2}.$$
This limit does not exist for any value $k > -1$: for example, $k = 0$.

40. Since $\cosh 0 = 1$, we can shift $\cosh x$ to the right by 1 and up 2. Thus, $f(x) = \cosh(x-1) + 2$ is a possibility.

41. True. We have $\tanh x = (\sinh x)\,/\cosh x = (e^x - e^{-x})/(e^x + e^{-x})$. Replacing x by $-x$ in this expression gives $(e^{-x} - e^x)/(e^{-x} + e^x) = -\tanh x$.

42. False. The second, fourth and all even derivatives of $\sinh x$ are all $\sinh x$.

43. True. The definitions of $\sinh x$ and $\cosh x$ give

$$\sinh x + \cosh x = \frac{e^x - e^{-x}}{2} + \frac{e^x + e^{-x}}{2} = \frac{2e^x}{2} = e^x.$$

44. False. Since $(\sinh x)' = \cosh x > 0$, the function $\sinh x$ is increasing everywhere so can never repeat any of its values.

45. False. Since $(\sinh^2 x)' = 2\sinh x \cosh x$ and $(2\sinh x \cosh x)' = 2\sinh^2 x + 2\cosh^2 x > 0$, the function $\sinh^2 x$ is concave up everywhere.

Solutions for Section 3.9

Exercises

1. With $f(x) = \sqrt{1+x}$, the chain rule gives $f'(x) = 1/(2\sqrt{1+x})$, so $f(0) = 1$ and $f'(0) = 1/2$. Therefore the tangent line approximation of f near $x = 0$,

$$f(x) \approx f(0) + f'(0)(x - 0),$$

becomes

$$\sqrt{1+x} \approx 1 + \frac{x}{2}.$$

This means that, near $x = 0$, the function $\sqrt{1+x}$ can be approximated by its tangent line $y = 1 + x/2$. (See Figure 3.12.)

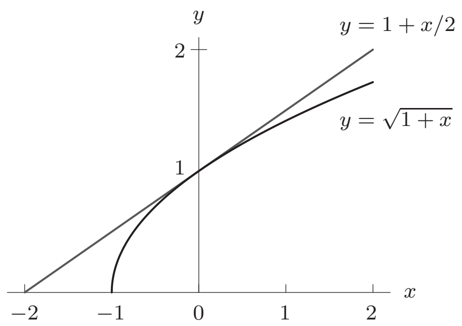

Figure 3.12

2. With $f(x) = e^x$, the tangent line approximation to f near $x = 0$ is $f(x) \approx f(0) + f'(0)(x - 0)$ which becomes $e^x \approx e^0 + e^0 x = 1 + 1x = 1 + x$. Thus, our local linearization of e^x near $x = 0$ is $e^x \approx 1 + x$.

3. With $f(x) = 1/x$, we see that the tangent line approximation to f near $x = 1$ is

$$f(x) \approx f(1) + f'(1)(x - 1),$$

which becomes

$$\frac{1}{x} \approx 1 + f'(1)(x - 1).$$

Since $f'(x) = -1/x^2$, $f'(1) = -1$. Thus our formula reduces to

$$\frac{1}{x} \approx 1 - (x - 1) = 2 - x.$$

This is the local linearization of $1/x$ near $x = 1$.

4. Since $f(1) = 1$ and we showed that $f'(1) = 2$, the local linearization is

$$f(x) \approx 1 + 2(x-1) = 2x - 1.$$

5. With $f(x) = e^{x^2}$, we get a tangent line approximation of $f(x) \approx f(1) + f'(1)(x-1)$ which becomes $e^{x^2} \approx e + \left(2xe^{x^2}\right)\Big|_{x=1}(x-1) = e + 2e(x-1) = 2ex - e$. Thus, our local linearization of e^{x^2} near $x = 1$ is $e^{x^2} \approx 2ex - e$.

6. With $f(x) = 1/(\sqrt{1+x})$, we see that the tangent line approximation to f near $x = 0$ is

$$f(x) \approx f(0) + f'(0)(x-0),$$

which becomes

$$\frac{1}{\sqrt{1+x}} \approx 1 + f'(0)x.$$

Since $f'(x) = (-1/2)(1+x)^{-3/2}$, $f'(0) = -1/2$. Thus our formula reduces to

$$\frac{1}{\sqrt{1+x}} \approx 1 - x/2.$$

This is the local linearization of $\dfrac{1}{\sqrt{1+x}}$ near $x = 0$.

7. Let $f(x) = e^{-x}$. Then $f'(x) = -e^{-x}$. So $f(0) = 1$, $f'(0) = -e^0 = -1$. Therefore, $e^{-x} \approx f(0) + f'(0)x = 1 - x$.

8. The graph of x^2 is concave up and lies above its tangent line; therefore, the linearization will always be too small. See Figure 3.13. The graph of $\sqrt{x}$ is concave down and lies below its tangent line, and therefore the linearization will be too large. See Figure 3.14.

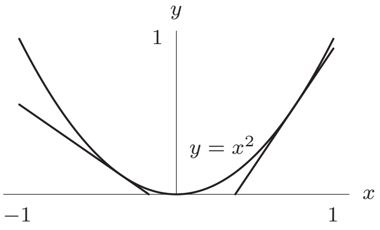

Figure 3.13

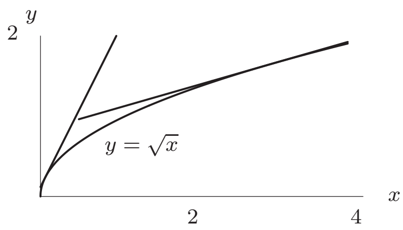

Figure 3.14

9. From Figure 3.15, we see that the error has its maximum magnitude at the end points of the interval, $x = \pm 1$. The magnitude of the error can be read off the graph as less than 0.2 or estimated as

$$|\text{Error}| \leq |1 - \sin 1| = 0.159 < 0.2.$$

The approximation is an overestimate for $x > 0$ and an underestimate for $x < 0$.

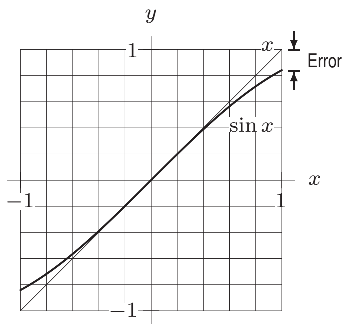

Figure 3.15

10. Figure 3.16 shows that $1 + x$ is an underestimate of e^x for $-1 \leq x \leq 1$. On this interval, the error has the largest magnitude at $x = 1$. Its magnitude can be estimated from the graph as less than 0.8, or estimated as

$$|\text{Error}| = e - 1 - 1 = 0.718 < 0.8.$$

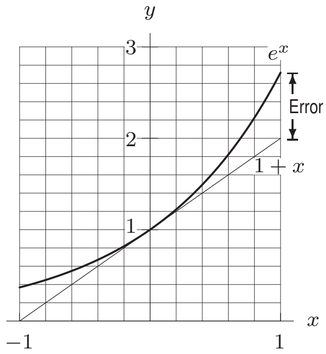

Figure 3.16

Problems

11. (a) If $f(x) = e^x$, then $f'(x) = e^x$, so $f'(0) = e^0 = 1$. Thus, the local linearization near $x = 0$ is

$$L(x) = f(0) + f'(0)(x - 0)$$
$$L(x) = 1 + x.$$

(b) Since the curve $f(x) = e^x$ is above the line $L(x) = 1 + x$ (see Figure 3.17), the error is positive everywhere except at $x = 0$, where it is 0.

(c) The true value of the function at $x = 1$ is $f(1) = e^1 = e = 2.718$. The approximation is $L(1) = 1 + 1 = 2$. The error is $E(1) = f(1) - L(1) = e - 2 = 0.718$. See Figure 3.17.

(d) We expect $E(1)$ to be larger than $E(0.1)$, because 0.1 is closer to $x = 0$, the point at which the linear approximation, $L(x)$, is exactly equal to the function, $f(x)$.

(e) We have

$$E(0.1) = f(0.1) - L(0.1) = e^{0.1} - (1 + 0.1) = 1.105 - 1.1 = 0.005.$$

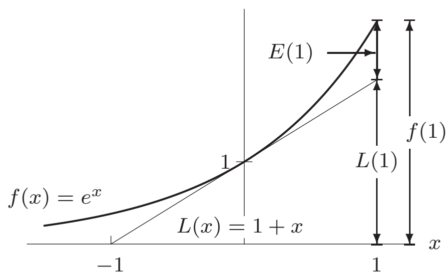

Figure 3.17

12. (a) Since

$$\frac{d}{dx}(\cos x) = -\sin x,$$

the slope of the tangent line is $-\sin(\pi/4) = -1/\sqrt{2}$. Since the tangent line passes through the point $(\pi/4, \cos(\pi/4)) = (\pi/4, 1/\sqrt{2})$, its equation is

$$y - \frac{1}{\sqrt{2}} = -\frac{1}{\sqrt{2}}\left(x - \frac{\pi}{4}\right)$$
$$y = -\frac{1}{\sqrt{2}}x + \frac{1}{\sqrt{2}}\left(\frac{\pi}{4} + 1\right).$$

Thus, the tangent line approximation to $\cos x$ is

$$\cos x \approx -\frac{1}{\sqrt{2}}x + \frac{1}{\sqrt{2}}\left(\frac{\pi}{4}+1\right).$$

(b) From Figure 3.18, we see that the tangent line approximation is an overestimate.

(c) From Figure 3.18, we see that the maximum error for $0 \le x \le \pi/2$ is either at $x = 0$ or at $x = \pi/2$. The error can either be estimated from the graph, or as follows. At $x = 0$,

$$|\text{Error}| = \left|\cos 0 - \frac{1}{\sqrt{2}}\left(\frac{\pi}{4}+1\right)\right| = 0.262 < 0.3.$$

At $x = \pi/2$,

$$|\text{Error}| = \left|\cos\frac{\pi}{2} + \frac{1}{\sqrt{2}}\frac{\pi}{2} - \frac{1}{\sqrt{2}}\left(\frac{\pi}{4}+1\right)\right| = 0.152 < 0.2.$$

Thus, for $0 \le x \le \pi/2$, we have

$$|\text{Error}| < 0.3.$$

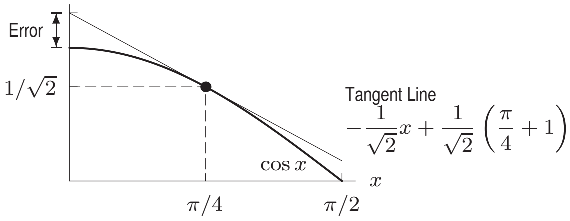

Figure 3.18

13. (a) See Figure 3.19.

(b) Since $f(2) = 2^3 - 3\cdot 2^2 + 3\cdot 2 + 1 = 3$, we have $f'(x) = 3x^2 - 6x + 3$, so $f'(2) = 3\cdot 2^2 - 6\cdot 2 + 3 = 3$, and the local linearization is $y = 3 + 3(x-2) = 3x - 3$.

(c) See Figure 3.19.

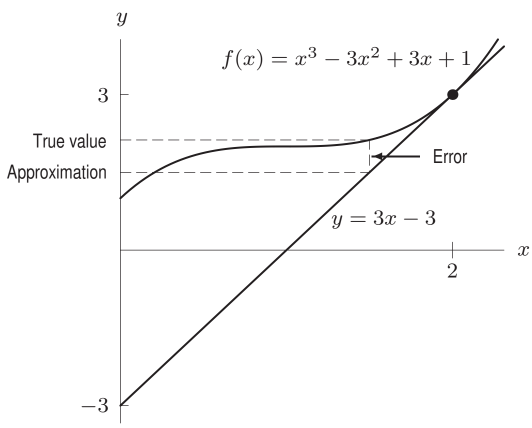

Figure 3.19

14. (a) Let $f(x) = (1+x)^k$. Then $f'(x) = k(1+x)^{k-1}$. Since

$$f(x) \approx f(0) + f'(0)(x-0)$$

is the tangent line approximation, and $f(0) = 1$, $f'(0) = k$, for small x we get

$$f(x) \approx 1 + kx.$$

(b) Since $\sqrt{1.1} = (1+0.1)^{1/2} \approx 1 + (1/2)0.1 = 1.05$ by the above method, this estimate is about right.

(c) The real answer is less than 1.05. Since $(1.05)^2 = (1+0.05)^2 = 1+2(1)(0.05)+(0.05)^2 = 1.1+(0.05)^2 > 1.1$, we have $(1.05)^2 > 1.1$ Therefore

$$\sqrt{1.1} < 1.05.$$

Graphically, this because the graph of $\sqrt{1+x}$ is concave down, so it bends below its tangent line. Therefore the true value ($\sqrt{1.1}$) which is on the curve is below the approximate value (1.05) which is on the tangent line.

15. Since the line meets the curve at $x = 1$, we have $a = 1$. Since the point with $x = 1$ lies on both the line and the curve, we have

$$f(a) = f(1) = 2 \cdot 1 - 1 = 1.$$

The approximation is an underestimate because the line lies under the curve. Since the linear function approximates $f(x)$, we have

$$f(1.2) \approx 2(1.2) - 1 = 1.4.$$

16. We have $f(x) = e^x + x$, so $f'(x) = e^x + 1$. Thus $f'(0) = 2$, so

$$\text{Local linearization near } x = 0 \qquad \text{is} \qquad f(x) \approx f(0) + f'(0)x = 1 + 2x.$$

We get an approximate solution using the local linearization instead of $f(x)$, so the equation becomes

$$1 + 2x = 2, \qquad \text{with solution} \qquad x = \frac{1}{2}.$$

A computer or calculator gives the actual solution as $x = 0.443$.

17. We have $f(x) = x + \ln(1+x)$, so $f'(x) = 1 + 1/(1+x)$. Thus $f'(0) = 2$ so

$$\text{Local linearization near } x = 0 \qquad \text{is} \qquad f(x) \approx f(0) + f'(0)x = 2x.$$

We get an approximate solution using the local linearization instead of $f(x)$, so the equation becomes

$$2x = 0.2, \qquad \text{with solution} \qquad x = 0.1.$$

A computer or calculator gives the actual value as $x = 0.102$.

18. (a) The line tangent to the graph of f at $x = 7$ is given by

$$\begin{aligned} y &= f(7) + f'(7)(x-7) \\ &= 13 - 0.38(x-7). \end{aligned}$$

We can use the tangent line to approximate the value of $f(7.1)$:

$$\begin{aligned} f(7.1) &\approx 13 - 0.38(7.1 - 7) \\ &= 13 - 0.38(0.1) \\ &= 12.962. \end{aligned}$$

(b) If $f''(x) < 0$, then the graph of f is everywhere concave down, so it lies below its tangent line. Thus, our tangent line approximation is an overestimate.

19. (a) Zooming in on the graphs of $y = e^t$ and $y = 0.02t + 1.098$ shows they cross just to the right of the origin. Numerically, we see that at $t = 0$

$$e^0 = 1 < 0.02 \cdot 0 + 1.098.$$

At $t = 0.2$, we have

$$e^{0.2} = 1.221 > 0.02 \cdot 2 + 1.098 = 1.102.$$

Therefore, somewhere between $t = 0$ and $t = 0.2$ the equation $e^t = 0.02t + 1.098$ has a solution.

(b) The linearization of e^t near 0 is $1 + t$, so the new equation is

$$\begin{aligned} 1 + t &= 0.02t + 1.098 \\ 0.98t &= 0.098 \\ t &= \frac{0.098}{0.98} = 0.1. \end{aligned}$$

20. We have

$$f(0) = 331.3$$
$$f'(T) = \frac{1}{2} \cdot 331.3 \left(1 + \frac{T}{273.15}\right)^{-1/2} \frac{1}{273.15}$$
$$f'(0) = 0.606.$$

Thus, for temperatures, T, near zero, we have

$$\text{Speed of sound} = f(T) \approx f(0) + f'(0)T = 331.3 + 0.606T \text{ meters/second.}$$

21. (a) See Figure 3.20.

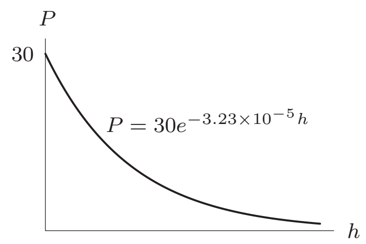

Figure 3.20

(b) Using the chain rule, we have

$$\frac{dP}{dh} = 30e^{-3.23\times 10^{-5}h}(-3.23 \times 10^{-5})$$

so

$$\left.\frac{dP}{dh}\right|_{h=0} = -30(3.23 \times 10^{-5}) = -9.69 \times 10^{-4}$$

Hence, at $h = 0$, the slope of the tangent line is -9.69×10^{-4}, so the equation of the tangent line is

$$y - 30 = (-9.69 \times 10^{-4})(h - 0)$$
$$y = (-9.69 \times 10^{-4})h + 30 = 30 - 0.000969h.$$

(c) The rule of thumb says

$$\begin{array}{c}\text{Drop in pressure from} \\ \text{sea level to height } h\end{array} = \frac{h}{1000}$$

But since the pressure at sea level is 30 inches of mercury, this drop in pressure is also $(30 - P)$, so

$$30 - P = \frac{h}{1000}$$

giving

$$P = 30 - 0.001h.$$

(d) The equations in (b) and (c) are almost the same: both have P intercepts of 30, and the slopes are almost the same $(9.69 \times 10^{-4} \approx 0.001)$. The rule of thumb calculates values of P which are very close to the tangent lines, and therefore yields values very close to the curve.

(e) The tangent line is slightly below the curve, and the rule of thumb line, having a slightly more negative slope, is slightly below the tangent line (for $h > 0$). Thus, the rule of thumb values are slightly smaller.

22. (a) The derivative gives the rate of change of the number of Android users. We estimate $A'(0)$ as the rate of change over the year:

$$A'(0) = \frac{10.9 - 0.866}{1} = 10.034 \text{ million users/year.}$$

(b) Similarly,

$$P'(0) = \frac{13.5 - 7.8}{1} = 5.7 \text{ million users/year.}$$

(c) Since $866{,}000 = 0.866$ million, the tangent line approximation to $A(t)$ near $t = 0$ is

$$A(t) \approx 0.866 + 10.034t.$$

The tangent line approximation for $P(t)$ is

$$P(t) \approx 7.8 + 5.7t.$$

The two groups of users are predicted to be the same size when

$$\begin{aligned} 0.866 + 10.034t &= 7.8 + 5.7t \\ 10.034t - 5.7t &= 7.8 - 0.866 \\ t &= \frac{7.8 - 0.866}{10.034 - 5.7} = 1.600 \text{ years.} \end{aligned}$$

Thus, Android and iPhones were predicted to have the same number of users 1.6 years after 2009; that is, in mid 2011.

(d) We are assuming that the rates of change of each group of users remain the same in the future.

23. (a) Suppose g is a constant and

$$T = f(l) = 2\pi\sqrt{\frac{l}{g}}.$$

Then

$$f'(l) = \frac{2\pi}{\sqrt{g}}\frac{1}{2}l^{-1/2} = \frac{\pi}{\sqrt{gl}}.$$

Thus, local linearity tells us that

$$f(l + \Delta l) \approx f(l) + \frac{\pi}{\sqrt{gl}}\Delta l.$$

Now $T = f(l)$ and $\Delta T = f(l + \Delta l) - f(l)$, so

$$\Delta T \approx \frac{\pi}{\sqrt{gl}}\Delta l = 2\pi\sqrt{\frac{l}{g}} \cdot \frac{1}{2}\frac{\Delta l}{l} = \frac{T}{2}\frac{\Delta l}{l}.$$

(b) Knowing that the length of the pendulum increases by 2% tells us that

$$\frac{\Delta l}{l} = 0.02.$$

Thus,

$$\Delta T \approx \frac{T}{2}(0.02) = 0.01T.$$

So

$$\frac{\Delta T}{T} \approx 0.01.$$

Thus, T increases by 1%.

24. (a) Considering l as a constant, we have

$$T = f(g) = 2\pi\sqrt{\frac{l}{g}}.$$

Then,

$$f'(g) = 2\pi\sqrt{l}\left(-\frac{1}{2}g^{-3/2}\right) = -\pi\sqrt{\frac{l}{g^3}}.$$

Thus, local linearity gives

$$f(g + \Delta g) \approx f(g) - \pi\sqrt{\frac{l}{g^3}}(\Delta g).$$

Since $T = f(g)$ and $\Delta T = f(g + \Delta g) - f(g)$, we have

$$\begin{aligned} \Delta T &\approx -\pi\sqrt{\frac{l}{g^3}}\Delta g = -2\pi\sqrt{\frac{l}{g}}\frac{\Delta g}{2g} = \frac{-T}{2}\frac{\Delta g}{g}. \\ \Delta T &\approx \frac{-T}{2}\frac{\Delta g}{g}. \end{aligned}$$

(b) If g increases by 1%, we know

$$\frac{\Delta g}{g} = 0.01.$$

Thus,

$$\frac{\Delta T}{T} \approx -\frac{1}{2}\frac{\Delta g}{g} = -\frac{1}{2}(0.01) = -0.005,$$

So, T decreases by 0.5%.

25. Since f has a positive second derivative, its graph is concave up, as in Figure 3.21 or 3.22. This means that the graph of $f(x)$ is above its tangent line. We see that in both cases

$$f(1+\Delta x) \geq f(1) + f'(1)\Delta x.$$

(The diagrams show Δx positive, but the result is also true if Δx is negative.)

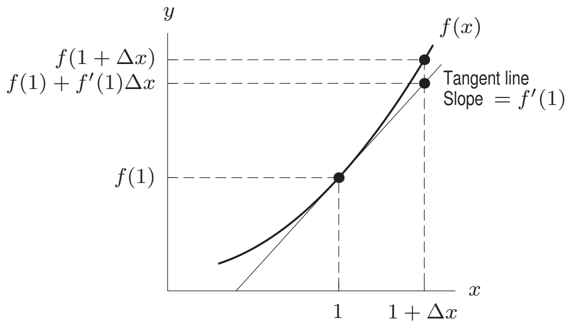

Figure 3.21

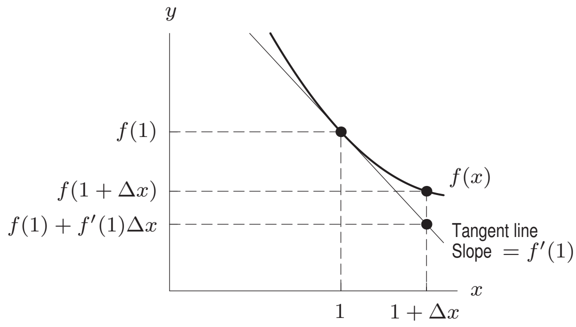

Figure 3.22

26. (a) Since f' is decreasing, $f'(5)$ is larger.
(b) Since f' is decreasing, its derivative, f'', is negative. Thus, $f''(5)$ is negative, so 0 is larger.
(c) Since $f''(x)$ is negative for all x, the graph of f is concave down. Thus the graph of $f(x)$ is below its tangent line. From Figure 3.23, we see that $f(5+\Delta x)$ is below $f(5) + f'(5)\Delta x$. Thus, $f(5) + f'(5)\Delta x$ is larger.

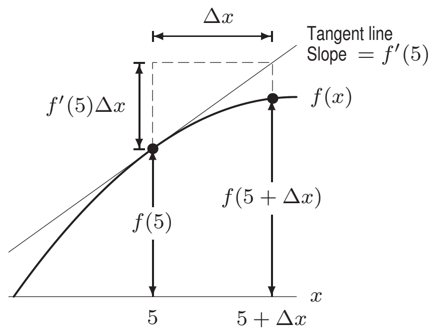

Figure 3.23

27. (a) The range is $f(20) = 16{,}398$ meters.
(b) We have

$$f'(\theta) = \frac{\pi}{90} 25510 \cos \frac{\pi\theta}{90}$$
$$f'(20) = 682.$$

Thus, for angles, θ, near 20°, we have

$$\text{Range} = f(\theta) \approx f(20) + f'(20)(\theta - 20) = 16398 + 682(\theta - 20) \text{ meters}.$$

(c) The true range for 21° is $f(21) = 17{,}070$ meters. The linear approximation gives

$$\text{Approximate range} = 16398 + 682(21 - 20) = 17080 \text{ meters}$$

which is a little too high.

28. (a) The time in the air is $t(20) = 34.9$ seconds
(b) We have

$$t'(\theta) = \frac{\pi}{180} 102 \cos\frac{\pi\theta}{180}$$
$$t'(20) = 1.67$$

Thus, for angles, θ, near 20°, we have

$$\text{Time in air} = t(\theta) \approx t(20) + t'(20)(\theta - 20) = 34.9 + 1.67(\theta - 20) \text{ seconds}.$$

(c) The true air time for 21° is $t(21) = 36.6$ seconds. The linear approximation gives

$$\text{Approximate peak altitude} = 34.9 + 1.67(21 - 20) = 36.6 \text{ seconds}$$

which is the correct value to three significant figures.

29. (a) The peak altitude is $h(20) = 1492$ meters
(b) We have

$$h'(\theta) = 2 \cdot \frac{\pi}{180} 12755 \sin\frac{\pi\theta}{180}\cos\frac{\pi\theta}{180}$$
$$h'(20) = 143.$$

Thus, for angles, θ, near 20°, we have

$$\text{Peak altitude} = h(\theta) \approx h(20) + h'(20)(\theta - 20) = 1490 + 143(\theta - 20) \text{ meters}.$$

(c) The true peak altitude for 21° is $h(21) = 1638$ meters. The linear approximation gives

$$\text{Approximate peak altitude} = 1492 + 143(21 - 20) = 1635 \text{ meters}$$

which is a little too low.

30. We have $f(x) = (1+x)^r$, so $f'(x) = r(1+x)^{r-1}$. Thus $f'(0) = r$ so the local linearization near $x = 0$ is

$$f(x) \approx f(0) + f'(0)x = 1 + rx.$$

Thus

$$(1+x)^r \approx 1 + rx \quad \text{for small values of } x.$$

Using the linearization with $r = 3/5$ and $x = 0.2$, we have

$$1.2^{3/5} = 1 + \frac{3}{5}0.2 = 1 + 0.12 = 1.12.$$

The actual value is $1.2^{3/5} = 1.117$.

31. We have $f(x) = e^{kx}$, so $f'(x) = ke^{kx}$. Thus $f'(0) = k$ so the local linearization near $x = 0$ is

$$f(x) \approx f(0) + f'(0)x = 1 + kx.$$

Thus

$$e^{kx} \approx 1 + kx \quad \text{for small values of } x.$$

Using the linearization with $k = 0.3$ and $x = 1$, we have

$$e^{0.3} \approx 1 + 0.3 = 1.3$$

The actual value is $e^{0.3} = 1.350$.

32. We have $f(x) = (b^2 + x)^{1/2}$, so $f'(x) = (1/2)(b^2 + x)^{-1/2}$. Thus $f'(0) = 1/(2b)$ so the local linearization near $x = 0$ is

$$f(x) \approx f(0) + f'(0)x = b + \frac{1}{2b}x.$$

Thus

$$\sqrt{b^2 + x} \approx b + \frac{1}{2b}x \quad \text{for small values of } x.$$

Using the linearization with $b = 5$ and $x = 1$, we have

$$\sqrt{26} \approx 5 + \frac{1}{10}1 = 5.1.$$

The actual value is $\sqrt{26} = 5.099$.

33. We have $f(1) = 1$ and $f'(1) = 4$. Thus

$$E(x) = x^4 - (1 + 4(x - 1)).$$

Values of $E(x)/(x - 1)$ near $x = 1$ are in Table 3.3.

Table 3.3

x	1.1	1.01	1.001
$E(x)/(x-1)$	0.641	0.060401	0.006004

From the table, we can see that

$$\frac{E(x)}{(x-1)} \approx 6(x - 1),$$

so $k = 6$ and

$$E(x) \approx 6(x - 1)^2.$$

In addition, $f''(1) = 12$, so

$$E(x) \approx 6(x - 1)^2 = \frac{f''(1)}{2}(x - 1)^2.$$

The same result can be obtained by rewriting the function x^4 using $x = 1 + (x - 1)$ and expanding:

$$x^4 = (1 + (x - 1))^4 = 1 + 4(x - 1) + 6(x - 1)^2 + 4(x - 1)^3 + (x - 1)^4.$$

Thus,

$$E(x) = x^4 - (1 + 4(x - 1)) = 6(x - 1)^2 + 4(x - 1)^3 + (x - 1)^4.$$

For x near 1, the value of $x - 1$ is small, so we ignore powers of $x - 1$ higher than the first, giving

$$E(x) \approx 6(x - 1)^2.$$

34. We have $f(0) = 1$ and $f'(0) = 0$. Thus

$$E(x) = \cos x - 1.$$

Values for $E(x)/(x - 0)$ near $x = 0$ are in Table 3.4.

Table 3.4

x	0.1	0.01	0.001
$E(x)/(x-0)$	-0.050	-0.0050	-0.00050

From the table, we can see that

$$\frac{E(x)}{(x-0)} \approx -0.5(x - 0),$$

so $k = -1/2$ and

$$E(x) \approx -\frac{1}{2}(x - 0)^2 = -\frac{1}{2}x^2.$$

In addition, $f''(0) = -1$, so

$$E(x) \approx -\frac{1}{2}x^2 = \frac{f''(0)}{2}x^2.$$

35. We have $f(0) = 1$ and $f'(0) = 1$. Thus

$$E(x) = e^x - (1 + x).$$

Values of $E(x)/(x - 0)$ near $x = 0$ are in Table 3.5.

Table 3.5

x	0.1	0.01	0.001
$E(x)/(x-0)$	0.052	0.0050	0.00050

From the table, we can see that

$$\frac{E(x)}{(x-0)} \approx 0.5(x - 0)$$

so $k = 1/2$ and

$$E(x) \approx \frac{1}{2}(x-0)^2 = \frac{1}{2}x^2.$$

In addition, $f''(0) = 1$, so

$$E(x) \approx \frac{1}{2}x^2 = \frac{f''(0)}{2}x^2$$

36. We have $f(1) = 1$ and $f'(1) = 1/2$. Thus

$$E(x) = \sqrt{x} - (1 + \frac{1}{2}(x - 1)).$$

Values of $E(x)/(x - 1)$ near $x = 1$ are in Table 3.6.

Table 3.6

x	1.1	1.01	1.001
$E(x)/(x-1)$	−0.0119	−0.00124	−0.000125

From the table, we can see that

$$\frac{E(x)}{(x-1)} \approx -0.125(x - 1)$$

so $k = -1/8$ and

$$E(x) \approx -\frac{1}{8}(x-1)^2.$$

In addition, $f''(1) = -1/4$, so

$$E(x) \approx -\frac{1}{8}(x-1)^2 = \frac{f''(1)}{2}(x-1)^2.$$

37. We have $f(1) = 0$ and $f'(1) = 1$. Thus

$$E(x) = \ln x - (x - 1).$$

Values of $E(x)/(x - 1)$ near $x = 1$ are in Table 3.7.

Table 3.7

x	1.1	1.01	1.001
$E(x)/(x-1)$	−0.047	−0.0050	−0.00050

From the table, we see that

$$\frac{E(x)}{(x-1)} \approx -0.5(x - 1),$$

so $k = -1/2$ and

$$E(x) \approx -\frac{1}{2}(x-1)^2.$$

In addition, $f''(1) = -1$, so

$$E(x) \approx -\frac{1}{2}(x-1)^2 = \frac{f''(1)}{2}(x-1)^2.$$

38. The local linearization of e^x near $x = 0$ is $1 + 1x$ so

$$e^x \approx 1 + x.$$

Squaring this yields, for small x,

$$e^{2x} = (e^x)^2 \approx (1 + x)^2 = 1 + 2x + x^2.$$

Local linearization of e^{2x} directly yields

$$e^{2x} \approx 1 + 2x$$

for small x. The two approximations are consistent because they agree: the tangent line approximation to $1 + 2x + x^2$ is just $1 + 2x$.

The first approximation is more accurate. One can see this numerically or by noting that the approximation for e^{2x} given by $1 + 2x$ is really the same as approximating e^y at $y = 2x$. Since the other approximation approximates e^y at $y = x$, which is twice as close to 0 and therefore a better general estimate, it's more likely to be correct.

39. (a) Let $f(x) = 1/(1+x)$. Then $f'(x) = -1/(1+x)^2$ by the chain rule. So $f(0) = 1$, and $f'(0) = -1$. Therefore, for x near 0, $1/(1 + x) \approx f(0) + f'(0)x = 1 - x$.

(b) We know that for small y, $1/(1 + y) \approx 1 - y$. Let $y = x^2$; when x is small, so is $y = x^2$. Hence, for small x, $1/(1 + x^2) \approx 1 - x^2$.

(c) Since the linearization of $1/(1 + x^2)$ is the line $y = 1$, and this line has a slope of 0, the derivative of $1/(1 + x^2)$ is zero at $x = 0$.

40. The local linearizations of $f(x) = e^x$ and $g(x) = \sin x$ near $x = 0$ are

$$f(x) = e^x \approx 1 + x$$

and

$$g(x) = \sin x \approx x.$$

Thus, the local linearization of $e^x \sin x$ is the local linearization of the product:

$$e^x \sin x \approx (1 + x)x = x + x^2 \approx x.$$

We therefore know that the derivative of $e^x \sin x$ at $x = 0$ must be 1. Similarly, using the local linearization of $1/(1 + x)$ near $x = 0$, $1/(1 + x) \approx 1 - x$, we have

$$\frac{e^x \sin x}{1+x} = (e^x)(\sin x)\left(\frac{1}{1+x}\right) \approx (1 + x)(x)(1 - x) = x - x^3$$

so the local linearization of the triple product $\dfrac{e^x \sin x}{1+x}$ at $x = 0$ is simply x. And therefore the derivative of $\dfrac{e^x \sin x}{1+x}$ at $x = 0$ is 1.

41. Note that

$$[f(x)g(x)]' = \lim_{h\to 0} \frac{f(x + h)g(x + h) - f(x)g(x)}{h}.$$

We use the hint: For small h, $f(x + h) \approx f(x) + f'(x)h$, and $g(x + h) \approx g(x) + g'(x)h$. Therefore

$$\begin{aligned} f(x + h)g(x + h) - f(x)g(x) &\approx [f(x) + hf'(x)][g(x) + hg'(x)] - f(x)g(x) \\ &= f(x)g(x) + hf'(x)g(x) + hf(x)g'(x) \\ &\quad + h^2 f'(x)g'(x) - f(x)g(x) \\ &= hf'(x)g(x) + hf(x)g'(x) + h^2 f'(x)g'(x). \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{h\to 0} \frac{f(x + h)g(x + h) - f(x)g(x)}{h} &= \lim_{h\to 0} \frac{hf'(x)g(x) + hf(x)g'(x) + h^2 f'(x)g'(x)}{h} \\ &= \lim_{h\to 0} \frac{h\left(f'(x)g(x) + f(x)g'(x) + hf'(x)g'(x)\right)}{h} \\ &= \lim_{h\to 0} \left(f'(x)g(x) + f(x)g'(x) + hf'(x)g'(x)\right) \\ &= f'(x)g(x) + f(x)g'(x). \end{aligned}$$

A more complete derivation can be given using the error term discussed in the section on Differentiability and Linear Approximation in Chapter 2. Adapting the notation of that section to this problem, we write

$$f(x+h) = f(x) + f'(x)h + E_f(h) \quad \text{and} \quad g(x+h) = g(x) + g'(x)h + E_g(h),$$

where $\lim_{h\to 0} \frac{E_f(h)}{h} = \lim_{h\to 0} \frac{E_g(h)}{h} = 0$. (This implies that $\lim_{h\to 0} E_f(h) = \lim_{h\to 0} E_g(h) = 0$.)

We have

$$\begin{aligned}\frac{f(x+h)g(x+h) - f(x)g(x)}{h} &= \frac{f(x)g(x)}{h} + f(x)g'(x) + f'(x)g(x) + f(x)\frac{E_g(h)}{h} + g(x)\frac{E_f(h)}{h} \\ &\quad + f'(x)g'(x)h + f'(x)E_g(h) + g'(x)E_f(h) + \frac{E_f(h)E_g(h)}{h} - \frac{f(x)g(x)}{h}\end{aligned}$$

The terms $f(x)g(x)/h$ and $-f(x)g(x)/h$ cancel out. All the remaining terms on the right, with the exception of the second and third terms, go to zero as $h \to 0$. Thus, we have

$$[f(x)g(x)]' = \lim_{h\to 0} \frac{f(x+h)g(x+h) - f(x)g(x)}{h} = f(x)g'(x) + f'(x)g(x).$$

42. Note that

$$[f(g(x))]' = \lim_{h\to 0} \frac{f(g(x+h)) - f(g(x))}{h}.$$

Using the local linearizations of f and g, we get that

$$\begin{aligned} f(g(x+h)) - f(g(x)) &\approx f\left(g(x) + g'(x)h\right) - f(g(x)) \\ &\approx f(g(x)) + f'(g(x))g'(x)h - f(g(x)) \\ &= f'(g(x))g'(x)h. \end{aligned}$$

Therefore,

$$\begin{aligned}[f(g(x))]' &= \lim_{h\to 0} \frac{f(g(x+h)) - f(g(x))}{h} \\ &= \lim_{h\to 0} \frac{f'(g(x))g'(x)h}{h} \\ &= \lim_{h\to 0} f'(g(x))g'(x) = f'(g(x))g'(x).\end{aligned}$$

A more complete derivation can be given using the error term discussed in the section on Differentiability and Linear Approximation in Chapter 2. Adapting the notation of that section to this problem, we write

$$f(z+k) = f(z) + f'(z)k + E_f(k) \quad \text{and} \quad g(x+h) = g(x) + g'(x)h + E_g(h),$$

where $\lim_{h\to 0} \frac{E_g(h)}{h} = \lim_{k\to 0} \frac{E_f(k)}{k} = 0$.

Now we let $z = g(x)$ and $k = g(x+h) - g(x)$. Then we have $k = g'(x)h + E_g(h)$. Thus,

$$\begin{aligned}\frac{f(g(x+h)) - f(g(x))}{h} &= \frac{f(z+k) - f(z)}{h} \\ &= \frac{f(z) + f'(z)k + E_f(k) - f(z)}{h} = \frac{f'(z)k + E_f(k)}{h} \\ &= \frac{f'(z)g'(x)h + f'(z)E_g(h)}{h} + \frac{E_f(k)}{k}\cdot\left(\frac{k}{h}\right) \\ &= f'(z)g'(x) + \frac{f'(z)E_g(h)}{h} + \frac{E_f(k)}{k}\left[\frac{g'(x)h + E_g(h)}{h}\right] \\ &= f'(z)g'(x) + \frac{f'(z)E_g(h)}{h} + \frac{g'(x)E_f(k)}{k} + \frac{E_g(h)\cdot E_f(k)}{h\cdot k}\end{aligned}$$

Now, if $h \to 0$ then $k \to 0$ as well, and all the terms on the right except the first go to zero, leaving us with the term $f'(z)g'(x)$. Substituting $g(x)$ for z, we obtain

$$[f(g(x))]' = \lim_{h\to 0} \frac{f(g(x+h)) - f(g(x))}{h} = f'(g(x))g'(x).$$

43. We want to show that

$$\lim_{x\to a}\frac{f(x)-f(a)}{x-a}=L.$$

Substituting for $f(x)$ we have

$$\begin{aligned}\lim_{x\to a}\frac{f(x)-f(a)}{x-a}&=\lim_{x\to a}\frac{f(a)+L(x-a)+E_L(x)-f(a)}{x-a}\\&=\lim_{x\to a}\left(L+\frac{E_L(x)}{x-a}\right)=L+\lim_{x\to 0}\frac{E_L(x)}{x-a}=L.\end{aligned}$$

Thus, we have shown that f is differentiable at $x=a$ and that its derivative is L, that is, $f'(a)=L$.

44. We know that the local linearization is $y=2x-1$. The fact that $f(x)$ is differentiable tells us that

$$\lim_{x\to 0}\frac{E(x)}{x-1}=\lim_{x\to 0}\frac{x^2-(2x-1)}{x-1}=0.$$

Suppose we take $\epsilon=1/10$, then there is a δ such that

$$\left|\frac{x^2-(2x-1)}{x-1}\right|<\frac{1}{10}\quad\text{for all}\quad |x-1|<\delta.$$

Thus

$$-\frac{1}{10}(x-1)<x^2-(2x-1)<\frac{1}{10}(x-1)\quad\text{for all}\quad 1-\delta<x<1+\delta.$$

To find this δ, we observe that

$$\left|\frac{x^2-(2x-1)}{x-1}\right|=\left|\frac{x^2-2x+1}{x-1}\right|=\left|\frac{(x-1)^2}{x-1}\right|=|x-1|.$$

Therefore we can take $\delta=1/10$. Then

$$\left|\frac{x^2-(2x-1)}{x-1}\right|<\frac{1}{10}\quad\text{for all}\quad |x-1|<\frac{1}{10}$$

so

$$-\frac{1}{10}(x-1)<|x^2-(2x-1)|<\frac{1}{10}(x-1).$$

Strengthen Your Understanding

45. The line $y=x+1$ is the linear approximation for $f(x)=e^x$ near $x=0$. If we move far from $x=0$, the approximation is useless.

For example, for $x=1$, the approximation gives $e^1\approx 2$ (instead of 2.718). For $x=2$, our estimate of 3 is not a good approximation for $e^2=7.389$.

This linear approximation is only useful near $x=0$.

46. The graph of F is concave down to the left of $x=0$ and concave up to the right. The tangent at $x=0$ lies beneath the graph for $x>0$ and above the graph for $x<0$. Thus, the linear approximation near $x=0$ is an overestimate for values less than zero and an underestimate for values greater than zero.

47. In order to have the same linear approximation, two functions f and g must go through the same point at $x=0$ and have the same slope at $x=0$. Thus, $f(0)=g(0)$ and $f'(0)=g'(0)$. While there are many answers, let $f(x)=x^3+1$ and $g(x)=x^4+1$. Then the linear approximation for both functions near $x=0$ is $y=1$.

48. One possible answer is $g(x)=\cos x$.

49. The linear approximation of a function f, for values of x near a, is given by $f(x)\approx f(a)+f'(a)(x-a)$. Since $f(x)=|x+1|$ does not have a derivative at $x=-1$ this function does not have a linear approximation for x near -1. Other answers are possible.

50. (a) False. Only if $k=f'(a)$ is L the local linearization of f.
(b) False. Since $f(a)=L(a)$ for any k, we have $\lim_{x\to a}(f(x)-L(x))=f(a)-L(a)=0$, but only if $k=f'(a)$ is L the local linearization of f.

Solutions for Section 3.10

Exercises

1. False. The derivative, $f'(x)$, is not equal to zero everywhere, because the function is not continuous at integral values of x, so $f'(x)$ does not exist there. Thus, the Constant Function Theorem does not apply.

2. True. If f' is positive on $[a, b]$, then f is continuous and the Increasing Function Theorem applies. Thus, f is increasing on $[a, b]$, so $f(a) < f(b)$.

3. False. Let $f(x) = x^3$ on $[-1, 1]$. Then $f(x)$ is increasing but $f'(x) = 0$ for $x = 0$.

4. False. The horse that wins the race may have been moving faster for some, but not all, of the race. The Racetrack Principle guarantees the converse—that if the horses start at the same time and one moves faster throughout the race, then that horse wins.

5. True. If $g(x)$ is the position of the slower horse at time x and $h(x)$ is the position of the faster, then $g'(x) \le h'(x)$ for $a < x < b$. Since the horses start at the same time, $g(a) = h(a)$, so, by the Racetrack Principle, $g(x) \le h(x)$ for $a \le x \le b$. Therefore, $g(b) \le h(b)$, so the slower horse loses the race.

6. Yes, it satisfies the hypotheses and the conclusion. This function has two points, c, at which the tangent to the curve is parallel to the secant joining $(a, f(a))$ to $(b, f(b))$, but this does not contradict the Mean Value Theorem. The function is continuous and differentiable on the interval $[a, b]$.

7. No, it does not satisfy the hypotheses. The function does not appear to be differentiable. There appears to be no tangent line, and hence no derivative, at the "corner."

No, it does not satisfy the conclusion as there is no horizontal tangent.

8. No. This function does not satisfy the hypotheses of the Mean Value Theorem, as it is not continuous.

However, the function has a point c such that

$$f'(c) = \frac{f(b) - f(a)}{b - a}.$$

Thus, this satisfies the conclusion of the theorem.

9. No, it does not satisfy the hypotheses. This function does not appear to be continuous.

No, it does not satisfy the conclusion as there is no horizontal tangent.

Problems

10. The Mean Value Theorem tells us that

$$f'(4) = \frac{f(b) - f(a)}{b - a} = \frac{9 - 5}{7 - 2} = \frac{4}{5}.$$

Thus, the slope of the tangent line is $4/5$. Its equation is

$$y = b + \frac{4}{5}x.$$

Substituting $x = 4, y = 8$ gives

$$\begin{aligned} 8 &= b + \frac{4}{5}(4) \\ \frac{24}{5} &= b. \end{aligned}$$

Thus, the tangent line is

$$y = \frac{24}{5} + \frac{4}{5}x.$$

11. The Mean Value Theorem tells us that

$$f'(c) = \frac{f(b) - f(a)}{b - a} = \frac{7 - 12}{13 - 3} = -0.5.$$

Since the slope at x_1 is negative but less steep than at c, we have

$$f'(x_1) > -0.5.$$

The slope at x_2 is negative and steeper than at c. Thus

$$f'(x_2) < -0.5.$$

12. We notice that $f(x) = p'(x)$. We have

$$p(1) = 1^5 + 8 \cdot 1^4 - 30 \cdot 1^3 + 30 \cdot 1^2 - 31 \cdot 1 + 22 = 0.$$
$$p(2) = 2^5 + 8 \cdot 2^4 - 30 \cdot 2^3 + 30 \cdot 2^2 - 31 \cdot 2 + 22 = 0.$$

Thus, by Rolle's Theorem, $f(x)$ has a zero between $x = 1$ and $x = 2$.

13. A polynomial $p(x)$ satisfies the conditions of Rolle's Theorem for all intervals $a \leq x \leq b$.

Suppose $a_1, a_2, a_3, a_4, a_5, a_6, a_7$ are the seven distinct zeros of $p(x)$ in increasing order. Thus $p(a_1) = p(a_2) = 0$, so by Rolle's Theorem, $p'(x)$ has a zero, c_1, between a_1 and a_2.

Similarly, $p'(x)$ has 6 distinct zeros, $c_1, c_2, c_3, c_4, c_5, c_6$, where

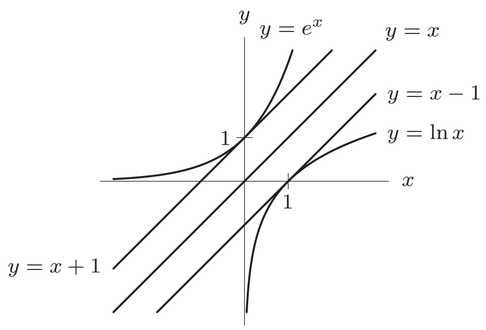
$$a_1 < c_1 < a_2$$
$$a_2 < c_2 < a_3$$
$$a_3 < c_3 < a_4$$
$$a_4 < c_4 < a_5$$
$$a_5 < c_5 < a_6$$
$$a_6 < c_6 < a_7.$$

The polynomial $p'(x)$ is of degree 6, so $p'(x)$ cannot have more than 6 zeros.

14. Let $f(x) = \sin x$ and $g(x) = x$. Then $f(0) = 0$ and $g(0) = 0$. Also $f'(x) = \cos x$ and $g'(x) = 1$, so for all $x \geq 0$ we have $f'(x) \leq g'(x)$. So the graphs of f and g both go through the origin and the graph of f climbs slower than the graph of g. Thus the graph of f is below the graph of g for $x \geq 0$ by the Racetrack Principle. In other words, $\sin x \leq x$ for $x \geq 0$.

15. Let $g(x) = \ln x$ and $h(x) = x - 1$. For $x \geq 1$, we have $g'(x) = 1/x \leq 1 = h'(x)$. Since $g(1) = h(1)$, the Racetrack Principle with $a = 1$ says that $g(x) \leq h(x)$ for $x \geq 1$, that is, $\ln x \leq x - 1$ for $x \geq 1$. For $0 < x \leq 1$, we have $h'(x) = 1 \leq 1/x = g'(x)$. Since $g(1) = h(1)$, the Racetrack Principle with $b = 1$ says that $g(x) \leq h(x)$ for $0 < x \leq 1$, that is, $\ln x \leq x - 1$ for $0 < x \leq 1$.

16.



Graphical solution: If f and g are inverse functions then the graph of g is just the graph of f reflected through the line $y = x$. But e^x and $\ln x$ are inverse functions, and so are the functions $x + 1$ and $x - 1$. Thus the equivalence is clear from the figure.

Algebraic solution: If $x > 0$ and

$$x + 1 \leq e^x,$$

then, replacing x by $x - 1$, we have

$$x \leq e^{x-1}.$$

Taking logarithms, and using the fact that $\ln$ is an increasing function, gives

$$\ln x \leq x - 1.$$

We can also go in the opposite direction, which establishes the equivalence.

17. The Decreasing Function Theorem is: Suppose that f is continuous on $[a, b]$ and differentiable on (a, b). If $f'(x) < 0$ on (a, b), then f is decreasing on $[a, b]$. If $f'(x) \leq 0$ on (a, b), then f is nonincreasing on $[a, b]$.

To prove the theorem, we note that if f is decreasing then $-f$ is increasing and vice-versa. Similarly, if f is nonincreasing, then $-f$ is nondecreasing. Thus if $f'(x) < 0$, then $-f'(x) > 0$, so $-f$ is increasing, which means f is decreasing. And if $f'(x) \leq 0$, then $-f'(x) \geq 0$, so $-f$ is nondecreasing, which means f is nonincreasing.

18. Dominic's trip lasted 88 minutes, so his average velocity for the trip was $116/88$ miles per minute, or $116/88 \cdot 60 \approx 79.1$ miles per hour. By the Mean Value Theorem, there must have been some time at which Dominic's instantaneous velocity was 79.1 miles per hour. Since the speed limit on I-10 between Phoenix and Tucson is never more than 75 miles per hour, Dominic must have been speeding at that time.

19. Use the Racetrack Principle, Theorem 3.10, with $g(x) = x$. Since $f'(x) \leq g'(x)$ for all x and $f(0) = g(0)$, then $f(x) \leq g(x) = x$ for all $x \geq 0$.

20. First apply the Racetrack Principle, Theorem 3.10, to $f'(t)$ and $g(t) = 3t$. Since $f''(t) \leq g'(t)$ for all t and $f'(0) = 0 = g(0)$, then $f'(t) \leq 3t$ for all $t \geq 0$. Next apply the Racetrack Principle again to $f(t)$ and $h(t) = \frac{3}{2}t^2$. Since $f'(t) \leq h'(t)$ for all $t \geq 0$ and $f(0) = 0 = h(0)$, then $f(t) \leq h(t) = \frac{3}{2}t^2$ for all $t \geq 0$.

21. Apply the Constant Function Theorem, Theorem 3.9, to $h(x) = f(x) - g(x)$. Then $h'(x) = 0$ for all x, so $h(x)$ is constant for all x. Since $h(5) = f(5) - g(5) = 0$, we have $h(x) = 0$ for all x. Therefore $f(x) - g(x) = 0$ for all x, so $f(x) = g(x)$ for all x.

22. By the Mean Value Theorem, Theorem 3.7, there is a number c, with $0 < c < 1$, such that

$$f'(c) = \frac{f(1) - f(0)}{1 - 0}.$$

Since $f(1) - f(0) > 0$, we have $f'(c) > 0$.

Alternatively if $f'(c) \leq 0$ for all c in $(0, 1)$, then by the Increasing Function Theorem, $f(0) \geq f(1)$.

23. Since $f''(t) \leq 7$ for $0 \leq t \leq 2$, if we apply the Racetrack Principle with $a = 0$ to the functions $f'(t) - f'(0)$ and $7t$, both of which go through the origin, we get

$$f'(t) - f'(0) \leq 7t \quad \text{for } 0 \leq t \leq 2.$$

The left side of this inequality is the derivative of $f(t) - f'(0)t$, so if we apply the Racetrack Principle with $a = 0$ again, this time to the functions $f(t) - f'(0)t$ and $(7/2)t^2 + 3$, both of which have the value 3 at $t = 0$, we get

$$f(t) - f'(0)t \leq \frac{7}{2}t^2 + 3 \quad \text{for } 0 \leq t \leq 2.$$

That is,

$$f(t) \leq 3 + 4t + \frac{7}{2}t^2 \quad \text{for } 0 \leq t \leq 2.$$

In the same way, we can show that the lower bound on the acceleration, $5 \leq f''(t)$ leads to:

$$f(t) \geq 3 + 4t + \frac{5}{2}t^2 \quad \text{for } 0 \leq t \leq 2.$$

If we substitute $t = 2$ into these two inequalities, we get bounds on the position at time 2:

$$21 \leq f(2) \leq 25.$$

24. Consider the function $f(x) = h(x) - g(x)$. Since $f'(x) = h'(x) - g'(x) \geq 0$, we know that f is nondecreasing by the Increasing Function Theorem. This means $f(x) \leq f(b)$ for $a \leq x \leq b$. However, $f(b) = h(b) - g(b) = 0$, so $f(x) \leq 0$, which means $h(x) \leq g(x)$.

25. If $f'(x) = 0$, then both $f'(x) \geq 0$ and $f'(x) \leq 0$. By the Increasing and Decreasing Function Theorems, f is both nondecreasing and nonincreasing, so f is constant.

26. Let $h(x) = f(x) - g(x)$. Then $h'(x) = f'(x) - g'(x) = 0$ for all x in (a, b). Hence, by the Constant Function Theorem, there is a constant C such that $h(x) = C$ on (a, b). Thus $f(x) = g(x) + C$.

27. We will show $f(x) = Ce^x$ by deducing that $f(x)/e^x$ is a constant. By the Constant Function Theorem, we need only show the derivative of $g(x) = f(x)/e^x$ is zero. By the quotient rule (since $e^x \neq 0$), we have

$$g'(x) = \frac{f'(x)e^x - e^x f(x)}{(e^x)^2}.$$

Since $f'(x) = f(x)$, we simplify and obtain

$$g'(x) = \frac{f(x)e^x - e^x f(x)}{(e^x)^2} = \frac{0}{e^{2x}} = 0,$$

which is what we needed to show.

28. Apply the Racetrack Principle to the functions $f(x) - f(a)$ and $M(x-a)$; we can do this since $f(a) - f(a) = M(a-a)$ and $f'(x) \leq M$. We conclude that $f(x) - f(a) \leq M(x-a)$. Similarly, apply the Racetrack Principle to the functions $m(x-a)$ and $f(x) - f(a)$ to obtain $m(x-a) \leq f(x) - f(a)$. If we substitute $x = b$ into these inequalities we get

$$m(b-a) \leq f(b) - f(a) \leq M(b-a).$$

Now, divide by $b - a$.

29. (a) Since $f''(x) \geq 0$, $f'(x)$ is nondecreasing on (a, b). Thus $f'(c) \leq f'(x)$ for $c \leq x < b$ and $f'(x) \leq f'(c)$ for $a < x \leq c$.

(b) Let $g(x) = f(c) + f'(c)(x-c)$ and $h(x) = f(x)$. Then $g(c) = f(c) = h(c)$, and $g'(x) = f'(c)$ and $h'(x) = f'(x)$. If $c \leq x < b$, then $g'(x) \leq h'(x)$, and if $a < x \leq c$, then $g'(x) \geq h'(x)$, by (a). By the Racetrack Principle, $g(x) \leq h'(x)$ for $c \leq x < b$ and for $a < x \leq c$, as we wanted.

Strengthen Your Understanding

30. The function f is not differentiable at $x = 0$, so the Mean value Theorem does not apply.

31. This function does not satisfy the conclusion of the Mean Value Theorem because it is not continuous at $x = 0$.

32. To apply the Constant Function Theorem, we need f to be continuous on $a \leq x \leq b$ and differentiable on $a < x < b$.

For example, the function

$$f(x) = \begin{cases} 1 & \text{if } 0 \leq x < 1 \\ 0 & \text{if } x = 1 \end{cases}$$

has a zero derivative on $0 < x < 1$ but is not constant on $0 \leq x \leq 1$.

33. The function f must be continuous on $a \leq x \leq b$ and differentiable on $a < x < b$. Any interval avoiding $x \leq 0$ will suffice, so, for example $1 \leq x \leq 2$.

34. The function f must be continuous on $a \leq x \leq b$ and differentiable on $a < x < b$. Any interval including $x = 0$ will suffice, so, for example $-1 \leq x \leq 1$.

35. The function $f(x) = |x|$ is continuous on $[-1, 1]$, but there is no number c, with $-1 < c < 1$, such that

$$f'(c) = \frac{|1| - |-1|}{1 - (-1)} = 0;$$

that is, the slope of $f(x) = |x|$ is never 0.

36. Let f be defined by

$$f(x) = \begin{cases} x & \text{if } 0 \leq x < 2 \\ 19 & \text{if } x = 2 \end{cases}$$

Then f is differentiable on $(0, 2)$ and $f'(x) = 1$ for all x in $(0, 2)$. Thus there is no c in $(0, 2)$ such that

$$f'(c) = \frac{f(2) - f(0)}{2 - 0} = \frac{19}{2}.$$

The reason that this function does not satisfy the conclusion of the Mean Value Theorem is that it is not continuous at $x = 2$.

37. Let f be defined by

$$f(x)=\begin{cases} x^2 & \text{if } 0\le x<1 \\ 1/2 & \text{if } x=1. \end{cases}$$

Then f is not continuous at $x=1$, but f is differentiable on $(0,1)$ and $f'(x)=2x$ for $0<x<1$. Thus, $c=1/4$ satisfies

$$f'(c)=\frac{f(1)-f(0)}{1-0}=\frac{1}{2},\quad \text{since}\quad f'\left(\frac{1}{4}\right)=2\cdot\frac{1}{4}=\frac{1}{2}.$$

38. True, by the Increasing Function Theorem, Theorem 3.8.

39. False. For example, let $f(x)=x+5$, and $g(x)=2x-3$. Then $f'(x)\le g'(x)$ for all x, but $f(0)>g(0)$.

40. False. For example, let $f(x)=3x+1$ and $g(x)=3x+7$.

41. False. For example, if $f(x)=-x$, then $f'(x)\le 1$ for all x, but $f(-2)=2$, so $f(-2)>-2$.

Solutions for Chapter 3 Review

Exercises

1. $w'=100(t^2+1)^{99}(2t)=200t(t^2+1)^{99}$.

2. $f'(t)=e^{3t}\cdot 3=3e^{3t}$.

3. Using the quotient rule gives $\dfrac{dz}{dt}=\dfrac{(2t+3)(t+1)-(t^2+3t+1)}{(t+1)^2}$ or $\dfrac{dz}{dt}=\dfrac{t^2+2t+2}{(t+1)^2}$.

4. $y'=\dfrac{\frac{1}{2\sqrt{t}}(t^2+1)-\sqrt{t}(2t)}{(t^2+1)^2}$.

5. Using the quotient rule,

$$h'(t)=\frac{(-1)(4+t)-(4-t)}{(4+t)^2}=-\frac{8}{(4+t)^2}.$$

6. $f'(x)=ex^{e-1}$.

7. $f'(x)=\dfrac{3x^2}{9}(3\ln x-1)+\dfrac{x^3}{9}\left(\dfrac{3}{x}\right)=x^2\ln x-\dfrac{x^2}{3}+\dfrac{x^2}{3}=x^2\ln x$

8.

$$\begin{aligned} f'(x)&=\frac{(2+3x+4x^2)(1)-(1+x)(3+8x)}{(2+3x+4x^2)^2}\\ &=\frac{2+3x+4x^2-3-11x-8x^2}{(2+3x+4x^2)^2}\\ &=\frac{-4x^2-8x-1}{(2+3x+4x^2)^2}. \end{aligned}$$

9. Using the chain rule, $g'(\theta)=(\cos\theta)e^{\sin\theta}$.

10. Since $y=\sqrt{\theta}\left(\sqrt{\theta}+\dfrac{1}{\sqrt{\theta}}\right)=\theta^{1/2}\theta^{1/2}+\dfrac{\sqrt{\theta}}{\sqrt{\theta}}=\theta+1$, we have $\frac{dy}{dx}=1$.

11. $f'(w)=\dfrac{1}{\cos(w-1)}[-\sin(w-1)]=-\tan(w-1)$.

[This could be done easily using the answer from Problem 20 and the chain rule.]

12. $\dfrac{d}{dy}\ln\ln(2y^3)=\dfrac{1}{\ln(2y^3)}\dfrac{1}{2y^3}6y^2=\dfrac{3}{y\ln(2y^3)}$.

13. $g'(x)=\dfrac{d}{dx}\left(x^k+k^x\right)=kx^{k-1}+k^x\ln k$.

14. $y'=0$

15. $\dfrac{dz}{d\theta}=3\sin^2\theta\cos\theta$

16.

$$\begin{aligned} f'(t) &= 2\cos(3t+5)\cdot(-\sin(3t+5))3 \\ &= -6\cos(3t+5)\cdot\sin(3t+5) \end{aligned}$$

17.

$$\begin{aligned} M'(\alpha) &= 2\tan(2+3\alpha)\cdot\frac{1}{\cos^2(2+3\alpha)}\cdot 3 \\ &= 6\cdot\frac{\tan(2+3\alpha)}{\cos^2(2+3\alpha)} \end{aligned}$$

18. $s'(\theta) = \frac{d}{d\theta}\sin^2(3\theta-\pi) = 6\cos(3\theta-\pi)\sin(3\theta-\pi)$.

19. $h'(t) = \frac{1}{e^{-t}-t}\left(-e^{-t}-1\right)$.

20.

$$\begin{aligned} \frac{d}{d\theta}\left(\frac{\sin(5-\theta)}{\theta^2}\right) &= \frac{\cos(5-\theta)(-1)\theta^2-\sin(5-\theta)(2\theta)}{\theta^4} \\ &= -\frac{\theta\cos(5-\theta)+2\sin(5-\theta)}{\theta^3}. \end{aligned}$$

21. $w'(\theta) = \frac{1}{\sin^2\theta} - \frac{2\theta\cos\theta}{\sin^3\theta}$

22. $f'(\theta) = -1(1+e^{-\theta})^{-2}(e^{-\theta})(-1) = \frac{e^{-\theta}}{(1+e^{-\theta})^2}$.

23. $g'(w) = \frac{d}{dw}\left(\frac{1}{2^w+e^w}\right) = -\frac{2^w\ln 2+e^w}{(2^w+e^w)^2}$.

24. $f(t) = \frac{1}{t^2}+\frac{1}{t}-\frac{1}{t^4} = t^{-2}+t^{-1}-t^{-4}$
$f'(t) = -2t^{-3}-t^{-2}+4t^{-5}$.

25. Using the quotient rule and the chain rule,

$$\begin{aligned} h'(z) &= \frac{1}{2}\left(\frac{\sin(2z)}{\cos(2z)}\right)^{-1/2}\left[\frac{2\cos(2z)\cos(2z)-\sin(2z)(-2\sin(2z))}{\cos^2(2z)}\right] \\ &= \left(\frac{\cos(2z)}{\sin(2z)}\right)^{1/2}\left[\frac{\cos^2(2z)+\sin^2(2z)}{\cos^2(2z)}\right] \\ &= \frac{(\cos(2z))^{1/2}}{(\sin(2z))^{1/2}\cos^2(2z)} = \frac{1}{\sqrt{\sin(2z)}\sqrt{\cos^3(2z)}}. \end{aligned}$$

26. Using the chain rule and simplifying,

$$q'(\theta) = \frac{1}{2}(4\theta^2-\sin^2(2\theta))^{-1/2}(8\theta-2\sin(2\theta)(2\cos(2\theta))) = \frac{4\theta-2\sin(2\theta)\cos(2\theta)}{\sqrt{4\theta^2-\sin^2(2\theta)}}.$$

27. Using the product rule and factoring gives $\frac{dw}{dz} = 2^{-4z}\left[-4\ln(2)\sin(\pi z)+\pi\cos(\pi z)\right]$.

28. $g'(t) = \frac{3}{(3t-4)^2+1}$.

29. $r'(\theta) = \frac{d}{d\theta}\left(e^{\left(e^\theta+e^{-\theta}\right)}\right) = e^{\left(e^\theta+e^{-\theta}\right)}\left(e^\theta-e^{-\theta}\right)$.

30. Using the chain rule, we get:

$$m'(n) = \cos(e^n)\cdot(e^n)$$

31. Using the chain rule we get:

$$G'(\alpha) = e^{\tan(\sin\alpha)}(\tan(\sin\alpha))' = e^{\tan(\sin\alpha)} \cdot \frac{1}{\cos^2(\sin\alpha)} \cdot \cos\alpha.$$

32. Here we use the product rule, and then the chain rule, and then the product rule.

$$\begin{aligned} g'(t) &= \cos(\sqrt{t}e^t) + t(\cos\sqrt{t}e^t)' = \cos(\sqrt{t}e^t) + t(-\sin(\sqrt{t}e^t)\cdot(\sqrt{t}e^t)') \\ &= \cos(\sqrt{t}e^t) - t\sin(\sqrt{t}e^t)\cdot\left(\sqrt{t}e^t + \frac{1}{2\sqrt{t}}e^t\right) \end{aligned}$$

33. $f'(r) = e(\tan 2 + \tan r)^{e-1}(\tan 2 + \tan r)' = e(\tan 2 + \tan r)^{e-1}\left(\frac{1}{\cos^2 r}\right)$

34. $\frac{d}{dx}xe^{\tan x} = e^{\tan x} + xe^{\tan x}\frac{1}{\cos^2 x}.$

35. $\frac{dy}{dx} = 2e^{2x}\sin^2(3x) + e^{2x}(2\sin(3x)\cos(3x)3) = 2e^{2x}\sin(3x)(\sin(3x) + 3\cos(3x))$

36. $g'(x) = \frac{6x}{1+(3x^2+1)^2} = \frac{6x}{9x^4+6x^2+2}$

37. $\frac{dy}{dx} = (\ln 2)2^{\sin x}\cos x\cdot\cos x + 2^{\sin x}(-\sin x) = 2^{\sin x}\left((\ln 2)\cos^2 x - \sin x\right)$

38. Simplifying first gives $F(x) = ax\ln e + b = ax + b$. Thus $F'(x) = a$.
The same result is obtained by differentiating first and then simplifying.

39. $y = e^\theta e^{-1}$ $\quad y' = \frac{d}{d\theta}(e^\theta e^{-1}) = e^{-1}\frac{d}{d\theta}e^\theta = e^\theta e^{-1} = e^{\theta-1}.$

40. Using the product rule and factoring gives $f'(t) = e^{-4kt}(\cos t - 4k\sin t)$.

41. Using the product rule gives

$$\begin{aligned} H'(t) &= 2ate^{-ct} - c(at^2+b)e^{-ct} \\ &= (-cat^2 + 2at - bc)e^{-ct}. \end{aligned}$$

42. $\frac{d}{d\theta}\sqrt{a^2-\sin^2\theta} = \frac{1}{2\sqrt{a^2-\sin^2\theta}}(-2\sin\theta\cos\theta) = -\frac{\sin\theta\cos\theta}{\sqrt{a^2-\sin^2\theta}}.$

43. $y' = (\ln 5)5^x$.

44. Using the quotient rule gives

$$f'(x) = \frac{(-2x)(a^2+x^2) - (2x)(a^2-x^2)}{(a^2+x^2)^2} = \frac{-4a^2x}{(a^2+x^2)^2}.$$

45. Using the quotient rule gives

$$\begin{aligned} w'(r) &= \frac{2ar(b+r^3) - 3r^2(ar^2)}{(b+r^3)^2} \\ &= \frac{2abr - ar^4}{(b+r^3)^2}. \end{aligned}$$

46. Using the quotient rule gives

$$\begin{aligned} f'(s) &= \frac{-2s\sqrt{a^2+s^2} - \frac{s}{\sqrt{a^2+s^2}}(a^2-s^2)}{(a^2+s^2)} \\ &= \frac{-2s(a^2+s^2) - s(a^2-s^2)}{(a^2+s^2)^{3/2}} \\ &= \frac{-2a^2s - 2s^3 - a^2s + s^3}{(a^2+s^2)^{3/2}} \\ &= \frac{-3a^2s - s^3}{(a^2+s^2)^{3/2}}. \end{aligned}$$

47. $\dfrac{dy}{dx} = \dfrac{1}{1+\left(\frac{2}{x}\right)^2}\left(\dfrac{-2}{x^2}\right) = \dfrac{-2}{x^2+4}$

48. Using the chain rule gives $r'(t) = \dfrac{\cos(\frac{t}{k})}{\sin(\frac{t}{k})}\left(\dfrac{1}{k}\right)$.

49. Since $g(w) = 5(a^2 - w^2)^{-2}$, $g'(w) = -10(a^2-w^2)^{-3}(-2w) = \dfrac{20w}{(a^2-w^2)^3}$

50. $\dfrac{dy}{dx} = \dfrac{2e^{2x}(x^2+1) - e^{2x}(2x)}{(x^2+1)^2} = \dfrac{2e^{2x}(x^2+1-x)}{(x^2+1)^2}$

51. $g'(u) = \dfrac{ae^{au}}{a^2+b^2}$

52. Using the quotient and chain rules, we have

$$\begin{aligned}\frac{dy}{dx} &= \frac{(ae^{ax}+ae^{-ax})(e^{ax}+e^{-ax}) - (e^{ax}-e^{-ax})(ae^{ax}-ae^{-ax})}{(e^{ax}+e^{-ax})^2}\\ &= \frac{a(e^{ax}+e^{-ax})^2 - a(e^{ax}-e^{-ax})^2}{(e^{ax}+e^{-ax})^2}\\ &= \frac{a[(e^{2ax}+2+e^{-2ax}) - (e^{2ax}-2+e^{-2ax})]}{(e^{ax}+e^{-ax})^2}\\ &= \frac{4a}{(e^{ax}+e^{-ax})^2}\end{aligned}$$

53. Using the quotient rule gives

$$\begin{aligned}f'(x) &= \frac{1+\ln x - x(\frac{1}{x})}{(1+\ln x)^2}\\ &= \frac{\ln x}{(1+\ln x)^2}.\end{aligned}$$

54. Using the quotient and chain rules

$$\begin{aligned}\frac{dz}{dt} &= \frac{\frac{d}{dt}(e^{t^2}+t)\cdot\sin(2t) - (e^{t^2}+t)\frac{d}{dt}(\sin(2t))}{(\sin(2t))^2}\\ &= \frac{\left(e^{t^2}\cdot\frac{d}{dt}(t^2)+1\right)\sin(2t) - (e^{t^2}+t)\cos(2t)\frac{d}{dt}(2t)}{\sin^2(2t)}\\ &= \frac{(2te^{t^2}+1)\sin(2t) - (e^{t^2}+t)2\cos(2t)}{\sin^2(2t)}.\end{aligned}$$

55. Using the chain rule twice:

$$f'(t) = \cos\sqrt{e^t+1}\frac{d}{dt}\sqrt{e^t+1} = \cos\sqrt{e^t+1}\frac{1}{2\sqrt{e^t+1}}\cdot\frac{d}{dt}(e^t+1) = \cos\sqrt{e^t+1}\frac{1}{2\sqrt{e^t+1}}e^t = e^t\frac{\cos\sqrt{e^t+1}}{2\sqrt{e^t+1}}.$$

56. Using the chain rule twice:

$$g'(y) = e^{2e^{(y^3)}}\frac{d}{dy}\left(2e^{(y^3)}\right) = 2e^{2e^{(y^3)}}e^{(y^3)}\frac{d}{dy}(y^3) = 6y^2e^{(y^3)}e^{2e^{(y^3)}}.$$

57. $y' = 18x^2 + 8x - 2$.

58. $g(z) = z^5 + 5z^4 - z$
$g'(z) = 5z^4 + 20z^3 - 1$.

59. $f'(z) = (2\ln 3)z + (\ln 4)e^z$.

60. $\dfrac{dy}{dx} = 3 - 2(\ln 4)4^x$.

61. $f'(x) = 3x^2 + 3^x \ln 3$

62. $f'(\theta) = 2\theta\sin\theta + \theta^2\cos\theta + 2\cos\theta - 2\theta\sin\theta - 2\cos\theta = \theta^2\cos\theta$.

63.

$$\begin{aligned}\frac{dy}{d\theta} &= \frac{1}{2}(\cos(5\theta))^{-\frac{1}{2}}(-\sin(5\theta)\cdot 5) + 2\sin(6\theta)\cos(6\theta)\cdot 6\\ &= -\frac{5}{2}\frac{\sin(5\theta)}{\sqrt{\cos(5\theta)}} + 12\sin(6\theta)\cos(6\theta)\end{aligned}$$

64. $r'(\theta) = \dfrac{d}{d\theta}\sin[(3\theta-\pi)^2] = \cos[(3\theta-\pi)^2]\cdot 2(3\theta-\pi)\cdot 3 = 6(3\theta-\pi)\cos[(3\theta-\pi)^2]$.

65. It is easier to do this by multiplying it out first, rather than using the product rule first: $z = s^4 - s, \quad z' = 4s^3 - 1$.

66. Since $\tan(\arctan(k\theta)) = k\theta$, because tangent and arctangent are inverse functions, we have $N'(\theta) = k$.

67. Using the product rule gives $h'(t) = ke^{kt}(\sin at + \cos bt) + e^{kt}(a\cos at - b\sin bt)$.

68. $f'(y) = (\ln 4)4^y(2-y^2) + 4^y(-2y) = 4^y((\ln 4)(2-y^2) - 2y)$.

69. $f'(t) = 4(\sin(2t) - \cos(3t))^3[2\cos(2t) + 3\sin(3t)]$

70. Since $\cos^2 y + \sin^2 y = 1$, we have $s(y) = \sqrt[3]{1+3} = \sqrt[3]{4}$. Thus $s'(y) = 0$.

71.

$$\begin{aligned}f'(x) &= (-2x+6x^2)(6-4x+x^7) + (4-x^2+2x^3)(-4+7x^6)\\ &= (-12x+44x^2-24x^3-2x^8+6x^9) + (-16+4x^2-8x^3+28x^6-7x^8+14x^9)\\ &= -16-12x+48x^2-32x^3+28x^6-9x^8+20x^9\end{aligned}$$

72.

$$\begin{aligned}h'(x) &= \left(-\frac{1}{x^2}+\frac{2}{x^3}\right)\left(2x^3+4\right) + \left(\frac{1}{x}-\frac{1}{x^2}\right)\left(6x^2\right)\\ &= -2x+4-\frac{4}{x^2}+\frac{8}{x^3}+6x-6\\ &= 4x-2-4x^{-2}+8x^{-3}\end{aligned}$$

73. Note: $f(z) = (5z)^{1/2} + 5z^{1/2} + 5z^{-1/2} - \sqrt{5}z^{-1/2} + \sqrt{5}$, so $f'(z) = \dfrac{5}{2}(5z)^{-1/2} + \dfrac{5}{2}z^{-1/2} - \dfrac{5}{2}z^{-3/2} + \dfrac{\sqrt{5}}{2}z^{-3/2}$.

74.

$$\begin{aligned}3x^2 + 3y^2\frac{dy}{dx} - 8xy - 4x^2\frac{dy}{dx} &= 0\\ (3y^2-4x^2)\frac{dy}{dx} &= 8xy - 3x^2\\ \frac{dy}{dx} &= \frac{8xy-3x^2}{3y^2-4x^2}\end{aligned}$$

75. Using the relation $\cos^2 y + \sin^2 y = 1$, the equation becomes:
$1 = y + 2$ or $y = -1$. Hence, $\dfrac{dy}{dx} = 0$.

76. We wish to find the slope $m = dy/dx$. To do this, we can implicitly differentiate the given formula in terms of x:

$$\begin{aligned}x^2 + 3y^2 &= 7\\ 2x + 6y\frac{dy}{dx} &= \frac{d}{dx}(7) = 0\\ \frac{dy}{dx} &= \frac{-2x}{6y} = \frac{-x}{3y}.\end{aligned}$$

Thus, at $(2,-1)$, $m = -(2)/3(-1) = 2/3$.

77. Taking derivatives implicitly, we find

$$\frac{dy}{dx} + \cos y \frac{dy}{dx} + 2x = 0$$
$$\frac{dy}{dx} = \frac{-2x}{1+\cos y}$$

So, at the point $x = 3, y = 0$,

$$\frac{dy}{dx} = \frac{(-2)(3)}{1+\cos 0} = \frac{-6}{2} = -3.$$

78. First, we differentiate with respect to x:

$$x \cdot \frac{dy}{dx} + y \cdot 1 + 2y\frac{dy}{dx} = 0$$
$$\frac{dy}{dx}(x+2y) = -y$$
$$\frac{dy}{dx} = \frac{-y}{x+2y}.$$

At $x = 3$, we have

$$3y + y^2 = 4$$
$$y^2 + 3y - 4 = 0$$
$$(y-1)(y+4) = 0.$$

Our two points, then, are $(3, 1)$ and $(3, -4)$.

At $(3,1)$, $\frac{dy}{dx} = \frac{-1}{3+2(1)} = -\frac{1}{5}$; Tangent line: $(y-1) = -\frac{1}{5}(x-3)$.

At $(3,-4)$, $\frac{dy}{dx} = \frac{-(-4)}{3+2(-4)} = -\frac{4}{5}$; Tangent line: $(y+4) = -\frac{4}{5}(x-3)$.

Problems

79. $f'(t) = 6t^2 - 8t + 3$ and $f''(t) = 12t - 8$.

80.

$$f'(x) = -8 + 2\sqrt{2}x$$
$$f'(r) = -8 + 2\sqrt{2}r = 4$$
$$r = \frac{12}{2\sqrt{2}} = 3\sqrt{2}.$$

81. Since $f(x) = x^3 - 6x^2 - 15x + 20$, we have $f'(x) = 3x^2 - 12x - 15$. To find the points at which $f'(x) = 0$, we solve

$$3x^2 - 12x - 15 = 0$$
$$3(x^2 - 4x - 5) = 0$$
$$3(x+1)(x-5) = 0.$$

We see that $f'(x) = 0$ at $x = -1$ and at $x = 5$. The graph of $f(x)$ in Figure 3.24 appears to be horizontal at $x = -1$ and at $x = 5$, confirming what we found analytically.

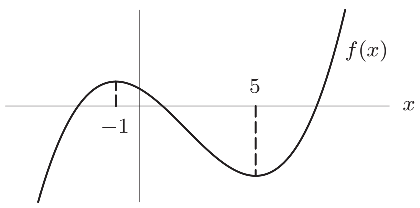


Figure 3.24

82. (a) Since the power of x will go down by one every time you take a derivative (until the exponent is zero after which the derivative will be zero), we can see immediately that $f^{(8)}(x) = 0$.
(b) $f^{(7)}(x) = 7 \cdot 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 \cdot x^0 = 5040$.

83. (a) Applying the product rule to $h(x)$ we get $h'(1) = t'(1)s(1) + t(1)s'(1) \approx (-2) \cdot 3 + 0 \cdot 0 = -6$.
(b) Applying the product rule to $h(x)$ we get $h'(0) = t'(0)s(0) + t(0)s'(0) \approx (-2) \cdot 2 + 2 \cdot 2 = 0$.
(c) Applying the quotient rule to $p(x)$ we get $p'(0) = \dfrac{t'(0)s(0) - t(0)s'(0)}{(s(0))^2} \approx \dfrac{(-2) \cdot 2 - 2 \cdot 2}{2^2} = -2$.

Note that since $t(x)$ is a linear function whose slope looks like -2 from the graph, $t'(x) \approx -2$ everywhere. To find $s'(1)$, draw a line tangent to the curve at the point $(1, s(1))$, and estimate the slope.

84. Since $r(x) = s(t(x))$, the chain rule gives $r'(x) = s'(t(x)) \cdot t'(x)$. Thus,

$$r'(0) = s'(t(0)) \cdot t'(0) \approx s'(2) \cdot (-2) \approx (-2)(-2) = 4.$$

Note that since $t(x)$ is a linear function whose slope looks like -2 from the graph, $t'(x) \approx -2$ everywhere. To find $s'(2)$, draw a line tangent to the curve at the point $(2, s(2))$, and estimate the slope.

85. (a) Applying the chain rule we get $h'(1) = s'(s(1)) \cdot s'(1) \approx s'(3) \cdot 0 = 0$.
(b) Applying the chain rule we get $h'(2) = s'(s(2)) \cdot s'(2) \approx s'(2) \cdot s'(2) = (-2)^2 = 4$.
To find $s'(2)$, draw a line tangent to the curve at the point $(2, s(2))$, and estimate the slope.

86. We need to find all values for x such that

$$\frac{dy}{dx} = s'(s(x)) \cdot s'(x) = 0.$$

This is the case when either $s'(s(x)) = 0$ or $s'(x) = 0$. From the graph we see that $s'(x) = 0$ when $x \approx 1$. Also, $s'(s(x)) = 0$ when $s(x) \approx 1$, which happens when $x \approx -0.4$ or $x \approx 2.4$.

To find $s'(a)$, for any a, draw a line tangent to the curve at the point $(a, s(a))$, and estimate the slope.

87. (a) Applying the product rule we get $h'(-1) = 2 \cdot (-1) \cdot t(-1) + (-1)^2 \cdot t'(-1) \approx (-2) \cdot 4 + 1 \cdot (-2) = -10$.
(b) Applying the chain rule we get $p'(-1) = t'((-1)^2) \cdot 2 \cdot (-1) = -2 \cdot t'(1) \approx (-2) \cdot (-2) = 4$.
Note that since $t(x)$ is a linear function whose slope looks like -2 from the graph, $t'(x) \approx -2$ everywhere.

88. We have $r(1) = s(t(1)) \approx s(0) \approx 2$. By the chain rule, $r'(x) = s'(t(x)) \cdot t'(x)$, so

$$r'(1) = s'(t(1)) \cdot t'(1) \approx s'(0) \cdot (-2) \approx 2(-2) = -4.$$

Thus the equation of the tangent line is

$$y - 2 = -4(x - 1)$$
$$y = -4x + 6.$$

Note that since $t(x)$ is a linear function whose slope looks like -2 from the graph, $t'(x) \approx -2$ everywhere. To find $s'(0)$, draw a line tangent to the curve at the point $(0, s(0))$, and estimate the slope.

89. Estimates may vary. From the graphs, we estimate $g(1) \approx 2$, $g'(1) \approx 1$, and $f'(2) \approx 0.8$. Thus, by the chain rule,

$$h'(1) = f'(g(1)) \cdot g'(1) \approx f'(2) \cdot g'(1) \approx 0.8 \cdot 1 = 0.8.$$

90. Estimates may vary. From the graphs, we estimate $f(1) \approx -0.4$, $f'(1) \approx 0.5$, and $g'(-0.4) \approx 2$. Thus, by the chain rule,

$$k'(1) = g'(f(1)) \cdot f'(1) \approx g'(-0.4) \cdot 0.5 \approx 2 \cdot 0.5 = 1.$$

91. Estimates may vary. From the graphs, we estimate $g(2) \approx 1.6$, $g'(2) \approx -0.5$, and $f'(1.6) \approx 0.8$. Thus, by the chain rule,

$$h'(2) = f'(g(2)) \cdot g'(2) \approx f'(1.6) \cdot g'(2) \approx 0.8(-0.5) = -0.4.$$

92. Estimates may vary. From the graphs, we estimate $f(2) \approx 0.3$, $f'(2) \approx 1.1$, and $g'(0.3) \approx 1.7$. Thus, by the chain rule,

$$k'(2) = g'(f(2)) \cdot f'(2) \approx g'(0.3) \cdot f'(2) \approx 1.7 \cdot 1.1 \approx 1.9.$$

93. Taking the values of f, f', g, and g' from the table we get:

(a) $h(4) = f(g(4)) = f(3) = 1$.
(b) $h'(4) = f'(g(4))g'(4) = f'(3) \cdot 1 = 2$.
(c) $h(4) = g(f(4)) = g(4) = 3$.
(d) $h'(4) = g'(f(4))f'(4) = g'(4) \cdot 3 = 3$.
(e) $h'(4) = (f(4)g'(4) - g(4)f'(4))/f^2(4) = -5/16$.
(f) $h'(4) = f(4)g'(4) + g(4)f'(4) = 13$.

94. (a) $H'(2) = r'(2)s(2) + r(2)s'(2) = -1 \cdot 1 + 4 \cdot 3 = 11.$

(b) $H'(2) = \dfrac{r'(2)}{2\sqrt{r(2)}} = \dfrac{-1}{2\sqrt{4}} = -\dfrac{1}{4}.$

(c) $H'(2) = r'(s(2))s'(2) = r'(1) \cdot 3$, but we don't know $r'(1)$.

(d) $H'(2) = s'(r(2))r'(2) = s'(4)r'(2) = -3.$

95. (a) $f(x) = x^2 - 4g(x)$
$f'(x) = 2x - 4g'(x)$
$f'(2) = 2(2) - 4(-4) = 4 + 16 = 20$

(b) $f(x) = \frac{x}{g(x)}$
$f'(x) = \frac{g(x) - xg'(x)}{(g(x))^2}$
$f'(2) = \frac{g(2) - 2g'(2)}{(g(2))^2} = \frac{3 - 2(-4)}{(3)^2} = \frac{11}{9}$

(c) $f(x) = x^2 g(x)$
$f'(x) = 2xg(x) + x^2 g'(x)$
$f'(2) = 2(2)(3) + (2)^2(-4) = 12 - 16 = -4$

(d) $f(x) = (g(x))^2$
$f'(x) = 2g(x) \cdot g'(x)$
$f'(2) = 2(3)(-4) = -24$

(e) $f(x) = x \sin(g(x))$
$f'(x) = \sin(g(x)) + x\cos(g(x)) \cdot g'(x)$

$$\begin{aligned} f'(2) &= \sin(g(2)) + 2\cos(g(2)) \cdot g'(2) \\ &= \sin 3 + 2\cos(3) \cdot (-4) \\ &= \sin 3 - 8\cos 3 \end{aligned}$$

(f) $f(x) = x^2 \ln(g(x))$
$f'(x) = 2x \ln(g(x)) + x^2(\frac{g'(x)}{g(x)})$

$$\begin{aligned} f'(2) &= 2(2)\ln 3 + (2)^2(\tfrac{-4}{3}) \\ &= 4\ln 3 - \tfrac{16}{3} \end{aligned}$$

96. (a) $f(x) = x^2 - 4g(x)$
$f(2) = 4 - 4(3) = -8$
$f'(2) = 20$
Thus, we have a point $(2, -8)$ and slope $m = 20$. This gives

$$\begin{aligned} -8 &= 2(20) + b \\ b &= -48, \quad \text{so} \\ y &= 20x - 48. \end{aligned}$$

(b) $f(x) = \dfrac{x}{g(x)}$
$f(2) = \dfrac{2}{3}$
$f'(2) = \dfrac{11}{9}$
Thus, we have point $(2, \frac{2}{3})$ and slope $m = \frac{11}{9}$. This gives

$$\begin{aligned} \frac{2}{3} &= (\frac{11}{9})(2) + b \\ b &= \frac{2}{3} - \frac{22}{9} = \frac{-16}{9}, \quad \text{so} \\ y &= \frac{11}{9}x - \frac{16}{9}. \end{aligned}$$

(c) $f(x) = x^2 g(x)$
$f(2) = 4 \cdot g(2) = 4(3) = 12$
$f'(2) = -4$
Thus, we have point $(2, 12)$ and slope $m = -4$. This gives

$$12 = 2(-4) + b$$

$$b = 20, \quad \text{so}$$
$$y = -4x + 20.$$

(d) $f(x) = (g(x))^2$
$f(2) = (g(2))^2 = (3)^2 = 9$
$f'(2) = -24$
Thus, we have point $(2, 9)$ and slope $m = -24$. This gives

$$9 = 2(-24) + b$$
$$b = 57, \quad \text{so}$$
$$y = -24x + 57.$$

(e) $f(x) = x\sin(g(x))$
$f(2) = 2\sin(g(2)) = 2\sin 3$
$f'(2) = \sin 3 - 8\cos 3$
We will use a decimal approximation for $f(2)$ and $f'(2)$, so the point $(2, 2\sin 3) \approx (2, 0.28)$ and $m \approx 8.06$. Thus,

$$0.28 = 2(8.06) + b$$
$$b = -15.84, \quad \text{so}$$
$$y = 8.06x - 15.84.$$

(f) $f(x) = x^2 \ln g(x)$
$f(2) = 4\ln g(2) = 4\ln 3 \approx 4.39$
$f'(2) = 4\ln 3 - \dfrac{16}{3} \approx -0.94.$
Thus, we have point $(2, 4.39)$ and slope $m = -0.94$. This gives

$$4.39 = 2(-0.94) + b$$
$$b = 6.27, \quad \text{so}$$
$$y = -0.94x + 6.27.$$

97. When we zoom in on the origin, we find that two functions are not defined there. The other functions all look like straight lines through the origin. The only way we can tell them apart is their slope.

The following functions all have slope 0 and are therefore indistinguishable:
$\sin x - \tan x$, $\frac{x^2}{x^2+1}$, $x - \sin x$, and $\frac{1-\cos x}{\cos x}$.

These functions all have slope 1 at the origin, and are thus indistinguishable:
$\arcsin x$, $\frac{\sin x}{1+\sin x}$, $\arctan x$, $e^x - 1$, $\frac{x}{x+1}$, and $\frac{x}{x^2+1}$.

Now, $\frac{\sin x}{x} - 1$ and $-x\ln x$ both are undefined at the origin, so they are distinguishable from the other functions. In addition, while $\frac{\sin x}{x} - 1$ has a slope that approaches zero near the origin, $-x\ln x$ becomes vertical near the origin, so they are distinguishable from each other.

Finally, $x^{10} + \sqrt[10]{x}$ is the only function defined at the origin and with a vertical tangent there, so it is distinguishable from the others.

98. It makes sense to define the angle between two curves to be the angle between their tangent lines. (The tangent lines are the best linear approximations to the curves). See Figure 3.25. The functions $\sin x$ and $\cos x$ are equal at $x = \frac{\pi}{4}$.

$$\text{For } f_1(x) = \sin x, \quad f_1'(\frac{\pi}{4}) = \cos(\frac{\pi}{4}) = \frac{\sqrt{2}}{2}$$
$$\text{For } f_2(x) = \cos x, \quad f_2'(\frac{\pi}{4}) = -\sin(\frac{\pi}{4}) = -\frac{\sqrt{2}}{2}.$$

Using the point $(\frac{\pi}{4}, \frac{\sqrt{2}}{2})$ for each tangent line we get $y = \frac{\sqrt{2}}{2}x + \frac{\sqrt{2}}{2}(1 - \frac{\pi}{4})$ and $y = -\frac{\sqrt{2}}{2}x + \frac{\sqrt{2}}{2}(1 + \frac{\pi}{4})$, respectively.

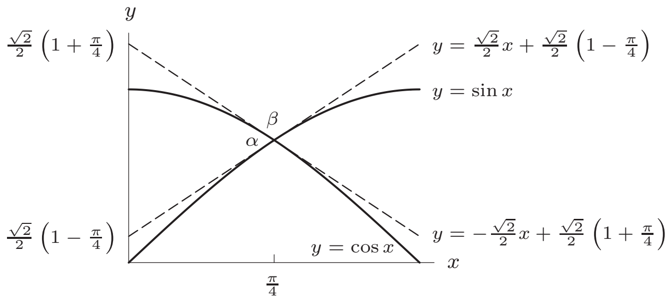

Figure 3.25

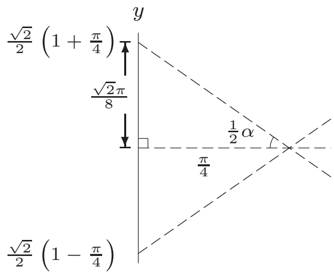

Figure 3.26

There are two possibilities of how to define the angle between the tangent lines, indicated by α and β above. The choice is arbitrary, so we will solve for both. To find the angle, α, we consider the triangle formed by these two lines and the y-axis. See Figure 3.26.

$$\tan\left(\frac{1}{2}\alpha\right)=\frac{\sqrt{2}\pi/8}{\pi/4}=\frac{\sqrt{2}}{2}$$
$$\frac{1}{2}\alpha=0.61548 \text{ radians}$$
$$\alpha=1.231 \text{ radians, or } 70.5^\circ.$$

Now let us solve for β, the other possible measure of the angle between the two tangent lines. Since α and β are supplementary, $\beta=\pi-1.231=1.909$ radians, or 109.4°.

99. The curves meet when $1+x-x^2=1-x+x^2$, that is when $2x(1-x)=0$ so that $x=1$ or $x=0$. Let

$$y_1(x)=1+x-x^2 \quad \text{and} \quad y_2(x)=1-x+x^2.$$

Then

$$y_1{}'=1-2x \quad \text{and} \quad y_2{}'=-1+2x.$$

At $x=0$, $y_1{}'=1$, $y_2{}'=-1$ so that $y_1{}'\cdot y_2{}'=-1$ and the curves are perpendicular. At $x=1$, $y_1{}'=-1$, $y_2{}'=1$ so that $y_1{}'\cdot y_2{}'=-1$ and the curves are perpendicular.

100. The curves meet when $1-x^3/3=x-1$, that is when $x^3+3x-6=0$. So the roots of this equation give us the x-coordinates of the intersection point. By numerical methods, we see there is one solution near $x=1.3$. See Figure 3.27. Let

$$y_1(x)=1-\frac{x^3}{3} \quad \text{and} \quad y_2(x)=x-1.$$

So we have

$$y_1{}'=-x^2 \quad \text{and} \quad y_2{}'=1.$$

However, $y_2{}'(x)=+1$, so if the curves are to be perpendicular when they cross, then $y_1{}'$ must be -1. Since $y_1{}'=-x^2$, $y_1{}'=-1$ only at $x=\pm1$ which is not the point of intersection. The curves are therefore not perpendicular when they cross.

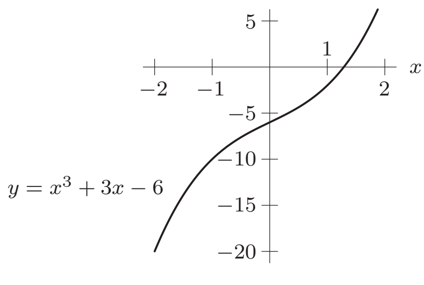

Figure 3.27

101. Differentiating gives $\dfrac{dy}{dx} = \ln x + 1 - b$.

To find the point at which the graph crosses the x-axis, set $y = 0$ and solve for x:

$$\begin{aligned} 0 &= x \ln x - bx \\ 0 &= x(\ln x - b). \end{aligned}$$

Since $x > 0$, we have

$$\begin{aligned} \ln x - b &= 0 \\ x &= e^b. \end{aligned}$$

At the point $(e^b, 0)$, the slope is

$$\frac{dy}{dx} = \ln\left(e^b\right) + 1 - b = b + 1 - b = 1.$$

Thus the equation of the tangent line is

$$\begin{aligned} y - 0 &= 1(x - e^b) \\ y &= x - e^b. \end{aligned}$$

102. Using the definition of $\cosh x$ and $\sinh x$, we have $\cosh 2x = \dfrac{e^{2x} + e^{-2x}}{2}$ and $\sinh 3x = \dfrac{e^{3x} - e^{-3x}}{2}$. Therefore

$$\begin{aligned} \lim_{x\to-\infty} \frac{\cosh(2x)}{\sinh(2x)} &= \lim_{x\to-\infty} \frac{e^{2x} + e^{-2x}}{e^{3x} - e^{-3x}} \\ &= \lim_{x\to-\infty} \frac{e^{-2x}(e^{4x} + 1)}{e^{-2x}(e^{5x} - e^{-x})} \\ &= \lim_{x\to-\infty} \frac{e^{4x} + 1}{e^{5x} - e^{-x}} \\ &= 0. \end{aligned}$$

103. Using the definition of $\sinh x$ we have $\sinh 2x = \dfrac{e^{2x} - e^{-2x}}{2}$. Therefore

$$\begin{aligned} \lim_{x\to-\infty} \frac{e^{-2x}}{\sinh(2x)} &= \lim_{x\to-\infty} \frac{2e^{-2x}}{e^{2x} - e^{-2x}} \\ &= \lim_{x\to-\infty} \frac{2}{e^{4x} - 1} \\ &= -2. \end{aligned}$$

104. Using the definition of $\cosh x$ and $\sinh x$, we have $\cosh x^2 = \dfrac{e^{x^2} + e^{-x^2}}{2}$ and $\sinh x^2 = \dfrac{e^{x^2} - e^{-x^2}}{2}$. Therefore

$$\begin{aligned} \lim_{x\to-\infty} \frac{\sinh(x^2)}{\cosh(x^2)} &= \lim_{x\to-\infty} \frac{e^{x^2} - e^{-x^2}}{e^{x^2} + e^{-x^2}} \\ &= \lim_{x\to-\infty} \frac{e^{x^2}(1 - e^{-2x^2})}{e^{x^2}(1 + e^{-2x^2})} \\ &= \lim_{x\to-\infty} \frac{1 - e^{-2x^2}}{1 + e^{-2x^2}} \\ &= 1. \end{aligned}$$

105. (a) Since $f(x) = \sqrt{x}$, we have $f'(x) = (1/2)x^{-1/2}$. So $f(4) = \sqrt{4} = 2$ and $f'(4) = (1/2)4^{-1/2} = 1/4$, and the tangent line approximation is

$$\begin{aligned} f(x) &\approx f(4) + f'(4)(x-4) \\ &\approx 2 + \frac{1}{4}(x-4). \end{aligned}$$

See Figure 3.28.

(b) For $x = 4.1$, the true value is

$$f(4.1) = \sqrt{4.1} = 2.02485...,$$

whereas the approximation is

$$f(4.1) \approx 2 + \frac{1}{4}(4.1 - 4) = 2.025.$$

Thus, the approximation differs from the true value by about 0.00015.

(c) For $x = 16$ the true value is:

$$f(16) = \sqrt{16} = 4$$

whereas the approximation is

$$f(16) \approx 2 + \frac{1}{4}(16 - 4) = 5.$$

Thus, the approximation differs from the true value by 1.

(d) The tangent line is a good approximation to the graph near $x = 4$, but not necessarily far away. Of course, there's no reason to expect that the curve will look like the tangent line if we go too far away, and usually it does not. (See Figure 3.28.) The problem is that we have traveled too far from the place where the curve looks like a line with slope $1/4$.

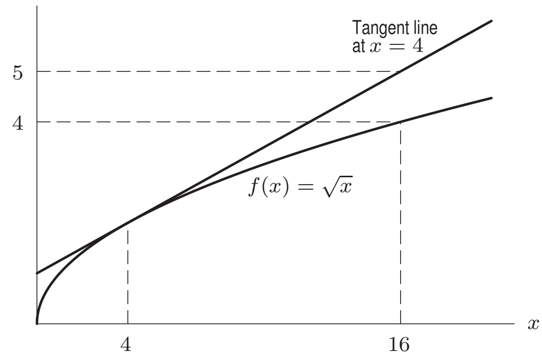

Figure 3.28: Local linearization: Approximating $f(x) = \sqrt{x}$ by its tangent line at $x = 4$

106. (a) From the figure, we see $a = 2$. The point with $x = 2$ lies on both the line and the curve. Since

$$y = -3 \cdot 2 + 7 = 1,$$

we have

$$f(a) = 1.$$

Since the slope of the line is -3, we have

$$f'(a) = -3.$$

(b) We use the line to approximate the function, so

$$f(2.1) \approx -3(2.1) + 7 = 0.7.$$

This is an underestimate, because the line is beneath the curve for $x > 2$. Similarly,

$$f(1.98) \approx -3(1.98) + 7 = 1.06.$$

This is an overestimate because the line is above the curve for $x < 2$.

The approximation $f(1.98) \approx 1.06$ is likely to be more accurate because 1.98 is closer to 2 than 2.1 is. Since the graph of $f(x)$ appears to bend away from the line at approximately the same rate on either side of $x = 2$, in this example, the error is larger for points farther from $x = 2$.

107. (a) The function $f(t)$ is linear; $g(t)$ is quadratic (polynomial of degree 2); and $h(t)$ is exponential.
(b) In 2010, we have $t = 130$. For $f(t)$, the rate of change is

$$f'(t) = 0.006$$
$$f'(130) = 0.006^\circ\text{C per year.}$$

For $g(t)$

$$g'(t) = 0.00012t - 0.0017$$
$$g'(130) = 0.00012 \cdot 130 - 0.0017 = 0.0139^\circ\text{C per year.}$$

For $h(t)$

$$h'(t) = 13.63(0.0004)e^{0.0004t} = 0.00545e^{0.0004t}$$
$$h'(130) = 0.00545e^{0.0004(130)} = 0.00574^\circ\text{C per year.}$$

(c) For $f(t)$: Change $= 0.006 \cdot 130 = 0.78^\circ$C.
For $g(t)$: Change $= 0.0139 \cdot 130 = 1.807^\circ$C.
For $h(t)$: Change $= 0.00574 \cdot 130 = 0.746^\circ$C.
(d) For $f(t)$: Predicted change $= f(130) - f(0) = (13.625 + 0.006 \cdot 130) - 13.625 = 0.78^\circ$C.
For $g(t)$: Predicted change $= g(130) - g(0) = (0.00006(130^2) - 0.0017(130) + 13.788) - 13.788 = 0.793^\circ$C
For $h(t)$: Predicted change $= h(130) - h(0) = 13.63e^{0.0004(130)} - 13.63 = 0.728^\circ$C.
(e) For the linear model, the answers in parts (c) and (d) are equal.
(f) For the quadratic model, the discrepancy is largest.

108. (a) We have $P = 9.906(0.997)^{11} = 9.584$ million.
(b) Differentiating, we have

$$\frac{dP}{dt} = 9.906(\ln 0.997)(0.997)^t$$
$$\text{so} \quad \left.\frac{dP}{dt}\right|_{t=11} = 9.906(\ln 0.997)(0.997)^{11} = -0.0288 \text{ million/year.}$$

Thus in 2020, Hungary's population will be decreasing by about 28,800 people per year.

109. $\dfrac{dF}{dr} = -\dfrac{2GMm}{r^3}$.

110. (a) If the distance $s(t) = 20e^{\frac{t}{2}}$, then the velocity, $v(t)$, is given by

$$v(t) = s'(t) = \left(20e^{\frac{t}{2}}\right)' = \left(\frac{1}{2}\right)\left(20e^{\frac{t}{2}}\right) = 10e^{\frac{t}{2}}.$$

(b) Observing the differentiation in (a), we note that

$$s'(t) = v(t) = \frac{1}{2}\left(20e^{\frac{t}{2}}\right) = \frac{1}{2}s(t).$$

Substituting $s(t)$ for $20e^{\frac{t}{2}}$, we obtain $s'(t) = \frac{1}{2}s(t)$.

111. (a) The rate of change of the population is $P'(t)$. If $P'(t)$ is proportional to $P(t)$, we have

$$P'(t) = kP(t).$$

(b) If $P(t) = Ae^{kt}$, then $P'(t) = kAe^{kt} = kP(t)$.

112. (a) Differentiating, we see

$$v = \frac{dy}{dt} = -2\pi\omega y_0 \sin(2\pi\omega t)$$
$$a = \frac{dv}{dt} = -4\pi^2\omega^2 y_0 \cos(2\pi\omega t).$$

(b) We have

$$y = y_0 \cos(2\pi\omega t)$$
$$v = -2\pi\omega y_0 \sin(2\pi\omega t)$$
$$a = -4\pi^2\omega^2 y_0 \cos(2\pi\omega t).$$

So

$$\text{Amplitude of } y \text{ is } |y_0|,$$
$$\text{Amplitude of } v \text{ is } |2\pi\omega y_0| = 2\pi\omega|y_0|,$$
$$\text{Amplitude of } a \text{ is } |4\pi^2\omega^2 y_0| = 4\pi^2\omega^2|y_0|.$$

The amplitudes are different (provided $2\pi\omega \neq 1$). The periods of the three functions are all the same, namely $1/\omega$.

(c) Looking at the answer to part (a), we see

$$\begin{aligned}\frac{d^2y}{dt^2} &= a = -4\pi^2\omega^2\left(y_0\cos(2\pi\omega t)\right)\\ &= -4\pi^2\omega^2 y.\end{aligned}$$

So we see that

$$\frac{d^2y}{dt^2} + 4\pi^2\omega^2 y = 0.$$

113. (a) Since $\lim_{t\to\infty} e^{-0.1t} = 0$, we see that $\lim_{t\to\infty}\frac{1000000}{1+5000e^{-0.1t}} = 1000000$. Thus, in the long run, close to 1,000,000 people will have had the disease. This can be seen in Figure 3.29.

(b) The rate at which people fall sick is given by the first derivative $N'(t)$.
$N'(t) \approx \frac{\Delta N}{\Delta t}$, where $\Delta t = 1$ day.

$$N'(t) = \frac{500{,}000{,}000}{e^{0.1t}(1+5000e^{-0.1t})^2} = \frac{500{,}000{,}000}{e^{0.1t} + 25{,}000{,}000e^{-0.1t} + 10^4}$$

In Figure 3.30, we see that the maximum value of $N'(t)$ is approximately 25,000. Therefore the maximum number of people to fall sick on any given day is 25,000. Thus there are no days on which a quarter million or more get sick.

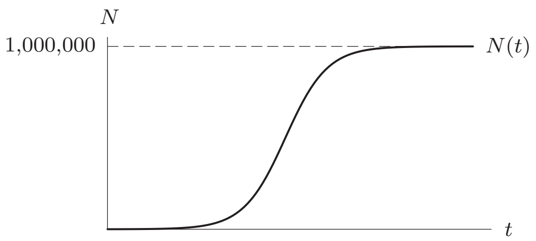

Figure 3.29

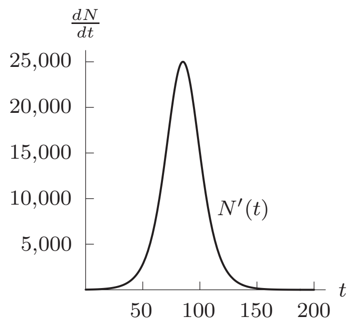

Figure 3.30

114. (a) We solve for t to find the time it takes for the population to reach 10 billion.

$$\begin{aligned}P(t) &= 10\\ 6.7e^{kt} &= 10\\ e^{kt} &= \frac{10}{6.7}\\ t &= \frac{\ln(10/6.7)}{k} = \frac{0.40048}{k} \text{ years}\end{aligned}$$

Thus the time is

$$f(k) = \frac{0.40048}{k} \text{ years.}$$

(b) The time to reach 10 billion with a growth rate of 1.2% is

$$f(0.012) = \frac{0.40048}{0.012} = 33.4 \text{ years.}$$

(c) We have

$$f'(k) = \frac{-0.40048}{k^2}$$
$$f'(0.012) = -2781.$$

Thus, for growth rates, k, near 1.2% we have

$$\text{Time for world population to reach 10 billion} = f(k) \approx f(0.012) + f'(0.012)(k - 0.012)$$
$$f(k) = 33.4 - 2781(k - 0.012) \text{ years}$$

(d) True time to reach 10 billion when the growth rate is 1.0% is $f(0.01) = 0.40048/0.01 = 40.0$ years. The linear approximation gives

$$\text{Approximate time} = 33.4 - 2781(0.01 - 0.012) = 39.0 \text{ years.}$$

115. (a) Suppose

$$g = f(r) = \frac{GM}{r^2}.$$

Then

$$f'(r) = \frac{-2GM}{r^3}.$$

So

$$f(r + \Delta r) \approx f(r) - \frac{2GM}{r^3}(\Delta r).$$

Since $f(r + \Delta r) - f(r) = \Delta g$, and $g = GM/r^2$, we have

$$\Delta g \approx -2\frac{GM}{r^3}(\Delta r) = -2g\frac{\Delta r}{r}.$$

(b) The negative sign tells us that the acceleration due to gravity decreases as the distance from the center of the earth increases.

(c) The fractional change in g is given by

$$\frac{\Delta g}{g} \approx -2\frac{\Delta r}{r}.$$

So, since $\Delta r = 4.315$ km and $r = 6400$ km, we have

$$\frac{\Delta g}{g} \approx -2\left(\frac{4.315}{6400}\right) = -0.00135 = -0.135\%.$$

116. Since g is the inverse of f, we know that $g(4) = f^{-1}(4) = 3$, so

$$g'(4) = \frac{1}{f'(g(4))} = \frac{1}{f'(3)} = \frac{1}{6}.$$

117. We must have

$$(f^{-1})'(5) = \frac{1}{f'(f^{-1}(5))} = \frac{1}{f'(10)} = \frac{1}{8}.$$

118. We know that the velocity is given by

$$\frac{dx}{dt} = v(x).$$

By the chain rule,

$$\text{Acceleration } = \frac{dv}{dt} = \frac{dv}{dx} \cdot \frac{dx}{dt} = v'(x)v(x).$$

119. Since $f(x)$ is decreasing, its inverse function $f^{-1}(x)$ is also decreasing. Thus $(f^{-1})'(x) \leq 0$ for all x. Option (b) is incorrect.

120. (a) If $y = \ln x$, then

$$\begin{aligned} y' &= \frac{1}{x} \\ y'' &= -\frac{1}{x^2} \\ y''' &= \frac{2}{x^3} \\ y'''' &= -\frac{3\cdot 2}{x^4} \end{aligned}$$

and so

$$y^{(n)} = (-1)^{n+1}(n-1)!x^{-n}.$$

(b) If $y = xe^x$, then

$$\begin{aligned} y' &= xe^x + e^x \\ y'' &= xe^x + 2e^x \\ y''' &= xe^x + 3e^x \end{aligned}$$

so that

$$y^{(n)} = xe^x + ne^x.$$

(c) If $y = e^x \cos x$, then

$$\begin{aligned} y' &= e^x(\cos x - \sin x) \\ y'' &= -2e^x \sin x \\ y''' &= e^x(-2\cos x - 2\sin x) \\ y^{(4)} &= -4e^x \cos x \\ y^{(5)} &= e^x(-4\cos x + 4\sin x) \\ y^{(6)} &= 8e^x \sin x. \end{aligned}$$

Combining these results we get

$$\begin{aligned} y^{(n)} &= (-4)^{(n-1)/4}e^x(\cos x - \sin x), && n = 4m+1, \quad m = 0,1,2,3,\dots \\ y^{(n)} &= -2(-4)^{(n-2)/4}e^x \sin x, && n = 4m+2, \quad m = 0,1,2,3,\dots \\ y^{(n)} &= -2(-4)^{(n-3)/4}e^x(\cos x + \sin x), && n = 4m+3, \quad m = 0,1,2,3,\dots \\ y^{(n)} &= (-4)^{(n/4)}e^x \cos x, && n = 4m, \quad m = 1,2,3,\dots. \end{aligned}$$

121. (a) We multiply through by $h = f\cdot g$ and cancel as follows:

$$\begin{aligned} \frac{f'}{f} + \frac{g'}{g} &= \frac{h'}{h} \\ \left(\frac{f'}{f} + \frac{g'}{g}\right)\cdot fg &= \frac{h'}{h}\cdot fg \\ \frac{f'}{f}\cdot fg + \frac{g'}{g}\cdot fg &= \frac{h'}{h}\cdot h \\ f'\cdot g + g'\cdot f &= h', \end{aligned}$$

which is the product rule.

(b) We start with the product rule, multiply through by $1/(fg)$ and cancel as follows:

$$\begin{aligned} f'\cdot g + g'\cdot f &= h' \\ (f'\cdot g + g'\cdot f)\cdot\frac{1}{fg} &= h'\cdot\frac{1}{fg} \\ (f'\cdot g)\cdot\frac{1}{fg} + (g'\cdot f)\cdot\frac{1}{fg} &= h'\cdot\frac{1}{fg} \\ \frac{f'}{f} + \frac{g'}{g} &= \frac{h'}{h}, \end{aligned}$$

which is the additive rule shown in part (a).

122. This problem can be solved by using either the quotient rule or the fact that

$$\frac{f'}{f} = \frac{d}{dx}(\ln f) \quad \text{and} \quad \frac{g'}{g} = \frac{d}{dx}(\ln g).$$

We use the second method. The relative rate of change of f/g is $(f/g)'/(f/g)$, so

$$\frac{(f/g)'}{f/g} = \frac{d}{dx}\ln\left(\frac{f}{g}\right) = \frac{d}{dx}(\ln f - \ln g) = \frac{d}{dx}(\ln f) - \frac{d}{dx}(\ln g) = \frac{f'}{f} - \frac{g'}{g}.$$

Thus, the relative rate of change of f/g is the difference between the relative rates of change of f and of g.

CAS Challenge Problems

123. (a) Answers from different computer algebra systems may be in different forms. One form is:

$$\frac{d}{dx}(x+1)^x = x(x+1)^{x-1} + (x+1)^x\ln(x+1)$$
$$\frac{d}{dx}(\sin x)^x = x\cos x(\sin x)^{x-1} + (\sin x)^x\ln(\sin x)$$

(b) Both the answers in part (a) follow the general rule:

$$\frac{d}{dx}f(x)^x = xf'(x)\,(f(x))^{x-1} + (f(x))^x\ln(f(x)).$$

(c) Applying this rule to $g(x)$, we get

$$\frac{d}{dx}(\ln x)^x = x(1/x)(\ln x)^{x-1} + (\ln x)^x\ln(\ln x) = (\ln x)^{x-1} + (\ln x)^x\ln(\ln x).$$

This agrees with the answer given by the computer algebra system.

(d) We can write $f(x) = e^{\ln(f(x))}$. So

$$(f(x))^x = (e^{\ln(f(x))})^x = e^{x\ln(f(x))}.$$

Therefore, using the chain rule and the product rule,

$$\begin{aligned}\frac{d}{dx}(f(x))^x &= \frac{d}{dx}(x\ln(f(x)))\cdot e^{x\ln(f(x))} = \left(\ln(f(x)) + x\frac{d}{dx}\ln(f(x))\right)e^{x\ln(f(x))}\\ &= \left(\ln(f(x)) + x\frac{f'(x)}{f(x)}\right)(f(x))^x = \ln(f(x))\,(f(x))^x + xf'(x)\,(f(x))^{x-1}\\ &= xf'(x)\,(f(x))^{x-1} + (f(x))^x\ln(f(x)).\end{aligned}$$

124. (a) A CAS gives $f'(x) = 1$.

(b) By the chain rule,

$$f'(x) = \cos(\arcsin x)\cdot\frac{1}{\sqrt{1-x^2}}.$$

Now $\cos t = \pm\sqrt{1-\sin^2 t}$. Furthermore, if $-\pi/2 \le t \le \pi/2$ then $\cos t \ge 0$, so we take the positive square root and get $\cos t = \sqrt{1-\sin^2 t}$. Since $-\pi/2 \le \arcsin x \le \pi/2$ for all x in the domain of arcsin, we have

$$\cos(\arcsin x) = \sqrt{1-(\sin(\arcsin x))^2} = \sqrt{1-x^2},$$

so

$$\frac{d}{dx}\sin(\arcsin(x)) = \sqrt{1-x^2}\cdot\frac{1}{\sqrt{1-x^2}} = 1.$$

(c) Since $\sin(\arcsin(x)) = x$, its derivative is 1.

125. (a) A CAS gives $g'(r) = 0$.

(b) Using the product rule,

$$\begin{aligned}g'(r) &= \frac{d}{dr}(2^{-2r})\cdot 4^r + 2^{-2r}\frac{d}{dr}(4^r) = -2\ln 2\cdot 2^{-2r}4^r + 2^{-2r}\ln 4\cdot 4^r\\ &= -\ln 4\cdot 2^{-2r}4^r + \ln 4\cdot 2^{-2r}4^r = (-\ln 4 + \ln 4)2^{-2r}4^r = 0\cdot 2^{-2r}4^r = 0.\end{aligned}$$

(c) By the laws of exponents, $4^r = (2^2)^r = 2^{2r}$, so $2^{-2r}4^r = 2^{-2r}2^{2r} = 2^0 = 1$. Therefore, its derivative is zero.

126. (a) A CAS gives $h'(t) = 0$

(b) By the chain rule

$$h'(t) = \frac{\frac{d}{dt}\left(1-\frac{1}{t}\right)}{1-\frac{1}{t}} + \frac{\frac{d}{dt}\left(\frac{t}{t-1}\right)}{\frac{t}{t-1}} = \frac{\frac{1}{t^2}}{\frac{t-1}{t}} + \frac{\frac{1}{t-1} - \frac{t}{(t-1)^2}}{\frac{t}{t-1}}$$
$$= \frac{1}{t^2-t} + \frac{(t-1)-t}{t^2-t} = \frac{1}{t^2-t} + \frac{-1}{t^2-t} = 0.$$

(c) The expression inside the first logarithm is $1-(1/t) = (t-1)/t$. Using the property $\log A + \log B = \log(AB)$, we get

$$\ln\left(1-\frac{1}{t}\right) + \ln\left(\frac{t}{t-1}\right) = \ln\left(\frac{t-1}{t}\right) + \ln\left(\frac{t}{t-1}\right)$$
$$= \ln\left(\frac{t-1}{t}\cdot\frac{t}{1-t}\right) = \ln 1 = 0.$$

Thus $h(t) = 0$, so $h'(t) = 0$ also.

PROJECTS FOR CHAPTER THREE

1. Let $r = i/100$. (For example if $i = 5\%$, $r = 0.05$.) Then the balance, $\$B$, after t years is given by

$$B = P(1+r)^t,$$

where $\$P$ is the original deposit. If we are doubling our money, then $B = 2P$, so we wish to solve for t in the equation $2P = P(1+r)^t$. This is equivalent to

$$2 = (1+r)^t.$$

Taking natural logarithms of both sides and solving for t yields

$$\ln 2 = t\ln(1+r),$$
$$t = \frac{\ln 2}{\ln(1+r)}.$$

We now approximate $\ln(1+r)$ near $r = 0$. Let $f(r) = \ln(1+r)$. Then $f'(r) = 1/(1+r)$. Thus, $f(0) = 0$ and $f'(0) = 1$, so

$$f(r) \approx f(0) + f'(0)r$$

becomes

$$\ln(1+r) \approx r.$$

Therefore,

$$t = \frac{\ln 2}{\ln(1+r)} \approx \frac{\ln 2}{r} = \frac{100\ln 2}{i} \approx \frac{70}{i},$$

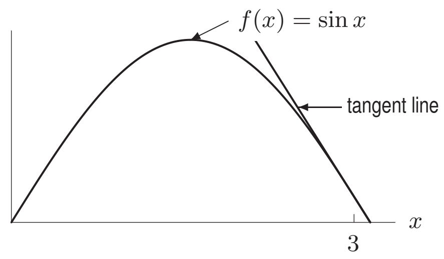
as claimed. We expect this approximation to hold for small values of i; it turns out that values of i up to 10 give good enough answers for most everyday purposes.

2. **(a)** (i) Set $f(x) = \sin x$, so $f'(x) = \cos x$. Guess $x_0 = 3$. Then

$$x_1 = 3 - \frac{\sin 3}{\cos 3} \approx 3.1425$$
$$x_2 = x_1 - \frac{\sin x_1}{\cos x_1} \approx 3.1415926533,$$

which is correct to one billionth!

(ii) Newton's method uses the tangent line at $x = 3$, i.e. $y - \sin 3 = \cos(3)(x - 3)$. Around $x = 3$, however, $\sin x$ is almost linear, since the second derivative $\sin''(\pi) = 0$. Thus using the tangent line to get an approximate value for the root gives us a very good approximation.



(iii) For $f(x) = \sin x$, we have

$$f(3) = 0.14112$$
$$f(4) = -0.7568,$$

so there is a root in $[3, 4]$. We now continue bisecting:

$$[3, 3.5] : f(3.5) = -0.35078 \text{ (bisection 1)}$$
$$[3, 3.25] : f(3.25) = -0.10819 \text{ (bisection 2)}$$
$$[3.125, 3.25] : f(3.125) = \quad 0.01659 \text{ (bisection 3)}$$
$$[3.125, 3.1875] : f(3.1875) = -0.04584 \text{ (bisection 4)}$$

We continue this process; after 11 bisections, we know the root lies between 3.1411 and 3.1416, which still is not as good an approximation as what we get from Newton's method in just two steps.

(b) (i) We have $f(x) = \sin x - \frac{2}{3}x$ and $f'(x) = \cos x - \frac{2}{3}$.
Using $x_0 = 0.904$,

$$x_1 = 0.904 - \frac{\sin(0.904) - \frac{2}{3}(0.904)}{\cos(0.904) - \frac{2}{3}} \approx 4.704,$$

$$x_2 = 4.704 - \frac{\sin(4.704) - \frac{2}{3}(4.704)}{\cos(4.704) - \frac{2}{3}} \approx -1.423,$$

$$x_3 = -1.433 - \frac{\sin(-1.423) - \frac{2}{3}(-1.423)}{\cos(-1.423) - \frac{2}{3}} \approx -1.501,$$

$$x_4 = -1.499 - \frac{\sin(-1.501) - \frac{2}{3}(-1.501)}{\cos(-1.501) - \frac{2}{3}} \approx -1.496,$$

$$x_5 = -1.496 - \frac{\sin(-1.496) - \frac{2}{3}(-1.496)}{\cos(-1.496) - \frac{2}{3}} \approx -1.496.$$

Using $x_0 = 0.905$,

$$x_1 = 0.905 - \frac{\sin(0.905) - \frac{2}{3}(0.905)}{\cos(0.905) - \frac{2}{3}} \approx 4.643,$$

$$x_2 = 4.643 - \frac{\sin(4.643) - \frac{2}{3}(4.643)}{\cos(4.643) - \frac{2}{3}} \approx -0.918,$$

$$x_3 = -0.918 - \frac{\sin(-0.918) - \frac{2}{3}(-0.918)}{\cos(-0.918) - \frac{2}{3}} \approx -3.996,$$

$$x_4 = -3.996 - \frac{\sin(-3.996) - \frac{2}{3}(-3.996)}{\cos(-3.996) - \frac{2}{3}} \approx -1.413,$$

$$x_5 = -1.413 - \frac{\sin(-1.413) - \frac{2}{3}(-1.413)}{\cos(-1.413) - \frac{2}{3}} \approx -1.502,$$

$$x_6 = -1.502 - \frac{\sin(-1.502) - \frac{2}{3}(-1.502)}{\cos(-1.502) - \frac{2}{3}} \approx -1.496.$$

Now using $x_0 = 0.906$,

$$x_1 = 0.906 - \frac{\sin(0.906) - \frac{2}{3}(0.906)}{\cos(0.906) - \frac{2}{3}} \approx 4.584,$$

$$x_2 = 4.584 - \frac{\sin(4.584) - \frac{2}{3}(4.584)}{\cos(4.584) - \frac{2}{3}} \approx -0.509,$$

$$x_3 = -0.510 - \frac{\sin(-0.509) - \frac{2}{3}(-0.509)}{\cos(-0.509) - \frac{2}{3}} \approx .207,$$

$$x_4 = -1.300 - \frac{\sin(.207) - \frac{2}{3}(.207)}{\cos(.207) - \frac{2}{3}} \approx -0.009,$$

$$x_5 = -1.543 - \frac{\sin(-0.009) - \frac{2}{3}(-0.009)}{\cos(-0.009) - \frac{2}{3}} \approx 0,$$

(ii) Starting with 0.904 and 0.905 yields the same value, but the two paths to get to the root are very different. Starting with 0.906 leads to a different root. Our starting points were near the maximum value of f. Consequently, a small change in x_0 makes a large change in x_1.

CHAPTER FOUR

Solutions for Section 4.1

Exercises

1. See Figure 4.1.

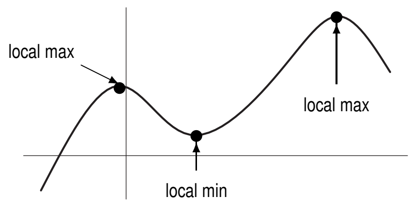


Figure 4.1

2. There are many possible answers. One possible graph is shown in Figure 4.2.

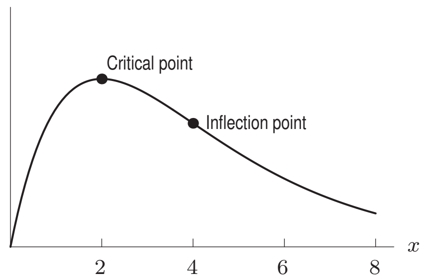

Figure 4.2

3. We sketch a graph which is horizontal at the two critical points. One possibility is shown in Figure 4.3.

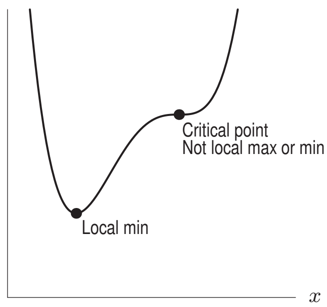

Figure 4.3

4. To find the critical points, we set $f'(x) = 0$. Since $f'(x) = 3x^2 - 18x + 24$, we have

$$\begin{aligned} 3x^2 - 18x + 24 &= 0 \\ 3(x^2 - 6x + 8) &= 0 \\ 3(x-2)(x-4) &= 0 \\ x &= 2, 4. \end{aligned}$$

There are two critical points: at $x = 2$, $x = 4$.
To find the inflection points, we look for points where f'' is zero or undefined. Since $f''(x) = 6x - 18$, it is defined everywhere, and setting $f''(x) = 0$ we get

$$\begin{aligned} 6x - 18 &= 0 \\ x &= 3. \end{aligned}$$

Furthermore, $6x - 18$ is positive when $x > 3$ and negative when $x < 3$, so f'' changes sign at $x = 3$. Thus, there is one inflection point: $x = 3$.

5. To find the critical points, we set $f'(x) = 0$. Since $f'(x) = 5x^4 - 30x^2$, we have

$$\begin{aligned} 5x^4 - 30x^2 &= 0 \\ 5x^2(x^2 - 6) &= 0 \\ x &= 0, -\sqrt{6}, \sqrt{6}. \end{aligned}$$

There are three critical points: $x = 0$, $x = -\sqrt{6}$, and $x = \sqrt{6}$.
To find the inflection points, we look for points where f'' is undefined or zero. Since $f''(x) = 20x^3 - 60x$, it is defined everywhere. Setting it equal to zero, we get

$$\begin{aligned} 20x^3 - 60x &= 0 \\ 20x(x^2 - 3) &= 0 \\ x &= 0, -\sqrt{3}, \sqrt{3}. \end{aligned}$$

Furthermore, $20x^3 - 60x$ is positive when $-\sqrt{3} < x < 0$ or $x > \sqrt{3}$ and negative when $x < -\sqrt{3}$ or $0 < x < \sqrt{3}$, so f'' changes sign at each of the solutions. Thus, there are three inflection points: $x = 0$, $x = -\sqrt{3}$, and $x = \sqrt{3}$.

6. To find the critical points, we set $f'(x) = 0$. Since $f'(x) = 5x^4 + 60x^3$, we have

$$\begin{aligned} 5x^4 + 60x^3 &= 0 \\ 5x^3(x + 12) &= 0 \\ x &= 0, -12. \end{aligned}$$

There are two critical points: $x = 0$, $x = -12$.
To find the inflection points, look for points where f'' is undefined or zero. Since $f''(x) = 20x^3 + 180x^2$, it is defined everywhere. Setting it equal to zero, we get

$$\begin{aligned} 20x^3 + 180x^2 &= 0 \\ 20x^2(x + 9) &= 0 \\ x &= 0, -9. \end{aligned}$$

Furthermore, $20x^2(x + 9)$ is negative when $x < -9$, and positive or zero when $x > -9$. So f'' does change sign at $x = -9$, but not at $x = 0$. Thus, there is one inflection point: $x = -9$.

7. To find the critical points, we set $f'(x) = 0$. Since $f'(x) = 5 - 3(1/x)$, we have

$$\begin{aligned} 5 - \frac{3}{x} &= 0 \\ 5 &= \frac{3}{x} \\ 5x &= 3 \\ x &= 3/5. \end{aligned}$$

There is one critical point, at $x = 3/5$.
To find the inflection points, we look for points where $f''(x)$ is undefined or zero. Since $f''(x) = 3x^{-2}$, it is undefined at $x = 0$. However, $f(x)$ is also undefined at $x = 0$, so this is not an inflection point. Also, $3/x^2$ is never equal to zero, so there are no inflection points.

8. To find the critical points, we set $f'(x) = 0$. Using the product rule, we have $f'(x) = 4x \cdot (e^{3x} \cdot 3) + 4 \cdot e^{3x}$.

$$\begin{aligned} 12xe^{3x} + 4e^{3x} &= 0 \\ 4e^{3x}(3x+1) &= 0 \\ x &= -1/3. \end{aligned}$$

There is one critical point, at $x = -1/3$.
To find the inflection points, we look for points where f'' is zero or undefined. Since $f''(x) = 12x \cdot (e^{3x} \cdot 3) + 12 \cdot e^{3x} + 4e^{3x} \cdot 3 = 12e^{3x}(3x+2)$, it is defined everywhere. Setting it equal to zero, we get

$$\begin{aligned} 12e^{3x}(3x+2) &= 0 \\ x &= -2/3. \end{aligned}$$

Since $12e^{3x}$ is always positive, $12e^{3x}(3x+2)$ is negative when $x < -2/3$ and positive when $x > -2/3$, so f'' changes sign at $x = -2/3$. Thus, there is one inflection point, at $x = -2/3$.

9. $f'(x) = 12x^3 - 12x^2$. To find critical points, we set $f'(x) = 0$. This implies $12x^2(x-1) = 0$. So the critical points of f are $x = 0$ and $x = 1$. To the left of $x = 0$, $f'(x) < 0$. Between $x = 0$ and $x = 1$, $f'(x) < 0$. To the right of $x = 1$, $f'(x) > 0$. Therefore, $f(1)$ is a local minimum, but $f(0)$ is not a local extremum. See Figure 4.4.

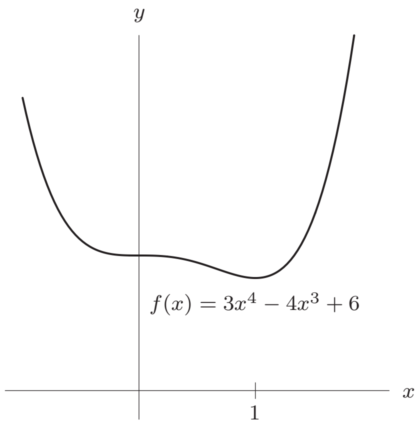

Figure 4.4

10. $f'(x) = 7(x^2-4)^6 2x = 14x(x-2)^6(x+2)^6$. The critical points of f are $x = 0$, $x = \pm 2$. To the left of $x = -2$, $f'(x) < 0$. Between $x = -2$ and $x = 0$, $f'(x) < 0$. Between $x = 0$ and $x = 2$, $f'(x) > 0$. To the right of $x = 2$, $f'(x) > 0$. Thus, $f(0)$ is a local minimum, whereas $f(-2)$ and $f(2)$ are not local extrema. See Figure 4.5.

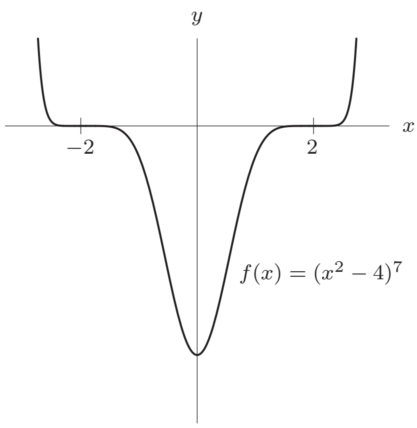

Figure 4.5

11. $f'(x) = 4(x^3-8)^3 3x^2$
$= 12x^2(x-2)^3(x^2+2x+4)^3$.
So the critical points are $x = 0$ and $x = 2$.
To the left of $x = 0$, $f'(x) < 0$.
Between $x = 0$ and $x = 2$, $f'(x) < 0$.
To the right of $x = 2$, $f'(x) > 0$.
Thus, $f(2)$ is a local minimum, whereas $f(0)$ is not a local extremum. See Figure 4.6.

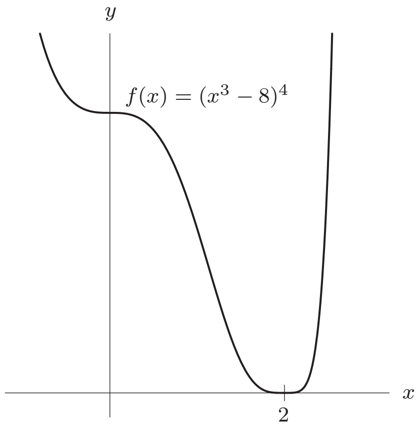

Figure 4.6

12.

$$f'(x) = \frac{x^2+1-x\cdot 2x}{(x^2+1)^2} = \frac{1-x^2}{(x^2+1)^2} = \frac{(1-x)(1+x)}{(x^2+1)^2}.$$

Critical points are $x = \pm 1$. To the left of $x = -1$, $f'(x) < 0$.
Between $x = -1$ and $x = 1$, $f'(x) > 0$.
To the right of $x = 1$, $f'(x) < 0$.
So, $f(-1)$ is a local minimum, $f(1)$ a local maximum. See Figure 4.7.

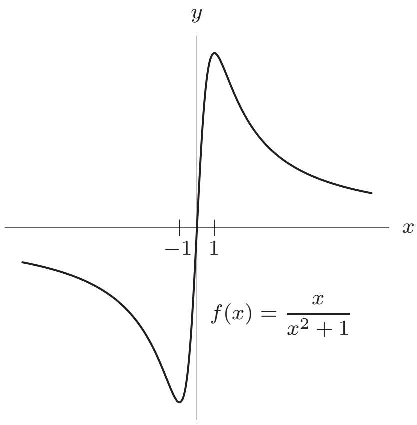

Figure 4.7

13. We have

$$g'(x) = e^{-3x} - 3xe^{-3x} = (1-3x)e^{-3x}.$$

To find critical points, we set $g'(x) = 0$. Then

$$(1-3x)e^{-3x} = 0.$$

Therefore, the critical point of g is $x = 1/3$. To the left of $x = 1/3$, we have $g'(x) > 0$. To the right of $x = 1/3$, we have $g'(x) < 0$. Thus $g(1/3)$ is a local maximum. See Figure 4.8.

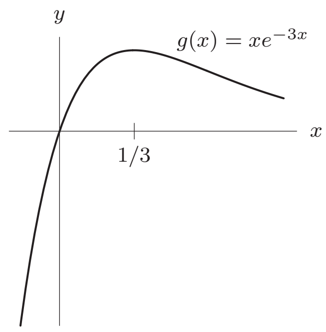

Figure 4.8

14. We have

$$h'(x) = 1 - 1/x^2.$$

To find critical points, we set $h'(x) = 0$. Then

$$\begin{aligned} 1 - \frac{1}{x^2} &= 0 \\ 1 &= \frac{1}{x^2} \\ x &= \pm 1. \end{aligned}$$

Therefore, the critical points of h are $x = -1$ and $x = 1$. For $0 < x < 1$, we have $h'(x) < 0$, and for $x > 1$, we have $h'(x) > 0$. Thus we have a local minimum at $x = 1$. For $x < -1$, we have $h'(x) > 0$ and for $-1 < x < 0$, we have $h'(x) < 0$. Thus $x = -1$ is a local maximum. See Figure 4.9.

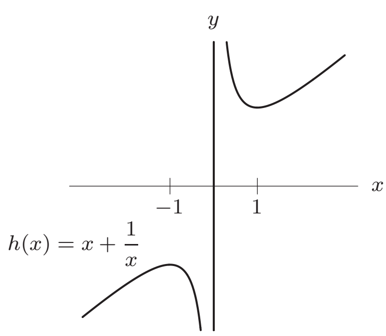

Figure 4.9

15. (a) A graph of $f(x) = e^{-x^2}$ is shown in Figure 4.10. It appears to have one critical point, at $x = 0$, and two inflection points, one between 0 and 1 and the other between 0 and -1.

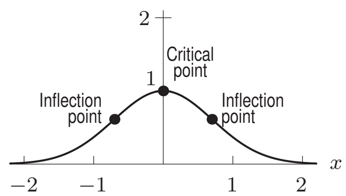

Figure 4.10

(b) To find the critical points, we set $f'(x) = 0$. Since $f'(x) = -2xe^{-x^2} = 0$, there is one solution, $x = 0$. The only critical point is at $x = 0$.
To find the inflection points, we first use the product rule to find $f''(x)$. We have

$$f''(x) = (-2x)(e^{-x^2}(-2x)) + (-2)(e^{-x^2}) = 4x^2e^{-x^2} - 2e^{-x^2}.$$

We set $f''(x) = 0$ and solve for x by factoring:

$$\begin{aligned} 4x^2e^{-x^2} - 2e^{-x^2} &= 0 \\ (4x^2 - 2)e^{-x^2} &= 0. \end{aligned}$$

Since e^{-x^2} is never zero, we have

$$\begin{aligned} 4x^2 - 2 &= 0 \\ x^2 &= \frac{1}{2} \\ x &= \pm 1/\sqrt{2}. \end{aligned}$$

There are exactly two inflection points, at $x = 1/\sqrt{2} \approx 0.707$ and $x = -1/\sqrt{2} \approx -0.707$.

16. (a) Increasing for $x > 0$, decreasing for $x < 0$.
(b) $f(0)$ is a local and global minimum, and f has no global maximum.

17. (a) Increasing for all x.
(b) No maxima or minima.

18. (a) Decreasing for $x < 0$, increasing for $0 < x < 4$, and decreasing for $x > 4$.
(b) $f(0)$ is a local minimum, and $f(4)$ is a local maximum.

19. (a) Decreasing for $x < -1$, increasing for $-1 < x < 0$, decreasing for $0 < x < 1$, and increasing for $x > 1$.
(b) $f(-1)$ and $f(1)$ are local minima, $f(0)$ is a local maximum.

Problems

20. (a) The function $f(x)$ is defined for $x \geq 0$. We set the derivative equal to zero to find critical points:

$$\begin{aligned} f'(x) = 1 + \frac{1}{2}ax^{-1/2} &= 0 \\ 1 + \frac{a}{2\sqrt{x}} &= 0. \end{aligned}$$

Since $a > 0$ and $\sqrt{x} > 0$ for $x > 0$, we have $f'(x) > 0$ for $x > 0$, so there is no critical point with $x > 0$. The only critical point is at $x = 0$ where $f'(x)$ is undefined.
(b) We see in part (a) that the derivative is positive for $x > 0$ so the function is increasing for all $x > 0$. The second derivative is

$$f''(x) = -\frac{1}{4}ax^{-3/2}.$$

Since a and $x^{-3/2}$ are positive for $x > 0$, the second derivative is negative for all $x > 0$. Thus the graph of f is concave down for all $x > 0$.

21. (a) This function is defined for $x > 0$. We set the derivative equal to zero and solve for x to find critical points:

$$\begin{aligned} f'(x) = 1 - b\frac{1}{x} &= 0 \\ 1 &= \frac{b}{x} \\ x &= b. \end{aligned}$$

The only critical point is at $x = b$.
(b) Since $f'(x) = 1 - bx^{-1}$, the second derivative is

$$f''(x) = bx^{-2} = \frac{b}{x^2}.$$

Since $b > 0$, the second derivative is always positive. Thus, the function is concave up everywhere and f has a local minimum at $x = b$.

22. (a) To find the critical points, we set the derivative of $f(x) = ax^{-2} + x$ equal to zero and solve for x.

$$\begin{aligned} f'(x) = -2ax^{-3} + 1 &= 0 \\ \frac{-2a}{x^3} + 1 &= 0 \\ x^3 &= 2a \\ x &= \sqrt[3]{2a}. \end{aligned}$$

There is one critical point, at $x = \sqrt[3]{2a}$. Although f' is undefined at $x = 0$, this is not a critical point since it is not in the domain of f.

(b) The second derivative is

$$f''(x) = 6ax^{-4} = \frac{6a}{x^4}.$$

If a and x^4 are positive, $f''(x)$ is positive and the graph is concave up everywhere, so the function has a local minimum at $x = \sqrt[3]{2a}$. Similarly, if a is negative, then $f''(x)$ is negative and the graph is concave down everywhere, so the function has a local maximum at $x = \sqrt[3]{2a}$.

23. To find the critical points, we set the derivative equal to zero and solve for t.

$$\begin{aligned} F'(t) = Ue^t + Ve^{-t}(-1) &= 0 \\ Ue^t - \frac{V}{e^t} &= 0 \\ Ue^t &= \frac{V}{e^t} \\ Ue^{2t} &= V \\ e^{2t} &= \frac{V}{U} \\ 2t &= \ln(V/U) \\ t &= \frac{\ln(V/U)}{2}. \end{aligned}$$

The derivative $F'(t)$ is never undefined, so the only critical point is $t = 0.5\ln(V/U)$.

24. The critical points of f are zeros of f'. Just to the left of the first critical point $f' > 0$, so f is increasing. Immediately to the right of the first critical point $f' < 0$, so f is decreasing. Thus, the first point must be a maximum. To the left of the second critical point, $f' < 0$, and to its right, $f' > 0$; hence it is a minimum. On either side of the last critical point, $f' > 0$, so it is neither a maximum nor a minimum. See the figure below. See Figure 4.11.

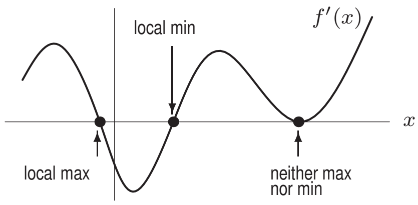

Figure 4.11

25. To find inflection points of the function f we must find points where f'' changes sign. However, because f'' is the derivative of f', any point where f'' changes sign will be a local maximum or minimum on the graph of f'. See Figure 4.12.

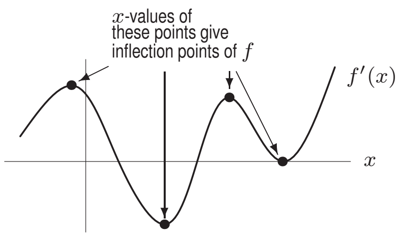

Figure 4.12

26. The inflection points of f are the points where f'' changes sign. See Figure 4.13.

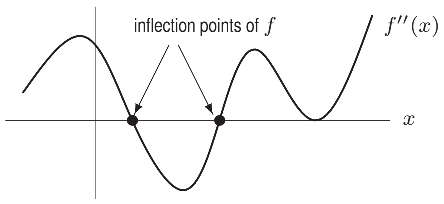

Figure 4.13

27. See Figure 4.14.

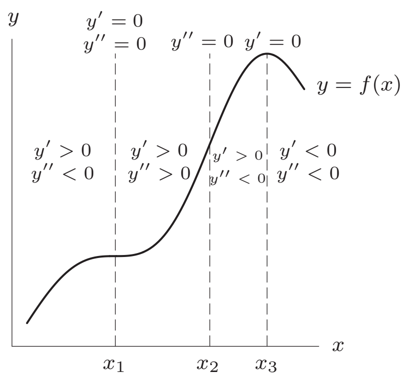

Figure 4.14

28. See Figure 4.15.

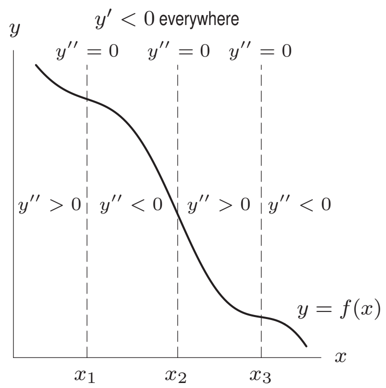

Figure 4.15

29. See Figure 4.16.

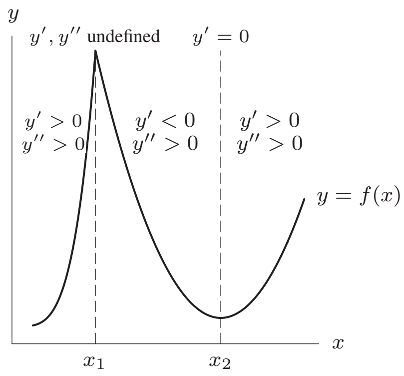

Figure 4.16

30. See Figure 4.17.

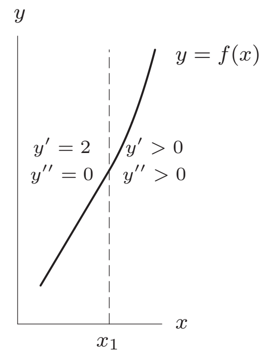

Figure 4.17

31. (a) A critical point occurs when $f'(x) = 0$. Since $f'(x)$ changes sign between $x = 2$ and $x = 3$, between $x = 6$ and $x = 7$, and between $x = 9$ and $x = 10$, we expect critical points at around $x = 2.5$, $x = 6.5$, and $x = 9.5$.

(b) Since $f'(x)$ goes from positive to negative at $x \approx 2.5$, a local maximum should occur there. Similarly, $x \approx 6.5$ is a local minimum and $x \approx 9.5$ a local maximum.

32. (a) It appears that this function has a local maximum at about $x = 1$, a local minimum at about $x = 4$, and a local maximum at about $x = 8$.

(b) The table now gives values of the derivative, so critical points occur where $f'(x) = 0$. Since f' is continuous, this occurs between 2 and 3, so there is a critical point somewhere around 2.5. Since f' is positive for values less than 2.5 and negative for values greater than 2.5, it appears that f has a local maximum at about $x = 2.5$. Similarly, it appears that f has a local minimum at about $x = 6.5$ and another local maximum at about $x = 9.5$.

33. See Figure 4.18.

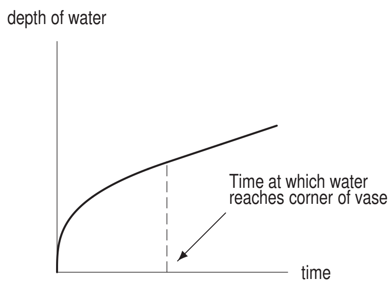

Figure 4.18

34. See Figure 4.19.

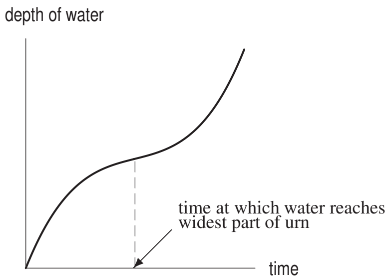

Figure 4.19

35. Differentiating using the product rule gives

$$f'(x) = 3x^2(1-x)^4 - 4x^3(1-x)^3 = x^2(1-x)^3(3(1-x)-4x) = x^2(1-x)^3(3-7x).$$

The critical points are the solutions to

$$f'(x) = x^2(1-x)^3(3-7x) = 0$$
$$x = 0, 1, \frac{3}{7}.$$

For $x < 0$, since $1-x > 0$ and $3-7x > 0$, we have $f'(x) > 0$.
For $0 < x < \frac{3}{7}$, since $1-x > 0$ and $3-7x > 0$, we have $f'(x) > 0$.
For $\frac{3}{7} < x < 1$, since $1-x > 0$ and $3-7x < 0$, we have $f'(x) < 0$.
For $1 < x$, since $1-x < 0$ and $3-7x < 0$, we have $f'(x) > 0$.

Thus, $x = 0$ is neither a local maximum nor a local minimum; $x = 3/7$ is a local maximum; $x = 1$ is a local minimum.

36. By the product rule

$$\begin{aligned} f'(x) = \frac{dx^m(1-x)^n}{dt} &= mx^{m-1}(1-x)^n - nx^m(1-x)^{n-1} \\ &= x^{m-1}(1-x)^{n-1}(m(1-x)-nx) \\ &= x^{m-1}(1-x)^{n-1}(m-(m+n)x). \end{aligned}$$

We have $f'(x) = 0$ at $x = 0$, $x = 1$, and $x = m/(m+n)$, so these are the three critical points of f.

We can classify the critical points by determining the sign of $f'(x)$.
If $x < 0$, then $f'(x)$ has the same sign as $(-1)^{m-1}$: negative if m is even, positive if m is odd.
If $0 < x < m/(m+n)$, then $f'(x)$ is positive.
If $m/(m+n) < x < 1$, then $f'(x)$ is negative.
If $1 < x$, then $f'(x)$ has the same sign as $(-1)^n$: positive if n is even, negative if n is odd.
If m is even, then $f'(x)$ changes from negative to positive at $x = 0$, so f has a local minimum at $x = 0$.
If m is odd, then $f'(x)$ is positive to both the left and right of 0, so $x = 0$ is an inflection point of f.

At $x = m/(m+n)$, the derivative $f'(x)$ changes from positive to negative, so $x = m/(m+n)$ is a local maximum of f.

If n is even, then $f'(x)$ changes from negative to positive at $x = 1$, so f has a local minimum at $x = 1$. If n is odd, then $f'(x)$ is negative to both the left and right of 1, so $x = 1$ is an inflection point of f.

37. (a) From the graph of $P = \dfrac{2000}{1+e^{(5.3-0.4t)}}$ in Figure 4.20, we see that the population levels off at about 2000 rabbits.

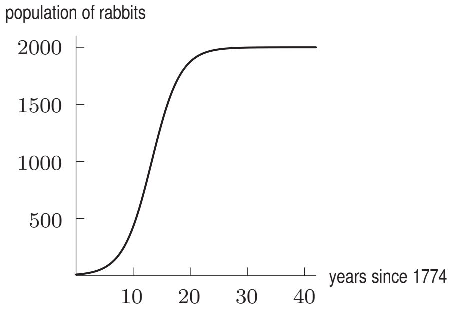

Figure 4.20

(b) The population appears to have been growing fastest when there were about 1000 rabbits, about 13 years after Captain Cook left them there.

(c) The rabbits reproduce quickly, so their population initially grew very rapidly. Limited food and space availability and perhaps predators on the island probably account for the population being unable to grow past 2000.

38. First, we wish to have $f'(6) = 0$, since $f(6)$ should be a local minimum:

$$\begin{aligned} f'(x) &= 2x + a = 0 \\ x &= -\frac{a}{2} = 6 \\ a &= -12. \end{aligned}$$

Next, we need to have $f(6) = -5$, since the point $(6, -5)$ is on the graph of $f(x)$. We can substitute $a = -12$ into our equation for $f(x)$ and solve for b:

$$\begin{aligned} f(x) &= x^2 - 12x + b \\ f(6) &= 36 - 72 + b = -5 \\ b &= 31. \end{aligned}$$

Thus, $f(x) = x^2 - 12x + 31$.

39. We wish to have $f'(3) = 0$. Differentiating to find $f'(x)$ and then solving $f'(3) = 0$ for a gives:

$$\begin{aligned} f'(x) &= x(ae^{ax}) + 1(e^{ax}) = e^{ax}(ax+1) \\ f'(3) &= e^{3a}(3a+1) = 0 \\ 3a + 1 &= 0 \\ a &= -\frac{1}{3}. \end{aligned}$$

Thus, $f(x) = xe^{-x/3}$.

40. Using the product rule on the function $f(x) = axe^{bx}$, we have $f'(x) = ae^{bx} + abxe^{bx} = ae^{bx}(1+bx)$. We want $f(\frac{1}{3}) = 1$, and since this is to be a maximum, we require $f'(\frac{1}{3}) = 0$. These conditions give

$$\begin{aligned} f(1/3) &= a(1/3)e^{b/3} = 1, \\ f'(1/3) &= ae^{b/3}(1 + b/3) = 0. \end{aligned}$$

Since $ae^{(1/3)b}$ is non-zero, we can divide both sides of the second equation by $ae^{(1/3)b}$ to obtain $0 = 1 + \frac{b}{3}$. This implies $b = -3$. Plugging $b = -3$ into the first equation gives us $a(\frac{1}{3})e^{-1} = 1$, or $a = 3e$. How do we know we have a maximum at $x = \frac{1}{3}$ and not a minimum? Since $f'(x) = ae^{bx}(1+bx) = (3e)e^{-3x}(1-3x)$, and $(3e)e^{-3x}$ is always positive, it follows that $f'(x) > 0$ when $x < \frac{1}{3}$ and $f'(x) < 0$ when $x > \frac{1}{3}$. Since f' is positive to the left of $x = \frac{1}{3}$ and negative to the right of $x = \frac{1}{3}$, $f(\frac{1}{3})$ is a local maximum.

41. The graph of $f(x) = x + \sin x$ is in Figure 4.21 and the graph of $f'(x) = 1 + \cos x$ is in Figure 4.22.

Where is f increasing most rapidly? At the points $x = \ldots, -2\pi, 0, 2\pi, 4\pi, 6\pi, \ldots,$ because these points are local maxima for f', and f' has the same value at each of them. Likewise f is increasing least rapidly at the points $x = \ldots, -3\pi, -\pi, \pi, 3\pi, 5\pi, \ldots,$ since these points are local minima for f'. Notice that the points where f is increasing most rapidly and the points where it is increasing least rapidly are inflection points of f.

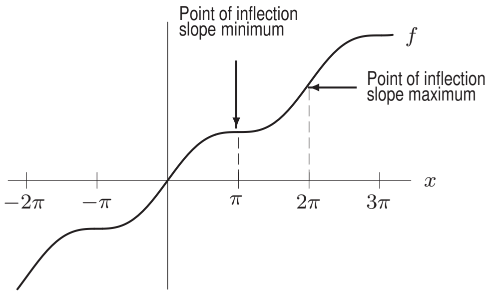

Figure 4.21: Graph of $f(x) = x + \sin x$

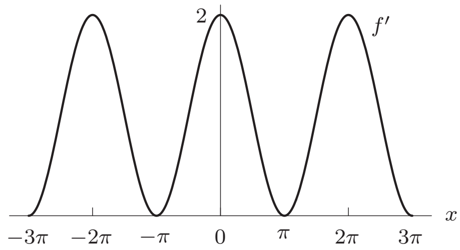

Figure 4.22: Graph of $f'(x) = 1 + \cos x$

42. Figure 4.23 contains the graph of $f(x) = x^2 + \cos x$.

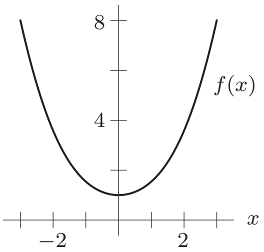

Figure 4.23

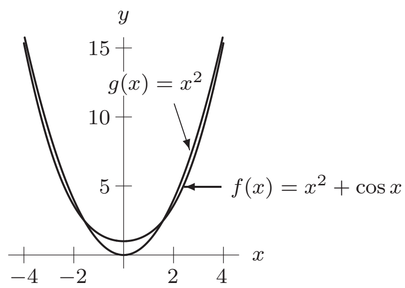

Figure 4.24

The graph looks like a parabola with no waves because $f''(x) = 2 - \cos x$, which is always positive. Thus, the graph of f is concave up everywhere; there are no waves. If you plot the graph of $f(x)$ together with the graph of $g(x) = x^2$, you see that the graph of f does wave back and forth across the graph of g, but never enough to change the concavity of f. See Figure 4.24.

43. Neither B nor C is 0 where A has its maxima and minimum. Therefore neither B nor C is the derivative of A, so $A = f''$. We can see B could be the derivative of C because where C has a maximum, B is 0. However, C is not the derivative of B because B is decreasing for some x-values and C is never negative. Thus, $C = f$, $B = f'$, and $A = f''$.

44. A has zeros where B has maxima and minima, so A could be a derivative of B. This is confirmed by comparing intervals on which B is increasing and A is positive. (They are the same.) So, C is either the derivative of A or the derivative of C is B. However, B does not have a zero at the point where C has a minimum, so B cannot be the derivative of C. Therefore, C is the derivative of A. So $B = f$, $A = f'$, and $C = f''$.

45. Since the derivative of an even function is odd and the derivative of an odd function is even, f and f'' are either both odd or both even, and f' is the opposite. Graphs I and III represent even functions; II represents an odd function, so II is f'. Since the maxima and minima of II occur where I crosses the x-axis, I must be the derivative of f', that is, f''. In addition, the maxima and minima of III occur where II crosses the x-axis, so III is f.

46. Since the derivative of an even function is odd and the derivative of an odd function is even, f and f'' are either both odd or both even, and f' is the opposite. Graphs I and II represent odd functions; III represents an even function, so III is f'. Since the maxima and minima of III occur where I crosses the x-axis, I must be the derivative of f', that is, f''. In addition, the maxima and minima of II occur where III crosses the x-axis, so II is f.

47. Using the quotient rule, since we have

$$f(x) = \frac{x + 50}{x^2 + 525},$$

$$f'(x) = \frac{x^2+525-2x(x+50)}{(x^2+525)^2} = \frac{-x^2-100x+525}{(x^2+525)^2}.$$

Since the denominator is positive for all x, setting $f'(x)=0$ gives:

$$x^2+100x-525=0$$
$$(x-5)(x+105)=0$$
$$x=5,-105.$$

These are the only two critical points. Checking signs using the formula for $f'(x)$, we find $f(x)$ is increasing for $-105 < x < 5$ and $f(x)$ is decreasing for $x < -105$ and $x > 5$.

It is difficult to solve this problem with a calculator for two reasons. First, the critical points are at -105 and 5, which are very far apart. Second, the range of values around the critical points is very small. For example,

$$f(-100) = -0.0047506$$
$$f(-105) = -0.0047619$$
$$f(-110) = -0.0047525$$

Thus, although $x=-105$ gives a local minimum, the graph of f is extremely flat in the neighborhood of -105. It is hard to see these small differences on a graph of f.

48. (a) When a number grows larger, its reciprocal grows smaller. Therefore, since f is increasing near x_0, we know that g (its reciprocal) must be decreasing. Another argument can be made using derivatives. We know that (since f is increasing) $f'(x) > 0$ near x_0. We also know (by the chain rule) that $g'(x) = (f(x)^{-1})' = -\frac{f'(x)}{f(x)^2}$. Since both $f'(x)$ and $f(x)^2$ are positive, this means $g'(x)$ is negative, which in turn means $g(x)$ is decreasing near $x=x_0$.

(b) Since f has a local maximum near x_1, $f(x)$ increases as x nears x_1, and then $f(x)$ decreases as x exceeds x_1. Thus the reciprocal of f, g, decreases as x nears x_1 and then increases as x exceeds x_1. Thus g has a local minimum at $x=x_1$. To put it another way, since f has a local maximum at $x=x_1$, we know $f'(x_1)=0$. Since $g'(x) = -\frac{f'(x)}{f(x)^2}$, $g'(x_1)=0$. To the left of x_1, $f'(x_1)$ is positive, so $g'(x)$ is negative. To the right of x_1, $f'(x_1)$ is negative, so $g'(x)$ is positive. Therefore, g has a local minimum at x_1.

(c) Since f is concave down at x_2, we know $f''(x_2) < 0$. We also know (from above) that

$$g''(x_2) = \frac{2f'(x_2)^2}{f(x_2)^3} - \frac{f''(x_2)}{f(x_2)^2} = \frac{1}{f(x_2)^2}\left(\frac{2f'(x_2)^2}{f(x_2)} - f''(x_2)\right).$$

Since $\frac{1}{f(x_2)^2} > 0$, $2f'(x_2)^2 > 0$, and $f(x_2) > 0$ (as f is assumed to be everywhere positive), we see that $g''(x_2)$ is positive. Thus g is concave up at x_2.

Note that for the first two parts of the problem, we did not need to require f to be positive (only non-zero). However, it was necessary here.

49. We know that $x=1$ is the only solution to $f(x)=0$, and that $x=2$ is the only solution to $f'(x)=0$.

(a) To find the zeros of this function, we solve the equation $y=0$:

$$\begin{aligned} f\left(x^2-3\right) &= 0 \\ x^2-3 &= 1 \qquad \text{because } f(1)=0 \\ x &= \pm 2. \end{aligned}$$

Thus, the zeros are $x=\pm 2$,

(b) To find the critical points of this function, we solve the equation $y'=0$:

$$\begin{aligned} \left(f\left(x^2-3\right)\right)' &= 0 \\ f'\left(x^2-3\right)(x^2-3)' &= 0 \qquad \text{Chain rule} \\ f'\left(x^2-3\right)\cdot 2x &= 0 \\ \text{so either} \quad 2x &= 0 \\ x &= 0 \\ \text{or} \quad f'\left(x^2-3\right) &= 0 \end{aligned}$$

$$\begin{aligned} x^2 - 3 &= 2 \qquad \text{because } f'(2) = 0 \\ x &= \pm\sqrt{5}. \end{aligned}$$

Thus, the critical points are $x = 0, \pm\sqrt{5}$.

50. We know that $x = 1$ is the only solution to $f(x) = 0$, and that $x = 2$ is the only solution to $f'(x) = 0$.

(a) To find the zeros of this function, we solve the equation $y = 0$:

$$\begin{aligned} (f(x))^2 + 3 &= 0 \\ (f(x))^2 &= -3. \quad \text{no solution} \end{aligned}$$

Thus, this function has no zeros.

(b) To find the critical points of this function, we solve the equation $y' = 0$:

$$\begin{aligned} \left((f(x))^2 + 3\right)' &= 0 \\ 2f(x)f'(x) &= 0 \quad \text{Chain rule} \\ \text{so either} \quad f(x) &= 0 \\ x &= 1 \quad \text{because } f(1) = 0 \\ \text{or} \quad f'(x) &= 0 \\ x &= 2. \quad \text{because } f'(2) = 0 \end{aligned}$$

Thus, this function has critical points at $x = 1, 2$.

51. We know $f'(x) < 0$ for all x. Since the graph of f lies entirely above the x-axis, we know $f(x) > 0$ for all x.

For $y = (f(x))^2$, we have:

$$\begin{aligned} \frac{dy}{dx} &= \frac{d}{dx}(f(x))^2 \\ &= 2f(x)f'(x) \\ &= 2\underbrace{(\text{A positive number})}_{f(x)>0}\underbrace{(\text{A negative number})}_{f'(x)<0} \\ &= \text{A negative number.} \end{aligned}$$

We see that dy/dx is everywhere negative.

(a) Since the derivative is defined everywhere and has no zeros, there are no critical points.

(b) Since the derivative is everywhere negative, this is a decreasing function.

52. We know $f'(x) < 0$ for all x. Since the graph of f lies entirely above the x-axis, we know $f(x) > 0$ for all x.

For $y = f(x^2)$, we have:

$$\begin{aligned} \frac{dy}{dx} &= \frac{d}{dx}f\left(x^2\right) \\ &= 2xf'\left(x^2\right) \\ &= 2x \cdot \underbrace{(\text{A negative number})}_{f'\left(x^2\right)<0} \\ &= 2x \cdot (\text{A negative number}). \end{aligned}$$

We see that:

- $dy/dx = 0$ at $x = 0$
- $dy/dx < 0$ for $x > 0$
- $dy/dx > 0$ for $x < 0$

(a) Since $dy/dx = 0$ at $x = 0$, this means there is a critical point at $x = 0$.

(b) Since $dy/dx < 0$ for $x > 0$, the function decreases for $x > 0$. And since $dy/dx > 0$ for $x < 0$, the function increases for $x < 0$.

Strengthen Your Understanding

53. The function $f(x) = x^3$ is increasing and has an inflection point at $x = 0$.

54. Consider $f(x) = x^4$. We have $f''(x) = 12x^2$ so $f''(0) = 0$. However, f'' is positive for all $x \neq 0$. Thus, the graph of f does not change concavity at $x = 0$.

55. One possible example is $f(x) = x$, for which $f'(x) = 1$, so there are no critical points. There are many other examples.

56. One possible example is $f(x) = |x - 1|$. The function is defined at $x = 1$ since $f(1) = 0$, but f is not differentiable at $x = 1$. Thus, f has a critical point at $x = 1$.

57. One possible answer is $f(x) = \cos x$ which has local maxima at $0, \pm 2\pi, \pm 4\pi, \ldots$ (that is, at $x = 2n\pi$ for all integers n). The value at all the local maxima is 1. The local minima are at $\pm\pi, \pm 3\pi, \ldots$ (that is, at $x = (2n + 1)\pi$), all with value -1.

The function $f(x) = \sin x$ is another possibility, and there are many more.

58. True. Since the domain of f is all real numbers, all local minima occur at critical points.

59. True. Since the domain of f is all real numbers, all local maxima occur at critical points. Thus, if $x = p$ is a local maximum, $x = p$ must be a critical point.

60. False. A local maximum of f might occur at a point where f' does not exist. For example, $f(x) = -|x|$ has a local maximum at $x = 0$, but the derivative is not 0 (or defined) there.

61. False, because $x = p$ could be a local minimum of f. For example, if $f(x) = x^2$, then $f'(0) = 0$, so $x = 0$ is a critical point, but $x = 0$ is not a local maximum of f.

62. False. For example, if $f(x) = x^3$, then $f'(0) = 0$, but $f(x)$ does not have either a local maximum or a local minimum at $x = 0$.

63. True. Suppose f is increasing at some points and decreasing at others. Then $f'(x)$ takes both positive and negative values. Since $f'(x)$ is continuous, by the Intermediate Value Theorem, there would be some point where $f'(x)$ is zero, so that there would be a critical point. Since we are told there are no critical points, f must be increasing everywhere or decreasing everywhere.

64. True. Since f'' changes sign at the inflection point $x = p$, by the Intermediate Value Theorem, $f''(p) = 0$.

65. False. For example, if $f(x) = x^3$, then $f'(0) = 0$, so $x = 0$ is a critical point, but $x = 0$ is neither a local maximum nor a local minimum.

66. True. A cubic polynomial is a function of the form $f(x) = Ax^3 + Bx^2 + Cx + D$ with $A \neq 0$. We have $f''(x) = 6Ax + 2B$. There is an inflection point where $f''(x) = 0$, at $x = -B/(3A)$.

67. $f(x) = x^2 + 1$ is positive for all x and concave up.

68. This is impossible. If $f(a) > 0$, then the downward concavity forces the graph of f to cross the x-axis to the right or left of $x = a$, which means $f(x)$ cannot be positive for all values of x. More precisely, suppose that $f(x)$ is positive for all x and f is concave down. Thus there must be some value $x = a$ where $f(a) > 0$ and $f'(a)$ is not zero, since a constant function is not concave down. The tangent line at $x = a$ has nonzero slope and hence must cross the x-axis somewhere to the right or left of $x = a$. Since the graph of f must lie below this tangent line, it must also cross the x-axis, contradicting the assumption that $f(x)$ is positive for all x.

69. $f(x) = -x^2 - 1$ is negative for all x and concave down.

70. This is impossible. If $f(a) < 0$, then the upward concavity forces the graph of f to cross the x-axis to the right or left of $x = a$, which means $f(x)$ cannot be negative for all values of x. More precisely, suppose that $f(x)$ is negative for all x and f is concave up. Thus there must be some value $x = a$ where $f(a) < 0$ and $f'(a)$ is not zero, since a constant function is not concave up. The tangent line at $x = a$ has nonzero slope and hence must cross the x-axis somewhere to the right or left of $x = a$. Since the graph of f must lie above this tangent line, it must also cross the x-axis, contradicting the assumption that $f(x)$ is negative for all x.

71. This is impossible. Since f'' exists, so must f', which means that f is differentiable and hence continuous. If $f(x)$ were positive for some values of x and negative for other values, then by the Intermediate Value Theorem, $f(x)$ would have to be zero somewhere, but this is impossible since $f(x)f''(x) < 0$ for all x. Thus either $f(x) > 0$ for all values of x, in which case $f''(x) < 0$ for all values of x, that is f is concave down. But this is impossible by Problem 68. Or else $f(x) < 0$ for all x, in which case $f''(x) > 0$ for all x, that is f is concave up. But this is impossible by Problem 70.

72. This is impossible. Since f''' exists, f'' must be continuous. By the Intermediate Value Theorem, $f''(x)$ cannot change sign, since $f''(x)$ cannot be zero. In the same way, we can show that $f'(x)$ and $f(x)$ cannot change sign. Since the product of these three with $f'''(x)$ cannot change sign, $f'''(x)$ cannot change sign. Thus $f(x)f''(x)$ and $f'(x)f'''(x)$ cannot change sign. Since their product is negative for all x, one or the other must be negative for all x. By Problem 71, this is impossible.

73. (a) and (c). a is a critical point and $f(a)$ is a local minimum.

Solutions for Section 4.2

Exercises

1. See Figure 4.25.

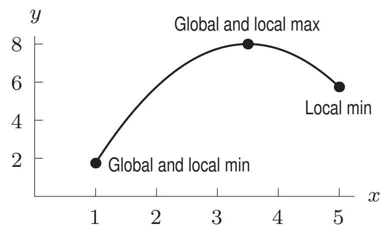

Figure 4.25

2. The global maximum is achieved at the two local maxima, which are at the same height. See Figure 4.26.

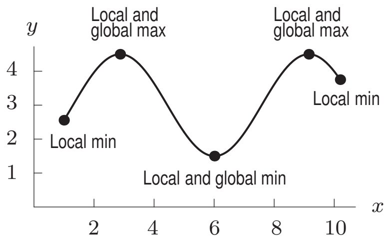

Figure 4.26

3. (a) We see in Figure 4.27 that the maximum occurs at about $x = 4$ and the maximum value of y is about $y = 60$.
(b) The maximum value occurs at a critical point, so we find all critical points of y:

$$\begin{aligned}\frac{dy}{dx} &= 12x - 3x^2 = 0\\ 3x(4-x) &= 0\\ x &= 0, x = 4.\end{aligned}$$

Since y is a cubic polynomial with negative leading coefficient, the critical point $x = 0$ gives a local minimum and the critical point $x = 4$ gives a local maximum. Since we require $x > 0$, the maximum value of the function occurs at $x = 4$. We find the maximum value of y by substituting $x = 4$:

$$\text{Maximum value of } y = 25 + 6 \cdot 4^2 - 4^3 = 57.$$

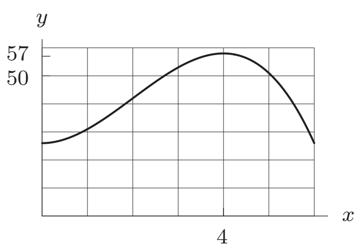

Figure 4.27

4. Since $f(x) = x^3 - 3x^2 + 20$ is continuous and the interval $-1 \leq x \leq 3$ is closed, there must be a global maximum and minimum. The candidates are critical points in the interval and endpoints. Since there are no points where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find all the critical points:

$$f'(x) = 3x^2 - 6x = 3x(x-2) = 0,$$

so $x = 0$ and $x = 2$ are the critical points; both are in the interval. We then compare the values of f at the critical points and the endpoints:

$$f(-1) = 16, \quad f(0) = 20, \quad f(2) = 16, \quad f(3) = 20.$$

Thus the global maximum is 20 at $x = 0$ and $x = 3$, and the global minimum is 16 at $x = -1$ and $x = 2$.

5. Since $f(x) = x^4 - 8x^2$ is continuous and the interval $-3 \leq x \leq 1$ is closed, there must be a global maximum and minimum. The possible candidates are critical points in the interval and endpoints. Since there are no points where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find all the critical points:

$$f'(x) = 4x^3 - 16x = 4x(x^2 - 4) = 0,$$

so $x = -2, 0, 2$ are the critical points; only $x = -2, 0$ are in the interval. We then compare the values of f at the critical points and the endpoints:

$$f(-3) = 9, \quad f(-2) = -16, \quad f(0) = 0, \quad f(1) = -7.$$

Thus the global maximum is 9 at $x = -3$ and the global minimum is -16 at $x = -2$.

6. Since $f(x) = xe^{-x^2/2}$ is continuous and the interval $-2 \leq x \leq 2$ is closed, there must be a global maximum and minimum. The possible candidates are critical points in the interval and endpoints. Since there are no points where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find all the critical points:

$$f'(x) = e^{-x^2/2} + xe^{-x^2/2}(-x) = e^{-x^2/2}(1 - x^2).$$

Since $e^{-x^2/2} \neq 0$, the critical points are $x = -1, 1$; both are in the interval. We then compare the values of f at the critical points and the endpoints:

$$f(2) = 2e^{-2} = 0.271, \quad f(1) = e^{-1/2} = 0.607, \quad f(-1) = -f(1) = -0.607 \quad f(-2) = -f(2) = -0.271.$$

Thus, the global maximum is 0.607 at $x = 1$ and the global minimum is -0.607 at $x = -1$

7. Since $f(x) = 3x^{1/3} - x$ is continuous and the interval $-1 \leq x \leq 8$ is closed, there must be a global maximum and minimum. The possible candidates are critical points in the interval and endpoints. One critical point is $x = 0$, since f' is undefined there. We solve $f'(x) = 0$ to find the other critical points:

$$f'(x) = x^{-2/3} - 1 = 0,$$

so $x = -1$ and $x = 1$. Thus the critical points are $x = -1, 0, 1$; all are in the interval. We then compare the values of f at the critical points and the endpoints:

$$f(-1) = -2, \quad f(0) = 0, \quad f(1) = 2, \quad f(8) = -2.$$

Thus, the global maximum is 2 at $x = 1$, and the global minimum is -2 at $x = -1$ and $x = 8$.

8. Since $f(x) = x - 2\ln(x+2)$ is continuous on the closed interval $0 \leq x \leq 2$, there must be a global maximum and minimum. The possible candidates are critical points in the interval and endpoints. Since there are no points in the interval where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find the critical points:

$$f'(x) = 1 - \frac{2}{x+1} = 0,$$

so $x + 1 - 2 = 0$. Thus the only critical point is $x = 1$, which is in the interval. We then compare the values of f at the critical point and the endpoints:

$$f(0) = 0, \quad f(1) = 1 - 2\ln(2) = -0.386, \quad f(2) = 2 - 2\ln(3) = -0.197.$$

Thus, the global maximum is 0 at $x = 0$, and the global minimum is -0.386 at $x = 1$.

9. Since $f(x) = x^2 - 2|x|$ is continuous and the interval $-3 \le x \le 4$ is closed, there must be a global maximum and minimum. The possible candidates are critical points in the interval and endpoints. The derivative f' is not defined at $x = 0$. To find the other critical points we solve $f'(x) = 0$. For $x > 0$ we have

$$f(x) = x^2 - 2x, \text{ so } f'(x) = 2x - 2 = 0.$$

Thus, $x = 1$ is the only critical point for $0 < x < 4$. For $x < 0$, we have:

$$f(x) = x^2 + 2x, \text{ so } f'(x) = 2x + 2 = 0.$$

Thus $x = -1$ is the only critical point for $-3 < x < 0$. We then compare the values of f at the critical points and the endpoints:

$$f(-3) = 3, \quad f(-1) = -1, \quad f(0) = 0, \quad f(1) = -1. \quad f(4) = 8.$$

Thus the global maximum is 8 at $x = 4$ and the global minimum is -1 at $x = -1$ and $x = 1$.

10. Since the denominator is never 0, we have that $f(x) = (x+1)/(x^2+3)$ is continuous. As the interval $-1 \le x \le 2$ is closed, there must be a global maximum and minimum. The candidates are critical points in the interval and endpoints. Since there are no points where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find all the critical points:

$$f'(x) = \frac{(x^2+3) - (x+1)(2x)}{(x^2+3)^2} = \frac{-x^2 - 2x + 3}{(x^2+3)^2} = 0.$$

Thus $-x^2 - 2x + 3 = -(x+3)(x-1) = 0$, so $x = -3$ and $x = 1$ are the critical points; only $x = 1$ is in the interval. We then compare the values of f at the critical points and the endpoints:

$$f(-1) = 0, \quad f(1) = \frac{1}{2}, \quad f(2) = \frac{3}{7}.$$

Thus the global maximum is $1/2$ at $x = 1$, and the global minimum is 0 at $x = -1$.

11. (a) We have $f'(x) = 10x^9 - 10 = 10(x^9 - 1)$. This is zero when $x = 1$, so $x = 1$ is a critical point of f. For values of x less than 1, x^9 is less than 1, and thus $f'(x)$ is negative when $x < 1$. Similarly, $f'(x)$ is positive for $x > 1$. Thus $f(1) = -9$ is a local minimum.

We also consider the endpoints $f(0) = 0$ and $f(2) = 1004$. Since $f'(0) < 0$ and $f'(2) > 0$, we see $x = 0$ and $x = 2$ are local maxima.

(b) Comparing values of f shows that the global minimum is at $x = 1$, and the global maximum is at $x = 2$.

12. (a) $f'(x) = 1 - 1/x$. This is zero only when $x = 1$. Now $f'(x)$ is positive when $1 < x \le 2$, and negative when $0.1 < x < 1$. Thus $f(1) = 1$ is a local minimum. The endpoints $f(0.1) \approx 2.4026$ and $f(2) \approx 1.3069$ are local maxima.

(b) Comparing values of f shows that $x = 0.1$ gives the global maximum and $x = 1$ gives the global minimum.

13. (a) Differentiating gives

$$f(x) = \sin^2 x - \cos x \quad \text{for } 0 \le x \le \pi$$
$$f'(x) = 2\sin x \cos x + \sin x = (\sin x)(2\cos x + 1),$$

so $f'(x) = 0$ when $\sin x = 0$ or when $2\cos x + 1 = 0$. Now, $\sin x = 0$ when $x = 0$ or when $x = \pi$. On the other hand, $2\cos x + 1 = 0$ when $\cos x = -1/2$, which happens when $x = 2\pi/3$. So the critical points are $x = 0$, $x = 2\pi/3$, and $x = \pi$.

Note that $\sin x > 0$ for $0 < x < \pi$. Also, $2\cos x + 1 < 0$ if $2\pi/3 < x \le \pi$ and $2\cos x + 1 > 0$ if $0 < x < 2\pi/3$. Therefore,

$$f'(x) < 0 \quad \text{for} \quad \frac{2\pi}{3} < x < \pi$$
$$f'(x) > 0 \quad \text{for} \quad 0 < x < \frac{2\pi}{3}.$$

Thus f has a local maximum at $x = 2\pi/3$ and local minima at $x = 0$ and $x = \pi$.

(b) We have

$$f(0) = [\sin(0)]^2 - \cos(0) = -1$$
$$f\left(\frac{2\pi}{3}\right) = \left[\sin\left(\frac{2\pi}{3}\right)\right]^2 - \cos\frac{2\pi}{3} = 1.25$$
$$f(\pi) = [\sin(\pi)]^2 - \cos(\pi) = 1.$$

Thus, the global maximum is at $x = 2\pi/3$, and the global minimum is at $x = 0$.

14. This is a parabola opening downward. We find the critical points by setting $g'(x) = 0$:

$$g'(x) = 4 - 2x = 0$$
$$x = 2.$$

Since $g'(x) > 0$ for $x < 2$ and $g'(x) < 0$ for $x > 2$, the critical point at $x = 2$ is a local maximum.

As $x \to \pm\infty$, the value of $g(x) \to -\infty$. Thus, the local maximum at $x = 2$ is a global maximum of $g(2) = 4 \cdot 2 - 2^2 - 5 = -1$. There is no global minimum. See Figure 4.28.

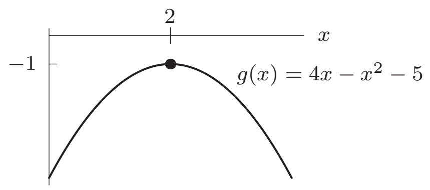

Figure 4.28

15. Differentiating gives

$$f'(x) = 1 - \frac{1}{x^2},$$

so the critical points satisfy

$$1 - \frac{1}{x^2} = 0$$
$$x^2 = 1$$
$$x = 1 \quad \text{(We want } x > 0\text{).}$$

Since f' is negative for $0 < x < 1$ and f' is positive for $x > 1$, there is a local minimum at $x = 1$.

Since $f(x) \to \infty$ as $x \to 0^+$ and as $x \to \infty$, the local minimum at $x = 1$ is a global minimum; there is no global maximum. See Figure 4.29. The the global minimum is $f(1) = 2$.

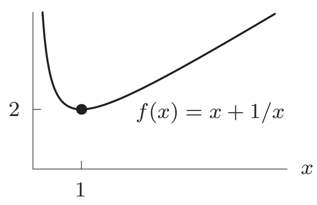

Figure 4.29

16. Differentiating using the product rule gives

$$g'(t) = 1 \cdot e^{-t} - te^{-t} = (1 - t)e^{-t},$$

so the critical point is $t = 1$.

Since $g'(t) > 0$ for $0 < t < 1$ and $g'(t) < 0$ for $t > 1$, the critical point is a local maximum.

As $t \to \infty$, the value of $g(t) \to 0$, and as $t \to 0^+$, the value of $g(t) \to 0$. Thus, the local maximum at $x = 1$ is a global maximum of $g(1) = 1e^{-1} = 1/e$. In addition, the value of $g(t)$ is positive for all $t > 0$; it tends to 0 but never reaches 0. Thus, there is no global minimum. See Figure 4.30.

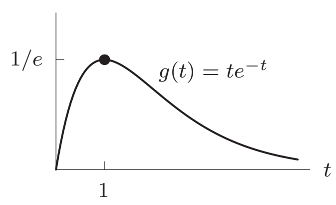

Figure 4.30

17. Differentiating gives

$$f'(x) = 1 - \frac{1}{x},$$

so the critical points satisfy

$$\begin{aligned} 1 - \frac{1}{x} &= 0 \\ \frac{1}{x} &= 1 \\ x &= 1. \end{aligned}$$

Since f' is negative for $0 < x < 1$ and f' is positive for $x > 1$, there is a local minimum at $x = 1$.

Since $f(x) \to \infty$ as $x \to 0^+$ and as $x \to \infty$, the local minimum at $x = 1$ is a global minimum; there is no global maximum. See Figure 4.31. Thus, the global minimum is $f(1) = 1$.

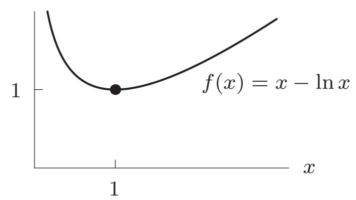

Figure 4.31

18. Differentiating using the quotient rule gives

$$f'(t) = \frac{1(1+t^2) - t(2t)}{(1+t^2)^2} = \frac{1-t^2}{(1+t^2)^2}.$$

The critical points are the solutions to

$$\begin{aligned} \frac{1-t^2}{(1+t^2)^2} &= 0 \\ t^2 &= 1 \\ t &= \pm 1. \end{aligned}$$

Since $f'(t) > 0$ for $-1 < t < 1$ and $f'(t) < 0$ otherwise, there is a local minimum at $t = -1$ and a local maximum at $t = 1$.

As $t \to \pm\infty$, we have $f(t) \to 0$. Thus, the local maximum at $t = 1$ is a global maximum of $f(1) = 1/2$, and the local minimum at $t = -1$ is a global minimum of $f(-1) = -1/2$. See Figure 4.32.

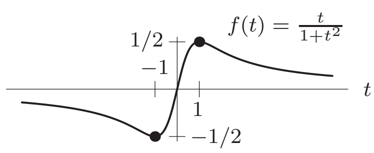

Figure 4.32

19. Differentiating using the product rule gives

$$\begin{aligned} f'(t) = 2\sin t\cos t \cdot \cos t - (\sin^2 t + 2)\sin t &= 0 \\ \sin t(2\cos^2 t - \sin^2 t - 2) &= 0 \\ \sin t(2(1-\sin^2 t) - \sin^2 t - 2) &= 0 \\ \sin t(-3\sin^2 t) = -3\sin^3 t &= 0. \end{aligned}$$

Thus, the critical points are where $\sin t = 0$, so

$$t = 0, \pm\pi, \pm 2\pi, \pm 3\pi, \ldots.$$

Since $f'(t) = -3\sin^3 t$ is negative for $-\pi < t < 0$, positive for $0 < t < \pi$, negative for $\pi < t < 2\pi$, and so on, we find that $t = 0, \pm 2\pi, \ldots$ give local minima, while $t = \pm\pi, \pm 3\pi, \ldots$ give local maxima. Evaluating gives

$$f(0) = f(\pm 2\pi) = (0+2)1 = 2$$
$$f(\pm\pi) = f(\pm 3\pi) = (0+2)(-1) = -2.$$

Thus, the global maximum of $f(t)$ is 2, occurring at $t = 0, \pm 2\pi, \ldots$, and the global minimum of $f(t)$ is -2, occurring at $t = \pm\pi, \pm 3\pi, \ldots$. See Figure 4.33.

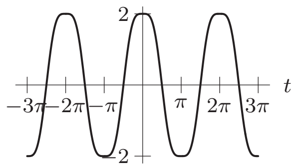

Figure 4.33

20. Let $y = x^3 - 4x^2 + 4x$. To locate the critical points, we solve $y' = 0$. Since $y' = 3x^2 - 8x + 4 = (3x-2)(x-2)$, the critical points are $x = 2/3$ and $x = 2$. To find the global minimum and maximum on $0 \le x \le 4$, we check the critical points and the endpoints: $y(0) = 0$; $y(2/3) = 32/27$; $y(2) = 0$; $y(4) = 16$. Thus, the global minimum is at $x = 0$ and $x = 2$, the global maximum is at $x = 4$, and $0 \le y \le 16$.

21. Let $y = e^{-x^2}$. Since $y' = -2xe^{-x^2}$, y is increasing for $x < 0$ and decreasing for $x > 0$. Hence $y = e^0 = 1$ is a global maximum.

When $x = \pm 0.3$, $y = e^{-0.09} \approx 0.9139$, which is a global minimum on the given interval. Thus $e^{-0.09} \le y \le 1$ for $|x| \le 0.3$.

22. Examination of the graph suggests that $0 \le x^3e^{-x} \le 2$. The lower bound of 0 is the best possible lower bound since

$$f(0) = (0)^3e^{-0} = 0.$$

To find the best possible upper bound, we find the critical points. Differentiating, using the product rule, yields

$$f'(x) = 3x^2e^{-x} - x^3e^{-x}$$

Setting $f'(x) = 0$ and factoring gives

$$3x^2e^{-x} - x^3e^{-x} = 0$$
$$x^2e^{-x}(3-x) = 0$$

So the critical points are $x = 0$ and $x = 3$. Note that $f'(x) < 0$ for $x > 3$ and $f'(x) > 0$ for $x < 3$, so $f(x)$ has a local maximum at $x = 3$. Examination of the graph tells us that this is the global maximum. So $0 \le x^3e^{-x} \le f(3)$.

$$f(3) = 3^3e^{-3} \approx 1.34425$$

So $0 \le x^3e^{-x} \le 3^3e^{-3} \approx 1.34425$ are the best possible bounds for the function.

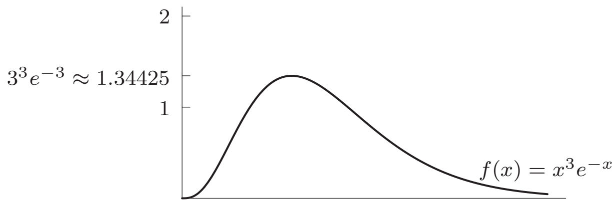

Figure 4.34

23. The graph of $y = x + \sin x$ in Figure 4.35 suggests that the function is nondecreasing over the entire interval. You can confirm this by looking at the derivative:

$$y' = 1 + \cos x$$

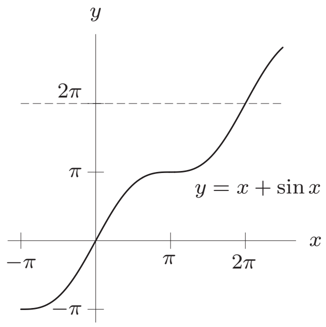

Figure 4.35: Graph of $y = x + \sin x$

Since $\cos x \geq -1$, we have $y' \geq 0$ everywhere, so y never decreases. This means that a lower bound for y is 0 (its value at the left endpoint of the interval) and an upper bound is 2π (its value at the right endpoint). That is, if $0 \leq x \leq 2\pi$:

$$0 \leq y \leq 2\pi.$$

These are the best bounds for y over the interval.

24. Let $y = \ln(1 + x)$. Since $y' = 1/(1 + x)$, y is increasing for all $x \geq 0$. The lower bound is at $x = 0$, so, $\ln(1) = 0 \leq y$. There is no upper bound.

25. Let $y = \ln(1 + x^2)$. Then $y' = 2x/(1 + x^2)$. Since the denominator is always positive, the sign of y' is determined by the numerator $2x$. Thus $y' > 0$ when $x > 0$, and $y' < 0$ when $x < 0$, and we have a local (and global) minimum for y at $x = 0$. Since $y(-1) = \ln 2$ and $y(2) = \ln 5$, the global maximum is at $x = 2$. Thus $0 \leq y \leq \ln 5$, or (in decimals) $0 \leq y < 1.61$. (Note that our upper bound has been rounded *up* from 1.6094.)

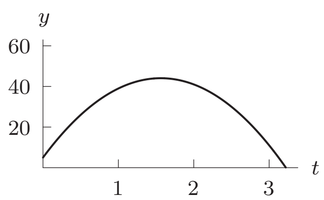
Problems

26. We want to maximize the height, y, of the grapefruit above the ground, as shown in the figure below. Using the derivative we can find exactly when the grapefruit is at the highest point. We can think of this in two ways. By common sense, at the peak of the grapefruit's flight, the velocity, dy/dt, must be zero. Alternately, we are looking for a global maximum of y, so we look for critical points where $dy/dt = 0$. We have

$$\frac{dy}{dt} = -32t + 50 = 0 \qquad \text{and so} \qquad t = \frac{-50}{-32} \approx 1.56 \text{ sec.}$$

Thus, we have the time at which the height is a maximum; the maximum value of y is then

$$y \approx -16(1.56)^2 + 50(1.56) + 5 = 44.1 \text{ feet.}$$



27. We find all critical points:

$$\frac{dy}{dx} = 2ax + b = 0$$
$$x = -\frac{b}{2a}.$$

Since y is a quadratic polynomial, its graph is a parabola which opens up if $a > 0$ and down if $a < 0$. The critical value is a maximum if $a < 0$ and a minimum if $a > 0$.

28. To find the value of w that minimizes S, we set dS/dw equal to zero and solve for w. To find dS/dw, we first solve for S:

$$S - 5pw = 3qw^2 - 6pq$$
$$S = 5pw + 3qw^2 - 6pq.$$

We now find the critical points:

$$\frac{dS}{dw} = 5p + 6qw = 0$$
$$w = -\frac{5p}{6q}.$$

There is one critical point. Since S is a quadratic function of w with a positive leading coefficient, the function has a minimum at this critical point.

29. To find the value of t that maximizes y, we set dy/dt equal to zero and solve for t. We use the product rule to find dy/dt.

$$\frac{dy}{dt} = at^2e^{-bt}(-b) + 2ate^{-bt} = 0$$
$$\frac{dy}{dt} = ate^{-bt}(-bt+2) = 0$$
$$t = 0, t = \frac{2}{b}.$$

Since a, t are nonnegative, ate^{-bt} is nonnegative. Thus dy/dt is positive for $-bt+2 > 0$ and negative for $-bt+2 < 0$. Also, $t \geq 0$, so

dy/dt $= 0$ for $t = 0, 2/b$
dy/dt is positive for $0 < t < 2/b$
dy/dt is negative for $t > 2/b$.

Thus, y has a local maximum, and also a global maximum, at $t = 2/b$. The graph of $y = at^2e^{-bt}$, using $a = 1$ and $b = 1$, is shown in Figure 4.36. We see that the function has a minimum at the critical point $t = 0$ and a maximum at $t = 2/b$.

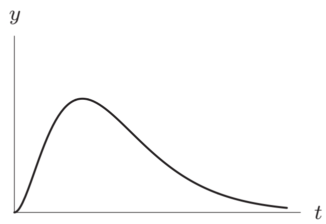


Figure 4.36

30. (a) We have

$$T(D) = \left(\frac{C}{2} - \frac{D}{3}\right)D^2 = \frac{CD^2}{2} - \frac{D^3}{3},$$

and

$$\frac{dT}{dD} = CD - D^2 = D(C - D).$$

Since, by this formula, dT/dD is zero when $D = 0$ or $D = C$, negative when $D > C$, and positive when $D < C$, we have (by the first derivative test) that the temperature change is maximized when $D = C$.

(b) The sensitivity is $dT/dD = CD - D^2$; its derivative is $d^2T/dD^2 = C - 2D$, which is zero if $D = C/2$, negative if $D > C/2$, and positive if $D < C/2$. Thus by the first derivative test the sensitivity is maximized at $D = C/2$.

31. (a) Since a/q decreases with q, this term represents the ordering cost. Since bq increases with q, this term represents the storage cost.

(b) At the minimum,

$$\frac{dC}{dq} = \frac{-a}{q^2} + b = 0$$

giving

$$q^2 = \frac{a}{b} \quad \text{so} \quad q = \sqrt{\frac{a}{b}}.$$

Since

$$\frac{d^2C}{dq^2} = \frac{2a}{q^3} > 0 \quad \text{for} \quad q > 0,$$

we know that $q = \sqrt{a/b}$ gives a local minimum. Since $q = \sqrt{a/b}$ is the only critical point, this must be the global minimum.

32. We look for critical points of M:

$$\frac{dM}{dx} = \frac{1}{2}wL - wx.$$

Now $dM/dx = 0$ when $x = L/2$. At this point $d^2M/dx^2 = -w$ so this point is a local maximum. The graph of $M(x)$ is a parabola opening downward, so the local maximum is also the global maximum.

33. (a) If we expect the rate to be nonnegative, then we must have $0 \le y \le a$. See Figure 4.37.

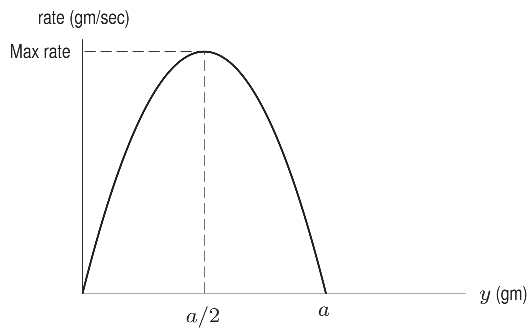

Figure 4.37

(b) The maximum value of the rate occurs at $y = a/2$, as can be seen from Figure 4.37, or by setting

$$\frac{d}{dy}(\text{rate}) = 0$$

$$\frac{d}{dy}(\text{rate}) = \frac{d}{dy}(kay - ky^2) = ka - 2ky = 0$$

$$y = \frac{a}{2}.$$

From the graph, we see that $y = a/2$ gives the global maximum.

34. We set $dU/dx = 0$ to find the critical points:

$$b\left(\frac{-2a^2}{x^3} + \frac{a}{x^2}\right) = 0$$

$$-2a^2 + ax = 0$$

$$x = 2a.$$

The only critical point is at $x = 2a$. When $x < 2a$ we have $dU/dx < 0$, and when $x > 2a$ we have $dU/dx > 0$. The potential energy, U, is minimized at $x = 2a$.

35. We set $f'(r) = 0$ to find the critical points:

$$\begin{aligned}\frac{2A}{r^3} - \frac{3B}{r^4} &= 0\\ \frac{2Ar - 3B}{r^4} &= 0\\ 2Ar - 3B &= 0\\ r &= \frac{3B}{2A}.\end{aligned}$$

The only critical point is at $r = 3B/(2A)$. If $r > 3B/(2A)$, we have $f' > 0$ and if $r < 3B/(2A)$, we have $f' < 0$. Thus, the force between the atoms is minimized at $r = 3B/(2A)$.

36. (a) To show that R is an increasing function of r_1, we show that $dR/dr_1 > 0$ for all values of r_1. We first solve for R:

$$\begin{aligned}\frac{1}{R} &= \frac{1}{r_1} + \frac{1}{r_2}\\ \frac{1}{R} &= \frac{r_2 + r_1}{r_1 r_2}\\ R &= \frac{r_1 r_2}{r_2 + r_1}.\end{aligned}$$

We use the quotient rule (and remember that r_2 is a constant) to find dR/dr_1:

$$\frac{dR}{dr_1} = \frac{(r_2 + r_1)(r_2) - (r_1 r_2)(1)}{(r_2 + r_1)^2} = \frac{(r_2)^2}{(r_2 + r_1)^2}.$$

Since dR/dr_1 is the square of a number, we have $dR/dr_1 > 0$ for all values of r_1, and thus R is increasing for all r_1.

(b) Since R is increasing on any interval $a \le r_1 \le b$, the maximum value of R occurs at the right endpoint $r_1 = b$.

37. (a) We want the maximum value of I. Using the properties of logarithms, we rewrite the expression for I as

$$I = k(\ln S - \ln S_0) - S + S_0 + I_0.$$

Since k and S_0 are constant, differentiating with respect to S gives

$$\frac{dI}{dS} = \frac{k}{S} - 1.$$

Thus, the critical point is at $S = k$. Since dI/dS is positive for $S < k$ and dI/dS is negative for $S > k$, we see that $S = k$ is a local maximum.

We only consider positive values of S. Since $S = k$ is the only critical point, it gives the global maximum value for I, which is

$$I = k(\ln k - \ln S_0) - k + S_0 + I_0.$$

(b) Since both k and S_0 are in the expression for the maximum value of I, both the particular disease and how it starts influence the maximum.

38. Suppose the points are given by x and $-x$, where $x \ge 0$. The function is odd, since

$$y = \frac{(-x)^3}{1 + (-x)^4} = -\frac{x^3}{1 + x^4},$$

so the corresponding y-coordinates are also opposite. See Figure 4.38. For $x > 0$, we have

$$m = \frac{\frac{x^3}{1+x^4} - \left(-\frac{x^3}{1+x^4}\right)}{x - (-x)} = \frac{1}{2x} \cdot \frac{2x^3}{1 + x^4} = \frac{x^2}{1 + x^4}.$$

For the maximum slope,

$$\begin{aligned}\frac{dm}{dx} = \frac{2x}{1 + x^4} - \frac{x^2(4x^3)}{(1 + x^4)^2} &= 0\\ \frac{2x(1 + x^4) - 4x^5}{(1 + x^4)^2} &= 0\end{aligned}$$

$$\begin{aligned}\frac{2x(1-x^4)}{(1+x^4)^2} &= 0\\ x\left(1-x^4\right) &= 0\\ x &= 0, \pm 1.\end{aligned}$$

For $x > 0$, there is one critical point, $x = 1$. Since m tends to 0 when $x \to 0$ and when $x \to \infty$, the critical point $x = 1$ gives the maximum slope. Thus, the maximum slope occurs when the line has endpoints

$$\left(-1, -\frac{1}{2}\right) \text{ and } \left(1, \frac{1}{2}\right).$$

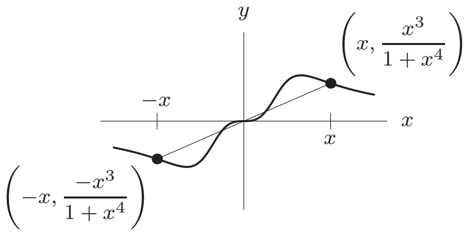

Figure 4.38

39. Since the function is positive, the graph lies above the x-axis. If there is a global maximum at $x = 3$, $t'(x)$ must be positive, then negative. Since $t'(x)$ and $t''(x)$ have the same sign for $x < 3$, they must both be positive, and thus the graph must be increasing and concave up. Since $t'(x)$ and $t''(x)$ have opposite signs for $x > 3$ and $t'(x)$ is negative, $t''(x)$ must again be positive and the graph must be decreasing and concave up. A possible sketch of $y = t(x)$ is shown in Figure 4.39.

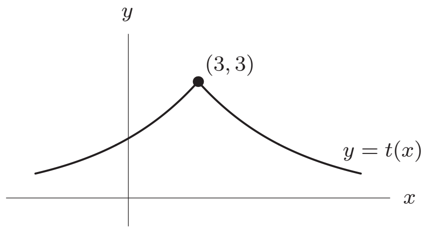

Figure 4.39

40. One possible graph of g is in Figure 4.40.

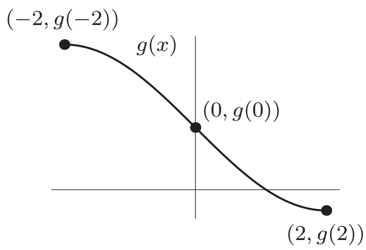

Figure 4.40

(a) From left to right, the graph of $g(x)$ starts "flat", decreases slowly at first then more rapidly, most rapidly at $x = 0$. The graph then continues to decrease but less and less rapidly until flat again at $x = 2$. The graph should exhibit symmetry about the point $(0, g(0))$.

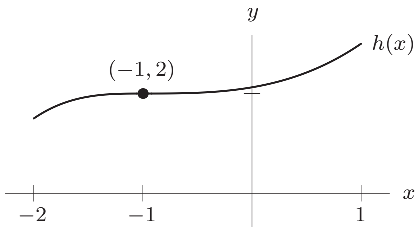
(b) The graph has an inflection point at $(0, g(0))$ where the slope changes from negative and decreasing to negative and increasing.
(c) The function has a global maximum at $x = -2$ and a global minimum at $x = 2$.
(d) Since the function is decreasing over the interval $-2 \le x \le 2$

$$g(-2) = 5 > g(0) > g(2).$$

Since the function appears symmetric about $(0, g(0))$, we have

$$g(-2) - g(0) = g(0) - g(2).$$

41. (a) We know that $h''(x) < 0$ for $-2 \le x < -1$, $h''(-1) = 0$, and $h''(x) > 0$ for $x > -1$. Thus, $h'(x)$ decreases to its minimum value at $x = -1$, which we know to be zero, and then increases; it is never negative.
(b) Since $h'(x)$ is non-negative for $-2 \le x \le 1$, we know that $h(x)$ is never decreasing on $[-2, 1]$. So a global maximum must occur at the right hand endpoint of the interval.
(c) The graph below shows a function that is increasing on the interval $-2 \le x \le 1$ with a horizontal tangent and an inflection point at $(-1, 2)$.



42. Suppose f has critical points $x = a$ and $x = b$. Suppose $a < b$. By the Extreme Value Theorem, we know that the derivative function, $f'(x)$, has global extrema on $[a, b]$. If both the maximum and minimum of $f'(x)$ occur at the endpoints of $[a, b]$, then $f'(a) = 0 = f'(b)$, so $f'(x) = 0$ for all x in $[a, b]$. In this case, f would have more than two critical points. Since f has only two critical points, there is a local maximum or minimum of f' inside the interval $[a, b]$.

43. To find the critical points, set $dD/dx = 0$:

$$\frac{dD}{dx} = 2(x - a_1) + 2(x - a_2) + 2(x - a_3) + \cdots + 2(x - a_n) = 0.$$

Dividing by 2 and solving for x gives

$$x + x + x + \cdots + x = a_1 + a_2 + a_3 + \cdots + a_n.$$

Since there are n terms on the left,

$$nx = a_1 + a_2 + a_3 + \cdots + a_n$$
$$x = \frac{a_1 + a_2 + a_3 + \cdots + a_n}{n} = \frac{1}{n}\sum_{i=1}^{n} a_i.$$

The expression on the right is the average of $a_1, a_2, a_3, \cdots, a_n$.
Since D is a quadratic with positive leading coefficient, this critical point is a minimum.

44. (a) If both the global minimum and the global maximum are at the endpoints, then $f(x) = 0$ everywhere in $[a, b]$, since $f(a) = f(b) = 0$. In that case $f'(x) = 0$ everywhere as well, so any point in (a, b) will do for c.
(b) Suppose that either the global maximum or the global minimum occurs at an interior point of the interval. Let c be that point. Then c must be a local extremum of f, so, by the theorem concerning local extrema on page 188, we have $f'(c) = 0$, as required.

45. (a) The equation of the secant line between $x = a$ and $x = b$ is

$$y = f(a) + \frac{f(b) - f(a)}{b - a}(x - a)$$

and

$$g(x) = f(x) - f(a) - \frac{f(b) - f(a)}{b - a}(x - a),$$

so $g(x)$ is the difference, or distance, between the graph of $f(x)$ and the secant line. See Figure 4.41.

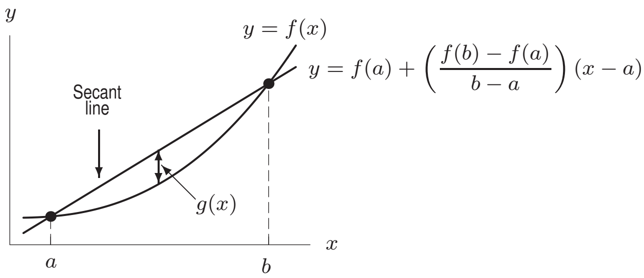


Figure 4.41: Value of $g(x)$ is the difference between the secant line and the graph of $f(x)$

(b) Figure 4.41 shows that $g(a) = g(b) = 0$. You can also easily check this from the formula for $g(x)$. By Rolle's Theorem, there must be a point c in (a, b) where $g'(c) = 0$.

(c) Differentiating the formula for $g(x)$, we have

$$g'(x) = f'(x) - \frac{f(b) - f(a)}{b - a}.$$

So from $g'(c) = 0$, we get

$$f'(c) = \frac{f(b) - f(a)}{b - a},$$

as required.

Strengthen Your Understanding

46. The function f has a critical point at $x = 1$ where $f'' < 0$, so f has a local maximum at $(1, 0)$. However, checking the endpoints we find that f takes its largest value at the endpoint $x = 3$, where $f(3) = 4$.

47. Consider the interval $1 \le x \le 2$. Since f is increasing on this interval, its global minimum occurs at the left end-point of the interval, $x = 1$. If $x = 0$ is inside the interval $a \le x \le b$, then the global minimum of f occurs at $x = 0$. Otherwise, the global minimum of f will occur at an endpoint.

48. The function has a vertical asymptote at $x = 1$ where it is not defined. There is no global minimum nor maximum and therefore no upper or lower bound for $f(x)$.

49. One possible answer is $f(x) = 1 - x$ for which $f'(x) = -1$ so there are no critical points. Also $f(0) = 1$ is a global maximum and $f(1) = 0$ is a global minimum. There are many other possible answers.

50. The function must be a constant. One possible answer is $f(x) = 1$. Any constant function's global maximum is equal to its global minimum.

51. Solving $x^2 = 5$ and $x^2 = 2$, we see that one such interval is $\sqrt{2} \le x \le \sqrt{5}$. A second possible interval is $-\sqrt{5} \le x \le -\sqrt{2}$.

52. The function $f(x) = \sin x$ is differentiable and has 1 as its global maximum and -1 as its global minimum on any interval containing $-\pi/2 \le x \le \pi/2$ such as the interval $-4 \le x \le 4$. The function $f(x) = \cos x$ is another such function. There are many other possibilities.

53. True, $f(x) \le 4$ on the interval $(0, 2)$.

54. False. The values of $f(x)$ get arbitrarily close to 4, but $f(x) < 4$ for all x in the interval $(0, 2)$.

55. True. The values of $f(x)$ get arbitrarily close to 0, but $f(x) > 0$ for all x in the interval $(0, 2)$.

56. False. On the interval $(-1, 1)$, the global minimum is 0.

57. True, by the Extreme Value Theorem, Theorem 4.2.

58. (a) This is not implied; just because a function satisfies the conclusions of the statement, that does not mean it has to satisfy the conditions.

(b) This is not implied; if a function fails to satisfy the conditions of the statement, then the statement does not tell us anything about it.

(c) This is implied; if a function fails to satisfy the conclusions of the statement, then it could not satisfy the conditions of the statement, because if it did the statement would imply it also satisfied the conclusions.

59. False, since $f(x) = 1/x$ takes on arbitrarily large values as $x \to 0^+$. The Extreme Value Theorem requires the interval to be closed as well as bounded.

60. False. The Extreme Value Theorem says that continuous functions have global maxima and minima on every closed, bounded interval. It does not say that only continuous functions have such maxima and minima.

61. True. If the maximum is not at an endpoint, then it must be at critical point of f. But $x = 0$ is the only critical point of $f(x) = x^2$ and it gives a minimum, not a maximum.

62. True. For example, $A = 1$ and $A = 2$ are both upper bounds for $f(x) = \sin x$.

63. True. If $f'(0) > 0$, then f would be increasing at 0 and so $f(0) < f(x)$ for x just to the right of 0. Then $f(0)$ would not be a maximum for f on the interval $0 \le x \le 10$.

Solutions for Section 4.3

Exercises

1. Let the numbers be x and y. Then $x + y = 100$, so $y = 100 - x$.
Since both numbers are nonnegative, we restrict to $0 \le x \le 100$.

The product is

$$P = xy = x(100 - x) = 100x - x^2.$$

Differentiating to find the maximum,

$$\frac{dP}{dx} = 100 - 2x = 0$$
$$x = \frac{100}{2} = 50.$$

So there is a critical point at $x = 50$; the end points are at $x = 0, 100$.

Evaluating gives
At $x = 0$, we have $P = 0$.
At $x = 50$, we have $P = 50(100 - 50) = 2500$.
At $x = 100$, we have $P = 100(100 - 100) = 0$.
Thus the maximum value is 2500.

2. Let the numbers be x and y. Then $xy = 784$, so $y = 784/x$.
Since both numbers are positive, we restrict to $x > 0$.

The sum is

$$S = x + y = x + \frac{784}{x}.$$

Differentiating to find the minimum,

$$\frac{dS}{dx} = 1 - \frac{784}{x^2} = 0$$
$$x^2 = 784 \quad \text{so} \quad x = \pm\sqrt{784} = \pm 28.$$

For $x > 0$, there is only one critical point at $x = 28$. We find

$$\frac{d^2S}{dx^2} = 2\frac{784}{x^3}.$$

Since $d^2S/dx^2 > 0$ for $x > 0$, there is a local minimum at $x = 28$. The derivative dS/dx is negative for $0 < x < 28$ and dS/dx is positive for $x > 28$. Thus, $x = 28$ gives the global minimum for $x > 0$.

The minimum value of the sum is

$$S = 28 + \frac{784}{28} = 56.$$

3. Let the numbers be x, y, z and let $y = 2x$. Then

$$x + y + z = 3x + z = 36, \quad \text{so} \quad z = 36 - 3x.$$

Since all the numbers are nonnegative, we restrict to $0 \le x \le 12$.

The product is

$$P = xyz = x \cdot 2x \cdot (36 - 3x) = 72x^2 - 6x^3.$$

Differentiating to find the maximum,

$$\begin{aligned} \frac{dP}{dx} &= 144x - 18x^2 = 0 \\ -18x(x-8) &= 0 \\ x &= 0, 8. \end{aligned}$$

So there are critical points at $x = 0$ and $x = 8$; the end points are at $x = 0, 12$.

Evaluating gives:
At $x = 0$, we have $P = 0$.
At $x = 8$, we have $P = 8 \cdot 16 \cdot (36 - 3 \cdot 8) = 1536$.
At $x = 12$, we have $P = 12 \cdot 24 \cdot (36 - 3 \cdot 12) = 0$.
Thus, the maximum value of the product is 1536.

4. Let the sides be x and y cm. Then $2x + 2y = 64$, so $y = 32 - x$.
Since both sides are nonnegative, we restrict to $0 \le x \le 32$.

The area in cm^2 is

$$A = xy = x(32 - x) = 32x - x^2.$$

Differentiating to find the maximum,

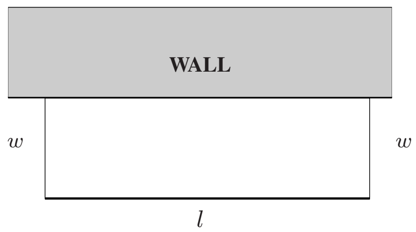
$$\begin{aligned} \frac{dA}{dx} &= 32 - 2x = 0 \\ x &= \frac{32}{2} = 16. \end{aligned}$$

So there is a critical point at $x = 16$ cm; the end points are at $x = 0$ and $x = 32$ cm.

Evaluating gives:
At $x = 0$, we have $A = 0\ \text{cm}^2$.
At $x = 16$, we have $A = 16(32 - 16) = 256\ \text{cm}^2$.
At $x = 32$, we have $A = 32(32 - 32) = 0\ \text{cm}^2$.
Thus, the maximum area occurs in a square of side 16 cm.

5. Let w and l be the width and length, respectively, of the rectangular area you wish to enclose. Then

$$\begin{aligned} w + w + l &= 100 \text{ feet} \\ l &= 100 - 2w \\ \text{Area} = w \cdot l &= w(100 - 2w) = 100w - 2w^2 \end{aligned}$$



To maximize area, we solve $A' = 0$ to find critical points. This gives $A' = 100 - 4w = 0$, so $w = 25$, $l = 50$. So the area is $25 \cdot 50 = 1250$ square feet. This is a local maximum by the second derivative test because $A'' = -4 < 0$. Since the graph of A is a parabola, the local maximum is in fact a global maximum.

6. We want to minimize the surface area S of the box, shown in Figure 4.42. The box has 6 faces: the top and bottom, each of which has area x^2 and the four sides, each of which has area xh. Thus we want to minimize

$$S = 2x^2 + 4xh.$$

The volume of the box is $8 = x^2h$, so $h = 8/x^2$. Substituting this expression in for h in the formula for S gives

$$S = 2x^2 + 4x \cdot \frac{8}{x^2} = 2x^2 + \frac{32}{x}.$$

Differentiating gives

$$\frac{dS}{dx} = 4x - \frac{32}{x^2}.$$

To minimize S we look for critical points, so we solve $0 = 4x - 32/x^2$. Multiplying by x^2 gives

$$0 = 4x^3 - 32,$$

so $x = 8^{1/3}$. Then we can find

$$h = \frac{8}{x^2} = \frac{8}{8^{2/3}} = 8^{1/3}.$$

Thus $x = h = 8^{1/3}$ cm (the box is a cube).

We can check that this critical point is a minimum of S by checking the sign of

$$\frac{d^2S}{dx^2} = 4 + \frac{64}{x^3}$$

which is positive when $x > 0$. So S is concave up at the critical point and therefore $x = 8^{1/3}$ gives a minimum value of S.

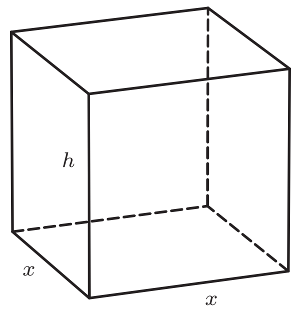


Figure 4.42

7. We want to minimize the surface area S of the box, shown in Figure 4.43. The box has 5 faces: the bottom which has area x^2 and the four sides, each of which has area xh. Thus we want to minimize

$$S = x^2 + 4xh.$$

The volume of the box is $8 = x^2h$, so $h = 8/x^2$. Substituting this expression in for h in the formula for S gives

$$S = x^2 + 4x \cdot \frac{8}{x^2} = x^2 + \frac{32}{x}.$$

Differentiating gives

$$\frac{dS}{dx} = 2x - \frac{32}{x^2}.$$

To minimize S we look for critical points, so we solve $0 = 2x - 32/x^2$. Multiplying by x^2 gives

$$0 = 2x^3 - 32,$$

so $x = 16^{1/3}$ cm. Then we can find

$$h = \frac{8}{x^2} = \frac{8}{16^{2/3}} = \frac{16}{2 \cdot 16^{2/3}} = \frac{16^{1/3}}{2}$$

cm.

We can check that this critical point is a minimum of S by checking the sign of

$$\frac{d^2S}{dx^2} = 2 + \frac{64}{x^3}$$

which is positive when $x > 0$. So S is concave up at the critical point and therefore $x = 16^{1/3}$ gives a minimum value of S.

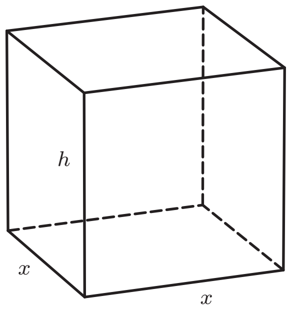

Figure 4.43

8. We want to minimize the surface area S of the cylinder, shown in Figure 4.44. The cylinder has 3 pieces: the top and bottom disks, each of which has area πr^2 and the tube, which has area $2\pi rh$. Thus we want to minimize

$$S = 2\pi r^2 + 2\pi rh.$$

The volume of the cylinder is $8 = \pi r^2 h$, so $h = 8/\pi r^2$. Substituting this expression for h in the formula for S gives

$$S = 2\pi r^2 + 2\pi r \cdot \frac{8}{\pi r^2} = 2\pi r^2 + \frac{16}{r}.$$

Differentiating gives

$$\frac{dS}{dr} = 4\pi r - \frac{16}{r^2}.$$

To minimize S we look for critical points, so we solve $0 = 4\pi r - 16/r^2$. Multiplying by r^2 gives

$$0 = 4\pi r^3 - 16,$$

so $r = (4/\pi)^{1/3}$ cm. Then we can find

$$h = \frac{8}{\pi r^2} = \frac{8}{\pi\left(\frac{4}{\pi}\right)^{2/3}} = \frac{2\left(\frac{4}{\pi}\right)}{\left(\frac{4}{\pi}\right)^{2/3}} = 2\left(\frac{4}{\pi}\right)^{1/3}.$$

We can check that this critical point is a minimum of S by checking the sign of

$$\frac{d^2S}{dr^2} = 4\pi + \frac{32}{r^3}$$

which is positive when $r > 0$. So S is concave up at the critical point and therefore $r = (4/\pi)^{1/3}$ cm is a minimum.

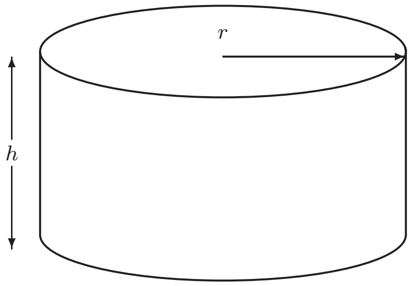

Figure 4.44

9. We want to minimize the surface area S of the cylinder, shown in Figure 4.45. The cylinder has two pieces: one disk (the base) which has area πr^2 and the tube (the sides), which has area $2\pi rh$. Thus we want to minimize

$$S = \pi r^2 + 2\pi rh.$$

The volume of the cylinder is $8 = \pi r^2 h$, so $h = 8/\pi r^2$. Substituting this expression in for h in the formula for S gives

$$S = \pi r^2 + 2\pi r \cdot \frac{8}{\pi r^2} = \pi r^2 + \frac{16}{r}.$$

Differentiating gives

$$\frac{dS}{dr} = 2\pi r - \frac{16}{r^2}.$$

To minimize S we look for critical points, so we solve $0 = 2\pi r - 16/r^2$. Multiplying by r^2 gives

$$0 = 2\pi r^3 - 16,$$

so $r = (8/\pi)^{1/3}$ cm. Then we can find

$$h = \frac{8}{\pi r^2} = \frac{8}{\pi\left(\frac{8}{\pi}\right)^{2/3}} = \frac{\frac{8}{\pi}}{\left(\frac{8}{\pi}\right)^{2/3}} = \left(\frac{8}{\pi}\right)^{1/3}.$$

We can check that this critical point is a minimum of S by checking the sign of

$$\frac{d^2S}{dr^2} = 2\pi + \frac{32}{r^3}$$

which is positive when $r > 0$. So S is concave up at the critical point and therefore $r = (8/\pi)^{1/3}$ cm is a minimum.

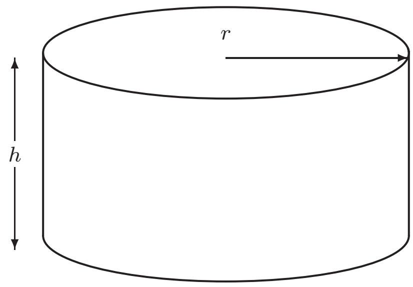

Figure 4.45

10. We want to maximize the area function

$$\begin{aligned} A(x) &= \text{Base} \times \text{Height} \\ &= xf(x) \\ &= \frac{1}{3}x^3 - 50x^2 + 1000x. \end{aligned}$$

Critical points of A are solutions of

$$A'(x) = x^2 - 100x + 1000 = 0.$$

There are two critical points, $x = 50 - 10\sqrt{15} = 11.27$ and $x = 50 + 10\sqrt{15} = 88.73$, but only the first is in the interval $0 \le x \le 20$.

The maximum occurs at the critical point in the interval or at one of the endpoints. Since

$$A(0) = 0 \qquad A(11.27) = 5396.5 \qquad A(20) = 2666.67$$

the maximum area occurs with $x = 50 - 10\sqrt{15} = 11.270$.

11. We want to maximize the area function

$$\begin{aligned} A(x) &= \frac{1}{2} \times \text{Base} \times \text{Height} \\ &= \frac{1}{2} \cdot 20 \cdot f(x) \\ &= \frac{10x^2}{3} - 500x + 10000. \end{aligned}$$

Critical points of A are solutions of

$$A'(x) = \frac{20x}{3} - 500 = 0.$$

There is one critical point, $x = 75$, but it is outside the interval $0 \le x \le 20$.

The maximum of A in the interval occurs at one of the endpoints. Since

$$A(0) = 10000 \qquad A(20) = 4000/3 = 1333.3$$

the maximum area occurs with $x = 0$.

We can also see that $x = 0$ gives te maximum area without calculus, since the base of the triangle is always 20 and the height is largest when $x = 0$.

12. The rectangle in Figure 4.46 has area, A, given by

$$A = 2xy = \frac{2x}{1+x^2} \qquad \text{for } x \ge 0.$$

At a critical point,

$$\begin{aligned} \frac{dA}{dx} = \frac{2}{1+x^2} + 2x\left(\frac{-2x}{(1+x^2)^2}\right) &= 0 \\ \frac{2(1+x^2-2x^2)}{(1+x^2)^2} &= 0 \\ 1 - x^2 &= 0 \\ x &= \pm 1. \end{aligned}$$

Since $A = 0$ for $x = 0$ and $A \to 0$ as $x \to \infty$, the critical point $x = 1$ is a local and global maximum for the area. Then $y = 1/2$, so the vertices are

$$(-1, 0)\,,\ (1, 0)\,,\ \left(1, \frac{1}{2}\right),\ \left(-1, \frac{1}{2}\right).$$

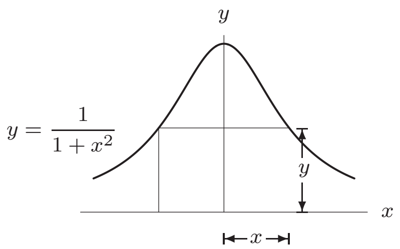

Figure 4.46

13. The triangle in Figure 4.47 has area, A, given by

$$A = \frac{1}{2}xy = \frac{x}{2}e^{-x/3}.$$

At a critical point,

$$\begin{aligned} \frac{dA}{dx} = \frac{1}{2}e^{-x/3} - \frac{x}{6}e^{-x/3} &= 0 \\ \frac{1}{6}e^{-x/3}(3 - x) &= 0 \\ x &= 3. \end{aligned}$$

Substituting the critical point and the endpoints into the formula for the area gives:

For $x = 1$, we have $A = \frac{1}{2}e^{-1/3} = 0.358$

For $x = 3$, we have $A = \frac{3}{2}e^{-1} = 0.552$

For $x = 5$, we have $A = \frac{5}{2}e^{-5/3} = 0.472$

Thus, the maximum area is 0.552 and the minimum area is 0.358.

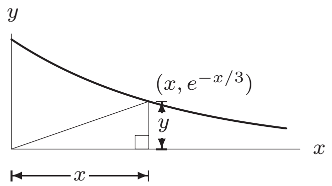

Figure 4.47

14. (a) The rectangle in Figure 4.48 has area, A, given by

$$A = xy = xe^{-2x}.$$

At a critical point, we have

$$\begin{aligned} \frac{dA}{dx} &= 1 \cdot e^{-2x} - 2xe^{-2x} = 0 \\ e^{-2x}(1-2x) &= 0 \\ x &= \frac{1}{2}. \end{aligned}$$

Since $A = 0$ when $x = 0$ and $A \to 0$ as $x \to \infty$, the critical point $x = 1/2$ is a local and global maximum. Thus the maximum area is

$$A = \frac{1}{2}e^{-2(1/2)} = \frac{1}{2e}.$$

(b) The rectangle in Figure 4.48 has perimeter, P, given by

$$P = 2x + 2y = 2x + 2e^{-2x}.$$

At a critical point, we have

$$\begin{aligned} \frac{dP}{dx} = 2 - 4e^{-2x} &= 0 \\ e^{-2x} &= \frac{1}{2} \\ -2x &= \ln\frac{1}{2} \\ x &= -\frac{1}{2}\ln\frac{1}{2} = \frac{1}{2}\ln 2. \end{aligned}$$

To see if this critical point gives a maximum or minimum, we find

$$\frac{d^2P}{dx^2} = 8e^{-2x}.$$

Since $d^2P/dx^2 > 0$ for all x, including $x = \frac{1}{2}\ln 2$, the critical point is a local and global minimum. Thus, the minimum perimeter is

$$P = 2\left(\frac{1}{2}\ln 2\right) + 2e^{-2\left(\frac{1}{2}\ln 2\right)} = \ln 2 + 2e^{-\ln 2} = \ln 2 + 2 \cdot \frac{1}{2} = \ln 2 + 1.$$

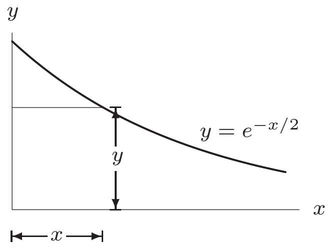

Figure 4.48

Problems

15. We take the derivative, set it equal to 0, and solve for x:

$$\begin{aligned}
\frac{dt}{dx} &= \frac{1}{6} - \frac{1}{4}\cdot\frac{1}{2}\left((2000-x)^2+600^2\right)^{-1/2}\cdot 2(2000-x) = 0\\
(2000-x) &= \frac{2}{3}\left((2000-x)^2+600^2\right)^{1/2}\\
(2000-x)^2 &= \frac{4}{9}\left((2000-x)^2+600^2\right)\\
\frac{5}{9}(2000-x)^2 &= \frac{4}{9}\cdot 600^2\\
2000-x &= \sqrt{\frac{4}{5}\cdot 600^2} = \frac{1200}{\sqrt{5}}\\
x &= 2000 - \frac{1200}{\sqrt{5}} \text{ feet.}
\end{aligned}$$

Note that $2000-(1200/\sqrt{5}) \approx 1463$ feet, as given in the example.

16. Let the sides of the rectangle have lengths a and b. We shall look for the minimum of the square s of the length of either diagonal, i.e. $s = a^2+b^2$. The area is $A = ab$, so $b = A/a$. This gives

$$s(a) = a^2 + \frac{A^2}{a^2}.$$

To find the minimum squared length we need to find the critical points of s. Differentiating s with respect to a gives

$$\frac{ds}{da} = 2a + (-2)A^2a^{-3} = 2a\left(1-\frac{A^2}{a^4}\right)$$

The derivative $ds/da = 0$ when $a = \sqrt{A}$, that is when $a = b$ and so the rectangle is a square. Because $\frac{d^2s}{da^2} = 2\left(1+\frac{3A^2}{a^4}\right) > 0$, this is a minimum.

17. From the triangle shown in Figure 4.49, we see that

$$\begin{aligned}
\left(\frac{w}{2}\right)^2 + \left(\frac{h}{2}\right)^2 &= 30^2\\
w^2+h^2 &= 4(30)^2 = 3600.
\end{aligned}$$

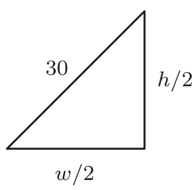

Figure 4.49

The strength, S, of the beam is given by

$$S = kwh^2,$$

for some constant k. To make S a function of only one variable, substitute for h^2, giving

$$S = kw(3600 - w^2) = k(3600w - w^3).$$

Differentiating and setting $dS/dw = 0$,

$$\frac{dS}{dw} = k(3600 - 3w^2) = 0.$$

Solving for w gives

$$w = \sqrt{1200} = 34.64 \text{ cm},$$

so

$$h^2 = 3600 - w^2 = 3600 - 1200 = 2400$$
$$h = \sqrt{2400} = 48.99 \text{ cm}.$$

Thus, $w = 34.64$ cm and $h = 48.99$ cm give a critical point. To check that this is a local maximum, we compute

$$\frac{d^2S}{dw^2} = -6w < 0 \quad \text{for} \quad w > 0.$$

Since $d^2S/dw^2 < 0$, we see that $w = 34.64$ cm is a local maximum. It is the only critical point, so it is a global maximum.

18. The area of the rectangle on the left is $2x$. The entire rectangle has area 2, so the area of the rectangle on the right is $2 - 2x$. We are to maximize the product

$$f(x) = 2x(2 - 2x) = 4x - 4x^2$$

of the two areas where $0 \leq x \leq 1$.

The critical points of f occur where

$$f'(x) = 4 - 8x = 0$$

at $x = 1/2$.

The maximum of f on the interval $0 \leq x \leq 1$ is at the critical point $x = 1/2$ or one of the endpoints $x = 0$ or $x = 1$. We have

$$f(0) = f(1) = 0 \text{ and } f\left(\frac{1}{2}\right) = 1.$$

The product of the areas is a maximum when $x = 1/2$.

19. First find the length h of the vertical segment at x. Since the top edge of the triangle has slope $h/x = 2/1$, we have $h = 2x$. Thus

$$\text{Area of smaller triangle} = \frac{1}{2} \times \text{Base} \times \text{Height} = \frac{1}{2} \cdot x \cdot 2x = x^2.$$

The entire triangle has area 1, so the area of the trapezoid on the right is $1 - x^2$. We are to maximize the product

$$f(x) = x^2(1 - x^2) = x^2 - x^4$$

of the two areas where $0 \leq x \leq 1$

The critical points of f occur where

$$f'(x) = 2x - 4x^3 = 2x(1 - 2x^2) = 0$$

at $x = 0$, $x = 1/\sqrt{2}$ or $x = -1/\sqrt{2}$. The only critical point in the interval $0 < x < 1$ is $x = 1/\sqrt{2}$.

The maximum of f on the interval $0 \leq x \leq 1$ is at one of the endpoints $x = 0$ or $x = 1$ or at the critical point $x = 1/\sqrt{2}$. We have

$$f(0) = f(1) = 0 \text{ and } f\left(\frac{1}{\sqrt{2}}\right) = \frac{1}{4}.$$

The product of the areas is a maximum when $x = 1/\sqrt{2}$.

20. (a) The rectangle on the left has area xy, and the semicircle on the right with radius $y/2$ has area $(1/2)\pi(y/2)^2 = \pi y^2/8$. We have

$$\text{Area of entire region} = xy + \frac{\pi}{8}y^2.$$

(b) The perimeter of the figure is made of two horizontal line segments of length x each, one vertical segment of length y, and a semicircle of radius $y/2$ of length $\pi y/2$. We have

$$\text{Perimeter of entire region} = 2x + y + \frac{\pi}{2}y = 2x + (1 + \frac{\pi}{2})y.$$

(c) We want to maximize the area $xy + \pi y^2/8$, with the perimeter condition $2x + (1 + \pi/2)y = 100$. Substituting

$$x = 50 - \left(\frac{1}{2} + \frac{\pi}{4}\right) y = 50 - \frac{2+\pi}{4}y$$

into the area formula, we must maximize

$$A(y) = \left(50 - \left(\frac{1}{2} + \frac{\pi}{4}\right) y\right) y + \frac{\pi}{8}y^2 = 50y - \left(\frac{1}{2} + \frac{\pi}{8}\right) y^2$$

on the interval

$$0 \le y \le 200/(2+\pi) = 38.8985$$

where $y \ge 0$ because y is a length and $y \le 200/(2+\pi)$ because $x \ge 0$ is a length.

The critical point of A occurs where

$$A'(y) = 50 - \left(1 + \frac{\pi}{4}\right) y = 0$$

at

$$y = \frac{200}{4+\pi} = 28.005.$$

A maximum for A must occur at the critical point $y = 200/(4+\pi)$ or at one of the endpoints $y = 0$ or $y = 200/(2+\pi)$. Since

$$A(0) = 0 \qquad A\left(\frac{200}{4+\pi}\right) = 700.124 \qquad A\left(\frac{200}{2+\pi}\right) = 594.2$$

the maximum is at

$$y = \frac{200}{4+\pi}.$$

Hence

$$x = 50 - \frac{2+\pi}{4}y = 50 - \frac{2+\pi}{4}\frac{200}{4+\pi} = \frac{100}{4+\pi}.$$

The dimensions giving maximum area with perimeter 100 are

$$x = \frac{100}{4+\pi} = 14.0 \qquad y = \frac{200}{4+\pi} = 28.0.$$

The length y is twice as great as x.

21. (a) The rectangle has area xy. The two semicircles together form a circle of radius $y/2$ and area $\pi(y/2)^2 = \pi y^2/4$. We have

$$\text{Area of entire region} = xy + \frac{\pi}{4}y^2.$$

(b) The perimeter of the figure is the sum $2x$ of the lengths of the two straight sections and the circumference πy of a circle of diameter y. Thus

$$\text{Perimeter of entire region} = 2x + \pi y.$$

(c) We want to maximize the area $xy + \pi y^2/4$, with the perimeter condition

$$2x + \pi y = 100.$$

Substituting

$$x = 50 - \frac{\pi}{2}y$$

into the area formula, we must maximize

$$A(y) = \left(50 - \frac{\pi}{2}y\right) y + \frac{\pi}{4}y^2 = 50y - \frac{\pi}{4}y^2$$

on the interval

$$0 \le y \le \frac{100}{\pi}$$

where $y \ge 0$ because y is a length and $y \le 100/\pi$ because $x \ge 0$ is a length.

The critical point of A occurs where

$$A'(y) = 50 - \frac{\pi}{2}y = 0$$

at $y = 100/\pi$, which is an endpoint. A maximum for A occurs at one of the endpoints $y = 0$ or $y = 100/\pi$. Since

$$A(0) = 0 \qquad A\left(\frac{100}{\pi}\right) = \frac{2500}{\pi}$$

the maximum is at $y = 100/\pi$. Hence $x = 0$.

The dimensions giving maximum area with perimeter 100 are $x = 0$, $y = 100/\pi$. The figure is a circle.

22. (a) The rectangle has area xy, the two semicircles with radius $x/2$ together have area $\pi(x/2)^2 = \pi x^2/4$, and the two semicircles with radius $y/2$ together have area $\pi y^2/4$. We have

$$\text{Area of entire figure} = xy + \frac{\pi}{4}x^2 + \frac{\pi}{4}y^2.$$

(b) The perimeter of the figure is the sum of the circumference of a circle of diameter x and a circle of diameter y. Thus

$$\text{Perimeter of entire figure} = \pi x + \pi y.$$

(c) We want to maximize the area $xy + \pi x^2/4 + \pi y^2/4$, with the perimeter condition

$$\pi x + \pi y = 100.$$

Substituting

$$x = \frac{100}{\pi} - y$$

into the area formula, we must maximize

$$A(y) = \left(\frac{100}{\pi} - y\right)y + \frac{\pi}{4}\left(\frac{100}{\pi} - y\right)^2 + \frac{\pi}{4}y^2$$

on the interval

$$0 \le y \le 100/\pi = 31.831$$

where $y \ge 0$ because y is a length and $y \le 100/\pi$ because $x \ge 0$ is a length.

The critical point of A occurs where

$$A'(y) = \frac{100}{\pi} - 50 + (\pi - 2)y = 0$$

at $y = 50/\pi = 15.916$. A maximum for A must occur at one of the endpoints $y = 0$ or $y = 100/\pi$ or at the critical point $y = 50/\pi$. Since

$$A(0) = A\left(\frac{100}{\pi}\right) = \frac{2500}{\pi} = 795.8 \qquad A\left(\frac{50}{\pi}\right) = 651.2,$$

the maximum is at $y = 0$, giving $x = 100/\pi$, or at $y = 100/\pi$, when $x = 0$.

The dimensions giving maximum area with perimeter 100 are $x = 0, y = 100/\pi$ and $x = 100/\pi, y = 0$. The figure is a circle.

23. (a) The length of the piece of wire made into a circle is x cm, so the length of the piece made into a square is $(L - x)$ cm. See Figure 4.50.

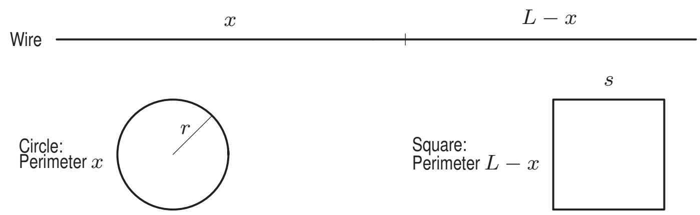

Figure 4.50

The circumference of the circle is x, so its radius, r cm, is given by

$$r = \frac{x}{2\pi} \text{ cm.}$$

The perimeter of the square is $(L - x)$, so the side length, s cm, is given by

$$s = \frac{L-x}{4} \text{ cm.}$$

Thus, the sum of areas is given by

$$A = \pi r^2 + s^2 = \pi\left(\frac{x}{2\pi}\right)^2 + \left(\frac{L-x}{4}\right)^2 = \frac{x^2}{4\pi} + \frac{(L-x)^2}{16}, \quad \text{for } 0 \le x \le L.$$

Setting $dA/dx = 0$ to find the critical points gives

$$\begin{aligned} \frac{dA}{dx} = \frac{x}{2\pi} - \frac{(L-x)}{8} &= 0 \\ 8x &= 2\pi L - 2\pi x \\ (8+2\pi)x &= 2\pi L \\ x &= \frac{2\pi L}{8+2\pi} = \frac{\pi L}{4+\pi} \approx 0.44L. \end{aligned}$$

To find the maxima and minima, we substitute the critical point and the endpoints, $x = 0$ and $x = L$, into the area function.

For $x = 0$, we have $A = \dfrac{L^2}{16}$.

For $x = \dfrac{\pi L}{4+\pi}$, we have $L - x = L - \dfrac{\pi L}{4+\pi} = \dfrac{4L}{4+\pi}$. Then

$$\begin{aligned} A &= \frac{\pi^2 L^2}{4\pi(4+\pi)^2} + \frac{1}{16}\left(\frac{4L}{4+\pi}\right)^2 = \frac{\pi L^2}{4(4+\pi)^2} + \frac{L^2}{(4+\pi)^2} \\ &= \frac{\pi L^2 + 4L^2}{4(4+\pi)^2} = \frac{L^2}{4(4+\pi)} = \frac{L^2}{16+4\pi}. \end{aligned}$$

For $x = L$, we have $A = \dfrac{L^2}{4\pi}$.

Thus, $x = \dfrac{\pi L}{4+\pi}$ gives the minimum value of $A = \dfrac{L^2}{16+4\pi}$.

Since $4\pi < 16$, we see that $x = L$ gives the maximum value of $A = \dfrac{L^2}{4\pi}$.

This corresponds to the situation in which we do not cut the wire at all and use the single piece to make a circle.

(b) At the maximum, $x = L$, so

$$\frac{\text{Length of wire in square}}{\text{Length of wire in circle}} = \frac{0}{L} = 0.$$
$$\frac{\text{Area of square}}{\text{Area of circle}} = \frac{0}{L^2/4\pi} = 0.$$

At the minimum, $x = \dfrac{\pi L}{4+\pi}$, so $L - x = L - \dfrac{\pi L}{4+\pi} = \dfrac{4L}{4+\pi}$.

$$\frac{\text{Length of wire in square}}{\text{Length of wire in circle}} = \frac{4L/(4+\pi)}{\pi L/(4+\pi)} = \frac{4}{\pi}.$$
$$\frac{\text{Area of square}}{\text{Area of circle}} = \frac{L^2/(4+\pi)^2}{\pi L^2/(4(4+\pi)^2)} = \frac{4}{\pi}.$$

(c) For a general value of x,

$$\frac{\text{Length of wire in square}}{\text{Length of wire in circle}} = \frac{L-x}{x}.$$
$$\frac{\text{Area of square}}{\text{Area of circle}} = \frac{(L-x)^2/16}{x^2/(4\pi)} = \frac{\pi}{4}\cdot\frac{(L-x)^2}{x^2}.$$

If the ratios are equal, we have

$$\frac{L-x}{x} = \frac{\pi}{4} \cdot \frac{(L-x)^2}{x^2}.$$

So either $L - x = 0$, giving $x = L$, or we can cancel $(L - x)$ and multiply through by $4x^2$, giving

$$\begin{aligned} 4x &= \pi(L-x) \\ x &= \frac{\pi L}{4+\pi}. \end{aligned}$$

Thus, the two values of x found in part (a) are the only values of x in $0 \le x \le L$ making the ratios in part (b) equal. (The ratios are not defined if $x = 0$.)

24. The minimum value of x in the interval $0 \le x \le 10$ is $x = 0$ and the maximum is $x = 10$.

25. The geometry shows that as x increases from 0 to 10 the length y decreases. The minimum value of y is 5 when $x = 10$, and the maximum value of y is $\sqrt{10^2 + 5^2} = \sqrt{125}$ when $x = 0$.

We can also use calculus. By the Pythagorean theorem we have

$$y = \sqrt{5^2 + (10-x)^2}.$$

The extreme values of

$$y = f(x) = \sqrt{5^2 + (10-x)^2}$$

for $0 \le x \le 10$ occur at the endpoints $x = 0$ or $x = 10$ or at a critical point of f. The only solution of the equation

$$f'(x) = \frac{x-10}{\sqrt{5^2 + (10-x)^2}} = 0$$

is $x = 10$, which is the only critical point of f. We have

$$f(0) = \sqrt{125} = 11.18 \qquad f(10) = 5.$$

Therefore the minimum value of y is 5 and the maximum value is $\sqrt{125} = 5\sqrt{5}$.

26. By the Pythagorean Theorem we have

$$y = \sqrt{5^2 + (10-x)^2}.$$

The extreme values of

$$f(x) = x + 2y = x + 2\sqrt{5^2 + (10-x)^2}$$

for $0 \le x \le 10$ occur at the endpoints $x = 0$ or $x = 10$ or at a critical point of f in the interval.

To find critical points, solve the equation

$$\begin{aligned} f'(x) &= 0 \\ 1 - \frac{2(10-x)}{\sqrt{5^2 + (10-x)^2}} &= 0 \\ 2(10-x) &= \sqrt{5^2 + (10-x)^2} \\ 3(10-x)^2 &= 5^2 \\ x &= 10 \pm \frac{5}{\sqrt{3}}. \end{aligned}$$

The only critical point of f in the interval $0 \le x \le 10$ is at $x = 10 - 5/\sqrt{3}$. Comparing values at the endpoints and critical points we have

$$f(0) = 10\sqrt{5} = 22.36 \qquad f(10) = 20 \qquad f(10 - \frac{5}{\sqrt{3}}) = 10 + 5\sqrt{3} = 18.66.$$

Therefore the minimum value of $x + 2y$ for $0 \le x \le 10$ is $10 + 5\sqrt{3}$ and the maximum value is $10\sqrt{5}$.

27. By the Pythagorean theorem we have

$$y = \sqrt{5^2 + (10-x)^2}.$$

The extreme values of

$$f(x) = 2x + y = 2x + \sqrt{5^2 + (10-x)^2}$$

for $0 \le x \le 10$ occur at the endpoints $x = 0$ or $x = 10$ or at a critical point of f in the interval.

To find critical points, solve the equation

$$\begin{aligned} f'(x) &= 0 \\ 2 - \frac{10-x}{\sqrt{5^2 + (10-x)^2}} &= 0 \\ 10 - x &= 2\sqrt{5^2 + (10-x)^2} \\ 3(10-x)^2 &= -100. \end{aligned}$$

The function f has no critical points. Comparing values at the endpoints we have

$$f(0) = 5\sqrt{5} = 11.18 \qquad f(10) = 25.$$

The minimum value of $2x + y$ for $0 \le x \le 10$ is $5\sqrt{5}$ and the maximum value is 25.

28. The distance $d(x)$ from the point $(x, \sqrt{1-x})$ on the curve to the origin is given by

$$d(x) = \sqrt{x^2 + (\sqrt{1-x})^2} = \sqrt{x^2 + (1-x)}.$$

Since x is in the domain of $y = \sqrt{1-x}$, we have $-\infty < x \le 1$. Differentiating gives

$$d'(x) = \frac{2x - 1}{2\sqrt{x^2 - x + 1}},$$

so $x = 1/2$ is the only critical point. Since $d'(x) < 0$ for $x < 1/2$ and $d'(x) > 0$ for $x > 1/2$, the point $x = 1/2$ is a minimum for x. The point $(1/2, 1/\sqrt{2})$ is the closest point on the curve to the origin.

29. (a) For points (x, y) on the ellipse, we have $y^2 = 1 - x^2/9$ and $-3 \le x \le 3$. We wish to minimize the distance

$$D = \sqrt{(x-2)^2 + (y-0)^2} = \sqrt{(x-2)^2 + 1 - \frac{x^2}{9}}.$$

To do so, we find the value of x minimizing $d = D^2$ for $-3 \le x \le 3$. This x also minimizes D. Since $d = (x-2)^2 + 1 - x^2/9$, we have

$$d'(x) = 2(x-2) - \frac{2x}{9} = \frac{16x}{9} - 4,$$

which is 0 when $x = 9/4$. Since $d''(9/4) = 16/9 > 0$, we see d has a local minimum at $x = 9/4$. Since the graph of d is a parabola, the local minimum is in fact a global minimum. Solving for y, we have

$$y^2 = 1 - \frac{x^2}{9} = 1 - \left(\frac{9}{4}\right)^2 \cdot \frac{1}{9} = \frac{7}{16},$$

so $y = \pm\sqrt{7}/4$. Therefore, the points on the ellipse closest to $(2, 0)$ are $\left(9/4, \pm\sqrt{7}/4\right)$.

(b) This time, we wish to minimize

$$D = \sqrt{(x - \sqrt{8})^2 + 1 - \frac{x^2}{9}}.$$

Again, let $d = D^2$ and minimize $d(x)$ for $-3 \le x \le 3$. Since $d = (x - \sqrt{8})^2 + 1 - x^2/9$,

$$d'(x) = 2(x - 2\sqrt{2}) - \frac{2x}{9} = \frac{16x}{9} - 4\sqrt{2}.$$

Therefore, $d'(x) = 0$ when $x = 9\sqrt{2}/4$. But $9\sqrt{2}/4 > 3$, so there are not any critical points on the interval $-3 \le x \le 3$. The minimum distance must be attained at an endpoint. Since $d'(x) < 0$ for all x between -3 and 3, the minimum is at $x = 3$. So $(3, 0)$ is the point on the ellipse closest to $(\sqrt{8}, 0)$.

30. Let the radius of the can be r and let its height be h. The surface area, S, and volume, V, of the can are given by

$$\begin{aligned} S &= \text{Area of the sides of can} + \text{Area of top and bottom} \\ S &= 2\pi rh + 2\pi r^2 \\ V &= \pi r^2 h. \end{aligned}$$

Since $S = 280$, we have $2\pi rh + 2\pi r^2 = 280$, we have

$$h = \frac{140 - \pi r^2}{\pi r}$$

and

$$V = \pi r^2 \frac{140 - \pi r^2}{\pi r} = 140r - \pi r^3.$$

Since $h \geq 0$, we have $\pi r^2 \leq 140$ and thus $0 < r \leq \sqrt{140/\pi} = 6.676$.

We have

$$V'(r) = 140 - 3\pi r^2,$$

so the only critical point of V with $r > 0$ is $r = \sqrt{140/3\pi} = 3.854$. The critical point is in the domain $0 < r \leq 6.676$.

Since $V''(r) = -6\pi r$ is negative for all $r > 0$, the critical point $r = 3.854$ cm gives the maximum value of the volume. For this value of r, we have $h = 7.708$ cm and $V = 359.721$ cm^3.

31. Figure 4.51 shows the vertical cross section through the cylinder and sphere. The circle has equation $y = \sqrt{1 - x^2}$, so if the cylinder has radius x and height y, its volume, V, is given by

$$V = \pi x^2 y = \pi x^2 \sqrt{1 - x^2} \qquad \text{for } 0 \leq x \leq 1.$$

At a critical point, $dV/dx = 0$, so

$$\begin{aligned} \frac{dV}{dx} = 2\pi x\sqrt{1-x^2} + \pi x^2\left(\frac{1}{2}(1-x^2)^{-1/2}(-2x)\right) &= 0 \\ 2\pi x\sqrt{1-x^2} - \frac{\pi x^3}{\sqrt{1-x^2}} &= 0 \\ \frac{\pi x}{\sqrt{1-x^2}}\left(2\left(\sqrt{1-x^2}\right)^2 - x^2\right) &= 0 \\ x(2 - 3x^2) &= 0 \\ x &= 0, \ \pm\sqrt{\frac{2}{3}}. \end{aligned}$$

Since $V = 0$ at the endpoints $x = 0$ and $x = 1$, and V is positive at the only critical point, $x = \sqrt{2/3}$, in the interval, the critical point $x = \sqrt{2/3}$ is a local and global maximum. Thus, the cylinder with maximum volume has

$$\text{Radius } = x = \sqrt{\frac{2}{3}}$$

$$\text{Height } = y = \sqrt{1 - \left(\sqrt{\frac{2}{3}}\right)^2} = \sqrt{\frac{1}{3}}.$$

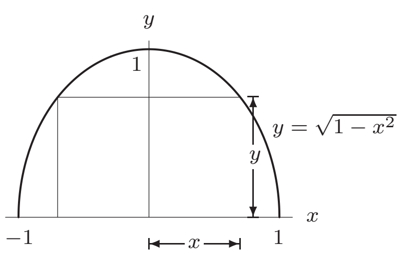

Figure 4.51

32. (a) If we expect the rate to be nonnegative, we must have $0 \le y \le a$ and $0 \le y \le b$. Since we assume $a < b$, we restrict y to $0 \le y \le a$.

In fact, the expression for the rate is nonnegative for y greater than b, but these values of y are not meaningful for the reaction. See Figure 4.52.

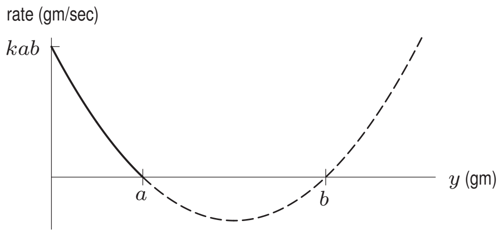

Figure 4.52

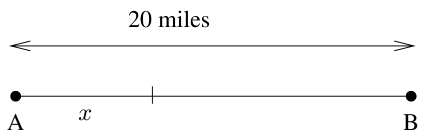
(b) From the graph, we see that the maximum rate occurs when $y = 0$; that is, at the start of the reaction.

33. Call the stacks A and B. (See below.) Assume that A corresponds to k_1, and B corresponds to k_2.



Suppose the point where the concentration of deposit is a minimum occurs at a distance of x miles from stack A. We want to find x such that

$$S = \frac{k_1}{x^2} + \frac{k_2}{(20-x)^2} = k_2\left(\frac{7}{x^2} + \frac{1}{(20-x)^2}\right)$$

is a minimum, which is the same thing as minimizing $f(x) = 7x^{-2} + (20-x)^{-2}$ since k_2 is nonnegative.

We have

$$f'(x) = -14x^{-3} - 2(20-x)^{-3}(-1) = \frac{-14}{x^3} + \frac{2}{(20-x)^3} = \frac{-14(20-x)^3 + 2x^3}{x^3(20-x)^3}.$$

Thus we want to find x such that $-14(20-x)^3 + 2x^3 = 0$, which implies $2x^3 = 14(20-x)^3$. That's equivalent to $x^3 = 7(20-x)^3$, or $\frac{20-x}{x} = (1/7)^{1/3} \approx 0.523$. Solving for x, we have $20 - x = 0.523x$, whence $x = 20/1.523 \approx 13.13$.

To verify that this minimizes f, we take the second derivative:

$$f''(x) = 42x^{-4} + 6(20-x)^{-4} = \frac{42}{x^4} + \frac{6}{(20-x)^4} > 0$$

for any $0 < x < 20$, so by the second derivative test the concentration is minimized 13.13 miles from A.

34. We only consider $\lambda > 0$. For such λ, the value of $v \to \infty$ as $\lambda \to \infty$ and as $\lambda \to 0^+$. Thus, v does not have a maximum velocity. It will have a minimum velocity. To find it, we set $dv/d\lambda = 0$:

$$\frac{dv}{d\lambda} = k\frac{1}{2}\left(\frac{\lambda}{c} + \frac{c}{\lambda}\right)^{-1/2}\left(\frac{1}{c} - \frac{c}{\lambda^2}\right) = 0.$$

Solving, and remembering that $\lambda > 0$, we obtain

$$\begin{aligned} \frac{1}{c} - \frac{c}{\lambda^2} &= 0 \\ \frac{1}{c} &= \frac{c}{\lambda^2} \\ \lambda^2 &= c^2, \end{aligned}$$

so

$$\lambda = c.$$

Thus, we have one critical point. Since

$$\frac{dv}{d\lambda} < 0 \quad \text{for } \lambda < c$$

and

$$\frac{dv}{d\lambda} > 0 \quad \text{for } \lambda > c,$$

the first derivative test tells us that we have a local minimum of v at $x = c$. Since $\lambda = c$ is the only critical point, it gives the global minimum. Thus the minimum value of v is

$$v = k\sqrt{\frac{c}{c} + \frac{c}{c}} = \sqrt{2}k.$$

35. The domain for E is all real x. Note $E \to 0$ as $x \to \pm\infty$. The critical points occur where $dE/dx = 0$. The derivative is

$$\begin{aligned}\frac{dE}{dx} &= \frac{k}{(x^2 + r_0^2)^{3/2}} - \frac{3}{2} \cdot \frac{kx(2x)}{(x^2 + r_0^2)^{5/2}} \\ &= \frac{k\left(x^2 + r_0^2 - 3x^2\right)}{(x^2 + r_0^2)^{5/2}} \\ &= \frac{k\left(r_0^2 - 2x^2\right)}{(x^2 + r_0^2)^{5/2}}.\end{aligned}$$

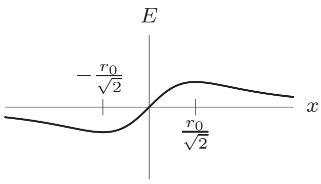
So $dE/dx = 0$ where

$$\begin{aligned} r_0^2 - 2x^2 &= 0 \\ x &= \pm\frac{r_0}{\sqrt{2}}.\end{aligned}$$

Looking at the formula for dE/dx shows

$$\begin{aligned}\frac{dE}{dx} &> 0 \text{ for } -\frac{r_0}{\sqrt{2}} < x < \frac{r_0}{\sqrt{2}} \\ \frac{dE}{dx} &< 0 \text{ for } x < -\frac{r_0}{\sqrt{2}} \\ \frac{dE}{dx} &< 0 \text{ for } x > \frac{r_0}{\sqrt{2}}.\end{aligned}$$

Therefore, $x = -r_0/\sqrt{2}$ gives the minimum value of E and $x = r_0/\sqrt{2}$ gives the maximum value of E.



36. A graph of F against θ is shown in Figure 4.53.

Taking the derivative:

$$\frac{dF}{d\theta} = -\frac{mg\mu(\cos\theta - \mu\sin\theta)}{(\sin\theta + \mu\cos\theta)^2}.$$

At a critical point, $dF/d\theta = 0$, so

$$\begin{aligned}\cos\theta - \mu\sin\theta &= 0 \\ \tan\theta &= \frac{1}{\mu} \\ \theta &= \arctan\left(\frac{1}{\mu}\right).\end{aligned}$$

If $\mu = 0.15$, then $\theta = \arctan(1/0.15) = 1.422 \approx 81.5^\circ$. To calculate the maximum and minimum values of F, we evaluate at this critical point and the endpoints:

$$\text{At } \theta = 0, \quad F = \frac{0.15mg}{\sin 0 + 0.15\cos 0} = 1.0mg \text{ newtons.}$$

$$\text{At } \theta = 1.422, \quad F = \frac{0.15mg}{\sin(1.422) + 0.15\cos(1.422)} = 0.148mg \text{ newtons.}$$

$$\text{At } \theta = \pi/2, \quad F = \frac{0.15mg}{\sin(\frac{\pi}{2}) + 0.15\cos(\frac{\pi}{2})} = 0.15mg \text{ newtons.}$$

Thus, the maximum value of F is $1.0mg$ newtons when $\theta = 0$ (her arm is vertical) and the minimum value of F is $0.148mg$ newtons is when $\theta = 1.422$ (her arm is close to horizontal). See Figure 4.54.

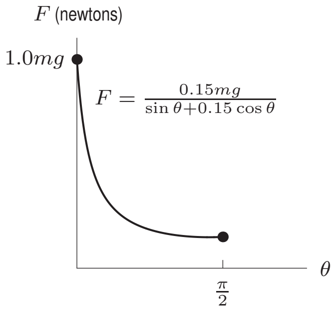


Figure 4.53

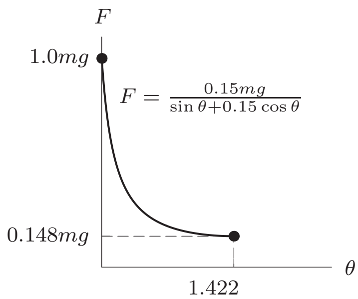

Figure 4.54

37. (a) We must locate the critical point(s) of $A(r)$ — i.e. the places where its derivative is zero. The derivative is

$$A'(r) = \frac{2r}{T} - \frac{T}{r^2},$$

so $A'(r) = 0$ when

$$\begin{aligned} A'(r) = \frac{2r}{T} - \frac{T}{r^2} &= 0 \\ \frac{2r}{T} &= \frac{T}{r^2} \\ 2r^3 &= T^2 \\ r^3 &= \frac{T^2}{2} \\ r &= \frac{T^{2/3}}{2^{1/3}}. \end{aligned}$$

The only critical point of $A(r)$ is thus $r = (T^{2/3})/(2^{1/3})$. To check that this is a local (and, since it is the only critical point, global) minimum, we employ the second derivative test. The second derivative $A''(r)$ is

$$A''(r) = \frac{2}{T} + \frac{2T}{r^3},$$

and at the critical point we have

$$A''\left(\frac{T^{2/3}}{2^{1/3}}\right) = \frac{2}{T} + \frac{4}{T} = \frac{6}{T} > 0,$$

which implies A is concave up at this critical point. It is therefore a local and global minimum.

(b) The new period is $2T$. To find the radius for this new period, substitute $2T$ for T in the expression for r:

$$\begin{aligned} r &= \frac{(2T)^{2/3}}{2^{1/3}} \\ &= 2^{2/3}\frac{T^{2/3}}{2^{1/3}}. \end{aligned}$$

Notice this is $2^{2/3}$ times the original radius. To find the percentage increase, compute $2^{2/3} \approx 1.5874$. The new radius therefore represents an increase of 58.74% over the original.

38. Let x equal the number of chairs ordered in excess of 300, so $0 \leq x \leq 100$.

$$\begin{aligned}\text{Revenue} = R &= (90 - 0.25x)(300 + x)\\ &= 27,000 - 75x + 90x - 0.25x^2 = 27,000 + 15x - 0.25x^2\end{aligned}$$

At a critical point $dR/dx = 0$. Since $dR/dx = 15 - 0.5x$, we have $x = 30$, and the maximum revenue is $\$27,225$ since the graph of R is a parabola which opens downward. The minimum is $\$0$ (when no chairs are sold).

39. If v is the speed of the boat in miles per hour, then

$$\text{Cost of fuel per hour (in \$/hour)} = kv^3,$$

where k is the constant of proportionality. To find k, use the information that the boat uses $\$100$ worth of fuel per hour when cruising at 10 miles per hour: $100 = k10^3$, so $k = 100/10^3 = 0.1$. Thus,

$$\text{Cost of fuel per hour (in \$/hour)} = 0.1v^3.$$

From the given information, we also have

$$\text{Cost of other operations (labor, maintenance, etc.) per hour (in \$/hour)} = 675.$$

So

$$\begin{aligned}\text{Total Cost per hour (in \$/hour)} &= \text{Cost of fuel (in \$/hour) + Cost of other (in \$/hour)}\\ &= 0.1v^3 + 675.\end{aligned}$$

However, we want to find the Cost per *mile*, which is the Total Cost per *hour* divided by the number of miles that the ferry travels in one hour. Since v is the speed in miles/hour at which the ferry travels, the number of miles that the ferry travels in one hour is simply v miles. Let C = Cost per *mile*. Then

$$\begin{aligned}\text{Cost per } \textit{mile} \text{ (in \$/mile)} &= \frac{\text{Total Cost per } \textit{hour} \text{ (in \$/hour)}}{\text{Distance traveled per hour (in miles/hour)}}\\ C &= \frac{0.1v^3 + 675}{v} = 0.1v^2 + \frac{675}{v}.\end{aligned}$$

We also know that $0 < v < \infty$. To find the speed at which Cost per *mile* is minimized, set

$$\frac{dC}{dv} = 2(0.1)v - \frac{675}{v^2} = 0$$

so

$$\begin{aligned}2(0.1)v &= \frac{675}{v^2}\\ v^3 &= \frac{675}{2(0.1)} = 3375\\ v &= 15 \text{ miles/hour.}\end{aligned}$$

Since

$$\frac{d^2C}{dv^2} = 0.2 + \frac{2(675)}{v^3} > 0$$

for $v > 0$, $v = 15$ gives a local minimum for C by the second-derivative test. Since this is the only critical point for $0 < v < \infty$, it must give a global minimum.

40. (a) The business must reorder often enough to keep pace with sales. If reordering is done every t months, then,

$$\begin{aligned}\text{Quantity sold in } t \text{ months} &= \text{Quantity reordered in each batch}\\ rt &= q\\ t &= \frac{q}{r} \text{ months.}\end{aligned}$$

(b) The amount spent on each order is $a + bq$, which is spent every q/r months. To find the monthly expenditures, divide by q/r. Thus, on average,

$$\text{Amount spent on ordering per month} = \frac{a + bq}{q/r} = \frac{ra}{q} + rb \text{ dollars.}$$

(c) The monthly cost of storage is $kq/2$ dollars, so

$$C = \text{Ordering costs} + \text{Storage costs}$$
$$C = \frac{ra}{q} + rb + \frac{kq}{2} \text{ dollars.}$$

(d) The optimal batch size minimizes C, so

$$\frac{dC}{dq} = \frac{-ra}{q^2} + \frac{k}{2} = 0$$
$$\frac{ra}{q^2} = \frac{k}{2}$$
$$q^2 = \frac{2ra}{k}$$

so

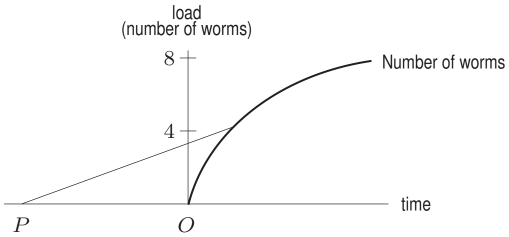
$$q = \sqrt{\frac{2ra}{k}} \text{ items per order.}$$

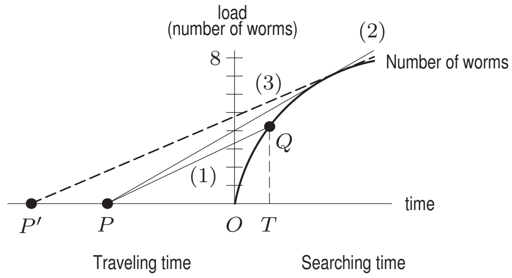
41. (a) The line in the left-hand figure has slope equal to the rate worms arrive. To understand why, see line (1) in the right-hand figure. (This is the same line.) For any point Q on the loading curve, the line PQ has slope

$$\frac{QT}{PT} = \frac{QT}{PO + OT} = \frac{\text{load}}{\text{traveling time} + \text{searching time}}.$$

(b) The slope of the line PQ is maximized when the line is tangent to the loading curve, which happens with line (2). The load is then approximately 7 worms.

(c) If the traveling time is increased, the point P moves to the left, to point P', say. If line (3) is tangent to the curve, it will be tangent to the curve further to the right than line (2), so the optimal load is larger. This makes sense: if the bird has to fly further, you'd expect it to bring back more worms each time.





42. Let x be as indicated in the figure in the text. Then the distance from S to Town 1 is $\sqrt{1+x^2}$ and the distance from S to Town 2 is $\sqrt{(4-x)^2+4^2} = \sqrt{x^2-8x+32}$.

$$\text{Total length of pipe } = f(x) = \sqrt{1+x^2} + \sqrt{x^2-8x+32}.$$

We want to look for critical points of f. The easiest way is to graph f and see that it has a local minimum at about $x = 0.8$ miles. Alternatively, we can use the formula:

$$\begin{aligned} f'(x) &= \frac{2x}{2\sqrt{1+x^2}} + \frac{2x-8}{2\sqrt{x^2-8x+32}} \\ &= \frac{x}{\sqrt{1+x^2}} + \frac{x-4}{\sqrt{x^2-8x+32}} \\ &= \frac{x\sqrt{x^2-8x+32} + (x-4)\sqrt{1+x^2}}{\sqrt{1+x^2}\sqrt{x^2-8x+32}} = 0. \end{aligned}$$

$f'(x)$ is equal to zero when the numerator is equal to zero.

$$x\sqrt{x^2-8x+32} + (x-4)\sqrt{1+x^2} = 0$$
$$x\sqrt{x^2-8x+32} = (4-x)\sqrt{1+x^2}.$$

Squaring both sides and simplifying, we get

$$\begin{aligned}x^2(x^2-8x+32) &= (x^2-8x+16)(14x^2)\\ x^4-8x^3+32x^2 &= x^4-8x^3+17x^2-8x+16\\ 15x^2+8x-16 &= 0,\\ (3x+4)(5x-4) &= 0.\end{aligned}$$

So $x = 4/5$. (Discard $x = -4/3$ since we are only interested in x between 0 and 4, between the two towns.) Using the second derivative test, we can verify that $x = 4/5$ is a local minimum.

43. (a) The distance the pigeon flies over water is

$$\overline{BP} = \frac{\overline{AB}}{\sin\theta} = \frac{500}{\sin\theta},$$

and over land is

$$\overline{PL} = \overline{AL} - \overline{AP} = 2000 - \frac{500}{\tan\theta} = 2000 - \frac{500\cos\theta}{\sin\theta}.$$

Therefore the energy required is

$$\begin{aligned}E &= 2e\left(\frac{500}{\sin\theta}\right) + e\left(2000 - \frac{500\cos\theta}{\sin\theta}\right)\\ &= 500e\left(\frac{2-\cos\theta}{\sin\theta}\right) + 2000e, \quad \text{for} \quad \arctan\left(\frac{500}{2000}\right) \le \theta \le \frac{\pi}{2}.\end{aligned}$$

(b) Notice that E and the function $f(\theta) = \dfrac{2-\cos\theta}{\sin\theta}$ must have the same critical points since the graph of E is just a stretch and a vertical shift of the graph of f. The graph of $\dfrac{2-\cos\theta}{\sin\theta}$ for $\arctan(\frac{500}{2000}) \le \theta \le \frac{\pi}{2}$ in Figure 4.55 shows that E has precisely one critical point, and that a minimum for E occurs at this point.

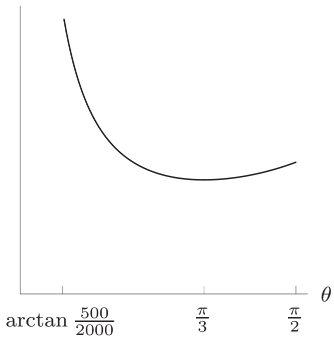


Figure 4.55: Graph of $f(\theta) = \frac{2-\cos\theta}{\sin\theta}$ for $\arctan(\frac{500}{2000}) \le \theta \le \frac{\pi}{2}$

To find the critical point θ, we solve $f'(\theta) = 0$ or

$$\begin{aligned}E' = 0 &= 500e\left(\frac{\sin\theta\cdot\sin\theta - (2-\cos\theta)\cdot\cos\theta}{\sin^2\theta}\right)\\ &= 500e\left(\frac{1-2\cos\theta}{\sin^2\theta}\right).\end{aligned}$$

Therefore $1 - 2\cos\theta = 0$ and so $\theta = \pi/3$.

(c) Letting $a = \overline{AB}$ and $b = \overline{AL}$, our formula for E becomes

$$\begin{aligned}E &= 2e\left(\frac{a}{\sin\theta}\right) + e\left(b - \frac{a\cos\theta}{\sin\theta}\right)\\ &= ea\left(\frac{2-\cos\theta}{\sin\theta}\right) + eb, \quad \text{for} \quad \arctan\left(\frac{a}{b}\right) \le \theta \le \frac{\pi}{2}.\end{aligned}$$

Again, the graph of E is just a stretch and a vertical shift of the graph of $\dfrac{2-\cos\theta}{\sin\theta}$. Thus, the critical point $\theta = \pi/3$ is independent of e, a, and b. But the maximum of E *on the domain* $\arctan(a/b) \le \theta \le \frac{\pi}{2}$ is dependent on the ratio $a/b = \dfrac{\overline{AB}}{\overline{AL}}$. In other words, the optimal angle is $\theta = \pi/3$ provided $\arctan(a/b) \le \frac{\pi}{3}$; otherwise, the optimal angle is $\arctan(a/b)$, which means the pigeon should fly over the lake for the entire trip—this occurs when $a/b > 1.733$.

44. We want to maximize the viewing angle, which is $\theta = \theta_1 - \theta_2$. See Figure 4.56. Now

$$\tan(\theta_1) = \frac{92}{x} \quad \text{so } \theta_1 = \arctan\left(\frac{92}{x}\right)$$
$$\tan(\theta_2) = \frac{46}{x} \quad \text{so } \theta_2 = \arctan\left(\frac{46}{x}\right).$$

Then

$$\theta = \arctan\left(\frac{92}{x}\right) - \arctan\left(\frac{46}{x}\right) \quad \text{for} \quad x > 0.$$

We look for critical points of the function by computing $d\theta/dx$:

$$\begin{aligned}\frac{d\theta}{dx} &= \frac{1}{1+(92/x)^2}\left(\frac{-92}{x^2}\right) - \frac{1}{1+(46/x)^2}\left(\frac{-46}{x^2}\right)\\ &= \frac{-92}{x^2+92^2} - \frac{-46}{x^2+46^2}\\ &= \frac{-92(x^2+46^2)+46(x^2+92^2)}{(x^2+92^2)\cdot(x^2+46^2)}\\ &= \frac{46(4232-x^2)}{(x^2+92^2)\cdot(x^2+46^2)}.\end{aligned}$$

Setting $d\theta/dx = 0$ gives

$$\begin{aligned}x^2 &= 4232\\ x &= \pm\sqrt{4232}.\end{aligned}$$

Since $x > 0$, the critical point is $x = \sqrt{4232} \approx 65.1$ meters. To verify that this is indeed where θ attains a maximum, we note that $d\theta/dx > 0$ for $0 < x < \sqrt{4232}$ and $d\theta/dx < 0$ for $x > \sqrt{4232}$. By the First Derivative Test, θ attains a maximum at $x = \sqrt{4232} \approx 65.1$.

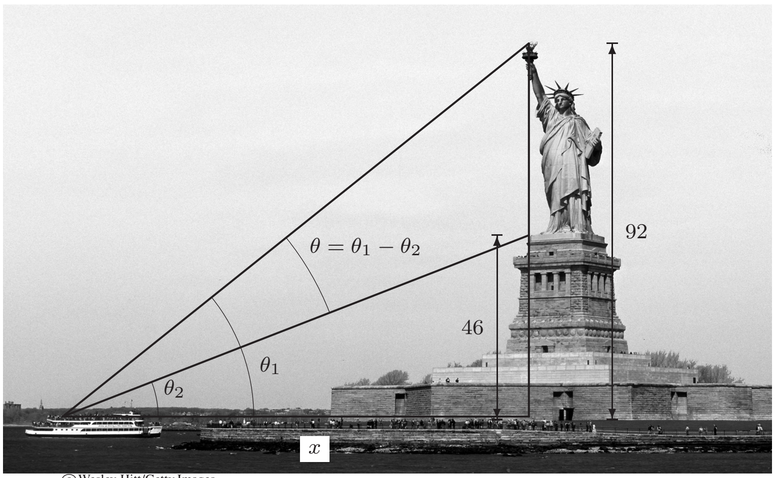

Figure 4.56

45. (a) Since the speed of light is a constant, the time of travel is minimized when the distance of travel is minimized. From Figure 4.57,

$$\text{Distance } \overrightarrow{OP} = \sqrt{x^2+1^2} = \sqrt{x^2+1}$$
$$\text{Distance } \overrightarrow{PQ} = \sqrt{(2-x)^2+1^2} = \sqrt{(2-x)^2+1}$$

Thus,

$$\text{Total distance traveled } = s = \sqrt{x^2+1} + \sqrt{(2-x)^2+1}.$$

The total distance is a minimum if

$$\frac{ds}{dx} = \frac{1}{2}(x^2+1)^{-1/2} \cdot 2x + \frac{1}{2}((2-x)^2+1)^{-1/2} \cdot 2(2-x)(-1) = 0,$$

giving

$$\frac{x}{\sqrt{x^2+1}} - \frac{2-x}{\sqrt{(2-x)^2+1}} = 0$$
$$\frac{x}{\sqrt{x^2+1}} = \frac{2-x}{\sqrt{(2-x)^2+1}}$$

Squaring both sides gives

$$\frac{x^2}{x^2+1} = \frac{(2-x)^2}{(2-x)^2+1}.$$

Cross multiplying gives

$$x^2((2-x)^2+1) = (2-x)^2(x^2+1).$$

Multiplying out

$$x^2(4-4x+x^2+1) = (4-4x+x^2)(x^2+1)$$
$$4x^2-4x^3+x^4+x^2 = 4x^2-4x^3+x^4+4-4x+x^2.$$

Collecting terms and canceling gives

$$0 = 4-4x$$
$$x = 1.$$

We can see that this value of x gives a minimum by comparing the value of s at this point and at the endpoints, $x=0, x=2$.

At $x=1$,

$$s = \sqrt{1^2+1} + \sqrt{(2-1)^2+1} = 2.83.$$

At $x=0$,

$$s = \sqrt{0^2+1} + \sqrt{(2-0)^2+1} = 3.24.$$

At $x=2$,

$$s = \sqrt{2^2+1} + \sqrt{(2-2)^2+1} = 3.24.$$

Thus the shortest travel time occurs when $x=1$; that is, when P is at the point $(1,1)$.

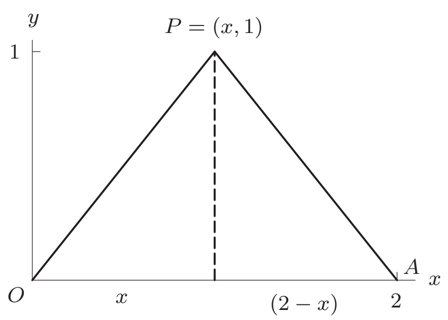

Figure 4.57

(b) Since $x=1$ is halfway between $x=0$ and $x=2$, the angles θ_1 and θ_2 are equal.

46. (a) We have

$$x^{1/x} = e^{\ln(x^{1/x})} = e^{(1/x)\ln x}.$$

Thus

$$\begin{aligned}\frac{d(x^{1/x})}{dx} &= \frac{d(e^{(1/x)\ln x})}{dx} = \frac{d(\frac{1}{x}\ln x)}{dx}e^{(1/x)\ln x} \\ &= \left(-\frac{\ln x}{x^2} + \frac{1}{x^2}\right)x^{1/x} \\ &= \frac{x^{1/x}}{x^2}(1-\ln x)\begin{cases} = 0 & \text{when } x = e \\ < 0 & \text{when } x > e \\ > 0 & \text{when } x < e.\end{cases}\end{aligned}$$

Hence $e^{1/e}$ is the global maximum for $x^{1/x}$, by the first derivative test.

(b) Since $x^{1/x}$ is increasing for $0 < x < e$ and decreasing for $x > e$, and 2 and 3 are the closest integers to e, either $2^{1/2}$ or $3^{1/3}$ is the maximum for $n^{1/n}$. We have $2^{1/2} \approx 1.414$ and $3^{1/3} \approx 1.442$, so $3^{1/3}$ is the maximum.

(c) Since $e < 3 < \pi$, and $x^{1/x}$ is decreasing for $x > e$, $3^{1/3} > \pi^{1/\pi}$.

47. (a) If, following the hint, we set $f(x) = (a+x)/2 - \sqrt{ax}$, then $f(x)$ represents the difference between the arithmetic and geometric means for some fixed a and any $x > 0$. We can find where this difference is minimized by solving $f'(x) = 0$. Since $f'(x) = \frac{1}{2} - \frac{1}{2}\sqrt{a}x^{-1/2}$, if $f'(x) = 0$ then $\frac{1}{2}\sqrt{a}x^{-1/2} = \frac{1}{2}$, or $x = a$. Since $f''(x) = \frac{1}{4}\sqrt{a}x^{-3/2}$ is positive for all positive x, by the second derivative test $f(x)$ has a minimum at $x = a$, and $f(a) = 0$. Thus $f(x) = (a+x)/2 - \sqrt{ax} \geq 0$ for all $x > 0$, which means $(a+x)/2 \geq \sqrt{ax}$. This means that the arithmetic mean is greater than the geometric mean unless $a = x$, in which case the two means are equal.

Alternatively, and without using calculus, we obtain

$$\begin{aligned}\frac{a+b}{2} - \sqrt{ab} &= \frac{a - 2\sqrt{ab} + b}{2} \\ &= \frac{(\sqrt{a} - \sqrt{b})^2}{2} \geq 0,\end{aligned}$$

and again we have $(a+b)/2 \geq \sqrt{ab}$.

(b) Following the hint, set $f(x) = \frac{a+b+x}{3} - \sqrt[3]{abx}$. Then $f(x)$ represents the difference between the arithmetic and geometric means for some fixed a, b and any $x > 0$. We can find where this difference is minimized by solving $f'(x) = 0$. Since $f'(x) = \frac{1}{3} - \frac{1}{3}\sqrt[3]{ab}x^{-2/3}$, $f'(x) = 0$ implies that $\frac{1}{3}\sqrt[3]{ab}x^{-2/3} = \frac{1}{3}$, or $x = \sqrt{ab}$. Since $f''(x) = \frac{2}{9}\sqrt[3]{ab}x^{-5/3}$ is positive for all positive x, by the second derivative test $f(x)$ has a minimum at $x = \sqrt{ab}$. But

$$f(\sqrt{ab}) = \frac{a+b+\sqrt{ab}}{3} - \sqrt[3]{ab\sqrt{ab}} = \frac{a+b+\sqrt{ab}}{3} - \sqrt{ab} = \frac{a+b-2\sqrt{ab}}{3}.$$

By the first part of this problem, we know that $\frac{a+b}{2} - \sqrt{ab} \geq 0$, which implies that $a + b - 2\sqrt{ab} \geq 0$. Thus $f(\sqrt{ab}) = \frac{a+b-2\sqrt{ab}}{3} \geq 0$. Since f has a maximum at $x = \sqrt{ab}$, $f(x)$ is always nonnegative. Thus $f(x) = \frac{a+b+x}{3} - \sqrt[3]{abx} \geq 0$, so $\frac{a+b+c}{3} \geq \sqrt[3]{abc}$. Note that equality holds only when $a = b = c$. (Part (b) may also be done without calculus, but it's harder than (a).)

48. For $x > 0$, the line in Figure 4.58 has

$$\text{Slope} = \frac{y}{x} = \frac{x^2e^{-3x}}{x} = xe^{-3x}.$$

If the slope has a maximum, it occurs where

$$\begin{aligned}\frac{d}{dx}(\text{Slope}) &= 1\cdot e^{-3x} - 3xe^{-3x} = 0 \\ e^{-3x}(1-3x) &= 0 \\ x &= \frac{1}{3}.\end{aligned}$$

For this x-value,

$$\text{Slope} = \frac{1}{3}e^{-3(1/3)} = \frac{1}{3}e^{-1} = \frac{1}{3e}.$$

Figure 4.58 shows that the slope tends toward 0 as $x \to \infty$; the formula for the slope shows that the slope tends toward 0 as $x \to 0$. Thus the only critical point, $x = 1/3$, must give a local and global maximum.

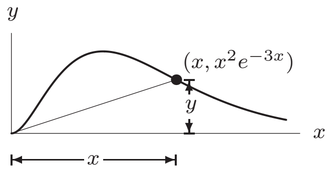

Figure 4.58

49. (a) For a point (t, s), the line from the origin has rise $= s$ and run $= t$; See Figure 4.59. Thus, the slope of the line OP is s/t.

(b) Sketching several lines from the origin to points on the curve (see Figure 4.60), we see that the maximum slope occurs at the point P, where the line to the origin is tangent to the graph. Reading from the graph, we see $t \approx 2$ hours at this point.

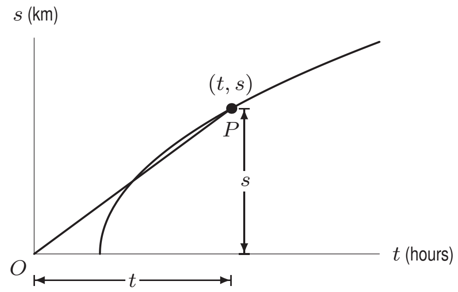

Figure 4.59

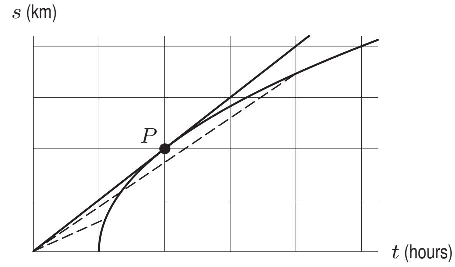

Figure 4.60

(c) The instantaneous speed of the cyclist at any time is given by the slope of the corresponding point on the curve. At the point P, the line from the origin is tangent to the curve, so the quantity s/t equals the cyclist's speed at the point P.

50. (a) To maximize benefit (surviving young), we pick 10, because that's the highest point of the benefit graph.

(b) To optimize the vertical distance between the curves, we can either do it by inspection or note that the slopes of the two curves will be the same where the difference is maximized. Either way, one gets approximately 9.

51. (a) At higher speeds, the bird uses more energy so the graph rises to the right. The initial drop is due to the fact that the energy it takes a bird to fly at very low speeds is greater than that needed to fly at a slightly higher speeds. (This is analogous to our swimming in a pool).

(b) The value of $f(v)$ measures energy per second; the value of $a(v)$ measures energy per meter. In one second, a bird traveling at rate v travels v meters and consumes $v \cdot a(v)$ joules. Thus $v \cdot a(v)$ represents the energy consumption per second, so $f(v) = v \cdot a(v)$.

(c) Since $v \cdot a(v) = f(v)$, we have
$$a(v) = \frac{f(v)}{v}.$$
This ratio is the slope of a line passing from the origin through the point $(v, f(v))$ on the curve. (See Figure 4.61.) Thus $a(v)$ is minimal when the slope of this line is minimal. This occurs where the line is tangent to the curve.

To find the value of v minimizing $a(v)$ symbolically, we solve $a'(v) = 0$. By the quotient rule,
$$a'(v) = \frac{vf'(v) - f(v)}{v^2}.$$
Thus $a'(v) = 0$ when $vf'(v) = f(v)$, or when $f'(v) = f(v)/v = a(v)$. Thus $a(v)$ is minimized when $a(v) = f'(v)$.

(d) Assuming the bird wants to go from one particular point to another, that is, when the distance is fixed, the bird should minimize $a(v)$. Then minimizing $a(v)$ minimizes the total energy used for the flight.

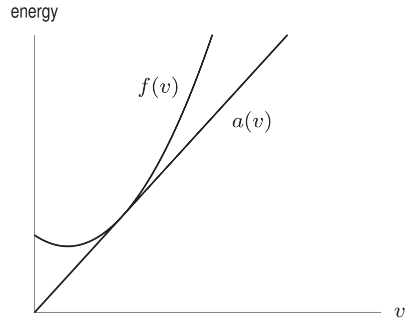

Figure 4.61

52. (a) Figure 4.62 contains the graph of total drag, plotted on the same coordinate system with induced and parasite drag. It was drawn by adding the vertical coordinates of Induced and Parasite drag.

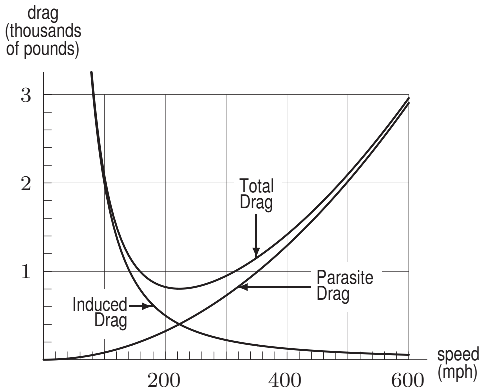

Figure 4.62

(b) Air speeds of approximately 160 mph and 320 mph each result in a total drag of 1000 pounds. Since two distinct air speeds are associated with a single total drag value, the total drag function does not have an inverse. The parasite and induced drag functions do have inverses, because they are strictly increasing and strictly decreasing functions, respectively.

(c) To conserve fuel, fly the at the air speed which minimizes total drag. This is the air speed corresponding to the lowest point on the total drag curve in part (a): that is, approximately 220 mph.

53. (a) To obtain $g(v)$, which is in gallons per mile, we need to divide $f(v)$ (in gallons per hour) by v (in miles per hour). Thus, $g(v) = f(v)/v$.

(b) By inspecting the graph, we see that $f(v)$ is minimized at approximately 220 mph.

(c) Note that a point on the graph of $f(v)$ has the coordinates $(v, f(v))$. The line passing through this point and the origin $(0, 0)$ has

$$\text{Slope } = \frac{f(v) - 0}{v - 0} = \frac{f(v)}{v} = g(v).$$

So minimizing $g(v)$ corresponds to finding the line of minimum slope from the family of lines which pass through the origin $(0, 0)$ and the point $(v, f(v))$ on the graph of $f(v)$. This line is the unique member of the family which is tangent to the graph of $f(v)$. The value of v corresponding to the point of tangency will minimize $g(v)$. This value of v will satisfy $f(v)/v = f'(v)$. From the graph in Figure 4.63, we see that $v \approx 300$ mph.

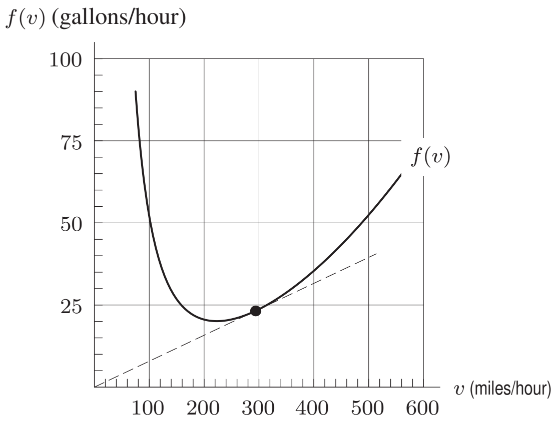

Figure 4.63

(d) The pilot's goal with regard to $f(v)$ and $g(v)$ would depend on the purpose of the flight, and might even vary within a given flight. For example, if the mission involved aerial surveillance or banner-towing over some limited area, or if the plane was flying a holding pattern, then the pilot would want to minimize $f(v)$ so as to remain aloft as long as possible. In a more normal situation where the purpose was economical travel between two fixed points, then the minimum net fuel expenditure for the trip would result from minimizing $g(v)$.

Strengthen Your Understanding

54. Since $A = 2x^2$, the area increases with x, and the maximum A occurs at the endpoint $x = 10$.

55. The function $V = h(20 - 2h)^2$ has domain $0 \le h \le 10$ for this model, or we cannot make the box from the cardboard. We maximize V on $0 \le h \le 10$.

56. The solution of an optimization problem depends on both the modeling function and the interval over which that function is optimized. The solution can occur either at a critical point of the function or at an endpoint of the interval. For example, if the modeling function is $f(x) = -(x-2)^2 + 6$ on the interval $5 \le x \le 10$, the absolute minimum occurs at $x = 10$ and the maximum occurs at $x = 5$; neither occurs at the vertex $x = 2$.

57. For example, if sides are 9 cm and 1 cm, the perimeter is 20 cm and the area is 9 cm^2.

58. If we interpret xy as the area of a rectangular field and $2x + 6y$ as a weighted perimeter of the field, one possible problem would be: A farmer would like to fence in a rectangular field of area 120 square feet. Fencing material along the north and south sides of the field costs \$1 per foot and along the east and west sides it costs \$3 per foot. What dimensions of the field minimize the cost for the fencing material?

59. The only additional information we have to provide is the cost of the material of the can. One possible choice is: The material for the bottom and the top of the can costs 2 cents per square centimeter and the material for the side of the can costs 1 cent per square centimeter.

Solutions for Section 4.4

Exercises

1. (a) See Figure 4.64.

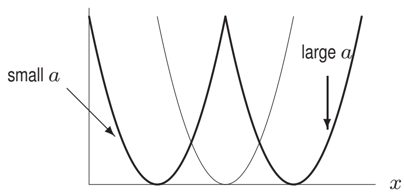

Figure 4.64

(b) We see in Figure 4.64 that in each case the graph of f is a parabola with one critical point, its vertex, on the positive x-axis. The critical point moves to the right along the x-axis as a increases.

(c) To find the critical points, we set the derivative equal to zero and solve for x.

$$f'(x) = 2(x-a) = 0$$
$$x = a.$$

The only critical point is at $x = a$. As we saw in the graph, and as a increases, the critical point moves to the right.

2. (a) See Figure 4.65.

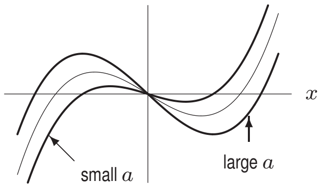

Figure 4.65

(b) We see in Figure 4.65 that in each case f has two critical points placed symmetrically about the origin, one in each of quadrants II and IV. As a increases, they appear to move farther apart, the one in quadrant II up and to the left, the one in quadrant IV down and to the right.

(c) To find the critical points, we set the derivative equal to zero and solve for x.

$$f'(x) = 3x^2 - a = 0$$
$$x^2 = \frac{a}{3}$$
$$x = \pm\sqrt{\frac{a}{3}}.$$

There are two critical points, at $x = \sqrt{a/3}$ and $x = -\sqrt{a/3}$. (Since the parameter a is positive, the critical points exist.) As we saw in the graph, and as a increases, the critical points both move away from the vertical axis.

3. (a) See Figure 4.66.

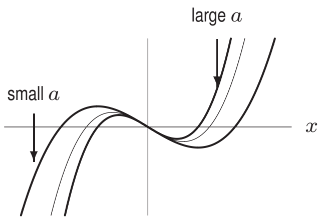

Figure 4.66

(b) We see in Figure 4.66 that in each case f has two critical points placed symmetrically about the origin, one in each of quadrants II and IV. As a increases, the critical points appear to move closer together, the one in quadrant II down and to the right, the one in quadrant IV up and to the left.

(c) To find the critical points, we set the derivative equal to zero and solve for x.

$$f'(x) = 3ax^2 - 1 = 0$$
$$x^2 = \frac{1}{3a}$$
$$x = \pm\sqrt{\frac{1}{3a}}.$$

There are two critical points, at $x = \sqrt{1/(3a)}$ and $x = -\sqrt{1/(3a)}$. (Since the parameter a is positive, the critical points exist.) As we saw in the graph, and as a increases, the critical points both move toward the vertical axis.

4. (a) See Figure 4.67.

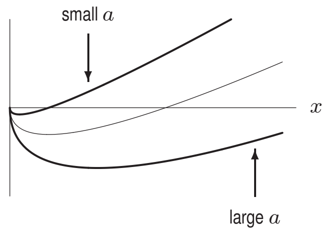

Figure 4.67

(b) The domain of f is $x \geq 0$ since the formula for $f(x)$ contains the square root of x. We see in Figure 4.67 that in each case f appears to have one critical point in quadrant IV where the function has a local minimum and possibly a second critical point at the origin where the graph appears to have a vertical tangent line. As the parameter a increases, the critical point in quadrant IV appears to move down and to the right.

(c) To find the critical points, we set the derivative equal to zero and solve for x.

$$\begin{aligned} f'(x) = 1 - \frac{1}{2}ax^{-1/2} &= 0 \\ 1 - \frac{a}{2\sqrt{x}} &= 0 \\ 2\sqrt{x} &= a \\ \sqrt{x} &= \frac{a}{2} \\ x &= \frac{a^2}{4}. \end{aligned}$$

There is a critical point at $x = a^2/4$. Since f' is undefined at $x = 0$, there is also a critical point at $x = 0$. Increasing a has no effect on the critical point at $x = 0$. As we saw in the graph, as a increases the x-value of the other critical point increases and the critical point moves to the right.

5. (a) See Figure 4.68.

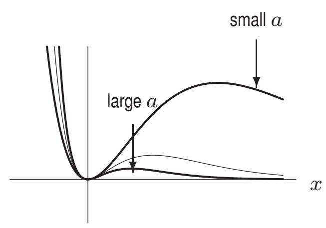

Figure 4.68

(b) We see in Figure 4.68 that in each case f appears to have two critical points. One critical point is a local minimum at the origin and the other is a local maximum in quadrant I. As the parameter a increases, the critical point in quadrant I appears to move down and to the left, closer to the origin.

(c) To find the critical points, we set the derivative equal to zero and solve for x. Using the product rule, we have:

$$\begin{aligned} f'(x) = x^2 \cdot e^{-ax}(-a) + 2x \cdot e^{-ax} &= 0 \\ xe^{-ax}(-ax + 2) &= 0 \\ x = 0 \quad \text{and} \quad x &= \frac{2}{a}. \end{aligned}$$

There are two critical points, at $x = 0$ and $x = 2/a$. As we saw in the graph, as a increases the nonzero critical point moves to the left.

6. (a) See Figure 4.69.

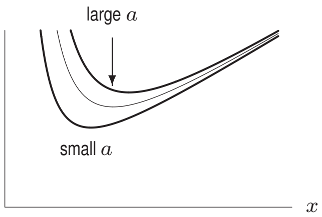

Figure 4.69

(b) We see in Figure 4.69 that in each case f appears to have one critical point, a local minimum in quadrant I. As the parameter a increases, the critical point appears to move up and to the right.

(c) To find the critical points, we set the derivative equal to zero and solve for x.

$$\begin{aligned} f'(x) = -2ax^{-3} + 1 &= 0 \\ 1 &= \frac{2a}{x^3} \\ x^3 &= 2a \\ x &= \sqrt[3]{2a}. \end{aligned}$$

There is one critical point, at $x = \sqrt[3]{2a}$. As we saw in the graph, as a increases the critical point moves to the right.

7. (a) The larger the value of $|A|$, the steeper the graph (for the same x-value).

(b) The graph is shifted horizontally by B. The shift is to the left for positive B, to the right for negative B. There is a vertical asymptote at $x = -B$. See Figure 4.70.

(c)

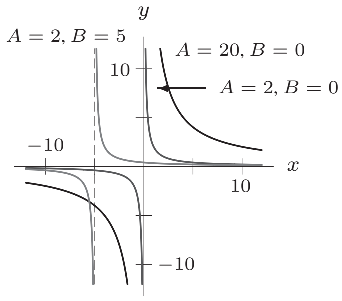

Figure 4.70

8. To find the critical points, we set the derivative of $f(w) = Aw^{-2} - Bw^{-1}$ equal to zero and solve for w.

$$\begin{aligned} f'(w) = -2Aw^{-3} - (-1)Bw^{-2} &= 0 \\ \frac{-2A}{w^3} + \frac{B}{w^2} &= 0 \\ \frac{-2A + Bw}{w^3} &= 0 \\ -2A + Bw &= 0 \\ w &= \frac{2A}{B}. \end{aligned}$$

Although f' is undefined at $w = 0$, this is not a critical point since it is not in the domain of f. The only critical point is $w = 2A/B$.

9. We have $f'(x) = -ae^{-ax}$, so that $f'(0) = -a$. We see that as a increases the slopes of the curves at the origin become more and more negative. Thus, A corresponds to $a = 1$, B to $a = 2$, and C to $a = 5$.

10. We have $f'(x) = (1 - ax)e^{-ax}$, so that the critical points occur when $1 - ax = 0$, that is, when $x = 1/a$. We see that as a increases the x-value of the extrema moves closer to the origin. Looking at the figure we see that A's local maximum is the farthest from the origin, while C's is the closest. Thus, A corresponds to $a = 1$, B to $a = 2$, and C to $a = 3$.

11. (a) Figure 4.71 shows the effect of varying a with $b = 1$.
(b) Figure 4.72 shows the effect of varying b with $a = 1$.

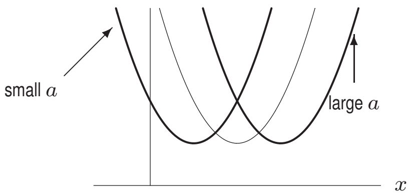

Figure 4.71

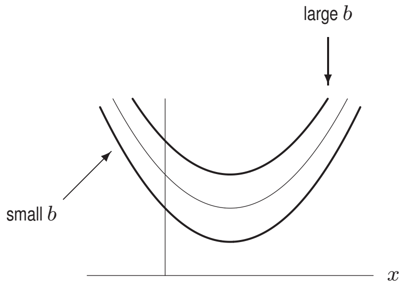

Figure 4.72

(c) From Figure 4.71 it appears that increasing a shifts the graph and its critical point to the right. From Figure 4.72 it appears that increasing b moves the graph and its critical point up.
(d) To find the critical points, we set the derivative equal to zero and solve for x.

$$f'(x) = 2(x - a) = 0$$
$$x = a.$$

There is one critical point, at $x = a$. As we saw in the graph, as a increases the critical point moves to the right. As b increases the critical point does not move horizontally.

12. (a) Figure 4.73 shows the effect of varying a with $b = 1$.
(b) Figure 4.74 shows the effect of varying b with $a = 1$.

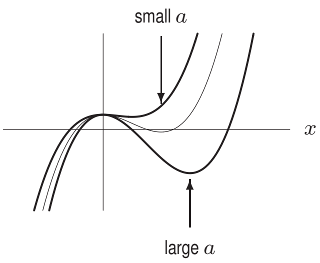

Figure 4.73

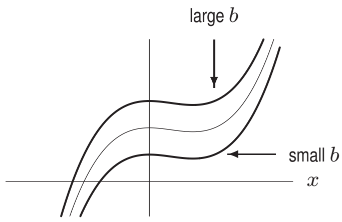

Figure 4.74

(c) From the graphs it appears that there are two critical points, a local maximum at $x = 0$ and a local minimum in the region $x > 0$. From Figure 4.73 it appears that increasing a moves the local minimum down and to the right, and does not move the local maximum. From Figure 4.74 it appears that increasing b moves both critical points up.
(d) To find the critical points, we set the derivative equal to zero and solve for x.

$$f'(x) = 3x^2 - 2ax = 0$$
$$x(3x - 2a) = 0$$
$$x = 0 \quad \text{or} \quad x = \frac{2a}{3}.$$

There are two critical points, at $x = 0$ and at $x = 2a/3$. As a increases the critical point to the right moves farther right. As b increases, neither critical point moves horizontally. This matches what we saw in the graphs.

13. (a) Figure 4.75 shows the effect of varying a with $b = 1$.
(b) Figure 4.76 shows the effect of varying b with $a = 1$.

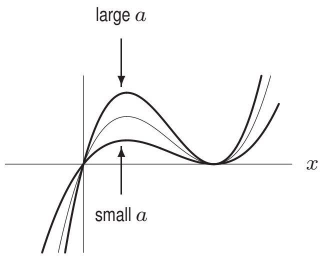

Figure 4.75

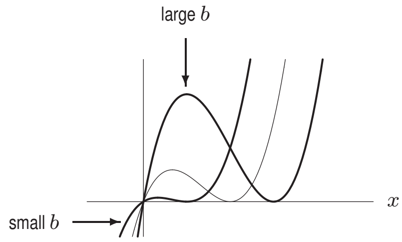

Figure 4.76

(c) In each case f appears to have two critical points, a local maximum in quadrant I and a local minimum on the positive x-axis. From Figure 4.75 it appears that increasing a moves the local maximum up and does not move the local minimum. From Figure 4.76 it appears that increasing b moves the local maximum up and to the right and moves the local minimum to the right along the x-axis.

(d) To find the critical points, we set the derivative equal to zero and solve for x. Using the product rule, we have:

$$\begin{aligned} f'(x) = ax \cdot 2(x-b) + a \cdot (x-b)^2 &= 0 \\ a(x-b)(2x + (x-b)) &= 0 \\ a(x-b)(3x-b) &= 0 \\ x = b \quad \text{or} \quad x &= \frac{b}{3}. \end{aligned}$$

There are two critical points, at $x = b$ and at $x = b/3$. Increasing a does not move either critical point horizontally. Increasing b moves both critical points to the right. This confirms what we saw in the graphs.

14. (a) Figure 4.77 shows the effect of varying a with $b = 1$.

(b) Figure 4.78 shows the effect of varying b with $a = 1$.

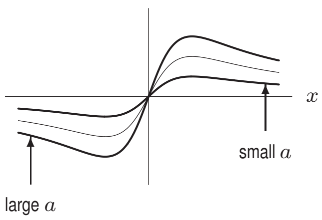

Figure 4.77

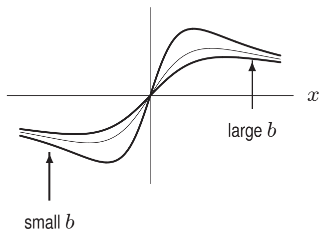

Figure 4.78

(c) From the graphs it appears that in all cases f has two critical points symmetrically placed about the origin, a local maximum in quadrant I and a local minimum in quadrant III. From Figure 4.77 it appears that increasing a moves the local maximum up and the local minimum down. From Figure 4.78 it appears that increasing b moves the local maximum down and to the right and the local minimum up and to the left. Thus increasing b appears to move both critical points closer to the horizontal axis and farther from the vertical axis.

(d) To find the critical points, we set the derivative equal to zero and solve for x. Using the quotient rule, we have:

$$\begin{aligned} f'(x) = \frac{(x^2+b)\cdot a - ax \cdot 2x}{(x^2+b)^2} &= 0 \\ \frac{ax^2 + ab - 2ax^2}{(x^2+b)^2} &= 0 \\ \frac{ab - ax^2}{(x^2+b)^2} &= 0 \\ ab - ax^2 &= 0 \\ a(b - x^2) &= 0 \\ x &= \pm\sqrt{b}. \end{aligned}$$

There are two critical points, at $x = \sqrt{b}$ and $x = -\sqrt{b}$. Increasing a does not move either critical point horizontally. Increasing b moves both critical points farther from the vertical axis. This confirms what we saw in the graphs.

15. (a) Figure 4.79 shows the effect of varying a with $b = 1$.
(b) Figure 4.80 shows the effect of varying b with $a = 1$.

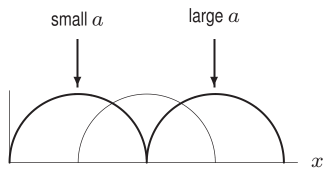

Figure 4.79

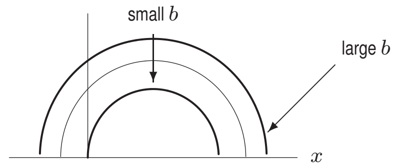

Figure 4.80

(c) The domain of $f(x) = \sqrt{b-(x-a)^2}$ is limited by the square root to $b-(x-a)^2 \geq 0$, so it is $a-\sqrt{b} < x < a+\sqrt{b}$.
From the graphs in parts (a) and (b) it appears that in all cases f has three critical points, one a local maximum and the other two on the x-axis at the endpoints of the domain of f where the graph of the function has a vertical tangent line. From Figure 4.79 it appears that increasing a moves all three critical points to the right. From Figure 4.80 it appears that increasing b moves the local maximum up and moves the other two critical points away from each other horizontally along the x-axis.
(d) To find the critical points, we set the derivative equal to zero and solve for x. Using the chain rule, we have:

$$\begin{aligned} f'(x) = \frac{1}{2}(b-(x-a)^2)^{-1/2}(-2(x-a)) &= 0 \\ \frac{-(x-a)}{\sqrt{b-(x-a)^2}} &= 0 \\ -(x-a) &= 0 \\ x &= a. \end{aligned}$$

There is a critical point of f at $x = a$. As a increases this critical point moves to the right. As b increases, it does not move horizontally.
The derivative of f is undefined when $\sqrt{b-(x-a)^2} = 0$. Solving for x, we have:

$$\begin{aligned} \sqrt{b-(x-a)^2} &= 0 \\ b-(x-a)^2 &= 0 \\ (x-a)^2 &= b \\ x-a &= \pm\sqrt{b} \\ x &= a \pm \sqrt{b}. \end{aligned}$$

The function f has two additional critical points, at $x = a+\sqrt{b}$ and $x = a-\sqrt{b}$, where the derivative f' is not defined and the graph of f has a vertical tangent. As a increases both these critical points move to the right, and as b increases they move in opposite directions away from the line $x = a$ containing the other critical point. We saw this in the graphs.

16. (a) Figure 4.81 shows the effect of varying a with $b = 1$.
(b) Figure 4.82 shows the effect of varying b with $a = 1$.

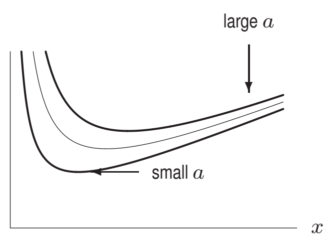

Figure 4.81

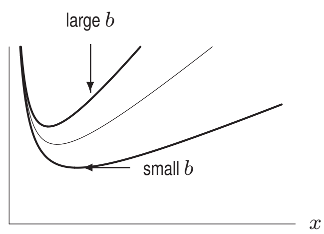

Figure 4.82

(c) It appears from the graphs that in all cases f has one critical point, a local minimum in quadrant I. From Figure 4.81 it appears that increasing a moves the critical point up and to the right. From Figure 4.82 it appears that increasing b moves the critical point up and to the left.

(d) To find the critical points, we set the derivative equal to zero and solve for x.

$$\begin{aligned} f'(x) = -ax^{-2} + b &= 0 \\ \frac{-a}{x^2} + b &= 0 \\ b &= \frac{a}{x^2} \\ x^2 &= \frac{a}{b} \\ x &= \pm\sqrt{\frac{a}{b}}. \end{aligned}$$

Since the domain of f is $x > 0$ we are only interested in positive values for x, so there is one critical point at $x = \sqrt{a/b}$. As a increases, this value gets larger and the critical point moves to the right. As b increases, this value gets smaller and the critical point moves to the left. This confirms what we see in the graphs.

Problems

17. We have $f'(x) = 1 - a^2/x^2$, so the critical points occur at $1 - a^2/x^2 = 0$, that is $x = \pm a$. We see that A has a minimum at $x = 3$, B at $x = 2$, and C at $x = 1$. Thus, C corresponds to $a = 1$, B to $a = 2$, and A to $a = 3$. The third value is 3.

18. For the curves to intersect in the same point for any positive value of a, say a and $b \neq a$, we need $x + a\sin x = x + b\sin x$, that is $(a-b)\sin x = 0$. Because $a - b \neq 0$, we find that $\sin x = 0$, which occurs at $x = 0, \pm\pi, \pm 2\pi \ldots$. For any integer n, the graphs go through the points $(n\pi, n\pi)$ for all a.

19. (a) Graphs of $y = xe^{-bx}$ for $b = 1, 2, 3, 4$ are in Figure 4.83. All the graphs rise at first, passing through the origin, reach a maximum and then decay toward 0. If b is small, the graph rises longer and to a higher maximum before the decay begins.

(b) Since

$$\frac{dy}{dx} = (1 - bx)e^{-bx},$$

we see

$$\frac{dy}{dx} = 0 \quad \text{at} \quad x = \frac{1}{b}.$$

The critical point has coordinates $(1/b, 1/(be))$. If b is small, the x and y-coordinates of the critical point are both large, indicating a higher maximum further to the right. See Figure 4.84.

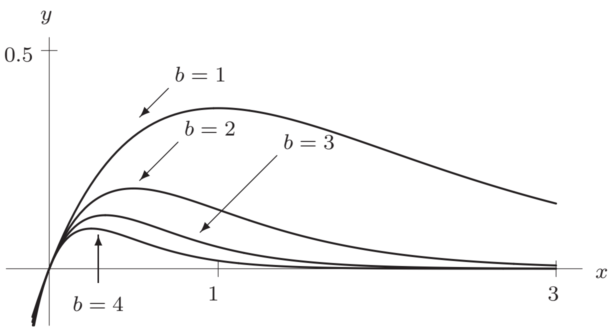

Figure 4.83

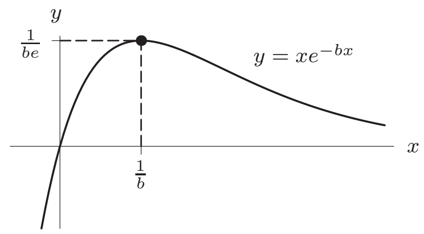

Figure 4.84

20. (a) Let $f(x) = axe^{-bx}$. To find the local maxima and local minima of f, we solve

$$f'(x) = ae^{-bx} - abxe^{-bx} = ae^{-bx}(1 - bx) \begin{cases} = 0 & \text{if } x = 1/b \\ < 0 & \text{if } x > 1/b \\ > 0 & \text{if } x < 1/b. \end{cases}$$

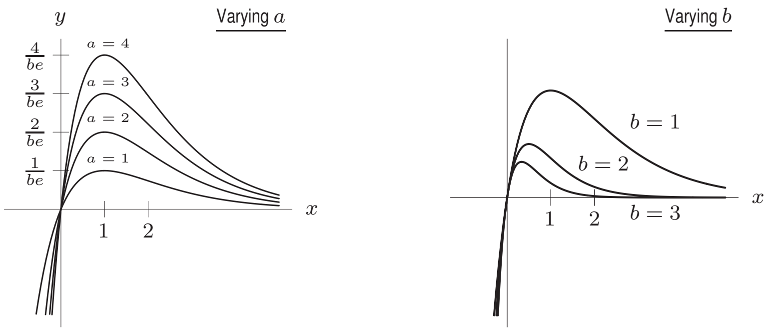
Therefore, f is increasing ($f' > 0$) for $x < 1/b$ and decreasing ($f' > 0$) for $x > 1/b$. A local maximum occurs at $x = 1/b$. There are no local minima. To find the points of inflection, we write

$$
\begin{aligned}
f''(x) &= -abe^{-bx} + ab^2xe^{-bx} - abe^{-bx} \\
&= -2abe^{-bx} + ab^2xe^{-bx} \\
&= ab(bx-2)e^{-bx},
\end{aligned}
$$

so $f'' = 0$ at $x = 2/b$. Therefore, f is concave up for $x < 2/b$ and concave down for $x > 2/b$, and the inflection point is $x = 2/b$.

(b) Varying a stretches or flattens the graph but does not affect the critical point $x = 1/b$ and the inflection point $x = 2/b$. Since the critical and inflection points are depend on b, varying b will change these points, as well as the maximum $f(1/b) = a/be$. For example, an increase in b will shift the critical and inflection points to the left, and also lower the maximum value of f.

(c)



21. Cubic polynomials are all of the form $f(x) = Ax^3 + Bx^2 + Cx + D$. There is an inflection point at the origin $(0, 0)$ if $f''(0) = 0$ and $f(0) = 0$. Since $f(0) = D$, we must have $D = 0$. Since $f''(x) = 6Ax + 2B$, giving $f''(0) = 2B$, we must have $B = 0$. The family of cubic polynomials with inflection point at the origin is the two parameter family $f(x) = Ax^3 + Cx$.

22. (a) Writing $y = L(1 + Ae^{-kt})^{-1}$, we find the first derivative by the chain rule

$$\frac{dy}{dt} = -L(1 + Ae^{-kt})^{-2}(-Ake^{-kt}) = \frac{LAke^{-kt}}{(1 + Ae^{-kt})^2}.$$

Using the quotient rule to calculate the second derivative gives

$$
\begin{aligned}
\frac{d^2y}{dt^2} &= \frac{\left(-LAk^2e^{-kt}(1 + Ae^{-kt})^2 - 2LAke^{-kt}(1 + Ae^{-kt})(-Ake^{-kt})\right)}{(1 + Ae^{-kt})^4} \\
&= \frac{LAk^2e^{-kt}(-1 + Ae^{-kt})}{(1 + Ae^{-kt})^3}.
\end{aligned}
$$

(b) Since $L, A > 0$ and $e^{-kt} > 0$ for all t, the factor LAk^2e^{-kt} and the denominator are never zero. Thus, possible inflection points occur where

$$-1 + Ae^{-kt} = 0.$$

Solving for t gives

$$t = \frac{\ln A}{k}.$$

(c) The second derivative is positive to the left of $t = \ln(A)/k$ and negative to the right, so the function changes from concave up to concave down at $t = \ln(A)/k$.

23. (a) See Figure 4.85.

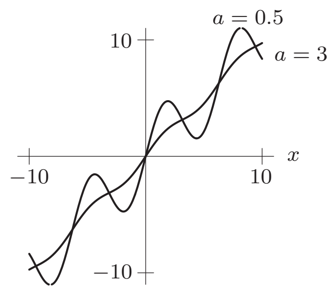


Figure 4.85

(b) The function $f(x) = x + a \sin x$ is increasing for all x if $f'(x) > 0$ for all x. We have $f'(x) = 1 + a \cos x$. Because $\cos x$ varies between -1 and 1, we have $1 + a \cos x > 0$ for all x if $-1 < a < 1$ but not otherwise. When $a = 1$, the function $f(x) = x + \sin x$ is increasing for all x, as is $f(x) = x - \sin x$, obtained when $a = -1$. Thus $f(x)$ is increasing for all x if $-1 \le a \le 1$.

24. (a) See Figure 4.86.

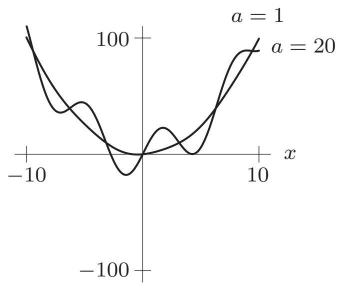

Figure 4.86

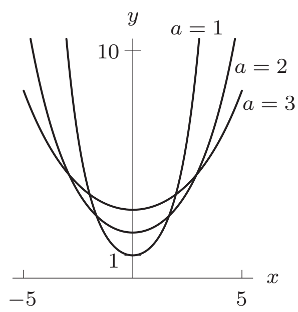
(b) The function $f(x) = x^2 + a \sin x$ is concave up for all x if $f''(x) > 0$ for all x. We have $f''(x) = 2 - a \sin x$. Because $\sin x$ varies between -1 and 1, we have $2 - a \sin x > 0$ for all x if $-2 < a < 2$ but not otherwise. Thus $f(x)$ is concave up for all x if $-2 < a < 2$.

25. For $-5 \le x \le 5$, we have the graphs of $y = a \cosh(x/a)$ shown below.



Increasing the value of a makes the graph flatten out and raises the minimum value. The minimum value of y occurs at $x = 0$ and is given by

$$y = a \cosh\left(\frac{0}{a}\right) = a\left(\frac{e^{0/a} + e^{-0/a}}{2}\right) = a.$$

26. Graphs of $y = e^{-ax}\sin(bx)$ for $b = 1$ and various values of a are shown in Figure 4.87. The parameter a controls the amplitude of the oscillations.

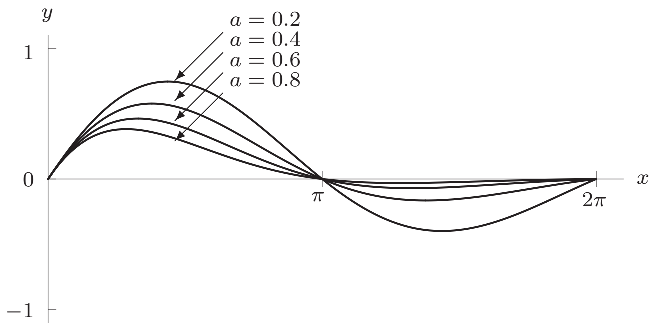


Figure 4.87

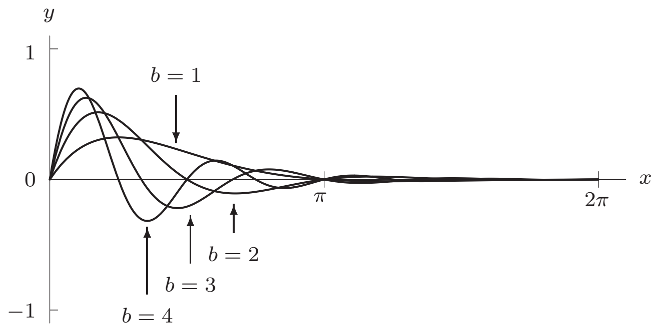
27.



The larger the value of b, the narrower the humps and more humps per given region there are in the graph.

28. Since $f'(x) = abe^{-bx}$, we have $f'(x) > 0$ for all x. Therefore, f is increasing for all x. Since $f''(x) = -ab^2e^{-bx}$, we have $f''(x) < 0$ for all x. Therefore, f is concave down for all x.

29. (a) The critical point will occur where $f'(x) = 0$. But by the product rule,

$$\begin{aligned} f'(x) = be^{1+bx} + b^2xe^{1+bx} &= 0 \\ be^{1+bx}(1+bx) &= 0 \\ 1 + bx &= 0 \\ x &= -\frac{1}{b}. \end{aligned}$$

Thus the critical point of f is located at $x = -\frac{1}{b}$.

(b) To determine whether this critical point is a local minimum or local maximum, we can use the first derivative test. Since both b and e^{1+bx} are positive for all x, the sign of $f'(x) = be^{1+bx}(1 + bx)$ depends on the sign of $1 + bx$.

$$\begin{aligned} &\text{for } x < -\tfrac{1}{b}, \quad f'(x) \text{ is negative} \\ &\text{for } x = \tfrac{1}{b}, \quad f'(x) = 0 \\ &\text{for } x > -\tfrac{1}{b}, \quad f'(x) \text{ is positive} \end{aligned}$$

Therefore, f goes from decreasing to increasing at $x = -\frac{1}{b}$, making this point a local minimum.

(c) We only need to substitute the critical point $x = -\frac{1}{b}$ into the original function f:

$$\begin{aligned} f\left(-\frac{1}{b}\right) &= b\left(-\frac{1}{b}\right)e^{1+b\left(-\frac{1}{b}\right)} \\ &= -1e^{1-1} \\ &= -1. \end{aligned}$$

This answer does not depend on the value of b. Though the x-coordinate of the critical point depends on b, the y-coordinate does not.

30. We study $h'(x) = k - e^{-x}$. Notice that the critical point of h, if it exists, is located where $h'(x) = 0$:

$$\begin{aligned} h'(x) = k - e^{-x} &= 0 \\ e^{-x} &= k \\ -x &= \ln k \\ x &= -\ln k. \end{aligned}$$

(a) Since the domain of the natural logarithm is all positive real numbers, $x = -\ln k$ does not exist (and hence there will be no critical point of h) if $k \leq 0$.
(b) In order for the critical point $x = -\ln k$ to exist, we must have $k > 0$.
(c) There is a horizontal asymptote for h only when $\lim_{x\to-\infty} h(x)$ or $\lim_{x\to+\infty} h(x)$ exists and is finite. But

$$\lim_{x\to-\infty} e^{-x} = +\infty \quad \text{and} \quad \lim_{x\to+\infty} e^{-x} = 0,$$

so

$$\lim_{x\to-\infty} h(x) = +\infty \quad \text{and} \quad \lim_{x\to+\infty} h(x) = \lim_{x\to+\infty} kx.$$

The first limit is never finite and the only way to make the second one finite is to set $k = 0$.

31. The function g will have a critical point when $g'(x) = 0$. Solving this equation gives

$$\begin{aligned} g'(x) = 1 - ke^{x} &= 0 \\ ke^{x} &= 1 \\ e^{x} &= \frac{1}{k} \\ x &= \ln\frac{1}{k} = -\ln k. \end{aligned}$$

Since the natural logarithm has a domain of all positive real numbers, such a value for x may only exist for $k > 0$.

32. Since the horizontal asymptote is $y = 5$, we know $a = 5$. The value of b can be any number. Thus $y = 5(1 - e^{-bx})$ for any $b > 0$.

33. Since the maximum is on the y-axis, $a = 0$. At that point, $y = be^{-0^2/2} = b$, so $b = 3$.

34. The maximum of $y = e^{-(x-a)^2/b}$ occurs at $x = a$. (This is because the exponent $-(x-a)^2/b$ is zero when $x = a$ and negative for all other x-values. The same result can be obtained by taking derivatives.) Thus we know that $a = 2$.

Points of inflection occur where d^2y/dx^2 changes sign, that is, where $d^2y/dx^2 = 0$. Differentiating gives

$$\begin{aligned} \frac{dy}{dx} &= -\frac{2(x-2)}{b}e^{-(x-2)^2/b} \\ \frac{d^2y}{dx^2} &= -\frac{2}{b}e^{-(x-2)^2/b} + \frac{4(x-2)^2}{b^2}e^{-(x-2)^2/b} = \frac{2}{b}e^{-(x-2)^2/b}\left(-1 + \frac{2}{b}(x-2)^2\right). \end{aligned}$$

Since $e^{-(x-2)^2/b}$ is never zero, $d^2y/dx^2 = 0$ where

$$-1 + \frac{2}{b}(x-2)^2 = 0.$$

We know $d^2y/dx^2 = 0$ at $x = 1$, so substituting $x = 1$ gives

$$-1 + \frac{2}{b}(1-2)^2 = 0.$$

Solving for b gives

$$\begin{aligned} -1 + \frac{2}{b} &= 0 \\ b &= 2. \end{aligned}$$

Since $a = 2$, the function is

$$y = e^{-(x-2)^2/2}.$$

You can check that at $x = 2$, we have

$$\frac{d^2y}{dx^2} = \frac{2}{2}e^{-0}(-1+0) < 0$$

so the point $x = 2$ does indeed give a maximum. See Figure 4.88.

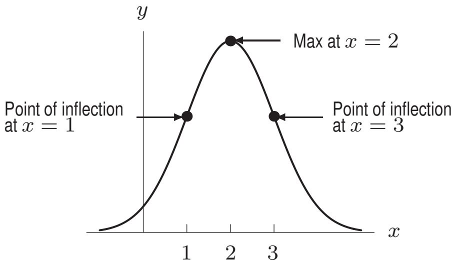


Figure 4.88: Graph of $y = e^{-(x-2)^2/2}$

35. We want a function of the form

$$y = \frac{L}{1 + Ae^{-kt}}.$$

Since the carrying capacity is 12, we have $L = 12$. The y-intercept is 4, so

$$\frac{L}{1+A} = \frac{12}{1+A} = 4$$
$$A = 2.$$

The point of inflection is at $(0.5, 6)$, so

$$0.5 = \frac{\ln(A)}{k} = \frac{\ln(2)}{k}$$
$$k = 1.386.$$

Thus, the function is

$$y = \frac{12}{1 + 2e^{-1.386x}}.$$

36. Since $y(0) = a/(1+b) = 2$, we have $a = 2 + 2b$. To find a point of inflection, we calculate

$$\frac{dy}{dt} = \frac{abe^{-t}}{(1+be^{-t})^2},$$

and using the quotient rule,

$$\frac{d^2y}{dx^2} = \frac{-abe^{-t}(1+be^{-t})^2 - abe^{-t}2(1+be^{-t})(-be^{-t})}{(1+be^{-t})^4}$$
$$= \frac{abe^{-t}(-1+be^{-t})}{(1+be^{-t})^3}.$$

The second derivative is equal to 0 when $be^{-t} = 1$, or $b = e^t$. When $t = 1$, we have $b = e$. The second derivative changes sign at this point, so we have an inflection point. Thus

$$y = \frac{2+2e}{1+e^{1-t}}.$$

37. Since the x^3 term has coefficient 1, the polynomial is of the form

$$y = x^3 + ax^2 + bx + c.$$

Differentiating gives

$$\frac{dy}{dx} = 3x^2 + 2ax + b.$$

There is a critical point at $x = 2$, so $dy/dx = 0$ at $x = 2$. Thus

$$\left.\frac{dy}{dx}\right|_{x=2} = 3(2^2) + 2a(2) + b = 12 + 4a + b = 0, \text{ so } 4a + b = -12.$$

We take the second derivative to look for the inflection point. We find

$$\frac{d^2y}{dx^2} = 6x + 2a,$$

and for an inflection point at $x = 1$, we have $6 + 2a = 0$, so $a = -3$. We now use $a = -3$ and the relationship $4a + b = -12$, which gives $4(-3) + b = -12$, so $b = 0$.

We now have

$$y = x^3 - 3x^2 + c,$$

and using the point (1,4) gives

$$\begin{aligned} 1 - 3 + c &= 4, \\ c &= 6. \end{aligned}$$

Thus, $y = x^3 - 3x^2 + 6$.

38. Since the graph is symmetric about the y-axis, the polynomial must have only even powers. Also, since the y-intercept is 0, the constant term must be zero. Thus, the polynomial is of the form

$$y = ax^4 + bx^2.$$

Differentiating gives

$$\frac{dy}{dx} = 4ax^3 + 2bx = x(4ax^2 + 2b).$$

Thus $dy/dx = 0$ at $x = 0$ and when $4ax^2 + 2b = 0$. Since the maxima occur where $x = \pm 1$, we have $4a + 2b = 0$, so $b = -2a$.

We are given $y = 2$ when $x = \pm 1$, so using $y = ax^4 + bx^2$ gives

$$\begin{aligned} a + b &= 2, \\ a - 2a = -a &= 2, \end{aligned}$$

which gives $a = -2$ and $b = 4$. Thus

$$y = -2x^4 + 4x^2.$$

To see if the points $(1, 2)$ and $(-1, 2)$ are local maxima, we take the second derivative,

$$\frac{d^2y}{dx^2} = -24x^2 + 8,$$

which is negative if $x = \pm 1$. The critical points at $x = \pm 1$ are local maxima. Since the leading coefficient of this polynomial is negative, we know the graph decreases without bound as $|x|$ approaches $\pm\infty$, so these critical points are also global maxima. Note that at $x = 0$ the second derivative is positive, so the point $(0, 0)$ is a local minimum. There is no global minimum.

39. Differentiating gives

$$\frac{dy}{dt} = 2abt\cos(bt^2).$$

Since the first critical point for positive t occurs at $t = 1$, we have $b = \pi/2$. Then at $t = 2$, we have

$$\left.\frac{dy}{dt}\right|_{t=2} = \pi a(2)\cos(2\pi) = 2a\pi = 3,$$

so $a = \dfrac{3}{2\pi}$, and

$$y = \frac{3}{2\pi}\sin\left(\frac{\pi t^2}{2}\right).$$

40. Differentiating gives

$$\frac{dy}{dx} = -2abt\sin(bt^2).$$

Since the first critical point for positive t occurs at $t = 1$, we have $b = \pi$. Then at $t = 1/\sqrt{2}$, we have

$$\left.\frac{dy}{dt}\right|_{t=\frac{1}{\sqrt{2}}} = -\frac{2\pi a}{\sqrt{2}}\sin\left(\frac{\pi}{2}\right) = -\frac{2a\pi}{\sqrt{2}} = -2,$$

so $a = \dfrac{\sqrt{2}}{\pi}$, and

$$y = \frac{\sqrt{2}}{\pi}\cos(\pi t^2).$$

41. Differentiating $y = ae^{-x} + bx$ gives

$$\frac{dy}{dx} = -ae^{-x} + b.$$

Since the global minimum occurs for $x = 1$, we have $-a/e + b = 0$, so $b = a/e$.

The value of the function at $x = 1$ is 2, so we have $2 = a/e + b$, which gives

$$2 = \frac{a}{e} + \frac{a}{e} = \frac{2a}{e},$$

so $a = e$ and $b = 1$. Thus

$$y = e^{1-x} + x.$$

We compute $d^2y/dx^2 = e^{1-x}$, which is always positive, so this confirms that $x = 1$ is a local minimum. Because the value of $e^{1-x} + x$ as $x \to \pm\infty$ grows without bound, this local minimum is a global minimum.

42. Differentiating $y = bxe^{-ax}$ gives

$$\frac{dy}{dx} = be^{-ax} - abxe^{-ax} = be^{-ax}(1 - ax).$$

Since we have a critical point at $x = 3$, we know that $1 - 3a = 0$, so $a = 1/3$.

If $b > 0$, the first derivative goes from positive values to the left of $x = 3$ to negative values on the right of $x = 3$, so we know this critical point is a local maximum. Since the function value at this local maximum is 6, we have

$$6 = 3be^{-3/3} = \frac{3b}{e},$$

so $b = 2e$ and

$$y = 2xe^{1-x/3}.$$

43. Notice that since y is an odd function, choosing a and b so there is a minimum at $(3, 12)$ automatically results in a local maximum at $(-3, -12)$.

Differentiating $y = at + b/t$, we have

$$\frac{dy}{dt} = a - bt^{-2}, \text{ and } \frac{d^2y}{dt^2} = 2bt^{-3}.$$

The critical points require $dy/dt = 0$ at $t = \pm 3$. This gives $a - b/9 = 0$ so $b = 9a$.

Substituting the point $(3, 12)$ in the original equation, we have

$$12 = 3a + 9a/3 = 6a.$$

Thus $a = 2$, and $b = 18$, and

$$y = 2t + 18/t.$$

The second derivative test affirms that $(3, 12)$ is a local minimum, as the second derivative is positive at $t = 3$.

44. We begin by finding the intercepts, which occur where $f(x) = 0$, that is

$$x - k\sqrt{x} = 0$$
$$\sqrt{x}(\sqrt{x} - k) = 0$$

$$\text{so} \quad x = 0 \quad \text{or} \quad \sqrt{x} = k, \quad x = k^2.$$

So 0 and k^2 are the x-intercepts. Now we find the location of the critical points by setting $f'(x)$ equal to 0:

$$f'(x) = 1 - k\left(\frac{1}{2}x^{-(1/2)}\right) = 1 - \frac{k}{2\sqrt{x}} = 0.$$

This means

$$1 = \frac{k}{2\sqrt{x}}, \quad \text{so} \quad \sqrt{x} = \frac{1}{2}k, \quad \text{and} \quad x = \frac{1}{4}k^2.$$

We can use the second derivative to verify that $x = \frac{k^2}{4}$ is a local minimum. $f''(x) = 1 + \frac{k}{4x^{3/2}}$ is positive for all $x > 0$. So the critical point, $x = \frac{1}{4}k^2$, is $1/4$ of the way between the x-intercepts, $x = 0$ and $x = k^2$. Since $f''(x) = \frac{1}{4}kx^{-3/2}$, $f''(\frac{1}{4}k^2) = 2/k^2 > 0$, this critical point is a minimum.

45. (a) The x-intercept occurs where $f(x) = 0$, so

$$\begin{aligned} ax - x\ln x &= 0 \\ x(a - \ln x) &= 0. \end{aligned}$$

Since $x > 0$, we must have

$$\begin{aligned} a - \ln x &= 0 \\ \ln x &= a \\ x &= e^a. \end{aligned}$$

(b) See Figures 4.89 and 4.90.

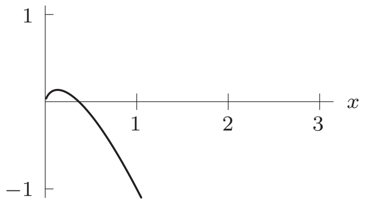

Figure 4.89: Graph of $f(x)$ with $a = -1$

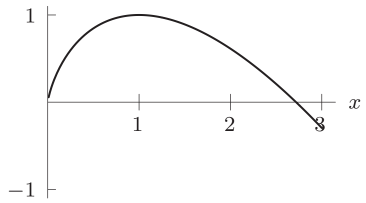

Figure 4.90: Graph of $f(x)$ with $a = 1$

(c) Differentiating gives $f'(x) = a - \ln x - 1$. Critical points are obtained by solving

$$\begin{aligned} a - \ln x - 1 &= 0 \\ \ln x &= a - 1 \\ x &= e^{a-1}. \end{aligned}$$

Since $e^{a-1} > 0$ for all a, there is no restriction on a. Now,

$$f(e^{a-1}) = ae^{a-1} - e^{a-1}\ln(e^{a-1}) = ae^{a-1} - (a-1)e^{a-1} = e^{a-1},$$

so the coordinates of the critical point are (e^{a-1}, e^{a-1}). From the graphs, we see that this critical point is a local maximum; this can be confirmed using the second derivative:

$$f''(x) = -\frac{1}{x} < 0 \qquad \text{for } x = e^{a-1}.$$

46. (a) Figures 4.91- 4.94 show graphs of $f(x) = x^2 + \cos(kx)$ for various values of k. For $k = 0.5$ and $k = 1$, the graphs look like parabolas. For $k = 3$, there is some waving in the parabola, which becomes more noticeable if $k = 5$. The waving begins to happen at about $k = 1.5$.

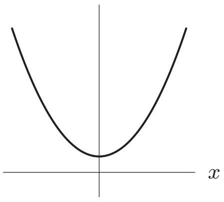

Figure 4.91: $k = 0.5$

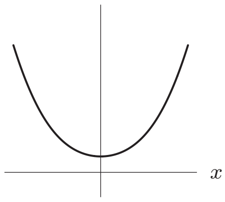

Figure 4.92: $k = 1$

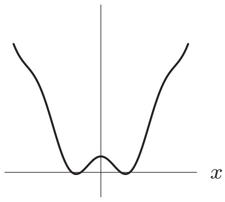

Figure 4.93: $k = 3$

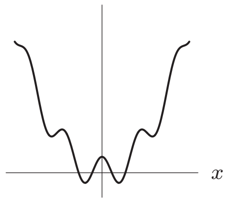

Figure 4.94: $k = 5$

(b) Differentiating, we have

$$f'(x) = 2x - k\sin(kx)$$
$$f''(x) = 2 - k^2\cos(kx).$$

If $k^2 \le 2$, then $f''(x) \ge 2 - 2\cos(kx) \ge 0$, since $\cos(kx) \le 1$. Thus, the graph is always concave up if $k \le \sqrt{2}$. If $k^2 > 2$, then $f''(x)$ changes sign whenever $\cos(kx) = 2/k^2$, which occurs for infinitely many values of x, since $0 < 2/k^2 < 1$.

(c) Since $f'(x) = 2x - k\sin(kx)$, we want to find all points where

$$2x - k\sin(kx) = 0.$$

Since

$$-1 \le \sin(kx) \le 1,$$

$f'(x) \ne 0$ if $x > k/2$ or $x < -k/2$. Thus, all the roots of $f'(x)$ must be in the interval $-k/2 \le x \le k/2$. The roots occur where the line $y = 2x$ intersects the curve $y = k\sin(kx)$, and there are only a finite number of such points for $-k/2 \le x \le k/2$.

47. (a) Figure 4.95 suggests that each graph decreases to a local minimum and then increases sharply. The local minimum appears to move to the right as k increases. It appears to move up until $k = 1$, and then to move back down.

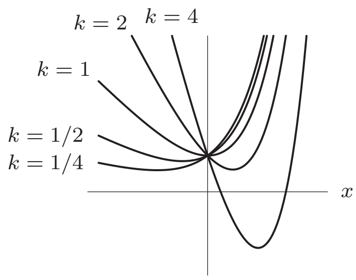

Figure 4.95

(b) $f'(x) = e^x - k = 0$ when $x = \ln k$. Since $f'(x) < 0$ for $x < \ln k$ and $f'(x) > 0$ for $x > \ln k$, f is decreasing to the left of $x = \ln k$ and increasing to the right, so f reaches a local minimum at $x = \ln k$.

(c) The minimum value of f is

$$f(\ln k) = e^{\ln k} - k(\ln k) = k - k\ln k.$$

Since we want to maximize the expression $k - k\ln k$, we can imagine a function $g(k) = k - k\ln k$. To maximize this function we simply take its derivative and find the critical points. Differentiating, we obtain

$$g'(k) = 1 - \ln k - k(1/k) = -\ln k.$$

Thus $g'(k) = 0$ when $k = 1$, $g'(k) > 0$ for $k < 1$, and $g'(k) < 0$ for $k > 1$. Thus $k = 1$ is a local maximum for $g(k)$. That is, the largest global minimum for f occurs when $k = 1$.

48. (a) The graph of r has a vertical asymptote if the denominator is zero. Since $(x-b)^2$ is nonnegative, the denominator can only be zero if $a \le 0$. Then

$$a + (x-b)^2 = 0$$
$$(x-b)^2 = -a$$
$$x - b = \pm\sqrt{-a}$$
$$x = b \pm \sqrt{-a}.$$

In order for there to be a vertical asymptote, a must be less than or equal to zero. There are no restrictions on b.

(b) Differentiating gives

$$r'(x) = \frac{-1}{(a+(x-b)^2)^2} \cdot 2(x-b),$$

so $r' = 0$ when $x = b$. If $a \le 0$, then r' is undefined at the same points at which r is undefined. Thus the only critical point is $x = b$. Since we want $r(x)$ to have a maximum at $x = 3$, we choose $b = 3$. Also, since $r(3) = 5$, we have

$$r(3) = \frac{1}{a + (3-3)^2} = \frac{1}{a} = 5 \qquad \text{so} \qquad a = \frac{1}{5}.$$

49. (a) $f'(x) = 4x^3 + 2ax = 2x(2x^2 + a)$; so $x = 0$ and $x = \pm\sqrt{-a/2}$ (if $\pm\sqrt{-a/2}$ is real, i.e. if $-a/2 \geq 0$) are critical points.

(b) $x = 0$ is a critical point for any value of a. In order to guarantee that $x = 0$ is the only critical point, the factor $2x^2 + a$ should not have a root other than possibly $x = 0$. This means $a \geq 0$, since $2x^2 + a$ has only one root ($x = 0$) for $a = 0$, and no roots for $a > 0$. There is no restriction on the constant b.

Now $f''(x) = 12x^2 + 2a$ and $f''(0) = 2a$.

If $a > 0$, then by the second derivative test, $f(0)$ is a local minimum.

If $a = 0$, then $f(x) = x^4 + b$, which has a local minimum at $x = 0$.

So $x = 0$ is a local minimum when $a \geq 0$.

(c) Again, b will have no effect on the location of the critical points. In order for $f'(x) = 2x(2x^2 + a)$ to have three different roots, the constant a has to be negative. Let $a = -2c^2$, for some $c > 0$. Then

$f'(x) = 4x(x^2 - c^2) = 4x(x - c)(x + c)$.

The critical points of f are $x = 0$ and $x = \pm c = \pm\sqrt{-a/2}$.

To the left of $x = -c$, $f'(x) < 0$.

Between $x = -c$ and $x = 0$, $f'(x) > 0$.

Between $x = 0$ and $x = c$, $f'(x) < 0$.

To the right of $x = c$, $f'(x) > 0$.

So, $f(-c)$ and $f(c)$ are local minima and $f(0)$ is a local maximum.

(d) For $a \geq 0$, there is exactly one critical point, $x = 0$. For $a < 0$ there are exactly three different critical points. These exhaust all the possibilities. (Notice that the value of b is irrelevant here.)

50. (a) The graphs are shown in Figures 4.96–4.101.

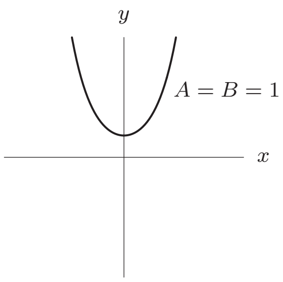

Figure 4.96: $A > 0, B > 0$

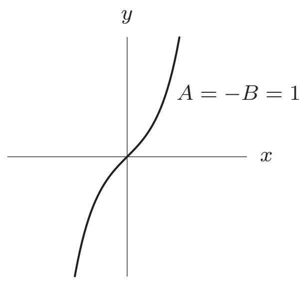

Figure 4.97: $A > 0, B < 0$

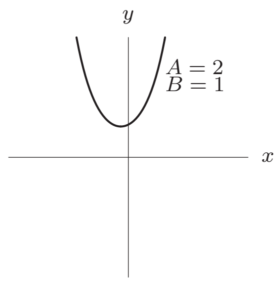

Figure 4.98: $A > 0, B > 0$

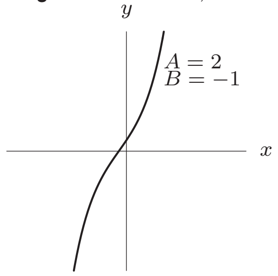

Figure 4.99: $A > 0, B < 0$

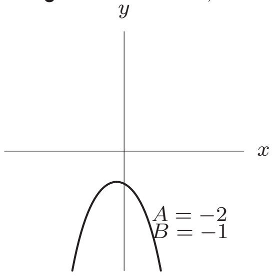

Figure 4.100: $A < 0, B < 0$

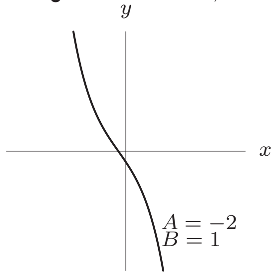

Figure 4.101: $A < 0, B > 0$

(b) If A and B have the same sign, the graph is U-shaped. If A and B are both positive, the graph opens upward. If A and B are both negative, the graph opens downward.

(c) If A and B have different signs, the graph appears to be everywhere increasing (if $A > 0, B < 0$) or decreasing (if $A < 0, B > 0$).

(d) The function appears to have a local maximum if $A < 0$ and $B < 0$, and a local minimum if $A > 0$ and $B > 0$.

To justify this, calculate the derivative

$$\frac{dy}{dx} = Ae^x - Be^{-x}.$$

Setting $dy/dx = 0$ gives

$$Ae^x - Be^{-x} = 0$$

$$\begin{aligned} Ae^x &= Be^{-x} \\ e^{2x} &= \frac{B}{A}. \end{aligned}$$

This equation has a solution only if B/A is positive, that is, if A and B have the same sign. In that case,

$$\begin{aligned} 2x &= \ln\left(\frac{B}{A}\right) \\ x &= \frac{1}{2}\ln\left(\frac{B}{A}\right). \end{aligned}$$

This value of x gives the only critical point.

To determine whether the critical point is a local maximum or minimum, we use the first derivative test. Since

$$\frac{dy}{dx} = Ae^x - Be^{-x},$$

we see that:

If $A > 0, B > 0$, we have $dy/dx > 0$ for large positive x and $dy/dx < 0$ for large negative x, so there is a local minimum.

If $A < 0, B < 0$, we have $dy/dx < 0$ for large positive x and $dy/dx > 0$ for large negative x, so there is a local maximum.

51. $T(t) =$ the temperature at time $t = a(1 - e^{-kt}) + b$.

(a) Since at time $t = 0$ the yam is at 20°C, we have

$$T(0) = 20^\circ = a\left(1 - e^0\right) + b = a(1-1) + b = b.$$

Thus $b = 20^\circ$C. Now, common sense tells us that after a period of time, the yam will heat up to about 200°, or oven temperature. Thus the temperature T should approach 200° as the time t grows large:

$$\lim_{t\to\infty} T(t) = 200^\circ\text{C} = a(1-0) + b = a + b.$$

Since $a + b = 200^\circ$, and $b = 20^\circ$C, this means $a = 180^\circ$C.

(b) Since we're talking about how quickly the yam is heating up, we need to look at the derivative, $T'(t) = ake^{-kt}$:

$$T'(t) = (180)ke^{-kt}.$$

We know $T'(0) = 2^\circ$C/min, so

$$2 = (180)ke^{-k(0)} = (180)(k).$$

So $k = (2^\circ\text{C/min})/180^\circ\text{C} = \frac{1}{90}\,\text{min}^{-1}$.

52. (a) Since

$$U = b\left(\frac{a^2 - ax}{x^2}\right) = 0 \quad \text{when} \quad x = a,$$

the x-intercept is $x = a$. There is a vertical asymptote at $x = 0$ and a horizontal asymptote at $U = 0$.

(b) Setting $dU/dx = 0$, we have

$$\frac{dU}{dx} = b\left(-\frac{2a^2}{x^3} + \frac{a}{x^2}\right) = b\left(\frac{-2a^2 + ax}{x^3}\right) = 0.$$

So the critical point is

$$x = 2a.$$

When $x = 2a$,

$$U = b\left(\frac{a^2}{4a^2} - \frac{a}{2a}\right) = -\frac{b}{4}.$$

The second derivative of U is

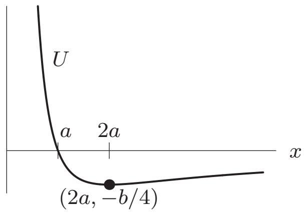
$$\frac{d^2U}{dx^2} = b\left(\frac{6a^2}{x^4} - \frac{2a}{x^3}\right).$$

When we evaluate this at $x = 2a$, we get

$$\frac{d^2U}{dx^2} = b\left(\frac{6a^2}{(2a)^4} - \frac{2a}{(2a)^3}\right) = \frac{b}{8a^2} > 0.$$

Since $d^2U/dx^2 > 0$ at $x = 2a$, we see that the point $(2a, -b/4)$ is a local minimum.

(c)



53. Both U and F have asymptotes at $x = 0$ and the x-axis. In Problem 52 we saw that U has intercept $(a, 0)$ and local minimum $(2a, -b/4)$. Differentiating U gives

$$F = b\left(\frac{2a^2}{x^3} - \frac{a}{x^2}\right).$$

Since

$$F = b\left(\frac{2a^2 - ax}{x^3}\right) = 0 \quad \text{for} \quad x = 2a,$$

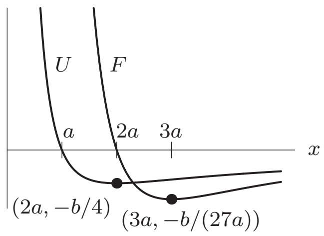
F has one intercept: $(2a, 0)$. Differentiating again to find the critical points:

$$\frac{dF}{dx} = b\left(-\frac{6a^2}{x^4} + \frac{2a}{x^3}\right) = b\left(\frac{-6a^2 + 2ax}{x^4}\right) = 0,$$

so $x = 3a$. When $x = 3a$,

$$F = b\left(\frac{2a^2}{27a^3} - \frac{a}{9a^2}\right) = -\frac{b}{27a}.$$

By the first or second derivative test, $x = 3a$ is a local minimum of F. See figure below.



54. (a) To find $\lim_{r\to 0^+} V(r)$, first rewrite $V(r)$ with a common denominator:

$$\begin{aligned}\lim_{r\to 0^+} V(r) &= \lim_{r\to 0^+} \frac{A}{r^{12}} - \frac{B}{r^6} \\ &= \lim_{r\to 0^+} \frac{A - Br^6}{r^{12}} \\ &\to \frac{A}{0^+} \to +\infty.\end{aligned}$$

As the distance between the two atoms becomes small, the potential energy diverges to $+\infty$.

(b) The critical point of $V(r)$ will occur where $V'(r) = 0$:

$$\begin{aligned}V'(r) = -\frac{12A}{r^{13}} + \frac{6B}{r^7} &= 0 \\ \frac{-12A + 6Br^6}{r^{13}} &= 0 \\ -12A + 6Br^6 &= 0 \\ r^6 &= \frac{2A}{B} \\ r &= \left(\frac{2A}{B}\right)^{1/6}\end{aligned}$$

To determine whether this is a local maximum or minimum, i we can use the first derivative test. Since r is positive, the sign of $V'(r)$ is determined by the sign of $-12A+6Br^6$. Notice that this is an increasing function of r for $r > 0$, so $V'(r)$ changes sign from $-$ to $+$ at $r = (2A/B)^{1/6}$. The first derivative test yields

r	$\leftarrow$	$\left(\frac{2A}{B}\right)^{1/6}$	$\rightarrow$
$V'(r)$	neg.	zero	pos.

Thus $V(r)$ goes from decreasing to increasing at the critical point $r = (2A/B)^{1/6}$, so this is a local minimum.

(c) Since $F(r) = -V'(r)$, the force is zero exactly where $V'(r) = 0$, i.e. at the critical points of V. The only critical point was the one found in part (b), so the only such point is $r = (2A/B)^{1/6}$.

(d) Since the numerator in $r = (2A/B)^{1/6}$ is proportional to $A^{1/6}$, the equilibrium size of the molecule increases when the parameter A is increased. Conversely, since B is in the denominator, when B is increased the equilibrium size of the molecules decrease.

55. (a) The force is zero where

$$\begin{aligned} f(r) = -\frac{A}{r^2} + \frac{B}{r^3} &= 0 \\ Ar^3 &= Br^2 \\ r &= \frac{B}{A}. \end{aligned}$$

The vertical asymptote is $r = 0$ and the horizontal asymptote is the r-axis.

(b) To find critical points, we differentiate and set $f'(r) = 0$:

$$\begin{aligned} f'(r) &= \frac{2A}{r^3} - \frac{3B}{r^4} = 0 \\ 2Ar^4 &= 3Br^3 \\ r &= \frac{3B}{2A}. \end{aligned}$$

Thus, $r = 3B/(2A)$ is the only critical point. Since $f'(r) < 0$ for $r < 3B/(2A)$ and $f'(r) > 0$ for $r > 3B/(2A)$, we see that $r = 3B/(2A)$ is a local minimum. At that point,

$$f\left(\frac{3B}{2A}\right) = -\frac{A}{9B^2/4A^2} + \frac{B}{27B^3/8A^3} = -\frac{4A^3}{27B^2}.$$

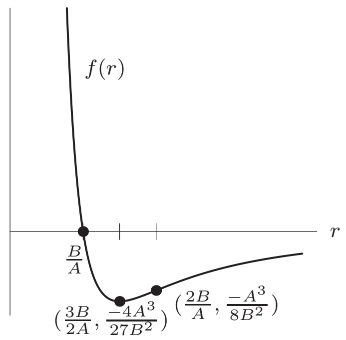
Differentiating again, we have

$$f''(r) = -\frac{6A}{r^4} + \frac{12B}{r^5} = -\frac{6}{r^5}(Ar - 2B).$$

So $f''(r) < 0$ where $r > 2B/A$ and $f''(r) > 0$ when $r < 2B/A$. Thus, $r = 2B/A$ is the only point of inflection. At that point

$$f\left(\frac{2B}{A}\right) = -\frac{A}{4B^2/A^2} + \frac{B}{8B^3/A^3} = -\frac{A^3}{8B^2}.$$

(c)



(d) (i) Increasing B means that the r-values of the zero, the minimum, and the inflection point increase, while the $f(r)$ values of the minimum and the point of inflection decrease in magnitude. See Figure 4.102.

(ii) Increasing A means that the r-values of the zero, the minimum, and the point of inflection decrease, while the $f(r)$ values of the minimum and the point of inflection increase in magnitude. See Figure 4.103.

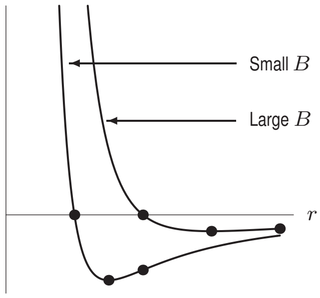


Figure 4.102: Increasing B

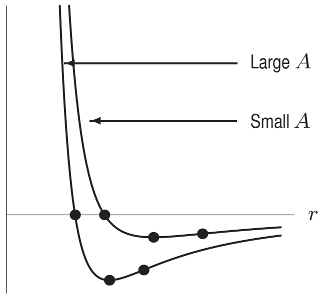

Figure 4.103: Increasing A

56. (a) The vertical intercept is $W = Ae^{-e^{b-c\cdot 0}} = Ae^{-e^b}$. There is no horizontal intercept since the exponential function is always positive. There is a horizontal asymptote. As $t \to \infty$, we see that $e^{b-ct} = e^b/e^{ct} \to 0$, since t is positive. Therefore $W \to Ae^0 = A$, so there is a horizontal asymptote at $W = A$.

(b) The derivative is

$$\frac{dW}{dt} = Ae^{-e^{b-ct}}(-e^{b-ct})(-c) = Ace^{-e^{b-ct}}e^{b-ct}.$$

Thus, dW/dt is always positive, so W is always increasing and has no critical points. The second derivative is

$$\begin{aligned}\frac{d^2W}{dt^2} &= \frac{d}{dt}(Ace^{-e^{b-ct}})e^{b-ct} + Ace^{-e^{b-ct}}\frac{d}{dt}(e^{b-ct}) \\ &= Ac^2e^{-e^{b-ct}}e^{b-ct}e^{b-ct} + Ace^{-e^{b-ct}}(-c)e^{b-ct} \\ &= Ac^2e^{-e^{b-ct}}e^{b-ct}(e^{b-ct} - 1).\end{aligned}$$

Now e^{b-ct} decreases from $e^b > 1$ when $t = 0$ toward 0 as $t \to \infty$. The second derivative changes sign from positive to negative when $e^{b-ct} = 1$, i.e., when $b - ct = 0$, or $t = b/c$. Thus the curve has an inflection point at $t = b/c$, where $W = Ae^{-e^{b-(b/c)c}} = Ae^{-1}$.

(c) See Figure 4.104.

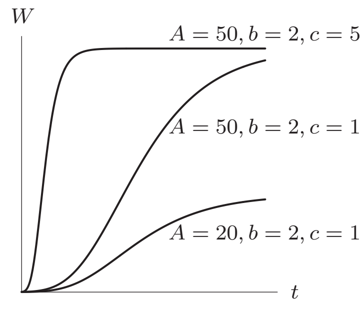

Figure 4.104

(d) The final size of the organism is given by the horizontal asymptote $W = A$. The curve is steepest at its inflection point, which occurs at $t = b/c$, $W = Ae^{-1}$. Since $e = 2.71828\ldots \approx 3$, the size the organism when it is growing fastest is about $A/3$, one third its final size. So yes, the Gompertz growth function is useful in modeling such growth.

Strengthen Your Understanding

57. As a counterexample, $f(x) = x^2 + 1$ has no zeros.

58. Differentiating f we see that $f'(x) = -a/x^2 + b$. Solving $f'(x) = 0$ we see that $x = \pm\sqrt{a/b}$ are critical points provided a and b have the same sign. So for example, $f(x) = 1/x + x$ has two critical points. But if a and b have opposite sign, f has no critical points. The function $f(x) = 1/x - x$ has no critical points, for example.

59. The family of functions $f(x) = kx(x - b)$ are all quadratics and satisfy $f(0) = f(b) = 0$, as required.

60. The condition for critical points is $f'(x) = 3ax^2 - b = 0$ or

$$x^2 = \frac{b}{3a}.$$

So there will be no critical points if

$$\frac{b}{3a} < 0.$$

As long as a and b have opposite signs, we have $b/(3a) < 0$. For example, we can take $a = 1, b = -1$ to get $f(x) = x^3 + x$.

61. Let $f(x) = ax^2$, with $a \neq 0$. Then $f'(x) = 2ax$, so f has a critical point only at $x = 0$.

62. Let $g(x) = ax^3 + bx^2$, where neither a nor b are allowed to be zero. Then

$$g'(x) = 3ax^2 + 2bx = x(3ax + 2b).$$

Then $g(x)$ has two distinct critical points, at $x = 0$ and at $x = -2b/3a$. Since

$$g''(x) = 6ax + 2b,$$

there is exactly one point of inflection, $x = -2b/6a = -b/3a$.

63. (a) and (c). Since the critical points of $f(x)$ are $x = \pm\sqrt{b/a}$, then as b increases $\left|\pm\sqrt{b/a}\right|$ increases. Therefore (a). The critical values of $f(x)$ are $f(\pm\sqrt{b/a}) = a(\pm\sqrt{b/a}) + \dfrac{b}{\pm\sqrt{b/a}} = \pm\sqrt{ab} \pm \sqrt{ab} = \pm 2\sqrt{ab}$. Therefore (c) is also true.

64. (b) and (c). Since the critical points of $f(x)$ are $x = \pm\sqrt{b/a}$, then as a increases $\left|\pm\sqrt{b/a}\right|$ decreases. Therefore (b). The critical values of $f(x)$ are $f(\pm\sqrt{b/a}) = a(\pm\sqrt{b/a}) + \dfrac{b}{\pm\sqrt{b/a}} = \pm\sqrt{ab} \pm \sqrt{ab} = \pm 2\sqrt{ab}$. Therefore (c) is also true.

Solutions for Section 4.5

Exercises

1. The profit function is positive when $R(q) > C(q)$, and negative when $C(q) > R(q)$. It's positive for $5.5 < q < 12.5$, and negative for $0 < q < 5.5$ and $12.5 < q$. Profit is maximized when $R(q) > C(q)$ and $R'(q) = C'(q)$ which occurs at about $q = 9.5$. See Figure 4.105.

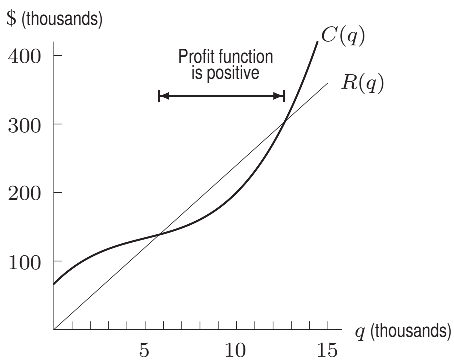

Figure 4.105

2. Since fixed costs are represented by the vertical intercept, they are $\$1.1$ million. The quantity that maximizes profit is about $q = 70$, and the profit achieved is $\$(3.7 - 2.5) = \$1.2$ million

3. The fixed costs are $\$5000$, the marginal cost per item is $\$2.40$, and the price per item is $\$4$.

4. The cost function $C(q) = b + mq$ satisfies $C(0) = 500$, so $b = 500$, and $MC = m = 6$. So

$$C(q) = 500 + 6q.$$

The revenue function is $R(q) = 12q$, so the profit function is

$$\pi(q) = R(q) - C(q) = 12q - 500 - 6q = 6q - 500.$$

5. The cost function $C(q) = b + mq$ satisfies $C(0) = 35{,}000$, so $b = 35{,}000$, and $MC = m = 10$. So

$$C(q) = 35{,}000 + 10q.$$

The revenue function is $R(q) = 15q$, so the profit function is

$$\pi(q) = R(q) - C(q) = 15q - 35{,}000 - 10q = 5q - 35{,}000.$$

6. The cost function $C(q) = b + mq$ satisfies $C(0) = 5000$, so $b = 5000$, and $MC = m = 15$. So

$$C(q) = 5000 + 15q.$$

The revenue function is $R(q) = 60q$, so the profit function is

$$\pi(q) = R(q) - C(q) = 60q - 5000 - 15q = 45q - 5000.$$

7. The cost function $C(q) = b + mq$ satisfies $C(0) = 0$, so $b = 0$. There are 32 ounces in a quart, so 160 in 5 quarts, or 20 cups at 8 ounces per cup. Thus each cup costs the operator 20 cents $= 0.20$ dollars, so $MC = m = 0.20$. So

$$C(q) = 0.20q.$$

The revenue function is $R(q) = 0.25q$. So the profit function is

$$\pi(q) = R(q) - C(q) = 0.25q - 0.20q = 0.05q.$$

8. The profit $\pi(q)$ is given by

$$\pi(q) = R(q) - C(q) = 500q - q^2 - (150 + 10q) = 490q - q^2 - 150.$$

The maximum profit occurs when

$$\pi'(q) = 490 - 2q = 0 \quad \text{so} \quad q = 245 \text{ items}.$$

Since $\pi''(q) = -2$, this critical point is a maximum. Alternatively, we obtain the same result from the fact that the graph of π is a parabola opening downward.

9. First find marginal revenue and marginal cost.

$$MR = R'(q) = 450$$

$$MC = C'(q) = 6q$$

Setting $MR = MC$ yields $6q = 450$, so marginal cost is equal to marginal revenue when

$$q = \frac{450}{6} = 75 \text{ units}.$$

Is profit maximized at $q = 75$? Profit $= R(q) - C(q)$;

$$\begin{aligned} R(75) - C(75) &= 450(75) - (10{,}000 + 3(75)^2) \\ &= 33{,}750 - 26{,}875 = \$6875. \end{aligned}$$

Testing $q = 74$ and $q = 76$:

$$\begin{aligned} R(74) - C(74) &= 450(74) - (10{,}000 + 3(74)^2) \\ &= 33{,}300 - 26{,}428 = \$6872. \end{aligned}$$

$$\begin{aligned} R(76) - C(76) &= 450(76) - (10{,}000 + 3(76)^2) \\ &= 34{,}200 - 27{,}328 = \$6872. \end{aligned}$$

Since profit at $q = 75$ is more than profit at $q = 74$ and $q = 76$, we conclude that profit is maximized locally at $q = 75$. The only endpoint we need to check is $q = 0$.

$$\begin{aligned} R(0) - C(0) &= 450(0) - (10{,}000 + 3(0)^2) \\ &= -\$10{,}000. \end{aligned}$$

This is clearly not a maximum, so we conclude that the profit is maximized globally at $q = 75$, and the total profit at this production level is \$6,875.

10. The marginal revenue, MR, is given by differentiating the total revenue function, R. We use the chain rule so

$$MR = \frac{dR}{dq} = \frac{1}{1 + 1000q^2} \cdot \frac{d}{dq}\left(1000q^2\right) = \frac{1}{1 + 1000q^2} \cdot 2000q.$$

When $q = 10$,

$$\text{Marginal revenue } = \frac{2000 \cdot 10}{1 + 1000 \cdot 10^2} = \$0.20\text{/item}.$$

When 10 items are produced, each additional item produced gives approximately \$0.20 in additional revenue.

11. (a) Profit is maximized when $R(q) - C(q)$ is as large as possible. This occurs at $q = 2500$, where profit $= 7500 - 5500 =$ \$2000.
(b) We see that $R(q) = 3q$ and so the price is $p = 3$, or \$3 per unit.
(c) Since $C(0) = 3000$, the fixed costs are \$3000.

12. (a) At $q = 5000$, $MR > MC$, so the marginal revenue to produce the next item is greater than the marginal cost. This means that the company will make money by producing additional units, and production should be increased.
(b) Profit is maximized where $MR = MC$, and where the profit function is going from increasing ($MR > MC$) to decreasing ($MR < MC$). This occurs at $q = 8000$.

Problems

13. (a) The value of $C(0)$ represents the fixed costs before production, that is, the cost of producing zero units, incurred for initial investments in equipment, and so on.
(b) The marginal cost decreases slowly, and then increases as quantity produced increases. See Problem 74, graph (b).
(c) Concave down implies decreasing marginal cost, while concave up implies increasing marginal cost.
(d) An inflection point of the cost function is (locally) the point of maximum or minimum marginal cost.
(e) One would think that the more of an item you produce, the less it would cost to produce extra items. In economic terms, one would expect the marginal cost of production to decrease, so we would expect the cost curve to be concave down. In practice, though, it eventually becomes more expensive to produce more items, because workers and resources may become scarce as you increase production. Hence after a certain point, the marginal cost may rise again. This happens in oil production, for example.

14. Since marginal revenue is larger than marginal cost around $q = 2000$, as you produce more of the product your revenue increases faster than your costs, so profit goes up, and maximal profit will occur at a production level above 2000.

15. Since for $q = 500$, we have $MC(500) = C'(500) = 75$ and $MR(500) = R'(500) = 100$, so $MR(500) > MC(500)$. Thus, increasing production from $q = 500$ increases profit.

16. Her marginal cost is at a minimum of \$25 when the quantity sold is 100, which is still below the marginal revenue of \$35. Thus she will continue to make a profit as the quantity increases, although her profit will start to decrease if the marginal cost goes above \$35. So the quantity that maximizes profit is greater than 100.

17. (a) We know that Profit = Revenue − Cost, so differentiating with respect to q gives:

$$\text{Marginal Profit} = \text{Marginal Revenue} - \text{Marginal Cost}.$$

We see from the figure in the problem that just to the left of $q = a$, marginal revenue is less than marginal cost, so marginal profit is negative there. To the right of $q = a$ marginal revenue is greater than marginal cost, so marginal profit is positive there. At $q = a$ marginal profit changes from negative to positive. This means that profit is decreasing to the left of a and increasing to the right. The point $q = a$ corresponds to a local minimum of profit, and does not maximize profit. It would be a terrible idea for the company to set its production level at $q = a$.

(b) We see from the figure in the problem that just to the left of $q = b$ marginal revenue is greater than marginal cost, so marginal profit is positive there. Just to the right of $q = b$ marginal revenue is less than marginal cost, so marginal profit is negative there. At $q = b$ marginal profit changes from positive to negative. This means that profit is increasing to the left of b and decreasing to the right. The point $q = b$ corresponds to a local maximum of profit. In fact, since the area between the MC and MR curves in the figure in the text between $q = a$ and $q = b$ is bigger than the area between $q = 0$ and $q = a$, $q = b$ is in fact a global maximum.

18. (a) The fixed cost is 0 because $C(0) = 0$.

(b) Profit, $\pi(q)$, is equal to money from sales, $7q$, minus total cost to produce those items, $C(q)$.

$$\pi = 7q - 0.01q^3 + 0.6q^2 - 13q$$
$$\pi' = -0.03q^2 + 1.2q - 6$$
$$\pi' = 0 \quad \text{if} \quad q = \frac{-1.2 \pm \sqrt{(1.2)^2 - 4(0.03)(6)}}{-0.06} \approx 5.9 \quad \text{or} \quad 34.1.$$

Now $\pi'' = -0.06q + 1.2$, so $\pi''(5.9) > 0$ and $\pi''(34.1) < 0$. This means $q = 5.9$ is a local min and $q = 34.1$ a local max. We now evaluate the endpoint, $\pi(0) = 0$, and the points nearest $q = 34.1$ with integer q-values:

$$\pi(35) = 7(35) - 0.01(35)^3 + 0.6(35)^2 - 13(35) = 245 - 148.75 = 96.25,$$
$$\pi(34) = 7(34) - 0.01(34)^3 + 0.6(34)^2 - 13(34) = 238 - 141.44 = 96.56.$$

So the (global) maximum profit is $\pi(34) = 96.56$. The money from sales is \$238, the cost to produce the items is \$141.44, resulting in a profit of \$96.56.

(c) The money from sales is equal to price×quantity sold. If the price is raised from \$7 by \$$x$ to \$$(7 + x)$, the result is a reduction in sales from 34 items to $(34 - 2x)$ items. So the result of raising the price by \$$x$ is to change the money from sales from $(7)(34)$ to $(7 + x)(34 - 2x)$ dollars. If the production level is fixed at 34, then the production costs are fixed at \$141.44, as found in part (b), and the profit is given by:

$$\pi(x) = (7 + x)(34 - 2x) - 141.44$$

This expression gives the profit as a function of change in price x, rather than as a function of quantity as in part (b). We set the derivative of π with respect to x equal to zero to find the change in price that maximizes the profit:

$$\frac{d\pi}{dx} = (1)(34 - 2x) + (7 + x)(-2) = 20 - 4x = 0$$

So $x = 5$, and this must give a maximum for $\pi(x)$ since the graph of π is a parabola which opens downward. The profit when the price is \$12 $(= 7 + x = 7 + 5)$ is thus $\pi(5) = (7 + 5)(34 - 2(5)) - 141.44 = \$146.56$. This is indeed higher than the profit when the price is \$7, so the smart thing to do is to raise the price by \$5.

19. For each month,

$$\text{Profit} = \text{Revenue} - \text{Cost}$$
$$\pi = pq - wL = pcK^{\alpha}L^{\beta} - wL$$

The variable on the right is L, so at the maximum

$$\frac{d\pi}{dL} = \beta pcK^{\alpha}L^{\beta-1} - w = 0$$

Now $\beta - 1$ is negative, since $0 < \beta < 1$, so $1 - \beta$ is positive and we can write

$$\frac{\beta pcK^{\alpha}}{L^{1-\beta}} = w$$

giving

$$L = \left(\frac{\beta pcK^{\alpha}}{w}\right)^{\frac{1}{1-\beta}}$$

Since $\beta - 1$ is negative, when L is just above 0, the quantity $L^{\beta-1}$ is huge and positive, so $d\pi/dL > 0$. When L is large, $L^{\beta-1}$ is small, so $d\pi/dL < 0$. Thus the value of L we have found gives a global maximum, since it is the only critical point.

20. (a) We have $N(x) = 100 + 20x$, graphed in Figure 4.106.

(b) (i) Differentiating gives $N'(x) = 20$ and the graph of N' is a horizontal line. This means that rate of increase of the number of bees with acres of clover is constant—each acre of clover brings 20 more bees.

(ii) On the other hand, $N(x)/x = 100/x + 20$ means that the average number of bees per acre of clover approaches 20 as more acres are put under clover. See Figure 4.107. As x increases, $100/x$ decreases to 0, so $N(x)/x$ approaches 20 (i.e. $N(x)/x \to 20$). Since the total number of bees is 20 per acre plus the original 100, the average number of bees per acre is 20 plus the 100 shared out over x acres. As x increases, the 100 are shared out over more acres, and so its contribution to the average becomes less. Thus the average number of bees per acre approaches 20 for large x.

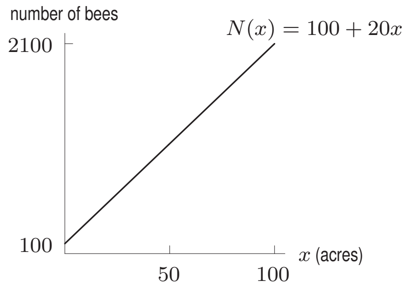

Figure 4.106

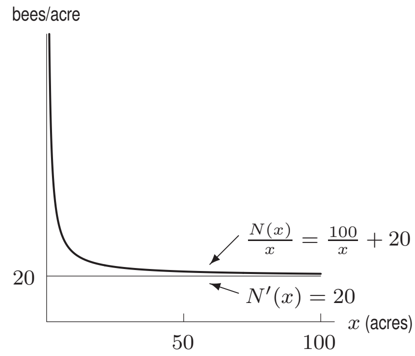

Figure 4.107

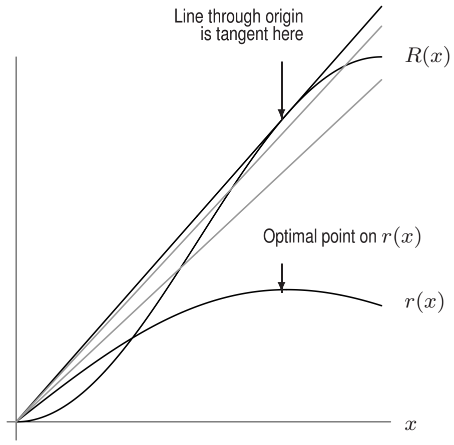
21. This question implies that the line from the origin to the point $(x, R(x))$ has some relationship to $r(x)$. The slope of this line is $R(x)/x$, which is $r(x)$. So the point x_0 at which $r(x)$ is maximal will also be the point at which the slope of this line is maximal. The question claims that the line from the origin to $(x_0, R(x_0))$ will be tangent to the graph of $R(x)$. We can understand this by trying to see what would happen if it were otherwise.

If the line from the origin to $(x_0, R(x_0))$ intersects the graph of $R(x)$, but is not tangent to the graph of $R(x)$ at x_0, then there are points of this graph on both sides of the line — and, in particular, there is some point x_1 such that the line from the origin to $(x_1, R(x_1))$ has larger slope than the line to $(x_0, R(x_0))$. (See the graph below.) But we picked x_0 so that no other line had larger slope, and therefore no such x_1 exists. So the original supposition is false, and the line from the origin to $(x_0, R(x_0))$ is tangent to the graph of $R(x)$.

(a) See (b).

(b)



(c)

$$r(x) = \frac{R(x)}{x}$$
$$r'(x) = \frac{xR'(x) - R(x)}{x^2}$$

So when $r(x)$ is maximized $0 = xR'(x) - R(x)$, the numerator of $r'(x)$, or $R'(x) = R(x)/x = r(x)$. i.e. when $r(x)$ is maximized, $r(x) = R'(x)$.

Let us call the x-value at which the maximum of r occurs x_m. Then the line passing through $R(x_m)$ and the origin is $y = x \cdot R(x_m)/x_m$. Its slope is $R(x_m)/x_m$, which also happens to be $r(x_m)$. In the previous paragraph, we showed that at x_m, this is also equal to the slope of the tangent to $R(x)$. So, the line through the origin is the tangent line.

22. (a) The value of MC is the slope of the tangent to the curve at q_0. See Figure 4.108.
(b) The line from the curve to the origin joins $(0, 0)$ and $(q_0, C(q_0))$, so its slope is $C(q_0)/q_0 = a(q_0)$.
(c) Figure 4.109 shows that the line whose slope is the minimum $a(q)$ is tangent to the curve $C(q)$. This line, therefore, also has slope MC, so $a(q) = MC$ at the q making $a(q)$ minimum.

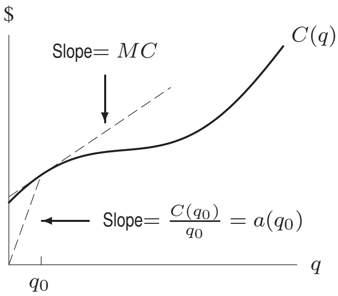


Figure 4.108

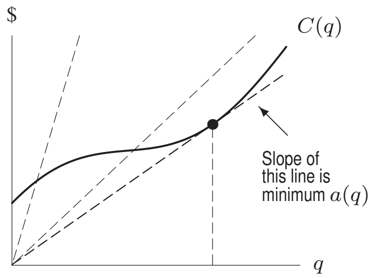

Figure 4.109

23. (a) The average cost is $a(q) = C(q)/q$, so the total cost is $C(q) = 0.01q^3 - 0.6q^2 + 13q$.
(b) Taking the derivative of $C(q)$ gives an expression for the marginal cost:

$$C'(q) = MC(q) = 0.03q^2 - 1.2q + 13.$$

To find the smallest MC we take its derivative and find the value of q that makes it zero. So: $MC'(q) = 0.06q - 1.2 = 0$ when $q = 1.2/0.06 = 20$. This value of q must give a minimum because the graph of $MC(q)$ is a parabola opening upward. Therefore the minimum marginal cost is $MC(20) = 1$. So the marginal cost is at a minimum when the additional cost per item is \$1.
(c) Differentiating gives $a'(q) = 0.02q - 0.6$.
Setting $a'(q) = 0$ and solving for q gives $q = 30$ as the quantity at which the average is minimized, since the graph of a is a parabola which opens upward. The minimum average cost is $a(30) = 4$ dollars per item.
(d) The marginal cost at $q = 30$ is $MC(30) = 0.03(30)^2 - 1.2(30) + 13 = 4$. This is the same as the average cost at this quantity. Note that since $a(q) = C(q)/q$, we have $a'(q) = (qC'(q) - C(q))/q^2$. At a critical point, q_0, of $a(q)$, we have

$$0 = a'(q_0) = \frac{q_0 C'(q_0) - C(q_0)}{q_0^2},$$

so $C'(q_0) = C(q_0)/q_0 = a(q_0)$. Therefore $C'(30) = a(30) = 4$ dollars per item.

Another way to see why the marginal cost at $q = 30$ must equal the minimum average cost $a(30) = 4$ is to view $C'(30)$ as the approximate cost of producing the 30^{th} or 31^{st} good. If $C'(30) < a(30)$, then producing the 31^{st} good would lower the average cost, i.e. $a(31) < a(30)$. If $C'(30) > a(30)$, then producing the 30^{th} good would raise the average cost, i.e. $a(30) > a(29)$. Since $a(30)$ is the global minimum, we must have $C'(30) = a(30)$.

24. (a) Since the company can produce more goods if it has more raw materials to use, the function $f(x)$ is increasing. Thus, we expect the derivative $f'(x)$ to be positive.
(b) The cost to the company of acquiring x units of raw material is wx, and the revenue from the sale of $f(x)$ units of the product is $pf(x)$. The company's profit is $\pi(x) = \text{Revenue} - \text{Cost} = pf(x) - wx$.
(c) Since profit $\pi(x)$ is maximized at $x = x^*$, we have $\pi'(x^*) = 0$. From $\pi'(x) = pf'(x) - w$, we have $pf'(x^*) - w = 0$. Thus $f'(x^*) = w/p$.
(d) Computing the second derivative of $\pi(x)$ gives $\pi''(x) = pf''(x)$. Since $\pi(x)$ has a maximum at $x = x^*$, the second derivative $\pi''(x^*) = pf''(x^*)$ is negative. Thus $f''(x^*)$ is negative.
(e) Differentiate both sides of $pf'(x^*) - w = 0$ with respect to w. The chain rule gives

$$p\frac{d}{dw}f'(x^*) - 1 = 0$$

$$pf''(x^*)\frac{dx^*}{dw} - 1 = 0$$
$$\frac{dx^*}{dw} = \frac{1}{pf''(x^*)}.$$

Since $f''(x^*) < 0$, we see dx^*/dw is negative.

(f) Since $dx^*/dw < 0$, the quantity x^* is a decreasing function of w. If the price w of the raw material goes up, the company should buy less.

25. (a) See Figure 4.110.

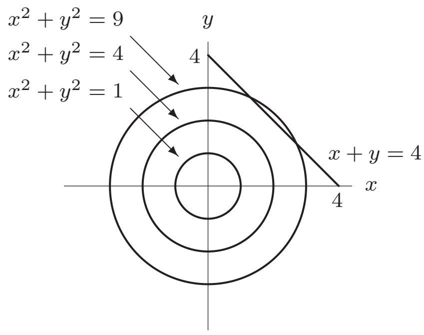

Figure 4.110

(b) As C increases in the equation $x^2 + y^2 = C$, the circle expands outward. For $C = 4$, the circle does not intersect the line. As C increases from 4, the circle expands until it touches the line. At $C = 9$, the circle cuts the line twice.

The minimum value of $C = x^2 + y^2$ occurs where a circle tangent to the line. For larger C-values, $x^2 + y^2 = C$ cuts the line twice, for smaller C-values, the circle does not touch the line.

(c) At the point at when the circle touches the line, the slope of the circle equals the slope of the line, namely -1. Implicit differentiation gives the slope of $x^2 + y^2 = C$:

$$2x + 2y \cdot y' = 0$$
$$y' = \frac{-x}{y}.$$

Thus, at the point where a circle touches the line, we have

$$-\frac{x}{y} = -1$$
$$x = y.$$

Substitution into $x + y = 4$ gives $2x = 4$, so $x = 2$ and $y = 2$. Thus, the minimum is $x^2 + y^2 = 2^2 + 2^2 = 8$.

26. (a) See Figure 4.111.

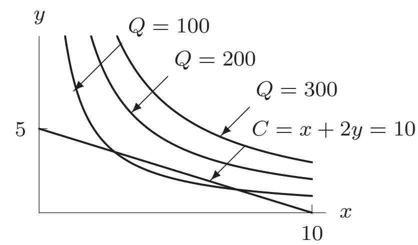

Figure 4.111

(b) Comparing the curves $Q = 100$, $Q = 200$, and $Q = 300$, we see that production increases as we move away from the origin. The curve $Q = 100$ cuts the line $C = x + 2y = 10$ twice while the curves $Q = 200$ and $Q = 300$ do not cut the line.

The maximum possible Q occurs where a curve touches the line. At this point, the slope of the production curve equals the slope of the budget line, namely $-1/2$.

(c) Using implicit differentiation, the slope of the curve $10xy = C$ is given by

$$10y + 10xy' = 0$$
$$y' = -\frac{y}{x}.$$

Thus, at the point where the curve touches the line, whose slope is $-1/2$, we have

$$-\frac{y}{x} = -\frac{1}{2}$$
$$y = \frac{x}{2}.$$

Substituting into $C = x + 2y = 10$ gives $2x = 10$, so $x = 5$ and $y = 5/2$. Thus, the maximum production is

$$Q = 10 \cdot 5 \cdot \frac{5}{2} = 125.$$

27. (a) See Figure 4.112.

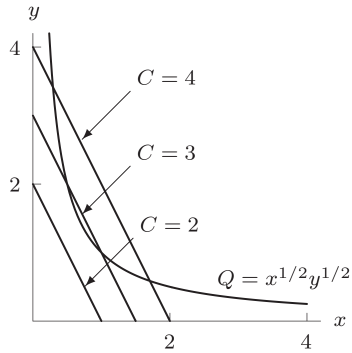

Figure 4.112

(b) Comparing the lines $C = 2,\ C = 3,\ C = 4$, we see that the cost increases as we move away from the origin. The line $C = 2$ does not cut the curve $Q = 1$; the lines $C = 3$ and $C = 4$ cut twice.

The minimum cost occurs where a cost line is tangent to the production curve.

(c) Using implicit differentiation, the slope of $x^{1/2}y^{1/2} = 1$ is given by

$$\frac{1}{2}x^{-1/2}y^{1/2} + \frac{1}{2}x^{1/2}y^{-1/2}y' = 0$$
$$y' = \frac{-x^{-1/2}y^{1/2}}{x^{1/2}y^{-1/2}} = -\frac{y}{x}.$$

The cost lines all have slope -2. Thus, if the curve is tangent to a line, we have

$$-\frac{y}{x} = -2$$
$$y = 2x.$$

Substituting into $Q = x^{1/2}y^{1/2} = 1$ gives

$$x^{1/2}(2x)^{1/2} = 1$$
$$\sqrt{2}x = 1$$
$$x = \frac{1}{\sqrt{2}}$$
$$y = 2 \cdot \frac{1}{\sqrt{2}} = \sqrt{2}.$$

Thus the minimum cost is

$$C = 2\frac{1}{\sqrt{2}} + \sqrt{2} = 2\sqrt{2}.$$

Strengthen Your Understanding

28. We are only given the cost and revenue when $q = 100$. Since we do not have any information about the marginal revenue and the marginal cost at $q = 100$, we do not know how an increase in production will affect either the revenue or the cost. Thus we cannot determine whether the profit will increase or decrease if production is increased from 100. We only know that when $q = 100$ the profit will be $R(100) - C(100) = \$60$.

29. The profit, π is given by

$$\pi(q) = R(q) - C(q).$$

Thus we have

$$\pi'(q) = R'(q) - C'(q),$$

and the critical points of $\pi(q)$ occur where $R'(q) = C'(q)$. In Figure 4.82, there are two such points, at approximately $q = 3.5$ and $q = 13$. To the left of $q = 10$, the graph shows that the costs exceed revenue, so the company is losing money. Profit is positive between $q = 10$ and $q = 15$. So the critical point at which profit is a maximum is $q = 13$. The maximum profit occurs when the quantity produced is about 13,000 units.

30. We want a quantity where the slope of the cost curve, C, is greater than the slope of the revenue curve, R. For example, small quantities, such as $q = 2$, or large quantities, such as $q = 15$.

31. The cost curve, C, lies above the revenue curve, R, for all quantities, q. See Figure 4.113.

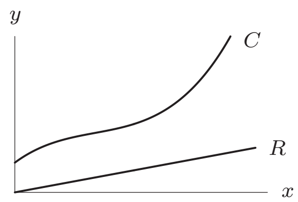

Figure 4.113

32. (e). A company should maximize profit, that is, it should maximize revenue minus cost.

33. (a) If $MR - MC > 0$, so $MR > MC$, then revenue is increasing faster than cost with production, so profit increases.

Solutions for Section 4.6

Exercises

1. The rate of change of temperature is

$$\frac{dH}{dt} = 16(-0.02)e^{-0.02t} = -0.32e^{-0.02t}.$$

When $t = 0$,

$$\frac{dH}{dt} = -0.32e^{0} = -0.32^\circ\text{C/min}.$$

When $t = 10$,

$$\frac{dH}{dt} = -0.32e^{-0.02(10)} = -0.262^\circ\text{C/min}.$$

2. The rate of growth, in billions of people per year, was

$$\frac{dP}{dt} = 6.7(0.011)e^{0.011t}.$$

On January 1, 2007, we have $t = 0$, so

$$\frac{dP}{dt} = 6.7(0.011)e^{0} = 0.0737 \text{ billion/year } = 73.7 \text{ million people/year}.$$

3. The rate of change of the power dissipated is given by

$$\frac{dP}{dR} = -\frac{81}{R^2}.$$

4. (a) The rate of change of the period is given by

$$\frac{dT}{dl} = \frac{2\pi}{\sqrt{9.8}}\frac{d}{dl}(\sqrt{l}) = \frac{2\pi}{\sqrt{9.8}} \cdot \frac{1}{2}l^{-1/2} = \frac{\pi}{\sqrt{9.8}} \cdot \frac{1}{\sqrt{l}} = \frac{\pi}{\sqrt{9.8l}}.$$

(b) The rate decreases since $\sqrt{l}$ is in the denominator.

5. Let $y(t)$ be the height of the aircraft, in feet, as a function of time, t, in minutes, and $H(y)$ be the outside temperature in $^\circ C$ as a function of height, y, in feet. We have

$$\frac{dy}{dt} = 500 \text{ feet/minute}, \qquad \frac{dH}{dy} = \frac{-2}{1000}{}^\circ C/\text{foot},$$

so we have

$$\begin{aligned} \frac{dH}{dt} &= \frac{dH}{dy} \cdot \frac{dy}{dt} \\ &= \frac{-2}{1000} \cdot 500 \\ &= -1^\circ C/\text{minute} \end{aligned}$$

6. (a) Since $P = 25$, we have

$$\begin{aligned} 25 &= 30e^{-3.23\times 10^{-5}h} \\ h &= \frac{\ln(25/30)}{-3.23 \times 10^{-5}} = 5644 \text{ ft.} \end{aligned}$$

(b) Both P and h are changing over time, and we differentiate with respect to time t, in minutes:

$$\frac{dP}{dt} = 30e^{-3.23\times 10^{-5}h}\left(-3.23 \times 10^{-5}\frac{dh}{dt}\right).$$

We see in part (a) that $h = 5644$ ft when $P = 25$ inches of mercury, and we know that $dP/dt = 0.1$. Substituting gives:

$$\begin{aligned} 0.1 &= 30e^{-3.23\times 10^{-5}\times 5644.630}\left(-3.23 \times 10^{-5}\frac{dh}{dt}\right) \\ \frac{dh}{dt} &= -124 \text{ ft/minute.} \end{aligned}$$

The glider's altitude is decreasing at a rate of about 124 feet per minute.

7. We differentiate $F = k/r^2$ with respect to t using the chain rule to give

$$\frac{dF}{dt} = -\frac{2k}{r^3} \cdot \frac{dr}{dt}.$$

We know that $k = 10^{13}$ newton $\cdot$ km^2 and that the rocket is moving at 0.2 km/sec when $r = 10^4$ km. In other words, $dr/dt = 0.2$ km/sec when $r = 10^4$. Substituting gives

$$\frac{dF}{dt} = -\frac{2 \cdot 10^{13}}{(10^4)^3} \cdot 0.2 = -4 \text{ newtons/sec.}$$

8. We know $dR/dt = 0.2$ when $R = 5$ and $V = 9$ and we want to know dI/dt. Differentiating $I = V/R$ with V constant gives

$$\frac{dI}{dt} = V\left(-\frac{1}{R^2}\frac{dR}{dt}\right),$$

so substituting gives

$$\frac{dI}{dt} = 9\left(-\frac{1}{5^2} \cdot 0.2\right) = -0.072 \text{ amps per second.}$$

9. We have

$$\frac{dA}{dt} = \frac{9}{16}[4 - 4\cos(4\theta)]\frac{d\theta}{dt}.$$

So

$$\left.\frac{dA}{dt}\right|_{\theta=\pi/4} = \frac{9}{16}\left(4 - 4\cos\left(4\cdot\frac{\pi}{4}\right)\right)0.2 = \frac{9}{16}(4+4)0.2 = 0.9\ \text{cm}^2/\text{min}.$$

10. Differentiating with respect to time t, in seconds, we have

$$\frac{d\phi}{dt} = 2\pi\left(\frac{1}{2}(x^2+4)^{-1/2}\left(2x\frac{dx}{dt}\right) - \frac{dx}{dt}\right).$$

Since the point is moving to the left, $dx/dt = -0.2$. Substituting $x = 3$ and $dx/dt = -0.2$, we have

$$\frac{d\phi}{dt} = 2\pi\left(\frac{1}{2}(3^2+4)^{-1/2}(2\cdot 3(-0.2)) - (-0.2)\right) = 0.211.$$

The potential is changing at a rate of 0.211 units per second.

11. (a) The rate of change of average cost as quantity increases is

$$\frac{dC}{dq} = -\frac{a}{q^2}\ \text{dollars/cell phone}.$$

(b) We are told that $dq/dt = 100$, and we want dC/dt. The chain rule gives

$$\frac{dC}{dt} = \frac{dC}{dq}\cdot\frac{dq}{dt} = -\frac{a}{q^2}\cdot 100 = -\frac{100a}{q^2}\ \text{dollars/week}.$$

Since a is positive, dC/dt is negative, so C is decreasing.

12. When we differentiate $x^2 + y^2 = 25$ with respect to time, we have

$$2x\frac{dx}{dt} + 2y\frac{dy}{dt} = 0.$$

(a) We use the fact that $x^2 + y^2 = 25$ to solve for y when $x = 0$. Since $0^2 + y^2 = 25$, we have $y = 5$ since y is positive. Substituting, we have

$$\begin{aligned} 2x\frac{dx}{dt} + 2y\frac{dy}{dt} &= 0 \\ 2(0)(6) + 2(5)\frac{dy}{dt} &= 0 \\ \frac{dy}{dt} &= 0. \end{aligned}$$

(b) We use the fact that $x^2 + y^2 = 25$ to solve for y when $x = 3$. Since $3^2 + y^2 = 25$, we have $y = 4$ since y is positive. Substituting, we have

$$\begin{aligned} 2x\frac{dx}{dt} + 2y\frac{dy}{dt} &= 0 \\ 2(3)(6) + 2(4)\frac{dy}{dt} &= 0 \\ \frac{dy}{dt} &= -4.5. \end{aligned}$$

(c) We use the fact that $x^2 + y^2 = 25$ to solve for y when $x = 4$. Since $4^2 + y^2 = 25$, we have $y = 3$ since y is positive. Substituting, we have

$$\begin{aligned} 2x\frac{dx}{dt} + 2y\frac{dy}{dt} &= 0 \\ 2(4)(6) + 2(3)\frac{dy}{dt} &= 0 \\ \frac{dy}{dt} &= -8. \end{aligned}$$

13. Since h is constant, we have
$$\frac{dV}{dt} = \frac{2}{3}xh\frac{dx}{dt}.$$
Thus for $h = 120$, $x = 150$, and $dx/dt = -0.002$, we have
$$\frac{dV}{dt} = \frac{2}{3}(150)(120)(-0.002) = -24\,\text{meters}^3/\text{yr}.$$
The volume is decreasing at 24 meters^3 per year.

14. (a) Treating a and l as constants, by the chain and quotient rules, we have
$$\frac{dF}{dt} = -\frac{K(2a+l)}{[a(a+l)]^2}\frac{da}{dt} = -\frac{K(35)}{[15(20)]^2}2 = -K(7.78\times 10^{-4})\,\text{newtons/min}.$$
(b) We have
$$\frac{dF}{dt} = -\frac{Ka}{[a(a+l)]^2}\frac{dl}{dt} = -\frac{K(15)}{[15(20)]^2}(-2) = K(3.33\times 10^{-4})\,\text{newtons/min}.$$

15. (a) We have
$$\text{Surface area} = 0.01(60^{0.25})(150^{0.75}) = 1.19\text{ meters}^2.$$
(b) Since $h = 150$ is constant, we have
$$s = 0.01w^{0.25}150^{0.75}.$$
Differentiating with respect to time t, in years,we have
$$\frac{ds}{dt} = 0.01\left(0.25w^{-0.75}\frac{dw}{dt}\right)150^{0.75}.$$
Substituting $dw/dt = 0.5$ and $w = 62$, we have
$$\frac{ds}{dt} = 0.01(0.25(62^{-0.75})(0.5))(150^{0.75}) = 0.0024\text{ meter}^2\text{/year}.$$
The surface area is increasing at a rate of 0.0024 meter^2 per year, or 24 cm^2 per year.

Problems

16. Let the other side of the rectangle be x cm. Then the area is $A = 10x$, so differentiating with respect to time gives
$$\frac{dA}{dt} = 10\frac{dx}{dt}.$$
We are interested in the instant when $x = 12$ and $dx/dt = 3$, giving
$$\frac{dA}{dt} = 10\frac{dx}{dt} = 10\cdot 3 = 30\text{ cm}^2\text{ per minute.}$$

17. Let the other side of the rectangle be x cm. Then the diagonal is
$$D = \sqrt{8^2+x^2} = \sqrt{64+x^2}.$$
Differentiating with respect to time gives
$$\frac{dD}{dt} = \frac{2x}{2\sqrt{64+x^2}}\frac{dx}{dt} = \frac{x}{\sqrt{64+x^2}}\frac{dx}{dt}.$$
We are interested in the instant when $x = 6$ and $dx/dt = 3$, giving
$$\frac{dD}{dt} = \frac{6}{\sqrt{64+6^2}}\cdot 3 = \frac{6}{10}\cdot 3 = 1.8\text{ cm per minute.}$$

18. Let the other leg be x cm. Then the area is

$$A = \frac{1}{2}7x = \frac{7}{2}x.$$

Differentiating with respect to time gives

$$\frac{dA}{dt} = \frac{7}{2}\frac{dx}{dt}.$$

We are interested in the instant when $x = 10$ and $dx/dt = -2$, where the negative sign reflects the fact that x is decreasing. Thus

$$\frac{dA}{dt} = \frac{7}{2}(-2) = -7 \text{ cm}^2 \text{ per second.}$$

The area is decreasing at 7 cm^2 per second.

19. The side length is $s = \sqrt{A}$ cm. Differentiating with respect to time gives

$$\frac{ds}{dt} = \frac{1}{2}\frac{1}{\sqrt{A}}\frac{dA}{dt}.$$

We are interested in the instant when $A = 576$ and $dA/dt = 3$, giving

$$\frac{ds}{dt} = \frac{1}{2}\frac{1}{\sqrt{576}}3 = \frac{1}{16}.$$

Thus, the side is increasing at $1/16$ cm per minute.

20. Since R_1 is constant, we know $dR_1/dt = 0$. We know that $dR_2/dt = 2$ ohms/min when $R_2 = 20$ ohms. At the moment we are interested in, $R_1 = 10$ and $R_2 = 20$, so

$$\frac{1}{R} = \frac{1}{10} + \frac{1}{20} = \frac{3}{20}, \quad \text{so} \quad R = \frac{20}{3} \text{ ohms.}$$

Differentiating with respect to time t,

$$\frac{1}{R} = \frac{1}{R_1} + \frac{1}{R_2},$$

gives

$$-\frac{1}{R^2}\frac{dR}{dt} = -\frac{1}{{R_1}^2}\frac{dR_1}{dt} - \frac{1}{{R_2}^2}\frac{dR_2}{dt}.$$

Substituting gives

$$-\frac{1}{(20/3)^2}\frac{dR}{dt} = -\frac{1}{10^2}\cdot 0 - \frac{1}{20^2}\cdot 2$$

$$\frac{dR}{dt} = \left(\frac{20}{3}\right)^2 \cdot \frac{1}{20^2}\cdot 2 = \frac{2}{9} \text{ ohms/min.}$$

21. (a) The rate of change of temperature change is

$$\frac{dT}{dD} = \frac{d}{dD}\left(\frac{CD^2}{2} - \frac{D^3}{3}\right) = \frac{2CD}{2} - \frac{3D^2}{3} = CD - D^2.$$

(b) We want to know for what values of D the value of dT/dD is positive. This occurs when

$$\frac{dT}{dD} = (C - D)\,D > 0.$$

We only consider positive values of D, since a zero dosage obviously has no effect and a negative dosage does not make sense. If $D > 0$, then $(C - D)D > 0$ when $C - D > 0$, or $D < C$. So the rate of change of temperature change is positive for doses less than C.

22. (a) (i) Differentiating thinking of r as a constant gives

$$\frac{dP}{dt} = 500e^{rt/100}\cdot\frac{r}{100} = 5re^{rt/100}.$$

Substituting $t = 0$ gives

$$\frac{dP}{dt} = 5re^{r\cdot 0/100} = 5r \text{ dollars/yr.}$$

(ii) Substituting $t = 2$ gives
$$\frac{dP}{dt} = 5re^{r\cdot 2/100} = 5re^{0.02r} \text{ dollars/yr.}$$

(b) To differentiate thinking of r as variable, think of the function as
$$P = 500e^{r(t)\cdot t/100},$$
and use the chain rule (for $e^{rt/100}$) and the product rule (for $r(t)\cdot t$):
$$\frac{dP}{dt} = 500e^{r(t)\cdot t/100}\cdot\frac{1}{100}\cdot\frac{d}{dt}(r(t)\cdot t) = 5e^{r(t)\cdot t/100}\left(r(t)\cdot 1 + r'(t)\cdot t\right).$$
Substituting $t = 2$, $r = 4$, and $r'(2) = 0.3$ gives
$$\frac{dP}{dt} = 5e^{4\cdot 2/100}\left(4 + 0.3\cdot 2\right) = 24.916 \text{ dollars/year}$$
Thus, the price is increasing by about \$25 per year at that time.

23. (a) The rate of change of force with respect to distance is
$$\frac{dF}{dr} = \frac{2A}{r^3} - \frac{3B}{r^4}.$$
The units are units of force per units of distance.

(b) We are told that $dr/dt = k$ and we want dF/dt. By the chain rule
$$\frac{dF}{dt} = \frac{dF}{dr}\cdot\frac{dr}{dt} = \left(\frac{2A}{r^3} - \frac{3B}{r^4}\right)k.$$
The units are units of force per unit time.

24. The rate of change of velocity is given by
$$\frac{dv}{dt} = -\frac{mg}{k}\left(-\frac{k}{m}e^{-kt/m}\right) = ge^{-kt/m}.$$
When $t = 0$,
$$\left.\frac{dv}{dt}\right|_{t=0} = g.$$
When $t = 1$,
$$\left.\frac{dv}{dt}\right|_{t=1} = ge^{-k/m}.$$
These answers give the acceleration at $t = 0$ and $t = 1$. The acceleration at $t = 0$ is g, the acceleration due to gravity, and at $t = 1$, the acceleration is $ge^{-k/m}$, a smaller value.

25. We let x represent the distance from the base of the wall to the base of the ladder and y represent the distance from the top of the ladder to the base of the wall. Notice that x and y are changing over time, but that the length of the ladder is fixed at 10 m. Using the Pythagorean Theorem, we have
$$x^2 + y^2 = 10^2.$$
Differentiating with respect to time, we have
$$2x\frac{dx}{dt} + 2y\frac{dy}{dt} = 0.$$
We have $dx/dt = 0.5$ and we are finding dy/dt.

(a) When $x = 4$, we have $4^2 + y^2 = 10^2$ so $y = 9.165$. Substituting, we have
$$2(4)(0.5) + 2(9.165)\frac{dy}{dt} = 0$$
$$\frac{dy}{dt} = -0.218 \text{ m/sec.}$$
The top of the ladder is sliding down at 0.218 m/sec.

(b) When $x = 8$, we have $8^2 + y^2 = 10^2$ so $y = 6$. Substituting, we have
$$2(8)(0.5) + 2(6)\frac{dy}{dt} = 0$$
$$\frac{dy}{dt} = -0.667 \text{ m/sec.}$$
The top of the ladder is sliding down at 0.667 m/sec. Notice that the top slides down faster and faster as the bottom moves away at a constant speed.

26. Since the radius is 3 feet, the volume of the gas when the depth is h is given by

$$V = \pi 3^2 h = 9\pi h.$$

We want to find dV/dt when $h = 4$ and $dh/dt = 0.2$. Differentiating gives

$$\frac{dV}{dt} = 9\pi\frac{dh}{dt} = 9\pi(0.2) = 5.655 \text{ ft}^3/\text{sec}.$$

Notice that the value $H = 4$ is not used. This is because V is proportional to h so dV/dt does not depend on h.

27. The rate of 3 meters^3/min is a derivative and the units tell us it is dV/dt where V is volume in cubic meters and t is time in minutes. The rate at which the water level is rising is dh/dt where h is the height of the water in meters. We must relate V and h.

When the water level is h, the volume, V, of water in the cylinder is

$$V = \pi r^2 h$$

where $r = 5$ meters is the radius, so

$$V = 25\pi h.$$

Differentiating with respect to time gives

$$\frac{dV}{dt} = 25\pi\frac{dh}{dt}.$$

We substitute $dV/dt = 3$ and solve for dh/dt:

$$3 = 25\pi\frac{dh}{dt}$$
$$\frac{dh}{dt} = \frac{3}{25\pi} = 0.038 \text{ meter/min}.$$

The water level is rising 0.038 meters per minute. Notice that this rate does not depend on the fact that the cylinder is half full. We have $dh/dt = 0.038$ for all water levels h.

28. When the radius is r, the volume V of the snowball is

$$V = \frac{4}{3}\pi r^3.$$

We know that $dr/dt = -0.2$ when $r = 15$ and we want to know dV/dt at that time. Differentiating, we have

$$\frac{dV}{dt} = \frac{4}{3}\pi 3r^2\frac{dr}{dt} = 4\pi r^2\frac{dr}{dt}.$$

Substituting $dr/dt = -0.2$ gives

$$\left.\frac{dV}{dt}\right|_{r=15} = 4\pi(15)^2(-0.2) = -180\pi = -565.487 \text{ cm}^3/\text{hr}.$$

Thus, the volume is decreasing at 565.487 cm^3 per hour.

29. If V is the volume of the balloon and r is its radius, then

$$V = \frac{4}{3}\pi r^3.$$

We want to know the rate at which air is being blown into the balloon, which is the rate at which the volume is increasing, dV/dt. We are told that

$$\frac{dr}{dt} = 2\,\text{cm/sec} \quad \text{when} \quad r = 10\,\text{cm}.$$

Using the chain rule, we have

$$\frac{dV}{dt} = \frac{dV}{dr}\cdot\frac{dr}{dt} = 4\pi r^2\frac{dr}{dt}.$$

Substituting gives

$$\frac{dV}{dt} = 4\pi(10)^2 2 = 800\pi = 2513.3\,\text{cm}^3/\text{sec}.$$

30. If C represents circulation time in seconds and B represent body mass in kilograms, we have

$$C = 17.40B^{1/4}.$$

As the child grows, both the body mass and the circulation time change. Differentiating with respect to time t, we have

$$\frac{dC}{dt} = 17.40\left(\frac{1}{4}B^{-3/4}\frac{dB}{dt}\right).$$

Substituting $B = 45$ and $dB/dt = 0.1$, we have

$$\frac{dC}{dt} = 17.40\left(\frac{1}{4}(45)^{-3/4}(0.1)\right) = 0.025.$$

The circulation time is increasing at a rate of 0.025 seconds per month.

31. (a) Since $P = 1$ when $V = 20$, we have

$$k = 1 \cdot (20^{1.4}) = 66.29.$$

Thus, we have

$$P = 66.29V^{-1.4}.$$

Differentiating gives

$$\frac{dP}{dV} = 66.29(-1.4V^{-2.4}) = -92.8V^{-2.4}\text{ atmospheres/cm}^3.$$

(b) We are given that $dV/dt = 2\,\text{cm}^3/\text{min}$ when $V = 30\,\text{cm}^3$. Using the chain rule, we have

$$\begin{aligned}\frac{dP}{dt} = \frac{dP}{dV}\cdot\frac{dV}{dt} &= \left(-92.8V^{-2.4}\,\frac{\text{atm}}{\text{cm}^3}\right)\left(2\frac{\text{cm}^3}{\text{min}}\right)\\ &= -92.8\left(30^{-2.4}\right)2\frac{\text{atm}}{\text{min}}\\ &= -0.0529\text{ atmospheres/min}\end{aligned}$$

Thus, the pressure is decreasing at 0.0529 atmospheres per minute.

32. If the length of a horizontal rod is x and the length of a vertical rod is h, the volume, V, is given by

$$V = x^2h.$$

Taking derivatives gives

$$\frac{dV}{dt} = 2xh\frac{dx}{dt} + x^2\frac{dh}{dt}.$$

When the area of the square base is 9 cm^2, we have $x = 3$ cm. Since the volume is then 180 cm^3, we know $h = 180/9 = 20$ cm. So

$$\frac{dV}{dt} = 2\cdot 3\cdot 20(0.001) + 3^2(0.002) = 0.138\,\text{cm}^3/\text{hr}.$$

33. (a) Since the slick is circular, if its radius is r meters, its area, A, is $A = \pi r^2$. Differentiating with respect to time using the chain rule gives

$$\frac{dA}{dt} = 2\pi r\frac{dr}{dt}.$$

We know $dr/dt = 0.1$ when $r = 150$, so

$$\frac{dA}{dt} = 2\pi 150(0.1) = 30\pi = 94.248\text{ m}^2/\text{min}.$$

(b) If the thickness of the slick is h, its volume, V, is given by

$$V = Ah.$$

Differentiating with respect to time using the product rule gives

$$\frac{dV}{dt} = \frac{dA}{dt}h + A\frac{dh}{dt}.$$

We know $h = 0.02$ and $A = \pi(150)^2$ and $dA/dt = 30\pi$. Since V is fixed, $dV/dt = 0$, so

$$0 = 0.02(30\pi) + \pi(150)^2 \frac{dh}{dt}.$$

Thus

$$\frac{dh}{dt} = -\frac{0.02(30\pi)}{\pi(150)^2} = -0.0000267 \text{ m/min},$$

so the thickness is decreasing at 0.0000267 meters per minute.

34. Let the volume of clay be V. The clay is in the shape of a cylinder, so $V = \pi r^2 L$. We know $dL/dt = 0.1$ cm/sec and we want to know dr/dt when $r = 1$ cm and $L = 5$ cm. Differentiating with respect to time t gives

$$\frac{dV}{dt} = \pi 2rL\frac{dr}{dt} + \pi r^2 \frac{dL}{dt}.$$

However, the amount of clay is unchanged, so $dV/dt = 0$ and

$$2rL\frac{dr}{dt} = -r^2\frac{dL}{dt},$$

therefore

$$\frac{dr}{dt} = -\frac{r}{2L}\frac{dL}{dt}.$$

When the radius is 1 cm and the length is 5 cm, and the length is increasing at 0.1 cm per second, the rate at which the radius is changing is

$$\frac{dr}{dt} = -\frac{1}{2\cdot 5}\cdot 0.1 = -0.01 \text{ cm/sec}.$$

Thus, the radius is decreasing at 0.01 cm/sec.

35. (a) When full

$$\text{Volume of water in filter } = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi 6^2 \cdot 10 = 120\pi.$$

Water flows out at a rate of 1.5 cm^3 per second, so

$$\text{Time to empty } = \frac{120\pi}{1.5} = 80\pi = 251.327 \text{ secs}.$$

The time taken is 251.327 sec or just over 4 minutes.

(b) Let the radius of the surface of the water be r cm when the depth is h cm. See Figure 4.114. Then by similar triangles

$$\frac{6}{10} = \frac{r}{h}$$
$$r = \frac{3}{5}h.$$

Thus, when the depth of the water is h,

$$\text{Volume of water } = V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi\left(\frac{3}{5}h\right)^2 h = \frac{3}{25}\pi h^3 \text{ cm}^3.$$

(c) We know that water is flowing out at 1.5 cm^3 per second, so $dV/dt = -1.5$. We want to know dh/dt when $h = 8$. Differentiating the answer to part (b), we have

$$\frac{dV}{dt} = \frac{3}{25}\pi 3h^2\frac{dh}{dt} = \frac{9}{25}\pi h^2\frac{dh}{dt}.$$

Substituting $dV/dt = -1.5$ and $h = 8$ gives

$$-1.5 = \frac{9}{25}\pi 8^2 \cdot \frac{dh}{dt}$$
$$\frac{dh}{dt} = -\frac{1.5\cdot 25}{9\pi 8^2} = -0.0207 \text{ cm/sec}.$$

Thus, the water level is dropping by 0.0207 cm per second.

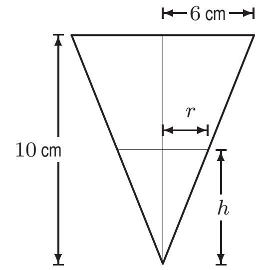

Figure 4.114

36. The surface area of an open cone is given by $A = \pi r s$ where s is the length of the side of the cone. Thus, if the height of the cone is h and the radius r, the side $s = \sqrt{r^2 + h^2}$. Since the cone has radius 4 in and depth 4 in, when the depth is h, the radius of the surface of the water is also h, so $r = h$. Thus

$$A = \pi r\sqrt{r^2 + h^2} = \pi r\sqrt{r^2 + r^2} = \sqrt{2}\pi r^2.$$

We want dA/dt when $r = 2.5$ and $dr/dt = 3$ in/min. Differentiating gives

$$\frac{dA}{dt} = 2\sqrt{2}\pi r\frac{dr}{dt}$$
$$\frac{dA}{dt} = 2\sqrt{2}\pi \cdot 2.5 \cdot 3 = 66.643 \text{ in}^2/\text{min}.$$

37. Since the slant side of the cone makes an angle of 45° with the vertical, we have $r = h$, so the volume of the cone is

$$V = \frac{1}{3}\pi h^3.$$

Differentiating with respect to time gives

$$\frac{dV}{dt} = \pi h^2\frac{dh}{dt}.$$

We know $dV/dt = 2$ cubic meters/min, and we want to know dh/dt when $h = 0.5$ meters. Substituting gives

$$2 = \pi(0.5)^2\frac{dh}{dt},$$
$$\frac{dh}{dt} = \frac{2}{\pi(0.5)^2} = \frac{8}{\pi} \text{ meters/min.}$$

38. (a) Let $x,\ y$ be the distances, in miles, of the car and truck respectively, from the gas station. See Figure 4.115. If the car and truck are h miles apart, Pythagoras' Theorem gives

$$h^2 = x^2 + y^2.$$

We know that when $x = 3,\ dx/dt = -100$ (the negative sign represents the fact that the distance from the gas station is decreasing), and $y = 4,\ dy/dt = 80$. Thus

$$h^2 = 3^2 + 4^2 = 25 \text{ so } h = 5 \text{ miles.}$$

We want to find dh/dt. Differentiating $h^2 = x^2 + y^2$ gives

$$2h\frac{dh}{dt} = 2x\frac{dx}{dt} + 2y\frac{dy}{dt}$$
$$5\frac{dh}{dt} = 3(-100) + 4(80)$$
$$\frac{dh}{dt} = \frac{-300 + 320}{5} = 4 \text{ mph.}$$

Thus, the distance is increasing at 4 mph.

(b) If $dy/dt = 70$, we have

$$5\frac{dh}{dt} = 3(-100) + 4(70)$$
$$\frac{dh}{dt} = \frac{-300+280}{5} = -4 \text{ mph.}$$

Thus, the distance is decreasing at 4 mph.

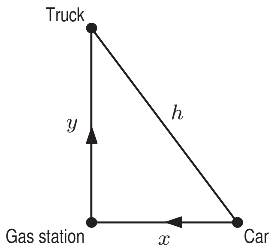

Figure 4.115

39. Let the origin be at the center of the wheel and (x, y) be the coordinates of a point on the wheel. Then $x^2 + y^2 = R^2$, where $R = 67.5$ meters is the radius of the wheel. One minute into the ride, we know the passenger is rising at 0.06 meters per second, so $dy/dt = 0.06$. We want to know dx/dt. Differentiating with respect to t gives

$$2x\frac{dx}{dt} + 2y\frac{dy}{dt} = 0,$$

so

$$\frac{dx}{dt} = -\frac{y}{x}\frac{dy}{dt}.$$

Suppose we are looking at the wheel in such a way that it appears to be rotating counter clockwise. In one minute, the wheel travels through $360°/27 = 13.33°$. From Figure 4.116, we see that at this time the coordinates of the passenger are $x = R\sin 13.33°$ and $y = -R\cos 13.33°$. Since the vertical speed of the cabin is $dy/dt = 0.06$ meters per second, the horizontal speed of the wheel, dx/dt, is

$$\frac{dx}{dt} = -\frac{-R\cos 13.33°}{R\sin 13.33°}0.06 = 0.253 \text{ meters/second.}$$

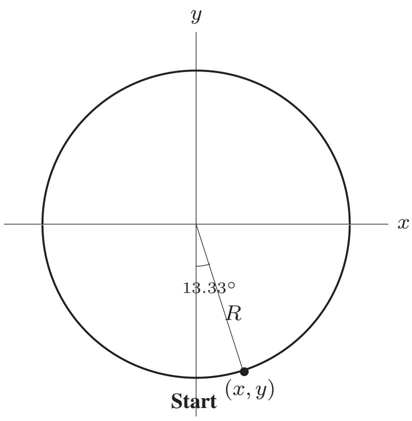

Figure 4.116

40. (a) From the second figure in the problem, we see that $\theta \approx 3.3$ when $t = 2$. The coordinates of P are given by $x = \cos\theta$, $y = \sin\theta$. When $t = 2$, the coordinates of P are

$$(x, y) \approx (\cos 3.3, \sin 3.3) = (-0.99, -0.16).$$

(b) Using the chain rule, the velocity in the x-direction is given by

$$v_x = \frac{dx}{dt} = \frac{dx}{d\theta} \cdot \frac{d\theta}{dt} = -\sin\theta \cdot \frac{d\theta}{dt}.$$

From Figure 4.117, we estimate that when $t = 2$,

$$\left.\frac{d\theta}{dt}\right|_{t=2} \approx 2.$$

So

$$v_x = \frac{dx}{dt} \approx -(-0.16) \cdot (2) = 0.32.$$

Similarly, the velocity in the y-direction is given by

$$v_y = \frac{dy}{dt} = \frac{dy}{d\theta} \cdot \frac{d\theta}{dt} = \cos\theta \cdot \frac{d\theta}{dt}.$$

When $t = 2$

$$v_y = \frac{dy}{dt} \approx (-0.99) \cdot (2) = -1.98.$$

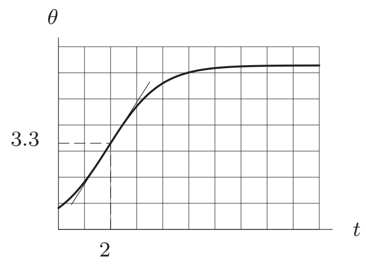

Figure 4.117

41. (a) On the interval $0 < M < 70$, we have

$$\text{Slope } = \frac{\Delta G}{\Delta M} = \frac{2.8}{70} = 0.04 \text{ gallons per mile.}$$

On the interval $70 < M < 100$, we have

$$\text{Slope } = \frac{\Delta G}{\Delta M} = \frac{4.6 - 2.8}{100 - 70} = \frac{1.8}{30} = 0.06 \text{ gallons per mile.}$$

(b) Gas consumption, in miles per gallon, is the reciprocal of the slope, in gallons per mile. On the interval $0 < M < 70$, gas consumption is $1/(0.04) = 25$ miles per gallon. On the interval $70 < M < 100$, gas consumption is $1/(0.06) = 16.667$ miles per gallon.

(c) In Figure 4.90 in the text, we see that the velocity for the first hour of this trip is 70 mph and the velocity for the second hour is 30 mph. The first hour may have been spent driving on an interstate highway and the second hour may have been spent driving in a city. The answers to part (b) would then tell us that this car gets 25 miles to the gallon on the highway and about 16 miles to the gallon in the city.

(d) Since $M = h(t)$, we have $G = f(M) = f(h(t)) = k(t)$. The function k gives the total number of gallons of gas used t hours into the trip. We have

$$G = k(0.5) = f(h(0.5)) = f(35) = 1.4 \text{ gallons.}$$

The car consumes 1.4 gallons of gas during the first half hour of the trip.

(e) Since $k(t) = f(h(t))$, by the chain rule, we have

$$\frac{dG}{dt} = k'(t) = f'(h(t)) \cdot h'(t).$$

Therefore:

$$\left.\frac{dG}{dt}\right|_{t=0.5} = k'(0.5) = f'(h(0.5)) \cdot h'(0.5) = f'(35) \cdot 70 = 0.04 \cdot 70 = 2.8 \text{ gallons per hour,}$$

and

$$\left.\frac{dG}{dt}\right|_{t=1.5} = k'(1.5) = f'(h(1.5)) \cdot h'(1.5) = f'(85) \cdot 30 = 0.06 \cdot 30 = 1.8 \text{ gallons per hour.}$$

Gas is being consumed at a rate of 2.8 gallons per hour at time $t = 0.5$ and is being consumed at a rate of 1.8 gallons per hour at time $t = 1.5$. Notice that gas is being consumed more quickly on the highway, even though the gas mileage is significantly better there.

42. The rate of change of temperature with distance, dH/dy, at altitude 4000 ft approximated by

$$\frac{dH}{dy} \approx \frac{\Delta H}{\Delta y} = \frac{38-52}{6-4} = -7^\circ\text{F/thousand ft.}$$

A speed of 3000 ft/min tells us $dy/dt = 3000$, so

$$\text{Rate of change of temperature with time} = \frac{dH}{dy} \cdot \frac{dy}{dt} \approx -7\frac{^\circ\text{F}}{\text{thousand ft}} \cdot \frac{3 \text{ thousand ft}}{\text{min}} = -21^\circ\text{F/min.}$$

Other estimates can be obtained by estimating the derivative as

$$\frac{dH}{dy} \approx \frac{\Delta H}{\Delta y} = \frac{52-60}{4-2} = -4^\circ\text{F/thousand ft}$$

or by averaging the two estimates

$$\frac{dH}{dy} \approx \frac{-7-4}{2} = -5.5^\circ\text{F/thousand ft.}$$

If the rate of change of temperature with distance is -4°/thousand ft, then

$$\text{Rate of change of temperature with time} = \frac{dH}{dy} \cdot \frac{dy}{dt} \approx -4\frac{^\circ\text{F}}{\text{thousand ft}} \cdot \frac{3 \text{ thousand ft}}{\text{min}} = -12^\circ\text{F/min.}$$

Thus, estimates for the rate at which temperature was decreasing range from 12°F/min to 21°F/min.

43. (a) Assuming that $T(1) = 98.6 - 2 = 96.6$, we get

$$\begin{aligned} 96.6 &= 68 + 30.6e^{-k\cdot 1} \\ 28.6 &= 30.6e^{-k} \\ 0.935 &= e^{-k}. \end{aligned}$$

So

$$k = -\ln(0.935) \approx 0.067.$$

(b) We're looking for a value of t which gives $T'(t) = -1$. First we find $T'(t)$:

$$\begin{aligned} T(t) &= 68 + 30.6e^{-0.067t} \\ T'(t) &= (30.6)(-0.067)e^{-0.067t} \approx -2e^{-0.067t}. \end{aligned}$$

Setting this equal to -1 per hour gives

$$\begin{aligned} -1 &= -2e^{-0.067t} \\ \ln(0.5) &= -0.067t \\ t &= -\frac{\ln(0.5)}{0.067} \approx 10.3. \end{aligned}$$

Thus, when $t \approx 10.3$ hours, we have $T'(t) \approx -1^\circ$F per hour.

(c) The coroner's rule of thumb predicts that in 24 hours the body temperature will decrease 25°F, to about 73.6°F. The formula predicts a temperature of

$$T(24) = 68 + 30.6e^{-0.067\cdot 24} \approx 74.1^\circ\text{F.}$$

44. (a) Using Pythagoras' theorem, we see

$$z^2 = 0.5^2 + x^2$$

so

$$z = \sqrt{0.25 + x^2}.$$

(b) We want to calculate dz/dt. Using the chain rule, we have

$$\frac{dz}{dt} = \frac{dz}{dx} \cdot \frac{dx}{dt} = \frac{2x}{2\sqrt{0.25 + x^2}} \frac{dx}{dt}.$$

Because the train is moving at 0.8 km/hr, we know that

$$\frac{dx}{dt} = 0.8 \text{ km/hr}.$$

At the moment we are interested in $z = 1$ km so

$$1^2 = 0.25 + x^2$$

giving

$$x = \sqrt{0.75} = 0.866 \text{ km}.$$

Therefore

$$\frac{dz}{dt} = \frac{2(0.866)}{2\sqrt{0.25 + 0.75}} \cdot 0.8 = 0.866 \cdot 0.8 = 0.693 \text{ km/min}.$$

(c) We want to know $d\theta/dt$, where θ is as shown in Figure 4.118. Since

$$\frac{x}{0.5} = \tan\theta$$

we know

$$\theta = \arctan\left(\frac{x}{0.5}\right),$$

so

$$\frac{d\theta}{dt} = \frac{1}{1 + (x/0.5)^2} \cdot \frac{1}{0.5} \frac{dx}{dt}.$$

We know that $dx/dt = 0.8$ km/min and, at the moment we are interested in, $x = \sqrt{0.75}$. Substituting gives

$$\frac{d\theta}{dt} = \frac{1}{1 + 0.75/0.25} \cdot \frac{1}{0.5} \cdot 0.8 = 0.4 \text{ radians/min}.$$

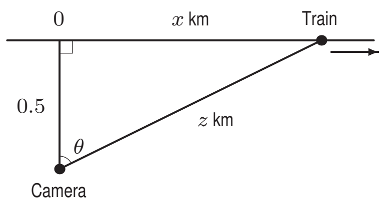

Figure 4.118

45. Using the triangle OSL in Figure 4.119, we label the distance x.

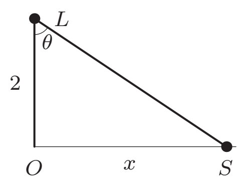

Figure 4.119

We want to calculate $dx/d\theta$. First we must find x as a function of θ. From the triangle, we see

$$\frac{x}{2} = \tan\theta \quad \text{so} \quad x = 2\tan\theta.$$

Thus,

$$\frac{dx}{d\theta} = \frac{2}{\cos^2\theta}.$$

46. The radius r is related to the volume by the formula $V = \frac{4}{3}\pi r^3$. By implicit differentiation, we have

$$\frac{dV}{dt} = \frac{4}{3}\pi 3r^2\frac{dr}{dt} = 4\pi r^2\frac{dr}{dt}.$$

The surface area of a sphere is $4\pi r^2$, so we have

$$\frac{dV}{dt} = s \cdot \frac{dr}{dt},$$

but since $\frac{dV}{dt} = \frac{1}{3}s$ was given, we have

$$\frac{dr}{dt} = \frac{1}{3}.$$

47. The volume of a cube is $V = x^3$. So

$$\frac{dV}{dt} = 3x^2\frac{dx}{dt},$$

and

$$\frac{1}{V}\frac{dV}{dt} = \frac{3}{x}\frac{dx}{dt}.$$

The surface area of a cube is $A = 6x^2$. So

$$\frac{dA}{dt} = 12x\frac{dx}{dt},$$

and

$$\frac{1}{A}\frac{dA}{dt} = \frac{2}{x}\frac{dx}{dt}.$$

Thus the percentage rate of change of the volume of the cube, $\frac{1}{V}\frac{dV}{dt}$, is larger.

48. (a) The end of the pipe sweeps out a circle of circumference $2\pi \cdot 20 = 40\pi$ meters in 5 minutes, so

$$\text{Speed } = \frac{40\pi}{5} = 8\pi = 25.133 \text{ meters/min.}$$

(b) The distance, h, between P and Q is given by the Law of Cosines:

$$h^2 = 50^2 + 20^2 - 2 \cdot 50 \cdot 20 \cos\theta.$$

When $\theta = \pi/2$, we have

$$h^2 = 50^2 + 20^2 - 2 \cdot 50 \cdot 20 \cdot 0.$$
$$h = \sqrt{2900} = 53.852 \text{ m.}$$

When $\theta = 0$, we have $h = 30$ m.

Since the pipe makes one rotation of 2π radians every 5 minutes, we know

$$\frac{d\theta}{dt} = \frac{2\pi}{5} \text{ radians/minute.}$$

Differentiating the relationship $h^2 = 50^2 + 20^2 - 2 \cdot 50 \cdot 20 \cos\theta$ gives

$$2h\frac{dh}{dt} = 2 \cdot 50 \cdot 20 \sin\theta\frac{d\theta}{dt}.$$

When $\theta = \pi/2$, we have

$$2\sqrt{2900}\frac{dh}{dt} = 2 \cdot 50 \cdot 20 \cdot 1 \cdot \frac{2\pi}{5}$$
$$\frac{dh}{dt} = \frac{50 \cdot 20}{\sqrt{2900}} \cdot \frac{2\pi}{5} = 23.335 \text{ meters/min.}$$

When $\theta = 0$, we have

$$2 \cdot 30\frac{dh}{dt} = 2 \cdot 50 \cdot 20 \cdot 0 \cdot \frac{2\pi}{5}$$
$$\frac{dh}{dt} = 0 \text{ meters/min.}$$

49. The volume, V, of a cone of radius r and height h is

$$V = \frac{1}{3}\pi r^2 h.$$

Figure 4.120 shows that $h/r = 10/8$, thus $r = 8h/10$, so

$$V = \frac{1}{3}\pi\left(\frac{8}{10}h\right)^2 h = \frac{64}{300}\pi h^3.$$

Differentiating V with respect to time, t, gives

$$\frac{dV}{dt} = \frac{64}{100}\pi h^2 \frac{dh}{dt}.$$

Since water is flowing into the tank at 0.1 cubic meters/min but leaking out at a rate of $0.004h^2$ cubic meters/min, we also have

$$\frac{dV}{dt} = 0.1 - 0.004h^2.$$

Equating the two expressions for dV/dt, we have

$$\frac{64}{100}\pi h^2 \frac{dh}{dt} = 0.1 - 0.004h^2.$$

Solving for dh/dt gives

$$\frac{dh}{dt} = \frac{0.1(100 - 4h^2)}{64\pi h^2}.$$

Notice dh/dt is positive when

$$100 - 4h^2 > 0 \text{ that is, when } 4h^2 < 100.$$

We conclude that if $h < 5$ then $dh/dt > 0$. Therefore, the depth increases until $h = 5$. For $h > 5$, we have $dh/dt < 0$, so the depth decreases whenever $h > 5$. Since the tank is more than 5 meters deep, it does not overflow.

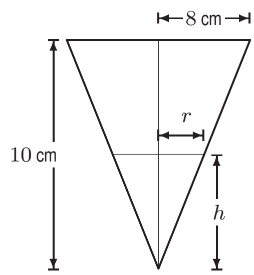

Figure 4.120

50. (a) Since the elevator is descending at 30 ft/sec, its height from the ground is given by $h(t) = 300 - 30t$, for $0 \leq t \leq 10$.

(b) From the triangle in the figure,

$$\tan\theta = \frac{h(t) - 100}{150} = \frac{300 - 30t - 100}{150} = \frac{200 - 30t}{150}.$$

Therefore

$$\theta = \arctan\left(\frac{200 - 30t}{150}\right)$$

and

$$\frac{d\theta}{dt} = \frac{1}{1 + \left(\frac{200-30t}{150}\right)^2}\cdot\left(\frac{-30}{150}\right) = -\frac{1}{5}\left(\frac{150^2}{150^2 + (200 - 30t)^2}\right).$$

Notice that $\frac{d\theta}{dt}$ is always negative, which is reasonable since θ decreases as the elevator descends.

(c) If we want to know when θ changes (decreases) the fastest, we want to find out when $d\theta/dt$ has the largest magnitude. This will occur when the denominator, $150^2 + (200 - 30t)^2$, in the expression for $d\theta/dt$ is the smallest, or when $200 - 30t = 0$. This occurs when $t = \frac{200}{30}$ seconds, and so $h(\frac{200}{30}) = 100$ feet, i.e., when the elevator is at the level of the observer.

51. (a) We differentiate $a^2(t)+b^2(t)=c$ with respect to t to find

$$\frac{d}{dt}(a^2(t)+b^2(t))=\frac{d}{dt}c,$$

or

$$2a(t)\cdot a'(t)-2b(t)\cdot b'(t)=0,$$

giving

$$a(t)\cdot a'(t)=-b(t)\cdot b'(t).$$

(b) (i) If Angela likes Brian, then $a(t)>0$, so $b'(t)<0$. This means that $b(t)$ is decreasing, so Brian's affection decreases when Angela likes him.

(ii) If Angela dislikes Brian, then $a(t)<0$, so $b'(t)>0$. This means that $b(t)$ is increasing, so Brian's affection increases when Angela dislikes him.

(c) Substituting $b'(t)=-a(t)$ into $a(t)\cdot a'(t)=-b(t)\cdot b'(t)$ gives

$$a(t)\cdot a'(t)=-b(t)\cdot b'(t)=-b(t)(-a(t)),$$

so

$$a'(t)=b(t).$$

(i) If Brian likes Angela, then $b(t)>0$, so $a'(t)>0$. This means that $a(t)$ is increasing, so Angela's affection increases when Brian likes her.

(ii) If Brian dislikes Angela, then $b(t)<0$, so $a'(t)<0$. This means that $a(t)$ is decreasing, so Angela's affection decreases when Brian dislikes her.

(d) When $t=0$, they both like each other. This means that Angela's affection increases, while Brian's decreases. Eventually $b(t)<0$, when he dislikes her.

52. (a) We have either $x(0)=50$ and $y(0)=40$, or $y(0)=50$ and $x(0)=40$. In the first case $c=x^2(0)-y^2(0)=50^2-40^2=900$ whereas in the second $c=x^2(0)-y^2(0)=40^2-50^2=-900$. But $c>0$, so $c=900$ and we have $x^2(t)-y^2(t)=900$.

(b) Because $x^2(t)-y^2(t)=900$ we have $x^2(3)-y^2(3)=900$ so $x^2(3)=y^2(3)+900=16^2+900=1156$, giving $x(3)=\sqrt{1156}=34$. After 3 hours, y has 16 ships, and x has 34 ships.

(c) The condition $y(T)=0$ means that there are no more ships on that side, so the battle ends at time T hours.

(d) We have $x^2(T)-y^2(T)=900$ with $y(T)=0$ so $x(T)=30$ ships.

(e) The rate per hour at which y loses ships is $y'(t)$, so $y'(t)=kx$. Because y is decreasing, k is negative.

(f) We differentiate $x^2(t)-y^2(t)=900$ with respect to t to find

$$\frac{d}{dt}(x^2(t)-y^2(t))=\frac{d}{dt}900,$$

or

$$2x(t)\cdot x'(t)-2y(t)\cdot y'(t)=0,$$

giving

$$x'(t)=\frac{y(t)}{x(t)}y'(t).$$

But $y'(t)=kx(t)$ so

$$x'(t)=\frac{y(t)}{x(t)}kx(t)=ky(t).$$

(g) From part (b), we know that when $t=3$ we have $x(3)=34$, $y(3)=16$; we are now given that $x'(3)=32$. But $x'(t)=ky(t)$ so $32=ky(3)=16k$ giving $k=2$. In this case $y'(3)=kx(3)=2\cdot 34=68$ ships/hour.

Strengthen Your Understanding

53. The radius of a circle and the circle's diameter are related by the linear function $D=2R$. Thus, $\frac{dD}{dt}=\frac{dD}{dR}\frac{dR}{dt}=2\frac{dR}{dt}$. The rate of change of the diameter is twice the rate of change of the radius. For example, if the radius is increasing at a constant rate of 5 feet per second, then the circle's diameter is increasing at a constant rate of 10 feet per second.

54. Differentiating $y=1-x^2$ with respect to t gives

$$\frac{dy}{dt}=-2x\frac{dx}{dt}.$$

55. We want $dx/dt = g'(t)$ to be constant, so g can be any linear function of t, such as $g(t) = 5t$. Since $\frac{dy}{dt} = \frac{dy}{dx}\frac{dx}{dt}$, in order for dy/dt to be constant, we must also have dy/dx a constant. Choosing, for example, $f(x) = 2x + 1$ we have:

$$\frac{dx}{dt} = 5 \qquad \text{and} \qquad \frac{dy}{dt} = 2 \cdot \frac{dx}{dt} = 2(5) = 10.$$

There are many other possible solutions.

56. We want $dx/dt = g'(t)$ to be constant, so g can be any linear function of t, such as $g(t) = 5t$. If we choose f to be a linear function, then dy/dt will be constant. So we choose a function f which is not linear, such as $f(x) = x^2$. With $y = x^2$ and $x = 5t$, we have

$$\frac{dx}{dt} = 5 \qquad \text{and} \qquad \frac{dy}{dt} = \frac{dy}{dx} \cdot \frac{dx}{dt} = 2x(5) = 10t.$$

There are other possible examples.

57. True. The circumference C and radius r are related by $C = 2\pi r$, so $dC/dt = 2\pi dr/dt$. Thus if dr/dt is constant, so is dC/dt.

58. False. The circumference A and radius r are related by $A = \pi r^2$, so $dA/dt = 2\pi r dr/dt$. Thus dA/dt depends on r and since r is not constant, neither is dA/dt.

59. (c). Differentiating $x = 5\tan\theta$ gives

$$\frac{dx}{dt} = \frac{5}{\cos^2\theta}\frac{d\theta}{dt}.$$

Since the light rotates at 2 revolutions per minute $= 4\pi$ radians per minute, we know $d\theta/dt = 4\pi$. Thus, we can calculate dx/dt, the speed at which the spot is moving, for any angle θ.

Differentiating any of the other relationships introduces dr/dt, whose values we cannot find as easily as we can find $d\theta/dt$.

Solutions for Section 4.7

Exercises

1. Since $\lim_{x\to 2}(x-2) = \lim_{x\to 2}(x^2-4) = 0$, this is a $0/0$ form, and l'Hopital's rule applies:

$$\lim_{x\to 2}\frac{x-2}{x^2-4} = \lim_{x\to 2}\frac{1}{2x} = \frac{1}{4}.$$

2. Since $\lim_{x\to 1}(x^2+3x-4) = \lim_{x\to 1}(x-1) = 0$, this is a $0/0$ form, and l'Hopital's rule applies:

$$\lim_{x\to 1}\frac{x^2+3x-4}{x-1} = \lim_{x\to 1}\frac{2x+3}{1} = 5.$$

3. Since $\lim_{x\to 1}(x^6-1) = \lim_{x\to 1}(x^4-1) = 0$, this is a $0/0$ form, and l'Hopital's rule applies:

$$\lim_{x\to 1}\frac{x^6-1}{x^4-1} = \lim_{x\to 1}\frac{6x^5}{4x^3} = \frac{6}{4} = 1.5.$$

4. Since $\lim_{x\to 0}(e^x-1) = \lim_{x\to 0}(\sin x) = 0$, this is a $0/0$ form, and l'Hopital's rule applies:

$$\lim_{x\to 0}\frac{e^x-1}{\sin x} = \lim_{x\to 0}\frac{e^x}{\cos x} = \frac{1}{1} = 1.$$

5. Since the limit is not in the form $0/0$ or ∞/∞, l'Hopital's rule does not apply in this case. We have

$$\lim_{x\to 0}\frac{\sin x}{e^x} = \frac{0}{1} = 0.$$

6. Since $\lim_{x\to1}(\ln x) = \lim_{x\to1}(x-1) = 0$, this is a $0/0$ form, and l'Hopital's rule applies:

$$\lim_{x\to1} \frac{\ln x}{x-1} = \lim_{x\to1} \frac{(1/x)}{1} = \frac{1}{1} = 1.$$

7. Since $\lim_{x\to\infty}(\ln x) = \lim_{x\to\infty}(x) = \infty$, this is an ∞/∞ form, and l'Hopital's rule applies:

$$\lim_{x\to\infty} \frac{\ln x}{x} = \lim_{x\to\infty} \frac{(1/x)}{1} = 0.$$

8. Since $\lim_{x\to\infty}((\ln x)^3) = \lim_{x\to\infty}(x^2) = \infty$, this is an ∞/∞ form, and l'Hopital's rule applies. In fact, after applying l'Hopital's rule, we again obtain the ∞/∞ form. We apply l'Hopital's rule repeatedly, simplifying algebraically at each step:

$$\lim_{x\to\infty} \frac{(\ln x)^3}{x^2} = \lim_{x\to\infty} \frac{3(\ln x)^2(1/x)}{2x} = \lim_{x\to\infty} \frac{3(\ln x)^2}{2x^2} = \lim_{x\to\infty} \frac{6\ln x(1/x)}{4x} = \lim_{x\to\infty} \frac{6\ln x}{4x^2} = \lim_{x\to\infty} \frac{6/x}{8x} = \lim_{x\to\infty} \frac{6}{8x^2}.$$

The last limit has the form $6/\infty$ so the limit is 0.

9. Since $\lim_{x\to0}(e^{4x}-1) = 0$ and $\lim_{x\to0}(\cos x) = 1$, l'Hopital's rule does not apply in this case. We have

$$\lim_{x\to0} \frac{e^{4x}-1}{\cos x} = \frac{0}{1} = 0.$$

10. Since $\lim_{x\to1}(x^a-1) = \lim_{x\to1}(x^b-1) = 0$, this is a $0/0$ form, and l'Hopital's rule applies:

$$\lim_{x\to1} \frac{x^a-1}{x^b-1} = \lim_{x\to1} \frac{ax^{a-1}}{bx^{b-1}} = \frac{a}{b}.$$

11. Since $\lim_{x\to a}(\sqrt[3]{x} - \sqrt[3]{a}) = \lim_{x\to a}(x-a) = 0$, this is a $0/0$ form, and l'Hopital's rule applies:

$$\lim_{x\to a} \frac{\sqrt[3]{x} - \sqrt[3]{a}}{x-a} = \lim_{x\to a} \frac{(1/3)x^{-2/3}}{1} = \frac{1}{3}a^{-2/3}.$$

12. The larger power dominates. Using l'Hopital's rule

$$\begin{aligned} \lim_{x\to\infty} \frac{x^5}{0.1x^7} &= \lim_{x\to\infty} \frac{5x^4}{0.7x^6} = \lim_{x\to\infty} \frac{20x^3}{4.2x^5} \\ &= \lim_{x\to\infty} \frac{60x^2}{21x^4} = \lim_{x\to\infty} \frac{120x}{84x^3} = \lim_{x\to\infty} \frac{120}{252x^2} = 0 \end{aligned}$$

so $0.1x^7$ dominates.

13. We apply l'Hopital's rule twice to the ratio $50x^2/0.01x^3$:

$$\lim_{x\to\infty} \frac{50x^2}{0.01x^3} = \lim_{x\to\infty} \frac{100x}{0.03x^2} = \lim_{x\to\infty} \frac{100}{0.06x} = 0.$$

Since the limit is 0, we see that $0.01x^3$ is much larger than $50x^2$ as $x\to\infty$.

14. The power function dominates. Using l'Hopital's rule

$$\lim_{x\to\infty} \frac{\ln(x+3)}{x^{0.2}} = \lim_{x\to\infty} \frac{\frac{1}{(x+3)}}{0.2x^{-0.8}} = \lim_{x\to\infty} \frac{x^{0.8}}{0.2(x+3)}.$$

Using l'Hopital's rule again gives

$$\lim_{x\to\infty} \frac{x^{0.8}}{0.2(x+3)} = \lim_{x\to\infty} \frac{0.8x^{-0.2}}{0.2} = 0,$$

so $x^{0.2}$ dominates.

15. The exponential dominates. After 10 applications of l'Hopital's rule

$$\lim_{x\to\infty}\frac{x^{10}}{e^{0.1x}}=\lim_{x\to\infty}\frac{10x^9}{0.1e^{0.1x}}=\cdots=\lim_{x\to\infty}\frac{10!}{(0.1)^{10}e^{0.1x}}=0,$$

so $e^{0.1x}$ dominates.

Problems

16. Observe that both $f(4)$ and $g(4)$ are zero. Also, $f'(4)=1.4$ and $g'(4)=-0.7$, so by l'Hopital's rule,

$$\lim_{x\to 4}\frac{f(x)}{g(x)}=\frac{f'(4)}{g'(4)}=\frac{1.4}{-0.7}=-2.$$

17. Since $f'(a)>0$ and $g'(a)<0$, l'Hopital's rule tells us that

$$\lim_{x\to a}\frac{f(x)}{g(x)}=\frac{f'(a)}{g'(a)}<0.$$

18. Since $f'(a)<0$ and $g'(a)<0$, l'Hopital's rule tells us that

$$\lim_{x\to a}\frac{f(x)}{g(x)}=\frac{f'(a)}{g'(a)}>0.$$

19. Here $f(a)=g(a)=f'(a)=g'(a)=0$, and $f''(a)>0$ and $g''(a)<0$.

$$\lim_{x\to a}\frac{f(x)}{g(x)}=\lim_{x\to a}\frac{f'(x)}{g'(x)}=\frac{f''(a)}{g''(a)}<0$$

20. Note that $f(0)=g(0)=0$ and $f'(0)=g'(0)$. Since $x=0$ looks like a point of inflection for each curve, $f''(0)=g''(0)=0$. Therefore, applying l'Hopital's rule successively gives us

$$\lim_{x\to 0}\frac{f(x)}{g(x)}=\lim_{x\to 0}\frac{f'(x)}{g'(x)}=\lim_{x\to 0}\frac{f''(x)}{g''(x)}=\lim_{x\to 0}\frac{f'''(x)}{g'''(x)}.$$

Now notice how the concavity of f changes: for $x<0$, it is concave up, so $f''(x)>0$, and for $x>0$ it is concave down, so $f''(x)<0$. Thus $f''(x)$ is a decreasing function at 0 and so $f'''(0)$ is negative. Similarly, for $x<0$, we see g is concave down and for $x>0$ it is concave up, so $g''(x)$ is increasing at 0 and so $g'''(0)$ is positive. Consequently,

$$\lim_{x\to 0}\frac{f(x)}{g(x)}=\lim_{x\to 0}\frac{f'''(0)}{g'''(0)}<0.$$

21. The denominator approaches zero as x goes to zero and the numerator goes to zero even faster, so you should expect that the limit to be 0. You can check this by substituting several values of x close to zero. Alternatively, using l'Hopital's rule, we have

$$\lim_{x\to 0}\frac{x^2}{\sin x}=\lim_{x\to 0}\frac{2x}{\cos x}=0.$$

22. The numerator goes to zero faster than the denominator, so you should expect the limit to be zero. Using l'Hopital's rule, we have

$$\lim_{x\to 0}\frac{\sin^2 x}{x}=\lim_{x\to 0}\frac{2\sin x\cos x}{1}=0.$$

23. The denominator goes to zero more slowly than x does, so the numerator goes to zero faster than the denominator, so you should expect the limit to be zero. With l'Hopital's rule,

$$\lim_{x\to 0}\frac{\sin x}{x^{1/3}}=\lim_{x\to 0}\frac{\cos x}{\frac{1}{3}x^{-2/3}}=\lim_{x\to 0}3x^{2/3}\cos x=0.$$

24. The denominator goes to zero more slowly than x. Therefore, you should expect that the limit to be 0. Using l'Hopital's rule,

$$\lim_{x\to 0}\frac{x}{(\sin x)^{1/3}} = \lim_{x\to 0}\frac{1}{\frac{1}{3}(\sin x)^{-2/3}\cos x} = \lim_{x\to 0}\frac{3(\sin x)^{2/3}}{\cos x} = 0,$$

since $\sin 0 = 0$ and $\cos 0 = 1$.

25. Since $\lim_{x\to\infty} x = \lim_{x\to\infty} e^x = \infty$, this is an ∞/∞ form, and l'Hopital's rule applies directly.

26. We have $\lim_{x\to 1} x = 1$ and $\lim_{x\to 1}(x-1) = 0$, so l'Hopital's rule does not apply.

27. We have $\lim_{t\to\infty}(1/t) - (2/t^2) = 0 - 0 = 0$. This is not an indeterminate form and l'Hopital's rule does not apply.

28. We have $\lim_{t\to 0^+} 1/t = \lim_{t\to 0^+} 1/(e^t - 1) = \infty$, so this is an $\infty - \infty$ form. Adding the fractions we get

$$\lim_{t\to 0^+}\frac{e^t - 1 - t}{t(e^t - 1)},$$

which is a $0/0$ form to which l'Hopital's rule can be applied.

29. We have $\lim_{x\to 0}(1+x)^x = (1+0)^0 = 1$. This is not an indeterminate form and l'Hopital's rule does not apply.

30. This is an ∞^0 form. With $y = \lim_{x\to\infty}(1+x)^{1/x}$, we take logarithms to get

$$\ln y = \lim_{x\to\infty}\frac{1}{x}\ln(1+x).$$

This limit is a $0\cdot\infty$ form,

$$\lim_{x\to\infty}\frac{1}{x}\ln(1+x),$$

which can be rewritten as the ∞/∞ form

$$\lim_{x\to\infty}\frac{\ln(1+x)}{x},$$

to which l'Hopital's rule applies.

31. Let $f(x) = \ln x$ and $g(x) = x^2 - 1$, so $f(1) = 0$ and $g(1) = 0$ and l'Hopital's rule can be used. To apply l'Hopital's rule, we first find $f'(x) = 1/x$ and $g'(x) = 2x$, then

$$\lim_{x\to 1}\frac{\ln x}{x^2 - 1} = \lim_{x\to 1}\frac{1/x}{2x} = \lim_{x\to 1}\frac{1}{2x^2} = \frac{1}{2}.$$

32. Let $f(t) = \sin^2 t$ and $g(t) = t - \pi$, then $f(\pi) = 0$ and $g(\pi) = 0$ but $f'(t) = 2\sin t\cos t$ and $g'(t) = 1$, so $f'(\pi) = 0$ and $g'(\pi) = 1$. L'Hopital's rule can be used, giving

$$\lim_{t\to\pi}\frac{\sin^2 t}{t - \pi} = \frac{0}{1} = 0.$$

33. Rewriting this as $\lim\limits_{n\to\infty} n^{1/n}$, we see that it is an ∞^0 form. The logarithm of the limit is

$$\lim_{n\to\infty}\frac{1}{n}\ln n = \lim_{n\to\infty}\frac{\ln n}{n} = \lim_{n\to\infty}\frac{1/n}{1} = 0.$$

Thus the original limit is $e^0 = 1$.

34. Let $f(x) = \ln x$ and $g(x) = 1/x$ so $f'(x) = 1/x$ and $g'(x) = -1/x^2$ and

$$\lim_{x\to 0^+}\frac{\ln x}{1/x} = \lim_{x\to 0^+}\frac{1/x}{-1/x^2} = \lim_{x\to 0^+}\frac{x}{-1} = 0.$$

35. If $f(x) = \sinh(2x)$ and $g(x) = x$, then $f(0) = g(0) = 0$, so we use l'Hopital's Rule:

$$\lim_{x\to 0}\frac{\sinh 2x}{x} = \lim_{x\to 0}\frac{2\cosh 2x}{1} = 2.$$

36. If $f(x) = 1 - \cosh(3x)$ and $g(x) = x$, then $f(0) = g(0) = 0$, so we use l'Hopital's Rule:

$$\lim_{x\to 0} \frac{1-\cosh 3x}{x} = \lim_{x\to 0} \frac{-3\sinh 3x}{1} = 0.$$

37. Since $\cos 0 = 1$, we have $\cos^{-1}(1) = 0$ and $\lim_{x\to 1^{-1}} \cos^{-1} x = 0$. Therefore, both $\cos^{-1} x$ and $(x-1)$ tend to 0 as $x \to 1^-$, so l'Hopital's rule can be applied. Let $f(x) = \cos^{-1} x$ and $g(x) = x - 1$, and differentiate to get $f'(x) = -1/\sqrt{1-x^2}$ and $g'(x) = 1$. Applying l'Hopital's rule gives

$$\begin{aligned}\lim_{x\to 1^-} \frac{\cos^{-1} x}{x-1} &= \lim_{x\to 1^-} \frac{-1/\sqrt{1-x^2}}{1}\\ &= \lim_{x\to 1^-} \frac{-1}{\sqrt{1-x^2}}.\end{aligned}$$

However, $\sqrt{1-x^2} \to 0$ as $x \to 1^-$, so the limit does not exist.

38. To get this expression in a form in which l'Hopital's rule applies, we combine the fractions:

$$\frac{1}{x} - \frac{1}{\sin x} = \frac{\sin x - x}{x \sin x}.$$

Letting $f(x) = \sin x - x$ and $g(x) = x\sin x$, we have $f(0) = 0$ and $g(0) = 0$ so l'Hopital's rule can be used. Differentiating gives $f'(x) = \cos x - 1$ and $g'(x) = x\cos x + \sin x$, so $f'(0) = 0$ and $g'(0) = 0$, so $f'(0)/g'(0)$ is undefined. Therefore, to apply l'Hopital's rule we differentiate again to obtain $f''(x) = -\sin x$ and $g''(x) = 2\cos x - x\sin x$, for which $f''(0) = 0$ and $g''(0) = 2 \neq 0$. Then

$$\begin{aligned}\lim_{x\to 0}\left(\frac{1}{x} - \frac{1}{\sin x}\right) &= \lim_{x\to 0}\left(\frac{\sin x - x}{x\sin x}\right)\\ &= \lim_{x\to 0}\left(\frac{\cos x - 1}{x\cos x + \sin x}\right)\\ &= \lim_{x\to 0}\left(\frac{-\sin x}{2\cos x - x\sin x}\right)\\ &= \frac{0}{2} = 0.\end{aligned}$$

39. Adding the fractions, we get

$$\lim_{t\to 0^+}\left(\frac{2}{t} - \frac{1}{e^t - 1}\right) = \lim_{t\to 0^+} \frac{2e^t - 2 - t}{t(e^t-1)} = \lim_{t\to 0^+} \frac{2e^t - 1}{e^t + te^t - 1} = \frac{1}{0} = \infty.$$

Note that the limit is ∞, not $-\infty$ because $e^t > 1$ for $t > 0$, so the denominator is always positive.

40. Adding the fractions and applying l'Hopital's rule, we get

$$\lim_{t\to 0}\left(\frac{1}{t} - \frac{1}{e^t - 1}\right) = \lim_{t\to 0} \frac{e^t - 1 - t}{t(e^t - 1)} = \lim_{t\to 0} \frac{e^t - 1}{e^t + te^t - 1}.$$

This is again a $0/0$ form, so we apply l'Hopital's rule again to get

$$\lim_{t\to 0} \frac{e^t - 1}{e^t + te^t - 1} = \lim_{t\to 0} \frac{e^t}{2e^t + te^t} = \frac{1}{2}$$

41. Let $y = (1 + \sin 3/x)^x$. Taking logs gives

$$\ln y = x \ln\left(1 + \sin \frac{3}{x}\right).$$

To use l'Hopital's rule, we rewrite $\ln y$ as a fraction:

$$\begin{aligned}\lim_{x\to\infty} \ln y &= \lim_{x\to\infty} x \ln\left(1 + \sin\left(\frac{3}{x}\right)\right) \\ &= \lim_{x\to\infty} \frac{\ln(1+\sin(3/x))}{1/x}.\end{aligned}$$

Let $f(x) = \ln(1 + \sin(3/x))$ and $g(x) = 1/x$ then

$$f'(x) = \frac{\cos(3/x)(-3/x^2)}{(1+\sin(3/x))} \quad \text{and} \quad g'(x) = -\frac{1}{x^2}.$$

Now apply l'Hopital's rule to get

$$\begin{aligned}\lim_{x\to\infty} \ln y &= \lim_{x\to\infty} \frac{f(x)}{g(x)} \\ &= \lim_{x\to\infty} \frac{f'(x)}{g'(x)} \\ &= \lim_{x\to\infty} \frac{\cos(3/x)(-3/x^2)/(1+\sin(3/x))}{-1/x^2} \\ &= \lim_{x\to\infty} \frac{3\cos(3/x)}{1+\sin(3/x)} = \frac{3\cos 0}{1+\sin 0} \\ &= 3.\end{aligned}$$

Since $\lim_{x\to\infty} \ln y = 3$, we have

$$\lim_{x\to\infty} y = e^3.$$

Thus,

$$\lim_{x\to\infty} \left(1 + \sin\frac{3}{x}\right)^x = e^3.$$

42. Since $\lim_{t\to 0} \sin^2 At = 0$ and $\lim_{t\to 0} \cos At - 1 = 1 - 1 = 0$, this is a $0/0$ form. Applying l'Hopital's rule we get

$$\lim_{t\to 0} \frac{\sin^2 At}{\cos At - 1} = \lim_{t\to 0} \frac{2A\sin At\cos At}{-A\sin At} = \lim_{t\to 0} -2\cos At = -2.$$

43. We rewrite this in the form

$$\lim_{t\to\infty} e^t - t^n = \lim_{t\to\infty} e^t\left(1 - \frac{t^n}{e^t}\right).$$

From Example 5 on page 244 of the text, with $k = A = 1$ and $p = n$, we know that e^t dominates t^n, so

$$\lim_{t\to\infty} e^t\left(1 - \frac{t^n}{e^t}\right) = \infty \cdot (1 - 0) = \infty.$$

44. To get this expression in a form in which l'Hopital's rule applies, we rewrite it as a fraction:

$$x^a \ln x = \frac{\ln x}{x^{-a}}.$$

Letting $f(x) = \ln x$ and $g(x) = x^{-a}$, we have

$$\lim_{x\to 0^+} f(x) = \lim_{x\to 0^+} \ln x = -\infty, \quad \text{and} \quad \lim_{x\to 0^+} g(x) = \lim_{x\to 0^+} \frac{1}{x^a} = \infty.$$

So l'Hopital's rule can be used. To apply l'Hopital's rule we differentiate to get $f'(x) = 1/x$ and $g'(x) = -ax^{-a-1}$. Then

$$\begin{aligned}\lim_{x\to0^+} x^a \ln x &= \lim_{x\to0^+} \frac{\ln x}{x^{-a}}\\ &= \lim_{x\to0^+} \frac{1/x}{-ax^{-a-1}}\\ &= -\frac{1}{a}\lim_{x\to0^+} x^a\\ &= 0.\end{aligned}$$

45. Let $f(x) = \sin(2x)$ and $g(x) = x$. Observe that $f(1) = \sin 2 \neq 0$ and $g(1) = 1 \neq 0$. Therefore l'Hopital's rule does not apply. However,

$$\lim_{x\to1} \frac{\sin 2x}{x} = \frac{\sin 2}{1} = 0.909297.$$

46. Let $f(x) = \cos x$ and $g(x) = x$. Observe that since $f(0) = 1$, l'Hopital's rule does not apply. But since $g(0) = 0$,

$$\lim_{x\to0} \frac{\cos x}{x} \quad \text{does not exist.}$$

47. Let $f(x) = e^{-x}$ and $g(x) = \sin x$. Observe that as x increases, $f(x)$ approaches 0 but $g(x)$ oscillates between -1 and 1. Since $g(x)$ does not approach 0 in the limit, l'Hopital's rule does not apply. Because $g(x)$ is in the denominator and oscillates through 0 forever, the limit does not exist.

48. Let $n = 1/x$, so $n \to \infty$ as $x \to 0^+$. Thus

$$\lim_{x\to0^+} (1+x)^{1/x} = \lim_{n\to\infty} \left(1+\frac{1}{n}\right)^n = e.$$

49. Let $k = n/2$, so $k \to \infty$ as $n \to \infty$. Thus,

$$\lim_{n\to\infty} \left(1+\frac{2}{n}\right)^n = \lim_{k\to\infty} \left(1+\frac{1}{k}\right)^{2k} = \lim_{k\to\infty} \left(\left(1+\frac{1}{k}\right)^k\right)^2 = e^2.$$

50. Let $n = 1/(kx)$, so $n \to \infty$ as $x \to 0^+$. Thus

$$\lim_{x\to0^+} (1+kx)^{t/x} = \lim_{n\to\infty} \left(1+\frac{1}{n}\right)^{nkt} = \lim_{n\to\infty} \left(\left(1+\frac{1}{n}\right)^n\right)^{kt} = e^{kt}.$$

51. Let

$$y = \left(1-\frac{1}{n}\right)^n.$$

Then

$$\ln y = \ln\left(1-\frac{1}{n}\right)^n = n\ln\left(1-\frac{1}{n}\right) = \frac{\ln(1-1/n)}{1/n}.$$

As $n \to \infty$, both the numerator and the denominator of the last fraction tend to 0. Thus, applying L'Hopital's rule, we have

$$\lim_{n\to\infty} \frac{\ln(1-1/n)}{1/n} = \lim_{n\to\infty} \frac{\frac{1}{1-1/n}\cdot\frac{1}{n^2}}{-1/n^2} = \lim_{n\to\infty} -\frac{1}{1-1/n} = -1.$$

Thus,

$$\lim_{n\to\infty} \ln y = -1$$
$$\lim_{n\to\infty} y = e^{-1},$$

so

$$\lim_{n\to\infty} \left(1-\frac{1}{n}\right) = e^{-1}.$$

52. Let $k = n/\lambda$, so $k \to \infty$ as $n \to \infty$. Thus

$$\lim_{n\to\infty}\left(1-\frac{\lambda}{n}\right)^n = \lim_{k\to\infty}\left(1-\frac{1}{k}\right)^{k\lambda} = \lim_{k\to\infty}\left(\left(1-\frac{1}{k}\right)^k\right)^\lambda = (e^{-1})^\lambda = e^{-\lambda}.$$

53. This limit is of the form 0^0 so we apply l'Hopital's rule to

$$\ln f(t) = \frac{\ln\left((3^t+5^t)/2\right)}{t}.$$

We have

$$\begin{aligned}
\lim_{t\to-\infty}\ln f(t) &= \lim_{t\to-\infty}\frac{\left((\ln 3)3^t+(\ln 5)5^t\right)/\left(3^t+5^t\right)}{1}\\
&= \lim_{t\to-\infty}\frac{(\ln 3)3^t+(\ln 5)5^t}{3^t+5^t}\\
&= \lim_{t\to-\infty}\frac{\ln 3+(\ln 5)(5/3)^t}{1+(5/3)^t}\\
&= \frac{\ln 3+0}{1+0} = \ln 3.
\end{aligned}$$

Thus

$$\lim_{t\to-\infty} f(t) = \lim_{t\to-\infty} e^{\ln f(t)} = e^{\lim_{t\to-\infty}\ln f(t)} = e^{\ln 3} = 3.$$

54. This limit is of the form ∞^0 so we apply l'Hopital's rule to

$$\ln f(t) = \frac{\ln\left((3^t+5^t)/2\right)}{t}.$$

We have

$$\begin{aligned}
\lim_{t\to+\infty}\ln f(t) &= \lim_{t\to+\infty}\frac{\left((\ln 3)3^t+(\ln 5)5^t\right)/\left(3^t+5^t\right)}{1}\\
&= \lim_{t\to+\infty}\frac{(\ln 3)3^t+(\ln 5)5^t}{3^t+5^t}\\
&= \lim_{t\to+\infty}\frac{(\ln 3)(3/5)^t+\ln 5}{(3/5)^t+1}\\
&= \lim_{t\to+\infty}\frac{0+\ln 5}{0+1} = \ln 5.
\end{aligned}$$

Thus

$$\lim_{t\to-\infty} f(t) = \lim_{t\to-\infty} e^{\ln f(t)} = e^{\lim_{t\to-\infty}\ln f(t)} = e^{\ln 5} = 5.$$

55. This limit is of the form 1^∞ so we apply l'Hopital's rule to

$$\ln f(t) = \frac{\ln\left((3^t+5^t)/2\right)}{t}.$$

We have

$$\begin{aligned}
\lim_{t\to 0}\ln f(t) &= \lim_{t\to 0}\frac{\left((\ln 3)3^t+(\ln 5)5^t\right)/\left(3^t+5^t\right)}{1}\\
&= \lim_{t\to 0}\frac{(\ln 3)3^t+(\ln 5)5^t}{3^t+5^t}\\
&= \frac{\ln 3+\ln 5}{1+1} = \frac{\ln 15}{2}.
\end{aligned}$$

Thus

$$\lim_{t\to-\infty} f(t) = \lim_{t\to-\infty} e^{\ln f(t)} = e^{\lim_{t\to-\infty}\ln f(t)} = e^{(\ln 15)/2} = \sqrt{15}.$$

56. To evaluate, we use l'Hopital's Rule:

$$\lim_{x\to 0}\frac{\sinh 2x}{x}=\lim_{x\to 0}\frac{2\cosh 2x}{1}=2.$$

57. To evaluate, we use l'Hopital's Rule:

$$\lim_{x\to 0}\frac{1-\cosh 3x}{x}=\lim_{x\to 0}\frac{-3\sinh 3x}{1}=0.$$

58. To evaluate, we use l'Hopital's Rule:

$$\lim_{x\to 0}\frac{1-\cosh 5x}{x^2}=\lim_{x\to 0}\frac{-5\sinh 5x}{2x}=\lim_{x\to 0}\frac{-25\cosh 5x}{2}=-25/2.$$

59. To evaluate, we use l'Hopital's Rule:

$$\lim_{x\to 0}\frac{x-\sinh x}{x^3}=\lim_{x\to 0}\frac{1-\cosh x}{3x^2}=\lim_{x\to 0}\frac{-\sinh x}{6x}=\lim_{x\to 0}\frac{-\cosh x}{6}=-1/6.$$

60. Since the limit is of the form $0/0$, we can apply l'Hopital's rule. Doing it twice we have

$$\begin{aligned}\lim_{x\to 0}\frac{e^x-1-\ln(1+x)}{x^2}&=\lim_{x\to 0}\frac{e^x-1/(1+x)}{2x}\\&=\lim_{x\to 0}\frac{e^x+1/(1+x)^2}{2}=\frac{1+1}{2}=1.\end{aligned}$$

61. Since the limit is of the form $0/0$, we can apply l'Hopital's rule. We have

$$\lim_{x\to \pi/2}\frac{1-\sin x+\cos x}{\sin x+\cos x-1}=\lim_{x\to \pi/2}\frac{-\cos x-\sin x}{\cos x-\sin x}=\frac{-1}{-1}=1.$$

62. Since the limit is of the form $0/0$, we can apply l'Hopital's rule. First note that

$$\frac{dx^x}{dx}=\frac{de^{x\ln x}}{dx}=e^{x\ln x}\left(x\cdot\frac{1}{x}+1\cdot\ln x\right)=x^x+x^x\ln x.$$

Applying l'Hopital's rule twice we have

$$\begin{aligned}\lim_{x\to 1}\frac{x^x-x}{1-x+\ln x}&=\lim_{x\to 1}\frac{x^x+x^x\ln x-1}{-1+1/x}\\&=\lim_{x\to 1}\frac{x^x+x^x\ln x+(x^x+x^x\ln x)\ln x+x^x(1/x)}{-1/x^2}=\frac{1+0+0+1}{-1}=-2.\end{aligned}$$

Strengthen Your Understanding

63. There is no such n because the function e^x dominates x^n for every n, no matter how large. This means that for any n, the values of e^x are much larger than the values of x^n for large x. Thus, x^n cannot dominate e^x.

To see why e^x dominates x^n for all positive integers n, let $f(x)=x^n$ and $g(x)=e^x$. Then $\lim_{x\to\infty} f(x)=\infty$ and $\lim_{x\to\infty} g(x)=\infty$ so we apply l'Hopital's rule:

$$\begin{aligned}\lim_{x\to\infty}\frac{x^n}{e^x}=\lim_{x\to\infty}\frac{f(x)}{g(x)}&=\lim_{x\to\infty}\frac{f'(x)}{g'(x)}\\&=\lim_{x\to\infty}\frac{nx^{n-1}}{e^x}\\&=\lim_{x\to\infty}\frac{n\cdot(n-1)x^{n-2}}{e^x}\\&\vdots\\&=\lim_{x\to\infty}\frac{n!}{e^x}=0\end{aligned}$$

so e^x dominates x^n for all positive integers n.

64. If $f(x) = 5x + \cos x$ and $g(x) = x$, we have $\lim_{x\to\infty} f(x) = \infty$ and $\lim_{x\to\infty} g(x) = \infty$, so we try to use l'Hopital's rule:

$$\lim_{x\to\infty} \frac{5x + \cos x}{x} = \lim_{x\to\infty} \frac{f(x)}{g(x)} = \lim_{x\to\infty} \frac{f'(x)}{g'(x)} = \lim_{x\to\infty} \frac{5 - \sin x}{1}.$$

However, $\lim_{x\to\infty} 5 - \sin x$ does not exist, so l'Hopital's rule is not applicable.

65. When finding $\lim_{x\to a} f(x)/g(x)$, we can only apply l'Hopital's rule if $f(a) = g(a) = 0$ or $\lim_{x\to a} f(x) = \pm\infty$ and $\lim_{x\to a} g(x) = \pm\infty$. Thus, there are many examples of limits of rational functions to which l'Hopital's rule cannot be applied. One example is $\lim_{x\to 0} \frac{x+1}{x+2}$.

66. Since $\lim_{x\to\infty} \ln x = \infty$, if $\lim_{x\to\infty} f(x) = \pm\infty$ we could apply L'Hopital's rule to try to find $\lim_{x\to\infty} \frac{f(x)}{\ln x}$. One possible example is $f(x) = x$.

67. False. To use l'Hopital's rule, we need $f(a) = g(a) = 0$. For example, if $f(x) = 3$ and $g(x) = x$, then $g(1) = 1$ and $f'(1)/g'(1) = 0/1 = 0$, but $\lim_{x\to 1}(f(x)/g(x)) = 3/1 = 3$.

Solutions for Section 4.8

Exercises

1. Between times $t = 0$ and $t = 1$, x goes at a constant rate from 0 to 1 and y goes at a constant rate from 1 to 0. So the particle moves in a straight line from $(0, 1)$ to $(1, 0)$. Similarly, between times $t = 1$ and $t = 2$, it goes in a straight line to $(0, -1)$, then to $(-1, 0)$, then back to $(0, 1)$. So it traces out the diamond shown in Figure 4.121.

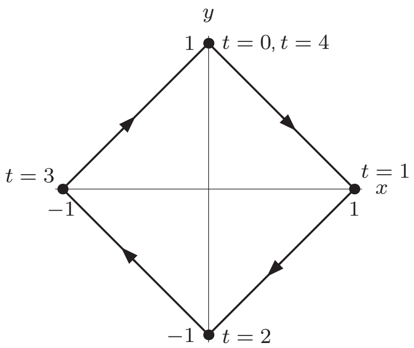

Figure 4.121

2. This is like Example 2, except that the x-coordinate goes all the way to 2 and back. So the particle traces out the rectangle shown in Figure 4.122.

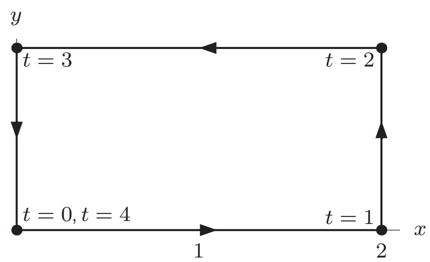

Figure 4.122

3. As the x-coordinate goes at a constant rate from 2 to 0, the y-coordinate goes from 0 to 1, then down to -1, then back to 0. So the particle zigs and zags from $(2, 0)$ to $(1.5, 1)$ to $(1, 0)$ to $(.5, -1)$ to $(0, 0)$. Then it zigs and zags back again, forming the shape in Figure 4.123.

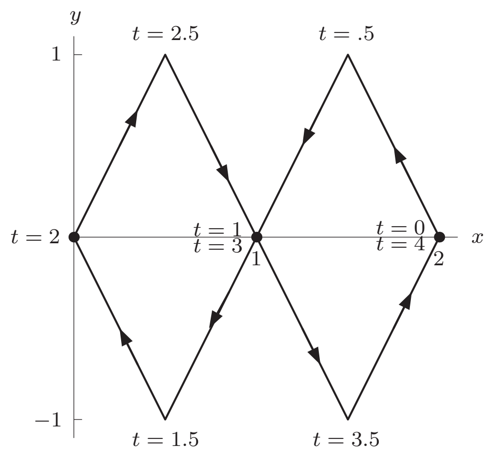

Figure 4.123

4. Between times $t = 0$ and $t = 1$, x goes from -1 to 1, while y stays fixed at 1. So the particle goes in a straight line from $(-1, 1)$ to $(1, 1)$. Then both the x- and y-coordinates decrease at a constant rate from 1 to -1. So the particle goes in a straight line from $(1, 1)$ to $(-1, -1)$. Then it moves across to $(1, -1)$, then back diagonally to $(-1, 1)$. See Figure 4.124.

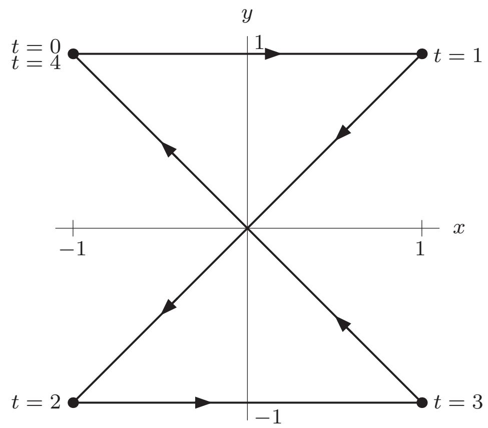

Figure 4.124

5. One possible answer is $x = 3\cos t, y = -3\sin t, 0 \le t \le 2\pi$.

6. One possible answer is $x = -2, y = t$.

7. One possible answer is $x = 2 + 5\cos t, y = 1 + 5\sin t, 0 \le t \le 2\pi$.

8. The parameterization $x = 2\cos t$, $y = 2\sin t$, $0 \le t \le 2\pi$, is a circle of radius 2 traced out counterclockwise starting at the point $(2, 0)$. To start at $(-2, 0)$, put a negative in front of the first coordinate

$$x = -2\cos t \quad y = 2\sin t, \qquad 0 \le t \le 2\pi.$$

Now we must check whether this parameterization traces out the circle clockwise or counterclockwise. Since when t increases from 0, $\sin t$ is positive, the point (x, y) moves from $(-2, 0)$ into the second quadrant. Thus, the circle is traced out clockwise and so this is one possible parameterization.

9. The slope of the line is

$$m = \frac{3-(-1)}{1-2} = -4.$$

The equation of the line with slope -4 through the point $(2,-1)$ is $y-(-1)=(-4)(x-2)$, so one possible parameterization is $x=t$ and $y=-4t+8-1=-4t+7$.

10. The ellipse $x^2/25+y^2/49=1$ can be parameterized by $x=5\cos t, y=7\sin t, 0\le t\le 2\pi$.

11. The parameterization $x=-3\cos t$, $y=7\sin t$, $0\le t\le 2\pi$, starts at the right point but sweeps out the ellipse in the wrong direction (the y-coordinate becomes positive as t increases). Thus, a possible parameterization is $x=-3\cos(-t)=-3\cos t, y=7\sin(-t)=-7\sin t, 0\le t\le 2\pi$.

12. For $0\le t\le \frac{\pi}{2}$, we have $x=\sin t$ increasing and $y=\cos t$ decreasing, so the motion is clockwise for $0\le t\le\frac{\pi}{2}$. Similarly, we see that the motion is clockwise for the time intervals $\frac{\pi}{2}\le t\le\pi, \pi\le t\le\frac{3\pi}{2}$, and $\frac{3\pi}{2}\le t\le 2\pi$.

13. The particle moves clockwise: For $0\le t\le\frac{\pi}{2}$, we have $x=\cos t$ decreasing and $y=-\sin t$ decreasing. Similarly, for the time intervals $\frac{\pi}{2}\le t\le\pi, \pi\le t\le\frac{3\pi}{2}$, and $\frac{3\pi}{2}\le t\le 2\pi$, we see that the particle moves clockwise.

14. Let $f(t)=t^2$. The particle is moving clockwise when $f(t)$ is decreasing, that is, when $f'(t)=2t<0$, so when $t<0$. The particle is moving counterclockwise when $f'(t)=2t>0$, so when $t>0$.

15. Let $f(t)=t^3-t$. The particle is moving clockwise when $f(t)$ is decreasing, that is, when $f'(t)=3t^2-1<0$, and counterclockwise when $f'(t)=3t^2-1>0$. That is, it moves clockwise when $-\sqrt{\frac{1}{3}}<t<\sqrt{\frac{1}{3}}$, between $(\cos((-\sqrt{\frac{1}{3}})^3+\sqrt{\frac{1}{3}}), \sin((-\sqrt{\frac{1}{3}})^3+\sqrt{\frac{1}{3}}))$ and $(\cos((\sqrt{\frac{1}{3}})^3-\sqrt{\frac{1}{3}}), \sin((\sqrt{\frac{1}{3}})^3-\sqrt{\frac{1}{3}})$, and counterclockwise when $t<-\sqrt{\frac{1}{3}}$ or $t>\sqrt{\frac{1}{3}}$.

16. Let $f(t)=\ln t$. Then $f'(t)=\frac{1}{t}$. The particle is moving counterclockwise when $f'(t)>0$, that is, when $t>0$. Any other time, when $t\le 0$, the position is not defined.

17. Let $f(t)=\cos t$. Then $f'(t)=-\sin t$. The particle is moving clockwise when $f'(t)<0$, or $-\sin t<0$, that is, when

$$2k\pi<t<(2k+1)\pi,$$

where k is an integer. The particle is otherwise moving counterclockwise, that is, when

$$(2k-1)\pi<t<2k\pi,$$

where k is an integer. Actually, the particle does not fully trace out a circle. The range of $f(t)$ is $[-1,1]$ so the particle oscillates between the points $(\cos(-1),\sin(-1))$ and $(\cos 1,\sin 1)$.

18. The circle $(x-2)^2+(y-2)^2=1$.

19. The line segment $y+x=4$, for $1\le x\le 3$.

20. The parabola $y=(x-2)^2$, for $1\le x\le 3$.

21. We see from the parametric equations that the particle moves along a line. It suffices to plot two points: at $t=0$, the particle is at point $(1,-4)$, and at $t=1$, the particle is at point $(4,-3)$. Since x increases as t increases, the motion is left to right on the line as shown in Figure 4.125.

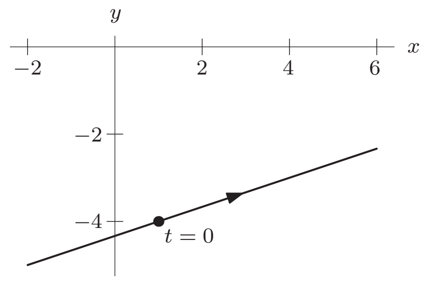

Figure 4.125

Alternately, we can solve the first equation for t, giving $t=(x-1)/3$, and substitute this into the second equation to get

$$y=\frac{x-1}{3}-4=\frac{1}{3}x-\frac{13}{3}.$$

The line is $y=\frac{1}{3}x-\frac{13}{3}$.

22. If we eliminate the parameter t, we see that

$$y = (x - 3) - 2 = x - 5.$$

Thus, the particle moves along a line. Notice, however, that $t^2 + 3 \geq 3$ and so $x \geq 3$. Similarly, $y \geq -2$. The graph is the ray, or half-line, shown in Figure 4.126.

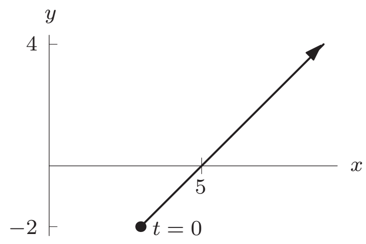

Figure 4.126

Notice that at $t = 0$, the particle is at point $(3, -2)$, at $t = 1$, the particle is at point $(4, -1)$, and at $t = -1$, the particle is at point $(4, -1)$. The particle is at the endpoint of the ray when $t = 0$. As t increases through negative t values, the particle moves down the ray toward the point $(3, -2)$. At $t = 0$, it changes direction. As t increases through positive t values, the particle moves up the ray again.

23. The Cartesian equation of the motion is obtained by eliminating the parameter t, giving

$$y = (x - 4)^2 - 3 = x^2 - 8x + 13.$$

The graph of this parabola is shown in Figure 4.127. At $t = 0$, the particle is at the vertex of the parabola $(4, -3)$, and the motion is left to right since x increases steadily as t increases.

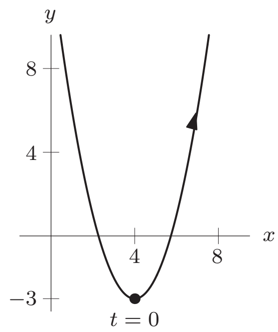

Figure 4.127

24. The graph is a circle centered at the origin with radius 1. The equation is

$$x^2 + y^2 = (\cos 3t)^2 + (\sin 3t)^2 = 1.$$

The particle is at the point $(1, 0)$ when $t = 0$, and motion is counterclockwise. See Figure 4.128.

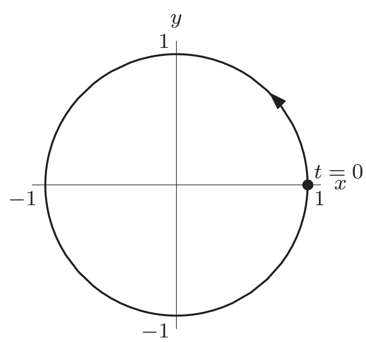

Figure 4.128

25. The graph is a circle centered at the origin with radius 3. The equation is

$$x^2 + y^2 = (3\cos t)^2 + (3\sin t)^2 = 9.$$

The particle is at the point $(3, 0)$ when $t = 0$, and motion is counterclockwise. See Figure 4.129.

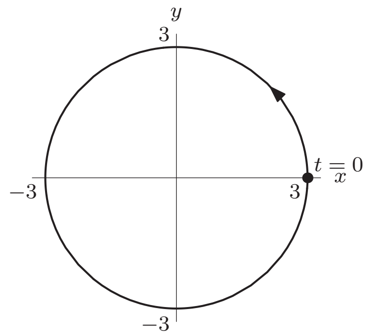

Figure 4.129

26. The graph is a circle centered at the point $(2, 7)$ with radius 5. The equation is

$$(x-2)^2 + (y-7)^2 = (5\cos t)^2 + (5\sin t)^2 = 25.$$

The particle is at the point $(7, 7)$ when $t = 0$, and motion is counterclockwise. See Figure 4.130.

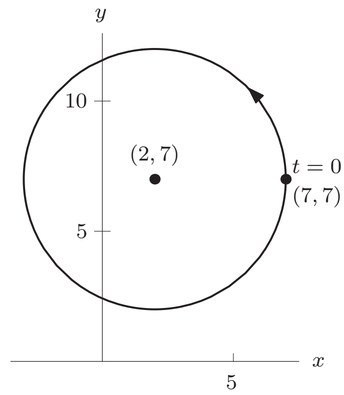

Figure 4.130

27. We have

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{2t}{3t^2 - 1}.$$

Thus when $t = 2$, the slope of the tangent line is $4/11$. Also when $t = 2$, we have

$$x = 2^3 - 2 = 6, \quad y = 2^2 = 4.$$

Therefore the equation of the tangent line is

$$(y - 4) = \frac{4}{11}(x - 6).$$

28. We have

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{2t+2}{2t-2}.$$

When $t = 1$, the denominator is zero and the numerator is nonzero, so the tangent line is vertical. Since $x = -1$ when $t = 1$, the equation of the tangent line is $x = -1$.

29. We have
$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{4\cos(4t)}{3\cos(3t)}.$$
Thus when $t = \pi$, the slope of the tangent line is $-4/3$. Since $x = 0$ and $y = 0$ when $t = \pi$, the equation of the tangent line is $y = -(4/3)x$.

30. We have $dx/dt = 2t$ and $dy/dt = 3t^2$. Therefore, the speed of the particle is
$$v = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} = \sqrt{((2t)^2 + (3t^2)^2)} = |t| \cdot \sqrt{(4 + 9t^2)}.$$
The particle comes to a complete stop when its speed is 0, that is, if $t\sqrt{4 + 9t^2} = 0$, and so when $t = 0$.

31. We have $dx/dt = -2t\sin(t^2)$ and $dy/dt = 2t\cos(t^2)$. Therefore, the speed of the particle is given by
$$\begin{aligned} v &= \sqrt{(-2t\sin(t^2))^2 + (2t\cos(t^2))^2} \\ &= \sqrt{4t^2(\sin(t^2))^2 + 4t^2(\cos(t^2))^2} \\ &= 2|t|\sqrt{\sin^2(t^2) + \cos^2(t^2)} \\ &= 2|t|. \end{aligned}$$
The particle comes to a complete stop when speed is 0, that is, if $2|t| = 0$, and so when $t = 0$.

32. We have
$$\frac{dx}{dt} = -2\sin 2t, \frac{dy}{dt} = \cos t.$$
The speed is
$$v = \sqrt{4\sin^2(2t) + \cos^2 t}.$$
Thus, $v = 0$ when $\sin(2t) = \cos t = 0$, and so the particle stops when $t = \pm\pi/2, \pm 3\pi/2, \ldots$ or $t = (2n+1)\frac{\pi}{2}$, for any integer n.

33. We have
$$\frac{dx}{dt} = 2t - 4, \quad \frac{dy}{dt} = 3t^2 - 12.$$
The speed is given by:
$$v = \sqrt{(2t-4)^2 + (3t^2 - 12)^2}.$$
The particle stops when $2t - 4 = 0$ and $3t^2 - 12 = 0$. Since these are both satisfied only by $t = 2$, this is the only time that the particle stops.

34. At $t = 2$, the position is $(2^2, 2^3) = (4, 8)$, the velocity in the x-direction is $2 \cdot 2 = 4$, and the velocity in the y-direction is $3 \cdot 2^2 = 12$. So we want the line going through the point $(4, 8)$, with the given x- and y-velocities:
$$x = 4 + 4t, \quad y = 8 + 12t.$$

Problems

35. The graphs are in Figure 4.131.

Figure 4.131

36. The graphs are in Figure 4.132.

Figure 4.132

37. (a) We get the part of the line with $x < 10$ and $y < 0$.
(b) We get the part of the line between the points $(10, 0)$ and $(11, 2)$.

38. (a) If $t \geq 0$, we have $x \geq 2, y \geq 4$, so we get the part of the line to the right of and above the point $(2, 4)$.
(b) When $t = 0$, $(x, y) = (2, 4)$. When $t = -1$, $(x, y) = (-1, -3)$. Restricting t to the interval $-1 \leq t \leq 0$ gives the part of the line between these two points.
(c) If $x < 0$, giving $2 + 3t < 0$ or $t < -2/3$. Thus $t < -2/3$ gives the points on the line to the left of the y-axis.

39. (a) Eliminating t between

$$x = 2 + t, \quad y = 4 + 3t$$

gives

$$y - 4 = 3(x - 2),$$
$$y = 3x - 2.$$

Eliminating t between

$$x = 1 - 2t, \quad y = 1 - 6t$$

gives

$$y - 1 = 3(x - 1),$$
$$y = 3x - 2.$$

Since both parametric equations give rise to the same equation in x and y, they both parameterize the same line.
(b) Slope $= 3$, $\quad y$-intercept $= -2$.

40. In all three cases, $y = x^2$, so that the motion takes place on the parabola $y = x^2$.

In case (a), the x-coordinate always increases at a constant rate of one unit distance per unit time, so the equations describe a particle moving to the right on the parabola at constant horizontal speed.

In case (b), the x-coordinate is never negative, so the particle is confined to the right half of the parabola. As t moves from $-\infty$ to $+\infty$, $x = t^2$ goes from ∞ to 0 to ∞. Thus the particle first comes down the right half of the parabola, reaching the origin $(0, 0)$ at time $t = 0$, where it reverses direction and goes back up the right half of the parabola.

In case (c), as in case (a), the particle traces out the entire parabola $y = x^2$ from left to right. The difference is that the horizontal speed is not constant. This is because a unit change in t causes larger and larger changes in $x = t^3$ as t approaches $-\infty$ or ∞. The horizontal motion of the particle is faster when it is farther from the origin.

41. (a) C_1 has center at the origin and radius 5, so $a = b = 0, k = 5$ or -5.
(b) C_2 has center at $(0, 5)$ and radius 5, so $a = 0, b = 5, k = 5$ or -5.
(c) C_3 has center at $(10, -10)$, so $a = 10, b = -10$. The radius of C_3 is $\sqrt{10^2 + (-10)^2} = \sqrt{200}$, so $k = \sqrt{200}$ or $k = -\sqrt{200}$.

42. (I) has a positive slope and so must be l_1 or l_2. Since its y-intercept is negative, these equations must describe l_2. (II) has a negative slope and positive x-intercept, so these equations must describe l_3.

43. It is a straight line through the point $(3, 5)$ with slope -1. A linear parameterization of the same line is $x = 3 + t$, $y = 5 - t$.

44. (a) The curve is a spiral as shown in Figure 4.133.

(b) At $t = 2$, the position is $(2\cos 2, 2\sin 2) = (-0.8323, 1.8186)$, and at $t = 2.01$ the position is $(2.01\cos 2.01, 2.01\sin 2.01) = (-0.8546, 1.8192)$. The distance between these points is

$$\sqrt{(-0.8546 - (-0.8323))^2 + (1.8192 - 1.8186)^2} \approx 0.022.$$

Thus the speed is approximately $0.022/0.01 \approx 2.2$. See Figure 4.134.

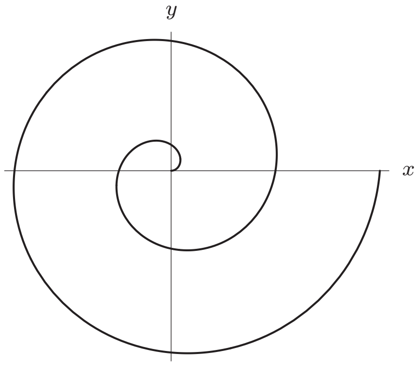

Figure 4.133: The spiral $x = t\cos t, y = t\sin t$ for $0 \le t \le 4\pi$

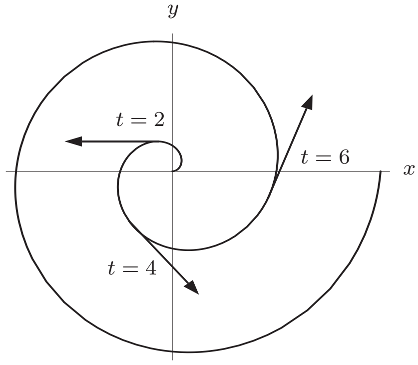

Figure 4.134: The spiral $x = t\cos t, y = t\sin t$ and three velocity vectors

(c) Evaluating the exact formula

$$v = \sqrt{(\cos t - t\sin t)^2 + (\sin t + t\cos t)^2}$$

gives :

$$v(2) = \sqrt{(-2.235)^2 + (0.077)^2} = 2.2363.$$

45. (a) The chain rule gives

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{4e^{2t}}{e^t} = 4e^t.$$

(b) We are given $y = 2e^{2t}$ so $y = 2(e^t)^2$. Since $x = e^t$, we can substitute x for e^t. Thus $y = 2x^2$.

(c) Differentiating $y = 2x^2$ with respect to x, we get $dy/dx = 4x$. Notice that, since $x = e^t$, this is equivalent to the answer that we obtained in part (a).

46. (a) In order for the particle to stop, its velocity both dx/dt and dy/dt must be zero,

$$\frac{dx}{dt} = 3t^2 - 3 = 3(t-1)(t+1) = 0,$$
$$\frac{dy}{dt} = 2t - 2 = 2(t-1) = 0.$$

The value $t = 1$ is the only solution. Therefore, the particle stops when $t = 1$ at the point $(t^3 - 3t,\ t^2 - 2t)|_{t=1} = (-2, -1)$.

(b) In order for the particle to be traveling straight up or down, the velocity in the x-direction must be 0. Thus, we solve $dx/dt = 3t^2 - 3 = 0$ and obtain $t = \pm 1$. However, at $t = 1$ the particle has no vertical motion, as we saw in part (a). Thus, the particle is moving straight up or down only when $t = -1$. The position at that time is $(t^3 - 3t,\ t^2 - 2t)|_{t=-1} = (2, 3)$.

(c) For horizontal motion we need $dy/dt = 0$. That happens when $dy/dt = 2t - 2 = 0$, and so $t = 1$. But from part (a) we also have $dx/dt = 0$ also at $t = 1$, so the particle is not moving at all when $t = 1$. Thus, there is no time when the motion is horizontal.

47. (a) (i) A horizontal tangent occurs when $dy/dt = 0$ and $dx/dt \ne 0$. Thus,

$$\frac{dy}{dt} = 6e^{2t} - 2e^{-2t} = 0$$
$$6e^{2t} = 2e^{-2t}$$
$$e^{4t} = \frac{1}{3}$$
$$4t = \ln\frac{1}{3}$$
$$t = \frac{1}{4}\ln\frac{1}{3} = -0.25\ln 3 = -0.275.$$

We need to check that $dx/dt \neq 0$ when $t = -0.25 \ln 3$. Since $dx/dt = 2e^{2t} + 2e^{-2t}$ is always positive, dx/dt is never zero.

(ii) A vertical tangent occurs when $dx/dt = 0$ and $dy/dt \neq 0$. Since $dx/dt = 2e^{2t} + 2e^{-2t}$ is always positive, there is no vertical tangent.

(b) The chain rule gives

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{6e^{2t} - 2e^{-2t}}{2e^{2t} + 2e^{-2t}} = \frac{3e^{2t} - e^{-2t}}{e^{2t} + e^{-2t}}.$$

(c) As $t \to \infty$, we have $e^{-2t} \to 0$. Thus,

$$\lim_{t\to\infty} \frac{dy}{dx} = \lim_{t\to\infty} \frac{3e^{2t} - e^{-2t}}{e^{2t} + e^{-2t}} = \lim_{t\to\infty} \frac{3e^{2t}}{e^{2t}} = 3.$$

As $t \to \infty$, the fraction gets closer and closer to 3.

48. (a) Since $y = f'(t) > 0$ for all points on the curve, f is increasing.

(b) Since $x = f(t)$ is increasing by part (a), the motion is to the right from P to Q.

(c) As t increases and the curve is traced from P to Q, the values of the derivative $y = f'(t)$ decrease, so f is concave down.

49. (a) Figure 4.135 shows the path and the clockwise direction of motion. (The curve is an ellipse.)

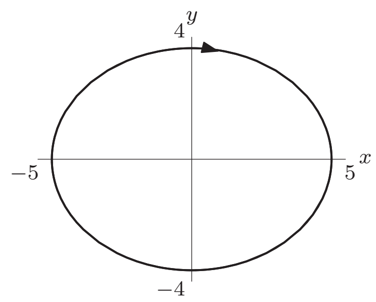

Figure 4.135

(b) At $t = \pi/4$, the position is given by

$$x(\pi/4) = 5\sin\frac{2\pi}{4} = 5\sin\frac{\pi}{2} = 5 \quad \text{and} \quad y(\pi/4) = 4\cos\frac{2\pi}{4} = 4\cos\frac{\pi}{2} = 0.$$

Differentiating, we get $x'(t) = 10\cos(2t)$ and $y'(t) = -8\sin(2t)$. At $t = \pi/4$, the velocity is given by

$$x'(\pi/4) = 10\cos\frac{2\pi}{4} = 10\cos\frac{\pi}{2} = 0 \quad \text{and} \quad y'(\pi/4) = -8\sin\frac{2\pi}{4} = -8\sin\frac{\pi}{2} = -8.$$

(c) As t increases from 0 to 2π, the ellipse is traced out twice. Thus, the particle passes through the point $(5, 0)$ twice.

(d) Since $x'(\pi/4) = 0$ and $y'(\pi/4) = -8$, when $t = \pi/4$, the particle is moving in the negative y-direction, parallel to the y-axis.

(e) At time t,

$$\text{Speed} = \sqrt{(x'(t))^2 + (y'(t))^2} = \sqrt{(10\cos(2t))^2 + (-8\sin(2t))^2}.$$

When $t = \pi$,

$$\text{Speed} = \sqrt{(10\cos(2\pi))^2 + (-8\sin(2\pi))^2} = \sqrt{(10 \cdot 1)^2 + (-8 \cdot 0)^2} = 10.$$

50. (a) Substituting $\alpha = 36^\circ = \pi/5$ and $v_0 = 60$ into $x(t) = (v_0 \cos\alpha)t$ and $y(t) = (v_0 \sin\alpha)t - \frac{1}{2}gt^2$, we get

$$x(t) = \left(60\cos\frac{\pi}{5}\right)t \quad \text{and} \quad y(t) = \left(60\sin\frac{\pi}{5}\right)t - \frac{1}{2}(32)t^2 = \left(60\sin\frac{\pi}{5}\right)t - 16t^2.$$

(b) Figure 4.136 shows the path and the direction of motion.

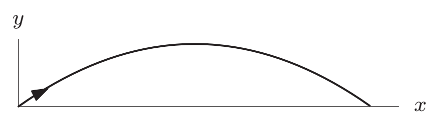

Figure 4.136

(c) When the football hits the ground, $y(t) = 0$, so

$$\begin{aligned}\left(60\sin\frac{\pi}{5}\right)t - 16t^2 &= 0\\ 4t\left(15\sin\frac{\pi}{5} - 4t\right) &= 0\\ t = 0 \quad \text{or} \quad t = \frac{15\sin(\pi/5)}{4} &= 2.204 \text{ seconds.}\end{aligned}$$

The ball hits the ground in approximately 2.204 seconds. The ball's distance from the spot where it was kicked is $x(2.204) = 106.994$ feet.

(d) At its highest point, the football is moving neither upward nor downward, so $y'(t)$ is zero. To find the time when the football reaches its maximum height, we set $y'(t) = 0$, giving

$$\begin{aligned}y'(t) = \left(60\sin\frac{\pi}{5}\right) - 32t &= 0\\ t = \frac{60\sin(\pi/5)}{32} &= 1.102 \text{ seconds.}\end{aligned}$$

This makes sense since this is half the time it took the football to reach the ground. The maximum height is $y(1.102) = 19.434$ feet. Thus the football reaches 19.434 feet.

(e) Since $x(t) = \left(60\cos\frac{\pi}{5}\right)t$ and $y(t) = \left(60\sin\frac{\pi}{5}\right)t - 16t^2$, we have

$$x'(t) = 60\cos\frac{\pi}{5} \quad \text{and} \quad y'(t) = 60\sin\frac{\pi}{5} - 32t.$$

Thus,

$$\text{Speed} = \sqrt{(x'(t))^2 + (y'(t))^2} = \sqrt{\left(60\cos\frac{\pi}{5}\right)^2 + \left(60\sin\frac{\pi}{5} - 32t\right)^2}.$$

At $t = 1$,

$$\text{Speed} = \sqrt{\left(60\cos\frac{\pi}{5}\right)^2 + \left(60\sin\frac{\pi}{5} - 32\right)^2} = 48.651 \text{ feet/sec.}$$

51. (a) To determine if the particles collide, we check whether they are ever at the same point at the same time. We first set the two x-coordinates equal to each other:

$$\begin{aligned}4t - 4 &= 3t\\ t &= 4.\end{aligned}$$

When $t = 4$, both x-coordinates are 12. Now we check whether the y-coordinates are also equal at $t = 4$:

$$\begin{aligned}y_A(4) &= 2\cdot 4 - 5 = 3\\ y_B(4) &= 4^2 - 2\cdot 4 - 1 = 7.\end{aligned}$$

Thus, the particles do not collide since they are not at the same point at the same time.

(b) For the particles to collide, we need both x- and y-coordinates to be equal. Since the x-coordinates are equal at $t = 4$, we find the k value making $y_A(4) = y_B(4)$.

Substituting $t = 4$ into $y_A(t) = 2t - k$ and $y_B(t) = t^2 - 2t - 1$, we have

$$\begin{aligned}8 - k &= 16 - 8 - 1\\ k &= 1.\end{aligned}$$

(c) To find the speed of the particles, we differentiate.

For particle A,
$x(t) = 4t - 4$, so $x'(t) = 4$, and $x'(4) = 4$
$y(t) = 2t - 1$, so $y'(t) = 2$, and $y'(4) = 2$

$$\text{Speed}_A = \sqrt{(x'(t))^2 + (y'(t))^2} = \sqrt{4^2 + 2^2} = \sqrt{20}.$$

For particle B,
$x(t) = 3t$, so $x'(t) = 3$, and $x'(4) = 3$
$y(t) = t^2 - 2t - 1$, so $y'(t) = 2t - 2$, and $y'(4) = 6$

$$\text{Speed}_B = \sqrt{(x'(t))^2 + (y'(t))^2} = \sqrt{3^2 + 6^2} = \sqrt{45}.$$

Thus, when $t = 4$, particle B is moving faster.

52. (a) Since $x = t^3 + t$ and $y = t^2$, we have

$$w = \frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{2t}{3t^2+1}.$$

Differentiating w with respect to t, we get

$$\frac{dw}{dt} = \frac{(3t^2+1)2 - (2t)(6t)}{(3t^2+1)^2} = \frac{-6t^2+2}{(3t^2+1)^2},$$

so

$$\frac{d^2y}{dx^2} = \frac{dw}{dx} = \frac{dw/dt}{dx/dt} = \frac{-6t^2+2}{(3t^2+1)^3}.$$

(b) When $t = 1$, we have $d^2y/dx^2 = -1/16 < 0$, so the curve is concave down.

53. (a) The x and y-coordinates of the point on the graph when $t = \pi/3$ are given by

$$x = 3 \cdot \frac{\pi}{3} = \pi \quad \text{and} \quad y = \cos\left(\frac{2\pi}{3}\right) = -\frac{1}{2}.$$

Thus when $t = \pi/3$, the particle is at the point $(\pi, -1/2)$.

To find the slope, we find dy/dx

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{-2\sin(2t)}{3}.$$

When $t = \pi/3$,

$$\frac{dy}{dx} = \frac{-2\sin(2\pi/3)}{3} = -\frac{\sqrt{3}}{3}.$$

The equation of the tangent line when $t = \pi/3$ is:

$$y + \frac{1}{2} = -\frac{\sqrt{3}}{3}(x - \pi).$$

(b) To find the smallest positive value of t for which the y-coordinate is a local maximum, we set $dy/dt = 0$. We have

$$\frac{dy}{dt} = -2\sin(2t) = 0$$

$$2t = \pi \quad \text{or} \quad 2t = 2\pi$$

$$t = \frac{\pi}{2} \quad \text{or} \quad t = \pi.$$

There is a minimum of $y = \cos(2t)$ at $t = \pi/2$, and a maximum at $t = \pi$.

(c) To find d^2y/dx^2 when $t = 2$, we use the formula:

$$\frac{d^2y}{dx^2} = \frac{dw/dt}{dx/dt} \quad \text{where} \quad w = \frac{dy}{dx}.$$

Since $w = -2\sin(2t)/3$ from part (a), we have

$$\frac{d^2y}{dx^2} = \frac{-4\cos(2t)/3}{3}.$$

When $t = 2$, we have

$$\frac{d^2y}{dx^2} = \frac{-4\cos(4)/3}{3} = 0.291.$$

Since the second derivative is positive, the graph is concave up when $t = 2$.

54. (a) We differentiate for both x and y in terms of t, giving us:

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{2e^{2t} + 6e^t}{e^t} = 2e^t + 6.$$

(b) To find d^2y/dx^2, we use the formula:

$$\frac{d^2y}{dx^2} = \frac{dw/dt}{dx/dt} \quad \text{where} \quad w = \frac{dy}{dx}$$
$$\frac{d^2y}{dx^2} = \frac{2e^t}{e^t} = 2.$$

Since the second derivative is always positive, the graph is concave up everywhere.

(c) We are given $y = e^{2t} + 6e^t + 9$. We can factor this to $y = (e^t + 3)^2$. Since $x = e^t + 3$, we can substitute x for $e^t + 3$. Thus, $y = x^2$ for $x > 3$.

(d) Since $y = x^2$, $dy/dx = 2x$ and $d^2y/dx^2 = 2$.

From part (a), we have $dy/dx = 2e^t + 6$. We can factor this to $dy/dx = 2(e^t + 3) = 2x$.

Part (b) tells us that $d^2y/dx^2 = 2$, which is what we have just determined.

Our graph is a parabola that is concave up everywhere.

55. (a) The particle touches the x-axis when $y = 0$. Since $y = \cos(2t) = 0$ for the first time when $2t = \pi/2$, we have $t = \pi/4$. To find the speed of the particle at that time, we use the formula

$$\text{Speed} = \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} = \sqrt{(\cos t)^2 + (-2\sin(2t))^2}.$$

When $t = \pi/4$,

$$\text{Speed} = \sqrt{(\cos(\pi/4))^2 + (-2\sin(\pi/2))^2} = \sqrt{(\sqrt{2}/2)^2 + (-2\cdot 1)^2} = \sqrt{9/2}.$$

(b) The particle is at rest when its speed is zero. Since $\sqrt{(\cos t)^2 + (-2\sin(2t))^2} \geq 0$, the speed is zero when

$$\cos t = 0 \quad \text{and} \quad -2\sin(2t) = 0.$$

Now $\cos t = 0$ when $t = \pi/2$ or $t = 3\pi/2$. Since $-2\sin(2t) = -4\sin t\cos t$, we see that this expression also equals zero when $t = \pi/2$ or $t = 3\pi/2$.

(c) We need to find d^2y/dx^2. First, we must determine dy/dx. We know

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{-2\sin 2t}{\cos t} = \frac{-4\sin t\cos t}{\cos t} = -4\sin t.$$

Since $dy/dx = -4\sin t$, we can now use the formula:

$$\frac{d^2y}{dx^2} = \frac{dw/dt}{dx/dt} \quad \text{where} \quad w = \frac{dy}{dx}$$
$$\frac{d^2y}{dx^2} = \frac{-4\cos t}{\cos t} = -4.$$

Since d^2y/dx^2 is always negative, our graph is concave down everywhere.

Using the identity $y = \cos(2t) = 1 - 2\sin^2 t$, we can eliminate the parameter and write the original equation as $y = 1 - 2x^2$, which is a parabola that is concave down everywhere.

56. Let

$$w = \frac{dy}{dx} = \frac{dy/dt}{dx/dt}.$$

We want to find

$$\frac{d^2y}{dx^2} = \frac{dw}{dx} = \frac{dw/dt}{dx}dt.$$

To find dw/dt, we use the quotient rule:

$$\frac{dw}{dt} = \frac{(dx/dt)(d^2y/dt^2) - (dy/dt)(d^2x/dt^2)}{(dx/dt)^2}.$$

We then divide this by dx/dt again to get the required formula, since

$$\frac{d^2y}{dx^2} = \frac{dw}{dx} = \frac{dw/dt}{dx/dt}.$$

57. For $0 \leq t \leq 2\pi$, we get Figure 4.137.

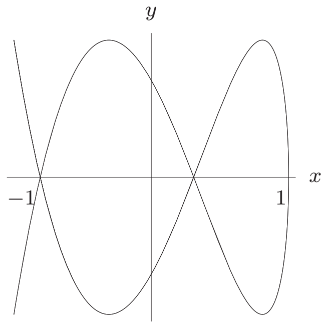

Figure 4.137

58. For $0 \leq t \leq 2\pi$, we get Figure 4.138.

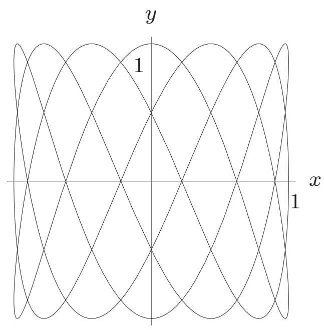

Figure 4.138

59. For $0 \leq t \leq 2\pi$, we get Figure 4.139.

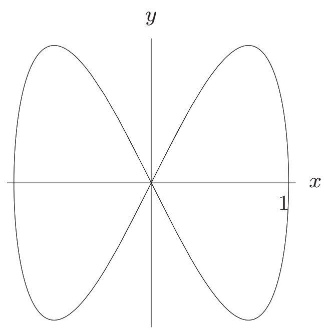

Figure 4.139

60. This curve never closes on itself. The plot for $0 \leq t \leq 8\pi$ is in Figure 4.140.

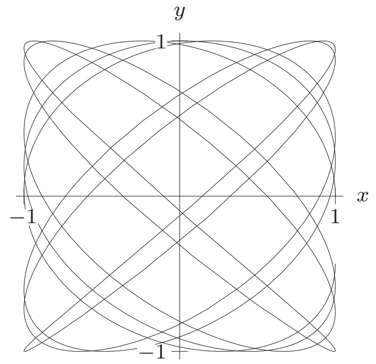

Figure 4.140

61. (a) To find the equations of the moon's motion relative to the star, you must first calculate the equation of the planet's motion relative to the star, and then the moon's motion relative to the planet, and then add the two together.

The distance from the planet to the star is R, and the time to make one revolution is one unit, so the parametric equations for the planet relative to the star are $x = R\cos t$, $y = R\sin t$.

The distance from the moon to the planet is 1, and the time to make one revolution is twelve units, therefore, the parametric equations for the moon relative to the planet are $x = \cos 12t$, $y = \sin 12t$.

Adding these together, we get:

$$x = R\cos t + \cos 12t,$$
$$y = R\sin t + \sin 12t.$$

(b) For the moon to stop completely at time t, the velocity of the moon must be equal to zero. Therefore,

$$\frac{dx}{dt} = -R\sin t - 12\sin 12t = 0,$$
$$\frac{dy}{dt} = R\cos t + 12\cos 12t = 0.$$

There are many possible values to choose for R and t that make both of these equations equal to zero. We choose $t = \pi$, and $R = 12$.

(c) The graph with $R = 12$ is shown in Figure 4.141.

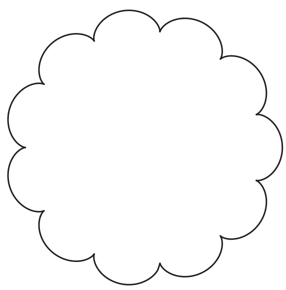

Figure 4.141

Strengthen Your Understanding

62. The parameterization does give the required line segment but traversed in the wrong direction.

63. The given parametric equations give a circle of radius 2 but centered at $(0, 0)$. We need $x = 2\cos\pi t$, $y = 1 + 2\sin\pi t$, $0 \le t \le 2$. There are many other possibilities.

64. One possible choice is $x = 2\cos t$, $y = 2\sin t$, $0 \le t \le \frac{\pi}{2}$. There are many other possibilities.

65. One possible choice is $x = t$, $y = 2t$, $0 \le t \le 1$. There are many other possibilities.

66. False. If the particle tracing out the curve comes to a complete stop, it can then head off in a completely new direction. For example, the curve given parametrically by $x = t^3$ and $y = t^2$ is the same as the graph of $y = x^{2/3}$ which has a cusp at $x = 0$.

67. False. The slope is given by

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{2t\cos(t^2)}{-2t\sin(t^2)} = -\frac{\cos(t^2)}{\sin(t^2)}.$$

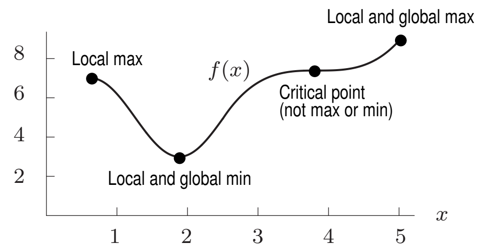

Figure 4.143

3. (a) We wish to investigate the behavior of $f(x) = x^3 - 3x^2$ on the interval $-1 \le x \le 3$. We find:

$$f'(x) = 3x^2 - 6x = 3x(x-2)$$
$$f''(x) = 6x - 6 = 6(x-1)$$

(b) The critical points of f are $x = 2$ and $x = 0$ since $f'(x) = 0$ at those points. Using the second derivative test, we find that $x = 0$ is a local maximum since $f'(0) = 0$ and $f''(0) = -6 < 0$, and that $x = 2$ is a local minimum since $f'(2) = 0$ and $f''(2) = 6 > 0$.

(c) There is an inflection point at $x = 1$ since f'' changes sign at $x = 1$.

(d) At the critical points, $f(0) = 0$ and $f(2) = -4$.
At the endpoints: $f(-1) = -4$, $f(3) = 0$.
So the global maxima are $f(0) = 0$ and $f(3) = 0$, while the global minima are $f(-1) = -4$ and $f(2) = -4$.
(e) See Figure 4.144.

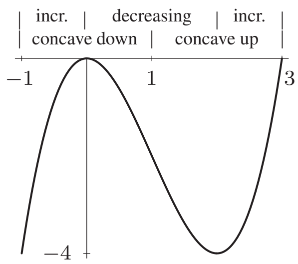

Figure 4.144

4. (a) First we find f' and f''; $f'(x) = 1 + \cos x$ and $f''(x) = -\sin x$.
(b) The critical point of f is $x = \pi$, since $f'(\pi) = 0$.
(c) Since f'' changes sign at $x = \pi$, it means that $x = \pi$ is an inflection point.
(d) Evaluating f at the critical point and endpoints, we find $f(0) = 0,\ f(\pi) = \pi,\ f(2\pi) = 2\pi$,. Therefore, the global maximum is $f(2\pi) = 2\pi$, and the global minimum is $f(0) = 0$. Note that $x = \pi$ is not a local maximum or minimum of f, and that the second derivative test is inconclusive here.
(e) See Figure 4.145.

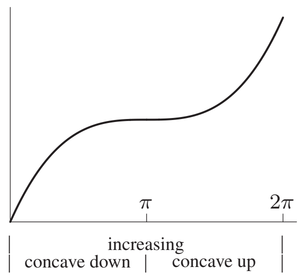

Figure 4.145

5. (a) First we find f' and f'':

$$\begin{aligned} f'(x) &= -e^{-x}\sin x + e^{-x}\cos x \\ f''(x) &= e^{-x}\sin x - e^{-x}\cos x \\ &\quad -e^{-x}\cos x - e^{-x}\sin x \\ &= -2e^{-x}\cos x \end{aligned}$$

(b) The critical points are $x = \pi/4, 5\pi/4$, since $f'(x) = 0$ here.
(c) The inflection points are $x = \pi/2, 3\pi/2$, since f'' changes sign at these points.
(d) At the endpoints, $f(0) = 0,\ f(2\pi) = 0$. So we have $f(\pi/4) = (e^{-\pi/4})(\sqrt{2}/2)$ as the global maximum; $f(5\pi/4) = -e^{-5\pi/4}(\sqrt{2}/2)$ as the global minimum.
(e) See Figure 4.146.

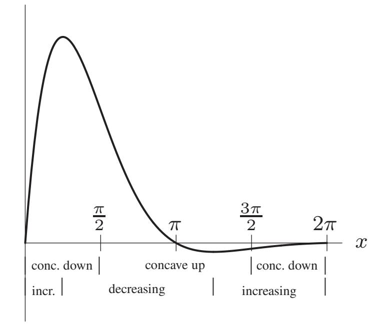

Figure 4.146

6. (a) We first find f' and f'':

$$f'(x) = -\frac{2}{3}x^{-\frac{5}{3}} + \frac{1}{3}x^{-\frac{2}{3}} = \frac{1}{3}x^{-\frac{5}{3}}(x-2)$$
$$f''(x) = \frac{10}{9}x^{-\frac{8}{3}} - \frac{2}{9}x^{-\frac{5}{3}} = -\frac{2}{9}x^{-\frac{8}{3}}(x-5)$$

(b) Critical point: $x = 2$.
(c) There are no inflection points, since f'' does not change sign on the interval $1.2 \leq x \leq 3.5$.
(d) At the endpoints, $f(1.2) \approx 1.94821$ and $f(3.5) \approx 1.95209$. So, the global minimum is $f(2) \approx 1.88988$ and the global maximum is $f(3.5) \approx 1.95209$.
(e) See Figure 4.147.

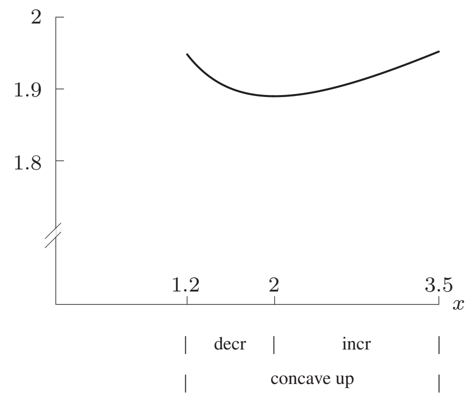

Figure 4.147

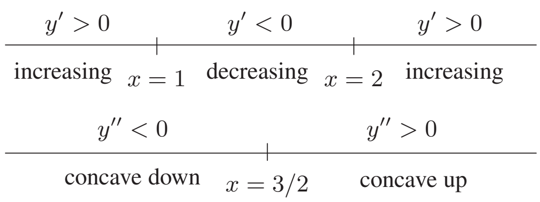
7. The polynomial $f(x)$ behaves like $2x^3$ as x goes to ∞. Therefore, $\lim_{x\to\infty} f(x) = \infty$ and $\lim_{x\to-\infty} f(x) = -\infty$.

We have $f'(x) = 6x^2 - 18x + 12 = 6(x-2)(x-1)$, which is zero when $x = 1$ or $x = 2$.

Also, $f''(x) = 12x - 18 = 6(2x-3)$, which is zero when $x = 3/2$. For $x < 3/2$, $f''(x) < 0$; for $x > 3/2$, $f''(x) > 0$. Thus $x = 3/2$ is an inflection point.

The critical points are $x = 1$ and $x = 2$, and $f(1) = 6$, $f(2) = 5$. By the second derivative test, $f''(1) = -6 < 0$, so $x = 1$ is a local maximum; $f''(2) = 6 > 0$, so $x = 2$ is a local minimum.

Now we can draw the diagrams below.



The graph of $f(x) = 2x^3 - 9x^2 + 12x + 1$ is shown in Figure 4.148. It has no global maximum or minimum.

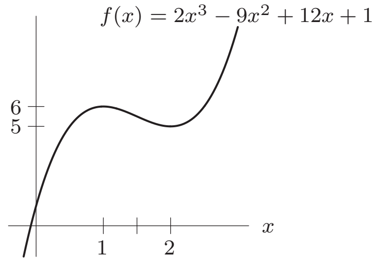


Figure 4.148

8. If we divide the denominator and numerator of $f(x)$ by x^2 we have

$$\lim_{x\to\pm\infty} \frac{4x^2}{x^2+1} = \lim_{x\to\pm\infty} \frac{4}{1+\frac{1}{x^2}} = 4$$

since

$$\lim_{x\to\pm\infty} \frac{1}{x^2} = 0.$$

Using the quotient rule we get

$$f'(x) = \frac{(x^2+1)8x - 4x^2(2x)}{(x^2+1)^2} = \frac{8x}{(x^2+1)^2},$$

which is zero when $x = 0$, positive when $x > 0$, and negative when $x < 0$. Thus $f(x)$ has a local minimum when $x = 0$, with $f(0) = 0$.

Because $f'(x) = 8x/(x^2+1)^2$, the quotient rule implies that

$$f''(x) = \frac{(x^2+1)^2 8 - 8x[2(x^2+1)2x]}{(x^2+1)^4}$$
$$= \frac{8x^2 + 8 - 32x^2}{(x^2+1)^3} = \frac{8(1-3x^2)}{(x^2+1)^3}.$$

The denominator is always positive, so $f''(x) = 0$ when $x = \pm\sqrt{1/3}$, positive when $-\sqrt{1/3} < x < \sqrt{1/3}$, and negative when $x > \sqrt{1/3}$ or $x < -\sqrt{1/3}$. This gives the diagram

$y' < 0$		$y' > 0$
decreasing	$x = 0$	increasing

$y'' < 0$		$y'' > 0$		$y'' < 0$
concave down	$x = -\sqrt{1/3}$	concave up	$x = \sqrt{1/3}$	concave down

and the graph of f looks Figure 4.149.

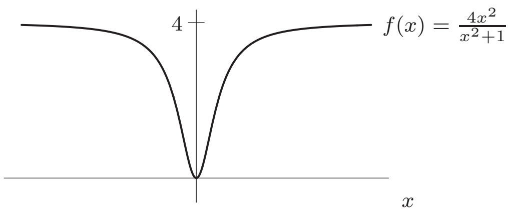

Figure 4.149

with inflection points $x = \pm\sqrt{1/3}$, a global minimum at $x = 0$, and no local or global maxima (since $f(x)$ never equals 4).

9. As $x \to -\infty$, $e^{-x} \to \infty$, so $xe^{-x} \to -\infty$. Thus $\lim_{x\to-\infty} xe^{-x} = -\infty$.

As $x \to \infty$, $\frac{x}{e^x} \to 0$, since e^x grows much more quickly than x. Thus $\lim_{x\to\infty} xe^{-x} = 0$.

Using the product rule,

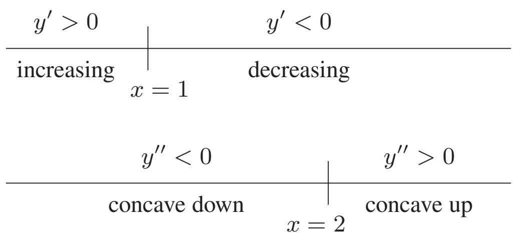
$$f'(x) = e^{-x} - xe^{-x} = (1-x)e^{-x},$$

which is zero when $x = 1$, negative when $x > 1$, and positive when $x < 1$. Thus $f(1) = 1/e^1 = 1/e$ is a local maximum.

Again, using the product rule,

$$\begin{aligned} f''(x) &= -e^{-x} - e^{-x} + xe^{-x} \\ &= xe^{-x} - 2e^{-x} \\ &= (x-2)e^{-x}, \end{aligned}$$

which is zero when $x = 2$, positive when $x > 2$, and negative when $x < 2$, giving an inflection point at $(2, \frac{2}{e^2})$. With the above, we have the following diagram:



The graph of f is shown in Figure 4.150.

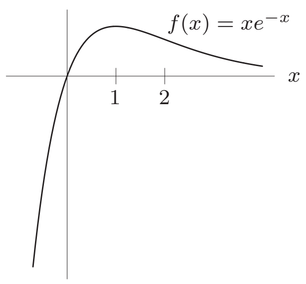


Figure 4.150

and $f(x)$ has one global maximum at $1/e$ and no local or global minima.

10. Since $f(x) = e^{-x}\sin x$ is continuous and the interval $0 \le x \le 2\pi$ is closed, there must be a global maximum and minimum. The possible candidates are critical points in the interval and endpoints. Since there are no points where f' is undefined, we solve $f'(x) = 0$ to find all critical points:

$$f'(x) = -e^{-x}\sin x + e^{-x}\cos x = e^{-x}(-\sin x + \cos x) = 0.$$

Since $e^{-x} \ne 0$, the critical points are when $\sin x = \cos x$; the only solutions in the given interval are $x = \pi/4$ and $x = 5\pi/4$. We then compare the values of f at the critical points and the endpoints:

$$f(0) = 0, \quad f(\pi/4) = e^{-\pi/4}\left(\frac{\sqrt{2}}{2}\right) = 0.322, \quad f(5\pi/4) = e^{-5\pi/4}\left(\frac{-\sqrt{2}}{2}\right) = -0.0139, \quad f(2\pi) = 0.$$

Thus the global maximum is 0.322 at $x = \pi/4$, and the global minimum is -0.0139 at $x = 5\pi/4$.

11. Since $f(x) = e^x + \cos x$ is continuous on the closed interval $0 \le x \le \pi$, there must be a global maximum and minimum. The possible candidates are critical points in the interval and endpoints. Since there are no points in the interval where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find the critical points:

$$f'(x) = e^x - \sin x = 0.$$

Since $e^x > 1$ for all $x > 0$ and $\sin x \le 1$ for all x, the only possibility is $x = 0$, but $e^0 - \sin 0 = 1$. Thus there are no critical points in the interval. We then compare the values of f at the endpoints:

$$f(0) = 2, \quad f(\pi) = e^\pi + \cos(\pi) = 22.141.$$

Thus, the global maximum is 22.141 at $x = \pi$, and the global minimum is 2 at $x = 0$.

12. Since $f(x) = x^2 + 2x + 1$ is continuous and the interval $0 \le x \le 3$ is closed, there must be a global maximum and minimum. The candidates are critical points in the interval and endpoints. Since there are no points where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find all the critical points:

$$f'(x) = 2x + 2 = 0,$$

so the only critical point, $x = -1$, is not in the interval $0 \le x \le 3$. At the endpoints, we have

$$f(0) = 1, \quad f(3) = 16.$$

Thus, the global maximum is 16 at $x = 3$, and the global minimum is 1 at $x = 0$.

13. Since $f(x) = e^{-x^2}$ is continuous and the interval $0 \le x \le 10$ is closed, there must be a global maximum and minimum. The candidates are critical points in the interval and endpoints. Since there are no points where $f'(x)$ is undefined, we solve $f'(x) = 0$ to find all the critical points:

$$f'(x) = -2xe^{-x^2} = 0,$$

so the only critical point, $x = 0$, is at an endpoint of the interval. At the endpoints, we have

$$f(0) = 1, \quad f(10) = e^{-100} \approx 0.$$

Thus, the global maximum is 1 at $x = 0$, and the global minimum is near 0 at $x = 10$.

14. We rewrite $h(z)$ as $h(z) = z^{-1} + 4z^2$.

Differentiating gives

$$h'(z) = -z^{-2} + 8z,$$

so the critical points satisfy

$$\begin{aligned} -z^{-2} + 8z &= 0 \\ z^{-2} &= 8z \\ 8z^3 &= 1 \\ z^3 &= \frac{1}{8} \\ z &= \frac{1}{2}. \end{aligned}$$

Since h' is negative for $0 < z < 1/2$ and h' is positive for $z > 1/2$, there is a local minimum at $z = 1/2$.

Since $h(z) \to \infty$ as $z \to 0^+$ and as $z \to \infty$, the local minimum at $z = 1/2$ is a global minimum; there is no global maximum. See Figure 4.151. Thus, the global minimum is $h(1/2) = 3$.

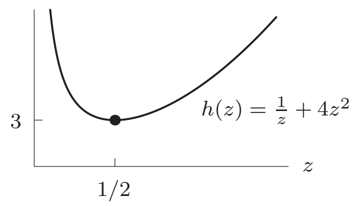

Figure 4.151

15. Since $g(t)$ is always decreasing for $t \geq 0$, we expect it to a global maximum at $t = 0$ but no global minimum. At $t = 0$, we have $g(0) = 1$, and as $t \to \infty$, we have $g(t) \to 0$.

Alternatively, rewriting as $g(t) = (t^3 + 1)^{-1}$ and differentiating using the chain rule gives

$$g'(t) = -(t^3 + 1)^{-2} \cdot 3t^2.$$

Since $3t^2 = 0$ when $t = 0$, there is a critical point at $t = 0$, and g decreases for all $t > 0$. See Figure 4.152.

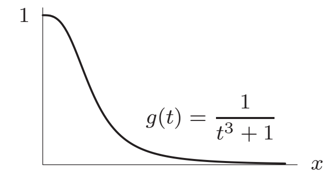

Figure 4.152

16. We begin by rewriting $f(x)$:

$$f(x) = \frac{1}{(x-1)^2 + 2} = ((x-1)^2 + 2)^{-1} = (x^2 - 2x + 3)^{-1}.$$

Differentiating using the chain rule gives

$$f'(x) = -(x^2 - 2x + 3)^{-2}(2x - 2) = \frac{2 - 2x}{(x^2 - 2x + 3)^2},$$

so the critical points satisfy

$$\begin{aligned} \frac{2 - 2x}{(x^2 - 2x + 3)^2} &= 0 \\ 2 - 2x &= 0 \\ 2x &= 2 \\ x &= 1. \end{aligned}$$

Since f' is positive for $x < 1$ and f' is negative for $x > 1$, there is a local maximum at $x = 1$.

Since $f(x) \to 0$ as $x \to \infty$ and as $x \to -\infty$, the local maximum at $x = 1$ is a global maximum; there is no global minimum. See Figure 4.153. Thus, the global maximum is $f(1) = 1/2$.

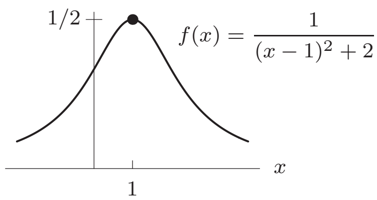

Figure 4.153

17. $\lim_{x \to \infty} f(x) = +\infty$, and $\lim_{x \to -\infty} f(x) = -\infty$.
There are no asymptotes.
$f'(x) = 3x^2 + 6x - 9 = 3(x+3)(x-1)$. Critical points are $x = -3$, $x = 1$.
$f''(x) = 6(x+1)$.

x		-3		-1		1	
f'	+	0	−	−	−	0	+
f''	−	−	−	0	+	+	+
f	↗⌢		↘⌢		↘⌣		↗⌣

Thus, $x = -1$ is an inflection point. $f(-3) = 12$ is a local maximum; $f(1) = -20$ is a local minimum. There are no global maxima or minima. See Figure 4.154.

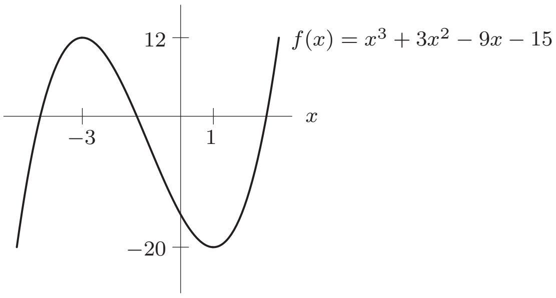

Figure 4.154

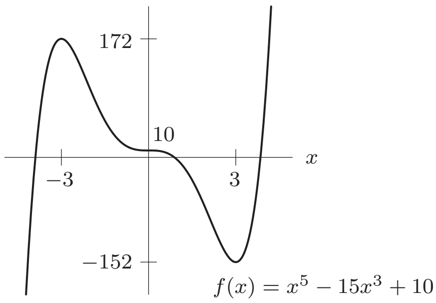
18. $\lim_{x\to+\infty} f(x) = +\infty$, and $\lim_{x\to-\infty} f(x) = -\infty$.
There are no asymptotes.
$f'(x) = 5x^4 - 45x^2 = 5x^2(x^2 - 9) = 5x^2(x+3)(x-3)$.
The critical points are $x = 0$, $x = \pm 3$. f' changes sign at 3 and -3 but not at 0.
$f''(x) = 20x^3 - 90x = 10x(2x^2 - 9)$. f'' changes sign at 0, $\pm 3/\sqrt{2}$.
So, inflection points are at $x = 0$, $x = \pm 3/\sqrt{2}$.

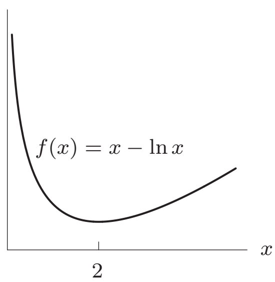
x		-3		$-3/\sqrt{2}$		0		$3/\sqrt{2}$		3	
f'	+	0	−		−	0	−		−	0	+
f''	−	−	−	0	+	0	−	0	+	+	+
f	↗⌢		↘⌢		↘⌣		↘⌢		↘⌣		↗⌣

Thus, $f(-3)$ is a local maximum; $f(3)$ is a local minimum. There are no global maxima or minima.



19. $\lim_{x\to+\infty} f(x) = +\infty$, and $\lim_{x\to 0^+} f(x) = +\infty$.
Hence, $x = 0$ is a vertical asymptote.
$f'(x) = 1 - \dfrac{2}{x} = \dfrac{x-2}{x}$, so $x = 2$ is the only critical point.
$f''(x) = \dfrac{2}{x^2}$, which can never be zero. So there are no inflection points.

x		2	
f'	−	0	+
f''	+	+	+
f	↘⌣		↗⌣



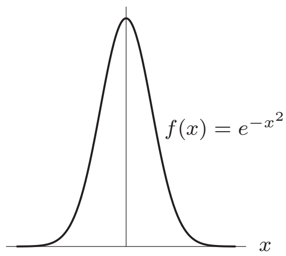
Thus, $f(2)$ is a local and global minimum.

20. Since $\lim_{x\to-\infty} f(x) = \lim_{x\to+\infty} f(x) = 0$, $y = 0$ is a horizontal asymptote.
$f'(x) = -2xe^{-x^2}$. So, $x = 0$ is the only critical point.
$f''(x) = -2(e^{-x^2} + x(-2x)e^{-x^2}) = 2e^{-x^2}(2x^2 - 1) = 2e^{-x^2}(\sqrt{2}x - 1)(\sqrt{2}x + 1)$.
Thus, $x = \pm 1/\sqrt{2}$ are inflection points.

Table 4.1

x		$-1/\sqrt{2}$		0		$1/\sqrt{2}$	
f'	+	+	+	0	–	–	–
f''	+	0	–	–	–	0	+
f	↗⌣		↗⌢		↘⌢		↘⌣

Thus, $f(0) = 1$ is a local and global maximum.

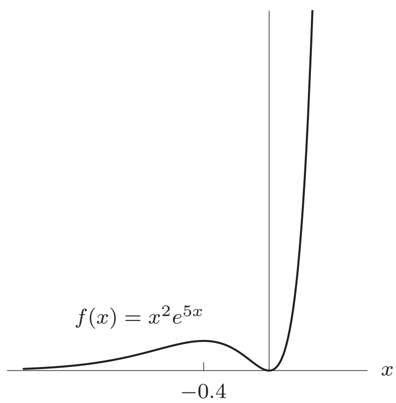


21. $\lim_{x\to+\infty} f(x) = +\infty$, $\lim_{x\to-\infty} f(x) = 0$.
$y = 0$ is the horizontal asymptote.
$f'(x) = 2xe^{5x} + 5x^2e^{5x} = xe^{5x}(5x + 2)$.
Thus, $x = -\frac{2}{5}$ and $x = 0$ are the critical points.

$$\begin{aligned} f''(x) &= 2e^{5x} + 2xe^{5x}\cdot 5 + 10xe^{5x} + 25x^2e^{5x} \\ &= e^{5x}(25x^2 + 20x + 2). \end{aligned}$$

So, $x = \dfrac{-2 \pm \sqrt{2}}{5}$ are inflection points.

x		$\frac{-2-\sqrt{2}}{5}$		$-\frac{2}{5}$		$\frac{-2+\sqrt{2}}{5}$		0	
f'	+	+	+	0	–	–	–	0	+
f''	+	0	–	–	–	0	+	+	+
f	↗⌣		↗⌢		↘⌢		↘⌣		↗⌣



So, $f(-\frac{2}{5})$ is a local maximum; $f(0)$ is a local and global minimum.

22. $\lim_{x\to+\infty} f(x) = \lim_{x\to-\infty} f(x) = 1.$
Thus, $y = 1$ is a horizontal asymptote. Since $x^2 + 1$ is never 0, there are no vertical asymptotes.

$$f'(x) = \frac{2x(x^2+1) - x^2(2x)}{(x^2+1)^2} = \frac{2x}{(x^2+1)^2}.$$

So, $x = 0$ is the only critical point.

$$\begin{aligned} f''(x) &= \frac{2(x^2+1)^2 - 2x \cdot 2(x^2+1) \cdot 2x}{(x^2+1)^4} \\ &= \frac{2(x^2+1-4x^2)}{(x^2+1)^3} \\ &= \frac{2(1-3x^2)}{(x^2+1)^3}. \end{aligned}$$

So, $x = \pm\frac{1}{\sqrt{3}}$ are inflection points.

Table 4.2

x		$\frac{-1}{\sqrt{3}}$		0		$\frac{1}{\sqrt{3}}$	
f'	−	−	−	0	+	+	+
f''	−	0	+	+	+	0	−
f	↘⌢		↘⌣		↗⌣		↗⌢

Thus, $f(0) = 0$ is a local and global minimum. A graph of $f(x)$ can be found in Figure 4.155.

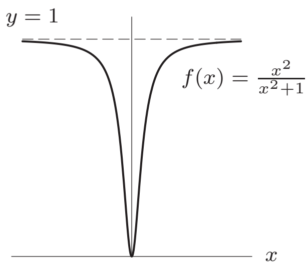


Figure 4.155

23. For $0 \le r \le a$, the speed at which air is expelled is given by

$$v(r) = k(a-r)r^2 = kar^2 - kr^3.$$

Thus, the derivative is defined for all r and given by

$$v'(r) = 2kar - 3kr^2 = 2kr\left(a - \frac{3}{2}r\right).$$

The derivative is zero if $r = \frac{2}{3}a$ or $r = 0$. These are the critical points of v. To decide if the critical points give global maxima or minima, we evaluate v at the critical point:

$$\begin{aligned} v\left(\frac{2}{3}a\right) &= k\left(a - \frac{2}{3}a\right)\left(\frac{2}{3}a\right)^2 \\ &= k\left(\frac{a}{3}\right)\frac{4a^2}{9} \\ &= \frac{4ka^3}{27}, \end{aligned}$$

and we evaluate v at the endpoints:

$$v(0) = v(a) = 0.$$

Thus, v has a global maximum at $r = \frac{2}{3}a$. The global minimum of $v = 0$ occurs at both endpoints $r = 0$ and $r = a$.

24. The slope of the curve, dy/dt, is given by

$$\frac{dy}{dt} = -50\left(1+6e^{-2t}\right)^{-2}\left(-12e^{-2t}\right) = 600e^{-2t}\left(1+6e^{-2t}\right)^{-2}.$$

If the slope has a maximum, it occurs at a critical point of dy/dt or at the endpoint $t=0$. We have

$$\begin{aligned}\frac{d^2y}{dt^2} &= 600\left(-2e^{-2t}\right)\left(1+6e^{-2t}\right)^{-2} - 1200e^{-2t}\left(1+6e^{-2t}\right)^{-3}\left(-12e^{-2t}\right)\\ &= \frac{1200e^{-2t}}{(1+6e^{-2t})^3}\left(6e^{-2t}-1\right).\end{aligned}$$

At a critical point of dy/dt, we have $d^2y/dt^2 = 0$, so

$$\begin{aligned}6e^{-2t}-1 &= 0\\ t &= \frac{1}{2}\ln 6 = 0.896.\end{aligned}$$

Since

$$\left.\frac{dy}{dt}\right|_{t=0} = \frac{600}{49} = 12.25 \quad\text{and}\quad \left.\frac{dy}{dt}\right|_{t=(1/2)\ln 6} = 25,$$

the maximum slope occurs at $t=\frac{1}{2}\ln 6$.

We see in Figure 4.156 that the slope increases as t increases from 0 and tends to 0 as $t\to\infty$, so the only critical point of slope, $t=\frac{1}{2}\ln 6$, is a local and global maximum for the slope. At $t=\frac{1}{2}\ln 6$, we have $y=25$. The point $\left(\frac{1}{2}\ln 6, 25\right)$ is the point where slope is maximum.

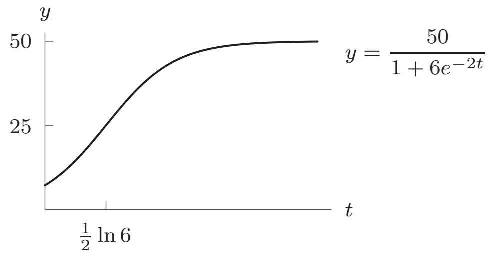

Figure 4.156

25. We have $f'(x) = (a^2-x^2)/(x^2+a^2)^2$, so that the critical points occur when $a^2-x^2=0$, that is, when $x=\pm a$. We see that as a increases the x-value of the extrema moves away the origin.

Looking at the figure we see that A's local maximum has the smallest x-value, while C's has the largest x-value. Thus, A corresponds to $a=1$, B to $a=2$, and C to $a=3$.

26. We have $f'(x) = ae^{-ax}$, so that $f'(0)=a$. We see that as a increases the slopes of the curves at the origin become more and more positive. Thus, C corresponds to $a=1$, B to $a=2$, and A to $a=3$.

27. (a) We set the derivative equal to zero and solve for x to find critical points:

$$\begin{aligned}f'(x) = 4x^3 - 4ax &= 0\\ 4x(x^2-a) &= 0.\end{aligned}$$

We see that there are three critical points:

$$\text{Critical points:}\quad x=0,\quad x=\sqrt{a},\quad x=-\sqrt{a}.$$

To find possible inflection points, we set the second derivative equal to zero and solve for x:

$$f''(x) = 12x^2 - 4a = 0.$$

There are two possible inflection points:

$$\text{Possible inflection points:}\quad x=\sqrt{\frac{a}{3}},\quad x=-\sqrt{\frac{a}{3}}.$$

To see if these are inflection points, we determine whether concavity changes by evaluating f'' at values on either side of each of the potential inflection points. We see that

$$f''(-2\sqrt{\frac{a}{3}}) = 12(4\frac{a}{3}) - 4a = 16a - 4a = 12a > 0,$$

so f is concave up to the left of $x = -\sqrt{a/3}$. Also,

$$f''(0) = -4a < 0,$$

so f is concave down between $x = -\sqrt{a/3}$ and $x = \sqrt{a/3}$. Finally, we see that

$$f''(2\sqrt{\frac{a}{3}}) = 12(4\frac{a}{3}) - 4a = 16a - 4a = 12a > 0,$$

so f is concave up to the right of $x = \sqrt{a/3}$. Since $f(x)$ changes concavity at $x = \sqrt{a/3}$ and $x = -\sqrt{a/3}$, both points are inflection points.

(b) The only positive critical point is at $x = \sqrt{a}$, so to have a critical point at $x = 2$, we substitute:

$$\begin{aligned} x &= \sqrt{a} \\ 2 &= \sqrt{a} \\ a &= 4. \end{aligned}$$

Since the critical point is at the point $(2, 5)$, we have

$$\begin{aligned} f(2) &= 5 \\ 2^4 - 2(4)2^2 + b &= 5 \\ 16 - 32 + b &= 5 \\ b &= 21. \end{aligned}$$

The function is $f(x) = x^4 - 8x^2 + 21$.

(c) We have seen that $a = 4$, so the inflection points are at $x = \sqrt{4/3}$ and $x = -\sqrt{4/3}$.

28. (a) The function $f(x)$ is defined for $x \geq 0$.

We set the derivative equal to zero and solve for x to find critical points:

$$\begin{aligned} f'(x) = 1 - \frac{1}{2}ax^{-1/2} &= 0 \\ 1 - \frac{a}{2\sqrt{x}} &= 0 \\ 2\sqrt{x} &= a \\ x &= \frac{a^2}{4}. \end{aligned}$$

Notice that f' is undefined at $x = 0$ so there are two critical points: $x = 0$ and $x = a^2/4$.

(b) We want the critical point $x = a^2/4$ to occur at $x = 5$, so we have:

$$\begin{aligned} 5 &= \frac{a^2}{4} \\ 20 &= a^2 \\ a &= \pm\sqrt{20}. \end{aligned}$$

Since a is positive, we use the positive square root. The second derivative,

$$f''(x) = \frac{1}{4}ax^{-3/2} = \frac{1}{4}\sqrt{20}x^{-3/2}$$

is positive for all $x > 0$, so the function is concave up and $x = 5$ gives a local minimum. See Figure 4.157.

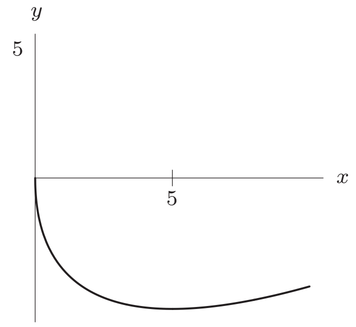

Figure 4.157

29. The domain is all real numbers except $x = b$. The function is undefined at $x = b$ and has a vertical asymptote there. To find the critical points, we set the derivative equal to zero and solve for x. Using the quotient rule, we have:

$$f'(x) = \frac{(x-b)2ax - (ax^2)1}{(x-b)^2} = 0$$
$$\frac{2ax^2 - 2abx - ax^2}{(x-b)^2} = 0$$
$$\frac{ax^2 - 2abx}{(x-b)^2} = 0.$$

The first derivative is equal to zero if

$$ax^2 - 2abx = 0$$
$$ax(x - 2b) = 0$$
$$x = 0 \quad \text{or} \quad x = 2b.$$

There are two critical points: at $x = 0$ and $x = 2b$.

30. Let the numbers be x and y. Then

$$\text{Average } = \frac{x+y}{2} = 180, \quad \text{so} \quad y = 360 - x.$$

Since both numbers are nonnegative, we restrict to $0 \le x \le 360$.

The product is

$$P = xy = x(360 - x) = 360x - x^2.$$

Differentiating to find the maximum,

$$\frac{dP}{dx} = 360 - 2x = 0$$
$$x = \frac{360}{2} = 180.$$

So there is a critical point at $x = 180$; the end points are at $x = 0, 360$.

Evaluating gives
At $x = 0$, we have $P = 0$.
At $x = 180$, we have $P = 180(360 - 180) = 32{,}400$.
At $x = 360$, we have $P = 360(360 - 360) = 0$.
Thus, the maximum value is 32,400.

31. Let the numbers be x, y, z and let $y = 2x$. Then

$$xyz = 2x^2 z = 192, \quad \text{so} \quad z = \frac{192}{2x^2} = \frac{96}{x^2}.$$

Since all the numbers are positive, we restrict to $x > 0$.

The sum is

$$S = x + y + z = x + 2x + \frac{96}{x^2} = 3x + \frac{96}{x^2}.$$

Differentiating to find the minimum,

$$\begin{aligned}\frac{dS}{dx} &= 3 - 2\frac{96}{x^3} = 0\\ 3 &= \frac{192}{x^3}\\ x^3 &= \frac{192}{3} = 64 \quad \text{so} \quad x = 4.\end{aligned}$$

There is only one critical point at $x = 4$. We find

$$\frac{d^2S}{dx^2} = 3\frac{192}{x^4}.$$

Since $d^2S/dx^2 > 0$ for all x, there is a local minimum at $x = 4$. The derivative dS/dx is negative for $0 < x < 4$ and dS/dx is positive for $x > 4$. Thus, $x = 4$ gives the global minimum for $x > 0$.

The minimum value of the sum obtained from the three numbers 4, 8, and 6 is

$$S = 3 \cdot 4 + \frac{96}{4^2} = 18.$$

32. Let x be the larger number and y be the smaller number. Then $x - y = 24$, so $y = x - 24$. Since both numbers are 100 or larger, we restrict to $x \geq 124$.

The product is

$$P = xy = x(x - 24) = x^2 - 24x.$$

Differentiating to find the minimum,

$$\begin{aligned}\frac{dP}{dx} &= 2x - 24 = 0\\ x &= \frac{24}{2} = 12.\end{aligned}$$

So there is a critical point at $x = 12$. There is an end point at $x = 124$; the domain $x \geq 124$ has no critical points.

Since the derivative, dP/dx, is positive for all x greater than 12, the minimum value of P occurs at the left end of the domain, $x = 124$.

The minimum value of the product is

$$P = 124(124 - 24) = 12{,}400.$$

33. (a) Total cost, in millions of dollars, $C(q) = 3 + 0.4q$.
(b) Revenue, in millions of dollars, $R(q) = 0.5q$.
(c) Profit, in millions of dollars, $\pi(q) = R(q) - C(q) = 0.5q - (3 + 0.4q) = 0.1q - 3$.

34. The square is $S = x^2$. Differentiating with respect to time gives

$$\frac{dS}{dt} = 2x\frac{dx}{dt}.$$

We are interested in the instant when $x = 10$ and $dS/dt = 5$, giving

$$5 = 2 \cdot 10\frac{dx}{dt},$$

so

$$\frac{dx}{dt} = \frac{5}{20} = \frac{1}{4} \text{ unit per second.}$$

35. We have

$$\frac{dM}{dt} = (3x^2 + 0.4x^3)\frac{dx}{dt}.$$

If $x = 5$, then

$$\frac{dM}{dt} = [3(5^2) + 0.4(5^3)](0.02) = 2.5 \text{ gm/hr}.$$

36. We have
$$\frac{dA}{dt} = (3 + 4\cos\theta + \cos(2\theta))\frac{d\theta}{dt}.$$
So
$$\left.\frac{dA}{dt}\right|_{\theta=\pi/2} = \left(3 + 4\cos\left(\frac{\pi}{2}\right) + \cos\pi\right) 0.3 = 0.6 \text{ cm}^2/min.$$

37. We see from the parametric equations that the particle moves along a line. It suffices to plot two points: at $t = 0$, the particle is at point $(4, 1)$, and at $t = 1$, the particle is at point $(2, 5)$. Since x decreases as t increases, the motion is right to left and the curve is shown in Figure 4.158.

Alternately, we can solve the first equation for t, giving $t = -(x-4)/2$, and substitute this into the second equation to get
$$y = 4\left(\frac{-(x-4)}{2}\right) + 1 = -2x + 9.$$
The line is $y = -2x + 9$.

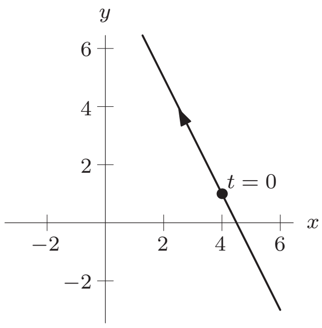

Figure 4.158

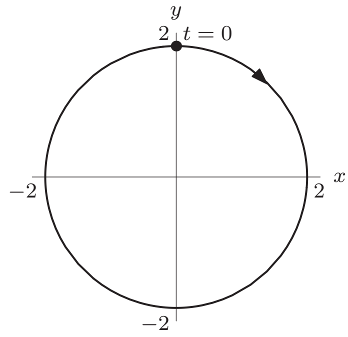

Figure 4.159

38. The graph is a circle centered at the origin with radius 2. The equation is
$$x^2 + y^2 = (2\sin t)^2 + (2\cos t)^2 = 4.$$
The particle is at the point $(0, 1)$ when $t = 0$, and motion is clockwise. See Figure 4.159.

Problems

39. (a) The function f is a local maximum where $f'(x) = 0$ and $f' > 0$ to the left, $f' < 0$ to the right. This occurs at the point x_3.

(b) The function f is a local minimum where $f'(x) = 0$ and $f' < 0$ to the left, $f' > 0$ to the right. This occurs at the points x_1 and x_5.

(c) The graph of f is climbing fastest where f' is a maximum, which is at the point x_2.

(d) The graph of f is falling most steeply where f' is the most negative, which is at the point 0.

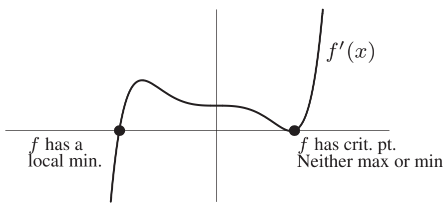
40. The function f has critical points at $x = 1, x = 3, x = 5$.

By the first derivative test, since f' is positive to the left of $x = 1$ and negative to the right, $x = 1$ is a local maximum.

Since f' is negative to the left of $x = 3$ and positive to the right, $x = 3$ is a local minimum.

Since f' does not change sign at $x = 5$, this point is neither a local maximum nor a local minimum.

41. The critical points of f occur where f' is zero. These two points are indicated in the figure below.



Note that the point labeled as a local minimum of f is not a critical point of f'.

42. From the first condition, we get that $x = 2$ is a local minimum for f. From the second condition, it follows that $x = 4$ is an inflection point. A possible graph is shown in Figure 4.160.

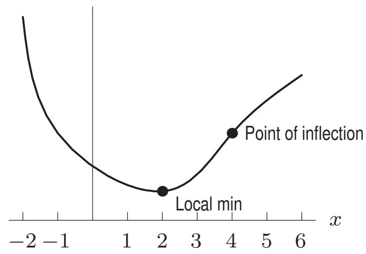


Figure 4.160

43. Since the x^3 term has coefficient of 1, the cubic polynomial is of the form $y = x^3 + ax^2 + bx + c$. We now find a, b, and c. Differentiating gives

$$\frac{dy}{dx} = 3x^2 + 2ax + b.$$

The derivative is 0 at local maxima and minima, so

$$\left.\frac{dy}{dx}\right|_{x=1} = 3(1)^2 + 2a(1) + b = 3 + 2a + b = 0$$

$$\left.\frac{dy}{dx}\right|_{x=3} = 3(3)^2 + 2a(3) + b = 27 + 6a + b = 0$$

Subtracting the first equation from the second and solving for a and b gives

$$24 + 4a = 0 \qquad \text{so} \qquad a = -6$$
$$b = -3 - 2(-6) = 9.$$

Since the y-intercept is 5, the cubic is

$$y = x^3 - 6x^2 + 9x + 5.$$

Since the coefficient of x^3 is positive, $x = 1$ is the maximum and $x = 3$ is the minimum. See Figure 4.161. To confirm that $x = 1$ gives a maximum and $x = 3$ gives a minimum, we calculate

$$\frac{d^2y}{dx^2} = 6x + 2a = 6x - 12.$$

At $x = 1$, $\dfrac{d^2y}{dx^2} = -6 < 0$, so we have a maximum.

At $x = 3$, $\dfrac{d^2y}{dx^2} = 6 > 0$, so we have a minimum.

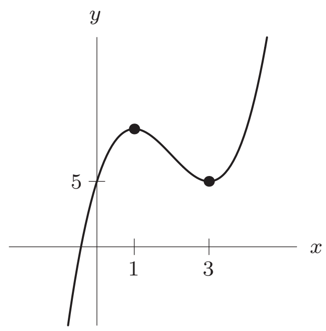

Figure 4.161: Graph of $y = x^3 - 6x^2 + 9x + 5$

44. Since the graph of the quartic polynomial is symmetric about the y-axis, the quartic must have only even powers and be of the form

$$y = ax^4 + bx^2 + c.$$

The y-intercept is 3, so $c = 3$. Differentiating gives

$$\frac{dy}{dx} = 4ax^3 + 2bx.$$

Since there is a maximum at $(1, 4)$, we have $dy/dx = 0$ if $x = 1$, so

$$4a(1)^3 + 2b(1) = 4a + 2b = 0 \qquad \text{so} \qquad b = -2a.$$

The fact that $dy/dx = 0$ if $x = -1$ gives us the same relationship

$$-4a - 2b = 0 \qquad \text{so} \qquad b = -2a.$$

We also know that $y = 4$ if $x = \pm 1$, so

$$a(1)^4 + b(1)^2 + 3 = a + b + 3 = 4 \qquad \text{so} \qquad a + b = 1.$$

Solving for a and b gives

$$a - 2a = 1 \qquad \text{so} \qquad a = -1 \text{ and } b = 2.$$

Finding d^2y/dx^2 so that we can check that $x = \pm 1$ are maxima, not minima, we see

$$\frac{d^2y}{dx^2} = 12ax^2 + 2b = -12x^2 + 4.$$

Thus $\dfrac{d^2y}{dx^2} = -8 < 0$ for $x = \pm 1$, so $x = \pm 1$ are maxima. See Figure 4.162.

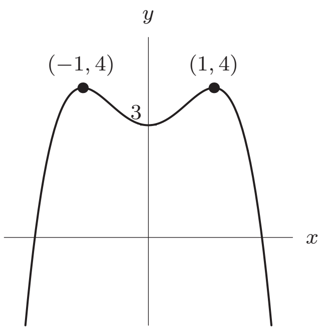

Figure 4.162: Graph of $y = -x^4 + 2x^2 + 3$

45. Differentiating $y = ax^b \ln x$, we have

$$\frac{dy}{dx} = abx^{b-1} \ln x + ax^b \cdot \frac{1}{x} = ax^{b-1}(b \ln x + 1).$$

Since the maximum occurs at $x = e^2$, we know that

$$a(e^2)^{b-1}(b \ln(e^2) + 1) = 0.$$

Since $a \neq 0$ and $(e^2)^{b-1} \neq 0$ for all b, we have

$$b \ln(e^2) + 1 = 0.$$

Since $\ln(e^2) = 2$, the equation becomes

$$\begin{aligned} 2b + 1 &= 0 \\ b &= -\frac{1}{2}. \end{aligned}$$

Thus $y = ax^{-1/2}\ln x$. When $x = e^2$, we know $y = 6e^{-1}$, so

$$y = a(e^2)^{-1/2}\ln e^2 = ae^{-1}(2) = 6e^{-1}$$
$$a = 3.$$

Thus $y = 3x^{-1/2}\ln x$. To check that $x = e^2$ gives a local maximum, we differentiate twice

$$\frac{dy}{dx} = -\frac{3}{2}x^{-3/2}\ln x + 3x^{-1/2}\cdot\frac{1}{x} = -\frac{3}{2}x^{-3/2}\ln x + 3x^{-3/2},$$
$$\frac{d^2y}{dx^2} = \frac{9}{4}x^{-5/2}\ln x - \frac{3}{2}x^{-3/2}\cdot\frac{1}{x} - \frac{3}{2}\cdot 3x^{-5/2}$$
$$= \frac{9}{4}x^{-5/2}\ln x - 6x^{-5/2} = \frac{3}{4}x^{-5/2}(3\ln x - 8).$$

At $x = e^2$, since $\ln(e^2) = 2$, we have a maximum because

$$\frac{d^2y}{dx^2} = \frac{3}{4}(e^2)^{-5/2}\left(3\ln(e^2) - 8\right) = \frac{3}{4}e^{-5}(3\cdot 2 - 8) < 0.$$

See Figure 4.163.

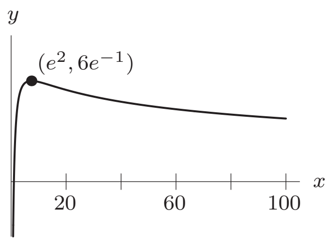

Figure 4.163: Graph of $y = 3x^{-1/2}\ln x$

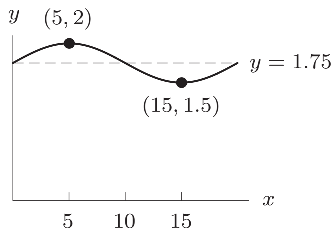

Figure 4.164: Graph of $y = 0.25\sin(\pi x/10) + 1.75$

46. Since the maximum is $y = 2$ and the minimum is $y = 1.5$, the amplitude is $A = (2 - 1.5)/2 = 0.25$. Between the maximum and the minimum, the x-value changes by 10. There is half a period between a maximum and the next minimum, so the period is 20. Thus

$$\frac{2\pi}{B} = 20 \qquad \text{so} \qquad B = \frac{\pi}{10}.$$

The mid-line is $y = C = (2 + 1.5)/2 = 1.75$. Figure 4.164 shows a graph of the function

$$y = 0.25\sin\left(\frac{\pi x}{10}\right) + 1.75.$$

47. First notice that since this function approaches 0 as x approaches either plus or minus infinity, any local extrema that we find are also global extrema.

Differentiating $y = axe^{-bx^2}$ gives

$$\frac{dy}{dx} = ae^{-bx^2} - 2abx^2e^{-bx^2} = ae^{-bx^2}(1 - 2bx^2).$$

Since we have a critical points at $x = 1$ and $x = -1$, we know $1 - 2b = 0$, so $b = 1/2$.

The global maximum is 2 at $x = 1$, so we have $2 = ae^{-1/2}$ which gives $a = 2e^{1/2}$. Notice that this value of a also gives the global minimum at $x = -1$.

Thus,

$$y = 2xe^{(\frac{1-x^2}{2})}.$$

48. We want to maximize the volume $V = x^2h$ of the box, shown in Figure 4.165. The box has 6 faces: the top and bottom, each of which has area x^2 and the four sides, each of which has area xh. Thus $8 = 2x^2 + 4xh$, so

$$h = \frac{8 - 2x^2}{4x}.$$

Substituting this expression in for h in the formula for V gives

$$V = x^2 \cdot \frac{8 - 2x^2}{4x} = \frac{1}{4}(8x - 2x^3).$$

Differentiating gives

$$\frac{dV}{dx} = \frac{1}{4}(8 - 6x^2).$$

To maximize V we look for critical points, so we solve $0 = (8 - 6x^2)/4$, getting $x = \pm\sqrt{4/3}$. We discard the negative solution, since x is a positive length. Then we can find

$$h = \frac{8 - 2x^2}{4x} = \frac{8 - 2\left(\frac{4}{3}\right)}{4\sqrt{\frac{4}{3}}} = \frac{\frac{16}{3}}{4\sqrt{\frac{4}{3}}} = \frac{\frac{4}{3}}{\sqrt{\frac{4}{3}}} = \sqrt{\frac{4}{3}}.$$

Thus $x = h = \sqrt{4/3}$ cm (the box is a cube).

We can check that this critical point is a maximum of V by checking the sign of

$$\frac{d^2V}{dx^2} = -3x^2$$

which is negative when $x \neq 0$. So V is concave down at the critical point and therefore $x = \sqrt{4/3}$ gives a maximum value of V.

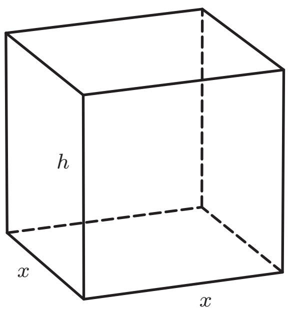

Figure 4.165

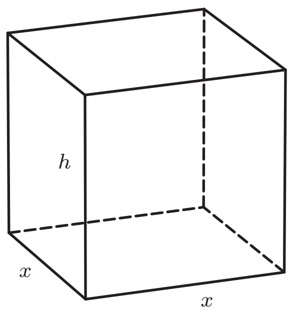

Figure 4.166

49. We want to maximize the volume $V = x^2h$ of the box, shown in Figure 4.166. The box has 5 faces: the bottom, which has area x^2 and the four sides, each of which has area xh. Thus $8 = x^2 + 4xh$, so

$$h = \frac{8 - x^2}{4x}.$$

Substituting this expression in for h in the formula for V gives

$$V = x^2 \cdot \frac{8 - x^2}{4x} = \frac{1}{4}(8x - x^3).$$

Differentiating gives

$$\frac{dV}{dx} = \frac{1}{4}(8 - 3x^2).$$

To maximize V we look for critical points, so we solve $0 = (8 - 3x^2)/4$, getting $x = \pm\sqrt{8/3}$. We discard the negative solution, since x is a positive length. Then we can find

$$h = \frac{8 - x^2}{4x} = \frac{8 - \frac{8}{3}}{4\sqrt{\frac{8}{3}}} = \frac{\frac{16}{3}}{4\sqrt{\frac{8}{3}}} = \frac{\frac{4}{3}}{2\sqrt{\frac{2}{3}}} = \sqrt{\frac{2}{3}}.$$

Thus $x = \sqrt{8/3}$ cm and $h = \sqrt{2/3}$ cm.

We can check that this critical point is a maximum of V by checking the sign of

$$\frac{d^2V}{dx^2} = -\frac{3}{2}x,$$

which is negative when $x > 0$. So V is concave down at the critical point and therefore $x = \sqrt{8/3}$ gives a maximum value of V.

50. We want to maximize the volume $V = \pi r^2 h$ of the cylinder, shown in Figure 4.167. The cylinder has 3 pieces: the top and bottom disks, each of which has area πr^2 and the tube, which has area $2\pi rh$. Thus $8 = 2\pi r^2 + 2\pi rh$. Solving for h gives

$$h = \frac{8 - 2\pi r^2}{2\pi r}.$$

Substituting this expression in for h in the formula for V gives

$$V = \pi r^2 \cdot \frac{8 - 2\pi r^2}{2\pi r} = 4r - \pi r^3.$$

Differentiating gives

$$\frac{dV}{dr} = 4 - 3\pi r^2.$$

To maximize V we look for critical points, so we solve $0 = 4 - 3\pi r^2$, thus $r = \pm 2/\sqrt{3\pi}$. We discard the negative solution, since r is a positive length. Substituting this value in for r in the formula for h gives

$$h = \frac{8 - 2\pi\left(\frac{4}{3\pi}\right)}{2\pi\frac{2}{\sqrt{3\pi}}} = \frac{\frac{16}{3}}{2\pi\frac{2}{\sqrt{3\pi}}} = \frac{\frac{8}{3\pi}}{\frac{2}{\sqrt{3\pi}}} = \frac{4}{\sqrt{3\pi}}.$$

We can check that this critical point is a maximum of V by checking the sign of

$$\frac{d^2V}{dr^2} = -6\pi r$$

which is negative when $r > 0$. So V is concave down at the critical point and therefore $r = 2/\sqrt{3\pi}$ is a maximum.

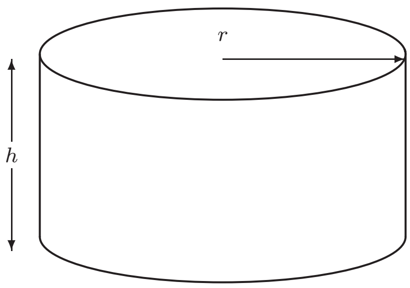

Figure 4.167

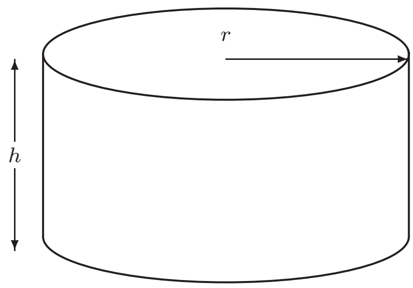

Figure 4.168

51. We want to maximize the volume $V = \pi r^2 h$ of the cylinder, shown in Figure 4.168. The cylinder has 2 pieces: the end disk, of area πr^2 and the tube, which has area $2\pi rh$. Thus $8 = \pi r^2 + 2\pi rh$. Solving for h gives

$$h = \frac{8 - \pi r^2}{2\pi r}.$$

Substituting this expression in for h in the formula for V gives

$$V = \pi r^2 \cdot \frac{8 - \pi r^2}{2\pi r} = \frac{1}{2}(8r - \pi r^3).$$

Differentiating gives

$$\frac{dV}{dr} = \frac{1}{2}(8 - 3\pi r^2).$$

To maximize V we look for critical points, so we solve $0 = (8-3\pi r^2)/2$, thus $r = \pm\sqrt{8/(3\pi)}$. We discard the negative solution, since r is a positive length. Substituting this value in for r in the formula for h gives

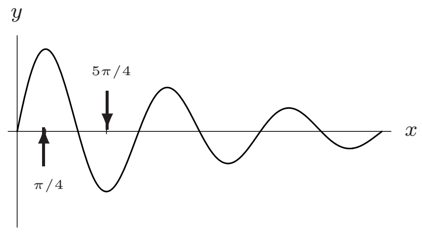
$$h = \frac{8 - \pi\left(\frac{8}{3\pi}\right)}{2\pi\sqrt{\frac{8}{3\pi}}} = \frac{\frac{16}{3}}{2\pi\sqrt{\frac{8}{3\pi}}} = \frac{\frac{8}{3\pi}}{\sqrt{\frac{8}{3\pi}}} = \sqrt{\frac{8}{3\pi}}.$$

We can check that this critical point is a maximum of V by checking the sign of

$$\frac{d^2V}{dr^2} = -3\pi r$$

which is negative when $r > 0$. So V is concave down at the critical point and therefore $r = \sqrt{8/(3\pi)}$ is a maximum.

52.



Letting $f(x) = e^{-x}\sin x$, we have

$$f'(x) = -e^{-x}\sin x + e^{-x}\cos x.$$

Solving $f'(x) = 0$, we get $\sin x = \cos x$. This means $x = \arctan(1) = \pi/4$, and $\pi/4$ plus multiples of π, are the critical points of $f(x)$. By evaluating $f(x)$ at the points $k\pi + \pi/4$, where k is an integer, we can find:

$$e^{-5\pi/4}\sin(5\pi/4) \le e^{-x}\sin x \le e^{-\pi/4}\sin(\pi/4),$$

since $f(0) = 0$ at the endpoint. So

$$-0.014 \le e^{-x}\sin x \le 0.322.$$

53. Let $f(x) = x\sin x$. Then $f'(x) = x\cos x + \sin x$.
$f'(x) = 0$ when $x = 0, x \approx 2$, and $x \approx 5$. The latter two estimates we can get from the graph of $f'(x)$.

Zooming in (or using some other approximation method), we can find the zeros of $f'(x)$ with more precision. They are (approximately) 0, 2.029, and 4.913. We check the endpoints and critical points for the global maximum and minimum.

$$f(0) = 0, \qquad f(2\pi) = 0,$$
$$f(2.029) \approx 1.8197, \qquad f(4.914) \approx -4.814.$$

Thus for $0 \le x \le 2\pi$, $-4.81 \le f(x) \le 1.82$.

54. To find the best possible bounds for $f(x) = x^3 - 6x^2 + 9x + 5$ on $0 \le x \le 5$, we find the global maximum and minimum for the function on the interval. First, we find the critical points. Differentiating yields

$$f'(x) = 3x^2 - 12x + 9$$

Letting $f'(x) = 0$ and factoring yields

$$\begin{aligned} 3x^2 - 12x + 9 &= 0 \\ 3(x^2 - 4x + 3) &= 0 \\ 3(x-3)(x-1) &= 0 \end{aligned}$$

So $x = 1$ and $x = 3$ are critical points for the function on $0 \le x \le 5$. Evaluating the function at the critical points and endpoints gives us

$$\begin{aligned} f(0) &= (0)^3 - 6(0)^2 + 9(0) + 5 = 5 \\ f(1) &= (1)^3 - 6(1)^2 + 9(1) + 5 = 9 \\ f(3) &= (3)^3 - 6(3)^2 + 9(3) + 5 = 5 \\ f(5) &= (5)^3 - 6(5)^2 + 9(5) + 5 = 25 \end{aligned}$$

So the global minimum on this interval is $f(0) = f(3) = 5$ and the global maximum is $f(5) = 25$. From this we conclude

$$5 \le x^3 - 6x^2 + 9x + 5 \le 25$$

are the best possible bounds for the function on the interval $0 \le x \le 5$.

55. We first solve for P

$$P = -6jm^2 + 4jk - 5km,$$

and find the derivative

$$\frac{dP}{dm} = -12jm - 5k.$$

Since the derivative is defined for all m, we find the critical points by solving $dP/dm = 0$:

$$\frac{dP}{dm} = -12jm - 5k = 0,$$
$$m = -\frac{5k}{12j}.$$

There is one critical point at $m = -5k/(12j)$. Since P is a quadratic function of m with a negative leading coefficient $-6j$, the critical point gives the global maximum of P. There is no global minimum because $P \to -\infty$ as $m \to \pm\infty$.

56. Differentiating gives

$$\frac{dy}{dx} = a(e^{-bx} - bxe^{-bx}) = ae^{-bx}(1 - bx).$$

Thus, $dy/dx = 0$ when $x = 1/b$. Then

$$y = a\frac{1}{b}e^{-b \cdot 1/b} = \frac{a}{b}e^{-1}.$$

Differentiating again gives

$$\frac{d^2y}{dx^2} = -abe^{-bx}(1 - bx) - abe^{-bx}$$
$$= -abe^{-bx}(2 - bx)$$

When $x = 1/b$,

$$\frac{d^2y}{dx^2} = -abe^{-b \cdot 1/b}\left(2 - b \cdot \frac{1}{b}\right) = -abe^{-1}.$$

Therefore the point $(\frac{1}{b}, \frac{a}{b}e^{-1})$ is a maximum if a and b are positive. We can make $(2, 10)$ a maximum by setting

$$\frac{1}{b} = 2 \quad \text{so} \quad b = \frac{1}{2}$$

and

$$\frac{a}{b}e^{-1} = \frac{a}{1/2}e^{-1} = 2ae^{-1} = 10 \quad \text{so} \quad a = 5e.$$

Thus $a = 5e$, $b = 1/2$.

57. (a) We set the derivative equal to zero and solve for t to find critical points. Using the product rule, we have:

$$f'(t) = (at^2)(e^{-bt}(-b)) + (2at)e^{-bt} = 0$$
$$ate^{-bt}(-bt + 2) = 0$$
$$t = 0 \quad \text{or} \quad t = \frac{2}{b}.$$

There are two critical points: $t = 0$ and $t = 2/b$.

(b) Since we want a critical point at $t = 5$, we substitute and solve for b:

$$5 = 2/b$$
$$b = \frac{2}{5} = 0.4.$$

To find the value of a, we use the fact that $f(5) = 12$, so we have:

$$a(5^2)e^{-0.4(5)} = 12$$
$$a \cdot 25e^{-2} = 12$$
$$a = \frac{12e^2}{25} = 3.547.$$

(c) To show that $f(t)$ has a local minimum at $t = 0$ and a local maximum at $t = 5$, we can use the first derivative test or the second derivative test. Using the first derivative test, we evaluate f' at values on either side of $t = 0$ and $t = 5$. Since $f'(t) = 3.547te^{-0.4t}(-0.4t + 2)$, we have

$$f'(-1) = -3.547e^{0.4}(2.4) = -12.700 < 0$$

and

$$f'(1) = 3.547e^{-0.4}(1.6) = 3.804 > 0,$$

and

$$f'(6) = 3.547(6)e^{-2.4}(-0.4) = -0.772 < 0.$$

The function f is decreasing to the left of $t = 0$, increasing between $t = 0$ and $t = 5$, and decreasing to the right of $t = 5$. Therefore, $f(t)$ has a local minimum at $t = 0$ and a local maximum at $t = 5$. See Figure 4.169.

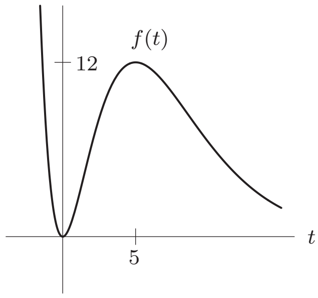


Figure 4.169

58. We have $f(x) = x^2 + 2ax = x(x + 2a) = 0$ when $x = 0$ or $x = -2a$.

$$f'(x) = 2x + 2a = 2(x + a) \begin{cases} = 0 & \text{when } x = -a \\ > 0 & \text{when } x > -a \\ < 0 & \text{when } x < -a. \end{cases}$$

See Figure 4.170. Furthermore, $f''(x) = 2$, so that $f(-a) = -a^2$ is a global minimum, and the graph is always concave up.

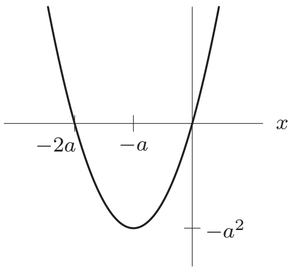

Figure 4.170

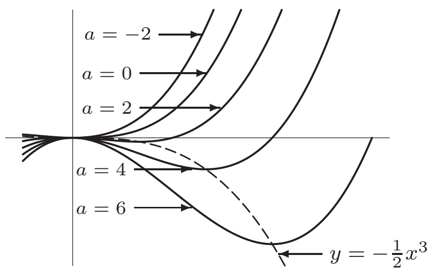
Increasing $|a|$ stretches the graph horizontally. Also, the critical value (the value of f at the critical point) drops further beneath the x-axis. Letting $a < 0$ would reflect the graph shown through the y-axis.

59.



To solve for the critical points, we set $\frac{dy}{dx} = 0$. Since $\frac{d}{dx}\left(x^3 - ax^2\right) = 3x^2 - 2ax$, we want $3x^2 - 2ax = 0$, so $x = 0$ or $x = \frac{2}{3}a$. At $x = 0$, we have $y = 0$. This first critical point is independent of a and lies on the curve $y = -\frac{1}{2}x^3$. At $x = \frac{2}{3}a$, we calculate $y = -\frac{4}{27}a^3 = -\frac{1}{2}\left(\frac{2}{3}a\right)^3$. Thus the second critical point also lies on the curve $y = -\frac{1}{2}x^3$.

60. We want the maximum value of $r(t) = ate^{-bt}$ to be 0.3 ml/sec and to occur at $t = 0.5$ sec. Differentiating gives

$$r'(t) = ae^{-bt} - abte^{-bt},$$

so $r'(t) = 0$ when

$$ae^{-bt}(1 - bt) = 0 \qquad \text{or} \qquad t = \frac{1}{b}.$$

Since the maximum occurs at $t = 0.5$, we have

$$\frac{1}{b} = 0.5 \qquad \text{so} \qquad b = 2.$$

Thus, $r(t) = ate^{-2t}$. The maximum value of r is given by

$$r(0.5) = a(0.5)e^{-2(0.5)} = 0.5ae^{-1}.$$

Since the maximum value of r is 0.3, we have

$$0.5ae^{-1} = 0.3 \qquad \text{so} \qquad a = \frac{0.3e}{0.5} = 1.63.$$

Thus, $r(t) = 1.63te^{-2t}$ ml/sec.

61. We know that $dp/dt = -3$ mm/sec when $p = 35$ mm and we want to know q and dq/dt at that time. We also know that $f = 15$ mm. Since

$$\frac{1}{p} + \frac{1}{q} = \frac{1}{f},$$

substituting $p = 35$ and $f = 15$ gives

$$\frac{1}{q} = \frac{1}{15} - \frac{1}{35} = \frac{4}{105}, \quad \text{so} \quad q = \frac{105}{4} = 26.25 \text{ mm}.$$

Differentiating with respect to time t gives,

$$-\frac{1}{p^2}\frac{dp}{dt} - \frac{1}{q^2}\frac{dq}{dt} = 0.$$

Substituting gives

$$-\frac{1}{35^2}(-3) - \frac{1}{(105/4)^2}\frac{dq}{dt} = 0,$$

so

$$\frac{dq}{dt} = \frac{(105/4)^2 3}{35^2} = \frac{27}{16} = 1.688 \text{ mm/sec}.$$

Thus, the image is moving away from the lens at 1.688 mm per second.

62.

$$\begin{aligned} r(\lambda) &= a(\lambda)^{-5}(e^{b/\lambda} - 1)^{-1} \\ r'(\lambda) &= a(-5\lambda^{-6})(e^{b/\lambda} - 1)^{-1} + a(\lambda^{-5})\left(\frac{b}{\lambda^2}e^{b/\lambda}\right)(e^{b/\lambda} - 1)^{-2} \end{aligned}$$

$(0.96, 3.13)$ is a maximum, so $r'(0.96) = 0$ implies that the following holds, with $\lambda = 0.96$:

$$\begin{aligned} 5\lambda^{-6}(e^{b/\lambda} - 1)^{-1} &= \lambda^{-5}\left(\frac{b}{\lambda^2}e^{b/\lambda}\right)(e^{b/\lambda} - 1)^{-2} \\ 5\lambda(e^{b/\lambda} - 1) &= be^{b/\lambda} \\ 5\lambda e^{b/\lambda} - 5\lambda &= be^{b/\lambda} \\ 5\lambda e^{b/\lambda} - be^{b/\lambda} &= 5\lambda \\ \left(\frac{5\lambda - b}{5\lambda}\right)e^{b/\lambda} &= 1 \\ \frac{4.8 - b}{4.8}e^{b/0.96} - 1 &= 0. \end{aligned}$$

Using Newton's method, or some other approximation method, we search for a root. The root should be near 4.8. Using our initial guess, we get $b \approx 4.7665$. At $\lambda = 0.96$, $r = 3.13$, so

$$\begin{aligned} 3.13 &= \frac{a}{0.96^5(e^{b/0.96}-1)} \qquad \text{or} \\ a &= 3.13(0.96)^5(e^{b/0.96}-1) \\ &\approx 363.23. \end{aligned}$$

As a check, we try $r(4) \approx 0.155$, which looks about right on the given graph.

63. Since $I(t)$ is a periodic function with period $2\pi/w$, it is enough to consider $I(t)$ for $0 \le wt \le 2\pi$. Differentiating, we find

$$\frac{dI}{dt} = -w\sin(wt) + \sqrt{3}w\cos(wt).$$

At a critical point

$$\begin{aligned} -w\sin(wt) + \sqrt{3}w\cos(wt) &= 0 \\ \sin(wt) &= \sqrt{3}\cos(wt) \\ \tan(wt) &= \sqrt{3}. \end{aligned}$$

So $wt = \pi/3$ or $4\pi/3$, or these values plus multiples of 2π. Substituting into I, we see

$$\text{At } wt = \frac{\pi}{3}: \quad I = \cos\left(\frac{\pi}{3}\right) + \sqrt{3}\sin\left(\frac{\pi}{3}\right) = \frac{1}{2} + \sqrt{3}\cdot\left(\frac{\sqrt{3}}{2}\right) = 2.$$

$$\text{At } wt = \frac{4\pi}{3}: \quad I = \cos\left(\frac{4\pi}{3}\right) + \sqrt{3}\sin\left(\frac{4\pi}{3}\right) = -\frac{1}{2} - \sqrt{3}\cdot\left(\frac{\sqrt{3}}{2}\right) = -2.$$

Thus, the maximum value is 2 amps and the minimum is -2 amps.

64.

$$\frac{dE}{d\theta} = \frac{(\mu+\theta)(1-2\mu\theta) - (\theta - \mu\theta^2)}{(\mu+\theta)^2} = \frac{\mu(1-2\mu\theta-\theta^2)}{(\mu+\theta)^2}.$$

Now $dE/d\theta = 0$ when $\theta = -\mu \pm \sqrt{1+\mu^2}$. Since $\theta > 0$, the only possible critical point is when $\theta = -\mu + \sqrt{\mu^2+1}$. Differentiating again gives $E'' < 0$ at this point and so it is a local maximum. Since $E(\theta)$ is continuous for $\theta > 0$ and $E(\theta)$ has only one critical point, the local maximum is the global maximum.

65. The top half of the circle has equation $y = \sqrt{1-x^2}$. The rectangle in Figure 4.171 has area, A, given by

$$A = 2xy = 2x\sqrt{1-x^2}, \qquad \text{for } 0 \le x \le 1.$$

At a critical point,

$$\begin{aligned} \frac{dA}{dt} = 2\sqrt{1-x^2} + 2x\left(\frac{1}{2}\left(1-x^2\right)^{-1/2}(-2x)\right) &= 0 \\ 2\sqrt{1-x^2} - \frac{2x^2}{\sqrt{1-x^2}} &= 0 \\ \frac{2\left(\sqrt{1-x^2}\right)^2 - 2x^2}{\sqrt{1-x^2}} &= 0 \\ \frac{2(1-x^2-x^2)}{\sqrt{1-x^2}} &= 0 \\ 2(1-2x^2) &= 0 \\ x &= \pm\frac{1}{\sqrt{2}}. \end{aligned}$$

Since $A = 0$ at the endpoints $x = 0$ and $x = 1$, and since A is positive at the only critical point, $x = 1/\sqrt{2}$, in the interval $0 \le x \le 1$, the critical point is a local and global maximum. The vertices on the circle have $y = \sqrt{1-(1/2)^2} = 1/\sqrt{2}$. Thus the coordinates of the rectangle with maximum area are

$$\left(\frac{1}{\sqrt{2}}, 0\right); \quad \left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right); \quad \left(-\frac{1}{\sqrt{2}}, 0\right); \quad \left(-\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)$$

and the maximum area is

$$A = 2\frac{1}{\sqrt{2}} \cdot \frac{1}{\sqrt{2}} = 1.$$

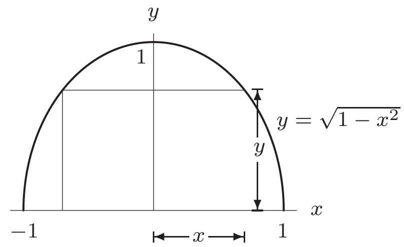


Figure 4.171

66. The triangle in Figure 4.172 has area, A, given by

$$A = \frac{1}{2}x \cdot y = \frac{1}{2}x^3e^{-3x}.$$

If the area has a maximum, it occurs where

$$\begin{aligned}\frac{dA}{dx} = \frac{3}{2}x^2e^{-3x} - \frac{3}{2}x^3e^{-3x} &= 0\\ \frac{3}{2}x^2\left(1-x\right)e^{-3x} &= 0\\ x &= 0, 1.\end{aligned}$$

The value $x = 0$ gives the minimum area, $A = 0$, for $x \geq 0$. Since

$$\frac{dA}{dx} = \frac{3}{2}x^2(1-x)e^{-3x},$$

we see that

$$\frac{dA}{dx} > 0 \text{ for } 0 < x < 1 \qquad \text{and} \qquad \frac{dA}{dx} < 0 \text{ for } x > 1.$$

Thus, $x = 1$ gives the local and global maximum of

$$A = \frac{1}{2}1^3e^{-3\cdot 1} = \frac{1}{2e^3}.$$

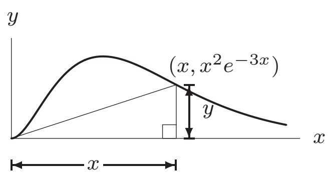

Figure 4.172

67. The distance from a given point on the parabola (x, x^2) to $(1, 0)$ is given by

$$D = \sqrt{(x-1)^2 + (x^2-0)^2}.$$

Minimizing this is equivalent to minimizing $d = (x-1)^2 + x^4$. (We can ignore the square root if we are only interested in minimizing because the square root is smallest when the thing it is the square root of is smallest.) To minimize d, we find its critical points by solving $d' = 0$. Since $d = (x-1)^2 + x^4 = x^2 - 2x + 1 + x^4$,

$$d' = 2x - 2 + 4x^3 = 2(2x^3 + x - 1).$$

By graphing $d' = 2(2x^3 + 2x - 1)$ on a calculator, we see that it has only 1 root, $x \approx 0.59$. This must give a minimum because $d \to \infty$ as $x \to -\infty$ and as $x \to +\infty$, and d has only one critical point. This is confirmed by the second derivative test: $d'' = 12x^2 + 2 = 2(6x^2 + 1)$, which is always positive. Thus the point $(0.59, 0.59^2) \approx (0.59, 0.35)$ is approximately the closest point of $y = x^2$ to $(1, 0)$.

68. Any point on the curve can be written (x, x^2). The distance between such a point and $(3, 0)$ is given by

$$s(x) = \sqrt{(3-x)^2 + (0-x^2)^2} = \sqrt{(3-x)^2 + x^4}.$$

Plotting this function in Figure 4.173, we see that there is a minimum near $x = 1$.

To find the value of x that minimizes the distance we can instead minimize the function $Q = s^2$ (the derivative is simpler). Then we have

$$Q(x) = (3-x)^2 + x^4.$$

Differentiating $Q(x)$ gives

$$\frac{dQ}{dx} = -6 + 2x + 4x^3.$$

Plotting the function $4x^3 + 2x - 6$ shows that there is one real solution at $x = 1$, which can be verified by substitution; the required coordinates are therefore $(1, 1)$. Because $Q''(x) = 2 + 12x^2$ is always positive, $x = 1$ is indeed the minimum. See Figure 4.174.

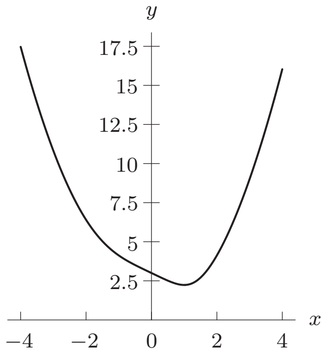

Figure 4.173

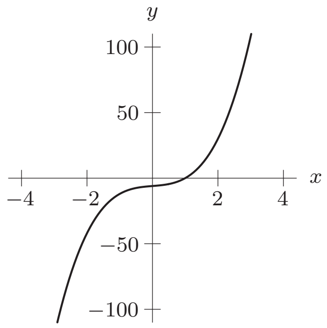

Figure 4.174

69. We see that the width of the tunnel is $2r$. The area of the rectangle is then $(2r)h$. The area of the semicircle is $(\pi r^2)/2$. The cross-sectional area, A, is then

$$A = 2rh + \frac{1}{2}\pi r^2$$

and the perimeter, P, is

$$P = 2h + 2r + \pi r.$$

From $A = 2rh + (\pi r^2)/2$ we get

$$h = \frac{A}{2r} - \frac{\pi r}{4}.$$

Thus,

$$P = 2\left(\frac{A}{2r} - \frac{\pi r}{4}\right) + 2r + \pi r = \frac{A}{r} + 2r + \frac{\pi r}{2}.$$

We now have the perimeter in terms of r and the constant A. Differentiating, we obtain

$$\frac{dP}{dr} = -\frac{A}{r^2} + 2 + \frac{\pi}{2}.$$

To find the critical points we set $P' = 0$:

$$\begin{aligned} -\frac{A}{r^2} + \frac{\pi}{2} + 2 &= 0 \\ \frac{r^2}{A} &= \frac{2}{4+\pi} \\ r &= \sqrt{\frac{2A}{4+\pi}}. \end{aligned}$$

Substituting this back into our expression for h, we have

$$h = \frac{A}{2} \cdot \frac{\sqrt{4+\pi}}{\sqrt{2A}} - \frac{\pi}{4} \cdot \frac{\sqrt{2A}}{\sqrt{4+\pi}}.$$

Since $P \to \infty$ as $r \to 0^+$ and as $r \to \infty$, this critical point must be a global minimum. Notice that the h-value simplifies to

$$h = \sqrt{\frac{2A}{4+\pi}} = r.$$

70. Consider the rectangle of sides x and y shown in Figure 4.175.

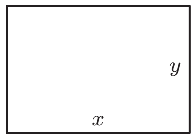

Figure 4.175

The total area is $xy = 3000$, so $y = 3000/x$. Suppose the left and right edges and the lower edge have the shrubs and the top edge has the fencing. The total cost is

$$\begin{aligned} C &= 45(x+2y) + 20(x) \\ &= 65x + 90y. \end{aligned}$$

Since $y = 3000/x$, this reduces to

$$C(x) = 65x + 90(3000/x) = 65x + 270{,}000/x.$$

Therefore, $C'(x) = 65 - 270{,}000/x^2$. We set this to 0 to find the critical points:

$$\begin{aligned} 65 - \frac{270{,}000}{x^2} &= 0 \\ \frac{270{,}000}{x^2} &= 65 \\ x^2 &= 4153.85 \\ x &= 64.450 \text{ ft} \end{aligned}$$

so that

$$y = 3000/x = 46.548 \text{ ft}.$$

Since $C(x) \to \infty$ as $x \to 0^+$ and $x \to \infty$, we see that $x = 64.450$ is a minimum. The minimum total cost is then

$$C(64.450) \approx \$8378.54.$$

71. Figure 4.176 shows the the pool has dimensions x by y and the deck extends 5 feet at either side and 10 feet at the ends of the pool.

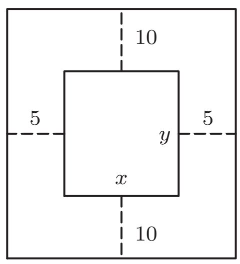

Figure 4.176

The dimensions of the plot of land containing the pool are then $(x+5+5)$ by $(y+10+10)$. The area of the land is then

$$A = (x+10)(y+20),$$

which is to be minimized. We also are told that the area of the pool is $xy = 1800$, so

$$y = 1800/x$$

and

$$\begin{aligned} A &= (x+10)\left(\frac{1800}{x}+20\right) \\ &= 1800 + 20x + \frac{18000}{x} + 200. \end{aligned}$$

We find dA/dx and set it to zero to get

$$\begin{aligned} \frac{dA}{dx} = 20 - \frac{18000}{x^2} &= 0 \\ 20x^2 &= 18000 \\ x^2 &= 900 \\ x &= 30 \text{ feet.} \end{aligned}$$

Since $A \to \infty$ as $x \to 0^+$ and as $x \to \infty$, this critical point must be a global minimum. Also, $y = 1800/30 = 60$ feet. The plot of land is therefore $(30 + 10) = 40$ by $(60 + 20) = 80$ feet.

72. (a) Suppose n passengers sign up for the cruise. If $n \le 100$, then the cruise's revenue is $R = 2000n$, so the maximum revenue is

$$R = 2000 \cdot 100 = 200{,}000.$$

If $n > 100$, then the price is

$$p = 2000 - 10(n - 100)$$

and hence the revenue is

$$R = n(2000 - 10(n - 100)) = 3000n - 10n^2.$$

To find the maximum revenue, we set $dR/dn = 0$, giving $20n = 3000$ or $n = 150$. Then the revenue is

$$R = (2000 - 10 \cdot 50) \cdot 150 = 225{,}000.$$

Since this is more than the maximum revenue when $n \le 100$, the boat maximizes its revenue with 150 passengers, each paying \$1500.

(b) We approach this problem in a similar way to part (a), except now we are dealing with the profit function π. If $n \le 100$, we have

$$\pi = 2000n - 80{,}000 - 400n,$$

so π is maximized with 100 passengers yielding a profit of

$$\pi = 1600 \cdot 100 - 80{,}000 = \$80{,}000.$$

If $n > 100$, we have

$$\pi = n(2000 - 10(n - 100)) - (80{,}000 + 400n).$$

We again set $d\pi/dn = 0$, giving $2600 = 20n$, so $n = 130$. The profit is then \$89,000. So the boat maximizes profit by boarding 130 passengers, each paying \$1700. This gives the boat \$89,000 in profit.

73. (a) $\pi(q)$ is maximized when $R(q) > C(q)$ and they are as far apart as possible. See Figure 4.177.

(b) $\pi'(q_0) = R'(q_0) - C'(q_0) = 0$ implies that $C'(q_0) = R'(q_0) = p$.

Graphically, the slopes of the two curves at q_0 are equal. This is plausible because if $C'(q_0)$ were greater than p or less than p, the maximum of $\pi(q)$ would be to the left or right of q_0, respectively. In economic terms, if the cost were rising more quickly than revenues, the profit would be maximized at a lower quantity (and if the cost were rising more slowly, at a higher quantity).

(c) See Figure 4.178.

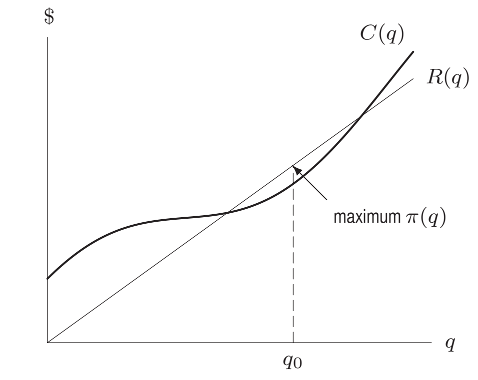

Figure 4.177

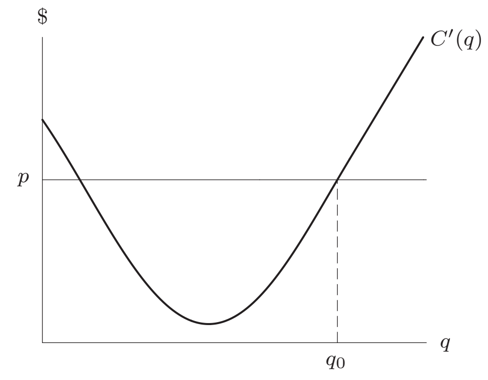

Figure 4.178

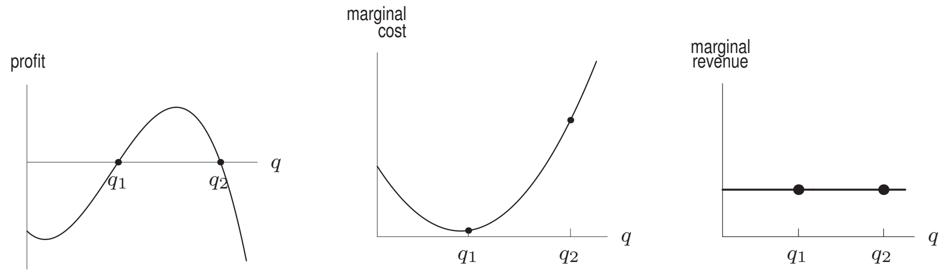
74.



75.

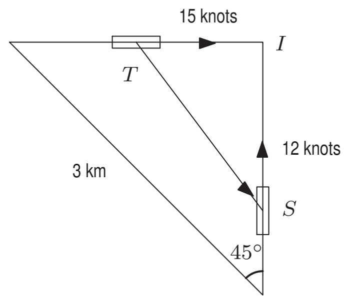


Figure 4.179: Position of the tanker and ship

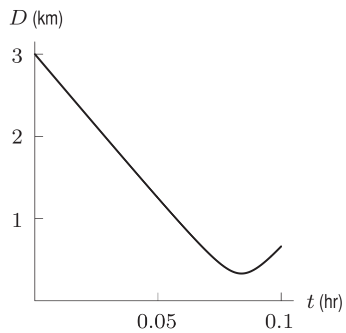

Figure 4.180: Distance between the ship at S and the tanker at T

Suppose t is the time, in hours, since the ships were 3 km apart. Then $\overline{TI} = \frac{3\sqrt{2}}{2} - (15)(1.85)t$ and $\overline{SI} = \frac{3\sqrt{2}}{2} - (12)(1.85)t$. So the distance, $D(t)$, in km, between the ships at time t is

$$D(t) = \sqrt{\left(\frac{3\sqrt{2}}{2} - 27.75t\right)^2 + \left(\frac{3\sqrt{2}}{2} - 22.2t\right)^2}.$$

Differentiating gives

$$\frac{dD}{dt} = \frac{-55.5\left(\frac{3}{\sqrt{2}} - 27.75\,t\right) - 44.4\left(\frac{3}{\sqrt{2}} - 22.2\,t\right)}{2\sqrt{\left(\frac{3}{\sqrt{2}} - 27.75\,t\right)^2 + \left(\frac{3}{\sqrt{2}} - 22.2\,t\right)^2}}.$$

Solving $dD/dt = 0$ gives a critical point at $t = 0.0839$ hours when the ships will be approximately 331 meters apart. So the ships do not need to change course. Alternatively, tracing along the curve in Figure 4.180 gives the same result. Note that this is after the eastbound ship crosses the path of the northbound ship.

76. Since the volume is fixed at 200 ml (i.e. 200 cm^3), we can solve the volume expression for h in terms of r to get (with h and r in centimeters)

$$h = \frac{200 \cdot 3}{7\pi r^2}.$$

Using this expression in the surface area formula we arrive at

$$S = 3\pi r\sqrt{r^2 + \left(\frac{600}{7\pi r^2}\right)^2}$$

By plotting $S(r)$ we see that there is a minimum value near $r = 2.7$ cm.

77. (a) We have $g'(t) = \frac{t(1/t) - \ln t}{t^2} = \frac{1 - \ln t}{t^2}$, which is zero if $t = e$, negative if $t > e$, and positive if $t < e$, since $\ln t$ is increasing. Thus $g(e) = \frac{1}{e}$ is a global maximum for g. Since $t = e$ was the only point at which $g'(t) = 0$, there is no minimum.

(b) Now $\ln t/t$ is increasing for $0 < t < e$, $\ln 1/1 = 0$, and $\ln 5/5 \approx 0.322 < \ln(e)/e$. Thus, for $1 < t < e$, $\ln t/t$ increases from 0 to above $\ln 5/5$, so there must be a t between 1 and e such that $\ln t/t = \ln 5/5$. For $t > e$, there is only one solution to $\ln t/t = \ln 5/5$, namely $t = 5$, since $\ln t/t$ is decreasing for $t > e$. For $0 < t < 1$, $\ln t/t$ is negative and so cannot equal $\ln 5/5$. Thus $\ln x/x = \ln t/t$ has exactly two solutions.

(c) The graph of $\ln t/t$ intersects the horizontal line $y = \ln 5/5$, at $x = 5$ and $x \approx 1.75$.

78. (a) x-intercept: $(a, 0)$, y-intercept: $(0, \frac{1}{a^2+1})$

(b) Area $= \frac{1}{2}(a)(\frac{1}{a^2+1}) = \frac{a}{2(a^2+1)}$

(c)

$$\begin{aligned} A &= \frac{a}{2(a^2+1)} \\ A' &= \frac{2(a^2+1) - a(4a)}{4(a^2+1)^2} \\ &= \frac{2(1-a^2)}{4(a^2+1)^2} \\ &= \frac{(1-a^2)}{2(a^2+1)^2}. \end{aligned}$$

If $A' = 0$, then $a = \pm 1$. We only consider positive values of a, and we note that A' changes sign from positive to negative at $a = 1$. Hence $a = 1$ is a local maximum of A which is a global maximum because $A' < 0$ for all $a > 1$ and $A' > 0$ for $0 < a < 1$.

(d) $A = \frac{1}{2}(1)(\frac{1}{2}) = \frac{1}{4}$

(e) Set $\frac{a}{2(a^2+a)} = \frac{1}{3}$ and solve for a:

$$\begin{aligned} 5a &= 2a^2 + 2 \\ 2a^2 - 5a + 2 &= 0 \\ (2a-1)(a-2) &= 0. \end{aligned}$$

79. (a) Since the volume of water in the container is proportional to its depth, and the volume is increasing at a constant rate,

$$d(t) = \text{ Depth at time } t = Kt,$$

where K is some positive constant. So the graph is linear, as shown in Figure 4.181. Since initially no water is in the container, we have $d(0) = 0$, and the graph starts from the origin.

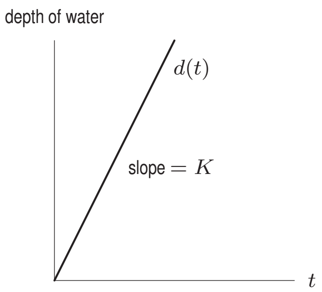

Figure 4.181

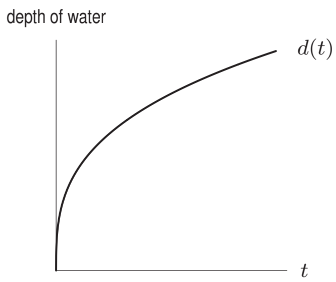

Figure 4.182

(b) As time increases, the additional volume needed to raise the water level by a fixed amount increases. Thus, although the depth, $d(t)$, of water in the cone at time t, continues to increase, it does so more and more slowly. This means $d'(t)$ is positive but decreasing, i.e., $d(t)$ is concave down. See Figure 4.182.

80. (a) The concavity changes at t_1 and t_3, as shown in Figure 4.183.

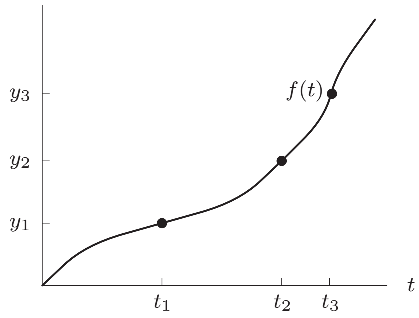

Figure 4.183

(b) $f(t)$ grows most quickly where the vase is skinniest (at y_3) and most slowly where the vase is widest (at y_1). The diameter of the widest part of the vase looks to be about 4 times as large as the diameter at the skinniest part. Since the area of a cross section is given by πr^2, where r is the radius, the ratio between areas of cross sections at these two places is about 4^2, so the growth rates are in a ratio of about 1 to 16 (the wide part being 16 times slower).

81. The volume, V, of a cone of radius r and height h is

$$V = \frac{1}{3}\pi r^2 h.$$

However, Figure 4.184 shows that $h/r = 12/5$, thus $r = 5h/12$, so

$$V = \frac{1}{3}\pi\left(\frac{5}{12}h\right)^2 h = \frac{25}{432}\pi h^3.$$

Differentiating with respect to time, t, gives

$$\frac{dV}{dt} = \frac{25}{144}\pi h^2 \frac{dh}{dt}.$$

When the depth of chemical in the tank is 1 meter, the level is falling at 0.1 meter/min so $h = 1$ and $dh/dt = -0.1$. Thus

$$\frac{dV}{dt} = -\frac{25}{144}\cdot\pi\cdot 1^2\cdot 0.1 = -0.0545 \text{ m}^3/\text{min}.$$

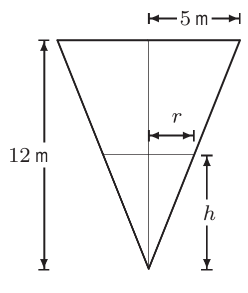

Figure 4.184

82. Evaluating the limits in the numerator and the denominator we get $0/e^0 = 0/1 = 0$, so this is not an indeterminate form. l'Hopital's rule does not apply.

83. We have $\lim_{x\to 1}\sin\pi x = \sin\pi = 0$, and $\lim_{x\to 1} x - 1 = 0$, so this is a $0/0$ form and l'Hopital's rule applies directly.

84. This is a $0/0$ form. Applying l'Hopital's rule twice, we get

$$\lim_{t\to 0}\frac{e^t-1-t}{t^2}=\lim_{t\to 0}\frac{e^t-0-1}{2t}=\lim_{t\to 0}\frac{e^t}{2}=\frac{1}{2}.$$

85. Let $f(t)=3\sin t-\sin 3t$ and $g(t)=3\tan t-\tan 3t$, then $f(0)=0$ and $g(0)=0$. Similarly,

$f'(t)=3\cos t-3\cos 3t$ $\qquad f'(0)=0$

$f''(t)=-3\sin t+9\sin 3t$ $\qquad f''(0)=0$

$f'''(t)=-3\cos t+27\cos 3t$ $\qquad f'''(0)=24$

$g'(t)=3\sec^2 t-3\sec^2 3t$ $\qquad g'(0)=0$

$g''(t)=6\sec^2 t\tan t-18\sec^2 3t\tan 3t$ $\qquad g''(0)=0$

$g'''(t)=-54\sec^4 3t-108\sec^2 37\tan^2 3t+6\sec^4 t+12\sec^2 t\tan^2 t$ $\qquad g'''(0)=-48$

Since the first and second derivatives of f and g are both 0 at $t=0$, we have to go as far as the third derivative to use l'Hopital's rule. Applying l'Hopital's rule gives

$$\lim_{t\to 0^+}\frac{3\sin t-\sin 3t}{3\tan t-\tan 3t}=\lim_{t\to 0^+}\frac{f'(t)}{g'(t)}=\lim_{t\to 0^+}\frac{f''(t)}{g''(t)}=\lim_{t\to 0^+}\frac{f'''(t)}{g'''(t)}=\frac{24}{-48}=-\frac{1}{2}.$$

86. If $f(x)=1-\cosh(5x)$ and $g(x)=x^2$, then $f(0)=g(0)=0$, so we use l'Hopital's Rule:

$$\lim_{x\to 0}\frac{1-\cosh 5x}{x^2}=\lim_{x\to 0}\frac{-5\sinh 5x}{2x}=\lim_{x\to 0}\frac{-25\cosh 5x}{2}=-\frac{25}{2}.$$

87. If $f(x)=x-\sinh x$ and $g(x)=x^3$, then $f(0)=g(0)=0$. However, $f'(0)=g'(0)=f''(0)=g''(0)=0$ also, so we use l'Hopital's Rule three times. Since $f'''(x)=-\cosh x$ and $g'''(x)=6$:

$$\lim_{x\to 0}\frac{x-\sinh x}{x^3}=\lim_{x\to 0}\frac{1-\cosh x}{3x^2}=\lim_{x\to 0}\frac{-\sinh x}{6x}=\lim_{x\to 0}\frac{-\cosh x}{6}=-\frac{1}{6}.$$

88. (a) The population is increasing if $dP/dt>0$, that is, if

$$kP(L-P)>0.$$

Since $P\geq 0$ and $k,L>0$, we must have $P>0$ and $L-P>0$ for this to be true. Thus, the population is increasing if $0<P<L$.

The population is decreasing if $dP/dt<0$, that is, if $P>L$.

The population remains constant if $dP/dt=0$, so $P=0$ or $P=L$.

(b) Differentiating with respect to t using the chain rule gives

$$\begin{aligned}\frac{d^2P}{dt^2}=\frac{d}{dt}\left(kP(L-P)\right)=\frac{d}{dP}(kLP-kP^2)\cdot\frac{dP}{dt}&=(kL-2kP)(kP(L-P))\\&=k^2P(L-2P)(L-P).\end{aligned}$$

89. We are given that the volume is increasing at a constant rate $\frac{dV}{dt}=400$. The radius r is related to the volume by the formula $V=\frac{4}{3}\pi r^3$. By implicit differentiation, we have

$$\frac{dV}{dt}=\frac{4}{3}\pi 3r^2\frac{dr}{dt}=4\pi r^2\frac{dr}{dt}$$

Plugging in $\frac{dV}{dt}=400$ and $r=10$, we have

$$400=400\pi\frac{dr}{dt}$$

so $\frac{dr}{dt}=\frac{1}{\pi}\approx 0.32\mu$m/day.

90. Let r be the radius of the raindrop. Then its volume $V=\frac{4}{3}\pi r^3$ cm^3 and its surface area is $S=4\pi r^2$ cm^2. It is given that

$$\frac{dV}{dt}=2S=8\pi r^2.$$

Furthermore,

$$\frac{dV}{dr} = 4\pi r^2,$$

so from the chain rule,

$$\frac{dV}{dt} = \frac{dV}{dr} \cdot \frac{dr}{dt} \quad \text{and thus} \quad \frac{dr}{dt} = \frac{dV/dt}{dV/dr} = 2.$$

Since dr/dt is a constant, $dr/dt = 2$, the radius is increasing at a constant rate of 2 cm/sec.

91. (a) Since $d\theta/dt$ represents the rate of change of θ with time, $d\theta/dt$ represents the angular velocity of the disk.
(b) Suppose P is the point on the rim shown in Figure 4.185.

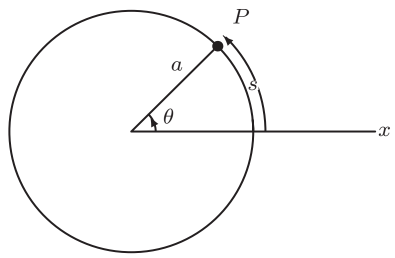

Figure 4.185

Any other point on the rim is moving at the same speed, though in a different direction. We know that since θ is in radians,

$$s = a\theta.$$

Since a is a constant, we know

$$\frac{ds}{dt} = a\frac{d\theta}{dt}.$$

But $ds/dt = v$, the speed of the point on the rim, so

$$v = a\frac{d\theta}{dt}.$$

92. We have

$$\frac{dD}{dt} = K[e^{-r} - (r+1)e^{-r}]\frac{dr}{dt} = -Kre^{-r}\frac{dr}{dt}.$$

93. We have

$$\frac{dM}{dt} = K\left(1 - \frac{1}{1+r}\right)\frac{dr}{dt}.$$

94. Let V be the volume of the ice, so that $V = 3\pi(r^2 - 1^2)$. Now,

$$\frac{dV}{dt} = 6\pi r\frac{dr}{dt}.$$

Thus for $r = 1.5$, we have

$$\frac{dV}{dt} = 6\pi(1.5)(0.03) = 0.848\,\text{cm}^3/\text{hr}.$$

95. The volume, V, of a cone of height h and radius r is

$$V = \frac{1}{3}\pi r^2 h.$$

Since the angle of the cone is $\pi/6$, so $r = h\tan(\pi/6) = h/\sqrt{3}$

$$V = \frac{1}{3}\pi\left(\frac{h}{\sqrt{3}}\right)^2 h = \frac{1}{9}\pi h^3.$$

Differentiating gives

$$\frac{dV}{dh} = \frac{1}{3}\pi h^2.$$

To find dh/dt, use the chain rule to obtain

$$\frac{dV}{dt} = \frac{dV}{dh}\frac{dh}{dt}.$$

So,

$$\frac{dh}{dt} = \frac{dV/dt}{dV/dh} = \frac{0.1\text{meters/hour}}{\pi h^2/3} = \frac{0.3}{\pi h^2} \text{ meters/hour}.$$

Since $r = h\tan(\pi/6) = h/\sqrt{3}$, we have

$$\frac{dr}{dt} = \frac{dh}{dt}\frac{1}{\sqrt{3}} = \frac{1}{\sqrt{3}}\frac{0.3}{\pi h^2} \text{ meters/hour}.$$

96. (a) The surface of the water is circular with radius r cm. Applying Pythagoras' Theorem to the triangle in Figure 4.186 shows that

$$(10-h)^2 + r^2 = 10^2$$

so

$$r = \sqrt{10^2 - (10-h)^2} = \sqrt{20h - h^2} \text{ cm}.$$

(b) We know $dh/dt = -0.1$ cm/hr and we want to know dr/dt when $h = 5$ cm. Differentiating

$$r = \sqrt{20h - h^2}$$

gives

$$\frac{dr}{dt} = \frac{1}{2}(20h - h^2)^{-1/2}\left(20\frac{dh}{dt} - 2h\frac{dh}{dt}\right) = \frac{10-h}{\sqrt{20h-h^2}} \cdot \frac{dh}{dt}.$$

Substituting $dh/dt = -0.1$ and $h = 5$ gives

$$\left.\frac{dr}{dt}\right|_{h=5} = \frac{5}{\sqrt{20\cdot 5 - 5^2}} \cdot (-0.1) = -\frac{1}{2\sqrt{75}} = -0.0577 \text{ cm/hr}.$$

Thus, the radius is decreasing at 0.0577 cm per hour.

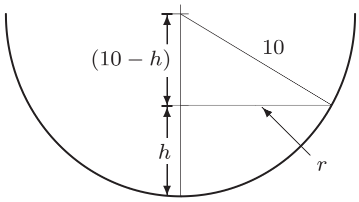

Figure 4.186

97. We have

$$\frac{dF}{dt} = \frac{K(a^2 - 2y^2)}{(a^2+y^2)^{5/2}}\frac{dy}{dt}.$$

(a) When $y = 0$, we have

$$\frac{dF}{dt} = Ka^{-3}\frac{dy}{dt}.$$

So, dF/dt is positive and F is increasing.

(b) When $y = a/\sqrt{2}$, we have

$$\frac{dF}{dt} = \frac{K(a^2 - a^2)}{(a^2 + (a^2/2))^{5/2}}\frac{dy}{dt} = 0.$$

So, $dF/dt = 0$ and F is not changing.

(c) When $y = 2a$, we have

$$\frac{dF}{dt} = \frac{K(a^2 - 8a^2)}{(a^2 + 4a^2)^{5/2}}\frac{dy}{dt} = -\frac{7Ka^2}{(5a^2)^{5/2}}\frac{dy}{dt}.$$

So, dF/dt is negative and F is decreasing.

98. The rate at which the voltage, V, is changing is obtained by differentiating $V = IR$ to get

$$\frac{dV}{dt} = I\frac{dR}{dt} + R\frac{dI}{dt}.$$

Since the voltage remains constant, $dV/dt = 0$. Thus

$$\frac{dR}{dt} = -\frac{R}{I}\frac{dI}{dt},$$

and the rate at which the resistance is changing is

$$\frac{dR}{dt} = -\frac{1000}{0.1}(0.001) = -10 \text{ ohms/min}.$$

We conclude that the resistance is falling by 10 ohms/min.

99. From Figure 4.187, Pythagoras' Theorem shows that the ground distance, d, between the train and the point, B, vertically below the plane is given by

$$d^2 = x^2 + y^2.$$

Figure 4.188 shows that

$$z^2 = d^2 + 4^2$$

so

$$z^2 = x^2 + y^2 + 4^2.$$

We know that when $x = 1,\ dx/dt = 80,\ y = 5,\ dy/dt = 500$, and we want to know dz/dt. First, we find z:

$$z^2 = 1^2 + 5^2 + 4^2 = 42, \text{ so } z = \sqrt{42}.$$

Differentiating $z^2 = x^2 + y^2 + 4^2$ gives

$$2z\frac{dz}{dt} = 2x\frac{dx}{dt} + 2y\frac{dy}{dt}.$$

Canceling 2s and substituting gives

$$\sqrt{42}\frac{dz}{dt} = 1(80) + 5(500)$$

$$\frac{dz}{dt} = \frac{2580}{\sqrt{42}} = 398.103 \text{ mph}.$$

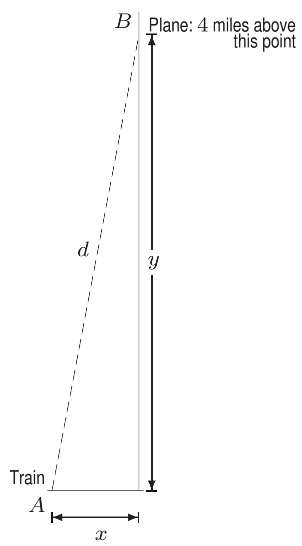

Figure 4.187: View from air

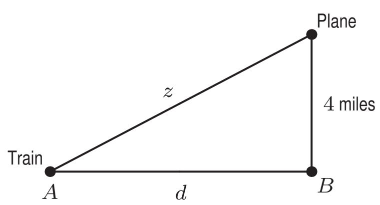

Figure 4.188: Vertical view

100. We want to find dP/dV. Solving $PV = k$ for P gives

$$P = k/V$$

so,

$$\frac{dP}{dV} = -\frac{k}{V^2}.$$

101. (a) Since $V = k/P$, the volume decreases.

(b) Since $PV = k$ and $P = 2$ when $V = 10$, we have $k = 20$, so

$$V = \frac{20}{P}.$$

We think of both P and V as functions of time, so by the chain rule

$$\frac{dV}{dt} = \frac{dV}{dP}\frac{dP}{dt},$$
$$\frac{dV}{dt} = -\frac{20}{P^2}\frac{dP}{dt}.$$

We know that $dP/dt = 0.05$ atm/min when $P = 2$ atm, so

$$\frac{dV}{dt} = -\frac{20}{2^2} \cdot (0.05) = -0.25 \text{ cm}^3\text{/min}.$$

CAS Challenge Problems

102. (a) Since $k > 0$, we have $\lim\limits_{t\to\infty} e^{-kt} = 0$. Thus

$$\lim_{t\to\infty} P = \lim_{t\to\infty} \frac{L}{1 + Ce^{-kt}} = \frac{L}{1 + C \cdot 0} = L.$$

The constant L is called the carrying capacity of the environment because it represents the long-run population in the environment.

(b) Using a CAS, we find

$$\frac{d^2P}{dt^2} = -\frac{LCk^2e^{-kt}(1 - Ce^{-kt})}{(1 + Ce^{-kt})^3}.$$

Thus, $d^2P/dt^2 = 0$ when

$$1 - Ce^{-kt} = 0$$
$$t = -\frac{\ln(1/C)}{k}.$$

Since e^{-kt} and $(1 + Ce^{-kt})$ are both always positive, the sign of d^2P/dt^2 is negative when $(1 - Ce^{-kt}) > 0$, that is, for $t > -\ln(1/C)/k$. Similarly, the sign of d^2P/dt^2 is positive when $(1 - Ce^{-kt}) < 0$, that is, for $t < -\ln(1/C)/k$. Thus, there is an inflection point at $t = -\ln(1/C)/k$.

For $t = -\ln(1/C)/k$,

$$P = \frac{L}{1 + Ce^{\ln(1/C)}} = \frac{L}{1 + C(1/C)} = \frac{L}{2}.$$

Thus, the inflection point occurs where $P = L/2$.

103. (a) The graph has a jump discontinuity whose position depends on a. The function is increasing, and the slope at a given x-value seems to be the same for all values of a. See Figure 4.189.

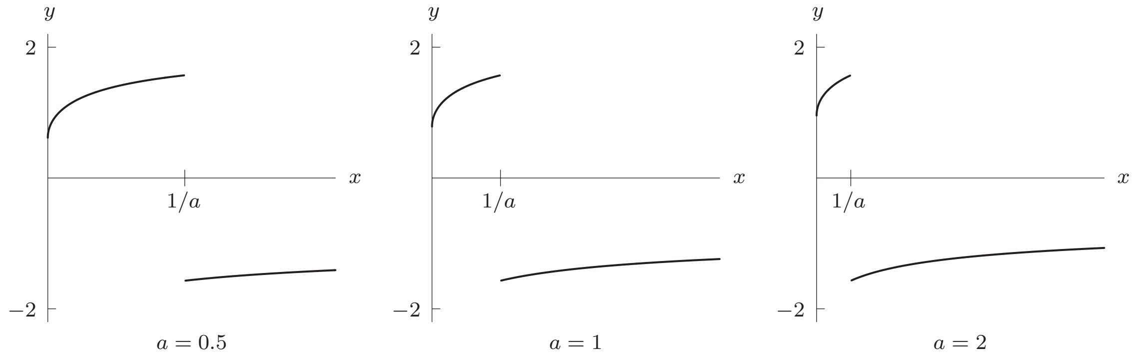

Figure 4.189

(b) Most computer algebra systems will give a fairly complicated answer for the derivative. Here is one example; others may be different.

$$\frac{dy}{dx} = \frac{\sqrt{x} + \sqrt{a}\,\sqrt{a\,x}}{2\,x\,\left(1 + a + 2\,\sqrt{a}\,\sqrt{x} + x + a\,x - 2\,\sqrt{a\,x}\right)}.$$

When we graph the derivative, it appears that we get the same graph for all values of a. See Figure 4.190.

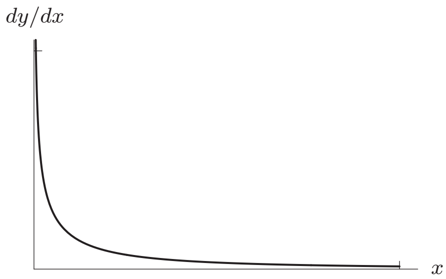

Figure 4.190

(c) Since a and x are positive, we have $\sqrt{ax} = \sqrt{a}\sqrt{x}$. We can use this to simplify the expression we found for the derivative:

$$\begin{aligned}\frac{dy}{dx} &= \frac{\sqrt{x} + \sqrt{a}\sqrt{ax}}{2x\left(1 + a + 2\sqrt{a}\sqrt{x} + x + ax - 2\sqrt{ax}\right)}\\ &= \frac{\sqrt{x} + \sqrt{a}\sqrt{a}\sqrt{x}}{2x\left(1 + a + 2\sqrt{a}\sqrt{x} + x + ax - 2\sqrt{a}\sqrt{x}\right)}\\ &= \frac{\sqrt{x} + a\sqrt{x}}{2x\,(1 + a + x + ax)} = \frac{(1+a)\sqrt{x}}{2x(1+a)(1+x)} = \frac{\sqrt{x}}{2x(1+x)}\end{aligned}$$

Since a has canceled out, the derivative is independent of a. This explains why all the graphs look the same in part (b). (In fact they are not exactly the same, because $f'(x)$ is undefined where $f(x)$ has its jump discontinuity. The point at which this happens changes with a.)

104. (a) A CAS gives

$$\frac{d}{dx}\text{arcsinh}\, x = \frac{1}{\sqrt{1+x^2}}$$

(b) Differentiating both sides of $\sinh(\text{arcsinh}\, x) = x$, we get

$$\begin{aligned}\cosh(\text{arcsinh}\, x)\frac{d}{dx}(\text{arcsinh}\, x) &= 1\\ \frac{d}{dx}(\text{arcsinh}\, x) &= \frac{1}{\cosh(\text{arcsinh}\, x)}.\end{aligned}$$

Since $\cosh^2 x - \sinh^2 x = 1$, $\cosh x = \pm\sqrt{1+\sinh^2 x}$. Furthermore, since $\cosh x > 0$ for all x, we take the positive square root, so $\cosh x = \sqrt{1+\sinh^2 x}$. Therefore, $\cosh(\text{arcsinh}\, x) = \sqrt{1+(\sinh(\text{arcsinh}\, x))^2} = \sqrt{1+x^2}$. Thus

$$\frac{d}{dx}\text{arcsinh}\, x = \frac{1}{\sqrt{1+x^2}}.$$

105. (a) A CAS gives

$$\frac{d}{dx}\text{arccosh}\, x = \frac{1}{\sqrt{x^2-1}}, \quad x \geq 1.$$

(b) Differentiating both sides of $\cosh(\text{arccosh}\, x) = x$, we get

$$\sinh(\text{arccosh}\, x)\frac{d}{dx}(\text{arccosh}\, x) = 1$$
$$\frac{d}{dx}(\text{arccosh}\, x) = \frac{1}{\sinh(\text{arccosh}\, x)}.$$

Since $\cosh^2 x - \sinh^2 x = 1$, $\sinh x = \pm\sqrt{\cosh^2 x - 1}$. If $x \geq 0$, then $\sinh x \geq 0$, so we take the positive square root. So $\sinh x = \sqrt{\cosh^2 x - 1}$, $x \geq 0$. Therefore, $\sinh(\text{arccosh}\, x) = \sqrt{(\cosh(\text{arccosh}\, x))^2 - 1} = \sqrt{x^2-1}$, for $x \geq 1$. Thus

$$\frac{d}{dx}\text{arccosh}\, x = \frac{1}{\sqrt{x^2-1}}.$$

106. (a) Using a computer algebra system or differentiating by hand, we get

$$f'(x) = \frac{1}{2\sqrt{a+x}(\sqrt{a}+\sqrt{x})} - \frac{\sqrt{a+x}}{2\sqrt{x}(\sqrt{a}+\sqrt{x})^2}.$$

Simplifying gives

$$f'(x) = \frac{-a+\sqrt{a}\,\sqrt{x}}{2\left(\sqrt{a}+\sqrt{x}\right)^2\sqrt{x}\,\sqrt{a+x}}.$$

The denominator of the derivative is always positive if $x > 0$, and the numerator is zero when $x = a$. Writing the numerator as $\sqrt{a}(\sqrt{x}-\sqrt{a})$, we see that the derivative changes from negative to positive at $x = a$. Thus, by the first derivative test, the function has a local minimum at $x = a$.

(b) As a increases, the local minimum moves to the right. See Figure 4.191. This is consistent with what we found in part (a), since the local minimum is at $x = a$.

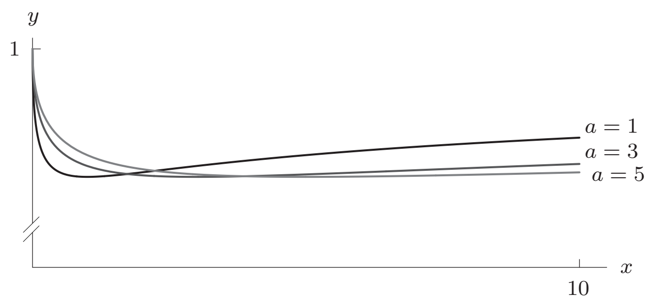

Figure 4.191

(c) Using a computer algebra system to find the second derivative when $a = 2$, we get

$$f''(x) = \frac{4\sqrt{2}+12\sqrt{x}+6\,x^{3/2}-3\sqrt{2}\,x^2}{4\left(\sqrt{2}+\sqrt{x}\right)^3 x^{3/2}\,(2+x)^{3/2}}.$$

Using the computer algebra system again to solve $f''(x) = 0$, we find that it has one zero at $x = 4.6477$. Graphing the second derivative, we see that it goes from positive to negative at $x = 4.6477$, so this is an inflection point.

107. (a) Different CASs give different answers. (In fact, their answers could be more complicated than what you get by hand.) One possible answer is

$$\frac{dy}{dx} = \frac{\tan\left(\frac{x}{2}\right)}{2\sqrt{\frac{1-\cos x}{1+\cos x}}}.$$

(b) The graph in Figure 4.192 is a step function:

$$f(x) = \begin{cases} 1/2 & 2n\pi < x < (2n+1)\pi \\ -1/2 & (2n+1)\pi < x < (2n+2)\pi. \end{cases}$$

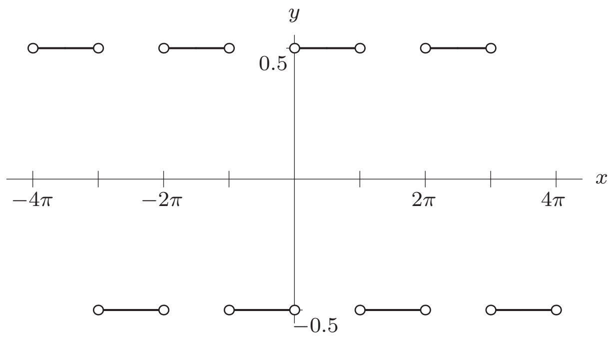

Figure 4.192

Figure 4.192, which shows the graph in disconnected line segments, is correct. However, unless you select certain graphing options in your CAS, it may join up the segments. Use the double angle formula $\cos(x) = \cos^2(x/2) - \sin^2(x/2)$ to simplify the answer in part (a). We find

$$\frac{dy}{dx} = \frac{\tan(x/2)}{2\sqrt{\frac{1-\cos x}{1+\cos x}}} = \frac{\tan(x/2)}{2\sqrt{\frac{1-\cos(2\cdot(x/2))}{1+\cos(2\cdot(x/2))}}} = \frac{\tan(x/2)}{2\sqrt{\frac{1-\cos^2(x/2)+\sin^2(x/2)}{1+\cos^2(x/2)-\sin^2(x/2)}}}$$

$$= \frac{\tan(x/2)}{2\sqrt{\frac{2\sin^2(x/2)}{2\cos^2(x/2)}}} = \frac{\tan(x/2)}{2\sqrt{\tan^2(x/2)}} = \frac{\tan(x/2)}{2\,|\tan(x/2)|}$$

Thus, $dy/dx = 1/2$ when $\tan(x/2) > 0$, i.e. when $0 < x < \pi$ (more generally, when $2n\pi < x < (2n+1)\pi$), and $dy/dx = -1/2$ when $\tan(x/2) < 0$, i.e., when $\pi < x < 2\pi$ (more generally, when $(2n+1)\pi < x < (2n+2)\pi$, where n is any integer).

108. (a)

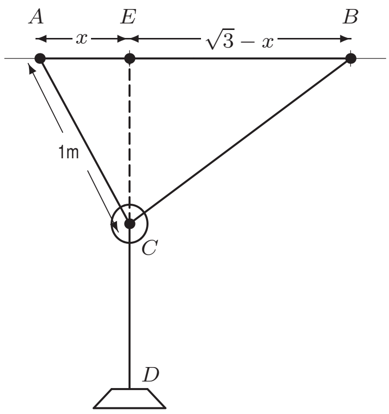

Figure 4.193

We want to maximize the sum of the lengths EC and CD in Figure 4.193. Let x be the distance AE. Then x can be between 0 and 1, the length of the left rope. By the Pythagorean theorem,

$$EC = \sqrt{1 - x^2}.$$

The length of the rope from B to C can also be found by the Pythagorean theorem:

$$BC = \sqrt{EC^2 + EB^2} = \sqrt{1 - x^2 + (\sqrt{3} - x)^2} = \sqrt{4 - 2\sqrt{3}x}.$$

Since the entire rope from B to D has length 3 m, the length from C to D is

$$CD = 3 - \sqrt{4 - 2\sqrt{3}x}.$$

The distance we want to maximize is

$$f(x) = EC + CD = \sqrt{1 - x^2} + 3 - \sqrt{4 - 2\sqrt{3}x}, \quad \text{for} \quad 0 \le x \le 1.$$

Differentiating gives

$$f'(x) = \frac{-2x}{2\sqrt{1 - x^2}} - \frac{-2\sqrt{3}}{2\sqrt{4 - 2\sqrt{3}x}}.$$

Setting $f'(x) = 0$ gives the cubic equation

$$2\sqrt{3}x^3 - 7x^2 + 3 = 0.$$

Using a computer algebra system to solve the equation gives three roots: $x = -1/\sqrt{3}, x = \sqrt{3}/2, x = \sqrt{3}$. We discard the negative root. Since x cannot be larger than 1 meter (the length of the left rope), the only critical point of interest is $x = \sqrt{3}/2$, that is, halfway between A and B.

To find the global maximum, we calculate the distance of the weight from the ceiling at the critical point and at the endpoints:

$$f(0) = \sqrt{1} + 3 - \sqrt{4} = 2$$
$$f\left(\frac{\sqrt{3}}{2}\right) = \sqrt{1 - \frac{3}{4}} + 3 - \sqrt{4 - 2\sqrt{3} \cdot \frac{\sqrt{3}}{2}} = 2.5$$
$$f(1) = \sqrt{0} + 3 - \sqrt{4 - 2\sqrt{3}} = 4 - \sqrt{3} = 2.27.$$

Thus, the weight is at the maximum distance from the ceiling when $x = \sqrt{3}/2$; that is, the weight comes to rest at a point halfway between points A and B.

(b) No, the equilibrium position depends on the length of the rope. For example, suppose that the left-hand rope was 1 cm long. Then there is no way for the pulley at its end to move to a point halfway between the anchor points.

PROJECTS FOR CHAPTER FOUR

1.

(a) (i) The slope, dV/dt, is the rate of change of the volume of air that has been exhaled over time. Thus, it is the rate of flow of the air out of the lungs, measured in liters per second. The greater the slope, the faster air is being expelled from the lungs. Notice that dV/dt is a volume flow; that is, the rate at which the volume of air exhaled is changing. It is not the speed at which air particles are leaving the lungs, which would be measured in meters per second.

(ii) As the horizontal asymptote on the graph, the vital capacity VC is the volume of air expelled at the end of the exhalation. It is the maximum volume of air the patient can exhale in one breath.

(b) (i) The slope of the flow-volume curve tells you how much the flow rate of air out of the lungs changes in response to exhalation of an additional volume of air.

(ii) For V near 0, when little air has been exhaled, the slope of the flow-volume curve is steep and positive. This means that the flow rate dV/dt is rapidly increasing as air is exhaled. The patient is expelling air faster and faster. The flow volume curve has zero slope when approximately 1 liter has been exhaled. This corresponds to the maximum flow rate dV/dt; air is expelled most rapidly at this stage. Thereafter, the slope of the flow-volume curve is negative, so the flow rate decreases and air is expelled slower and slower until approximately 5.5 liters of air have been exhaled. At that point, the patient has no more air to exhale and must take a breath.

(iii) Suppose the flow rate, dV/dt, is given as function of V by the function f, so $dV/dt = f(V)$; the flow-volume curve we were given is a graph of f. Now we are asked to plot $f'(V)$, whose graph is in Figure 4.194.

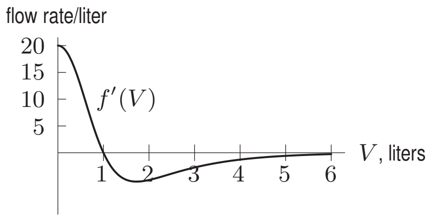

Figure 4.194

(iv) The maximal rate is identified as the highest point on the flow-volume curve, which occurs at about $V = 1$ liter. Thus, the patient's peak expiratory flow occurs when 1 liter of air has been exhaled. The peak expiratory flow is about 11.5 liters per second.

On the slope graph in Figure 4.194, a critical point occurs where the slope is 0; that is, where the slope graph intersects the horizontal axis. This occurs at $V = 1$. The first derivative test tells us that this critical point gives a maximum flow rate since the slope is positive to the left of $V = 1$ and negative to the right of $V = 1$.

(c) The increased resistance to airflow means that the patient exhales more slowly. This makes the volume-time curve rise more slowly. In fact, sometimes the patient exhales so slowly that they "run out of time" and cannot exhale all the volume they want to, leading to air trapping. This corresponds to a lowered vital capacity, VC. See Figure 4.195.

The peak expiratory flow will be lower. This means that the flow-volume curve does not rise as high. See Figure 4.196.

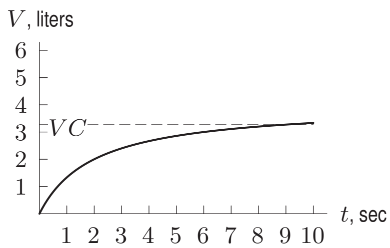

Figure 4.195: Volume-time curve for an asthmatic

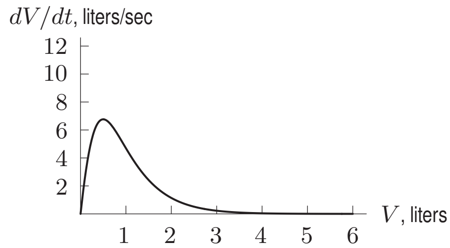

Figure 4.196: Flow-volume curve for an asthmatic

2.

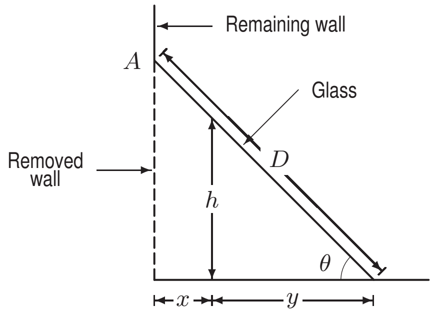

Figure 4.197: A Cross-section of the Projected Greenhouse

Suppose that the glass is at an angle θ (as shown in Figure 4.197), that the length of the wall is l, and that the glass has dimensions D ft by l ft. Since your parents will spend a fixed amount, the area of the glass, say k ft^2, is fixed:

$$Dl = k.$$

The width of the extension is $D\cos\theta$. If h is the height of your tallest parent, he or she can walk in a distance of x, and

$$\frac{h}{y} = \tan\theta, \quad \text{so} \quad y = \frac{h}{\tan\theta}.$$

Thus,

$$x = D\cos\theta - y = D\cos\theta - \frac{h}{\tan\theta} \quad \text{for } 0 < \theta < \frac{\pi}{2}.$$

We maximize x since doing so maximizes the usable area:

$$\begin{aligned}
\frac{dx}{d\theta} &= -D\sin\theta + \frac{h}{(\tan\theta)^2}\cdot\frac{1}{(\cos\theta)^2} = 0 \\
\sin^3\theta &= \frac{h}{D} \\
\theta &= \arcsin\left(\left(\frac{h}{D}\right)^{1/3}\right).
\end{aligned}$$

This is the only critical point, and $x \to 0$ when $\theta \to 0$ and when $\theta \to \pi/2$. Thus, the critical point is a global maximum. Since

$$\cos\theta = \sqrt{1-\sin^2\theta} = \sqrt{1-\left(\frac{h}{D}\right)^{2/3}},$$

the maximum value of x is

$$\begin{aligned}
x &= D\cos\theta - \frac{h}{\tan\theta} = D\cos\theta - \frac{h\cos\theta}{\sin\theta} \\
&= \left(D - \frac{h}{\sin\theta}\right)\cos\theta = \left(D - \frac{h}{(h/D)^{1/3}}\right)\cdot\left(1-\left(\frac{h}{D}\right)^{2/3}\right)^{1/2} \\
&= (D - h^{2/3}D^{1/3})\cdot\left(1-\frac{h^{2/3}}{D^{2/3}}\right)^{1/2} \\
&= D\left(1-\frac{h^{2/3}}{D^{2/3}}\right)\cdot\left(1-\frac{h^{2/3}}{D^{2/3}}\right)^{1/2} = D\left(1-\frac{h^{2/3}}{D^{2/3}}\right)^{3/2}.
\end{aligned}$$

This means

$$\begin{aligned}\text{Maximum Usable Area} &= lx \\ &= lD\left(1-\frac{h^{2/3}}{D^{2/3}}\right)^{3/2} \\ &= k\left(1-\left(\frac{hl}{k}\right)^{2/3}\right)^{3/2}\end{aligned}$$

3. **(a)** The point on the line $y = mx$ corresponding to the point $(2, 3.5)$ has y-coordinate given by $y = m(2) = 2m$. Thus, for the point $(2, 3.5)$

$$\text{Vertical distance to the line} = |2m - 3.5|.$$

We calculate the distance similarly for the other two points. We want to minimize the sum, S, of the squares of these vertical distances

$$S = (2m - 3.5)^2 + (3m - 6.8)^2 + (5m - 9.1)^2.$$

Differentiating with respect to m gives

$$\frac{dS}{dm} = 2(2m - 3.5)\cdot 2 + 2(3m - 6.8)\cdot 3 + 2(5m - 9.1)\cdot 5.$$

Setting $dS/dm = 0$ gives

$$2\cdot 2(2m - 3.5) + 2\cdot 3(3m - 6.8) + 2\cdot 5(5m - 9.1) = 0.$$

Canceling a 2 and multiplying out gives

$$\begin{aligned}4m - 7 + 9m - 20.4 + 25m - 45.5 &= 0 \\ 38m &= 72.9 \\ m &= 1.92.\end{aligned}$$

Thus, the best fitting line has equation $y = 1.92x$.

(b) To fit a line of the form $y = mx$ to the data, we take $y = V$ and $x = r^3$. Then k will be the slope m. So we make the following table of data:

r	2	5	7	8
$x = r^3$	8	125	343	512
$y = V$	8.7	140.3	355.8	539.2

To find the best fitting line of the form $y = mx$, we minimize the sums of the squares of the vertical distances from the line. For the point $(8, 8.7)$ the corresponding point on the line has $y = 8m$, so

$$\text{Vertical distance} = |8m - 8.7|.$$

We find distances from the other points similarly. Thus we want to minimize

$$S = (8m - 8.7)^2 + (125m - 140.3)^2 + (343m - 355.8)^2 + (512m - 539.2)^2.$$

Differentiating with respect to m, which is the variable, and setting the derivative to zero:

$$\frac{dS}{dm} = 2(8m - 8.7)\cdot 8 + 2(125m - 140.3)\cdot 125 + 2(343m - 355.8)\cdot 343 + 2(512m - 539.2)\cdot 512 = 0.$$

After canceling a 2, solving for m leads to the equation

$$8^2m + 125^2m + 343^2m + 512^2m = 8 \cdot 8.7 + 125 \cdot 140.3 + 343 \cdot 355.8 + 512 \cdot 539.2$$
$$m = 1.051.$$

Thus, $k = 1.051$ and the relationship between V and r is

$$V = 1.051r^3.$$

(In fact, the correct relationship is $V = \pi r^3/3$, so the exact value of k is $\pi/3 = 1.047$.)

(c) The best fitting line minimizes the sum of the squares of the vertical distances from points to the line. Since the point on the line $y = mx$ corresponding to (x_1, y_1) is the point with $y = mx_1$; for this point we have

$$\text{Vertical distance} = |mx_1 - y_1|.$$

We calculate the distance from the other points similarly. Thus we want to minimize

$$S = (mx_1 - y_1)^2 + (mx_2 - y_2)^2 \cdots + (mx_n - y_n)^2.$$

The variable is m (the x_is and y_is are all constants), so

$$\frac{dS}{dm} = 2(mx_1 - y_1)x_1 + 2(mx_2 - y_2)x_2 + \cdots + 2(mx_n - y_n)x_n = 0$$
$$2(m(x_1^2 + x_2^2 + \cdots + x_n^2) - (x_1y_1 + x_2y_2 + \cdots + x_ny_n)) = 0.$$

Solving for m gives

$$m = \frac{x_1y_1 + x_2y_2 + \cdots + x_ny_n}{x_1^2 + x_2^2 + \cdots + x_n^2} = \frac{\sum_{i=1}^{n} x_iy_i}{\sum_{i=1}^{n} x_i^2}.$$

4. (a) (i) We want to minimize A, the total area lost to the forest, which is made up of n firebreaks and 1 stand of trees lying between firebreaks. The area of each firebreak is $(50\text{ km})(0.01\text{ km}) = 0.5\text{ km}^2$, so the total area lost to the firebreaks is $0.5n\text{ km}^2$. There are n total stands of trees between firebreaks. The area of a single stand of trees can be found by subtracting the firebreak area from the forest and dividing by n, so

$$\text{Area of one stand of trees} = \frac{2500 - 0.5n}{n}.$$

Thus, the total area lost is

$$A = \text{Area of one stand} + \text{Area lost to firebreaks}$$
$$= \frac{2500 - 0.5n}{n} + 0.5n = \frac{2500}{n} - 0.5 + 0.5n.$$

We assume that A is a differentiable function of a continuous variable, n. Differentiating this function yields

$$\frac{dA}{dn} = -\frac{2500}{n^2} + 0.5.$$

At critical points, $dA/dn = 0$, so $0.5 = 2500/n^2$ or $n = \sqrt{2500/0.5} \approx 70.7$. Since n must be an integer, we check that when $n = 71$, $A = 70.211$ and when $n = 70$, $A = 70.214$. Thus, $n = 71$ gives a smaller area lost.

We can check that this is a local minimum since the second derivative is positive everywhere

$$\frac{d^2A}{dn^2} = \frac{5000}{n^3} > 0.$$

Finally, we check the endpoints: $n = 1$ yields the entire forest lost after a fire, since there is only one stand of trees in this case and it all burns. The largest n is 5000, and in this case the firebreaks remove the entire forest. Both of these cases maximize the area of forest lost. Thus, $n = 71$ is a global minimum. So 71 firebreaks minimizes the area of forest lost.

(ii) Repeating the calculation using b for the width gives

$$A = \frac{2500}{n} - 50b + 50bn,$$

and

$$\frac{dA}{dn} = \frac{-2500}{n^2} + 50b,$$

with a critical point when $b = 50/n^2$ so $n = \sqrt{50/b}$. So, for example, if we make the width b four times as large we need half as many firebreaks.

(b) We want to minimize A, the total area lost to the forest, which is made up of n firebreaks in one direction, n firebreaks in the other, and one square of trees surrounded by firebreaks. The area of each firebreak is 0.5 km^2, and there are $2n$ of them, giving a total of $0.5 \cdot 2n$. But this is larger than the total area covered by the firebreaks, since it counts the small intersection squares, of size $(0.01)^2$, twice. Since there are n^2 intersections, we must subtract $(0.01)^2n^2$ from the total area of the $2n$ firebreaks. Thus,

$$\text{Area covered by the firebreaks } = 0.5 \cdot 2n - (0.01)^2n^2.$$

To this we must add the area of one square patch of trees lost in a fire. These are squares of side $(50 - 0.01n)/n = 50/n - 0.01$. Thus the total area lost is

$$A = n - 0.0001n^2 + (50/n - 0.01)^2$$

Treating n as a continuous variable and differentiating this function yields

$$\frac{dA}{dn} = 1 - 0.0002n + 2\left(\frac{50}{n} - 0.01\right)\left(\frac{-50}{n^2}\right).$$

Using a computer algebra system to find critical points we find that $dA/dn = 0$ when $n \approx 17$ and $n = 5000$. Thus $n = 17$ gives a minimum lost area, since the endpoints of $n = 1$ and $n = 5000$ both yield $A = 2500$ or the entire forest lost. So we use 17 firebreaks in each direction.

CHAPTER FIVE

Solutions for Section 5.1

Exercises

1. (a) Left sum
(b) Upper estimate
(c) 6
(d) $\Delta t = 2$
(e) Upper estimate is approximately $4 \cdot 2 + 2.9 \cdot 2 + 2 \cdot 2 + 1.5 \cdot 2 + 1 \cdot 2 + 0.8 \cdot 2 = 24.4$.

2. (a) (i) Since the velocity is increasing, for an upper estimate we use a right sum. Using $n = 4$, we have $\Delta t = 3$, so

$$\text{Upper estimate } = (37)(3) + (38)(3) + (40)(3) + (45)(3) = 480.$$

(ii) Using $n = 2$, we have $\Delta t = 6$, so

$$\text{Upper estimate } = (38)(6) + (45)(6) = 498.$$

(b) The answer using $n = 4$ is more accurate as it uses the values of $v(t)$ when $t = 3$ and $t = 9$.
(c) Since the velocity is increasing, for a lower estimate we use a left sum. Using $n = 4$, we have $\Delta t = 3$, so

$$\text{Lower estimate } = (34)(3) + (37)(3) + (38)(3) + (40)(3) = 447.$$

3. (a) Since the velocity is decreasing, for an upper estimate, we use a left sum. With $n = 5$,we have $\Delta t = 2$. Then

$$\text{Upper estimate } = (44)(2) + (42)(2) + (41)(2) + (40)(2) + (37)(2) = 408.$$

(b) For a lower estimate, we use a right sum, so

$$\text{Lower estimate } = (42)(2) + (41)(2) + (40)(2) + (37)(2) + (35)(2) = 390.$$

4. (a) Lower estimate $= 60 + 40 + 25 + 10 + 0 = 135$ feet. Upper estimate $= 88 + 60 + 40 + 25 + 10 = 223$ feet.
(b) See Figure 5.1.

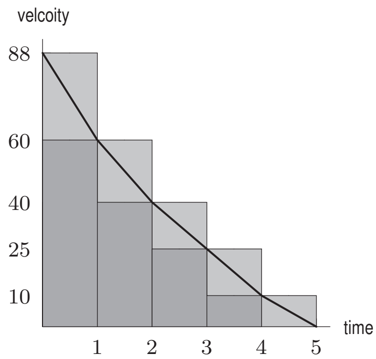

Figure 5.1

(c) The difference between the estimates $= 223 - 135 = 88$ feet. This is the sum of the lightly shaded areas in the graph, namely $(88 - 0) \cdot 1 = 88$ feet.

5. The distance traveled is represented by area under the velocity curve. We can approximate the area using left- and right-hand sums. Alternatively, counting the squares (each of which has area 10), and allowing for the broken squares, we can see that the area under the curve from 0 to 6 is between 140 and 150. Hence the distance traveled is between 140 and 150 meters.

6. Using $\Delta t = 2$,

$$\begin{aligned}\text{Lower estimate} &= v(0)\cdot 2 + v(2)\cdot 2 + v(4)\cdot 2\\ &= 1(2) + 5(2) + 17(2)\\ &= 46\\ \text{Upper estimate} &= v(2)\cdot 2 + v(4)\cdot 2 + v(6)\cdot 2\\ &= 5(2) + 17(2) + 37(2)\\ &= 118\\ \text{Average} &= \frac{46+118}{2} = 82\\ \text{Distance traveled} &\approx 82\,\text{meters.}\end{aligned}$$

7. (a) The velocity is always positive, so the particle is moving in the same direction throughout. However, the particle is speeding up until shortly before $t = 0$, and slowing down thereafter.

(b) The distance traveled is represented by the area under the curve. We can calculate over and understimates for the area using a combination of left- and right-hand sums. Alternatively, using whole grid squares, we can overestimate the area as $3+3+3+3+2+1 = 15$ cm, and we can underestimate the area as $1+2+2+1+0+0 = 6$ cm.

8. Using $\Delta t = 0.2$, our upper estimate is

$$\frac{1}{1+0}(0.2) + \frac{1}{1+0.2}(0.2) + \frac{1}{1+0.4}(0.2) + \frac{1}{1+0.6}(0.2) + \frac{1}{1+0.8}(0.2) \approx 0.75.$$

The lower estimate is

$$\frac{1}{1+0.2}(0.2) + \frac{1}{1+0.4}(0.2) + \frac{1}{1+0.6}(0.2) + \frac{1}{1+0.8}(0.2)\frac{1}{1+1}(0.2) \approx 0.65.$$

Since v is a decreasing function, the bug has crawled more than 0.65 meters, but less than 0.75 meters. We average the two to get a better estimate:

$$\frac{0.65+0.75}{2} = 0.70 \text{ meters.}$$

9. From $t = 0$ to $t = 3$ the velocity is constant and positive, so the change in position is $2\cdot 3$ cm, that is 6 cm to the right. From $t = 3$ to $t = 5$, the velocity is negative and constant, so the change in position is $-3\cdot 2$ cm, that is 6 cm to the left. Thus the total change in position is 0. The particle moves 6 cm to the right, followed by 6 cm to the left, and returns to where it started.

10. From $t = 0$ to $t = 5$ the velocity is positive so the change in position is to the right. The area under the velocity graph gives the distance traveled. The region is a triangle, and so has area $(1/2)bh = (1/2)5\cdot 10 = 25$. Thus the change in position is 25 cm to the right.

11. The velocity is constant and negative, so the change in position is $-3\cdot 5$ cm, that is 15 cm to the left.

12. From $t = 0$ to $t = 4$ the velocity is positive so the change in position is to the right. The area under the velocity graph gives the distance traveled. The region is a triangle, and so has area $(1/2)bh = (1/2)4\cdot 8 = 16$. Thus the change in position is 16 cm to the right for $t = 0$ to $t = 4$. From $t = 4$ to $t = 5$, the velocity is negative so the change in position is to the left. The distance traveled to the left is given by the area of the triangle, $(1/2)bh = (1/2)1\cdot 2 = 1$. Thus the total change in position is $16 - 1 = 15$ cm to the right.

13. (a) With $n = 4$, we have $\Delta t = 2$. Then

$$t_0 = 15, t_1 = 17, t_2 = 19, t_3 = 21, t_4 = 23 \quad\text{and}\quad f(t_0) = 10, f(t_1) = 13, f(t_2) = 18, f(t_3) = 20, f(t_4) = 30$$

(b)

$$\begin{aligned}\text{Left sum} &= (10)(2) + (13)(2) + (18)(2) + (20)(2) = 122\\ \text{Right sum} &= (13)(2) + (18)(2) + (20)(2) + (30)(2) = 162.\end{aligned}$$

(c) With $n = 2$,we have $\Delta t = 4$. Then

$$t_0 = 15, t_1 = 19, t_2 = 23 \quad \text{and} \quad f(t_0) = 10, f(t_1) = 18, f(t_2) = 30$$

(d)

$$\begin{aligned}\text{Left sum } &= (10)(4) + (18)(4) = 112\\ \text{Right sum } &= (18)(4) + (30)(4) = 192.\end{aligned}$$

14. (a) With $n = 4$, we have $\Delta t = 4$. Then

$$t_0 = 0, t_1 = 4, t_2 = 8, t_3 = 12, t_4 = 16 \quad \text{and} \quad f(t_0) = 25, f(t_1) = 23, f(t_2) = 22, f(t_3) = 20, f(t_4) = 17$$

(b)

$$\begin{aligned}\text{Left sum } &= (25)(4) + (23)(4) + (22)(4) + (20)(4) = 360\\ \text{Right sum } &= (23)(4) + (22)(4) + (20)(4) + (17)(4) = 328.\end{aligned}$$

(c) With $n = 2$,we have $\Delta t = 8$. Then

$$t_0 = 0, t_1 = 8, t_2 = 16 \quad \text{and} \quad f(t_0) = 25, f(t_1) = 22, f(t_2) = 17$$

(d)

$$\begin{aligned}\text{Left sum } &= (25)(8) + (22)(8) = 376\\ \text{Right sum } &= (22)(8) + (17)(8) = 312.\end{aligned}$$

Problems

15. (a) Note that 15 minutes equals 0.25 hours. Lower estimate $= 11(0.25) + 10(0.25) = 5.25$ miles. Upper estimate $= 12(0.25) + 11(0.25) = 5.75$ miles.

(b) Lower estimate $= 11(0.25) + 10(0.25) + 10(0.25) + 8(0.25) + 7(0.25) + 0(0.25) = 11.5$ miles. Upper estimate $= 12(0.25) + 11(0.25) + 10(0.25) + 10(0.25) + 8(0.25) + 7(0.25) = 14.5$ miles.

(c) The difference between Roger's pace at the beginning and the end of his run is 12 mph. If the time between the measurements is h, then the difference between the upper and lower estimates is $12h$. We want $12h < 0.1$, so

$$h < \frac{0.1}{12} \approx 0.0083 \text{ hours} = 30 \text{ seconds}$$

Thus Jeff would have to measure Roger's pace every 30 seconds.

16. The change in position is calculated from the area between the velocity graph and the t-axis, with the region below the axis corresponding to negatives velocities and counting negatively.

Figure 5.2 shows the graph of $f(t)$. From $t = 0$ to $t = 3$ the velocity is positive. The region under the graph of $f(t)$ is a triangle with height 6 cm/sec and base 3 seconds. Thus, from $t = 0$ to $t = 3$, the particle moves

$$\text{Distance moved to right } = \frac{1}{2} \cdot 3 \cdot 6 = 9 \text{ centimeters.}$$

From $t = 3$ to $t = 4$, the velocity is negative. The region between the graph of $f(t)$ and the t-axis is a triangle with height 2 cm/sec and base 1 second, so in this interval the particle moves

$$\text{Distance moved to left } = \frac{1}{2} \cdot 1 \cdot 2 = 1 \text{ centimeter.}$$

Thus, the total change in position is $9 - 1 = 8$ centimeters to the right.

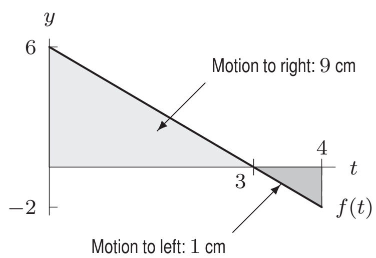

Figure 5.2

17. Since f is increasing, the right-hand sum is the upper estimate and the left-hand sum is the lower estimate. We have $f(a) = 13$, $f(b) = 23$ and $\Delta t = (b - a)/n = 2/100$. Thus,

$$\begin{aligned} |\text{Difference in estimates}| &= |f(b) - f(a)|\Delta t \\ &= |23 - 13|\frac{1}{50} = \frac{1}{5}. \end{aligned}$$

18. Since f is decreasing, the right-hand sum is the lower estimate and the left-hand sum is the upper estimate. We have $f(a) = 24$, $f(b) = 9$ and $\Delta t = (b - a)/n = 3/500$. Thus,

$$\begin{aligned} |\text{Difference in estimates}| &= |f(b) - f(a)|\Delta t \\ &= |9 - 24|\frac{3}{500} = 0.09. \end{aligned}$$

19. Since f is increasing, the right-hand sum is the upper estimate and the left-hand sum is the lower estimate. We have $f(0) = 0$, $f(\pi/2) = 1$ and $\Delta t = (b - a)/n = \pi/200$. Thus,

$$\begin{aligned} |\text{Difference in estimates}| &= |f(b) - f(a)|\Delta t \\ &= |1 - 0|\frac{\pi}{200} = 0.0157. \end{aligned}$$

20. Since f is decreasing, the right-hand sum is the lower estimate and the left-hand sum is the upper estimate. We have $f(0) = 1$, $f(2) = e^{-2}$ and $\Delta t = (b - a)/n = 2/20 = 1/10$. Thus,

$$\begin{aligned} |\text{Difference in estimates}| &= |f(b) - f(a)|\Delta t \\ &= |e^{-2} - 1|\frac{1}{10} = 0.086. \end{aligned}$$

21. (a) See Figure 5.3.
(b) The peak of the flight is when the velocity is 0, namely $t = 3$. The height at $t = 3$ is given by the area under the graph of the velocity from $t = 0$ to $t = 3$; see Figure 5.3. The region is a triangle of base 3 seconds and altitude 96 ft/sec, so the height is $(1/2)3 \cdot 96 = 144$ feet.
(c) The velocity is negative from $t = 3$ to $t = 5$, so the motion is downward then. The distance traveled downward can be calculated by the area of the triangular region which has base of 2 seconds and altitude of -64 ft/sec. Thus, the baseball travels $(1/2)2 \cdot 64 = 64$ feet downward from its peak height of 144 feet at $t = 3$. Thus, the height at time $t = 5$ is the total change in position, $144 - 64 = 80$ feet.

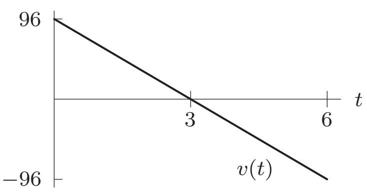

Figure 5.3

22. From $t = 0$ to $t = 3$, you are moving away from home ($v > 0$); thereafter you move back toward home. So you are the farthest from home at $t = 3$. To find how far you are then, we can measure the area under the v curve as about 9 squares, or $9 \cdot 10$ km/hr $\cdot$ 1 hr $= 90$ km. To find how far away from home you are at $t = 5$, we measure the area from $t = 3$ to $t = 5$ as about 25 km, except that this distance is directed toward home, giving a total distance from home during the trip of $90 - 25 = 65$ km.

23. (a) When the aircraft is climbing at v ft/min, it takes $1/v$ minutes to climb 1 foot. Therefore

$$\begin{aligned}\text{Lower estimate } &= \left(\frac{1 \text{ min}}{925 \text{ ft}}\right)(1000 \text{ ft}) + \left(\frac{1 \text{ min}}{875 \text{ ft}}\right)(1000 \text{ ft}) + \cdots + \left(\frac{1 \text{ min}}{490 \text{ ft}}\right)(1000 \text{ ft}) \\ &\approx 14.73 \text{ minutes.} \\ \text{Upper estimate } &= \left(\frac{1 \text{ min}}{875 \text{ ft}}\right)(1000 \text{ ft}) + \left(\frac{1 \text{ min}}{830 \text{ ft}}\right)(1000 \text{ ft}) + \cdots + \left(\frac{1 \text{ min}}{440 \text{ ft}}\right)(1000 \text{ ft}) \\ &\approx 15.93 \text{ minutes.}\end{aligned}$$

Note: The Pilot Operating Manual for this aircraft gives 16 minutes as the estimated time required to climb to $10{,}000$ ft.

(b) The difference between upper and lower sums with $\Delta x = 500$ ft would be

$$\text{Difference } = \left(\frac{1 \text{ min}}{440 \text{ ft}} - \frac{1 \text{ min}}{925 \text{ ft}}\right)(500 \text{ ft}) = 0.60 \text{ minutes.}$$

24. (a) At $t = 20$ minutes, she stops moving toward the lake (with $v > 0$) and starts to move away from the lake (with $v < 0$). So at $t = 20$ minutes the cyclist turns around.

(b) The cyclist is going the fastest when v has the greatest magnitude, either positive or negative. Looking at the graph, we can see that this occurs at $t = 40$ minutes, when $v = -25$ and the cyclist is pedaling at 25 km/hr away from the lake.

(c) From $t = 0$ to $t = 20$ minutes, the cyclist comes closer to the lake, since $v > 0$; thereafter, $v < 0$ so the cyclist moves away from the lake. So at $t = 20$ minutes, the cyclist comes the closest to the lake. To find out how close she is, note that between $t = 0$ and $t = 20$ minutes the distance she has come closer is equal to the area under the graph of v. Each box represents 5/6 of a kilometer, and there are about 2.5 boxes under the graph, giving a distance of about 2 km. Since she was originally 5 km away, she then is about $5 - 2 = 3$ km from the lake.

(d) At $t = 20$ minutes she turns around , since v changes sign then. Since the area below the t-axis is greater than the area above, the farthest she is from the lake is at $t = 60$ minutes. Between $t = 20$ and $t = 60$ minutes, the area under the graph is about 10.8 km. (Since 13 boxes $\cdot\, 5/6 = 10.8$.) So at $t = 60$ she will be about $3 + 10.8 = 13.8$ km from the lake.

25. (a) Since car B starts at $t = 2$, the tick marks on the horizontal axis (which we assume are equally spaced) are 2 hours apart. Thus car B stops at $t = 6$ and travels for 4 hours.
Car A starts at $t = 0$ and stops at $t = 8$, so it travels for 8 hours.

(b) Car A's maximum velocity is approximately twice that of car B, that is 100 km/hr.

(c) The distance traveled is given by the area of under the velocity graph. Using the formula for the area of a triangle, the distances are given approximately by

$$\begin{aligned}\text{Car } A \text{ travels} &= \frac{1}{2} \cdot \text{Base} \cdot \text{Height} = \frac{1}{2} \cdot 8 \cdot 100 = 400 \text{ km} \\ \text{Car } B \text{ travels} &= \frac{1}{2} \cdot \text{Base} \cdot \text{Height} = \frac{1}{2} \cdot 4 \cdot 50 = 100 \text{ km.}\end{aligned}$$

26. (a) Car A has the largest maximum velocity because the peak of car A's velocity curve is higher than the peak of B's.

(b) Car A stops first because the curve representing its velocity hits zero (on the t-axis) first.

(c) Car B travels farther because the area under car B's velocity curve is the larger.

27. (a) See Figure 5.4.

(b) The distance traveled is the area under the graph of the velocity in Figure 5.4. The region is a triangle of base 5 seconds and altitude 50 ft/sec, so the distance traveled is $(1/2)5 \cdot 50 = 125$ feet.

(c) The slope of the graph of the velocity function is the same, so the triangular region under it has twice the altitude and twice the base (it takes twice as long to stop). See Figure 5.5. Thus, the area is 4 times as large and the car travels 4 times as far.

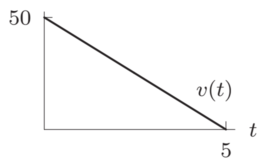

Figure 5.4

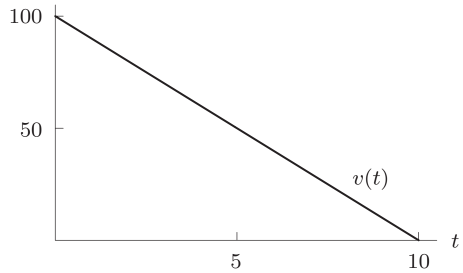

Figure 5.5

28. The graph of her velocity against time is a straight line from 0 mph to 60 mph; see Figure 5.6. Since the distance traveled is the area under the curve, we have

$$\text{Shaded area} = \frac{1}{2} \cdot t \cdot 60 = 10 \text{ miles}$$

Solving for t gives

$$t = \frac{1}{3}\text{hr} = 20 \text{ minutes} .$$

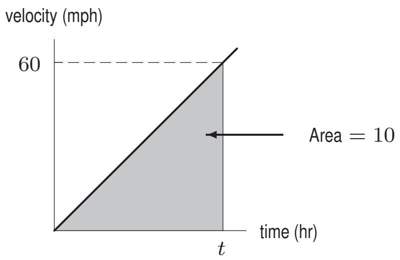

Figure 5.6

29. Since acceleration is the derivative of velocity $(a(t) = v'(t))$, and $a(t)$ is a constant, $v(t)$ must be a linear function. Its v-intercept is 0 since the object has zero initial velocity. Thus the graph of v is a line through the origin with slope 32 and equation $v(t) = 32t$ ft/sec. See Figure 5.7.

Using $\Delta t = 1$, the right sum, $32 + 64 + 96 + 128 = 320$ feet, is an upper bound on the distance traveled. The left sum, $0 + 32 + 64 + 96 = 192$ feet, is a lower bound.

To find the actual distance, we find the exact area of the region below the line—it is the triangle in Figure 5.7 with height $32 \cdot 4 = 128$ and base 4, so its area is 256 ft.

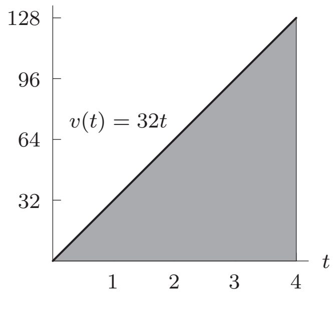

Figure 5.7

30. No, the 2010 Prius Plug-in Prototype cannot travel half a mile in EV-only mode in under 25 seconds, because the upper estimate for the distance traveled in 25 seconds is only about 0.3 miles. To see this, we convert seconds to hours (1 sec $= 1/3600$ hours) so that the upper distance estimate is in miles:

$$\begin{array}{c}\text{Total distance traveled}\\ \text{between } t = 0 \text{ and } t = 25\\ \text{(Upper estimate)}\end{array} = 20 \cdot \frac{5}{3600} + 33 \cdot \frac{5}{3600} + 45 \cdot \frac{5}{3600} + 50 \cdot \frac{5}{3600} + 59 \cdot \frac{5}{3600} < 0.3 \text{ miles}$$

31. To estimate the distance between the two cars at $t = 15$, we calculate upper and lower bound estimates for this distance and then average these estimates. Note that because the speed of the Prius is in miles per hour, we need to convert seconds to hours (1 sec $= 1/3600$ hours) to calculate the distance estimates in miles. We may then convert miles to feet (1 mile $= 5280$ feet).

$$\begin{aligned}\text{Distance between cars at } t = 15 \ (\text{Upper Estimate}) &\approx (\text{Difference in speeds at } t = 5)\cdot(\text{Travel time})\\ &+ (\text{Difference in speeds at } t = 10)\cdot(\text{Travel time})\\ &+ (\text{Difference in speeds at } t = 15)\cdot(\text{Travel time})\\ &= (33-20)\cdot\frac{5}{3600} + (53-33)\cdot\frac{5}{3600} + (70-45)\cdot\frac{5}{3600} = 0.081 \text{ miles}\end{aligned}$$

$$\begin{aligned}\text{Distance between cars at } t = 15 \ (\text{Lower Estimate}) &\approx (\text{Difference in speeds at } t = 0)\cdot(\text{Travel time})\\ &+ (\text{Difference in speeds at } t = 5)\cdot(\text{Travel time})\\ &+ (\text{Difference in speeds at } t = 10)\cdot(\text{Travel time})\\ &= (0-0)\cdot\frac{5}{3600} + (33-20)\cdot\frac{5}{3600} + (53-33)\cdot\frac{5}{3600} = 0.046 \text{ miles}\end{aligned}$$

Since:

$$\text{Average of Lower and Upper Estimates of distance between cars at } t = 15 = \frac{0.081 + 0.046}{2} = 0.0635 \text{ miles} = 335 \text{ feet},$$

the distance between the two cars is about 335 feet, 15 seconds after leaving the stoplight.

Strengthen Your Understanding

32. This is only true if the car accelerates at a constant rate, that is, if the graph of the velocity is a linear function increasing from 0 to 50 in 10 seconds. If the graph of velocity is above that line, the car travels further, and if the graph of velocity is below that line the car travels less far.

33. Recording the velocity every 0.1 seconds means there are 10 subdivisions, so if the velocity of the car in ft/sec is $f(t)$ after t seconds, and if f is increasing during the second, then the difference between the lower and upper estimates is

$$(f(b) - f(a))\frac{b-a}{10},$$

where $[a, b]$ is the interval during which the velocity is recorded. Since the interval is one second long, $b - a = 1$, so the difference is $(f(b) - f(a))/10$. This could be much bigger than 0.1 feet if the car is accelerating quickly. For example, if $f(a) = 0$ and $f(b) = 10$, then the difference between the estimates is 1 foot.

34. If f is decreasing on the interval then the right sum is less than the left sum, so $f(x) = x^2$, $[a, b] = [-2, -1]$ is an example.

35. If $f(t)$ is increasing on the interval $[a, b]$, then the difference between the upper and lower estimates is $|f(b)-f(a)|\cdot\Delta t = |f(b) - f(a)|(b - a)/n$, where n is the number of subdivisions. So if, for example, $f(b) - f(a) = 10$ and $b - a = 1$, then

$$|f(b) - f(a)|\frac{b-a}{n} = \frac{10}{n},$$

and n would have to be ≥ 100 to make this ≤ 0.1. A velocity function and interval that satisfy these conditions are $f(x) = 10x$ and $[a, b] = [0, 1]$.

36. True. Since the velocity is increasing, each term in the left-hand sum is less than the corresponding term in the right-hand sum.

37. True. If the velocity is $f(t)$ and the interval is $a \leq t \leq b$, then

$$\text{Difference between left and right sums } = (f(a) - f(b))\cdot\Delta t.$$

Since Δt is halved when the number of subdivisions is doubled, the difference is halved also.

38. False. For example, for a constant function, the difference does not get smaller, since it is always 0. Another example is the velocity function $f(x) = x^2$ on the interval $-1 \le x \le 1$. By the symmetry of the graph, for an even number of subdivisions the difference between the left and right sums is always 0.

39. (a) On $[3, 5]$ and on $[9, 10]$, since $v = 0$ there.
(b) 3600 feet to the east, since this is the area under the velocity curve between $t = 0$ and $t = 3$.
(c) At $t = 8$ minutes, since the areas above and below the curve between $t = 0$ and $t = 8$ are equal.
(d) It will take her 30 seconds longer. By calculating areas, we see that at $t = 11$,

$$\text{Distance from home } = 2 \cdot 30 \cdot 60 - 3 \cdot 30 \cdot 60 + 0.5 \cdot 30 \cdot 60 = -900 \text{ feet.}$$

Thus, at $t = 11$, she is 900 feet west of home. At a velocity of 30 ft/sec eastward, it takes $900/30 = 30$ seconds to get home.

Solutions for Section 5.2

Exercises

1. (a) Right sum
(b) Upper estimate
(c) 3
(d) $\Delta x = 2$

2. (a) Left sum
(b) Lower estimate
(c) 3
(d) $\Delta x = 2$

3. (a) Left-hand sum. Right-hand sum would be smaller.
(b) We have $a = 0$, $b = 2$, $n = 6$, $\Delta x = \frac{2}{6} = \frac{1}{3}$.

4.

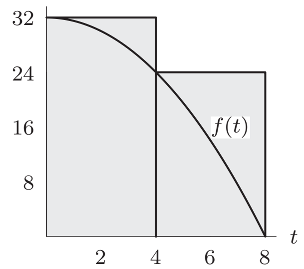

Figure 5.8: Left Sum, $\Delta t = 4$

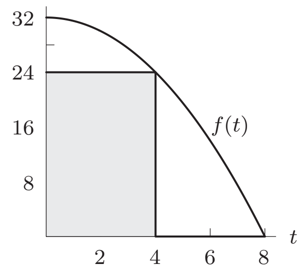

Figure 5.9: Right Sum, $\Delta t = 4$

(a) Left-hand sum $= 32 \cdot 4 + 24 \cdot 4 = 224$.
(b) Right-hand sum $= 24 \cdot 4 + 0 \cdot 4 = 96$.

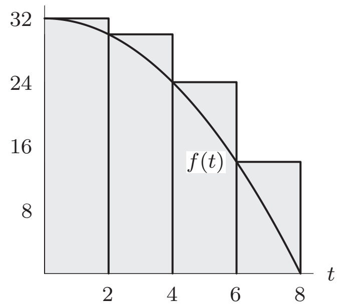

Figure 5.10: Left Sum, $\Delta t = 2$

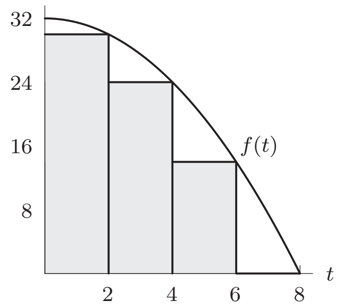

Figure 5.11: Right Sum, $\Delta t = 2$

(c) Left-hand sum $= 32 \cdot 2 + 30 \cdot 2 + 24 \cdot 2 + 14 \cdot 2 = 200$.
(d) Right-hand sum $= 30 \cdot 2 + 24 \cdot 2 + 14 \cdot 2 + 0 \cdot 2 = 136$.

5. We use a calculator or computer to see that $\int_1^4 (x^2+x)\,dx = 28.5$.

6. We use a calculator or computer to see that $\int_0^3 2^x\,dx = 10.0989$.

7. We use a calculator or computer to see that $\int_{-1}^1 e^{-x^2}\,dx = 1.4936$.

8. We use a calculator or computer to see that $\int_0^3 \ln(y^2+1)\,dy = 3.406$.

9. We use a calculator or computer to see that $\int_0^1 \sin(t^2)dt = 0.3103$.

10. We use a calculator or computer to see that $\int_3^4 \sqrt{e^z+z}\,dz = 6.111$.

11. We estimate $\int_0^{40} f(x)dx$ using left- and right-hand sums:

$$\text{Left sum} = 350\cdot 10 + 410\cdot 10 + 435\cdot 10 + 450\cdot 10 = 16{,}450.$$
$$\text{Right sum} = 410\cdot 10 + 435\cdot 10 + 450\cdot 10 + 460\cdot 10 = 17{,}550.$$

We estimate that

$$\int_0^{40} f(x)dx \approx \frac{16450+17550}{2} = 17{,}000.$$

In this estimate, we used $n=4$ and $\Delta x = 10$.

12. With $\Delta x = 3$, we have

$$\text{Left-hand sum } = 3(32+22+15+11) = 240,$$
$$\text{Right-hand sum } = 3(22+15+11+9) = 171.$$

The average of these two sums is our best guess for the value of the integral;

$$\int_0^{12} f(x)\,dx \approx \frac{240+171}{2} = 205.5.$$

13. We take $\Delta x = 3$. Then:

$$\begin{aligned}\text{Left-hand sum} &= 50(3)+48(3)+44(3)+36(3)+24(3)\\ &= 606\\ \text{Right-hand sum} &= 48(3)+44(3)+36(3)+24(3)+8(3)\\ &= 480\\ \text{Average} &= \frac{606+480}{2} = 543.\end{aligned}$$

So,

$$\int_0^{15} f(x)\,dx \approx 543.$$

14. Since we have 5 subdivisions,

$$\Delta x = \frac{b-a}{n} = \frac{7-3}{5} = 0.8.$$

The interval begins at $x=3$ and ends at $x=7$. Table 5.1 gives the value of $f(x)$ at the pertinent points.

Table 5.1

x	3.0	3.8	4.6	5.4	6.2	7.0
$f(x)$	$\frac{1}{1+3.0}$	$\frac{1}{1+3.8}$	$\frac{1}{1+4.6}$	$\frac{1}{1+5.4}$	$\frac{1}{1+6.2}$	$\frac{1}{1+7.0}$

So a right-hand sum is

$$\frac{1}{1+3.8}(0.8) + \frac{1}{1+4.6}(0.8) + \cdots + \frac{1}{1+7.0}(0.8).$$

15. $\int_0^{20} f(x)\,dx$ is equal to the area shaded in Figure 5.12. We estimate the area by counting boxes. There are about 15 boxes and each box represents 4 square units, so the area shaded is about 60. We have

$$\int_0^{20} f(x)\,dx \approx 60.$$

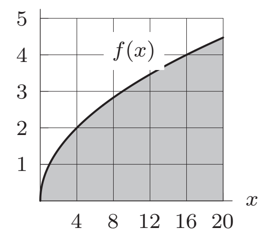

Figure 5.12

16. We know that

$$\int_{-10}^{15} f(x)dx = \text{Area under } f(x) \text{ between } x = -10 \text{ and } x = 15.$$

The area under the curve consists of approximately 14 boxes, and each box has area $(5)(5) = 25$. Thus, the area under the curve is about $(14)(25) = 350$, so

$$\int_{-10}^{15} f(x)dx \approx 350.$$

17. We know that

$$\int_{-3}^{5} f(x)dx = \text{Area above the axis} - \text{Area below the axis.}$$

The area above the axis is about 3 boxes. Since each box has area $(1)(5) = 5$, the area above the axis is about $(3)(5) = 15$. The area below the axis is about 11 boxes, giving an area of about $(11)(5) = 55$. We have

$$\int_{-3}^{5} f(x)dx \approx 15 - 55 = -40.$$

Problems

18. The graph given shows that f is positive for $0 \le t \le 1$. Since the graph is contained within a rectangle of height 100 and length 1, the answers -98.35 and 100.12 are both either too small or too large to represent $\int_0^1 f(t)dt$. Since the graph of f is above the horizontal line $y = 80$ for $0 \le t \le 0.95$, the best estimate is IV, 93.47 and not 71.84.

19. (a) The total area between $f(x)$ and the x-axis is the sum of the two given areas, so

$$\text{Area} = 7 + 6 = 13.$$

(b) To find the integral, we note that from $x = 3$ to $x = 5$, the function lies below the x-axis, and hence makes a negative contribution to the integral. So

$$\int_0^5 f(x)\,dx = \int_0^3 f(x)dx + \int_3^5 f(x)dx = 7 - 6 = 1.$$

20. The graph of $y = 4 - x^2$ crosses the x-axis at $x = 2$ since solving $y = 4 - x^2 = 0$ gives $x = \pm 2$. See Figure 5.13. To find the total area, we find the area above the axis and the area below the axis separately. We have

$$\int_0^2 (4 - x^2)dx = 5.3333 \quad \text{and} \quad \int_2^3 (4 - x^2)dx = -2.3333.$$

As expected, the integral from 2 to 3 is negative. The area above the axis is 5.3333 and the area below the axis is 2.3333, so

$$\text{Total area } = 5.3333 + 2.3333 = 7.6666.$$

Thus the area is 7.667.

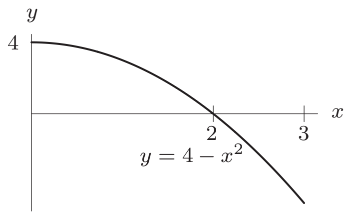

Figure 5.13

21. (a) The graph of $f(x) = x^3 - x$ crosses the x-axis at $x = 1$ since solving $f(x) = x^3 - x = 0$ gives $x = 0$ and $x = \pm 1$. See Figure 5.14. To find the total area, we find the area above the axis and the area below the axis separately. We have

$$\int_0^1 (x^3 - x)dx = -0.25 \quad \text{and} \quad \int_1^3 (x^3 - x)dx = 16.$$

As expected, the integral from 0 to 1 is negative. The area above the axis is 16 and the area below the axis is 0.25 so

$$\text{Total area } = 16.25.$$

(b) We have

$$\int_0^3 (x^3 - x)dx = 15.75.$$

Notice that the integral is equal to the area above the axis minus the area below the axis, as expected.

(c) No, they are not the same, since the integral counts area below the axis negatively while total area counts all area as positive. The two answers are not expected to be the same unless all the area lies above the horizontal axis.

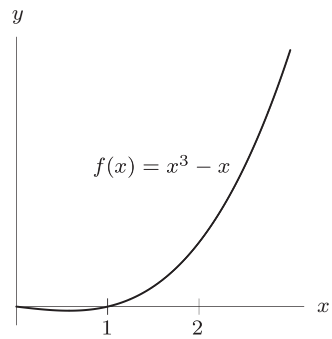

Figure 5.14

22. A graph of $y = 6x^3 - 2$ shows that this function is nonnegative on the interval $x = 5$ to $x = 10$. Thus,

$$\text{Area } = \int_5^{10} (6x^3 - 2)\, dx = 14{,}052.5.$$

The integral was evaluated on a calculator.

23. Since $\cos t \geq 0$ for $0 \leq t \leq \pi/2$, the area is given by

$$\text{Area} = \int_0^{\pi/2} \cos t\, dt = 1.$$

The integral was evaluated on a calculator.

24. A graph of $y = \ln x$ shows that this function is non-negative on the interval $x = 1$ to $x = 4$. Thus,

$$\text{Area} = \int_1^4 \ln x\, dx = 2.545.$$

The integral was evaluated on a calculator.

25. A graph of $y = 2\cos(t/10)$ shows that this function is nonnegative on the interval $t = 1$ to $t = 2$. Thus,

$$\text{Area} = \int_1^2 2\cos\frac{t}{10}\, dt = 1.977.$$

The integral was evaluated on a calculator.

26. Since $\cos\sqrt{x} > 0$ for $0 \leq x \leq 2$, the area is given by

$$\text{Area} = \int_0^2 \cos\sqrt{x}\, dx = 1.106.$$

The integral was evaluated on a calculator.

27. The graph of $y = 7 - x^2$ has intercepts $x = \pm\sqrt{7}$. See Figure 5.15. Therefore we have

$$\text{Area} = \int_{-\sqrt{7}}^{\sqrt{7}} (7 - x^2)\, dx = 24.694.$$

The integral was evaluated on a calculator.

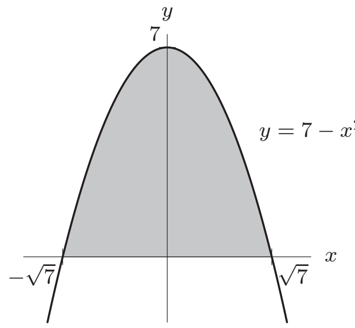

Figure 5.15

28. The graph of $y = x^4 - 8$ has intercepts $x = \pm\sqrt[4]{8}$. See Figure 5.16. Since the region is below the x-axis, the integral is negative, so

$$\text{Area} = -\int_{-\sqrt[4]{8}}^{\sqrt[4]{8}} (x^4 - 8)\, dx = 21.527.$$

The integral was evaluated on a calculator.

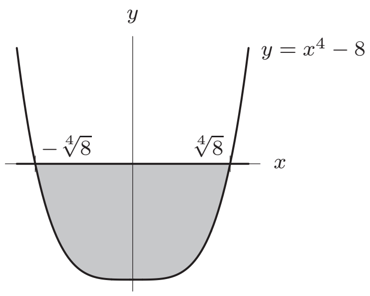

Figure 5.16

29. (a) The area between the graph of f and the x-axis between $x = a$ and $x = b$ is 13, so

$$\int_a^b f(x)\,dx = 13.$$

(b) Since the graph of $f(x)$ is below the x-axis for $b < x < c$,

$$\int_b^c f(x)\,dx = -2.$$

(c) Since the graph of $f(x)$ is above the x-axis for $a < x < b$ and below for $b < x < c$,

$$\int_a^c f(x)\,dx = 13 - 2 = 11.$$

(d) The graph of $|f(x)|$ is the same as the graph of $f(x)$ except that the part below the x-axis is reflected to be above it. See Figure 5.17. Thus

$$\int_a^c |f(x)|\,dx = 13 + 2 = 15.$$

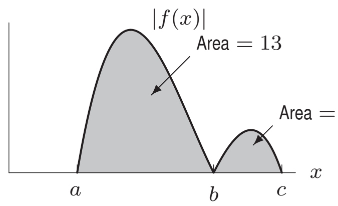

Figure 5.17

30. The region shaded between $x = 0$ and $x = 2$ appears to have approximately the same area as the region shaded between $x = -2$ and $x = 0$, but it lies below the axis. Since $\int_{-2}^{0} f(x)dx = 4$, we have the following results:

(a) $\int_0^2 f(x)dx \approx -\int_{-2}^{0} f(x)dx = -4.$
(b) $\int_{-2}^{2} f(x)dx \approx 4 - 4 = 0.$
(c) The total area shaded is approximately $4 + 4 = 8$.

31. (a) $\displaystyle\int_{-3}^{0} f(x)\,dx = -2.$

(b) $\displaystyle\int_{-3}^{4} f(x)\,dx = \int_{-3}^{0} f(x)\,dx + \int_{0}^{3} f(x)\,dx + \int_{3}^{4} f(x)\,dx = -2 + 2 - \frac{A}{2} = -\frac{A}{2}.$

32. We can compute each integral in this problem by finding the difference between the area that lies above the x-axis and the area that lies below the x-axis on the given interval.

(a) For $\int_0^2 f(x)\,dx$, on $0 \le x \le 1$ the area under the graph is 1; on $1 \le x \le 2$ the areas above and below the x-axis are equal and cancel each other out. Therefore, $\int_0^2 f(x)\,dx = 1$.

(b) On $3 \le x \le 7$ the graph of $f(x)$ is the upper half circle of radius 2 centered at $(5, 0)$. The integral is equal to the area between the graph of $f(x)$ and the x-axis, which is the area of a semicircle of radius 2. This area is 2π, and so

$$\int_3^7 f(x)\,dx = \frac{\pi 2^2}{2} = 2\pi.$$

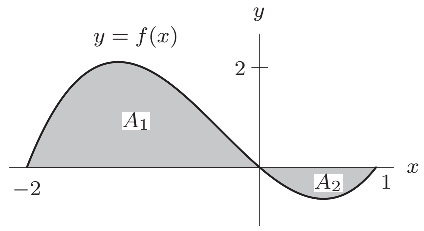
(c) On $2 \le x \le 7$ we are looking at two areas: We already know that the area of the semicircle on $3 \le x \le 7$ is 2π. On $2 \le x \le 3$, the graph lies below the x-axis and the area of the triangle is $\frac{1}{2}$. Therefore,

$$\int_2^7 f(x)\,dx = -\frac{1}{2} + 2\pi.$$

(d) For this portion of the problem, we can split the region between the graph and the x-axis into a quarter circle on $5 \le x \le 7$ and a trapezoid on $7 \le x \le 8$ below the x-axis. The semicircle has area π, the trapezoid has area $3/2$. Therefore,

$$\int_5^8 f(x)\,dx = \pi - \frac{3}{2}.$$

33. (a)



(b) $A_1 = \int_{-2}^{0} f(x)\,dx = 2.667.$

$A_2 = -\int_{0}^{1} f(x)\,dx = 0.417.$

So total area $= A_1 + A_2 \approx 3.084$. Note that while A_1 and A_2 are accurate to 3 decimal places, the quoted value for $A_1 + A_2$ is accurate only to 2 decimal places.

(c) $\int_{-2}^{1} f(x)\,dx = A_1 - A_2 = 2.250.$

34. $\int_0^4 \cos\sqrt{x}\,dx = 0.80 =$ Area A_1 – Area A_2. See Figure 5.18.

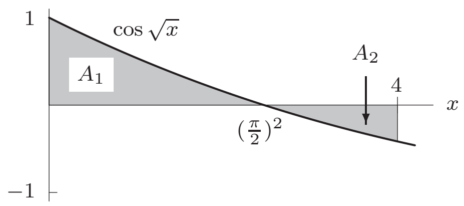


Figure 5.18

35. Looking at the graph of $e^{-x}\sin x$ for $0 \le x \le 2\pi$ in Figure 5.19, we see that the area, A_1, below the curve for $0 \le x \le \pi$ is much greater than the area, A_2, above the curve for $\pi \le x \le 2\pi$. Thus, the integral is

$$\int_0^{2\pi} e^{-x}\sin x\,dx = A_1 - A_2 > 0.$$

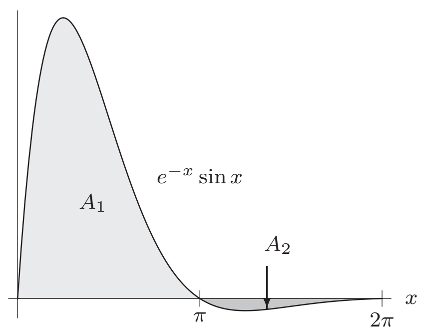

Figure 5.19

36. Since e^{-x^2} is decreasing between $x = 0$ and $x = 1$, the left sum is an overestimate and the right sum is an underestimate of the integral. Letting $f(x) = e^{-x^2}$, we divide the interval $0 \le x \le 1$ into $n = 5$ sub-intervals to create Table 5.2.

Table 5.2

x	0.0	0.2	0.4	0.6	0.8	1.0
$f(x)$	1.000	0.961	0.852	0.698	0.527	0.368

(a) Letting $\Delta x = (1-0)/5 = 0.2$, we have:

$$\begin{aligned}\text{Left-hand sum} &= f(0)\Delta x + f(0.2)\Delta x + f(0.4)\Delta x + f(0.6)\Delta x + f(0.8)\Delta x \\ &= 1(0.2) + 0.961(0.2) + 0.852(0.2) + 0.698(0.2) + 0.527(0.2) \\ &= 0.808.\end{aligned}$$

(b) Again letting $\Delta x = (1-0)/5 = 0.2$, we have:

$$\begin{aligned}\text{Right-hand sum} &= f(0.2)\Delta x + f(0.4)\Delta x + f(0.6)\Delta x + f(0.8)\Delta x + f(1)\Delta x \\ &= 0.961(0.2) + 0.852(0.2) + 0.698(0.2) + 0.527(0.2) + 0.368(0.2) \\ &= 0.681.\end{aligned}$$

37. (a) See Figure 5.20.

$$\text{Left sum} = f(1)\Delta x + f(1.5)\Delta x = (\ln 1)0.5 + \ln(1.5)0.5 = (\ln 1.5)0.5.$$

(b) See Figure 5.21.

$$\text{Right sum} = f(1.5)\Delta x + f(2)\Delta x = (\ln 1.5)0.5 + (\ln 2)0.5.$$

(c) Right sum is an overestimate, left sum is an underestimate.

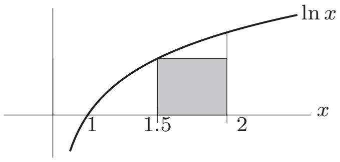

Figure 5.20: Left sum

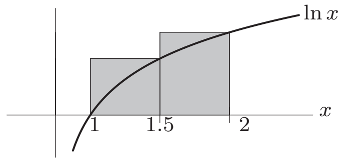

Figure 5.21: Right sum

38. (a) See Figure 5.22.
(b) See Figure 5.23.
(c) Since the rectangle above the curve in Figure 5.22 and the rectangle below the curve in Figure 5.23 look approximately equal in area (in fact, they are exactly equal), the left hand approximation to $\int_{-\pi}^{\pi} \sin x\, dx$ is 0.

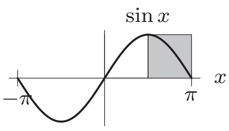

Figure 5.22

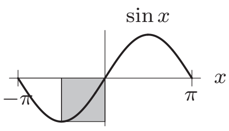

Figure 5.23

39. (a) The integral gives the shaded area in Figure 5.24. We find

$$\int_0^6 (x^2+1)\, dx = 78.$$

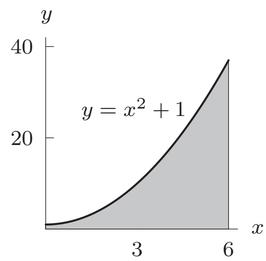

Figure 5.24

(b) Using $n = 3$, we have

$$\text{Left-hand sum} = f(0)\cdot 2 + f(2)\cdot 2 + f(4)\cdot 2 = 1\cdot 2 + 5\cdot 2 + 17\cdot 2 = 46.$$

This sum is an underestimate. See Figure 5.25.

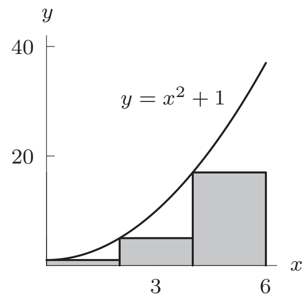

Figure 5.25

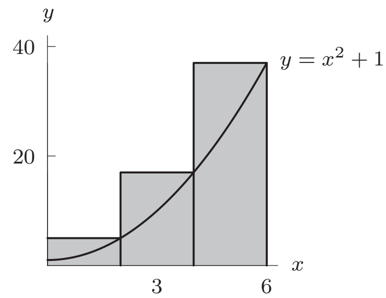

Figure 5.26

(c) Using $n = 3$ gives

$$\text{Right-hand sum} = f(2)\cdot 2 + f(4)\cdot 2 + f(6)\cdot 2 = 5\cdot 2 + 17\cdot 2 + 37\cdot 2 = 118.$$

This sum is an overestimate. See Figure 5.26.

40. (a) See Figure 5.27.

(b) Since each of the triangular regions in Figure 5.27 have area $1/2$, we have

$$\int_0^2 f(x)\,dx = \frac{1}{2} + \frac{1}{2} = 1.$$

(c) Using $\Delta x = 1/2$ in the 4-term Riemann sum shown in Figure 5.28, we have

$$\begin{aligned}\text{Left hand sum } &= f(0)\Delta x + f(0.5)\Delta x + f(1)\Delta x + f(1.5)\Delta x\\ &= 1\left(\frac{1}{2}\right) + \frac{1}{2}\left(\frac{1}{2}\right) + 0\left(\frac{1}{2}\right) + \frac{1}{2}\left(\frac{1}{2}\right) = 1.\end{aligned}$$

We notice that in this case the approximation is exactly equal to the exact value of the integral.

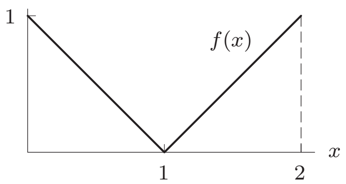

Figure 5.27

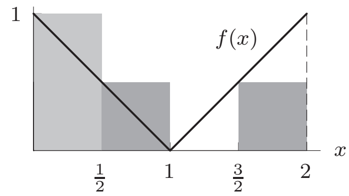

Figure 5.28

41. Left-hand sum gives: $1^2(1/4) + (1.25)^2(1/4) + (1.5)^2(1/4) + (1.75)^2(1/4) = 1.96875$.
Right-hand sum gives: $(1.25)^2(1/4) + (1.5)^2(1/4) + (1.75)^2(1/4) + (2)^2(1/4) = 2.71875$.

We estimate the value of the integral by taking the average of these two sums, which is 2.34375. Since x^2 is monotonic on $1 \le x \le 2$, the true value of the integral lies between 1.96875 and 2.71875. Thus the most our estimate could be off is 0.375. We expect it to be much closer. (And it is—the true value of the integral is $7/3 \approx 2.333$.)

42. We have $\Delta x = 2/500 = 1/250$. The formulas for the left- and right-hand Riemann sums give us that

$$\begin{aligned}\text{Left} &= \Delta x[f(-1) + f(-1+\Delta x) + \ldots + f(1-2\Delta x) + f(1-\Delta x)]\\ \text{Right} &= \Delta x[f(-1+\Delta x) + f(-1+2\Delta x) + \ldots + f(1-\Delta x) + f(1)].\end{aligned}$$

Subtracting these yields

$$\text{Right} - \text{Left} = \Delta x[f(1) - f(-1)] = \frac{1}{250}[6-2] = \frac{4}{250} = \frac{2}{125}.$$

43. See Figure 5.29.

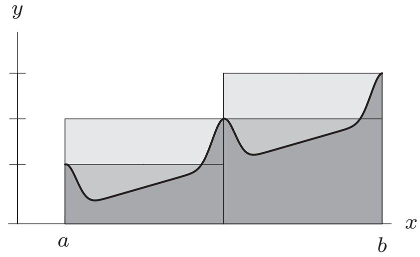

Figure 5.29: Integral vs. Left- and Right-Hand Sums

44. The statement is rarely true. The graph of almost any non-linear monotonic function, such as x^{10} for $0 < x < 1$, should provide convincing geometric evidence. Furthermore, if the statement were true, then (LHS+RHS)/2 would always give the exact value of the definite integral. This is not true.

45. (a) If the interval $1 \le t \le 2$ is divided into n equal subintervals of length $\Delta t = 1/n$, the subintervals are given by

$$1 \le t \le 1 + \frac{1}{n},\ 1 + \frac{1}{n} \le t \le 1 + \frac{2}{n},\ \ldots,\ 1 + \frac{n-1}{n} \le t \le 2.$$

The left-hand sum is given by

$$\text{Left sum } = \sum_{r=0}^{n-1} f\left(1 + \frac{r}{n}\right)\frac{1}{n} = \sum_{r=0}^{n-1} \frac{1}{1+r/n} \cdot \frac{1}{n} = \sum_{r=0}^{n-1} \frac{1}{n+r}$$

and the right-hand sum is given by

$$\text{Right sum } = \sum_{r=1}^{n} f\left(1 + \frac{r}{n}\right)\frac{1}{n} = \sum_{r=1}^{n} \frac{1}{n+r}.$$

Since $f(t) = 1/t$ is decreasing in the interval $1 \le t \le 2$, we know that the right-hand sum is less than $\int_1^2 1/t\,dt$ and the left-hand sum is larger than this integral. Thus we have

$$\sum_{r=1}^{n} \frac{1}{n+r} \quad < \quad \int_1^t \frac{1}{t}\,dt \quad < \quad \sum_{r=0}^{n-1} \frac{1}{n+r}.$$

(b) Subtracting the sums gives

$$\sum_{r=0}^{n-1} \frac{1}{n+r} - \sum_{r=1}^{n} \frac{1}{n+r} = \frac{1}{n} - \frac{1}{2n} = \frac{1}{2n}.$$

(c) Here we need to find n such that

$$\frac{1}{2n} \le 5 \times 10^{-6}, \quad \text{so} \quad n \ge \frac{1}{10} \times 10^{6} = 10^{5}.$$

Strengthen Your Understanding

46. This does not say that $f(x) \ge 0$. If $f(x) < 0$ on $[1, 3]$ then the integral is negative, but an area cannot be negative.

47. There are too many terms in the sum; last term should be $\sin(1.9)$. So the correct left-hand sum is

$$0.1\left(\sin(1) + \sin(1.1) + \cdots + \sin(1.9)\right).$$

48. Any function which is negative on the whole interval will do, for example $f(x) = -1$ and $[a, b] = [0, 1]$. There are also examples like $f(x) = -1 + x$ with $0 \le x \le 1.1$.

49. This is true if the function is negative on the interval $[2, 3]$; for example $f(x) = 2 - x$.

50. False. The integral is the change in position from $t = a$ to $t = b$. If the velocity changes sign in the interval, the total distance traveled and the change in position will not be the same.

51. False. A counterexample is given by $f(x) = 1$ on $[0, 2]$.Then

$$\int_0^2 f(x)\,dx = 2.$$

On the other hand, using $\Delta x = 1/2$ in the 4-term Riemann sum we have

$$\begin{aligned}\text{Left hand sum} &= f(0)\Delta x + f(0.5)\Delta x + f(1)\Delta x + f(1.5)\Delta x \\ &= 1\left(\frac{1}{2}\right) + 1\left(\frac{1}{2}\right) + 1\left(\frac{1}{2}\right) + 1\left(\frac{1}{2}\right) = 2.\end{aligned}$$

52. False. A counterexample is given by the functions f and g in Figure 5.30. The function f is decreasing, g is increasing, and we have

$$\int_1^2 f(x)\,dx = \int_1^2 g(x)\,dx,$$

because both integrals equal $1/2$, the area of of the same sized triangle.

Figure 5.30

53. False. Any function $f(x)$ that is negative between $x = 2$ and $x = 3$ has $\int_2^3 f(x)\,dx < 0$, so $\int_0^2 f(x)\,dx > \int_0^3 f(x)\,dx$.

54. True. Since $\int_0^2 f(x)\,dx$ is a number, if we use the variable t instead of the variable x in the function f, we get the same number for the definite integral.

55. False. Let $f(x) = x$ and $g(x) = 5$. Then $\int_2^6 f(x)\,dx = 16$ and $\int_2^6 g(x)\,dx = 20$, so $\int_2^6 f(x)\,dx \le \int_2^6 g(x)\,dx$, but $f(x) > g(x)$ for $5 < x < 6$.

56. An example is graphed in Figure 5.31.

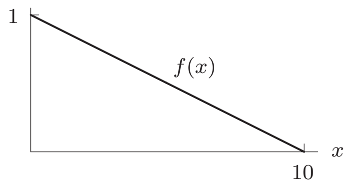

Figure 5.31

57. An example is graphed in Figure 5.32.

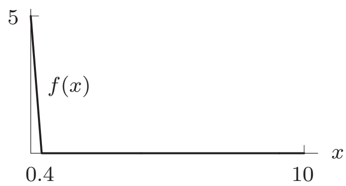

Figure 5.32

Solutions for Section 5.3

Exercises

1. The units of measurement are dollars.

2. The units of measurement are meters per second (which are units of velocity).

3. The units of measurement are foot-pounds (which are units of work).

4. The integral $\int_1^3 v(t)\,dt$ represents the change in position between time $t = 1$ and $t = 3$ seconds; it is measured in meters.

5. The integral $\int_0^6 a(t)\,dt$ represents the change in velocity between times $t = 0$ and $t = 6$ seconds; it is measured in km/hr.

6. The integral $\int_{2005}^{2011} f(t)\,dt$ represents the change in the world's population between the years 2005 and 2011. It is measured in billions of people.

7. The integral $\int_0^5 s(x)\,dx$ represents the change in salinity (salt concentration) in the first 5 cm of water; it is measured in gm/liter.

8. (a) One small box on the graph corresponds to moving at 750 ft/min for 15 seconds, which corresponds to a distance of 187.5 ft. Estimating the area beneath the velocity curves, we find:
Distance traveled by car 1 ≈ 5.5 boxes $= 1031.25$ ft.
Distance traveled by car 2 ≈ 3 boxes $= 562.5$ ft.

(b) The two cars will have gone the same distance when the areas beneath their velocity curves are equal. Since the two areas overlap, they are equal when the two shaded regions have equal areas, at $t \approx 1.6$ minutes. See Figure 5.33.

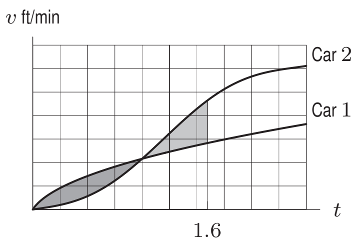

Figure 5.33

9. We have $f(t) = F'(t) = 2t$, so by the Fundamental Theorem of Calculus,

$$\int_1^3 2t\,dt = F(3) - F(1) = 9 - 1 = 8.$$

10. We have $f(t) = F'(t) = 6t + 4$, so by the Fundamental Theorem of Calculus,

$$\int_2^5 (6t+4)\,dt = F(5) - F(2) = 95 - 20 = 75.$$

11. We have $f(t) = F'(t) = 1/t$, so by the Fundamental Theorem of Calculus,

$$\int_1^5 \frac{1}{t}\,dt = F(5) - F(1) = \ln 5 - \ln 1 = \ln 5.$$

12. We have $f(t) = F'(t) = \cos t$, so by the Fundamental Theorem of Calculus,

$$\int_0^{\pi/2} \cos t\,dt = F(\pi/2) - F(0) = 1 - 0 = 1.$$

13. We have $f(t) = F'(t) = 7\ln(4)\cdot 4^t$, so by the Fundamental Theorem of Calculus,

$$\int_2^3 7\ln(4)\cdot 4^t\,dt = F(3) - F(2) = 448 - 112 = 336.$$

14. We have $f(t) = F'(t) = 1/(\cos^2 t)$, so by the Fundamental Theorem of Calculus,

$$\int_0^\pi 1/(\cos^2 t)\,dt = F(\pi) - F(0) = 0 - 0 = 0.$$

Problems

15. (a) We have

$$\frac{d}{dx}(x^3 + x) = 3x^2 + 1.$$

(b) By the Fundamental Theorem of Calculus with $F'(x) = 3x^2 + 1$ and $F(x) = x^3 + x$, we have

$$\int_0^2 (3x^2 + 1)\,dx = F(2) - F(0) = (2^3 + 2) - (0^3 + 0) = 10.$$

16. (a) We have

$$\frac{d}{dt}(\sin t) = \cos t.$$

(b) Since $v(t)$ is the derivative of distance traveled, by the Fundamental Theorem of Calculus with $F'(t) = v(t) = \cos t$ and $F(t) = \sin t$, we have

$$\text{Distance} = \int_0^{\pi/2} v(t)\,dt = \int_0^{\pi/2} \cos t\,dt = F\left(\frac{\pi}{2}\right) - F(0) = \sin\left(\frac{\pi}{2}\right) - \sin 0 = 1.$$

17. (a) By the chain rule,

$$\frac{d}{dx}\left(\frac{1}{2}\sin^2 t\right) = \frac{1}{2}\cdot 2\sin t\cos t = \sin t\cos t.$$

(i) Using a calculator, $\int_{0.2}^{0.4} \sin t\cos t\,dt = 0.056$

(ii) The Fundamental Theorem of Calculus tells us that the integral is

$$\int_{0.2}^{0.4} \sin t\cos t\,dt = F(0.4) - F(0.2) = \frac{1}{2}\left(\sin^2(0.4) - \sin^2(0.2)\right) = 0.05609.$$

18. (a) By the chain rule,

$$F'(x) = \frac{d}{dx}\left(e^{x^2}\right) = 2xe^{x^2}.$$

(i) Using a calculator, $\int_0^1 2xe^{x^2}\,dx = 1.718.$

(ii) The Fundamental Theorem of Calculus says we can get the exact value of the integral by looking at

$$\int_0^1 2xe^{x^2}\,dx = F(1) - F(0) = e^{1^2} - e^{0^2} = e - 1 = 1.71828.$$

19. (a) On day 12 pollution is removed from the lake at a rate of 500 kg/day.

(b) The limits of the integral are $t = 5$ and $t = 15$. Since t is time in days, the units of the 5 and 15 are days. The units of the integral are obtained by multiplying the units of $f(t)$, kg/day, by the units of dt, day. Thus the units of the integral are

$$\frac{\text{kg}}{\text{day}} \times \text{day} = \text{kg}.$$

The 4000 has units of kilograms.

(c) The integral of a rate gives the total change. Here $f(t)$ is the rate of change of the quantity of pollution that has been removed from the lake. The integral gives the change in the quantity of pollution that has been removed during the time interval; in other words, the total quantity removed during that time period. During the 10 days from day 5 to day 15, a total of 4000 kg were removed from the lake.

20. For any t, consider the interval $[t, t+\Delta t]$. During this interval, oil is leaking out at an approximately constant rate of $f(t)$ gallons/minute. Thus, the amount of oil which has leaked out during this interval can be expressed as

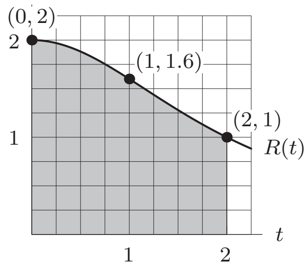
$$\text{Amount of oil leaked} = \text{Rate} \times \text{Time} = f(t)\,\Delta t$$

and the units of $f(t)\,\Delta t$ are gallons/minute $\times$ minutes $=$ gallons. The total amount of oil leaked is obtained by adding all these amounts between $t = 0$ and $t = 60$. (An hour is 60 minutes.) The sum of all these infinitesimal amounts is the integral

$$\begin{matrix}\text{Total amount of} \\ \text{oil leaked, in gallons}\end{matrix} = \int_0^{60} f(t)\,dt.$$

21. (a) The amount leaked between $t = 0$ and $t = 2$ is $\int_0^2 R(t)\,dt$.

(b)



(c) The rectangular boxes on the diagram each have area $\frac{1}{16}$. Of these 45 are wholly beneath the curve, hence the area under the curve is certainly more than $\frac{45}{16} > 2.81$. There are 9 more partially beneath the curve, and so the desired area is completely covered by 54 boxes. Therefore the area is less than $\frac{54}{16} < 3.38$.

These are very safe estimates but far apart. We can do much better by estimating what fractions of the broken boxes are beneath the curve. Using this method, we can estimate the area to be about 3.2, which corresponds to 3.2 gallons leaking over two hours.

22. (a) Using rectangles under the curve, we get

$$\text{Acres defaced } \approx (1)(0.2 + 0.4 + 1 + 2) = 3.6 \text{ acres.}$$

(b) Using rectangles above the curve, we get

$$\text{Acres defaced } \approx (1)(0.4 + 1 + 2 + 3.5) = 6.9 \text{ acres.}$$

(c) The number of acres defaced is between 3.6 and 6.9, so we estimate the average, 5.25 acres.

23. (a) Quantity used $= \int_0^5 f(t)\,dt$.

(b) Using a left sum, our approximation is

$$32e^{0.05(0)} + 32e^{0.05(1)} + 32e^{0.05(2)} + 32e^{0.05(3)} + 32e^{0.05(4)} = 177.270.$$

Since f is an increasing function, this represents an underestimate.

(c) Each term is a lower estimate of one year's consumption of oil.

24. (a) Solving $v(t) = -4t^2 + 16t = 0$ gives $t = 0$ and $t = 4$. At $t = 0$ the jump has just started; at $t = 4$ the jumper is momentarily stopped before starting back up. In Figure 5.34, we see the velocity is positive from $t = 0$ to $t = 4$ and negative from $t = 4$ to $t = 5$. The total number of meters traveled is given by the total area between the velocity curve and the t-axis. We find the total area by finding the areas above and below the axis separately. We have

$$\int_0^4 (-4t^2 + 16t)\,dt = 42.6667 \quad \text{and} \quad \int_4^5 (-4t^2 + 16t)\,dt = -9.3333.$$

The jumper traveled 42.6667 meters downward and then 9.3333 meters upward, so

$$\text{Total number of meters traveled } = 42.6667 + 9.3333 = 52 \text{ meters.}$$

(b) Since the jumper fell 42.6667 meters downward and came back up 9.3333 meters,

$$\text{Ending position } = 42.6667 - 9.3333 = 33.333 \text{ meters below the starting point.}$$

(c) We find that

$$\int_0^5 (-4t^2 + 16t)\,dt = 33.333 \text{ meters}.$$

Thus, the net change in position is a positive 33.333 meters, or 33.333 meters below the starting point. The net change is given by the integral, while the total number of meters traveled is given by the total area.

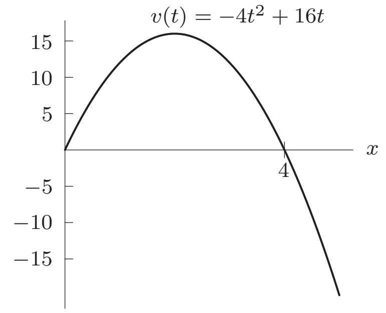


Figure 5.34

25. (a) Note that the rate $r(t)$ sometimes increases and sometimes decreases in the interval. We can calculate an upper estimate of the volume by choosing $\Delta t = 5$ and then choosing the highest value of $r(t)$ on each interval, and similarly a lower estimate by choosing the lowest value of $r(t)$ on each interval:

$$\text{Upper estimate} = 5[20 + 24 + 24] = 340 \text{ liters}.$$
$$\text{Lower estimate} = 5[12 + 20 + 16] = 240 \text{ liters}.$$

(b) A graph of $r(t)$ along with the areas represented by the choices of $r(t)$ in calculating the lower estimate is shown in Figure 5.35.

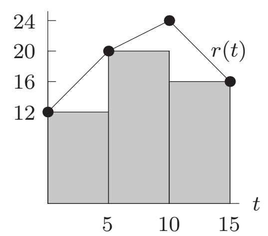

Figure 5.35

26. We use left- and right-hand sums to estimate the total amount of coal produced during this period:

$$\text{Left sum} = (1.090)2 + (1.094)2 + (1.121)2 + (1.072)2 + (1.132)2 + (1.147)2 = 13.312.$$

$$\text{Right sum} = (1.094)2 + (1.121)2 + (1.072)2 + (1.132)2 + (1.147)2 + (1.073)2 = 13.278.$$

We see that

$$\text{Total amount of coal produced} \approx \frac{13.312 + 13.278}{2} = 13.295 \text{ billion tons}.$$

The total amount of coal produced is the definite integral of the rate of coal production $r = f(t)$ given in the table. Since t is in years since 1997, the limits of integration are $t = 0$ and $t = 12$. We have

$$\text{Total amount of coal produced} = \int_0^{12} f(t)\,dt \text{ billion tons}.$$

27. Since W is in tons per week and t is in weeks since January 1, 2005, the integral $\int_0^{52} W\,dt$ gives the amount of waste, in tons, produced during the year 2005.

$$\text{Total waste during the year} = \int_0^{52} 3.75e^{-0.008t}dt = 159.5249 \text{ tons.}$$

Since waste removal costs $\$15/\text{ton}$, the cost of waste removal for the company is $159.5249 \cdot 15 = \$2392.87$.

28. The total number of "worker-hours" is equal to the area under the curve. The total area is about 14.5 boxes. Since each box represents (10 workers)(8 hours) $= 80$ worker-hours, the total area is 1160 worker-hours. At \$10 per hour, the total cost is \$11,600.

29. The time period 9am to 5pm is represented by the time $t = 0$ to $t = 8$ and $t = 24$ to $t = 32$. The area under the curve, or total number of worker-hours for these times, is about 9 boxes or $9(80) = 720$ worker-hours. The total cost for 9am to 5pm is $(720)(10) = \$7200$. The area under the rest of the curve is about 5.5 boxes, or $5.5(80) = 440$ worker-hours. The total cost for this time period is $(440)(15) = \$6600$. The total cost is about $7200 + 6600 = \$13{,}800$.

30. The area under the curve represents the number of cubic feet of storage times the number of days the storage was used. This area is given by

$$\begin{aligned}\text{Area under graph} &= \text{Area of rectangle} + \text{Area of triangle}\\ &= 30 \cdot 10{,}000 + \frac{1}{2} \cdot 30(30{,}000 - 10{,}000)\\ &= 600{,}000.\end{aligned}$$

Since the warehouse charges \$5 for every 10 cubic feet of storage used for a day, the company will have to pay $(5)(60{,}000) = \$300{,}000$.

31. If $H(t)$ is the temperature of the coffee at time t, by the Fundamental Theorem of Calculus

$$\text{Change in temperature} = H(10) - H(0) = \int_0^{10} H'(t)\,dt = \int_0^{10} -7e^{-0.1t}\,dt.$$

Therefore,

$$H(10) = H(0) + \int_0^{10} -7(0.9^t)\,dt \approx 90 - 44.2 = 45.8^\circ\text{C}.$$

32. The change in the amount of water is the integral of rate of change, so we have

$$\text{Number of liters pumped out} = \int_0^{60} (5 - 5e^{-0.12t})dt = 258.4 \text{ liters.}$$

Since the tank contained 1000 liters of water initially, we see that

$$\text{Amount in tank after one hour} = 1000 - 258.4 = 741.6 \text{ liters.}$$

33. By the Fundamental Theorem,

$$f(1) - f(0) = \int_0^1 f'(x)\,dx,$$

Since $f'(x)$ is negative for $0 \le x \le 1$, this integral must be negative and so $f(1) < f(0)$.

34. First rewrite each of the quantities in terms of f', since we have the graph of f'. If A_1 and A_2 are the positive areas shown in Figure 5.36:

$$\begin{aligned}f(3) - f(2) &= \int_2^3 f'(t)\,dt = -A_1\\ f(4) - f(3) &= \int_3^4 f'(t)\,dt = -A_2\\ \frac{f(4) - f(2)}{2} &= \frac{1}{2}\int_2^4 f'(t)\,dt = -\frac{A_1 + A_2}{2}\end{aligned}$$

Since Area $A_1 >$ Area A_2,

$$A_2 < \frac{A_1 + A_2}{2} < A_1$$

so

$$-A_1 < -\frac{A_1 + A_2}{2} < -A_2$$

and therefore

$$f(3) - f(2) < \frac{f(4) - f(2)}{2} < f(4) - f(3).$$

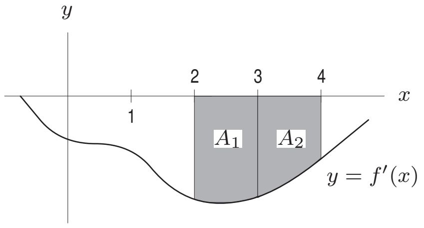

Figure 5.36

35. We know that the the integral of F, and therefore the work, can be obtained by computing the areas in Figure 5.37.

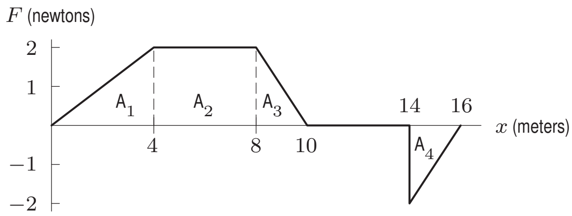

Figure 5.37

$$\begin{aligned} W = \int_0^{16} F(x)\,dx &= \text{Area above } x\text{-axis} - \text{Area below } x\text{-axis} \\ &= A_1 + A_2 + A_3 - A_4 \\ &= \frac{1}{2}\cdot 4\cdot 2 + 4\cdot 2 + \frac{1}{2}\cdot 2\cdot 2 - \frac{1}{2}\cdot 2\cdot 2 \\ &= 12 \text{ newton} \cdot \text{meters.} \end{aligned}$$

36. According to the Fundamental Theorem,

$$f(2) - \underbrace{f(1)}_{7} = \int_1^2 f'(t)\,dt$$

$$f(2) = 7 + \int_1^2 e^{-t^2}\,dt, \quad \text{since } f'(t) = e^{-t^2}.$$

We estimate the integral using left and right sums. Since $f'(t) = e^{-t^2}$ is decreasing between $t = 1$ and $t = 2$, the left sum overestimates and the right sum underestimates the integral.

To find left- and right-hand sums of 5 rectangles, we let $\Delta t = (2 - 1)/5 = 0.2$. The table gives values of $f'(t)$.

t	1.0	1.2	1.4	1.6	1.8	2.0
$f'(t)$	0.368	0.237	0.141	0.077	0.039	0.018

We have the following estimates:

$$LHS = \Delta t\left(f'(1.0) + f'(1.2) + f'(1.4) + f'(1.6) + f'(1.8)\right) = 0.2\,(0.862) = 0.1724$$
$$RHS = \Delta t\left(f'(1.2) + f'(1.4) + f'(1.6) + f'(1.8) + f'(2.0)\right) = 0.2(0.512) = 0.1024.$$

So

$$0.1024 < \int_1^2 e^{-t^2}\,dt < 0.1734.$$

Adding 7, we estimate that

$$7.1024 < f(2) < 7.1724.$$

37. All the integrals have positive values, since $f \geq 0$. The integral in (ii) is about one-half the integral in (i), due to the apparent symmetry of f. The integral in (iv) will be much larger than the integral in (i), since the two peaks of f^2 rise to 10,000. The integral in (iii) will be smaller than half of the integral in (i), since the peaks in $f^{1/2}$ will only rise to 10. So

$$\int_0^2 (f(x))^{1/2}\,dx < \int_0^1 f(x)\,dx < \int_0^2 f(x)\,dx < \int_0^2 (f(x))^2\,dx.$$

38. (a) V, since the slope is constant.
(b) IV, since the net area under this curve is the most negative.
(c) III, since the area under the curve is largest.
(d) II, since the steepest ascent at $t = 0$ occurs on this curve.
(e) III, since average velocity is (total distance)/5, and III moves the largest total distance.
(f) I, since average acceleration is $\frac{1}{5}\int_0^5 v'(t)\,dt = \frac{1}{5}(v(5) - v(0))$, and in I, the velocity increases the most from start ($t = 0$) to finish ($t = 5$).

39. To make this estimate, we first observe that, for constant speed,

$$\text{Fuel used } = \frac{\text{Miles traveled}}{\text{Miles/gallon}} = \frac{\text{Speed} \cdot \text{Time}}{\text{Miles/gallon}}.$$

We make estimates at the start and end of each of the six intervals given. The 60 mph increase in speed (from 10 mph to 70 mph) takes half an hour, or 30 minutes. Since the speed increases at a constant rate, each 10 mph increase takes 5 minutes.

At the start of the first 5 minutes, the speed is 10 mph and at the end, the speed is 20 mph. Since 5min $= 5/60$ hour, during the first 5 minutes the distance traveled is between

$$10 \cdot \frac{5}{60} \text{ mile} \qquad \text{and} \qquad 20 \cdot \frac{5}{60} \text{ mile.}$$

During this first five minute period, the speed is between 10 and 20 mph, so the fuel efficiency is between 15 mpg and 18 mpg. So the fuel used during this period is between

$$\frac{1}{18} \cdot 10 \cdot \frac{5}{60} \text{ gallons} \qquad \text{and} \qquad \frac{1}{15} \cdot 20 \cdot \frac{5}{60} \text{ gallons.}$$

Thus, an underestimate of the fuel used is

$$\text{Fuel } = \left(\frac{1}{18} \cdot 10 + \frac{1}{21} \cdot 20 + \frac{1}{23} \cdot 30 + \frac{1}{24} \cdot 40 + \frac{1}{25} \cdot 50 + \frac{1}{26} \cdot 60\right)\frac{5}{60} = 0.732 \text{ gallons.}$$

An overestimate of the fuel used is

$$\text{Fuel } = \left(\frac{1}{15} \cdot 20 + \frac{1}{18} \cdot 30 + \frac{1}{21} \cdot 40 + \frac{1}{23} \cdot 50 + \frac{1}{24} \cdot 60 + \frac{1}{25} \cdot 70\right)\frac{5}{60} = 1.032 \text{ gallons.}$$

We can get better bounds by using the actual distance traveled during each five minute period. For example, in the first five minutes the average speed is 15 mph (halfway between 10 and 20 mph because the speed is increasing at a constant rate). Since 5 minutes is 5/60 of an hour, in the first five minutes the car travels 15(5/60)=5/4 miles. Thus the fuel used during this period was between

$$\frac{5}{4} \cdot \frac{1}{18} \qquad \text{and} \qquad \frac{5}{4} \cdot \frac{1}{15}.$$

Using this method for each five minute period gives a lower estimate of 0.843 gallons and an upper estimate of 0.909 gallons.

40. The value of this integral tells us how much oil is pumped from the well between day $t = 0$ and day $t = t_0$.

41. The time period from t_0 to $2t_0$ is shorter (and contained within) the time period from 0 to $2t_0$. Thus, the amount of oil pumped out during the shorter time period, $\int_{t_0}^{2t_0} r(t)\,dt$, is less than the amount of oil pumped out in the longer timer period, $\int_0^{2t_0} r(t)\,dt$. This means

$$\int_{t_0}^{2t_0} r(t)\,dt < \int_0^{2t_0} r(t)\,dt.$$

The length of the time period from $2t_0$ to $3t_0$ is the same as the length from t_0 to $2t_0$: both are t_0 days. But the rate at which oil is pumped is going down, since $r'(t) < 0$. Thus, less oil is pumped out during the later time period, so

$$\int_{2t_0}^{3t_0} r(t)\,dt < \int_{t_0}^{2t_0} r(t)\,dt.$$

We conclude that $\int_{2t_0}^{3t_0} r(t)\,dt < \int_{t_0}^{2t_0} r(t)\,dt < \int_0^{2t_0} r(t)\,dt.$

42. (a) The black curve is for boys, the colored one for girls. The area under each curve represents the change in growth in centimeters. Since men are generally taller than women, the curve with the larger area under it is the height velocity of the boys.

(b) Each square below the height velocity curve has area 1 cm/yr · 1 yr = 1 cm. Counting squares lying below the black curve gives about 43 cm. Thus, on average, boys grow about 43 cm between ages 3 and 10.

(c) Counting squares lying below the black curve gives about 23 cm growth for boys during their growth spurt. Counting squares lying below the colored curve gives about 18 cm for girls during their growth spurt.

(d) We can measure the difference in growth by counting squares that lie between the two curves. Between ages 2 and 12.5, the average girl grows faster than the average boy. Counting squares yields about 5 cm between the colored and black curves for $2 \leq x \leq 12.5$. Counting squares between the curves for $12.5 \leq x \leq 18$ gives about 18 squares. Thus, there is a net increase of boys over girls by about $18 - 5 = 13$ cm.

43. Using a left-hand Riemann sum with $\Delta t = 0.1$, we have:

$$\begin{aligned}\int_0^{0.5} f(t)\,dt &\approx f(0)\Delta t + f(0.1)\Delta t + \cdots + f(0.4)\Delta t\\ &= 0.3(0.1) + 0.2(0.1) + 0.2(0.1) + 0.3(0.1) + 0.4(0.1) \quad \text{using values from the table}\\ &= 0.14.\end{aligned}$$

44. From the Fundamental Theorem of Calculus, we have:

$$\begin{aligned}\int_{0.2}^{0.5} g'(t)\,dt &= g(0.5) - g(0.2) \quad \text{since } g \text{ is an antiderivative of } g'\\ &= 0.8 - 5.1 \quad \text{using values from the table}\\ &= -4.3.\end{aligned}$$

45. Referring to the table, we see that:

$$\begin{aligned}g\left(f(0.0)\right) &= g(0.3) = 5.1\\ g\left(f(0.1)\right) &= g(0.2) = 5.1\\ g\left(f(0.2)\right) &= g(0.2) = 5.1\end{aligned}$$

Using a left-hand Riemann sum with $\Delta t = 0.1$, we have:

$$\begin{aligned}\int_0^{0.3} g\left(f(t)\right)\,dt &\approx g\left(f(0)\right)\Delta t + g\left(f(0.1)\right)\Delta t + g\left(f(0.2)\right)\Delta t.\\ &= 5.1(0.1) + 5.1(0.1) + 5.1(0.1)\\ &= 1.53.\end{aligned}$$

46. Since C is an antiderivative of c, we know by the Fundamental Theorem that

$$\int_{15}^{24} c(n)\,dn = C(24) - C(15) = 13 - 8 = 5.$$

Since $C(24)$ is the cost to plow a 24 inch snowfall, and $C(15)$ is the cost to plow a 15 inch snowfall, this tells us that it costs \$5 million more to plow a 24 inch snowfall than a 15 inch snowfall.

47. Since C is an antiderivative of c, we know from the Fundamental Theorem that

$$\underbrace{\int_{0}^{15} c(n)\,dn}_{7.5} = \underbrace{C(15)}_{8} - C(0)$$
$$\text{so}\quad C(0) = 8 - 7.5 = 0.5.$$

This tells us the cost of preparing for a storm, even if no snow falls, is \$0.5 million, or \$500,000.

48. By the Fundamental Theorem, we have

$$\begin{aligned} c(15) + \int_{15}^{24} c'(n)\,dn &= c(15) + c(24) - c(15) \\ &= c(24) = 0.4. \end{aligned}$$

Since $c(n) = C'(n)$, we have $C'(24) = 0.4$, which tells us the cost of plowing increases at the instantaneous rate of \$0.4 million/inch, or by \$400,000 per each additional inch, after 24 inches have already fallen.

49. The expression $\int_0^2 r(t)\,dt$ represents the amount of water that leaked from the ruptured pipe during the first two hours. Likewise, the expression $\int_2^4 r(t)\,dt$ represents the amount of water that leaked from the ruptured pipe during the next two hours. Since the leak "worsened throughout the afternoon," we know that r is an increasing function, which means that more water leaked out during the second two hours than during the first two hours. Therefore,

$$\int_0^2 r(t)\,dt < \int_2^4 r(t)\,dt.$$

50. The expression $\int_0^4 r(t)\,dt$ represents the amount of water that leaked from the ruptured pipe during the first four hours.

The expression $r(4)$ represents the rate water was leaking from the pipe at time $t = 4$, or four hours after the leak began. Had water leaked at this rate during the whole four-hour time period,

$$\begin{array}{c}\text{Total amount of water leaked} \\ \text{at a constant rate of } r(4)\end{array} = \underbrace{\text{Rate}}_{r(4)} \times \underbrace{\text{Time elapsed}}_{4} = 4r(4) \text{ gallons.}$$

According to the article, the leak "worsened throughout the afternoon," so the rate that water leaked out initially was less than $r(4)$. Thus, $4r(4)$ overestimates the total amount of water leaked during the first four hours.

We conclude that

$$\int_0^4 r(t)\,dt < 4r(4).$$

51. According to the article, the leak "worsened throughout the afternoon," eventually reaching (before being shut off) 8 million gallons/hour. Thus, $0 < r(t) < 8$ million gal/hr. The leak began around 10 am and ended after 6 pm. The expression $\int_0^8 r(t)\,dt$ represents the total amount of water leaked during the first 8 hours (or almost the total amount of water leaked altogether). Since $r(t) < 8$ million gal/hr,

$$\begin{array}{c}\text{Total amount of water leaked} \\ \text{during first 8 hours}\end{array} < \underbrace{\text{Rate (million gal/hr)}}_{8} \times \underbrace{\text{Time elapsed}}_{8} = 64 \text{ million gallons.}$$

Thus,

$$\int_0^8 r(t)\,dt < 64 \text{ million gallons.}$$

Strengthen Your Understanding

52. Since $f(t)$ represents the rate of change of the weight of the dog, $\int_0^4 f(t)dt$ represents the total change in the weight of the dog from the time the dog is born to its fourth birthday. This is not the same as the weight of the dog when it is four years old, because the dog has a nonzero weight when it is born.

53. In the Fundamental Theorem of Calculus, the integrand is the derivative of the function that is evaluated at the limits of the integral. Since $\sqrt{x}$ is not the derivative of $\sqrt{x}$, the statement is not correct. One way to write a correct statement is $\int_4^9 1/(2\sqrt{x})\,dx = \sqrt{9} - \sqrt{4}$.

54. Since $\frac{d}{dx}e^x = e^x$, $f(x) = e^x$ with $a = 2$ and $b = 4$ is one example.

55. If the car travels at a constant velocity of 50 miles per hour, it travels 200 miles in 4 hours as shown in Figure 5.38.

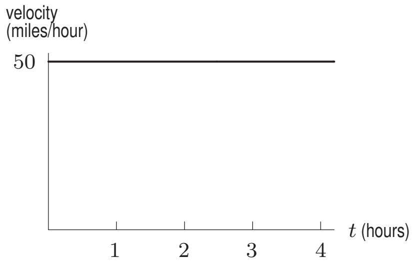

Figure 5.38

56. False. The units of the integral are the product of the units for $f(x)$ times the units for x.

Solutions for Section 5.4

Exercises

1. Note that $\int_a^b g(x)\,dx = \int_a^b g(t)\,dt$. Thus, we have

$$\int_a^b (f(x) + g(x))\,dx = \int_a^b f(x)\,dx + \int_a^b g(x)\,dx = 8 + 2 = 10.$$

2. Note that $\int_a^b f(z)\,dz = \int_a^b f(x)\,dx$. Thus, we have

$$\int_a^b cf(z)\,dz = c\int_a^b f(z)\,dz = 8c.$$

3. Note that $\int_a^b (g(x))^2\,dx = \int_a^b (g(t))^2\,dt$. Thus, we have

$$\int_a^b \left((f(x))^2 - (g(x))^2\right)\,dx = \int_a^b (f(x))^2\,dx - \int_a^b (g(x))^2\,dx = 12 - 3 = 9.$$

4. We have

$$\int_a^b (f(x))^2\,dx - \left(\int_a^b f(x)\,dx\right)^2 = 12 - 8^2 = -52.$$

5. We write

$$\begin{aligned}\int_a^b \left(c_1g(x)+(c_2f(x))^2\right)\,dx &= \int_a^b \left(c_1g(x)+c_2^2(f(x))^2\right)\,dx\\ &= \int_a^b c_1g(x)\,dx+\int_a^b c_2^2(f(x))^2\,dx\\ &= c_1\int_a^b g(x)\,dx + c_2^2\int_a^b (f(x))^2\,dx\\ &= c_1(2)+c_2^2(12) = 2c_1+12c_2^2.\end{aligned}$$

6. The graph of $y = f(x-5)$ is the graph of $y = f(x)$ shifted to the right by 5. Since the limits of integration have also shifted by 5 (to $a+5$ and $b+5$), the areas corresponding to $\int_{a+5}^{b+5} f(x-5)\,dx$ and $\int_a^b f(x)\,dx$ are the same. Thus,

$$\int_{a+5}^{b+5} f(x-5)\,dx = \int_a^b f(x)\,dx = 8.$$

7. Average value $= \dfrac{1}{2-0}\displaystyle\int_0^2 (1+t)\,dt = \dfrac{1}{2}(4) = 2.$

8. Average value $= \dfrac{1}{10-0}\displaystyle\int_0^{10} e^t\,dt = \dfrac{1}{10}(22025) = 2202.5$

9. We have

$$\begin{aligned}\text{Average value} &= \frac{1}{b-a}\int_a^b f(x)\,dx\\ &= \frac{1}{b-a}\int_a^b 2\,dx = \frac{1}{b-a}\cdot\begin{pmatrix}\text{Area of rectangle}\\ \text{of height 2 and base } b-a\end{pmatrix}\\ &= \frac{1}{b-a}\left[2(b-a)\right] = 2.\end{aligned}$$

10. Sketch the graph of f on $1 \le x \le 3$. The integral is the area under the curve, which is a trapezoidal area. So the average value is

$$\frac{1}{3-1}\int_1^3 (4x+7)\,dx = \frac{1}{2}\cdot\frac{11+19}{2}\cdot 2 = \frac{30}{2} = 15.$$

11. The integral represents the area below the graph of $f(x)$ but above the x-axis.

(a) Since each square has area 1, by counting squares and half-squares we find

$$\int_1^6 f(x)\,dx = 8.5.$$

(b) The average value is $\dfrac{1}{6-1}\displaystyle\int_1^6 f(x)\,dx = \dfrac{8.5}{5} = \dfrac{17}{10} = 1.7.$

12. Since the average value is given by

$$\text{Average value} = \frac{1}{b-a}\int_a^b f(x)\,dx,$$

the units for dx inside the integral are canceled by the units for $1/(b-a)$ outside the integral, leaving only the units for $f(x)$. This is as it should be, since the average value of f should be measured in the same units as $f(x)$.

13. The graph of $y = e^x$ is above the line $y = 1$ for $0 \le x \le 2$. See Figure 5.39. Therefore

$$\text{Area} = \int_0^2 (e^x - 1)\,dx = 4.389.$$

The integral was evaluated on a calculator.

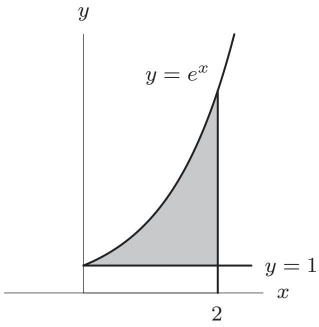

Figure 5.39

14. The graph of $y = 5\ln(2x)$ is above the line $y = 3$ for $3 \leq x \leq 5$. See Figure 5.40. Therefore

$$\text{Area } = \int_3^5 (5\ln(2x) - 3)\,dx = 14.688.$$

The integral was evaluated on a calculator.

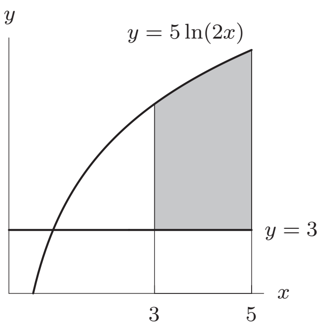

Figure 5.40

15. Since $x^3 \leq x^2$ for $0 \leq x \leq 1$, we have

$$\text{Area } = \int_0^1 (x^2 - x^3)\,dx = 0.083.$$

The integral was evaluated on a calculator.

16. Since $x^{1/2} \leq x^{1/3}$ for $0 \leq x \leq 1$, we have

$$\text{Area } = \int_0^1 (x^{1/3} - x^{1/2})\,dx = 0.0833.$$

The integral was evaluated on a calculator.

17. The graph of $y = \sin x + 2$ is above the line $y = 0.5$ for $6 \leq x \leq 10$. See Figure 5.41. Therefore

$$\text{Area } = \int_6^{10} \sin x + 2 - 0.5\,dx = 7.799.$$

The integral was evaluated on a calculator.

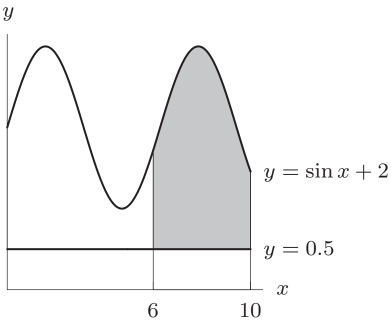

Figure 5.41

18. The graph of $y = \cos t$ is above the graph of $y = \sin t$ for $0 \le t \le \pi/4$ and $y = \cos t$ is below $y = \sin t$ for $\pi/4 < t < \pi$. See Figure 5.42. Therefore, we find the area in two pieces:

$$\text{Area } = \int_0^{\pi/4} (\cos t - \sin t)\,dt + \int_{\pi/4}^{\pi} (\sin t - \cos t)\,dt = 2.828.$$

The integral was evaluated on a calculator.

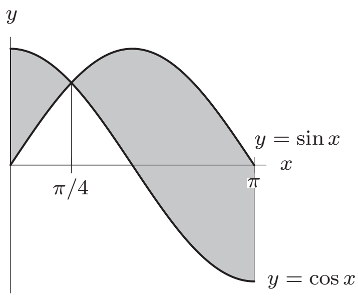

Figure 5.42

19. To find the points of intersection of the two curves, we must solve the equation

$$e^{-x} = 4(x - x^2).$$

This equation cannot be solved exactly, but numerical methods (for example, zooming in on the graph on a calculator) give $x = 0.261$ and $x = 0.883$. See Figure 5.43. Since $y = 4(x - x^2)$ is above $y = e^{-x}$ on this interval,

$$\text{Area } = \int_{0.261}^{0.883} (4(x - x^2) - e^{-x})\,dx = 0.172.$$

The integral was evaluated numerically.

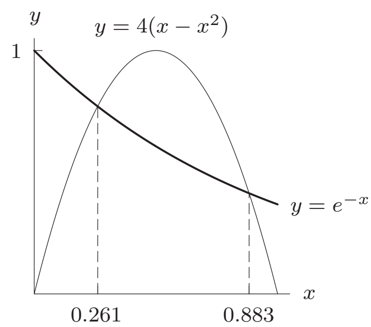

Figure 5.43

20. The curves $y = e^{-x}$ and $y = \ln x$ cross where

$$e^{-x} = \ln x.$$

Numerical methods (for example, zooming in on the graph on a calculator) give $x = 1.310$. See Figure 5.44. Since $y = e^{-x}$ is above $y = \ln x$ for $1 \le x \le 1.310$ and $y = e^{-x}$ is below $y = \ln x$ for $1.310 < x \le 2$, we break the area into two parts:

$$\text{Area} = \int_1^{1.310} (e^{-x} - \ln x)\, dx + \int_{1.310}^{2} (\ln x - e^{-x})\, dx.$$

Evaluating the integrals numerically gives

$$\text{Area} = 0.054 + 0.208 = 0.262.$$

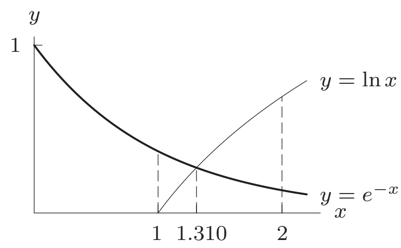

Figure 5.44

Problems

21. (a) For $0 \le x \le 3$, we have

$$\text{Average value} = \frac{1}{3-0}\int_0^3 f(x)dx = \frac{1}{3}(6) = 2.$$

(b) If $f(x)$ is even, the graph is symmetric about the x-axis. For example, see Figure 5.45. By symmetry, the area between $x = -3$ and $x = 3$ is twice the area between $x = 0$ and $x = 3$, so

$$\int_{-3}^{3} f(x)dx = 2(6) = 12.$$

Thus for $-3 \le x \le 3$, we have

$$\text{Average value} = \frac{1}{3-(-3)}\int_{-3}^{3} f(x)dx = \frac{1}{6}(12) = 2.$$

The graph confirms that the average value between $x = -3$ and $x = 3$ is the same as the average value between $x = 0$ and $x = 3$, which is 2.

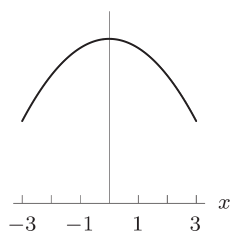

Figure 5.45

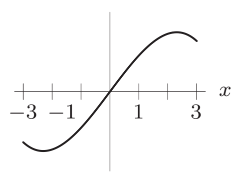

Figure 5.46

(c) If $f(x)$ is odd, then the graph is symmetric about the origin. For example, see Figure 5.46. By symmetry, the area above the x-axis cancels out the area below the x-axis, so

$$\int_{-3}^{3} f(x)dx = 0.$$

Thus for $-3 \le x \le 3$, we have

$$\text{Average value } = \frac{1}{3-(-3)}\int_{-3}^{3} f(x)dx = \frac{1}{6}(0) = 0.$$

The graph confirms that the average value between $x = -3$ and $x = 3$ is zero.

22. We know that we can divide the integral up as follows:

$$\int_0^3 f(x)\,dx = \int_0^1 f(x)\,dx + \int_1^3 f(x)\,dx.$$

The graph suggests that f is an even function for $-1 \le x \le 1$, so $\int_{-1}^{1} f(x)\,dx = 2\int_0^1 f(x)\,dx$. Substituting this in to the preceding equation, we have

$$\int_0^3 f(x)\,dx = \frac{1}{2}\int_{-1}^{1} f(x)\,dx + \int_1^3 f(x)\,dx.$$

23. (a) The integral represents the area of a rectangle with height 1 and base $b - a$. See Figure 5.47. Thus $\int_a^b 1\,dx = b - a$.

(b) (i) $\int_2^5 1\,dx = 3$.

(ii) $\int_{-3}^{8} 1\,dx = 11$.

(iii) $\int_1^3 23\,dx = 23\int_1^3 1\,dx = 46$.

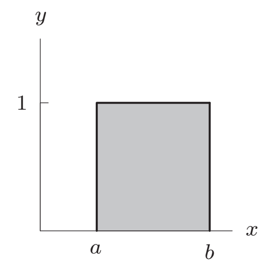

Figure 5.47

24. Using properties of the definite integral, we have:

$$\begin{aligned}
\int_2^5 (2f(x)+3)\,dx &= 17\\
2\int_2^5 f(x)\,dx + 3\int_2^5 1\,dx &= 17\\
2\int_2^5 f(x)\,dx + 3\cdot 3 &= 17\\
2\int_2^5 f(x)\,dx &= 8\\
\int_2^5 f(x)\,dx &= 4.
\end{aligned}$$

25. Since $t = 0$ in 1975 and $t = 35$ in 2010, we want:

$$\begin{aligned}
\text{Average Value } &= \frac{1}{35-0}\int_0^{35} 225(1.15)^t\,dt\\
&= \frac{1}{35}(212{,}787) = \$6080.
\end{aligned}$$

26. (a) The integral represents the area above the x-axis and below the line $y = x$ between $x = a$ and $x = b$. See Figure 5.48. This area is

$$A_1 + A_2 = a(b-a) + \frac{1}{2}(b-a)^2 = \left(a + \frac{b-a}{2}\right)(b-a) = \frac{b+a}{2}(b-a) = \frac{b^2-a^2}{2}.$$

The formula holds similarly for negative values.

(b) (i) $\int_2^5 x\,dx = 21/2$.
(ii) $\int_{-3}^8 x\,dx = 55/2$.
(iii) $\int_1^3 5x\,dx = 5\int_1^3 x\,dx = 20$.

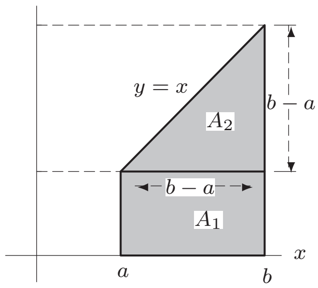

Figure 5.48

27. We have

$$30 = \int_{-2}^3 f\,dx = \int_{-2}^2 f(x)\,dx + \int_2^3 f(x)\,dx.$$

Since f is odd, $\int_{-2}^2 f(x)\,dx = 0$, so $\int_2^3 f(x)\,dx = 30$.

28. We have

$$8 = \int_{-2}^2 (f(x)-3)\,dx = \int_{-2}^2 f(x)\,dx - 3\int_{-2}^2 1\,dx.$$

Thus $\int_{-2}^2 f(x)\,dx = 8 + 3(2-(-2)) = 20$. Since f is even, $\int_0^2 f(x)\,dx = (1/2)20 = 10$.

29. This integral is 0 because the function $x^3\cos(x^2)$ is odd (meaning $f(-x) = -f(x)$), and so the negative contribution to the integral from $-\frac{\pi}{4} < x < 0$ exactly cancels the positive contribution from $0 < x < \frac{\pi}{4}$. See Figure 5.49.

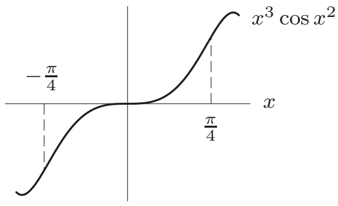

Figure 5.49

30. On the interval $2 \le x \le 5$,

$$\text{Average value of } f = \frac{1}{5-2}\int_2^5 f(x)\,dx = 4,$$

so

$$\int_2^5 f(x)\,dx = 12.$$

Thus

$$\int_2^5 (3f(x)+2)\,dx = 3\int_2^5 f(x)\,dx + 2\int_2^5 1\,dx = 3(12) + 2(5-2) = 42.$$

31. We know

$$\int_1^3 (x^2 - x)\,dx = \int_1^3 x^2\,dx - \int_1^3 x\,dx.$$

Since $\int_1^3 3x^2 dx = 3\int_1^3 x^2 dx$ and we are given $\int_1^3 3x^2\,dx = 26$, we have

$$\int_1^3 x^2\,dx = \frac{26}{3}.$$

Similarly, since $\int_1^3 2x dx = 2\int_1^3 x dx$ and $\int_1^3 2x\,dx = 8$, we have

$$\int_1^3 x\,dx = 4.$$

Thus,

$$\int_1^3 (x^2 - x)\,dx = \frac{26}{3} - 4 = \frac{14}{3}.$$

32. (a) Over the interval $[-1, 3]$, we estimate that the total change of the population is about 1.5, by counting boxes between the curve and the x-axis; we count about 1.5 boxes below the x-axis from $x = -1$ to $x = 1$ and about 3 above from $x = 1$ to $x = 3$. So the average rate of change is just the total change divided by the length of the interval, that is $1.5/4 = 0.375$ thousand/hour.

(b) We can estimate the total change of the algae population by counting boxes between the curve and the x-axis. Here, there is about 1 box above the x-axis from $x = -3$ to $x = -2$, about 0.75 of a box below the x-axis from $x = -2$ to $x = -1$, and a total change of about 1.5 boxes thereafter (as discussed in part (a)). So the total change is about $1 - 0.75 + 1.5 = 1.75$ thousands of algae.

33. (a) The integral is the area above the x-axis minus the area below the x-axis. Thus, we can see that $\int_{-3}^3 f(x)\,dx$ is about $-6 + 2 = -4$ (the negative of the area from $t = -3$ to $t = 1$ plus the area from $t = 1$ to $t = 3$.)

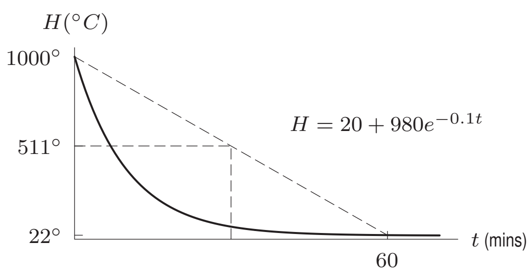
(b) Since the integral in part (a) is negative, the average value of $f(x)$ between $x = -3$ and $x = 3$ is negative. From the graph, however, it appears that the average value of $f(x)$ from $x = 0$ to $x = 3$ is positive. Hence (ii) is the larger quantity.

34. (a) At the end of one hour $t = 60$, and $H = 22°$C.

(b)

$$\begin{aligned}\text{Average temperature} &= \frac{1}{60}\int_0^{60} (20 + 980e^{-0.1t})dt \\ &= \frac{1}{60}(10976) = 183°\text{C}.\end{aligned}$$

(c) Average temperature at beginning and end of hour $= (1000 + 22)/2 = 511°$C. The average found in part (b) is smaller than the average of these two temperatures because the bar cools quickly at first and so spends less time at high temperatures. Alternatively, the graph of H against t is concave up.



35. (a) We have

$$\text{Average population} = \frac{1}{40}\int_0^{40} 112(1.011)^t\,dt.$$

Evaluating the integral numerically gives

$$\text{Average population} = 140.508 \text{ million}.$$

(b) In 2010, $t = 0$, and $P = 112(1.011)^0 = 112$
In 2050, $t = 40$, and $P = 112(1.011)^{40} = 173.486$.

$$\text{Average} = \frac{1}{2}(112 + 173.486) = 142.743 \text{ million.}$$

(c) If P had been linear, the average value found in part (a) would have been the same as we found in part (b). Since the population graph is concave up, it is below the secant line. Thus, the actual values of P are less than the corresponding values on the secant line, so the average found in part (a) is smaller than that found in part (b).

36. (a) See Figure 5.50. Since the shaded region lies within a rectangle of area 1, the area is less than 1.
(b) Since the area is given by the integral

$$\text{Area} = \int_0^1 e^{-x^2/2}\,dx = 0.856.$$

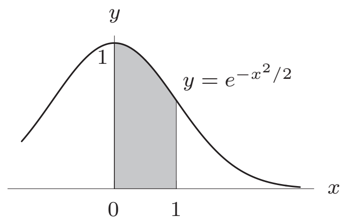


Figure 5.50

37. Notice that $f(x) = \sqrt{1+x^3}$ is increasing for $0 \le x \le 2$, since x^3 gets bigger as x increases. This means that $f(0) \le f(x) \le f(2)$. For this function, $f(0) = 1$ and $f(2) = 3$. Thus, the area under $f(x)$ lies between the area under the line $y = 1$ and the area under the line $y = 3$ on the interval $0 \le x \le 2$. See Figure 5.51. That is,

$$1(2-0) \le \int_0^2 \sqrt{1+x^3}\,dx \le 3(2-0).$$

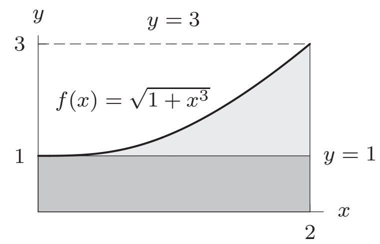

Figure 5.51

38. (a) The integrand is positive, so the integral cannot be negative.
(b) The integrand ≥ 0. If the integral $= 0$, then the integrand must be identically 0, which is not true.

39. See Figure 5.52.

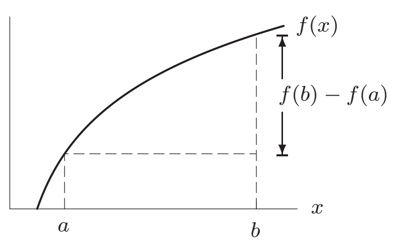

Figure 5.52

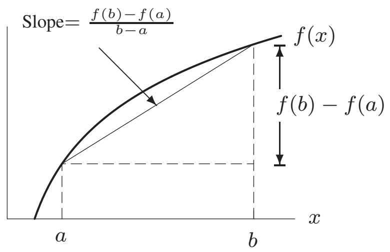

Figure 5.53

40. See Figure 5.53.

41. See Figure 5.54.

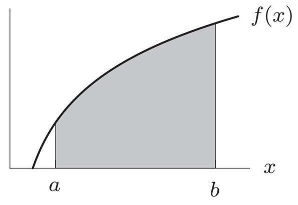

Figure 5.54

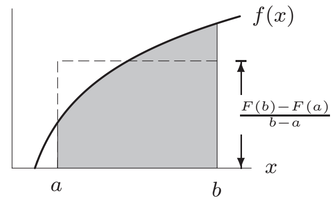

Figure 5.55

42. See Figure 5.55. Note that we are using the interpretation of the definite integral as the length of the interval times the average value of the function on that interval, which we developed in Section 5.3.

43. See Figure 5.56. Since $\int_0^1 f(x)\,dx = A_1$ and $\int_1^2 f(x)\,dx = -A_2$ and $\int_2^3 f(x)\,dx = A_3$, we know that

$$0 < \int_0^1 f(x)\,dx < -\int_1^2 f(x)\,dx < \int_2^3 f(x)\,dx.$$

In addition, $\int_0^2 f(x)\,dx = A_1 - A_2$, which is negative, but smaller in magnitude than $\int_1^2 f(x)\,dx$. Thus

$$\int_1^2 f(x)\,dx < \int_0^2 f(x)\,dx < 0.$$

The area A_3 lies inside a rectangle of height 20 and base 1, so $A_3 < 20$. The area A_2 lies inside a rectangle below the x-axis of height 10 and width 1, so $-10 < A_2$. Thus:

$$\text{(viii)} < \text{(ii)} < \text{(iii)} < \text{(vi)} < \text{(i)} < \text{(v)} < \text{(iv)} < \text{(vii)}.$$

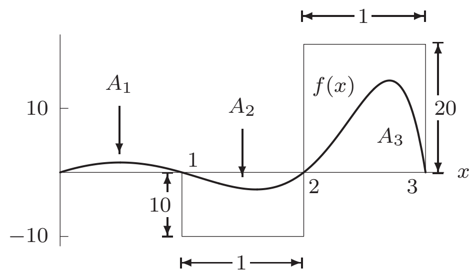

Figure 5.56

44. (a) (i) Since the triangular region under the graphs of $f(x)$ has area $1/2$, we have

$$\text{Average}(f) = \frac{1}{2-0}\int_0^2 f(x)\,dx = \frac{1}{2}\cdot\frac{1}{2} = \frac{1}{4}.$$

(ii) Similarly,

$$\text{Average}(g) = \frac{1}{2-0}\int_0^2 g(x)\,dx = \frac{1}{2}\cdot\frac{1}{2} = \frac{1}{4}$$

(iii) Since $f(x)$ is nonzero only for $0 \le x < 1$ and $g(x)$ is nonzero only for $1 < x \le 2$, the product $f(x)g(x) = 0$ for all x. Thus

$$\text{Average}(f\cdot g) = \frac{1}{2-0}\int_0^2 f(x)g(x)\,dx = \frac{1}{2}\int_0^2 0\,dx = 0.$$

(b) Since the average values of $f(x)$ and $g(x)$ are nonzero, their product is nonzero. Thus the left side of the statement is nonzero. However, the average of the product $f(x)g(x)$ is zero. Thus, the right side of the statement is zero, so the statement is not true.

45. (a) Since $f(x) = \sin x$ over $[0, \pi]$ is between 0 and 1, the average of $f(x)$ must itself be between 0 and 1. Furthermore, since the graph of $f(x)$ is concave down on this interval, the average value must be greater than the average height of the triangle shown in Figure 5.57, namely, 0.5.

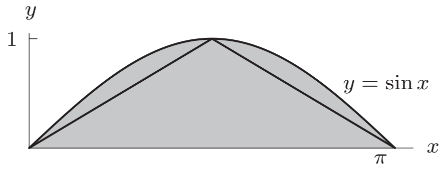

Figure 5.57

(b) Average $= \dfrac{1}{\pi - 0}\displaystyle\int_0^\pi \sin x\, dx = 0.64.$

46. (a) Splitting the integral in order to make use of the values in the table gives:

$$\frac{1}{\sqrt{2\pi}}\int_1^3 e^{-x^2/2}\,dx = \frac{1}{\sqrt{2\pi}}\int_0^3 e^{-x^2/2}\,dx - \frac{1}{\sqrt{2\pi}}\int_0^1 e^{-x^2/2}\,dx = 0.4987 - 0.3413 = 0.1574.$$

(b) Using the symmetry of $e^{x^2/2}$, we have

$$\begin{aligned}\frac{1}{\sqrt{2\pi}}\int_{-2}^3 e^{-x^2/2}\,dx &= \frac{1}{\sqrt{2\pi}}\int_{-2}^0 e^{-x^2/2}\,dx + \frac{1}{\sqrt{2\pi}}\int_0^3 e^{-x^2/2}\,dx \\ &= \frac{1}{\sqrt{2\pi}}\int_0^2 e^{-x^2/2}\,dx + \frac{1}{\sqrt{2\pi}}\int_0^3 e^{-x^2/2}\,dx \\ &= 0.4772 + 0.4987 = 0.9759.\end{aligned}$$

47. There is not enough information to decide. If we had more information—say, for example, we knew that g was periodic or had even or odd symmetry—we might be able to evaluate this expression.

48. The graph of $y = g(-x)$ is the graph of $y = g(x)$ reflected horizontally across the y-axis. This does not change the total area. Thus, the two integrals are equal, so $\displaystyle\int_{-4}^4 g(-x)\,dx = 12.$

49. Since $\displaystyle\int_0^7 f(x)\,dx = 25$, we have $\sqrt{\displaystyle\int_0^7 f(x)\,dx} = \sqrt{25} = 5.$

50. There is not enough information to decide. In terms of area, knowing the area under the graph of f on $0 \le x \le 7$ does not help us find the area on $0 \le x \le 3.5$. It depends on the shape of the graph and where it lies above and below the x-axis.

51. The graph of $g(x) = f(x+2)$ is the graph of $y = f(x)$ shifted left by 2 units. Thus, the area under the graph of g on $-2 \le x \le 5$ is the same as the area under the graph of f on $0 \le x \le 7$. Therefore,

$$\int_{-2}^5 f(x+2)\,dx = 25.$$

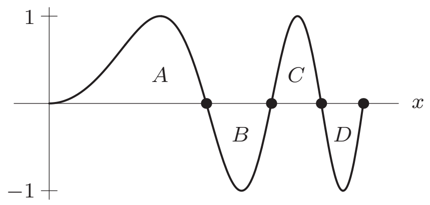
52. We have

$$\int_0^7 (f(x)+2)\,dx = \underbrace{\int_0^7 f(x)\,dx}_{25} + \underbrace{\int_0^7 2\,dx}_{7\cdot 2 = 14} = 39.$$

Note that, thinking graphically, $\int_0^7 2\,dx$ is the area of a rectangle of height 2 and width 7.

53. (a) Clearly, the points where $x = \sqrt{\pi}, \sqrt{2\pi}, \sqrt{3\pi}, \sqrt{4\pi}$ are where the graph intersects the x-axis because $f(x) = \sin(x^2) = 0$ where x is the square root of some multiple of π.

(b) Let $f(x) = \sin(x^2)$, and let A, B, C, and D be the areas of the regions indicated in the figure below. Then we see that $A > B > C > D$.



Note that

$$\int_0^{\sqrt{\pi}} f(x)\,dx = A, \quad \int_0^{\sqrt{2\pi}} f(x)\,dx = A - B,$$

$$\int_0^{\sqrt{3\pi}} f(x)\,dx = A - B + C, \quad \text{and} \quad \int_0^{\sqrt{4\pi}} f(x)\,dx = A - B + C - D.$$

It follows that

$$\int_0^{\sqrt{\pi}} f(x)\,dx = A > \int_0^{\sqrt{3\pi}} f(x)\,dx = A - (B - C) = A - B + C >$$

$$\int_0^{\sqrt{4\pi}} f(x)\,dx = A - B + C - D > \int_0^{\sqrt{2\pi}} f(x)\,dx = (A - B) > 0.$$

And thus the ordering is $n = 1$, $n = 3$, $n = 4$, and $n = 2$ from largest to smallest. All the numbers are positive.

54. See Figure 5.58.

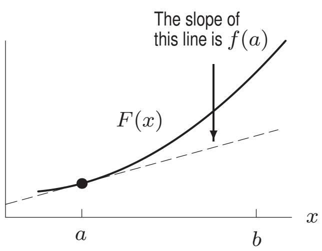


Figure 5.58

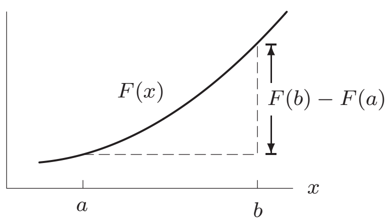

Figure 5.59

55. See Figure 5.59.

56. See 5.60.

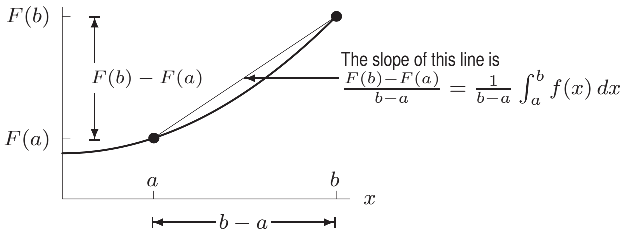

Figure 5.60

57. On the interval $a \leq t \leq b$, we have

$$\text{Average value of } v(t) = \frac{1}{b-a}\int_a^b v(t)\,dt.$$

Since $v(t) = s'(t)$, by the Fundamental Theorem of Calculus, we get:

$$\frac{1}{b-a}\int_a^b v(t)\,dt = \frac{1}{b-a}(s(b) - s(a)) = \text{ Average velocity}.$$

Strengthen Your Understanding

58. It is possible that $f(x)$ has both positive and negative values on the interval $[a, b]$, even if the integral is positive.

For example, suppose that $a = 0$ and $b = 3$, and let $f(x) = 2 - x$ for all x. Then by finding areas, we can see that $\int_0^3 f(x)dx = 3/2$, which is nonnegative. However, $f(x) < 0$ for x in the interval $(2, 3]$.

59. Using the properties of definite integrals, we have

$$\begin{aligned}\int_a^b (5 + 3f(x))\,dx &= \int_a^b 5\,dx + \int_a^b 3f(x)\,dx\\ &= 5(b-a) + 3\int_a^b f(x)\,dx.\end{aligned}$$

The value of the integral $\int_a^b 5\,dx$ is $5(b-a)$ because the integral represents the area of a rectangle with height 5 and width $b - a$.

60. The time needs to be expressed in days in the definite integral, since the population is a function of time t in days. If the six-month period contains 181 days, the correct integral is

$$\frac{1}{181}\int_0^{181} f(t)\,dt.$$

For a different six-month period, the number 181 may be different.

61. If we let $A = \int_0^1 f(x)\,dx$, then we have $\int_0^1 2f(x)\,dx = 2\int_0^1 f(x)\,dx = 2A$. We want to define $f(x)$ so that $2A < A$. In order for this to happen, A must be negative. So we'll define $f(x)$ to be negative on $[0, 1]$; for example, $f(x) = -1$. Then $\int_0^1 f(x)\,dx = -1$, and $\int_0^1 2f(x)\,dx = \int_0^1 -2\,dx = -2$.

62. Let's try the function $f(x) = 2 - x$. The area between the graph of the function $f(x) = 2 - x$ and the x-axis on the interval $[0, 4]$ consists of two isosceles right triangles with legs of length 2: one above the x-axis and one below. When we compute the integral $\int_0^4 (2 - x)\,dx$, the areas of these two congruent triangles cancel out, and the integral is zero.

63. If the car is going $v(t)$ miles per hour at time t hours, then

$$\text{Average speed } = \frac{1}{5-0}\int_0^5 v(t)\,dt.$$

64. True, since $\int_0^2 (f(x) + g(x))\,dx = \int_0^2 f(x)\,dx + \int_0^2 g(x)\,dx$.

65. False. It is possible that $\int_0^2 (f(x) + g(x))\,dx = 10$ and $\int_0^2 f(x)\,dx = 4$ and $\int_0^2 g(x)\,dx = 6$, for instance. For example, if $f(x) = 5x - 3$ and $g(x) = 3$, then $\int_0^2 (f(x) + g(x))\,dx = \int_0^2 5x\,dx = 10$, but $\int_0^2 f(x)\,dx = 4$ and $\int_0^2 g(x)\,dx = 6$.

66. False. We know that $\int_0^4 f(x)\,dx = \int_0^2 f(x)\,dx + \int_2^4 f(x)\,dx$, but it is not true that $\int_2^4 f(x)\,dx$ must be the same value as $\int_0^2 f(x)\,dx$. For example, if $f(x) = 3x$, then $\int_0^2 f(x)\,dx = 6$, but $\int_0^4 f(x)\,dx = 24$.

67. True, since $\int_0^2 2f(x)\,dx = 2\int_0^2 f(x)\,dx$.

68. False. This would be true if $h(x) = 5f(x)$. However, we cannot assume that $f(5x) = 5f(x)$, so for many functions this statement is false. For example, if f is the constant function $f(x) = 3$, then $h(x) = 3$ as well, so $\int_0^2 f(x)\,dx = \int_0^2 h(x)\,dx = 6$.

69. True. If $a = b$, then $\Delta x = 0$ for any Riemann sum for f on the interval $[a, b]$, so every Riemann sum has value 0. Thus, the limit of the Riemann sums is 0.

70. False. For example, let $a = -1$ and $b = 1$ and $f(x) = x$.Then the areas bounded by the graph of f and the x-axis on the two halves of the interval $[-1, 1]$ cancel with each other and make $\int_{-1}^1 f(x)\,dx = 0$. See Figure 5.61.

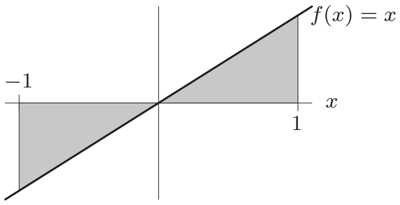

Figure 5.61

71. False. Let $f(x) = 7$ and $g(x) = 9$ for all x.
Then $\int_1^2 f(x)\,dx + \int_2^3 g(x)\,dx = 7 + 9 = 16$, but $\int_1^3 (f(x) + g(x))\,dx = \int_1^3 16\,dx = 32$.

72. False. If the graph of f is symmetric about the y-axis, this is true, but otherwise it is usually not true. For example, if $f(x) = x + 1$ the area under the graph of f for $-1 \le x \le 0$ is less than the area under the graph of f for $0 \le x \le 1$, so $\int_{-1}^1 f(x)\,dx < 2\int_0^1 f(x)\,dx$. See Figure 5.62.

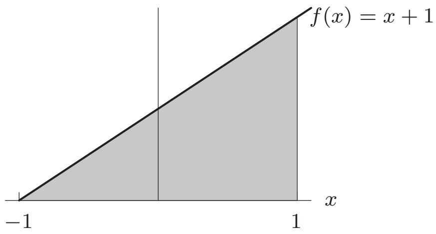

Figure 5.62

73. True, by Theorem 5.4 on Comparison of Definite Integrals:

$$\frac{1}{b-a}\int_a^b f(x)\,dx \le \frac{1}{b-a}\int_a^b g(x)\,dx.$$

74. True. We have

$$\begin{aligned}
\text{Average value of } f \text{ on } [0,10] &= \frac{1}{10-0}\int_0^{10} f(x)\,dx \\
&= \frac{1}{10}\left(\int_0^5 f(x)\,dx + \int_5^{10} f(x)\,dx\right) \\
&= \frac{1}{2}\left(\frac{1}{5}\int_0^5 f(x)\,dx + \frac{1}{5}\int_5^{10} f(x)\,dx\right) \\
&= \begin{array}{l}\text{The average of the average value of } f \text{ on } [0,5] \text{ and} \\ \text{the average value of } f \text{ on } [5,10].\end{array}
\end{aligned}$$

75. False. If the values of $f(x)$ on the interval $[c, d]$ are larger than the values of $f(x)$ in the rest of the interval $[a, b]$, then the average value of f on the interval $[c, d]$ is larger than the average value of f on the interval $[a, b]$. For example, suppose

$$f(x) = \begin{cases} 0 & x < 1 \text{ or } x > 2 \\ 1 & 1 \le x \le 2. \end{cases}$$

Then the average value of f on the interval $[1, 2]$ is 1, whereas the average value of f on the interval $[0, 3]$ is $(1/(3 - 0))\int_0^3 f(x)\,dx = 1/3$.

76. True. We have by the properties of integrals in Theorem 5.3,

$$\int_1^9 f(x)\,dx = \int_1^4 f(x)\,dx + \int_4^9 f(x)\,dx.$$

Since $(1/(4-1))\int_1^4 f(x)\,dx = A$ and $(1/(9-4))\int_4^9 f(x)\,dx = B$, we have

$$\int_1^9 f(x)\,dx = 3A + 5B.$$

Dividing this equation through by 8, we get that the average value of f on the interval $[1,9]$ is $(3/8)A + (5/8)B$.

77. True. By the properties of integrals in Theorem 5.3, we have:

$$\int_a^b (f(x)+g(x))\,dx = \int_a^b f(x)\,dx + \int_a^b g(x)\,dx.$$

Dividing both sides of this equation through by $b-a$, we get that the average value of $f(x)+g(x)$ is average value of $f(x)$ plus the average value of $g(x)$:

$$\frac{1}{b-a}\int_a^b (f(x)+g(x))\,dx = \frac{1}{b-a}\int_a^b f(x)\,dx + \frac{1}{b-a}\int_a^b g(x)\,dx.$$

78. False. A counterexample is given by

$$f(x) = \begin{cases} 3 & 0 \le x \le 1 \\ 0 & 1 < x \le 2 \end{cases} \quad \text{and} \quad g(x) = \begin{cases} 0 & 0 \le x \le 1 \\ 3 & 1 < x \le 2. \end{cases}$$

Since $f(x)$ is nonzero for $0 \le x < 1$ and $g(x)$ is nonzero for $1 < x \le 2$, the product $f(x)g(x) = 0$ for all x. Thus the average values of $f(x)$ and $g(x)$ are nonzero, but the average of the product is zero.

Specifically, on $[0,2]$ we have

$$\begin{aligned} \text{Average}(f) &= \frac{1}{2-0}\int_0^2 f(x)\,dx = \frac{3}{2} \\ \text{Average}(g) &= \frac{1}{2-0}\int_0^2 g(x)\,dx = \frac{3}{2} \\ \text{Average}(f\cdot g) &= \frac{1}{2-0}\int_0^2 f(x)g(x)\,dx = \frac{1}{2}\int_0^2 0\,dx = 0. \end{aligned}$$

but

$$\text{Average}(f)\cdot\text{Average}(g) = \frac{3}{2}\cdot\frac{3}{2} = \frac{9}{4}.$$

79. (a) Does not follow; the statement implies that

$$\int_a^b f(x)\,dx + \int_a^b g(x)\,dx = 5 + 7 = 12,$$

but the fact that the two integrals add to 12 does not tell us what the integrals are individually. For example, we could have $\int_a^b f(x)\,dx = 10$ and $\int_a^b g(x)\,dx = 2$.

(b) This follows:

$$\int_a^b (f(x)+g(x))\,dx = \int_a^b f(x)\,dx + \int_a^b g(x)\,dx = 7 + 7 = 14.$$

(c) This follows: rearranging the original statement by subtracting $\int_a^b g(x)\,dx$ from both sides gives

$$\int_a^b (f(x)+g(x))\,dx - \int_a^b g(x)\,dx = \int_a^b f(x)\,dx.$$

Since $f(x)+g(x) = h(x)$, we have $f(x) = h(x) - g(x)$. Substituting for $f(x)$, we get

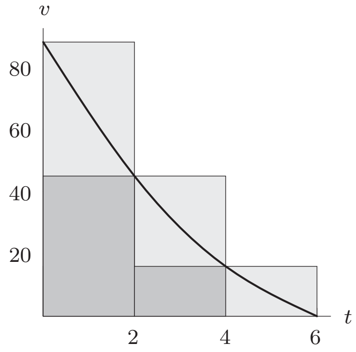
$$\int_a^b h(x)\,dx - \int_a^b g(x)\,dx = \int_a^b (h(x)-g(x))\,dx.$$

Solutions for Chapter 5 Review

Exercises

1. (a) Lower estimate $= (45)(2) + (16)(2) + (0)(2) = 122$ feet.
Upper estimate $= (88)(2) + (45)(2) + (16)(2) = 298$ feet.

(b)



2. To find the distance the car moved before stopping, we estimate the distance traveled for each two-second interval. Since speed decreases throughout, we know that the left-handed sum will be an overestimate to the distance traveled and the right-hand sum an underestimate. Applying the formulas for these sums with $\Delta t = 2$ gives:

$$\begin{aligned} \text{LEFT} &= 2(100 + 80 + 50 + 25 + 10) = 530 \text{ ft.} \\ \text{RIGHT} &= \;\; 2(80 + 50 + 25 + 10 + 0) \;\; = 330 \text{ ft.} \end{aligned}$$

(a) The best estimate of the distance traveled will be the average of these two estimates, or

$$\text{Best estimate} = \frac{530 + 330}{2} = 430 \text{ ft.}$$

(b) All we can be sure of is that the distance traveled lies between the upper and lower estimates calculated above. In other words, all the black-box data tells us for sure is that the car traveled between 330 and 530 feet before stopping. So we don't know whether it hit the skunk or not; the answer is (ii).

3. $\int_0^3 f(x)\,dx$ is equal to the area shaded. We estimate the area by counting shaded rectangles. There are 3 fully shaded and about 4 partially shaded rectangles, for a total of approximately 5 shaded rectangles. Since each rectangle represents 4 square units, our estimated area is $5(4) = 20$. We have

$$\int_0^3 f(x)\,dx \approx 20.$$

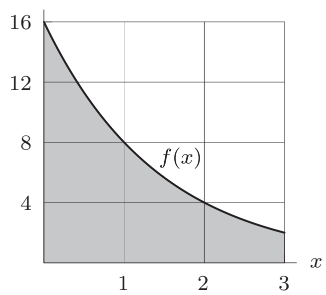


Figure 5.63

4. With $\Delta x = 5$, we have

$$\text{Left-hand sum } = 5(0+100+200+100+200+250+275) = 5625,$$

$$\text{Right-hand sum } = 5(100+200+100+200+250+275+300) = 7125.$$

The average of these two sums is our best guess for the value of the integral;

$$\int_{-15}^{20} f(x)\,dx \approx \frac{5625+7125}{2} = 6375.$$

5. We take $\Delta t = 20$. Then:

$$\begin{aligned}\text{Left-hand sum} &= 1.2(20)+2.8(20)+4.0(20)+4.7(20)+5.1(20)\\ &= 356.\\ \text{Right-hand sum} &= 2.8(20)+4.0(20)+4.7(20)+5.1(20)+5.2(20)\\ &= 436.\\ \int_0^{100} f(t)\,dt \approx \text{Average} &= \frac{356+436}{2} = 396.\end{aligned}$$

6. (a) Suppose $f(t)$ is the flow rate in m^3/hr at time t. We are only given two values of the flow rate, so in making our estimates of the flow, we use one subinterval, with $\Delta t = 3/1 = 3$:

$$\text{Left estimate} = 3[f(6\text{ am})] = 3\cdot 100 = 300\text{ m}^3 \quad \text{(an underestimate)}$$
$$\text{Right estimate} = 3[f(9\text{ am})] = 3\cdot 280 = 840\text{ m}^3 \quad \text{(an overestimate).}$$

The best estimate is the average of these two estimates,

$$\text{Best estimate} = \frac{\text{Left}+\text{Right}}{2} = \frac{300+840}{2} = 570\text{ m}^3.$$

(b) Since the flow rate is increasing throughout, the error, i.e., the difference between over- and under-estimates, is given by

$$\text{Error} \le \Delta t\,[f(9\text{ am}) - f(6\text{ am})] = \Delta t[280-100] = 180\Delta t.$$

We wish to choose Δt so that the the error $180\Delta t \le 6$, or $\Delta t \le 6/180 = 1/30$. So the flow rate gauge should be read every $1/30$ of an hour, or every 2 minutes.

7. (a) An upper estimate is $9.81+8.03+6.53+5.38+4.41 = 34.16$ m/sec. A lower estimate is $8.03+6.53+5.38+4.41+3.61 = 27.96$ m/sec.

(b) The average is $\frac{1}{2}(34.16+27.96) = 31.06$ m/sec. Because the graph of acceleration is concave up, this estimate is too high, as can be seen in Figure 5.64. The area of the shaded region is the average of the areas of the rectangles $ABFE$ and $CDFE$.

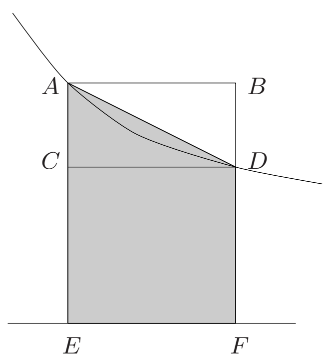

Figure 5.64

8. We have $f(t) = F'(t) = 4t^3$, so by the Fundamental Theorem of Calculus,

$$\int_{-1}^{1} 4t^3\,dt = F(1) - F(-1) = 1 - 1 = 0.$$

Notice in this case the integral is 0 because the function being integrated, $f(t) = 4t^3$, is odd: the negative contribution to the integral from $a = -1$ to $b = 1$ exactly cancels the positive.

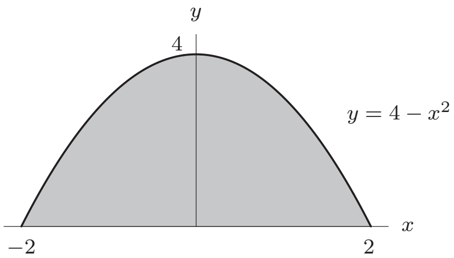
9. We have $f(t) = F'(t) = 12t^3 - 15t^2 + 5$, so by the Fundamental Theorem of Calculus,

$$\int_{-2}^{1} (12t^3 - 15t^2 + 5)\,dt = F(1) - F(-2) = 3 - 78 = -75.$$

10. The x intercepts of $y = 4 - x^2$ are $x = -2$ and $x = 2$, and the graph is above the x-axis on the interval $[-2, 2]$.

$$\text{Area} = \int_{-2}^{2} (4 - x^2)\,dx = 10.667.$$

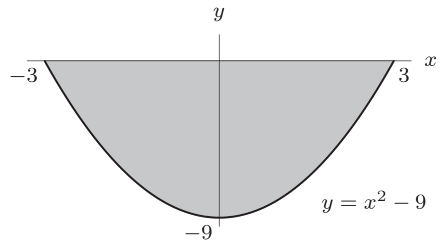
The integral was evaluated on a calculator.



11. The x intercepts of $y = x^2 - 9$ are $x = -3$ and $x = 3$, and since the graph is below the x axis on the interval $[-3, 3]$.

$$\text{Area} = -\int_{-3}^{3} (x^2 - 9)\,dx = 36.$$

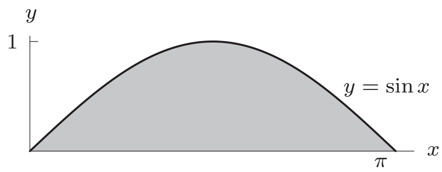
The integral was evaluated on a calculator.



12. Since x intercepts are $x = 0, \pi, 2\pi, \ldots$,

$$\text{Area} = \int_{0}^{\pi} \sin x\,dx = 2.$$

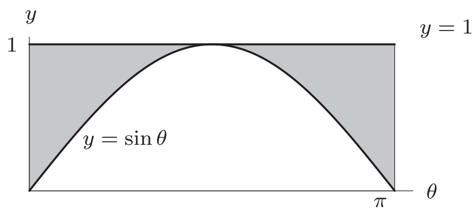
The integral was evaluated on a calculator.



13. Since the θ intercepts of $y = \sin\theta$ are $\theta = 0, \pi, 2\pi, \ldots$,

$$\text{Area} = \int_{0}^{\pi} (1 - \sin\theta)\,d\theta = 1.142.$$

The integral was evaluated on a calculator.



14. The graph of $y = -x^2 + 5x - 4$ is shown in Figure 5.65. We wish to find the area shaded. Since the graph crosses the x-axis at $x = 1$, we must split the integral at $x = 1$. For $x < 1$, the graph is below the x-axis, so the area is the negative of the integral. Thus

$$\text{Area shaded} = -\int_{0}^{1} (-x^2 + 5x - 4)dx + \int_{1}^{3} (-x^2 + 5x - 4)dx.$$

Using a calculator or computer, we find

$$\int_{0}^{1} (-x^2 + 5x - 4)dx = -1.8333 \quad\text{and}\quad \int_{1}^{3} (-x^2 + 5x - 4)dx = 3.3333.$$

Thus,

$$\text{Area shaded} = 1.8333 + 3.3333 = 5.167.$$

(Notice that $\int_0^3 f(x)dx = -1.8333 + 3.333 = 1.5$, but the value of this integral is not the area shaded.)

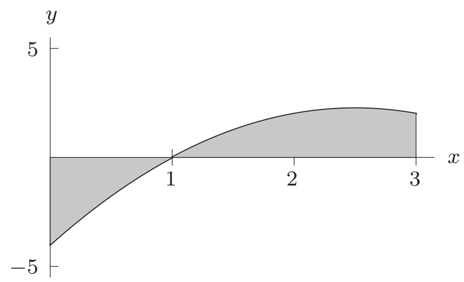


Figure 5.65

15. The graph of $y = \cos x + 7$ is above $y = \ln(x - 3)$ for $5 \le x \le 7$. See Figure 5.66. Therefore

$$\text{Area } = \int_5^7 \cos x + 7 - \ln(x - 3)\, dx = 13.457.$$

The integral was evaluated on a calculator.

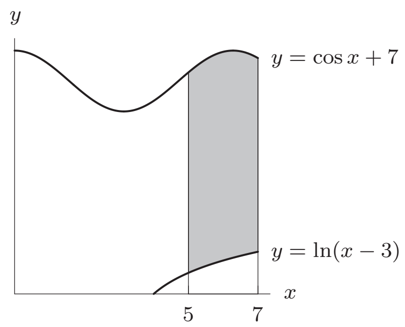

Figure 5.66

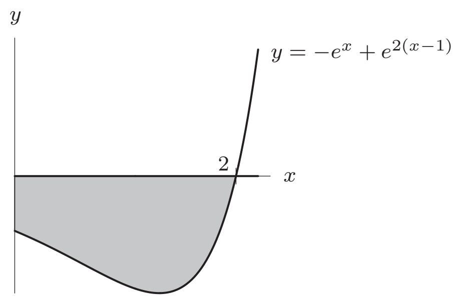

Figure 5.67

16. The graph of $y = -e^x + e^{2(x-1)}$ has intercepts where $e^x = e^{2(x-1)}$, or where $x = 2(x - 1)$, so $x = 2$. See Figure 5.67. Since the region is below the x-axis, the integral is negative, so

$$\text{Area } = -\int_0^2 -e^x + e^{2(x-1)}\, dx = 2.762.$$

The integral was evaluated on a calculator.

Problems

17. This integral represents the area of two triangles, each of base 1 and height 1. See Figure 5.68. Therefore:

$$\int_{-1}^1 |x|\, dx = \frac{1}{2} \cdot 1 \cdot 1 + \frac{1}{2} \cdot 1 \cdot 1 = 1.$$

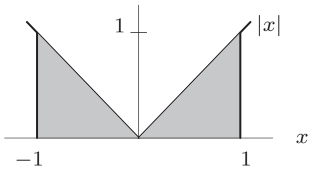

Figure 5.68

18. The distance traveled is represented by area under the velocity curve. We can approximate the area using left- and right-hand sums. Alternatively, by counting squares and fractions of squares, we find that the area under the graph appears to be around 310 (miles/hour) sec, within about 10. So the distance traveled was about 310 $\left(\frac{5280}{3600}\right) \approx 455$ feet, within about 10 $\left(\frac{5280}{3600}\right) \approx 15$ feet. (Note that 455 feet is about 0.086 miles)

19. (a) We calculate the right- and left-hand sums as follows:

$$\text{Left} = 2[80 + 52 + 28 + 10] = 340 \text{ ft.}$$
$$\text{Right} = 2[52 + 28 + 10 + 0] = 180 \text{ ft.}$$

Our best estimate will be the average of these two sums,

$$\text{Best} = \frac{\text{Left} + \text{Right}}{2} = \frac{340 + 180}{2} = 260 \text{ ft.}$$

(b) Since v is decreasing throughout,

$$\begin{aligned}\text{Left} - \text{Right} &= \Delta t \cdot [f(0) - f(8)] \\ &= 80\Delta t.\end{aligned}$$

Since our best estimate is the average of Left and Right, the maximum error is $(80)\Delta t/2$. For $(80)\Delta t/2 \leq 20$, we must have $\Delta t \leq 1/2$. In other words, we must measure the velocity every 0.5 second.

20. As illustrated in Figure 5.69, the left- and right-hand sums are both equal to $(4\pi) \cdot 3 = 12\pi$, while the integral is smaller. Thus we have:

$$\int_0^{4\pi} (2 + \cos x)\, dx < \text{Left-hand sum} = \text{Right-hand sum}.$$

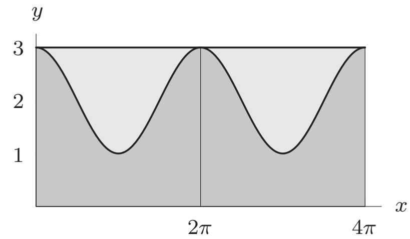

Figure 5.69: Integral vs. Left- and Right-Hand Sums

21. Distance traveled = $\displaystyle\int_0^{1.1} \sin(t^2)\, dt = 0.399$ miles.

22. Since $v(t) \geq 0$ for $0 \leq t \leq 3$, we can find the total distance traveled by integrating the velocity from $t = 0$ to $t = 3$. Using a calculator to compute the integral gives

$$\text{Distance} = \int_0^3 \ln(t^2 + 1)\, dt = 3.406 \text{ ft.}$$

23. (a) The integral $\int_0^{30} f(t)dt$ represents the total emissions of nitrogen oxides, in millions of metric tons, during the period 1970 to 2000.

(b) We estimate the integral using left- and right-hand sums:

$$\text{Left sum} = (26.9)5 + (26.4)5 + (27.1)5 + (25.8)5 + (25.5)5 + (25.0)5 = 783.5.$$

$$\text{Right sum} = (26.4)5 + (27.1)5 + (25.8)5 + (25.5)5 + (25.0)5 + (22.6)5 = 762.0.$$

We average the left- and right-hand sums to find the best estimate of the integral:

$$\int_0^{30} f(t)dt \approx \frac{783.5 + 762.0}{2} = 772.8 \text{ million metric tons.}$$

Between 1970 and 2000, about 772.8 million metric tons of nitrogen oxides were emitted.

24. (a) If the level first becomes acceptable at time t_1, then $R_0 = 4R(t_1)$, and

$$\frac{1}{4}R_0 = R_0 e^{-0.004t_1}$$
$$\frac{1}{4} = e^{-0.004t_1}.$$

Taking natural logs on both sides yields

$$\ln\frac{1}{4} = -0.004t_1$$
$$t_1 = \frac{\ln\frac{1}{4}}{-0.004} \approx 346.574 \text{ hours.}$$

(b) Since the initial radiation was four times the acceptable limit of 0.6 millirems/hour, we have $R_0 = 4(0.6) = 2.4$. The rate at which radiation is emitted is $R(t) = R_0 e^{-0.004t}$, so

$$\text{Total radiation emitted} = \int_0^{346.574} 2.4e^{-0.004t}\,dt.$$

Evaluating the integral numerically, we find that 450 millirems were emitted during this time.

25. (a) An overestimate is 7 tons. An underestimate is 5 tons.
(b) An overestimate is $7+8+10+13+16+20 = 74$ tons. An underestimate is $5+7+8+10+13+16 = 59$ tons.
(c) If measurements are made every Δt months, then the error is $|f(6) - f(0)| \cdot \Delta t$. So for this to be less than 1 ton, we need $(20-5)\cdot\Delta t < 1$, or $\Delta t < 1/15$. So measurements every 2 days or so will guarantee an error in over- and underestimates of less than 1 ton.

26. Suppose $F(t)$ represents the total quantity of water in the water tower at time t, where t is in days since April 1. Then the graph shown in the problem is a graph of $F'(t)$. By the Fundamental Theorem,

$$F(30) - F(0) = \int_0^{30} F'(t)dt.$$

We can calculate the change in the quantity of water by calculating the area under the curve. If each box represents about 300 liters, there is about one box, or -300 liters, from $t = 0$ to $t = 12$, and 6 boxes, or about $+1800$ liters, from $t = 12$ to $t = 30$. Thus

$$\int_0^{30} F'(t)dt = 1800 - 300 = 1500,$$

so the final amount of water is given by

$$F(30) = F(0) + \int_0^{30} F'(t)dt = 12{,}000 + 1500 = 13{,}500 \text{ liters.}$$

27. (a) Average value of $f = \frac{1}{5}\int_0^5 f(x)\,dx$.
(b) Average value of $|f| = \frac{1}{5}\int_0^5 |f(x)|\,dx = \frac{1}{5}\left(\int_0^2 f(x)\,dx - \int_2^5 f(x)\,dx\right)$.

28. We'll show that in terms of the average value of f,

$$\text{I} > \text{II} = \text{IV} > \text{III}$$

Using the definition of average value and the fact that f is even, we have

$$\begin{aligned}\text{Average value of } f \text{ on II} &= \frac{\int_0^2 f(x)dx}{2} = \frac{\frac{1}{2}\int_{-2}^2 f(x)dx}{2}\\ &= \frac{\int_{-2}^2 f(x)dx}{4}\\ &= \text{Average value of } f \text{ on IV.}\end{aligned}$$

Since f is decreasing on [0,5], the average value of f on the interval $[0, c]$, where $0 \le c \le 5$, is decreasing as a function of c. The larger the interval the more low values of f are included. Hence

$$\begin{array}{c}\text{Average value of } f \\ \text{on } [0,1]\end{array} > \begin{array}{c}\text{Average value of } f \\ \text{on } [0,2]\end{array} > \begin{array}{c}\text{Average value of } f \\ \text{on } [0,5]\end{array}$$

29. (a) A graph of $f'(x) = \sin(x^2)$ is shown in Figure 5.70. Since the derivative $f'(x)$ is positive between $x = 0$ and $x = 1$, the change in $f(x)$ is positive, so $f(1)$ is larger than $f(0)$. Between $x = 2$ and $x = 2.5$, we see that $f'(x)$ is negative, so the change in $f(x)$ is negative; thus, $f(2)$ is greater than $f(2.5)$.

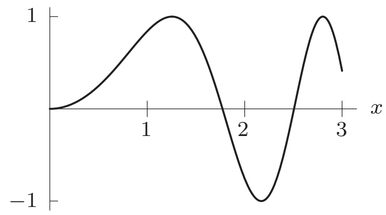

Figure 5.70: Graph of $f'(x) = \sin(x^2)$

(b) The change in $f(x)$ between $x = 0$ and $x = 1$ is given by the Fundamental Theorem of Calculus:

$$f(1) - f(0) = \int_0^1 \sin(x^2)dx = 0.310.$$

Since $f(0) = 2$, we have

$$f(1) = 2 + 0.310 = 2.310.$$

Similarly, since

$$f(2) - f(0) = \int_0^2 \sin(x^2)dx = 0.805,$$

we have

$$f(2) = 2 + 0.805 = 2.805.$$

Since

$$f(3) - f(0) = \int_0^3 \sin(x^2)dx = 0.774,$$

we have

$$f(3) = 2 + 0.774 = 2.774.$$

The results are shown in the table.

x	0	1	2	3
$f(x)$	2	2.310	2.805	2.774

30. (a) By the product rule

$$F'(t) = 1 \cdot \ln t + t \cdot \frac{1}{t} - 1 = \ln t.$$

(b) (i) Using a calculator, we find $\int_{10}^{12} \ln t\, dt = 4.793$.

(ii) The Fundamental Theorem of Calculus tells us that we can get the exact value of the integral by looking at

$$\int_{10}^{12} \ln t\, dt = F(12) - F(10) = (12\ln 12 - 12) - (10\ln 10 - 10) = 12\ln 12 - 10\ln 10 - 2 = 4.79303.$$

31. (a) $F(0) = 0$.
(b) F increases because $F'(x) = e^{-x^2}$ is positive.
(c) Using a calculator, we get $F(1) \approx 0.7468$, $F(2) \approx 0.8821$, $F(3) \approx 0.8862$.

32. We have

$$8 = \int_{-2}^{5} f(x)\,dx = \int_{-2}^{2} f(x)\,dx + \int_{2}^{5} f(x)\,dx.$$

Since f is odd, $\int_{-2}^{2} f(x)\,dx = 0$, so $\int_{-2}^{5} f(x)\,dx = 8$.

33. Since f is even, $\int_0^2 f(x)\,dx = (1/2)6 = 3$ and $\int_0^5 f(x)\,dx = (1/2)14 = 7$. Therefore

$$\int_2^5 f(x)\,dx = \int_0^5 f(x)\,dx - \int_0^2 f(x)\,dx = 7 - 3 = 4.$$

34. We have

$$18 = \int_2^5 (3f(x) + 4)\,dx = 3\int_2^5 f(x)\,dx + \int_2^5 4\,dx.$$

Thus, since $\int_2^5 4\,dx = 4(5-2) = 12$, we have

$$3\int_2^5 f(x)\,dx = 18 - 12 = 6,$$

so

$$\int_2^5 f(x)\,dx = 2.$$

35. We have $\int_2^4 f(x)\,dx = 8/2 = 4$ and $\int_4^5 f(x)\,dx = -\int_5^4 f(x)\,dx = -1$. Thus

$$\int_2^5 f(x)\,dx = \int_2^4 f(x)\,dx + \int_4^5 f(x)\,dx = 4 - 1 = 3.$$

36. (a) 0, since the integrand is an odd function and the limits are symmetric around 0.
(b) 0, since the integrand is an odd function and the limits are symmetric around 0.

37. Let $A = \int_0^p f(x)\,dx$. We are told $A > 0$. We can interpret A as the area under f on this interval. Since the graph of f repeats periodically every p units, the area under the graph also repeats. This means

$$\underbrace{\int_0^p f(x)\,dx}_{\text{area under one full period}} = \underbrace{\int_p^{2p} f(x)\,dx}_{\text{area under one full period}} = \underbrace{\int_{2p}^{3p} f(x)\,dx}_{\text{area under one full period}} = \cdots = A.$$

We have that

$$\int_0^{2p} f(x)\,dx = \underbrace{\int_0^p f(x)\,dx}_{A} + \underbrace{\int_p^{2p} f(x)\,dx}_{A} = 2A$$

$$\int_p^{5p} f(x)\,dx = \underbrace{\int_p^{2p} f(x)\,dx}_{A} + \cdots + \underbrace{\int_{4p}^{5p} f(x)\,dx}_{A} = 4A$$

$$\int_{5p}^{7p} f(x)\,dx = \underbrace{\int_{5p}^{6p} f(x)\,dx}_{A} + \underbrace{\int_{6p}^{7p} f(x)\,dx}_{A} = 2A,$$

so

$$\frac{\int_0^{2p} f(x)\,dx + \int_p^{5p} f(x)\,dx}{\int_{5p}^{7p} f(x)\,dx} = \frac{2A + 4A}{2A} = 3.$$

38. Since the graph is symmetrical, we know that

$$\int_{-r}^{0} f(x)\,dx = \int_{0}^{r} f(x)\,dx = \frac{1}{2}\int_{-r}^{r} f(x)\,dx.$$

This means that if we let $A = \int_{-r}^{0} f(x)\,dx$ then

$$\frac{\overbrace{\int_{-r}^{r} f(x)\,dx}^{2A} + \overbrace{\int_{0}^{r} f(x)\,dx}^{A}}{\underbrace{\int_{-r}^{0} f(x)\,dx}_{A}} = \frac{2A + A}{A} = 3.$$

39. (a) Since the function is odd, the areas above and below the x-axis cancel. Thus,

$$\int_{-3}^{0} xe^{-x^2}\,dx = -\int_{0}^{3} xe^{-x^2}\,dx,$$

so

$$\int_{-3}^{3} xe^{-x^2}\,dx = \int_{-3}^{0} xe^{-x^2}\,dx + \int_{0}^{3} xe^{-x^2}\,dx = 0.$$

(b) For $0 \le x \le 3$ with $n = 3$, we have $x_0 = 0$, $x_1 = 1$, $x_2 = 2$, $x_3 = 3$, and $\Delta x = 1$. See Figure 5.71. Thus,

$$\text{Left sum } = f(x_0)\Delta x + f(x_1)\Delta x + f(x_2)\Delta x = 0e^{-0^2} \cdot 1 + 1e^{-1^2} \cdot 1 + 2e^{-2^2} \cdot 1 = 0.4045.$$

(c) For $-3 \le x \le 0$, with $n = 3$, we have $x_0 = -3$, $x_1 = -2$, $x_2 = -1$, $x_3 = 0$, and $\Delta x = 1$. See Figure 5.71. Thus,

$$\text{Left sum } = f(x_0)\Delta x + f(x_1)\Delta x + f(x_2)\Delta x = -3e^{-(-3)^2} \cdot 1 - 2e^{-(-2)^2} \cdot 1 - 1e^{-(-1)^2} \cdot 1 = -0.4049.$$

(d) No. The rectangles between -3 and 0 are not the same size as those between 0 and 3. See Figure 5.71. There are three rectangles with nonzero height on $[-3, 0]$ and only two on $[0, 3]$.

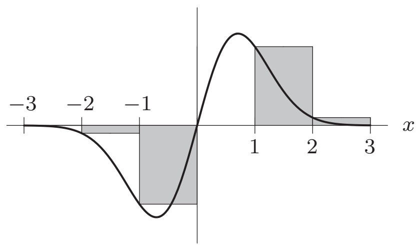

Figure 5.71

40. (a) Train A starts earlier than Train B, and stops later. At every moment Train A is going faster than Train B. Both trains increase their speed at a constant rate through the first half of their trip and slow down during the second half. Both trains reach their maximum speed at the same time. The area under the velocity graph for Train A is larger than the area under the velocity graph for Train B, meaning that Train A travels farther—as would be expected, given that its speed is always higher than B's.

(b) (i) The maximum velocity is read off the vertical axis. The graph for Train A appears to go about twice as high as the graph for Train B; see Figure 5.72. So

$$\frac{\text{Maximum velocity of Train } A}{\text{Maximum velocity of Train } B} = \frac{v_A}{v_B} \approx 2.$$

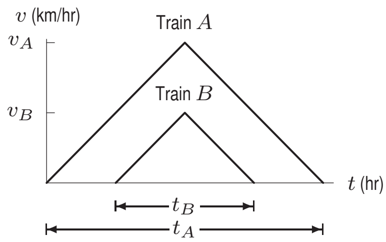

Figure 5.72

(ii) The time of travel is the horizontal distance between the start and stop times (the two t-intercepts). The horizontal distance for Train A appears to be about twice the corresponding distance for Train B; see Figure 5.72. So

$$\frac{\text{Time traveled by Train } A}{\text{Time traveled by Train } B} = \frac{t_A}{t_B} \approx 2.$$

(iii) The distance traveled by each train is given by the area under its graph. Since the area of triangle is $\frac{1}{2}$ · Base · Height, and since the base and height for Train A is approximately twice that for Train B, we have

$$\frac{\text{Distance traveled by Train } A}{\text{Distance traveled by Train } B} = \frac{\frac{1}{2} \cdot v_A \cdot t_A}{\frac{1}{2} \cdot v_B \cdot t_B} \approx 2 \cdot 2 = 4.$$

41. (a) The model indicates that wind capacity was 21,000 in 2000 and $21{,}000e^{0.22 \cdot 10} = 189{,}525.284$ in 2010.
(b) Since the continuous growth rate was 0.22, the wind energy generating capacity was increasing by 22% per year.
(c) We use the formula for average value between $t = 0$ and $t = 10$:

$$\text{Average value } = \frac{1}{10-0}\int_0^{10} 21{,}000e^{0.22t}\,dt = \frac{1}{10}(766{,}024.02) = 76{,}602.402 \text{ megawatts.}$$

42. We know that T is the time at which all the fuel has burned, so $\int_0^T r(t)\,dt$ is the total amount of fuel burned during the entire time period. We also know that Q is the initial amount of fuel.

Since the fuel is completely burned at time $t = T$, we conclude that $\int_0^T r(t)\,dt = Q$.

43. The expression $\int_0^{0.5T} r(t)\,dt$ is the amount of fuel burned during the first half of the total time.

The expression $\int_{0.5T}^{T} r(t)\,dt$ is the amount of fuel burned during the second half of the total time.

Since $r'(t) < 0$, we know the rate fuel burns is going down. Thus, fuel is burned faster at first, then slower later on, so more fuel is burned during the first half of the total time than during the second half.

We conclude that $\int_0^{0.5T} r(t)\,dt > \int_{0.5T}^{T} r(t)\,dt$.

44. The expression $\int_0^{T/3} r(t)\,dt$ is the amount of fuel burned during the first one-third of the total time. The expression $Q/3$ is one-third of the total fuel burned.

Since $r'(t) < 0$, we know the rate fuel burns is going down. Thus, fuel is burned faster at first, then slower later on, so more than one-third of the total fuel burned is burned during the first one-third of the total time.

We conclude that $\int_0^{T/3} r(t)\,dt > Q/3$.

45. We know that T_h is the time at which half the fuel has burned, so $\int_0^{T_h} r(t)\,dt$ equals half the fuel burned.

We know that T is the time at which all the fuel has burned, so $0.5T$ is halfway through the entire time period. This means $\int_0^{0.5T} r(t)\,dt$ is the amount of fuel burned halfway through the total time period.

Since $r'(t) < 0$, we know the rate fuel burns is going down. This means more than half the fuel is burned during the first half of the total time period than the second half.

We conclude that more than half the fuel is burned during the first half of the time period, so $\int_0^{T_h} r(t)\,dt. < \int_0^{0.5T} r(t)\,dt$

46. By the given property, $\int_a^a f(x)\,dx = -\int_a^a f(x)\,dx$, so $2\int_a^a f(x)\,dx = 0$. Thus $\int_a^a f(x)\,dx = 0$.

47. We know that the average value of $v(x) = 4$, so

$$\frac{1}{6-1}\int_1^6 v(x)\,dx = 4, \text{ and thus } \int_1^6 v(x)\,dx = 20.$$

Similarly, we are told that

$$\frac{1}{8-6}\int_6^8 v(x)\,dx = 5, \text{ so } \int_6^8 v(x)\,dx = 10.$$

The average value for $1 \le x \le 8$ is given by

$$\text{Average value} = \frac{1}{8-1}\int_1^8 v(x)\,dx = \frac{1}{7}\left(\int_1^6 v(x)\,dx + \int_6^8 v(x)\,dx\right) = \frac{20+10}{7} = \frac{30}{7}.$$

48. (a) Yes.
(b) No, because the sum of the left sums has 20 subdivisions. The result is the left-sum approximation with 20 subdivisions to $\int_1^3 f(x)\,dx$.

49. In Figure 5.73 the area A_1 is largest, A_2 is next, and A_3 is smallest. We have

$$\text{I} = \int_a^b f(x)\,dx = A_1, \quad \text{II} = \int_a^c f(x)\,dx = A_1 - A_2, \quad \text{III} = \int_a^e f(x)\,dx = A_1 - A_2 + A_3,$$
$$\text{IV} = \int_b^e f(x)\,dx = -A_2 + A_3, \quad \text{V} = \int_b^c f(x)\,dx = -A_2.$$

The relative sizes of A_1, A_2, and A_3 mean that I is positive and largest, III is next largest (since $-A_2 + A_3$ is negative, but less negative than $-A_2$), II is next largest, but still positive (since A_1 is larger than A_2). The integrals IV and V are both negative, but V is more negative. Thus

$$\text{V} < \text{IV} < 0 < \text{II} < \text{III} < \text{I}.$$

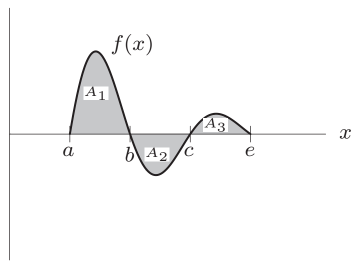

Figure 5.73

50. Since $f(t) = F'(t)$, we know from the Fundamental Theorem of Calculus that

$$\int_7^9 f(t)\,dt = \underbrace{F(9)}_{5} - \underbrace{F(7)}_{4} = 1.$$

This tells us that between the hours of 7 am and 9 am, the ice thickness increased by 1 inch.

51. Since $f(t) = F'(t)$, we know from the Fundamental Theorem of Calculus that

$$\int_4^7 f(t)\,dt = F(7) - F(4)$$
$$\text{so} \quad F(4) = \underbrace{F(7)}_{4} - \underbrace{\int_4^7 f(t)\,dt}_{1.5} = 2.5.$$

This tells us that at 4 am the ice is 2.5 inches thick.

52. We know that $f(t) = F'(t)$, so $F'(3.5) = f(3.5)$. We have:

$$\int_2^{3.5} f'(t)\,dt = 0.75$$
$$f(3.5) - f(2) = 0.75 \qquad \text{Fundamental Theorem of Calculus}$$
$$f(3.5) = \underbrace{f(2)}_{0.5} + 0.75 = 1.25,$$

so $F'(3.5) = 1.25$. This tells us that the ice thickness is growing by 1.25 inches/hour at 3:30 am.

53. (a) For $-2 \le x \le 2$, f is symmetrical about the y-axis, so $\int_{-2}^0 f(x)\,dx = \int_0^2 f(x)\,dx$ and $\int_{-2}^2 f(x)\,dx = 2\int_0^2 f(x)\,dx$.

(b) For any function f, $\int_0^2 f(x)\,dx = \int_0^5 f(x)\,dx - \int_2^5 f(x)\,dx$.

(c) Note that $\int_{-2}^0 f(x)\,dx = \frac{1}{2}\int_{-2}^2 f(x)\,dx$, so $\int_0^5 f(x)\,dx = \int_{-2}^5 f(x)\,dx - \int_{-2}^0 f(x)\,dx = \int_{-2}^5 f(x)\,dx - \frac{1}{2}\int_{-2}^2 f(x)\,dx$.

54. (a) We know that $\int_2^5 f(x)\,dx = \int_0^5 f(x)\,dx - \int_0^2 f(x)\,dx$. By symmetry, $\int_0^2 f(x)\,dx = \frac{1}{2}\int_{-2}^2 f(x)\,dx$, so $\int_2^5 f(x)\,dx = \int_0^5 f(x)\,dx - \frac{1}{2}\int_{-2}^2 f(x)\,dx$.

(b) $\int_2^5 f(x)\,dx = \int_{-2}^5 f(x)\,dx - \int_{-2}^2 f(x)\,dx = \int_{-2}^5 f(x)\,dx - 2\int_{-2}^0 f(x)\,dx$.

(c) Using symmetry again, $\int_0^2 f(x)\,dx = \frac{1}{2}\left(\int_{-2}^5 f(x)\,dx - \int_2^5 f(x)\,dx\right)$.

55. (a) The mouse changes direction (when its velocity is zero) at about times 17, 23, and 27.

(b) The mouse is moving most rapidly to the right at time 10 and most rapidly to the left at time 40.

(c) The mouse is farthest to the right when the integral of the velocity, $\int_0^t v(t)\,dt$, is most positive. Since the integral is the sum of the areas above the axis minus the areas below the axis, the integral is largest when the velocity is zero at about 17 seconds. The mouse is farthest to the left of center when the integral is most negative at 40 seconds.

(d) The mouse's speed decreases during seconds 10 to 17, from 20 to 23 seconds, and from 24 seconds to 27 seconds.

(e) The mouse is at the center of the tunnel at any time t for which the integral from 0 to t of the velocity is zero. This is true at time 0 and again somewhere around 35 seconds.

56. To estimate the distance traveled during the first 15 seconds, we calculate upper and lower bound estimates for this distance, and then average these estimates. Note that because the speed of the Prius is in miles per hour, we need to convert seconds to hours (1 sec $= 1/3600$ hours) to calculate the distance estimates in miles. We then convert miles to feet (1 mile $= 5280$ feet).

$$\begin{array}{c}\text{Total distance traveled}\\ \text{between } t=0 \text{ and } t=15\\ \text{(Lower Estimate)}\end{array} = 0 \cdot \frac{5}{3600} + 20 \cdot \frac{5}{3600} + 33 \cdot \frac{5}{3600} = 0.0736 \text{ miles or 389 feet}$$

$$\begin{array}{c}\text{Total distance traveled}\\ \text{between } t=0 \text{ and } t=15\\ \text{(Upper Estimate)}\end{array} = 20 \cdot \frac{5}{3600} + 33 \cdot \frac{5}{3600} + 45 \cdot \frac{5}{3600} = 0.1361 \text{ miles or 719 feet}$$

Since:

$$\begin{array}{c}\text{Average of Lower and Upper}\\ \text{Estimates}\end{array} = \frac{389 + 719}{2} = 554 \text{ feet},$$

the 2010 Prius Prototype travels about 554 feet, roughly a tenth of a mile, during the first 15 seconds of movement in EV-only mode.

57. To estimate the distance between the two cars at $t = 5$, we calculate upper and lower bound estimates for this distance and then average these estimates. Note that because the speed of the Prius is in miles per hour, we need to convert seconds to hours (1 sec $= 1/3600$ hours) to calculate the distance estimates in miles. We may then convert miles to feet (1 mile $= 5280$ feet).

$$\begin{aligned}\text{Distance between cars at } t=5 \text{ (Upper Estimate)} &\approx (\text{Difference in speeds at } t=5)\cdot(\text{Travel time})\\ &= (33-20)\cdot\frac{5}{3600} = 0.018 \text{ miles}\end{aligned}$$

$$\begin{aligned}\text{Distance between cars at } t=5 \text{ (Lower Estimate)} &\approx (\text{Difference in speeds at } t=0)\cdot(\text{Travel time})\\ &= (0-0)\cdot\frac{5}{3600} = 0 \text{ miles}\end{aligned}$$

Since:

$$\text{Average of Lower and Upper Estimates of distance between cars at } t=5 = \frac{0.018+0}{2} = 0.009 \text{ miles} = 48 \text{ feet},$$

the distance between the two cars is about 48 feet, five seconds after leaving the stoplight.

58. (a) The acceleration is positive for $0 \le t < 40$ and for a tiny period before $t = 60$, since the slope is positive over these intervals. Just to the left of $t = 40$, it looks like the acceleration is approaching 0. Between $t = 40$ and a moment just before $t = 60$, the acceleration is negative.

(b) The maximum altitude was about 500 feet, when t was a little greater than 40 (here we are estimating the area under the graph for $0 \le t \le 42$).

(c) The acceleration is greatest when the slope of the velocity is most positive. This happens just before $t = 60$, where the magnitude of the velocity is plunging and the direction of the acceleration is positive, or up.

(d) The deceleration is greatest when the slope of the velocity is most negative. This happens just after $t = 40$.

(e) After the Montgolfier Brothers hit their top climbing speed (at $t = 40$), they suddenly stopped climbing and started to fall. This suggests some kind of catastrophe—the flame going out, the balloon ripping, etc. (In actual fact, in their first flight in 1783, the material covering their balloon, held together by buttons, ripped and the balloon landed in flames.)

(f) The total change in altitude for the Montgolfiers and their balloon is the definite integral of their velocity, or the total area under the given graph (counting the part after $t = 42$ as negative, of course). As mentioned before, the total area of the graph for $0 \le t \le 42$ is about 500. The area for $t > 42$ is about 220. So subtracting, we see that the balloon finished 280 feet or so higher than where it began.

59. (a) About 300 meter^3/sec.

(b) About 250 meter^3/sec.

(c) Looking at the graph, we can see that the 1996 flood reached its maximum just between March and April, for a high of about 1250 meter^3/sec. Similarly, the 1957 flood reached its maximum in mid-June, for a maximum flow rate of 3500 meter^3/sec.

(d) The 1996 flood lasted about $1/3$ of a month, or about 10 days. The 1957 flood lasted about 4 months.

(e) The area under the controlled flood graph is about $2/3$ box. Each box represents 500 meter^3/sec for one month. Since

$$\begin{aligned}1 \text{ month} &= 30\frac{\text{days}}{\text{month}}\cdot 24\frac{\text{hours}}{\text{day}}\cdot 60\frac{\text{minutes}}{\text{hour}}\cdot 60\frac{\text{seconds}}{\text{minute}}\\ &= 2.592\cdot 10^6 \approx 2.6\cdot 10^6 \text{seconds},\end{aligned}$$

each box represents

$$\text{Flow} \approx (500 \text{ meter}^3/\text{sec})\cdot(2.6\cdot 10^6 \text{ sec}) = 13\cdot 10^8 \text{ meter}^3 \text{of water.}$$

So, for the artificial flood,

$$\text{Additional flow} \approx \frac{2}{3}\cdot 13\cdot 10^8 = 8.7\cdot 10^8 \text{ meter}^3 \approx 10^9 \text{ meter}^3.$$

(f) The 1957 flood released a volume of water represented by about 12 boxes above the 250 meter/sec baseline. Thus, for the natural flood,

$$\text{Additional flow} \approx 12\cdot 13\cdot 10^8 = 1.95\cdot 10^{10} \approx 2\cdot 10^{10} \text{ meter}^3.$$

So, the natural flood was nearly 20 times larger than the controlled flood and lasted much longer.

60. In (a), $f'(1)$ is the slope of a tangent line at $x = 1$, which is negative. As for (c), the rate of change in $f(x)$ is given by $f'(x)$, and the average value of this over $0 \le x \le a$ is

$$\frac{1}{a-0}\int_0^a f'(x)\,dx = \frac{f(a)-f(0)}{a-0}.$$

This is the slope of the line through the points $(0,1)$ and $(a,0)$, which is less negative that the tangent line at $x = 1$. Therefore, $(a) < (c) < 0$. The quantity (b) is $\left(\int_0^a f(x)\,dx\right)/a$ and (d) is $\int_0^a f(x)\,dx$, which is the net area under the graph of f (counting the area as negative for f below the x-axis). Since $a > 1$ and $\int_0^a f(x)\,dx > 0$, we have 0 <(b)<(d). Therefore

$$\text{(a)} < \text{(c)} < \text{(b)} < \text{(d)}.$$

61. This expression gives the tangent-line approximation to $f(3.1)$. Since $f''(x) < 0$, this tells us that the graph of f is concave-down, which means that the graph of f lies below its tangent line. Thus, this value overestimates $f(3.1)$.

62. From the Fundamental Theorem of Calculus, we see that

$$f(3) + \int_3^{3.1} f'(t)\,dt = f(3) + f(3.1) - f(3) = f(3.1),$$

so this value is exact.

63. The expression $\dfrac{F(3.11) - F(3.1)}{0.01}$ gives the slope of the secant line to the graph of F from $x = 3.1$ to $x = 3.11$. This approximates the value of $F'(3.1)$. Since $f(x) = F'(x)$, this means the expressions approximates the value of $f(3.1)$.

Notice that $f'(x) = F''(x)$; since $f'(x) > 0$, this means $F''(x) > 0$, which tells us that the graph of F is concave-up. This means the slope of the secant line from $x = 3.1$ to $x = 3.11$ is greater (either "less negative" or "more positive") than the slope of the tangent line at $x = 3.1$. Thus, this expression overestimates $F'(3.1)$, so it is an overestimate of $f(3.1)$.

64. We see that $\displaystyle\sum_{i=1}^{n} f'(x_i)\,\Delta x$ is a right-hand Riemann sum. Since $f''(x) < 0$ for all x, we know that $f'(x)$ is a decreasing function, which means the right-hand sum is an underestimate of the true value. Thus,

$$\begin{aligned} f(3) + \sum_{i=1}^{n} f'(x_i)\,\Delta x &< f(3) + \int_3^{3.1} f'(x)\,dx \\ &= f(3) + f(3.1) - f(3) \quad \text{Fundamental Theorem of Calculus} \\ &= f(3.1). \end{aligned}$$

This means the expression is an underestimate of $f(3.1)$.

65. (a) Divide the interval $0 \le t \le T$ into small subintervals of length Δt on which the temperature is approximately constant. Then if t_i is the i^{th} interval, on that interval

$$\Delta S \approx (H - H_{\text{min}})\Delta t = (f(t_i) - H_{\text{min}})\Delta t.$$

Thus, the total number of degree-days is approximated by

$$S \approx \sum_{i=1}^{n} (f(t_i) - H_{\text{min}})\Delta t.$$

As $n \to \infty$, we have

$$S = \int_0^T (f(t) - H_{\text{min}})\,dt.$$

(b) Since $H_{\text{min}} = 15^\circ\text{C}$ and $S = 125$ degree-days, the formula in part (a) gives

$$125 = \int_0^T (f(t) - 15)dt.$$

We approximate the definite integral using a Riemann sum:

$$\int_0^T (f(t)-15)dt = \sum_{i=1}^{n}(f(t_i)-15)\Delta t.$$

In the table, we have $\Delta t = 1$. We want to find how many terms in the sum are required to (approximately) equal the required number of degree-days, $S = 125$. From the table, we have

$$\sum_{i=1}^{2}(f(t_i)-15)\Delta t = (20-15)1 + (22-15)1 = 12,$$

so the sum of degree-days over a two-day period is much smaller than the required sum of 125. Likewise, the sum over a three-day period is only 24:

$$\sum_{i=1}^{3}(f(t_i)-15)\Delta t = (20-15)1 + (22-15)1 + (27-15)1 = 24.$$

Summing over a ten-day period and an eleven-day period, we find, respectively, that

$$\begin{aligned}\sum_{i=1}^{10}(f(t_i)-15)\Delta t &= (20-15)1 + (22-15)1 + (27-15)1 + (28-15)1 + (27-15)1 + (31-15)1\\ &\quad +(29-15)1 + (30-15)1 + (28-15)1 + (25-15)1 = 117\\ \sum_{i=1}^{11}(f(t_i)-15)\Delta t &= (20-15)1 + (22-15)1 + (27-15)1 + (28-15)1 + (27-15)1 + (31-15)1\\ &\quad +(29-15)1 + (30-15)1 + (28-15)1 + (25-15)1 + (24-15)1 = 126.\end{aligned}$$

Thus, the sum reaches 125 degree-days somewhere just short of $T = 11$ days.

66. (a) The slope of a line is the tangent of the angle the line makes with the horizontal. Thus the slope, $f'(x)$, of the tangent line at x is the tangent of the angle θ.

(b) Using the identity

$$1 + \tan^2\theta = \frac{1}{\cos^2\theta}$$

and part (a) we have

$$1 + (f'(x))^2 = \frac{1}{\cos^2\theta}.$$

(c) Using the chain rule, we have

$$\frac{d}{dx}(\tan\theta) = \frac{1}{\cos^2\theta}\frac{d\theta}{dx}.$$

Therefore, using parts (a) and (b), we have

$$\begin{aligned}\frac{d\theta}{dx} &= \cos^2\theta \frac{d}{dx}f'(x)\\ &= \frac{1}{1+(f'(x))^2}f''(x).\end{aligned}$$

(d) By the Fundamental Theorem of Calculus we have

$$\theta(b) - \theta(a) = \int_a^b \theta'(x)\,dx = \int_a^b \frac{f''(x)}{1+(f'(x))^2}\,dx.$$

CAS Challenge Problems

67. (a) We have $\Delta x = (1-0)/n = 1/n$ and $x_i = 0 + i\cdot\Delta x = i/n$. So we get

$$\text{Right-hand sum } = \sum_{i=1}^{n}(x_i)^4\Delta x = \sum_{i=1}^{n}\left(\frac{i}{n}\right)^4\left(\frac{1}{n}\right) = \sum_{i=1}^{n}\frac{i^4}{n^5}.$$

(b) The CAS gives

$$\text{Right-hand sum} = \sum_{i=1}^{n} \frac{i^4}{n^5} = \frac{6n^4 + 15n^3 + 10n^2 - 1}{30n^4}.$$

(The results may look slightly different depending on the CAS you use.)

(c) Using a CAS or by hand, we get

$$\lim_{n\to\infty} \frac{6n^4 + 15n^3 + 10n^2 - 1}{30n^4} = \lim_{n\to\infty} \frac{6n^4}{30n^4} = \frac{1}{5}.$$

The numerator is dominated by the highest power term, which is $6n^4$, so when n is large, the ratio behaves like $6n^4/30n^4 = 1/5$ as $n \to \infty$. Thus we see that

$$\int_0^1 x^4 dx = \frac{1}{5}.$$

68. (a) A Riemann sum with n subdivisions of $[0,1]$ has $\Delta x = 1/n$ and $x_i = i/n$. Thus,

$$\text{Right-hand sum } = \sum_{i=1}^{n} \left(\frac{i}{n}\right)^5 \left(\frac{1}{n}\right) = \sum_{i=1}^{n} \frac{i^5}{n^6}.$$

(b) A CAS gives

$$\text{Right-hand sum } = \sum_{i=1}^{n} \frac{i^5}{n^6} = \frac{2n^4 + 6n^3 + 5n^2 - 1}{12n^4}.$$

(c) Taking the limit by hand or using a CAS gives

$$\lim_{n\to\infty} \frac{2n^4 + 6n^3 + 5n^2 - 1}{12n^4} = \lim_{n\to\infty} \frac{2n^4}{12n^4} = \frac{1}{6}.$$

The numerator is dominated by the highest power term, which is $2n^4$, so the ratio behaves like $2n^4/12n^4 = 1/6$, as $n \to \infty$. Thus we see that

$$\int_0^1 x^5 dx = \frac{1}{6}.$$

69. (a) Since the length of the interval of integration is $2 - 1 = 1$, the width of each subdivision is $\Delta t = 1/n$. Thus the endpoints of the subdivision are

$$t_0 = 1, \quad t_1 = 1 + \Delta t = 1 + \frac{1}{n}, \quad t_2 = 1 + 2\Delta t = 1 + \frac{2}{n}, \ldots,$$
$$t_i = 1 + i\Delta t = 1 + \frac{i}{n}, \ldots, \quad t_{n-1} = 1 + (n-1)\Delta t = 1 + \frac{n-1}{n}.$$

Thus, since the integrand is $f(t) = t$,

$$\text{Left-hand sum} = \sum_{i=0}^{n-1} f(t_i)\Delta t = \sum_{i=0}^{n-1} t_i \Delta t = \sum_{i=0}^{n-1} \left(1 + \frac{i}{n}\right) \frac{1}{n} = \sum_{i=0}^{n-1} \frac{n+i}{n^2}.$$

(b) The CAS finds the formula for the Riemann sum

$$\sum_{i=0}^{n-1} \frac{n+i}{n^2} = \frac{\frac{(-1+n)\,n}{2} + n^2}{n^2} = \frac{3}{2} - \frac{1}{2n}.$$

(c) Taking the limit as $n \to \infty$

$$\lim_{n\to\infty} \left(\frac{3}{2} - \frac{1}{2n}\right) = \lim_{n\to\infty} \frac{3}{2} - \lim_{n\to\infty} \frac{1}{2n} = \frac{3}{2} + 0 = \frac{3}{2}.$$

(d) The shape under the graph of $y = t$ between $t = 1$ and $t = 2$ is a trapezoid of width 1, height 1 on the left and 2 on the right. So its area is $1 \cdot (1 + 2)/2 = 3/2$. This is the same answer we got by computing the definite integral.

70. (a) Since the length of the interval of integration is $2 - 1 = 1$, the width of each subdivision is $\Delta t = 1/n$. Thus the endpoints of the subdivision are

$$t_0 = 1, \quad t_1 = 1 + \Delta t = 1 + \frac{1}{n}, \quad t_2 = 1 + 2\Delta t = 1 + \frac{2}{n}, \ldots,$$
$$t_i = 1 + i\Delta t = 1 + \frac{i}{n}, \ldots, \quad t_{n-1} = 1 + (n-1)\Delta t = 1 + \frac{n-1}{n}.$$

Thus, since the integrand is $f(t) = t^2$,

$$\text{Left-hand sum} = \sum_{i=0}^{n-1} f(t_i)\Delta t = \sum_{i=0}^{n-1} t_i^2 \Delta t = \sum_{i=0}^{n-1} \left(1 + \frac{i}{n}\right)^2 \frac{1}{n} = \sum_{i=0}^{n-1} \frac{(n+i)^2}{n^3}.$$

(b) Using a CAS to find the sum, we get

$$\sum_{i=0}^{n-1} \frac{(n+i)^2}{n^3} = \frac{(-1+2n)(-1+7n)}{6n^2} = \frac{7}{3} + \frac{1}{6n^2} - \frac{3}{2n}.$$

(c) Taking the limit as $n \to \infty$

$$\lim_{n\to\infty}\left(\frac{7}{3} + \frac{1}{6n^2} - \frac{3}{2n}\right) = \lim_{n\to\infty}\frac{7}{3} + \lim_{n\to\infty}\frac{1}{6n^2} - \lim_{n\to\infty}\frac{3}{2n} = \frac{7}{3} + 0 + 0 = \frac{7}{3}.$$

(d) We have calculated $\int_1^2 t^2\,dt$ using Riemann sums. Since t^2 is above the t-axis between $t = 1$ and $t = 2$, this integral is the area; so the area is 7/3.

71. (a) Since the length of the interval of integration is π, the width of each subdivision is $\Delta x = \pi/n$. Thus the endpoints of the subdivision are

$$x_0 = 0, \quad x_1 = 0 + \Delta x = \frac{\pi}{n}, \quad x_2 = 0 + 2\Delta x = \frac{2\pi}{n}, \ldots,$$
$$x_i = 0 + i\Delta x = \frac{i\pi}{n}, \quad \ldots, \quad x_n = 0 + n\Delta x = \frac{n\pi}{n} = \pi.$$

Thus, since the integrand is $f(x) = \sin x$,

$$\text{Right-hand sum} = \sum_{i=1}^{n} f(x_i)\Delta x = \sum_{i=1}^{n} \sin(x_i)\Delta x = \sum_{i=1}^{n} \sin\left(\frac{i\pi}{n}\right)\frac{\pi}{n}.$$

(b) If the CAS can evaluate this sum, we get

$$\sum_{i=1}^{n} \sin\left(\frac{i\pi}{n}\right)\frac{\pi}{n} = \frac{\pi\cot(\pi/2n)}{n} = \frac{\pi\cos(\pi/2n)}{n\sin(\pi/2n)}.$$

(c) Using the computer algebra system, we find that

$$\lim_{n\to\infty}\frac{\pi\cos(\pi/2n)}{n\sin(\pi/2n)} = 2.$$

(d) The computer algebra system gives

$$\int_0^\pi \sin x\,dx = 2.$$

72. (a) A CAS gives

$$\int_a^b \sin(cx)\,dx = \frac{\cos(ac)}{c} - \frac{\cos(bc)}{c}.$$

(b) If $F(x)$ is an antiderivative of $\sin(cx)$, then the Fundamental Theorem of Calculus says that

$$\int_a^b \sin(cx)\,dx = F(b) - F(a).$$

Comparing this with the answer to part (a), we see that

$$F(b) - F(a) = \frac{\cos(ac)}{c} - \frac{\cos(bc)}{c} = \left(-\frac{\cos(cb)}{c}\right) - \left(-\frac{\cos(ca)}{c}\right).$$

This suggests that

$$F(x) = -\frac{\cos(cx)}{c}.$$

Taking the derivative confirms this:

$$\frac{d}{dx}\left(-\frac{\cos(cx)}{c}\right) = \sin(cx).$$

73. (a) Different systems may give different answers. A typical answer is

$$\int_a^c \frac{x}{1+bx^2}\,dx = \frac{\ln\left(\frac{|c^2b+1|}{|a^2b+1|}\right)}{2b}.$$

Some CASs may not have the absolute values in the answer; since $b > 0$, the answer is correct without the absolute values.

(b) Using the properties of logarithms, we can rewrite the answer to part (a) as

$$\int_a^c \frac{x}{1+bx^2}\,dx = \frac{\ln|c^2b+1| - \ln|a^2b+1|}{2b} = \frac{\ln|c^2b+1|}{2b} - \frac{\ln|a^2b+1|}{2b}.$$

If $F(x)$ is an antiderivative of $x/(1+bx^2)$, then the Fundamental Theorem of Calculus says that

$$\int_a^c \frac{x}{1+bx^2}\,dx = F(c) - F(a).$$

Thus

$$F(c) - F(a) = \frac{\ln|c^2b+1|}{2b} - \frac{\ln|a^2b+1|}{2b}.$$

This suggests that

$$F(x) = \frac{\ln|1+bx^2|}{2b}.$$

(Since $b > 0$, we know $|1+bx^2| = 1+bx^2$.) Taking the derivative confirms this:

$$\frac{d}{dx}\left(\frac{\ln(1+b\,x^2)}{2\,b}\right) = \frac{x}{1+b\,x^2}.$$

PROJECTS FOR CHAPTER FIVE

1. (a) The work done by the ventricle wall on the blood is the force exerted on the blood times the distance the wall pushes the blood; that is, the distance the wall moves. In Phases 1 and 3 there is no work done because the ventricle wall is motionless.

The wall moves in Phases 2 and 4. The work done by the wall is positive if the force from the wall to the blood is in the direction of the movement, and it is negative if the force and movement are in opposite directions. In Phase 4, the ventricle is contracting, pushing the blood, so the work is positive. In Phase 2, the ventricle is expanding, being pushed out by the blood, so the work is negative.

(b) Since pressure is expressed in units of force per unit area (newtons/cm^2) and volume is expressed in units of length cubed (cm^3), area in the pressure-volume plane has units of

$$\frac{\text{newtons}}{(\text{cm})^2} \times (\text{cm})^3 = \text{newtons} \times \text{cm}.$$

The units of area in the pressure-volume plane are force times distance, which are the units of work and energy.

(c) (i) Let the area of the LV wall be A. The force exerted by the wall in Phase 4 when the LV has volume V is the pressure, $f(V)$, times the area A. When the wall moves inward during Phase 4 a small distance Δx, the volume, which decreases, changes by approximately $\Delta V = -A\Delta x$. The work done during this movement is approximately

$$\text{Force} \cdot \text{Distance} = f(V)A \cdot \Delta x = -f(V)\,\Delta V.$$

Thus, the total work done in Phase 4 as the volume decreases from b to a is $\int_b^a -f(V)\,dV = \int_a^b f(V)\,dV$.

(ii) The force exerted by the wall in Phase 2 when the LV has volume V is the pressure, $g(V)$, times the area of the LV wall, A. When the wall moves outward during Phase 2 a small distance Δx, the volume, which increases, changes by approximately $\Delta V = A\Delta x$. Since the force from the wall to the blood is in the direction opposite the direction of motion, the work done during this movement is approximately

$$-\text{Force} \cdot \text{Distance} = -g(V)A \cdot \Delta x = -g(V)\,\Delta V.$$

Thus, the total work done in Phase 2 as the volume increases from a to b is $\int_a^b -g(V)\,dV = -\int_a^b g(V)\,dV$.

(d) Since Phases 1 and 3 are vertical lines, the area of the pressure-volume loop is the area between $f(V)$ and $g(V)$ from $V = a$ to $V = b$. Thus,

$$\text{Area enclosed} = \int_a^b (f(V) - g(V))\,dV.$$

Since the LV does no work in Phases 1 and 3, using part (c), we have

$$\begin{aligned}\text{Area enclosed} &= \int_a^b f(V)\,dV - \int_a^b g(V)\,dV \\ &= \text{Work done in Phase 4} + \text{Work done in Phase 2} \\ &= \text{Work done by LV in one cardiac cycle.}\end{aligned}$$

2. To find distances from the velocity graph, we use the fact that if t is the time measured from noon, and v is the velocity, then

$$\begin{matrix}\text{Distance traveled} \\ \text{by car up to time } T\end{matrix} = \int_0^T v\,dt = \begin{matrix}\text{Area under velocity} \\ \text{graph between 0 and } T.\end{matrix}$$

The truck's motion can be represented on the same graph by the horizontal line $v = 50$, starting at $t = 1$. The distance traveled by the truck is then the rectangular area under this line, and the distance between the two vehicles is the difference between these areas. Note each small rectangle on the graph corresponds to moving at 10 mph for a half hour (that is, to a distance of 5 miles).

(a) The distance traveled by the car when the truck starts is represented by the shaded area in Figure 5.74, which totals about seven rectangles or about 35 miles.

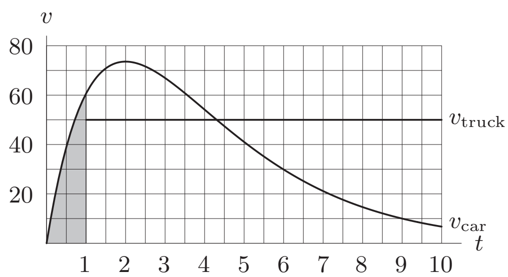

Figure 5.74: Shaded area represents distance traveled by car from noon to 1pm

(b) At 3 pm, the car is traveling with a velocity of about 67 mph, while the truck has a velocity of 50 mph. Because the car is ahead of the truck at 3 pm and is traveling at a greater velocity, the distance between the car and the truck is increasing at this time. If d_{car} and d_{truck} represent the distance traveled by the car and the truck respectively, then

$$\text{Distance apart} = d_{\text{car}} - d_{\text{truck}}.$$

The rate of change of the distance apart is given by its derivative:

$$\begin{aligned}(\text{Distance apart})' &= (d_{\text{car}})' - (d_{\text{truck}})' \\ &= v_{\text{car}} - v_{\text{truck}}\end{aligned}$$

At 3 pm, we have $(\text{Distance apart})' = 67$ mph $- 50$ mph $= 17$ mph. Thus, at 3 pm the car is traveling with a velocity 17 mph greater than the truck's velocity, and the distance between them is increasing at 17 miles per hour.

At 2 pm, the car's velocity is greatest. Because the truck's velocity is constant, $v_{\text{car}} - v_{\text{truck}}$ is largest when the car's velocity is largest. Thus, at 2 pm the distance between the car and the truck is increasing fastest—that is, the car is pulling away at the greatest rate.

(Note: This only takes into account the time when the truck is moving. When the truck is not moving (from 12:00 to 1:00), the car pulls away from the truck at an even greater rate.)

(c) The car starts ahead of the truck, and the distance between them increases as long as the velocity of the car is greater than the velocity of the truck. Later, when the truck's velocity exceeds the car's, the truck starts to gain on the car. In other words, the distance between the car and the truck increases as long as $v_{\text{car}} > v_{\text{truck}}$, and it decreases when $v_{\text{car}} < v_{\text{truck}}$. Therefore, the maximum distance occurs when $v_{\text{car}} = v_{\text{truck}}$, that is, when $t \approx 4.3$ hours (at about 4:20 pm). (See Figure 5.75.)

The distance traveled by the car is the area under the v_{car} graph between $t = 0$ and $t = 4.3$; the distance traveled by the truck is the area under the v_{truck} line between $t = 1$ (when it started) and $t = 4.3$. So the distance between the car and truck is represented by the shaded area in Figure 5.75. Thus, approximately

$$\text{Distance between car and truck } = 35 \text{ miles } + 50 \text{ miles} = 85 \text{ miles}.$$

(d) The truck overtakes the car when both have traveled the same distance. This occurs when the area under the curve (v_{car}) up to that time equals the area under the line v_{truck} up to that time. Since the areas under v_{car} and v_{truck} overlap (see Figure 5.76), they are equal when the lightly shaded area equals the heavily shaded area (which we know is about 85 miles). This happens when $t \approx 8.3$ hours, or about 8:20 pm. At this time, each has traveled about 365 miles.

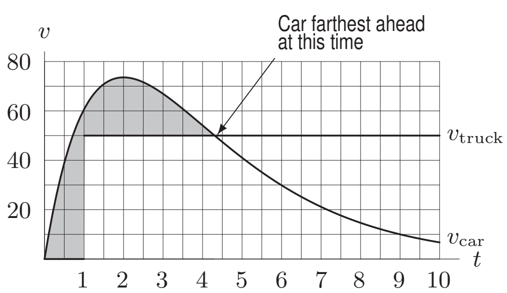

Figure 5.75: Shaded area = distance by which car is ahead at about 4:20 pm

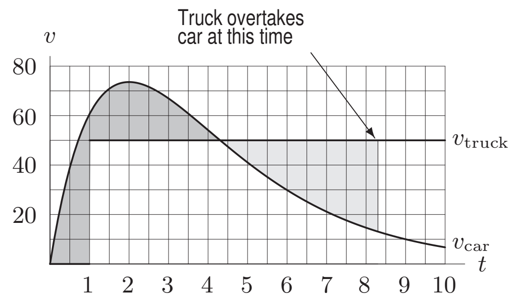

Figure 5.76: Truck overtakes car when dark and light shaded areas are equal

(e) See Figure 5.77.

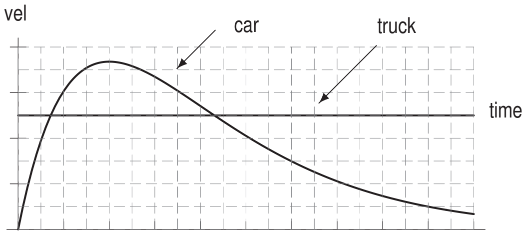

Figure 5.77

(f) The graphs intersect twice, at about 0.7 hours and 4.3 hours. At each intersection point, the velocity of the car is equal to the velocity of the truck, so $v_{\text{car}} = v_{\text{truck}}$. From the time they start until 0.7 hours later, the truck is traveling at a greater velocity than the car, so the truck is ahead of the car and is pulling farther away. At 0.7 hours they are traveling at the same velocity, and after 0.7 hours the car is traveling faster than the truck, so that the car begins to gain on the truck. Thus, at 0.7 hours the truck is farther from the car than it is immediately before or after 0.7 hours.

Similarly, because the car's velocity is greater than the truck's after 0.7 hours, it will catch up with the truck and eventually pass and pull away from the truck until 4.3 hours, at which point the two are again traveling at the same velocity. After 4.3 hours the truck travels faster than the car, so that it now gains on the car. Thus, 4.3 hours represents the point where the car is farthest ahead of the truck.

3. (a) For Operation 1, we have the following:

(i) A plot of current use versus time is given in Figure 5.78.

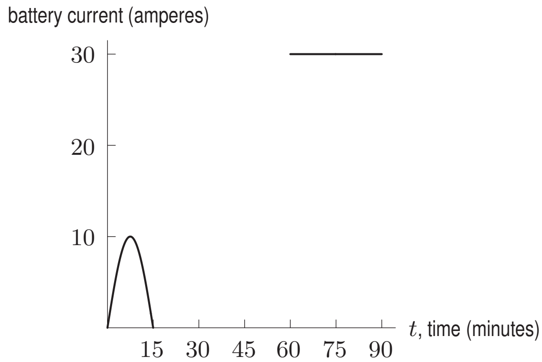

Figure 5.78: Operation 1

The battery current function is given by the formulas

$$D(t) = \begin{cases} 10\sin\dfrac{2\pi t}{30} & 0 \le t \le 15 \\ 0 & 15 \le t \le 60 \\ 30 & 60 \le t \le 90. \end{cases}$$

(ii) The battery current function gives the rate at which the current is flowing. Thus, the total discharge is given by the integral of the battery current function:

$$\begin{aligned} \text{Total discharge } &= \int_0^{90} D(t)\,dt = \int_0^{15} 10\sin\frac{2\pi t}{30}\,dt + \int_{15}^{60} 0\,dt + \int_{60}^{90} 30\,dt \\ &\approx 95.5 + 900 \\ &= 995.5 \text{ ampere-minutes} = 16.6 \text{ ampere-hours.} \end{aligned}$$

(iii) The battery can discharge up to 40% of 50 ampere-hours, which is 20 ampere-hours, without damage. Since Operation 1 can be performed with just 16.6 ampere-hours, it is safe.

(b) For Operation 2, we have the following:

(i) The total battery discharge is given by the area under the battery current curve in Figure 5.79. The area under the right-most portion of the curve, (when the satellite is shadowed by the earth), is easily calculated as 30 amps$\cdot$ 30 minutes $=$ 900 ampere-minutes $=$ 15 ampere-hours. For the other part we estimate by trapezoids, which are the average of left and right rectangles on each subinterval. Estimated values of the function are in Table 5.3.

Table 5.3 *Estimated values of the battery current*

Time	0	5	10	15	20	25	30
Current	5	16	18	12	5	12	0

Using $\Delta t = 5$, we see

$$\begin{aligned}\text{Total discharge } &= \frac{1}{2}(5+16)\cdot 5 + \frac{1}{2}(16+18)\cdot 5 + \frac{1}{2}(18+12)\cdot 5 \\ &\quad + \frac{1}{2}(12+5)\cdot 5 + \frac{1}{2}(5+12)\cdot 5 + \frac{1}{2}(12+0)\cdot 5 \\ &\approx 330 \text{ ampere-minutes} = 5.5 \text{ ampere-hours.}\end{aligned}$$

The total estimated discharge is 20.5 ampere-hours.

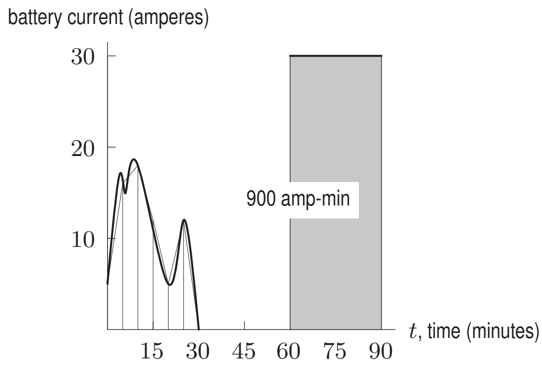

Figure 5.79: Operation 2

(ii) Since the estimated discharge appears to be an underestimate, Operation 2 probably should not be performed.

CHAPTER SIX

Solutions for Section 6.1

Exercises

1. (a) If $f(x)$ is positive over an interval, then $F(x)$ is increasing over the interval.
(b) If $f(x)$ is increasing over an interval, then $F(x)$ is concave up over the interval.

2. Since dP/dt is positive for $t < 3$ and negative for $t > 3$, we know that P is increasing for $t < 3$ and decreasing for $t > 3$. Between each two integer values, the magnitude of the change is equal to the area between the graph dP/dt and the t-axis. For example, between $t = 0$ and $t = 1$, we see that the change in P is 1. Since $P = 0$ at $t = 0$, we must have $P = 1$ at $t = 1$. The other values are found similarly, and are shown in Table 6.1.

Table 6.1

t	0	1	2	3	4	5
P	0	1	2	2.5	2	1

3. Since dP/dt is negative for $t < 3$ and positive for $t > 3$, we know that P is decreasing for $t < 3$ and increasing for $t > 3$. Between each two integer values, the magnitude of the change is equal to the area between the graph dP/dt and the t-axis. For example, between $t = 0$ and $t = 1$, we see that the change in P is -1. Since $P = 2$ at $t = 0$, we must have $P = 1$ at $t = 1$. The other values are found similarly, and are shown in Table 6.2.

Table 6.2

t	1	2	3	4	5
P	1	0	$-1/2$	0	1

4. See Figure 6.1.

10. See Figure 6.7.

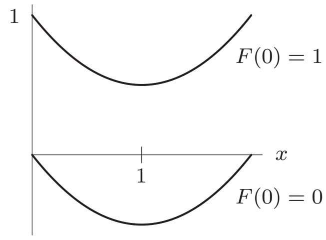

Figure 6.7

11. See Figure 6.8

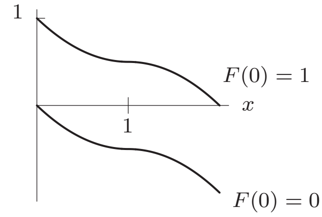

Figure 6.8

Problems

12. (a) If $\int_2^5 f(x)\,dx = 4$, and $F(5) = 10$ then $F(2) = 6$, since $\int_2^5 f(x)\,dx$ gives the total change in $F(x)$ between $x = 2$ and $x = 5$.

(b) If $\int_0^{100} f(x)\,dx = 0$, then $F(100) = F(0)$, since the total change in $F(x)$ from $x = 0$ to $x = 100$ is 0.

13. By the Fundamental Theorem of Calculus, we know that

$$f(2) - f(0) = \int_0^2 f'(x)dx.$$

Using a left-hand sum, we estimate $\int_0^2 f'(x)dx \approx (10)(2) = 20$. Using a right-hand sum, we estimate $\int_0^2 f'(x)dx \approx (18)(2) = 36$. Averaging, we have

$$\int_0^2 f'(x)dx \approx \frac{20+36}{2} = 28.$$

We know $f(0) = 100$, so

$$f(2) = f(0) + \int_0^2 f'(x)dx \approx 100 + 28 = 128.$$

Similarly, we estimate

$$\int_2^4 f'(x)dx \approx \frac{(18)(2) + (23)(2)}{2} = 41,$$

so

$$f(4) = f(2) + \int_2^4 f'(x)dx \approx 128 + 41 = 169.$$

Similarly,

$$\int_4^6 f'(x)dx \approx \frac{(23)(2) + (25)(2)}{2} = 48,$$

so

$$f(6) = f(4) + \int_4^6 f'(x)dx \approx 169 + 48 = 217.$$

The values are shown in the table.

x	0	2	4	6
$f(x)$	100	128	169	217

14. The change in $f(x)$ between 0 and 2 is equal to $\int_0^2 f'(x)\,dx$. A left-hand estimate for this integral is $(17)(2) = 34$ and a right hand estimate is $(15)(2) = 30$. Our best estimate is the average, 32. The change in $f(x)$ between 0 and 2 is $+32$. Since $f(0) = 50$, we have $f(2) = 82$. We find the other values similarly. The results are shown in Table 6.3.

Table 6.3

x	0	2	4	6
$f(x)$	50	82	107	119

15. Between $t = 0$ and $t = 1$, the particle moves at 10 km/hr for 1 hour. Since it starts at $x = 5$, the particle is at $x = 15$ when $t = 1$. See Figure 6.9. The graph of distance is a straight line between $t = 0$ and $t = 1$ because the velocity is constant then.

Between $t = 1$ and $t = 2$, the particle moves 10 km to the left, ending at $x = 5$. Between $t = 2$ and $t = 3$, it moves 10 km to the right again. See Figure 6.9.

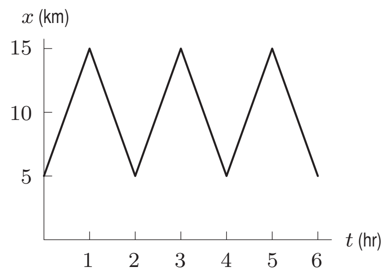

Figure 6.9

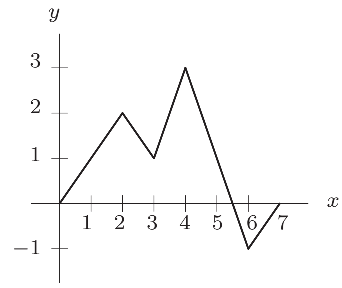
As an aside, note that the original velocity graph is not entirely realistic as it suggests the particle reverses direction instantaneously at the end of each hour. In practice this means the reversal of direction occurs over a time interval that is short in comparison to an hour.

16. (a) We know that $\int_0^3 f'(x)dx = f(3) - f(0)$ from the Fundamental Theorem of Calculus. From the graph of f' we can see that $\int_0^3 f'(x)dx = 2 - 1 = 1$ by subtracting areas between f' and the x-axis. Since $f(0) = 0$, we find that $f(3) = 1$. Similar reasoning gives $f(7) = \int_0^7 f'(x)dx = 2 - 1 + 2 - 4 + 1 = 0$.

(b) We have $f(0) = 0$, $f(2) = 2$, $f(3) = 1$, $f(4) = 3$, $f(6) = -1$, and $f(7) = 0$. So the graph, beginning at $x = 0$, starts at zero, increases to 2 at $x = 2$, decreases to 1 at $x = 3$, increases to 3 at $x = 4$, then passes through a zero as it decreases to -1 at $x = 6$, and finally increases to 0 at 7. Thus, there are three zeroes: $x = 0$, $x = 5.5$, and $x = 7$.

(c)



17. Let $y'(t) = dy/dt$. Then y is the antiderivative of y' such that $y(0) = 0$. We know that

$$y(x) = \int_0^x y'(t)\,dt.$$

Thus, $y(x)$ is the area under the graph of dy/dt from $t = 0$ to $t = x$, where regions below the t-axis contribute negatively to the integral. We see that $y(t_1) = 2$, $y(t_3) = 2 - 2 = 0$, and $y(t_5) = 2$. See Figure 6.10.

Since y' is positive on the intervals $(0, t_1)$ and (t_3, ∞), we know that y is increasing on those intervals. Since y' is negative on the interval (t_1, t_3), we know that y is decreasing on that interval.

Since y' is increasing on the interval (t_2, t_4), we know that y is concave up on that interval; since y' is decreasing on $(0, t_2)$, we know that y is concave down there. The point where the concavity changes, t_2, is an inflection point. Finally, since y' is constant and positive on the interval (t_4, ∞), the graph of y is linear with positive slope on this interval. The value $y(t_1) = 2$ is a local maximum and $y(t_3) = 0$ is a local minimum.

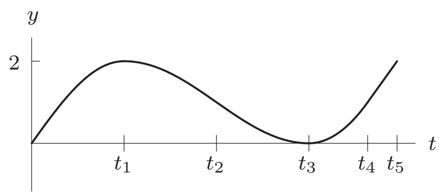


Figure 6.10

18. Let $y'(t) = dy/dt$. Then y is the antiderivative of y' such that $y(0) = 0$. We know that

$$y(x) = \int_0^x y'(t)\,dt.$$

Thus $y(x)$ is the area under the graph of dy/dt from $t = 0$ to $t = x$, with regions below the t-axis contributing negatively to the integral. We see that $y(t_1) = -2$, $y(t_3) = -2 + 2 = 0$, and $y(t_5) = -2$. See Figure 6.11.

Since y' is positive on the interval (t_1, t_3), we know that y is increasing on that interval. Since y' is negative on the intervals $(0, t_1)$ and (t_3, ∞), we know y is decreasing on those intervals.

Since y' is increasing on $(0, t_2)$, we know that y is concave up on that interval. Since y' is decreasing on (t_2, t_4), we know that y is concave down there. The point where concavity changes, t_2, is an inflection point. In addition, since y' is a negative constant on the interval (t_4, ∞), the graph of y is a line with negative slope on this interval. The value $y(t_1) = -2$ is a local minimum and $y(t_3) = 0$ is a local maximum.

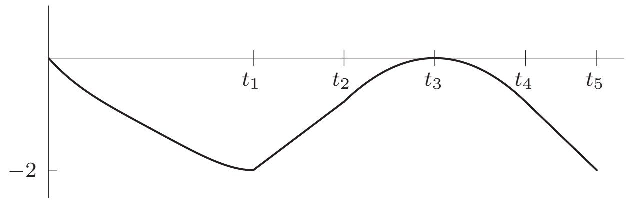

Figure 6.11

19. The critical points are at $(0, 5)$, $(2, 21)$, $(4, 13)$, and $(5, 15)$. A graph is given in Figure 6.12.

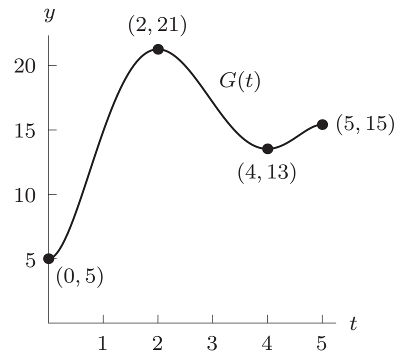

Figure 6.12

20. Looking at the graph of g' in Figure 6.13, we see that the critical points of g occur when $x = 15$ and $x = 40$, since $g'(x) = 0$ at these values. Inflection points of g occur when $x = 10$ and $x = 20$, because $g'(x)$ has a local maximum or minimum at these values. Knowing these four key points, we sketch the graph of $g(x)$ in Figure 6.14.

We start at $x = 0$, where $g(0) = 50$. Since g' is negative on the interval $[0, 10]$, the value of $g(x)$ is decreasing there. At $x = 10$ we have

$$\begin{aligned} g(10) &= g(0) + \int_0^{10} g'(x)\,dx \\ &= 50 - (\text{area of shaded trapezoid } T_1) \\ &= 50 - \left(\frac{10+20}{2} \cdot 10\right) = -100. \end{aligned}$$

Similarly,

$$\begin{aligned} g(15) &= g(10) + \int_{10}^{15} g'(x)\,dx \\ &= -100 - (\text{area of triangle } T_2) \\ &= -100 - \frac{1}{2}(5)(20) = -150. \end{aligned}$$

Continuing,

$$g(20) = g(15) + \int_{15}^{20} g'(x)\,dx = -150 + \frac{1}{2}(5)(10) = -125,$$

and

$$g(40) = g(20) + \int_{20}^{40} g'(x)\,dx = -125 + \frac{1}{2}(20)(10) = -25.$$

We now find concavity of $g(x)$ in the intervals $[0, 10]$, $[10, 15]$, $[15, 20]$, $[20, 40]$ by checking whether $g'(x)$ increases or decreases in these same intervals. If $g'(x)$ increases, then $g(x)$ is concave up; if $g'(x)$ decreases, then $g(x)$ is concave down. Thus we finally have the graph of $g(x)$ in Figure 6.14.

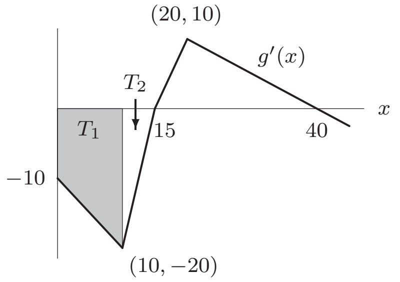

Figure 6.13

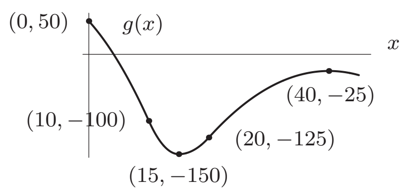

Figure 6.14

21. The rate of change is negative for $t < 5$ and positive for $t > 5$, so the concentration of adrenaline decreases until $t = 5$ and then increases. Since the area under the t-axis is greater than the area over the t-axis, the concentration of adrenaline goes down more than it goes up. Thus, the concentration at $t = 8$ is less than the concentration at $t = 0$. See Figure 6.15.

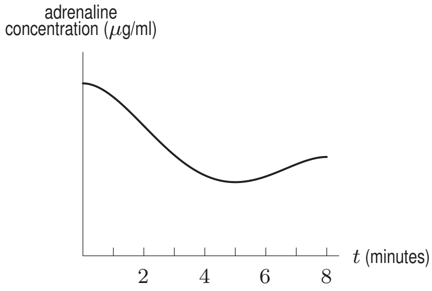

Figure 6.15

22. (a) The total volume emptied must increase with time and cannot decrease. The smooth graph (I) that is always increasing is therefore the volume emptied from the bladder. The jagged graph (II) that increases then decreases to zero is the flow rate.

(b) The total change in volume is the integral of the flow rate. Thus, the graph giving total change (I) shows an antiderivative of the rate of change in graph (II).

23. See Figure 6.16. Note that since $f(x_1) = 0$ and $f'(x_1) < 0$, $F(x_1)$ is a local maximum; since $f(x_3) = 0$ and $f'(x_3) > 0$, $F(x_3)$ is a local minimum. Also, since $f'(x_2) = 0$ and f changes from decreasing to increasing about $x = x_2$, F has an inflection point at $x = x_2$.

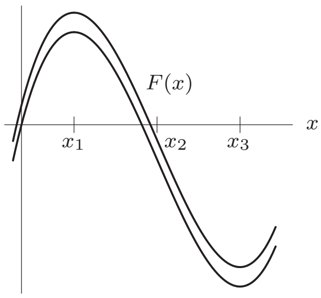

Figure 6.16

24. See Figure 6.17. Note that since $f(x_1) = 0$ and $f'(x_1) > 0$, $F(x_1)$ is a local minimum; since $f(x_3) = 0$ and $f'(x_3) < 0$, $F(x_3)$ is a local maximum. Also, since $f'(x_2) = 0$ and f changes from decreasing to increasing about $x = x_2$, F has an inflection point at $x = x_2$.

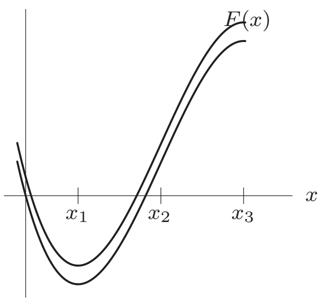

Figure 6.17

25. See Figure 6.18. Note that since $f(x_1) = 0$, $F(x_1)$ is either a local minimum or a point of inflection; it is impossible to tell which from the graph. Since $f'(x_3) = 0$, and f' changes sign around $x = x_3$, $F(x_3)$ is an inflection point. Also, since $f'(x_2) = 0$ and f changes from increasing to decreasing about $x = x_2$, F has another inflection point at $x = x_2$.

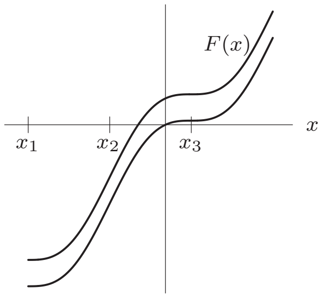

Figure 6.18

26. See Figure 6.19. Since $f(x_1) = 0$ and $f'(x_1) < 0$, we see that $F(x_1)$ is a local maximum. Since $f(x_3) = 0$ and $f'(x_3) > 0$, we see that $F(x_3)$ is a local minimum. Since $f'(x_2) = 0$ and f changes from decreasing to increasing at $x = x_2$, we see that F has an inflection point at $x = x_2$.

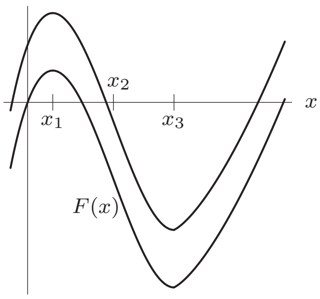

Figure 6.19

27. The graph of $f(x) = 2\sin(x^2)$ is shown in Figure 6.20. We see that there are roots at $x = 1.77$ and $x = 2.51$. These are the critical points of $F(x)$. Looking at the graph, it appears that of the three areas marked, A_1 is the largest, A_2 is next, and A_3 is smallest. Thus, as x increases from 0 to 3, the function $F(x)$ increases (by A_1), decreases (by A_2), and then increases again (by A_3). Therefore, the maximum is attained at the critical point $x = 1.77$.

What is the value of the function at this maximum? We know that $F(1) = 5$, so we need to find the change in F between $x = 1$ and $x = 1.77$. We have

$$\text{Change in } F = \int_1^{1.77} 2\sin(x^2)\,dx = 1.17.$$

We see that $F(1.77) = 5 + 1.17 = 6.17$, so the maximum value of F on this interval is 6.17.

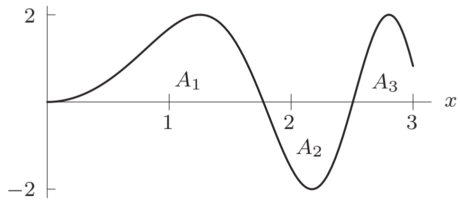

Figure 6.20

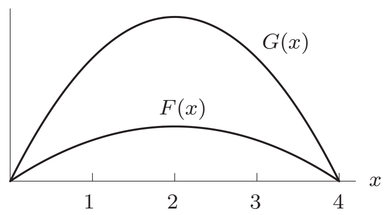
28. Both $F(x)$ and $G(x)$ have roots at $x = 0$ and $x = 4$. Both have a critical point (which is a local maximum) at $x = 2$. However, since the area under $g(x)$ between $x = 0$ and $x = 2$ is larger than the area under $f(x)$ between $x = 0$ and $x = 2$, the y-coordinate of $G(x)$ at 2 will be larger than the y-coordinate of $F(x)$ at 2. See below.



29. (a) Let $r(t)$ be the leakage rate in liters per second at time t minutes, shown in the graph. Since time is in minutes, it is helpful to express leakage in units of liters per minute. The leakage rate in liters per minute is $60r(t)$. The quantity leaked during the first b minutes, in liters, is given by $\int_0^b 60r(t)\,dt$.

We can evaluate the quantity leaked by computing area under the rate graph, by counting grid squares. Each grid square contributes area

$$\text{1 grid square} = \left(10\,\frac{\text{liter}}{\text{sec}}\right) \times (10\text{ minutes}) = 60 \cdot 10\frac{\text{liters}}{\text{minute}} \times (10\text{ minutes}) = 6000\text{ liters}.$$

Thus each grid square represents 6000 liters of leakage. So

$$\begin{matrix}\text{Total spill over} \\ \text{first 10 minutes}\end{matrix} = \frac{1}{2}\text{ grid square } \cdot 6000 = 3000\text{ liters}.$$

$$\begin{matrix}\text{Total spill over} \\ \text{20 minutes}\end{matrix} = 2\text{ grid squares } \cdot 6000 = 12{,}000\text{ liters}.$$

Continuing, we have

Time t (minutes)	0	10	20	30	40	50
Total spill, over t minutes (liters)	0	3000	12,000	21,000	27,000	30,000

(b) Plotting the values from part (a) and connecting with a smooth curve gives Figure 6.21.

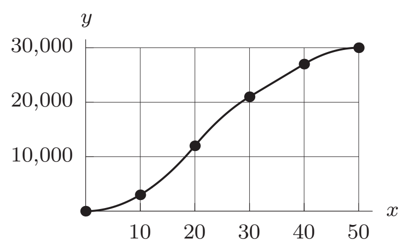


Figure 6.21

30. (a) Suppose $Q(t)$ is the amount of water in the reservoir at time t. Then

$$Q'(t) = \begin{matrix}\text{Rate at which water} \\ \text{in reservoir is changing}\end{matrix} = \begin{matrix}\text{Inflow} \\ \text{rate}\end{matrix} - \begin{matrix}\text{Outflow} \\ \text{rate}\end{matrix}$$

Thus the amount of water in the reservoir is increasing when the inflow curve is above the outflow, and decreasing when it is below. This means that $Q(t)$ is a maximum where the curves cross in July 2007 (as shown in Figure 6.22), and $Q(t)$ is decreasing fastest when the outflow is farthest above the inflow curve, which occurs about October 2007 (see Figure 6.22).

To estimate values of $Q(t)$, we use the Fundamental Theorem which says that the change in the total quantity of water in the reservoir is given by

$$Q(t) - Q(\text{Jan 2007}) = \int_{\text{Jan 07}}^{t} (\text{inflow rate} - \text{outflow rate})\, dt$$

or

$$Q(t) = Q(\text{Jan 2007}) + \int_{\text{Jan 07}}^{t} (\text{Inflow rate} - \text{Outflow rate})\, dt.$$

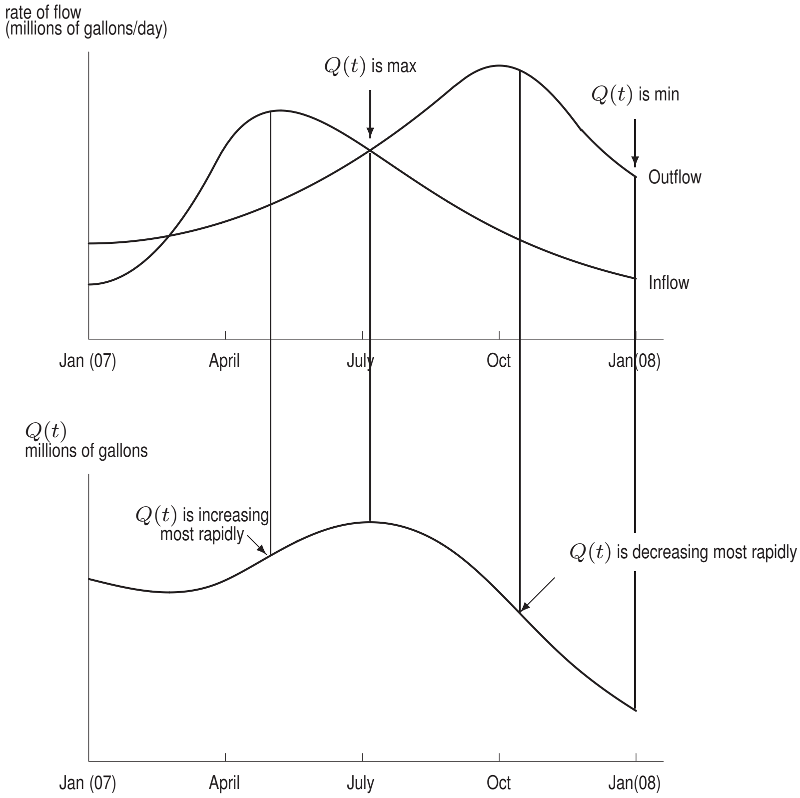

Figure 6.22

(b) See Figure 6.22. Maximum in July 2007. Minimum in Jan 2008.
(c) See Figure 6.22. Increasing fastest in May 2007. Decreasing fastest in Oct 2007.
(d) In order for the water to be the same as Jan 2007 the total amount of water which has flowed into the reservoir minus the total amount of water which has flowed out of the reservoir must be 0. Referring to Figure 6.23, we have

$$\int_{\text{Jan 07}}^{\text{July 08}} (\text{Inflow} - \text{Outflow})\, dt = -A_1 + A_2 - A_3 + A_4 = 0$$

giving $A_1 + A_3 = A_2 + A_4$

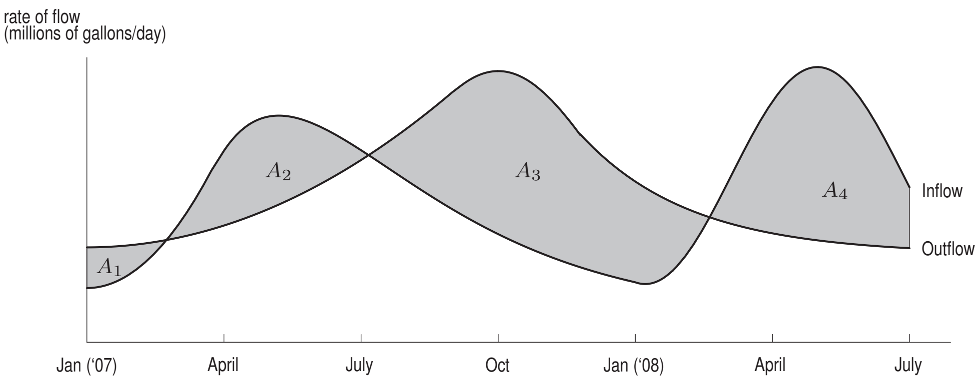

Figure 6.23

Strengthen Your Understanding

31. The statement has $f(x)$ and $F(x)$ reversed. Namely if an antiderivative $F(x)$ is increasing, then $F'(x) = f(x) \geq 0$.

We can see the statement given is not always true by looking for a counterexample. The function $f(x) = 2x$ is always increasing, but it has antiderivatives that are less than 0. For example, the antiderivative $F(x)$ with $F(0) = -1$ is negative at 0. See Figure 6.24.

A correct statement is: If $f(x) > 0$ everywhere, then $F(x)$ is increasing everywhere.

Figure 6.24: $f(x) = 2x$ increasing and its antiderivative $F(x)$ is not always positive

32. Consider $F(x) = x^2$ and $G(x) = x^2 + 1$ which are both antiderivatives of $f(x) = 2x$. Then $H(x) = F(x) + G(x) = 2x^2 + 1$, and $H'(x) = 4x \neq f(x)$. Thus, $H(x) = F(x) + G(x)$ is not an antiderivative of $f(x)$.

33. Any function for which the area between the function's graph above the x-axis is equal to the area between the function's graph below the x-axis will work. One such function, $f(x) = 1 - x$, is shown in Figure 6.25.

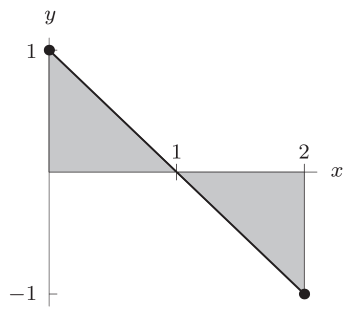

Figure 6.25: $f(x) = 1 - x$

34. Any positive function will work. One such function is $f(x) = 1$; see Figure 6.26.

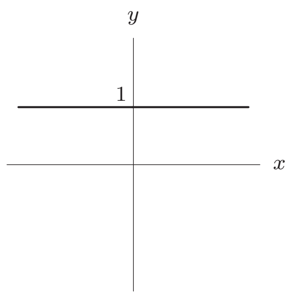

Figure 6.26

35. True. A function can have only one derivative.

36. False. If $f(t)$ is an increasing function, then F' is increasing, so F changes at an increasing rate. Thus F is not linear.

11. e^z

12. $-\cos t$

13. $\frac{2}{3}t^3 + \frac{3}{4}t^4 + \frac{4}{5}t^5$

14. $\dfrac{t^4}{4} - \dfrac{t^3}{6} - \dfrac{t^2}{2}$

15. $\dfrac{t^2+1}{t} = t + \dfrac{1}{t}$, which has antiderivative $\dfrac{t^2}{2} + \ln|t|$

16. $\dfrac{5}{2}x^2 - \dfrac{2}{3}x^{\frac{3}{2}}$

17. $F(t) = \displaystyle\int 6t\,dt = 3t^2 + C$

18. $H(x) = \displaystyle\int (x^3 - x)\,dx = \dfrac{x^4}{4} - \dfrac{x^2}{2} + C$

19. $F(x) = \displaystyle\int (x^2 - 4x + 7)\,dx = \dfrac{x^3}{3} - 2x^2 + 7x + C$

20. $G(t) = \displaystyle\int \sqrt{t}\,dt = \dfrac{2}{3}t^{3/2} + C$

21. $R(t) = \displaystyle\int (t^3 + 5t - 1)\,dt = \dfrac{t^4}{4} + \dfrac{5}{2}t^2 - t + C$

22. $F(z) = \displaystyle\int (z + e^z)\,dz = \dfrac{z^2}{2} + e^z + C$

23. $G(x) = \displaystyle\int (\sin x + \cos x)\,dx = -\cos x + \sin x + C$

24. $H(x) = \displaystyle\int (4x^3 - 7)\,dx = x^4 - 7x + C$

25. $P(t) = \displaystyle\int \dfrac{1}{\sqrt{t}}\,dt = 2t^{1/2} + C$

26. $P(t) = \displaystyle\int (2 + \sin t)\,dt = 2t - \cos t + C$

27. $G(x) = \displaystyle\int \dfrac{5}{x^3}\,dx = -\dfrac{5}{2x^2} + C$

28. $H(t) = \int \frac{7}{\cos^2 t}\,dt = 7\tan t + C$

29. $f(x) = 3$, so $F(x) = 3x + C$. $F(0) = 0$ implies that $3 \cdot 0 + C = 0$, so $C = 0$. Thus $F(x) = 3x$ is the only possibility.

30. $f(x) = 2x$, so $F(x) = x^2 + C$. $F(0) = 0$ implies that $0^2 + C = 0$, so $C = 0$. Thus $F(x) = x^2$ is the only possibility.

31. $f(x) = -7x$, so $F(x) = \frac{-7x^2}{2} + C$. $F(0) = 0$ implies that $-\frac{7}{2} \cdot 0^2 + C = 0$, so $C = 0$. Thus $F(x) = -7x^2/2$ is the only possibility.

32. $f(x) = 2 + 4x + 5x^2$, so $F(x) = 2x + 2x^2 + \frac{5}{3}x^3 + C$. $F(0) = 0$ implies that $C = 0$. Thus $F(x) = 2x + 2x^2 + \frac{5}{3}x^3$ is the only possibility.

33. $f(x) = \frac{1}{4}x$, so $F(x) = \frac{x^2}{8} + C$. $F(0) = 0$ implies that $\frac{1}{8} \cdot 0^2 + C = 0$, so $C = 0$. Thus $F(x) = x^2/8$ is the only possibility.

34. $f(x) = x^2$, so $F(x) = \dfrac{x^3}{3} + C$. $F(0) = 0$ implies that $\dfrac{0^3}{3} + C = 0$, so $C = 0$. Thus $F(x) = \dfrac{x^3}{3}$ is the only possibility.

35. $f(x) = x^{1/2}$, so $F(x) = \frac{2}{3}x^{3/2} + C$. $F(0) = 0$ implies that $\frac{2}{3} \cdot 0^{3/2} + C = 0$, so $C = 0$. Thus $F(x) = \frac{2}{3}x^{3/2}$ is the only possibility.

36. $f(x) = \sin x$, so $F(x) = -\cos x + C$. $F(0) = 0$ implies that $-\cos 0 + C = 0$, so $C = 1$. Thus $F(x) = -\cos x + 1$ is the only possibility.

37. $\frac{5}{2}x^2 + 7x + C$

38. $\int (4t + \frac{1}{t})\,dt = 2t^2 + \ln|t| + C$

39. $\int (2 + \cos t)\,dt = 2t + \sin t + C$

40. $\int 7e^x\,dx = 7e^x + C$

41. $\int (3e^x + 2\sin x)\,dx = 3e^x - 2\cos x + C$

42. We have:

$$\begin{aligned}\int (4e^x - 3\sin x)\ dx &= \int 4e^x\,dx - \int 3\sin x\,dx \\ &= 4\int e^x\,dx - 3\int \sin x\,dx \\ &= 4e^x - 3(-\cos x) + C \\ &= 4e^x + 3\cos x + C.\end{aligned}$$

43. We have

$$\begin{aligned}\int \left(5x^2 + 2\sqrt{x}\right)\ dx &= \int 5x^2\,dx + \int 2\sqrt{x}\,dx \\ &= 5\int x^2\,dx + 2\int x^{1/2}\,dx \\ &= 5\left(\frac{1}{3}x^3\right) + 2\left(\frac{2}{3}\cdot x^{3/2}\right) + C \\ &= \frac{5}{3}\cdot x^3 + \frac{4}{3}\cdot x^{3/2} + C.\end{aligned}$$

44. $\int (x+3)^2\,dx = \int (x^2 + 6x + 9)\,dx = \dfrac{x^3}{3} + 3x^2 + 9x + C$

45. $\int \frac{8}{\sqrt{x}}\,dx = 16x^{1/2} + C$

46. $3\ln|t| + \dfrac{2}{t} + C$

47. $e^x + 5x + C$

48. Expand the integrand and then integrate

$$\int t^3(t^2+1)\,dt = \int (t^5+t^3)\,dt = \frac{1}{6}t^6 + \frac{1}{4}t^4 + C.$$

49. $\frac{2}{5}x^{5/2} - 2\ln|x| + C$

50. Since $f(x) = \dfrac{x+1}{x} = 1 + \dfrac{1}{x}$, the indefinite integral is $x + \ln|x| + C$

51. $\displaystyle\int_0^3 (x^2+4x+3)\,dx = \left(\frac{x^3}{3} + 2x^2 + 3x\right)\Big|_0^3 = (9+18+9) - 0 = 36$

52. $\displaystyle\int_1^3 \frac{1}{t}\,dt = \ln|t|\Big|_1^3 = \ln|3| - \ln|1| = \ln 3 \approx 1.0986.$

53. $\displaystyle\int_0^{\pi/4} \sin x\,dx = -\cos x\Big|_0^{\pi/4} = -\cos\frac{\pi}{4} - (-\cos 0) = -\frac{\sqrt{2}}{2} + 1 = 0.293.$

54. $\displaystyle\int_0^1 2e^x\,dx = 2e^x\Big|_0^1 = 2e - 2 \approx 3.437.$

55. $\displaystyle\int_0^2 3e^x\,dx = 3e^x\Big|_0^2 = 3e^2 - 3e^0 = 3e^2 - 3 = 19.167.$

56. $\displaystyle\int_2^5 (x^3 - \pi x^2)\,dx = \left(\frac{x^4}{4} - \frac{\pi x^3}{3}\right)\Big|_2^5 = \frac{609}{4} - 39\pi \approx 29.728.$

57. $\displaystyle\int_0^1 \sin\theta\,d\theta = -\cos\theta\Big|_0^1 = 1 - \cos 1 \approx 0.460.$

58. Since $\dfrac{1+y^2}{y} = \dfrac{1}{y} + y,$

$$\int_1^2 \frac{1+y^2}{y}\,dy = \left(\ln|y| + \frac{y^2}{2}\right)\Big|_1^2 = \ln 2 + \frac{3}{2} \approx 2.193.$$

59. $\displaystyle\int_0^2 \left(\frac{x^3}{3} + 2x\right)dx = \left(\frac{x^4}{12} + x^2\right)\Big|_0^2 = \frac{4}{3} + 4 = 16/3 \approx 5.333.$

60. $\displaystyle\int_0^{\pi/4} (\sin t + \cos t)\,dt = (-\cos t + \sin t)\Big|_0^{\pi/4} = \left(-\frac{\sqrt{2}}{2} + \frac{\sqrt{2}}{2}\right) - (-1+0) = 1.$

Problems

61. The rate at which water is entering the tank (in volume per unit time) is

$$\frac{dV}{dt} = 120 - 6t \text{ ft}^3/\text{min}.$$

Thus, the total quantity of water in the tank at time $t = 4$, in ft^3, is

$$V = \int_0^4 (120 - 6t)\,dt.$$

Since an antiderivative to $120 - 6t$ is

$$120t - 3t^2,$$

we have

$$\begin{aligned} V &= \int_0^4 (120-6t)\,dt = (120t - 3t^2)\Big|_0^4 \\ &= (120\cdot 4 - 3\cdot 4^2) - (120\cdot 0 - 3\cdot 0^2) \\ &= 432 \text{ ft}^3. \end{aligned}$$

The radius is 5 feet, so if the height is h ft, the volume is $V = \pi 5^2 h = 25\pi h$. Thus, at time $t = 4$, we have $V = 432$, so

$$\begin{aligned} 432 &= 25\pi h \\ h &= \frac{432}{25\pi} = 5.500 \text{ ft.} \end{aligned}$$

62. (a) The formula $v = 6 - 2t$ implies that $v > 0$ (the car is moving forward) if $0 \le t < 3$ and that $v < 0$ (the car is moving backward) if $t > 3$. When $t = 3$, $v = 0$, so the car is not moving at the instant $t = 3$. The car is decelerating when $|v|$ is decreasing; since v decreases (from 6 to 0) on the interval $0 \le t < 3$, the car decelerates on that interval. The car accelerates when $|v|$ is increasing, which occurs on the domain $t > 3$.

(b) The car moves forward on the interval $0 \le t < 3$, so it is furthest to the right at $t = 3$. For all $t > 3$, the car is decelerating. There is no upper bound on the car's distance behind its starting point since it is decelerating for all $t > 3$.

(c) Let $s(t)$ be the position of the car at time t. Then

$$v(t) = s'(t),$$

so $s(t)$ is an antiderivative of $v(t)$. Thus,

$$s(t) = \int v(t)\,dt = \int (6 - 2t)\,dt = 6t - t^2 + C.$$

Since the car's position is measured from its starting point, we have $s(0) = 0$, so $C = 0$. Thus, $s(t) = 6t - t^2$.

63. (a) Since the rotor is slowing down at a constant rate,

$$\text{Angular acceleration } = \frac{260 - 350}{1.5} = -60 \text{ revs/min}^2.$$

Units are revolutions per minute per minute, or revs/min^2.

(b) To decrease from 350 to 0 revs/min at a deceleration of 60 revs/min^2,

$$\text{Time needed } = \frac{350}{60} \approx 5.83 \text{ min.}$$

(c) We know angular acceleration is the derivative of angular velocity. Since

$$\text{Angular acceleration } = -60 \text{ revs/min}^2,$$

we have

$$\text{Angular velocity } = -60t + C.$$

Measuring time from the moment when angular velocity is 350 revs/min, we get $C = 350$. Thus

$$\text{Angular velocity } = -60t + 350.$$

So, the total number of revolutions made between the time the angular speed is 350 revs/min and stopping is given by:

$$\begin{aligned} \text{Number of revolutions } &= \int_0^{5.83} (\text{Angular velocity})\,dt \\ &= \int_0^{5.83} (-60t + 350)dt = -30t^2 + 350t \Big|_0^{5.83} \\ &= 1020.83 \text{ revolutions.} \end{aligned}$$

64. Since $C'(x) = 4000 + 10x$ we want to evaluate the indefinite integral

$$\int (4000 + 10x)\,dx = 4000x + 5x^2 + K$$

where K is a constant. Thus $C(x) = 5x^2 + 4000x + K$, and the fixed cost of 1,000,000 riyal means that $C(0) = 1{,}000{,}000 = K$. Therefore, the total cost is

$$C(x) = 5x^2 + 4000x + 1{,}000{,}000.$$

Since $C(x)$ depends on x^2, the square of the depth drilled, costs will increase dramatically when x grows large.

65. $\displaystyle\int_0^3 x^2\,dx = \frac{x^3}{3}\Bigg|_0^3 = 9 - 0 = 9.$

66. Since $y = x^3 - x = x(x-1)(x+1)$, the graph crosses the axis at the three points shown in Figure 6.27. The two regions have the same area (by symmetry). Since the graph is below the axis for $0 < x < 1$, we have

$$\begin{aligned}\text{Area } &= 2\left(-\int_0^1 \left(x^3 - x\right)\,dx\right)\\ &= -2\left[\frac{x^4}{4} - \frac{x^2}{2}\right]_0^1 = -2\left(\frac{1}{4} - \frac{1}{2}\right) = \frac{1}{2}.\end{aligned}$$

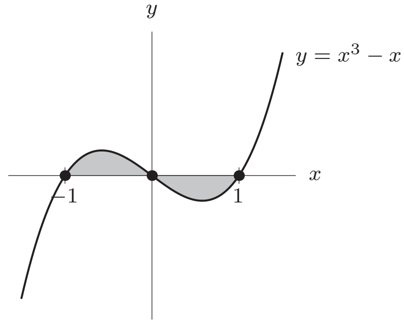

Figure 6.27

67. The area we want (the shaded area in Figure 6.28) is symmetric about the y-axis and so is given by

$$\begin{aligned}\text{Area } &= 2\int_0^{\pi/3}\left(\cos x - \frac{1}{2}\left(\frac{3}{\pi}x\right)^2\right)\,dx\\ &= 2\int_0^{\pi/3}\cos x\,dx - \int_0^{\pi/3}\frac{9}{\pi^2}x^2\,dx\\ &= 2\sin x\Bigg|_0^{\pi/3} - \frac{9}{\pi^2}\cdot\frac{x^3}{3}\Bigg|_0^{\pi/3}\\ &= 2\cdot\frac{\sqrt{3}}{2} - \frac{3}{\pi^2}\cdot\frac{\pi^3}{3^3} = \sqrt{3} - \frac{\pi}{9}.\end{aligned}$$

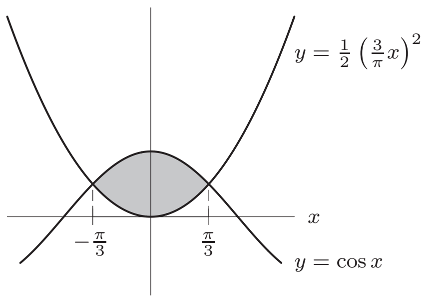

Figure 6.28

68. Since $y < 0$ from $x = 0$ to $x = 1$ and $y > 0$ from $x = 1$ to $x = 3$, we have

$$\begin{aligned}\text{Area} &= -\int_0^1 \left(3x^2 - 3\right)\,dx + \int_1^3 \left(3x^2 - 3\right)\,dx\\ &= -\left(x^3 - 3x\right)\Bigg|_0^1 + \left(x^3 - 3x\right)\Bigg|_1^3\\ &= -(-2 - 0) + (18 - (-2)) = 2 + 20 = 22.\end{aligned}$$

69. (a) See Figure 6.29. Since $f(x) > 0$ for $0 < x < 2$ and $f(x) < 0$ for $2 < x < 5$, we have

$$\begin{aligned}
\text{Area} &= \int_0^2 f(x)\,dx - \int_2^5 f(x)\,dx \\
&= \int_0^2 (x^3 - 7x^2 + 10x)\,dx - \int_2^5 (x^3 - 7x^2 + 10x)\,dx \\
&= \left(\frac{x^4}{4} - \frac{7x^3}{3} + 5x^2\right)\Bigg|_0^2 - \left(\frac{x^4}{4} - \frac{7x^3}{3} + 5x^2\right)\Bigg|_2^5 \\
&= \left[\left(4 - \frac{56}{3} + 20\right) - (0 - 0 + 0)\right] - \left[\left(\frac{625}{4} - \frac{875}{3} + 125\right) - \left(4 - \frac{56}{3} + 20\right)\right] \\
&= \frac{253}{12}.
\end{aligned}$$

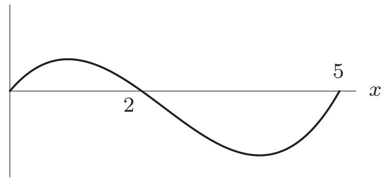

Figure 6.29: Graph of $f(x) = x^3 - 7x^2 + 10x$

(b) Calculating $\int_0^5 f(x)\,dx$ gives

$$\begin{aligned}
\int_0^5 f(x)\,dx &= \int_0^5 (x^3 - 7x^2 + 10x)\,dx \\
&= \left(\frac{x^4}{4} - \frac{7x^3}{3} + 5x^2\right)\Bigg|_0^5 \\
&= \left(\frac{625}{4} - \frac{875}{3} + 125\right) - (0 - 0 + 0) \\
&= -\frac{125}{12}.
\end{aligned}$$

This integral measures the difference between the area above the x-axis and the area below the x-axis. Since the definite integral is negative, the graph of $f(x)$ lies more below the x-axis than above it. Since the function crosses the axis at $x = 2$,

$$\int_0^5 f(x)\,dx = \int_0^2 f(x)\,dx + \int_2^5 f(x)\,dx = \frac{16}{3} - \frac{63}{4} = \frac{-125}{12},$$

whereas

$$\text{Area} = \int_0^2 f(x)\,dx - \int_2^5 f(x)\,dx = \frac{16}{3} + \frac{64}{4} = \frac{253}{12}.$$

70. The graph of $y = e^x - 2$ is below the x-axis at $x = 0$ and above the x-axis at $x = 2$. The graph crosses the axis where

$$\begin{aligned}
e^x - 2 &= 0 \\
x &= \ln 2.
\end{aligned}$$

See Figure 6.30. Thus we find the area by dividing the region at $x = \ln 2$:

$$\begin{aligned}
\text{Area} &= -\int_0^{\ln 2} (e^x - 2)\,dx + \int_{\ln 2}^2 (e^x - 2)\,dx \\
&= (-e^x + 2x)\Bigg|_0^{\ln 2} + (e^x - 2x)\Bigg|_{\ln 2}^2 \\
&= -e^{\ln 2} + 2\ln 2 + e^0 + e^2 - 4 - (e^{\ln 2} - 2\ln 2) \\
&= -2e^{\ln 2} + 4\ln 2 - 3 + e^2 \\
&= -2 \cdot 2 + 4\ln 2 - 3 + e^2 = e^2 + 4\ln 2 - 7.
\end{aligned}$$

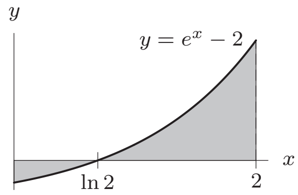

Figure 6.30

71. Solving $x^2 = 2 - x^2$ shows that the curves intersect at $x = \pm 1$. To find the area between the curves for $-1 \le x \le 1$ we integrate the top curve $y = 2 - x^2$ minus the bottom curve $y = x^2$. Thus

$$\text{Area between curves} = \int_{-1}^{1} (2 - x^2 - x^2)\,dx = 2x - \frac{2}{3}x^3\Big|_{-1}^{1} = 2 - \frac{2}{3} - \left(-2 + \frac{2}{3}\right) = \frac{8}{3}.$$

72. The function is a cubic polynomial which crosses the x-axis at $x = 1, 2, 3$, with $f(x) \ge 0$ for $1 \le x \le 2$ and $f(x) \le 0$ for $2 \le x \le 3$. Thus the total area is given by

$$\text{Total area} = \int_1^2 f(x)\,dx + \left|\int_2^3 f(x)\,dx\right|.$$

Since $f(x) = x^3 - 6x^2 + 11x - 6$, we can evaluate each integral to get

$$\text{Total area} = \left(\frac{x^4}{4} - 2x^3 + \frac{11}{2}x^2 - 6x\right)\Big|_1^2 + \left|\left(\frac{x^4}{4} - 2x^3 + \frac{11}{2}x^2 - 6x\right)\Big|_2^3\right| = \frac{1}{4} + \left|-\frac{1}{4}\right| = \frac{1}{2}.$$

73. The graph of $y = e^x - 2$ starts below the x-axis at $x = 0$ and climbs. See Figure 6.31. The graph crosses the axis where

$$e^x = 2$$
$$x = \ln 2.$$

Since the integral

$$\int_0^c (e^x - 2)\,dx = -A_1 + A_2,$$

we choose c to make the integral 0:

$$\int_0^c (e^x - 2)\,dx = (e^x - 2x)\Big|_0^c = e^c - 2c - 1 = 0$$
$$e^c - 2c = 1.$$

Solving numerically (for example, by zooming in on the graph on a calculator), we get

$$c = 0 \quad \text{and} \quad c = 1.257.$$

The solution we want is $c = 1.257$.

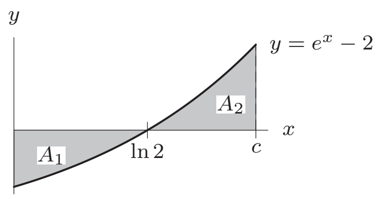

Figure 6.31

74. Since the area under the curve is 6, we have

$$\int_1^b \frac{1}{\sqrt{x}}\,dx = 2x^{1/2}\Big|_1^b = 2b^{1/2} - 2(1) = 6.$$

Thus $b^{1/2} = 4$ and $b = 16$.

75. The graph of $y = c(1-x^2)$ has x-intercepts of $x = \pm 1$. See Figure 6.32. Since it is symmetric about the y-axis, we have

$$\begin{aligned}\text{Area } &= \int_{-1}^1 c(1-x^2)\,dx = 2c\int_0^1 (1-x^2)\,dx \\ &= 2c\left(x - \frac{x^3}{3}\right)\Big|_0^1 = \frac{4c}{3}.\end{aligned}$$

We want the area to be 1, so

$$\frac{4c}{3} = 1, \quad \text{giving} \quad c = \frac{3}{4}.$$

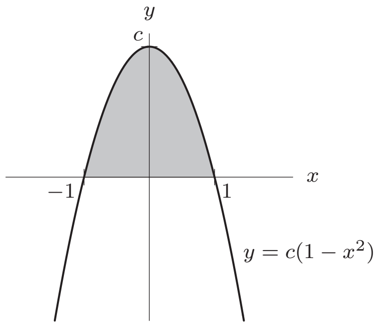

Figure 6.32

76. The curves intersect at $(0,0)$ and $(\pi, 0)$. At any x-coordinate the "height" between the two curves is $\sin x - x(x-\pi)$. See Figure 6.33.

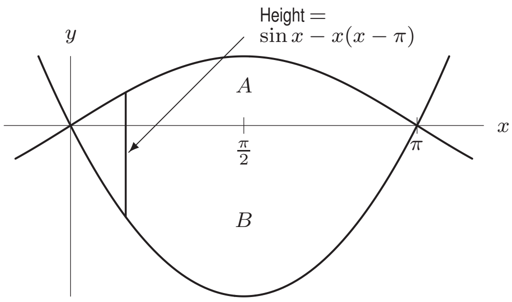

Figure 6.33

Thus the total area is

$$\begin{aligned}\int_0^\pi [\sin x - x(x-\pi)]\,dx = &= \int_0^\pi (\sin x - x^2 + \pi x)\,dx \\ &= \left(-\cos x - \frac{x^3}{3} + \frac{\pi x^2}{2}\right)\Big|_0^\pi \\ &= \left(1 - \frac{\pi^3}{3} + \frac{\pi^3}{2}\right) - (-1) \\ &= 2 + \frac{\pi^3}{6}.\end{aligned}$$

Another approach is to notice that the area between the two curves is (area A) + (area B).

$$\begin{aligned}\text{Area B} &= -\int_0^\pi x(x-\pi)\,dx \text{ since the function is negative on } 0 \le x \le \pi \\ &= -\left(\frac{x^3}{3} - \frac{\pi x^2}{2}\right)\Bigg|_0^\pi = \frac{\pi^3}{2} - \frac{\pi^3}{3} = \frac{\pi^3}{6}; \\ \text{Area A} &= \int_0^\pi \sin x\,dx = -\cos x\Bigg|_0^\pi = 2.\end{aligned}$$

Thus the area is $2 + \dfrac{\pi^3}{6}$.

77. See Figure 6.34. The average value of $f(x)$ is given by

$$\text{Average } = \frac{1}{9-0}\int_0^9 \sqrt{x}\,dx = \frac{1}{9}\left(\frac{2}{3}x^{3/2}\Bigg|_0^9\right) = \frac{1}{9}\left(\frac{2}{3}9^{3/2} - 0\right) = \frac{1}{9}18 = 2.$$

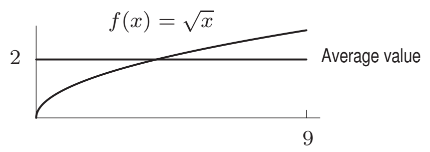

Figure 6.34

78. We have

$$\begin{aligned} f\left(x^{-1}\right) &= 4\left(x^{-1}\right)^{-3} \qquad \text{because } f(x) = 4x^{-3} \\ &= 4x^3 \\ \text{so} \quad \int_1^3 f\left(x^{-1}\right)\,dx &= \int_1^3 4x^3\,dx \\ &= 4\left(\frac{1}{4}\right)x^4\Bigg|_1^3 \\ &= 3^4 - 1^4 = 80.\end{aligned}$$

79. By the Fundamental theorem,

$$\int_1^3 f'(x)\,dx = f(3) - f(1) = 4x^{-3}\Bigg|_1^3 = 4\cdot 3^{-3} - 4\cdot 1^{-3} = -3.8519.$$

80. The curves $y = x$ and $y = x^n$ cross at $x = 0$ and $x = 1$. For $0 < x < 1$, the curve $y = x$ is above $y = x^n$. Thus the area is given by

$$A_n = \int_0^1 (x - x^n)d\,x = \left[\frac{x^2}{2} - \frac{x^{n+1}}{n+1}\right]_0^1 = \frac{1}{2} - \frac{1}{n+1} \to \frac{1}{2}.$$

Since $x^n \to 0$ for $0 \le x < 1$, as $n \to \infty$, the area between the curves approaches the area under the line $y = x$ between $x = 0$ and $x = 1$.

81. (a) Recall that $x = e^{\ln x}$. Thus $x^x = (e^{\ln x})^x = e^{x\ln x}$.

(b) Using part (a) and the chain rule

$$\frac{d}{dx}(x^x) = \frac{d}{dx}(e^{x\ln x}) = e^{x\ln x}\frac{d}{dx}(x\ln x) = e^{x\ln x}(\ln x + 1) = x^x(\ln x + 1).$$

(c) By the Fundamental Theorem of Calculus and part (b),

$$\int x^x(1 + \ln x)\,dx = x^x + C.$$

(d) By the Fundamental Theorem of Calculus,

$$\int_1^2 x^x(1+\ln x)dx = x^x\Big|_1^2 = 2^2 - 1^1 = 3.$$

Using a calculator, we get $\int_1^2 x^x(1+\ln x)\,dx = 3$.

82. (a) The average value of $f(t) = \sin t$ over $0 \le t \le 2\pi$ is given by the formula

$$\begin{aligned}\text{Average} &= \frac{1}{2\pi - 0}\int_0^{2\pi} \sin t\,dt \\ &= \frac{1}{2\pi}(-\cos t)\Big|_0^{2\pi} \\ &= \frac{1}{2\pi}(-\cos 2\pi - (-\cos 0)) = 0.\end{aligned}$$

We can check this answer by looking at the graph of $\sin t$ in Figure 6.35. The area below the curve and above the t-axis over the interval $0 \le t \le \pi$, A_1, is the same as the area above the curve but below the t-axis over the interval $\pi \le t \le 2\pi$, A_2. When we take the integral of $\sin t$ over the entire interval $0 \le t \le 2\pi$, we get $A_1 - A_2 = 0$.

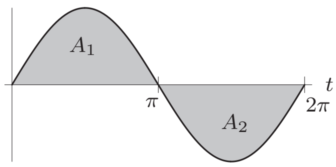

Figure 6.35

(b) Since

$$\int_0^{\pi} \sin t\,dt = -\cos t\Big|_0^{\pi} = -\cos\pi - (-\cos 0) = -(-1) - (-1) = 2,$$

the average value of $\sin t$ on $0 \le t \le \pi$ is given by

$$\text{Average value } = \frac{1}{\pi}\int_0^{\pi} \sin t\,dt = \frac{2}{\pi}.$$

83. The area beneath the curve in Figure 6.36 is given by

$$\int_0^a y\,dx = \int_0^a (\sqrt{a} - \sqrt{x})^2 dx = \left[a\,x - \frac{4\sqrt{a}\,x^{3/2}}{3} + \frac{x^2}{2}\right]_0^a = \frac{a^2}{6}.$$

The area of the square is a^2 so the area above the curve is $5a^2/6$. Thus, the ratio of the areas is 5 to 1.

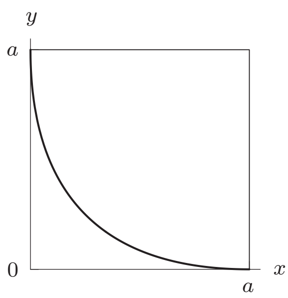

Figure 6.36: The curve $\sqrt{x} + \sqrt{y} = \sqrt{a}$

Strengthen Your Understanding

84. We cannot integrate the numerator and denominator separately. Using the quotient rule to differentiate we see that

$$\frac{d}{dx}\left(\frac{x^3+x}{x^2}+C\right)=\frac{(3x^2+1)(x^2)-(x^3+x)(2x)}{x^4},$$

which is not equal to $\frac{3x^2+1}{2x}$.

To compute the correct integral, we can split the integrand into two terms:

$$\int\frac{3x^2+1}{2x}\,dx=\int\left(\frac{3}{2}x+\frac{1}{2x}\right)\,dx=\frac{3}{4}x^2+\frac{1}{2}\ln|x|+C.$$

85. The statement is true for all $n\neq-1$, since $\int x^{-1}\,dx=\ln|x|+C$.

86. If two functions $F(x)$ and $G(x)$ differ by a constant, they have the same derivative. Therefore, $F(x)=x^4$ and $G(x)=x^4-8$ both have the same derivative.

87. We are given $F(x)=mx+C$ with m a negative constant. Since $F'(x)=f(x)=m$, any negative constant function will work, for example $f(x)=-1$.

88. True. Check by differentiating $\frac{d}{dx}(2(x+1)^{3/2})=2\cdot\frac{3}{2}(x+1)^{1/2}=3\sqrt{x+1}$.

89. True. Any antiderivative of $3x^2$ is obtained by adding a constant to x^3.

90. True. Any antiderivative of $1/x$ is obtained by adding a constant to $\ln|x|$.

91. False. Differentiating using the product and chain rules gives

$$\frac{d}{dx}\left(\frac{-1}{2x}e^{-x^2}\right)=\frac{1}{2x^2}e^{-x^2}+e^{-x^2}.$$

92. False. It is not true in general that $\int xf(x)\,dx=x\int f(x)\,dx$, so this statement is false for many functions $f(x)$. For example, if $f(x)=1$, then $\int xf(x)\,dx=x^2/2+C$, but $x\int f(x)\,dx=x(x+C)$.

93. True. Adding a constant to an antiderivative gives another antiderivative.

94. True. Since $F(x)$ and $G(x)$ are antiderivatives of the same function on an interval, $F(x)-G(x)$ is a constant function. Thus $F(10)-G(10)=F(5)-G(5)>0$.

95. False. For a counterexample, take $f(x)=g(x)=1$. Then $F(x)=x$ and $G(x)=x$ are antiderivatives of $f(x)$ and $g(x)$, but $F(x)\cdot G(x)=x^2$ is not an antiderivative of $f(x)\cdot g(x)=1$.

96. True. The derivative of $F(x)-G(x)$ is $(F(x)-G(x))'=f(x)-f(x)=0$, so $F(x)-G(x)$ is a constant function.

Solutions for Section 6.3

Exercises

1. We differentiate $y=xe^{-x}+2$ using the product rule to obtain

$$\begin{aligned}\frac{dy}{dx}&=x\left(e^{-x}(-1)\right)+(1)e^{-x}+0\\&=-xe^{-x}+e^{-x}\\&=(1-x)e^{-x},\end{aligned}$$

and so $y=xe^{-x}+2$ satisfies the differential equation. We now check that $y(0)=2$:

$$\begin{aligned}y&=xe^{-x}+2\\y(0)&=0e^0+2=2.\end{aligned}$$

2. First, we check that $y = \sin(2t)$ satisfies the initial condition $y(0) = 0$:

$$\sin(2 \cdot 0) = 0.$$

Next, we substitute $y = \sin(2t)$ into each side of the differential equation and check that we get the same result. The left-hand side gives

$$\frac{dy}{dt} = 2\cos(2t).$$

For $0 \le t \le \pi/4$, the right-hand side gives

$$2\sqrt{1-y^2} = 2\sqrt{1-\sin^2(2t)} = 2\cos(2t).$$

Thus for $0 \le t \le \pi/4$ the initial value problem is satisfied.

3. We need to find a function whose derivative is $2x$, so one antiderivative is x^2. The general solution is

$$y = x^2 + C.$$

To check, we differentiate to get

$$\frac{dy}{dx} = \frac{d}{dx}\left(x^2 + C\right) = 2x,$$

as required.

4. We need to find a function whose derivative is t^2, so one antiderivative is $t^3/3$. The general solution is

$$y = \frac{t^3}{3} + C.$$

To check, we differentiate to get

$$\frac{dy}{dt} = \frac{d}{dt}\left(\frac{t^3}{3} + C\right) = t^2,$$

as required.

5. We need to find a function whose derivative is $x^3 + 5x^4$, so one antiderivative is $x^4/4 + x^5$. The general solution is

$$y = \frac{x^4}{4} + x^5 + C.$$

To check, we differentiate to get

$$\frac{dy}{dx} = \frac{d}{dx}\left(\frac{x^4}{4} + x^5 + C\right) = x^3 + 5x^4,$$

as required.

6. We need to find a function whose derivative is e^t, so one antiderivative is e^t. The general solution is

$$y = e^t + C.$$

To check, we differentiate to get

$$\frac{dy}{dt} = \frac{d}{dt}\left(e^t + C\right) = e^t,$$

as required.

7. We need to find a function whose derivative is $\cos x$, so one antiderivative is $\sin x$. The general solution is

$$y = \sin x + C.$$

To check, we differentiate to get

$$\frac{dy}{dx} = \frac{d}{dx}(\sin x + C) = \cos x,$$

as required.

8. We need to find a function whose derivative is $1/x$, so one antiderivative is $\ln x$. The general solution is

$$y = \ln x + C.$$

To check, we differentiate to get

$$\frac{dy}{dx} = \frac{d}{dx}(\ln x + C) = \frac{1}{x},$$

as required.

9. Integrating gives
$$\int \frac{dy}{dx}\,dx = \int (3x^2)\,dx = x^3 + C.$$
If $y = 5$ when $x = 0$, then $0^3 + C = 5$ so $C = 5$. Thus $y = x^3 + 5$.

10. Integrating gives
$$\int \frac{dy}{dx}\,dx = \int (x^5 + x^6)\,dx = \frac{x^6}{6} + \frac{x^7}{7} + C.$$
If $y = 2$ when $x = 1$, then $1^6/6 + 1^7/7 + C = 2$ so
$$C = 2 - \frac{1}{6} - \frac{1}{7} = \frac{71}{42}.$$
Thus
$$y = \frac{x^6}{6} + \frac{x^7}{7} + \frac{71}{42}.$$

11. Integrating gives
$$\int \frac{dy}{dx}\,dx = \int (e^x)\,dx = e^x + C.$$
If $y = 7$ when $x = 0$, then $e^0 + C = 7$ so $C = 6$. Thus $y = e^x + 6$.

12. Integrating gives
$$\int \frac{dy}{dx}\,dx = \int (\sin x)\,dx = -\cos x + C.$$
If $y = 3$ when $x = 0$, then $-\cos 0 + C = 3$ so $C = 4$. Thus $y = -\cos x + 4$.

Problems

13. The acceleration is $a(t) = -32$, so the velocity is $v(t) = -32t + C$. We find C using $v(0) = -10$, (negative velocity is downward) so
$$v(t) = -32t - 10.$$
Then, the height of the rock above the water is
$$s(t) = -16t^2 - 10t + D.$$
We find D using $s(0) = 100$, so
$$s(t) = -16t^2 - 10t + 100.$$
Now we can find when the rock hits the water by solving the quadratic equation
$$0 = -16t^2 - 10t + 100.$$
There are two solutions: $t = 2.207$ seconds and $t = -2.832$ seconds. We discard the negative solution. So, at $t = 2.207$ the rock is traveling with a velocity of
$$v(2.207) = -32(2.207) - 10 = -80.624 \text{ ft/sec}.$$
Thus the rock is traveling with a speed of 80.624 ft/sec downward when it hits the water.

14. (a) To find the height of the balloon, we integrate its velocity with respect to time:
$$\begin{aligned} h(t) &= \int v(t)\,dt \\ &= \int (-32t + 40)\,dt \\ &= -32\frac{t^2}{2} + 40t + C. \end{aligned}$$
Since at $t = 0$, we have $h = 30$, we can solve for C to get $C = 30$, giving us a height of
$$h(t) = -16t^2 + 40t + 30.$$

(b) To find the average velocity between $t = 1.5$ and $t = 3$, we find the total displacement and divide by time.

$$\text{Average velocity} = \frac{h(3) - h(1.5)}{3 - 1.5} = \frac{6 - 54}{1.5} = -32 \text{ ft/sec}.$$

The balloon's average velocity is 32 ft/sec downward.

(c) First, we must find the time when $h(t) = 6$. Solving the equation $-16t^2 + 40t + 30 = 6$, we get

$$\begin{aligned}6 &= -16t^2 + 40t + 30\\ 0 &= -16t^2 + 40t + 24\\ 0 &= 2t^2 - 5t - 3\\ 0 &= (2t + 1)(t - 3).\end{aligned}$$

Thus, $t = -1/2$ or $t = 3$. Since $t = -1/2$ makes no physical sense, we use $t = 3$ to calculate the balloon's velocity. At $t = 3$, we have a velocity of $v(3) = -32(3) + 40 = -56$ ft/sec. So the balloon's velocity is 56 ft/sec downward at the time of impact.

15. Since the acceleration $a = dv/dt$, where v is the velocity of the car, we have

$$\frac{dv}{dt} = -0.6t + 4.$$

Integrating gives

$$v = -0.6\frac{t^2}{2} + 4t + C.$$

The car starts from rest, so $v = 0$ when $t = 0$, and therefore $C = 0$. If x is the distance from the starting point, $v = dx/dt$ and

$$\frac{dx}{dt} = -0.3t^2 + 4t,$$

so

$$x = -\frac{0.3}{3}t^3 + \frac{4}{2}t^2 + C = -0.1t^3 + 2t^2 + C.$$

Since $x = 0$ when $t = 0$, we have $C = 0$, so

$$x = -0.1t^3 + 2t^2.$$

We want to solve for t when $x = 100$:

$$100 = -0.1t^3 + 2t^2.$$

This equation can be rewritten as

$$\begin{aligned}0.1t^3 - 2t^2 + 100 &= 0\\ t^3 - 20t^2 + 1000 &= 0.\end{aligned}$$

The equation can be solved numerically, or by tracing along a graph, or by factoring

$$(t - 10)(t^2 - 10t - 100) = 0.$$

The solutions are $t = 10$ and $t = \frac{10 \pm \sqrt{500}}{2} = -6.18,\ 16.18$. Since we are told $0 \le t \le 12$, the solution we want is $t = 10$ sec.

16.

$$\begin{aligned}\frac{dy}{dt} &= k\sqrt{t} = kt^{1/2}\\ y &= \frac{2}{3}kt^{3/2} + C.\end{aligned}$$

Since $y = 0$ when $t = 0$, we have $C = 0$, so

$$y = \frac{2}{3}kt^{3/2}.$$

17. (a) Since

$$R'(p) = 25 - 2p$$
$$R(p) = \int (25 - 2p)\,dp = 25p - p^2 + C.$$

We assume that the revenue is 0 when the price is 0. Substituting gives

$$0 = 25 \cdot 0 - 0^2 + C$$
$$C = 0.$$

Thus

$$R(p) = 25p - p^2.$$

(b) The revenue increases with price if $R'(p) > 0$, that is $25 - 2p > 0$, so $p < 12.5$ dollars. The revenue decreases with price if $R'(p) < 0$, that is $25 - 2p < 0$, so $p > 12.5$.

18. (a) The marginal cost, MC, is found by differentiating the total cost function, C, with respect to q so $MC = C'(q)$. Thus the differential equation is

$$C'(q) = 3q^2 + 6q + 9.$$

(b) Solving the differential equation gives

$$C(q) = \int \left(3q^2 + 6q + 9\right)\,dq$$
$$= q^3 + 3q^2 + 9q + D,$$

where D is a constant. We can check this by noting

$$C'(q) = \frac{d}{dq}\left(q^3 + 3q^2 + 9q + D\right) = 3q^2 + 6q + 9 = MC.$$

The fixed costs are 400, so $C = 400$ when $q = 0$. Thus,

$$400 = 0^3 + 3 \cdot 0^2 + 9 \cdot 0 + D,$$

so $D = 400$. The total cost function is

$$C(q) = q^3 + 3q^2 + 9q + 400.$$

19. (a) Acceleration = $a(t) = -9.8$ m/sec^2
Velocity = $v(t) = -9.8t + 40$ m/sec
Height = $h(t) = -4.9t^2 + 40t + 25$ m
.

(b) At the highest point,

$$v(t) = -9.8t + 40 = 0,$$

so

$$t = \frac{40}{9.8} = 4.082 \text{ seconds.}$$

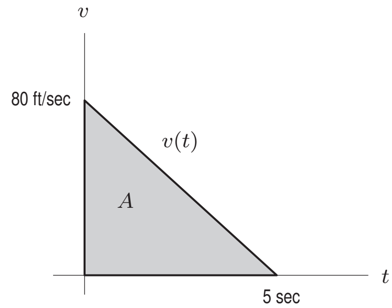
At that time, $h(4.082) = 106.633$ m. We see that the tomato reaches a height of 106.633 m, at 4.082 seconds after it is thrown.

(c) The tomato lands when $h(t) = 0$, so

$$-4.9t^2 + 40t + 25 = 0.$$

The solutions are $t = -0.583$ and $t = 8.747$ seconds. We see that it lands 8.747 seconds after it is thrown.

20. (a)



(b) The total distance is represented by the shaded region A, the area under the graph of $v(t)$.
(c) The area A, a triangle, is given by

$$A = \frac{1}{2}(\text{base})(\text{height}) = \frac{1}{2}(5\,\text{sec})(80\,\text{ft/sec}) = 200\,\text{ft}.$$

(d) Using integration and the Fundamental Theorem of Calculus, we have $A = \int_0^5 v(t)\,dt$ or $A = s(5) - s(0)$, where $s(t)$ is an antiderivative of $v(t)$.

We have that $a(t)$, the acceleration, is constant: $a(t) = k$ for some constant k. Therefore $v(t) = kt + C$ for some constant C. We have $80 = v(0) = k(0) + C = C$, so that $v(t) = kt + 80$. Putting in $t = 5$, $0 = v(5) = (k)(5) + 80$, or $k = -80/5 = -16$.

Thus $v(t) = -16t + 80$, and an antiderivative for $v(t)$ is $s(t) = -8t^2 + 80t + C$. Since the total distance traveled at $t = 0$ is 0, we have $s(0) = 0$ which means $C = 0$. Finally, $A = \int_0^5 v(t)\,dt = s(5) - s(0) = (-8(5)^2 + (80)(5)) - (-8(0)^2 + (80)(0)) = 200\,\text{ft}$, which agrees with the previous part.

21. (a) The velocity is decreasing at 32 ft/sec^2, the acceleration due to gravity.
(b) The graph is a line because the velocity is decreasing at a constant rate.
(c) The highest point is reached when the velocity is 0, which occurs when

$$\text{Time} = \frac{160}{32} = 5 \text{ sec}.$$

(d) The object hits the ground at $t = 10$ seconds, since by symmetry if the object takes 5 seconds to go up, it takes 5 seconds to come back down.
(e) See Figure 6.37.
(f) The maximum height is the distance traveled when going up, which is represented by the area A of the triangle above the time axis.

$$\text{Area} = \frac{1}{2}(160 \text{ ft/sec})(5 \text{ sec}) = 400 \text{ feet}.$$

(g) The slope of the line is -32 so

$$v(t) = -32t + 160.$$

Antidifferentiating, we get

$$s(t) = -16t^2 + 160t + s_0.$$

Since the object starts on the ground, $s_0 = 0$, so

$$s(t) = -16t^2 + 160t.$$

At $t = 5$, we have

$$s(t) = -400 + 800 = 400 \text{ ft}.$$

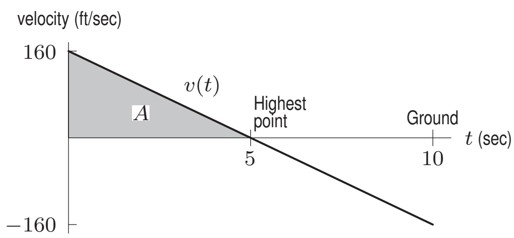


Figure 6.37

22. The equation of motion is $y = -\frac{gt^2}{2} + v_0 t + y_0 = -16t^2 + 128t + 320$. Taking the first derivative, we get $v = -32t + 128$. The second derivative gives us $a = -32$.

(a) At its highest point, the stone's velocity is zero:
$v = 0 = -32t + 128$, so $t = 4$.

(b) At $t = 4$, the height is $y = -16(4)^2 + 128(4) + 320 = 576$ ft

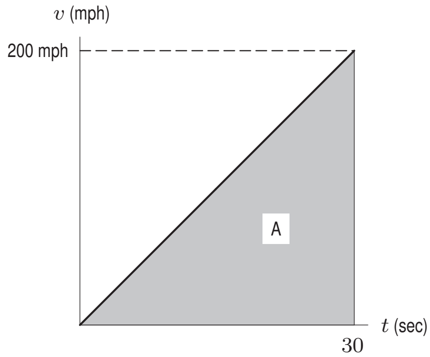
(c) When the stone hits the beach,

$$\begin{aligned} y = 0 &= -16t^2 + 128t + 320 \\ 0 &= -t^2 + 8t + 20 = (10 - t)(2 + t). \end{aligned}$$

So $t = 10$ seconds.

(d) Impact is at $t = 10$. The velocity, v, at this time is $v(10) = -32(10) + 128 = -192$ ft/sec. Upon impact, the stone's velocity is 192 ft/sec downward.

23. Since the acceleration is constant, a graph of the velocity versus time looks like this:



The distance traveled in 30 seconds, which is how long the runway must be, is equal to the area represented by A. We have $A = \frac{1}{2}(\text{base})(\text{height})$. First we convert the required velocity into miles per second.

$$\begin{aligned} 200 \text{ mph} &= \frac{200 \text{ miles}}{\text{hour}} \left(\frac{1 \text{ hour}}{60 \text{ minutes}}\right)\left(\frac{1 \text{ minute}}{60 \text{ seconds}}\right) \\ &= \frac{200}{3600} \frac{\text{miles}}{\text{second}} \\ &= \frac{1}{18} \text{ miles/second.} \end{aligned}$$

Therefore $A = \frac{1}{2}(30 \text{ sec})(200 \text{ mph}) = \frac{1}{2}(30 \text{ sec})\left(\frac{1}{18} \text{ miles/sec}\right) = \frac{5}{6}$ miles.

24. The height of an object above the ground which begins at rest and falls for t seconds is

$$s(t) = -16t^2 + K,$$

where K is the initial height. Here the flower pot falls from 200 ft, so $K = 200$. To see when the pot hits the ground, solve $-16t^2 + 200 = 0$. The solution is

$$t = \sqrt{\frac{200}{16}} \approx 3.54 \text{ seconds.}$$

Now, velocity is given by $s'(t) = v(t) = -32t$. So, the velocity when the pot hits the ground is

$$v(3.54) \approx -113.1 \text{ ft/sec},$$

which is approximately 77 mph downward.

25. The first thing we should do is convert our units. We'll bring everything into feet and seconds. Thus, the initial speed of the car is

$$\frac{70 \text{ miles}}{\text{hour}}\left(\frac{1 \text{ hour}}{3600 \text{ sec}}\right)\left(\frac{5280 \text{ feet}}{1 \text{ mile}}\right) \approx 102.7 \text{ ft/sec.}$$

We assume that the acceleration is constant as the car comes to a stop. A graph of its velocity versus time is given in Figure 6.38. We know that the area under the curve represents the distance that the car travels before it comes to a stop, 157 feet. But this area is a triangle, so it is easy to find t_0, the time the car comes to rest. We solve

$$\frac{1}{2}(102.7)t_0 = 157,$$

which gives

$$t_0 \approx 3.06 \text{ sec}.$$

Since acceleration is the rate of change of velocity, the car's acceleration is given by the slope of the line in Figure 6.38. Thus, the acceleration, k, is given by

$$k = \frac{102.7 - 0}{0 - 3.06} \approx -33.56 \text{ ft/sec}^2.$$

Notice that k is negative because the car is slowing down.

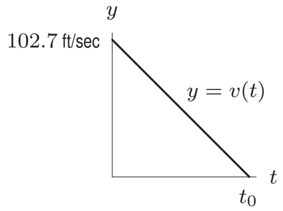


Figure 6.38: Graph of velocity versus time

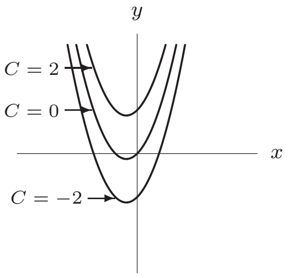
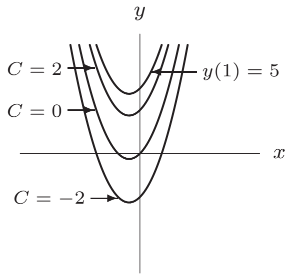
26. (a) $y = \int (2x + 1)\, dx$, so the solution is $y = x^2 + x + C$.

(b)





(c) At $y(1) = 5$, we have $1^2 + 1 + C = 5$ and so $C = 3$. Thus we have the solution $y = x^2 + x + 3$.

27. (a) We are asking for a function whose derivative is $\sin x + 2$. One antiderivative of $\sin x + 2$ is

$$y = -\cos x + 2x.$$

The general solution is therefore

$$y = -\cos x + 2x + C,$$

where C is any constant. Figure 6.39 shows several curves in this family.

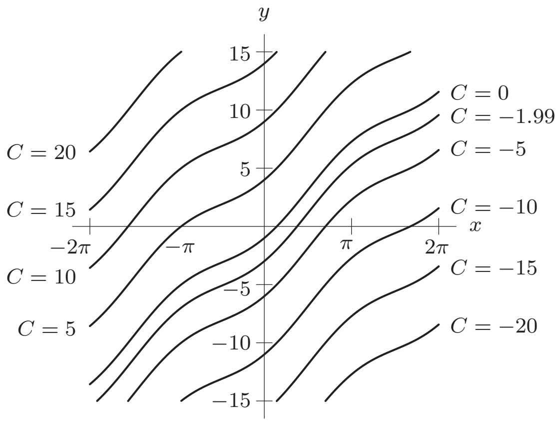


Figure 6.39

(b) We have already seen that the general solution to the differential equation is $y = -\cos x + 2x + C$. The initial condition allows us to determine the constant C. Substituting $y(3) = 5$ gives

$$5 = y(3) = -\cos 3 + 2 \cdot 3 + C,$$

so C is given by

$$C = 5 + \cos 3 - 6 \approx -1.99.$$

Thus, the (unique) solution is

$$y = -\cos x + 2x - 1.99.$$

Figure 6.39 shows this particular solution, marked $C = -1.99$.

28. (a) $a(t) = 1.6$, so $v(t) = 1.6t + v_0 = 1.6t$, since the initial velocity is 0.
(b) $s(t) = 0.8t^2 + s_0$, where s_0 is the rock's initial height.

29. (a) $s = v_0 t - 16t^2$, where $v_0 =$ initial velocity, and $v = s' = v_0 - 32t$. At the maximum height, $v = 0$, so $v_0 = 32t_{\text{max}}$. Plugging into the distance equation yields $100 = 32t_{\text{max}}^2 - 16t_{\text{max}}^2 = 16t_{\text{max}}^2$, so $t_{\text{max}} = \frac{5}{2}$ seconds, from which we get $v_0 = 32\left(\frac{5}{2}\right) = 80$ ft/sec.
(b) This time $g = 5$ ft/sec^2, so $s = v_0 t - 2.5t^2 = 80t - 2.5t^2$, and $v = s' = 80 - 5t$. At the highest point, $v = 0$, so $t_{\text{max}} = \frac{80}{5} = 16$ seconds. Plugging into the distance equation yields $s = 80(16) - 2.5(16)^2 = 640$ ft.

30. The velocity as a function of time is given by: $v = v_0 + at$. Since the object starts from rest, $v_0 = 0$, and the velocity is just the acceleration times time: $v = -32t$. Integrating this, we get position as a function of time: $y = -16t^2 + y_0$, where the last term, y_0, is the initial position at the top of the tower, so $y_0 = 400$ feet. Thus we have a function giving position as a function of time: $y = -16t^2 + 400$.

To find at what time the object hits the ground, we find t when $y = 0$. We solve $0 = -16t^2 + 400$ for t, getting $t^2 = 400/16 = 25$, so $t = 5$. Therefore the object hits the ground after 5 seconds. At this time it is moving with a velocity $v = -32(5) = -160$ feet/second.

31. In Problem 30 we used the equation $0 = -16t^2 + 400$ to learn that the object hits the ground after 5 seconds. In a more general form this is the equation $y = -\frac{g}{2}t^2 + v_0 t + y_0$, and we know that $v_0 = 0$, $y_0 = 400$ ft. So the moment the object hits the ground is given by $0 = -\frac{g}{2}t^2 + 400$. In Problem 30 we used $g = 32$ ft/sec^2, but in this case we want to find a g that results in the object hitting the ground after only 5/2 seconds. We put in 5/2 for t and solve for g:

$$0 = -\frac{g}{2}\left(\frac{5}{2}\right)^2 + 400, \text{ so } g = \frac{2(400)}{(5/2)^2} = 128 \text{ ft/sec}^2.$$

32. $a(t) = -32$. Since $v(t)$ is the antiderivative of $a(t)$, $v(t) = -32t + v_0$. But $v_0 = 0$, so $v(t) = -32t$. Since $s(t)$ is the antiderivative of $v(t)$, $s(t) = -16t^2 + s_0$, where s_0 is the height of the building. Since the ball hits the ground in 5 seconds, $s(5) = 0 = -400 + s_0$. Hence $s_0 = 400$ feet, so the window is 400 feet high.

33. Let time $t = 0$ be the moment when the astronaut jumps up. If acceleration due to gravity is 5 ft/sec^2 and initial velocity is 10 ft/sec, then the velocity of the astronaut is described by

$$v(t) = 10 - 5t.$$

Suppose $y(t)$ describes his distance from the surface of the moon. By the Fundamental Theorem,

$$y(t) - y(0) = \int_0^t (10 - 5x)\, dx$$
$$y(t) = 10t - \frac{1}{2}5t^2.$$

since $y(0) = 0$ (assuming the astronaut jumps off the surface of the moon).

The astronaut reaches the maximum height when his velocity is 0, i.e. when

$$\frac{dy}{dt} = v(t) = 10 - 5t = 0.$$

Solving for t, we get $t = 2$ sec as the time at which he reaches the maximum height from the surface of the moon. At this time his height is

$$y(2) = 10(2) - \frac{1}{2}5(2)^2 = 10 \text{ ft}.$$

When the astronaut is at height $y = 0$, he either just landed or is about to jump. To find how long it is before he comes back down, we find when he is at height $y = 0$. Set $y(t) = 0$ to get

$$\begin{aligned} 0 &= 10t - \frac{1}{2}5t^2 \\ 0 &= 20t - 5t^2 \\ 0 &= 4t - t^2 \\ 0 &= t(t-4). \end{aligned}$$

So we have $t = 0$ sec (when he jumps off) and $t = 4$ sec (when he lands, which gives the time he spent in the air).

34.
- For $[0, t_1]$, the acceleration is constant and positive and the velocity is positive so the displacement is positive. Thus, the work done is positive.
- For $[t_1, t_2]$, the acceleration, and therefore the force, is zero. Therefore, the work done is zero.
- For $[t_2, t_3]$, the acceleration is negative and thus the force is negative. The velocity, and thus the displacement, is positive; therefore the work done is negative.
- For $[t_3, t_4]$, the acceleration (and thus the force) and the velocity (and thus the displacement) are negative. Thus, the work done is positive.
- For $[t_2, t_4]$, the acceleration and thus the force is constant and negative. Velocity both positive and negative; total displacement is 0. Since force is constant, work is 0.

35. Since

$$\text{Acceleration } = \frac{dv}{dt} = -g,$$

velocity is the antiderivative of $-g$, so

$$v = -gt + C.$$

Since the initial velocity is v_0, then $C = v_0$, so

$$v = -gt + v_0.$$

We know that

$$\frac{ds}{dt} = v = -gt + v_0.$$

Therefore, we can find s by antidifferentiating again, giving:

$$s = -\frac{gt^2}{2} + v_0 t + C.$$

If the initial position is s_0, then we must have

$$s = -\frac{gt^2}{2} + v_0 t + s_0.$$

36. Let the acceleration due to gravity equal $-k$ meters/sec^2, for some positive constant k, and suppose the object falls from an initial height of $s(0)$ meters. We have $a(t) = dv/dt = -k$, so that

$$v(t) = -kt + v_0.$$

Since the initial velocity is zero, we have

$$v(0) = -k(0) + v_0 = 0,$$

which means $v_0 = 0$. Our formula becomes

$$v(t) = \frac{ds}{dt} = -kt.$$

This means

$$s(t) = \frac{-kt^2}{2} + s_0.$$

Since

$$s(0) = \frac{-k(0)^2}{2} + s_0,$$

we have $s_0 = s(0)$, and our formula becomes

$$s(t) = \frac{-kt^2}{2} + s(0).$$

Suppose that the object falls for t seconds. Assuming it has not hit the ground, its height is

$$s(t) = \frac{-kt^2}{2} + s(0),$$

so that the distance traveled is

$$s(0) - s(t) = \frac{kt^2}{2} \text{ meters},$$

which is proportional to t^2.

37. (a) $t = \dfrac{s}{\frac{1}{2}v_{\max}}$, where t is the time it takes for an object to travel the distance s, starting from rest with uniform acceleration a. $v_{\max}$ is the highest velocity the object reaches. Since its initial velocity is 0, the mean of its highest velocity and initial velocity is $\frac{1}{2}v_{\max}$.

(b) By Problem 36, $s = \frac{1}{2}gt^2$, where g is the acceleration due to gravity, so it takes $\sqrt{200/32} = 5/2$ seconds for the body to hit the ground. Since $v = gt, v_{\max} = 32(\frac{5}{2}) = 80$ ft/sec. Galileo's statement predicts $(100 \text{ ft})/(40 \text{ ft/sec}) = 5/2$ seconds, and so Galileo's result is verified.

(c) If the acceleration is a constant a, then $s = \frac{1}{2}at^2$, and $v_{\max} = at$. Thus

$$\frac{s}{\frac{1}{2}v_{\max}} = \frac{\frac{1}{2}at^2}{\frac{1}{2}at} = t.$$

38. (a) Since the gravitational force is acting downward

$$-\frac{GMm}{r^2} = m\frac{d^2s}{dt^2}.$$

Hence,

$$\frac{d^2s}{dt^2} = -\frac{GM}{r^2} = \text{Constant}.$$

If we define $g = GM/r^2$, then

$$\frac{d^2s}{dt^2} = -g.$$

(b) The fact that the mass cancels out of Newton's equations of motion reflects Galileo's experimental observation that the acceleration due to gravity is independent of the mass of the body.

39. (a) Since $s(t) = -\frac{1}{2}gt^2$, the distance a body falls in the first second is

$$s(1) = -\frac{1}{2}\cdot g\cdot 1^2 = -\frac{g}{2}.$$

In the second second, the body travels

$$s(2) - s(1) = -\frac{1}{2}\left(g\cdot 2^2 - g\cdot 1^2\right) = -\frac{1}{2}(4g - g) = -\frac{3g}{2}.$$

In the third second, the body travels

$$s(3) - s(2) = -\frac{1}{2}\left(g\cdot 3^2 - g\cdot 2^2\right) = -\frac{1}{2}(9g - 4g) = -\frac{5g}{2},$$

and in the fourth second, the body travels

$$s(4) - s(3) = -\frac{1}{2}\left(g\cdot 4^2 - g\cdot 3^2\right) = -\frac{1}{2}(16g - 9g) = -\frac{7g}{2}.$$

(b) Galileo seems to have been correct. His observation follows from the fact that the differences between consecutive squares are consecutive odd numbers. For, if n is any number, then $n^2 - (n-1)^2 = 2n - 1$, which is the n^{th} odd number (where 1 is the first).

Strengthen Your Understanding

40. The dropped rock has constant acceleration, $dv/dt = -32$ ft/sec^2. Assuming that the rock is not thrown, we let initial velocity be zero, so $v = ds/dt = -32t$. Thus $s = -16t^2 + K$, where K is the initial height, in feet, from which the rock was dropped. We compare the two formulas for s:

$$s_1(t) = -16t^2 + 400$$

and

$$s_2(t) = -16t^2 + 200.$$

The rock dropped from the 400-foot cliff hits the ground when $s_1(t) = 0$ or at $t = 5$ seconds, and the second rock hits the ground when $s_2(t) = 0$, approximately $t = 3.5$ seconds. Thus, the rock dropped from a 400-foot cliff takes less than twice as long to hit the ground as the rock dropped from a 200-foot cliff.

41. If $y = \cos(t^2)$, then $dy/dt = -2t\sin(t^2)$. Thus, $y = \cos(t^2)$ does not satisfy the differential equation.

42. The differential equation has solutions of the form $y = F(x) + C$ with $F'(x) = f(x)$. Two solutions correspond to different values of C and do not cross at any point.

43. The differential equation $dy/dx = 0$ has general solution $y = C$, which is a family of constant solutions.

44. Solutions are of the form

$$y = \frac{t^2}{2} + 3t + C.$$

Different solutions correspond to different values of C. For example

$$y = \frac{t^2}{2} + 3t + 1$$
$$y = \frac{t^2}{2} + 3t + 2.$$

45. If $y = \cos(5x)$, we have $dy/dx = -5\sin(5x)$. The equation $dy/dx = -5\sin(5x)$ is therefore a differential equation that has $y = \cos(5x)$ as a solution.

46. True. If $F(x)$ is an antiderivative of $f(x)$, then $F'(x) = f(x)$, so $dy/dx = f(x)$. Therefore, $y = F(x)$ is a solution to this differential equation.

47. True. If $y = F(x)$ is a solution to the differential equation $dy/dx = f(x)$, then $F'(x) = f(x)$, so $F(x)$ is an antiderivative of $f(x)$.

48. True. If acceleration is $a(t) = k$ for some constant k, $k \neq 0$, then we have

$$\text{Velocity} = v(t) = \int a(t)\,dt = \int k\,dt = kt + C_1,$$

for some constant C_1. We integrate again to find position as a function of time:

$$\text{Position} = s(t) = \int v(t)\,dt = \int (kt + C_1)\,dt = \frac{kt^2}{2} + C_1 t + C_2,$$

for some constant C_2. Since $k \neq 0$, this is a quadratic polynomial.

49. False. In an initial value problem the value of y is specified at one value of x, but it does not have to be $x = 0$.

50. False. The solution of the initial value problem $dy/dx = 1$ with $y(0) = -5$ is a solution of the differential equation that is not positive at $x = 0$.

51. True. If $dy/dx = f(x) > 0$, then all solutions $y(x)$ have positive derivative and thus are increasing functions.

52. True. Two solutions $y = F(x)$ and $y = G(x)$ of the same differential equation $dy/dx = f(x)$ are both antiderivatives of $f(x)$ and hence they differ by a constant: $F(x) - G(x) = C$ for all x. Since $F(3) \neq G(3)$ we have $C \neq 0$.

53. True. If $y = f(x)$ satisfies the differential equation $dy/dx = \sin x/x$, then $f'(x) = \sin x/x$. Since $(f(x) + 5)' = f'(x) = \sin x/x$, the function $y = f(x) + 5$ is also a solution of the same differential equation.

54. True. All solutions of the differential equation $dy/dt = 3t^2$ are in the family $y(t) = t^3 + C$ of antiderivatives of $3t^2$. The initial condition $y(1) = \pi$ tells us that $y(1) = \pi = 1^3 + C$, so $C = \pi - 1$. Thus $y(t) = t^3 + \pi - 1$ is the only solution of the initial value problem.

Exercises

1.

Table 6.4

x	0	0.5	1	1.5	2
$I(x)$	0	0.50	1.09	2.03	3.65

2. Using the Fundamental Theorem, we know that the change in F between $x = 0$ and $x = 0.5$ is given by

$$F(0.5) - F(0) = \int_0^{0.5} \sin t \cos t \, dt \approx 0.115.$$

Since $F(0) = 1.0$, we have $F(0.5) \approx 1.115$. The other values are found similarly, and are given in Table 6.5.

Table 6.5

b	0	0.5	1	1.5	2	2.5	3
$F(b)$	1	1.11492	1.35404	1.4975	1.41341	1.17908	1.00996

3. (a) Again using 0.00001 as the lower limit, because the integral is improper, gives $\text{Si}(4) = 1.76$, $\text{Si}(5) = 1.55$.
(b) $\text{Si}(x)$ decreases when the integrand is negative, which occurs when $\pi < x < 2\pi$.

4. If $f'(x) = \sin(x^2)$, then $f(x)$ is of the form

$$f(x) = C + \int_a^x \sin(t^2)\, dt.$$

Since $f(0) = 7$, we take $a = 0$ and $C = 7$, giving

$$f(x) = 7 + \int_0^x \sin(t^2)\, dt.$$

5. If $f'(x) = \dfrac{\sin x}{x}$, then $f(x)$ is of the form

$$f(x) = C + \int_a^x \frac{\sin t}{t}\, dt.$$

Since $f(1) = 5$, we take $a = 1$ and $C = 5$, giving

$$f(x) = 5 + \int_1^x \frac{\sin t}{t}\, dt.$$

6. If $f'(x) = \text{Si}(x)$, then $f(x)$ is of the form

$$f(x) = C + \int_a^x \text{Si}(t)\, dt.$$

Since $f(0) = 2$, we take $a = 0$ and $C = 2$, giving

$$f(x) = 2 + \int_0^x \text{Si}(t)\, dt.$$

7. By the Fundamental Theorem, $f(x) = F'(x)$. Since f is positive and increasing, F is increasing and concave up. Since $F(0) = \int_0^0 f(t)dt = 0$, the graph of F must start from the origin. See Figure 6.40.

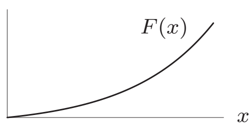

Figure 6.40

8. By the Fundamental Theorem, $f(x) = F'(x)$. Since f is positive and decreasing, F is increasing and concave down. Since $F(0) = \int_0^0 f(t)dt = 0$, the graph of F must start from the origin. See Figure 6.41.

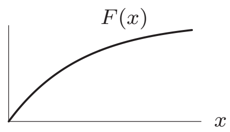

Figure 6.41

9. Since f is always positive, F is always increasing. F has an inflection point where $f' = 0$. Since $F(0) = \int_0^0 f(t)dt = 0$, F goes through the origin. See Figure 6.42.

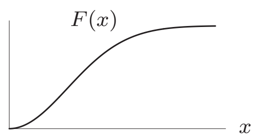

Figure 6.42

10. Since f is always non-negative, F is increasing. F is concave up where f is increasing and concave down where f is decreasing; F has inflection points at the critical points of f. Since $F(0) = \int_0^0 f(t)dt = 0$, the graph of F goes through the origin. See Figure 6.43.

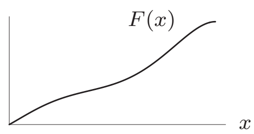

Figure 6.43

11. $\cos(x^2)$.

12. From

$$\frac{d}{dt}\int_a^t f(x)\,dx = f(t)$$

we have

$$\frac{d}{dt}\int_4^t \sin(\sqrt{x})\,dx = \sin(\sqrt{t}).$$

13. $(1+x)^{200}$.

14. From

$$\frac{d}{dx}\int_a^x f(t)\,dt = f(x)$$

we have

$$\frac{d}{dx}\int_2^x \ln(t^2+1)\,dt = \ln(x^2+1).$$

15. $\arctan(x^2)$.

16. Considering $\mathrm{Si}(x^2)$ as the composition of $\mathrm{Si}(u)$ and $u(x) = x^2$, we may apply the chain rule to obtain

$$\begin{aligned}\frac{d}{dx} &= \frac{d(\mathrm{Si}(u))}{du} \cdot \frac{du}{dx} \\ &= \frac{\sin u}{u} \cdot 2x \\ &= \frac{2\sin(x^2)}{x}.\end{aligned}$$

Problems

17. We need to find where $F''(x)$ is positive or negative. First, we compute

$$F'(x) = e^{-x^2},$$

then

$$F''(x) = -2xe^{-x^2}.$$

Since $e^{-x^2} > 0$ for all x, we see that

$$F''(x) > 0 \text{ for } x < 0$$

and

$$F''(x) < 0 \text{ for } x > 0.$$

Thus the graph of $F(x)$ is concave up for $x < 0$ and concave down for $x > 0$.

18. The graph of $f(x) = xe^{-x}$ is shown in Figure 6.44. We see that $f(x) < 0$ when $x < 0$ and $f(x) > 0$ when $x > 0$. There is some value a with $-1 < a < 0$, for which the area of $f(x)$ below the x-axis from $x = a$ to $x = 0$ equals the area above the x-axis from $x = 0$ to $x = 1$. Then for this value of a,

$$F(a) = \int_1^a f(t)\,dt = \int_1^a te^{-t}\,dt = 0.$$

Also

$$F(1) = \int_1^1 te^{-t}\,dt = 0.$$

There are no other values of x for which $F(x) = 0$, since for $x > 1$, the area under the graph of $f(x)$ increases, because $f(x) > 0$. Similarly, for $x < a$, we have $f(x) < 0$ and the area under the graph of $f(x)$ increases as x gets more negative.

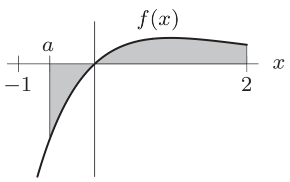

Figure 6.44

19. By the Fundamental Theorem of Calculus,

$$F(x) - F(0) = \int_0^x f(t)\,dt = \int_0^x \sin(t^2)\,dt.$$

Since $F(0) = 0$, we have

$$F(x) = \int_0^x \sin(t^2)\,dt.$$

Using a calculator, we get

$$\begin{aligned} F(0) &= 0 \\ F(0.5) &= 0.041 \\ F(1) &= 0.310 \\ F(1.5) &= 0.778 \\ F(2) &= 0.805 \\ F(2.5) &= 0.431. \end{aligned}$$

20. The graph of $f(x) = F'(x) = \sin(x^2)$ is in Figure 6.45. The function $F(x)$ is increasing where $F'(x) = f(x) > 0$, that is, for $0 < x < \sqrt{\pi} \approx 1.772$. The function $F(x)$ is decreasing where $F'(x) = f(x) < 0$, that is, for $1.772 < x \le 2.5$.

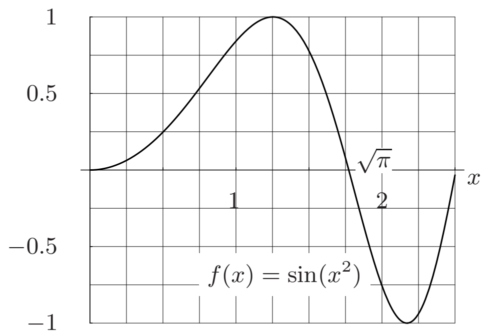

Figure 6.45

21. Using the solution to Problem 20, we see that $F(x)$ is increasing for $x < \sqrt{\pi}$ and $F(x)$ is decreasing for $x > \sqrt{\pi}$. Thus $F(x)$ has its maximum value when $x = \sqrt{\pi}$.

By the Fundamental Theorem of Calculus,

$$F(\sqrt{\pi}) - F(0) = \int_0^{\sqrt{\pi}} f(t)\,dt = \int_0^{\sqrt{\pi}} \sin(t^2)\,dt.$$

Since $F(0) = 0$, calculating Riemann sums gives

$$F(\sqrt{\pi}) = \int_0^{\sqrt{\pi}} \sin(t^2)\,dt = 0.895.$$

22. See Figure 6.46.

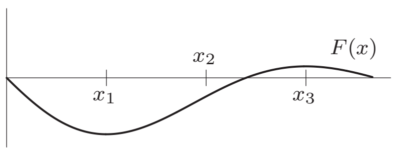

Figure 6.46

23. We know that $F(x)$ increases for $x < 50$ because the derivative of F is positive there. See Figure 6.47. Similarly, $F(x)$ decreases for $x > 50$. Therefore, the graph of F rises until $x = 50$, and then it begins to fall. Thus, the maximum value attained by F is $F(50)$. To evaluate $F(50)$, we use the Fundamental Theorem:

$$F(50) - F(20) = \int_{20}^{50} F'(x)\,dx,$$

which gives

$$F(50) = F(20) + \int_{20}^{50} F'(x)\,dx = 150 + \int_{20}^{50} F'(x)\,dx.$$

The definite integral equals the area of the shaded region under the graph of F', which is roughly 350. Therefore, the greatest value attained by F is $F(50) \approx 150 + 350 = 500$.

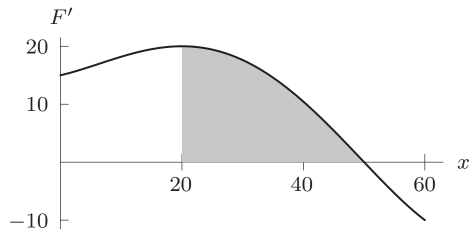

Figure 6.47

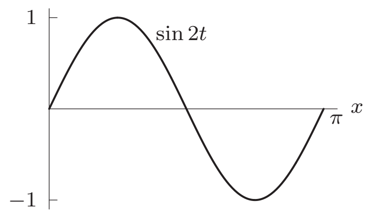
24. (a) The definition of g gives $g(0) = \int_0^0 f(t)\,dt = 0$.
(b) The Fundamental Theorem gives $g'(1) = f(1) = -2$.
(c) The function g is concave upward where g'' is positive. Since $g'' = f'$, we see that g is concave up where f is increasing. This occurs on the interval $1 \le x \le 6$.
(d) The function g decreases from $x = 0$ to $x = 3$ and increases for $3 < x \le 8$, and the magnitude of the increase is more than the magnitude of the decrease. Thus g takes its maximum value at $x = 8$.

25. (a) Since $\frac{d}{dt}(\cos(2t)) = -2\sin(2t)$, we have $F(\pi) = \int_0^\pi \sin(2t)\,dt = -\frac{1}{2}\cos(2t)\Big|_0^\pi = -\frac{1}{2}(1-1) = 0$.
(b) $F(\pi) =$ (Area above t-axis) $-$ (Area below t-axis) $= 0$. (The two areas are equal.)

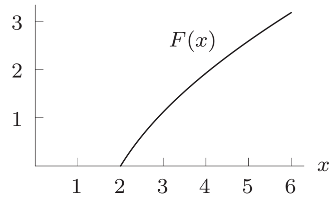


(c) $F(x) \ge 0$ everywhere. $F(x) = 0$ only at integer multiples of π. This can be seen for $x \ge 0$ by noting $F(x) =$ (Area above t-axis) $-$ (Area below t-axis), which is always non-negative and only equals zero when x is an integer multiple of π. For $x > 0$

$$\begin{aligned} F(-x) &= \int_0^{-x} \sin 2t\,dt \\ &= -\int_{-x}^{0} \sin 2t\,dt \\ &= \int_0^{x} \sin 2t\,dt = F(x), \end{aligned}$$

since the area from $-x$ to 0 is the negative of the area from 0 to x. So we have $F(x) \ge 0$ for all x.

26. (a) $F'(x) = \dfrac{1}{\ln x}$ by the Construction Theorem.
(b) For $x \ge 2$, $F'(x) > 0$, so $F(x)$ is increasing. Since $F''(x) = -\dfrac{1}{x(\ln x)^2} < 0$ for $x \ge 2$, the graph of $F(x)$ is concave down.
(c)



27. (a) The definition of R gives

$$R(0) = \int_0^0 \sqrt{1+t^2}\,dt = 0$$

and

$$R(-x) = \int_0^{-x} \sqrt{1+t^2}\,dt.$$

Changing the variable of integration by letting $t = -z$ gives

$$\int_0^{-x} \sqrt{1+t^2}\,dt = \int_0^{x} \sqrt{1+(-z)^2}(-dz) = -\int_0^{x} \sqrt{1+z^2}\,dz.$$

Thus R is an odd function.

(b) Using the Second Fundamental Theorem gives $R'(x) = \sqrt{1+x^2}$, which is always positive, so R is increasing everywhere.

(c) Since

$$R''(x) = \frac{x}{\sqrt{1+x^2}},$$

then R is concave up if $x > 0$ and concave down if $x < 0$.

(d) See Figure 6.48.

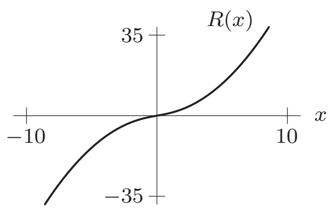


Figure 6.48

(e) We have

$$\lim_{x\to\infty} \frac{R(x)}{x^2} = \lim_{x\to\infty} \frac{\int_0^x \sqrt{1+t^2}\,dt}{x^2}.$$

Using l'Hopital's rule gives

$$\lim_{x\to\infty} \frac{\sqrt{1+x^2}}{2x} = \lim_{x\to\infty} \frac{\sqrt{1/x^2+1}}{2} = \frac{1}{2}.$$

Thus the limit exists; its value is 1/2.

28. (a) We have $F(x) = \int_a^x f(t)\,dx = 0$ for all x.

(b) We have $F'(x) = f(x)$ by the Second Fundamental Theorem. We have $F'(x) = 0$ by part (a). Hence $f(x) = 0$.

29. Since $F'(x) = e^{-x^2}$ and $F(0) = 2$, we have

$$F(x) = F(0) + \int_0^x e^{-t^2}\,dt = 2 + \int_0^x e^{-t^2}\,dt.$$

Substituting $x = 1$ and evaluating the integral numerically gives

$$F(1) = 2 + \int_0^1 e^{-t^2}\,dt = 2.747.$$

30. Since $G'(x) = \cos(x^2)$ and $G(0) = -3$, we have

$$G(x) = G(0) + \int_0^x \cos(t^2)\,dt = -3 + \int_0^x \cos(t^2)\,dt.$$

Substituting $x = -1$ and evaluating the integral numerically gives

$$G(-1) = -3 + \int_0^{-1} \cos(t^2)\,dt = -3.905.$$

31. We have

$$\begin{aligned} w(0.4) &= \int_0^{0.4} q(x)\,dx \\ &\approx 0.1q(0.0) + 0.1q(0.1) + 0.1q(0.2) + 0.1q(0.3) \qquad \text{left-hand sum with } \Delta t = 0.1 \\ &= 0.1(5.3) + 0.1(5.2) + 0.1(4.9) + 0.1(4.5) = 1.99. \end{aligned}$$

Since $q'(x) < 0$, we know a left-hand sum provides an overestimate.

Alternatively, we could use a right-hand sum to provide an underestimate:

$$\begin{aligned} w(0.4) &= \int_0^{0.4} q(x)\,dx \\ &\approx 0.1q(0.1) + 0.1q(0.2) + 0.1q(0.3) + 0.1q(0.4) \qquad \text{right-hand sum with } \Delta t = 0.1 \\ &= 0.1(5.2) + 0.1(4.9) + 0.1(4.5) + 0.1(3.9) = 1.85. \end{aligned}$$

32. We have:

$$\begin{aligned} v(0.4) &= \int_0^{0.4} q'(x)\,dx, \\ &= q(0.4) - q(0) \qquad \text{Fundamental Theorem of Calculus} \\ &= 3.9 - 5.3 \qquad \text{from the table} \\ &= -1.4. \end{aligned}$$

This answer is exact.

33. Since $w(t) = \int_0^t q(x)\,dx$, we know from the Construction Theorem that w is an antiderivative of q. This means:

$$\begin{aligned} w'(t) &= q(t), \\ \text{so} \quad w'(0.4) &= q(0.4) = 3.9 \quad \text{from the table.} \end{aligned}$$

This answer is exact.

34. Since $v(t) = \int_0^t q'(x)\,dx$, we know from the Construction Theorem that v is an antiderivative of q'. This means:

$$\begin{aligned} v'(t) &= q'(t) \\ \text{so} \quad v'(0.4) &= q'(0.4) \\ &\approx \frac{q(0.5) - q(0.4)}{0.1} \qquad \text{average rate of change of } q \\ &= \frac{3.1 - 3.9}{0.1} = -8. \end{aligned}$$

Since q' and q'' are both negative, we know q is decreasing and its graph is concave-down. This tells us that the secant line from $x = 0.4$ to $x = 0.5$ is steeper (its slope is "more negative") than the tangent line, making -8 an underestimate.

Alternatively we can write

$$\begin{aligned} v'(0.4) = q'(0.4) &\approx \frac{q(0.4) - q(0.3)}{0.1} \qquad \text{average rate of change of } q \\ &= \frac{3.9 - 4.5}{0.1} = -6. \end{aligned}$$

Here, the secant line from $x = 0.3$ to $x = 0.4$ is less steep (its slope is "less negative") than the tangent line, making -6 an overestimate.

35. If we let $F(x) = \int_0^x \ln(1 + t^2)\,dt$, using the chain rule gives

$$\frac{d}{dx}F(x^2) = 2xF'(x^2) = 2x\ln(1 + (x^2)^2) = 2x\ln(1 + x^4).$$

36. If we let $f(t) = \int_1^t \cos(x^2)\,dx$ and $g(t) = \sin t$, using the chain rule gives

$$\frac{d}{dt}\int_1^{\sin t} \cos(x^2)\,dx = f'(g(t)) \cdot g'(t) = \cos((\sin t)^2) \cdot \cos t = \cos(\sin^2 t)(\cos t).$$

37. We first write

$$\int_{2t}^{4} \sin(\sqrt{x})\,dx$$

as

$$-\int_{4}^{2t} \sin(\sqrt{x})\,dx.$$

Letting

$$F(t) = -\int_4^t \sin(\sqrt{x})\,dx,$$

and using the chain rule gives

$$\frac{d}{dt}F(2t) = 2F'(2t) = 2[-\sin(\sqrt{2t})] = -2\sin(\sqrt{2t}).$$

38. If we split the integral at $x = 0$, we have

$$\int_{-x^2}^{x^2} e^{t^2}\,dt = \int_{-x^2}^{0} e^{t^2}\,dt + \int_0^{x^2} e^{t^2}\,dt = -\int_0^{-x^2} e^{t^2}\,dt + \int_0^{x^2} e^{t^2}\,dt.$$

If we let

$$F(x) = \int_0^x e^{t^2}\,dt,$$

using the chain rule on each part separately gives

$$\frac{d}{dx}[-F(-x^2) + F(x^2)] = -(-2x)F'(-x^2) + (2x)F'(x^2) = (2x)e^{(-x^2)^2} + (2x)e^{(x^2)^2} = 4xe^{x^4}.$$

39.

$$\begin{aligned}\frac{d}{dx}[x\,\text{erf}(x)] &= \text{erf}(x)\frac{d}{dx}(x) + x\frac{d}{dx}[\text{erf}(x)] \\ &= \text{erf}(x) + x\frac{d}{dx}\left(\frac{2}{\sqrt{\pi}}\int_0^x e^{-t^2}\,dt\right) \\ &= \text{erf}(x) + \frac{2}{\sqrt{\pi}}xe^{-x^2}.\end{aligned}$$

40. If we let $f(x) = \text{erf}(x)$ and $g(x) = \sqrt{x}$, then we are looking for $\frac{d}{dx}[f(g(x))]$. By the chain rule, this is the same as $g'(x)f'(g(x))$. Since

$$\begin{aligned}f'(x) &= \frac{d}{dx}\left(\frac{2}{\sqrt{\pi}}\int_0^x e^{-t^2}\,dt\right) \\ &= \frac{2}{\sqrt{\pi}}e^{-x^2}\end{aligned}$$

and $g'(x) = \dfrac{1}{2\sqrt{x}}$, we have

$$f'(g(x)) = \frac{2}{\sqrt{\pi}}e^{-x},$$

and so

$$\frac{d}{dx}[\text{erf}(\sqrt{x})] = \frac{1}{2\sqrt{x}}\frac{2}{\sqrt{\pi}}e^{-x} = \frac{1}{\sqrt{\pi x}}e^{-x}.$$

41. If we let $f(x) = \int_0^x e^{-t^2}\,dt$ and $g(x) = x^3$, then we use the chain rule because we are looking for $\frac{d}{dx}f(g(x)) = f'(g(x)) \cdot g'(x)$. Since $f'(x) = e^{-x^2}$, we have

$$\frac{d}{dx}\left(\int_0^{x^3} e^{-t^2}\,dt\right) = f'(x^3) \cdot 3x^2 = e^{-(x^3)^2} \cdot 3x^2 = 3x^2 e^{-x^6}.$$

42. We split the integral $\int_x^{x^3} e^{-t^2}\,dt$ into two pieces, say at $t = 1$ (though it could be at any other point):

$$\int_x^{x^3} e^{-t^2}\,dt = \int_1^{x^3} e^{-t^2}\,dt + \int_x^1 e^{-t^2}\,dt = \int_1^{x^3} e^{-t^2}\,dt - \int_1^x e^{-t^2}\,dt.$$

We have used the fact that $\int_x^1 e^{-t^2}\,dt = -\int_1^x e^{-t^2}\,dt$. Differentiating gives

$$\frac{d}{dx}\left(\int_x^{x^3} e^{-t^2}\,dt\right) = \frac{d}{dx}\left(\int_1^{x^3} e^{-t^2}\,dt\right) - \frac{d}{dx}\left(\int_1^{x} e^{-t^2}\,dt\right)$$

For the first integral, we use the chain rule with $g(x) = x^3$ as the inside function, so the final answer is

$$\frac{d}{dx}\left(\int_x^{x^3} e^{-t^2}\,dt\right) = e^{-(x^3)^2} \cdot 3x^2 - e^{-x^2} = 3x^2 e^{-x^6} - e^{-x^2}.$$

Strengthen Your Understanding

43. Note that $\displaystyle\int_0^5 t^2\,dt$ is a constant, therefore its derivative is zero.

44. $f(x) = x^2$ has a minimum at $x = 0$. However, $F(x)$ is non-decreasing for all x since $F'(x) = x^2 \geq 0$ everywhere.

45. The derivative of $F(x)$, which is $f(x)$, has a local minimum at $x = 2$. The function $F(x)$ has local minimums at $x = -1$ and $x = 3$, where $f(x)$ goes from negative to positive.

46. From the Second Fundamental Theorem of Calculus, we have $F(x) = \int_0^x f(t)dt$ (so that $F(0) = 0$). In order to assure that F is a nondecreasing function, we need only pick a function $f(t)$ that is nonnegative for all t. The choices are many, but one possible example is $f(t) = t^2$, giving $F(x) = \int_0^x t^2\,dt$.

47. From the Second Fundamental Theorem of Calculus, we have $G(x) = \int_a^x g(t)dt$. Since $G(7) = 0$, we let $a = 7$, and in order to ensure that G is concave up, we need a function $g(t)$ that has a positive derivative. One possible example is $g(t) = e^t$, giving $G(x) = \int_7^x e^t dt$.

48. True. The Construction Theorem for Antiderivatives gives a method for building an antiderivative with a definite integral.

49. True, by the Second Fundamental Theorem of Calculus.

50. True. We see that

$$F(5) - F(3) = \int_0^5 f(t)\,dt - \int_0^3 f(t)\,dt = \int_3^5 f(t)\,dt.$$

51. False. If f is positive then F is increasing, but if f is negative then F is decreasing.

52. True. Since F and G are both antiderivatives of f, they must differ by a constant. In fact, we can see that the constant C is equal to $\int_0^2 f(t)\,dt$ since

$$F(x) = \int_0^x f(t)\,dt = \int_2^x f(t)\,dt + \int_0^2 f(t)\,dt = G(x) + C.$$

53. True, since $\int_0^x (f(t) + g(t))\,dt = \int_0^x f(t)\,dt + \int_0^x g(t)\,dt$.

Solutions for Chapter 6 Review

Exercises

1. We find the changes in $f(x)$ between any two values of x by counting the area between the curve of $f'(x)$ and the x-axis. Since $f'(x)$ is linear throughout, this is quite easy to do. From $x = 0$ to $x = 1$, we see that $f'(x)$ outlines a triangle of area $1/2$ below the x-axis (the base is 1 and the height is 1). By the Fundamental Theorem,

$$\int_0^1 f'(x)\,dx = f(1) - f(0),$$

so

$$f(0) + \int_0^1 f'(x)\,dx = f(1)$$
$$f(1) = 2 - \frac{1}{2} = \frac{3}{2}$$

Similarly, between $x = 1$ and $x = 3$ we can see that $f'(x)$ outlines a rectangle below the x-axis with area -1, so $f(2) = 3/2 - 1 = 1/2$. Continuing with this procedure (note that at $x = 4$, $f'(x)$ becomes positive), we get the table below.

x	0	1	2	3	4	5	6
$f(x)$	2	$3/2$	$1/2$	$-1/2$	-1	$-1/2$	$1/2$

2. Since $F(0) = 0$, $F(b) = \int_0^b f(t)\,dt$. For each b we determine $F(b)$ graphically as follows:
$F(0) = 0$
$F(1) = F(0) +$ Area of 1×1 rectangle $= 0 + 1 = 1$
$F(2) = F(1) +$ Area of triangle $(\frac{1}{2} \cdot 1 \cdot 1) = 1 + 0.5 = 1.5$
$F(3) = F(2) +$ Negative of area of triangle $= 1.5 - 0.5 = 1$
$F(4) = F(3) +$ Negative of area of rectangle $= 1 - 1 = 0$
$F(5) = F(4) +$ Negative of area of rectangle $= 0 - 1 = -1$
$F(6) = F(5) +$ Negative of area of triangle $= -1 - 0.5 = -1.5$
The graph of $F(t)$, for $0 \le t \le 6$, is shown in Figure 6.49.

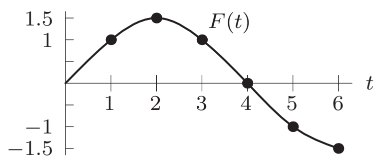

Figure 6.49

3. F is increasing because f is positive; F is concave up because f is increasing. See Figure 6.50.

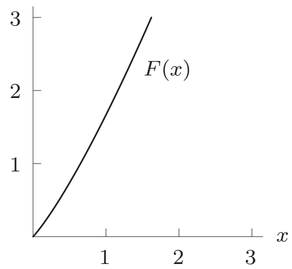

Figure 6.50

4. F is increasing because f is positive; F is concave up because f is increasing. See Figure 6.51.

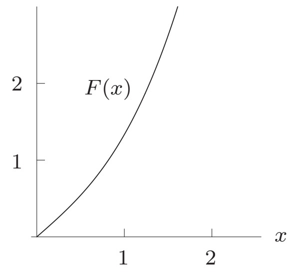

Figure 6.51

5. (a) The value of the integral is negative since the area below the x-axis is greater than the area above the x-axis. We count boxes: The area below the x-axis includes approximately 11.5 boxes and each box has area $(2)(1) = 2$, so

$$\int_0^5 f(x)dx \approx -23.$$

The area above the x-axis includes approximately 2 boxes, each of area 2, so

$$\int_5^7 f(x)dx \approx 4.$$

So we have

$$\int_0^7 f(x)dx = \int_0^5 f(x)dx + \int_5^7 f(x)dx \approx -23 + 4 = -19.$$

(b) By the Fundamental Theorem of Calculus, we have

$$F(7) - F(0) = \int_0^7 f(x)dx$$

so,

$$F(7) = F(0) + \int_0^7 f(x)dx = 25 + (-19) = 6.$$

6. $\int 5x\,dx = \frac{5}{2}x^2 + C.$

7. $\int x^3\,dx = \frac{x^4}{4} + C$

8. $\int \sin\theta\,d\theta = -\cos\theta + C$

9. $\int (x^3 - 2)\,dx = \frac{x^4}{4} - 2x + C$

10. $\int (t^2 + \frac{1}{t^2})\,dt = \frac{t^3}{3} - \frac{1}{t} + C$

11. $\int \frac{4}{t^2}\,dt = -\frac{4}{t} + C$

12. $\int (x^2 + 5x + 8)\,dx = \frac{x^3}{3} + \frac{5x^2}{2} + 8x + C$

13. $\int 4\sqrt{w}\,dw = \frac{8}{3}w^{3/2} + C$

14. $2t^2 + 7t + C$

15. $\sin\theta + C$

16. $\int \left(t^{3/2} + t^{-3/2}\right)\, dt = \frac{2t^{5/2}}{5} - 2t^{-1/2} + C$

17. $\frac{x^2}{2} + 2x^{1/2} + C$

18. $\pi x + \frac{x^{12}}{12} + C$

19. $3\sin t + 2t^{3/2} + C$

20. $\int \left(y - \frac{1}{y}\right)^2 dy = \int \left(y^2 - 2 + \frac{1}{y^2}\right) dy = \frac{y^3}{3} - 2y - \frac{1}{y} + C$

21. $\tan x + C$

22. $2\ln|x| - \pi\cos x + C$

23. Since $f(x) = x + 1 + \frac{1}{x}$, the indefinite integral is $\frac{1}{2}x^2 + x + \ln|x| + C$

24. $5e^z + C$

25. $\frac{1}{\ln 2}2^x + C$, since $\frac{d}{dx}(2^x) = (\ln 2)\cdot 2^x$

26. $3\sin x + 7\cos x + C$

27. $2e^x - 8\sin x + C$

28. $\int_{-3}^{-1} \frac{2}{r^3}\, dr = -r^{-2}\Big|_{-3}^{-1} = -1 + \frac{1}{9} = -8/9 \approx -0.889.$

29. We have

$$\int_{-\pi/2}^{\pi/2} 2\cos\phi d\phi = 2\left(\sin\phi\Big|_{-\pi/2}^{\pi/2}\right) = 2\left(\sin\frac{\pi}{2} - \sin\frac{-\pi}{2}\right) = 2\left(1 - (-1)\right). = 4.$$

30. $F(x) = \int f(x)\, dx = \int x^2\, dx = \frac{x^3}{3} + C$. If $F(0) = 4$, then $F(0) = 0 + C = 4$ and thus $C = 4$. So $F(x) = \frac{x^3}{3} + 4$.

31. We have $F(x) = \frac{x^4}{4} + 2x^3 - 4x + C$. Since $F(0) = 4$, we have $4 = 0 + C$, so $C = 4$. So $F(x) = \frac{x^4}{4} + 2x^3 - 4x + 4$.

32. $F(x) = \int \sqrt{x}\, dx = \frac{2}{3}x^{3/2} + C$. If $F(0) = 4$, then $F(0) = 0 + C = 4$ and thus $C = 4$. So $F(x) = \frac{2}{3}x^{3/2} + 4$.

33. $F(x) = \int e^x\, dx = e^x + C$. If $F(0) = 4$, then $F(0) = 1 + C = 4$ and thus $C = 3$. So $F(x) = e^x + 3$.

34. $F(x) = \int \sin x\, dx = -\cos x + C$. If $F(0) = 4$, then $F(0) = -1 + C = 4$ and thus $C = 5$. So $F(x) = -\cos x + 5$.

35. $F(x) = \int \cos x\, dx = \sin x + C$. If $F(0) = 4$, then $F(0) = 0 + C = 4$ and thus $C = 4$. So $F(x) = \sin x + 4$.

36. Since $(x^x)' = x^x(1 + \ln x)$, we have

$$\int_1^3 x^x(1 + \ln x)\, dx = x^x\Big|_1^3 = 3^3 - 1^1 = 26.$$

37. Since $y = x + \sin x - \pi$, we differentiate to see that $dy/dx = 1 + \cos x$, so y satisfies the differential equation. To show that it also satisfies the initial condition, we check that $y(\pi) = 0$:

$$y = x + \sin x - \pi$$
$$y(\pi) = \pi + \sin\pi - \pi = 0.$$

38. Differentiating y with respect to x gives

$$y' = nx^{n-1}$$

for all values of A.

39. $y = \int (x^3 + 5)\,dx = \frac{x^4}{4} + 5x + C$

40. $y = \int \left(8x + \frac{1}{x}\right)\,dx = 4x^2 + \ln|x| + C$

41. $W = \int 4\sqrt{t}\,dt = \frac{8}{3}t^{3/2} + C$

42. $r = \int 3\sin p\,dp = -3\cos p + C$

43. $y = \int (6x^2 + 4x)\,dx = 2x^3 + 2x^2 + C$. If $y(2) = 10$, then $2(2)^3 + 2(2)^2 + C = 10$ and $C = 10 - 16 - 8 = -14$. Thus, $y = 2x^3 + 2x^2 - 14$.

44. $P = \int 10e^t\,dt = 10e^t + C$. If $P(0) = 25$, then $10e^0 + C = 25$ so $C = 15$. Thus, $P = 10e^t + 15$.

45. $s = \int (-32t + 100)\,dt = -16t^2 + 100t + C$. If $s = 50$ when $t = 0$, then $-16(0)^2 + 100(0) + C = 50$, so $C = 50$. Thus $s = -16t^2 + 100t + 50$.

46. Integrating gives

$$\int \frac{dq}{dz}\,dz = \int (2 + \sin z)\,dz = 2z - \cos z + C.$$

If $q = 5$ when $z = 0$, then $2(0) - \cos(0) + C = 5$ so $C = 6$. Thus $q = 2z - \cos z + 6$.

47. $\frac{d}{dt}\int_t^\pi \cos(z^3)\,dz = \frac{d}{dt}\left(-\int_\pi^t \cos(z^3)\,dz\right) = -\cos(t^3)$.

48. $\frac{d}{dx}\int_x^1 \ln t\,dt = \frac{d}{dx}\left(-\int_1^x \ln t\,dt\right) = -\ln x$.

Problems

49. We can start by finding four points on the graph of $F(x)$. The first one is given: $F(2) = 3$. By the Fundamental Theorem of Calculus, $F(6) = F(2) + \int_2^6 F'(x)dx$. The value of this integral is -7 (the area is 7, but the graph lies below the x-axis), so $F(6) = 3 - 7 = -4$. Similarly, $F(0) = F(2) - 2 = 1$, and $F(8) = F(6) + 4 = 0$. We sketch a graph of $F(x)$ by connecting these points, as shown in Figure 6.52.

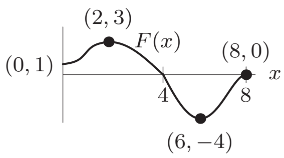

Figure 6.52

50. Between time $t = 0$ and time $t = B$, the velocity of the cork is always positive, which means the cork is moving upward. At time $t = B$, the velocity is zero, and so the cork has stopped moving altogether. Since shortly thereafter the velocity of the cork becomes negative, the cork will next begin to move downward. Thus when $t = B$ the cork has risen as far as it ever will, and is riding on top of the crest of the wave.

From time $t = B$ to time $t = D$, the velocity of the cork is negative, which means it is falling. When $t = D$, the velocity is again zero, and the cork has ceased to fall. Thus when $t = D$ the cork is riding on the bottom of the trough of the wave.

Since the cork is on the crest at time B and in the trough at time D, it is probably midway between crest and trough when the time is midway between B and D. Thus at time $t = C$ the cork is moving through the equilibrium position on its way down. (The equilibrium position is where the cork would be if the water were absolutely calm.) By symmetry, $t = A$ is the time when the cork is moving through the equilibrium position on the way up.

Since acceleration is the derivative of velocity, points where the acceleration is zero would be critical points of the velocity function. Since point A (a maximum) and point C (a minimum) are critical points, the acceleration is zero there.

A possible graph of the height of the cork is shown in Figure 6.53. The horizontal axis represents a height equal to the average depth of the ocean at that point (the equilibrium position of the cork).

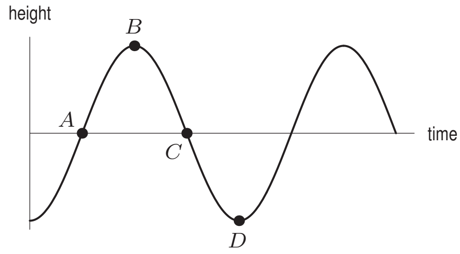

Figure 6.53

51. (a) Critical points of $F(x)$ are the zeros of f: $x = 1$ and $x = 3$.
(b) $F(x)$ has a local minimum at $x = 1$ and a local maximum at $x = 3$.
(c) See Figure 6.54.

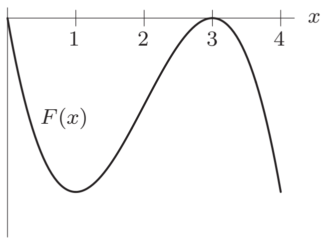

Figure 6.54

Notice that the graph could also be above or below the x-axis at $x = 3$.

52. (a) Critical points of $F(x)$ are $x = -1$, $x = 1$ and $x = 3$.
(b) $F(x)$ has a local minimum at $x = -1$, a local maximum at $x = 1$, and a local minimum at $x = 3$.
(c) See Figure 6.55.

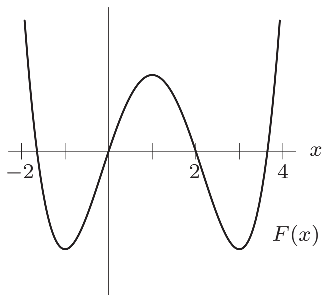

Figure 6.55

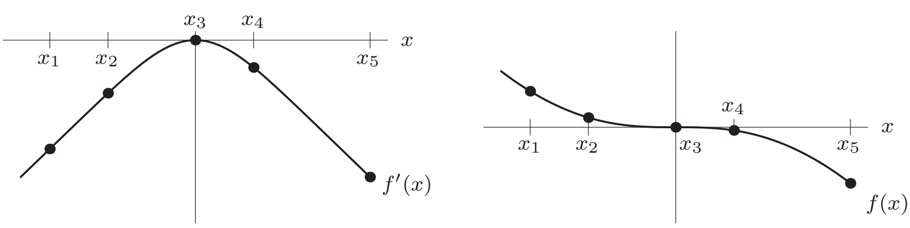
53.



(a) $f(x)$ is greatest at x_1.

(b) $f(x)$ is least at x_5.
(c) $f'(x)$ is greatest at x_3..
(d) $f'(x)$ is least at x_5.
(e) $f''(x)$ is greatest at x_1.
(f) $f''(x)$ is least at x_5.

54. (a) Starting at $x = 3$, we are given that $f(3) = 0$. Moving to the left on the interval $2 < x < 3$, we have $f'(x) = -1$, so $f(2) = f(3) - (1)(-1) = 1$. On the interval $0 < x < 2$, we have $f'(x) = 1$, so

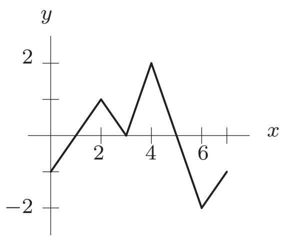
$$f(0) = f(2) + 1(-2) = -1.$$

Moving to the right from $x = 3$, we know that $f'(x) = 2$ on $3 < x < 4$. So $f(4) = f(3) + 2 = 2$. On the interval $4 < x < 6$, $f'(x) = -2$ so

$$f(6) = f(4) + 2(-2) = -2.$$

On the interval $6 < x < 7$, we have $f'(x) = 1$, so

$$f(7) = f(6) + 1 = -2 + 1 = -1.$$



(b) In part (a) we found that $f(0) = -1$ and $f(7) = -1$.
(c) The integral $\int_0^7 f'(x)\,dx$ is given by the sum

$$\int_0^7 f'(x)\,dx = (1)(2) + (-1)(1) + (2)(1) + (-2)(2) + (1)(1) = 0.$$

Alternatively, knowing $f(7)$ and $f(0)$ and using the Fundamental Theorem of Calculus, we have

$$\int_0^7 f'(x)\,dx = f(7) - f(0) = -1 - (-1) = 0.$$

55. We have

$$\text{Area} = \int_1^4 x^2\,dx = \left.\frac{x^3}{3}\right|_1^4 = \frac{4^3}{3} - \frac{1^3}{3} = \frac{64-1}{3} = 21.$$

56. The graph crosses the x-axis where

$$7 - 8x + x^2 = 0$$
$$(x-7)(x-1) = 0;$$

so $x = 1$ and $x = 7$. See Figure 6.56. The parabola opens upward and the region is below the x-axis, so

$$\begin{aligned}\text{Area} &= -\int_1^7 (7 - 8x + x^2)\,dx \\ &= -\left(7x - 4x^2 + \frac{x^3}{3}\right)\Bigg|_1^7 = 36.\end{aligned}$$

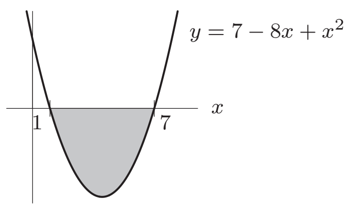


Figure 6.56

57. Since $y = x^3(1-x)$ is positive for $0 \le x \le 1$ and $y = 0$, when $x = 0, 1$, the area is given by

$$\text{Area } = \int_0^1 x^3(1-x)\,dx = \int_0^1 (x^3 - x^4)\,dx = \frac{x^4}{4} - \frac{x^5}{5}\bigg|_0^1 = \frac{1}{20}.$$

58. Since $y = 0$ only when $x = 0$ and $x = 1$, the area lies between these limits and is given by

$$\begin{aligned}\text{Area } &= \int_0^1 x^2(1-x)^2 dx = \int_0^1 x^2(1-2x+x^2)\,dx = \int_0^1 (x^2 - 2x^3 + x^4)\,dx \\ &= \frac{x^3}{3} - \frac{2}{4}x^4 + \frac{x^5}{5}\bigg|_0^1 = \frac{1}{30}.\end{aligned}$$

59. The curves cross at the origin and at $(1, 1)$. See Figure 6.57. Since the upper half of $x = y^2$ is given by $y = \sqrt{x}$ and this curve is above $y = x^2$, we have

$$\text{Area } = \int_0^1 (\sqrt{x} - x^2)\,dx = \left(\frac{x^{3/2}}{3/2} - \frac{x^3}{3}\right)\bigg|_0^1 = \frac{2}{3} - \frac{1}{3} = \frac{1}{3}.$$

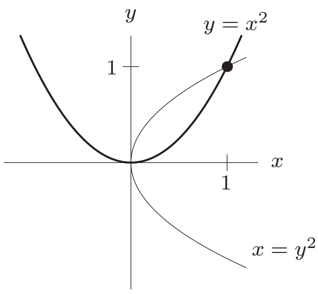

Figure 6.57

60. The graph is shown in Figure 6.58. Since $\cos\theta \ge \sin\theta$ for $0 \le \theta \le \pi/4$, we have

$$\begin{aligned}\text{Area } &= \int_0^{\pi/4} (\cos\theta - \sin\theta)\,d\theta \\ &= (\sin\theta + \cos\theta)\bigg|_0^{\pi/4} \\ &= \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}} - 1 = \sqrt{2} - 1.\end{aligned}$$

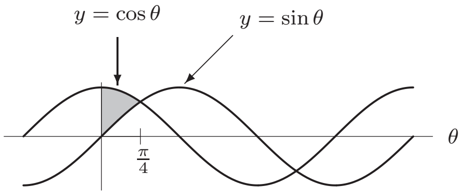

Figure 6.58

61. The graphs of $f(\theta) = \sin\theta$ and $g(\theta) = \cos\theta$ cross at $\theta = \pi/4$ and $\theta = 5\pi/4$. See Figure 6.59. Since $\sin\theta$ is above $\cos\theta$ between these two crossing points and $\cos\theta$ is above $\sin\theta$ outside, we have

$$\text{Area } = \int_0^{\pi/4} (\cos\theta - \sin\theta)\,d\theta + \int_{\pi/4}^{5\pi/4} (\sin\theta - \cos\theta)\,d\theta + \int_{5\pi/4}^{2\pi} (\cos\theta - \sin\theta)\,d\theta$$

$$= (\sin\theta + \cos\theta)\Big|_0^{\pi/4} + (-\cos\theta - \sin\theta)\Big|_{\pi/4}^{5\pi/4} + (\sin\theta + \cos\theta)\Big|_{5\pi/4}^{2\pi}$$
$$= \left(\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}} - 1\right) + \left(-\left(-\frac{1}{\sqrt{2}}\right) - \left(-\frac{1}{\sqrt{2}}\right) - \left(-\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}\right)\right) + \left(1 - \left(-\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}\right)\right)$$
$$= \frac{8}{\sqrt{2}} = 4\sqrt{2}.$$

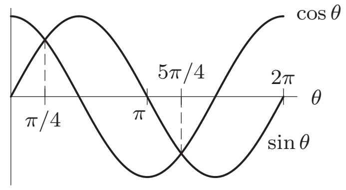

Figure 6.59

62. Since the graph of $y = e^x$ is above the graph of $y = \cos x$ (see Figure 6.60) we have

$$\begin{aligned}\text{Area } &= \int_0^1 (e^x - \cos x)\,dx \\ &= \int_0^1 e^x\,dx - \int_0^1 \cos x\,dx \\ &= e^x\Big|_0^1 - \sin x\Big|_0^1 \\ &= e^1 - e^0 - \sin 1 + \sin 0 \\ &= e - 1 - \sin 1.\end{aligned}$$

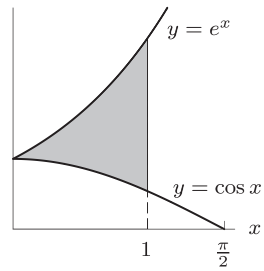

Figure 6.60

63. The area is given by

$$\begin{aligned}A = \int_{-1}^1 (\cosh x - \sinh x)\,dx &= (\sinh x - \cosh x)\Big|_{-1}^1 \\ &= \sinh 1 - \cosh 1 - (\sinh(-1) - \cosh(-1)) \\ &= 2\sinh 1.\end{aligned}$$

64. The area under $f(x) = 8x$ between $x = 1$ and $x = b$ is given by $\int_1^b (8x)dx$. Using the Fundamental Theorem to evaluate the integral:

$$\text{Area } = 4x^2\Big|_1^b = 4b^2 - 4.$$

Since the area is 192, we have

$$\begin{aligned} 4b^2 - 4 &= 192 \\ 4b^2 &= 196 \\ b^2 &= 49 \\ b &= \pm 7. \end{aligned}$$

Since b is larger than 1, we have $b = 7$.

65. The graph of $y = x^2 - c^2$ has x-intercepts of $x = \pm c$. See Figure 6.61. The shaded area is given by

$$\begin{aligned} \text{Area } &= -\int_{-c}^{c} (x^2 - c^2)\, dx \\ &= -2\int_0^c (x^2 - c^2)\, dx \\ &= -2\left(\frac{x^3}{3} - c^2 x\right)\Big|_0^c = -2\left(\frac{c^3}{3} - c^3\right) = \frac{4}{3}c^3. \end{aligned}$$

We want c to satisfy $(4c^3)/3 = 36$, so $c = 3$.

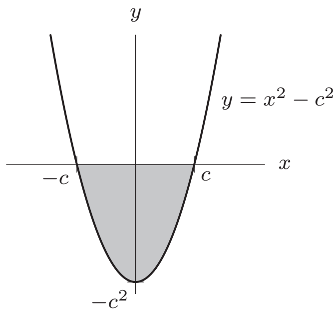

Figure 6.61

66. We have

$$\text{Average value } = \frac{1}{10-0}\int_0^{10} (x^2+1)dx = \frac{1}{10}\left(\frac{x^3}{3} + x\right)\Big|_0^{10} = \frac{1}{10}\left(\frac{10^3}{3} + 10 - 0\right) = \frac{103}{3}.$$

We see in Figure 6.62 that the average value of $103/3 \approx 34.33$ for $f(x)$ looks right.

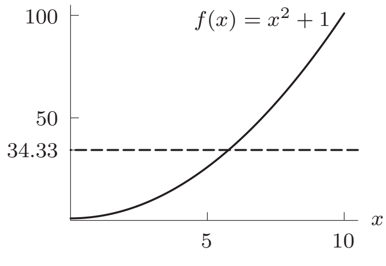

Figure 6.62

67. The average value of $v(x)$ on the interval $1 \le x \le c$ is

$$\frac{1}{c-1}\int_1^c \frac{6}{x^2}\,dx = \frac{1}{c-1}\left(-\frac{6}{x}\right)\Big|_1^c = \frac{1}{c-1}\left(\frac{-6}{c}+6\right) = \frac{6}{c}.$$

Since $\frac{1}{c-1}\int_1^c \frac{6}{x^2}dx = 1$, we have $\frac{6}{c} = 1$, so $c = 6$.

68. Letting $y = f(x)$, we have $x = f^{-1}(y)$:

$$\begin{aligned} y &= 5\sqrt{x} \\ \sqrt{x} &= 0.2y \\ x &= 0.04y^2 \\ \text{so}\quad f^{-1}(x) &= 0.04x^2. \end{aligned}$$

Letting $k = 0.04$ and $n = 2$, we have

$$\begin{aligned} \int_1^4 f^{-1}(x)\,dx &= \frac{0.04}{2+1}\cdot x^{2+1}\Big|_1^4 \\ &= \frac{0.04}{3}\cdot x^3\Big|_1^4 \\ &= \frac{0.04}{3}\left(4^3 - 1^3\right) \\ &= 0.84. \end{aligned}$$

69. We have

$$\begin{aligned} (f(x))^{-1} &= \left(5\sqrt{x}\right)^{-1} \\ &= \frac{1}{5x^{0.5}} \\ &= 0.2x^{-0.5}. \end{aligned}$$

Letting $k = 0.2$ and $n = -0.5$, we have

$$\begin{aligned} \int_1^4 (f(x))^{-1}\,dx &= \frac{0.2}{-0.5+1}\cdot x^{-0.5+1}\Big|_1^4 \\ &= \frac{0.2}{0.5}\cdot x^{0.5}\Big|_1^4 \\ &= 0.4\left(4^{0.5} - 1^{0.5}\right) \\ &= 0.4. \end{aligned}$$

70. Letting $k = 5$ and $n = 0.5$, we have

$$\begin{aligned} \int_1^4 f(x)\,dx &= \frac{5}{0.5+1}\cdot x^{0.5+1}\Big|_1^4 \\ &= \frac{5}{3/2}\cdot x^{3/2}\Big|_1^4 \\ &= \frac{10}{3}\cdot\left(4^{3/2} - 1^{3/2}\right) \\ &= \frac{10}{3}\cdot 7 = \frac{70}{3}. \end{aligned}$$

Thus,

$$\left(\int_1^4 f(x)\,dx\right)^{-1} = \left(\frac{70}{3}\right)^{-1} = \frac{3}{70}.$$

71. We have:

$$\begin{aligned} f(2) &= \int_0^2 2x^2\,dx \\ &= 2\int_0^2 x^2\,dx \\ &= 2\cdot\frac{1}{3}x^3\Big|_0^2 \\ &= \frac{16}{3}. \end{aligned}$$

72. We have:

$$\begin{aligned} f(n) &= \int_0^n nx^2\,dx \\ &= n\int_0^n x^2\,dx \quad n \text{ is a constant} \\ &= n\cdot\frac{1}{3}x^3\Big|_0^n \\ &= \frac{1}{3}n^4. \end{aligned}$$

73. If we let $f(x) = \int_2^x \sin(t^2)\,dt$ and $g(x) = x^3$, using the chain rule gives

$$\frac{d}{dx}\int_2^{x^3} \sin(t^2)\,dt = f'(g(x))\cdot g'(x) = \sin((x^3)^2)\cdot 3x^2 = 3x^2\sin(x^6).$$

74. Since $\int_{\cos x}^3 e^{t^2}\,dt = -\int_3^{\cos x} e^{t^2}\,dt$, if we let $f(x) = \int_3^x e^{t^2}\,dt$ and $g(x) = \cos x$, using the chain rule gives

$$\frac{d}{dx}\int_{\cos x}^3 e^{t^2}\,dt = -\frac{d}{dx}\int_3^{\cos x} e^{t^2}\,dt = -f'(g(x))\cdot g'(x) = -e^{(\cos x)^2}(-\sin x) = \sin x e^{\cos^2 x}.$$

75. If we split the integral at $x = 0$, we have

$$\int_{-x}^x e^{-t^4}\,dt = \int_{-x}^0 e^{-t^4}\,dt + \int_0^x e^{-t^4}\,dt = -\int_0^{-x} e^{-t^4}\,dt + \int_0^x e^{-t^4}\,dt.$$

If we let

$$F(x) = \int_0^x e^{-t^4}\,dt,$$

using the chain rule on each part separately gives

$$\frac{d}{dx}[-F(-x) + F(x)] = -(-1)F'(-x) + (1)F'(x) = e^{-(-x)^4} + e^{-x^4} = 2e^{-x^4}.$$

76. We split the integral at $x = 1$ (or any other point we choose):

$$\int_{e^t}^{t^3} \sqrt{1+x^2}\,dx = \int_1^{t^3} \sqrt{1+x^2}\,dx + \int_{e^t}^1 \sqrt{1+x^2}\,dx = \int_1^{t^3} \sqrt{1+x^2}\,dx - \int_1^{e^t} \sqrt{1+x^2}\,dx.$$

Differentiating each part separately and using the chain rule gives

$$\begin{aligned} \frac{d}{dt}\int_{e^t}^{t^3} \sqrt{1+x^2}\,dx &= \frac{d}{dt}\int_1^{t^3} \sqrt{1+x^2}\,dx - \frac{d}{dt}\int_1^{e^t} \sqrt{1+x^2}\,dx \\ &= \sqrt{1+(t^3)^2}\cdot 3t^2 - \sqrt{1+(e^t)^2}\cdot e^t \\ &= 3t^2\sqrt{1+t^6} - e^t\sqrt{1+e^{2t}}. \end{aligned}$$

77. (a) Inventory at time t is $f(t) = Q - \frac{Q}{A}t$. See Figure 6.63.

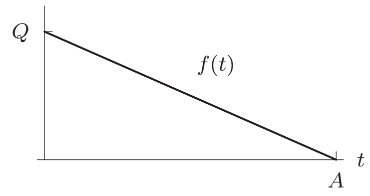

Figure 6.63

(b) Over the period $0 \le t \le A$,

$$\begin{aligned}\text{Average inventory} &= \frac{1}{A}\int_0^A f(t)\,dt \\ &= \frac{1}{A}\int_0^A \left(Q - \frac{Q}{A}t\right)\,dt \\ &= \frac{1}{A}\left(Qt - \frac{Q}{2A}t^2\right)\bigg|_0^A = \frac{1}{A}\left(QA - \frac{QA}{2}\right) = \frac{1}{2}Q.\end{aligned}$$

Graphically, the average is the y coordinate of the midpoint of the line in the graph above. Thus, the answer should be $\frac{Q+0}{2} = \frac{Q}{2}$.

Common sense tells us that since the rate is constant, the average amount should equal the amount at the midpoint of the interval, which is indeed $Q/2$.

78. (a) The distance traveled is equal to the area of the region under the graph of $v(t)$ between $t = 0$ and $t = 10$, or, the area of the trapezoid T in Figure 6.64.

$$\text{Area of } T = \frac{v(0) + v(10)}{2}\Delta t = \frac{(2 + 10\cdot 0) + (2 + 10\cdot 10)}{2}10 = 520 \text{ ft.}$$

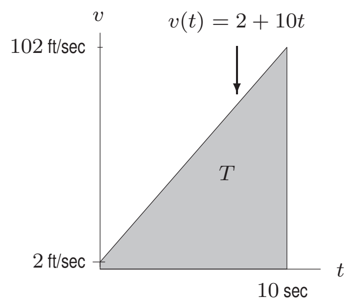

Figure 6.64

(b) Since $v(t) = 2 + 10t > 0$ for all $t \ge 0$, the car is always moving in the same direction. If the car's initial position is $s(0)$, then its position at time t is simply $s(0)+$ distance traveled in t seconds. To find this distance we calculate the area of the trapezoid where the right-hand limit is t rather than 10.

$$\text{Area of trapezoid} = \frac{v(0) + v(t)}{2}\Delta t = \frac{(2 + 10\cdot 0) + (2 + 10t)}{2}t = \frac{4 + 10t}{2}t = 5t^2 + 2t.$$

Thus $s(t) = s(0) + 5t^2 + 2t$ feet.

(c) The distance traveled by the car between $t = 0$ and $t = 10$ seconds is found by substituting into $s(t)$:

$$s(10) - s(0) = \left(s(0) + 5(10)^2 + 2\cdot 10\right) - s(0) = 5(10)^2 + 2\cdot 10 = 520 \text{ ft.}$$

This is the same answer we found in part (a).

(d) The distance traveled by the car between $t = 0$ and $t = 10$ is the area of the region under the graph of $v(t)$ and between $t = 0$ and $t = 10$, that is

$$\text{Total distance} = \int_0^{10} v(t)\,dt = \int_0^{10} (2 + 10t)\,dt.$$

The Fundamental Theorem of Calculus asserts that since $s(t)$ is an antiderivative for $v(t)$,

$$\int_0^{10} (2 + 10t)\,dt = s(10) - s(0).$$

The integral on the left is given by the area we found in part (a) and the difference on the right is what we found in part (c). Thus the Fundamental Theorem guarantees that the distances found in parts (a) and (c) are the same.

79. (a) Since $f'(t)$ is positive on the interval $0 < t < 2$ and negative on the interval $2 < t < 5$, the function $f(t)$ is increasing on $0 < t < 2$ and decreasing on $2 < t < 5$. Thus $f(t)$ attains its maximum at $t = 2$. Since the area under the t-axis is greater than the area above the t-axis, the function $f(t)$ decreases more than it increases. Thus, the minimum is at $t = 5$.

(b) To estimate the value of f at $t = 2$, we see that the area under $f'(t)$ between $t = 0$ and $t = 2$ is about 1 box, which has area 5. Thus,

$$f(2) = f(0) + \int_0^2 f'(t)dt \approx 50 + 5 = 55.$$

The maximum value attained by the function is $f(2) \approx 55$.

The area between $f'(t)$ and the t-axis between $t = 2$ and $t = 5$ is about 3 boxes, each of which has an area of 5. Thus

$$f(5) = f(2) + \int_2^5 f'(t)dt \approx 55 + (-15) = 40.$$

The minimum value attained by the function is $f(5) = 40$.

(c) Using part (b), we have $f(5) - f(0) = 40 - 50 = -10$. Alternately, we can use the Fundamental Theorem:

$$f(5) - f(0) = \int_0^5 f'(t)dt \approx 5 - 15 = -10.$$

80. Let v be the velocity and s be the position of the particle at time t. We know that $a = dv/dt$, so acceleration is the slope of the velocity graph. Similarly, velocity is the slope of the position graph. Graphs of v and s are shown in Figures 6.65 and 6.66, respectively.

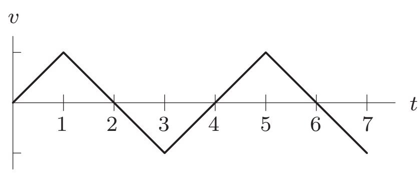

Figure 6.65: Velocity against time

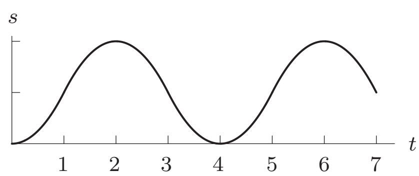

Figure 6.66: Position against time

81. (a) Since 6 sec = $1/10$ min,

$$\text{Angular acceleration} = \frac{2500 - 1100}{1/10} = 14{,}000 \text{ revs/min}^2.$$

(b) We know angular acceleration is the derivative of angular velocity. Since

$$\text{Angular acceleration} = 14{,}000,$$

we have

$$\text{Angular velocity} = 14{,}000t + C.$$

Measuring time from the moment at which the angular velocity is 1100 revs/min, we have $C = 1100$. Thus,

$$\text{Angular velocity} = 14{,}000t + 1100.$$

Thus the total number of revolutions performed during the period from $t = 0$ to $t = 1/10$ min is given by

$$\begin{array}{c}\text{Number of}\\ \text{revolutions}\end{array} = \int_0^{1/10} (14000t + 1100)dt = 7000t^2 + 1100t\Big|_0^{1/10} = 180 \text{ revolutions}.$$

82. (a) We find F for each piece, $0 \leq x \leq 1$ and $1 \leq x \leq 2$.
For $0 \leq x \leq 1$, we have $f(x) = -x + 1$, so F is of the form

$$\int (-x+1)\,dx = -\frac{x^2}{2} + x + C.$$

Since we want $F(1) = 1$, we need $C = 1/2$. See Figure 6.67.
For $1 \leq x \leq 2$, we have $f(x) = x - 1$, so F is of the form

$$\int (x-1)\,dx = \frac{x^2}{2} - x + C.$$

Again, since we want $F(1) = 1$, we have $C = 3/2$. See Figure 6.67.

(b) Evaluating

$$F(2) - F(0) = \left(\frac{2^2}{2} - 2 + \frac{3}{2}\right) - \left(-\frac{0^2}{2} + 0 + \frac{1}{2}\right) = 1.$$

The region under the graph of f consists of two triangles, whose area is

$$\text{Area } = \frac{1}{2} + \frac{1}{2} = 1.$$

(c) The Fundamental Theorem of Calculus says

$$\int_0^2 f(x)\,dx = F(2) - F(0).$$

Since the value of the integral is just the area under the curve, we have shown this in part (b).

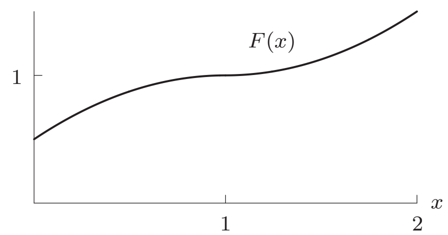

Figure 6.67

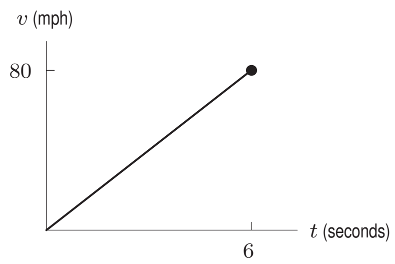
83. Since the car's acceleration is constant, a graph of its velocity against time t is linear, as shown below.



The acceleration is just the slope of this line:

$$\frac{dv}{dt} = \frac{80 - 0 \text{ mph}}{6 \text{ sec}} = \frac{40}{3} = 13.33\frac{\text{mph}}{\text{sec}}.$$

To convert our units into ft/sec^2,

$$\frac{40}{3} \cdot \frac{\text{mph}}{\text{sec}} \cdot \frac{5280 \text{ ft}}{1 \text{ mile}} \frac{1 \text{ hour}}{3600 \text{ sec}} = 19.55\frac{\text{ft}}{\text{sec}^2}$$

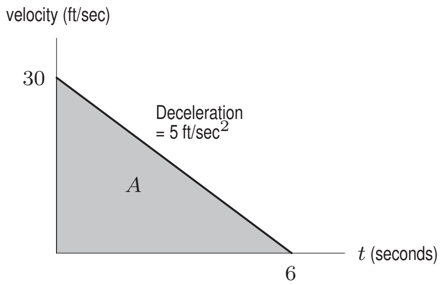
84. (a) Since the velocity is constantly decreasing, and $v(6) = 0$, the car stops after 6 seconds.

t (sec)	0	0.5	1	1.5	2	2.5	3	3.5	4	4.5	5	5.5	6
$v(t)$ (ft/sec)	30	27.5	25	22.5	20	17.5	15	12.5	10	7.5	5	2.5	0

(b) Over the interval $a \le t \le a + \frac{1}{2}$, the left-hand velocity is $v(a)$, and the right-hand velocity is $v(a + \frac{1}{2})$. Since we are considering half-second intervals, $\Delta t = \frac{1}{2}$, and $n = 12$. The left sum is 97.5 ft., and the right sum is 82.5 ft.

(c) Area A in the figure below represents distance traveled.

$$A = \frac{1}{2}(\text{base})(\text{height}) = \frac{1}{2} \cdot 6 \cdot 30 = 90 \text{ ft.}$$



(d) The velocity is constantly decreasing at a rate of 5 ft/sec per second, i.e. after each second the velocity has dropped by 5 units. Therefore $v(t) = 30 - 5t$.

An antiderivative for $v(t)$ is $s(t)$, where $s(t) = 30t - \frac{5}{2}t^2$. Thus by the Fundamental Theorem of Calculus, the distance traveled $= s(6) - s(0) = (30(6) - \frac{5}{2}(6)^2) - (30(0) - \frac{5}{2}(0)^2) = 90$ ft. Since $v(t)$ is decreasing, the left-hand sum in part (b) overestimates the distance traveled, while the right-hand sum underestimates it.

The area A is equal to the average of the left-hand and right-hand sums: 90 ft $= \frac{1}{2}(97.5 \text{ ft} + 82.5 \text{ ft})$. The left-hand sum is an overestimate of A; the right-hand sum is an underestimate.

85. (a) Using $g = -32$ ft/sec^2, we have

t (sec)	0	1	2	3	4	5
$v(t)$ (ft/sec)	80	48	16	−16	−48	−80

(b) The object reaches its highest point when $v = 0$, which appears to be at $t = 2.5$ seconds. By symmetry, the object should hit the ground again at $t = 5$ seconds.

(c) Left sum $= 80(1) + 48(1) + 16(\frac{1}{2}) = 136$ ft , which is an overestimate.
Right sum $= 48(1) + 16(1) + (-16)(\frac{1}{2}) = 56$ ft , which is an underestimate.
Note that we used a smaller third rectangle of width $1/2$ to end our sum at $t = 2.5$.

(d) We have $v(t) = 80 - 32t$, so antidifferentiation yields $s(t) = 80t - 16t^2 + s_0$.
But $s_0 = 0$, so $s(t) = 80t - 16t^2$.
At $t = 2.5$, $s(t) = 100$ ft., so 100 ft. is the highest point.

86. Since $A'(r) = C(r)$ and $C(r) = 2\pi r$, we have

$$A'(r) = 2\pi r.$$

Thus, we have, for some arbitrary constant K:

$$A(r) = \int 2\pi r \, dr = 2\pi \int r \, dr = 2\pi \frac{r^2}{2} + K = \pi r^2 + K.$$

Since a circle of radius $r = 0$ has area $= 0$, we substitute to find K:

$$0 = \pi 0^2 + K$$
$$K = 0.$$

Thus

$$A(r) = \pi r^2.$$

87. Since $V'(r) = S(r)$ and $S(r) = 4\pi r^2$, we have

$$V'(r) = 4\pi r^2.$$

Thus, we have, for some arbitrary constant K:

$$V(r) = \int 4\pi r^2\,dr = 4\pi \int r^2\,dr = 4\pi \frac{r^3}{3} + K = \frac{4}{3}\pi r^3 + K.$$

Since a sphere of radius $r = 0$ has volume $= 0$, we substitute to find K:

$$0 = \frac{4}{3}\pi 0^3 + K$$
$$K = 0.$$

Thus

$$V(r) = \frac{4}{3}\pi r^3.$$

88. The velocity of the car decreases at a constant rate, so we can write: $dv/dt = -a$. Integrating this gives $v = -at + C$. The constant of integration C is the velocity when $t = 0$, so $C = 60$ mph $= 88$ ft/sec, and $v = -at + 88$. From this equation we can see the car comes to rest at time $t = 88/a$.

Integrating the expression for velocity we get $s = -\frac{a}{2}t^2 + 88t + C$, where C is the initial position, so $C = 0$. We can use fact that the car comes to rest at time $t = 88/a$ after traveling 200 feet. Start with

$$s = -\frac{a}{2}t^2 + 88t,$$

and substitute $t = 88/a$ and $s = 200$:

$$200 = -\frac{a}{2}\left(\frac{88}{a}\right)^2 + 88\left(\frac{88}{a}\right) = \frac{88^2}{2a}$$
$$a = \frac{88^2}{2(200)} = 19.36 \text{ ft/sec}^2$$

89. (a) In the beginning, both birth and death rates are small; this is consistent with a very small population. Both rates begin climbing, the birth rate faster than the death rate, which is consistent with a growing population. The birth rate is then high, but it begins to decrease as the population increases.

(b)

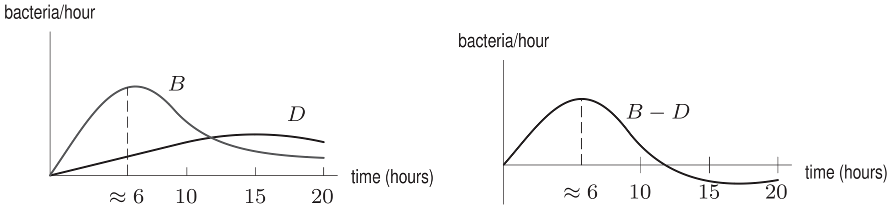


Figure 6.68: Difference between B and D is greatest at $t \approx 6$

The bacteria population is growing most quickly when $B - D$, the rate of change of population, is maximal; that happens when B is farthest above D, which is at a point where the slopes of both graphs are equal. That point is $t \approx 6$ hours.

(c) Total number born by time t is the area under the B graph from $t = 0$ up to time t. See Figure 6.69.

Total number alive at time t is the number born minus the number that have died, which is the area under the B graph minus the area under the D graph, up to time t. See Figure 6.70.

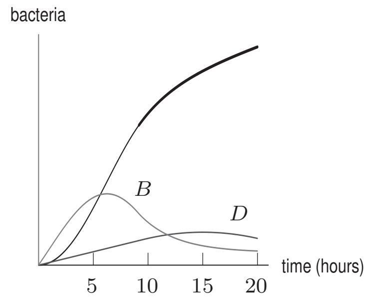

Figure 6.69: Number born by time t is $\int_0^t B(x)\,dx$

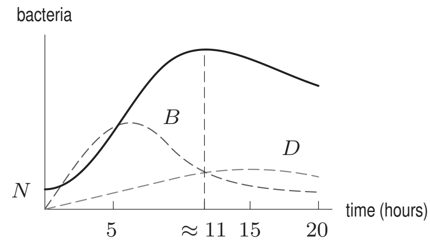

Figure 6.70: Number alive at time t is $\int_0^t (B(x) - D(x))\,dx$

From Figure 6.70, we see that the population is at a maximum when $B = D$, that is, after about 11 hours. This stands to reason, because $B - D$ is the rate of change of population, so population is maximized when $B - D = 0$, that is, when $B = D$.

90. See Figure 6.71.

Suppose t_1 is the time to fill the left side to the top of the middle ridge. Since the container gets wider as you go up, the rate dH/dt decreases with time. Therefore, for $0 \le t \le t_1$, graph is concave down.

At $t = t_1$, water starts to spill over to right side and so depth of left side does not change. It takes as long for the right side to fill to the ridge as the left side, namely t_1. Thus the graph is horizontal for $t_1 \le t \le 2t_1$.

For $t \ge 2t_1$, water level is above the central ridge. The graph is climbing because the depth is increasing, but at a slower rate than for $t \le t_1$ because the container is wider. The graph is concave down because width is increasing with depth. Time t_3 represents the time when container is full.

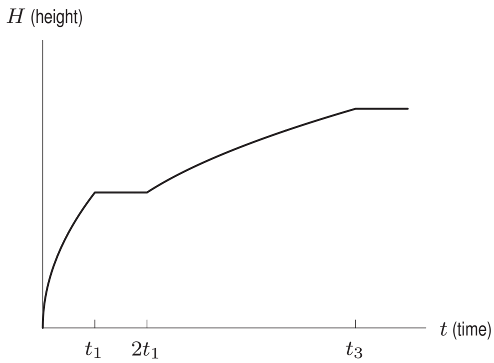

Figure 6.71

91. By the Second Fundamental Theorem, we know that $N'(t) = r(t)$. Since $r(t) > 0$, this means $N'(t) > 0$, so N is an increasing function. Since $r'(t) < 0$, this means $N''(t) < 0$, so the graph of N is concave down.

92. Since $r(x) > 0$ and $r'(x) < 0$, we know that the graph of r lies above the axis and is dropping from left to right. From the definition of N, we see that:

$$\begin{aligned}
N(20) &= \int_0^{20} r(x)\,dx = \text{Area from } t = 0 \text{ to } t = 20\\
N(10) &= \int_0^{10} r(x)\,dx = \text{Area from } t = 0 \text{ to } t = 10\\
N(20) - N(10) &= \int_{10}^{20} r(x)\,dx = \text{Area from } t = 10 \text{ to } t = 20\\
N(15) - N(5) &= \int_5^{15} r(x)\,dx = \text{ Area from } t = 5 \text{ to } t = 15.
\end{aligned}$$

- The largest area is described by $N(20) = \int_0^{20} r(x)\,dx$. This corresponds to the amount of pollutant leeched out during the first 20 days.

- The remaining three areas all describe 10-day intervals. Since the function is decreasing, areas to the left are larger than areas to the right. Thus,

$$\underbrace{\int_{10}^{20} r(x)\,dx}_{N(20)-N(10)} < \underbrace{\int_{5}^{15} r(x)\,dx}_{N(15)-N(5)} < \underbrace{\int_{0}^{10} r(x)\,dx}_{N(10)}.$$

These correspond (from least to greatest) the amount of pollutant leeched out from day 10 to day 20, from day 5 to day 15, and from day 0 to day 10.
- In conclusion: $N(20) - N(10) < N(15) - N(5) < N(10) < N(20)$.

93. (a) We know that $F(0) = \int_0^0 f(t)\,dt = 0$. so F has a zero at $x = 0$.

We know that

$$F(5) = \int_0^5 f(t)\,dt = \int_0^3 f(t)\,dt + \int_3^5 f(t)\,dt = 0 \text{ since } \int_0^3 f(t)\,dt = -\int_3^5 f(t)\,dt.$$

So F has a zero at $x = 5$.

We know that $f(x) = F'(x)$, so $F'(3) = f(3) = 0$.

This means F has at least two zeros, at $x = 0, 5$, and one critical point, at $x = 3$.

(b) We know that $G(1) = \int_1^1 F(t)\,dt = 0$, so G has a zero at $x = 1$.

We know that $F(x) = G'(x)$, so $G'(5) = F(5) = 0$ and $G'(0) = F(0) = 0$.

This means G has at least one zero, at $x = 1$, and two critical points, at $x = 0, 5$.

94. (a) The definition of P gives

$$P(0) = \int_0^0 \arctan(t^2)\,dt = 0$$

and

$$P(-x) = \int_0^{-x} \arctan(t^2)\,dt.$$

Changing the variable of integration by letting $t = -z$ gives

$$\int_0^{-x} \arctan(t^2)\,dt = \int_0^x \arctan((-z)^2)(-dz) = -\int_0^x \arctan(z^2)\,dz.$$

Thus P is an odd function.

(b) Using the Second Fundamental Theorem gives $P'(x) = \arctan(x^2)$, which is greater than 0 for $x \neq 0$. Thus P is increasing everywhere.

(c) Since

$$P''(x) = \frac{2x}{1 + x^4},$$

we have P concave up if $x > 0$ and concave down if $x < 0$.

(d) See Figure 6.72.

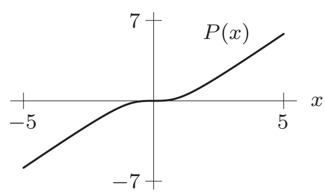

Figure 6.72

CAS Challenge Problems

95. (a) We have $\Delta x = \dfrac{(b-a)}{n}$ and $x_i = a + i(\Delta x) = a + i\left(\dfrac{b-a}{n}\right)$, so, since $f(x_i) = {x_i}^3$,

$$\text{Riemann sum } = \sum_{i=1}^{n} f(x_i)\Delta x = \sum_{i=1}^{n}\left[a + i\left(\frac{b-a}{n}\right)\right]^3\left(\frac{b-a}{n}\right).$$

(b) A CAS gives

$$\sum_{i=1}^{n}\left[a + \frac{i(b-a)}{n}\right]^3\frac{(b-a)}{n} = -\frac{(a-b)(a^3(n-1)^2 + (a^2b+ab^2)(n^2-1) + b^3(n+1)^3)}{4n^2}.$$

Taking the limit as $n \to \infty$ gives

$$\lim_{n\to\infty}\sum_{i=1}^{n}\left[a + i\left(\frac{b-a}{n}\right)\right]^3\left(\frac{b-a}{n}\right) = -\frac{(a+b)(a-b)(a^2+b^2)}{4}.$$

(c) The answer to part (b) simplifies to $\dfrac{b^4}{4} - \dfrac{a^4}{4}$. Since $\dfrac{d}{dx}\left(\dfrac{x^4}{4}\right) = x^3$, the Fundamental Theorem of Calculus says that

$$\int_a^b x^3 dx = \left.\frac{x^4}{4}\right|_a^b = \frac{b^4}{4} - \frac{a^4}{4}.$$

96. (a) A CAS gives

$$\int e^{2x}\,dx = \frac{1}{2}e^{2x} \qquad \int e^{3x}\,dx = \frac{1}{3}e^{3x} \qquad \int e^{3x+5}\,dx = \frac{1}{3}e^{3x+5}.$$

(b) The three integrals in part (a) obey the rule

$$\int e^{ax+b}\,dx = \frac{1}{a}e^{ax+b}.$$

(c) Checking the formula by calculating the derivative

$$\begin{aligned}\frac{d}{dx}\left(\frac{1}{a}e^{ax+b}\right) &= \frac{1}{a}\frac{d}{dx}e^{ax+b} && \text{by the constant multiple rule}\\ &= \frac{1}{a}e^{ax+b}\frac{d}{dx}(ax+b) && \text{by the chain rule}\\ &= \frac{1}{a}e^{ax+b}\cdot a = e^{ax+b}.\end{aligned}$$

97. (a) A CAS gives

$$\int \sin(3x)\,dx = -\frac{1}{3}\cos(3x) \qquad \int \sin(4x)\,dx = -\frac{1}{4}\cos(4x) \qquad \int \sin(3x-2)\,dx = -\frac{1}{3}\cos(3x-2).$$

(b) The three integrals in part (a) obey the rule

$$\int \sin(ax+b)\,dx = -\frac{1}{a}\cos(ax+b).$$

(c) Checking the formula by calculating the derivative

$$\begin{aligned}\frac{d}{dx}\left(-\frac{1}{a}\cos(ax+b)\right) &= -\frac{1}{a}\frac{d}{dx}\cos(ax+b) && \text{by the constant multiple rule}\\ &= -\frac{1}{a}(-\sin(ax+b))\frac{d}{dx}(ax+b) && \text{by the chain rule}\\ &= -\frac{1}{a}(-\sin(ax+b))\cdot a = \sin(ax+b).\end{aligned}$$

98. (a) A CAS gives

$$\int \frac{x-2}{x-1}\,dx = x - \ln|x-1|$$
$$\int \frac{x-3}{x-1}\,dx = x - 2\ln|x-1|$$
$$\int \frac{x-1}{x-2}\,dx = x + \ln|x-2|$$

Although the absolute values are needed in the answer, some CASs may not include them.

(b) The three integrals in part (a) obey the rule

$$\int \frac{x-a}{x-b}\,dx = x + (b-a)\ln|x-b|.$$

(c) Checking the formula by calculating the derivative

$$\frac{d}{dx}\left(x + (b-a)\ln|x-b|\right) = 1 + (b-a)\frac{1}{x-b} \quad \text{by the sum and constant multiple rules}$$
$$= \frac{(x-b)+(b-a)}{x-b} = \frac{x-a}{x-b}$$

99. (a) A CAS gives

$$\int \frac{1}{(x-1)(x-3)}\,dx = \frac{1}{2}(\ln|x-3| - \ln|x-1|)$$
$$\int \frac{1}{(x-1)(x-4)}\,dx = \frac{1}{3}(\ln|x-4| - \ln|x-1|)$$
$$\int \frac{1}{(x-1)(x+3)}\,dx = \frac{1}{4}(\ln|x+3| - \ln|x-1|).$$

Although the absolute values are needed in the answer, some CASs may not include them.

(b) The three integrals in part (a) obey the rule

$$\int \frac{1}{(x-a)(x-b)}\,dx = \frac{1}{b-a}(\ln|x-b| - \ln|x-a|).$$

(c) Checking the formula by calculating the derivative

$$\frac{d}{dx}\left(\frac{1}{b-a}(\ln|x-b| - \ln|x-a|)\right) = \frac{1}{b-a}\left(\frac{1}{x-b} - \frac{1}{x-a}\right)$$
$$= \frac{1}{b-a}\left(\frac{(x-a)-(x-b)}{(x-a)(x-b)}\right)$$
$$= \frac{1}{b-a}\left(\frac{b-a}{(x-a)(x-b)}\right) = \frac{1}{(x-a)(x-b)}.$$

PROJECTS FOR CHAPTER SIX

1. (a) If the poorest $p\%$ of the population has exactly $p\%$ of the goods, then $F(x) = x$.

(b) Any such F is increasing. For example, the poorest 50% of the population includes the poorest 40%, and so the poorest 50% must own more than the poorest 40%. Thus $F(0.4) \le F(0.5)$, and so, in general, F is increasing. In addition, it is clear that $F(0) = 0$ and $F(1) = 1$.

The graph of F is concave up by the following argument. Consider $F(0.05) - F(0.04)$. This is the fraction of resources the fifth poorest percent of the population has. Similarly, $F(0.20) - F(0.19)$ is the fraction of resources that the twentieth poorest percent of the population has. Since the twentieth poorest percent owns more than the fifth poorest percent, we have

$$F(0.05) - F(0.04) \le F(0.20) - F(0.19).$$

More generally, we can see that

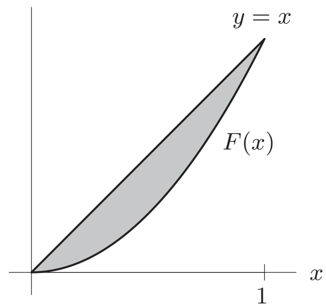
$$F(x_1 + \Delta x) - F(x_1) \le F(x_2 + \Delta x) - F(x_2)$$

for any x_1 smaller than x_2 and for any increment Δx. Dividing this inequality by Δx and taking the limit as $\Delta x \to 0$, we get

$$F'(x_1) \le F'(x_2).$$

So, the derivative of F is an increasing function, i.e. F is concave up.

(c) G is twice the shaded area below in the following figure. If the resource is distributed evenly, then G is zero. The larger G is, the more unevenly the resource is distributed. The maximum possible value of G is 1.



2. (a) In Figure 6.73, the area of the shaded region is $F(M)$. Thus, $F(M) = \int_0^M y(t)\,dt$ and, by the Fundamental Theorem, $F'(M) = y(M)$.

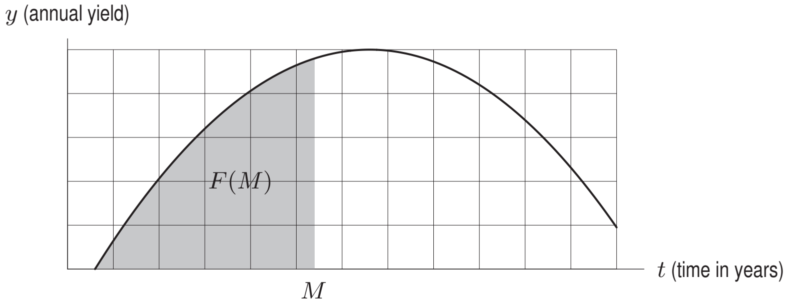


Figure 6.73

(b) Figure 6.74 is a graph of $F(M)$. Note that the graph of y looks like the graph of a quadratic function. Thus, the graph of F looks like a cubic.

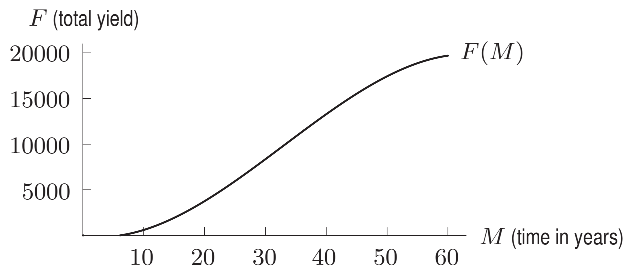

Figure 6.74

(c) We have

$$a(M) = \frac{1}{M}F(M) = \frac{1}{M}\int_0^M y(t)\,dt.$$

(d) If the function $a(M)$ takes on its maximum at some point M, then $a'(M) = 0$. Since

$$a(M) = \frac{1}{M}F(M),$$

differentiating using the quotient rule gives

$$a'(M) = \frac{MF'(M) - F(M)}{M^2} = 0,$$

so $MF'(M) = F(M)$. Since $F'(M) = y(M)$, the condition for a maximum may be written as

$$My(M) = F(M)$$

or as

$$y(M) = a(M).$$

To estimate the value of M which satisfies $My(M) = F(M)$, use the graph of $y(t)$. Notice that $F(M)$ is the area under the curve from 0 to M, and that $My(M)$ is the area of a rectangle of base M and height $y(M)$. Thus, we want the area under the curve to be equal to the area of the rectangle, or $A = B$ in Figure 6.75. This happens when $M \approx 50$ years. In other words, the orchard should be cut down after about 50 years.

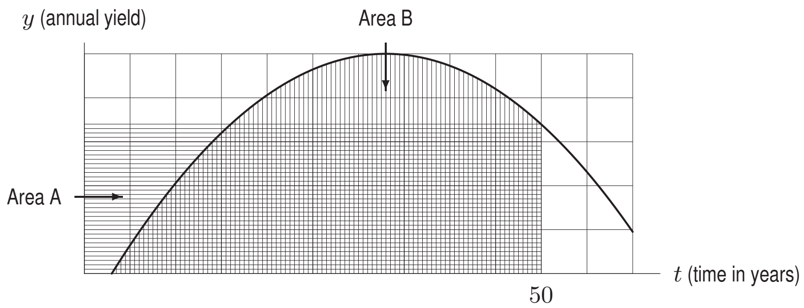

Figure 6.75

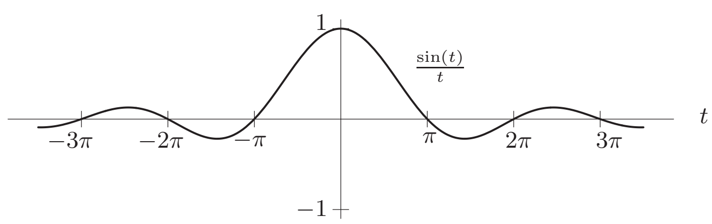
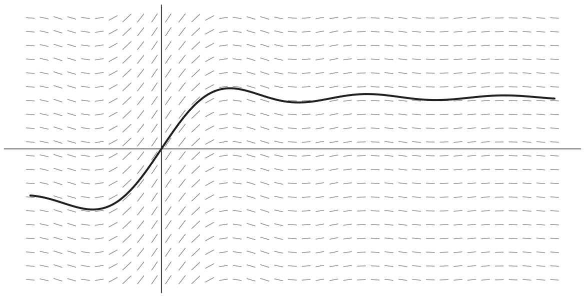
3. (a) (i)



(ii) $\text{Si}(x)$ neither always decreases nor always increases, since its derivative, $x^{-1}\sin x$, has both positive and negative values for $x > 0$. For positive x, $\text{Si}(x)$ is the area under the curve $\frac{\sin t}{t}$ and above the t-axis from $t = 0$ to $t = x$, minus the area above the curve and below the t-axis. Looking at the graph above, one can see that this difference of areas is going to always be positive.

(iii)

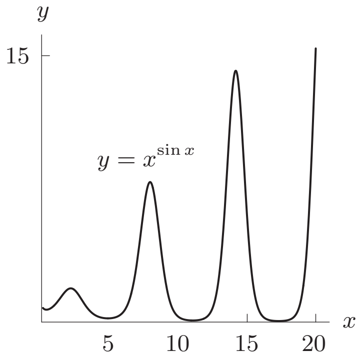


It seems that the limit exists: the curve drawn in the slope field,

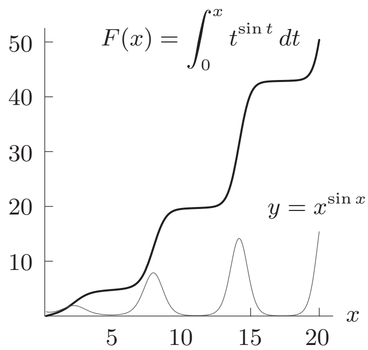
$$y = Si(x) = \int_0^x \frac{\sin t}{t}\,dt,$$

seems to approach some limiting height as $x \to \infty$. (In fact, the limiting height is $\pi/2$.)

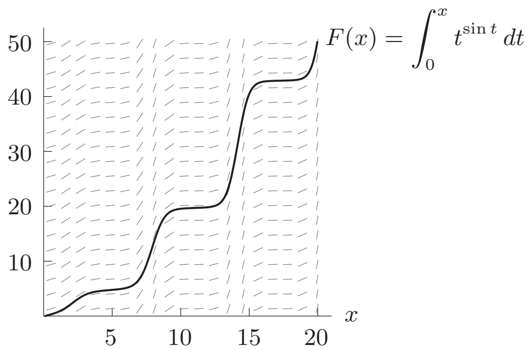
(b) (i)



(ii)



(iii)



(c) (i) The most obvious feature of the graph of $y = \sin(x^2)$ is its symmetry about the y-axis. This means the function $g(x) = \sin(x^2)$ is an even function, i.e. for all x, we have $g(x) = g(-x)$. Since $\sin(x^2)$ is even, its antiderivative F must be odd, that is $F(-x) = -F(-x)$. To see this, set $F(t) = \int_0^t \sin(x^2)\,dx$, then

$$F(-t) = \int_0^{-t} \sin(x^2)\,dx = -\int_{-t}^{0} \sin(x^2)\,dx = -\int_0^t \sin(x^2)\,dx = -F(t),$$

since the area from $-t$ to 0 is the same as the area from 0 to t. Thus $F(t) = -F(-t)$ and F is odd.

The second obvious feature of the graph of $y = \sin(x^2)$ is that it oscillates between -1 and 1 with a "period" which goes to zero as $|x|$ increases. This implies that $F'(x)$ alternates between intervals where it is positive or negative, and increasing or decreasing, with frequency growing arbitrarily large as $|x|$ increases. Thus $F(x)$ itself similarly alternates between intervals where it is increasing or decreasing, and concave up or concave down.

Finally, since $y = \sin(x^2) = F'(x)$ passes through $(0, 0)$, and $F(0) = 0$, F is tangent to the x-axis at the origin.

(ii)

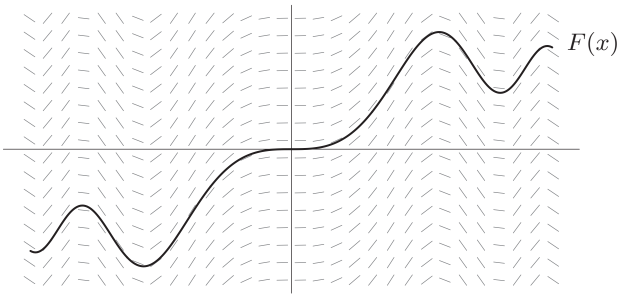


Figure 6.76

F never crosses the x-axis in the region $x > 0$, and $\lim_{x\to\infty} F(x)$ exists. One way to see these facts is to note that by the Construction Theorem,

$$F(x) = F(x) - F(0) = \int_0^x F'(t)\, dt.$$

So $F(x)$ is just the area between the curve $y = \sin(t^2)$ and the t-axis for $0 \le t \le x$ (with area above the t-axis counting positively, and area below the t-axis counting negatively). Now looking at the graph of curve, we see that this area will include alternating pieces above and below the t-axis. We can also see that the area of these pieces is approaching 0 as we go further out. So we add a piece, take a piece away, add another piece, take another piece away, and so on.

It turns out that this means that the sums of the pieces converge. To see this, think of walking from point A to point B. If you walk almost to B, then go a smaller distance toward A, then a yet smaller distance back toward B, and so on, you will eventually approach some point between A and B. So we can see that $\lim_{x\to\infty} F(x)$ exists. Also, since we always subtract a smaller piece than we just added, and the first piece is added instead of subtracted, we see that we never get a negative sum; thus $F(x)$ is never negative in the region $x > 0$, so $F(x)$ never crosses the x-axis there.

CHAPTER SEVEN

Solutions for Section 7.1

Exercises

1. (a) We substitute $w = 1 + x^2$, $dw = 2x\,dx$.

$$\int_{x=0}^{x=1} \frac{x}{1+x^2}\,dx = \frac{1}{2}\int_{w=1}^{w=2} \frac{1}{w}\,dw = \frac{1}{2}\ln|w|\bigg|_1^2 = \frac{1}{2}\ln 2.$$

(b) We substitute $w = \cos x$, $dw = -\sin x\,dx$.

$$\int_{x=0}^{x=\frac{\pi}{4}} \frac{\sin x}{\cos x}\,dx = -\int_{w=1}^{w=\sqrt{2}/2} \frac{1}{w}\,dw$$
$$= -\ln|w|\bigg|_1^{\sqrt{2}/2} = -\ln\frac{\sqrt{2}}{2} = \frac{1}{2}\ln 2.$$

2. (a) $\frac{d}{dx}\sin(x^2+1) = 2x\cos(x^2+1)$; $\quad \frac{d}{dx}\sin(x^3+1) = 3x^2\cos(x^3+1)$
(b) (i) $\frac{1}{2}\sin(x^2+1) + C$ (ii) $\frac{1}{3}\sin(x^3+1) + C$
(c) (i) $-\frac{1}{2}\cos(x^2+1) + C$ (ii) $-\frac{1}{3}\cos(x^3+1) + C$

3. We use the substitution $w = 3x$, $dw = 3\,dx$.

$$\int e^{3x}dx = \frac{1}{3}\int e^w dw = \frac{1}{3}e^w + C = \frac{1}{3}e^{3x} + C.$$

Check: $\frac{d}{dx}(\frac{1}{3}e^{3x} + C) = \frac{1}{3}e^{3x}(3) = e^{3x}$.

4. Make the substitution $w = t^2$, $dw = 2t\,dt$. The general antiderivative is $\int te^{t^2}\,dt = (1/2)e^{t^2} + C$.

5. We use the substitution $w = -x$, $dw = -\,dx$.

$$\int e^{-x}dx = -\int e^w dw = -e^w + C = -e^{-x} + C.$$

Check: $\frac{d}{dx}(-e^{-x} + C) = -(-e^{-x}) = e^{-x}$.

6. We use the substitution $w = -0.2t$, $dw = -0.2\,dt$.

$$\int 25e^{-0.2t}dt = \frac{25}{-0.2}\int e^w dw = -125e^w + C = -125e^{-0.2t} + C.$$

Check: $\frac{d}{dt}(-125e^{-0.2t} + C) = -125e^{-0.2t}(-0.2) = 25e^{-0.2t}$.

7. We use the substitution $w = 2x$, $dw = 2\,dx$.

$$\int \sin(2x)dx = \frac{1}{2}\int \sin(w)dw = -\frac{1}{2}\cos(w) + C = -\frac{1}{2}\cos(2x) + C.$$

Check: $\frac{d}{dx}(-\frac{1}{2}\cos(2x) + C) = \frac{1}{2}\sin(2x)(2) = \sin(2x)$.

8. We use the substitution $w = t^2$, $dw = 2t\,dt$.

$$\int t\cos(t^2)dt = \frac{1}{2}\int \cos(w)dw = \frac{1}{2}\sin(w) + C = \frac{1}{2}\sin(t^2) + C.$$

Check: $\dfrac{d}{dt}(\dfrac{1}{2}\sin(t^2) + C) = \dfrac{1}{2}\cos(t^2)(2t) = t\cos(t^2)$.

9. We use the substitution $w = 3 - t$, $dw = -\,dt$.

$$\int \sin(3-t)dt = -\int \sin(w)dw = -(-\cos(w)) + C = \cos(3-t) + C.$$

Check: $\frac{d}{dt}(\cos(3-t) + C) = -\sin(3-t)(-1) = \sin(3-t)$.

10. We use the substitution $w = -x^2$, $dw = -2x\,dx$.

$$\int xe^{-x^2}\,dx = -\frac{1}{2}\int e^{-x^2}(-2x\,dx) = -\frac{1}{2}\int e^w\,dw$$
$$= -\frac{1}{2}e^w + C = -\frac{1}{2}e^{-x^2} + C.$$

Check: $\frac{d}{dx}(-\frac{1}{2}e^{-x^2} + C) = (-2x)(-\frac{1}{2}e^{-x^2}) = xe^{-x^2}$.

11. Either expand $(r+1)^3$ or use the substitution $w = r + 1$. If $w = r + 1$, then $dw = dr$ and

$$\int (r+1)^3\,dr = \int w^3\,dw = \frac{1}{4}w^4 + C = \frac{1}{4}(r+1)^4 + C.$$

12. We use the substitution $w = y^2 + 5$, $dw = 2y\,dy$.

$$\int y(y^2+5)^8\,dy = \frac{1}{2}\int (y^2+5)^8(2y\,dy)$$
$$= \frac{1}{2}\int w^8\,dw = \frac{1}{2}\frac{w^9}{9} + C$$
$$= \frac{1}{18}(y^2+5)^9 + C.$$

Check: $\frac{d}{dy}(\frac{1}{18}(y^2+5)^9 + C) = \frac{1}{18}[9(y^2+5)^8(2y)] = y(y^2+5)^8$.

13. We use the substitution $w = 1 + 2x^3$, $dw = 6x^2\,dx$.

$$\int x^2(1+2x^3)^2\,dx = \int w^2(\frac{1}{6}\,dw) = \frac{1}{6}(\frac{w^3}{3}) + C = \frac{1}{18}(1+2x^3)^3 + C.$$

Check: $\frac{d}{dx}\left[\frac{1}{18}(1+2x^2)^3 + C\right] = \frac{1}{18}[3(1+2x^3)^2(6x^2)] = x^2(1+2x^3)^2$.

14. We use the substitution $w = t^3 - 3$, $dw = 3t^2\,dt$.

$$\int t^2(t^3-3)^{10}\,dt = \frac{1}{3}\int (t^3-3)^{10}(3t^2dt) = \int w^{10}\left(\frac{1}{3}\,dw\right)$$
$$= \frac{1}{3}\frac{w^{11}}{11} + C = \frac{1}{33}(t^3-3)^{11} + C.$$

Check: $\frac{d}{dt}[\frac{1}{33}(t^3-3)^{11} + C] = \frac{1}{3}(t^3-3)^{10}(3t^2) = t^2(t^3-3)^{10}$.

15. We use the substitution $w = x^2 + 3$, $dw = 2x\,dx$.

$$\int x(x^2+3)^2\,dx = \int w^2(\frac{1}{2}\,dw) = \frac{1}{2}\frac{w^3}{3} + C = \frac{1}{6}(x^2+3)^3 + C.$$

Check: $\frac{d}{dx}\left[\frac{1}{6}(x^2+3)^3 + C\right] = \frac{1}{6}\left[3(x^2+3)^2(2x)\right] = x(x^2+3)^2$.

16. We use the substitution $w = x^2 - 4$, $dw = 2x\,dx$.

$$\int x(x^2-4)^{7/2}\,dx = \frac{1}{2}\int (x^2-4)^{7/2}(2xdx) = \frac{1}{2}\int w^{7/2}\,dw$$
$$= \frac{1}{2}\left(\frac{2}{9}w^{9/2}\right) + C = \frac{1}{9}(x^2-4)^{9/2} + C.$$

Check: $\frac{d}{dx}\left(\frac{1}{9}(x^2-4)^{9/2} + C\right) = \frac{1}{9}\left(\frac{9}{2}(x^2-4)^{7/2}\right)2x = x(x^2-4)^{7/2}$.

17. In this case, it seems easier not to substitute.

$$\int y^2(1+y)^2\,dy = \int y^2(y^2+2y+1)\,dy = \int (y^4+2y^3+y^2)\,dy$$
$$= \frac{y^5}{5}+\frac{y^4}{2}+\frac{y^3}{3}+C.$$

Check: $\dfrac{d}{dy}\left(\dfrac{y^5}{5}+\dfrac{y^4}{2}+\dfrac{y^3}{3}+C\right) = y^4+2y^3+y^2 = y^2(y+1)^2.$

18. We use the substitution $w = 2t-7,\ dw = 2\,dt.$

$$\int (2t-7)^{73}\,dt = \frac{1}{2}\int w^{73}\,dw = \frac{1}{(2)(74)}w^{74}+C = \frac{1}{148}(2t-7)^{74}+C.$$

Check: $\dfrac{d}{dt}\left[\dfrac{1}{148}(2t-7)^{74}+C\right] = \dfrac{74}{148}(2t-7)^{73}(2) = (2t-7)^{73}.$

19. We use the substitution $w = x^3+1$, $dw = 3x^2\,dx$, to get

$$\int x^2e^{x^3+1}\,dx = \frac{1}{3}\int e^w\,dw = \frac{1}{3}e^w+C = \frac{1}{3}e^{x^3+1}+C.$$

Check: $\dfrac{d}{dx}\left(\dfrac{1}{3}e^{x^3+1}+C\right) = \dfrac{1}{3}e^{x^3+1}\cdot 3x^2 = x^2e^{x^3+1}.$

20. We use the substitution $w = y+5$, $dw = dy$, to get

$$\int \frac{dy}{y+5} = \int \frac{dw}{w} = \ln|w|+C = \ln|y+5|+C.$$

Check: $\dfrac{d}{dy}(\ln|y+5|+C) = \dfrac{1}{y+5}.$

21. We use the substitution $w = 4-x,\ dw = -dx.$

$$\int \frac{1}{\sqrt{4-x}}\,dx = -\int \frac{1}{\sqrt{w}}\,dw = -2\sqrt{w}+C = -2\sqrt{4-x}+C.$$

Check: $\dfrac{d}{dx}(-2\sqrt{4-x}+C) = -2\cdot\dfrac{1}{2}\cdot\dfrac{1}{\sqrt{4-x}}\cdot -1 = \dfrac{1}{\sqrt{4-x}}.$

22. In this case, it seems easier not to substitute.

$$\int (x^2+3)^2\,dx = \int (x^4+6x^2+9)\,dx = \frac{x^5}{5}+2x^3+9x+C.$$

Check: $\dfrac{d}{dx}\left[\dfrac{x^5}{5}+2x^3+9x+C\right] = x^4+6x^2+9 = (x^2+3)^2.$

23. We use the substitution $w = \cos\theta+5,\ dw = -\sin\theta\,d\theta.$

$$\int \sin\theta(\cos\theta+5)^7\,d\theta = -\int w^7\,dw = -\frac{1}{8}w^8+C$$
$$= -\frac{1}{8}(\cos\theta+5)^8+C.$$

Check:

$$\frac{d}{d\theta}\left[-\frac{1}{8}(\cos\theta+5)^8+C\right] = -\frac{1}{8}\cdot 8(\cos\theta+5)^7\cdot(-\sin\theta)$$
$$= \sin\theta(\cos\theta+5)^7$$

24. We use the substitution $w = \cos 3t,\ dw = -3\sin 3t\,dt$.

$$\int \sqrt{\cos 3t}\sin 3t\,dt = -\frac{1}{3}\int \sqrt{w}\,dw$$
$$= -\frac{1}{3}\cdot\frac{2}{3}w^{\frac{3}{2}} + C = -\frac{2}{9}(\cos 3t)^{\frac{3}{2}} + C.$$

Check:

$$\frac{d}{dt}\left[-\frac{2}{9}(\cos 3t)^{\frac{3}{2}} + C\right] = -\frac{2}{9}\cdot\frac{3}{2}(\cos 3t)^{\frac{1}{2}}\cdot(-\sin 3t)\cdot 3$$
$$= \sqrt{\cos 3t}\sin 3t.$$

25. We use the substitution $w = \sin\theta,\ dw = \cos\theta\,d\theta$.

$$\int \sin^6\theta\cos\theta\,d\theta = \int w^6\,dw = \frac{w^7}{7} + C = \frac{\sin^7\theta}{7} + C.$$

Check: $\dfrac{d}{d\theta}\left[\dfrac{\sin^7\theta}{7} + C\right] = \sin^6\theta\cos\theta.$

26. We use the substitution $w = \sin\alpha,\ dw = \cos\alpha\,d\alpha$.

$$\int \sin^3\alpha\cos\alpha\,d\alpha = \int w^3\,dw = \frac{w^4}{4} + C = \frac{\sin^4\alpha}{4} + C.$$

Check: $\dfrac{d}{d\alpha}\left(\dfrac{\sin^4\alpha}{4} + C\right) = \dfrac{1}{4}\cdot 4\sin^3\alpha\cdot\cos\alpha = \sin^3\alpha\cos\alpha.$

27. We use the substitution $w = \sin 5\theta,\ dw = 5\cos 5\theta\,d\theta$.

$$\int \sin^6 5\theta\cos 5\theta\,d\theta = \frac{1}{5}\int w^6\,dw = \frac{1}{5}(\frac{w^7}{7}) + C = \frac{1}{35}\sin^7 5\theta + C.$$

Check: $\dfrac{d}{d\theta}(\dfrac{1}{35}\sin^7 5\theta + C) = \dfrac{1}{35}[7\sin^6 5\theta](5\cos 5\theta) = \sin^6 5\theta\cos 5\theta.$

Note that we could also use Problem 25 to solve this problem, substituting $w = 5\theta$ and $dw = 5\,d\theta$ to get:

$$\int \sin^6 5\theta\cos 5\theta\,d\theta = \frac{1}{5}\int \sin^6 w\cos w\,dw$$
$$= \frac{1}{5}(\frac{\sin^7 w}{7}) + C = \frac{1}{35}\sin^7 5\theta + C.$$

28. We use the substitution $w = \cos 2x,\ dw = -2\sin 2x\,dx$.

$$\int \tan 2x\,dx = \int \frac{\sin 2x}{\cos 2x}\,dx = -\frac{1}{2}\int \frac{dw}{w}$$
$$= -\frac{1}{2}\ln|w| + C = -\frac{1}{2}\ln|\cos 2x| + C.$$

Check:

$$\frac{d}{dx}\left[-\frac{1}{2}\ln|\cos 2x| + C\right] = -\frac{1}{2}\cdot\frac{1}{\cos 2x}\cdot -2\sin 2x$$
$$= \frac{\sin 2x}{\cos 2x} = \tan 2x.$$

29. We use the substitution $w = \ln z, dw = \frac{1}{z}\,dz$.

$$\int \frac{(\ln z)^2}{z}\,dz = \int w^2\,dw = \frac{w^3}{3} + C = \frac{(\ln z)^3}{3} + C.$$

Check: $\dfrac{d}{dz}\left[\dfrac{(\ln z)^3}{3} + C\right] = 3\cdot\dfrac{1}{3}(\ln z)^2\cdot\dfrac{1}{z} = \dfrac{(\ln z)^2}{z}.$

30. We use the substitution $w = e^t + t,\ dw = (e^t + 1)\,dt$.

$$\int \frac{e^t + 1}{e^t + t}\,dt = \int \frac{1}{w}\,dw = \ln|w| + C = \ln|e^t + t| + C.$$

Check: $\frac{d}{dt}(\ln|e^t + t| + C) = \frac{e^t + 1}{e^t + t}$.

31. It seems easier not to substitute.

$$\int \frac{(t+1)^2}{t^2}\,dt = \int \frac{(t^2 + 2t + 1)}{t^2}\,dt$$
$$= \int \left(1 + \frac{2}{t} + \frac{1}{t^2}\right)\,dt = t + 2\ln|t| - \frac{1}{t} + C.$$

Check: $\frac{d}{dt}(t + 2\ln|t| - \frac{1}{t} + C) = 1 + \frac{2}{t} + \frac{1}{t^2} = \frac{(t+1)^2}{t^2}$.

32. We use the substitution $w = y^2 + 4,\ dw = 2y\,dy$.

$$\int \frac{y}{y^2 + 4}\,dy = \frac{1}{2}\int \frac{dw}{w} = \frac{1}{2}\ln|w| + C = \frac{1}{2}\ln(y^2 + 4) + C.$$

(We can drop the absolute value signs since $y^2 + 4 \geq 0$ for all y.)

Check: $\frac{d}{dy}\left[\frac{1}{2}\ln(y^2 + 4) + C\right] = \frac{1}{2} \cdot \frac{1}{y^2 + 4} \cdot 2y = \frac{y}{y^2 + 4}$.

33. Let $w = \sqrt{2}x$, so $dw = \sqrt{2}dx$. Then, since $\frac{d}{dw}\arctan w = \frac{1}{1 + w^2}$, we have

$$\int \frac{dx}{1 + 2x^2} = \frac{1}{\sqrt{2}}\int \frac{dw}{1 + w^2} = \frac{1}{\sqrt{2}}\arctan w + C = \frac{1}{\sqrt{2}}\arctan(\sqrt{2}x) + C.$$

34. Let $w = 2x$, then $dw = 2\,dx$ so that

$$\int \frac{dx}{\sqrt{1 - 4x^2}} = \frac{1}{2}\int \frac{dw}{\sqrt{1 - w^2}} = \frac{1}{2}\arcsin w + C = \frac{1}{2}\arcsin(2x) + C.$$

35. We use the substitution $w = \sqrt{x},\ dw = \frac{1}{2\sqrt{x}}\,dx$.

$$\int \frac{\cos\sqrt{x}}{\sqrt{x}}\,dx = \int \cos w(2\,dw) = 2\sin w + C = 2\sin\sqrt{x} + C.$$

Check: $\frac{d}{dx}(2\sin\sqrt{x} + C) = 2\cos\sqrt{x}\left(\frac{1}{2\sqrt{x}}\right) = \frac{\cos\sqrt{x}}{\sqrt{x}}$.

36. We use the substitution $w = \sqrt{y},\ dw = \frac{1}{2\sqrt{y}}\,dy$.

$$\int \frac{e^{\sqrt{y}}}{\sqrt{y}}\,dy = 2\int e^w\,dw = 2e^w + C = 2e^{\sqrt{y}} + C.$$

Check: $\frac{d}{dy}(2e^{\sqrt{y}} + C) = 2e^{\sqrt{y}} \cdot \frac{1}{2\sqrt{y}} = \frac{e^{\sqrt{y}}}{\sqrt{y}}$.

37. We use the substitution $w = x + e^x,\ dw = (1 + e^x)\,dx$.

$$\int \frac{1 + e^x}{\sqrt{x + e^x}}\,dx = \int \frac{dw}{\sqrt{w}} = 2\sqrt{w} + C = 2\sqrt{x + e^x} + C.$$

Check: $\frac{d}{dx}(2\sqrt{x + e^x} + C) = 2 \cdot \frac{1}{2}(x + e^x)^{-\frac{1}{2}} \cdot (1 + e^x) = \frac{1 + e^x}{\sqrt{x + e^x}}$.

38. We use the substitution $w = 2 + e^x$, $dw = e^x\,dx$.

$$\int \frac{e^x}{2+e^x}\,dx = \int \frac{dw}{w} = \ln|w| + C = \ln(2+e^x) + C.$$

(We can drop the absolute value signs since $2 + e^x \geq 0$ for all x.)

Check: $\frac{d}{dx}[\ln(2+e^x) + C] = \frac{1}{2+e^x} \cdot e^x = \frac{e^x}{2+e^x}$.

39. We use the substitution $w = x^2 + 2x + 19$, $dw = 2(x+1)dx$.

$$\int \frac{(x+1)dx}{x^2+2x+19} = \frac{1}{2}\int \frac{dw}{w} = \frac{1}{2}\ln|w| + C = \frac{1}{2}\ln(x^2+2x+19) + C.$$

(We can drop the absolute value signs, since $x^2 + 2x + 19 = (x+1)^2 + 18 > 0$ for all x.)

Check: $\frac{1}{dx}[\frac{1}{2}\ln(x^2+2x+19)] = \frac{1}{2}\frac{1}{x^2+2x+19}(2x+2) = \frac{x+1}{x^2+2x+19}$.

40. We use the substitution $w = 1 + 3t^2$, $dw = 6t\,dt$.

$$\int \frac{t}{1+3t^2}\,dt = \int \frac{1}{w}(\frac{1}{6}\,dw) = \frac{1}{6}\ln|w| + C = \frac{1}{6}\ln(1+3t^2) + C.$$

(We can drop the absolute value signs since $1 + 3t^2 > 0$ for all t).

Check: $\frac{d}{dt}\left[\frac{1}{6}\ln(1+3t^2) + C\right] = \frac{1}{6}\frac{1}{1+3t^2}(6t) = \frac{t}{1+3t^2}$.

41. We use the substitution $w = e^x + e^{-x}$, $dw = (e^x - e^{-x})\,dx$.

$$\int \frac{e^x - e^{-x}}{e^x + e^{-x}}\,dx = \int \frac{dw}{w} = \ln|w| + C = \ln(e^x + e^{-x}) + C.$$

(We can drop the absolute value signs since $e^x + e^{-x} > 0$ for all x).

Check: $\frac{d}{dx}[\ln(e^x + e^{-x}) + C] = \frac{1}{e^x + e^{-x}}(e^x - e^{-x})$.

42. We use the substitution $w = \sin(x^2)$, $dw = 2x\cos(x^2)\,dx$.

$$\int \frac{x\cos(x^2)}{\sqrt{\sin(x^2)}}\,dx = \frac{1}{2}\int w^{-\frac{1}{2}}\,dw = \frac{1}{2}(2w^{\frac{1}{2}}) + C = \sqrt{\sin(x^2)} + C.$$

Check: $\frac{d}{dx}(\sqrt{\sin(x^2)} + C) = \frac{1}{2\sqrt{\sin(x^2)}}[\cos(x^2)]2x = \frac{x\cos(x^2)}{\sqrt{\sin(x^2)}}$.

43. Since $d(\cosh 3t)/dt = 3\sinh 3t$, we have

$$\int \sinh 3t\,dt = \frac{1}{3}\cosh 3t + C.$$

44. Since $d(\sinh x)/dx = \cosh x$, we have

$$\int \cosh x\,dx = \sinh x + C.$$

45. Since $d(\sinh(2w+1))/dw = 2\cosh(2w+1)$, we have

$$\int \cosh(2w+1)\,dw = \frac{1}{2}\sinh(2w+1) + C.$$

46. Since $d(\cosh z)/dz = \sinh z$, the chain rule shows that

$$\frac{d}{dz}(e^{\cosh z}) = (\sinh z)e^{\cosh z}.$$

Thus,

$$\int (\sinh z)e^{\cosh z}\,dz = e^{\cosh z} + C.$$

47. Use the substitution $w = \cosh x$ and $dw = \sinh x\, dx$ so

$$\int \cosh^2 x \sinh x\, dx = \int w^2\, dw = \frac{1}{3}w^3 + C = \frac{1}{3}\cosh^3 x + C.$$

Check this answer by taking the derivative: $\frac{d}{dx}\left[\frac{1}{3}\cosh^3 x + C\right] = \cosh^2 x \sinh x.$

48. We use the substitution $w = x^2$ and $dw = 2x dx$ so

$$\int x \cosh x^2\, dx = \frac{1}{2}\int \cosh w\, dw = \frac{1}{2}\sinh w + C = \frac{1}{2}\sinh x^2 + C.$$

Check this answer by taking the derivative: $\frac{d}{dx}\left[\frac{1}{2}\sinh x^2 + C\right] = x\cosh x^2.$

49. The general antiderivative is $\int(\pi t^3 + 4t)\, dt = (\pi/4)t^4 + 2t^2 + C.$

50. Make the substitution $w = 3x$, $dw = 3\, dx$. We have
$$\int \sin 3x\, dx = \frac{1}{3}\int \sin w\, dw = \frac{1}{3}(-\cos w) + C = -\frac{1}{3}\cos 3x + C.$$

51. Make the substitution $w = x^2$, $dw = 2x\, dx$. We have
$$\int 2x\cos(x^2)\, dx = \int \cos w\, dw = \sin w + C = \sin x^2 + C.$$

52. Make the substitution $w = t^3$, $dw = 3t^2\, dt$. The general antiderivative is $\int 12t^2\cos(t^3)\, dt = 4\sin(t^3) + C.$

53. Make the substitution $w = 2 - 5x$, then $dw = -5dx$. We have
$$\int \sin(2-5x)dx = \int \sin w\left(-\frac{1}{5}\right) dw = -\frac{1}{5}(-\cos w) + C = \frac{1}{5}\cos(2-5x) + C.$$

54. Make the substitution $w = \sin x$, $dw = \cos x\, dx$. We have
$$\int e^{\sin x}\cos x\, dx = \int e^w\, dw = e^w + C = e^{\sin x} + C.$$

55. Make the substitution $w = x^2 + 1$, $dw = 2x\, dx$. We have
$$\int \frac{x}{x^2+1}dx = \frac{1}{2}\int \frac{dw}{w} = \frac{1}{2}\ln|w| + C = \frac{1}{2}\ln(x^2+1) + C.$$
(Notice that since $x^2 + 1 \geq 0$, $|x^2+1| = x^2 + 1$.)

56. Make the substitution $w = 2x$, then $dw = 2dx$. We have

$$\begin{aligned}\int \frac{1}{3\cos^2 2x}\, dx &= \frac{1}{3}\int \frac{1}{\cos^2 w}\left(\frac{1}{2}\right) dw\\ &= \frac{1}{6}\int \frac{1}{\cos^2 w}\, dw = \frac{1}{6}\tan w + C = \frac{1}{6}\tan 2x + C.\end{aligned}$$

57. $\int_0^\pi \cos(x+\pi)\, dx = \sin(x+\pi)\Big|_0^\pi = \sin(2\pi) - \sin(\pi) = 0 - 0 = 0$

58. We substitute $w = \pi x$. Then $dw = \pi\, dx$.

$$\int_{x=0}^{x=\frac{1}{2}} \cos\pi x\, dx = \int_{w=0}^{w=\pi/2} \cos w\left(\frac{1}{\pi}\, dw\right) = \frac{1}{\pi}(\sin w)\Big|_0^{\pi/2} = \frac{1}{\pi}$$

59. $\int_0^{\pi/2} e^{-\cos\theta}\sin\theta\, d\theta = e^{-\cos\theta}\Big|_0^{\pi/2} = e^{-\cos(\pi/2)} - e^{-\cos(0)} = 1 - \frac{1}{e}$

60. $\int_1^2 2xe^{x^2}\, dx = e^{x^2}\Big|_1^2 = e^{2^2} - e^{1^2} = e^4 - e = e(e^3 - 1)$

61. Let $\sqrt{x} = w$, $\frac{1}{2}x^{-\frac{1}{2}}dx = dw$, $\frac{dx}{\sqrt{x}} = 2\, dw$. If $x = 1$ then $w = 1$, and if $x = 4$ so $w = 2$. So we have

$$\int_1^4 \frac{e^{\sqrt{x}}}{\sqrt{x}}\, dx = \int_1^2 e^w \cdot 2\, dw = 2e^w\Big|_1^2 = 2(e^2 - e) \approx 9.34.$$

62. We substitute $w = t + 2$, so $dw = dt$.

$$\int_{t=-1}^{t=e-2} \frac{1}{t+2} dt = \int_{w=1}^{w=e} \frac{dw}{w} = \ln|w| \Big|_1^e = \ln e - \ln 1 = 1.$$

63. We substitute $w = \sqrt{x}$. Then $dw = \frac{1}{2}x^{-1/2}dx$.

$$\int_{x=1}^{x=4} \frac{\cos\sqrt{x}}{\sqrt{x}}\, dx = \int_{w=1}^{w=2} \cos w(2\, dw)$$
$$= 2(\sin w)\Big|_1^2 = 2(\sin 2 - \sin 1).$$

64. We substitute $w = 1 + x^2$. Then $dw = 2x\, dx$.

$$\int_{x=0}^{x=2} \frac{x}{(1+x^2)^2}\, dx = \int_{w=1}^{w=5} \frac{1}{w^2}\left(\frac{1}{2}\, dw\right) = -\frac{1}{2}\left(\frac{1}{w}\right)\Big|_1^5 = \frac{2}{5}.$$

65. $\displaystyle\int_{-1}^{3} (x^3 + 5x)\, dx = \frac{x^4}{4}\Big|_{-1}^{3} + \frac{5x^2}{2}\Big|_{-1}^{3} = 40.$

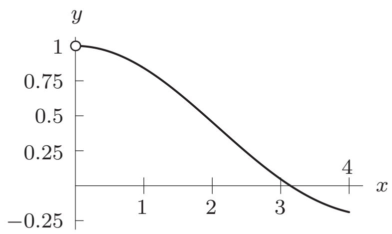
66. $\displaystyle\int_{-1}^{1} \frac{1}{1+y^2}\, dy = \tan^{-1} y\Big|_{-1}^{1} = \frac{\pi}{2}.$

67. $\displaystyle\int_{1}^{3} \frac{1}{x}\, dx = \ln x\Big|_{1}^{3} = \ln 3.$

68. $\displaystyle\int_{1}^{3} \frac{dt}{(t+7)^2} = \frac{-1}{t+7}\Big|_{1}^{3} = \left(-\frac{1}{10}\right) - \left(-\frac{1}{8}\right) = \frac{1}{40}$

69. $\displaystyle\int_{-1}^{2} \sqrt{x+2}\, dx = \frac{2}{3}(x+2)^{3/2}\Big|_{-1}^{2} = \frac{2}{3}\left[(4)^{3/2} - (1)^{3/2}\right] = \frac{2}{3}(7) = \frac{14}{3}$

70. It turns out that $\frac{\sin x}{x}$ cannot be integrated using elementary methods. However, the function is decreasing on [1,2]. One way to see this is to graph the function on a calculator or computer, as has been done below:



So since our function is monotonic, the error for our left- and right-hand sums is less than or equal to $\left|\frac{\sin 2}{2} - \frac{\sin 1}{1}\right| \Delta t \approx 0.61\Delta t$. So with 13 intervals, our error will be less than 0.05. With $n = 13$, the left sum is about 0.674, and the right sum is about 0.644. For more accurate sums, with $n = 100$ the left sum is about 0.6613 and the right sum is about 0.6574. The actual integral is about 0.6593.

71. Let $w = \sqrt{y+1}$, so $y = w^2 - 1$ and $dy = 2w\, dw$. Thus

$$\int y\sqrt{y+1}\, dy = \int (w^2 - 1)w2w\, dw = 2\int w^4 - w^2\, dw$$
$$= \frac{2}{5}w^5 - \frac{2}{3}w^3 + C = \frac{2}{5}(y+1)^{5/2} - \frac{2}{3}(y+1)^{3/2} + C.$$

72. Let $w = (z+1)^{1/3}$, so $z = w^3 - 1$ and $dz = 3w^2\,dw$. Thus

$$\int z(z+1)^{1/3}\,dz = \int (w^3-1)w3w^2\,dw = 3\int w^6 - w^3\,dw$$
$$= \frac{3}{7}w^7 - \frac{3}{4}w^4 + C = \frac{3}{7}(z+1)^{7/3} - \frac{3}{4}(z+1)^{4/3} + C.$$

73. Let $w = \sqrt{t+1}$, so $t = w^2 - 1$ and $dt = 2w\,dw$. Thus

$$\int \frac{t^2+t}{\sqrt{t+1}}\,dt = \int \frac{(w^2-1)^2 + (w^2-1)}{w}2w\,dw = 2\int w^4 - w^2\,dw$$
$$= \frac{2}{5}w^5 - \frac{2}{3}w^3 + C = \frac{2}{5}(t+1)^{5/2} - \frac{2}{3}(t+1)^{3/2} + C.$$

74. Let $w = 2 + 2\sqrt{x}$, so $x = ((w-2)/2)^2 = (w/2-1)^2$, and $dx = 2(w/2-1)(1/2)\,dw = (w/2-1)\,dw$. Thus

$$\int \frac{dx}{2+2\sqrt{x}} = \int \frac{(w/2-1)\,dw}{w} = \int \left(\frac{1}{2} - \frac{1}{w}\right)\,dw$$
$$= \frac{w}{2} - \ln|w| + C = \frac{1}{2}(2+2\sqrt{x}) - \ln|2+2\sqrt{x}| + C$$
$$= 1 + \sqrt{x} - \ln|2+2\sqrt{x}| + C = \sqrt{x} - \ln|2+2\sqrt{x}| + C.$$

In the last line, the 1 has been combined with the C.

75. Let $w = \sqrt{x-2}$, so $x = w^2 + 2$ and $dx = 2w\,dw$. Thus

$$\int x^2\sqrt{x-2}\,dx = \int (w^2+2)^2 w2w\,dw = 2\int w^6 + 4w^4 + 4w^2\,dw$$
$$= \frac{2}{7}w^7 + \frac{8}{5}w^5 + \frac{8}{3}w^3 + C$$
$$= \frac{2}{7}(x-2)^{7/2} + \frac{8}{5}(x-2)^{5/2} + \frac{8}{3}(x-2)^{3/2} + C.$$

76. Let $w = \sqrt{1-z}$, so $z = 1 - w^2$ and $dz = -2w\,dw$. Thus

$$\int (z+2)\sqrt{1-z}\,dz = \int (1-w^2+2)w(-2w)\,dw = 2\int w^4 - 3w^2\,dw$$
$$= \frac{2}{5}w^5 - 2w^3 + C = \frac{2}{5}(1-z)^{5/2} - 2(1-z)^{3/2} + C.$$

77. Let $w = \sqrt{t+1}$, so $t = w^2 - 1$ and $dt = 2w\,dw$. Thus

$$\int \frac{t}{\sqrt{t+1}}\,dt = \int \frac{w^2-1}{w}2w\,dw = 2\int w^2 - 1\,dw$$
$$= \frac{2}{3}w^3 - 2w + C = \frac{2}{3}(t+1)^{3/2} - 2(t+1)^{1/2} + C.$$

78. Let $w = \sqrt{2x+1}$, so $x = \frac{1}{2}(w^2-1)$ and $dx = w\,dw$. Thus

$$\int \frac{3x-2}{\sqrt{2x+1}}\,dx = \int \frac{3\cdot\frac{1}{2}(w^2-1) - 2}{w}w\,dw = \int \frac{3}{2}w^2 - \frac{7}{2}\,dw$$
$$= \frac{1}{2}w^3 - \frac{7}{2}w + C = \frac{1}{2}(2x+1)^{3/2} - \frac{7}{2}(2x+1)^{1/2} + C.$$

Problems

79. If we let $y = 3x$ in the first integral, we get $dy = 3dx$. Also, the limits $x = 0$ and $x = \pi/3$ become $y = 0$ and $y = 3(\pi/3) = \pi$. Thus

$$\int_0^{\pi/3} 3\sin^2(3x)\,dx = \int_0^{\pi/3} \sin^2(3x)\,3dx = \int_0^{\pi} \sin^2(y)\,dy.$$

80. If we let $t = s^2$ in the first integral, we get $dt = 2s\,ds$, so

$$2\,ds = \frac{1}{s}dt = \frac{1}{\sqrt{t}}dt.$$

Also, the limits $s = 1$ and $s = 2$ become $t = 1$ and $t = 4$. Thus

$$\int_1^2 2\ln(s^2+1)\,ds = \int_1^2 \ln(s^2+1)2\,ds = \int_1^4 \ln(t+1)\frac{1}{\sqrt{t}}\,dt.$$

81. If we let $w = e^z$ in the first integral, we get $dw = e^z dz$ and $z = \ln w$. Also, the limits $w = 1$ and $w = e$ become $z = 0$ and $z = 1$. Thus

$$\int_1^e (\ln w)^3\,dw = \int_0^1 z^3 e^z\,dz.$$

82. If we let $t = \pi - x$ in the first integral, we get $dt = -dx$ and $x = \pi - t$. Also, the limits $x = 0$ and $x = \pi$ become $t = \pi$ and $t = 0$. Thus

$$\int_0^\pi x\cos(\pi - x)\,dx = -\int_\pi^0 (\pi - t)\cos t\,dt = \int_0^\pi (\pi - t)\cos t\,dt.$$

83. As x goes from $\sqrt{a}$ to $\sqrt{b}$ the values of $w = x^2$ increase from a to b. Since $x = \sqrt{w}$ we have $dx = dw/(2\sqrt{w})$. Hence

$$\int_{\sqrt{a}}^{\sqrt{b}} dx = \int_a^b \frac{1}{2\sqrt{w}}dw = \int_a^b g(w)dw$$

with

$$g(w) = \frac{1}{2\sqrt{w}}.$$

84. As x goes from a to b the values of $w = e^x$ increase from e^a to e^b. We have $e^{-x} = 1/w$. Since $x = \ln w$ we have $dx = dw/w$. Hence

$$\int_a^b e^{-x}dx = \int_{e^a}^{e^b} \frac{1}{w}\frac{dw}{w} = \int_{e^a}^{e^b} g(w)dw$$

with

$$g(w) = \frac{1}{w^2}.$$

85. After the substitution $w = e^x$ and $dw = e^x\,dx$, the first integral becomes

$$\frac{1}{2}\int \frac{1}{1+w^2}\,dw,$$

while after the substitution $w = \sin x$ and $dw = \cos x\,dx$, the second integral becomes

$$\int \frac{1}{1+w^2}\,dw.$$

86. The substitution $w = \ln x$, $dw = \frac{1}{x}\,dx$ transforms the first integral into $\int w\,dw$, which is just a respelling of the integral $\int x\,dx$.

87. For the first integral, let $w = \sin x$, $dw = \cos x\,dx$. Then

$$\int e^{\sin x}\cos x\,dx = \int e^w\,dw.$$

For the second integral, let $w = \arcsin x$, $dw = \frac{1}{\sqrt{1-x^2}}dx$. Then

$$\int \frac{e^{\arcsin x}}{\sqrt{1-x^2}}\,dx = \int e^w\,dw.$$

88. The substitutions $w = \sin x$, $dw = \cos w$ and $w = x^3 + 1$, $dw = 3x^2\,dx$ transform the integrals into

$$\int w^3\,dw \quad \text{and} \quad \frac{1}{3}\int w^3\,dw.$$

89. For the first integral, let $w = x + 1$, $dw = dx$. Then

$$\int \sqrt{x+1}\,dx = \int \sqrt{w}\,dw.$$

For the second integral, let $w = 1 + \sqrt{x}$, $dw = \frac{1}{2}x^{-\frac{1}{2}}\,dx = \frac{1}{2\sqrt{x}}\,dx$. Then, $\frac{dx}{\sqrt{x}} = 2\,dw$, and

$$\int \frac{\sqrt{1+\sqrt{x}}}{\sqrt{x}}\,dx = \int \sqrt{1+\sqrt{x}}\left(\frac{dx}{\sqrt{x}}\right) = 2\int \sqrt{w}\,dw.$$

90. Using substitution, we can show

$$\int_0^1 f'(x)\sin f(x)\,dx = -\cos f(x)\bigg|_0^1 = -\cos f(1) + \cos f(0) = \cos 5 - \cos 7.$$

91. Using substitution, we have

$$\int_1^3 f'(x)e^{f(x)}\,dx = e^{f(x)}\bigg|_1^3 = e^{f(3)} - e^{f(1)} = e^{11} - e^7.$$

92. Using substitution, we have

$$\int_1^3 \frac{f'(x)}{f(x)}\,dx = \ln|f(x)|\bigg|_1^3 = \ln|f(3)| - \ln|f(1)| = \ln 11 - \ln 7 = \ln(11/7).$$

93. Using substitution, we have

$$\int_0^1 e^x f'(e^x)\,dx = f(e^x)\bigg|_0^1 = f(e^1) - f(e^0) = f(e) - f(1) = 10 - 7 = 3.$$

94. Using substitution, we have

$$\int_1^e \frac{f'(\ln x)}{x}\,dx = f(\ln x)\bigg|_1^e = f(\ln e) - f(\ln 1) = f(1) - f(0) = 7 - 5 = 2.$$

95. Using substitution, we can show

$$\int_0^1 f'(x)(f(x))^2\,dx = \frac{(f(x))^3}{3}\bigg|_0^1 = \frac{(f(1))^3}{3} - \frac{(f(0))^3}{3} = \frac{7^3}{3} - \frac{5^3}{3} = \frac{218}{3}.$$

96. Using substitution, we have

$$\int_0^{\pi/2} \sin x \cdot f'(\cos x)\,dx = -f(\cos x)\bigg|_0^{\pi/2} = -f\left(\cos\left(\frac{\pi}{2}\right)\right) + f(\cos 0) = -f(0) + f(1) = -5 + 7 = 2.$$

97. By substitution with $w = g(x)$, we have

$$\int g'(x)(g(x))^4\,dx = \int w^4 dw = \frac{w^5}{5} + C = \frac{(g(x))^5}{5} + C.$$

98. By substitution with $w = g(x)$, we have

$$\int g'(x)e^{g(x)}\,dx = \int e^w dw = e^w + C = e^{g(x)} + C.$$

99. By substitution with $w = g(x)$, we have

$$\int g'(x)\sin g(x)\,dx = \int \sin w\,dw = -\cos w + C = -\cos g(x) + C.$$

100. By substitution with $w = 1 + g(x)$, we have

$$\int g'(x)\sqrt{1+g(x)}\,dx = \int \sqrt{w}\,dw = \int w^{1/2}dw = \frac{w^{3/2}}{3/2} + C = \frac{2}{3}(1+g(x))^{3/2} + C.$$

101. Letting $w = 1 - 4x^3, dw = -12x^2\,dx$, we have

$$\int x^2\sqrt{1-4x^3}\,dx = \int (\underbrace{1-4x^3}_{w})^{1/2}\left(-\frac{1}{12}\right)\underbrace{(-12x^2\,dx)}_{dw} = \int \left(-\frac{1}{12}\right)w^{1/2}\,dw,$$

so $w = 1 - 4x^3, k = -1/12, n = 1/2$.

102. Letting $w = \sin t, dw = \cos t\,dt$, we have

$$\int \frac{\cos t}{\sin t}\,dt = \int (\underbrace{\sin t}_{w})^{-1}\underbrace{\cos t\,dt}_{dw} = \int 1\cdot w^{-1}\,dw,$$

so $w = \sin t, k = 1, n = -1$.

103. Letting $w = x^2 - 3, dw = 2x\,dx$, we have

$$\int \frac{\overbrace{2x\,dx}^{dw}}{(\underbrace{x^2-3}_{w})^2} = \int 1\cdot w^{-2}\,dw,$$

so $w = x^2 - 3, k = 1, n = -2$.

104. Since $w = 5x^2 + 7$ we have $dw = 10x\,dx$ so $x\,dx = 0.1\,dw$. Finding the limits of integration in terms of w gives:

$$w_0 = 5(1)^2 + 7 = 12$$
$$w_1 = 5(5)^2 + 7 = 132.$$

This gives

$$\int_1^5 \frac{3x\,dx}{\sqrt{5x^2+7}} = \int_{12}^{132}\frac{3(0.1\,dw)}{w^{1/2}} = \int_{12}^{132} 0.3w^{-1/2}\,dw,$$

so $k = 0.3, n = -1/2, w_0 = 12, w_1 = 132$.

105. Since $w = 2^x + 3$ we have $dw = 2^x\ln 2\,dx$, so $2^x\,dx = dw/\ln 2$. Finding the limits of integration in terms of w gives:

$$w_0 = 2^0 + 3 = 4$$
$$w_1 = 2^5 + 3 = 35.$$

This gives

$$\int_0^5 \frac{2^x\,dx}{2^x+3} = \int_4^{35}\frac{dw/\ln 2}{2^x+3} = \int_4^{35}\frac{1}{\ln 2}w^{-1}\,dw,$$

so $k = 1/\ln 2, n = -1, w_0 = 4, w_1 = 35$.

106. Since $w = \sin 2x$ we have $dw = 2\cos 2x\,dx$, so $\cos 2x\,dx = 0.5\,dw$. Finding the limits of integration in terms of w gives:

$$w_0 = \sin\left(2\cdot\frac{\pi}{12}\right) = \sin\left(\frac{\pi}{6}\right) = 0.5$$
$$w_1 = \sin\left(2\cdot\frac{\pi}{4}\right) = \sin\left(\frac{\pi}{2}\right) = 1.$$

This gives

$$\int_{\pi/12}^{\pi/4} \sin^7(2x)\cos(2x)\,dx = \int_{0.5}^{1} 0.5w^7\,dw,$$

so $k = 0.5, n = 7, w_0 = 0.5, w_1 = 1$.

107. Letting $w = -x^2, dw = -2x\,dx$, we have

$$\int xe^{-x^2}\,dx = \int\left(-\frac{1}{2}\right)e^w\,dw,$$

so $w = -x^2, k = -1/2$.

108. Letting $w = \sin\phi, dw = \cos\phi$, we have

$$\int e^{\sin\phi}\cos\phi d\phi = \int 1\cdot e^w\,dw,$$

so $w = \sin\phi, k = 1$.

109. We have

$$\int\sqrt{e^r}\,dr = \int (e^r)^{1/2}\,dr$$
$$= \int e^{0.5r}\,dr.$$

Letting $w = 0.5r, dw = 0.5\,dr$, and $dr = 2\,dw$, we have

$$\int\sqrt{e^r}\,dr = \int 2e^w\,dw,$$

so $w = 0.5r, k = 2$.

110. We have

$$\int\frac{z^2\,dz}{e^{-z^3}} = \int e^{z^3}z^2\,dz.$$

Letting $w = z^3$, so $dw = 3z^2\,dz$, we have

$$\int\frac{z^2\,dz}{e^{-z^3}} = \int\frac{1}{3}e^w\,dw,$$

so $w = z^3, k = 1/3$.

111. We have

$$\int e^{2t}e^{3t-4}\,dt = \int e^{-4}e^{5t}\,dt$$
$$= \int e^{-4}\cdot\frac{1}{5}e^w\,dw \quad \text{where } w = 5t, dw = 5\,dt,$$
$$= \int\frac{1}{5e^4}\cdot e^w\,dw,$$

so $w = 5t$ and $k = 1/(5e^4)$.

112. Let $w = 2t - 3, dw = 2\,dt$. Then

$$\int_3^7 e^{2t-3}\,dt = \int_{t=3}^{t=7} e^w 0.5\,dw = \int_{w=3}^{w=11} 0.5e^w\,dw,$$

so $a = 3, b = 11, A = 0.5, w = 2t - 3$.

113. Let $w = \cos(\pi t)$, $dw = -\pi \sin(\pi t)\, dt$. Then $\sin(\pi t)\, dt = -(1/\pi)\, dw$, giving

$$\int_0^1 e^{\cos(\pi t)} \sin(\pi t)\, dt = \int_{t=0}^{t=1} e^w \left(\frac{-1}{\pi}\right) dw = \int_{w=1}^{w=-1} \left(\frac{-1}{\pi}\right) e^w\, dw,$$

so $a = 1, b = -1, A = -1/\pi, w = \cos(\pi t)$. Note that since

$$\int_1^{-1} \frac{-1}{\pi} e^w\, dw = -\int_{-1}^1 \frac{-1}{\pi} e^w\, dw = \int_{-1}^1 \frac{1}{\pi} e^w\, dw,$$

another possible answer is $a = -1, b = 1, A = 1/\pi, w = \cos(\pi t)$.

114. (a) $2\sqrt{x} + C$
(b) $2\sqrt{x+1} + C$
(c) To get this last result, we make the substitution $w = \sqrt{x}$. Normally we would like to substitute $dw = \frac{1}{2\sqrt{x}}\, dx$, but in this case we cannot since there are no spare $\frac{1}{\sqrt{x}}$ terms around. Instead, we note $w^2 = x$, so $2w\, dw = dx$. Then

$$\begin{aligned}\int \frac{1}{\sqrt{x}+1}\, dx &= \int \frac{2w}{w+1}\, dw \\ &= 2\int \frac{(w+1)-1}{w+1}\, dw \\ &= 2\int \left(1 - \frac{1}{w+1}\right) dw \\ &= 2(w - \ln|w+1|) + C \\ &= 2\sqrt{x} - 2\ln(\sqrt{x}+1) + C.\end{aligned}$$

We also note that we can drop the absolute value signs, since $\sqrt{x} + 1 \geq 0$ for all x.

115. (a) This integral can be evaluated using integration by substitution. We use $w = x^2$, $dw = 2xdx$.

$$\int x \sin x^2 dx = \frac{1}{2}\int \sin(w) dw = -\frac{1}{2}\cos(w) + C = -\frac{1}{2}\cos(x^2) + C.$$

(b) This integral cannot be evaluated using a simple integration by substitution.
(c) This integral cannot be evaluated using a simple integration by substitution.
(d) This integral can be evaluated using integration by substitution. We use $w = 1 + x^2$, $dw = 2xdx$.

$$\int \frac{x}{(1+x^2)^2} dx = \frac{1}{2}\int \frac{1}{w^2} dw = \frac{1}{2}\left(\frac{-1}{w}\right) + C = \frac{-1}{2(1+x^2)} + C.$$

(e) This integral cannot be evaluated using a simple integration by substitution.
(f) This integral can be evaluated using integration by substitution. We use $w = 2 + \cos x$, $dw = -\sin x dx$.

$$\int \frac{\sin x}{2+\cos x} dx = -\int \frac{1}{w} dw = -\ln|w| + C = -\ln|2+\cos x| + C.$$

116. To find the area under the graph of $f(x) = xe^{x^2}$, we need to evaluate the definite integral

$$\int_0^2 xe^{x^2}\, dx.$$

This is done in Example 9, Section 7.1, using the substitution $w = x^2$, the result being

$$\int_0^2 xe^{x^2}\, dx = \frac{1}{2}(e^4 - 1).$$

117. Since $f(x) = 1/(x+1)$ is positive on the interval $x = 0$ to $x = 2$, we have

$$\text{Area} = \int_0^2 \frac{1}{x+1} dx = \ln(x+1)\Big|_0^2 = \ln 3 - \ln 1 = \ln 3.$$

The area is $\ln 3 \approx 1.0986$.

118. The area under $f(x) = \sinh(x/2)$ between $x = 0$ and $x = 2$ is given by

$$A = \int_0^2 \sinh\left(\frac{x}{2}\right)\, dx = 2\cosh\left(\frac{x}{2}\right)\Big|_0^2 = 2\cosh 1 - 2.$$

119. Since $(e^{\theta+1})^3 = e^{3\theta+3} = e^{3\theta} \cdot e^3$, we have

$$\begin{aligned}\text{Area } &= \int_0^2 (e^{\theta+1})^3\, d\theta = \int_0^2 e^{3\theta} \cdot e^3\, d\theta \\ &= e^3 \int_0^2 e^{3\theta}\, d\theta = e^3 \frac{1}{3} e^{3\theta}\Big|_0^2 = \frac{e^3}{3}(e^6 - 1).\end{aligned}$$

120. Since e^{t+1} is larger than e^t, we have

$$\text{Area } = \int_0^2 (e^{t+1} - e^t)\, dt = (e^{t+1} - e^t)\Big|_0^2 = e^3 - e^2 - e + 1.$$

(The integral $\int e^{t+1}\, dt = e^{t+1} + C$ can be done by substitution or guess and check.)

121. The curves $y = e^x$ and $y = 3$ cross where

$$e^x = 3 \quad \text{so} \quad x = \ln 3,$$

and the graph of $y = e^x$ is below the line $y = 3$ for $0 \le x \le \ln 3$. (See Figure 7.1.) Thus

$$\begin{aligned}\text{Area } &= \int_0^{\ln 3} (3 - e^x)\, dx = (3x - e^x)\Big|_0^{\ln 3} \\ &= 3\ln 3 - e^{\ln 3} - (0 - 1) = 3\ln 3 - 2.\end{aligned}$$

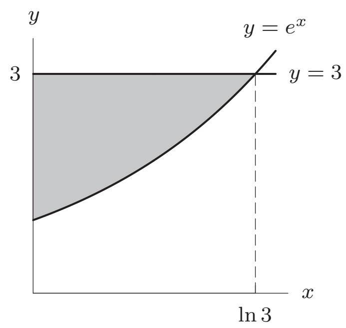


Figure 7.1

122. See Figure 7.2. The period of $V = V_0 \sin(\omega t)$ is $2\pi/\omega$, so the area under the first arch is given by

$$\begin{aligned}\text{Area} &= \int_0^{\pi/\omega} V_0 \sin(\omega t)\, dt \\ &= -\frac{V_0}{\omega} \cos(\omega t)\Big|_0^{\pi/\omega} \\ &= -\frac{V_0}{\omega}\cos(\pi) + \frac{V_0}{\omega}\cos(0) \\ &= -\frac{V_0}{\omega}(-1) + \frac{V_0}{\omega}(1) = \frac{2V_0}{\omega}.\end{aligned}$$

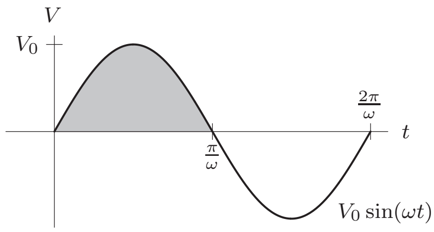

Figure 7.2

123. If $f(x) = \dfrac{1}{x+1}$, the average value of f on the interval $0 \le x \le 2$ is defined to be

$$\frac{1}{2-0}\int_0^2 f(x)\,dx = \frac{1}{2}\int_0^2 \frac{dx}{x+1}.$$

We'll integrate by substitution. We let $w = x+1$ and $dw = dx$, and we have

$$\int_{x=0}^{x=2} \frac{dx}{x+1} = \int_{w=1}^{w=3} \frac{dw}{w} = \ln w\bigg|_1^3 = \ln 3 - \ln 1 = \ln 3.$$

Thus, the average value of $f(x)$ on $0 \le x \le 2$ is $\frac{1}{2}\ln 3 \approx 0.5493$. See Figure 7.3.

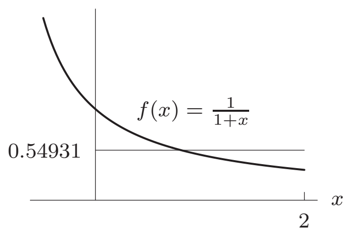

Figure 7.3

124. On the interval $[0, 2b]$

$$\text{Average value of } f = \frac{1}{2b}\int_0^{2b} f(x)\,dx.$$

If we let $x = 2u$ in this integral, we get

$$\frac{1}{2b}\int_0^{b} f(2u)\,2du = \frac{1}{b}\int_0^{b} g(u)\,du = \text{ Average value of } g \text{ on } [0, b].$$

125. (a) If $w = t/2$, then $dw = (1/2)dt$. When $t = 0$, $w = 0$; when $t = 4$, $w = 2$. Thus,

$$\int_0^4 g(t/2)\,dt = \int_0^2 g(w)\,2dw = 2\int_0^2 g(w)\,dw = 2 \cdot 5 = 10.$$

(b) If $w = 2 - t$, then $dw = -dt$. When $t = 0$, $w = 2$; when $t = 2$, $w = 0$. Thus,

$$\int_0^2 g(2-t)\,dt = \int_2^0 g(w)\,(-dw) = +\int_0^2 g(w)\,dw = 5.$$

126. (a) If $w = 2t$, then $dw = 2dt$. When $t = 0$, $w = 0$; when $t = 0.5$, $w = 1$. Thus,

$$\int_0^{0.5} f(2t)\,dt = \int_0^1 f(w)\,\frac{1}{2}dw = \frac{1}{2}\int_0^1 f(w)\,dw = \frac{3}{2}.$$

(b) If $w = 1 - t$, then $dw = -dt$. When $t = 0$, $w = 1$; when $t = 1$, $w = 0$. Thus,

$$\int_0^1 f(1-t)\,dt = \int_1^0 f(w)\,(-dw) = +\int_0^1 f(w)\,dw = 3.$$

(c) If $w = 3 - 2t$, then $dw = -2dt$. When $t = 1$, $w = 1$; when $t = 1.5$, $w = 0$. Thus,

$$\int_1^{1.5} f(3-2t)\,dt = \int_1^0 f(w)\left(-\frac{1}{2}dw\right) = +\frac{1}{2}\int_0^1 f(w)\,dw = \frac{3}{2}.$$

127. (a) The Fundamental Theorem gives

$$\int_{-\pi}^{\pi} \cos^2\theta\sin\theta\,d\theta = -\frac{\cos^3\theta}{3}\Big|_{-\pi}^{\pi} = \frac{-(-1)^3}{3} - \frac{-(-1)^3}{3} = 0.$$

This agrees with the fact that the function $f(\theta) = \cos^2\theta\sin\theta$ is odd and the interval of integration is centered at $x = 0$, thus we must get 0 for the definite integral.

(b) The area is given by

$$\text{Area } = \int_0^{\pi} \cos^2\theta\sin\theta\,d\theta = -\frac{\cos^3\theta}{3}\Big|_0^{\pi} = \frac{-(-1)^3}{3} - \frac{-(1)^3}{3} = \frac{2}{3}.$$

128. (a) $\displaystyle\int 4x(x^2+1)\,dx = \int (4x^3+4x)\,dx = x^4 + 2x^2 + C.$

(b) If $w = x^2 + 1$, then $dw = 2x\,dx$.

$$\int 4x(x^2+1)\,dx = \int 2w\,dw = w^2 + C = (x^2+1)^2 + C.$$

(c) The expressions from parts (a) and (b) look different, but they are both correct. Note that $(x^2+1)^2 + C = x^4 + 2x^2 + 1 + C$. In other words, the expressions from parts (a) and (b) differ only by a constant, so they are both correct antiderivatives.

129. (a) We first try the substitution $w = \sin\theta,\ dw = \cos\theta\,d\theta$. Then
$\displaystyle\int \sin\theta\cos\theta\,d\theta = \int w\,dw = \frac{w^2}{2} + C = \frac{\sin^2\theta}{2} + C.$

(b) If we instead try the substitution $w = \cos\theta,\ dw = -\sin\theta\,d\theta$, we get
$\displaystyle\int \sin\theta\cos\theta\,d\theta = -\int w\,dw = -\frac{w^2}{2} + C = -\frac{\cos^2\theta}{2} + C.$

(c) Once we note that $\sin 2\theta = 2\sin\theta\cos\theta$, we can also say
$\displaystyle\int \sin\theta\cos\theta\,d\theta = \frac{1}{2}\int \sin 2\theta\,d\theta.$
Substituting $w = 2\theta,\ dw = 2\,d\theta$, the above equals
$\displaystyle\frac{1}{4}\int \sin w\,dw = -\frac{\cos w}{4} + C = -\frac{\cos 2\theta}{4} + C.$

(d) All these answers are correct. Although they have different forms, they differ from each other only in terms of a constant, and thus they are all acceptable antiderivatives. For example, $1 - \cos^2\theta = \sin^2\theta$, so $\frac{\sin^2\theta}{2} = -\frac{\cos^2\theta}{2} + \frac{1}{2}$. Thus the first two expressions differ only by a constant C.
Similarly, $\cos 2\theta = \cos^2\theta - \sin^2\theta = 2\cos^2\theta - 1$, so $-\frac{\cos 2\theta}{4} = -\frac{\cos^2\theta}{2} + \frac{1}{4}$, and thus the second and third expressions differ only by a constant. Of course, if the first two expressions and the last two expressions differ only in the constant C, then the first and last only differ in the constant as well.

130. Letting $w = 6x\sqrt{x} = 6x^{3/2}$, we have $dw = (3/2)6x^{1/2}dx = 9\sqrt{x}dx$, so $\sqrt{x}dx = (1/9)dw$. This means we can write

$$\int_1^9 \overbrace{f\left(6x\sqrt{x}\right)}^{f(w)}\ \overbrace{\sqrt{x}dx}^{(1/9)\,dw} = \int_{x=1}^{x=9} f(w)\cdot\frac{1}{9}\,dw$$

$$= \int_{w=6}^{w=162} \frac{1}{9} \cdot f(w)\,dw,$$

so $k = 1/9, a = 6, b = 162$.

131. Letting $w = \ln\left(x^2+1\right)$, we have $dw = \left(x^2+1\right)^{-1} \cdot 2x dx$, so

$$\frac{x dx}{x^2+1} = \frac{1}{2} dw.$$

This means we can write

$$\begin{aligned}\int_2^5 \frac{f\left(\ln\left(x^2+1\right)\right) x\,dx}{x^2+1} &= \int_2^5 \overbrace{f\left(\ln\left(x^2+1\right)\right)}^{f(w)} \overbrace{\frac{x dx}{x^2+1}}^{(1/2)\,dw} \\ &= \int_{x=2}^{x=5} f(w) \cdot \frac{1}{2}\,dw \\ &= \int_{w=\ln 5}^{w=\ln 26} \frac{1}{2} \cdot f(w)\,dw,\end{aligned}$$

so $k = 1/2, a = \ln 5, b = \ln 26$.

132. Since $\tan x = \sin x / \cos x$, we use the substitution $w = \cos x$. Then we have

$$y = \int \tan x + 1\,dx = \int \frac{\sin x}{\cos x}\,dx + \int 1\,dx = -\ln|\cos x| + x + C.$$

Therefore, the general solution of the differential equation is

$$y = -\ln|\cos x| + x + C.$$

The initial condition allows us to determine the constant C. Substituting $y(0) = 1$ gives

$$1 = -\ln|\cos 0| + 0 + C.$$

Since $\ln|\cos 0| = \ln 1 = 0$, we have $C = 1$. The solution is

$$y = -\ln|\cos x| + x + 1.$$

133. We substitute $w = 1 - x$ into $I_{m,n}$. Then $dw = -dx$, and $x = 1 - w$.
When $x = 0$, $w = 1$, and when $x = 1$, $w = 0$, so

$$\begin{aligned}I_{m,n} &= \int_0^1 x^m (1-x)^n dx = \int_1^0 (1-w)^m w^n (-dw) \\ &= -\int_1^0 w^n (1-w)^m dw = \int_0^1 w^n (1-w)^m dw = I_{n,m}.\end{aligned}$$

134. (a) Since change of position is the integral of velocity, for t in seconds we have

$$\text{Change in position } = \int_0^{60} f(t)\,dt \text{ meters.}$$

(b) Since 1 minute is 60 seconds, $t = 60T$. The constant 60 has units sec/min, so $60T$ has units sec/min $\times$ min $=$ sec. Applying the substitution $t = 60T$ to the integral in part (a), we get

$$\text{Change in position} = \int_0^1 f(60T)\,60\,dT \text{ meters.}$$

135. (a) Integrating I, we have

$$C(t) = 1.3t + C_0.$$

Substituting $t = 0$ gives $C_0 = 311$, so

$$C(t) = 1.3t + 311.$$

Integrating II, we have

$$C(t) = 0.5t + 0.03\frac{t^2}{2} + C_0.$$

Substituting $t = 0$ gives $C_0 = 311$, so

$$C(t) = 0.5t + 0.015t^2 + 311.$$

Integrating III, we have

$$C(t) = \frac{0.5}{0.02}e^{0.02t} + C_0$$

Substituting $t = 0$ and $C_0 = 311$, we have

$$311 = 25e^{0.02(0)} + C_0$$
$$311 = 25 + C_0$$
$$C_0 = 286.$$

Thus

$$C(t) = 25e^{0.02t} + 286.$$

(b) In 2020, we have $t = 70$, so
I $C(70) = 1.3 \cdot 70 + 311 = 402$ ppm.
II $C(70) = 0.5 \cdot 70 + 0.015 \cdot 70^2 + 311 = 419.5$ ppm.
III $C(70) = 25e^{0.02(70)} + 286 = 387.380$ ppm.

136. (a) A time period of Δt hours with flow rate of $f(t)$ cubic meters per hour has a flow of $f(t)\Delta t$ cubic meters. Summing the flows, we get total flow $\approx \Sigma f(t)\Delta t$, so

$$\text{Total flow} = \int_0^{72} f(t)\,dt \text{ cubic meters.}$$

(b) Since 1 day is 24 hours, $t = 24T$. The constant 24 has units hours per day, so $24T$ has units hours/day $\times$ day $=$ hours. Applying the substitution $t = 24T$ to the integral in part (a), we get

$$\text{Total flow} = \int_0^{3} f(24T)\,24\,dT \text{ cubic meters.}$$

137. (a) In 2010, we have $P = 6.1e^{0.012\cdot 10} = 6.9$ billion people.
In 2020, we have $P = 6.1e^{0.012\cdot 20} = 7.8$ billion people.
(b) We have

$$\text{Average population} = \frac{1}{10-0}\int_0^{10} 6.1e^{0.012t}\,dt = \frac{1}{10}\cdot\frac{6.1}{0.012}e^{0.012t}\Big|_0^{10}$$
$$= \frac{1}{10}\left(\frac{6.1}{0.012}(e^{0.12} - e^0)\right) = 6.5.$$

The average population of the world between 2000 and 2010 is predicted to be 6.5 billion people.

138. (a) At time $t = 0$, the rate of oil leakage $= r(0) = 50$ thousand liters/minute.
At $t = 60$, rate $= r(60) = 15.06$ thousand liters/minute.
(b) To find the amount of oil leaked during the first hour, we integrate the rate from $t = 0$ to $t = 60$:

$$\text{Oil leaked} = \int_0^{60} 50e^{-0.02t}\,dt = \left(-\frac{50}{0.02}e^{-0.02t}\right)\Big|_0^{60}$$
$$= -2500e^{-1.2} + 2500e^0 = 1747 \text{ thousand liters.}$$

139. (a) $E(t) = 1.4e^{0.07t}$

(b)

$$\begin{aligned}
\text{Average Yearly Consumption} &= \frac{\text{Total Consumption for the Century}}{100 \text{ years}} \\
&= \frac{1}{100}\int_0^{100} 1.4e^{0.07t}\,dt \\
&= (0.014)\left[\frac{1}{0.07}e^{0.07t}\Big|_0^{100}\right] \\
&= (0.014)\left[\frac{1}{0.07}(e^7 - e^0)\right] \\
&= 0.2(e^7 - 1) \approx 219 \text{ million megawatt-hours.}
\end{aligned}$$

(c) We are looking for t such that $E(t) \approx 219$:

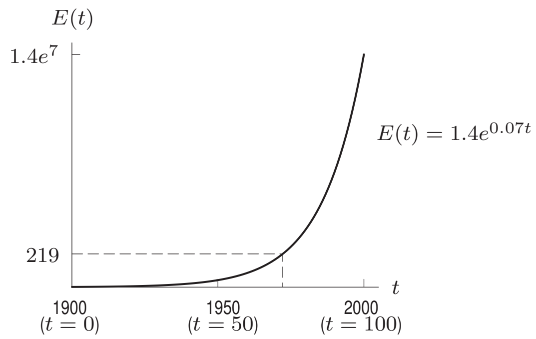
$$\begin{aligned}
1.4e^{0.07t} &\approx 219 \\
e^{0.07t} &= 156.4.
\end{aligned}$$

Taking natural logs,

$$\begin{aligned}
0.07t &= \ln 156.4 \\
t &\approx \frac{5.05}{0.07} \approx 72.18.
\end{aligned}$$

Thus, consumption was closest to the average during 1972.

(d) Between the years 1900 and 2000 the graph of $E(t)$ looks like



From the graph, we can see the t value such that $E(t) = 219$. It lies to the right of $t = 50$, and is thus in the second half of the century.

140. We have $Q'(t) = -I(t)$ and $I(t) = I_0e^{-t}$, so

$$Q'(t) = -I_0e^{-t}.$$

We have

$$Q(t) = I_0\int -e^{-t}\,dt = I_0e^{-t} + C.$$

Since $Q(0) = Q_0$, we have

$$Q_0 = I_0e^{-0} + C = I_0 + C,$$

so

$$C = Q_0 - I_0$$

Thus,

$$Q(t) = I_0e^{-t} + Q_0 - I_0.$$

141. Since $v = \dfrac{dh}{dt}$, it follows that $h(t) = \int v(t)\,dt$ and $h(0) = h_0$. Since

$$v(t) = \frac{mg}{k}\left(1 - e^{-\frac{k}{m}t}\right) = \frac{mg}{k} - \frac{mg}{k}e^{-\frac{k}{m}t},$$

we have

$$h(t) = \int v(t)\,dt = \frac{mg}{k}\int dt - \frac{mg}{k}\int e^{-\frac{k}{m}t}\,dt.$$

The first integral is simply $\dfrac{mg}{k}t + C$. To evaluate the second integral, make the substitution $w = -\frac{k}{m}t$. Then

$$dw = -\frac{k}{m}\,dt,$$

so

$$\int e^{-\frac{k}{m}t}\,dt = \int e^{w}\left(-\frac{m}{k}\right)dw = -\frac{m}{k}e^{w} + C = -\frac{m}{k}e^{-\frac{k}{m}t} + C.$$

Thus

$$\begin{aligned} h(t) &= \int v\,dt = \frac{mg}{k}t - \frac{mg}{k}\left(-\frac{m}{k}e^{-\frac{k}{m}t}\right) + C \\ &= \frac{mg}{k}t + \frac{m^2g}{k^2}e^{-\frac{k}{m}t} + C. \end{aligned}$$

Since $h(0) = h_0$,

$$\begin{aligned} h_0 &= \frac{mg}{k}\cdot 0 + \frac{m^2g}{k^2}e^{0} + C; \\ C &= h_0 - \frac{m^2g}{k^2}. \end{aligned}$$

Thus

$$\begin{aligned} h(t) &= \frac{mg}{k}t + \frac{m^2g}{k^2}e^{-\frac{k}{m}t} - \frac{m^2g}{k^2} + h_0 \\ h(t) &= \frac{mg}{k}t - \frac{m^2g}{k^2}\left(1 - e^{-\frac{k}{m}t}\right) + h_0. \end{aligned}$$

142. Since v is given as the velocity of a falling body, the height h is decreasing, so $v = -\frac{dh}{dt}$, and it follows that $h(t) = -\int v(t)\,dt$ and $h(0) = h_0$. Let $w = e^{t\sqrt{gk}} + e^{-t\sqrt{gk}}$. Then

$$dw = \sqrt{gk}\left(e^{t\sqrt{gk}} - e^{-t\sqrt{gk}}\right)dt,$$

so $\dfrac{dw}{\sqrt{gk}} = (e^{t\sqrt{gk}} - e^{-t\sqrt{gk}})\,dt$. Therefore,

$$\begin{aligned} -\int v(t)dt &= -\int \sqrt{\frac{g}{k}}\left(\frac{e^{t\sqrt{gk}} - e^{-t\sqrt{gk}}}{e^{t\sqrt{gk}} + e^{-t\sqrt{gk}}}\right)dt \\ &= -\sqrt{\frac{g}{k}}\int \frac{1}{e^{t\sqrt{gk}} + e^{-t\sqrt{gk}}}\left(e^{t\sqrt{gk}} - e^{-t\sqrt{gk}}\right)dt \\ &= -\sqrt{\frac{g}{k}}\int \left(\frac{1}{w}\right)\frac{dw}{\sqrt{gk}} \\ &= -\sqrt{\frac{g}{gk^2}}\ln|w| + C \\ &= -\frac{1}{k}\ln\left(e^{t\sqrt{gk}} + e^{-t\sqrt{gk}}\right) + C. \end{aligned}$$

Since

$$h(0) = -\frac{1}{k}\ln(e^{0} + e^{0}) + C = -\frac{\ln 2}{k} + C = h_0,$$

we have $C = h_0 + \dfrac{\ln 2}{k}$. Thus,

$$h(t) = -\frac{1}{k}\ln\left(e^{t\sqrt{gk}} + e^{-t\sqrt{gk}}\right) + \frac{\ln 2}{k} + h_0 = -\frac{1}{k}\ln\left(\frac{e^{t\sqrt{gk}} + e^{-t\sqrt{gk}}}{2}\right) + h_0.$$

143. (a) In the first case, we are given that $R_0 = 1000$ widgets/year. So we have $R = 1000e^{0.125t}$. To determine the total number sold, we need to integrate this rate over the time period from 0 to 10. Therefore

$$\text{Total number of widgets sold} = \int_0^{10} 1000e^{0.125t}\,dt = \frac{1000}{0.125}e^{0.125t}\bigg|_0^{10} = 8000(e^{1.25} - 1) = 19{,}923 \text{ widgets.}$$

In the second case,

$$\text{Total number of widgets sold} = \int_0^{10} 1{,}000{,}000e^{0.125t}\,dt = 1{,}000{,}000e^{0.125t}\bigg|_0^{10} = 19.9 \text{ million widgets.}$$

(b) We want to determine T such that

$$\int_0^T 1000e^{0.125t}\,dt = \frac{19{,}923}{2}.$$

Evaluating both sides, we get

$$\begin{aligned}
\frac{1000}{0.125}e^{0.0125t}\bigg|_0^T &= 8000(e^{0.125T} - 1) = 9{,}961\\
8000e^{0.125T} &= 17{,}961\\
e^{0.125T} &= 2.245\\
0.125T &= 0.8088,\\
T &= 6.47 \text{ years.}
\end{aligned}$$

Similarly, in the second case, we want T so that

$$\int_0^T 1{,}000{,}000e^{0.125t}\,dt = \frac{19{,}900{,}000}{2}$$

Evaluating both sides, we get

$$\begin{aligned}
\frac{1{,}000{,}000}{0.125}e^{0.125t}\bigg|_0^T &= 9{,}950{,}000\\
8{,}000{,}000(e^{0.125T} - 1) &= 9{,}950{,}000\\
8{,}000{,}000e^{0.125T} &= 17{,}950{,}000\\
e^{0.125T} &= 2.2438\\
T &= 6.47 \text{ years.}
\end{aligned}$$

So the half way mark is reached at the same time regardless of the initial rate.

(c) Since half the widgets are sold in the last $3\frac{1}{2}$ years of the decade, if each widget is expected to last at least 3.5 years, their claim could easily be true.

144. (a) Amount of water entering tank in a short period of time = Rate×Time = $r(t)\Delta t$.

(b) Summing the contribution from each of the small intervals Δt:

$$\begin{array}{c}\text{Amount of water entering the tank}\\ \text{between } t = 0 \text{ and } t = 5\end{array} \approx \sum_{i=0}^{n-1} r(t_i)\Delta t, \qquad \text{where } \Delta t = 5/n.$$

Taking a limit as $\Delta t \to 0$:

$$\begin{array}{c}\text{Amount of water entering the tank}\\ \text{between } t = 0 \text{ and } t = 5\end{array} = \int_0^5 r(t)\,dt.$$

(c) If $Q(t)$ is the amount of water in the tank at time t, then $Q'(t) = r(t)$. We want to calculate $Q(5) - Q(0)$. By the Fundamental Theorem,

$$\begin{aligned}\text{Amount which has entered tank} &= Q(5) - Q(0) = \int_0^5 r(t)\,dt = \int_0^5 20e^{0.02t}\,dt = \frac{20}{0.02}e^{0.02t}\Big|_0^5 \\ &= 1000(e^{0.02(5)} - 1) \approx 105.17 \text{ gallons.}\end{aligned}$$

(d) By the Fundamental Theorem again,

$$\begin{aligned}\text{Amount which has entered tank} &= Q(t) - Q(0) = \int_0^t r(t)\,dt \\ Q(t) - 3000 &= \int_0^t 20e^{0.02t}\,dt\end{aligned}$$

so

$$\begin{aligned}Q(t) &= 3000 + \int_0^t 20e^{0.02t}\,dt = 3000 + \frac{20}{0.02}e^{0.02t}\Big|_0^t \\ &= 3000 + 1000(e^{0.02t} - 1) \\ &= 1000e^{0.02t} + 2000.\end{aligned}$$

Strengthen Your Understanding

145. To do guess-and-check or substitution, we need an extra factor of $f'(x)$ in the integrand. For example, if $f(x) = 2x$, the left side is

$$\int (2x)^2\,dx = \int 4x^2\,dx = \frac{4x^3}{3} + C,$$

while the right side is $8x^3/3 + C$.

146. If we do guess-and-check and our guess is off by a constant factor, we can fix our guess by dividing our guess by that constant. This does not work if we are off by a factor which is not constant. In this case, if we check our answer by differentiating, we get, using the quotient rule:

$$\frac{d}{dx}\left(\frac{\sin(x^2)}{2x}\right) = \frac{\cos(x^2)(2x)(2x) - 2\sin x^2}{4x^2} \neq \cos x^2.$$

147. When we make a substitution in a definite integral, we must either change the limits of integration or return to the original variable before evaluating. Since $w = 3x$, the right side should be $(1/3)\int_0^{3\pi/2} \cos w\,dw$.

148. The inside function is $\cos\theta$, so $f(\theta)$ should be the derivative of $\cos\theta$ (or a constant multiple of the derivative). Thus, $f(\theta) = -\sin\theta$ works.

149. The integrand should have a factor that is a constant multiple of $3x^2 - 3$, for example $\int \sin(x^3 - 3x)(x^2 - 1)\,dx$.

150. True. Let $w = f(x)$, so $dw = f'(x)\,dx$, then

$$\int f'(x)\cos(f(x))\,dx = \int \cos w\,dw = \sin w + C = \sin(f(x)) + C.$$

151. False. Differentiating gives

$$\frac{d}{dx}\ln|f(x)| = \frac{1}{f(x)} \cdot f'(x),$$

so, in general

$$\int \frac{1}{f(x)}\,dx \neq \ln|f(x)| + C.$$

152. True. Let $w = 5 - t^2$, then $dw = -2t\,dt$.

Solutions for Section 7.2

Exercises

1. (a) Since we can change x^2 into a multiple of x^3 by integrating, let $v' = x^2$ and $u = e^x$. Using $v = x^3/3$ and $u' = e^x$ we get

$$\int x^2 e^x dx = \int uv' dx = uv - \int u'v dx$$
$$= \frac{x^3 e^x}{3} - \frac{1}{3}\int x^3 e^x dx.$$

(b) Since we can change x^2 into a multiple of x by differentiating, let $u = x^2$ and $v' = e^x$. Using $u' = 2x$ and $v = e^x$ we have

$$\int x^2 e^x dx = \int uv' dx = uv - \int u'v dx$$
$$= x^2 e^x - 2\int xe^x dx.$$

2. Let $u = \arctan x$, $v' = 1$. Then $v = x$ and $u' = \dfrac{1}{1+x^2}$. Integrating by parts, we get:

$$\int 1 \cdot \arctan x\, dx = x \cdot \arctan x - \int x \cdot \frac{1}{1+x^2}\, dx.$$

To compute the second integral use the substitution, $z = 1 + x^2$.

$$\int \frac{x}{1+x^2}\, dx = \frac{1}{2}\int \frac{dz}{z} = \frac{1}{2}\ln|z| + C = \frac{1}{2}\ln(1+x^2) + C.$$

Thus,

$$\int \arctan x\, dx = x \cdot \arctan x - \frac{1}{2}\ln(1+x^2) + C.$$

3. Let $u = t$, $v' = \sin t$. Thus, $v = -\cos t$ and $u' = 1$. With this choice of u and v, integration by parts gives:

$$\int t\sin t\, dt = -t\cos t - \int(-\cos t)\, dt$$
$$= -t\cos t + \sin t + C.$$

4. Let $u = t^2$, $v' = \sin t$ implying $v = -\cos t$ and $u' = 2t$. Integrating by parts, we get:

$$\int t^2 \sin t\, dt = -t^2\cos t - \int 2t(-\cos t)\, dt.$$

Again, applying integration by parts with $u = t$, $v' = \cos t$, we have:

$$\int t\cos t\, dt = t\sin t + \cos t + C.$$

Thus

$$\int t^2 \sin t\, dt = -t^2\cos t + 2t\sin t + 2\cos t + C.$$

5. Let $u = t$ and $v' = e^{5t}$, so $u' = 1$ and $v = \frac{1}{5}e^{5t}$.
Then $\int te^{5t}\, dt = \frac{1}{5}te^{5t} - \int \frac{1}{5}e^{5t}\, dt = \frac{1}{5}te^{5t} - \frac{1}{25}e^{5t} + C.$

6. Let $u = t^2$ and $v' = e^{5t}$, so $u' = 2t$ and $v = \frac{1}{5}e^{5t}$.
Then $\int t^2 e^{5t}\,dt = \frac{1}{5}t^2e^{5t} - \frac{2}{5}\int te^{5t}\,dt$.
Using Problem 5, we have $\int t^2e^{5t}\,dt = \frac{1}{5}t^2e^{5t} - \frac{2}{5}(\frac{1}{5}te^{5t} - \frac{1}{25}e^{5t}) + C$
$= \frac{1}{5}t^2e^{5t} - \frac{2}{25}te^{5t} + \frac{2}{125}e^{5t} + C$.

7. Let $u = p$ and $v' = e^{(-0.1)p}$, $u' = 1$. Thus, $v = \int e^{(-0.1)p}\,dp = -10e^{(-0.1)p}$. With this choice of u and v, integration by parts gives:

$$\begin{aligned}\int pe^{(-0.1)p}\,dp &= p(-10e^{(-0.1)p}) - \int(-10e^{(-0.1)p})\,dp\\ &= -10pe^{(-0.1)p} + 10\int e^{(-0.1)p}\,dp\\ &= -10pe^{(-0.1)p} - 100e^{(-0.1)p} + C.\end{aligned}$$

8. Let $u = z+1$, $v' = e^{2z}$. Thus, $v = \frac{1}{2}e^{2z}$ and $u' = 1$. Integrating by parts, we get:

$$\begin{aligned}\int(z+1)e^{2z}\,dz &= (z+1)\cdot\frac{1}{2}e^{2z} - \int\frac{1}{2}e^{2z}\,dz\\ &= \frac{1}{2}(z+1)e^{2z} - \frac{1}{4}e^{2z} + C\\ &= \frac{1}{4}(2z+1)e^{2z} + C.\end{aligned}$$

9. Integration by parts with $u = \ln x$, $v' = x$ gives

$$\int x\ln x\,dx = \frac{x^2}{2}\ln x - \int\frac{1}{2}x\,dx = \frac{1}{2}x^2\ln x - \frac{1}{4}x^2 + C.$$

Or use the integral table, III-13, with $n = 1$.

10. Let $u = \ln x$ and $v' = x^3$, so $u' = \frac{1}{x}$ and $v = \frac{x^4}{4}$. Then

$$\int x^3\ln x\,dx = \frac{x^4}{4}\ln x - \int\frac{x^3}{4}\,dx = \frac{x^4}{4}\ln x - \frac{x^4}{16} + C.$$

11. Let $u = \ln 5q$, $v' = q^5$. Then $v = \frac{1}{6}q^6$ and $u' = \dfrac{1}{q}$. Integrating by parts, we get:

$$\begin{aligned}\int q^5\ln 5q\,dq &= \frac{1}{6}q^6\ln 5q - \int(5\cdot\frac{1}{5q})\cdot\frac{1}{6}q^6\,dq\\ &= \frac{1}{6}q^6\ln 5q - \frac{1}{36}q^6 + C.\end{aligned}$$

12. Let $u = \theta^2$ and $v' = \cos 3\theta$, so $u' = 2\theta$ and $v = \frac{1}{3}\sin 3\theta$.
Then $\int\theta^2\cos 3\theta\,d\theta = \frac{1}{3}\theta^2\sin 3\theta - \frac{2}{3}\int\theta\sin 3\theta\,d\theta$. The integral on the right hand side is simpler than our original integral, but to evaluate it we need to again use integration by parts.
To find $\int\theta\sin 3\theta\,d\theta$, let $u = \theta$ and $v' = \sin 3\theta$, so $u' = 1$ and $v = -\frac{1}{3}\cos 3\theta$.
This gives

$$\int\theta\sin 3\theta\,d\theta = -\frac{1}{3}\theta\cos 3\theta + \frac{1}{3}\int\cos 3\theta\,d\theta = -\frac{1}{3}\theta\cos 3\theta + \frac{1}{9}\sin 3\theta + C.$$

Thus,

$$\int\theta^2\cos 3\theta d\theta = \frac{1}{3}\theta^2\sin 3\theta + \frac{2}{9}\theta\cos 3\theta - \frac{2}{27}\sin 3\theta + C.$$

13. Let $u = \sin\theta$ and $v' = \sin\theta$, so $u' = \cos\theta$ and $v = -\cos\theta$. Then

$$\begin{aligned}\int \sin^2\theta\,d\theta &= -\sin\theta\cos\theta + \int \cos^2\theta\,d\theta \\ &= -\sin\theta\cos\theta + \int (1-\sin^2\theta)\,d\theta \\ &= -\sin\theta\cos\theta + \int 1\,d\theta - \int \sin^2\theta\,d\theta.\end{aligned}$$

By adding $\int \sin^2\theta\,d\theta$ to both sides of the above equation, we find that $2\int \sin^2\theta\,d\theta = -\sin\theta\cos\theta + \theta + C$, so $\int \sin^2\theta\,d\theta = -\frac{1}{2}\sin\theta\cos\theta + \frac{\theta}{2} + C'$.

14. Let $u = \cos(3\alpha+1)$ and $v' = \cos(3\alpha+1)$, so $u' = -3\sin(3\alpha+1)$, and $v = \frac{1}{3}\sin(3\alpha+1)$. Then

$$\begin{aligned}\int \cos^2(3\alpha+1)\,d\alpha &= \int (\cos(3\alpha+1))\cos(3\alpha+1)\,d\alpha \\ &= \frac{1}{3}\cos(3\alpha+1)\sin(3\alpha+1) + \int \sin^2(3\alpha+1)\,d\alpha \\ &= \frac{1}{3}\cos(3\alpha+1)\sin(3\alpha+1) + \int \left(1-\cos^2(3\alpha+1)\right)\,d\alpha \\ &= \frac{1}{3}\cos(3\alpha+1)\sin(3\alpha+1) + \alpha - \int \cos^2(3\alpha+1)\,d\alpha.\end{aligned}$$

By adding $\int \cos^2(3\alpha+1)\,d\alpha$ to both sides of the above equation, we find that

$$2\int \cos^2(3\alpha+1)\,d\alpha = \frac{1}{3}\cos(3\alpha+1)\sin(3\alpha+1) + \alpha + C,$$

which gives

$$\int \cos^2(3\alpha+1)\,d\alpha = \frac{1}{6}\cos(3\alpha+1)\sin(3\alpha+1) + \frac{\alpha}{2} + C.$$

15. Let $u = (\ln t)^2$ and $v' = 1$, so $u' = \dfrac{2\ln t}{t}$ and $v = t$. Then

$$\int (\ln t)^2\,dt = t(\ln t)^2 - 2\int \ln t\,dt = t(\ln t)^2 - 2t\ln t + 2t + C.$$

(We use the fact that $\displaystyle\int \ln x\,dx = x\ln x - x + C$, a result which can be derived using integration by parts.)

16. Remember that $\ln(x^2) = 2\ln x$. Therefore,

$$\int \ln(x^2)\,dx = 2\int \ln x\,dx = 2x\ln x - 2x + C.$$

Check:

$$\frac{d}{dx}(2x\ln x - 2x + C) = 2\ln x + \frac{2x}{x} - 2 = 2\ln x = \ln(x^2).$$

17. Let $u = y$ and $v' = (y+3)^{1/2}$, so $u' = 1$ and $v = \frac{2}{3}(y+3)^{3/2}$:

$$\int y\sqrt{y+3}\,dy = \frac{2}{3}y(y+3)^{3/2} - \int \frac{2}{3}(y+3)^{3/2}\,dy = \frac{2}{3}y(y+3)^{3/2} - \frac{4}{15}(y+3)^{5/2} + C.$$

18. Let $u = t+2$ and $v' = \sqrt{2+3t}$, so $u' = 1$ and $v = \frac{2}{9}(2+3t)^{3/2}$. Then

$$\begin{aligned}\int (t+2)\sqrt{2+3t}\,dt &= \frac{2}{9}(t+2)(2+3t)^{3/2} - \frac{2}{9}\int (2+3t)^{3/2}\,dt \\ &= \frac{2}{9}(t+2)(2+3t)^{3/2} - \frac{4}{135}(2+3t)^{5/2} + C.\end{aligned}$$

19. Let $u = \theta + 1$ and $v' = \sin(\theta + 1)$, so $u' = 1$ and $v = -\cos(\theta + 1)$.

$$\int (\theta + 1)\sin(\theta + 1)\,d\theta = -(\theta + 1)\cos(\theta + 1) + \int \cos(\theta + 1)\,d\theta$$
$$= -(\theta + 1)\cos(\theta + 1) + \sin(\theta + 1) + C.$$

20. Let $u = z$, $v' = e^{-z}$. Thus $v = -e^{-z}$ and $u' = 1$. Integration by parts gives:

$$\int ze^{-z}\,dz = -ze^{-z} - \int (-e^{-z})\,dz$$
$$= -ze^{-z} - e^{-z} + C$$
$$= -(z + 1)e^{-z} + C.$$

21. Let $u = \ln x$, $v' = x^{-2}$. Then $v = -x^{-1}$ and $u' = x^{-1}$. Integrating by parts, we get:

$$\int x^{-2}\ln x\,dx = -x^{-1}\ln x - \int (-x^{-1})\cdot x^{-1}\,dx$$
$$= -x^{-1}\ln x - x^{-1} + C.$$

22. Let $u = y$ and $v' = \frac{1}{\sqrt{5-y}}$, so $u' = 1$ and $v = -2(5 - y)^{1/2}$.

$$\int \frac{y}{\sqrt{5 - y}}\,dy = -2y(5 - y)^{1/2} + 2\int (5 - y)^{1/2}\,dy = -2y(5 - y)^{1/2} - \frac{4}{3}(5 - y)^{3/2} + C.$$

23. $\displaystyle\int \frac{t + 7}{\sqrt{5 - t}}\,dt = \int \frac{t}{\sqrt{5 - t}}\,dt + 7\int (5 - t)^{-1/2}\,dt.$

To calculate the first integral, we use integration by parts. Let $u = t$ and $v' = \frac{1}{\sqrt{5-t}}$, so $u' = 1$ and $v = -2(5-t)^{1/2}$. Then

$$\int \frac{t}{\sqrt{5 - t}}\,dt = -2t(5 - t)^{1/2} + 2\int (5 - t)^{1/2}\,dt = -2t(5 - t)^{1/2} - \frac{4}{3}(5 - t)^{3/2} + C.$$

We can calculate the second integral directly: $7\displaystyle\int (5 - t)^{-1/2} = -14(5 - t)^{1/2} + C_1$. Thus

$$\int \frac{t + 7}{\sqrt{5 - t}}\,dt = -2t(5 - t)^{1/2} - \frac{4}{3}(5 - t)^{3/2} - 14(5 - t)^{1/2} + C_2.$$

24. Let $u = (\ln x)^4$ and $v' = x$, so $u' = \frac{4(\ln x)^3}{x}$ and $v = \frac{x^2}{2}$. Then

$$\int x(\ln x)^4\,dx = \frac{x^2(\ln x)^4}{2} - 2\int x(\ln x)^3\,dx.$$

$\int x(\ln x)^3\,dx$ is somewhat less complicated than $\int x(\ln x)^4\,dx$. To calculate it, we again try integration by parts, this time letting $u = (\ln x)^3$ (instead of $(\ln x)^4$) and $v' = x$. We find

$$\int x(\ln x)^3\,dx = \frac{x^2}{2}(\ln x)^3 - \frac{3}{2}\int x(\ln x)^2\,dx.$$

Once again, express the given integral in terms of a less-complicated one. Using integration by parts two more times, we find that

$$\int x(\ln x)^2\,dx = \frac{x^2}{2}(\ln x)^2 - \int x(\ln x)\,dx$$

and that

$$\int x\ln x\,dx = \frac{x^2}{2}\ln x - \frac{x^2}{4} + C.$$

Putting this all together, we have

$$\int x(\ln x)^4\,dx = \frac{x^2}{2}(\ln x)^4 - x^2(\ln x)^3 + \frac{3}{2}x^2(\ln x)^2 - \frac{3}{2}x^2\ln x + \frac{3}{4}x^2 + C.$$

25. Integrate by parts letting $u=(\ln r)^2$ and $dv=rdr$, then $du=(2/r)\ln r dr$ and $v=r^2/2$. We get

$$\int r(\ln r)^2\,dr=\frac{1}{2}r^2(\ln r)^2-\int r\ln r\,dr.$$

Then using integration by parts again with $u=\ln r$ and $dv=rdr$, so $du=dr/r$ and $v=r^2/2$, we get

$$\int r\ln^2 r\,dr=\frac{1}{2}r^2(\ln r)^2-\left[\frac{1}{2}r^2\ln r-\frac{1}{2}\int r\,dr\right]=\frac{1}{2}r^2(\ln r)^2-\frac{1}{2}r^2\ln r+\frac{1}{4}r^2+C.$$

26. Let $u=\arcsin w$ and $v'=1$, so $u'=\frac{1}{\sqrt{1-w^2}}$ and $v=w$. Then

$$\int \arcsin w\,dw=w\arcsin w-\int\frac{w}{\sqrt{1-w^2}}\,dw=w\arcsin w+\sqrt{1-w^2}+C.$$

27. Let $u=\arctan 7z$ and $v'=1$, so $u'=\frac{7}{1+49z^2}$ and $v=z$. Now $\int\frac{7z\,dz}{1+49z^2}$ can be evaluated by the substitution $w=1+49z^2$, $dw=98z\,dz$, so

$$\int\frac{7z\,dz}{1+49z^2}=7\int\frac{\frac{1}{98}\,dw}{w}=\frac{1}{14}\int\frac{dw}{w}=\frac{1}{14}\ln|w|+C=\frac{1}{14}\ln(1+49z^2)+C$$

So

$$\int\arctan 7z\,dz=z\arctan 7z-\frac{1}{14}\ln(1+49z^2)+C.$$

28. This integral can first be simplified by making the substitution $w=x^2$, $dw=2x\,dx$. Then

$$\int x\arctan x^2\,dx=\frac{1}{2}\int\arctan w\,dw.$$

To evaluate $\int\arctan w\,dw$, we'll use integration by parts. Let $u=\arctan w$ and $v'=1$, so $u'=\frac{1}{1+w^2}$ and $v=w$. Then

$$\int\arctan w\,dw=w\arctan w-\int\frac{w}{1+w^2}\,dw=w\arctan w-\frac{1}{2}\ln|1+w^2|+C.$$

Since $1+w^2$ is never negative, we can drop the absolute value signs. Thus, we have

$$\begin{aligned}\int x\arctan x^2\,dx&=\frac{1}{2}\left(x^2\arctan x^2-\frac{1}{2}\ln(1+(x^2)^2)+C\right)\\&=\frac{1}{2}x^2\arctan x^2-\frac{1}{4}\ln(1+x^4)+C.\end{aligned}$$

29. Let $u=x^2$ and $v'=xe^{x^2}$, so $u'=2x$ and $v=\frac{1}{2}e^{x^2}$. Then

$$\int x^3e^{x^2}\,dx=\frac{1}{2}x^2e^{x^2}-\int xe^{x^2}\,dx=\frac{1}{2}x^2e^{x^2}-\frac{1}{2}e^{x^2}+C.$$

Note that we can also do this problem by substitution and integration by parts. If we let $w=x^2$, so $dw=2x\,dx$, then $\int x^3e^{x^2}\,dx=\frac{1}{2}\int we^w\,dw$. We could then perform integration by parts on this integral to get the same result.

30. To simplify matters, let us try the substitution $w=x^3$, $dw=3x^2\,dx$. Then

$$\int x^5\cos x^3\,dx=\frac{1}{3}\int w\cos w\,dw.$$

Now we integrate by parts. Let $u=w$ and $v'=\cos w$, so $u'=1$ and $v=\sin w$. Then

$$\begin{aligned}\frac{1}{3}\int w\cos w\,dw&=\frac{1}{3}[w\sin w-\int\sin w\,dw]\\&=\frac{1}{3}[w\sin w+\cos w]+C\\&=\frac{1}{3}x^3\sin x^3+\frac{1}{3}\cos x^3+C\end{aligned}$$

31. Let $u = x, u' = 1$ and $v' = \sinh x, v = \cosh x$. Integrating by parts, we get

$$\begin{aligned}\int x \sinh x \, dx &= x \cosh x - \int \cosh x \, dx \\ &= x \cosh x - \sinh x + C.\end{aligned}$$

32. Let $u = x - 1, u' = 1$ and $v' = \cosh x, v = \sinh x$. Integrating by parts, we get

$$\begin{aligned}\int (x-1) \cosh x \, dx &= (x-1) \sinh x - \int \sinh x \, dx \\ &= (x-1) \sinh x - \cosh x + C.\end{aligned}$$

33. $\displaystyle\int_1^5 \ln t \, dt = (t \ln t - t)\Big|_1^5 = 5 \ln 5 - 4 \approx 4.047$

34. $\displaystyle\int_3^5 x \cos x \, dx = (\cos x + x \sin x)\Big|_3^5 = \cos 5 + 5 \sin 5 - \cos 3 - 3 \sin 3 \approx -3.944.$

35. We use integration by parts. Let $u = z$ and $v' = e^{-z}$, so $u' = 1$ and $v = -e^{-z}$. Then

$$\begin{aligned}\int_0^{10} ze^{-z} \, dz &= -ze^{-z}\Big|_0^{10} + \int_0^{10} e^{-z} \, dz \\ &= -10e^{-10} + (-e^{-z})\Big|_0^{10} \\ &= -11e^{-10} + 1 \\ &\approx 0.9995.\end{aligned}$$

36. $\displaystyle\int_1^3 t \ln t \, dt = \left(\frac{1}{2}t^2 \ln t - \frac{1}{4}t^2\right)\Big|_1^3 = \frac{9}{2} \ln 3 - 2 \approx 2.944.$

37. We use integration by parts. Let $u = \arctan y$ and $v' = 1$, so $u' = \frac{1}{1+y^2}$ and $v = y$. Thus

$$\begin{aligned}\int_0^1 \arctan y \, dy &= (\arctan y)y\Big|_0^1 - \int_0^1 \frac{y}{1+y^2} \, dy \\ &= \frac{\pi}{4} - \frac{1}{2} \ln |1 + y^2|\Big|_0^1 \\ &= \frac{\pi}{4} - \frac{1}{2} \ln 2 \approx 0.439.\end{aligned}$$

38. $\displaystyle\int_0^5 \ln(1+t) \, dt = ((1+t)\ln(1+t) - (1+t))\Big|_0^5 = 6 \ln 6 - 5 \approx 5.751.$

39. We use integration by parts. Let $u = \arcsin z$ and $v' = 1$, so $u' = \dfrac{1}{\sqrt{1-z^2}}$ and $v = z$. Then

$$\int_0^1 \arcsin z \, dz = z \arcsin z\Big|_0^1 - \int_0^1 \frac{z}{\sqrt{1-z^2}} \, dz = \frac{\pi}{2} - \int_0^1 \frac{z}{\sqrt{1-z^2}} \, dz.$$

To find $\int_0^1 \frac{z}{\sqrt{1-z^2}}\,dz$, we substitute $w = 1-z^2$, so $dw = -2z\,dz$.
Then

$$\int_{z=0}^{z=1} \frac{z}{\sqrt{1-z^2}}\,dz = -\frac{1}{2}\int_{w=1}^{w=0} w^{-\frac{1}{2}}\,dw = \frac{1}{2}\int_{w=0}^{w=1} w^{-\frac{1}{2}}\,dw = w^{\frac{1}{2}}\Big|_0^1 = 1.$$

Thus our final answer is $\frac{\pi}{2} - 1 \approx 0.571$.

40. To simplify the integral, we first make the substitution $z = u^2$, so $dz = 2u\,du$. Then

$$\int_{u=0}^{u=1} u \arcsin u^2\,du = \frac{1}{2}\int_{z=0}^{z=1} \arcsin z\,dz.$$

From Problem 39, we know that $\int_0^1 \arcsin z\,dz = \frac{\pi}{2} - 1$. Thus,

$$\int_0^1 u \arcsin u^2\,du = \frac{1}{2}(\frac{\pi}{2} - 1) \approx 0.285.$$

41. (a) This integral can be evaluated using integration by parts with $u = x$, $v' = \sin x$.
(b) We evaluate this integral using the substitution $w = 1 + x^3$.
(c) We evaluate this integral using the substitution $w = x^2$.
(d) We evaluate this integral using the substitution $w = x^3$.
(e) We evaluate this integral using the substitution $w = 3x + 1$.
(f) This integral can be evaluated using integration by parts with $u = x^2$, $v' = \sin x$.
(g) This integral can be evaluated using integration by parts with $u = \ln x$, $v' = 1$.

42. A calculator gives $\int_1^2 \ln x\,dx = 0.386$. An antiderivative of $\ln x$ is $x\ln x - 1$, so the Fundamental Theorem of Calculus gives

$$\int_1^2 \ln x\,dx = (x\ln x - x)\Big|_1^2 = 2\ln 2 - 1.$$

Since $2\ln 2 - 1 = 0.386$, the value from the Fundamental Theorem agrees with the numerical answer.

Problems

43. Using a log property, we have

$$\int \ln\left((5-3x)^2\right)\,dx = \int 2\ln(5-3x)\,dx.$$

So we let

$$\begin{aligned} w &= 5 - 3x \\ dw &= -3dx \\ dx &= -\frac{1}{3}\,dw, \end{aligned}$$

which gives,

$$\begin{aligned} \int \ln(5-3x)^2\,dx &= \int 2\ln\overbrace{(5-3x)}^{w}\ \overbrace{dx}^{-\frac{1}{3}dw} \\ &= \int -\frac{2}{3}\cdot \ln w\,dw. \end{aligned}$$

Thus, $w = 5 - 3x, k = -2/3$.

44. We have

$$\begin{aligned}\int \ln \frac{1}{\sqrt{4-5x}}\,dx &= \int \ln \frac{1}{(4-5x)^{1/2}}\,dx \\ &= \int \ln\left((4-5x)^{-1/2}\right)\,dx \\ &= \int -\frac{1}{2}\cdot \ln(4-5x)\,dx \qquad \text{log property.}\end{aligned}$$

So we let

$$\begin{aligned} w &= 4-5x \\ dw &= -5dx \\ dx &= -\frac{1}{5}\,dw,\end{aligned}$$

which gives

$$\begin{aligned}\int \ln \frac{1}{\sqrt{4-5x}}\,dx &= \int -\frac{1}{2}\cdot \ln \overbrace{(4-5x)}^{w}\ \overbrace{dx}^{-\frac{1}{5}\,dw} \\ &= \int \frac{1}{10}\ln w\,dw.\end{aligned}$$

Thus $w = 4-5x, k = 1/10$.

45. We have

$$\begin{aligned}\int \frac{\ln\left((\ln x)^3\right)}{x}\,dx &= \int \frac{3\ln(\ln x)}{x}\,dx \qquad \text{log property} \\ &= \int 3\ln(\ln x)\,x^{-1}\,dx.\end{aligned}$$

So we let

$$\begin{aligned} w &= \ln x \\ dw &= x^{-1}\,dx\end{aligned}$$

which gives

$$\begin{aligned}\int \frac{\ln\left((\ln x)^3\right)}{x}\,dx &= \int 3\ln \overbrace{(\ln x)}^{w}\ \overbrace{x^{-1}\,dx}^{dw} \\ &= \int 3\ln w\,dw.\end{aligned}$$

Thus $w = \ln x, k = 3$.

46. Using integration by parts with $u' = e^{-t}$, $v = t$, so $u = -e^{-t}$ and $v' = 1$, we have

$$\begin{aligned}\text{Area } &= \int_0^2 te^{-t}\,dt = -te^{-t}\Big|_0^2 - \int_0^2 -1\cdot e^{-t}\,dt \\ &= (-te^{-t} - e^{-t})\Big|_0^2 = -2e^{-2} - e^{-2} + 1 = 1 - 3e^{-2}.\end{aligned}$$

47. Since $\int \arctan z\,dz = \int 1\cdot\arctan z\,dz$, we take $u = \arctan z$, $v' = 1$, so $u' = 1/(1+z^2)$ and $v = z$. Then

$$\int \arctan z\,dz = z\arctan z - \int \frac{z}{1+z^2}\,dz = z\arctan z - \frac{1}{2}\ln(1+z^2) + C.$$

Thus, we have

$$\int_0^2 \arctan z\,dz = \left(z\arctan z - \frac{1}{2}\ln(z^2+1)\right)\Bigg|_0^2 = 2\arctan 2 - \frac{1}{2}\ln 5.$$

48. Since $\int \arcsin y\,dy = \int 1\cdot\arcsin y\,dy$, we take $u = \arcsin y$, $v' = 1$, so $u = 1/\sqrt{1-y^2}$ and $v = y$. Thus

$$\int \arcsin y\,dy = y\arcsin y - \int \frac{y}{\sqrt{1-y^2}}\,dy.$$

Substituting $w = 1-y^2, dw = -2y\,dy$, we have

$$\int \frac{y}{\sqrt{1-y^2}}\,dy = \int \frac{-1/2}{\sqrt{w}}\,dw = -\frac{1}{2}\int w^{-1/2}\,dw = w^{1/2} + C = \sqrt{1-y^2} + C.$$

Thus

$$\text{Area } = \int_0^1 \arcsin y\,dy = (y\arcsin y + \sqrt{1-y^2})\Bigg|_0^1 = 1\cdot\arcsin 1 - 1 = \frac{\pi}{2} - 1.$$

49. Since $\ln(x^2) = 2\ln x$ and $\int \ln x\,dx = x\ln x - x + C$, we have

$$\begin{aligned}\text{Area } &= \int_1^2 (\ln(x^2) - \ln x)\,dx = \int_1^2 (2\ln x - \ln x)\,dx \\ &= \int_1^2 \ln x\,dx = (x\ln x - x)\Bigg|_1^2 = 2\ln 2 - 2 - (1\ln 1 - 1) = 2\ln 2 - 1.\end{aligned}$$

50. Since the graph of $f(t) = \ln(t^2-1)$ is above the graph of $g(t) = \ln(t-1)$ for $t > 1$, we have

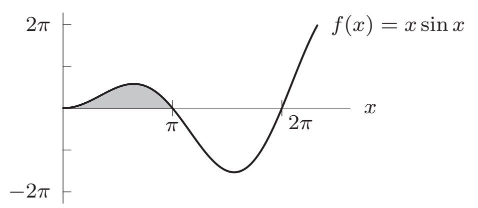
$$\text{Area } = \int_2^3 (\ln(t^2-1) - \ln(t-1))\,dt = \int_2^3 \ln\left(\frac{t^2-1}{t-1}\right)\,dt = \int_2^3 \ln(t+1)\,dt.$$

We can cancel the factor of $(t-1)$ in the last step above because the integral is over $2 \le t \le 3$, where $(t-1)$ is not zero.

We use $\int \ln x\,dx = x\ln x - 1$ with the substitution $x = t+1$. The limits $t = 2, t = 3$ become $x = 3, x = 4$, respectively. Thus

$$\begin{aligned}\text{Area } &= \int_2^3 \ln(t+1)\,dt = \int_3^4 \ln x\,dx = (x\ln x - x)\Bigg|_3^4 \\ &= 4\ln 4 - 4 - (3\ln 3 - 3) = 4\ln 4 - 3\ln 3 - 1.\end{aligned}$$

51.



The graph of $f(x) = x\sin x$ is shown above. The first positive zero is at $x = \pi$, so, using integration by parts,

$$\text{Area } = \int_0^\pi x\sin x\,dx$$

$$
\begin{aligned}
&= -x\cos x\Big|_0^{\pi} + \int_0^{\pi}\cos x\,dx \\
&= -x\cos x\Big|_0^{\pi} + \sin x\Big|_0^{\pi} \\
&= -\pi\cos\pi - (-0\cos 0) + \sin\pi - \sin 0 = \pi.
\end{aligned}
$$

52. From integration by parts in Problem 13, we obtain

$$\int \sin^2\theta\,d\theta = -\frac{1}{2}\sin\theta\cos\theta + \frac{1}{2}\theta + C.$$

Using the identity given in the book, we have

$$\int \sin^2\theta\,d\theta = \int \frac{1-\cos 2\theta}{2}\,d\theta = \frac{1}{2}\theta - \frac{1}{4}\sin 2\theta + C.$$

Although the answers differ in form, they are really the same, since (by one of the standard double angle formulas) $-\frac{1}{4}\sin 2\theta = -\frac{1}{4}(2\sin\theta\cos\theta) = -\frac{1}{2}\sin\theta\cos\theta$.

53. Integration by parts: let $u = \cos\theta$ and $v' = \cos\theta$, so $u' = -\sin\theta$ and $v = \sin\theta$.

$$
\begin{aligned}
\int \cos^2\theta\,d\theta &= \sin\theta\cos\theta - \int(-\sin\theta)(\sin\theta)\,d\theta \\
&= \sin\theta\cos\theta + \int \sin^2\theta\,d\theta.
\end{aligned}
$$

Now use $\sin^2\theta = 1 - \cos^2\theta$.

$$
\begin{aligned}
\int \cos^2\theta\,d\theta &= \sin\theta\cos\theta + \int(1-\cos^2\theta)\,d\theta \\
&= \sin\theta\cos\theta + \int d\theta - \int\cos^2\theta\,d\theta.
\end{aligned}
$$

Adding $\int\cos^2\theta\,d\theta$ to both sides, we have

$$
\begin{aligned}
2\int \cos^2\theta\,d\theta &= \sin\theta\cos\theta + \theta + C \\
\int \cos^2\theta\,d\theta &= \frac{1}{2}\sin\theta\cos\theta + \frac{1}{2}\theta + C'.
\end{aligned}
$$

Use the identity $\cos^2\theta = \frac{1+\cos 2\theta}{2}$.

$$\int \cos^2\theta\,d\theta = \int \frac{1+\cos 2\theta}{2}\,d\theta = \frac{1}{2}\theta + \frac{1}{4}\sin 2\theta + C.$$

The only difference is in the two terms $\frac{1}{2}\sin\theta\cos\theta$ and $\frac{1}{4}\sin 2\theta$, but since $\sin 2\theta = 2\sin\theta\cos\theta$, we have $\frac{1}{4}\sin 2\theta = \frac{1}{4}(2\sin\theta\cos\theta) = \frac{1}{2}\sin\theta\cos\theta$, so there is no real difference between the formulas.

54. First, let $u = e^x$ and $v' = \sin x$, so $u' = e^x$ and $v = -\cos x$.
Thus $\int e^x\sin x\,dx = -e^x\cos x + \int e^x\cos x\,dx$. To calculate $\int e^x\cos x\,dx$, we again need to use integration by parts.
Let $u = e^x$ and $v' = \cos x$, so $u' = e^x$ and $v = \sin x$.
Thus

$$\int e^x\cos x\,dx = e^x\sin x - \int e^x\sin x\,dx.$$

This gives

$$\int e^x\sin x\,dx = e^x\sin x - e^x\cos x - \int e^x\sin x\,dx.$$

By adding $\int e^x \sin x\,dx$ to both sides, we obtain

$$2\int e^x \sin x\,dx = e^x(\sin x - \cos x) + C.$$

$$\text{Thus } \int e^x \sin x\,dx = \frac{1}{2}e^x(\sin x - \cos x) + C.$$

This problem could also be done in other ways; for example, we could have started with $u = \sin x$ and $v' = e^x$ as well.

55. Let $u = e^\theta$ and $v' = \cos\theta$, so $u' = e^\theta$ and $v = \sin\theta$. Then $\int e^\theta \cos\theta\,d\theta = e^\theta \sin\theta - \int e^\theta \sin\theta\,d\theta$.

In Problem 54 we found that $\int e^x \sin x dx = \frac{1}{2}e^x(\sin x - \cos x) + C$.

$$\begin{aligned}\int e^\theta \cos\theta\,d\theta &= e^\theta \sin\theta - \left[\frac{1}{2}e^\theta(\sin\theta - \cos\theta)\right] + C\\ &= \frac{1}{2}e^\theta(\sin\theta + \cos\theta) + C.\end{aligned}$$

56. We integrate by parts. Since in Problem 54 we found that $\int e^x \sin x\,dx = \frac{1}{2}e^x(\sin x - \cos x)$, we let $u = x$ and $v' = e^x \sin x$, so $u' = 1$ and $v = \frac{1}{2}e^x(\sin x - \cos x)$.

$$\begin{aligned}\text{Then } \int xe^x \sin x\,dx &= \frac{1}{2}xe^x(\sin x - \cos x) - \frac{1}{2}\int e^x(\sin x - \cos x)\,dx\\ &= \frac{1}{2}xe^x(\sin x - \cos x) - \frac{1}{2}\int e^x \sin x\,dx + \frac{1}{2}\int e^x \cos x\,dx.\end{aligned}$$

Using Problems 54 and 55, we see that this equals

$$\begin{aligned}&\frac{1}{2}xe^x(\sin x - \cos x) - \frac{1}{4}e^x(\sin x - \cos x) + \frac{1}{4}e^x(\sin x + \cos x) + C\\ &\quad = \frac{1}{2}xe^x(\sin x - \cos x) + \frac{1}{2}e^x \cos x + C.\end{aligned}$$

57. Again we use Problems 54 and 55. Integrate by parts, letting $u = \theta$ and $v' = e^\theta \cos\theta$, so $u' = 1$ and $v = \frac{1}{2}e^\theta(\sin\theta + \cos\theta)$. Then

$$\begin{aligned}\int \theta e^\theta \cos\theta\,d\theta &= \frac{1}{2}\theta e^\theta(\sin\theta + \cos\theta) - \frac{1}{2}\int e^\theta(\sin\theta + \cos\theta)\,d\theta\\ &= \frac{1}{2}\theta e^\theta(\sin\theta + \cos\theta) - \frac{1}{2}\int e^\theta \sin\theta\,d\theta - \frac{1}{2}\int e^\theta \cos\theta\,d\theta\\ &= \frac{1}{2}\theta e^\theta(\sin\theta + \cos\theta) - \frac{1}{4}e^\theta(\sin\theta - \cos\theta) - \frac{1}{4}(\sin\theta + \cos\theta) + C\\ &= \frac{1}{2}\theta e^\theta(\sin\theta + \cos\theta) - \frac{1}{2}e^\theta \sin\theta + C.\end{aligned}$$

58. Using integration by parts on the first integral with $u(x) = \ln x$ and $v'(x) = f''(x)$, we have $u'(x) = 1/x$ and $v(x) = f'(x)$, so

$$\int f''(x)\ln x\,dx = f'(x)\ln x - \int \frac{f'(x)}{x}\,dx$$

Using integration by parts on the second integral with $u(x) = f(x)$ and $v'(x) = 1/x^2$, we have $u'(x) = f'(x)$ and $v(x) = -1/x$, so

$$\int \frac{f(x)}{x^2} = -\frac{f(x)}{x} + \int \frac{f'(x)}{x}\,dx.$$

Adding the results gives

$$\int f''(x)\ln x\,dx + \int \frac{f(x)}{x^2}\,dx = f'(x)\ln x - \int \frac{f'(x)}{x}\,dx - \frac{f(x)}{x} + \int \frac{f'(x)}{x}\,dx = f'(x)\ln x - \frac{f(x)}{x} + C$$

59. Using integration by parts with $u(x) = x$ and $v'(x) = f''(x)$ gives $u'(x) = 1$ and $v(x) = f'(x)$, so

$$\int x f''(x)\,dx = x f'(x) - \int f'(x)\,dx = x f'(x) - f(x) + C.$$

60. Using integration by parts, we let $u = x, v' = f'(x)$. This gives $u' = 1, v = f(x)$, and we have

$$\begin{aligned}
\int uv'\,dx &= uv - \int u'v\,dx \\
&= \overbrace{xf(x)}^{uv} - \int \overbrace{1 \cdot f(x)}^{u'v}\,dx \\
&= xf(x) - F(x) + C \qquad \text{since } f(x) = F'(x).
\end{aligned}$$

$$\begin{aligned}
\text{Therefore,} \quad \int_0^5 uv'\,dx &= (xf(x) - F(x))\Big|_0^5 \\
&= 5f(5) - F(5) - (0 \cdot f(0) - F(0)) \\
&= 5 \cdot 27 - 20 - (0 \cdot 2 - 10) = 125.
\end{aligned}$$

61. We integrate by parts. Since we know what the answer is supposed to be, it's easier to choose u and v'. Let $u = x^n$ and $v' = e^x$, so $u' = nx^{n-1}$ and $v = e^x$. Then

$$\int x^n e^x\,dx = x^n e^x - n \int x^{n-1} e^x\,dx.$$

62. We integrate by parts. Let $u = x^n$ and $v' = \cos ax$, so $u' = nx^{n-1}$ and $v = \frac{1}{a}\sin ax$. Then

$$\begin{aligned}
\int x^n \cos ax\,dx &= \frac{1}{a}x^n \sin ax - \int (nx^{n-1})(\frac{1}{a}\sin ax)\,dx \\
&= \frac{1}{a}x^n \sin ax - \frac{n}{a}\int x^{n-1} \sin ax\,dx.
\end{aligned}$$

63. We integrate by parts. Let $u = x^n$ and $v' = \sin ax$, so $u' = nx^{n-1}$ and $v = -\frac{1}{a}\cos ax$. Then

$$\begin{aligned}
\int x^n \sin ax\,dx &= -\frac{1}{a}x^n \cos ax - \int (nx^{n-1})(-\frac{1}{a}\cos ax)\,dx \\
&= -\frac{1}{a}x^n \cos ax + \frac{n}{a}\int x^{n-1} \cos ax\,dx.
\end{aligned}$$

64. We integrate by parts. Since we know what the answer is supposed to be, it's easier to choose u and v'. Let $u = \cos^{n-1} x$ and $v' = \cos x$, so $u' = (n-1)\cos^{n-2} x(-\sin x)$ and $v = \sin x$. Then

$$\begin{aligned}
\int \cos^n x\,dx &= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x \sin^2 x\,dx \\
&= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x(1 - \cos^2 x)\,dx \\
&= \cos^{n-1} x \sin x - (n-1)\int \cos^n x\,dx + (n-1)\int \cos^{n-2} x\,dx.
\end{aligned}$$

Thus, by adding $(n-1)\int \cos^n x\,dx$ to both sides of the equation, we find

$$\begin{aligned}
n\int \cos^n x\,dx &= \cos^{n-1} x \sin x + (n-1)\int \cos^{n-2} x\,dx, \\
\text{so} \int \cos^n\,dx &= \frac{1}{n}\cos^{n-1} x \sin x + \frac{n-1}{n}\int \cos^{n-2} x\,dx.
\end{aligned}$$

65. (a) One way to avoid integrating by parts is to take the derivative of the right hand side instead. Since $\int e^{ax}\sin bx\,dx$ is the antiderivative of $e^{ax}\sin bx$,

$$\begin{aligned} e^{ax}\sin bx &= \frac{d}{dx}[e^{ax}(A\sin bx + B\cos bx) + C] \\ &= ae^{ax}(A\sin bx + B\cos bx) + e^{ax}(Ab\cos bx - Bb\sin bx) \\ &= e^{ax}[(aA - bB)\sin bx + (aB + bA)\cos bx]. \end{aligned}$$

Thus $aA - bB = 1$ and $aB + bA = 0$. Solving for A and B in terms of a and b, we get

$$A = \frac{a}{a^2+b^2},\ B = -\frac{b}{a^2+b^2}.$$

Thus

$$\int e^{ax}\sin bx = e^{ax}\left(\frac{a}{a^2+b^2}\sin bx - \frac{b}{a^2+b^2}\cos bx\right) + C.$$

(b) If we go through the same process, we find

$$ae^{ax}[(aA - bB)\sin bx + (aB + bA)\cos bx] = e^{ax}\cos bx.$$

Thus $aA - bB = 0$, and $aB + bA = 1$. In this case, solving for A and B yields

$$A = \frac{b}{a^2+b^2},\ B = \frac{a}{a^2+b^2}.$$

Thus $\int e^{ax}\cos bx = e^{ax}(\frac{b}{a^2+b^2}\sin bx + \frac{a}{a^2+b^2}\cos bx) + C$.

66. Since $f'(x) = 2x$, integration by parts tells us that

$$\begin{aligned} \int_0^{10} f(x)g'(x)\,dx &= f(x)g(x)\Big|_0^{10} - \int_0^{10} f'(x)g(x)\,dx \\ &= f(10)g(10) - f(0)g(0) - 2\int_0^{10} xg(x)\,dx. \end{aligned}$$

We can use left and right Riemann Sums with $\Delta x = 2$ to approximate $\int_0^{10} xg(x)\,dx$:

$$\begin{aligned} \text{Left sum} &\approx 0\cdot g(0)\Delta x + 2\cdot g(2)\Delta x + 4\cdot g(4)\Delta x + 6\cdot g(6)\Delta x + 8\cdot g(8)\Delta x \\ &= (0(2.3) + 2(3.1) + 4(4.1) + 6(5.5) + 8(5.9))\,2 = 205.6. \\ \text{Right sum} &\approx 2\cdot g(2)\Delta x + 4\cdot g(4)\Delta x + 6\cdot g(6)\Delta x + 8\cdot g(8)\Delta x + 10\cdot g(10)\Delta x \\ &= (2(3.1) + 4(4.1) + 6(5.5) + 8(5.9) + 10(6.1))\,2 = 327.6. \end{aligned}$$

A good estimate for the integral is the average of the left and right sums, so

$$\int_0^{10} xg(x)\,dx \approx \frac{205.6 + 327.6}{2} = 266.6.$$

Substituting values for f and g, we have

$$\begin{aligned} \int_0^{10} f(x)g'(x)\,dx &= f(10)g(10) - f(0)g(0) - 2\int_0^{10} xg(x)\,dx \\ &\approx 10^2(6.1) - 0^2(2.3) - 2(266.6) = 76.8 \approx 77. \end{aligned}$$

67. Using integration by parts we have

$$\begin{aligned} \int_0^1 xf''(x)\,dx &= xf'(x)\Big|_0^1 - \int_0^1 f'(x)\,dx \\ &= 1\cdot f'(1) - 0\cdot f'(0) - [f(1) - f(0)] \\ &= 2 - 0 - 5 + 6 = 3. \end{aligned}$$

68. Letting $u=\sqrt{x}, u'=\dfrac{1}{2\sqrt{x}}, v=f(x), v'=f'(x)$, we have:

$$\begin{aligned}\int \underbrace{f'(x)\sqrt{x}}_{uv'}\,dx &= \underbrace{f(x)\sqrt{x}}_{uv} - \int \underbrace{f(x)\cdot\frac{1}{2\sqrt{x}}}_{vu'}\,dx\\ &= \underbrace{f(x)\sqrt{x}}_{h(x)} - \frac{1}{2}\int \underbrace{f(x)\cdot\frac{1}{\sqrt{x}}}_{g'(x)}\,dx\\ &= h(x) - \frac{1}{2}\int g'(x)\,dx\\ &= h(x) - \frac{1}{2}g(x) + C.\end{aligned}$$

69. Letting $u=x, v'=f'(x)$, we have $u'=1$ and $v=f(x)$. Integration by parts gives:

$$\int \overbrace{xf'(x)}^{uv'}\,dx = \overbrace{xf(x)}^{uv} - \int \overbrace{f(x)}^{vu'}\,dx.$$

This means

$$\begin{aligned}\int_0^7 xf'(x)\,dx &= xf(x)\Big|_0^7 - \underbrace{\int_0^7 f(x)\,dx}_{5}\\ &= 7\underbrace{f(7)}_{0} - 0\cdot f(0) - 5 \qquad x=7 \text{ is a zero of } f\\ &= -5.\end{aligned}$$

70. (a) We have

$$\begin{aligned}F(a) &= \int_0^a x^2e^{-x}\,dx\\ &= -x^2e^{-x}\Big|_0^a + \int_0^a 2xe^{-x}\,dx\\ &= (-x^2e^{-x} - 2xe^{-x})\Big|_0^a + 2\int_0^a e^{-x}\,dx\\ &= (-x^2e^{-x} - 2xe^{-x} - 2e^{-x})\Big|_0^a\\ &= -a^2e^{-a} - 2ae^{-a} - 2e^{-a} + 2.\end{aligned}$$

(b) $F(a)$ is increasing because x^2e^{-x} is positive, so as a increases, the area under the curve from 0 to a also increases and thus the integral increases.

(c) We have $F'(a)=a^2e^{-a}$, so

$$F''(a) = 2ae^{-a} - a^2e^{-a} = a(2-a)e^{-a}.$$

We see that $F''(a) > 0$ for $0 < a < 2$, so F is concave up on this interval.

71. We have

$$\text{Bioavailability} = \int_0^3 15te^{-0.2t}dt.$$

We first use integration by parts to evaluate the indefinite integral of this function. Let $u=15t$ and $v'=e^{-0.2t}dt$, so $u'=15dt$ and $v=-5e^{-0.2t}$. Then,

$$\begin{aligned}\int 15te^{-0.2t}dt &= (15t)(-5e^{-0.2t}) - \int(-5e^{-0.2t})(15dt)\\ &= -75te^{-0.2t} + 75\int e^{-0.2t}dt = -75te^{-0.2} - 375e^{-0.2t} + C.\end{aligned}$$

Thus,

$$\int_0^3 15te^{-0.2t}dt = (-75te^{-0.2t} - 375e^{-0.2t})\Big|_0^3 = -329.29 + 375 = 45.71.$$

The bioavailability of the drug over this time interval is 45.71 (ng/ml)-hours.

72. (a) Increasing V_0 increases the maximum value of V, since this maximum is V_0. Increasing ω or ϕ does not affect the maximum of V.

(b) Since

$$\frac{dV}{dt} = -\omega V_0 \sin(\omega t + \phi),$$

the maximum of dV/dt is ωV_0. Thus, the maximum of dV/dt is increased if V_0 or ω is increased, and is unaffected if ϕ is increased.

(c) The period of $V = V_0 \cos(\omega t + \phi)$ is $2\pi/\omega$, so

$$\text{Average value} = \frac{1}{2\pi/\omega}\int_0^{2\pi/\omega} (V_0\cos(\omega t + \phi))^2\, dt.$$

Substituting $x = \omega t + \phi$, we have $dx = \omega dt$. When $t = 0$, $x = \phi$, and when $t = 2\pi/\omega$, $x = 2\pi + \phi$. Thus,

$$\begin{aligned}\text{Average value} &= \frac{\omega}{2\pi}\int_\phi^{2\pi+\phi} V_0^2(\cos x)^2 \frac{1}{\omega}\, dx\\ &= \frac{V_0^2}{2\pi}\int_\phi^{2\pi+\phi} (\cos x)^2\, dx.\end{aligned}$$

Using integration by parts and the fact that $\sin^2 x = 1 - \cos^2 x$, we see that

$$\begin{aligned}\text{Average value} &= \frac{V_0^2}{2\pi}\left[\frac{1}{2}(\cos x \sin x + x)\right]_\phi^{2\pi+\phi}\\ &= \frac{V_0^2}{4\pi}\left[\cos(2\pi+\phi)\sin(2\pi+\phi) + (2\pi+\phi) - \cos\phi\sin\phi - \phi\right]\\ &= \frac{V_0^2}{4\pi}\cdot 2\pi = \frac{V_0^2}{2}.\end{aligned}$$

Thus, increasing V_0 increases the average value; increasing ω or ϕ has no effect.
However, it is not in fact necessary to compute the integral to see that ω does not affect the average value, since all ω's dropped out of the average value expression when we made the substitution $x = \omega t + \phi$.

73. (a) We know that $\dfrac{dE}{dt} = r$, so the total energy E used in the first T hours is given by $E = \displaystyle\int_0^T te^{-at}\, dt$. We use integration by parts. Let $u = t$, $v' = e^{-at}$. Then $u' = 1$, $v = -\frac{1}{a}e^{-at}$.

$$\begin{aligned}E &= \int_0^T te^{-at}\, dt\\ &= -\frac{t}{a}e^{-at}\Big|_0^T - \int_0^T \left(-\frac{1}{a}e^{-at}\right) dt\\ &= -\frac{1}{a}Te^{-aT} + \frac{1}{a}\int_0^T e^{-at}\, dt\\ &= -\frac{1}{a}Te^{-aT} + \frac{1}{a^2}(1 - e^{-aT}).\end{aligned}$$

(b)

$$\lim_{T\to\infty} E = -\frac{1}{a}\lim_{T\to\infty}\left(\frac{T}{e^{aT}}\right) + \frac{1}{a^2}\left(1 - \lim_{T\to\infty}\frac{1}{e^{aT}}\right).$$

Since $a > 0$, the second limit on the right hand side in the above expression is 0. In the first limit, although both the numerator and the denominator go to infinity, the denominator e^{aT} goes to infinity more quickly than T does. So in the end the denominator e^{aT} is much greater than the numerator T. Hence $\displaystyle\lim_{T\to\infty}\frac{T}{e^{aT}} = 0$. (You can check this by graphing $y = \dfrac{T}{e^{aT}}$ on a calculator or computer for some values of a.) Thus $\displaystyle\lim_{T\to\infty} E = \frac{1}{a^2}$.

74. Letting $u = \ln|x|, u' = \dfrac{1}{x}, v = f(x), v' = f'(x)$, we have:

$$\begin{aligned}\int \underbrace{f'(x)\ln|x|}_{uv'}\,dx &= \underbrace{f(x)\ln|x|}_{uv} - \int \underbrace{\frac{1}{x}\cdot f(x)}_{u'v}\,dx\\ &= \underbrace{f(x)\ln|x|}_{h(x)} - \int \underbrace{\frac{f(x)}{x}}_{g'(x)}\,dx\\ &= h(x) - g(x) + C.\end{aligned}$$

75. (a) We have $u = \operatorname{erf}(x), v' = 1$, which means $v = x$. From the Construction Theorem, we see that $\operatorname{erf}(x)$ is an antiderivative of $\dfrac{2}{\sqrt{\pi}}e^{-x^2}$, so $u' = \dfrac{2}{\sqrt{\pi}}e^{-x^2}$. Using integration by parts, we have

$$\begin{aligned}\int \overbrace{\operatorname{erf}(x)}^{uv'}\,dx &= \overbrace{x\operatorname{erf}(x)}^{uv} - \int \overbrace{x\frac{2}{\sqrt{\pi}}e^{-x^2}}^{u'v}\,dx\\ &= x\operatorname{erf}(x) - \int \frac{2}{\sqrt{\pi}}e^{-x^2}x\,dx.\end{aligned}$$

(b) One possibility is to let $w = -x^2, dw = -2xdx$, which gives:

$$\int \frac{2}{\sqrt{\pi}}e^{-x^2}x\,dx = \frac{2}{\sqrt{\pi}}\int e^w\left(-\frac{1}{2}\right)dw = -\frac{1}{\sqrt{\pi}}e^w + C = -\frac{1}{\sqrt{\pi}}e^{-x^2} + C.$$

Another possibility is to let $w = e^{-x^2}, dw = -2xe^{-x^2}dx$, which leads to the same result.

(c) Based on our answers to parts (a) and (b), we have:

$$\begin{aligned}\int \operatorname{erf}(x)\,dx &= x\operatorname{erf}(x) - \int \frac{2}{\sqrt{\pi}}e^{-x^2}x\,dx\\ &= x\operatorname{erf}(x) + \frac{1}{\sqrt{\pi}}e^{-x^2} + C.\end{aligned}$$

Checking our answer, we see that:

$$\begin{aligned}\frac{d}{dx}\left(x\operatorname{erf}(x) + \frac{1}{\sqrt{\pi}}e^{-x^2} + C\right) &= \frac{d}{dx}\left(x\operatorname{erf}(x)\right) + \frac{d}{dx}\left(\frac{1}{\sqrt{\pi}}e^{-x^2}\right)\\ &= 1\cdot\operatorname{erf}(x) + x\cdot\underbrace{(\operatorname{erf}(x))'}_{\frac{2}{\sqrt{\pi}}e^{-x^2}} + \frac{1}{\sqrt{\pi}}e^{-x^2}(-2x)\\ &= \operatorname{erf}(x) + \frac{2x}{\sqrt{\pi}}e^{-x^2} - \frac{2x}{\sqrt{\pi}}e^{-x^2}\\ &= \operatorname{erf}(x). \qquad \text{as required}\end{aligned}$$

76. Since $\operatorname{Li}(x) = \displaystyle\int_2^x \frac{1}{\ln t}\,dt$, we see from the Construction Theorem that $\operatorname{Li}(x)$ is an antiderivative of $1/\ln(x)$, which means that $(\operatorname{Li}(x))' = 1/\ln(x)$. We need to perform integration by parts where $u = \operatorname{Li}(x), v = \ln x$. We have:

$$u' = \frac{1}{\ln x} \quad \text{and} \quad v' = \frac{1}{x},$$

which means

$$\begin{aligned}\int \underbrace{\operatorname{Li}(x)x^{-1}}_{uv'}\,dx &= uv - \int u'v\,dx \qquad \text{integration by parts}\\ &= \underbrace{\operatorname{Li}(x)\ln x}_{uv} - \int \underbrace{\frac{1}{\ln(x)}\cdot\ln x}_{u'v}\,dx\\ &= \operatorname{Li}(x)\ln x - \int dx\\ &= \operatorname{Li}(x)\ln x - x + C.\end{aligned}$$

Strengthen Your Understanding

77. To use integration by parts on $\int t\ln t\,dt$, use $u=\ln t$, $v'=t$.

78. We can write $\arctan x = (1)(\arctan x)$. Then using $u=\arctan x$ and $v'=1$, we can evaluate the integral using integration by parts.

79. Using integration by parts with $u=f(x)$ and $v'=1$ gives $u'=f'(x)$, $v=x$, so we get

$$\int f(x)\,dx = xf(x) - \int xf'(x)\,dx.$$

80. The integral $\int \theta^2 \sin\theta\,d\theta$ requires integration by parts twice. Many other answers are possible.

81. $\int x^3e^x\,dx$

82. $\int e^x \sin x\,dx$, can be evaluated by applying integration by parts twice, both times with $u=e^x$, or by applying integration by parts once with $u=\sin x$ and then a second time with $u=\cos x$.

83. True. Let $u=t, v'=\sin(5-t)$, so $u'=1, v=\cos(5-t)$. Then the integral $\int 1\cdot\cos(5-t)\,dt$ can be done by guess-and-check or by substituting $w=5-t$.

84. True. If we let $u=t^2$ and $v'=e^{3-t}$ and integrate by parts twice, we obtain

$$\int t^2e^{3-t}\,dt = -t^2e^{3-t} + 2(-te^{3-t} - e^{3-t}) + C.$$

85. False. Suppose we have $\int x^2\sin x\,dx$. If we choose $u=\sin x$ and $v'=x^2$, the resulting integral is

$$\frac{x^3}{3}\sin x - \int \frac{x^3}{3}\cos x\,dx,$$

which is no simpler than the original integral. Choosing $u=x^2$ and $v'=\sin x$ make the integral simpler. After integrating twice, we get $-x^2\cos x + 2(x\sin x + 2\cos x) + C$.

Solutions for Section 7.3

Exercises

1. $\frac{1}{6}x^6\ln x - \frac{1}{36}x^6 + C$. (Let $n=5$ in III-13.)

2. $\frac{1}{10}e^{(-3\theta)}(-3\cos\theta + \sin\theta) + C$.
(Let $a=-3, b=1$ in II-9.)

3. The integrand, a polynomial, x^3, multiplied by $\sin 5x$, is in the form of III-15. There are only three successive derivatives of x^3 before 0 is reached (namely, $3x^2$, $6x$, and 6), so there will be four terms. The signs in the terms will be $-++-$, as given in III-15, so we get

$$\int x^3\sin 5x\,dx = -\frac{1}{5}x^3\cos 5x + \frac{1}{25}\cdot 3x^2\sin 5x + \frac{1}{125}\cdot 6x\cos 5x - \frac{1}{625}\cdot 6\sin 5x + C.$$

4. Formula III-13 applies only to functions of the form $x^n\ln x$, so we'll have to multiply out and separate into two integrals.

$$\int (x^2+3)\ln x\,dx = \int x^2\ln x\,dx + 3\int \ln x\,dx.$$

Now we can use formula III-13 on each integral separately, to get

$$\int (x^2+3)\ln x\,dx = \frac{x^3}{3}\ln x - \frac{x^3}{9} + 3(x\ln x - x) + C.$$

5. Note that you can't use substitution here: letting $w = x^3 + 5$ does not work, since there is no $dw = 3x^2\,dx$ in the integrand. What will work is simply multiplying out the square: $(x^3+5)^2 = x^6 + 10x^3 + 25$. Then use I-1:

$$\int (x^3+5)^2\,dx = \int x^6\,dx + 10\int x^3\,dx + 25\int 1\,dx = \frac{1}{7}x^7 + 10\cdot\frac{1}{4}x^4 + 25x + C.$$

6. $-\frac{1}{5}\cos^5 w + C$
(Let $x = \cos w$, as suggested in IV-23. Then $-\sin w\,dw = dx$, and $\int \sin w \cos^4 w\,dw = -\int x^4\,dx$.)

7. $-\frac{1}{4}\sin^3 x\cos x - \frac{3}{8}\sin x\cos x + \frac{3}{8}x + C.$
(Use IV-17.)

8. $\left(\frac{1}{2}x^3 - \frac{3}{4}x^2 + \frac{3}{4}x - \frac{3}{8}\right)e^{2x} + C.$
(Let $a = 2, p(x) = x^3$ in III-14.)

9. $\left(\frac{1}{3}x^2 - \frac{2}{9}x + \frac{2}{27}\right)e^{3x} + C.$
(Let $a = 3, p(x) = x^2$ in III-14.)

10. $\frac{1}{3}e^{x^3} + C.$
(Substitute $w = x^3$, $dw = 3x^2\,dx$. It is not necessary to use the table.)

11. $\left(\frac{1}{3}x^4 - \frac{4}{9}x^3 + \frac{4}{9}x^2 - \frac{8}{27}x + \frac{8}{81}\right)e^{3x} + C.$
(Let $a = 3, p(x) = x^4$ in III-14.)

12. Substitute $w = 5u,\ dw = 5\,du$. Then

$$\begin{aligned}\int u^5\ln(5u)\,du &= \frac{1}{5^6}\int w^5 \ln w\,dw \\ &= \frac{1}{5^6}\left(\frac{1}{6}w^6\ln w - \frac{1}{36}w^6 + C\right) \\ &= \frac{1}{6}u^6\ln 5u - \frac{1}{36}u^6 + C.\end{aligned}$$

Or use $\ln 5u = \ln 5 + \ln u$.

$$\begin{aligned}\int u^5 \ln 5u\,du &= \ln 5\int u^5\,du + \int u^5\ln u\,du \\ &= \frac{u^6}{6}\ln 5 + \frac{1}{6}u^6\ln u - \frac{1}{36}u^6 + C \quad \text{(using III-13)} \\ &= \frac{u^6}{6}\ln 5u - \frac{1}{36}u^6 + C.\end{aligned}$$

13. $\frac{1}{\sqrt{3}}\arctan\frac{y}{\sqrt{3}} + C.$
(Let $a = \sqrt{3}$ in V-24).

14. We first factor out the 9 and then use formula V-24:

$$\begin{aligned}\int \frac{dx}{9x^2+16} = \int \frac{dx}{9(x^2+16/9)} &= \frac{1}{9}\cdot\frac{1}{4/3}\arctan\left(\frac{x}{4/3}\right) + C \\ &= \frac{1}{12}\arctan\left(\frac{3x}{4}\right) + C.\end{aligned}$$

15. We first factor out the 16 and then use formula V-28 to get

$$\int \frac{dx}{\sqrt{25-16x^2}} = \int \frac{dx}{\sqrt{16(25/16 - x^2)}} = \frac{1}{4}\int \frac{dx}{\sqrt{(5/4)^2 - x^2}}$$

$$= \frac{1}{4}\arcsin\left(\frac{x}{5/4}\right) + C$$
$$= \frac{1}{4}\arcsin\left(\frac{4x}{5}\right) + C.$$

16. The integral suggests formula VI-29, but is not a perfect match because of the coefficient of 9. One way to deal with the 9 is to factor it out, so that, using formula IV-29,

$$\int \frac{dx}{\sqrt{9x^2+25}} = \int \frac{dx}{\sqrt{9(x^2+25/9)}} = \frac{1}{3}\int \frac{dx}{\sqrt{x^2+(5/3)^2}} = \frac{1}{3}\ln\left|x+\sqrt{x^2+\left(\frac{5}{3}\right)^2}\right| + C.$$

Alternatively, we can write

$$\int \frac{dx}{\sqrt{9x^2+25}} = \int \frac{dx}{\sqrt{(3x)^2+25}}.$$

We now use the substitution $w = 3x$, so that $dw = 3dx$, and the integral becomes

$$\int \frac{\frac{1}{3}dw}{\sqrt{w^2+25}} = \frac{1}{3}\ln\left|w+\sqrt{w^2+25}\right| + C = \frac{1}{3}\ln|3x+\sqrt{9x^2+25}| + C.$$

17. $\frac{5}{16}\sin 3\theta \sin 5\theta + \frac{3}{16}\cos 3\theta \cos 5\theta + C.$
(Let $a = 3, b = 5$ in II-12.)

18. $\frac{3}{16}\cos 3\theta \sin 5\theta - \frac{5}{16}\sin 3\theta \cos 5\theta + C.$
(Let $a = 3, b = 5$ in II-10.)

19. Let $m = 3$ in IV-21.

$$\int \frac{1}{\cos^3 x}\,dx = \frac{1}{2}\frac{\sin x}{\cos^2 x} + \frac{1}{2}\int \frac{1}{\cos x}\,dx$$
$$= \frac{1}{2}\frac{\sin x}{\cos^2 x} + \frac{1}{4}\ln\left|\frac{\sin x + 1}{\sin x - 1}\right| + C \text{ by IV-22.}$$

20. Use long division to reorganize the integral:

$$\int \frac{t^2+1}{t^2-1}\,dt = \int \left(1 + \frac{2}{t^2-1}\right)\,dt = \int dt + \int \frac{2}{(t-1)(t+1)}\,dt.$$

To get this second integral, let $a = 1, b = -1$ in V-26, so

$$\int \frac{t^2+1}{t^2-1}\,dt = t + \ln|t-1| - \ln|t+1| + C.$$

21. $\frac{1}{34}e^{5x}(5\sin 3x - 3\cos 3x) + C.$
(Let $a = 5, b = 3$ in II-8.)

22. $\frac{1}{45}(7\cos 2y \sin 7y - 2\sin 2y \cos 7y) + C.$
(Let $a = 2, b = 7$ in II-11.)

23.

$$\int y^2 \sin 2y\,dy = -\frac{1}{2}y^2\cos 2y + \frac{1}{4}(2y)\sin 2y + \frac{1}{8}(2)\cos 2y + C$$
$$= -\frac{1}{2}y^2\cos 2y + \frac{1}{2}y\sin 2y + \frac{1}{4}\cos 2y + C.$$

(Use $a = 2, p(y) = y^2$ in III-15.)

24. Substitute $w = x^2, dw = 2x\,dx$. Then $\int x^3 \sin x^2\,dx = \frac{1}{2}\int w \sin w\,dw$. By III-15, we have

$$\int w \sin w\,dw = -\frac{1}{2}w\cos w + \frac{1}{2}\sin w + C = -\frac{1}{2}x^2\cos x^2 + \frac{1}{2}\sin x^2 + C.$$

25. Substitute $w = 7x,\ dw = 7\,dx$. Then use IV-21.

$$\begin{aligned}\int \frac{1}{\cos^4 7x}\,dx = \frac{1}{7}\int \frac{1}{\cos^4 w}\,dw &= \frac{1}{7}\left[\frac{1}{3}\frac{\sin w}{\cos^3 w} + \frac{2}{3}\int \frac{1}{\cos^2 w}\,dw\right]\\ &= \frac{1}{21}\frac{\sin w}{\cos^3 w} + \frac{2}{21}\left[\frac{\sin w}{\cos w} + C\right]\\ &= \frac{1}{21}\frac{\tan w}{\cos^2 w} + \frac{2}{21}\tan w + C\\ &= \frac{1}{21}\frac{\tan 7x}{\cos^2 7x} + \frac{2}{21}\tan 7x + C.\end{aligned}$$

26. Substitute $w = 3\theta,\ dw = 3\,d\theta$. Then use IV-19, letting $m = 3$.

$$\begin{aligned}\int \frac{1}{\sin^3 3\theta}\,d\theta = \frac{1}{3}\int \frac{1}{\sin^3 w}\,dw &= \frac{1}{3}\left[-\frac{1}{2}\frac{\cos w}{\sin^2 w} + \frac{1}{2}\int \frac{1}{\sin w}\,dw\right]\\ &= -\frac{1}{6}\frac{\cos w}{\sin^2 w} + \frac{1}{6}\left[\frac{1}{2}\ln\left|\frac{\cos(w)-1}{\cos(w)+1}\right| + C\right] \quad \text{by IV-20}\\ &= -\frac{1}{6}\frac{\cos 3\theta}{\sin^2 3\theta} + \frac{1}{12}\ln\left|\frac{\cos(3\theta)-1}{\cos(3\theta)+1}\right| + C.\end{aligned}$$

27. Substitute $w = 2\theta,\ dw = 2\,d\theta$. Then use IV-19, letting $m = 2$.

$$\int \frac{1}{\sin^2 2\theta}\,d\theta = \frac{1}{2}\int \frac{1}{\sin^2 w}\,dw = \frac{1}{2}(-\frac{\cos w}{\sin w}) + C = -\frac{1}{2\tan w} + C = -\frac{1}{2\tan 2\theta} + C.$$

28. Use IV-21 twice to get the exponent down to 1:

$$\begin{aligned}\int \frac{1}{\cos^5 x}\,dx &= \frac{1}{4}\frac{\sin x}{\cos^4 x} + \frac{3}{4}\int \frac{1}{\cos^3 x}\,dx\\ \int \frac{1}{\cos^3 x}\,dx &= \frac{1}{2}\frac{\sin x}{\cos^2 x} + \frac{1}{2}\int \frac{1}{\cos x}\,dx.\end{aligned}$$

Now use IV-22 to get

$$\int \frac{1}{\cos x}\,dx = \frac{1}{2}\ln\left|\frac{(\sin x)+1}{(\sin x)-1}\right| + C.$$

Putting this all together gives

$$\int \frac{1}{\cos^5 x}\,dx = \frac{1}{4}\frac{\sin x}{\cos^4 x} + \frac{3}{8}\frac{\sin x}{\cos^2 x} + \frac{3}{16}\ln\left|\frac{(\sin x)+1}{(\sin x)-1}\right| + C.$$

29.

$$\int \frac{1}{x^2+4x+3}\,dx = \int \frac{1}{(x+1)(x+3)}\,dx = \frac{1}{2}(\ln|x+1| - \ln|x+3|) + C.$$

(Let $a = -1$ and $b = -3$ in V-26).

30.

$$\int \frac{1}{x^2+4x+4}\,dx = \int \frac{1}{(x+2)^2}\,dx = -\frac{1}{x+2} + C.$$

You need not use the table.

31.

$$\int \frac{dz}{z(z-3)} = -\frac{1}{3}(\ln|z| - \ln|z-3|) + C.$$

(Let $a = 0, b = 3$ in V-26.)

32.

$$\int \frac{dy}{4-y^2} = -\int \frac{dy}{(y+2)(y-2)} = -\frac{1}{4}(\ln|y-2| - \ln|y+2|) + C.$$

(Let $a = 2, b = -2$ in V-26.)

33. $\arctan(z+2) + C$.
(Substitute $w = z + 2$ and use V-24, letting $a = 1$.)

34.

$$\int \frac{1}{y^2+4y+5}\,dy = \int \frac{1}{1+(y+2)^2}\,dy = \arctan(y+2) + C.$$

(Substitute $w = y + 2$, and let $a = 1$ in V-24).

35. We use the method of IV-23 in the table. Using the Pythagorean Identity, we rewrite the integrand:

$$\sin^3 x = \left(\sin^2 x\right)\sin x = \left(1 - \cos^2 x\right)\sin x = \sin x - \cos^2 x \sin x.$$

Thus, we have

$$\begin{aligned}\int \sin^3 x\,dx &= \int \left(\sin x - \cos^2 x \sin x\right)dx \\ &= \int \sin x\,dx - \int \cos^2 x \sin x\,dx.\end{aligned}$$

The first of these new integrals can be easily found. The second can be found using the substitution $w = \cos x$ so $dw = -\sin x\,dx$. The second integral becomes

$$\begin{aligned}\int \cos^2 x \sin x\,dx &= -\int w^2 dw \\ &= -\frac{1}{3}w^3 + C \\ &= -\frac{1}{3}\cos^3 x + C,\end{aligned}$$

so the final answer is

$$\begin{aligned}\int \sin^3 x\,dx &= \int \sin x\,dx - \int \cos^2 x \sin x\,dx \\ &= -\cos x + (1/3)\cos^3 x + C.\end{aligned}$$

36. Using the advice in IV-23, since both m and n are even and since n is negative, we convert everything to cosines, since $\cos x$ is in the denominator.

$$\begin{aligned}\int \tan^4 x\,dx &= \int \frac{\sin^4 x}{\cos^4 x}\,dx \\ &= \int \frac{(1-\cos^2 x)^2}{\cos^4 x}\,dx \\ &= \int \frac{1}{\cos^4 x}\,dx - 2\int \frac{1}{\cos^2 x}\,dx + \int 1\,dx.\end{aligned}$$

By IV-21

$$\begin{aligned}\int \frac{1}{\cos^4 x}\,dx &= \frac{1}{3}\frac{\sin x}{\cos^3 x} + \frac{2}{3}\int \frac{1}{\cos^2 x}\,dx, \\ \int \frac{1}{\cos^2 x}\,dx &= \frac{\sin x}{\cos x} + C.\end{aligned}$$

Substituting back in, we get

$$\int \tan^4 x\,dx = \frac{1}{3}\frac{\sin x}{\cos^3 x} - \frac{4}{3}\frac{\sin x}{\cos x} + x + C.$$

37. Since $\cosh^2 x - \sinh^2 x = 1$ we rewrite $\sinh^3 x$ as $\sinh x \sinh^2 x = \sinh x(\cosh^2 x - 1)$. Then

$$\begin{aligned}\int \sinh^3 x \cosh^2 x\,dx &= \int \sinh x(\cosh^2 x - 1)\cosh^2 x\,dx \\ &= \int (\cosh^4 x - \cosh^2 x)\sinh x\,dx.\end{aligned}$$

Now use the substitution $w = \cosh x$, $dw = \sinh x\,dx$ to find

$$\int (w^4 - w^2)\,dw = \frac{1}{5}w^5 - \frac{1}{3}w^3 + C = \frac{1}{5}\cosh^5 x - \frac{1}{3}\cosh^3 x + C.$$

38. Since $\cosh^2 x - \sinh^2 x = 1$ we rewrite $\cosh^3 x$ as $\cosh x \cosh^2 x = \cosh x(1 + \sinh^2 x)$. This gives

$$\begin{aligned}\int \sinh^2 x \cosh^3 x\,dx &= \int \sinh^2 x(\sinh^2 x + 1)\cosh x\,dx \\ &= \int (\sinh^4 x + \sinh^2 x)\cosh x\,dx.\end{aligned}$$

Now use the substitution $w = \sinh x$, $dw = \cosh x\,dx$ to find

$$\int (w^4 - w^2)\,dw = \frac{1}{5}w^5 - \frac{1}{3}w^3 + C = \frac{1}{5}\sinh^5 x + \frac{1}{3}\sinh^3 x + C.$$

39.

$$\begin{aligned}\int \sin^3 3\theta \cos^2 3\theta\,d\theta &= \int (\sin 3\theta)(\cos^2 3\theta)(1 - \cos^2 3\theta)\,d\theta \\ &= \int \sin 3\theta(\cos^2 3\theta - \cos^4 3\theta)\,d\theta.\end{aligned}$$

Using an extension of the tip given in rule IV-23, we let $w = \cos 3\theta,\ dw = -3\sin 3\theta\,d\theta$.

$$\begin{aligned}\int \sin 3\theta(\cos^2 3\theta - \cos^4 3\theta)\,d\theta &= -\frac{1}{3}\int (w^2 - w^4)\,dw \\ &= -\frac{1}{3}(\frac{w^3}{3} - \frac{w^5}{5}) + C \\ &= -\frac{1}{9}(\cos^3 3\theta) + \frac{1}{15}(\cos^5 3\theta) + C.\end{aligned}$$

40. If we make the substitution $w = 2z^2$ then $dw = 4z\,dz$, and the integral becomes:

$$\int ze^{2z^2}\cos(2z^2)\,dz = \frac{1}{4}\int e^w \cos w\,dw$$

Now we can use Formula 9 from the table of integrals to get:

$$\begin{aligned}\frac{1}{4}\int e^w \cos w\,dw &= \frac{1}{4}\left[\frac{1}{2}e^w(\cos w + \sin w) + C\right] \\ &= \frac{1}{8}e^w(\cos w + \sin w) + C \\ &= \frac{1}{8}e^{2z^2}(\cos 2z^2 + \sin 2z^2) + C\end{aligned}$$

41. Substitute $w = 3\alpha$, $dw = 3\,d\alpha$. Then $d\alpha = \frac{1}{3}\,dw$. We have

$$\begin{aligned}\int_{\alpha=0}^{\alpha=\frac{\pi}{12}} \sin 3\alpha\, d\alpha &= \frac{1}{3}\int_{w=0}^{w=\frac{\pi}{4}} \sin w\, dw \\ &= -\frac{1}{3}\cos w\Big|_0^{\frac{\pi}{4}} \\ &= -\frac{1}{3}\left(\frac{\sqrt{2}}{2}-1\right) = \frac{1}{3}\left(1-\frac{\sqrt{2}}{2}\right).\end{aligned}$$

42. Let $a = 5$ and $b = 6$ in II-12. Then

$$\int_{-\pi}^{\pi} \sin 5x \cos 6x\, dx = \frac{1}{11}(6\sin 5x \sin 6x + 5\cos 5x \cos 6x)\Big|_{-\pi}^{\pi} = 0.$$

This answer makes sense since $\sin 5x \cos 6x$ is odd, so its integral over any interval $-a \le x \le a$ should be 0.

43. Using III-13:

$$\begin{aligned}\int_1^2 (x-2x^3)\ln x\, dx &= \int_1^2 x\ln x\, dx - 2\int_1^2 x^3 \ln x\, dx \\ &= \left(\frac{1}{2}x^2\ln x - \frac{1}{4}x^2\right)\Big|_1^2 - \left(\frac{1}{2}x^4\ln x - \frac{1}{8}x^4\right)\Big|_1^2 \\ &= 2\ln 2 - \frac{3}{4} - \left(8\ln 2 - \frac{15}{8}\right) \\ &= \frac{9}{8} - 6\ln 2 = -3.034.\end{aligned}$$

44. Let $a = \sqrt{3}$ in VI-30 and VI-28:

$$\int_0^1 \sqrt{3-x^2}\, dx = \left(\frac{1}{2}x\sqrt{3-x^2} + \frac{3}{2}\arcsin\frac{x}{\sqrt{3}}\right)\Big|_0^1 \approx 1.630.$$

45. $\displaystyle\int_0^1 \frac{1}{x^2+2x+1}\, dx = \int_0^1 \frac{1}{(x+1)^2}\, dx.$

We substitute $w = x+1$, so $dw = dx$. Note that when $x = 1$, we have $w = 2$, and when $x = 0$, we have $w = 1$.

$$\int_{x=0}^{x=1} \frac{1}{(x+1)^2}\, dx = \int_{w=1}^{w=2} \frac{1}{w^2}\, dw = -\frac{1}{w}\Big|_{w=1}^{w=2} = -\frac{1}{2}+1 = \frac{1}{2}.$$

46. Substitute $w = x+1$ and use V-24:

$$\begin{aligned}\int_0^1 \frac{dx}{x^2+2x+5} &= = \int_0^1 \frac{dx}{(x+1)^2+4} \\ &= \frac{1}{2}\arctan\frac{x+1}{2}\Big|_0^1 = \frac{1}{2}\arctan 1 - \frac{1}{2}\arctan\frac{1}{2} \approx 0.1609.\end{aligned}$$

47. Let $w = x^2$, $dw = 2x\,dx$. When $x = 0$, $w = 0$, and when $x = \frac{1}{\sqrt{2}}$, $w = \frac{1}{2}$. Then

$$\int_0^{\frac{1}{\sqrt{2}}} \frac{x\,dx}{\sqrt{1-x^4}} = \int_0^{\frac{1}{2}} \frac{\frac{1}{2}\,dw}{\sqrt{1-w^2}} = \frac{1}{2}\arcsin w\Big|_0^{\frac{1}{2}} = \frac{1}{2}\left(\arcsin\frac{1}{2} - \arcsin 0\right) = \frac{\pi}{12}.$$

48. Let $w = x + 2$, giving $dw = dx$. When $x = 0$, $w = 2$, and when $x = 1$, $w = 3$. Thus,

$$\int_0^1 \frac{(x+2)}{(x+2)^2+1} dx = \int_2^3 \frac{w}{w^2+1}\, dw.$$

For the last integral, we make the substitution $u = w^2 + 1$, $du = 2w\, dw$. Then, we have

$$\begin{aligned} \int_2^3 \frac{w}{w^2+1}\, dw &= \frac{1}{2} \ln |w^2+1| \Big|_2^3 \\ &= \frac{1}{2}(\ln|10| - \ln|5|) \\ &= \frac{1}{2} \ln\left(\frac{10}{5}\right) = \frac{1}{2}\ln(2) \end{aligned}$$

49. Using IV-19 with $m = 3$, followed by IV-20, we find that

$$\int_{\pi/4}^{\pi/3} \frac{dx}{\sin^3 x} = -\frac{1}{2}\frac{\cos x}{\sin^2 x} + \frac{1}{4} \ln \left| \frac{\cos x - 1}{\cos x + 1} \right| \Bigg|_{\pi/4}^{\pi/3} = 0.5398.$$

50. Substitute $w = x + 3$ and then use VI-29:

$$\begin{aligned} \int_{-3}^{-1} \frac{dx}{\sqrt{x^2+6x+10}} &= \int_{-3}^{-1} \frac{dx}{\sqrt{(x+3)^2+1}} = \ln|x+3+\sqrt{x^2+6x+10}| \Big|_{-3}^{-1}. \\ &= \ln|2+\sqrt{5}| \approx 1.4436. \end{aligned}$$

Problems

51. Letting $w = 2x + 1, dw = 2\, dx, dx = 0.5\, dw$, we find that $k = 0.5, w = 2x + 1, n = 3$:

$$\int (2x+1)^3 \ln(2x+1)\, dx = \int w^3 \ln(w) 0.5\, dw = \int 0.5 w^3 \ln w\, dw.$$

52. Letting $w = 2x + 1, dw = 2\, dx, dx = 0.5\, dw$, we see that $k = -1/4, w = 2x + 1, n = 3$:

$$\begin{aligned} \int (2x+1)^3 \ln \frac{1}{\sqrt{2x+1}}\, dx &= \int w^3 \ln\left(\frac{1}{w^{1/2}}\right) 0.5\, dw \\ &= \int 0.5 w^3 \ln\left(w^{-1/2}\right)\, dw \\ &= \int 0.5 w^3 \left(-\frac{1}{2}\right) \ln w\, dw \quad \text{log property} \\ &= \int -\frac{1}{4} w^3 \ln w\, dw. \end{aligned}$$

53. We can use form (i) by writing this as

$$\int \frac{dx}{5 - \dfrac{x}{4} - \dfrac{x^2}{6}} = \int \frac{dx}{-\dfrac{1}{6}x^2 + \left(-\dfrac{1}{4}\right)x + 5},$$

where $a = -1/6, b = -1/4, c = 5$.

54. We can use form (ii) by writing this as

$$\int \frac{dx}{2x+\frac{5}{7+3x}} = \int \frac{dx}{2x+\frac{5}{7+3x}} \cdot \frac{7+3x}{7+3x} \quad \text{simplify}$$

$$= \int \frac{3x+7}{2x(3x+7)+\frac{5}{7+3x}\cdot(3x+7)}\,dx \quad \text{distribute}$$

$$= \int \frac{3x+7}{6x^2+14x+5}\,dx,$$

with $m = 3, n = 7, a = 6, b = 14, c = 5$.

55. We can use form (iii) by writing this as:

$$\int \frac{dx}{(x^2-5x+6)^3(x^2-4x+4)^2(x^2-6x+9)^2} = \int \frac{dx}{(x^2-5x+6)^3\left((x-2)(x-2)\right)^2\left((x-3)(x-3)\right)^2} \quad \text{factor}$$

$$= \int \frac{dx}{(x^2-5x+6)^3(x-2)^4(x-3)^4} \quad \text{regroup}$$

$$= \int \frac{dx}{(x^2-5x+6)^3\left((x-2)(x-3)\right)^4} \quad \text{regroup}$$

$$= \int \frac{dx}{(x^2-5x+6)^3\left(x^2-5x+6\right)^4} \quad \text{multiply out}$$

$$= \int \frac{dx}{(x^2-5x+6)^7} \quad \text{simplify,}$$

where $a = 1, b = -5, c = 6, n = 7$.

56. We see that $a = e, b = 4, \lambda = 3$: $\int \frac{e^{6x}}{4+e^{3x+1}}\,dx = \int \frac{e^{6x}}{4+e^{3x}e^1}\,dx = \int \frac{e^{2\cdot 3x}}{e\cdot e^{3x}+4}\,dx.$

57. Multiplying the numerator and denominator by e^{-4x}, we see that $a = 5, b = 4, \lambda = 2$:

$$\int \frac{e^{8x}}{4e^{4x}+5e^{6x}}\,dx = \int \frac{e^{8x}}{4e^{4x}+5e^{6x}}\cdot\frac{e^{-4x}}{e^{-4x}}\,dx$$

$$= \int \frac{e^{8x-4x}}{4e^{4x}e^{-4x}+5e^{6x}e^{-4x}}\,dx$$

$$= \int \frac{e^{4x}}{4e^{4x-4x}+5e^{6x-4x}}\,dx$$

$$= \int \frac{e^{2\cdot 2x}}{5e^{2x}+4}\,dx,$$

58. (a) Let $w = x^2, dw = 2xdx$. Then

$$\int x^5 e^{bx^2}\,dx = \int x^4 e^{bx^2} x\,dx$$

$$= \int w^2 e^{bw}\frac{1}{2}\,dw \quad \text{since } x^4 = w^2 \text{ and } xdx = \tfrac{1}{2}dw$$

$$= \int kw^2 e^{bw}\,dw. \quad \text{where } k = \tfrac{1}{2}$$

(b) Using the identity from the table, we have

$$\int kw^2 e^{bw}\,dw = ke^{bw}\left(\frac{w^2}{b}-\frac{2w}{b^2}+\frac{2}{b^3}\right)+C,$$

so, since $k = \frac{1}{2}, w = x^2$,

$$\int kw^2 e^{bw}\,dw = \frac{1}{2}e^{bx^2}\left(\frac{x^4}{b}-\frac{2x^2}{b^2}+\frac{2}{b^3}\right)+C.$$

59. Using II-10 in the integral table, if $m \neq \pm n$, then

$$\begin{aligned}\int_{-\pi}^{\pi} \sin m\theta \sin n\theta \, d\theta &= \frac{1}{n^2 - m^2}[m \cos m\theta \sin n\theta - n \sin m\theta \cos n\theta]\Big|_{-\pi}^{\pi} \\ &= \frac{1}{n^2 - m^2}[(m \cos m\pi \sin n\pi - n \sin m\pi \cos n\pi) - \\ &\quad (m \cos(-m\pi) \sin(-n\pi) - n \sin(-m\pi) \cos(-n\pi))]\end{aligned}$$

But $\sin k\pi = 0$ for all integers k, so each term reduces to 0, making the whole integral reduce to 0.

60. Using formula II-11, if $m \neq \pm n$, then

$$\int_{-\pi}^{\pi} \cos m\theta \cos n\theta \, d\theta = \frac{1}{n^2 - m^2}(n \cos m\theta \sin n\theta - m \sin m\theta \cos n\theta)\Big|_{-\pi}^{\pi}.$$

We see that in the evaluation, each term will have a $\sin k\pi$ term, so the expression reduces to 0.

61. (a)

$$\begin{aligned}\frac{1}{1-0}\int_0^1 V_0 \cos(120\pi t) dt &= \frac{V_0}{120\pi}\sin(120\pi t)\Big|_0^1 \\ &= \frac{V_0}{120\pi}[\sin(120\pi) - \sin(0)] \\ &= \frac{V_0}{120\pi}[0 - 0] = 0.\end{aligned}$$

(b) Let's find the average of V^2 first.

$$\begin{aligned}\overline{V}^2 = \text{Average of } V^2 &= \frac{1}{1-0}\int_0^1 V^2 dt \\ &= \frac{1}{1-0}\int_0^1 (V_0 \cos(120\pi t))^2 dt \\ &= V_0^2 \int_0^1 \cos^2(120\pi t) dt\end{aligned}$$

Now, let $120\pi t = x$, and $dt = \dfrac{dx}{120\pi}$. So

$$\begin{aligned}\overline{V}^2 &= \frac{V_0^2}{120\pi}\int_0^{120\pi} \cos^2 x dx. \\ &= \frac{V_0^2}{120\pi}\left(\frac{1}{2}\cos x \sin x + \frac{1}{2}x\right)\Big|_0^{120\pi} \qquad \text{II-18} \\ &= \frac{V_0^2}{120\pi}60\pi = \frac{V_0^2}{2}.\end{aligned}$$

So, the average of V^2 is $\dfrac{V_0^2}{2}$ and $\overline{V} = \sqrt{\text{average of } V^2} = \dfrac{V_0}{\sqrt{2}}$.

(c) $V_0 = \sqrt{2} \cdot \overline{V} = 110\sqrt{2} \approx 156$ volts.

62. (a) Since $R(T)$ is the rate or production, we find the total production by integrating:

$$\begin{aligned}\int_0^N R(t)\, dt &= \int_0^N (A + Be^{-t}\sin(2\pi t))\, dt \\ &= NA + B\int_0^N e^{-t}\sin(2\pi t)\, dt.\end{aligned}$$

Let $a = -1$ and $b = 2\pi$ in II-8.

$$= NA + \frac{B}{1+4\pi^2} e^{-t}(-\sin(2\pi t) - 2\pi\cos(2\pi t))\Big|_0^N.$$

Since N is an integer (so $\sin 2\pi N = 0$ and $\cos 2\pi N = 1$),

$$\int_0^N R(t)\,dt = NA + B\frac{2\pi}{1+4\pi^2}(1-e^{-N}).$$

Thus the total production is $NA + \frac{2\pi B}{1+4\pi^2}(1-e^{-N})$ over the first N years.

(b) The average production over the first N years is

$$\int_0^N \frac{R(t)\,dt}{N} = A + \frac{2\pi B}{1+4\pi^2}\left(\frac{1-e^{-N}}{N}\right).$$

(c) As $N \to \infty$, $A + \frac{2\pi B}{1+4\pi^2}\frac{1-e^{-N}}{N} \to A$, since the second term in the sum goes to 0. This is why A is called the average!

(d) When t gets large, the term $Be^{-t}\sin(2\pi t)$ gets very small. Thus, $R(t) \approx A$ for most t, so it makes sense that the average of $\int_0^N R(t)\,dt$ is A as $N \to \infty$.

(e) This model is not reasonable for long periods of time, since an oil well has finite capacity and will eventually "run dry." Thus, we cannot expect average production to be close to constant over a long period of time.

Strengthen Your Understanding

63. To find the integral, we factor the denominator

$$7 - t^2 = -(t-\sqrt{7})(t+\sqrt{7})$$

and use V-26 with $a = \sqrt{7}$, $b = -\sqrt{7}$.

64. If $a = 3$, then $x^2 + 4x + 3 = (x+1)(x+3)$, so by Formula V-26, the answer involves $\ln$ not $\arctan$. In general, the antiderivative involves an $\arctan$ only if the quadratic has no real roots.

65. To use the table, we first make the substitution $w = 2x+1$. Then $dw = 2\,dx$. So the integral becomes

$$\int e^{2x+1}\sin(2x+1)\,dx = \frac{1}{2}\int e^w \sin w\,dw + C.$$

Now using Formula II-8 we get

$$\int e^{2x+1}\sin(2x+1)\,dx = \frac{1}{4}e^{2x+1}(\sin(2x+1) - \cos(2x+1)) + C.$$

66. Formula II-12 only holds for $a \neq b$; the integral is defined.

The integral can be solved using substitution. Let $\sin x = w$. Then $\cos x\,dx = dw$. We have

$$\int \sin x\cos x\,dx = \int w\,dw = \frac{w^2}{2} + C.$$

Substituting $w = \sin x$ back we get

$$\int \sin x\cos x\,dx = \frac{\sin^2 x}{2} + C.$$

67. The table only gives formulas for $\int p(x)\sin x\,dx$, where $p(x)$ is a polynomial. Since $1/x$ is not a polynomial, the table is no help. In fact, it is known that $\sin x/x$ does not have an elementary function as an antiderivative.

68. To evaluate $\int 1/\sqrt{2x-x^2}\,dx$, we must first complete the square for $2x - x^2$ to get $1-(x-1)^2$. Then we can substitute $w = x-1$ and use Formula V-28 in the table.

69. $\int 1/\sin^4 x\,dx$ can be evaluated by using Formula IV-19 twice.

70. True. Rewrite $\sin^7\theta = \sin\theta\sin^6\theta = \sin\theta(1-\cos^2\theta)^3$. Expanding, substituting $w = \cos\theta, dw = -\sin\theta\, d\theta$, and integrating gives a polynomial in w, which is a polynomial in $\cos\theta$.

71. False. Completing the square gives

$$\int \frac{dx}{x^2+4x+5} = \int \frac{dx}{(x+2)^2+1} = \arctan(x+2) + C.$$

72. False. Factoring gives

$$\int \frac{dx}{x^2+4x-5} = \int \frac{dx}{(x+5)(x-1)} = \frac{1}{6}\int \left(\frac{1}{x-1} - \frac{1}{x+5}\right) dx = \frac{1}{6}(\ln|x-1| - \ln|x+5|) + C.$$

73. True. Let $w = \ln x, dw = x^{-1}\,dx$. Then

$$\int x^{-1}((\ln x)^2 + (\ln x)^3)\,dx = \int (w^2+w^3)\,dw = \frac{w^3}{3} + \frac{w^4}{4} + C = \frac{(\ln x)^3}{3} + \frac{(\ln x)^4}{4} + C.$$

Solutions for Section 7.4

Exercises

1. Since $6x + x^2 = x(6+x)$, we take

$$\frac{x+1}{6x+x^2} = \frac{A}{x} + \frac{B}{6+x}.$$

So,

$$x+1 = A(6+x) + Bx$$
$$x+1 = (A+B)x + 6A,$$

giving

$$A + B = 1$$
$$6A = 1.$$

Thus $A = 1/6$, and $B = 5/6$ so

$$\frac{x+1}{6x+x^2} = \frac{1/6}{x} + \frac{5/6}{6+x}.$$

2. Since $25 - x^2 = (5-x)(5+x)$, we take

$$\frac{20}{25-x^2} = \frac{A}{5-x} + \frac{B}{5+x}.$$

So,

$$20 = A(5+x) + B(5-x)$$
$$20 = (A-B)x + 5A + 5B,$$

giving

$$A - B = 0$$
$$5A + 5B = 20.$$

Thus $A = B = 2$ and

$$\frac{20}{25-x^2} = \frac{2}{5-x} + \frac{2}{5+x}.$$

3. Since $w^4 - w^3 = w^3(w-1)$, we have

$$\frac{1}{w^4 - w^3} = \frac{A}{w-1} + \frac{B}{w} + \frac{C}{w^2} + \frac{D}{w^3}.$$

Thus,

$$\begin{aligned} 1 &= Aw^3 + B(w-1)w^2 + C(w-1)w + D(w-1) \\ 1 &= (A+B)w^3 + (-B+C)w^2 + (-C+D)w + (-D), \end{aligned}$$

giving

$$\begin{aligned} A + B &= 0 \\ -B + C &= 0 \\ -C + D &= 0 \\ -D &= 1. \end{aligned}$$

Thus $A = 1$, $B = -1$, $C = -1$ and $D = -1$ so

$$\frac{1}{w^4 - w^3} = \frac{1}{w-1} - \frac{1}{w} - \frac{1}{w^2} - \frac{1}{w^3}.$$

4. Since $y^3 - y^2 + y - 1 = (y-1)(y^2+1)$, we take

$$\frac{2y}{y^3 - y^2 + y - 1} = \frac{A}{y-1} + \frac{By + C}{y^2 + 1}$$

So,

$$\begin{aligned} 2y &= A(y^2+1) + (By+C)(y-1) \\ 2y &= (A+B)y^2 + (C-B)y + A - C, \end{aligned}$$

giving

$$\begin{aligned} A + B &= 0 \\ -B + C &= 2 \\ A - C &= 0. \end{aligned}$$

Thus $A = C = 1$, $B = -1$ so

$$\frac{2y}{y^3 - y^2 + y - 1} = \frac{1}{y-1} + \frac{1-y}{y^2+1}.$$

5. Since $y^3 - 4y = y(y-2)(y+2)$, we take

$$\frac{8}{y^3 - 4y} = \frac{A}{y} + \frac{B}{y-2} + \frac{C}{y+2}.$$

So,

$$\begin{aligned} 8 &= A(y-2)(y+2) + By(y+2) + Cy(y-2) \\ 8 &= (A+B+C)y^2 + (2B-2C)y - 4A, \end{aligned}$$

giving

$$\begin{aligned} A + B + C &= 0 \\ 2B - 2C &= 0 \\ -4A &= 8. \end{aligned}$$

Thus $A = -2$, $B = C = 1$ so

$$\frac{8}{y^3 - 4y} = \frac{-2}{y} + \frac{1}{y-2} + \frac{1}{y+2}.$$

6. Since $s^2+3s+2=(s+2)(s+1)$, we have

$$\frac{2(1+s)}{s(s^2+3s+2)} = \frac{2(1+s)}{s(s+2)(s+1)} = \frac{2}{s(s+2)},$$

so we take

$$\frac{2}{s(s+2)} = \frac{A}{s} + \frac{B}{s+2}.$$

Thus,

$$\begin{aligned} 2 &= A(s+2) + Bs \\ 2 &= (A+B)s + 2A, \end{aligned}$$

giving

$$\begin{aligned} A+B &= 0 \\ 2A &= 2. \end{aligned}$$

Thus $A=1$ and $B=-1$ and

$$\frac{2(1+s)}{s(s^2+3s+2)} = \frac{1}{s} - \frac{1}{s+2}.$$

7. Since $s^4-1=(s^2-1)(s^2+1)=(s-1)(s+1)(s^2+1)$, we have

$$\frac{2}{s^4-1} = \frac{A}{s-1} + \frac{B}{s+1} + \frac{Cs+D}{s^2+1}.$$

Thus,

$$\begin{aligned} 2 &= A(s+1)(s^2+1) + B(s-1)(s^2+1) + (Cs+D)(s-1)(s+1) \\ 2 &= (A+B+C)s^3 + (A-B+D)s^2 + (A+B-C)s + (A-B-D), \end{aligned}$$

giving

$$\begin{aligned} A+B+C &= 0 \\ A-B+D &= 0 \\ A+B-C &= 0 \\ A-B-D &= 2. \end{aligned}$$

From the first and third equations we find $A+B=0$ and $C=0$. From the second and fourth we find $A-B=1$ and $D=-1$. Thus $A=1/2$ and $B=-1/2$ and

$$\frac{2}{s^4-1} = \frac{1}{2(s-1)} - \frac{1}{2(s+1)} - \frac{1}{s^2+1}.$$

8. Using the result of Problem 1, we have

$$\int \frac{x+1}{6x+x^2}\,dx = \int \frac{1/6}{x}\,dx + \int \frac{5/6}{6+x}\,dx = \frac{1}{6}\left(\ln|x| + 5\ln|6+x|\right) + C.$$

9. Using the result of Problem 2, we have

$$\int \frac{20}{25-x^2}\,dx = \int \frac{2}{5-x}\,dx + \int \frac{2}{5+x}\,dx = -2\ln|5-x| + 2\ln|5+x| + C.$$

10. Using the result of Exercise 3, we have

$$\int \frac{1}{w^4-w^3}\,dw = \int \left(\frac{1}{w-1} - \frac{1}{w} - \frac{1}{w^2} - \frac{1}{w^3}\right) dw = \ln|w-1| - \ln|w| + \frac{1}{w} + \frac{1}{2w^2} + C.$$

11. Using the result of Problem 4, we have

$$\int \frac{2y}{y^3-y^2+y-1}\,dy = \int \frac{1}{y-1}\,dy + \int \frac{1-y}{y^2+1}\,dy = \ln|y-1| + \arctan y - \frac{1}{2}\ln\left|y^2+1\right| + C.$$

12. Using the result of Problem 5, we have

$$\int \frac{8}{y^3-4y}\,dy = \int \frac{-2}{y}\,dy + \int \frac{1}{y-2}\,dy + \int \frac{1}{y+2}\,dy = -2\ln|y| + \ln|y-2| + \ln|y+2| + C.$$

13. Using the result of Exercise 6, we have

$$\int \frac{2(1+s)}{s(s^2+3s+2)}\,ds = \int \left(\frac{1}{s} - \frac{1}{s+2}\right)\,ds = \ln|s| - \ln|s+2| + C.$$

14. Using the result of Exercise 7, we have

$$\int \frac{2}{s^4-1}\,ds = \int \left(\frac{1}{2(s-1)} - \frac{1}{2(s+1)} - \frac{1}{s^2+1}\right)\,ds = \frac{1}{2}\ln|s-1| - \frac{1}{2}\ln|s+1| - \arctan s + C.$$

15. We let

$$\frac{3x^2-8x+1}{x^3-4x^2+x+6} = \frac{A}{x-2} + \frac{B}{x+1} + \frac{C}{x-3}$$

giving

$$\begin{aligned} 3x^2-8x+1 &= A(x+1)(x-3) + B(x-2)(x-3) + C(x-2)(x+1) \\ 3x^2-8x+1 &= (A+B+C)x^2 - (2A+5B+C)x - 3A + 6B - 2C \end{aligned}$$

so

$$\begin{aligned} A+B+C &= 3 \\ -2A-5B-C &= -8 \\ -3A+6B-2C &= 1. \end{aligned}$$

Thus, $A=B=C=1$, so

$$\int \frac{3x^2-8x+1}{x^3-4x^2+x+6}\,dx = \int \frac{dx}{x-2} + \int \frac{dx}{x+1} + \int \frac{dx}{x-3} = \ln|x-2| + \ln|x+1| + \ln|x-3| + K.$$

We use K as the constant of integration, since we already used C in the problem.

16. We let

$$\frac{1}{x^3-x^2} = \frac{1}{x^2(x-1)} = \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x-1}$$

giving

$$\begin{aligned} 1 &= Ax(x-1) + B(x-1) + Cx^2 \\ 1 &= (A+C)x^2 + (B-A)x - B \end{aligned}$$

so

$$\begin{aligned} A+C &= 0 \\ B-A &= 0 \\ -B &= 1. \end{aligned}$$

Thus, $A=B=-1$, $C=1$, so

$$\int \frac{dx}{x^3-x^2} = -\int \frac{dx}{x} - \int \frac{dx}{x^2} + \int \frac{dx}{x-1} = -\ln|x| + x^{-1} + \ln|x-1| + K.$$

We use K as the constant of integration, since we already used C in the problem.

17. We let

$$\frac{10x+2}{x^3-5x^2+x-5} = \frac{10x+2}{(x-5)(x^2+1)} = \frac{A}{x-5} + \frac{Bx+C}{x^2+1}$$

giving

$$10x+2 = A(x^2+1) + (Bx+C)(x-5)$$
$$10x+2 = (A+B)x^2 + (C-5B)x + A - 5C$$

so

$$A+B = 0$$
$$C-5B = 10$$
$$A-5C = 2.$$

Thus, $A = 2$, $B = -2$, $C = 0$, so

$$\int \frac{10x+2}{x^3-5x^2+x-5}\,dx = \int \frac{2}{x-5}\,dx - \int \frac{2x}{x^2+1}\,dx = 2\ln|x-5| - \ln\left|x^2+1\right| + K.$$

18. Division gives

$$\frac{x^4+12x^3+15x^2+25x+11}{x^3+12x^2+11x} = x + \frac{4x^2+25x+11}{x^3+12x^2+11x}.$$

Since $x^3+12x^2+11x = x(x+1)(x+11)$, we write

$$\frac{4x^2+25x+11}{x^3+12x^2+11x} = \frac{A}{x} + \frac{B}{x+1} + \frac{C}{x+11}$$

giving

$$4x^2+25x+11 = A(x+1)(x+11) + Bx(x+11) + Cx(x+1)$$
$$4x^2+25x+11 = (A+B+C)x^2 + (12A+11B+C)x + 11A$$

so

$$A+B+C = 4$$
$$12A+11B+C = 25$$
$$11A = 11.$$

Thus, $A = B = 1$, $C = 2$ so

$$\int \frac{x^4+12x^3+15x^2+25x+11}{x^3+12x^2+11x}\,dx = \int x\,dx + \int \frac{dx}{x} + \int \frac{dx}{x+1} + \int \frac{2dx}{x+11}$$
$$= \frac{x^2}{2} + \ln|x| + \ln|x+1| + 2\ln|x+11| + K.$$

We use K as the constant of integration, since we already used C in the problem.

19. Division gives

$$\frac{x^4+3x^3+2x^2+1}{x^2+3x+2} = x^2 + \frac{1}{x^2+3x+2}.$$

Since $x^2+3x+2 = (x+1)(x+2)$, we write

$$\frac{1}{x^2+3x+2} = \frac{1}{(x+1)(x+2)} = \frac{A}{x+1} + \frac{B}{x+2},$$

giving

$$1 = A(x+2) + B(x+1)$$
$$1 = (A+B)x + 2A + B$$

so

$$A + B = 0$$
$$2A + B = 1.$$

Thus, $A = 1$, $B = -1$ so

$$\begin{aligned}\int \frac{x^4+3x^3+2x^2+1}{x^2+3x+2}\,dx &= \int x^2\,dx + \int \frac{dx}{x+1} - \int \frac{dx}{x+2} \\ &= \frac{x^3}{3} + \ln|x+1| - \ln|x+2| + C.\end{aligned}$$

20. Since $x = (3/2)\sin t$, we have $dx = (3/2)\cos t\,dt$. Substituting into the integral gives

$$\int \frac{1}{\sqrt{9-4x^2}} = \int \frac{1}{\sqrt{9-9\sin^2 t}}\left(\frac{3}{2}\cos t\right)dt = \int \frac{1}{2}dt = \frac{1}{2}t + C = \frac{1}{2}\arcsin\left(\frac{2x}{3}\right) + C.$$

21. Since $x = \sin t + 2$, we have

$$4x - 3 - x^2 = 4(\sin t + 2) - 3 - (\sin t + 2)^2 = 1 - \sin^2 t = \cos^2 t$$

and $dx = \cos t\,dt$, so substitution gives

$$\int \frac{1}{\sqrt{4x-3-x^2}} = \int \frac{1}{\sqrt{\cos^2 t}}\cos t\,dt = \int dt = t + C = \arcsin(x-2) + C.$$

22. Completing the square gives $x^2 + 4x + 5 = 1 + (x+2)^2$. Since $x + 2 = \tan t$ and $dx = (1/\cos^2 t)dt$, we have

$$\int \frac{1}{x^2+4x+5}\,dx = \int \frac{1}{1+\tan^2 t}\cdot\frac{1}{\cos^2 t}dt = \int dt = t + C = \arctan(x+2) + C.$$

23. (a) Yes, use $x = 3\sin\theta$.
(b) No; better to substitute $w = 9 - x^2$, so $dw = -2x\,dx$.

24. (a) Substitute $w = x^2 + 10$, so $dw = 2x\,dx$.
(b) Substitute $x = \sqrt{10}\tan\theta$.

Problems

25. We have

$$\begin{aligned} w &= (3x+2)(x-1) \\ &= 3x^2 - x - 2 \\ \text{so}\quad dw &= (6x-1)\,dx \\ \text{which means}\quad (12x-2)\,dx &= 2\,dw, \\ \text{giving}\quad \int \frac{12x-2}{(3x+2)(x-1)}\,dx &= 2\int \frac{dw}{w}, \end{aligned}$$

so $w = (3x+2)(x-1) = 3x^2 - x - 2$ and $k = 2$.

26. Using partial fractions, we have

$$\begin{aligned} \frac{12x-2}{(3x+2)(x-1)} &= \frac{A}{3x+2} + \frac{B}{x-1} \\ 12x - 2 &= \left(\frac{A}{3x+2} + \frac{B}{x-1}\right)(3x+2)(x-1) && \text{multiply by denominator} \\ 12x - 2 &= A(x-1) + B(3x+2) && \text{simplify} \\ &= (A+3B)x + 2B - A && \text{regroup} \\ \text{so}\quad A + 3B &= 12 && \text{matching coefficients of } x \end{aligned}$$

$$\begin{aligned}
\text{and} \quad 2B - A &= -2 && \text{matching constants}\\
\text{giving} \quad A + 3B + (2B - A) &= 12 + (-2) && \text{adding above two equations}\\
5B &= 10\\
B &= 2\\
\text{which means} \quad A + 3 \cdot 2 &= 12 && \text{letting } B = 2 \text{ in } A + 3B = 12\\
A &= 6
\end{aligned}$$

$$\text{yielding} \int \frac{12x-2}{(3x+2)(x-1)}\,dx = \int \frac{6}{3x+2} + \int \frac{2}{x-1}\,dx.$$

Checking our answer, we see that:

$$\begin{aligned}
\frac{6}{3x+2} + \frac{2}{x-1} &= \frac{6}{3x+2} \cdot \frac{x-1}{x-1} + \frac{2}{x-1} \cdot \frac{3x+2}{3x+2}\\
&= \frac{6(x-1) + 2(3x+2)}{(3x+2)(x-1)}\\
&= \frac{6x - 6 + 6x + 4}{(3x+2)(x-1)}\\
&= \frac{12x-2}{(3x+2)(x-1)},
\end{aligned}$$

as required.

27. Focusing on the integrand, we have:

$$\begin{aligned}
\frac{2x+9}{(3x+5)(4-5x)} &= \frac{2x+9}{3\left(x+\frac{5}{3}\right)(-5)\left(x-\frac{4}{5}\right)}\\
&= \frac{2x+9}{-15\left(x+\frac{5}{3}\right)\left(x-\frac{4}{5}\right)}\\
&= \frac{-\frac{2}{15} \cdot x + \left(-\frac{3}{5}\right)}{\left(x+\frac{5}{3}\right)\left(x-\frac{4}{5}\right)}.
\end{aligned}$$

So

$$\int \frac{2x+9}{(3x-5)(4-5x)}\,dx = \int \frac{\overbrace{-\frac{2}{15}}^{c} \cdot x + \overbrace{\left(-\frac{3}{5}\right)}^{d}}{\underbrace{\left(x - \left(-\frac{5}{3}\right)\right)}_{x-a}\underbrace{\left(x - \frac{4}{5}\right)}_{x-b}}\,dx.$$

We see that $a = -5/3, b = 4/5, c = -2/15, d = -3/5$.

28. We have:

$$\begin{aligned}
\sqrt{12 - 4x^2} &= \sqrt{4\,(3 - x^2)}\\
&= 2\sqrt{\left(\sqrt{3}\right)^2 - x^2},\\
\text{so} \quad \int \frac{dx}{\sqrt{12 - 4x^2}} &= \int \frac{dx}{2\sqrt{\left(\sqrt{3}\right)^2 - x^2}}\\
&= \int \frac{0.5\,dx}{\sqrt{\left(\sqrt{3}\right)^2 - x^2}}.
\end{aligned}$$

Thus, $a = \sqrt{3}, k = 0.5$.

29. Taking the hint, we see that

$$\begin{aligned} e^{2x} - 4e^x + 3 &= (e^x)^2 - 4e^x + 3 \\ &= w^2 - 4w + 3 \qquad \text{letting } w = e^x \\ &= (w-3)(w-1). \quad \text{factoring} \end{aligned}$$

Notice that $dw = e^x dx$ and that the numerator of the integrand can be written $2e^x + 1 = 2w + 1$. Using the method of partial fractions, we have:

$$\begin{aligned} \frac{2w+1}{(w-3)(w-1)} &= \frac{A}{w-3} + \frac{B}{w-1} \\ 2w+1 &= A(w-1) + B(w-3) \qquad \text{multiply through by } (w-3)(w-1) \\ &= (A+B)w + (-A-3B). \quad \text{regroup} \end{aligned}$$

Identifying the coefficients of w and the constant terms on both sides, we have:

$$\begin{aligned} A + B &= 2 \qquad \text{so } A = 2 - B \\ \text{and} \quad -A - 3B &= 1 \\ \text{so} \quad -(2-B) - 3B &= 1 \qquad \text{since } A = 2 - B \\ -2 - 2B &= 1 \\ \text{giving} \quad B &= -\frac{3}{2} \\ \text{and} \quad A &= 2 - B = \frac{7}{2}. \end{aligned}$$

This means $\dfrac{2w+1}{(w-3)(w-1)} = \dfrac{7/2}{w-3} + \dfrac{-3/2}{w-1}$, so:

$$\begin{aligned} \int_0^{\ln 7} \frac{2e^x+1}{e^{2x} - 4e^x + 3} e^x\, dx &= \int_{x=0}^{x=\ln 7} \frac{2w+1}{(w-3)(w-1)}\, dw \\ &= \int_{w=1}^{w=7} \frac{2w+1}{(w-3)(w-1)}\, dw \qquad \text{since } w = e^x \\ &= \int_1^7 \left(\frac{7/2}{w-3} + \frac{-3/2}{w-1} \right) dw. \end{aligned}$$

Thus,

$$A = \frac{7}{2}, B = -\frac{3}{2}, w = e^x, dw = e^x dx, r = 1, s = 7.$$

30. (a) We have

$$\frac{3x+6}{x^2+3x} = \frac{2(x+3)}{x(x+3)} + \frac{x}{x(x+3)} = \frac{2}{x} + \frac{1}{x+3}.$$

Thus

$$\int \frac{3x+6}{x^2+3x}\, dx = \int \left(\frac{2}{x} + \frac{1}{x+3} \right) dx = 2\ln|x| + \ln|x+3| + C.$$

(b) Let $a = 0, b = -3, c = 3$, and $d = 6$ in V-27.

$$\begin{aligned} \int \frac{3x+6}{x^2+3x}\, dx &= \int \frac{3x+6}{x(x+3)}\, dx \\ &= \frac{1}{3}(6\ln|x| + 3\ln|x+3|) + C = 2\ln|x| + \ln|x+3| + C. \end{aligned}$$

31. Since $x^2 + 2x + 2 = (x+1)^2 + 1$, we have

$$\int \frac{1}{x^2+2x+2}\, dx = \int \frac{1}{(x+1)^2+1} dx.$$

Substitute $x + 1 = \tan\theta$, so $x = (\tan\theta) - 1$.

32. Since $x^2 + 6x + 9$ is a perfect square, we write

$$\int \frac{1}{x^2+6x+25}dx = \int \frac{1}{(x^2+6x+9)+16}dx = \int \frac{1}{(x+3)^2+16}dx.$$

We use the trigonometric substitution $x + 3 = 4\tan\theta$, so $x = 4\tan\theta - 3$.

33. Since $y^2 + 3y + 3 = (y + 3/2)^2 + (3 - 9/4) = (y + 3/2)^2 + 3/4$, we have

$$\int \frac{dy}{y^2+3y+3} = \int \frac{dy}{(y+3/2)^2+3/4}.$$

Substitute $y + 3/2 = \tan\theta$, so $y = (\tan\theta) - 3/2$.

34. Since $x^2 + 2x + 2 = (x + 1)^2 + 1$, we have

$$\int \frac{x+1}{x^2+2x+2}\,dx = \int \frac{x+1}{(x+1)^2+1}dx.$$

Substitute $w = (x + 1)^2$, so $dw = 2(x + 1)\,dx$.

This integral can also be calculated without completing the square, by substituting $w = x^2 + 2x + 2$, so $dw = 2(x + 1)\,dx$.

35. Since $2z - z^2 = 1 - (z - 1)^2$, we have

$$\int \frac{4}{\sqrt{2z-z^2}}\,dz = 4\int \frac{1}{\sqrt{1-(z-1)^2}}\,dz.$$

Substitute $z - 1 = \sin\theta$, so $z = (\sin\theta) + 1$.

36. Since $2z - z^2 = 1 - (z - 1)^2$, we have

$$\int \frac{z-1}{\sqrt{2z-z^2}}\,dz = \int \frac{z-1}{\sqrt{1-(z-1)^2}}\,dz.$$

Substitute $w = 1 - (z - 1)^2$, so $dw = -2(z - 1)\,dz$.

37. Since $t^2 + 4t + 7 = (t + 2)^2 + 3$, we have

$$\int (t+2)\sin(t^2+4t+7)\,dt = \int (t+2)\sin((t+2)^2+3)\,dt.$$

Substitute $w = (t + 2)^2 + 3$, so $dw = 2(t + 2)\,dt$.

This integral can also be computed without completing the square, by substituting $w = t^2 + 4t + 7$, so $dw = (2t + 4)\,dt$.

38. Since $\theta^2 - 4\theta = (\theta - 2)^2 - 4$, we have

$$\int (2-\theta)\cos(\theta^2-4\theta)\,d\theta = \int -(\theta-2)\cos((\theta-2)^2-4)\,d\theta.$$

Substitute $w = (\theta - 2)^2 - 4$, so $dw = 2(\theta - 2)\,d\theta$.

This integral can also be computed without completing the square, by substituting $w = \theta^2 - 4\theta$, so $dw = (2\theta - 4)\,d\theta$.

39. We write

$$\frac{1}{(x-5)(x-3)} = \frac{A}{x-5} + \frac{B}{x-3},$$

giving

$$1 = A(x-3) + B(x-5)$$
$$1 = (A+B)x - (3A+5B)$$

so

$$A + B = 0$$
$$-3A - 5B = 1.$$

Thus, $A = 1/2$, $B = -1/2$, so

$$\int \frac{1}{(x-5)(x-3)}\,dx = \int \frac{1/2}{x-5}\,dx - \int \frac{1/2}{x-3}\,dx = \frac{1}{2}\ln|x-5| - \frac{1}{2}\ln|x-3| + C.$$

40. We write

$$\frac{1}{(x+2)(x+3)} = \frac{A}{x+2} + \frac{B}{x+3},$$

giving

$$\begin{aligned} 1 &= A(x+3) + B(x+2) \\ 1 &= (A+B)x + (3A+2B) \end{aligned}$$

so

$$\begin{aligned} A + B &= 0 \\ 3A + 2B &= 1. \end{aligned}$$

Thus, $A = 1$, $B = -1$, so

$$\int \frac{1}{(x+2)(x+3)}\,dx = \int \frac{1}{x+2}\,dx - \int \frac{1}{x+3}\,dx = \ln|x+2| - \ln|x+3| + C.$$

41. We write

$$\frac{1}{(x+7)(x-2)} = \frac{A}{x+7} + \frac{B}{x-2},$$

giving

$$\begin{aligned} 1 &= A(x-2) + B(x+7) \\ 1 &= (A+B)x + (-2A+7B) \end{aligned}$$

so

$$\begin{aligned} A + B &= 0 \\ -2A + 7B &= 1. \end{aligned}$$

Thus, $A = -1/9$, $B = 1/9$, so

$$\int \frac{1}{(x+7)(x-2)}\,dx = -\int \frac{1/9}{x+7}\,dx + \int \frac{1/9}{x-2}\,dx = -\frac{1}{9}\ln|x+7| + \frac{1}{9}\ln|x-2| + C.$$

42. The denominator $x^2 - 3x + 2$ can be factored as $(x-1)(x-2)$. Splitting the integrand into partial fractions with denominators $(x-1)$ and $(x-2)$, we have

$$\frac{x}{x^2-3x+2} = \frac{x}{(x-1)(x-2)} = \frac{A}{x-1} + \frac{B}{x-2}.$$

Multiplying by $(x-1)(x-2)$ gives the identity

$$x = A(x-2) + B(x-1)$$

so

$$x = (A+B)x - 2A - B.$$

Since this equation holds for all x, the constant terms on both sides must be equal. Similarly, the coefficient of x on both sides must be equal. So

$$\begin{aligned} -2A - B &= 0 \\ A + B &= 1. \end{aligned}$$

Solving these equations gives $A = -1$, $B = 2$ and the integral becomes

$$\int \frac{x}{x^2-3x+2}dx = -\int \frac{1}{x-1}dx + 2\int \frac{1}{x-2}dx = -\ln|x-1| + 2\ln|x-2| + C.$$

43. This can be done by formula V–26 in the integral table or by partial fractions

$$\int \frac{dz}{z^2+z} = \int \frac{dz}{z(z+1)} = \int \left(\frac{1}{z} - \frac{1}{z+1}\right) dz = \ln|z| - \ln|z+1| + C.$$

Check:

$$\frac{d}{dz}(\ln|z| - \ln|z+1| + C) = \frac{1}{z} - \frac{1}{z+1} = \frac{1}{z^2+z}.$$

44. We know $x^2 + 5x + 4 = (x+1)(x+4)$, so we can use V-26 of the integral table with $a = -1$ and $b = -4$ to write

$$\int \frac{dx}{x^2+5x+4} = \frac{1}{3}(\ln|x+1| - \ln|x+4|) + C.$$

45. We use partial fractions and write

$$\frac{1}{3P-3P^2} = \frac{A}{3P} + \frac{B}{1-P},$$

multiply through by $3P(1-P)$, and then solve for A and B, getting $A = 1$ and $B = 1/3$. So

$$\begin{aligned}\int \frac{dP}{3P-3P^2} &= \int \left(\frac{1}{3P} + \frac{1}{3(1-P)}\right) dP = \frac{1}{3}\int \frac{dP}{P} + \frac{1}{3}\int \frac{dP}{1-P} \\ &= \frac{1}{3}\ln|P| - \frac{1}{3}\ln|1-P| + C = \frac{1}{3}\ln\left|\frac{P}{1-P}\right| + C.\end{aligned}$$

46. Using partial fractions, we have:

$$\frac{3x+1}{x^2-3x+2} = \frac{3x+1}{(x-1)(x-2)} = \frac{A}{x-1} + \frac{B}{x-2}.$$

Multiplying by $(x-1)$ and $(x-2)$, this becomes

$$\begin{aligned}3x+1 &= A(x-2) + B(x-1) \\ &= (A+B)x - 2A - B\end{aligned}$$

which produces the system of equations

$$\begin{cases} A + B = 3 \\ -2A - B = 1. \end{cases}$$

Solving this system yields $A = -4$ and $B = 7$. So,

$$\begin{aligned}\int \frac{3x+1}{x^2-3x+2}dx &= \int \left(-\frac{4}{x-1} + \frac{7}{x-2}\right) dx \\ &= -4\int \frac{dx}{x-1} + 7\int \frac{dx}{x-2} \\ &= -4\ln|x-1| + 7\ln|x-2| + C.\end{aligned}$$

47. Since $2y^2 + 3y + 1 = (2y+1)(y+1)$, we write

$$\frac{y+2}{2y^2+3y+1} = \frac{A}{2y+1} + \frac{B}{y+1},$$

giving

$$\begin{aligned}y+2 &= A(y+1) + B(2y+1) \\ y+2 &= (A+2B)y + A + B\end{aligned}$$

so

$$\begin{aligned}A + 2B &= 1 \\ A + B &= 2.\end{aligned}$$

Thus, $A = 3$, $B = -1$, so

$$\int \frac{y+2}{2y^2+3y+1}\,dy = \int \frac{3}{2y+1}\,dy - \int \frac{1}{y+1}\,dy = \frac{3}{2}\ln|2y+1| - \ln|y+1| + C.$$

48. Since $x^3 + x = x(x^2+1)$ cannot be factored further, we write

$$\frac{x+1}{x^3+x} = \frac{A}{x} + \frac{Bx+C}{x^2+1}.$$

Multiplying by $x(x^2+1)$ gives

$$x+1 = A(x^2+1) + (Bx+C)x$$
$$x+1 = (A+B)x^2 + Cx + A,$$

so

$$A+B=0$$
$$C=1$$
$$A=1.$$

Thus, $A = C = 1$, $B = -1$, and we have

$$\int \frac{x+1}{x^3+x}\,dx = \int \left(\frac{1}{x} + \frac{-x+1}{x^2+1}\right) = \int \frac{dx}{x} - \int \frac{x\,dx}{x^2+1} + \int \frac{dx}{x^2+1}$$
$$= \ln|x| - \frac{1}{2}\ln\left|x^2+1\right| + \arctan x + K.$$

49. Since $x^2 + x^4 = x^2(1+x^2)$ cannot be factored further, we write

$$\frac{x-2}{x^2+x^4} = \frac{A}{x} + \frac{B}{x^2} + \frac{Cx+D}{1+x^2}.$$

Multiplying by $x^2(1+x^2)$ gives

$$x-2 = Ax(1+x^2) + B(1+x^2) + (Cx+D)x^2$$
$$x-2 = (A+C)x^3 + (B+D)x^2 + Ax + B,$$

so

$$A+C=0$$
$$B+D=0$$
$$A=1$$
$$B=-2.$$

Thus, $A = 1$, $B = -2$, $C = -1$, $D = 2$, and we have

$$\int \frac{x-2}{x^2+x^4}\,dx = \int \left(\frac{1}{x} - \frac{2}{x^2} + \frac{-x+2}{1+x^2}\right)dx = \int \frac{dx}{x} - 2\int \frac{dx}{x^2} - \int \frac{x\,dx}{1+x^2} + 2\int \frac{dx}{1+x^2}$$
$$= \ln|x| + \frac{2}{x} - \frac{1}{2}\ln\left|1+x^2\right| + 2\arctan x + K.$$

We use K as the constant of integration, since we already used C in the problem.

50. Let $y = 5\tan\theta$ so $dy = (5/\cos^2\theta)\,d\theta$. Since $1 + \tan^2\theta = 1/\cos^2\theta$, we have

$$\int \frac{y^2}{25+y^2}\,dy = \int \frac{25\tan^2\theta}{25(1+\tan^2\theta)} \cdot \frac{5}{\cos^2\theta}\,d\theta = 5\int \tan^2\theta\,d\theta.$$

Using $1 + \tan^2\theta = 1/\cos^2\theta$ again gives

$$\int \frac{y^2}{25+y^2}\,dy = 5\int \tan^2\theta\,d\theta = 5\int \left(\frac{1}{\cos^2\theta} - 1\right)d\theta = 5\tan\theta - 5\theta + C.$$

In addition, since $\theta = \arctan(y/5)$, we get

$$\int \frac{y^2}{25+y^2}\,dy = y - 5\arctan\left(\frac{y}{5}\right) + C.$$

51. Since $(4-z^2)^{3/2} = (\sqrt{4-z^2})^3$, we substitute $z = 2\sin\theta$, so $dz = 2\cos\theta\, d\theta$. We get

$$\int \frac{dz}{(4-z^2)^{3/2}} = \int \frac{2\cos\theta\, d\theta}{(4-4\sin^2\theta)^{3/2}} = \int \frac{2\cos\theta\, d\theta}{8\cos^3\theta} = \frac{1}{4}\int \frac{d\theta}{\cos^2\theta} = \frac{1}{4}\tan\theta + C$$

Since $\sin\theta = z/2$, we have $\cos\theta = \sqrt{1-(z/2)^2} = (\sqrt{4-z^2})/2$, so

$$\int \frac{dz}{(4-z^2)^{3/2}} = \frac{1}{4}\tan\theta + C = \frac{1}{4}\frac{\sin\theta}{\cos\theta} + C = \frac{1}{4}\frac{z/2}{(\sqrt{4-z^2})/2} + C = \frac{z}{4\sqrt{4-z^2}} + C$$

52. We have

$$\frac{10}{(s+2)(s^2+1)} = \frac{A}{s+2} + \frac{Bs+C}{s^2+1}.$$

Thus,

$$10 = A(s^2+1) + (Bs+C)(s+2)$$
$$10 = (A+B)s^2 + (2B+C)s + (A+2C),$$

giving

$$A + B = 0$$
$$2B + C = 0$$
$$A + 2C = 10.$$

Thus, from the first two equations we have $C = -2B = 2A$, which, when used in the third, gives $5A = 10$, so that $A = 2$, $B = -2$, and $C = 4$. We now have

$$\frac{10}{(s+2)(s^2+1)} = \frac{2}{s+2} + \frac{-2s+4}{s^2+1} = \frac{2}{s+2} - \frac{2s}{s^2+1} + \frac{4}{s^2+1},$$

so

$$\int \frac{10}{(s+2)(s^2+1)}\, ds = \int \left(\frac{2}{s+2} - \frac{2s}{s^2+1} + \frac{4}{s^2+1}\right) ds = 2\ln|s+2| - \ln\left|s^2+1\right| + 4\arctan s + K.$$

We use K as the constant of integration, since we already used C in the problem.

53. Completing the square, we get

$$x^2 + 4x + 13 = (x+2)^2 + 9.$$

We use the substitution $x + 2 = 3\tan t$, then $dx = (3/\cos^2 t)\, dt$. Since $\tan^2 t + 1 = 1/\cos^2 t$, the integral becomes

$$\int \frac{1}{(x+2)^2+9}\, dx = \int \frac{1}{9\tan^2 t + 9} \cdot \frac{3}{\cos^2 t}\, dt = \int \frac{1}{3}\, dt = \frac{1}{3}\arctan\left(\frac{x+2}{3}\right) + C.$$

54. Using the substitution $w = e^x$, we get $dw = e^x dx$, so we have

$$\int \frac{e^x}{(e^x-1)(e^x+2)}\, dx = \int \frac{dw}{(w-1)(w+2)}.$$

But

$$\frac{1}{(w-1)(w+2)} = \frac{1}{3}\left(\frac{1}{w-1} - \frac{1}{w+2}\right),$$

so

$$\int \frac{e^x}{(e^x-1)(e^x+2)}\, dx = \int \frac{1}{3}\left(\frac{1}{w-1} - \frac{1}{w+2}\right) dw$$
$$= \frac{1}{3}(\ln|w-1| - \ln|w+2|) + C$$
$$= \frac{1}{3}(\ln|e^x-1| - \ln|e^x+2|) + C.$$

55. Let $x = \tan\theta$ so $dx = (1/\cos^2\theta)d\theta$. Since $\sqrt{1+\tan^2\theta} = 1/\cos\theta$, we have

$$\int \frac{1}{x^2\sqrt{1+x^2}}\,dx = \int \frac{1/\cos^2\theta}{\tan^2\theta\sqrt{1+\tan^2\theta}}\,d\theta = \int \frac{\cos\theta}{\tan^2\theta\cos^2\theta}\,d\theta = \int \frac{\cos\theta}{\sin^2\theta}\,d\theta.$$

The last integral can be evaluated by guess-and-check or by substituting $w = \sin\theta$. The result is

$$\int \frac{1}{x^2\sqrt{1+x^2}}\,dx = \int \frac{\cos\theta}{\sin^2\theta}\,d\theta = -\frac{1}{\sin\theta} + C.$$

We need to know $\sin\theta$ in terms of x. From the triangle in Figure 7.4, which shows $x = \tan\theta$, we see that $\sin\theta = x/\sqrt{1+x^2}$. Thus

$$\int \frac{1}{x^2\sqrt{1+x^2}}\,dx = -\frac{1}{\sin\theta} + C = -\frac{\sqrt{1+x^2}}{x} + C.$$

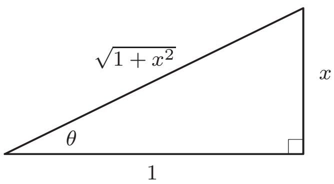


Figure 7.4: In this triangle, $\tan\theta = x$

56. Let $x = 3\sin\theta$ so $dx = 3\cos\theta\,d\theta$, giving

$$\int \frac{x^2}{\sqrt{9-x^2}}\,dx = \int \frac{9\sin^2\theta}{\sqrt{9-9\sin^2\theta}}3\cos\theta\,d\theta = \int \frac{(9\sin^2\theta)(3\cos\theta)}{3\cos\theta}\,d\theta = 9\int \sin^2\theta\,d\theta.$$

From formula IV-18, we get

$$\int \sin^2\theta\,d\theta = -\frac{1}{2}\sin\theta\cos\theta + \frac{\theta}{2} + C.$$

We have $\sin\theta = x/3$ and $\theta = \arcsin(x/3)$. From the triangle in Figure 7.5, which shows $\sin\theta = x/3$, we see that $\cos\theta = \sqrt{9-x^2}/3$. Therefore

$$\begin{aligned}\int \frac{x^2}{\sqrt{9-x^2}}\,dx &= 9\int \sin^2\theta\,d\theta = -\frac{9}{2}\sin\theta\cos\theta + \frac{9}{2}\theta + C \\ &= -\frac{9}{2}\cdot\frac{x}{3}\frac{\sqrt{9-x^2}}{3} + \frac{9}{2}\arcsin\left(\frac{x}{3}\right) + C = -\frac{x}{2}\sqrt{9-x^2} + \frac{9}{2}\arcsin\left(\frac{x}{3}\right) + C\end{aligned}$$

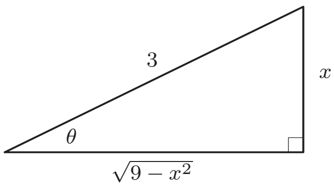

Figure 7.5: In this triangle, $\sin\theta = x/3$

57. Let $2x = \sin\theta$. Then $dx = (1/2)\cos\theta\,d\theta$ and $\sqrt{1-4x^2} = \sqrt{1-\sin^2\theta} = \cos\theta$, so

$$\begin{aligned}\int \frac{\sqrt{1-4x^2}}{x^2}\,dx &= \int \frac{\cos\theta}{(\sin^2\theta)/4}\left(\frac{1}{2}\cos\theta\,d\theta\right) = 2\int \frac{\cos^2\theta}{\sin^2\theta}\,d\theta \\ &= 2\int \frac{1-\sin^2\theta}{\sin^2\theta}\,d\theta = 2\int \left(\frac{1}{\sin^2\theta} - 1\right)\,d\theta.\end{aligned}$$

From formula IV-18, we get

$$\int \left(\frac{1}{\sin^2\theta} - 1\right) d\theta = -\frac{\cos\theta}{\sin\theta} - \theta + C.$$

We have $\sin\theta = 2x$ and $\theta = \arcsin(2x)$. From the triangle in Figure 7.6, which shows $\sin\theta = 2x$, we see that $\cos\theta = \sqrt{1-4x^2}$. Therefore

$$\int \frac{\sqrt{1-4x^2}}{x^2}\,dx = 2\left(-\frac{\cos\theta}{\sin\theta} - \theta\right) + C = 2\left(-\frac{\sqrt{1-4x^2}}{2x} - \arcsin(2x)\right) + C = -\frac{\sqrt{1-4x^2}}{x} - 2\arcsin(2x) + C$$

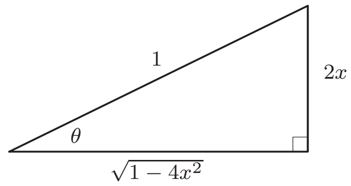

Figure 7.6: In this triangle, $\sin\theta = 2x$

58. Let $3x = 5\sin\theta$. Then $dx = (5/3)\cos\theta\,d\theta$ and $\sqrt{25-9x^2} = \sqrt{25 - 25\sin^2\theta} = 5\cos\theta$, so

$$\begin{aligned}\int \frac{\sqrt{25-9x^2}}{x}\,dx &= \int \frac{5\cos\theta}{(5/3)\sin\theta}\left(\frac{5}{3}\cos\theta\,d\theta\right) = 5\int \frac{\cos^2\theta}{\sin\theta}\,d\theta\\ &= 5\int \frac{1-\sin^2\theta}{\sin\theta}\,d\theta = 5\int\left(\frac{1}{\sin\theta} - \sin\theta\right)d\theta.\end{aligned}$$

From formula IV-21, we get

$$\int \left(\frac{1}{\sin\theta} - \sin\theta\right) d\theta = \frac{1}{2}\ln\left|\frac{\cos\theta - 1}{\cos\theta + 1}\right| + \cos\theta + C.$$

We have $\sin\theta = 3x/5$ and $\theta = \arcsin(3x/5)$. From the triangle in Figure 7.7, which shows $\sin\theta = 3x/5$, we see that $\cos\theta = \sqrt{25-9x^2}/5$. Therefore

$$\int \frac{\sqrt{25-9x^2}}{x}\,dx = 5\left(\frac{1}{2}\ln\left|\frac{\cos\theta-1}{\cos\theta+1}\right| + \cos\theta\right) + C = \frac{5}{2}\ln\left|\frac{5-\sqrt{25-9x^2}}{5+\sqrt{25-9x^2}}\right| + \sqrt{25-9x^2} + C$$

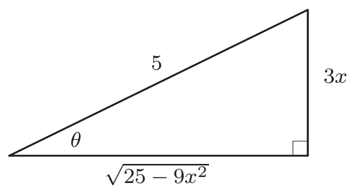

Figure 7.7: In this triangle, $\sin\theta = 3x/5$

59. Let $2x = 3\sin\theta$. Then $dx = (3/2)\cos\theta\,d\theta$ and $\sqrt{9-4x^2} = \sqrt{9-9\sin^2\theta} = 3\cos\theta$, so

$$\int \frac{1}{x\sqrt{9-4x^2}}\,dx = \int \frac{1}{(3\sin\theta/2)(3\cos\theta)}\left(\frac{3}{2}\cos\theta\,d\theta\right) = \frac{1}{3}\int\frac{1}{\sin\theta}\,d\theta.$$

From formula IV-21, we get

$$\int \frac{1}{\sin\theta}\,d\theta = \frac{1}{2}\ln\left|\frac{\cos\theta-1}{\cos\theta+1}\right| + C$$

From the triangle in Figure 7.8, which shows $\sin\theta = 2x/3$, we see that $\cos\theta = \sqrt{9-4x^2}/3$. Therefore

$$\int \frac{1}{x\sqrt{9-4x^2}}\,dx = \frac{1}{6}\ln\left|\frac{\cos\theta - 1}{\cos\theta + 1}\right| + C = \frac{1}{6}\ln\left|\frac{\sqrt{9-4x^2}/3 - 1}{\sqrt{9-4x^2}/3 + 1}\right| + C = \frac{1}{6}\ln\left|\frac{\sqrt{9-4x^2} - 3}{\sqrt{9-4x^2} + 3}\right| + C.$$

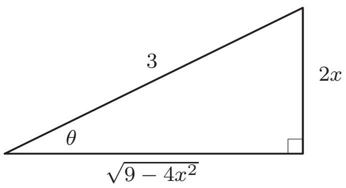

Figure 7.8: In this triangle, $\sin\theta = 2x/3$

60. Let $4x = \tan\theta$. Then $dx = (1/4)/\cos^2\theta\,d\theta$ and $\sqrt{1+16x^2} = \sqrt{1+\tan^2\theta} = 1/\cos\theta$, so

$$\int \frac{1}{x\sqrt{1+16x^2}}\,dx = \int \left(\frac{\cos\theta}{(1/4)\tan\theta}\right)\frac{1/4}{\cos^2\theta}\,d\theta = \int \frac{1}{\sin\theta}\,d\theta.$$

From formula IV-21, we get

$$\int \frac{1}{\sin\theta}\,d\theta = \frac{1}{2}\ln\left|\frac{\cos\theta - 1}{\cos\theta + 1}\right| + C$$

From the triangle in Figure 7.9, which shows $\tan\theta = 4x$, we see that $\cos\theta = 1/\sqrt{1+16x^2}$. Therefore

$$\int \frac{1}{x\sqrt{1+4x^2}}\,dx = \frac{1}{2}\ln\left|\frac{\cos\theta - 1}{\cos\theta + 1}\right| + C = \frac{1}{2}\ln\left|\frac{1/\sqrt{1+16x^2} - 1}{1/\sqrt{1+16x^2} + 1}\right| + C = \frac{1}{2}\ln\left|\frac{1 - \sqrt{1+16x^2}}{1 + \sqrt{1+16x^2}}\right| + C.$$

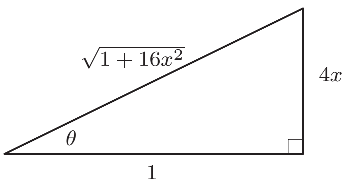

Figure 7.9: In this triangle, $\tan\theta = 4x$

61. Let $x = 2\sin\theta$ so $dx = 2\cos\theta d\theta$. Since $\sqrt{4 - 4\sin^2\theta} = 2\cos\theta$, we have

$$\int \frac{1}{x^2\sqrt{4-x^2}}\,dx = \int \frac{1}{(4\sin^2\theta)(2\cos\theta)} 2\cos\theta\,d\theta = \frac{1}{4}\int \frac{1}{\sin^2\theta}\,d\theta.$$

From formula IV-20 with $m = 2$, we get

$$\int \frac{1}{\sin^2\theta}\,d\theta = -\frac{\cos\theta}{\sin\theta} + C.$$

We need to know $\cos\theta$ in terms of x. From the triangle in Figure 7.10, which shows $x/2 = \sin\theta$, we see that $\cos\theta = \sqrt{4-x^2}/2$. Thus

$$\int \frac{1}{x^2\sqrt{4-x^2}}\,dx = -\frac{1}{4}\frac{\cos\theta}{\sin\theta} + C = -\frac{1}{4}\frac{\sqrt{4-x^2}/2}{x/2} + C = -\frac{1}{4}\frac{\sqrt{4-x^2}}{x} + C.$$

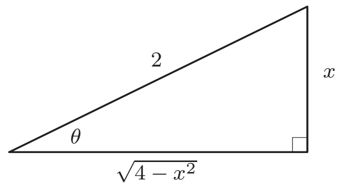

Figure 7.10: In this triangle, $\sin\theta = x/2$

62. Let $2x = 5\tan\theta$ so $dx = (5/2)(1/\cos^2\theta)d\theta$. Since

$$(25+4x^2)^{3/2} = (25+25\tan^2\theta)^{3/2} = (25/\cos^2\theta)^{3/2} = 125/\cos^3\theta,$$

we have

$$\int \frac{1}{(25+4x^2)^{3/2}}\,dx = \int \frac{\cos^3\theta}{125}\left(\frac{5}{2}\frac{1}{\cos^2\theta}\,d\theta\right) = \frac{1}{50}\int \cos\theta\,d\theta = \frac{1}{50}\sin\theta + C.$$

We need to know $\sin\theta$ in terms of x. From the triangle in Figure 7.11, which shows $2x/5 = \tan\theta$, we see that $\sin\theta = 2x/\sqrt{25+4x^2}$. Thus

$$\int \frac{1}{(25+4x^2)^{3/2}}\,dx = \frac{1}{50}\sin\theta + C = \frac{1}{50}\frac{2x}{\sqrt{25+4x^2}} + C = \frac{1}{25}\frac{x}{\sqrt{25+4x^2}} + C$$

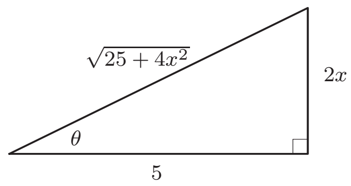

Figure 7.11: In this triangle, $\tan\theta = 2x/5$

63. Let $x = 4\sin\theta$ so $dx = 4\cos\theta\,d\theta$. Since

$$(16-x^2)^{3/2} = (16-16\sin^2\theta)^{3/2} = (16\cos^2\theta)^{3/2} = 64\cos^3\theta,$$

we have

$$\int \frac{1}{(16-x^2)^{3/2}}\,dx = \int \frac{1}{64\cos^3\theta}(4\cos\theta\,d\theta) = \frac{1}{16}\int \frac{1}{\cos^2\theta}\,d\theta.$$

From formula IV-22 with $m = 2$, we get

$$\int \frac{1}{\cos^2\theta}\,d\theta = \frac{\sin\theta}{\cos\theta} + C = \tan\theta + C.$$

We need to know $\tan\theta$ in terms of x. From the triangle in Figure 7.12, which shows $x/4 = \sin\theta$, we see that $\tan\theta = x/\sqrt{16-x^2}$. Thus

$$\int \frac{1}{(16-x^2)^{3/2}}\,dx = \frac{1}{16}\tan\theta + C = \frac{1}{16}\frac{x}{\sqrt{16-x^2}} + C$$

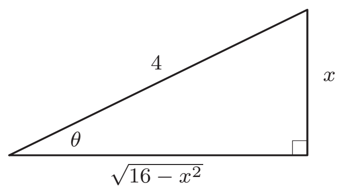

Figure 7.12: In this triangle, $\sin\theta = x/4$

64. Let $3x = \tan\theta$ so $dx = (1/3)(1/\cos^2\theta)\,d\theta$. Since $(1+9x^2)^{3/2} = (1+\tan^2\theta)^{3/2} = 1/\cos^3\theta$, we have

$$\int \frac{x^2}{(1+9x^2)^{3/2}}\,dx = \int \frac{1}{9}\frac{\sin^2\theta}{\cos^2\theta}(\cos^3\theta)\frac{1}{3\cos^2\theta}\,d\theta = \frac{1}{27}\int \frac{\sin^2\theta}{\cos\theta}\,d\theta.$$

From formula IV-22 with $m = 2$, we get

$$\int \frac{\sin^2\theta}{\cos\theta}\,d\theta = \int \frac{1-\cos^2\theta}{\cos\theta}\,d\theta = \int \left(\frac{1}{\cos\theta} - \cos\theta\right)\,d\theta = \frac{1}{2}\ln\left|\frac{\sin\theta+1}{\sin\theta-1}\right| - \sin\theta + C.$$

We need to know $\sin\theta$ in terms of x. From the triangle in Figure 7.13, which shows $3x = \tan\theta$, we see that $\sin\theta = 3x/\sqrt{1+9x^2}$. Thus

$$\int \frac{x^2}{(1+9x^2)^{3/2}}\,dx = \frac{1}{27}\left(\frac{1}{2}\ln\left|\frac{\sin\theta+1}{\sin\theta-1}\right| - \sin\theta\right) + C = \frac{1}{27}\left(\frac{1}{2}\ln\left|\frac{3x+\sqrt{1+9x^2}}{3x-\sqrt{1+9x^2}}\right| - \frac{3x}{\sqrt{1+9x^2}}\right) + C.$$

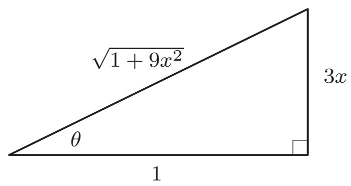

Figure 7.13: In this triangle, $\tan\theta = 3x$

65. Notice that because $\frac{3x}{(x-1)(x-4)}$ is negative for $2 \le x \le 3$,

$$\text{Area} = -\int_2^3 \frac{3x}{(x-1)(x-4)}dx.$$

Using partial fractions gives

$$\frac{3x}{(x-1)(x-4)} = \frac{A}{x-1} + \frac{B}{x-4} = \frac{(A+B)x - B - 4A}{(x-1)(x-4)}.$$

Multiplying through by $(x-1)(x-4)$ gives

$$3x = (A+B)x - B - 4A$$

so $A = -1$ and $B = 4$. Thus

$$-\int_2^3 \frac{3x}{(x-1)(x-4)}dx = -\int_2^3 \left(\frac{-1}{x-1} + \frac{4}{x-4}\right)\,dx = (\ln|x-1| - 4\ln|x-4|)\Big|_2^3 = 5\ln 2.$$

66. We have

$$\text{Area} = \int_0^1 \frac{3x^2+x}{(x^2+1)(x+1)}dx.$$

Using partial fractions gives

$$\begin{aligned}\frac{3x^2+x}{(x^2+1)(x+1)} &= \frac{Ax+B}{x^2+1} + \frac{C}{x+1}\\ &= \frac{(Ax+B)(x+1) + C(x^2+1)}{(x^2+1)(x+1)}\\ &= \frac{(A+C)x^2 + (A+B)x + B + C}{(x^2+1)(x+1)}.\end{aligned}$$

Thus

$$3x^2 + x = (A+C)x^2 + (A+B)x + B + C,$$

giving

$$3 = A + C, \quad 1 = A + B, \quad \text{and} \quad 0 = B + C,$$

with solution

$$A = 2, B = -1, C = 1.$$

Thus

$$\begin{aligned}
\text{Area} &= \int_0^1 \frac{3x^2 + x}{(x^2+1)(x+1)} dx \\
&= \int_0^1 \left(\frac{2x}{x^2+1} - \frac{1}{x^2+1} + \frac{1}{x+1} \right) dx \\
&= \ln(x^2+1) - \arctan x + \ln|x+1| \Big|_0^1 \\
&= 2\ln 2 - \pi/4.
\end{aligned}$$

67. We have

$$\text{Area} = \int_0^{1/2} \frac{x^2}{\sqrt{1-x^2}} dx.$$

Let $x = \sin\theta$ so $dx = \cos\theta\, d\theta$ and $\sqrt{1-x^2} = \sqrt{1-\sin^2\theta} = \cos\theta$. When $x = 0, \theta = 0$. When $x = 1/2, \theta = \pi/6$.

$$\begin{aligned}
\int_0^{1/2} \frac{x^2}{\sqrt{1-x^2}} dx &= \int_0^{\pi/6} \frac{\sin^2\theta}{\sqrt{1-\sin^2\theta}} \cos\theta\, d\theta = \int_0^{\pi/6} \sin^2\theta\, d\theta \\
&= \left(\frac{\theta}{2} - \frac{\sin\theta\cos\theta}{2} \right) \Bigg|_0^{\pi/6} = \frac{\pi}{12} - \frac{\sqrt{3}}{8}.
\end{aligned}$$

The integral $\int \sin^2\theta\, d\theta$ is done using parts and the identity $\cos^2\theta + \sin^2\theta = 1$.

68. We have

$$\text{Area} = \int_0^{\sqrt{2}} \frac{x^3}{\sqrt{4-x^2}}\, dx.$$

Let $x = 2\sin\theta$ so $dx = 2\cos\theta\, d\theta$ and $\sqrt{4-x^2} = \sqrt{4-4\sin^2\theta} = 2\cos\theta$. When $x = 0, \theta = 0$ and when $x = \sqrt{2}, \theta = \pi/4$.

$$\begin{aligned}
\int_0^{\sqrt{2}} \frac{x^3}{\sqrt{4-x^2}} dx &= \int_0^{\pi/4} \frac{(2\sin\theta)^3}{\sqrt{4-(2\sin\theta)^2}} 2\cos\theta\, d\theta \\
&= 8 \int_0^{\pi/4} \sin^3\theta\, d\theta = 8 \int_0^{\pi/4} (\sin\theta - \sin\theta\cos^2\theta)\, d\theta \\
&= 8 \left(-\cos\theta + \frac{\cos^3\theta}{3} \right) \Bigg|_0^{\pi/4} = 8 \left(\frac{2}{3} - \frac{5}{6\sqrt{2}} \right).
\end{aligned}$$

69. We have

$$\text{Area} = \int_0^3 \frac{1}{\sqrt{x^2+9}} dx.$$

Let $x = 3\tan\theta$ so $dx = (3/\cos^2\theta) d\theta$ and

$$\sqrt{x^2+9} = \sqrt{\frac{9\sin^2\theta}{\cos^2\theta} + 9} = \frac{3}{\cos\theta}.$$

When $x = 0, \theta = 0$ and when $x = 3, \theta = \pi/4$. Thus

$$\int_0^3 \frac{1}{\sqrt{x^2+9}} dx = \int_0^{\pi/4} \frac{1}{\sqrt{9\tan^2\theta + 9}} \frac{3}{\cos^2\theta} d\theta = \int_0^{\pi/4} \frac{1}{3/\cos\theta} \cdot \frac{3}{\cos^2\theta} d\theta = \int_0^{\pi/4} \frac{1}{\cos\theta} d\theta$$
$$= \frac{1}{2}\ln\left|\frac{\sin\theta+1}{\sin\theta-1}\right|\Bigg|_0^{\pi/4} = \frac{1}{2}\ln\left|\frac{1/\sqrt{2}+1}{1/\sqrt{2}-1}\right| = \frac{1}{2}\ln\left(\frac{1+\sqrt{2}}{\sqrt{2}-1}\right).$$

This answer can be simplified to $\ln(1+\sqrt{2})$ by multiplying the numerator and denominator of the fraction by $(\sqrt{2}+1)$ and using the properties of logarithms. The integral $\int(1/\cos\theta)d\theta$ is done using the Table of Integrals.

70. We have

$$\text{Area} = \int_{\sqrt{3}}^3 \frac{1}{x\sqrt{x^2+9}} dx.$$

Let $x = 3\tan\theta$ so $dx = (3/\cos^2\theta)d\theta$ and

$$x\sqrt{x^2+9} = 3\frac{\sin\theta}{\cos\theta}\sqrt{\frac{9\sin^2\theta}{\cos^2\theta}+9} = \frac{9\sin\theta}{\cos^2\theta}.$$

When $x = \sqrt{3}, \theta = \pi/6$ and when $x = 3, \theta = \pi/4$. Thus

$$\int_{\sqrt{3}}^3 \frac{1}{x\sqrt{x^2+9}} dx = \int_{\pi/6}^{\pi/4} \frac{1}{9\sin\theta/\cos^2\theta} \cdot \frac{3}{\cos^2\theta} d\theta = \frac{1}{3}\int_{\pi/6}^{\pi/4} \frac{1}{\sin\theta} d\theta$$
$$= \frac{1}{3}\cdot\frac{1}{2}\ln\left|\frac{\cos\theta-1}{\cos\theta+1}\right|\Bigg|_{\pi/6}^{\pi/4} = \frac{1}{6}\left(\ln\left|\frac{1/\sqrt{2}-1}{1/\sqrt{2}+1}\right| - \ln\left|\frac{\sqrt{3}/2-1}{\sqrt{3}/2+1}\right|\right)$$
$$= \frac{1}{6}\left(\ln\left|\frac{1-\sqrt{2}}{1+\sqrt{2}}\right| + \ln\left|\frac{\sqrt{3}+2}{\sqrt{3}-2}\right|\right).$$

This answer can be simplified by multiplying the first fraction by $(1-\sqrt{2})$ in numerator and denominator and the second one by $(\sqrt{3}+2)$. This gives

$$\text{Area} = \frac{1}{6}(\ln(3-2\sqrt{2}) + \ln(7+4\sqrt{3})) = \frac{1}{6}\ln((3-2\sqrt{2})(7+4\sqrt{3})).$$

The integral $\int(1/\sin\theta)d\theta$ is done using the Table of Integrals.

71. Using partial fractions, we write

$$\frac{1}{1-x^2} = \frac{A}{1+x} + \frac{B}{1-x}$$
$$1 = A(1-x) + B(1+x) = (B-A)x + A + B.$$

So, $B - A = 0$ and $A + B = 1$, giving $A = B = 1/2$. Thus

$$\int \frac{dx}{1-x^2} = \frac{1}{2}\int\left(\frac{1}{1+x} + \frac{1}{1-x}\right) dx = \frac{1}{2}(\ln|1+x| - \ln|1-x|) + C.$$

Using the substitution $x = \sin\theta$, we get $dx = \cos\theta\, d\theta$, we have

$$\int \frac{dx}{1-x^2} = \int \frac{\cos\theta}{1-\sin^2\theta} d\theta = \int \frac{\cos\theta}{\cos^2\theta} d\theta = \int \frac{1}{\cos\theta} d\theta.$$

The Table of Integrals Formula IV-22 gives

$$\int \frac{dx}{1-x^2} = \int \frac{1}{\cos\theta} d\theta = \frac{1}{2}\ln\left|\frac{(\sin\theta)+1}{(\sin\theta)-1}\right| + C = \frac{1}{2}\ln\left|\frac{x+1}{x-1}\right| + C.$$

The properties of logarithms and the fact that $|x-1| = |1-x|$ show that the two results are the same:

$$\frac{1}{2}\ln\left|\frac{x+1}{x-1}\right| = \frac{1}{2}(\ln|1+x| - \ln|1-x|).$$

72. Using partial fractions, we write

$$\frac{2x}{x^2-1} = \frac{A}{x+1} + \frac{B}{x-1}$$

$$2x = A(x-1) + B(x+1) = (A+B)x - A + B.$$

So, $A + B = 2$ and $-A + B = 0$, giving $A = B = 1$. Thus

$$\int \frac{2x}{x^2-1}\,dx = \int \left(\frac{1}{x+1} + \frac{1}{x-1}\right) dx = \ln|x+1| + \ln|x-1| + C.$$

Using the substitution $w = x^2 - 1$, we get $dw = 2x\,dx$, so we have

$$\int \frac{2x}{x^2-1}\,dx = \int \frac{dw}{w} = \ln|w| + C = \ln\left|x^2-1\right| + C.$$

The properties of logarithms show that the two results are the same:

$$\ln|x+1| + \ln|x-1| = \ln|(x+1)(x-1)| = \ln\left|x^2-1\right|.$$

73. Using partial fractions, we write

$$\frac{3x^2+1}{x^3+x} = \frac{3x^2+1}{x(x^2+1)} = \frac{A}{x} + \frac{Bx+C}{x^2+1}$$

$$3x^2 + 1 = A(x^2+1) + (Bx+C)x = (A+B)x^2 + Cx + A.$$

So, $A + B = 3$, $C = 0$ and $A = 1$, giving $B = 2$. Thus

$$\int \frac{3x^2+1}{x^3+x}\,dx = \int \left(\frac{1}{x} + \frac{2x}{x^2+1}\right) dx = \ln|x| + \ln\left|x^2+1\right| + K.$$

Using the substitution $w = x^3 + x$, we get $dw = (3x^2+1)dx$, so we have

$$\int \frac{3x^2+1}{x^3+x}\,dx = \int \frac{dw}{w} = \ln|w| + K = \ln\left|x^3+x\right| + K.$$

The properties of logarithms show that the two results are the same:

$$\ln|x| + \ln\left|x^2+1\right| + K = \ln\left|x(x^2+1)\right| + K = \ln\left|x^3+x\right| + K.$$

We use K as the constant of integration, since we already used C in the problem.

74. (a) We differentiate:

$$\frac{d}{d\theta}\left(-\frac{1}{\tan\theta}\right) = \frac{1}{\tan^2\theta}\cdot\frac{1}{\cos^2\theta} = \frac{1}{\frac{\sin^2\theta}{\cos^2\theta}}\cdot\frac{1}{\cos^2\theta} = \frac{1}{\sin^2\theta}.$$

Thus,

$$\int \frac{1}{\sin^2\theta}\,d\theta = -\frac{1}{\tan\theta} + C.$$

(b) Let $y = \sqrt{5}\sin\theta$ so $dy = \sqrt{5}\cos\theta\,d\theta$ giving

$$\int \frac{dy}{y^2\sqrt{5-y^2}} = \int \frac{\sqrt{5}\cos\theta}{5\sin^2\theta\sqrt{5-5\sin^2\theta}}\,d\theta = \frac{1}{5}\int \frac{\sqrt{5}\cos\theta}{\sin^2\theta\sqrt{5}\cos\theta}\,d\theta$$

$$= \frac{1}{5}\int \frac{1}{\sin^2\theta}\,d\theta = -\frac{1}{5\tan\theta} + C.$$

Since $\sin\theta = y/\sqrt{5}$, we have $\cos\theta = \sqrt{1-(y/\sqrt{5})^2} = \sqrt{5-y^2}/\sqrt{5}$. Thus,

$$\int \frac{dy}{y^2\sqrt{5-y^2}} = -\frac{1}{5\tan\theta} + C = -\frac{\sqrt{5-y^2}/\sqrt{5}}{5(y/\sqrt{5})} + C = -\frac{\sqrt{5-y^2}}{5y} + C.$$

75. (a) If $a \neq b$, we have

$$\int \frac{1}{(x-a)(x-b)}\,dx = \int \frac{1}{a-b}\left(\frac{1}{x-a} - \frac{1}{x-b}\right)\,dx = \frac{1}{a-b}(\ln|x-a| - \ln|x-b|) + C.$$

(b) If $a = b$, we have

$$\int \frac{1}{(x-a)(x-a)}\,dx = \int \frac{1}{(x-a)^2}\,dx = -\frac{1}{x-a} + C.$$

76. (a) If $a \neq b$, we have

$$\int \frac{x}{(x-a)(x-b)}\,dx = \int \frac{1}{a-b}\left(\frac{a}{x-a} - \frac{b}{x-b}\right)\,dx = \frac{1}{a-b}(a\ln|x-a| - b\ln|x-b|) + C.$$

(b) If $a = b$, we have

$$\int \frac{x}{(x-a)^2}\,dx = \int \left(\frac{1}{x-a} + \frac{a}{(x-a)^2}\right)\,dx = \ln|x-a| - \frac{a}{x-a} + C.$$

77. (a) If $a > 0$, then

$$x^2 - a = (x-\sqrt{a})(x+\sqrt{a}).$$

This means that we can use partial fractions:

$$\frac{1}{x^2-a} = \frac{A}{x-\sqrt{a}} + \frac{B}{x+\sqrt{a}},$$

giving

$$1 = A(x+\sqrt{a}) + B(x-\sqrt{a}),$$

so $A + B = 0$ and $(A-B)\sqrt{a} = 1$. Thus, $A = -B = 1/(2\sqrt{a})$.

So

$$\int \frac{1}{x^2-a}\,dx = \int \frac{1}{2\sqrt{a}}\left(\frac{1}{x-\sqrt{a}} - \frac{1}{x+\sqrt{a}}\right)\,dx = \frac{1}{2\sqrt{a}}\left(\ln\left|x-\sqrt{a}\right| - \ln\left|x+\sqrt{a}\right|\right) + C.$$

(b) If $a = 0$, we have

$$\int \frac{1}{x^2}\,dx = -\frac{1}{x} + C.$$

(c) If $a < 0$, then $-a > 0$ so $x^2 - a = x^2 + (-a)$ cannot be factored. Thus

$$\int \frac{1}{x^2-a}\,dx = \int \frac{1}{x^2+(-a)}\,dx = \frac{1}{\sqrt{-a}}\arctan\left(\frac{x}{\sqrt{-a}}\right) + C.$$

78. (a) We integrate to find

$$\int \frac{b}{x(1-x)}\,dx = b\int\left(\frac{1}{x} + \frac{1}{1-x}\right)\,dx = b(\ln|x| - \ln|1-x|) + C = b\ln\left|\frac{x}{1-x}\right| + C,$$

so

$$t(p) = \int_a^p \frac{b}{x(1-x)}\,dx = b\ln\left(\frac{p}{1-p}\right) - b\ln\left(\frac{a}{1-a}\right) = b\ln\left(\frac{p(1-a)}{a(1-p)}\right).$$

(b) We know that $t(0.01) = 0$ so

$$0 = b\ln\left(\frac{0.01(1-a)}{0.99a}\right).$$

But $b > 0$ and $\ln x = 0$ means $x = 1$, so

$$\begin{aligned}\frac{0.01(1-a)}{0.99a} &= 1\\ 0.01(1-a) &= 0.99a\\ 0.01 - 0.01a &= 0.99a\\ a &= 0.01.\end{aligned}$$

(c) We know that $t(0.5) = 1$ so

$$1 = b\ln\left(\frac{0.5\cdot 0.99}{0.5\cdot 0.01}\right) = b\ln 99, b = \frac{1}{\ln 99} = 0.218.$$

(d) We have

$$t(0.9) = \int_{0.01}^{0.9} \frac{0.218}{x(1-x)}\,dx = \frac{1}{\ln 99}\ln\left(\frac{0.9(1-0.01)}{0.01(1-0.9)}\right) = 1.478.$$

79. (a) We want to evaluate the integral

$$T = \int_0^{a/2} \frac{k\,dx}{(a-x)(b-x)}.$$

Using partial fractions, we have

$$\begin{aligned}\frac{k}{(a-x)(b-x)} &= \frac{C}{a-x} + \frac{D}{b-x}\\ k &= C(b-x) + D(a-x)\\ k &= -(C+D)x + Cb + Da\end{aligned}$$

so

$$\begin{aligned}0 &= -(C+D)\\ k &= Cb + Da,\end{aligned}$$

giving

$$C = -D = \frac{k}{b-a}.$$

Thus, the time is given by

$$\begin{aligned}T = \int_0^{a/2} \frac{k\,dx}{(a-x)(b-x)} &= \frac{k}{b-a}\int_0^{a/2}\left(\frac{1}{a-x} - \frac{1}{b-x}\right)dx\\ &= \frac{k}{b-a}\left(-\ln|a-x| + \ln|b-x|\right)\Big|_0^{a/2}\\ &= \frac{k}{b-a}\ln\left|\frac{b-x}{a-x}\right|\Big|_0^{a/2}\\ &= \frac{k}{b-a}\left(\ln\left(\frac{2b-a}{a}\right) - \ln\left(\frac{b}{a}\right)\right)\\ &= \frac{k}{b-a}\ln\left(\frac{2b-a}{b}\right).\end{aligned}$$

(b) A similar calculation with x_0 instead of $a/2$ leads to the following expression for the time

$$\begin{aligned}T = \int_0^{x_0} \frac{k\,dx}{(a-x)(b-x)} &= \frac{k}{b-a}\ln\left|\frac{b-x}{a-x}\right|\Big|_0^{x_0}\\ &= \frac{k}{b-a}\left(\ln\left|\frac{b-x_0}{a-x_0}\right| - \ln\left(\frac{b}{a}\right)\right).\end{aligned}$$

As $x_0 \to a$, the value of $|a-x_0| \to 0$, so $|b-x_0|/|a-x_0| \to \infty$. Thus, $T \to \infty$ as $x_0 \to a$. In other words, the time taken tends to infinity.

80. We complete the square in the exponent so that we can make a substitution:

$$\begin{aligned}m(t) &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} e^{tx}e^{-x^2/2}\,dx\\ &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} e^{-(x^2-2tx)/2}\,dx\\ &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} e^{-((x^2-2tx+t^2)-t^2)/2}\,dx\end{aligned}$$

$$= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-(x-t)^2/2} \cdot e^{t^2/2}\, dx$$
$$= \frac{e^{t^2/2}}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-(x-t)^2/2}\, dx.$$

Substitute $w = x - t$, then $dw = dx$ and $w = \infty$ when $x = \infty$, and $w = -\infty$ when $x = -\infty$. Thus

$$m(t) = \frac{e^{t^2/2}}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-w^2/2}\, dw = \frac{e^{t^2/2}}{\sqrt{2\pi}} \cdot \sqrt{2\pi}$$
$$m(t) = e^{t^2/2}.$$

Strengthen Your Understanding

81. The partial fractions required are of the form

$$\frac{1}{(x-1)^2(x-2)} = \frac{A}{x-1} + \frac{B}{(x-1)^2} + \frac{C}{x-2}.$$

82. We use $x = 2\tan\theta$.

83. Since $\int 1/(1+x^2)\, dx = \arctan x + C$, so $f(x) = 1/(1+x^2)$ works.

84. To evaluate $\int 1/(x^3 - x)\, dx$, we first factor $x^3 - x = x(x-1)(x+1)$ and then use partial fractions.

85. If $Q(x)$ does not decompose into linear factors, then we cannot decompose $P(x)/Q(x)$ into partial fractions. So for example, if $P(x) = x$ and $Q(x) = x^2 + 1$, then the rational function $P(x)/Q(x)$ does not have a partial fraction decomposition. Alternatively, if $Q(x)$ contains a repeated linear factor, then the partial fraction decomposition may not be in the given form. For example, if $P(x) = x + 1$ and $Q(x) = x^2 + 6x + 9$, then the partial fraction decomposition of $P(x)/Q(x)$ is

$$\frac{x+1}{x^2+6x+9} = \frac{1}{x+3} - \frac{2}{(x+3)^2}.$$

86. An example is the integral

$$\int \frac{dx}{\sqrt{9-4x^2}}.$$

If we make the substitution $x = \frac{3}{2}\sin\theta$, $dx = \frac{3}{2}\cos\theta\, d\theta$, then we obtain

$$\int \frac{dx}{\sqrt{9-4x^2}} = \int \frac{\frac{3}{2}\cos\theta}{\sqrt{9-9\sin^2\theta}}\, d\theta = \int \frac{\frac{3}{2}\cos\theta}{\sqrt{9\cos^2\theta}}\, d\theta = \int \frac{\frac{3}{2}\cos\theta}{3\cos\theta}\, d\theta$$
$$= \int \frac{1}{2}\, d\theta = \frac{1}{2}\theta + C = \frac{1}{2} \cdot \arcsin\left(\frac{2}{3}x\right) + C$$

87. False. If we use the given substitution the radicand becomes $9 - 9\tan^2\theta = 9(1 - \tan^2\theta)$. However, $1 - \tan^2\theta$ is not equal to a monomial.

88. True. Since the denominator can be factored into $x^2(x+1)$, involving the repeated factor x^2, we use partial fractions of the form

$$\int \frac{1}{x^3 + x^2}\, dx = \int \frac{A}{x} + \frac{B}{x^2} + \frac{C}{x+1}\, dx.$$

89. (e). $x = \sin\theta$ is appropriate.

90. (c) and (b). $\dfrac{x^2}{1-x^2} = -1 + \dfrac{1}{1-x^2} = 1 + \dfrac{1}{(1-x)(1+x)}$.

Solutions for Section 7.5

Exercises

1. (a) The approximation LEFT(2) uses two rectangles, with the height of each rectangle determined by the left-hand endpoint. See Figure 7.14. We see that this approximation is an underestimate.

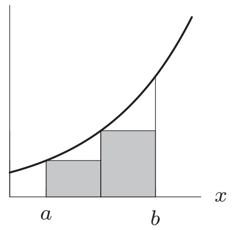

Figure 7.14

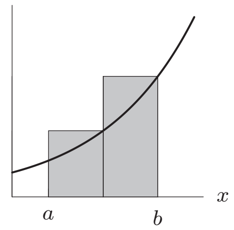

Figure 7.15

(b) The approximation RIGHT(2) uses two rectangles, with the height of each rectangle determined by the right-hand endpoint. See Figure 7.15. We see that this approximation is an overestimate.

(c) The approximation TRAP(2) uses two trapezoids, with the height of each trapezoid given by the secant line connecting the two endpoints. See Figure 7.16. We see that this approximation is an overestimate.

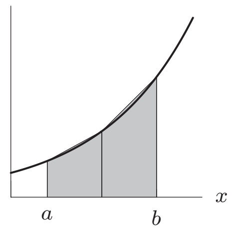

Figure 7.16

(d) The approximation MID(2) uses two rectangles, with the height of each rectangle determined by the height at the midpoint. Alternately, we can view MID(2) as a trapezoid rule where the height is given by the tangent line at the midpoint. Both interpretations are shown in Figure 7.17. We see from the tangent line interpretation that this approximation is an underestimate

Figure 7.17

2. (a) The approximation LEFT(2) uses two rectangles, with the height of each rectangle determined by the left-hand endpoint. See Figure 7.18. We see that this approximation is an overestimate.

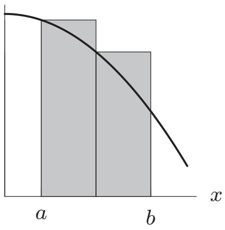

Figure 7.18

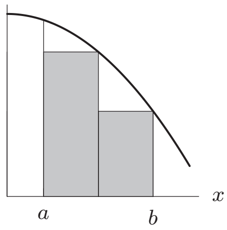

Figure 7.19

(b) The approximation RIGHT(2) uses two rectangles, with the height of each rectangle determined by the right-hand endpoint. See Figure 7.19. We see that this approximation is an underestimate.

(c) The approximation TRAP(2) uses two trapezoids, with the height of each trapezoid given by the secant line connecting the two endpoints. See Figure 7.20. We see that this approximation is an underestimate.

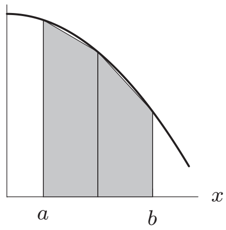

Figure 7.20

(d) The approximation MID(2) uses two rectangles, with the height of each rectangle determined by the height at the midpoint. Alternately, we can view MID(2) as a trapezoid rule where the height is given by the tangent line at the midpoint. Both interpretations are shown in Figure 7.21. We see from the tangent line interpretation that this approximation is an overestimate.

Figure 7.21

3. (a) The approximation LEFT(2) uses two rectangles, with the height of each rectangle determined by the left-hand endpoint. See Figure 7.22. We see that this approximation is an underestimate.

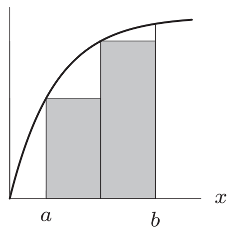

Figure 7.22

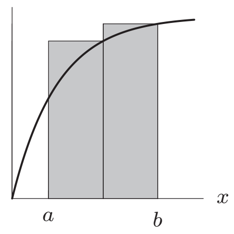

Figure 7.23

(b) The approximation RIGHT(2) uses two rectangles, with the height of each rectangle determined by the right-hand endpoint. See Figure 7.23. We see that this approximation is an overestimate.

(c) The approximation TRAP(2) uses two trapezoids, with the height of each trapezoid given by the secant line connecting the two endpoints. See Figure 7.24. We see that this approximation is an underestimate.

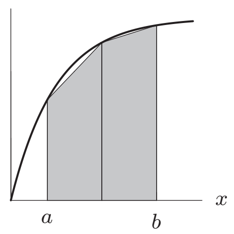

Figure 7.24

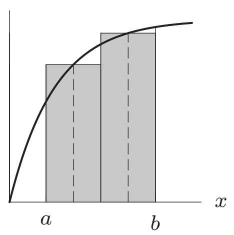
(d) The approximation MID(2) uses two rectangles, with the height of each rectangle determined by the height at the midpoint. Alternately, we can view MID(2) as a trapezoid rule where the height is given by the tangent line at the midpoint. Both interpretations are shown in Figure 7.25. We see from the tangent line interpretation that this approximation is an overestimate.



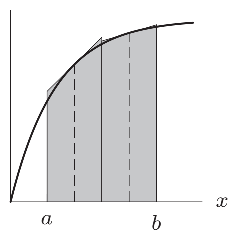


Figure 7.25

4. (a) The approximation LEFT(2) uses two rectangles, with the height of each rectangle determined by the left-hand endpoint. See Figure 7.26. We see that this approximation is an overestimate.

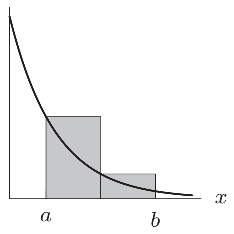

Figure 7.26

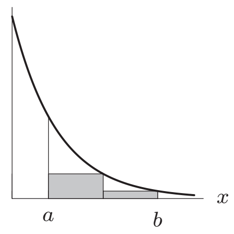

Figure 7.27

(b) The approximation RIGHT(2) uses two rectangles, with the height of each rectangle determined by the right-hand endpoint. See Figure 7.27. We see that this approximation is an underestimate.

(c) The approximation TRAP(2) uses two trapezoids, with the height of each trapezoid given by the secant line connecting the two endpoints. See Figure 7.28. We see that this approximation is an overestimate.

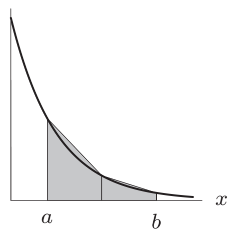

Figure 7.28

(d) The approximation MID(2) uses two rectangles, with the height of each rectangle determined by the height at the midpoint. Alternately, we can view MID(2) as a trapezoid rule where the height is given by the tangent line at the midpoint. Both interpretations are shown in Figure 7.29. We see from the tangent line interpretation that this approximation is an underestimate.

Figure 7.29

5. (a) The approximation LEFT(2) uses two rectangles, with the height of each rectangle determined by the left-hand endpoint. See Figure 7.30. We see that this approximation is an underestimate (that is, it is more negative).

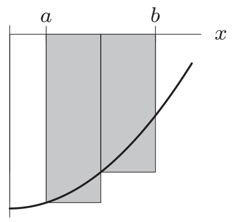

Figure 7.30

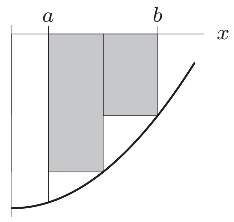

Figure 7.31

(b) The approximation RIGHT(2) uses two rectangles, with the height of each rectangle determined by the right-hand endpoint. See Figure 7.31. We see that this approximation is an overestimate (that is, it is less negative).

(c) The approximation TRAP(2) uses two trapezoids, with the height of each trapezoid given by the secant line connecting the two endpoints. See Figure 7.32. We see that this approximation is an overestimate (that is, it is less negative).

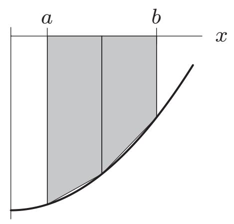

Figure 7.32

(d) The approximation MID(2) uses two rectangles, with the height of each rectangle determined by the height at the midpoint. Alternately, we can view MID(2) as a trapezoid rule where the height is given by the tangent line at the midpoint. Both interpretations are shown in Figure 7.33. We see from the tangent line interpretation that this approximation is an underestimate (that is, it is more negative).

Figure 7.33

6. (a) The approximation LEFT(2) uses two rectangles, with the height of each rectangle determined by the left-hand endpoint. See Figure 7.34. We see that this approximation is an overestimate (that is, it is less negative).

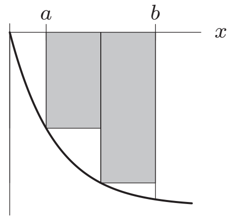

Figure 7.34

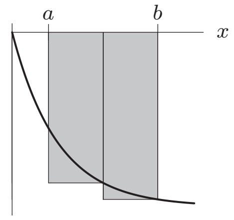

Figure 7.35

(b) The approximation RIGHT(2) uses two rectangles, with the height of each rectangle determined by the right-hand endpoint. See Figure 7.35. We see that this approximation is an underestimate (that is, it is more negative).

(c) The approximation TRAP(2) uses two trapezoids, with the height of each trapezoid given by the secant line connecting the two endpoints. See Figure 7.36. We see that this approximation is an overestimate (that is, it is less negative).

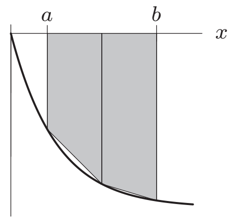

Figure 7.36

(d) The approximation MID(2) uses two rectangles, with the height of each rectangle determined by the height at the midpoint. Alternately, we can view MID(2) as a trapezoid rule where the height is given by the tangent line at the midpoint. Both interpretations are shown in Figure 7.37. We see from the tangent line interpretation that this approximation is an underestimate (that is, the approximation is more negative).

Figure 7.37

7. (a) Since two rectangles are being used, the width of each rectangle is 3. The height is given by the left-hand endpoint so we have

$$\text{LEFT(2)} = f(0)\cdot 3 + f(3)\cdot 3 = 0^2\cdot 3 + 3^2\cdot 3 = 27.$$

(b) Since two rectangles are being used, the width of each rectangle is 3. The height is given by the right-hand endpoint so we have

$$\text{RIGHT(2)} = f(3)\cdot 3 + f(6)\cdot 3 = 3^2\cdot 3 + 6^2\cdot 3 = 135.$$

(c) We know that TRAP is the average of LEFT and RIGHT and so

$$\text{TRAP(2)} = \frac{27+135}{2} = 81.$$

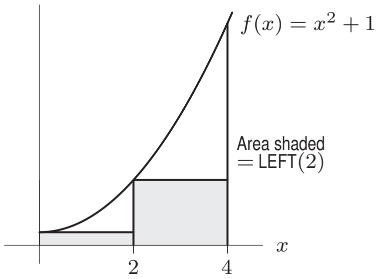
(d) Since two rectangles are being used, the width of each rectangle is 3. The height is given by the height at the midpoint so we have

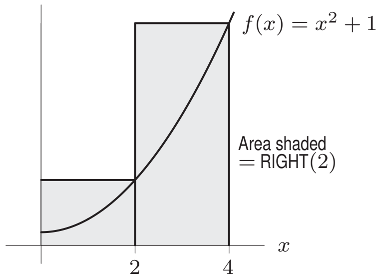
$$\text{MID(2)} = f(1.5)\cdot 3 + f(4.5)\cdot 3 = (1.5)^2\cdot 3 + (4.5)^2\cdot 3 = 67.5.$$

8. (a)

$$\begin{aligned}\text{LEFT}(2) &= 2 \cdot f(0) + 2 \cdot f(2) \\ &= 2 \cdot 1 + 2 \cdot 5 \\ &= 12 \\ \text{RIGHT}(2) &= 2 \cdot f(2) + 2 \cdot f(4) \\ &= 2 \cdot 5 + 2 \cdot 17 \\ &= 44\end{aligned}$$

(b)



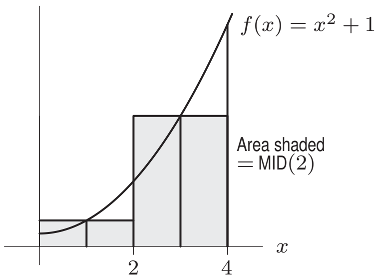


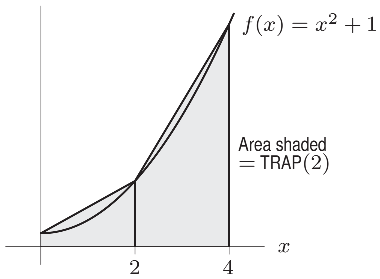
LEFT(2) is an underestimate, while RIGHT(2) is an overestimate.

9. (a)

$$\begin{aligned}\text{MID}(2) &= 2 \cdot f(1) + 2 \cdot f(3) \\ &= 2 \cdot 2 + 2 \cdot 10 \\ &= 24 \\ \text{TRAP}(2) &= \frac{\text{LEFT}(2) + \text{RIGHT}(2)}{2} \\ &= \frac{12 + 44}{2} \quad \text{(see Problem 8)} \\ &= 28\end{aligned}$$

(b)





MID(2) is an underestimate, since $f(x) = x^2 + 1$ is concave up and a tangent line will be below the curve. TRAP(2) is an overestimate, since a secant line lies above the curve.

10. (a) Since two rectangles are being used, the width of each rectangle is $\pi/2$. The height is given by the left-hand endpoint so we have

$$\text{LEFT}(2) = f(0) \cdot \frac{\pi}{2} + f(\pi/2) \cdot \frac{\pi}{2} = \sin 0 \cdot \frac{\pi}{2} + \sin(\pi/2) \cdot \frac{\pi}{2} = \frac{\pi}{2}.$$

(b) Since two rectangles are being used, the width of each rectangle is $\pi/2$. The height is given by the right-hand endpoint so we have

$$\text{RIGHT}(2) = f(\pi/2) \cdot \frac{\pi}{2} + f(\pi) \cdot \frac{\pi}{2} = \sin(\pi/2) \cdot \frac{\pi}{2} + \sin(\pi) \cdot \frac{\pi}{2} = \frac{\pi}{2}.$$

(c) We know that TRAP is the average of LEFT and RIGHT and so

$$\text{TRAP}(2) = \frac{\frac{\pi}{2} + \frac{\pi}{2}}{2} = \frac{\pi}{2}.$$

(d) Since two rectangles are being used, the width of each rectangle is $\pi/2$. The height is given by the height at the midpoint so we have

$$\text{MID}(2) = f(\pi/4)\cdot\frac{\pi}{2} + f(3\pi/4)\cdot\frac{\pi}{2} = \sin(\pi/4)\cdot\frac{\pi}{2} + \sin(3\pi/4)\cdot\frac{\pi}{2} = \frac{\sqrt{2}\pi}{2}.$$

Problems

11. For $n = 5$, we have $\Delta t = (2-1)/5 = 0.2$, so

$$\begin{aligned}\text{MID}(5) &= 0.2f(1.1) + 0.2f(1.3) + 0.2f(1.5) + 0.2f(1.7) + 0.2f(1.9)\\ &= 0.2\,(-2.9 - 3.7 - 3.2 - 1.7 + 0.5)\\ &= -2.2.\end{aligned}$$

12. For $n = 4$, we have $\Delta x = (2-0)/4 = 0.5$, so

$$\begin{aligned}\text{MID}(4) &= f(0.25)0.5 + f(0.75)(0.5) + f(1.25)(0.5) + f(1.75)(0.5)\\ &= 0.5(5.8 + 9.3 + 10.8 + 10.3)\\ &= 18.1.\end{aligned}$$

13. We have $n = 2$ and $\Delta x = 0.5$, so

$$\begin{aligned}\text{LEFT}(2) &= \Delta x\,(f(2) + f(2.5))\\ &= 0.5\left(\frac{1}{2^2} + \frac{1}{2.5^2}\right)\\ &= 0.5\left(\frac{1}{4} + \frac{4}{25}\right)\\ &= \frac{41}{200} = 0.205\\ \text{RIGHT}(2) &= \Delta x\,(f(2.5) + f(3))\\ &= 0.5\left(\frac{1}{2.5^2} + \frac{1}{3^2}\right)\\ &= 0.5\left(\frac{4}{25} + \frac{1}{9}\right)\\ &= \frac{61}{450} = 0.1356\\ \text{TRAP}(2) &= \frac{\text{LEFT}(2) + \text{RIGHT}(2)}{2}\\ &= \frac{\frac{41}{200} + \frac{61}{450}}{2} = 0.1703.\end{aligned}$$

14. We have $n = 2$ and $\Delta x = 0.5$, so

$$\begin{aligned}\text{MID}(2) &= \Delta x\,(f(2.25) + f(2.75))\\ &= 0.5\left(\frac{1}{2.25^2} + \frac{1}{2.75^2}\right)\\ &= 0.1649.\end{aligned}$$

15. (a) (i) Let $f(x) = \frac{1}{1+x^2}$. The left-hand Riemann sum is

$$\begin{aligned}&\frac{1}{8}\left(f(0) + f\left(\frac{1}{8}\right) + f\left(\frac{2}{8}\right) + \cdots + f\left(\frac{7}{8}\right)\right)\\ &= \frac{1}{8}\left(\frac{64}{64} + \frac{64}{65} + \frac{64}{68} + \frac{64}{73} + \frac{64}{80} + \frac{64}{89} + \frac{64}{100} + \frac{64}{113}\right)\\ &\approx 8(0.1020) = 0.8160.\end{aligned}$$

(ii) Let $f(x) = \frac{1}{1+x^2}$. The right-hand Riemann sum is

$$\begin{aligned}&\frac{1}{8}\left(f\left(\frac{1}{8}\right) + f\left(\frac{2}{8}\right) + f\left(\frac{3}{8}\right) + \cdots + f(1)\right)\\ &= \frac{1}{8}\left(\frac{64}{65} + \frac{64}{68} + \frac{64}{73} + \frac{64}{80} + \frac{64}{89} + \frac{64}{100} + \frac{64}{113} + \frac{64}{128}\right)\\ &\approx 0.8160 - \frac{1}{16} = 0.7535.\end{aligned}$$

(iii) The trapezoid rule gives us that

$$\text{TRAP}(8) = \frac{\text{LEFT}(8) + \text{RIGHT}(8)}{2} \approx 0.7847.$$

(b) Since $1 + x^2$ is increasing for $x > 0$, so $\dfrac{1}{1+x^2}$ is decreasing over the interval. Thus

$$\begin{aligned} \text{RIGHT}(8) < \int_0^1 \frac{1}{1+x^2}\,dx &< \text{LEFT}(8) \\ 0.7535 < \frac{\pi}{4} &< 0.8160 \\ 3.014 < \pi &< 3.264. \end{aligned}$$

16. Let $s(t)$ be the distance traveled at time t and $v(t)$ be the velocity at time t. Then the distance traveled during the interval $0 \le t \le 6$ is

$$\begin{aligned} s(6) - s(0) &= s(t)\Big|_0^6 \\ &= \int_0^6 s'(t)\,dt \quad \text{(by the Fundamental Theorem)} \\ &= \int_0^6 v(t)\,dt. \end{aligned}$$

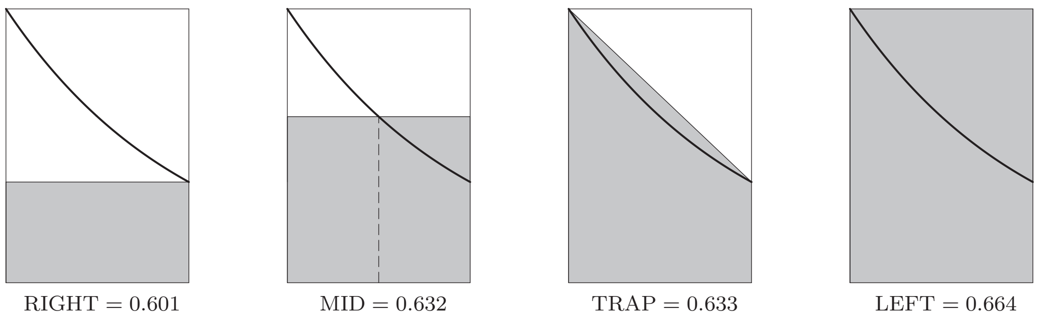
We estimate the distance by estimating this integral.

From the table, we find: $\text{LEFT}(6) = 31$, $\text{RIGHT}(6) = 39$, $\text{TRAP}(6) = 35$.

17. Since the function is decreasing, LEFT is an overestimate and RIGHT is an underestimate. Since the graph is concave down, secant lines lie below the graph so TRAP is an underestimate and tangent lines lie above the graph so MID is an overestimate. We can see that MID and TRAP are closer to the exact value than LEFT and RIGHT. In order smallest to largest, we have:
RIGHT(n) < TRAP(n) < Exact value < MID(n) < LEFT(n).

18. For a decreasing function whose graph is concave up, the diagrams below show that RIGHT < MID < TRAP < LEFT. Thus,

(a) $0.664 =$ LEFT, $0.633 =$ TRAP, $0.632 =$ MID, and $0.601 =$ RIGHT.
(b) $0.632 <$ true value < 0.633.



19. $f(x)$ is increasing, so RIGHT gives an overestimate and LEFT gives an underestimate.

20. $f(x)$ is concave down, so MID gives an overestimate and TRAP gives an underestimate.

21. $f(x)$ is decreasing and concave up, so LEFT and TRAP give overestimates and RIGHT and MID give underestimates.

22. $f(x)$ is concave up, so TRAP gives an overestimate and MID gives an underestimate.

23. (a) Since we are using $n = 2$ on the interval $x = 0$ to $x = 4$, we have $\Delta x = 2$. The midpoint of the first subinterval is 1 and the midpoint of the second subinterval is 3, so we have

$$\text{MID(2)} = 3\sqrt{1} \cdot 2 + 3\sqrt{3} \cdot 2 = 16.392.$$

(b) We have

$$\int_0^4 3x^{1/2} dx = 2x^{3/2}\Big|_0^4 = 2(4^{3/2}) = 16.$$

(c) Error $=$ Actual $-$ Approximation $= 16 - 16.392 = -0.392$.

(d) Since n is multiplied by 10 in going from $n = 2$ to $n = 20$, we expect the error to be multiplied by approximately $1/10^2$. We estimate that

$$\text{Error for MID(20)} \approx \frac{1}{100} \cdot (-0.392) = -0.00392.$$

(e) We expect the approximation for MID(20) to be an overestimate (since $f(x) = 3\sqrt{x}$ is concave down) and to be 0.00392 away from the exact value of 16. We have

$$\text{MID(20)} \approx 16.00392.$$

24. (a) Since $f(x)$ is closer to horizontal (that is, $|f'| < |g'|$), LEFT and RIGHT will be more accurate with $f(x)$.

(b) Since $g(x)$ has more curvature, MID and TRAP will be more accurate with $f(x)$.

25. (a) TRAP(4) gives probably the best estimate of the integral. We cannot calculate MID(4).

$$\text{LEFT(4)} = 3 \cdot 100 + 3 \cdot 97 + 3 \cdot 90 + 3 \cdot 78 = 1095$$
$$\text{RIGHT(4)} = 3 \cdot 97 + 3 \cdot 90 + 3 \cdot 78 + 3 \cdot 55 = 960$$
$$\text{TRAP(4)} = \frac{1095 + 960}{2} = 1027.5.$$

(b) Because there are no points of inflection, the graph is either concave down or concave up. By plotting points, we see that it is concave down. So TRAP(4) is an underestimate.

26. (a) $\displaystyle\int_0^{2\pi} \sin\theta \, d\theta = -\cos\theta\Big|_0^{2\pi} = 0.$

(b) See Figure 7.38. $\text{MID}(1)$ is 0 since the midpoint of 0 and 2π is π, and $\sin\pi = 0$. Thus $\text{MID}(1) = 2\pi(\sin\pi) = 0$. The midpoints we use for $\text{MID}(2)$ are $\pi/2$ and $3\pi/2$, and $\sin(\pi/2) = -\sin(3\pi/2)$. Thus $\text{MID}(2) = \pi\sin(\pi/2) + \pi\sin(3\pi/2) = 0$.

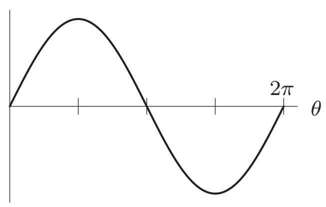


Figure 7.38

(c) $\text{MID}(3) = 0$.

In general, $\text{MID}(n) = 0$ for all n, even though your calculator (because of round-off error) might not return it as such. The reason is that $\sin(x) = -\sin(2\pi - x)$. If we use $\text{MID}(n)$, we will always take sums where we are adding pairs of the form $\sin(x)$ and $\sin(2\pi - x)$, so the sum will cancel to 0. (If n is odd, we will get a $\sin\pi$ in the sum which does not pair up with anything — but $\sin\pi$ is already 0.)

27. See Figure 7.39. We observe that the error in the left or right rule depends on how steeply the graph of f rises or falls. A steep curve makes the triangular regions missed by the left or right rectangles tall and hence large in area. This observation suggests that the error in the left or right rules depends on the magnitude of the derivative of f.

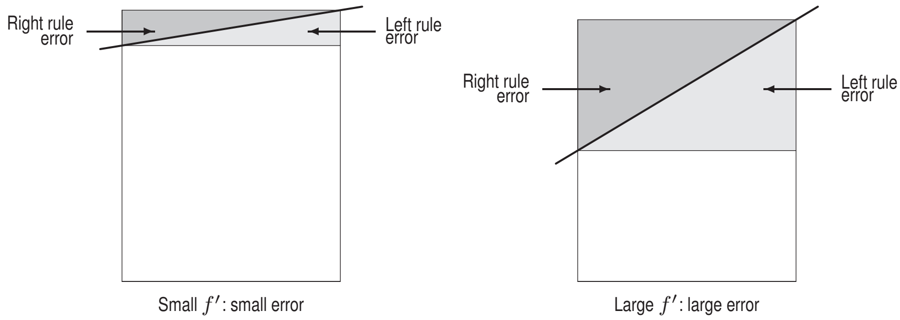

Figure 7.39: The error in the left and right rules depends on the steepness of the curve

28. From Figure 7.40 it appears that the errors in the trapezoid and midpoint rules depend on how much the curve is bent up or down. In other words, the concavity, and hence the magnitude of the second derivative, f'', has an effect on the errors of these two rules.

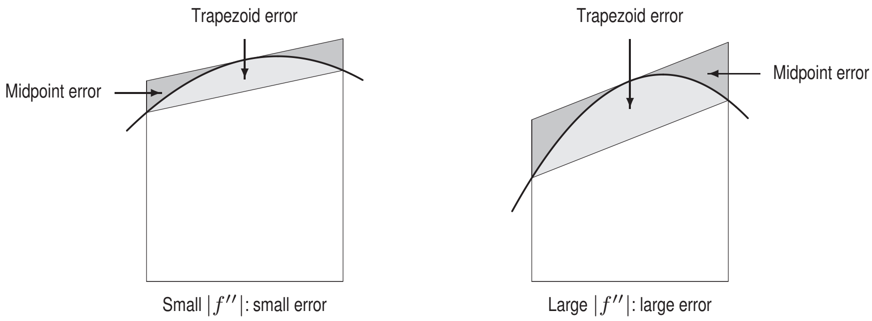

Figure 7.40: The error in the trapezoid and midpoint rules depends on how bent the curve is

29. (a) The graph of $y = \sqrt{2 - x^2}$ is the upper half of a circle of radius $\sqrt{2}$ centered at the origin. The integral represents the area under this curve between the lines $x = 0$ and $x = 1$. From Figure 7.41, we see that this area can be split into 2 parts, A_1 and A_2. Notice since $OQ = QP = 1$, $\triangle OQP$ is isosceles. Thus $\angle POQ = \angle ROP = \frac{\pi}{4}$, and A_1 is exactly $\frac{1}{8}$ of the entire circle. Thus the total area is

$$\text{Area} = A_1 + A_2 = \frac{1}{8}\pi(\sqrt{2})^2 + \frac{1 \cdot 1}{2} = \frac{\pi}{4} + \frac{1}{2}.$$

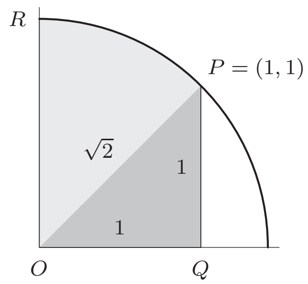

Figure 7.41

(b) $\text{LEFT}(5) \approx 1.32350$, $\text{RIGHT}(5) \approx 1.24066, T$
$\text{TRAP}(5) \approx 1.28208$, $\text{MID}(5) \approx 1.28705$

Exact value ≈ 1.285398163

Left-hand error ≈ -0.03810, Right-hand error ≈ 0.04474,
Trapezoidal error ≈ 0.00332, Midpoint error ≈ -0.001656

Thus right-hand error $>$ trapezoidal error $> 0 >$ midpoint error $>$ left-hand error, and |midpt error| $<$ |trap error| $<$ |left-error| $<$ |right-error|.

30. We approximate the area of the playing field by using Riemann sums. From the data provided,

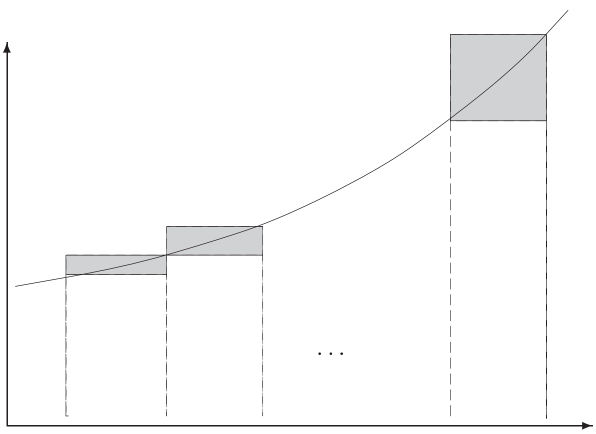
$$\text{LEFT}(10) = \text{RIGHT}(10) = \text{TRAP}(10) = 89{,}000 \text{ square feet.}$$

Thus approximately

$$\frac{89{,}000 \text{ sq. ft.}}{200 \text{ sq. ft./lb.}} = 445 \text{ lbs. of fertilizer}$$

should be necessary.

31.



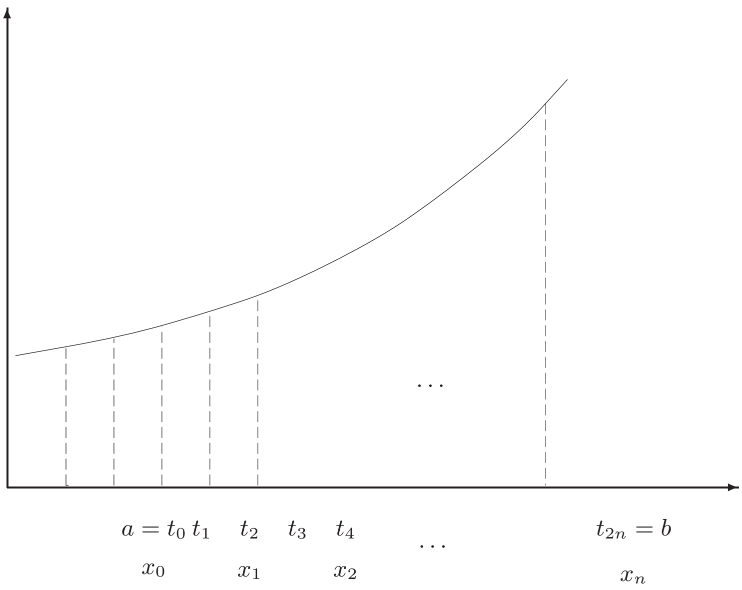
From the diagram, the difference between RIGHT(n) and LEFT(n) is the area of the shaded rectangles.
RIGHT$(n) = f(x_1)\Delta x + f(x_2)\Delta x + \cdots + f(x_n)\Delta x$
LEFT$(n) = f(x_0)\Delta x + f(x_1)\Delta x + \cdots + f(x_{n-1})\Delta x$
Notice that the terms in these two sums are the same, except that RIGHT(n) contains $f(x_n)\Delta x$ $(= f(b)\Delta x)$, and LEFT(n) contains $f(x_0)\Delta x$ $(= f(a)\Delta x)$. Thus

$$\begin{aligned}\text{RIGHT}(n) &= \text{LEFT}(n) + f(x_n)\Delta x - f(x_0)\Delta x \\ &= \text{LEFT}(n) + f(b)\Delta x - f(a)\Delta x\end{aligned}$$

32.

$$\begin{aligned}\text{TRAP}(n) &= \frac{\text{LEFT}(n) + \text{RIGHT}(n)}{2} \\ &= \frac{\text{LEFT}(n) + \text{LEFT}(n) + f(b)\Delta x - f(a)\Delta x}{2} \\ &= \text{LEFT}(n) + \frac{1}{2}(f(b) - f(a))\Delta x\end{aligned}$$

33.



Divide the interval $[a, b]$ into n pieces, by $x_0, x_1, x_2, \ldots, x_n$, and also into $2n$ pieces, by $t_0, t_1, t_2, \ldots, t_{2n}$. Then the x's coincide with the even t's, so $x_0 = t_0,\ x_1 = t_2,\ x_2 = t_4,\ \ldots,\ x_n = t_{2n}$ and $\Delta t = \frac{1}{2}\Delta x$.

$$\text{LEFT}(n) = f(x_0)\Delta x + f(x_1)\Delta x + \cdots + f(x_{n-1})\Delta x$$

Since $\text{MID}(n)$ is obtained by evaluating f at the midpoints $t_1, t_3, t_5, \ldots$ of the x intervals, we get

$$\text{MID}(n) = f(t_1)\Delta x + f(t_3)\Delta x + \cdots + f(t_{2n-1})\Delta x$$

Now

$$\text{LEFT}(2n) = f(t_0)\Delta t + f(t_1)\Delta t + f(t_2)\Delta t + \cdots + f(t_{2n-1})\Delta t.$$

Regroup terms, putting all the even t's first, the odd t's last:

$$\begin{aligned}\text{LEFT}(2n) &= f(t_0)\Delta t + f(t_2)\Delta t + \cdots + f(t_{2n-2})\Delta t + f(t_1)\Delta t + f(t_3)\Delta t + \cdots + f(t_{2n-1})\Delta t \\ &= \underbrace{f(x_0)\frac{\Delta x}{2} + f(x_1)\frac{\Delta x}{2} + \cdots + f(x_{n-1})\frac{\Delta x}{2}}_{\text{LEFT}(n)/2} + \underbrace{f(t_1)\frac{\Delta x}{2} + f(t_3)\frac{\Delta x}{2} + \cdots + f(t_{2n-1})\frac{\Delta x}{2}}_{\text{MID}(n)/2}\end{aligned}$$

So

$$\text{LEFT}(2n) = \frac{1}{2}(\text{LEFT}(n) + \text{MID}(n))$$

34. When $n = 10$, we have $a = 1; b = 2; \Delta x = \frac{1}{10}; f(a) = 1; f(b) = \frac{1}{2}$.
$\text{LEFT}(10) \approx 0.71877, \text{RIGHT}(10) \approx 0.66877, \text{TRAP}(10) \approx 0.69377$
We have
$\text{RIGHT}(10) = \text{LEFT}(10) + f(b)\Delta x - f(a)\Delta x = 0.71877 + \frac{1}{10}(\frac{1}{2}) - \frac{1}{10}(1) = 0.66877$, and $\text{TRAP}(10) = \text{LEFT}(10) + \frac{\Delta x}{2}(f(b) - f(a)) = 0.71877 + \frac{1}{10}\frac{1}{2}(\frac{1}{2} - 1) = 0.69377$,
so the equations are verified.

35. First, we compute:

$$\begin{aligned}(f(b) - f(a))\Delta x &= (f(b) - f(a))\left(\frac{b-a}{n}\right) \\ &= (f(5) - f(2))\left(\frac{3}{n}\right) \\ &= (21 - 13)\left(\frac{3}{n}\right) \\ &= \frac{24}{n}\end{aligned}$$

RIGHT(10) = LEFT(10) + 24 = 3.156 + 2.4 = 5.556.
TRAP(10) = LEFT(10) + $\frac{1}{2}$(2.4) = 3.156 + 1.2 = 4.356.
LEFT(20) = $\frac{1}{2}$(LEFT(10) + MID(10)) = $\frac{1}{2}$(3.156 + 3.242) = 3.199.
RIGHT(20) = LEFT(20) + 2.4 = 3.199 + 1.2 = 4.399.
TRAP(20) = LEFT(20) + $\frac{1}{2}$(1.2) = 3.199 + 0.6 = 3.799.

36. (a) If $f(x) = 1$, then

$$\int_a^b f(x)\,dx = (b-a).$$

Also,

$$\frac{h}{3}\left(\frac{f(a)}{2} + 2f(m) + \frac{f(b)}{2}\right) = \frac{b-a}{3}\left(\frac{1}{2} + 2 + \frac{1}{2}\right) = (b-a).$$

So the equation holds for $f(x) = 1$.

If $f(x) = x$, then

$$\int_a^b f(x)\,dx = \left.\frac{x^2}{2}\right|_a^b = \frac{b^2-a^2}{2}.$$

Also,

$$\begin{aligned}\frac{h}{3}\left(\frac{f(a)}{2} + 2f(m) + \frac{f(b)}{2}\right) &= \frac{b-a}{3}\left(\frac{a}{2} + 2\frac{a+b}{2} + \frac{b}{2}\right)\\ &= \frac{b-a}{3}\left(\frac{a}{2} + a + b + \frac{b}{2}\right)\\ &= \frac{b-a}{3}\left(\frac{3}{2}b + \frac{3}{2}a\right)\\ &= \frac{(b-a)(b+a)}{2}\\ &= \frac{b^2-a^2}{2}.\end{aligned}$$

So the equation holds for $f(x) = x$.

If $f(x) = x^2$, then $\int_a^b f(x)\,dx = \left.\frac{x^3}{3}\right|_a^b = \frac{b^3-a^3}{3}$. Also,

$$\begin{aligned}\frac{h}{3}\left(\frac{f(a)}{2} + 2f(m) + \frac{f(b)}{2}\right) &= \frac{b-a}{3}\left(\frac{a^2}{2} + 2\left(\frac{a+b}{2}\right)^2 + \frac{b^2}{2}\right)\\ &= \frac{b-a}{3}\left(\frac{a^2}{2} + \frac{a^2+2ab+b^2}{2} + \frac{b^2}{2}\right)\\ &= \frac{b-a}{3}\left(\frac{2a^2+2ab+2b^2}{2}\right)\\ &= \frac{b-a}{3}\left(a^2+ab+b^2\right)\\ &= \frac{b^3-a^3}{3}.\end{aligned}$$

So the equation holds for $f(x) = x^2$.

(b) For any quadratic function, $f(x) = Ax^2 + Bx + C$, the "Facts about Sums and Constant Multiples of Integrands" give us:

$$\int_a^b f(x)\,dx = \int_a^b (Ax^2 + Bx + C)\,dx = A\int_a^b x^2\,dx + B\int_a^b x\,dx + C\int_a^b 1\,dx.$$

Now we use the results of part (a) to get:

$$\begin{aligned}\int_a^b f(x)\,dx &= A\frac{h}{3}\left(\frac{a^2}{2} + 2m^2 + \frac{b^2}{2}\right) + B\frac{h}{3}\left(\frac{a}{2} + 2m + \frac{b}{2}\right) + C\frac{h}{3}\left(\frac{1}{2} + 2\cdot 1 + \frac{1}{2}\right)\\ &= \frac{h}{3}\left(\frac{Aa^2+Ba+C}{2} + 2(Am^2+Bm+C) + \frac{Ab^2+Bb+C}{2}\right)\end{aligned}$$

$$= \frac{h}{3}\left(\frac{f(a)}{2} + 2f(m) + \frac{f(b)}{2}\right)$$

37. (a) Suppose $q_i(x)$ is the quadratic function approximating $f(x)$ on the subinterval $[x_i, x_{i+1}]$, and m_i is the midpoint of the interval, $m_i = (x_i + x_{i+1})/2$. Then, using the equation in Problem 36, with $a = x_i$ and $b = x_{i+1}$ and $h = \Delta x = x_{i+1} - x_i$:

$$\int_{x_i}^{x_{i+1}} f(x)dx \approx \int_{x_i}^{x_{i+1}} q_i(x)dx = \frac{\Delta x}{3}\left(\frac{q_i(x_i)}{2} + 2q_i(m_i) + \frac{q_i(x_{i+1})}{2}\right).$$

(b) Summing over all subintervals gives

$$\int_a^b f(x)dx \approx \sum_{i=0}^{n-1}\int_{x_i}^{x_{i+1}} q_i(x)dx = \sum_{i=0}^{n-1}\frac{\Delta x}{3}\left(\frac{q_i(x_i)}{2} + 2q_i(m_i) + \frac{q_i(x_{i+1})}{2}\right).$$

Splitting the sum into two parts:

$$\begin{aligned} &= \frac{2}{3}\sum_{i=0}^{n-1} q_i(m_i)\Delta x + \frac{1}{3}\sum_{i=0}^{n-1}\frac{q_i(x_i)+q_i(x_{i+1})}{2}\Delta x \\ &= \frac{2}{3}\text{MID}(n) + \frac{1}{3}\text{TRAP}(n) \\ &= \text{SIMP}(n). \end{aligned}$$

Strengthen Your Understanding

38. The midpoint rule is exact if the integrand is a linear function.

39. As $n \to \infty$, the error approaches 0, so $\text{TRAP}(n) \to 0$ only if the value of the definite integral is 0.

40. It depends on the concavity. If f is concave up, then $\text{TRAP}(n) \geq \text{MID}(n)$, but if f is concave down, then $\text{TRAP}(n) \leq \text{MID}(n)$.

41. Since the total time for each extra two digits of TRAP goes up by a factor of 10, the total time grows exponentially with the number of digits. Thus there is much more additional time to go from 8 digits to 10 digits than from 1 digit to 3 digits.

42. Since we want RIGHT(10) to be an underestimate of $\int_0^1 f(x)dx$, we use a function $f(x)$ that is decreasing on $[0, 1]$. Since we want MID(10) to be an overestimate of the integral, we make $f(x)$ concave down on $[0, 1]$. The function $f(x) = 1 - x^2$ has both of these features. Since $f(x) = 1 - x^2$ is both decreasing and concave down on $[0, 1]$, we have

$$\text{RIGHT}(10) < \int_0^1 f(x)dx < \text{MID}(10).$$

43. In most cases, increasing the number of subintervals in a Trapezoid Rule approximation makes the approximation more accurate. Therefore, we try a function $f(x)$ for which the Trapezoid Rule overestimates the integral, since it is likely in this case that TRAP(40) is a greater overestimate of $\int_0^{10} f(x)dx$ than TRAP(80). Suppose that $f(x) = e^x$. Then $f(x)$ is concave up, and TRAP(40) and TRAP(80) are both overestimates. However, TRAP(80) is smaller, since all of the trapezoids that make up the estimate TRAP(80) fit inside the trapezoids that make up TRAP(40).

44. True. $y^2 - 1$ is concave up, and the midpoint rule always underestimates for a function that is concave up.

45. False. If the function $f(x)$ is a line, then the trapezoid rule gives the exact answer to $\int_a^b f(x)\,dx$.

46. False. The subdivision size $\Delta x = (1/10)(6 - 2) = 4/10$.

47. True, since $\Delta x = (6 - 2)/n = 4/n$.

48. False. If f is decreasing, then on each subinterval the value of $f(x)$ at the left endpoint is larger than the value at the right endpoint, which means that LEFT(n) >RIGHT(n) for any n.

49. False. As n approaches infinity, LEFT(n) approaches the value of the integral $\int_2^6 f(x)\,dx$, which is generally not 0.

50. True. We have

$$\text{LEFT}(n) - \text{RIGHT}(n) = (f(x_0) + f(x_1) + \cdots + f(x_{n-1}))\Delta x - (f(x_1) + f(x_2) + \cdots + f(x_n))\Delta x.$$

On the right side of the equation, all terms cancel except the first and last, so:

$$\text{LEFT}(n) - \text{RIGHT}(n) = (f(x_0) - f(x_n))\Delta x = (f(2) - f(6))\Delta x.$$

This is also discussed in Section 5.1.

51. True. This follows from the fact that $\Delta x = (6-2)/n = 4/n$.

52. False. Since $\text{LEFT}(n) - \text{RIGHT}(n) = (f(2) - f(6))\Delta x$, we have $\text{LEFT}(n) = \text{RIGHT}(n)$ for any function such that $f(2) = f(6)$. Such a function, for example $f(x) = (x-4)^2$, need not be a constant function.

53. False. Although TRAP(n) is usually a better estimate, it is not always better. If $f(2) = f(6)$, then $\text{LEFT}(n) = \text{RIGHT}(n)$ and hence $\text{TRAP}(n) = \text{LEFT}(n) = \text{RIGHT}(n)$, so in this case TRAP$(n)$ is no better.

54. False. This is true if f is an increasing function or if f is a decreasing function, but it is not true in general. For example, suppose that $f(2) = f(6)$. Then $\text{LEFT}(n) = \text{RIGHT}(n)$ for all n, which means that if $\int_2^6 f(x)\,dx$ lies between LEFT(n) and RIGHT(n), then it must equal LEFT(n), which is not always the case.

For example, if $f(x) = (x-4)^2$ and $n = 1$, then $f(2) = f(6) = 4$, so

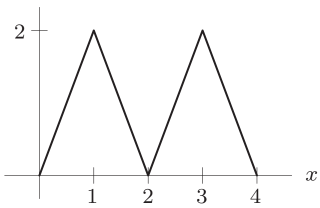
$$\text{LEFT}(1) = \text{RIGHT}(1) = 4 \cdot (6-2) = 16.$$

However

$$\int_2^6 (x-4)^2\,dx = \left.\frac{(x-4)^3}{3}\right|_2^6 = \frac{2^3}{3} - \left(-\frac{2^3}{3}\right) = \frac{16}{3}.$$

In this example, since $\text{LEFT}(n) = \text{RIGHT}(n)$, we have $\text{TRAP}(n) = \text{LEFT}(n)$. However trapezoids overestimate the area, since the graph of f is concave up. This is also discussed in Section 7.5.

55. False. Suppose f is the following:



Then $\text{LEFT}(2) = 0$, $\text{LEFT}(4) = 4$, and

$$\int_a^b f(x)\,dx = 4.$$

56. True. Since f' and g' are greater than 0, all left rectangles give underestimates. The bigger the derivative, the bigger the underestimate, so the bigger the error. (Note: if we did not have $0 < f' < g'$, but instead just had $f' < g'$, the statement would not necessarily be true. This is because some left rectangles could be overestimates and some could be underestimates–so, for example, it could be that the error in approximating g is 0! If $0 < f' < g'$, however, this can't happen.

Solutions for Section 7.6

Exercises

1. (a) See Figure 7.42. The area extends out infinitely far along the positive x-axis.

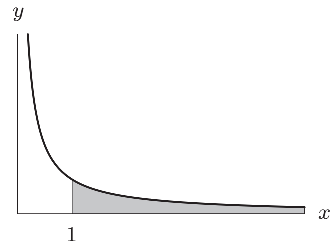


Figure 7.42

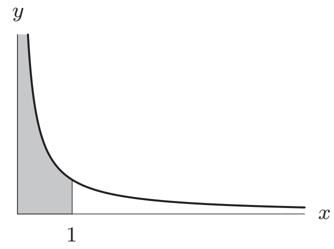

Figure 7.43

(b) See Figure 7.43. The area extends up infinitely far along the positive y-axis.

2. We have

$$\int_0^\infty e^{-0.4x}dx = \lim_{b\to\infty}\int_0^b e^{-0.4x}dx = \lim_{b\to\infty}(-2.5e^{-0.4x})\big|_0^b = \lim_{b\to\infty}(-2.5e^{-0.4b} + 2.5).$$

As $b \to \infty$, we know $e^{-0.4b} \to 0$ and so we see that the integral converges to 2.5. See Figure 7.44. The area continues indefinitely out to the right.

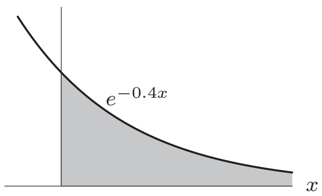

Figure 7.44

3. (a) We use a calculator or computer to evaluate the integrals.
When $b = 5$, we have $\int_0^5 xe^{-x}dx = 0.9596$.
When $b = 10$, we have $\int_0^{10} xe^{-x}dx = 0.9995$.
When $b = 20$, we have $\int_0^{20} xe^{-x}dx = 0.99999996$.

(b) It appears from the answers to part (a) that $\int_0^\infty xe^{-x}dx = 1.0$.

4. (a) See Figure 7.45. The total area under the curve is shaded.

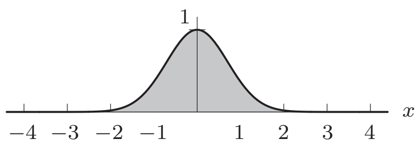

Figure 7.45

(b) When $a = 1$, we use a calculator or computer to see that $\int_{-1}^1 e^{-x^2}dx = 1.49365$.
Similarly, we have:
When $a = 2$, the value of the integral is 1.76416.
When $a = 3$, the value of the integral is 1.77241.
When $a = 4$, the value of the integral is 1.77245.
When $a = 5$, the value of the integral is 1.77245.

(c) It appears that the integral $\int_{-\infty}^\infty e^{-x^2}dx$ converges to approximately 1.77245.

5. We have

$$\int_1^\infty \frac{1}{5x+2}dx = \lim_{b\to\infty}\int_1^b \frac{1}{5x+2}dx = \lim_{b\to\infty}\left(\frac{1}{5}\ln(5x+2)\right)\Big|_1^b = \lim_{b\to\infty}\left(\frac{1}{5}\ln(5b+2)-\frac{1}{5}\ln(7)\right).$$

As $b \leftarrow \infty$, we know that $\ln(5b+2)\to\infty$, and so this integral diverges.

6. We have

$$\int_1^\infty \frac{1}{(x+2)^2}dx = \lim_{b\to\infty}\int_1^b \frac{1}{(x+2)^2}dx = \lim_{b\to\infty}\left(\frac{-1}{x+2}\right)\Big|_1^b = \lim_{b\to\infty}\left(\frac{-1}{b+2}-\frac{-1}{3}\right) = 0+\frac{1}{3}=\frac{1}{3}.$$

This integral converges to $1/3$.

7. This integral is improper at the lower end, so

$$\begin{aligned}\int_0^1 \ln x\,dx &= \lim_{a\to0^+}\int_a^1 \ln x\,dx\\ &= \lim_{a\to0^+}(x\ln x - x)\Big|_a^1\\ &= \lim_{a\to0^+}(1\ln 1-1)-(a\ln a-a))\\ &= -1+\lim_{a\to0^+} a(1-\ln a)\\ &= -1+\lim_{a\to0^+}\frac{1-\ln a}{a^{-1}}\\ &= -1+\lim_{a\to0^+}\frac{-1/a}{-1/a^2}\quad\text{by l'Hopital}\\ &= -1+\lim_{a\to0^+} a\\ &= -1.\end{aligned}$$

If the integral converges, we'd expect it to have a negative value because the logarithm graph is below the x-axis for $0<x<1$.

8. Use the substitution $w=\sqrt{x}$. Since $dw=\frac{1}{2}x^{-1/2}\,dx$, we have $dx=2w\,dw$, so

$$\int e^{-\sqrt{x}}\,dx = 2\int we^{-w}\,dw.$$

Note that this substitution leaves the limits unchanged. Using integration by parts with $u=w$ and $v'=e^{-w}$, we find that

$$\begin{aligned}2\int we^{-w}\,dw &= 2\left[-we^{-w}+\int e^{-w}\,dw\right]\\ &= 2[-we^{-w}-e^{-w}].\end{aligned}$$

So,

$$\begin{aligned}\int_0^\infty we^{-w}\,dx &= \lim_{b\to\infty}2\left[-we^{-w}-e^{-w}\right]_0^b\\ &= 2\lim_{b\to\infty}(-be^{-b}-e^{-b}+1)\\ &= 2\left[\lim_{b\to\infty}-\frac{b+1}{e^b}+1\right]\\ &= 2\left[\lim_{b\to\infty}-\frac{1}{e^b}+1\right]\quad\text{by l'Hopital}\\ &= 2.\end{aligned}$$

9. We have

$$\int_0^\infty xe^{-x^2}dx = \lim_{b\to\infty}\int_0^b xe^{-x^2}dx = \lim_{b\to\infty}\left(\frac{-1}{2}e^{-x^2}\right)\Big|_0^b = \lim_{b\to\infty}\left(\frac{-1}{2}e^{-b^2}-\frac{-1}{2}\right) = 0+\frac{1}{2}=\frac{1}{2}.$$

This integral converges to $1/2$.

10.

$$\int_1^\infty e^{-2x}\,dx = \lim_{b\to\infty}\int_1^b e^{-2x}\,dx = \lim_{b\to\infty} -\frac{e^{-2x}}{2}\bigg|_1^b$$
$$= \lim_{b\to\infty}(-e^{-2b}/2 + e^{-2}/2) = 0 + e^{-2}/2 = e^{-2}/2,$$

where the first limit is 0 because $\lim_{x\to\infty} e^{-x} = 0$.

11. Using integration by parts with $u = x$ and $v' = e^{-x}$, we find that

$$\int xe^{-x}\,dx = -xe^{-x} - \int -e^{-x}dx = -(1+x)e^{-x}$$

so

$$\begin{aligned}\int_0^\infty \frac{x}{e^x}\,dx &= \lim_{b\to\infty}\int_0^b \frac{x}{e^x}\,dx \\ &= \lim_{b\to\infty} -1(1+x)e^{-x}\bigg|_0^b \\ &= \lim_{b\to\infty}\left[1-(1+b)e^{-b}\right] \\ &= 1.\end{aligned}$$

12.

$$\int_1^\infty \frac{x}{4+x^2} = \lim_{b\to\infty}\int_1^b \frac{x}{4+x^2}\,dx = \lim_{b\to\infty}\frac{1}{2}\ln|4+x^2|\bigg|_1^b = \lim_{b\to\infty}\frac{1}{2}\ln|4+b^2| - \frac{1}{2}\ln 5.$$

As $b\to\infty$, $\ln|4+b^2|\to\infty$, so the limit diverges.

13.

$$\begin{aligned}\int_{-\infty}^0 \frac{e^x}{1+e^x}\,dx &= \lim_{b\to-\infty}\int_b^0 \frac{e^x}{1+e^x}\,dx \\ &= \lim_{b\to-\infty}\ln|1+e^x|\bigg|_b^0 \\ &= \lim_{b\to-\infty}[\ln|1+e^0| - \ln|1+e^b|] \\ &= \ln(1+1)-\ln(1+0) = \ln 2.\end{aligned}$$

14. First, we note that $1/(z^2+25)$ is an even function. Therefore,

$$\int_{-\infty}^\infty \frac{dz}{z^2+25} = \int_{-\infty}^0 \frac{dz}{z^2+25} + \int_0^\infty \frac{dz}{z^2+25} = 2\int_0^\infty \frac{dz}{z^2+25}.$$

We'll now evaluate this improper integral by using a limit:

$$\int_0^\infty \frac{dz}{z^2+25} = \lim_{b\to\infty}\left(\frac{1}{5}\arctan(b/5) - \frac{1}{5}\arctan(0)\right) = \frac{1}{5}\cdot\frac{\pi}{2} = \frac{\pi}{10}.$$

So the original integral is twice that, namely $\pi/5$.

15. This integral is improper because $1/\sqrt{x}$ is undefined at $x=0$. Then

$$\int_0^4 \frac{1}{\sqrt{x}}\,dx = \lim_{b\to0^+}\int_b^4 \frac{1}{\sqrt{x}}\,dx = \lim_{b\to0^+}\left(2\sqrt{x}\bigg|_b^4\right) = \lim_{b\to0^+}\left(4-2\sqrt{b}\right) = 4.$$

The integral converges.

16.

$$\begin{aligned}\int_{\pi/4}^{\pi/2} \frac{\sin x}{\sqrt{\cos x}}\,dx &= \lim_{b\to\pi/2^-} \int_{\pi/4}^{b} \frac{\sin x}{\sqrt{\cos x}}\,dx \\ &= \lim_{b\to\pi/2^-} -\int_{\pi/4}^{b} (\cos x)^{-1/2}(-\sin x)\,dx \\ &= \lim_{b\to\pi/2^-} -2(\cos x)^{1/2}\Big|_{\pi/4}^{b} \\ &= \lim_{b\to\pi/2^-} [-2(\cos b)^{1/2} + 2(\cos\pi/4)^{1/2}] \\ &= 2\left(\frac{\sqrt{2}}{2}\right)^{\frac{1}{2}} = 2^{\frac{3}{4}}.\end{aligned}$$

17. This integral is improper because $1/v$ is undefined at $v = 0$. Then

$$\int_0^1 \frac{1}{v}\,dv = \lim_{b\to 0^+} \int_b^1 \frac{1}{v}\,dv = \lim_{b\to 0^+} \left(\ln v\Big|_b^1\right) = -\ln b.$$

As $b \to 0^+$, this goes to infinity and the integral diverges.

18.

$$\lim_{a\to 0^+} \int_a^1 \frac{x^4+1}{x}\,dx = \lim_{a\to 0^+} \left(\frac{x^4}{4} + \ln x\right)\Big|_a^1 = \lim_{a\to 0^+} [1/4 - (a^4/4 + \ln a)],$$

which diverges as $a \to 0$, since $\ln a \to -\infty$.

19.

$$\begin{aligned}\int_1^\infty \frac{1}{x^2+1}\,dx &= \lim_{b\to\infty} \int_1^b \frac{1}{x^2+1}\,dx \\ &= \lim_{b\to\infty} \arctan(x)\Big|_1^b \\ &= \lim_{b\to\infty} [\arctan(b) - \arctan(1)] \\ &= \pi/2 - \pi/4 = \pi/4.\end{aligned}$$

20.

$$\begin{aligned}\int_1^\infty \frac{1}{\sqrt{x^2+1}}\,dx &= \lim_{b\to\infty} \int_1^b \frac{1}{\sqrt{x^2+1}}\,dx \\ &= \lim_{b\to\infty} \ln|x + \sqrt{x^2+1}|\Big|_1^b \\ &= \lim_{b\to\infty} \ln(b + \sqrt{b^2+1}) - \ln(1+\sqrt{2}).\end{aligned}$$

As $b \to \infty$, this limit does not exist, so the integral diverges.

21. We use V-26 with $a = 4$ and $b = -4$:

$$\begin{aligned}\int_0^4 \frac{-1}{u^2-16}\,du &= \lim_{b\to 4^-} \int_0^b \frac{-1}{u^2-16}\,du \\ &= \lim_{b\to 4^-} \int_0^b \frac{-1}{(u-4)(u+4)}\,du \\ &= \lim_{b\to 4^-} \frac{-(\ln|u-4| - \ln|u+4|)}{8}\Big|_0^b \\ &= \lim_{b\to 4^-} -\frac{1}{8}\left(\ln|b-4| + \ln 4 - \ln|b+4| - \ln 4\right).\end{aligned}$$

As $b \to 4^-$, $\ln|b-4| \to -\infty$, so the limit does not exist and the integral diverges.

22.

$$\int_1^\infty \frac{y}{y^4+1}\,dy = \lim_{b\to\infty} \frac{1}{2}\int_1^b \frac{2y}{(y^2)^2+1}\,dy$$
$$= \lim_{b\to\infty} \frac{1}{2}\arctan(y^2)\Big|_1^b$$
$$= \lim_{b\to\infty} \frac{1}{2}[\arctan(b^2) - \arctan 1]$$
$$= (1/2)[\pi/2 - \pi/4] = \pi/8.$$

23. With the substitution $w = \ln x$, $dw = \frac{1}{x}dx$,

$$\int \frac{dx}{x\ln x} = \int \frac{1}{w}\,dw = \ln|w| + C = \ln|\ln x| + C$$

so

$$\int_2^\infty \frac{dx}{x\ln x} = \lim_{b\to\infty}\int_2^b \frac{dx}{x\ln x}$$
$$= \lim_{b\to\infty} \ln|\ln x|\Big|_2^b$$
$$= \lim_{b\to\infty} [\ln|\ln b| - \ln|\ln 2|].$$

As $b \to \infty$, the limit goes to ∞ and hence the integral diverges.

24. With the substitution $w = \ln x$, $dw = \frac{1}{x}dx$,

$$\int \frac{\ln x}{x}\,dx = \int w\,dw = \frac{1}{2}w^2 + C = \frac{1}{2}(\ln x)^2 + C$$

so

$$\int_0^1 \frac{\ln x}{x}\,dx = \lim_{a\to 0^+}\int_a^1 \frac{\ln x}{x}\,dx = \lim_{a\to 0^+} \frac{1}{2}[\ln(x)]^2\Big|_a^1 = \lim_{a\to 0^+} -\frac{1}{2}[\ln(a)]^2.$$

As $a \to 0^+$, $\ln a \to -\infty$, so the integral diverges.

25. This is a proper integral; use V-26 in the integral table with $a = 4$ and $b = -4$.

$$\int_{16}^{20} \frac{1}{y^2-16}\,dy = \int_{16}^{20} \frac{1}{(y-4)(y+4)}\,dy$$
$$= \frac{\ln|y-4| - \ln|y+4|}{8}\Big|_{16}^{20}$$
$$= \frac{\ln 16 - \ln 24 - (\ln 12 - \ln 20)}{8}$$
$$= \frac{\ln 320 - \ln 288}{8} = \frac{1}{8}\ln(10/9) = 0.01317.$$

26. Using the substitution $w = -x^{\frac{1}{2}}$, $-2dw = x^{-\frac{1}{2}}\,dx$,

$$\int e^{-x^{\frac{1}{2}}} x^{-\frac{1}{2}}\,dx = -2\int e^w\,dw = -2e^{-x^{\frac{1}{2}}} + C.$$

So

$$\int_0^\pi \frac{1}{\sqrt{x}}e^{-\sqrt{x}}\,dx = \lim_{b\to 0^+}\int_b^\pi \frac{1}{\sqrt{x}}e^{-\sqrt{x}}\,dx$$
$$= \lim_{b\to 0^+} -2e^{-\sqrt{x}}\Big|_b^\pi$$
$$= 2 - 2e^{-\sqrt{\pi}}.$$

27. Letting $w = \ln x$, $dw = \frac{1}{x}dx$,

$$\int \frac{dx}{x(\ln x)^2} = \int w^{-2}dw = -w^{-1} + C = -\frac{1}{\ln x} + C,$$

so

$$\begin{aligned}\int_3^\infty \frac{dx}{x(\ln x)^2} &= \lim_{b\to\infty}\int_3^b \frac{dx}{x(\ln x)^2}\\ &= \lim_{b\to\infty}\left(-\frac{1}{\ln b} + \frac{1}{\ln 3}\right)\\ &= \frac{1}{\ln 3}.\end{aligned}$$

28.

$$\begin{aligned}\int_0^2 \frac{1}{\sqrt{4-x^2}}\,dx &= \lim_{b\to 2^-}\int_0^b \frac{1}{\sqrt{4-x^2}}\,dx\\ &= \lim_{b\to 2^-} \arcsin\frac{x}{2}\bigg|_0^b\\ &= \lim_{b\to 2^-} \arcsin\frac{b}{2} = \arcsin 1 = \frac{\pi}{2}.\end{aligned}$$

29. $\displaystyle\int_4^\infty \frac{dx}{(x-1)^2} = \lim_{b\to\infty}\int_4^b \frac{dx}{(x-1)^2} = \lim_{b\to\infty} -\frac{1}{(x-1)}\bigg|_4^b = \lim_{b\to\infty}\left[-\frac{1}{b-1} + \frac{1}{3}\right] = \frac{1}{3}.$

30. $\displaystyle\int \frac{dx}{x^2-1} = \int \frac{dx}{(x-1)(x+1)} = \frac{1}{2}(\ln|x-1| - \ln|x+1|) + C = \frac{1}{2}\left(\ln\frac{|x-1|}{|x+1|}\right) + C$, so

$$\begin{aligned}\int_4^\infty \frac{dx}{x^2-1} &= \lim_{b\to\infty}\int_4^b \frac{dx}{x^2-1}\\ &= \lim_{b\to\infty}\frac{1}{2}\left(\ln\frac{|x-1|}{|x+1|}\right)\bigg|_4^b\\ &= \lim_{b\to\infty}\left[\frac{1}{2}\ln\left(\frac{b-1}{b+1}\right) - \frac{1}{2}\ln\frac{3}{5}\right]\\ &= -\frac{1}{2}\ln\frac{3}{5} = \frac{1}{2}\ln\frac{5}{3}.\end{aligned}$$

31.

$$\begin{aligned}\int_7^\infty \frac{dy}{\sqrt{y-5}} &= \lim_{b\to\infty}\int_7^b \frac{dy}{\sqrt{y-5}}\\ &= \lim_{b\to\infty} 2\sqrt{y-5}\bigg|_7^b\\ &= \lim_{b\to\infty}(2\sqrt{b-5} - 2\sqrt{2}).\end{aligned}$$

As $b \to \infty$, this limit goes to ∞, so the integral diverges.

32. The integrand is undefined at $y = 3$.

$$\begin{aligned}\int_0^3 \frac{y\,dy}{\sqrt{9-y^2}} &= \lim_{b\to 3^-}\int_0^b \frac{y}{\sqrt{9-y^2}}\,dy = \lim_{b\to 3^-}\left(-(9-y^2)^{1/2}\right)\bigg|_0^b\\ &= \lim_{b\to 3^-}\left(3 - (9-b^2)^{1/2}\right) = 3.\end{aligned}$$

33. The integrand is undefined at $\theta = 4$, so we must split the integral there.

$$\int_4^6 \frac{d\theta}{(4-\theta)^2} = \lim_{a\to 4^+} \int_a^6 \frac{d\theta}{(4-\theta)^2} = \lim_{a\to 4^+} (4-\theta)^{-1}\Big|_a^6 = \lim_{a\to 4^+} \left(\frac{1}{-2} - \frac{1}{4-a}\right).$$

Since $1/(4-a) \to -\infty$ as $a \to 4$ from the right, the integral does not converge. It is not necessary to check the convergence of $\int_3^4 \frac{d\theta}{(4-\theta)^2}$. However, we could have started with $\int_3^4 \frac{d\theta}{(4-\theta)^2}$, instead of $\int_4^6 \frac{d\theta}{(4-\theta)^2}$, and arrived at the same conclusion.

Problems

34. We have

$$\begin{aligned} f(x) &= \int_{-\infty}^{x} e^t\,dt \\ &= \lim_{a\to-\infty} \int_a^x e^t\,dt \\ &= \lim_{a\to-\infty} (e^x - e^a) \\ &= e^x - \underbrace{\lim_{a\to-\infty} e^a}_{0} \\ &= e^x. \end{aligned}$$

35. (a) There is no simple antiderivative for this integrand, so we use numerical methods. We find

$$P(1) = \frac{1}{\sqrt{\pi}} \int_0^1 e^{-t^2}\,dt = 0.421.$$

(b) To calculate this improper integral, use numerical methods. If you cannot input infinity into your calculator, increase the upper limit until the value of the integral settles down. We find

$$P(\infty) = \frac{1}{\sqrt{\pi}} \int_0^\infty e^{-t^2}\,dt = 0.500.$$

36. Since the graph is above the x-axis for $x \ge 0$, we have

$$\begin{aligned} \text{Area } &= \int_0^\infty xe^{-x}\,dx = \lim_{b\to\infty} \int_0^b xe^{-x}\,dx \\ &= \lim_{b\to\infty} \left(-xe^{-x}\Big|_0^b + \int_0^b e^{-x}\,dx \right) \\ &= \lim_{b\to\infty} \left(-be^{-b} - e^{-x}\Big|_0^b \right) \\ &= \lim_{b\to\infty} (-be^{-b} - e^{-b} + e^0) = 1. \end{aligned}$$

37. The curve has an asymptote at $t = \frac{\pi}{2}$, and so the area integral is improper there.

$$\text{Area } = \int_0^{\frac{\pi}{2}} \frac{dt}{\cos^2 t} = \lim_{b\to\frac{\pi}{2}} \int_0^b \frac{dt}{\cos^2 t} = \lim_{b\to\frac{\pi}{2}} \tan t \Big|_0^b,$$

which diverges. Therefore the area is infinite.

38. We have:

$$f(3) = \int_0^\infty 3^{-t}dt = \lim_{b\to\infty} \int_0^b 3^{-t}dt = \lim_{b\to\infty} -\frac{1}{\ln 3} 3^{-t}\Big|_0^b = \lim_{b\to\infty} -\frac{1}{\ln 3}\left(3^{-b} - 3^0\right) = \frac{1}{\ln 3} = 0.910.$$

(Since $\lim_{b\to\infty} 3^{-b} = 0$.)

39. We have:

$$f(3) = \int_1^\infty t^{-3}dt = \lim_{b\to\infty}\int_1^b t^{-3}dt = \lim_{b\to\infty} -\frac{1}{2}t^{-2}\bigg|_1^b = \lim_{b\to\infty} -\frac{1}{2}\left(b^{-2}-1\right) = \frac{1}{2}.$$

(Since $\lim\limits_{b\to\infty} b^{-2} = 0$.)

40. We have:

$$f(3) = \int_0^\infty 3e^{-3t}\,dt = 3\lim_{b\to\infty}\int_0^b e^{-3t}\,dt = 3\left(-\frac{1}{3}\right)\lim_{b\to\infty} e^{-3t}\bigg|_0^b = -\lim_{b\to\infty}\left(e^{-3b}-1\right) = -(-1) = 1.$$

41. We have:

$$f(3) = \int_0^\infty 2t\cdot 3e^{-t(3)^2}\,dt = \int_0^\infty 6te^{-9t}\,dt = 6\lim_{b\to\infty}\int_0^b te^{-9t}\,dt.$$

Integration by parts with $u = t, du = dt, dv = e^{-9t}dt, v = (-1/9)e^{-9t}$ gives:

$$\int te^{-9t}\,dt = t\left(-\frac{1}{9}\right)e^{-9t} - \int\left(-\frac{1}{9}\right)e^{-9t}dt = -\frac{1}{9}te^{-9t} - \frac{1}{81}e^{-9t} + C.$$

Thus:

$$f(3) = 6\lim_{b\to\infty}\left(-\frac{1}{9}te^{-9t} - \frac{1}{81}e^{-9t}\right)\bigg|_0^b = 6\left(0+\frac{1}{81}\right) = \frac{2}{27}.$$

42. (a) We have

$$\int_0^\infty \frac{e^{-y/\alpha}}{\alpha}\,dy = \lim_{b\to\infty} -e^{-y/\alpha}\bigg|_0^b = \lim_{b\to\infty}(1-e^{-b/\alpha}) = 1.$$

(b) Using integration by parts with $u = y$ and $v' = (1/\alpha)e^{-y/\alpha}$, so $u' = 1$, $v = -e^{-y/\alpha}$, we have

$$\begin{aligned}\int_0^\infty \frac{ye^{-y/\alpha}}{\alpha}\,dy &= \lim_{b\to\infty}\int_0^b \frac{ye^{-y/\alpha}}{\alpha}\,dy\\ &= \lim_{b\to\infty}\left(-ye^{-y/\alpha}\bigg|_0^b + \int_0^b e^{-y/\alpha}\,dy\right)\\ &= \lim_{b\to\infty}\left(-be^{-b/\alpha} - \alpha e^{-y/\alpha}\bigg|_0^b\right)\\ &= \lim_{b\to\infty}(-be^{-b/\alpha} - \alpha e^{-b/\alpha} + \alpha)\end{aligned}$$

Since $\lim_{b\to\infty} -be^{-b/\alpha} = \lim_{b\to\infty} e^{-b/\alpha} = 0$, we have

$$\int \frac{ye^{-y/\alpha}}{\alpha}\,dy = \alpha.$$

(c) Using integration by parts, this time with $u = y^2$, $v' = (1/\alpha)e^{-y/\alpha}$, so $u' = 2y$, $v = -e^{-y/\alpha}$, we have

$$\begin{aligned}\int_0^\infty \frac{y^2e^{-y/\alpha}}{\alpha}\,dy &= \lim_{b\to\infty}\int_0^b \frac{y^2e^{-y/\alpha}}{\alpha}\,dy\\ &= \lim_{b\to\infty}\left(-y^2e^{-y/\alpha}\bigg|_0^b + 2\int_0^b ye^{-y/\alpha}\,dy\right)\\ &= \lim_{b\to\infty} -b^2e^{-b/\alpha} + 2\int_0^\infty ye^{-y/\alpha}\,dy\end{aligned}$$

Now $\lim_{b\to\infty} -b^2e^{-b/\alpha} = 0$ and in part (b) we found

$$\int_0^\infty \frac{ye^{-y/\alpha}}{\alpha}\,dy = \alpha,$$

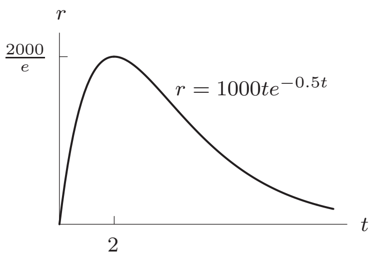
so

$$\int_0^\infty ye^{-y/\alpha}\,dy = \alpha^2.$$

Thus,

$$\int_0^\infty \frac{y^2e^{-y/\alpha}}{\alpha}\,dy = 2\int_0^\infty ye^{-y/\alpha}\,dy = 2\alpha^2.$$

43. (a) Using a calculator or a computer, the graph is:



(b) People are getting sick fastest when the rate of infection is highest, i.e. when r is at its maximum. Since

$$\begin{aligned} r' &= 1000e^{-0.5t} - 1000(0.5)te^{-0.5t} \\ &= 500e^{-0.5t}(2-t) \end{aligned}$$

this must occur at $t = 2$.

(c) The total number of sick people $= \displaystyle\int_0^\infty 1000te^{-0.5t}\,dt$.

Using integration by parts, with $u = t$, $v' = e^{-0.5t}$:

$$\begin{aligned} \text{Total} &= \lim_{b\to\infty} 1000\left(\frac{-t}{0.5}e^{-0.5t}\Big|_0^b - \int_0^b \frac{-1}{0.5}e^{-0.5t}\,dt\right) \\ &= \lim_{b\to\infty} 1000\left(-2be^{-0.5b} - \frac{2}{0.5}e^{-0.5b}\right)\Big|_0^b \\ &= \lim_{b\to\infty} 1000\left(-2be^{-0.5b} - 4e^{-0.5b} + 4\right) \\ &= 4000 \text{ people.} \end{aligned}$$

44. The energy required is

$$\begin{aligned} E &= \int_1^\infty \frac{kq_1q_2}{r^2}\,dr = kq_1q_2 \lim_{b\to\infty} -\frac{1}{r}\Big|_1^b \\ &= (9\times 10^9)(1)(1)(1) = 9\times 10^9 \text{ joules} \end{aligned}$$

45. We let $t = (x-a)/\sqrt{b}$. This means that $dt = dx/\sqrt{b}$, and that $t = \pm\infty$ when $x = \pm\infty$. We have

$$\int_{-\infty}^\infty e^{-(x-a)^2/b}\,dx = \int_{-\infty}^\infty e^{-t^2}\,(\sqrt{b}\,dt) = \sqrt{b}\int_{-\infty}^\infty e^{-t^2}\,dt = \sqrt{b}\sqrt{\pi} = \sqrt{b\pi}.$$

46. Applying integration by parts with $u = e^{-x^2/2}$ and $v' = g'(x)$, so $u' = -xe^{-x^2/2}$ and $v = g(x)$, we have

$$\int_{-\infty}^\infty g'(x)e^{-x^2/2}\,dx = g(x)e^{-x^2/2}\Big|_{-\infty}^\infty - \int_{-\infty}^\infty -xe^{-x^2/2}g(x)\,dx.$$

Since $g(x)$ is bounded, $\lim_{x\to\infty} g(x)e^{-x^2/2} = \lim_{x\to-\infty} g(x)e^{-x^2/2} = 0$. Thus

$$\int_{-\infty}^\infty g'(x)e^{-x^2/2}\,dx = \int_{-\infty}^\infty xg(x)e^{-x^2/2}\,dx.$$

47. Make the substitution $w = 2x$, so $dw = 2\,dx$ and $x = w/2$. When $x = 0$, $w = 0$ and when $x \to \infty$, we have $w \to \infty$. We have

$$\begin{aligned}\int_0^\infty \frac{x^4 e^{2x}}{(e^{2x}-1)^2}\,dx &= \int_0^\infty \frac{(w/2)^4 e^w}{(e^w-1)^2}\,dw/2\\ &= \frac{1}{32}\int_0^\infty \frac{w^4 e^w}{(e^w-1)^2}\,dw\\ &= \frac{1}{32}\frac{4\pi^4}{15} = \frac{\pi^4}{120}.\end{aligned}$$

48. (a)

$$\begin{aligned}\Gamma(1) &= \int_0^\infty e^{-t}\,dt\\ &= \lim_{b\to\infty}\int_0^b e^{-t}\,dt\\ &= \lim_{b\to\infty} -e^{-t}\Big|_0^b\\ &= \lim_{b\to\infty}[1-e^{-b}] = 1.\end{aligned}$$

Using Problem 11,

$$\Gamma(2) = \int_0^\infty te^{-t}\,dt = 1.$$

(b) We integrate by parts. Let $u = t^n$, $v' = e^{-t}$. Then $u' = nt^{n-1}$ and $v = -e^{-t}$, so

$$\int t^n e^{-t}\,dt = -t^n e^{-t} + n\int t^{n-1}e^{-t}\,dt.$$

So

$$\begin{aligned}\Gamma(n+1) &= \int_0^\infty t^n e^{-t}\,dt\\ &= \lim_{b\to\infty}\int_0^b t^n e^{-t}\,dt\\ &= \lim_{b\to\infty}\Big[-t^n e^{-t}\Big|_0^b + n\int_0^b t^{n-1}e^{-t}\,dt\Big]\\ &= \lim_{b\to\infty} -b^n e^{-b} + \lim_{b\to\infty} n\int_0^b t^{n-1}e^{-t}\,dt\\ &= 0 + n\int_0^\infty t^{n-1}e^{-t}\,dt\\ &= n\Gamma(n).\end{aligned}$$

(c) We already have $\Gamma(1) = 1$ and $\Gamma(2) = 1$. Using $\Gamma(n+1) = n\Gamma(n)$ we can get

$$\begin{aligned}\Gamma(3) &= 2\Gamma(2) = 2\\ \Gamma(4) &= 3\Gamma(3) = 3\cdot 2\\ \Gamma(5) &= 4\Gamma(4) = 4\cdot 3\cdot 2.\end{aligned}$$

So it appears that $\Gamma(n)$ is just the first $n-1$ numbers multiplied together, so $\Gamma(n) = (n-1)!$.

Strengthen Your Understanding

49. Let $f(x) = g(x) = 1/x$. Then both $\int_1^\infty f(x)\,dx$ and $\int_1^\infty g(x)\,dx$ diverge, but $\int_1^\infty f(x)g(x)\,dx = \int_1^\infty 1/x^2\,dx$, which converges.

50. If $f(x) = 1/x$, then $\int_1^\infty f(x)\,dx$ diverges, but $\lim_{x\to\infty} f(x) = 0$.

51. The function $f(x) = 1/x$ is an example. We know that $\lim_{x\to\infty} 1/x = 0$, but

$$\int_1^\infty \frac{1}{x}dx = \lim_{b\to\infty} \int_1^b \frac{1}{x}dx = \lim_{b\to\infty} (\ln b - \ln 1) = \infty.$$

Thus the improper integral diverges.

52. Since the integral is over a bounded interval, and $f(x)$ is continuous at $x = 2$ and at $x = 5$, we need to find a function $f(x)$ that has a discontinuity in the interval $(2, 5)$. Let's try $f(x) = 1/(x-3)^2$. Because this function is discontinuous at $x = 3$, we must split the improper integral $\int_2^5 1/(x-3)^2\,dx$ into two integrals:

$$\begin{aligned}\int_2^5 \frac{1}{(x-3)^2}\,dx &= \int_2^3 \frac{1}{(x-3)^2}\,dx + \int_3^5 \frac{1}{(x-3)^2}\,dx \\ &= \lim_{b\to 3^-} \int_2^b \frac{1}{(x-3)^2}\,dx + \lim_{a\to 3^+} \int_a^5 \frac{1}{(x-3)^2}\,dx \\ &= \lim_{b\to 3^-} \left(-\frac{1}{(b-3)} + \frac{1}{2-3}\right) + \lim_{a\to 3^+} \left(-\frac{1}{(5-3)} + \frac{1}{(a-3)}\right) \\ &= \lim_{b\to 3^-} \left(-\frac{1}{(b-3)} - 1\right) + \lim_{a\to 3^+} \left(\frac{1}{(a-3)} - \frac{1}{2}\right)\end{aligned}$$

Both of these limits go to ∞. Thus the improper integral $\int_2^5 f(x)dx$ diverges.

53. True. Since

$$\lim_{b\to\infty} \int_0^b f(x)\,dx = \int_0^a f(x)\,dx + \lim_{b\to\infty} \int_a^b f(x)\,dx,$$

the limit on the left side of the equation is finite exactly when the limit on the right side is finite. Thus, if $\int_0^\infty f(x)\,dx$ converges, then so does $\int_a^\infty f(x)\,dx$.

54. diverges.

True. Suppose that f has period p. Then $\int_0^p f(x)\,dx$, $\int_p^{2p} f(x)\,dx$, $\int_{2p}^{3p} f(x)\,dx$,... are all equal. If we let $k = \int_0^p f(x)\,dx$, then $\int_0^{np} f(x)\,dx = nk$, for any positive integer n. Since $f(x)$ is positive, so is k. Thus as n approaches ∞, the value of $\int_0^{np} f(x)\,dx = nk$ approaches ∞. That means that $\lim_{b\to\infty} \int_0^b f(x)\,dx$ is not finite; that is, the integral diverges.

55. False. Let $f(x) = 1/(x+1)$. Then

$$\int_0^\infty \frac{1}{x+1}\,dx = \lim_{b\to\infty} \ln|x+1|\Big|_0^b = \lim_{b\to\infty} \ln(b+1),$$

but $\lim_{b\to\infty} \ln(b+1)$ does not exist.

56. False. Let $f(x) = x + 1$. Then

$$\int_0^\infty \frac{1}{x+1}\,dx = \lim_{b\to\infty} \ln|x+1|\Big|_0^b = \lim_{b\to\infty} \ln(b+1),$$

but $\lim_{b\to\infty} \ln(b+1)$ does not exist.

57. True. By properties of integrals and limits,

$$\lim_{b\to\infty} \int_0^b (f(x) + g(x))\,dx = \lim_{b\to\infty} \int_0^b f(x)\,dx + \lim_{b\to\infty} \int_0^b g(x)\,dx.$$

Since the two limits on the right side of the equation are finite, the limit on the left side is also finite, that is, $\int_0^\infty (f(x) + g(x))\,dx$ converges.

58. False. For example, let $f(x) = x$ and $g(x) = -x$. Then $f(x) + g(x) = 0$, so $\int_0^\infty (f(x) + g(x))\,dx$ converges, even though $\int_0^\infty f(x)\,dx$ and $\int_0^\infty g(x)\,dx$ diverge.

59. True. By properties of integrals and limits,

$$\lim_{b\to\infty}\int_0^b af(x)\,dx = a\lim_{b\to\infty}\int_0^b f(x)\,dx.$$

Thus, the limit on the left of the equation is finite exactly when the limit on the right side of the equation is finite. Thus $\int_0^\infty af(x)\,dx$ converges if $\int_0^\infty f(x)\,dx$ converges.

60. True. Make the substitution $w = ax$. Then $dw = a\,dx$, so

$$\int_0^b f(ax)\,dx = \frac{1}{a}\int_0^c f(w)\,dw,$$

where $c = ab$. As b approaches infinity, so does c, since a is constant. Thus the limit of the left side of the equation as b approaches infinity is finite exactly when the limit of the right side of the equation as c approaches infinity is finite. That is, $\int_0^\infty f(ax)\,dx$ converges exactly when $\int_0^\infty f(x)\,dx$ converges.

61. True. Make the substitution $w = a + x$, so $dw = dx$. Then $w = a$ when $x = 0$, and $w = a + b$ when $x = b$, so

$$\int_0^b f(a+x)\,dx = \int_a^{b+a} f(w)\,dw = \int_a^c f(w)\,dw$$

where $c = b + a$. As b approaches infinity, so does c, since a is constant. Thus the limit of the left side of the equation as b approaches infinity is finite exactly when the limit of the right side of the equation as c approaches infinity is finite. Since $\int_0^\infty f(x)\,dx$ converges, we know that $\lim_{c\to\infty}\int_0^c f(w)\,dw$ is finite, so $\lim_{c\to\infty}\int_a^c f(w)\,dw$ is finite for any positive a. Thus, $\int_0^\infty f(a+x)\,dx$ converges.

62. False. We have

$$\int_0^b (a + f(x))\,dx = \int_0^b a\,dx + \int_0^b f(x)\,dx.$$

Since $\int_0^\infty f(x)\,dx$ converges, the second integral on the right side of the equation has a finite limit as b approaches infinity. But the first integral on the right side has an infinite limit as b approaches infinity, since $a \neq 0$. Thus the right side all together has an infinite limit, which means that $\int_0^\infty (a + f(x))\,dx$ diverges.

Solutions for Section 7.7

Exercises

1. For large x, the integrand behaves like $1/x^2$ because

$$\frac{x^2}{x^4+1} \approx \frac{x^2}{x^4} = \frac{1}{x^2}.$$

Since $\displaystyle\int_1^\infty \frac{dx}{x^2}$ converges, we expect our integral to converge. More precisely, since $x^4 + 1 > x^4$, we have

$$\frac{x^2}{x^4+1} < \frac{x^2}{x^4} = \frac{1}{x^2}.$$

Since $\displaystyle\int_1^\infty \frac{dx}{x^2}$ is convergent, the comparison test tells us that $\displaystyle\int_1^\infty \frac{x^2}{x^4+1}\,dx$ converges also.

2. For large x, the integrand behaves like $1/x$ because

$$\frac{x^3}{x^4-1} \approx \frac{x^3}{x^4} = \frac{1}{x}.$$

Since $\displaystyle\int_2^\infty \frac{1}{x}\,dx$ does not converge, we expect our integral not to converge. More precisely, since $x^4 - 1 < x^4$, we have

$$\frac{x^3}{x^4-1} > \frac{x^3}{x^4} = \frac{1}{x}.$$

Since $\displaystyle\int_2^\infty \frac{1}{x}\,dx$ does not converge, the comparison test tells us that $\displaystyle\int_2^\infty \frac{x^3}{x^4-1}\,dx$ does not converge either.

3. The integrand is continuous for all $x \geq 1$, so whether the integral converges or diverges depends only on the behavior of the function as $x \to \infty$. As $x \to \infty$, polynomials behave like the highest powered term. Thus, as $x \to \infty$, the integrand $\frac{x^2+1}{x^3+3x+2}$ behaves like $\frac{x^2}{x^3}$ or $\frac{1}{x}$. Since $\int_1^\infty \frac{1}{x}\,dx$ diverges, we predict that the given integral will diverge.

4. The integrand is continuous for all $x \geq 1$, so whether the integral converges or diverges depends only on the behavior of the function as $x \to \infty$. As $x \to \infty$, polynomials behave like the highest powered term. Thus, as $x \to \infty$, the integrand $\frac{1}{x^2+5x+1}$ behaves like $\frac{1}{x^2}$. Since $\int_1^\infty \frac{1}{x^2}\,dx$ converges, we predict that the given integral will converge.

5. The integrand is continuous for all $x \geq 1$, so whether the integral converges or diverges depends only on the behavior of the function as $x \to \infty$. As $x \to \infty$, polynomials behave like the highest powered term. Thus, as $x \to \infty$, the integrand $\frac{x}{x^2+2x+4}$ behaves like $\frac{x}{x^2}$ or $\frac{1}{x}$. Since $\int_1^\infty \frac{1}{x}\,dx$ diverges, we predict that the given integral will diverge.

6. The integrand is continuous for all $x \geq 1$, so whether the integral converges or diverges depends only on the behavior of the function as $x \to \infty$. As $x \to \infty$, polynomials behave like the highest powered term. Thus, as $x \to \infty$, the integrand $\frac{x^2-6x+1}{x^2+4}$ behaves like $\frac{x^2}{x^2}$ or 1. Since $\int_1^\infty 1\,dx$ diverges, we predict that the given integral will diverge.

7. The integrand is continuous for all $x \geq 1$, so whether the integral converges or diverges depends only on the behavior of the function as $x \to \infty$. As $x \to \infty$, polynomials behave like the highest powered term. Thus, as $x \to \infty$, the integrand $\frac{5x+2}{x^4+8x^2+4}$ behaves like $\frac{5x}{x^4}$ or $\frac{5}{x^3}$. Since $\int_1^\infty \frac{5}{x^3}\,dx$ converges, we predict that the given integral will converge.

8. For large t, the 2 is negligible in comparison to e^{5t}, so the integrand behaves like e^{-5t}. Thus

$$\frac{1}{e^{5t}+2} \approx \frac{1}{e^{5t}} = e^{-5t}.$$

More precisely, since $e^{5t}+2 > e^{5t}$, we have

$$\frac{1}{e^{5t}+2} < \frac{1}{e^{5t}} = e^{-5t}.$$

Since $\int_1^\infty e^{-5t}\,dt$ converges, by the Comparison Theorem $\int_1^\infty \frac{1}{e^{5t}+2}\,dt$ converges also.

9. The integrand is continuous for all $x \geq 1$, so whether the integral converges or diverges depends only on the behavior of the function as $x \to \infty$. As $x \to \infty$, polynomials behave like the highest powered term. Thus, as $x \to \infty$, the integrand $\frac{x^2+4}{x^4+3x^2+11}$ behaves like $\frac{x^2}{x^4}$ or $\frac{1}{x^2}$. Since $\int_1^\infty \frac{1}{x^2}\,dx$ converges, we predict that the given integral will converge.

10. It converges:

$$\int_{50}^\infty \frac{dz}{z^3} = \lim_{b\to\infty}\int_{50}^b \frac{dz}{z^3} = \lim_{b\to\infty}\left(-\frac{1}{2}z^{-2}\Big|_{50}^b\right) = \frac{1}{2}\lim_{b\to\infty}\left(\frac{1}{50^2}-\frac{1}{b^2}\right) = \frac{1}{5000}$$

11. Since $\frac{1}{1+x} \geq \frac{1}{2x}$ and $\frac{1}{2}\int_0^\infty \frac{1}{x}\,dx$ diverges, we have that $\int_1^\infty \frac{dx}{1+x}$ diverges.

12. If $x \geq 1$, we know that $\frac{1}{x^3+1} \leq \frac{1}{x^3}$, and since $\int_1^\infty \frac{dx}{x^3}$ converges, the improper integral $\int_1^\infty \frac{dx}{x^3+1}$ converges.

13. The integrand is unbounded as $t \to 5$. We substitute $w = t-5$, so $dw = dt$. When $t = 5$, $w = 0$ and when $t = 8$, $w = 3$.

$$\int_5^8 \frac{6}{\sqrt{t-5}}\,dt = \int_0^3 \frac{6}{\sqrt{w}}\,dw.$$

Since

$$\int_0^3 \frac{6}{\sqrt{w}}\,dw = \lim_{a\to0^+} 6\int_a^3 \frac{1}{\sqrt{w}}\,dw = 6\lim_{a\to0^+} 2w^{1/2}\Big|_a^3 = 12\lim_{a\to0^+}(\sqrt{3}-\sqrt{a}) = 12\sqrt{3},$$

our integral converges.

14. The integral converges.

$$\int_0^1 \frac{1}{x^{19/20}}\,dx = \lim_{a\to0}\int_a^1 \frac{1}{x^{19/20}}\,dx = \lim_{a\to0} 20x^{1/20}\Big|_a^1 = \lim_{a\to0} 20\left(1-a^{1/20}\right) = 20.$$

15. This integral diverges. To see this, substitute $t+1=w$, $dt=dw$. So,

$$\int_{t=-1}^{t=5} \frac{dt}{(t+1)^2} = \int_{w=0}^{w=6} \frac{dw}{w^2},$$

which diverges.

16. Since we know the antiderivative of $\dfrac{1}{1+u^2}$, we can use the Fundamental Theorem of Calculus to evaluate the integral. Since the integrand is even, we write

$$\int_{-\infty}^{\infty} \frac{du}{1+u^2} = 2\int_0^{\infty} \frac{du}{1+u^2} = 2\lim_{b\to\infty}\int_0^b \frac{du}{1+u^2}$$
$$= 2\lim_{b\to\infty} \arctan b = 2\left(\frac{\pi}{2}\right) = \pi.$$

Thus, the integral converges to π.

17. Since $\dfrac{1}{u+u^2} < \dfrac{1}{u^2}$ for $u \geq 1$, and since $\displaystyle\int_1^{\infty} \frac{du}{u^2}$ converges, $\displaystyle\int_1^{\infty} \frac{du}{u+u^2}$ converges.

18. This improper integral diverges. We expect this because, for large θ, $\dfrac{1}{\sqrt{\theta^2+1}} \approx \dfrac{1}{\sqrt{\theta^2}} = \dfrac{1}{\theta}$ and $\displaystyle\int_1^{\infty} \frac{d\theta}{\theta}$ diverges. More precisely, for $\theta \geq 1$

$$\frac{1}{\sqrt{\theta^2+1}} \geq \frac{1}{\sqrt{\theta^2+\theta^2}} = \frac{1}{\sqrt{2}\sqrt{\theta^2}} = \frac{1}{\sqrt{2}} \cdot \frac{1}{\theta}$$

and $\displaystyle\int_1^{\infty} \frac{d\theta}{\theta}$ diverges. (The factor $\frac{1}{\sqrt{2}}$ does not affect the divergence.)

19. For $\theta \geq 2$, we have $\dfrac{1}{\sqrt{\theta^3+1}} \leq \dfrac{1}{\sqrt{\theta^3}} = \dfrac{1}{\theta^{\frac{3}{2}}}$, and $\displaystyle\int_2^{\infty} \frac{d\theta}{\theta^{3/2}}$ converges (check by integration), so $\displaystyle\int_2^{\infty} \frac{d\theta}{\sqrt{\theta^3+1}}$ converges.

20. This integral is improper at $\theta = 0$. For $0 \leq \theta \leq 1$, we have $\dfrac{1}{\sqrt{\theta^3+\theta}} \leq \dfrac{1}{\sqrt{\theta}}$, and since $\displaystyle\int_0^1 \frac{1}{\sqrt{\theta}}\,d\theta$ converges, $\displaystyle\int_0^1 \frac{d\theta}{\sqrt{\theta^3+\theta}}$ converges.

21. Since $\dfrac{1}{1+e^y} \leq \dfrac{1}{e^y} = e^{-y}$ and $\displaystyle\int_0^{\infty} e^{-y}\,dy$ converges, the integral $\displaystyle\int_0^{\infty} \frac{dy}{1+e^y}$ converges.

22. This integral is convergent because, for $\phi \geq 1$,

$$\frac{2+\cos\phi}{\phi^2} \leq \frac{3}{\phi^2},$$

and $\displaystyle\int_1^{\infty} \frac{3}{\phi^2}d\phi = 3\int_1^{\infty} \frac{1}{\phi^2}d\phi$ converges.

23. Since $\dfrac{1}{e^z+2^z} < \dfrac{1}{e^z} = e^{-z}$ for $z \geq 0$, and $\displaystyle\int_0^{\infty} e^{-z}dz$ converges, $\displaystyle\int_0^{\infty} \frac{dz}{e^z+2^z}$ converges.

24. Since $\dfrac{1}{\phi^2} \leq \dfrac{2-\sin\phi}{\phi^2}$ for $0 < \phi \leq \pi$, and since $\displaystyle\int_0^{\pi} \frac{1}{\phi^2}d\phi$ diverges, $\displaystyle\int_0^{\pi} \frac{2-\sin\phi}{\phi^2}d\phi$ must diverge.

25. Since $\dfrac{3+\sin\alpha}{\alpha} \geq \dfrac{2}{\alpha}$ for $\alpha \geq 4$, and since $\displaystyle\int_4^{\infty} \frac{2}{\alpha}d\alpha$ diverges, then $\displaystyle\int_4^{\infty} \frac{3+\sin\alpha}{\alpha}d\alpha$ diverges.

Problems

26. (a) The area is infinite. The area under $1/x$ is infinite and the area under $1/x^2$ is 1. So the area between the two has to be infinite also.

(b) Since $f(x)$ is bounded between 0 and $1/x^2$, and the area under $1/x^2$ is finite, $f(x)$ will have finite area by the comparison test. Similarly, $h(x)$ lies above $1/x$, whose area is infinite, so $h(x)$ must have infinite area as well. We can tell nothing about the area of $g(x)$, because the comparison test tells us nothing about a function larger than a function with finite area but smaller than one with infinite area. Finally, $k(x)$ will certainly have infinite area, because it has a lower bound m, for some $m > 0$. Thus, $\int_0^a k(x)\,dx \geq ma$, and since the latter does not converge as $a \to \infty$, neither can the former.

27. The convergence or divergence of an improper integral depends on the long-term behavior of the integrand, not on its short-term behavior. Figure 7.46 suggests that $g(x) \leq f(x)$ for all values of x beyond $x = k$. Since $\int_k^\infty f(x)\,dx$ converges, we expect $\int_k^\infty g(x)\,dx$ converges also.

However we are interested in $\int_a^\infty g(x)\,dx$. Breaking the integral into two parts enables us to use the fact that $\int_k^\infty g(x)\,dx$ is finite:

$$\int_a^\infty g(x)\,dx = \int_a^k g(x)\,dx + \int_k^\infty g(x)\,dx.$$

The first integral is also finite because the interval from a to k is finite. Therefore, we expect $\int_a^\infty g(x)\,dx$ converges.

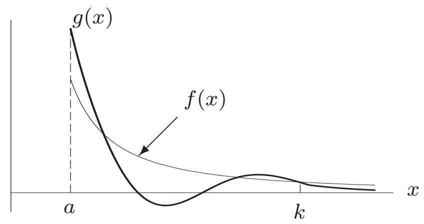


Figure 7.46

28. First let's calculate the indefinite integral $\displaystyle\int \frac{dx}{x(\ln x)^p}$. Let $\ln x = w$, then $\dfrac{dx}{x} = dw$. So

$$\begin{aligned}
\int \frac{dx}{x(\ln x)^p} &= \int \frac{dw}{w^p} \\
&= \begin{cases} \ln|w| + C, & \text{if } p = 1 \\ \frac{1}{1-p} w^{1-p} + C, & \text{if } p \neq 1 \end{cases} \\
&= \begin{cases} \ln|\ln x| + C, & \text{if } p = 1 \\ \frac{1}{1-p} (\ln x)^{1-p} + C, & \text{if } p \neq 1. \end{cases}
\end{aligned}$$

Notice that $\lim_{x\to\infty} \ln x = +\infty$.

(a) $p = 1$:

$$\int_2^\infty \frac{dx}{x \ln x} = \lim_{b\to\infty} \Big(\ln|\ln b| - \ln|\ln 2| \Big) = +\infty.$$

(b) $p < 1$:

$$\int_2^\infty \frac{dx}{x(\ln x)^p} = \frac{1}{1-p} \left(\lim_{b\to\infty} (\ln b)^{1-p} - (\ln 2)^{1-p} \right) = +\infty.$$

(c) $p > 1$:

$$\begin{aligned}
\int_2^\infty \frac{dx}{x(\ln x)^p} &= \frac{1}{1-p} \left(\lim_{b\to\infty} (\ln b)^{1-p} - (\ln 2)^{1-p} \right) \\
&= \frac{1}{1-p} \left(\lim_{b\to\infty} \frac{1}{(\ln b)^{p-1}} - (\ln 2)^{1-p} \right) \\
&= -\frac{1}{1-p} (\ln 2)^{1-p}.
\end{aligned}$$

Thus, $\displaystyle\int_2^\infty \frac{dx}{x(\ln x)^p}$ is convergent for $p > 1$, divergent for $p \leq 1$.

29. The indefinite integral $\int \frac{dx}{x(\ln x)^p}$ is computed in Problem 28. Let $\ln x = w$, then $\frac{dx}{x} = dw$. Notice that $\lim_{x\to 1} \ln x = 0$, and $\lim_{x\to 0^+} \ln x = -\infty$.

For this integral notice that $\ln 1 = 0$, so the integrand blows up at $x = 1$.

(a) $p = 1$:

$$\int_1^2 \frac{dx}{x\ln x} = \lim_{a\to 1^+}(\ln|\ln 2| - \ln|\ln a|)$$

Since $\ln a \to 0$ as $a \to 1$, $\ln|\ln a| \to -\infty$ as $b \to 1$. So the integral is divergent.

(b) $p < 1$:

$$\begin{aligned}\int_1^2 \frac{dx}{x(\ln x)^p} &= \frac{1}{1-p}\lim_{a\to 1^+}\left((\ln 2)^{1-p} - (\ln a)^{1-p}\right)\\ &= \frac{1}{1-p}(\ln 2)^{1-p}.\end{aligned}$$

(c) $p > 1$:

$$\int_1^2 \frac{dx}{x(\ln x)^p} = \frac{1}{1-p}\lim_{a\to 1^+}\left((\ln 2)^{1-p} - (\ln a)^{1-p}\right)$$

As $\lim_{a\to 1^+}(\ln a)^{1-p} = \lim_{a\to 1^+}\frac{1}{(\ln a)^{p-1}} = +\infty$, the integral diverges.

Thus, $\int_1^2 \frac{dx}{x(\ln x)^p}$ is convergent for $p < 1$, divergent for $p \geq 1$.

30. (a) Since $e^{-x^2} \leq e^{-3x}$ for $x \geq 3$,

$$\int_3^\infty e^{-x^2}\,dx \leq \int_3^\infty e^{-3x}\,dx$$

Now

$$\begin{aligned}\int_3^\infty e^{-3x}\,dx &= \lim_{b\to\infty}\int_3^b e^{-3x}\,dx = \lim_{b\to\infty} -\frac{1}{3}e^{-3x}\Big|_3^b\\ &= \lim_{b\to\infty}\frac{e^{-9}}{3} - \frac{e^{-3b}}{3} = \frac{e^{-9}}{3}.\end{aligned}$$

Thus

$$\int_3^\infty e^{-x^2}\,dx \leq \frac{e^{-9}}{3}.$$

(b) By reasoning similar to part (a),

$$\int_n^\infty e^{-x^2}\,dx \leq \int_n^\infty e^{-nx}\,dx,$$

and

$$\int_n^\infty e^{-nx}\,dx = \frac{1}{n}e^{-n^2},$$

so

$$\int_n^\infty e^{-x^2}\,dx \leq \frac{1}{n}e^{-n^2}.$$

31. (a) The tangent line to e^t has slope $(e^t)' = e^t$. Thus at $t = 0$, the slope is $e^0 = 1$. The line passes through $(0, e^0) = (0, 1)$. Thus the equation of the tangent line is $y = 1 + t$. Since e^t is everywhere concave up, its graph is always above the graph of any of its tangent lines; in particular, e^t is always above the line $y = 1 + t$. This is tantamount to saying

$$1 + t \leq e^t,$$

with equality holding only at the point of tangency, $t = 0$.

(b) If $t = \dfrac{1}{x}$, then the above inequality becomes

$$1 + \frac{1}{x} \leq e^{1/x}, \text{ or } e^{1/x} - 1 \geq \frac{1}{x}.$$

Since $t = \dfrac{1}{x}$, t is never zero. Therefore, the inequality is strict, and we write

$$e^{1/x} - 1 > \frac{1}{x}.$$

(c) Since $e^{1/x} - 1 > \dfrac{1}{x}$,

$$\frac{1}{x^5\left(e^{1/x} - 1\right)} < \frac{1}{x^5\left(\frac{1}{x}\right)} = \frac{1}{x^4}.$$

Since $\displaystyle\int_1^\infty \frac{dx}{x^4}$ converges, $\displaystyle\int_1^\infty \frac{dx}{x^5\left(e^{1/x} - 1\right)}$ converges.

Strengthen Your Understanding

32. We cannot compare the integrals, because the first integrand is sometimes less than the second and sometimes greater than the second, depending on the sign of $\sin x$.

33. We can use the comparison test with $\dfrac{1}{x^{\sqrt{2}}}$. Since $x > 0$, we have

$$0 < \frac{1}{x^{\sqrt{2}} + 1} < \frac{1}{x^{\sqrt{2}}},$$

and $\displaystyle\int_1^\infty \frac{1}{x^{\sqrt{2}}}\, dx$ is convergent ($p = \sqrt{2} > 1$), the original integral, $\displaystyle\int_1^\infty \frac{1}{x^{\sqrt{2}} + 1}\, dx$, converges.

34. The integral $\displaystyle\int_0^\infty f(x)\, dx$ might converge or diverge; the comparison test can not be used here.

35. Let $f(x) = \dfrac{1}{x^2}$. Then $\displaystyle\int_1^\infty \frac{1}{x^2}\, dx$ converges. However $\displaystyle\int_1^\infty \frac{1}{f(x)}\, dx = \int_1^\infty x^2\, dx$ diverges.

36. We know that the integral $\int_1^\infty 3/(2x^2)\, dx$ converges because

$$\int_1^\infty \frac{3}{2x^2} dx = \lim_{b\to\infty} \int_1^b \frac{3}{2x^2} dx = \lim_{b\to\infty} \left(-\frac{3}{2b} + \frac{3}{2}\right) = \frac{3}{2}.$$

So we know that if $f(x)$ is positive and $f(x) \leq 3/(2x^2)$ for all $x \geq 1$, then $\int_1^\infty f(x)dx$ converges. So the function $f(x) = 3/(2x^2 + 1)$ is a good example.

37. Since $-1 \leq \sin x \leq 1$ for all x, we know that, for all x,

$$7x - 2 \leq 7x - 2\sin x \leq 7x + 2.$$

So since $7x - 2\sin x \geq 0$ for all $x \geq 1$, we know that for all $x \geq 1$,

$$\frac{3}{7x - 2\sin x} \geq \frac{3}{7x + 2}.$$

So let

$$f(x) = \frac{3}{7x + 2}.$$

We then have

$$\int_1^\infty f(x)dx = \lim_{b\to\infty} \int_1^b \frac{3}{7x + 2} dx = \lim_{b\to\infty} \left(\frac{3}{7}\ln|7b + 2| - \frac{3}{7}\ln 9\right) = \infty$$

So the integral $\int_1^\infty f(x)dx$ diverges, as desired.

38. True. Since $\dfrac{1}{e^x + x} < \dfrac{1}{e^x}$ and $\displaystyle\int_0^\infty \frac{1}{e^x}\, dx$ converges, $\displaystyle\int_0^\infty \frac{dx}{e^x + x}$ converges.

39. True. Since $\dfrac{1}{x^2 - 3} > \dfrac{1}{x^2}$ and $\displaystyle\int_0^1 \frac{dx}{x^2}$ diverges, $\displaystyle\int_0^1 \frac{dx}{x^2 - 3}$ diverges.

Solutions for Chapter 7 Review

Exercises

1. $\frac{1}{3}(t+1)^3$
2. $-\cos 2\theta$
3. $\dfrac{5^x}{\ln 5}$
4. $e^t + 5\dfrac{1}{5}e^{5t} = e^t + e^{5t}$
5. Using the power rule gives $\dfrac{3}{2}w^2 + 7w + C$.
6. $\frac{1}{2}e^{2r} + C$
7. Since $\dfrac{d}{dt}\cos t = -\sin t$, we have

$$\int \sin t\, dt = -\cos t + C, \text{ where } C \text{ is a constant.}$$

8. Let $2t = w$, then $2dt = dw$, so $dt = \frac{1}{2}dw$, so

$$\int \cos 2t\, dt = \int \frac{1}{2}\cos w\, dw = \frac{1}{2}\sin w + C = \frac{1}{2}\sin 2t + C,$$

where C is a constant.

9. Let $5z = w$, then $5dz = dw$, which means $dz = \frac{1}{5}dw$, so

$$\int e^{5z}\, dz = \int e^w \cdot \frac{1}{5}dw = \frac{1}{5}\int e^w\, dw = \frac{1}{5}e^w + C = \frac{1}{5}e^{5z} + C,$$

where C is a constant.

10. $\sin(x+1) + C$
11. Since $\displaystyle\int \sin w\, d\theta = -\cos w + C$, the substitution $w = 2\theta$, $dw = 2\, d\theta$ gives $\displaystyle\int \sin 2\theta\, d\theta = -\frac{1}{2}\cos 2\theta + C$.
12. Let $w = x^3 - 1$, then $dw = 3x^2 dx$ so that

$$\int (x^3-1)^4 x^2 dx = \frac{1}{3}\int w^4 dw = \frac{1}{15}w^5 + C = \frac{1}{15}(x^3-1)^5 + C.$$

13. The power rule gives $\dfrac{2}{5}x^{5/2} + \dfrac{3}{5}x^{5/3} + C$
14. From the rule for antidifferentiation of exponentials, we get

$$\int \left(e^x + 3^x\right) dx = e^x + \frac{1}{\ln 3}\cdot 3^x + C.$$

15. $\displaystyle\int \frac{1}{e^z}\, dz = \int e^{-z}\, dz = -e^{-z} + C$
16. Rewrite the integrand as

$$\int \left(\frac{4}{x^2} - \frac{3}{x^3}\right) dx = 4\int x^{-2}\, dx - 3\int x^{-3}\, dx = -4x^{-1} + \frac{3}{2}x^{-2} + C.$$

17. Dividing by x^2 gives

$$\int \left(\frac{x^3+x+1}{x^2}\right) dx = \int \left(x + \frac{1}{x} + \frac{1}{x^2}\right) dx = \frac{1}{2}x^2 + \ln|x| - \frac{1}{x} + C.$$

18. Let $w = 1 + \ln x$, then $dw = dx/x$ so that

$$\int \frac{(1+\ln x)^2}{x}\,dx = \int w^2 dw = \frac{1}{3}w^3 + C = \frac{1}{3}(1+\ln x)^3 + C.$$

19. Substitute $w = t^2$, so $dw = 2t\,dt$.

$$\int te^{t^2}\,dt = \frac{1}{2}\int e^{t^2} 2t\,dt = \frac{1}{2}\int e^w\,dw = \frac{1}{2}e^w + C = \frac{1}{2}e^{t^2} + C.$$

Check:

$$\frac{d}{dt}\left(\frac{1}{2}e^{t^2} + C\right) = 2t\left(\frac{1}{2}e^{t^2}\right) = te^{t^2}.$$

20. Integration by parts with $u = x$, $v' = \cos x$ gives

$$\int x\cos x\,dx = x\sin x - \int \sin x\,dx + C = x\sin x + \cos x + C.$$

Or use III-16 with $p(x) = x$ and $a = 1$ in the integral table.

21. Integration by parts twice gives

$$\int x^2 e^{2x}\,dx = \frac{x^2 e^{2x}}{2} - \int 2xe^{2x}\,dx = \frac{x^2}{2}e^{2x} - \frac{x}{2}e^{2x} + \frac{1}{4}e^{2x} + C$$
$$= (\frac{1}{2}x^2 - \frac{1}{2}x + \frac{1}{4})e^{2x} + C.$$

Or use the integral table, III-14 with $p(x) = x^2$ and $a = 1$.

22. Using substitution with $w = 1 - x$ and $dw = -dx$, we get

$$\int x\sqrt{1-x}\,dx = -\int (1-w)\sqrt{w}dw = \frac{2}{5}w^{5/2} - \frac{2}{3}w^{3/2} + C = \frac{2}{5}(1-x)^{5/2} - \frac{2}{3}(1-x)^{3/2} + C.$$

23. Let $u = \ln y$, $v' = y$. Then, $v = \frac{1}{2}y^2$ and $u' = \dfrac{1}{y}$. Integrating by parts, we get:

$$\int y\ln y\,dy = \frac{1}{2}y^2\ln y - \int \frac{1}{2}y^2 \cdot \frac{1}{y}\,dy$$
$$= \frac{1}{2}y^2\ln y - \frac{1}{2}\int y\,dy$$
$$= \frac{1}{2}y^2\ln y - \frac{1}{4}y^2 + C.$$

24. We integrate by parts, with $u = y$, $v' = \sin y$. We have $u' = 1$, $v = -\cos y$, and

$$\int y\sin y\,dy = -y\cos y - \int (-\cos y)\,dy = -y\cos y + \sin y + C.$$

Check:

$$\frac{d}{dy}(-y\cos y + \sin y + C) = -\cos y + y\sin y + \cos y = y\sin y.$$

25. We integrate by parts, using $u = (\ln x)^2$ and $v' = 1$. Then $u' = 2\frac{\ln x}{x}$ and $v = x$, so

$$\int (\ln x)^2\,dx = x(\ln x)^2 - 2\int \ln x\,dx.$$

But, integrating by parts or using the integral table, $\int \ln x\,dx = x\ln x - x + C$. Therefore,

$$\int (\ln x)^2\,dx = x(\ln x)^2 - 2x\ln x + 2x + C.$$

Check:

$$\frac{d}{dx}\left[x(\ln x)^2 - 2x\ln x + 2x + C\right] = (\ln x)^2 + x\frac{2\ln x}{x} - 2\ln x - 2x\frac{1}{x} + 2 = (\ln x)^2.$$

26. Using the exponent rules and the chain rule, we have

$$\int e^{0.5-0.3t}\,dt = e^{0.5}\int e^{-0.3t}\,dt = -\frac{e^{0.5}}{0.3}e^{-0.3t} + C = -\frac{e^{0.5-0.3t}}{0.3} + C.$$

27. Let $\sin\theta = w$, then $\cos\theta\,d\theta = dw$, so

$$\int \sin^2\theta\cos\theta\,d\theta = \int w^2\,dw = \frac{1}{3}w^3 + C = \frac{1}{3}\sin^3\theta + C,$$

where C is a constant.

28. Substitute $w = 4 - x^2$, $dw = -2x\,dx$:

$$\int x\sqrt{4-x^2}\,dx = -\frac{1}{2}\int \sqrt{w}\,dw = -\frac{1}{3}w^{3/2} + C = -\frac{1}{3}(4-x^2)^{3/2} + C.$$

Check

$$\frac{d}{dx}\left[-\frac{1}{3}(4-x^2)^{3/2} + C\right] = -\frac{1}{3}\left[\frac{3}{2}(4-x^2)^{1/2}(-2x)\right] = x\sqrt{4-x^2}.$$

29. Expanding the numerator and dividing, we have

$$\int \frac{(u+1)^3}{u^2}\,du = \int \frac{(u^3+3u^2+3u+1)}{u^2}\,du = \int \left(u + 3 + \frac{3}{u} + \frac{1}{u^2}\right)du$$
$$= \frac{u^2}{2} + 3u + 3\ln|u| - \frac{1}{u} + C.$$

Check:

$$\frac{d}{du}\left(\frac{u^2}{2} + 3u + 3\ln|u| - \frac{1}{u} + C\right) = u + 3 + 3/u + 1/u^2 = \frac{(u+1)^3}{u^2}.$$

30. Substitute $w = \sqrt{y}$, $dw = 1/(2\sqrt{y})\,dy$. Then

$$\int \frac{\cos\sqrt{y}}{\sqrt{y}}\,dy = 2\int \cos w\,dw = 2\sin w + C = 2\sin\sqrt{y} + C.$$

Check:

$$\frac{d}{dy}2\sin\sqrt{y} + C = \frac{2\cos\sqrt{y}}{2\sqrt{y}} = \frac{\cos\sqrt{y}}{\sqrt{y}}.$$

31. Since $\frac{d}{dz}(\tan z) = \frac{1}{\cos^2 z}$, we have

$$\int \frac{1}{\cos^2 z}\,dz = \tan z + C.$$

Check:

$$\frac{d}{dz}(\tan z + C) = \frac{d}{dz}\frac{\sin z}{\cos z} = \frac{(\cos z)(\cos z) - (\sin z)(-\sin z)}{\cos^2 z} = \frac{1}{\cos^2 z}.$$

32. Denote $\int \cos^2\theta\,d\theta$ by A. Let $u = \cos\theta$, $v' = \cos\theta$. Then, $v = \sin\theta$ and $u' = -\sin\theta$. Integrating by parts, we get:

$$A = \cos\theta\sin\theta - \int(-\sin\theta)\sin\theta\,d\theta.$$

Employing the identity $\sin^2\theta = 1 - \cos^2\theta$, the equation above becomes:

$$A = \cos\theta\sin\theta + \int d\theta - \int \cos^2\theta\,d\theta$$
$$= \cos\theta\sin\theta + \theta - A + C.$$

Solving this equation for A, and using the identity $\sin 2\theta = 2\cos\theta\sin\theta$ we get:

$$A = \int \cos^2\theta\, d\theta = \frac{1}{4}\sin 2\theta + \frac{1}{2}\theta + C.$$

[Note: An alternate solution would have been to use the identity $\cos^2\theta = \frac{1}{2}\cos 2\theta + \frac{1}{2}$.]

33. Multiplying out and integrating term by term:

$$\int t^{10}(t-10)\, dt = \int (t^{11} - 10t^{10})\, dt = \int t^{11} dt - 10\int t^{10}\, dt = \frac{1}{12}t^{12} - \frac{10}{11}t^{11} + C.$$

34. Substitute $w = 2x - 6$. Then $dw = 2\, dx$ and

$$\begin{aligned}\int \tan(2x-6)\, dx &= \frac{1}{2}\int \tan w\, dw = \frac{1}{2}\int \frac{\sin w}{\cos w}\, dw \\ &= -\frac{1}{2}\ln|\cos w| + C \text{ by substitution or by I-7 of the integral table.} \\ &= -\frac{1}{2}\ln|\cos(2x-6)| + C.\end{aligned}$$

35. Let $\ln x = w$, then $\frac{1}{x}\, dx = dw$, so

$$\int \frac{(\ln x)^2}{x}\, dx = \int w^2\, dw = \frac{1}{3}w^3 + C = \frac{1}{3}(\ln x)^3 + C, \text{ where } C \text{ is a constant.}$$

36. Multiplying out, dividing, and then integrating yields

$$\int \frac{(t+2)^2}{t^3}\, dt = \int \frac{t^2+4t+4}{t^3}\, dt = \int \frac{1}{t}\, dt + \int \frac{4}{t^2}\, dt + \int \frac{4}{t^3}\, dt = \ln|t| - \frac{4}{t} - \frac{2}{t^2} + C,$$

where C is a constant.

37. Integrating term by term:

$$\int \left(x^2 + 2x + \frac{1}{x}\right)\, dx = \frac{1}{3}x^3 + x^2 + \ln|x| + C,$$

where C is a constant.

38. Dividing and then integrating, we obtain

$$\int \frac{t+1}{t^2}\, dt = \int \frac{1}{t}\, dt + \int \frac{1}{t^2}\, dt = \ln|t| - \frac{1}{t} + C, \text{ where } C \text{ is a constant.}$$

39. Let $t^2 + 1 = w$, then $2t\, dt = dw$, $t dt = \frac{1}{2}\, dw$, so

$$\int te^{t^2+1}\, dt = \int e^w \cdot \frac{1}{2}\, dw = \frac{1}{2}\int e^w\, dw = \frac{1}{2}e^w + C = \frac{1}{2}e^{t^2+1} + C,$$

where C is a constant.

40. Let $\cos\theta = w$, then $-\sin\theta\, d\theta = dw$, so

$$\begin{aligned}\int \tan\theta\, d\theta &= \int \frac{\sin\theta}{\cos\theta}\, d\theta = \int \frac{-1}{w}\, dw \\ &= -\ln|w| + C = -\ln|\cos\theta| + C,\end{aligned}$$

where C is a constant.

41. If $u = \sin(5\theta)$, $du = \cos(5\theta) \cdot 5\,d\theta$, so

$$\begin{aligned}\int \sin(5\theta)\cos(5\theta)d\theta &= \frac{1}{5}\int \sin(5\theta)\cdot 5\cos(5\theta)d\theta = \frac{1}{5}\int u\,du \\ &= \frac{1}{5}\left(\frac{u^2}{2}\right) + C = \frac{1}{10}\sin^2(5\theta) + C\end{aligned}$$

or

$$\begin{aligned}\int \sin(5\theta)\cos(5\theta)d\theta &= \frac{1}{2}\int 2\sin(5\theta)\cos(5\theta)d\theta = \frac{1}{2}\int \sin(10\theta)d\theta \quad \text{(using } \sin(2x) = 2\sin x\cos x) \\ &= \frac{-1}{20}\cos(10\theta) + C.\end{aligned}$$

42. Using substitution,

$$\begin{aligned}\int \frac{x}{x^2+1}\,dx &= \int \frac{1/2}{w}\,dw \qquad (x^2+1 = w, 2x\,dx = dw, xdx = \frac{1}{2}\,dw) \\ &= \frac{1}{2}\int \frac{1}{w}\,dw = \frac{1}{2}\ln|w| + C = \frac{1}{2}\ln|x^2+1| + C,\end{aligned}$$

where C is a constant.

43. Since $\dfrac{d}{dz}(\arctan z) = \dfrac{1}{1+z^2}$, we have

$$\int \frac{dz}{1+z^2} = \arctan z + C, \text{ where } C \text{ is a constant.}$$

44. Let $w = 2z$, so $dw = 2dz$. Then, since $\dfrac{d}{dw}\arctan w = \dfrac{1}{1+w^2}$, we have

$$\int \frac{dz}{1+4z^2} = \int \frac{\frac{1}{2}dw}{1+w^2} = \frac{1}{2}\arctan w + C = \frac{1}{2}\arctan 2z + C.$$

45. Let $w = \cos 2\theta$. Then $dw = -2\sin 2\theta\,d\theta$, hence

$$\int \cos^3 2\theta \sin 2\theta\,d\theta = -\frac{1}{2}\int w^3\,dw = -\frac{w^4}{8} + C = -\frac{\cos^4 2\theta}{8} + C.$$

Check:

$$\frac{d}{d\theta}\left(-\frac{\cos^4 2\theta}{8}\right) = -\frac{(4\cos^3 2\theta)(-\sin 2\theta)(2)}{8} = \cos^3 2\theta \sin 2\theta.$$

46. Let $\cos 5\theta = w$, then $-5\sin 5\theta\,d\theta = dw$, $\sin 5\theta\,d\theta = -\frac{1}{5}dw$. So

$$\begin{aligned}\int \sin 5\theta \cos^3 5\theta\,d\theta &= \int w^3\cdot(-\frac{1}{5})\,dw = -\frac{1}{5}\int w^3\,dw = -\frac{1}{20}w^4 + C \\ &= -\frac{1}{20}\cos^4 5\theta + C,\end{aligned}$$

where C is a constant.

47.

$$\begin{aligned}\int \sin^3 z\cos^3 z\,dz &= \int \sin z(1-\cos^2 z)\cos^3 z\,dz \\ &= \int \sin z\cos^3 z\,dz - \int \sin z\cos^5 z\,dz\end{aligned}$$

$$
\begin{aligned}
&= \int w^3\,(-dw) - \int w^5\,(-dw) \quad (\text{let } \cos z = w, \text{ so } -\sin z\,dz = dw)\\
&= -\int w^3\,dw + \int w^5\,dw\\
&= -\frac{1}{4}w^4 + \frac{1}{6}w^6 + C\\
&= -\frac{1}{4}\cos^4 z + \frac{1}{6}\cos^6 z + C,
\end{aligned}
$$

where C is a constant.

48. If $u = t - 10$, $t = u + 10$ and $dt = 1\,du$, so substituting we get

$$
\begin{aligned}
\int (u+10)u^{10} du = \int (u^{11} + 10u^{10})\,du &= \frac{1}{12}u^{12} + \frac{10}{11}u^{11} + C\\
&= \frac{1}{12}(t-10)^{12} + \frac{10}{11}(t-10)^{11} + C.
\end{aligned}
$$

49. Let $\sin\theta = w$, then $\cos\theta\,d\theta = dw$, so

$$
\begin{aligned}
\int \cos\theta\sqrt{1+\sin\theta}\,d\theta &= \int \sqrt{1+w}\,dw\\
&= \frac{(1+w)^{3/2}}{3/2} + C = \frac{2}{3}(1+\sin\theta)^{3/2} + C,
\end{aligned}
$$

where C is a constant.

50.

$$
\begin{aligned}
\int xe^x\,dx &= xe^x - \int e^x\,dx \qquad (\text{let } x = u, e^x = v', e^x = v)\\
&= xe^x - e^x + C,
\end{aligned}
$$

where C is a constant.

51.

$$
\begin{aligned}
\int t^3e^t\,dt &= t^3e^t - \int 3t^2e^t\,dt \qquad (\text{let } t^3 = u, e^t = v', 3t^2 = u', e^t = v)\\
&= t^3e^t - 3\int t^2e^t\,dt \qquad (\text{let } t^2 = u, e^t = v')\\
&= t^3e^t - 3(t^2e^t - \int 2te^t\,dt)\\
&= t^3e^t - 3t^2e^t + 6\int te^t\,dt \qquad (\text{let } t = u, e^t = v')\\
&= t^3e^t - 3t^2e^t + 6(te^t - \int e^t\,dt)\\
&= t^3e^t - 3t^2e^t + 6te^t - 6e^t + C,
\end{aligned}
$$

where C is a constant.

52. Let $x^2 = w$, then $2xdx = dw$, $x = 1 \Rightarrow w = 1$, $x = 3 \Rightarrow w = 9$. Thus,

$$
\begin{aligned}
\int_1^3 x(x^2+1)^{70}\,dx &= \int_1^9 (w+1)^{70}\frac{1}{2}\,dw\\
&= \frac{1}{2}\cdot\frac{1}{71}(w+1)^{71}\Big|_1^9\\
&= \frac{1}{142}(10^{71} - 2^{71}).
\end{aligned}
$$

53. Let $w = 3z + 5$ and $dw = 3\,dz$. Then

$$\int (3z+5)^3\,dz = \frac{1}{3}\int w^3 dw = \frac{1}{12}w^4 + C = \frac{1}{12}(3z+5)^4 + C.$$

54. Rewrite $9 + u^2$ as $9[1 + (u/3)^2]$ and let $w = u/3$, then $dw = du/3$ so that

$$\int \frac{du}{9+u^2} = \frac{1}{3}\int \frac{dw}{1+w^2} = \frac{1}{3}\arctan w + C = \frac{1}{3}\arctan\left(\frac{u}{3}\right) + C.$$

55. Let $u = \sin w$, then $du = \cos w\,dw$ so that

$$\int \frac{\cos w}{1+\sin^2 w}\,dw = \int \frac{du}{1+u^2} = \arctan u + C = \arctan(\sin w) + C.$$

56. Let $w = \ln x$, then $dw = (1/x)dx$ which gives

$$\int \frac{1}{x}\tan(\ln x)\,dx = \int \tan w\,dw = \int \frac{\sin w}{\cos w}\,dw = -\ln(|\cos w|) + C = -\ln(|\cos(\ln x)|) + C.$$

57. Let $w = \ln x$, then $dw = (1/x)dx$ so that

$$\int \frac{1}{x}\sin(\ln x)\,dx = \int \sin w\,dw = -\cos w + C = -\cos(\ln x) + C.$$

58. Let $u = 16 - w^2$, then $du = -2w\,dw$ so that

$$\int \frac{wdw}{\sqrt{16-w^2}} = -\frac{1}{2}\int \frac{du}{\sqrt{u}} = -\sqrt{u} + C = -\sqrt{16-w^2} + C.$$

59. Dividing and then integrating term by term, we get

$$\int \frac{e^{2y}+1}{e^{2y}}\,dy = \int \left(\frac{e^{2y}}{e^{2y}} + \frac{1}{e^{2y}}\right)dy = \int (1+e^{-2y})\,dy = \int dy + \left(-\frac{1}{2}\right)\int e^{-2y}(-2)\,dy$$
$$= y - \frac{1}{2}e^{-2y} + C.$$

60. Let $u = 1 - \cos w$, then $du = \sin w\,dw$ which gives

$$\int \frac{\sin w\,dw}{\sqrt{1-\cos w}} = \int \frac{du}{\sqrt{u}} = 2\sqrt{u} + C = 2\sqrt{1-\cos w} + C.$$

61. Let $w = \ln x$. Then $dw = (1/x)dx$ which gives

$$\int \frac{dx}{x\ln x} = \int \frac{dw}{w} = \ln|w| + C = \ln|\ln x| + C.$$

62. Let $w = 3u + 8$, then $dw = 3du$ and

$$\int \frac{du}{3u+8} = \int \frac{dw}{3w} = \frac{1}{3}\ln|3u+8| + C.$$

63. Let $w = \sqrt{x^2+1}$, then $dw = \dfrac{xdx}{\sqrt{x^2+1}}$ so that

$$\int \frac{x}{\sqrt{x^2+1}}\cos\sqrt{x^2+1}\,dx = \int \cos w\,dw = \sin w + C = \sin\sqrt{x^2+1} + C.$$

64. Integrating by parts using $u = t^2$ and $dv = \frac{t\,dt}{\sqrt{1+t^2}}$ gives $du = 2t\,dt$ and $v = \sqrt{1+t^2}$. Now

$$\begin{aligned}\int \frac{t^3}{\sqrt{1+t^2}}\,dt &= t^2\sqrt{1+t^2} - \int 2t\sqrt{1+t^2}\,dt\\ &= t^2\sqrt{1+t^2} - \frac{2}{3}(1+t^2)^{3/2} + C\\ &= \sqrt{1+t^2}(t^2 - \frac{2}{3}(1+t^2)) + C\\ &= \sqrt{1+t^2}\frac{(t^2-2)}{3} + C.\end{aligned}$$

65. Using integration by parts, let $r = u$ and $dt = e^{ku}du$, so $dr = du$ and $t = (1/k)e^{ku}$. Thus

$$\int ue^{ku}\,du = \frac{u}{k}e^{ku} - \frac{1}{k}\int e^{ku}\,du = \frac{u}{k}e^{ku} - \frac{1}{k^2}e^{ku} + C.$$

66. Let $u = w + 5$, then $du = dw$ and noting that $w = u - 5$ we obtain

$$\begin{aligned}\int (w+5)^4 w\,dw &= \int u^4(u-5)\,du\\ &= \int \left(u^5 - 5u^4\right)\,du\\ &= \frac{1}{6}u^6 - u^5 + C\\ &= \frac{1}{6}(w+5)^6 - (w+5)^5 + C.\end{aligned}$$

67. $\int e^{\sqrt{2}x+3}dx = \frac{1}{\sqrt{2}}\int e^{\sqrt{2}x+3}\sqrt{2}dx$. If $u = \sqrt{2}x + 3$, $du = \sqrt{2}dx$, so

$$\frac{1}{\sqrt{2}}\int e^u du = \frac{1}{\sqrt{2}}e^u + C = \frac{1}{\sqrt{2}}e^{\sqrt{2}x+3} + C.$$

68. $\int (e^x + x)^2 dx = \int (e^{2x} + 2xe^x + x^2)dy$. Separating into three integrals, we have

$$\int e^{2x}dx = \frac{1}{2}\int e^{2x}2\,dx = \frac{1}{2}e^{2x} + C_1,$$

$$\int 2xe^x dx = 2\int xe^x dx = 2xe^x - 2e^x + C_2$$

from Formula II-13 of the integral table or integration by parts, and

$$\int x^2\,dx = \frac{x^3}{3} + C_3.$$

Combining the results and writing $C = C_1 + C_2 + C_3$, we get

$$\frac{1}{2}e^{2x} + 2xe^x - 2e^x + \frac{x^3}{3} + C.$$

69. Integrate by parts, $r = \ln u$ and $dt = u^2\,du$, so $dr = (1/u)\,du$ and $t = (1/3)u^3$. We have

$$\int u^2 \ln u\,du = \frac{1}{3}u^3\ln u - \frac{1}{3}\int u^2\,du = \frac{1}{3}u^3\ln u - \frac{1}{9}u^3 + C.$$

70. The integral table yields

$$\int \frac{5x+6}{x^2+4}\,dx = \frac{5}{2}\ln|x^2+4| + \frac{6}{2}\arctan\frac{x}{2} + C$$
$$= \frac{5}{2}\ln|x^2+4| + 3\arctan\frac{x}{2} + C.$$

Check:

$$\frac{d}{dx}\left(\frac{5}{2}\ln|x^2+4| + \frac{6}{2}\arctan\frac{x}{2} + C\right) = \frac{5}{2}\left(\frac{1}{x^2+4}(2x) + 3\frac{1}{1+(x/2)^2}\frac{1}{2}\right)$$
$$= \frac{5x}{x^2+4} + \frac{6}{x^2+4} = \frac{5x+6}{x^2+4}.$$

71. Using Table IV-19, let $m = 3$, $w = 2x$, and $dw = 2dx$. Then

$$\int \frac{1}{\sin^3(2x)}\,dx = \frac{1}{2}\int \frac{1}{\sin^3 w}\,dw$$
$$= \frac{1}{2}\left[\frac{-1}{(3-1)}\frac{\cos w}{\sin^2 w}\right] + \frac{1}{4}\int \frac{1}{\sin w}\,dw,$$

and using Table IV-20, we have

$$\int \frac{1}{\sin w}\,dw = \frac{1}{2}\ln\left|\frac{\cos w - 1}{\cos w + 1}\right| + C.$$

Thus,

$$\int \frac{1}{\sin^3(2x)}\,dx = -\frac{\cos 2x}{4\sin^2 2x} + \frac{1}{8}\ln\left|\frac{\cos 2x - 1}{\cos 2x + 1}\right| + C.$$

72. We can factor $r^2 - 100 = (r-10)(r+10)$ so we can use Table V-26 (with $a = 10$ and $b = -10$) to get

$$\int \frac{dr}{r^2 - 100} = \frac{1}{20}\left[\ln|r-10| + \ln|r+10|\right] + C.$$

73. Integration by parts will be used twice here. First let $u = y^2$ and $dv = \sin(cy)\,dy$, then $du = 2y\,dy$ and $v = -(1/c)\cos(cy)$. Thus

$$\int y^2\sin(cy)\,dy = -\frac{y^2}{c}\cos(cy) + \frac{2}{c}\int y\cos(cy)\,dy.$$

Now use integration by parts to evaluate the integral in the right hand expression. Here let $u = y$ and $dv = \cos(cy)dy$ which gives $du = dy$ and $v = (1/c)\sin(cy)$. Then we have

$$\int y^2\sin(cy)\,dy = -\frac{y^2}{c}\cos(cy) + \frac{2}{c}\left(\frac{y}{c}\sin(cy) - \frac{1}{c}\int \sin(cy)\,dy\right)$$
$$= -\frac{y^2}{c}\cos(cy) + \frac{2y}{c^2}\sin(cy) + \frac{2}{c^3}\cos(cy) + C.$$

74. Integration by parts will be used twice. First let $u = e^{-ct}$ and $dv = \sin(kt)dt$, then $du = -ce^{-ct}dt$ and $v = (-1/k)\cos kt$. Then

$$\int e^{-ct}\sin kt\,dt = -\frac{1}{k}e^{-ct}\cos kt - \frac{c}{k}\int e^{-ct}\cos kt\,dt$$
$$= -\frac{1}{k}e^{-ct}\cos kt - \frac{c}{k}\left(\frac{1}{k}e^{-ct}\sin kt + \frac{c}{k}\int e^{-ct}\sin kt\,dt\right)$$
$$= -\frac{1}{k}e^{-ct}\cos kt - \frac{c}{k^2}e^{-ct}\sin kt - \frac{c^2}{k^2}\int e^{-ct}\sin kt\,dt$$

Solving for $\int e^{-ct}\sin kt\,dt$ gives

$$\frac{k^2+c^2}{k^2}\int e^{-ct}\sin kt\,dt = -\frac{e^{-ct}}{k^2}\left(k\cos kt + c\sin kt\right),$$

so

$$\int e^{-ct}\sin kt\,dt = -\frac{e^{-ct}}{k^2+c^2}\left(k\cos kt + c\sin kt\right) + C.$$

75. Using II-9 from the integral table, with $a = 5$ and $b = 3$, we have

$$\begin{aligned}\int e^{5x}\cos(3x)\,dx &= \frac{1}{25+9}e^{5x}\left[5\cos(3x)+3\sin(3x)\right]+C\\ &= \frac{1}{34}e^{5x}\left[5\cos(3x)+3\sin(3x)\right]+C.\end{aligned}$$

76. Since $\int (x^{\sqrt{k}} + (\sqrt{k})^x)dx = \int x^{\sqrt{k}}dx + \int (\sqrt{k})^x\,dx$, for the first integral, use Formula I-1 with $n = \sqrt{k}$. For the second integral, use Formula I-3 with $a = \sqrt{k}$. The result is

$$\int (x^{\sqrt{x}} + (\sqrt{k})^x)\,dx = \frac{x^{(\sqrt{k})+1}}{(\sqrt{k})+1} + \frac{(\sqrt{k})^x}{\ln\sqrt{k}} + C.$$

77. Factor $\sqrt{3}$ out of the integrand and use VI-30 of the integral table with $u = 2x$ and $du = 2dx$ to get

$$\begin{aligned}\int \sqrt{3+12x^2}\,dx &= \int \sqrt{3}\sqrt{1+4x^2}\,dx\\ &= \frac{\sqrt{3}}{2}\int \sqrt{1+u^2}\,du\\ &= \frac{\sqrt{3}}{4}\left(u\sqrt{1+u^2} + \int \frac{1}{\sqrt{1+u^2}}\,du\right).\end{aligned}$$

Then from VI-29, simplify the integral on the right to get

$$\begin{aligned}\int \sqrt{3+12x^2}\,dx &= \frac{\sqrt{3}}{4}\left(u\sqrt{1+u^2} + \ln|u+\sqrt{1+u^2}|\right) + C\\ &= \frac{\sqrt{3}}{4}\left(2x\sqrt{1+(2x)^2} + \ln|2x+\sqrt{1+(2x)^2}|\right) + C.\end{aligned}$$

78. By completing the square, we get

$$x^2-3x+2 = (x^2-3x+(-\frac{3}{2})^2)+2-\frac{9}{4} = (x-\frac{3}{2})^2-\frac{1}{4}.$$

Then

$$\int \frac{1}{\sqrt{x^2-3x+2}}\,dx = \int \frac{1}{\sqrt{(x-\frac{3}{2})^2-\frac{1}{4}}}\,dx.$$

Let $w = (x-(3/2))$, then $dw = dx$ and $a^2 = 1/4$. Then we have

$$\int \frac{1}{\sqrt{x^2-3x+2}}\,dx = \int \frac{1}{\sqrt{w^2-a^2}}\,dw$$

and from VI-29 of the integral table we have

$$\begin{aligned}\int \frac{1}{\sqrt{w^2-a^2}}\,dw &= \ln\left|w+\sqrt{w^2-a^2}\right| + C\\ &= \ln\left|\left(x-\frac{3}{2}\right)+\sqrt{\left(x-\frac{3}{2}\right)^2-\frac{1}{4}}\right| + C\\ &= \ln\left|\left(x-\frac{3}{2}\right)+\sqrt{x^2-3x+2}\right| + C.\end{aligned}$$

79. First divide x^2+3x+2 into x^3 to obtain

$$\frac{x^3}{x^2+3x+2} = x-3+\frac{7x+6}{x^2+3x+2}.$$

Since $x^2+3x+2=(x+1)(x+2)$, we can use V-27 of the integral table (with $c=7$, $d=6$, $a=-1$, and $b=-2$) to get

$$\int \frac{7x+6}{x^2+3x+2}\,dx = -\ln|x+1| + 8\ln|x+2| + C.$$

Including the terms $x-3$ from the long division and integrating them gives

$$\int \frac{x^3}{x^2+3x+2}\,dx = \int\left(x-3+\frac{7x+6}{x^2+3x+6}\right)dx = \frac{1}{2}x^2 - 3x - \ln|x+1| + 8\ln|x+2| + C.$$

80. First divide x^2+1 by x^2-3x+2 to obtain

$$\frac{x^2+1}{x^2-3x+2} = 1+\frac{3x-1}{x^2-3x+2}.$$

Factoring $x^2-3x+2=(x-2)(x-1)$ we can use V-27 (with $c=3$, $d=-1$, $a=2$ and $b=1$) to write

$$\int \frac{3x-1}{x^2-3x+2}\,dx = 5\ln|x-2| - 2\ln|x-1| + C.$$

Remembering to include the extra term of $+1$ we got when dividing, we get

$$\int \frac{x^2+1}{x^2-3x+2}\,dx = \int\left(1+\frac{3x-1}{x^2-3x+2}\right)dx = x + 5\ln|x-2| - 2\ln|x-1| + C.$$

81. We can factor the denominator into $ax(x+\frac{b}{a})$, so

$$\int \frac{dx}{ax^2+bx} = \frac{1}{a}\int \frac{1}{x(x+\frac{b}{a})}$$

Now we can use V-26 (with $A=0$ and $B=-\frac{b}{a}$ to give

$$\frac{1}{a}\int \frac{1}{x(x+\frac{b}{a})} = \frac{1}{a}\cdot\frac{a}{b}\left(\ln|x| - \ln\left|x+\frac{b}{a}\right|\right) + C = \frac{1}{b}\left(\ln|x| - \ln\left|x+\frac{b}{a}\right|\right) + C.$$

82. Let $w = ax^2+2bx+c$, then $dw=(2ax+2b)dx$ so that

$$\int \frac{ax+b}{ax^2+2bx+c}\,dx = \frac{1}{2}\int \frac{dw}{w} = \frac{1}{2}\ln|w| + C = \frac{1}{2}\ln|ax^2+2bx+c| + C.$$

83. Multiplying out and integrating term by term,

$$\int\left(\frac{x}{3}+\frac{3}{x}\right)^2 dx = \int\left(\frac{x^2}{9}+2+\frac{9}{x^2}\right)dx = \frac{1}{9}\left(\frac{x^3}{3}\right) + 2x + 9\left(\frac{x^{-1}}{-1}\right) + C = \frac{x^3}{27} + 2x - \frac{9}{x} + C.$$

84. If $u = 2^t+1$, $du = 2^t(\ln 2)\,dt$, so

$$\int \frac{2^t}{2^t+1}\,dt = \frac{1}{\ln 2}\int \frac{2^t\ln 2}{2^t+1}\,dt = \frac{1}{\ln 2}\int \frac{1}{u} = \frac{1}{\ln 2}\ln|u| + C = \frac{1}{\ln 2}\ln|2^t+1| + C.$$

85. If $u = 1-x$, $du = -1\,dx$, so

$$\int 10^{1-x}dx = -1\int 10^{1-x}(-1\,dx) = -1\int 10^u\,du = -1\frac{10^u}{\ln 10} + C = -\frac{1}{\ln 10}10^{1-x} + C.$$

86. Multiplying out and integrating term by term gives

$$\int (x^2+5)^3 dx = \int (x^6+15x^4+75x^2+125)dx = \frac{1}{7}x^7 + 15\frac{x^5}{5} + 75\frac{x^3}{3} + 125x + C$$
$$= \frac{1}{7}x^7 + 3x^5 + 25x^3 + 125x + C.$$

87. Integrate by parts letting $r = v$ and $dt = \arcsin v\, dv$ then $dr = dv$ and to find t we integrate $\arcsin v\, dv$ by parts letting $x = \arcsin v$ and $dy = dv$. This gives

$$t = v \arcsin v - \int (1/\sqrt{1-v^2}) v\, dv = v \arcsin v + \sqrt{1-v^2}.$$

Now, back to the original integration by parts, and we have

$$\int v \arcsin v\, dv = v^2 \arcsin v + v\sqrt{1-v^2} - \int \left[v \arcsin v + \sqrt{1-v^2} \right] dv.$$

Adding $\int v \arcsin v\, dv$ to both sides of the above line we obtain

$$2\int v \arcsin v\, dv = v^2 \arcsin v + v\sqrt{1-v^2} - \int \sqrt{1-v^2}\, dv$$
$$= v^2 \arcsin v + v\sqrt{1-v^2} - \frac{1}{2} v\sqrt{1-v^2} - \frac{1}{2}\arcsin v + C.$$

Dividing by 2 gives

$$\int v \arcsin v\, dv = \left(\frac{v^2}{2} - \frac{1}{4} \right) \arcsin v + \frac{1}{4} v\sqrt{1-v^2} + K,$$

where $K = C/2$.

88. By VI-30 in the table of integrals, we have

$$\int \sqrt{4-x^2}\, dx = \frac{x\sqrt{4-x^2}}{2} + 2\int \frac{1}{\sqrt{4-x^2}}\, dx.$$

The same table informs us in formula VI-28 that

$$\int \frac{1}{\sqrt{4-x^2}}\, dx = \arcsin \frac{x}{2} + C.$$

Thus

$$\int \sqrt{4-x^2}\, dx = \frac{x\sqrt{4-x^2}}{2} + 2 \arcsin \frac{x}{2} + C.$$

89. By long division, $\dfrac{z^3}{z-5} = z^2 + 5z + 25 + \dfrac{125}{z-5}$, so

$$\int \frac{z^3}{z-5} dz = \int \left(z^2 + 5z + 25 + \frac{125}{z-5} \right) dz = \frac{z^3}{3} + \frac{5z^2}{2} + 25z + 125\int \frac{1}{z-5} dz$$
$$= \frac{z^3}{3} + \frac{5}{2}z^2 + 25z + 125 \ln|z-5| + C.$$

90. If $u = 1 + \cos^2 w$, $du = 2(\cos w)^1(-\sin w)\, dw$, so

$$\int \frac{\sin w \cos w}{1+\cos^2 w}\, dw = -\frac{1}{2}\int \frac{-2\sin w \cos w}{1+\cos^2 w}\, dw = -\frac{1}{2}\int \frac{1}{u}\, du = -\frac{1}{2}\ln|u| + C$$
$$= -\frac{1}{2}\ln|1+\cos^2 w| + C.$$

91. $\int \frac{1}{\tan(3\theta)} d\theta = \int \frac{1}{\left(\frac{\sin(3\theta)}{\cos(3\theta)}\right)} d\theta = \int \frac{\cos(3\theta)}{\sin(3\theta)} d\theta$. If $u = \sin(3\theta)$, $du = \cos(3\theta) \cdot 3d\theta$, so

$$\int \frac{\cos(3\theta)}{\sin(3\theta)} d\theta = \frac{1}{3}\int \frac{3\cos(3\theta)}{\sin(3\theta)} d\theta = \frac{1}{3}\int \frac{1}{u} du = \frac{1}{3}\ln|u| + C = \frac{1}{3}\ln|\sin(3\theta)| + C.$$

92. $\int \frac{x}{\cos^2 x} dx = \int x \frac{1}{\cos^2 x} dx$. Using integration by parts with $u = x$, $du = dx$ and $dv = \frac{1}{\cos^2 x} dx$, $v = \tan x$, we have

$$\int x\left(\frac{1}{\cos^2 x} dx\right) = x\tan x - \int \tan x dx.$$

Formula I-7 gives the final result of $x\tan x - (-\ln|\cos x|) + C = x\tan x + \ln|\cos x| + C$.

93. Dividing and integrating term by term gives

$$\int \frac{x+1}{\sqrt{x}} dx = \int \left(\frac{x}{\sqrt{x}} + \frac{1}{\sqrt{x}}\right) dx = \int (x^{1/2} + x^{-1/2}) dx = \frac{x^{3/2}}{\frac{3}{2}} + \frac{x^{1/2}}{\frac{1}{2}} + C = \frac{2}{3}x^{3/2} + 2\sqrt{x} + C.$$

94. If $u = \sqrt{x+1}$, $u^2 = x + 1$ with $x = u^2 - 1$ and $dx = 2u\,du$. Substituting, we get

$$\int \frac{x}{\sqrt{x+1}} dx = \int \frac{(u^2-1)2u\,du}{u} = \int (u^2-1)2\,du = 2\int (u^2-1)\,du$$
$$= \frac{2u^3}{3} - 2u + C = \frac{2(\sqrt{x+1})^3}{3} - 2\sqrt{x+1} + C.$$

95. $\int \frac{\sqrt{\sqrt{x}+1}}{\sqrt{x}} = \int (\sqrt{x}+1)^{1/2} \frac{1}{\sqrt{x}} dx$; if $u = \sqrt{x} + 1$, $du = \frac{1}{2\sqrt{x}} dx$, so we have

$$2\int (\sqrt{x}+1)^{1/2} \frac{1}{2\sqrt{x}} dx = 2\int u^{1/2} du = 2\left(\frac{u^{3/2}}{\frac{3}{2}}\right) + C = \frac{4}{3}u^{3/2} + C = \frac{4}{3}(\sqrt{x}+1)^{3/2} + C.$$

96. If $u = e^{2y} + 1$, then $du = e^{2y} 2\,dy$, so

$$\int \frac{e^{2y}}{e^{2y}+1} dy = \frac{1}{2}\int \frac{2e^{2y}}{e^{2y}+1} dy = \frac{1}{2}\int \frac{1}{u} du = \frac{1}{2}\ln|u| + C = \frac{1}{2}\ln|e^{2y}+1| + C.$$

97. If $u = z^2 - 5$, $du = 2z\,dz$, then

$$\int \frac{z}{(z^2-5)^3} dz = \int (z^2-5)^{-3} z\,dz = \frac{1}{2}\int (z^2-5)^{-3} 2z\,dz = \frac{1}{2}\int u^{-3}\,du = \frac{1}{2}\left(\frac{u^{-2}}{-2}\right) + C$$
$$= \frac{1}{-4(z^2-5)^2} + C.$$

98. Letting $u = z - 5$, $z = u + 5$, $dz = du$, and substituting, we have

$$\int \frac{z}{(z-5)^3} dz = \int \frac{u+5}{u^3} du = \int (u^{-2} + 5u^{-3}) du = \frac{u^{-1}}{-1} + 5\left(\frac{u^{-2}}{-2}\right) + C$$
$$= \frac{-1}{(z-5)} + \frac{-5}{2(z-5)^2} + C.$$

99. If $u = 1 + \tan x$ then $du = \frac{1}{\cos^2 x} dx$, and so

$$\int \frac{(1+\tan x)^3}{\cos^2 x} dx = \int (1+\tan x)^3 \frac{1}{\cos^2 x} dx = \int u^3\,du = \frac{u^4}{4} + C = \frac{(1+\tan x)^4}{4} + C.$$

100. $\int \frac{(2x-1)e^{x^2}}{e^x}dx = \int e^{x^2-x}(2x-1)dx$. If $u = x^2 - x$, $du = (2x-1)dx$, so

$$\begin{aligned}\int e^{x^2-x}(2x-1)dx &= \int e^u du \\ &= e^u + c \\ &= e^{x^2-x} + C.\end{aligned}$$

101. We use the substitution $w = x^2 + x,\ dw = (2x+1)\,dx$.

$$\begin{aligned}\int (2x+1)e^{x^2}e^x\,dx &= \int (2x+1)e^{x^2+x}\,dx = \int e^w\,dw \\ &= e^w + C = e^{x^2+x} + C.\end{aligned}$$

Check: $\frac{d}{dx}(e^{x^2+x} + C) = e^{x^2+x}\cdot(2x+1) = (2x+1)e^{x^2}e^x$.

102. Let $w = y^2 - 2y + 1$, so $dw = 2(y-1)\,dy$. Then

$$\int \sqrt{y^2-2y+1}(y-1)\,dy = \int w^{1/2}\frac{1}{2}\,dw = \frac{1}{2}\cdot\frac{2}{3}w^{3/2} + C = \frac{1}{3}(y^2-2y+1)^{3/2} + C.$$

Alternatively, notice the integrand can be written $\sqrt{(y-1)^2}(y-1) = (y-1)^2$. This leads to a different-looking but equivalent answer.

103. Let $w = 2 + 3\cos x$, so $dw = -3\sin x\,dx$, giving $-\frac{1}{3}\,dw = \sin x\,dx$. Then

$$\begin{aligned}\int \sin x\left(\sqrt{2+3\cos x}\right)\,dx &= \int \sqrt{w}\left(-\frac{1}{3}\right)\,dw = -\frac{1}{3}\int \sqrt{w}\,dw \\ &= \left(-\frac{1}{3}\right)\frac{w^{\frac{3}{2}}}{\frac{3}{2}} + C = -\frac{2}{9}(2+3\cos x)^{\frac{3}{2}} + C.\end{aligned}$$

104. Using Table III-14, with $a = -4$ we have

$$\begin{aligned}\int (x^2-3x+2)e^{-4x}\,dx &= -\frac{1}{4}(x^2-3x+2)e^{-4x} \\ &\quad -\frac{1}{16}(2x-3)e^{-4x} - \frac{1}{64}(2)e^{-4x} + C. \\ &= \frac{1}{32}e^{-4x}(-11+20x-8x^2) + C.\end{aligned}$$

105. Let $x = 2\theta$, then $dx = 2d\theta$. Thus

$$\int \sin^2(2\theta)\cos^3(2\theta)\,d\theta = \frac{1}{2}\int \sin^2 x\cos^3 x\,dx.$$

We let $w = \sin x$ and $dw = \cos x\,dx$. Then

$$\begin{aligned}\frac{1}{2}\int \sin^2 x\cos^3 x\,dx &= \frac{1}{2}\int \sin^2 x\cos^2 x\cos x\,dx \\ &= \frac{1}{2}\int \sin^2 x(1-\sin^2 x)\cos x\,dx \\ &= \frac{1}{2}\int w^2(1-w^2)\,dw = \frac{1}{2}\int (w^2-w^4)\,dw \\ &= \frac{1}{2}\left(\frac{w^3}{3} - \frac{w^5}{5}\right) + C = \frac{1}{6}\sin^3 x - \frac{1}{10}\sin^5 x + C \\ &= \frac{1}{6}\sin^3(2\theta) - \frac{1}{10}\sin^5(2\theta) + C.\end{aligned}$$

106. If $u = 2\sin x$, then $du = 2\cos x\,dx$, so

$$\begin{aligned}\int \cos(2\sin x)\cos x\,dx &= \frac{1}{2}\int \cos(2\sin x)2\cos x\,dx = \frac{1}{2}\int \cos u\,du \\ &= \frac{1}{2}\sin u + C = \frac{1}{2}\sin(2\sin x) + C.\end{aligned}$$

107. Let $w = x + \sin x$, then $dw = (1+\cos x)\,dx$ which gives

$$\int (x+\sin x)^3(1+\cos x)\,dx = \int w^3\,dw = \frac{1}{4}w^4 + C = \frac{1}{4}(x+\sin x)^4 + C.$$

108. Using Table III-16,

$$\begin{aligned}\int \left(2x^3+3x+4\right)\cos(2x)\,dx &= \frac{1}{2}(2x^3+3x+4)\sin(2x) \\ &\quad +\frac{1}{4}(6x^2+3)\cos(2x) \\ &\quad -\frac{1}{8}(12x)\sin(2x) - \frac{3}{4}\cos(2x) + C. \\ &= 2\sin(2x) + x^3\sin(2x) + \frac{3x^2}{2}\cos(2x) + C.\end{aligned}$$

109. Use the substitution $w = \sinh x$ and $dw = \cosh x dx$ so

$$\int \sinh^2 x\cosh x\,dx = \int w^2\,dw = \frac{w^3}{3} + C = \frac{1}{3}\sinh^3 x + C.$$

Check this answer by taking the derivative: $\dfrac{d}{dx}\left[\dfrac{1}{3}\sinh^3 x + C\right] = \sinh^2 x\cosh x.$

110. We use the substitution $w = x^2 + 2x$ and $dw = (2x+2)\,dx$ so

$$\int (x+1)\sinh(x^2+2x)\,dx = \frac{1}{2}\int \sinh w\,dw = \frac{1}{2}\cosh w + C = \frac{1}{2}\cosh(x^2+2x) + C.$$

Check this answer by taking the derivative: $\dfrac{d}{dx}\left[\dfrac{1}{2}\cosh(x^2+2x) + C\right] = \dfrac{1}{2}(2x+2)\sinh(x^2+2x) = (x+1)\sinh(x^2+2x)$.

111. Substitute $w = 1 + x^2$, $dw = 2x\,dx$. Then $x\,dx = \dfrac{1}{2}\,dw$, and

$$\int_{x=0}^{x=1} x(1+x^2)^{20}\,dx = \frac{1}{2}\int_{w=1}^{w=2} w^{20}\,dw = \left.\frac{w^{21}}{42}\right|_1^2 = \frac{299593}{6} = 49932\frac{1}{6}.$$

112. Substitute $w = x^2 + 4,\ dw = 2x\,dx$. Then,

$$\begin{aligned}\int_{x=4}^{x=1} x\sqrt{x^2+4}\,dx &= \frac{1}{2}\int_{w=20}^{w=5} w^{\frac{1}{2}}\,dw = \left.\frac{1}{3}w^{\frac{3}{2}}\right|_{20}^{5} \\ &= \frac{1}{3}\left(5^{\frac{3}{2}} - 8\cdot 5^{\frac{3}{2}}\right) = -\frac{7}{3}\cdot 5^{3/2} = -\frac{35}{3}\sqrt{5}\end{aligned}$$

113. We substitute $w = \cos\theta + 5$, $dw = -\sin\theta\,d\theta$. Then

$$\int_{\theta=0}^{\theta=\pi} \sin\theta\,d\theta(\cos\theta+5)^7 = -\int_{w=6}^{w=4} w^7 dw = \int_{w=4}^{w=6} w^7 dw = \left.\frac{w^8}{8}\right|_4^6 = 201{,}760.$$

114. Let $w = 1 + 5x^2$. We have $dw = 10x\,dx$, so $\dfrac{dw}{10} = x\,dx$. When $x = 0$, $w = 1$. When $x = 1$, $w = 6$.

$$\begin{aligned}\frac{x\,dx}{1+5x^2} &= \int_1^6 \frac{\frac{1}{10}\,dw}{w} = \frac{1}{10}\int_1^6 \frac{dw}{w} = \frac{1}{10}\ln|w|\Big|_1^6 \\ &= \frac{1}{10}(\ln 6 - \ln 1) = \frac{\ln 6}{10}\end{aligned}$$

115.

$$\int_1^2 \frac{x^2+1}{x}dx = \int_1^2 (x + \frac{1}{x})dx = \left(\frac{x^2}{2} + \ln|x|\right)\Bigg|_1^2 = \frac{3}{2} + \ln 2.$$

116. Using integration by parts, we have

$$\int_1^3 \ln(x^3)\,dx = 3\int_1^3 \ln x\,dx = 3(x\ln x - x)\Big|_1^3 = 9\ln 3 - 6 \approx 3.8875.$$

This matches the approximation given by Simpson's rule with 10 intervals.

117. In Problem 25, we found that

$$\int (\ln x)^2\,dx = x(\ln x)^2 - 2x\ln x + 2x + C.$$

Thus

$$\int_1^e (\ln x)^2\,dx = [x(\ln x)^2 - 2x\ln x + 2x]\Big|_1^e = e - 2 \approx 0.71828.$$

This matches the approximation given by Simpson's rule with 10 intervals.

118. Integrating by parts, we take $u = e^{2x}$, $u' = 2e^{2x}$, $v' = \sin 2x$, and $v = -\frac{1}{2}\cos 2x$, so

$$\int e^{2x}\sin 2x\,dx = -\frac{e^{2x}}{2}\cos 2x + \int e^{2x}\cos 2x\,dx.$$

Integrating by parts again, with $u = e^{2x}$, $u' = 2e^{2x}$, $v' = \cos 2x$, and $v = \frac{1}{2}\sin 2x$, we get

$$\int e^{2x}\cos 2x\,dx = \frac{e^{2x}}{2}\sin 2x - \int e^{2x}\sin 2x\,dx.$$

Substituting into the previous equation, we obtain

$$\int e^{2x}\sin 2x\,dx = -\frac{e^{2x}}{2}\cos 2x + \frac{e^{2x}}{2}\sin 2x - \int e^{2x}\sin 2x\,dx.$$

Solving for $\int e^{2x}\sin 2x\,dx$ gives

$$\int e^{2x}\sin 2x\,dx = \frac{1}{4}e^{2x}(\sin 2x - \cos 2x) + C.$$

This result can also be obtained using II-8 in the integral table. Thus

$$\int_{-\pi}^{\pi} e^{2x}\sin 2x = [\frac{1}{4}e^{2x}(\sin 2x - \cos 2x)]\Big|_{-\pi}^{\pi} = \frac{1}{4}(e^{-2\pi} - e^{2\pi}) \approx -133.8724.$$

We get -133.37 using Simpson's rule with 10 intervals. With 100 intervals, we get -133.8724. Thus our answer matches the approximation of Simpson's rule.

119.

$$\begin{aligned}\int_0^{10} ze^{-z}\,dz &= [-ze^{-z}]\Big|_0^{10} - \int_0^{10} -e^{-z}\,dz \qquad (\text{let } z=u, e^{-z}=v', -e^{-z}=v)\\ &= -10e^{-10} - [e^{-z}]\Big|_0^{10}\\ &= -10e^{-10} - e^{-10} + 1\\ &= -11e^{-10} + 1.\end{aligned}$$

120. Let $\sin\theta = w$, $\cos\theta\,d\theta = dw$. So, if $\theta = -\frac{\pi}{3}$, then $w = -\frac{\sqrt{3}}{2}$, and if $\theta = \frac{\pi}{4}$, then $w = \frac{\sqrt{2}}{2}$. So we have

$$\int_{-\pi/3}^{\pi/4} \sin^3\theta\cos\theta\,d\theta = \int_{-\sqrt{3}/2}^{\sqrt{2}/2} w^3\,dw = \frac{1}{4}w^4\Big|_{-\sqrt{3}/2}^{\sqrt{2}/2} = \frac{1}{4}\left[\left(\frac{\sqrt{2}}{2}\right)^4 - \left(\frac{-\sqrt{3}}{2}\right)^4\right] = -\frac{5}{64}.$$

121. We substitute $w = \sqrt[3]{x} = x^{\frac{1}{3}}$. Then $dw = \frac{1}{3}x^{-\frac{2}{3}}\,dx = \frac{1}{3\sqrt[3]{x^2}}\,dx$.

$$\int_1^8 \frac{e^{\sqrt[3]{x}}}{\sqrt[3]{x^2}}dx = \int_{x=1}^{x=8} e^w(3\,dw) = 3e^w\Big|_{x=1}^{x=8} = 3e^{\sqrt[3]{x}}\Big|_1^8 = 3(e^2 - e).$$

122.

$$\int_0^1 \frac{dx}{x^2+1} = \tan^{-1}x\Big|_0^1 = \tan^{-1}1 - \tan^{-1}0 = \frac{\pi}{4} - 0 = \frac{\pi}{4}.$$

123. We put the integral in a convenient form for a substitution by using the fact that $\sin^2\theta = 1 - \cos^2\theta$. Thus: $\int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \cos^2\theta\sin^5\theta\,d\theta = \int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \cos^2\theta(1-\cos^2\theta)^2\sin\theta\,d\theta.$

Now, we can make a substitution which helps. We let $w = \cos\theta$, so $dw = -\sin\theta\,d\theta$.

Note that $w = \frac{\sqrt{2}}{2}$ when $\theta = -\frac{\pi}{4}$ and when $\theta = \frac{\pi}{4}$. Thus after our substitution, we get

$$-\int_{w=\frac{\pi}{4}}^{w=\frac{\pi}{4}} w^2(1-w^2)^2\,dw.$$

Since the upper and lower limits of integration are the same, this definite integral must equal 0. Notice that we could have deduced this fact immediately, since $\cos^2\theta$ is even and $\sin^5\theta$ is odd, so $\cos^2\theta\sin^5\theta$ is odd.

Thus $\int_{-\frac{\pi}{4}}^{0} \cos^2\theta\sin^5\theta\,d\theta = -\int_0^{\frac{\pi}{4}} \cos^2\theta\sin^5\theta\,d\theta$, and the given integral must evaluate to 0.

124. We substitute $w = x^2 + 4x + 5$, so $dw = (2x+4)\,dx$. Notice that when $x = -2, w = 1$, and when $x = 0, w = 5$.

$$\int_{x=-2}^{x=0} \frac{2x+4}{x^2+4x+5}\,dx = \int_{w=1}^{w=5} \frac{1}{w}\,dw = \ln|w|\Big|_{w=1}^{w=5} = \ln 5.$$

125. Since $\frac{1}{x^2-1} = \frac{1}{(x-1)(x+1)}$, let's imagine that our fraction is the result of adding together two terms, one with a denominator of $x-1$, the other with a denominator of $x+1$:

$$\frac{1}{(x-1)(x+1)} = \frac{A}{x-1} + \frac{B}{x+1}.$$

To find A and B, we multiply by the least common multiple of both sides to clear the fractions. This yields

$$\begin{aligned}1 &= A(x+1) + B(x-1)\\ &= (A+B)x + (A-B).\end{aligned}$$

Since the two sides are equal for all values of x in the domain, and there is no x term on the left-hand side, $A + B = 0$. Similarly, since A and $-B$ are constant terms on the right-hand side, and 1 is the constant term on the left-hand side, $A - B = 1$. Therefore, we have the system of equations

$$\begin{aligned} A + B &= 0 \\ A - B &= 1. \end{aligned}$$

Solving this gives us $A = 1/2$ and $B = -1/2$, so

$$\frac{1}{x^2 - 1} = \frac{1}{2(x-1)} - \frac{1}{2(x+1)}.$$

Now, we find the integral

$$\begin{aligned} \int \frac{1}{x^2-1} dx &= \int \left(\frac{1}{2(x-1)} - \frac{1}{2(x+1)} \right) dx \\ &= \frac{1}{2} \ln|x-1| - \frac{1}{2} \ln|x+1| + C. \end{aligned}$$

126. (a) We split $\frac{1}{x^2-x} = \frac{1}{x(x-1)}$ into partial fractions:

$$\frac{1}{x^2-x} = \frac{A}{x} + \frac{B}{x-1}.$$

Multiplying by $x(x-1)$ gives

$$1 = A(x-1) + Bx = (A+B)x - A,$$

so $-A = 1$ and $A + B = 0$, giving $A = -1$, $B = 1$. Therefore,

$$\int \frac{1}{x^2-x}\, dx = \int \left(\frac{1}{x-1} - \frac{1}{x} \right) dx = \ln|x-1| - \ln|x| + C.$$

(b) $\displaystyle\int \frac{1}{x^2-x}\, dx = \int \frac{1}{(x-1)(x)}\, dx$. Using $a = 1$ and $b = 0$ in V-26, we get $\ln|x-1| - \ln|x| + C$.

127. Split the integrand into partial fractions, giving

$$\begin{aligned} \frac{1}{x(L-x)} &= \frac{A}{x} + \frac{B}{L-x} \\ 1 &= A(L-x) + Bx = (B-A)x + AL. \end{aligned}$$

We have $B - A = 0$ and $AL = 1$, so $A = B = 1/L$. Thus,

$$\int \frac{1}{x(L-x)}\, dx = \int \frac{1}{L}\left(\frac{1}{x} + \frac{1}{L-x} \right) dx = \frac{1}{L}\left(\ln|x| - \ln|L-x| \right) + C.$$

128. Splitting the integrand into partial fractions with denominators $(x-2)$ and $(x+2)$, we have

$$\frac{1}{(x-2)(x+2)} = \frac{A}{x-2} + \frac{B}{x+2}.$$

Multiplying by $(x-2)(x+2)$ gives the identity

$$1 = A(x+2) + B(x-2)$$

so

$$1 = (A+B)x + 2A - 2B.$$

Since this equation holds for all x, the constant terms on both sides must be equal. Similarly, the coefficient of x on both sides must be equal. So

$$\begin{aligned} 2A - 2B &= 1 \\ A + B &= 0. \end{aligned}$$

Solving these equations gives $A = 1/4$, $B = -1/4$ and the integral becomes

$$\int \frac{1}{(x-2)(x+2)} dx = \frac{1}{4} \int \frac{1}{x-2} dx - \frac{1}{4} \int \frac{1}{x+2} dx = \frac{1}{4}\left(\ln|x-2| - \ln|x+2| \right) + C.$$

129. Let $x = 5\sin t$. Then $dx = 5\cos t\,dt$, so substitution gives

$$\int \frac{1}{\sqrt{25-x^2}} = \int \frac{5\cos t}{\sqrt{25-25\sin^2 t}}dt = \int dt = t + C = \arcsin\left(\frac{x}{5}\right) + C.$$

130. Splitting the integrand into partial fractions with denominators x and $(x+5)$, we have

$$\frac{1}{x(x+5)} = \frac{A}{x} + \frac{B}{x+5}.$$

Multiplying by $x(x+5)$ gives the identity

$$1 = A(x+5) + Bx$$

so

$$1 = (A+B)x + 5A.$$

Since this equation holds for all x, the constant terms on both sides must be equal. Similarly, the coefficient of x on both sides must be equal. So

$$\begin{aligned} 5A &= 1 \\ A + B &= 0. \end{aligned}$$

Solving these equations gives $A = 1/5$, $B = -1/5$ and the integral becomes

$$\int \frac{1}{x(x+5)}dx = \frac{1}{5}\int \frac{1}{x}dx - \frac{1}{5}\int \frac{1}{x+5}dx = \frac{1}{5}\left(\ln|x| - \ln|x+5|\right) + C.$$

131. We use the trigonometric substitution $3x = \sin\theta$. Then $dx = \frac{1}{3}\cos\theta\,d\theta$ and substitution gives

$$\begin{aligned} \int \frac{1}{\sqrt{1-9x^2}}\,dx &= \int \frac{1}{\sqrt{1-\sin^2\theta}} \cdot \frac{1}{3}\cos\theta\,d\theta = \frac{1}{3}\int \frac{\cos\theta}{\sqrt{\cos^2\theta}}\,d\theta \\ &= \frac{1}{3}\int 1\,d\theta = \frac{1}{3}\theta + C = \frac{1}{3}\arcsin(3x) + C. \end{aligned}$$

132. Splitting the integrand into partial fractions with denominators x, $(x+2)$ and $(x-1)$, we have

$$\frac{2x+3}{x(x+2)(x-1)} = \frac{A}{x} + \frac{B}{x+2} + \frac{C}{x-1}.$$

Multiplying by $x(x+2)(x-1)$ gives the identity

$$2x + 3 = A(x+2)(x-1) + Bx(x-1) + Cx(x+2)$$

so

$$2x + 3 = (A+B+C)x^2 + (A-B+2C)x - 2A.$$

Since this equation holds for all x, the constant terms on both sides must be equal. Similarly, the coefficient of x on both sides must be equal. So

$$\begin{aligned} -2A &= 3 \\ A - B + 2C &= 2 \\ A + B + C &= 0. \end{aligned}$$

Solving these equations gives $A = -3/2$, $B = -1/6$ and $C = 5/3$. The integral becomes

$$\begin{aligned} \int \frac{2x+3}{x(x+2)(x-1)}dx &= -\frac{3}{2}\int \frac{1}{x}dx - \frac{1}{6}\int \frac{1}{x+2} + \frac{5}{3}\int \frac{1}{x-1}dx \\ &= -\frac{3}{2}\ln|x| - \frac{1}{6}\ln|x+2| + \frac{5}{3}\ln|x-1| + K. \end{aligned}$$

We use K as the constant of integration, since we already used C in the problem.

133. The denominator can be factored to give $x(x-1)(x+1)$. Splitting the integrand into partial fractions with denominators x, $x-1$, and $x+1$, we have

$$\frac{3x+1}{x(x-1)(x+1)} = \frac{A}{x-1} + \frac{B}{x+1} + \frac{C}{x}.$$

Multiplying by $x(x-1)(x+1)$ gives the identity

$$3x+1 = Ax(x+1) + Bx(x-1) + C(x-1)(x+1)$$

so

$$3x+1 = (A+B+C)x^2 + (A-B)x - C.$$

Since this equation holds for all x, the constant terms on both sides must be equal. Similarly, the coefficient of x and x^2 on both sides must be equal. So

$$\begin{aligned} -C &= 1 \\ A-B &= 3 \\ A+B+C &= 0. \end{aligned}$$

Solving these equations gives $A = 2$, $B = -1$ and $C = -1$. The integral becomes

$$\begin{aligned} \int \frac{3x+1}{x(x+1)(x-1)}dx &= \int \frac{2}{x-1}dx - \int \frac{1}{x+1}dx - \int \frac{1}{x}dx \\ &= 2\ln|x-1| - \ln|x+1| - \ln|x| + K. \end{aligned}$$

We use K as the constant of integration, since we already used C in the problem.

134. Splitting the integrand into partial fractions with denominators $(1+x)$, $(1+x)^2$ and x, we have

$$\frac{1+x^2}{x(1+x)^2} = \frac{A}{1+x} + \frac{B}{(1+x)^2} + \frac{C}{x}.$$

Multiplying by $x(1+x)^2$ gives the identity

$$1+x^2 = Ax(1+x) + Bx + C(1+x)^2$$

so

$$1+x^2 = (A+C)x^2 + (A+B+2C)x + C.$$

Since this equation holds for all x, the constant terms on both sides must be equal. Similarly, the coefficient of x and x^2 on both sides must be equal. So

$$\begin{aligned} C &= 1 \\ A+B+2C &= 0 \\ A+C &= 1. \end{aligned}$$

Solving these equations gives $A = 0$, $B = -2$ and $C = 1$. The integral becomes

$$\int \frac{1+x^2}{(1+x)^2 x}dx = -2\int \frac{1}{(1+x)^2}dx + \int \frac{1}{x}dx = \frac{2}{1+x} + \ln|x| + K.$$

We use K as the constant of integration, since we already used C in the problem.

135. Completing the square, we get

$$x^2 + 2x + 2 = (x+1)^2 + 1.$$

We use the substitution $x + 1 = \tan t$, so $dx = (1/\cos^2 t)dt$. Since $\tan^2 t + 1 = 1/\cos^2 t$, the integral becomes

$$\int \frac{1}{(x+1)^2+1}dx = \int \frac{1}{\tan^2 t + 1} \cdot \frac{1}{\cos^2 t}dt = \int dt = t + C = \arctan(x+1) + C.$$

136. Completing the square in the denominator gives

$$\int \frac{dx}{x^2+4x+5} = \int \frac{dx}{(x+2)^2+1}.$$

We make the substitution $\tan\theta = x+2$. Then $dx = \frac{1}{\cos^2\theta}\,d\theta$.

$$\begin{aligned}\int \frac{dx}{(x+2)^2+1} &= \int \frac{d\theta}{\cos^2\theta(\tan^2\theta+1)}\\ &= \int \frac{d\theta}{\cos^2\theta(\frac{\sin^2\theta}{\cos^2\theta}+1)}\\ &= \int \frac{d\theta}{\sin^2\theta+\cos^2\theta}\\ &= \int d\theta = \theta + C\end{aligned}$$

But since $\tan\theta = x+2$, $\theta = \arctan(x+2)$, and so $\theta + C = \arctan(x+2)+C$.

137. We use the trigonometric substitution $bx = a\sin\theta$. Then $dx = \frac{a}{b}\cos\theta\,d\theta$, and we have

$$\begin{aligned}\int \frac{1}{\sqrt{a^2-(bx)^2}}\,dx &= \int \frac{1}{\sqrt{a^2-(a\sin\theta)^2}}\cdot\frac{a}{b}\cos\theta\,d\theta = \int \frac{1}{a\sqrt{1-\sin^2\theta}}\cdot\frac{a}{b}\cos\theta\,d\theta\\ &= \frac{1}{b}\int\frac{\cos\theta}{\sqrt{\cos^2\theta}}\,d\theta = \frac{1}{b}\int 1\,d\theta = \frac{1}{b}\theta + C = \frac{1}{b}\arcsin\left(\frac{bx}{a}\right)+C.\end{aligned}$$

138. Using the substitution $w = \sin x$, we get $dw = \cos x dx$, so we have

$$\int \frac{\cos x}{\sin^3 x+\sin x}\,dx = \int \frac{dw}{w^3+w}.$$

But

$$\frac{1}{w^3+w} = \frac{1}{w(w^2+1)} = \frac{1}{w} - \frac{w}{w^2+1},$$

so

$$\begin{aligned}\int \frac{\cos x}{\sin^3 x+\sin x}\,dx &= \int\left(\frac{1}{w}-\frac{w}{w^2+1}\right)dw\\ &= \ln|w| - \frac{1}{2}\ln\left|w^2+1\right| + C\\ &= \ln|\sin x| - \frac{1}{2}\ln\left|\sin^2 x+1\right| + C.\end{aligned}$$

139. Using the substitution $w = e^x$, we get $dw = e^x dx$, so we have

$$\int \frac{e^x}{e^{2x}-1}\,dx = \int \frac{dw}{w^2-1}.$$

But

$$\frac{1}{w^2-1} = \frac{1}{(w-1)(w+1)} = \frac{1}{2}\left(\frac{1}{w-1}-\frac{1}{w+1}\right),$$

so

$$\begin{aligned}\int \frac{e^x}{e^{2x}-1}\,dx &= \int \frac{1}{2}\left(\frac{1}{w-1}-\frac{1}{w+1}\right)dw\\ &= \frac{1}{2}(\ln|w-1| - \ln|w+1|) + C\\ &= \frac{1}{2}(\ln|e^x-1| - \ln|e^x+1|) + C.\end{aligned}$$

140. This is an improper integral because $\sqrt{16-x^2}=0$ at $x=4$. So

$$\begin{aligned}\int_0^4 \frac{dx}{\sqrt{16-x^2}} &= \lim_{b\to 4^-}\int_0^b \frac{dx}{\sqrt{16-x^2}}\\ &= \lim_{b\to 4^-}(\arcsin x/4)\Big|_0^b\\ &= \lim_{b\to 4^-}[\arcsin(b/4)-\arcsin(0)] = \pi/2-0=\pi/2.\end{aligned}$$

141. This integral is improper because $5/x^2$ is undefined at $x=0$. Then

$$\int_0^3 \frac{5}{x^2}\,dx = \lim_{b\to 0^+}\int_b^3 \frac{5}{x^2}\,dx = \lim_{b\to 0^+}\left(-5x^{-1}\Big|_b^3\right) = \lim_{b\to 0^+}\left(\frac{-5}{3}+\frac{5}{b}\right).$$

As $b\to 0^+$, this goes to infinity and the integral diverges.

142. This integral is improper because $1/(x-2)$ is undefined at $x=2$. Then

$$\int_0^2 \frac{1}{x-2}\,dx = \lim_{b\to 2^-}\int_0^b \frac{1}{x-2}\,dx = \lim_{b\to 2^-}\left(\ln|x-2|\Big|_0^b\right) = \lim_{b\to 2^-}\left(\ln|b-2|-\ln 2\right).$$

As $b\to 2^-$, this goes to negative infinity and the integral diverges.

143. This integral is improper because $1/\sqrt[3]{8-x}$ is undefined at $x=8$. Then

$$\int_0^8 \frac{1}{\sqrt[3]{8-x}}\,dx = \lim_{b\to 8^-}\int_0^b (8-x)^{-1/3}\,dx = \lim_{b\to 8^-}\left(-1.5(8-x)^{2/3}\Big|_0^b\right) = \lim_{b\to 8^-}\left(-1.5(8-b)^{2/3}+1.5(8^{2/3})\right)=6.$$

The integral converges.

144. $\displaystyle\int_4^\infty \frac{dt}{t^{3/2}}$ should converge, since $\displaystyle\int_1^\infty \frac{dt}{t^n}$ converges for $n>1$.
We calculate its value.
$$\int_4^\infty \frac{dt}{t^{3/2}} = \lim_{b\to\infty}\int_4^b t^{-3/2}\,dt = \lim_{b\to\infty} -2t^{-1/2}\Big|_4^b = \lim_{b\to\infty}\left(1-\frac{2}{\sqrt{b}}\right)=1.$$

145. $\displaystyle\int \frac{dx}{x\ln x} = \ln|\ln x| + C$. (Substitute $w=\ln x$, $dw=\frac{1}{x}\,dx$).
Thus
$$\int_{10}^\infty \frac{dx}{x\ln x} = \lim_{b\to\infty}\int_{10}^b \frac{dx}{x\ln x} = \lim_{b\to\infty}\ln|\ln x|\Big|_{10}^b = \lim_{b\to\infty}\ln(\ln b)-\ln(\ln 10).$$

As $b\to\infty$, $\ln(\ln b)\to\infty$, so this diverges.

146. To find $\displaystyle\int we^{-w}\,dw$, integrate by parts, with $u=w$ and $v'=e^{-w}$. Then $u'=1$ and $v=-e^{-w}$.
Then
$$\int we^{-w}\,dw = -we^{-w} + \int e^{-w}\,dw = -we^{-w}-e^{-w}+C.$$

Thus
$$\int_0^\infty we^{-w}\,dw = \lim_{b\to\infty}\int_0^b we^{-w}\,dw = \lim_{b\to\infty}(-we^{-w}-e^{-w})\Big|_0^b = 1.$$

147. The trouble spot is at $x=0$, so we write

$$\int_{-1}^1 \frac{1}{x^4}\,dx = \int_{-1}^0 \frac{1}{x^4}\,dx + \int_0^1 \frac{1}{x^4}\,dx.$$

However, both these integrals diverge. For example,

$$\int_0^1 \frac{1}{x^4}\,dx = \lim_{a\to 0^+}\int_a^1 \frac{1}{x^4}\,dx = \lim_{a\to 0^+} -\frac{x^{-3}}{3}\Big|_a^1 = \lim_{a\to 0^+}\left(\frac{1}{3a^3}-\frac{1}{3}\right).$$

Since this limit does not exist, $\int_0^1 \frac{1}{x^4}\,dx$ diverges and so the original integral diverges.

148. Since the value of $\tan\theta$ is between -1 and 1 on the interval $-\pi/4 \le \theta \le \pi/4$, our integral is not improper and so converges. Moreover, since $\tan\theta$ is an odd function, we have

$$\begin{aligned}\int_{-\frac{\pi}{4}}^{\frac{\pi}{4}} \tan\theta\,d\theta &= \int_{-\frac{\pi}{4}}^{0} \tan\theta\,d\theta + \int_0^{\frac{\pi}{4}} \tan\theta\,d\theta \\ &= -\int_{-\frac{\pi}{4}}^{0} \tan(-\theta)\,d\theta + \int_0^{\frac{\pi}{4}} \tan\theta\,d\theta \\ &= -\int_0^{\frac{\pi}{4}} \tan\theta\,d\theta + \int_0^{\frac{\pi}{4}} \tan\theta\,d\theta = 0.\end{aligned}$$

149. It is easy to see that this integral converges:

$$\frac{1}{4+z^2} < \frac{1}{z^2}, \quad \text{and so} \quad \int_2^\infty \frac{1}{4+z^2}\,dz < \int_2^\infty \frac{1}{z^2}\,dz = \frac{1}{2}.$$

We can also find its exact value.

$$\begin{aligned}\int_2^\infty \frac{1}{4+z^2}\,dz &= \lim_{b\to\infty}\int_2^b \frac{1}{4+z^2}\,dz \\ &= \lim_{b\to\infty}\left(\frac{1}{2}\arctan\frac{z}{2}\Big|_2^b\right) \\ &= \lim_{b\to\infty}\left(\frac{1}{2}\arctan\frac{b}{2} - \frac{1}{2}\arctan 1\right) \\ &= \frac{1}{2}\frac{\pi}{2} - \frac{1}{2}\frac{\pi}{4} = \frac{\pi}{8}.\end{aligned}$$

Note that $\frac{\pi}{8} < \frac{1}{2}$.

150. We find the exact value:

$$\begin{aligned}\int_{10}^\infty \frac{1}{z^2-4}\,dz &= \int_{10}^\infty \frac{1}{(z+2)(z-2)}\,dz \\ &= \lim_{b\to\infty}\int_{10}^b \frac{1}{(z+2)(z-2)}\,dz \\ &= \lim_{b\to\infty}\frac{1}{4}\left(\ln|z-2| - \ln|z+2|\right)\Big|_{10}^b \\ &= \frac{1}{4}\lim_{b\to\infty}\left[(\ln|b-2| - \ln|b+2|) - (\ln 8 - \ln 12)\right] \\ &= \frac{1}{4}\lim_{b\to\infty}\left[\left(\ln\frac{b-2}{b+2}\right) + \ln\frac{3}{2}\right] \\ &= \frac{1}{4}(\ln 1 + \ln 3/2) = \frac{\ln 3/2}{4}.\end{aligned}$$

151. Substituting $w = t+5$, we see that our integral is just $\int_0^{15} \frac{dw}{\sqrt{w}}$. This will converge, since $\int_0^b \frac{dw}{w^p}$ converges for $0 < p < 1$. We find its exact value:

$$\int_0^{15} \frac{dw}{\sqrt{w}} = \lim_{a\to 0^+}\int_a^{15} \frac{dw}{\sqrt{w}} = \lim_{a\to 0^+} 2w^{\frac{1}{2}}\Big|_a^{15} = 2\sqrt{15}.$$

152. Since $\sin\phi < \phi$ for $\phi > 0$,

$$\int_0^{\frac{\pi}{2}} \frac{1}{\sin\phi}\, d\phi > \int_0^{\frac{\pi}{2}} \frac{1}{\phi}\, d\phi,$$

The integral on the right diverges, so the integral on the left must also. Alternatively, we use IV-20 in the integral table to get

$$\begin{aligned}\int_0^{\frac{\pi}{2}} \frac{1}{\sin\phi}\, d\phi &= \lim_{b\to 0^+} \int_b^{\frac{\pi}{2}} \frac{1}{\sin\phi}\, d\phi \\ &= \lim_{b\to 0^+} \frac{1}{2}\ln\left|\frac{\cos\phi - 1}{\cos\phi + 1}\right|\Bigg|_b^{\frac{\pi}{2}} \\ &= -\frac{1}{2}\lim_{b\to 0^+} \ln\left|\frac{\cos b - 1}{\cos b + 1}\right|.\end{aligned}$$

As $b \to 0^+$, $\cos b - 1 \to 0$ and $\cos b + 1 \to 2$, so $\ln\left|\frac{\cos b - 1}{\cos b + 1}\right| \to -\infty$. Thus the integral diverges.

153. Let $\phi = 2\theta$. Then $d\phi = 2\, d\theta$, and

$$\begin{aligned}\int_0^{\pi/4} \tan 2\theta\, d\theta &= \int_0^{\pi/2} \frac{1}{2}\tan\phi\, d\phi = \int_0^{\pi/2} \frac{1}{2}\frac{\sin\phi}{\cos\phi}\, d\phi \\ &= \lim_{b\to(\pi/2)^-} \int_0^b \frac{1}{2}\frac{\sin\phi}{\cos\phi}\, d\phi = \lim_{b\to(\pi/2)^-} -\frac{1}{2}\ln|\cos\phi|\Bigg|_0^b.\end{aligned}$$

As $b \to \pi/2$, $\cos\phi \to 0$, so $\ln|\cos\phi| \to -\infty$. Thus the integral diverges.

One could also see this by noting that $\cos x \approx \pi/2 - x$ and $\sin x \approx 1$ for x close to $\pi/2$: therefore, $\tan x \approx 1/(\frac{\pi}{2} - x)$, the integral of which diverges.

154. The integrand $\dfrac{x}{x+1} \to 1$ as $x \to \infty$, so there's no way $\displaystyle\int_1^{\infty} \frac{x}{x+1}\, dx$ can converge.

155. This function is difficult to integrate, so instead we try to compare it with some other function. Since $\frac{\sin^2\theta}{\theta^2+1} \geq 0$, we see that $\int_0^{\infty} \frac{\sin^2\theta}{\theta^2+1}\, d\theta \geq 0$. Also, since $\sin^2\theta \leq 1$,

$$\int_0^{\infty} \frac{\sin^2\theta}{\theta^2+1}\, d\theta \leq \int_0^{\infty} \frac{1}{\theta^2+1}\, d\theta = \lim_{b\to\infty} \arctan\theta\Bigg|_0^b = \frac{\pi}{2}.$$

Thus $\int_0^{\infty} \frac{\sin^2\theta}{\theta^2+1}\, d\theta$ converges, and its value is between 0 and $\frac{\pi}{2}$.

156. $\displaystyle\int_0^{\pi} \tan^2\theta d\theta = \tan\theta - \theta + C$, by formula IV-23. The integrand blows up at $\theta = \frac{\pi}{2}$, so

$$\int_0^{\pi} \tan^2\theta d\theta = \int_0^{\frac{\pi}{2}} \tan^2\theta d\theta + \int_{\frac{\pi}{2}}^{\pi} \tan^2\theta d\theta = \lim_{b\to\frac{\pi}{2}} [\tan\theta - \theta]_0^b + \lim_{a\to\frac{\pi}{2}} [\tan\theta - \theta]_a^{\pi}$$

which is undefined.

157. Since $0 \leq \sin x < 1$ for $0 \leq x \leq 1$, we have

$$\begin{aligned} &(\sin x)^{\frac{3}{2}} < (\sin x) \\ \text{so} \quad &\frac{1}{(\sin x)^{\frac{3}{2}}} > \frac{1}{(\sin x)} \\ \text{or} \quad &(\sin x)^{-\frac{3}{2}} > (\sin x)^{-1}\end{aligned}$$

Thus $\displaystyle\int_0^1 (\sin x)^{-1} dx = \lim_{a\to 0} \ln\left|\frac{1}{\sin x} - \frac{1}{\tan x}\right|_a^1$, which is infinite.

Hence, $\int_0^1 (\sin x)^{-\frac{3}{2}} dx$ is infinite.

Problems

158. Since $(e^x)^2 = e^{2x}$, we have

$$\text{Area } = \int_0^1 (e^x)^2\,dx = \int_0^1 e^{2x}\,dx = \frac{1}{2}e^{2x}\bigg|_0^1 = \frac{1}{2}(e^2-1).$$

159. Since $(e^x)^3 = e^{3x}$ and $(e^x)^2 = e^{2x}$, and the graph of $(e^x)^3$ is above the graph of $(e^x)^2$ for $x > 0$, we have

$$\begin{aligned}\text{Area } &= \int_0^e (e^x)^3 - (e^x)^2\,dx = \int_0^3 (e^{3x} - e^{2x})\,dx = \left(\frac{1}{3}e^{3x} - \frac{1}{2}e^{2x}\right)\bigg|_0^3\\ &= \frac{1}{3}e^9 - \frac{1}{2}e^6 - \left(\frac{1}{3} - \frac{1}{2}\right) = \frac{1}{3}e^9 - \frac{1}{2}e^6 + \frac{1}{6}.\end{aligned}$$

160. The curves $y = e^x$ and $y = 5e^{-x}$ cross where

$$\begin{aligned}e^x &= 5e^{-x}\\ e^{2x} &= 5\\ x &= \frac{1}{2}\ln 5.\end{aligned}$$

Since the graph of $y = 5e^{-x}$ is above the graph of $y = e^x$ for $0 \le x \le \frac{1}{2}\ln 5$ (see Figure 7.47), we have

$$\begin{aligned}\text{Area } &= \int_0^{(\ln 5)/2} (5e^{-x} - e^x)\,dx\\ &= (-5e^{-x} - e^x)\bigg|_0^{(\ln 5)/2}\\ &= -5e^{-(\ln 5)/2} - e^{(\ln 5)/2} - (-5\cdot 1 - 1)\\ &= -5(e^{\ln 5})^{-1/2} - (e^{\ln 5})^{1/2} + 6\\ &= -5(5^{-1/2}) - (5)^{1/2} + 6\\ &= -\frac{5}{\sqrt{5}} - \sqrt{5} + 6 = -2\sqrt{5} + 6.\end{aligned}$$

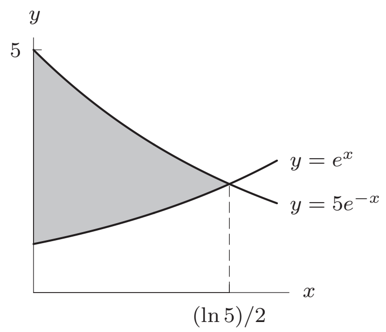

Figure 7.47

161. As is evident from Figure 7.48 showing the graphs of $y = \sin x$ and $y = \cos x$, the crossings occur at $x = \frac{\pi}{4}, \frac{5\pi}{4}, \frac{9\pi}{4}, \ldots$, and the regions bounded by any two consecutive crossings have the same area. So picking two consecutive crossings, we get an area of

$$\begin{aligned}\text{Area} &= \int_{\frac{\pi}{4}}^{\frac{5\pi}{4}} (\sin x - \cos x)\,dx\\ &= 2\sqrt{2}.\end{aligned}$$

(Note that we integrated $\sin x - \cos x$ here because for $\frac{\pi}{4} \le x \le \frac{5\pi}{4}$, $\sin x \ge \cos x$.)

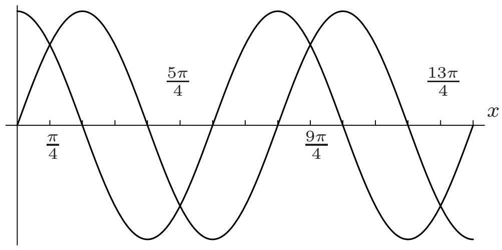

Figure 7.48

162. In the interval of $0 \le x \le 2$, the equation $y = \sqrt{4-x^2}$ represents one quadrant of the radius 2 circle centered at the origin. Interpreting the integral as an area gives a value of $\frac{1}{4}\pi 2^2 = \pi$.

163. Letting $w = 3x^5 + 2, dw = 15x^4\,dx$, we see that $x^4\,dx = dw/15$, so:

$$\begin{aligned}\int 3x^4\sqrt{3x^5+2}\,dx &= \int 3\left(3x^5+2\right)^{1/2}\cdot x^4\,dx\\ &= \int 3w^{1/2}\cdot\frac{1}{15}\cdot dw\\ &= \int \frac{1}{5}w^{1/2}\,dw,\end{aligned}$$

so $w = 3x^5+2, p = 1/2, k = 1/5$.

164. Letting $w = \cos(3\theta), dw = -3\sin(3\theta)\,d\theta$, we see that $\sin(3\theta)\,d\theta = (-1/3)\,dw$, so:

$$\begin{aligned}\int \frac{5\sin(3\theta)\,d\theta}{\cos^3(3\theta)} &= \int 5\left(\cos(3\theta)\right)^{-3}\sin(3\theta)\,d\theta\\ &= \int 5w^{-3}\cdot\frac{-dw}{3}\\ &= \int -\frac{5}{3}w^{-3}\,dw,\end{aligned}$$

so $w = \cos(3\theta), p = -3, k = -5/3$.

Alternatively, if we write

$$\frac{5\sin(3\theta)}{\cos^3(3\theta)} = \frac{5\sin(3\theta)}{\cos(3\theta)}\cdot\frac{1}{\cos^2(3\theta)}$$

and let $w = \tan(3\theta)$, so $dw = 3\,d\theta/\cos^2(3\theta)$, and we have

$$\int \frac{5\sin(3\theta)\,d\theta}{\cos^3(3\theta)} = \int 5\tan(3\theta)\frac{1}{\cos^2(3\theta)}\,d\theta = \int \frac{5}{3}w\,dw,$$

so here $w = \tan(3\theta), p = 1, k = 5/3$.

165. Using partial fractions we have

$$\begin{aligned}\frac{1}{(2x-3)(3x-2)} &= \frac{A}{2x-3} + \frac{B}{3x-2}\\ A(3x-2) + B(2x-3) &= 1\\ 3Ax - 2A + 2Bx - 3B &= 1\\ (3A+2B)x - 2A - 3B &= 1.\end{aligned}$$

We see that:

$$3A + 2B = 0$$

$$\begin{aligned} \text{so} \quad A &= -\frac{2}{3}\cdot B \\ \text{and} \quad -2A - 3B &= 1 \\ -2\left(-\frac{2}{3}\cdot B\right) - 3B &= 1 \qquad \text{since } A = -\tfrac{2}{3}B \\ \frac{4}{3}\cdot B - 3B &= 1 \\ -\frac{5}{3}B &= 1 \\ B &= -\frac{3}{5} = -0.6 \\ A &= -\frac{2}{3}\left(-\frac{3}{5}\right) \qquad \text{since } A = -\tfrac{2}{3}B \\ &= \frac{2}{5} = 0.4. \end{aligned}$$

Thus, $\displaystyle\int \frac{dx}{(2x-3)(3x-2)} = \int \left(\frac{0.4}{2x-3} + \frac{-0.6}{3x-2}\right)dx.$

166. Let $u = 0.5x - 1, du = 0.5\,dx$. Then $dx = 2\,du$ and, solving for x,

$$\begin{aligned} 0.5x - 1 &= u \\ 0.5x &= u + 1 \\ x &= 2u + 2. \end{aligned}$$

This means

$$\begin{aligned} x^2 + x &= (2u+2)^2 + 2u + 2 \\ &= 4u^2 + 10u + 6 \end{aligned}$$

so

$$\begin{aligned} \int (x^2+x)\cos(0.5x-1)\,dx &= \int (4u^2+10u+6)\cos u(2\,du) \\ &= \int (8u^2+20u+12)\cos u\,du, \end{aligned}$$

where $p(u) = 8u^2 + 20u + 12$.

167. Let $u = -x^2, du = -2x\,dx$, so that $x\,dx = -0.5du$. We have:

$$\begin{aligned} \int x^3 e^{-x^2}\,dx &= \int \underbrace{x^2}_{-u}\, e^{\overbrace{-x^2}^{u}} \cdot \underbrace{x\,dx}_{-0.5du} \\ &= \int 0.5ue^u\,du, \end{aligned}$$

so $k = 0.5, u = -x^2$.

168. Letting $u = \cos\sqrt{x}$, we have

$$\begin{aligned} du &= -\frac{1}{2}x^{-1/2}\sin\sqrt{x}\,dx \\ &= -\frac{\sin\sqrt{x}\,dx}{2\sqrt{x}}. \end{aligned}$$

So

$$\frac{\sin\sqrt{x}\,dx}{\sqrt{x}} = -2du.$$

Thus,

$$\int \frac{\cos^4\left(\sqrt{x}\right)\sin\sqrt{x}\,dx}{\sqrt{x}} = \int \frac{\left(\cos\left(\sqrt{x}\right)\right)^4\sin\sqrt{x}\,dx}{\sqrt{x}}$$

$$= \int \left(\cos\left(\sqrt{x}\right)\right)^4 \cdot \frac{\sin\sqrt{x}\,dx}{\sqrt{x}}$$
$$= \int -2u^4\,du,$$

where $k = -2, n = 4$, and $u = \cos\sqrt{x}$.

169. After the substitution $w = x^2$, the second integral becomes

$$\frac{1}{2}\int \frac{dw}{\sqrt{1-w^2}}.$$

170. After the substitution $w = x + 2$, the first integral becomes

$$\int w^{-2}\,dw.$$

After the substitution $w = x^2 + 1$, the second integral becomes

$$\frac{1}{2}\int w^{-2}\,dw.$$

171. After the substitution $w = 1 - x^2$, the first integral becomes

$$-\frac{1}{2}\int w^{-1}\,dw.$$

After the substitution $w = \ln x$, the second integral becomes

$$\int w^{-1}\,dw.$$

172. *First solution*: After the substitution $w = x + 1$, the first integral becomes

$$\int \frac{w-1}{w}\,dw = w - \int w^{-1}\,dw.$$

With this same substitution, the second integral becomes

$$\int w^{-1}\,dw.$$

Second solution: We note that the sum of the integrands is 1, so the sum of the integrals is x. Thus

$$\int \frac{x}{x+1}\,dx = x - \int \frac{1}{x+1}\,dx.$$

173. If we let $w = 2x$ in the first integral, we get $dw = 2dx$. Also, the limits $w = 0$ and $w = 2$ become $x = 0$ and $x = 1$. Thus

$$\int_0^2 e^{-w^2}\,dw = \int_0^1 e^{-4x^2}\,2\,dx.$$

174. If we let $t = 3u$ in the first integral, we get $dt = 3du$, so $dt/t = du/u$. Also, the limits $t = 0$ and $t = 3$ become $u = 0$ and $u = 1$. Thus

$$\int_0^3 \frac{\sin t}{t}\,dt = \int_0^1 \frac{\sin 3u}{u}\,du.$$

If we rename the variable u as t in the last integral, we have the equality we want.

175. Since the definition of f is different on $0 \le t \le 1$ than it is on $1 \le t \le 2$, break the definite integral at $t = 1$.

$$\begin{aligned}\int_0^2 f(t)\,dt &= \int_0^1 f(t)\,dt + \int_1^2 f(t)\,dt \\ &= \int_0^1 t^2\,dt + \int_1^2 (2-t)\,dt \\ &= \frac{t^3}{3}\bigg|_0^1 + \left(2t - \frac{t^2}{2}\right)\bigg|_1^2 \\ &= 1/3 + 1/2 = 5/6 \approx 0.833\end{aligned}$$

176. (a) (i) Multiplying out gives

$$\int (x^2 + 10x + 25)\,dx = \frac{x^3}{3} + 5x^2 + 25x + C.$$

(ii) Substituting $w = x + 5$, so $dw = dx$, gives

$$\int (x+5)^2\,dx = \int w^2\,dw = \frac{w^3}{3} + C = \frac{(x+5)^3}{3} + C.$$

(b) The results of the two calculations are not the same since

$$\frac{(x+5)^3}{3} + C = \frac{x^3}{3} + \frac{15x^2}{3} + \frac{75x}{3} + \frac{125}{3} + C.$$

However they differ only by a constant, $125/3$, as guaranteed by the Fundamental Theorem of Calculus.

177. (a) Since $h(z)$ is even, we know that $\int_0^1 h(z)\,dz = \int_{-1}^0 h(z)\,dz$. Since $\int_{-1}^1 h(z)\,dz = \int_{-1}^0 h(z)\,dz + \int_0^1 h(z)\,dz$, we see that $\int_{-1}^1 h(z)\,dz = 2\int_0^1 h(z)\,dz = 7$. Thus $\int_0^1 h(z)\,dz = 3.5$

(b) If $w = z + 3$, then $dw = dz$. When $z = -4$, $w = -1$; when $z = -2$, $w = 1$. Thus,

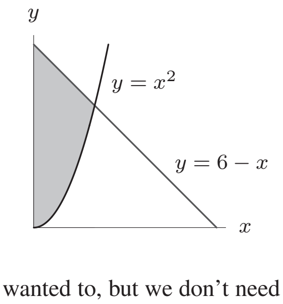
$$\int_{-4}^{-2} 5h(z+3)\,dt = 5\int_{-1}^{1} h(w)\,(dw) = 5 \cdot 7 = 35.$$

178. The point of intersection of the two curves $y = x^2$ and $y = 6 - x$ is at (2,4). The average height of the shaded area is the average value of the difference between the functions:

$$\frac{1}{(2-0)}\int_0^2 ((6-x) - x^2)\,dx = (3x - \frac{x^2}{4} - \frac{x^3}{6})\bigg|_0^2 = \frac{11}{3}.$$

179. The average width of the shaded area in the figure below is the average value of the horizontal distance between the two functions. If we call this horizontal distance $h(y)$, then the average width is

$$\frac{1}{(6-0)}\int_0^6 h(y)\,dy.$$

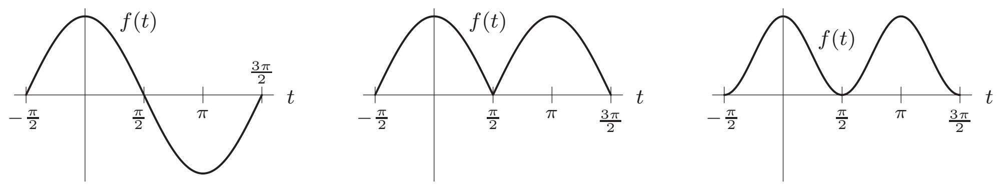


We could compute this integral if we wanted to, but we don't need to. We can simply note that the integral (without the $\frac{1}{6}$ term) is just the area of the shaded region; similarly, the integral in Problem 178 is *also* just the area of the shaded region. So they are the same. Now we know that our average width is just $\frac{1}{3}$ as much as the average height, since we divide by 6 instead of 2. So the answer is $\frac{11}{9}$.

180. (a) i. 0 ii. $\frac{2}{\pi}$ iii. $\frac{1}{2}$

(b) Average value of $f(t) <$ Average value of $k(t) <$ Average value of $g(t)$

We can look at the three functions in the range $-\frac{\pi}{2} \le x \le \frac{3\pi}{2}$, since they all have periods of 2π ($|\cos t|$ and $(\cos t)^2$ also have a period of π, but that does not hurt our calculation). It is clear from the graphs of the three functions below that the average value for $\cos t$ is 0 (since the area above the x-axis is equal to the area below it), while the average values for the other two are positive (since they are everywhere positive, except where they are 0).



It is also fairly clear from the graphs that the average value of $g(t)$ is greater than the average value of $k(t)$; it is also possible to see this algebraically, since

$$(\cos t)^2 = |\cos t|^2 \le |\cos t|$$

because $|\cos t| \le 1$ (and both of these $\le$'s are $<$'s at all the points where the functions are not 0 or 1).

181. This calculation cannot be correct because the integrand is positive everywhere, yet the value given for the integral is negative.

The calculation is incorrect because the integral is improper but has not been treated as such. The integral is improper because the integrand $1/x^2$ is undefined at $x = 0$. To determine whether the integral converges we split the integral into two improper integrals:

$$\int_{-2}^{2} \frac{1}{x^2} dx = \int_{-2}^{0} \frac{1}{x^2} dx + \int_{0}^{2} \frac{1}{x^2} dx.$$

To decide whether the second integral converges, we compute

$$\int_{0}^{2} \frac{1}{x^2} dx = \lim_{a \to 0^+} \int_{a}^{2} \frac{1}{x^2} dx = \lim_{a \to 0^+} \left(-\frac{1}{2} + \frac{1}{a}\right).$$

The limit does not exist, and $\int_0^2 (1/x^2)\,dx$ diverges, so the original the integral $\int_{-2}^{2} 1/x^2\,dx$ diverges.

182. (a) We have

$$E(x) + F(x) = \int \frac{e^x}{e^x + e^{-x}}\,dx + \int \frac{e^{-x}}{e^x + e^{-x}}\,dx = \int \frac{e^x + e^{-x}}{e^x + e^{-x}}\,dx = \int 1\,dx = x + C_1.$$

(b) We have

$$E(x) - F(x) = \int \frac{e^x}{e^x + e^{-x}}\,dx - \int \frac{e^{-x}}{e^x + e^{-x}}\,dx = \int \frac{e^x - e^{-x}}{e^x + e^{-x}}\,dx = \ln\left|e^x + e^{-x}\right| + C_2,$$

by using the substitution $w = e^x + e^{-x}$ in the final integral.

(c) We have

$$E(x) + F(x) = x + C_1$$
$$E(x) - F(x) = \ln\left|e^x + e^{-x}\right| + C_2.$$

Adding and subtracting we find

$$E(x) = \frac{x}{2} + \frac{1}{2}\ln\left|e^x + e^{-x}\right| + C,$$

where the arbitrary constant $C = (C_1 + C_2)/2$, and

$$F(x) = \frac{x}{2} - \frac{1}{2}\ln\left|e^x + e^{-x}\right| + C,$$

where $C = (C_1 - C_2)/2$.

183. Since $f(x)$ is decreasing on $[a, b]$, the left-hand Riemann sums are all overestimates and the right-hand sums are all underestimates. Because increasing the number of subintervals generally brings an approximation closer to the actual value, LEFT(10) is closer to the actual value (i.e., smaller, since the left sums are overestimates) than LEFT(5), and analogously for RIGHT(10) and RIGHT(5). Since the graph of $f(x)$ is concave down, a secant line lies below the curve and a tangent line lies above the curve. Therefore, TRAP is an underestimate and MID is an overestimate. Putting these observations together, we have

$$\text{RIGHT}(5) < \text{RIGHT}(10) < \text{TRAP}(10) < \text{Exact value} < \text{MID}(10) < \text{LEFT}(10) < \text{LEFT}(5).$$

184. (a) $f(x) = 1 + e^{-x}$ is concave up for $0 \le x \le 0.5$, so trapezoids will overestimate $\int_0^{0.5} f(x)dx$, and the midpoint rule will underestimate.

(b) $f(x) = e^{-x^2}$ is concave down for $0 \le x \le 0.5$, so trapezoids will underestimate $\int_0^{0.5} f(x)dx$ and midpoint will overestimate the integral.

(c) Both the trapezoid rule and the midpoint rule will give the exact value of the integral. Note that upper and lower sums will not, unless the line is horizontal.

185. (a) For the left-hand rule, error is approximately proportional to $\frac{1}{n}$. If we let n_p be the number of subdivisions needed for accuracy to p places, then there is a constant k such that

$$\begin{aligned} 5\times 10^{-5} &= \frac{1}{2}\times 10^{-4} \approx \frac{k}{n_4} \\ 5\times 10^{-9} &= \frac{1}{2}\times 10^{-8} \approx \frac{k}{n_8} \\ 5\times 10^{-13} &= \frac{1}{2}\times 10^{-12} \approx \frac{k}{n_{12}} \\ 5\times 10^{-21} &= \frac{1}{2}\times 10^{-20} \approx \frac{k}{n_{20}} \end{aligned}$$

Thus the ratios $n_4 : n_8 : n_{12} : n_{20} \approx 1 : 10^4 : 10^8 : 10^{16}$, and assuming the computer time necessary is proportional to n_p, the computer times are approximately

4 places:	2 seconds	
8 places:	2×10^4 seconds	$\approx$ 6 hours
12 places:	2×10^8 seconds	$\approx$ 6 years
20 places:	2×10^{16} seconds	$\approx$ 600 million years

(b) For the trapezoidal rule, error is approximately proportional to $\frac{1}{n^2}$. If we let N_p be the number of subdivisions needed for accuracy to p places, then there is a constant C such that

$$\begin{aligned} 5\times 10^{-5} &= \frac{1}{2}\times 10^{-4} \approx \frac{C}{{N_4}^2} \\ 5\times 10^{-9} &= \frac{1}{2}\times 10^{-8} \approx \frac{C}{{N_8}^2} \\ 5\times 10^{-13} &= \frac{1}{2}\times 10^{-12} \approx \frac{C}{{N_{12}}^2} \\ 5\times 10^{-21} &= \frac{1}{2}\times 10^{-20} \approx \frac{C}{{N_{20}}^2} \end{aligned}$$

Thus the ratios ${N_4}^2 : {N_8}^2 : {N_{12}}^2 : {N_{20}}^2 \approx 1 : 10^4 : 10^8 : 10^{16}$, and the ratios $N_4 : N_8 : N_{12} : N_{20} \approx 1 : 10^2 : 10^4 : 10^8$. So the computer times are approximately

4 places:	2 seconds	
8 places:	2×10^2 seconds	$\approx$ 3 minutes
12 places:	2×10^4 seconds	$\approx$ 6 hours
20 places:	2×10^8 seconds	$\approx$ 6 years

186. Use integration by parts, with $u = x$ and $dv = xe^{-x^2}$. Then $v = -(1/2)e^{-x^2}$, and

$$\int_0^b x^2 e^{-x^2}\,dx = -\frac{1}{2}xe^{-x^2}\Big|_0^b + \int_0^b \frac{1}{2}e^{-x^2}\,dx$$
$$= -\frac{1}{2}be^{-b^2} + \frac{1}{2}\int_0^b e^{-x^2}\,dx.$$

Since the exponential grows faster than any power,

$$\lim_{b\to\infty} be^{-b^2} = \lim_{b\to\infty}\frac{b}{e^{b^2}} = 0.$$

So

$$\int_0^b x^2 e^{-x^2}\,dx = 0 + \frac{1}{2}\int_0^\infty e^{-x^2}\,dx = \frac{1}{2}\cdot\frac{\sqrt{\pi}}{2} = \frac{\sqrt{\pi}}{4}.$$

187. (a) We calculate the integral using partial fractions with denominators P and $L - P$:

$$\frac{k}{P(L-P)} = \frac{A}{P} + \frac{B}{L-P}$$
$$k = A(L-P) + BP$$
$$k = (B-A)P + AL.$$

Thus,

$$B - A = 0$$
$$AL = k,$$

so $A = B = k/L$, and the time is given by

$$T = \int_{L/4}^{L/2} \frac{k\,dP}{P(L-P)} = \frac{k}{L}\int_{L/4}^{L/2}\left(\frac{1}{P} + \frac{1}{L-P}\right)dP = \frac{k}{L}(\ln|P| - \ln|L-P|)\Big|_{L/4}^{L/2}$$
$$= \frac{k}{L}\left(\ln\left(\frac{L}{2}\right) - \ln\left(\frac{L}{2}\right) - \ln\left(\frac{L}{4}\right) + \ln\left(\frac{3L}{4}\right)\right)$$
$$= \frac{k}{L}\ln\left(\frac{3L/4}{L/4}\right) = \frac{k}{L}\ln(3).$$

(b) A similar calculation gives the following expression for the time:

$$T = \frac{k}{L}(\ln|P| - \ln|L-P|)\Big|_{P_1}^{P_2} = \frac{k}{L}\left(\ln|P_2| - \ln|L-P_2| - \ln|P_1| + \ln|L-P_1|\right).$$

If $P_2 \to L$, then $L - P_2 \to 0$, so $\ln P_2 \to \ln L$, and $\ln(L - P_2) \to -\infty$. Thus the time tends to infinity.

188. If $I(t)$ is average per-capita income t years after 2005, then $I'(t) = r(t)$.

(a) Since $t = 10$ in 2015, by the Fundamental Theorem,

$$I(10) - I(0) = \int_0^{10} r(t)\,dt = \int_0^{10} 1556.37e^{0.045t}\,dt = \frac{1556.37}{0.045}e^{0.045t}\Big|_0^{10} = 19{,}655.65 \text{ dollars.}$$

so $I(10) = 34{,}586 + 19{,}655.65 = 54{,}241.65$.

(b) We have

$$I(t) - I(0) = \int_0^t r(t)\,dt = \int_0^t 1556.37e^{0.045t}\,dt = \frac{1556.37}{0.045}e^{0.045t}\Big|_0^t = 34{,}586\left(e^{0.045t} - 1\right).$$

Thus, since $I(0) = 34{,}586$,

$$I(t) = 34{,}586 + 34{,}586(e^{0.045t} - 1) = 34{,}586e^{0.045t} \text{ dollars.}$$

189. (a) Since the rate is given by $r(t) = 2te^{-2t}$ ml/sec, by the Fundamental Theorem of Calculus, the total quantity is given by the definite integral:

$$\text{Total quantity} \approx \int_0^\infty 2te^{-2t}\,dt = 2\lim_{b\to\infty}\int_0^b te^{-2t}\,dt.$$

Integration by parts with $u = t$, $v' = e^{-2t}$ gives

$$\begin{aligned}\text{Total quantity} &\approx 2\lim_{b\to\infty}\left(-\frac{t}{2}e^{-2t} - \frac{1}{4}e^{-2t}\right)\Big|_0^b \\ &= 2\lim_{b\to\infty}\left(\frac{1}{4} - \left(\frac{b}{2}+\frac{1}{4}\right)e^{-2b}\right) = 2\cdot\frac{1}{4} = 0.5 \text{ ml.}\end{aligned}$$

(b) At the end of 5 seconds,

$$\text{Quantity received} = \int_0^5 2te^{-2t}\,dt \approx 0.49975 \text{ ml.}$$

Since $0.49975/0.5 = 0.9995 = 99.95\%$, the patient has received 99.95% of the dose in the first 5 seconds.

190. The rate at which petroleum is being used t years after 1990 is given by

$$r(t) = 1.4\cdot 10^{20}(1.02)^t \text{ joules/year.}$$

Between 1990 and M years later

$$\begin{aligned}\text{Total quantity of petroleum used } &= \int_0^M 1.4\cdot 10^{20}(1.02)^t\,dt = 1.4\cdot 10^{20}\left.\frac{(1.02)^t}{\ln(1.02)}\right|_0^M \\ &= \frac{1.4\cdot 10^{20}}{\ln(1.02)}((1.02)^M - 1) \text{ joules.}\end{aligned}$$

Setting the total quantity used equal to 10^{22} gives

$$\begin{aligned}\frac{1.4\cdot 10^{20}}{\ln(1.02)}\left((1.02)^M - 1\right) &= 10^{22} \\ (1.02)^M &= \frac{100\ln(1.02)}{1.4} + 1 = 2.41 \\ M &= \frac{\ln(2.41)}{\ln(1.02)} \approx 45 \text{ years.}\end{aligned}$$

So we will run out of petroleum in 2035.

191. (a) We have

$$S = \int_0^{18}(30-10)dt = 20\int_0^{18} dt = 20(18-0) = 360.$$

The units of S are degree-days, because the integrand $f(t) - 10$ has units of °C, and dt has units of days.

(b) In Figure 7.49, $f(t)$ and H_{min} are represented by the horizontal lines at $H = 30$ and $H = 10$, and T is represented by a vertical line at $t = 18$. The value of S, given by the definite integral, is represented by the area of the rectangle bounded by the vertical lines $t = 0$ (the H-axis) and $t = 18$, and the horizontal lines $H = 10$ and $H = 30$.

(c) The temperature cycles from a high of 30°C to a low of 10°C once every 6 days. During the 18-day period the temperature completes 3 complete cycles. The area between this curve and the horizontal line $H = H_{\text{min}} = 10$ gives the value of the definite integral. See Figure 7.50. In order to get the same area as before, (namely $S = 360$), we see that T_2 must be larger than $T = 18$. Thus we want T_2 to satisfy:

$$S = \int_0^{T_2}(g(t)-10)dt = \int_0^{T_2}\left(10\cos\left(\frac{2\pi t}{6}\right)+10\right)\,dt = 360.$$

Notice that, by symmetry, the area on the interval $0 \le t \le 18$ is half the area shown in Figure 7.49. Thus, we expect that $T_2 = 2T = 36$. We can check this by calculation, using a substitution to evaluate the integral:

$$S = \int_0^{36}\left(10\cos\left(\frac{2\pi t}{6}\right)+10\right)\,dt = \left(10\cdot\frac{6}{2\pi}\sin\left(\frac{2\pi t}{6}\right)+10t\right)\Big|_0^{T_2} = 360.$$

Thus, if $T_2 = 36$, the integral evaluates to $S = 360$, as required. Thus, 36 days are required for development for with these temperatures.

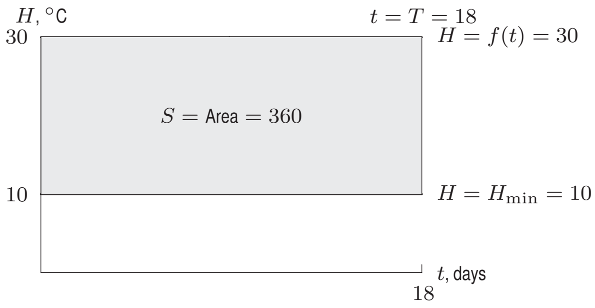


Figure 7.49

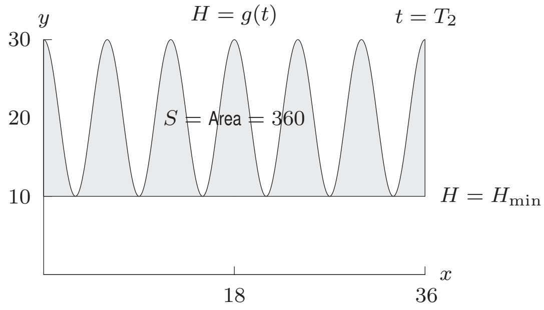

Figure 7.50

192. We want to calculate

$$\int_0^1 C_n \sin(n\pi x) \cdot C_m \sin(m\pi x)\, dx.$$

We use II-11 from the table of integrals with $a = n\pi$, $b = m\pi$. Since $n \neq m$, we see that

$$\begin{aligned}\int_0^1 \Psi_n(x) \cdot \Psi_m(x)\, dx &= C_n C_m \int_0^1 \sin(n\pi x)\sin(m\pi x)\, dx \\ &= \frac{C_n C_m}{m^2\pi^2 - n^2\pi^2} \left(n\pi \cos(n\pi x)\sin(m\pi x) - \ m\pi \sin(n\pi x)\cos(m\pi x)\right)\Big|_0^1 \\ &= \frac{C_n C_m}{(m^2 - n^2)\pi^2} \Big(n\pi \cos(n\pi)\sin(m\pi) - m\pi \sin(n\pi)\cos(m\pi) \\ &\qquad - n\pi \cos(0)\sin(0) + m\pi \sin(0)\cos(0)\Big) \\ &= 0\end{aligned}$$

since $\sin(0) = \sin(n\pi) = \sin(m\pi) = 0$.

CAS Challenge Problems

193. (a) A CAS gives

$$\int \frac{\ln x}{x}\, dx = \frac{(\ln x)^2}{2}$$
$$\int \frac{(\ln x)^2}{x}\, dx = \frac{(\ln x)^3}{3}$$
$$\int \frac{(\ln x)^3}{x}\, dx = \frac{(\ln x)^4}{4}$$

(b) Looking at the answers to part (a),

$$\int \frac{(\ln x)^n}{x}\, dx = \frac{(\ln x)^{n+1}}{n+1} + C.$$

(c) Let $w = \ln x$. Then $dw = (1/x)dx$, and

$$\int \frac{(\ln x)^n}{x}\, dx = \int w^n\, dw = \frac{w^{n+1}}{n+1} + C = \frac{(\ln x)^{n+1}}{n} + C.$$

194. (a) A CAS gives

$$\int \ln x\, dx = -x + x\ln x$$
$$\int (\ln x)^2\, dx = 2x - 2x\ln x + x(\ln x)^2$$
$$\int (\ln x)^3\, dx = -6x + 6x\ln x - 3x(\ln x)^2 + x(\ln x)^3$$
$$\int (\ln x)^4\, dx = 24x - 24x\ln x + 12x(\ln x)^2 - 4x(\ln x)^3 + x(\ln x)^4$$

(b) In each of the cases in part (a), the expression for the integral $\int (\ln x)^n\, dx$ has two parts. The first part is simply a multiple of the expression for $\int (\ln x)^{n-1}\, dx$. For example, $\int (\ln x)^2\, dx$ starts out with $2x - 2x\ln x = -2\int \ln x\, dx$. Similarly, $\int (\ln x)^3\, dx$ starts out with $-6x + 6x\ln x - 3(\ln x)^2 = -3\int (\ln x)^2\, dx$, and $\int (\ln x)^4\, dx$ starts out with $-4\int (\ln x)^3\, dx$. The remaining part of each antiderivative is a single term: it's $x(\ln x)^2$ in the case $n = 2$, it's $x(\ln x)^3$ for $n = 3$, and it's $x(\ln x)^4$ for $n = 4$. The general pattern is

$$\int (\ln x)^n\, dx = -n\int (\ln x)^{n-1}\, dx + x(\ln x)^n.$$

To check this formula, we use integration by parts. Let $u = (\ln x)^n$ so $u' = n(\ln x)^{n-1}/x$ and $v' = 1$ so $v = x$. Then

$$\int (\ln x)^n\, dx = x(\ln x)^n - \int n\frac{(\ln x)^{n-1}}{x}\cdot x\, dx$$
$$\int (\ln x)^n\, dx = x(\ln x)^n - n\int (\ln x)^{n-1}\, dx.$$

This is the result we obtained before.

Alternatively, we can check our result by differentiation:

$$\begin{aligned}\frac{d}{dx}\left(-n\int (\ln x)^{n-1}\, dx + x(\ln x)^n\right) &= -n(\ln x)^{n-1} + \frac{d}{dx}(x(\ln x)^n)\\ &= -n(\ln x)^{n-1} + (\ln x)^n + x\cdot n(\ln x)^{n-1}\frac{1}{x}\\ &= -n(\ln x)^{n-1} + (\ln x)^n + n(\ln x)^{n-1} = (\ln x)^n.\end{aligned}$$

Therefore,

$$\int (\ln x)^n\, dx = -n\int (\ln x)^{n-1}\, dx + x(\ln x)^n.$$

195. (a) A possible answer from the CAS is

$$\int \sin^3 x\, dx = \frac{-9\,\cos(x) + \cos(3\,x)}{12}.$$

(b) Differentiating

$$\frac{d}{dx}\left(\frac{-9\,\cos(x) + \cos(3\,x)}{12}\right) = \frac{9\,\sin(x) - 3\,\sin(3\,x)}{12} = \frac{3\sin x - \sin(3x)}{4}.$$

(c) Using the identities, we get

$$\begin{aligned}\sin(3x) = \sin(x + 2x) &= \sin x\cos 2x + \cos x\sin 2x\\ &= \sin x(1 - 2\sin^2 x) + \cos x(2\sin x\cos x)\\ &= \sin x - 2\sin^3 x + 2\sin x(1 - \sin^2 x)\\ &= 3\sin x - 4\sin^3 x.\end{aligned}$$

Thus,

$$3\sin x - \sin(3x) = 3\sin x - (3\sin x - 4\sin^3 x) = 4\sin^3 x,$$

so

$$\frac{3\sin x - \sin(3x)}{4} = \sin^3 x.$$

196. (a) A possible answer is

$$\int \sin x \cos x \cos(2x)\, dx = -\frac{\cos(4x)}{16}.$$

Different systems may give the answer in a different form.

(b)

$$\frac{d}{dx}\left(-\frac{\cos(4x)}{16}\right) = \frac{\sin(4x)}{4}.$$

(c) Using the double angle formula $\sin 2A = 2\sin A \cos A$ twice, we get

$$\frac{\sin(4x)}{4} = \frac{2\sin(2x)\cos(2x)}{4} = \frac{2 \cdot 2\sin x \cos x \cos(2x)}{4} = \sin x \cos x \cos(2x).$$

197. (a) A possible answer from the CAS is

$$\int \frac{x^4}{(1+x^2)^2}\, dx = x + \frac{x}{2\,(1+x^2)} - \frac{3}{2}\arctan(x).$$

Different systems may give the answer in different form.

(b) Differentiating gives

$$\frac{d}{dx}\left(x + \frac{x}{2\,(1+x^2)} - \frac{3}{2}\arctan(x)\right) = 1 - \frac{x^2}{\left(1+x^2\right)^2} - \frac{1}{1+x^2}.$$

(c) Putting the result of part (b) over a common denominator, we get

$$\begin{aligned} 1 - \frac{x^2}{\left(1+x^2\right)^2} - \frac{1}{1+x^2} &= \frac{\left(1+x^2\right)^2 - x^2 - (1+x^2)}{(1+x^2)^2} \\ &= \frac{1 + 2x^2 + x^4 - x^2 - 1 - x^2}{(1+x^2)^2} = \frac{x^4}{(1+x^2)^2}. \end{aligned}$$

PROJECTS FOR CHAPTER SEVEN

1. (a) If $e^t \geq 1 + t$, then

$$\begin{aligned} e^x &= 1 + \int_0^x e^t\, dt \\ &\geq 1 + \int_0^x (1+t)\, dt = 1 + x + \frac{1}{2}x^2. \end{aligned}$$

We can keep going with this idea. Since $e^t \geq 1 + t + \frac{1}{2}t^2$,

$$\begin{aligned} e^x &= 1 + \int_0^x e^t\, dt \\ &\geq 1 + \int_0^x (1 + t + \frac{1}{2}t^2)\, dt = 1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3. \end{aligned}$$

We notice that each term in our summation is of the form $\frac{x^n}{n!}$. Furthermore, we see that if we have a sum $1 + x + \frac{x^2}{2} + \cdots + \frac{x^n}{n!}$ such that

$$e^x \geq 1 + x + \frac{x^2}{2} + \cdots + \frac{x^n}{n!},$$

then

$$\begin{aligned} e^x &= 1 + \int_0^x e^t\, dt \\ &\geq 1 + \int_0^x \left(1 + t + \frac{t^2}{2} + \cdots + \frac{t^n}{n!}\right) dt \\ &= 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \cdots + \frac{x^{n+1}}{(n+1)!}. \end{aligned}$$

Thus we can continue this process as far as we want, so

$$e^x \geq 1 + x + \frac{1}{2}x^2 + \cdots + \frac{1}{n!}x^n = \sum_{j=0}^{n} \frac{x^j}{j!} \text{ for any } n.$$

(In fact, it turns out that if you let n get larger and larger and keep adding up terms, your values approach exactly e^x.)

(b) We note that $\sin x = \int_0^x \cos t\, dt$ and $\cos x = 1 - \int_0^x \sin t\, dt$. Thus, since $\cos t \leq 1$, we have

$$\sin x \leq \int_0^x 1\, dt = x.$$

Now using $\sin t \leq t$, we have

$$\cos x \leq 1 - \int_0^x t\, dt = 1 - \frac{1}{2}x^2.$$

Then we just keep going:

$$\sin x \leq \int_0^x \left(1 - \frac{1}{2}t^2\right)\, dt = x - \frac{1}{6}x^3.$$

Therefore

$$\cos x \leq 1 - \int_0^x \left(t - \frac{1}{6}t^3\right)\, dt = 1 - \frac{1}{2}x^2 + \frac{1}{24}x^4.$$

CHAPTER EIGHT

Solutions for Section 8.1

Exercises

1. (a) The strip stretches between $y = 0$ and $y = 2x$, so

$$\text{Area of region } \approx \sum (2x)\Delta x.$$

(b) We have

$$\text{Area } = \int_0^3 (2x)\,dx = x^2\Big|_0^3 = 9.$$

2. (a) The strip stretches between $y = 0$ and $y = -x^2 + 6x$, so

$$\text{Area of region } \approx \sum (-x^2 + 6x)\Delta x.$$

(b) We have

$$\text{Area } = \int_0^6 (-x^2 + 6x)\,dx = -\frac{x^3}{3} + 3x^2\Big|_0^6 = 36.$$

3. (a) The strip stretches from $x = y/2$ to $x = 3$, so

$$\text{Area of region } \approx \sum \left(3 - \frac{y}{2}\right)\,\Delta y.$$

(b) We have

$$\text{Area } = \int_0^6 \left(3 - \frac{y}{2}\right)\,dy = \left(3y - \frac{y^2}{4}\right)\Big|_0^6 = 9.$$

4. (a) The equation $y = -x^2 + 6x$ can be solved for x as

$$x^2 - 6x + y = 0$$
$$x = \frac{6 \pm \sqrt{36 - 4y}}{2} = 3 \pm \sqrt{9 - y}.$$

The left end of the strip is given by $x = 3 - \sqrt{9 - y}$, and the right end is given by $x = 3 + \sqrt{9 - y}$. Thus,

$$\text{Area of region } \approx \sum ((3 + \sqrt{9 - y}) - (3 - \sqrt{9 - y}))\Delta y = \sum 2\sqrt{9 - y}\,\Delta y.$$

(b) We have

$$\text{Area } = \int_0^9 2\sqrt{9 - y}\,dy = \frac{2(9 - y)^{3/2}}{-3/2}\Big|_0^9 = 36.$$

5. Each strip is a rectangle of length 3 and width Δx, so

$$\text{Area of strip } = 3\Delta x, \quad \text{so}$$
$$\text{Area of region } = \int_0^5 3\,dx = 3x\Big|_0^5 = 15.$$

Check: This area can also be computed using Length $\times$ Width $= 5 \cdot 3 = 15$.

6. Using similar triangles, the height, y, of the strip is given by

$$\frac{y}{3} = \frac{x}{6} \quad \text{so} \quad y = \frac{x}{2}.$$

Thus,

$$\text{Area of strip } \approx y\Delta x = \frac{x}{2}\Delta x,$$

so

$$\text{Area of region } = \int_0^6 \frac{x}{2}\,dx = \left.\frac{x^2}{4}\right|_0^6 = 9.$$

Check: This area can also be computed using the formula $\frac{1}{2}$ Base $\cdot$ Height $= \frac{1}{2} \cdot 6 \cdot 3 = 9$.

7. By similar triangles, if w is the length of the strip at height h, we have

$$\frac{w}{3} = \frac{5-h}{5} \quad \text{so} \quad w = 3\left(1 - \frac{h}{5}\right).$$

Thus,

$$\text{Area of strip } \approx w\Delta h = 3\left(1 - \frac{h}{5}\right)\Delta h.$$

$$\text{Area of region } = \int_0^5 3\left(1 - \frac{h}{5}\right)\,dh = \left.\left(3h - \frac{3h^2}{10}\right)\right|_0^5 = \frac{15}{2}.$$

Check: This area can also be computed using the formula $\frac{1}{2}$ Base $\cdot$ Height $= \frac{1}{2} \cdot 3 \cdot 5 = \frac{15}{2}$.

8. Suppose the length of the strip shown is w. Then the Pythagorean theorem gives

$$h^2 + \left(\frac{w}{2}\right)^2 = 3^2 \quad \text{so} \quad w = 2\sqrt{3^2 - h^2}.$$

Thus

$$\text{Area of strip } \approx w\Delta h = 2\sqrt{3^2 - h^2}\Delta h,$$

$$\text{Area of region } = \int_{-3}^{3} 2\sqrt{3^2 - h^2}\,dh.$$

Using VI-30 in the Table of Integrals, we have

$$\text{Area } = \left.\left(h\sqrt{3^2 - h^2} + 3^2 \arcsin\left(\frac{h}{3}\right)\right)\right|_{-3}^{3} = 9(\arcsin 1 - \arcsin(-1)) = 9\pi.$$

Check: This area can also be computed using the formula $\pi r^2 = 9\pi$.

9. The strip has width Δy, so the variable of integration is y. The length of the strip is x. Since $x^2 + y^2 = 10$ and the region is in the first quadrant, solving for x gives $x = \sqrt{10 - y^2}$. Thus

$$\text{Area of strip } \approx x\Delta y = \sqrt{10 - y^2}\,dy.$$

The region stretches from $y = 0$ to $y = \sqrt{10}$, so

$$\text{Area of region } = \int_0^{\sqrt{10}} \sqrt{10 - y^2}\,dy.$$

Evaluating using VI-30 from the Table of Integrals, we have

$$\text{Area } = \frac{1}{2}\left.\left(y\sqrt{10 - y^2} + 10\arcsin\left(\frac{y}{\sqrt{10}}\right)\right)\right|_0^{\sqrt{10}} = 5(\arcsin 1 - \arcsin 0) = \frac{5}{2}\pi.$$

Check: This area can also be computed using the formula $\frac{1}{4}\pi r^2 = \frac{1}{4}\pi(\sqrt{10})^2 = \frac{5}{2}\pi$.

10. The strip has width Δy, so the variable of integration is y. The length of the strip is $2x$ for $x \geq 0$. For positive x, we have $x = y$. Thus,

$$\text{Area of strip } \approx 2x\Delta y = 2y\Delta y.$$

Since the region extends from $y = 0$ to $y = 4$,

$$\text{Area of region } = \int_0^4 2y\,dy = y^2\Big|_0^4 = 16.$$

Check: The area of the region can be computed by $\frac{1}{2}$ Base $\cdot$ Height $= \frac{1}{2} \cdot 8 \cdot 4 = 16$.

11. The width of the strip is Δy, so the variable of integration is y. Since the graphs are $x = y$ and $x = y^2$, the length of the strip is $y - y^2$, and

$$\text{Area of strip } \approx (y - y^2)\Delta y.$$

The curves cross at the points $(0, 0)$ and $(1, 1)$, so

$$\text{Area of region } = \int_0^1 (y - y^2)\,dy = \frac{y^2}{2} - \frac{y^3}{3}\Big|_0^1 = \frac{1}{6}.$$

12. The width of the strip is Δx, so the variable of integration is x. The line has equation $y = 6 - 3x$. The length of the strip is $6 - 3x - (x^2 - 4) = 10 - 3x - x^2$. (Since $x^2 - 4$ is negative where the graph is below the x-axis, subtracting $x^2 - 4$ there adds the length below the x-axis.) Thus

$$\text{Area of strip } \approx (10 - 3x - x^2)\Delta x.$$

Both graphs cross the x-axis where $x = 2$, so

$$\text{Area of region } = \int_0^2 (10 - 3x - x^2)\,dx = 10x - \frac{3}{2}x^2 - \frac{x^3}{3}\Big|_0^2 = \frac{34}{3}.$$

13. Each slice is a circular disk with radius $r = 2$ cm.

$$\text{Volume of disk } = \pi r^2 \Delta x = 4\pi\Delta x \text{ cm}^3.$$

Summing over all disks, we have

$$\text{Total volume } \approx \sum 4\pi\Delta x \text{ cm}^3.$$

Taking a limit as $\Delta x \to 0$, we get

$$\text{Total volume } = \lim_{\Delta x \to 0} \sum 4\pi\Delta x = \int_0^9 4\pi\,dx \text{ cm}^3.$$

Evaluating gives

$$\text{Total volume } = 4\pi x\Big|_0^9 = 36\pi \text{ cm}^3.$$

Check: The volume of the cylinder can also be calculated using the formula $V = \pi r^2 h = \pi 2^2 \cdot 9 = 36\pi$ cm^3.

14. Each slice is a circular disk. Since the radius of the cone is 2 cm and the length is 6 cm, the radius is one-third of the distance from the vertex. Thus, the radius at x is $r = x/3$ cm. See Figure 8.1.

$$\text{Volume of slice } \approx \pi r^2 \Delta x = \frac{\pi x^2}{9}\Delta x \text{ cm}^3.$$

Summing over all disks, we have

$$\text{Total volume } \approx \sum \pi\frac{x^2}{9}\Delta x \text{ cm}^3.$$

Taking a limit as $\Delta x \to 0$, we get

$$\text{Total volume } = \lim_{\Delta x \to 0} \sum \pi\frac{x^2}{9}\Delta x = \int_0^6 \pi\frac{x^2}{9}\,dx \text{ cm}^3.$$

Evaluating, we get

$$\text{Total volume } = \frac{\pi}{9}\frac{x^3}{3}\bigg|_0^6 = \frac{\pi}{9}\cdot\frac{6^3}{3} = 8\pi \text{ cm}^3.$$

Check: The volume of the cone can also be calculated using the formula $V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi 2^2 \cdot 6 = 8\pi \text{ cm}^3$.

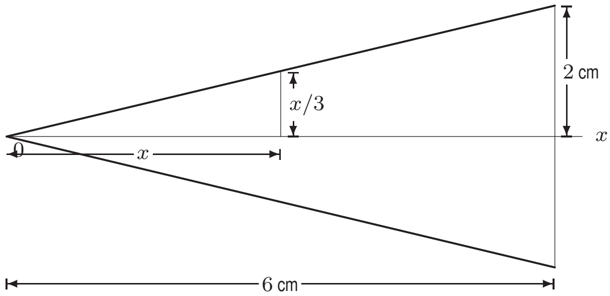

Figure 8.1

15. Each slice is a circular disk. From Figure 8.2, we see that the radius at height y is $r = \frac{2}{5}y$ cm. Thus

$$\text{Volume of disk } \approx \pi r^2 \Delta y = \pi\left(\frac{2}{5}y\right)^2 \Delta y = \frac{4}{25}\pi y^2 \Delta y \text{ cm}^3.$$

Summing over all disks, we have

$$\text{Total volume } \approx \sum \frac{4\pi}{25} y^2 \Delta y \text{ cm}^3.$$

Taking the limit as $\Delta y \to 0$, we get

$$\text{Total volume } = \lim_{\Delta y \to 0} \sum \frac{4\pi}{25} y^2 \Delta y = \int_0^5 \frac{4\pi}{25} y^2 dy \text{ cm}^3.$$

Evaluating gives

$$\text{Total volume } = \frac{4\pi}{25}\frac{y^3}{3}\bigg|_0^5 = \frac{20}{3}\pi \text{ cm}^3.$$

Check: The volume of the cone can also be calculated using the formula $V = \frac{1}{3}\pi r^2 h = \frac{\pi}{3} 2^2 \cdot 5 = \frac{20}{3}\pi \text{ cm}^3$.

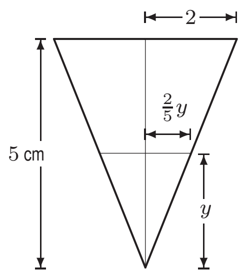

Figure 8.2

16. Each slice is a rectangular slab of length 10 m and width that decreases with height. See Figure 8.3. At height y, the length x is given by the Pythagorean Theorem

$$y^2 + x^2 = 7^2.$$

Solving gives $x = \sqrt{7^2 - y^2}$ m. Thus the width of the slab is $2x = 2\sqrt{7^2 - y^2}$ and

$$\text{Volume of slab } = \text{ Length } \cdot \text{ Width } \cdot \text{ Height } = 10 \cdot 2\sqrt{7^2 - y^2} \cdot \Delta y = 20\sqrt{7^2 - y^2}\Delta y \text{ m}^3.$$

Summing over all slabs, we have

$$\text{Total volume } \approx \sum 20\sqrt{7^2 - y^2}\Delta y \text{ m}^3.$$

Taking a limit as $\Delta y \to 0$, we get

$$\text{Total volume } = \lim_{\Delta y \to 0} \sum 20\sqrt{7^2 - y^2}\Delta y = \int_0^7 20\sqrt{7^2 - y^2}\, dy \text{ m}^3.$$

To evaluate, we use the table of integrals or the fact that $\int_0^7 \sqrt{7^2 - y^2}\, dy$ represents the area of a quarter circle of radius 7, so

$$\text{Total volume } = \int_0^7 20\sqrt{7^2 - y^2}\, dy = 20 \cdot \frac{1}{4}\pi 7^2 = 245\pi \text{ m}^3.$$

Check: the volume of a half cylinder can also be calculated using the formula $V = \frac{1}{2}\pi r^2 h = \frac{1}{2}\pi 7^2 \cdot 10 = 245\pi$ m^3.

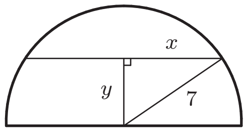

Figure 8.3

17. Each slice is a circular disk. See Figure 8.4. The radius of the sphere is 5 mm, and the radius r at height y is given by the Pythagorean Theorem

$$y^2 + r^2 = 5^2.$$

Solving gives $r = \sqrt{5^2 - y^2}$ mm. Thus,

$$\text{Volume of disk } \approx \pi r^2 \Delta y = \pi(5^2 - y^2)\Delta y \text{ mm}^3.$$

Summing over all disks, we have

$$\text{Total volume } \approx \sum \pi(5^2 - y^2)\Delta y \text{ mm}^3.$$

Taking the limit as $\Delta y \to 0$, we get

$$\text{Total volume } = \lim_{\Delta y \to 0} \sum \pi(5^2 - y^2)\Delta y = \int_0^5 \pi(5^2 - y^2)\, dy \text{ mm}^3.$$

Evaluating gives

$$\text{Total volume } = \pi \left(25y - \frac{y^3}{3}\right)\Bigg|_0^5 = \frac{250}{3}\pi \text{ mm}^3.$$

Check: The volume of a hemisphere can be calculated using the formula $V = \frac{2}{3}\pi r^3 = \frac{2}{3}\pi 5^3 = \frac{250}{3}\pi$ mm^3.

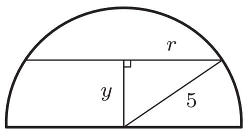

Figure 8.4

18. Each slice is a square; the side length decreases as we go up the pyramid. See Figure 8.5. Since the base of the pyramid is equal to its vertical height, the slice at distance y from the base, or $(2-y)$ from the top, has side $(2-y)$. Thus

$$\text{Volume of slice } \approx (2-y)^2 \Delta y \text{ m}^3.$$

Summing over all slices, we get

$$\text{Total volume } \approx \sum (2-y)^2 \Delta y \text{ m}^3.$$

$$\text{Total volume } = \lim_{\Delta y \to 0} \sum (2-y)^2 \Delta y = \int_0^2 (2-y)^2 dy \text{ m}^3.$$

Evaluating, we find

$$\text{Total volume } = \int_0^2 (4 - 4y + y^2)\, dy = \left(4y - 2y^2 + \frac{y^3}{3}\right)\bigg|_0^2 = \frac{8}{3} \text{ m}^3.$$

Check: The volume of the pyramid can also be calculated using the formula $V = \frac{1}{3}b^2h = \frac{1}{3}2^2 \cdot 2 = \frac{8}{3}$ m^3.

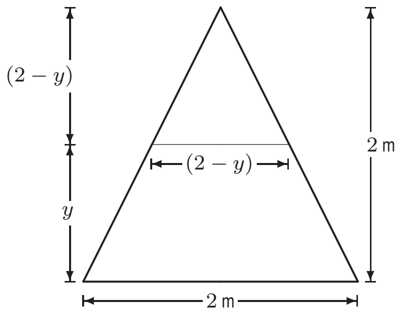

Figure 8.5

Problems

19. Triangle of base and height 1 and 3. See Figure 8.6. (Either 1 or 3 can be the base. A non-right triangle is also possible.)

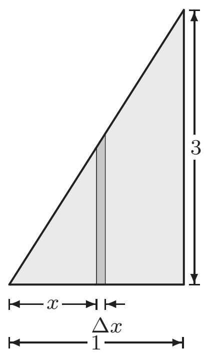

Figure 8.6

20. Semicircle of radius $r = 9$. See Figure 8.7.

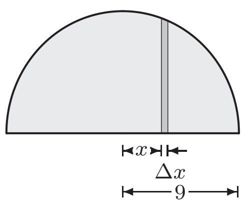

Figure 8.7

21. Quarter circle of radius $r = \sqrt{15}$. See Figure 8.8.

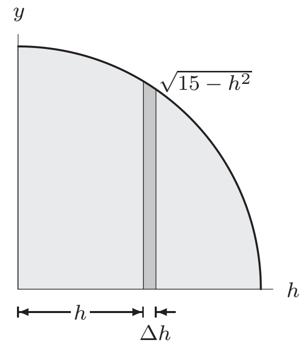

Figure 8.8

22. Triangle of base and height 7 and 5. See Figure 8.9. (Either 7 or 5 can be the base. A non-right triangle is also possible.)

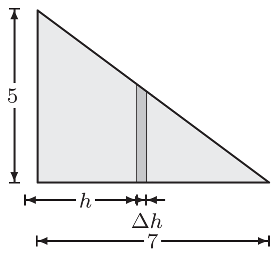

Figure 8.9

23. There are at least two possible answers. Since $y = x - x^2 \geq 0$ when $0 \leq x \leq 1$, one possibility is that the integral gives the area between the parabola $y = x - x^2$ and the line $y = 0$ as shown in Figure 8.10. Alternatively, since $x \geq x^2$ when $0 \leq x \leq 1$, the integral gives the area between the curves $y = x^2$ and $y = x$, as shown in Figure 8.11.

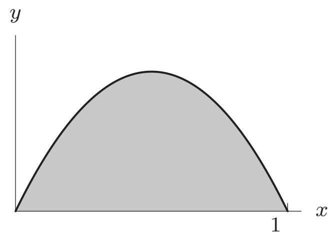

Figure 8.10

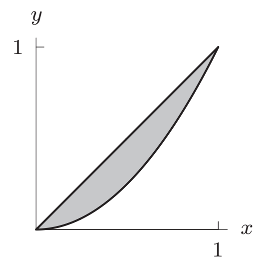

Figure 8.11

24. (a) The area is shown in Figure 8.12(a) with one vertical slice shown. Each slice is bounded on the top by $y = 3x$ and on the bottom by $y = x^2$, so the height of each slice is $3x - x^2$. The width of each slice is Δx, so the area is represented by

$$A = \int_0^3 (3x - x^2)\,dx = \frac{3}{2}x^2 - \frac{1}{3}x^3\bigg|_0^3$$
$$= \frac{3}{2} \cdot 3^2 - \frac{1}{3}\dot{3}^3 - (0 - 0)$$
$$= 4.5.$$

Figure 8.12

(b) The area is shown in Figure 8.12(b) with one horizontal slice shown. Each slice is bounded on the right by $y = x^2$, which is $x = \sqrt{y}$ distance out from the y-axis, and is bounded on the left by $y = 3x$, which is $x = y/3$ distance out from the y-axis. The length of each slice is $\sqrt{y} - y/3$. The width of each slice is Δy, and the area extends from $y = 0$ to $y = 9$ so the area is represented by

$$\begin{aligned} A = \int_0^9 \left(\sqrt{y} - \frac{y}{3}\right) dy &= \frac{2}{3}y^{3/2} - \frac{1}{6}y^2\Big|_0^9 \\ &= \frac{2}{3}\cdot 9^{3/2} - \frac{1}{6}\cdot 9^2 - (0-0) \\ &= 4.5. \end{aligned}$$

Notice that the two ways of computing the area give the same answer, as we expect.

25. (a) The area is shown in Figure 8.13(a) with one vertical slice shown. Each slice is bounded on the top by $y = 12 - x$ and on the bottom by $y = 2x$, so the height of each slice is $(12 - x) - 2x$. The width of each slice is Δx and the area ranges from $x = 0$ to $x = 4$, so the area is represented by

$$\begin{aligned} A = \int_0^4 ((12-x) - 2x)\, dx &= \int_0^4 12 - 3x\, dx \\ &= 12x - \frac{3}{2}x^2\Big|_0^4 \\ &= 12\cdot 4 - \frac{3}{2}\cdot 4^2 - (0-0) \\ &= 24. \end{aligned}$$

Figure 8.13

(b) The area is shown in Figure 8.13(b) with two horizontal slices shown. Because some of the slices are bounded on the right by $y = 12 - x$ while others are bounded on the right by $y = 2x$, we use two separate integrals to calculate this area using horizontal slices. The slices between $y = 0$ and $y = 8$ are bounded on the right by $y = 2x$, which is $x = y/2$ distance from the y-axis, and are bounded on the left by the y-axis, which is $x = 0$. This part of the area is given by

$$\text{Bottom part of the area } = \int_0^8 \frac{y}{2}\, dy = \frac{1}{4}y^2\Big|_0^8 = \frac{1}{4}\cdot 8^2 - 0 = 16.$$

The slices between $y = 8$ and $y = 12$ are bounded on the right by $y = 12 - x$, which is $x = 12 - y$ distance from the y-axis, and are bounded on the left by the y-axis, which is $x = 0$. This part of the area is given by

$$\text{Top part of the area } = \int_8^{12} (12-y)\, dy = 12y - \frac{1}{2}y^2\Big|_8^{12} = 12\cdot 12 - \frac{1}{2}\cdot 12^2 - \left(12\cdot 8 - \frac{1}{2}\cdot 8^2\right) = 8.$$

The total area is given by

$$\text{Total area } = \int_0^8 \frac{y}{2}\,dy + \int_8^{12} (12-y)\,dy = 16 + 8 = 24.$$

Notice that the two ways of computing the area give the same answer, as we expect.

26. (a) The area is shown in Figure 8.14(a) with two vertical slices shown. Because some of the slices are bounded on the top by $y = x^2$ while others are bounded on the top by $y = 6 - x$, we use two separate integrals to calculate this area using vertical slices. The slices between $x = 0$ and $x = 2$ are bounded on the top by $y = x^2$ and are bounded on the bottom by the x-axis, which is $y = 0$. This part of the area is given by

$$\text{Left part of the area } = \int_0^2 x^2\,dx = \frac{1}{3}x^3\Big|_0^2 = \frac{1}{3}\cdot 2^3 - 0 = 2.667.$$

The slices between $x = 2$ and $x = 6$ are bounded on the top by $y = 6 - x$ and are bounded on the bottom by the x-axis, which is $y = 0$. This part of the area is given by

$$\begin{aligned}\text{Right part of the area } &= \int_2^6 (6-x)\,dx = 6x - \frac{1}{2}x^2\Big|_2^6 \\ &= 6\cdot 6 - \frac{1}{2}\cdot 6^2 - \left(6\cdot 2 - \frac{1}{2}\cdot 2^2\right) = 8.\end{aligned}$$

The total area is given by

$$\text{Total area } = \int_0^2 x^2\,dx + \int_2^6 (6-x)\,dx = 2.667 + 8 = 10.667.$$

Figure 8.14

(b) The area is shown in Figure 8.14(b) with one horizontal slice shown. The slices are all bounded on the right by $y = 6 - x$, which is $x = 6 - y$ distance from the y-axis, and are bounded on the left by $y = x^2$, which is $x = \sqrt{y}$ distance from the y-axis. The area ranges from $y = 0$ to $y = 4$ so the area is given by

$$\begin{aligned}A = \int_0^4 ((6-y) - \sqrt{y})\,dy &= 6y - \frac{1}{2}y^2 - \frac{2}{3}\cdot y^{3/2}\Big|_0^4 \\ &= 6\cdot 4 - \frac{1}{2}\cdot 4^2 - \frac{2}{3}\cdot 4^{3/2} - 0 \\ &= 10.667.\end{aligned}$$

Notice that the two ways of computing the area give the same answer, as we expect.

27. (a) The area is shown in Figure 8.15(a) with two vertical slices shown. Because some of the slices are bounded on the top by $y = 2x$ while others are bounded on the top by $y = 6$, we need to use two separate integrals to calculate this area using vertical slices. The slices between $x = 0$ and $x = 3$ are bounded on the top by $y = 2x$ and are bounded on the bottom by the x-axis, which is $y = 0$. This part of the area is given by

$$\text{Left part of the area } = \int_0^3 2x\,dx = x^2\Big|_0^3 = 3^2 - 0 = 9.$$

The slices between $x = 3$ and $x = 5$ are bounded on the top by $y = 6$ and are bounded on the bottom by the x-axis, which is $y = 0$. This part of the area is given by

$$\text{Right part of the area } = \int_3^5 6\,dx = 6x\Big|_3^5 = 6 \cdot 5 - 6 \cdot 3 = 12.$$

The total area is given by

$$\text{Total area } = \int_0^3 2x\,dx + \int_3^5 6\,dx = 9 + 12 = 21.$$

Figure 8.15

(b) The area is shown in Figure 8.15(b) with one horizontal slice shown. The slices are all bounded on the right by $x = 5$ and are bounded on the left by $y = 2x$, which is $x = y/2$ distance from the y-axis. The area ranges from $y = 0$ to $y = 6$ so the area is given by

$$A = \int_0^6 (5 - (y/2))\,dy = 5x - \frac{1}{4}y^2\Big|_0^6 = 5 \cdot 6 - \frac{1}{4} \cdot 6^2 - 0 = 21.$$

Notice that the two ways of computing the area give the same answer, as we expect.

28. Hemisphere with radius 12. See Figure 8.16.

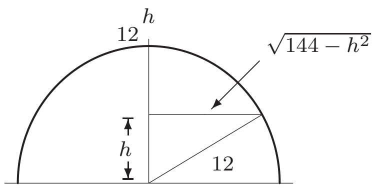

Figure 8.16

29. Cone with height 12 and radius $12/3 = 4$. See Figure 8.17.

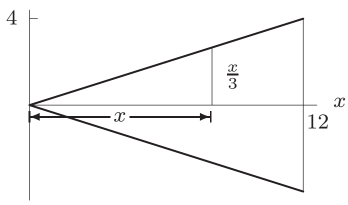

Figure 8.17

30. Cone with height 6 and radius 3. See Figure 8.18.

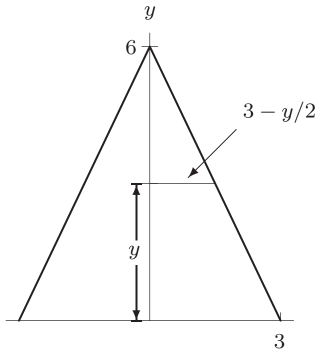

Figure 8.18

31. Hemisphere with radius 2. See Figure 8.19.

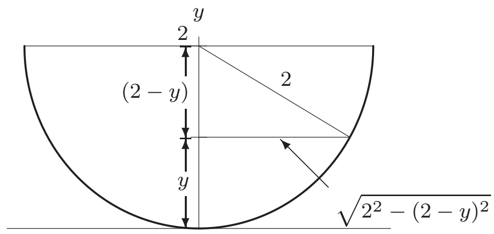

Figure 8.19

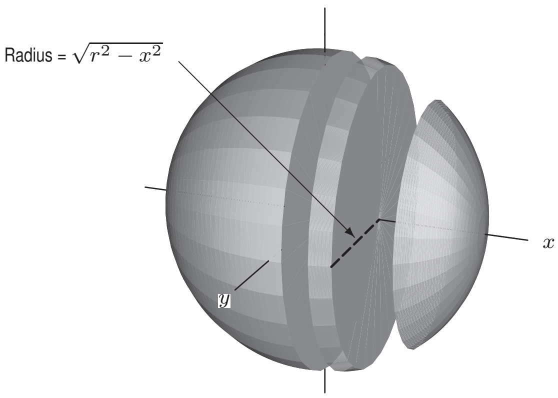
32.



We slice up the sphere in planes perpendicular to the x-axis. Each slice is a circle, with radius $y = \sqrt{r^2 - x^2}$; that's the radius because $x^2 + y^2 = r^2$ when $z = 0$. Then the volume is

$$V \approx \sum \pi(y^2)\,\Delta x = \sum \pi(r^2 - x^2)\,\Delta x.$$

Therefore, as Δx tends to zero, we get

$$\begin{aligned} V &= \int_{x=-r}^{x=r} \pi(r^2 - x^2)\,dx \\ &= 2\int_{x=0}^{x=r} \pi(r^2 - x^2)\,dx \\ &= 2\left(\pi r^2 x - \frac{\pi x^3}{3}\right)\Bigg|_0^r \\ &= \frac{4\pi r^3}{3}. \end{aligned}$$

33. We slice the cone horizontally into cylindrical disks with radius r and thickness Δh. See Figure 8.20. The volume of each disk is $\pi r^2 \Delta h$. We use the similar triangles in Figure 8.21 to write r as a function of h:

$$\frac{r}{h} = \frac{3}{12} \quad \text{so} \quad r = \frac{1}{4}h.$$

The volume of the disk at height h is $\pi(\frac{1}{4}h)^2\Delta h$. To find the total volume, we integrate this quantity from $h = 0$ to $h = 12$.

$$V = \int_0^{12} \pi\left(\frac{1}{4}h\right)^2 dh = \frac{\pi}{16}\frac{h^3}{3}\Bigg|_0^{12} = 36\pi = 113.097 \text{ m}^3.$$

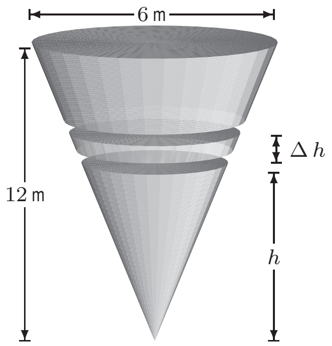


Figure 8.20

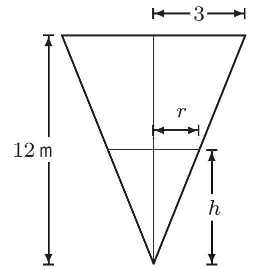

Figure 8.21

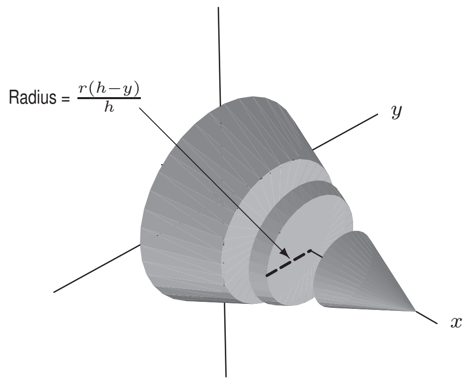
34.



This cone is what you get when you rotate the line $x = r(h-y)/h$ about the y–axis. So slicing perpendicular to the y–axis yields

$$V = \int_{y=0}^{y=h} \pi x^2\,dy = \pi \int_0^h \left(\frac{(h-y)r}{h}\right)^2 dy$$
$$= \pi \frac{r^2}{h^2} \int_0^h (h^2 - 2hy + y^2)\,dy$$
$$= \frac{\pi r^2}{h^2}\left[h^2 y - hy^2 + \frac{y^3}{3}\right]\Bigg|_0^h = \frac{\pi r^2 h}{3}.$$

35. (a) A vertical slice has a triangular shape and thickness Δx. See Figure 8.22.

$$\text{Volume of slice} = \text{Area of triangle} \cdot \Delta x = \frac{1}{2}\text{ Base} \cdot \text{Height} \cdot \Delta x = \frac{1}{2}\cdot 2 \cdot 3\Delta x = 3\Delta x \text{ cm}^3.$$

Thus,

$$\text{Total volume} = \lim_{\Delta x \to 0} \sum 3\Delta x = \int_0^4 3\,dx = 3x\Big|_0^4 = 12 \text{ cm}^3.$$

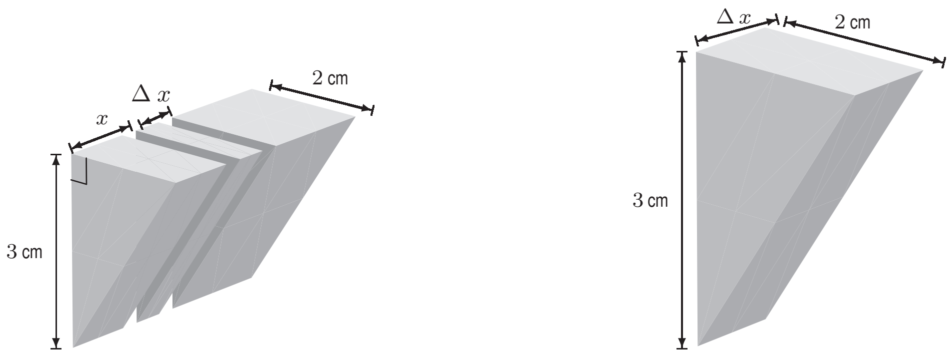


Figure 8.22

(b) A horizontal slice has a rectangular shape and thickness Δh. See Figure 8.23. Using similar triangles, we see that

$$\frac{w}{2} = \frac{3-h}{3},$$

so

$$w = \frac{2}{3}(3-h) = 2 - \frac{2}{3}h.$$

Thus

$$\text{Volume of slice } \approx 4w\Delta h = 4\left(2 - \frac{2}{3}h\right)\Delta h = \left(8 - \frac{8}{3}h\right)\Delta h.$$

So,

$$\text{Total volume } = \lim_{\Delta h \to 0} \sum \left(8 - \frac{8}{3}h\right)\Delta h = \int_0^3 \left(8 - \frac{8}{3}h\right) dh = \left(8h - \frac{4h^2}{3}\right)\Bigg|_0^3 = 12 \text{ cm}^3.$$

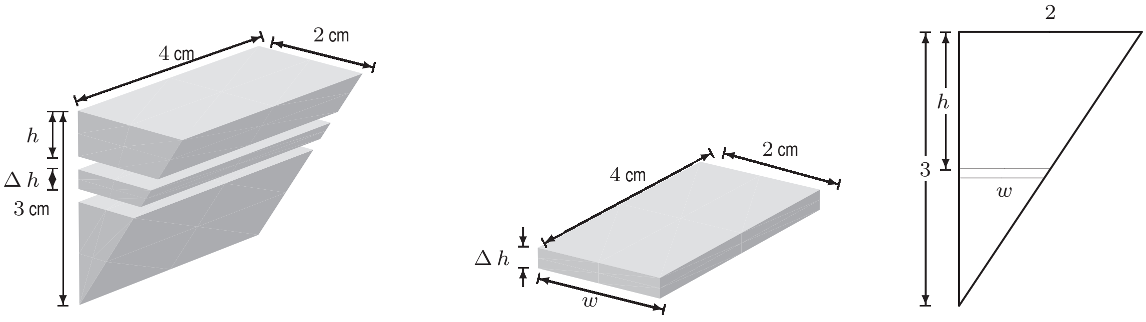

Figure 8.23

36. We slice the water into horizontal slices, each of which is a rectangle. See Figure 8.24.

$$\text{Volume of slice } \approx 150w\Delta h \text{ km}^3.$$

To find w in terms of h, we use the similar triangles in Figure 8.25:

$$\frac{w}{3} = \frac{h}{0.2} \quad \text{so} \quad w = 15h.$$

So

$$\text{Volume of slice } \approx 150 \cdot 15h\Delta h = 2250h\Delta h \text{ km}^3.$$

Summing over all slices and letting $\Delta h \to 0$ gives

$$\text{Total volume } = \lim_{\Delta h \to 0} \sum 2250h\Delta h = \int_0^{0.2} 2250h \, dh \text{ km}^3.$$

Evaluating the integral gives

$$\text{Total volume } = 2250 \frac{h^2}{2}\Bigg|_0^{0.2} = 45 \text{ km}^3.$$

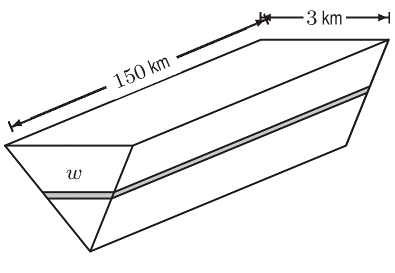

Figure 8.24

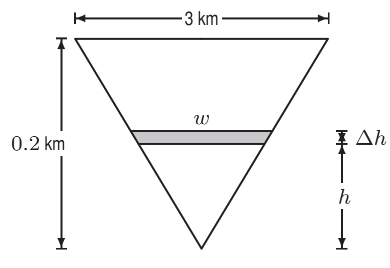

Figure 8.25

37. To calculate the volume of material, we slice the dam horizontally. See Figure 8.26. The slices are rectangular, so

$$\text{Volume of slice } \approx 1400w\Delta h \text{ m}^3.$$

Since w is a linear function of h, and $w = 160$ when $h = 0$, and $w = 10$ when $h = 150$, this function has slope $= (10 - 160)/150 = -1$. Thus

$$w = 160 - h \text{ meters,}$$

so

$$\text{Volume of slice } \approx 1400(160 - h)\Delta h \text{ m}^3.$$

Summing over all slices and taking the limit as $\Delta h \to 0$ gives

$$\text{Total volume } = \lim_{\Delta h \to 0} \sum 1400(160 - h)\Delta h = \int_0^{150} 1400(160 - h)\, dh \text{ m}^3.$$

Evaluating the integral gives

$$\text{Total volume } = 1400 \left(160h - \frac{h^2}{2}\right)\Bigg|_0^{150} = 1.785 \cdot 10^7 \text{ m}^3.$$

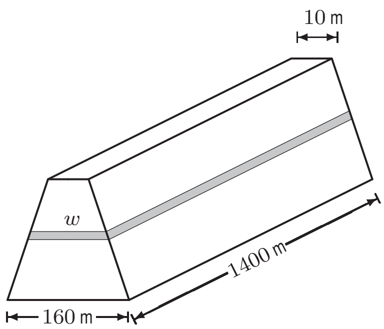

Figure 8.26

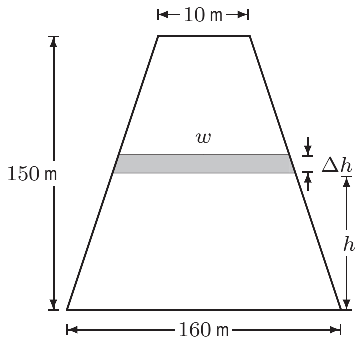

Figure 8.27

Strengthen Your Understanding

38. The horizontal slice at height y goes from $x = 0$ to a point on the line $y = 2x$. At this point, $x = y/2$. The correct integral for the area is $\int_0^8 y/2\, dy$.

39. Slice the sphere $x^2+y^2 = 10^2$ into slices of thickness Δx perpendicular to the x-axis. The typical slice is approximately a cylinder of radius $y = \sqrt{10^2 - x^2}$ and height $h = \Delta x$. The volume of the slice is approximately $\pi y^2 h = \pi(10^2 - x^2)\Delta x$. The volume of the sphere is thus $\int_{-10}^{10} \pi \left(10^2 - x^2\right)\, dx$.

40. It would be hard to use vertical slices to find the area of the shaded region in Figure 8.28 because the vertical slices on the right portion of the figure are in two pieces.

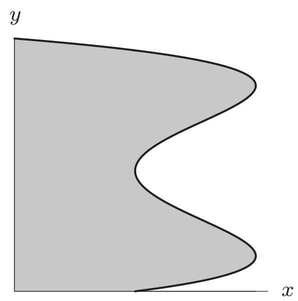

Figure 8.28

41. One possible answer is the region between the positive x-axis, the positive y-axis and the line $y = 1 - x$. For horizontal slices, the width of a slice at height y is $x = 1 - y$, and for vertical slices the height of a slice at position x is $y = 1 - x$.

42. True. Since $y = \pm\sqrt{9 - x^2}$ represent the top and bottom halves of the sphere, slicing disks perpendicular to the x-axis gives

$$\text{Volume of slice } \approx \pi y^2 \Delta x = \pi(9 - x^2)\Delta x$$
$$\text{Volume} = \int_{-3}^{3} \pi(9 - x^2)\, dx.$$

43. False. Evaluating does not give the volume of a cone $\pi r^2 h/3$:

$$\int_0^h \pi(r - y)\, dy = \pi\left(ry - \frac{y^2}{2}\right)\Bigg|_0^h = \pi\left(rh - \frac{h^2}{2}\right).$$

Alternatively, you can show by slicing that the integral representing this volume is $\int_0^h \pi r^2 (1 - y/h)^2\, dy$.

44. False. Using the table of integrals (VI-28 and VI-30) or a trigonometric substitution gives

$$\int_0^r \pi\sqrt{r^2 - y^2}\, dy = \frac{\pi}{2}\left(y\sqrt{r^2 - y^2} + r^2 \arcsin\left(\frac{y}{r}\right)\right)\Bigg|_0^r = \frac{\pi r^2}{2}(\arcsin 1 - \arcsin 0) = \frac{\pi^2 r^2}{4}.$$

The volume of a hemisphere is $2\pi r^3/3$.

Alternatively, you can show by slicing that the integral representing this volume is $\int_0^r \pi(r^2 - y^2)\, dy$.

45. True. Horizontal slicing gives rectangular slabs of length l, thickness Δy, and width $w = 2\sqrt{r^2 - y^2}$. So the volume of one slab is $2l\sqrt{r^2 - y^2}\Delta y$, and the integral is $\int_{-r}^{r} 2l\sqrt{r^2 - y^2}\, dy$.

Solutions for Section 8.2

Exercises

1. (a) The volume of a disk is given by

$$\Delta V \approx \pi(2x)^2 \Delta x = 4\pi x^2\, \Delta x,$$

so

$$\text{Volume } = \int_0^3 4\pi x^2\, dx.$$

(b) We have

$$\text{Volume } = 4\pi \frac{x^3}{3}\Bigg|_0^3 = 36\pi.$$

2. (a) The volume of a disk is given by

$$\Delta V \approx \pi(-x^2 + 6x)^2 \Delta x,$$

so

$$\text{Volume } = \int_0^6 \pi(-x^2 + 6x)^2\, dx.$$

(b) We have

$$\text{Volume } = \int_0^6 \pi(x^4 - 12x^3 + 36x^2)\, dx = \pi\left(\frac{x^5}{5} - 3x^4 + 12x^3\right)\Bigg|_0^6 = \frac{1296\pi}{5}.$$

3. (a) The strip stretches from $x = y/2$ to $x = 3$. The volume of a disk with a hole in it is

$$\Delta V \approx \pi\left(3^2 - \left(\frac{y}{2}\right)^2\right)\Delta y = \frac{\pi}{4}(36 - y^2)\,\Delta y,$$

so

$$\text{Volume } = \int_0^6 \frac{\pi}{4}(36 - y^2)\,dy.$$

(b) We have

$$\text{Volume } = \frac{\pi}{4}\left(36y - \frac{y^3}{3}\right)\Bigg|_0^6 = 36\pi.$$

4. (a) The equation $y = -x^2 + 6x$ can be solved for x as

$$\begin{aligned} x^2 - 6x + y &= 0 \\ x &= \frac{6 \pm \sqrt{36 - 4y}}{2} = 3 \pm \sqrt{9 - y}. \end{aligned}$$

The left end of the strip is given by $x = 3 - \sqrt{9-y}$, and the right end is given by $x = 3 + \sqrt{9-y}$. Thus, the volume of a disk with a hole is

$$\begin{aligned} \Delta V &\approx \pi((3 + \sqrt{9-y})^2 - (3 - \sqrt{9-y})^2)\,\Delta y \\ &= \pi((9 + 6\sqrt{9-y} + 9 - y) - (9 - 6\sqrt{9-y} + 9 - y))\,\Delta y \\ &= 12\pi\sqrt{9-y}\,\Delta y, \end{aligned}$$

so

$$\text{Volume } = 12\pi\int_0^9 \sqrt{9-y}\,dy.$$

(b) We have

$$\text{Volume } = \frac{12\pi(9-y)^{3/2}}{-3/2}\Bigg|_0^9 = 216\pi.$$

5. The volume is given by

$$V = \int_0^1 \pi y^2 dx = \int_0^1 \pi x^4 dx = \pi\frac{x^5}{5}\Bigg|_0^1 = \frac{\pi}{5}.$$

6. The volume is given by

$$V = \int_1^2 \pi y^2\,dx = \int_1^2 \pi(x+1)^4\,dx = \frac{\pi(x+1)^5}{5}\Bigg|_1^2 = \frac{211\pi}{5}.$$

7. The volume is given by

$$V = \int_{-2}^0 \pi(4 - x^2)^2\,dx = \pi\int_{-2}^0 (16 - 8x^2 + x^4)\,dx = \pi\left(16x - \frac{8x^3}{3} + \frac{x^5}{5}\right)\Bigg|_{-2}^0 = \frac{256\pi}{15}.$$

8. The volume is given by

$$V = \int_{-1}^1 \pi(\sqrt{x+1})^2\,dx = \pi\int_{-1}^1 (x+1)\,dx = \pi\left(\frac{x^2}{2} + x\right)\Bigg|_{-1}^1 = 2\pi.$$

9. The volume is given by

$$V = \int_{-1}^1 \pi y^2\,dx = \int_{-1}^1 \pi(e^x)^2\,dx = \int_{-1}^1 \pi e^{2x}\,dx = \frac{\pi}{2}e^{2x}\Bigg|_{-1}^1 = \frac{\pi}{2}(e^2 - e^{-2}).$$

10. The volume is given by

$$V = \int_0^{\pi/2} \pi y^2\, dx = \int_0^{\pi/2} \pi \cos^2 x\, dx.$$

Integration by parts gives

$$V = \frac{\pi}{2}(\cos x \sin x + x)\bigg|_0^{\pi/2} = \frac{\pi^2}{4}.$$

11. The volume is given by

$$V = \int_0^1 \pi \left(\frac{1}{x+1}\right)^2 dx = \pi \int_0^1 \frac{dx}{(x+1)^2} = -\pi(x+1)^{-1}\bigg|_0^1 = \pi\left(1 - \frac{1}{2}\right) = \frac{\pi}{2}.$$

12. The volume is given by

$$V = \pi \int_0^1 (\sqrt{\cosh 2x})^2\, dx = \pi \int_0^1 \cosh 2x\, dx = \frac{\pi}{2}\sinh 2x\bigg|_0^1 = \frac{\pi}{2}\sinh 2.$$

13. Since the graph of $y = x^2$ is below the graph of $y = x$ for $0 \le x \le 1$, the volume is given by

$$V = \int_0^1 \pi x^2\, dx - \int_0^1 \pi (x^2)^2\, dx = \pi \int_0^1 (x^2 - x^4)\, dx = \pi\left(\frac{x^3}{3} - \frac{x^5}{5}\right)\bigg|_0^1 = \frac{2\pi}{15}.$$

14. Since the graph of $y = e^{3x}$ is above the graph of $y = e^x$ for $0 \le x \le 1$, the volume is given by

$$V = \int_0^1 \pi (e^{3x})^2\, dx - \int_0^1 \pi (e^x)^2\, dx = \int_0^1 \pi(e^{6x} - e^{2x})\, dx = \pi\left(\frac{e^{6x}}{6} - \frac{e^{2x}}{2}\right)\bigg|_0^1 = \pi\left(\frac{e^6}{6} - \frac{e^2}{2} + \frac{1}{3}\right).$$

15. Since $f'(x) = x$, we evaluate the integral numerically or using the table to get

$$\text{Arc length } = \int_0^2 \sqrt{1 + x^2}\, dx = \frac{\ln(\sqrt{5} + 2)}{2} + \sqrt{5} = 2.958.$$

16. Since $f'(x) = -\sin x$, we evaluate the integral numerically to get

$$\text{Arc length } = \int_0^2 \sqrt{1 + \sin^2 x}\, dx = 2.508.$$

17. Since $f'(x) = 1/(x + 1)$, we evaluate the integral numerically to get

$$\text{Arc length } = \int_0^2 \sqrt{1 + \left(\frac{1}{x+1}\right)^2}\, dx = 2.302.$$

18. Note that this function is actually $x^{3/2}$ in disguise. So

$$\begin{aligned} L &= \int_0^2 \sqrt{1 + \left[\frac{3}{2}x^{\frac{1}{2}}\right]^2}\, dx = \int_{x=0}^{x=2} \sqrt{1 + \frac{9}{4}x}\, dx \\ &= \frac{4}{9}\int_{w=1}^{w=\frac{11}{2}} w^{\frac{1}{2}}\, dw \\ &= \frac{8}{27}w^{\frac{3}{2}}\bigg|_1^{\frac{11}{2}} = \frac{8}{27}\left(\left(\frac{11}{2}\right)^{\frac{3}{2}} - 1\right) \approx 3.526, \end{aligned}$$

where we set $w = 1 + \frac{9}{4}x$, so $dx = \frac{4}{9}dw$.

19. This is a one-quarter of the circumference of a circle of radius 2. That circumference is $2 \cdot 2\pi = 4\pi$, so the length is $\frac{4\pi}{4} = \pi$.

20. Since $f'(x) = \sinh x$, the arc length is given by

$$L = \int_0^2 \sqrt{1+\sinh^2 x}\,dx = \int_0^2 \sqrt{\cosh^2 x}\,dx = \int_0^2 \cosh x\,dx = \sinh x\Big|_0^2 = \sinh 2.$$

21. The length is

$$\int_1^2 \sqrt{(x'(t))^2+(y'(t))^2+(z'(t))^2}\,dt = \int_1^2 \sqrt{5^2+4^2+(-1)^2}\,dt = \sqrt{42}.$$

This is the length of a straight line from the point $(8,5,2)$ to $(13,9,1)$.

22. We have

$$\begin{aligned} D &= \int_0^1 \sqrt{(-e^t\sin(e^t))^2+(e^t\cos(e^t))^2}\,dt \\ &= \int_0^1 \sqrt{e^{2t}}\,dt = \int_0^1 e^t\,dt \\ &= e-1. \end{aligned}$$

This is the length of the arc of a unit circle from the point $(\cos 1, \sin 1)$ to $(\cos e, \sin e)$—in other words between the angles $\theta = 1$ and $\theta = e$. The length of this arc is $(e-1)$.

23. We have

$$D = \int_0^{2\pi} \sqrt{(-3\sin 3t)^2+(5\cos 5t)^2}\,dt.$$

We cannot find this integral symbolically, but numerical methods show $D \approx 24.6$.

24. Since $dx/dt = -3\cos^2 t\sin t$, $dy/dt = 3\sin^2 t\cos t$, we have

$$\begin{aligned} \text{Arc length } &= \int_0^{2\pi} \sqrt{9\cos^4 t\sin^2 t + 9\sin^4 t\cos^2 t}\,dt = 3\int_0^{2\pi} |\cos t\sin t|\sqrt{cos^2 t+\sin^2 t}\,dt \\ &= 3\int_0^{2\pi} |\cos t\sin t|\,dt. \end{aligned}$$

We calculate the integral over the interval $0 \le t \le \pi/2$, where both $\cos t$ and $\sin t$ are positive, and multiply by 4:

$$\text{Arc length } = 12\int_0^{\pi/2} \cos t\sin t\,dt = 6\sin^2 t\Big|_0^{\pi/2} = 6.$$

Problems

25. The two functions intersect at $(0,0)$ and $(8,2)$. We slice the volume with planes perpendicular to the line $x = 9$. This divides the solid into thin washers with volume

$$\text{Volume of slice } = \pi r_{out}^2\Delta y - \pi r_{in}^2\Delta y.$$

The outer radius is the horizontal distance from the line $x = 9$ to the curve $x = y^3$, so $r_{out} = 9 - y^3$. Similarly, the inner radius is the horizontal distance from the line $x = 9$ to the curve $x = 4y$, so $r_{in} = 9 - 4y$. Integrating from $y = 0$ to $y = 2$ we have

$$V = \int_0^2 [\pi(9-y^3)^2 - \pi(9-4y)^2]\,dy.$$

26. The two functions intersect at $(0,0)$ and $(8,2)$. We slice the volume with planes perpendicular to the line $y = 3$. This divides the solid into thin washers with

$$\text{Volume of slice } = \pi r_{out}^2\Delta x - \pi r_{in}^2\Delta x.$$

The outer radius is the vertical distance from the line $y = 3$ to the curve $y = \frac{1}{4}x$, so $r_{out} = 3 - \frac{1}{4}x$. Similarly, the inner radius is the vertical distance from the line $y = 3$ to the curve $y = \sqrt[3]{x}$, so $r_{in} = 3 - \sqrt[3]{x}$. Integrating from $x = 0$ to $x = 8$ we have

$$V = \int_0^8 \left[\pi(3-\frac{1}{4}x)^2 - \pi(3-\sqrt[3]{x})^2\right]\,dx.$$

27. Note that the lines $x = 9$ and $y = \frac{1}{3}x$ intersect at $(9, 3)$. We slice the volume with planes that are perpendicular to the line $y = -2$. This divides the solid into thin washers with

$$\text{Volume of slice } = \pi r_{out}^2 \Delta x - \pi r_{in}^2 \Delta x.$$

Note that the inner radius is the vertical distance from the line $y = -2$ to the x-axis, so $r_{in} = 2$. Similarly, the outer radius is the vertical distance from the line $y = -2$ to the line $y = \frac{1}{3}x$, so $r_{out} = 2 + \frac{1}{3}x$. Integrating from $x = 0$ to $x = 9$ we have

$$V = \int_0^9 \left[\pi(2 + \frac{1}{3}x)^2 - \pi 2^2\right] dx.$$

28. Note that the lines $x = 9$ and $y = \frac{1}{3}x$ intersect at $(9, 3)$. We slice the volume with planes that are perpendicular to the line $x = -1$. This divides the solid into thin washers with

$$\text{Volume of slice } = \pi r_{out}^2 \Delta y - \pi r_{in}^2 \Delta y.$$

Note that the inner radius is the horizontal distance from the line $x = -1$ to the line $x = 3y$, so $r_{in} = 1 + 3y$. Similarly, the outer radius is the horizontal distance from the line $x = -1$ to the line $x = 9$, so $r_{out} = 1 + 9$. Integrating from $y = 0$ to $y = 3$ we have

$$V = \int_0^3 [\pi(1 + 9)^2 - \pi(1 + 3y)^2]\, dy.$$

29. The two functions intersect at $(0, 0)$ and $(5, 25)$. We slice the volume with planes perpendicular to the x-axis. This divides the solid into thin washers with volume

$$\text{Volume of slice } = \pi((r_{out})^2 - (r_{in})^2)\Delta x.$$

The outer radius is the vertical distance from the x-axis to the curve $y = 5x$, so $r_{out} = 5x$. Similarly, the inner radius is the vertical distance from the x-axis to the curve $y = x^2$, so $r_{in} = x^2$. Integrating from $x = 0$ to $x = 5$ we have

$$V = \int_0^5 \pi((5x)^2 - (x^2)^2)\, dx.$$

30. The two functions intersect at $(0, 0)$ and $(5, 25)$. We slice the volume with planes perpendicular to the y-axis. This divides the solid into thin washers with volume

$$\text{Volume of slice } = \pi((r_{out})^2 - (r_{in})^2)\Delta y.$$

The outer radius is the horizontal distance from the y-axis to the curve $x = \sqrt{y}$, so $r_{out} = \sqrt{y}$. Similarly, the inner radius is the horizontal distance from the y-axis to the curve $x = y/5$, so $r_{in} = y/5$. Integrating from $y = 0$ to $y = 25$ we have

$$V = \int_0^{25} \pi((\sqrt{y})^2 - (y/5)^2)\, dy.$$

31. The two functions intersect at $(0, 0)$ and $(5, 25)$. We slice the volume with planes perpendicular to the horizontal line $y = -4$. This divides the solid into thin washers with volume

$$\text{Volume of slice } = \pi((r_{out})^2 - (r_{in})^2)\Delta x.$$

The outer radius is the vertical distance from the line $y = -4$ to the curve $y = 5x$, so $r_{out} = 4 + 5x$. Similarly, the inner radius is the vertical distance from the line $y = -4$ to the curve $y = x^2$, so $r_{in} = 4 + x^2$. Integrating from $x = 0$ to $x = 5$ we have

$$V = \int_0^5 \pi((4 + 5x)^2 - (4 + x^2)^2)\, dx.$$

32. The two functions intersect at $(0, 0)$ and $(5, 25)$. We slice the volume with planes perpendicular to the vertical line $x = -3$. This divides the solid into thin washers with volume

$$\text{Volume of slice } = \pi((r_{out})^2 - (r_{in})^2)\Delta y.$$

The outer radius is the horizontal distance from the line $x = -3$ to the curve $x = \sqrt{y}$, so $r_{out} = 3 + \sqrt{y}$. Similarly, the inner radius is the horizontal distance from the line $x = -3$ to the curve $x = y/5$, so $r_{in} = 3 + y/5$. Integrating from $y = 0$ to $y = 25$ we have

$$V = \int_0^{25} \pi((3 + \sqrt{y})^2 - (3 + y/5)^2)\, dy.$$

33. One arch of the sine curve lies between $x = 0$ and $x = \pi$. Since $d(\sin x)/dx = \cos x$, evaluating the integral numerically gives

$$\text{Arc length } = \int_0^{\pi} \sqrt{1 + \cos^2 x}\, dx = 3.820.$$

34. The curves cross at $(1, 1)$; see Figure 8.29. The straight side has length $\sqrt{2} = 1.414$; as this is the hypotenuse of a right triangle with sides $1, 1, \sqrt{2}$. The curved side has

$$\text{Arc length } = \int_0^1 \sqrt{1 + (2x)^2}\, dx = \frac{\ln(\sqrt{5} + 2)}{4} + \frac{\sqrt{5}}{2} = 1.479.$$

Thus the perimeter is $1.4142 + 1.479 = 2.893$.

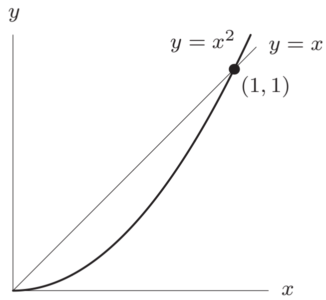

Figure 8.29

35. (a) Slicing the region perpendicular to the x-axis gives disks of radius y. See Figure 8.30.

$$\text{Volume of slice} \approx \pi y^2 \Delta x = \pi(x^2 - 1)\Delta x.$$

Thus,

$$\text{Total volume} = \lim_{\Delta x \to 0} \sum \pi(x^2 - 1)\Delta x = \int_2^3 \pi(x^2 - 1)\, dx = \pi \left(\frac{x^3}{3} - x \right) \Bigg|_2^3$$
$$= \pi \left(9 - 3 - \left(\frac{8}{3} - 2 \right) \right) = \frac{16\pi}{3}.$$

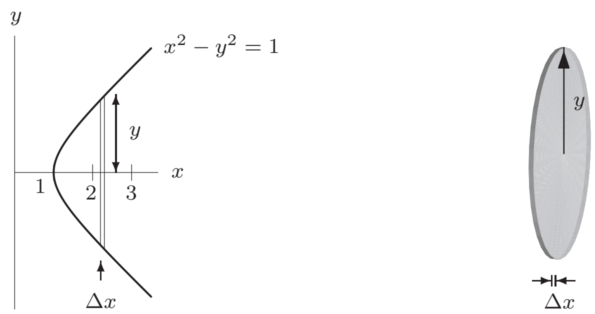

Figure 8.30

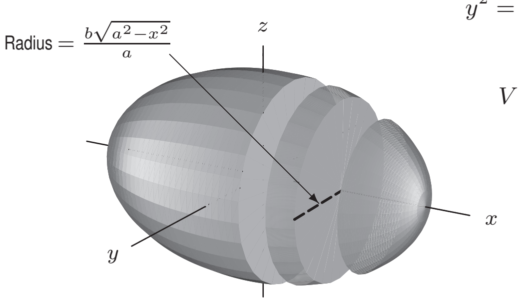
(b) The arc length, L, of the curve $y = f(x)$ is given by $L = \int_a^b \sqrt{1 + (f'(x))^2}\, dx$. In this problem y is an implicit function of x. Solving for y gives $y = \sqrt{x^2 - 1}$ as the equation of the top half of the hyperbola. Differentiating gives

$$\frac{dy}{dx} = \frac{1}{2}(x^2 - 1)^{-1/2}(2x) = \frac{x}{\sqrt{x^2 - 1}}.$$

Thus

$$\text{Arc length} = \int_2^3 \sqrt{1 + \left(\frac{x}{\sqrt{x^2 - 1}} \right)^2}\, dx = \int_2^3 \sqrt{1 + \frac{x^2}{x^2 - 1}}\, dx = \int_2^3 \sqrt{\frac{2x^2 - 1}{x^2 - 1}}\, dx = 1.48.$$

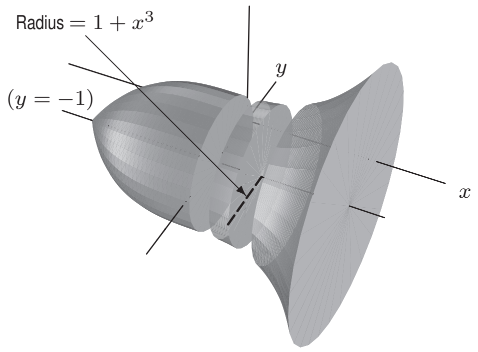
36.



$$y^2 = b^2\left(1 - \frac{x^2}{a^2}\right).$$

$$\begin{aligned} V &= \int_{-a}^{a} \pi y^2 dx = \pi \int_{-a}^{a} b^2\left(1 - \frac{x^2}{a^2}\right) dx \\ &= 2\pi b^2 \int_0^a \left(1 - \frac{x^2}{a^2}\right) dx = 2\pi b^2 \left[x - \frac{x^3}{3a^2}\right]_0^a \\ &= 2\pi b^2\left(a - \frac{a^3}{3a^2}\right) = 2\pi b^2 \left(a - \frac{1}{3}a\right) \\ &= \frac{4}{3}\pi a b^2. \end{aligned}$$

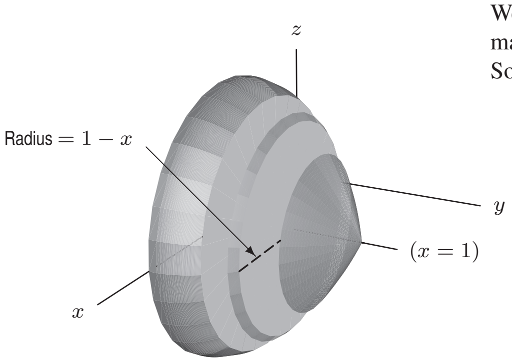
37.



We slice the region perpendicular to the x–axis. The Riemann sum we get is $\sum \pi(x^3+1)^2\Delta x$. So the volume V is the integral

$$\begin{aligned} V &= \int_{-1}^{1} \pi(x^3+1)^2\, dx \\ &= \pi \int_{-1}^{1} (x^6 + 2x^3 + 1)\, dx \\ &= \pi\left(\frac{x^7}{7} + \frac{x^4}{2} + x\right)\Bigg|_{-1}^{1} \\ &= (16/7)\pi \approx 7.18. \end{aligned}$$

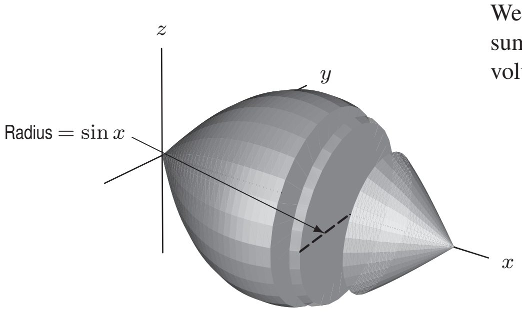
38.



We slice the region perpendicular to the y–axis. The Riemann sum we get is $\sum \pi(1-x)^2\Delta y = \sum \pi(1-y^2)^2 \Delta y$. So the volume V is the integral

$$\begin{aligned} V &= \int_0^1 \pi(1-y^2)^2\, dy \\ &= \pi\int_0^1 (1 - 2y^2 + y^4)\, dy \\ &= \pi\left(y - \frac{2y^3}{3} + \frac{y^5}{5}\right)\Bigg|_0^1 \\ &= (8/15)\pi \approx 1.68. \end{aligned}$$

39.



We take slices perpendicular to the x–axis. The Riemann sum for approximating the volume is $\sum \pi \sin^2 x \Delta x$. The volume is the integral corresponding to that sum, namely

$$\begin{aligned} V &= \int_0^\pi \pi \sin^2 x\, dx \\ &= \pi\left[-\frac{1}{2}\sin x \cos x + \frac{1}{2}x\right]\Bigg|_0^\pi = \frac{\pi^2}{2} \approx 4.935. \end{aligned}$$

40. Slice the object into disks horizontally, as in Figure 8.31. A typical disk has thickness Δy and radius $x = \sqrt{y}$. Thus

$$\text{Volume of slice } \approx \pi x^2 \Delta y = \pi y\, \Delta y.$$

$$\text{Volume of solid } = \lim_{\Delta y \to 0} \sum \pi y\, \Delta y = \int_0^1 \pi y\, dy = \pi \frac{y^2}{2}\Bigg|_0^1 = \frac{\pi}{2}.$$

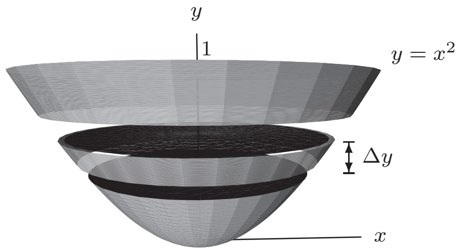


Figure 8.31

41. Slice the object into rings vertically, as is Figure 8.32. A typical ring has thickness Δx and outer radius $y = 1$ and inner radius $y = x^2$.

$$\text{Volume of slice } \approx \pi 1^2 \Delta x - \pi y^2 \Delta x = \pi(1 - x^4)\,\Delta x.$$

$$\text{Volume of solid } = \lim_{\Delta x \to 0} \sum \pi(1 - x^4)\,\Delta x = \int_0^1 \pi(1 - x^4)\,dx = \pi\left(x - \frac{x^5}{5}\right)\Bigg|_0^1 = \frac{4}{5}\pi.$$

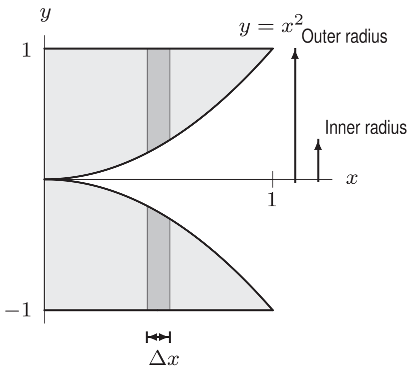

Figure 8.32: Cross-section of solid

42. The region is cylindrical with a hole around the axis of rotation, $y = -2$. Slice it into rings vertically, as in Figure 8.33. A typical ring has thickness Δx and outer radius $1 + 2 = 3$ and inner radius $y + 2 = x^2 + 2$. Thus

$$\text{Volume of slice } \approx \pi 3^2 \Delta x - \pi(x^2 + 2)^2 \Delta x = \pi(5 - x^4 - 4x^2)\,\Delta x.$$

$$\text{Volume of solid } = \int_0^1 \pi(5 - x^4 - 4x^2)\,\Delta x = \pi\left(5x - \frac{x^5}{5} - \frac{4}{3}x^3\right)\Bigg|_0^1 = \frac{52\pi}{15}.$$

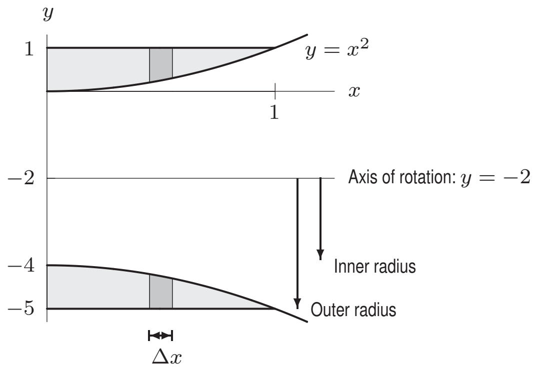

Figure 8.33: Cross-section of solid

43. Slicing perpendicularly to the x-axis gives squares whose thickness is Δx and whose side is $1 - y = 1 - x^2$. See Figure 8.34. Thus

$$\text{Volume of square slice } \approx (1-x^2)^2 \Delta x = (1 - 2x^2 + x^4)\,\Delta x.$$

$$\text{Volume of solid } = \int_0^1 (1 - 2x^2 + x^4)\,dx = x - \frac{2}{3}x^3 + \frac{x^5}{5}\Bigg|_0^1 = \frac{8}{15}.$$

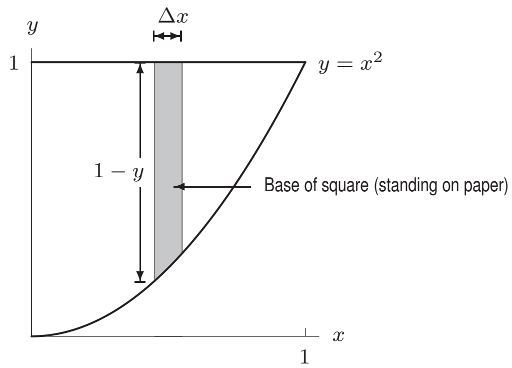

Figure 8.34: Base of solid

44. Slicing perpendicularly to the x-axis gives semicircles whose thickness is Δx and whose diameter is $1 - y = 1 - x^2$. See Figure 8.35. Thus

$$\text{Volume of semicircular slice } \approx \pi \left(\frac{1-x^2}{2}\right)^2 \Delta x = \frac{\pi}{4}(1 - 2x^2 + x^4)\,\Delta x.$$

$$\text{Volume of solid } = \int_0^1 \frac{\pi}{4}(1 - 2x^2 + x^4)\,dx = \frac{\pi}{4}\left(x - \frac{2}{3}x^3 + \frac{x^5}{5}\right)\Bigg|_0^1 = \frac{\pi}{4} \cdot \frac{8}{15} = \frac{2\pi}{15}.$$

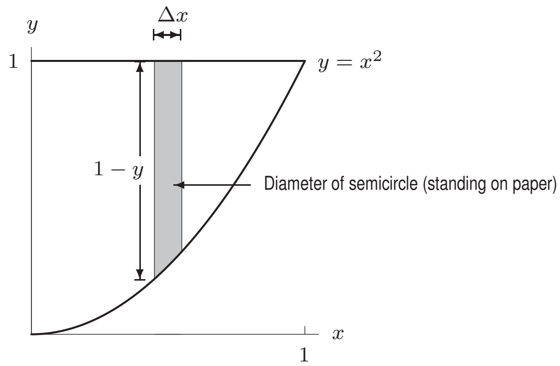

Figure 8.35: Base of solid

45. An equilateral triangle of side s has height $\sqrt{3}s/2$ and

$$\text{Area } = \frac{1}{2} \cdot s \cdot \frac{\sqrt{3}s}{2} = \frac{\sqrt{3}}{4}s^2.$$

Slicing perpendicularly to the y-axis gives equilateral triangles whose thickness is Δy and whose side is $x = \sqrt{y}$. See Figure 8.36. Thus

$$\text{Volume of triangular slice } \approx \frac{\sqrt{3}}{4}(\sqrt{y})^2 \Delta y = \frac{\sqrt{3}}{4} y\,\Delta y.$$

$$\text{Volume of solid } = \int_0^1 \frac{\sqrt{3}}{4} y\,dy = \frac{\sqrt{3}}{4}\frac{y^2}{2}\bigg|_0^1 = \frac{\sqrt{3}}{8}.$$

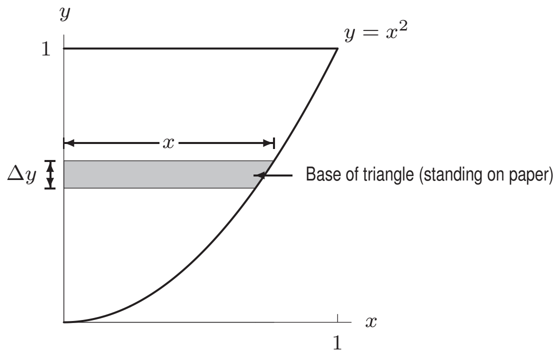

Figure 8.36: Base of solid

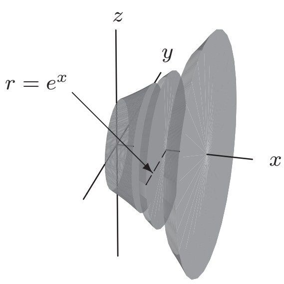
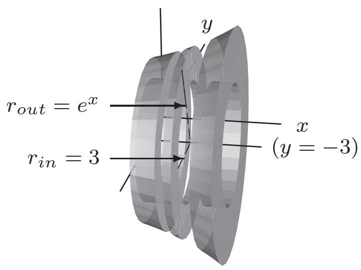
46.



This is the volume of revolution gotten from the rotating the curve $y = e^x$. Take slices perpendicular to the x-axis. They will be circles with radius e^x, so

$$V = \int_{x=0}^{x=1} \pi y^2\,dx = \pi \int_0^1 e^{2x}\,dx$$
$$= \frac{\pi e^{2x}}{2}\bigg|_0^1 = \frac{\pi(e^2-1)}{2} \approx 10.036.$$

47.



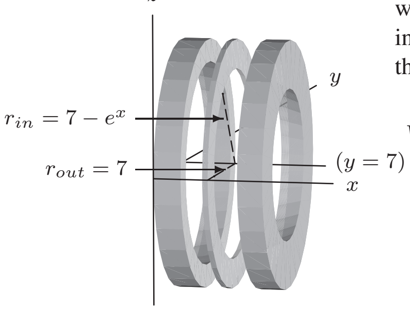
We slice the volume with planes perpendicular to the line $y = -3$. This divides the curve into thin washers, as in Example 3 on page 424 of the text, whose volumes are

$$\pi r_{\text{out}}^2 dx - \pi r_{\text{in}}^2 dx = \pi(3+y)^2 dx - \pi 3^2 dx.$$

So the integral we get from adding all these washers up is

$$V = \int_{x=0}^{x=1} [\pi(3+y)^2 - \pi 3^2]\,dx$$
$$= \pi \int_0^1 [(3+e^x)^2 - 9]\,dx$$
$$= \pi \int_0^1 [e^{2x} + 6e^x]\,dx = \pi[\frac{e^{2x}}{2} + 6e^x]\bigg|_0^1$$
$$= \pi[(e^2/2 + 6e) - (1/2 + 6)] \approx 42.42.$$

48.



This problem can be done by slicing the volume into washers with planes perpendicular to the axis of rotation, $y = 7$, just like in Example 3. This time the outside radius of a washer is 7, and the inside radius is $7 - e^x$. Therefore, the volume V is

$$V = \int_{x=0}^{x=1} [\pi 7^2 - \pi(7-e^x)^2]\,dx = \pi \int_0^1 (14e^x - e^{2x})\,dx$$
$$= \pi\left[14e^x - \frac{1}{2}e^{2x}\right]\bigg|_0^1 = \pi\left[14e - \frac{1}{2}e^2 - \left(14 - \frac{1}{2}\right)\right]$$
$$\approx 65.54.$$

49. We now slice perpendicular to the x-axis. As stated in the problem, the cross-sections obtained thereby will be squares, with base length e^x. The volume of one square slice is $(e^x)^2\,dx$. (See Figure 8.37.) Adding the volumes of the slices yields

$$\text{Volume } = \int_{x=0}^{x=1} y^2\,dx = \int_0^1 e^{2x}\,dx = \left.\frac{e^{2x}}{2}\right|_0^1 = \frac{e^2-1}{2} = 3.195.$$

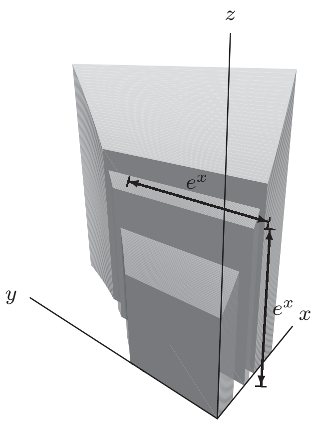


Figure 8.37

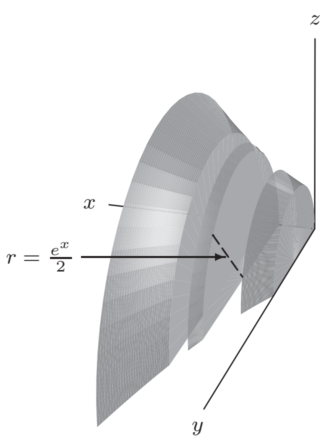
50.



We slice perpendicular to the x-axis. As stated in the problem, the cross-sections obtained thereby will be semicircles, with radius $\frac{e^x}{2}$. The volume of one semicircular slice is $\frac{1}{2}\pi\left(\frac{e^x}{2}\right)^2\,dx$. (Look at the picture.) Adding up the volumes of the slices yields

$$\begin{aligned}\text{Volume } &= \int_{x=0}^{x=1} \pi\frac{y^2}{2}\,dx = \frac{\pi}{8}\int_0^1 e^{2x}\,dx \\ &= \left.\frac{\pi e^{2x}}{16}\right|_0^1 = \frac{\pi(e^2-1)}{16} \approx 1.25.\end{aligned}$$

51. If we revolve the region $0 \le y \le g(x)$ around the x-axis, the volume of the resulting solid is given by $\displaystyle\int_0^\pi \pi\,(g(x))^2\,dx$.

Taking the hint, we can write our integral in this form:

$$\int_0^\pi \pi(4-4\cos^2 x)\,dx = \int_0^\pi 4\pi\left(1-\cos^2 x\right)\,dx = \int_0^\pi 4\pi\sin^2 x\,dx = \int_0^\pi \pi\underbrace{(2\sin x)^2}_{(g(x))^2}\,dx.$$

Therefore, $g(x) = 2\sin x$ or $g(x) = -2\sin x$.

52. At time $t = 6$, the particle has traveled $3 \cdot 6 = 18$ cm. Suppose it is then at the point $x = b$. Then the arc length from the origin to this point is 18 cm. Since

$$\frac{d}{dx}\left(\frac{2}{3}x^{3/2}\right) = x^{1/2},$$

we have

$$\text{Arc length } = \int_0^b \sqrt{1+(x^{1/2})^2}\,dx = \int_0^b \sqrt{1+x}\,dx = 18$$

$$\begin{aligned}
\frac{2}{3}(1+x)^{3/2}\Big|_0^b &= 18 \\
\frac{2}{3}(1+b)^{3/2} - \frac{2}{3} &= 18 \\
(1+b)^{3/2} &= 28 \\
b &= 28^{2/3} - 1 = 8.221.
\end{aligned}$$

When $x = 8.221$, $y = 15.714$.

53. We want to approximate $\int_0^{120} A(h)\,dh$, where h is height, and $A(h)$ represents the cross-sectional area of the trunk at height h. Since $A = \pi r^2$ (circular cross-sections), and $c = 2\pi r$, where c is the circumference, we have $A = \pi r^2 = \pi[c/(2\pi)]^2 = c^2/(4\pi)$. We make a table of $A(h)$ based on this:

Table 8.1

height (feet)	0	20	40	60	80	100	120
Area (square feet)	53.79	38.52	28.73	15.60	2.865	0.716	0.080

We now form left & right sums using the chart:

$$\begin{aligned}
\text{LEFT}(6) &= 53.79\cdot 20 + 38.52\cdot 20 + 28.73\cdot 20 + 15.60\cdot 20 + 2.865\cdot 20 + 0.716\cdot 20 \\
&= 2804.42. \\
\text{RIGHT}(6) &= 38.52\cdot 20 + 28.73\cdot 20 + 15.60\cdot 20 + 2.865\cdot 20 + 0.716\cdot 20 + 0.080\cdot 20 \\
&= 1730.22
\end{aligned}$$

So

$$\text{TRAP}(6) = \frac{\text{RIGHT}(6) + \text{LEFT}(6)}{2} = \frac{2804.42 + 1730.22}{2} = 2267.32 \text{ cubic feet.}$$

54. If $y = e^{-x^2/2}$, then $x = \sqrt{-2\ln y}$. (Note that since $0 < y \le 1$, $\ln y \le 0$.) A typical slice has thickness Δy and radius x. See Figure 8.38. So

$$\text{Volume of slice } = \pi x^2\,\Delta y = -2\pi \ln y\,\Delta y.$$

Thus,

$$\text{Total volume } = -2\pi \int_0^1 \ln y\,dy.$$

Since $\ln y$ is not defined at $y = 0$, this is an improper integral:

$$\begin{aligned}
\text{Total Volume } &= -2\pi \int_0^1 \ln y\,dy = -2\pi \lim_{a\to 0} \int_a^1 \ln y\,dy \\
&= -2\pi \lim_{a\to 0} (y\ln y - y)\Big|_a^1 = -2\pi \lim_{a\to 0}(-1 - a\ln a + a).
\end{aligned}$$

By looking at the graph of $x \ln x$ on a calculator, we see that $\lim_{a\to 0} a\ln a = 0$. Thus,

$$\text{Total volume } = -2\pi(-1) = 2\pi.$$

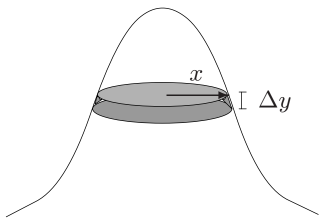


Figure 8.38

55. (a) We can begin by slicing the pie into horizontal slabs of thickness Δh located at height h. To find the radius of each slice, we note that radius increases linearly with height. Since $r = 4.5$ when $h = 3$ and $r = 3.5$ when $h = 0$, we should have $r = 3.5 + h/3$. Then the volume of each slab will be $\pi r^2\ \Delta h = \pi(3.5 + h/3)^2\ \Delta h$. To find the total volume of the pie, we integrate this from $h = 0$ to $h = 3$:

$$\begin{aligned} V &= \pi \int_0^3 \left(3.5 + \frac{h}{3}\right)^2\ dh \\ &= \pi \left[\frac{h^3}{27} + \frac{7h^2}{6} + \frac{49h}{4}\right]\Bigg|_0^3 \\ &= \pi \left[\frac{3^3}{27} + \frac{7(3^2)}{6} + \frac{49(3)}{4}\right] \approx 152 \text{ in}^3. \end{aligned}$$

(b) We use 1.5 in as a rough estimate of the radius of an apple. This gives us a volume of $(4/3)\pi(1.5)^3 \approx 10$ in^3. Since $152/10 \approx 15$, we would need about 15 apples to make a pie.

56. (a) The volume can be computed by several methods, not all of them requiring integration. We will slice horizontally, forming rectangular slabs of length 100 cm, height Δy, width w and integrate. See Figure 8.39.

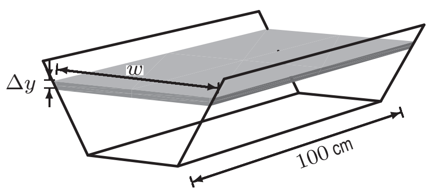

Figure 8.39

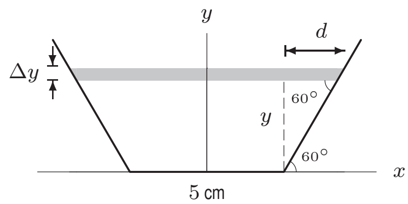

Figure 8.40

From the right triangle, we see

$$\frac{y}{d} = \tan 60^\circ = \sqrt{3}$$

so

$$d = \frac{y}{\sqrt{3}}.$$

Thus

$$w = 5 + 2d = 5 + \frac{2y}{\sqrt{3}}.$$

The volume of the slab is

$$\Delta V \approx 100 w \Delta y = 100\left(5 + \frac{2y}{\sqrt{3}}\right)\Delta y,$$

so the total volume is given by

$$\begin{aligned} \text{Volume} &= \lim_{\Delta y \to 0} \sum \Delta V = \lim_{\Delta y \to 0} \sum 100\left(5 + \frac{2y}{\sqrt{3}}\right)\Delta y \\ &= \int_0^h 100\left(5 + \frac{2y}{\sqrt{3}}\right) dy = 100\left(5y + \frac{y^2}{\sqrt{3}}\right)\Bigg|_0^h = 100\left(5h + \frac{h^2}{\sqrt{3}}\right) \text{ cm}^3. \end{aligned}$$

(b) The maximum value of h is $h = 5\sin 60^\circ = 5\sqrt{3}/2$ cm ≈ 4.33 cm.

(c) The maximum volume of water that the gutter can hold is given by substituting $h = 5\sqrt{3}/2$ into the volume:

$$\text{Maximum volume} = 100\left(5 \cdot \frac{5\sqrt{3}}{2} + \left(\frac{5\sqrt{3}}{2}\right)^2 \Big/ \sqrt{3}\right) = \frac{2500}{4}(2\sqrt{3} + \sqrt{3}) = 1875\sqrt{3} \approx 3247.6 \text{ cm}^3.$$

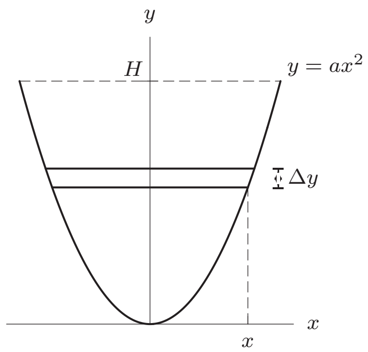
(d) Because the gutter is narrower at the bottom than the top, if it is filled with half the maximum possible volume of water, the gutter will be filled to a depth of more than half of 4.33 cm.

(e) We want to solve for the value of h such that

$$\text{Volume} = 100\left(5h + \frac{h^2}{\sqrt{3}}\right) = \frac{1}{2}\cdot 1875\sqrt{3} = \frac{1}{2}V_{\max}$$
$$5h + \frac{h^2}{\sqrt{3}} = 16.238.$$

Solving gives $h = 2.52$ and $h = -11.18$. Since only positive values of h are meaningful, $h = 2.52$ cm.

57.



We divide the interior of the boat into flat slabs of thickness Δy and width $2x = 2\sqrt{y/a}$. (See above.) We have

$$\text{Volume of slab } \approx 2xL\Delta y = 2L\sqrt{\frac{y}{a}}\Delta y.$$

We are interested in the total volume of the region $0 \le y \le H$, so

$$\begin{aligned}\text{Total volume } &= \lim_{\Delta y\to 0}\sum 2L\left(\frac{y}{a}\right)^{(1/2)}\Delta y = \int_0^H 2L\left(\frac{y}{a}\right)^{(1/2)} dy\\ &= \frac{2L}{\sqrt{a}}\int_0^H y^{(1/2)}dy = \frac{4LH^{(3/2)}}{3\sqrt{a}}.\end{aligned}$$

If L and H are in meters,

$$\text{Buoyancy force } = \frac{40,000LH^{(3/2)}}{3\sqrt{a}} \text{ newtons.}$$

58. We can find the volume of the tree by slicing it into a series of thin horizontal cylinders of height dh and circumference C. The volume of each cylindrical disk will then be

$$V = \pi r^2\, dh = \pi\left(\frac{C}{2\pi}\right)^2 dh = \frac{C^2\, dh}{4\pi}.$$

Summing all such cylinders, we have the total volume of the tree as

$$\text{Total volume} = \frac{1}{4\pi}\int_0^{120} C^2\, dh.$$

We can estimate this volume using a trapezoidal approximation to the integral with $\Delta h = 20$:

$$\begin{aligned}\text{LEFT estimate } &= \frac{1}{4\pi}[20(31^2+28^2+21^2+17^2+12^2+8^2)] = \frac{1}{4\pi}(53660).\\ \text{RIGHT estimate } &= \frac{1}{4\pi}[20(28^2+21^2+17^2+12^2+8^2+2^2)] = \frac{1}{4\pi}(34520).\\ \text{TRAP } &= \frac{1}{4\pi}(44090) \approx 3509 \text{ cubic inches.}\end{aligned}$$

59. (a) The volume, V, contained in the bowl when the surface has height h is

$$V = \int_0^h \pi x^2\, dy.$$

However, since $y = x^4$, we have $x^2 = \sqrt{y}$ so that

$$V = \int_0^h \pi\sqrt{y}\, dy = \frac{2}{3}\pi h^{3/2}.$$

Differentiating gives $dV/dh = \pi h^{1/2} = \pi\sqrt{h}$. We are given that $dV/dt = -6\sqrt{h}$, where the negative sign reflects the fact that V is decreasing. Using the chain rule we have

$$\frac{dh}{dt} = \frac{dh}{dV}\cdot\frac{dV}{dt} = \frac{1}{dV/dh}\cdot\frac{dV}{dt} = \frac{1}{\pi\sqrt{h}}\cdot(-6\sqrt{h}) = -\frac{6}{\pi}.$$

Thus, $dh/dt = -6/\pi$, a constant.

(b) Since $dh/dt = -6/\pi$ we know that $h = -6t/\pi + C$. However, when $t = 0$, $h = 1$, therefore $h = 1 - 6t/\pi$. The bowl is empty when $h = 0$, that is when $t = \pi/6$ units.

60. The problem appears complicated, because we are now working in three dimensions. However, if we take one dimension at a time, we will see that the solution is not too difficult. For example, let's just work at a constant depth, say 0. We apply the trapezoid rule to find the approximate area along the length of the boat. For example, by the trapezoid rule the approximate area at depth 0 from the front of the boat to 10 feet toward the back is $\frac{(2+8)\cdot 10}{2} = 50$. Overall, at depth 0 we have that the area for each length span is as follows:

Table 8.2

length span:	0–10	10–20	20–30	30–40	40–50	50–60
depth 0	50	105	145	165	165	130

We can fill in the whole chart the same way:

Table 8.3

length span:		0–10	10–20	20–30	30–40	40–50	50–60
	0	50	105	145	165	165	130
	2	25	60	90	105	105	90
depth	4	15	35	50	65	65	50
	6	5	15	25	35	35	25
	8	0	5	10	10	10	10

Now, to find the volume, we just apply the trapezoid rule to the depths and areas. For example, according to the trapezoid rule the approximate volume as the depth goes from 0 to 2 and the length goes from 0 to 10 is $\frac{(50+25)\cdot 2}{2} = 75$. Again, we fill in a chart:

Table 8.4

length span:		0–10	10–20	20–30	30–40	40–50	50–60
	0–2	75	165	235	270	270	220
depth	2–4	40	95	140	170	170	140
span	4–6	20	50	75	100	100	75
	6–8	5	20	35	45	45	35

Adding all this up, we find the volume is approximately 2595 cubic feet.

You might wonder what would have happened if we had done our trapezoids along the depth axis first instead of along the length axis. If you try this, you'd find that you come up with the same answers in the volume chart! For the trapezoid rule, it does not matter which axis you choose first.

61. (a) The equation of a circle of radius r around the origin is $x^2+y^2=r^2$. This means that $y^2=r^2-x^2$, so $2y(dy/dx) = -2x$, and $dy/dx = -x/y$. Since the circle is symmetric about both axes, its arc length is 4 times the arc length in the first quadrant, namely

$$4\int_0^r \sqrt{1+\left(\frac{dy}{dx}\right)^2}\,dx = 4\int_0^r \sqrt{1+\left(-\frac{x}{y}\right)^2}\,dx.$$

(b) Evaluating this integral yields

$$4\int_0^r \sqrt{1+\left(-\frac{x}{y}\right)^2}\,dx = 4\int_0^r \sqrt{1+\frac{x^2}{r^2-x^2}}\,dx = 4\int_0^r \sqrt{\frac{r^2}{r^2-x^2}}\,dx$$
$$= 4r\int_0^r \sqrt{\frac{1}{r^2-x^2}}\,dx = 4r(\arcsin(x/r))\Big|_0^r = 2\pi r.$$

This is the expected answer.

62. As can be seen in Figure 8.41, the region has three straight sides and one curved one. The lengths of the straight sides are 1, 1, and e. The curved side is given by the equation $y = f(x) = e^x$. We can find its length by the formula

$$\int_0^1 \sqrt{1+f'(x)^2}\,dx = \int_0^1 \sqrt{1+(e^x)^2}\,dx = \int_0^1 \sqrt{1+e^{2x}}\,dx.$$

Evaluating the integral numerically gives 2.0035. The total length, therefore, is about $1+1+e+2.0035 \approx 6.722$.

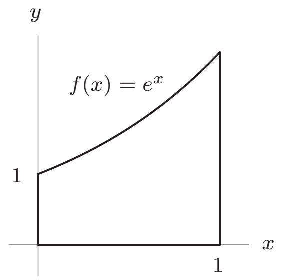


Figure 8.41

63. The graph of f is a downward-opening parabola with x-intercepts at $x = 0, 4$, and $f'(x) = (-x(x-4))' = 4-2x$. The arc length of the graph of f from $x=0$ to $x=4$ is given by

$$\text{Arc length} = \int_0^4 \sqrt{1+(f'(x))^2}\,dx$$
$$= \int_0^4 \sqrt{1+(4-2x)^2}\,dx. \quad \text{because } f'(x) = 4-2x$$

This integral can be simplified as $\int_0^4 \sqrt{4x^2-16x+17}\,dx$.

64. We would like to write the integrand in the form

$$\sqrt{1+\sqrt{x}} = \sqrt{1+(f'(x))^2}.$$

This suggests:

$$\begin{aligned}
\left(f'(x)\right)^2 &= x^{1/2} \\
f'(x) &= x^{1/4} && \text{alternatively } f'(x) = -x^{1/4} \\
f(x) &= \frac{4}{5}\cdot x^{5/4} + C \\
&= 0.8x^{5/4} && \text{letting } C = 0 \text{ for convenience.}
\end{aligned}$$

Thus,

$$\int_1^4 \sqrt{1+\sqrt{x}}\,dx = \int_1^4 \sqrt{1+\left(\left(0.8x^{5/4}\right)'\right)^2}\,dx,$$

which is the arc length of the curve $y = 0.8x^{5/4}$ from $x = 1$ to $x = 4$. Other possible solutions are any of the curves $y = \pm 0.8x^{5/4} + C$.

65. The graph of f is concave down where $f'' < 0$:

$$\begin{aligned} f(x) &= e^{-x^2}. \\ f'(x) &= -2xe^{-x^2} \\ f''(x) &= -2e^{-x^2} + 4x^2e^{-x^2} \\ &= 2e^{-x^2}\left(2x^2-1\right). \end{aligned}$$

This means that $f''(x) < 0$ where

$$\begin{aligned} 2x^2 - 1 &< 0 \\ x^2 &< \frac{1}{2}. \end{aligned}$$

Thus, the graph is concave down for $-\sqrt{1/2} < x < \sqrt{1/2}$. The arc length of this portion of the graph of f is given by

$$\begin{aligned} \text{Arc length} &= \int_{-\sqrt{1/2}}^{\sqrt{1/2}} \sqrt{1+(f'(x))^2}\,dx \\ &= \int_{-\sqrt{1/2}}^{\sqrt{1/2}} \sqrt{1+\left(-2xe^{-x^2}\right)^2}\,dx \\ &= \int_{-\sqrt{1/2}}^{\sqrt{1/2}} \sqrt{1+4x^2e^{-2x^2}}\,dx. \end{aligned}$$

66. The graph of f is concave down where $f''(x) < 0$:

$$\begin{aligned} f(x) &= x^4 - 8x^3 + 18x^2 + 3x + 7 \\ f'(x) &= 4x^3 - 24x^2 + 36x + 3 \\ f''(x) &= 12x^2 - 48x + 36 \\ &= 12(x-1)(x-3). \end{aligned}$$

Hence $f''(x) < 0$ for $1 < x < 3$. The arc length of this portion of the graph of f is given by

$$\begin{aligned} \text{Arc length} &= \int_1^3 \sqrt{1+(f'(x))^2}\,dx \\ &= \int_1^3 \sqrt{1+(4x^3-24x^2+36x+3)^2}\,dx. \end{aligned}$$

67. The arc length of the catenary between $x = -b$ and $x = b$ is 10 meters. Since

$$\frac{d}{dx}(\cosh x) = \sinh x = \frac{1}{2}(e^x - e^{-x}),$$

we have

$$\begin{aligned} \text{Arc length } &= \int_{-b}^{b} \sqrt{1+\frac{1}{4}(e^x-e^{-x})^2}\,dx = \int_{-b}^{b} \frac{1}{2}\sqrt{4+e^{2x}-2+e^{-2x}}\,dx \\ &= \int_{-b}^{b} \frac{1}{2}\sqrt{(e^x+e^{-x})^2}\,dx = \int_{-b}^{b} \frac{1}{2}(e^x+e^{-x})\,dx = \frac{1}{2}(e^x-e^{-x})\Big|_{-b}^{b} = e^b - e^{-b}. \end{aligned}$$

Thus

$$e^b - e^{-b} = 10.$$

Solving numerically gives $b = 2.312$ meters. Thus, the ends of the chain are $2(2.312) = 4.624$ meters apart.

68. Here are many functions which "work."

- Any linear function $y = mx + b$ "works." This follows because $\frac{dy}{dx} = m$ is constant for such functions. So

$$\int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx = \int_a^b \sqrt{1 + m^2}\, dx = (b - a)\sqrt{1 + m^2}.$$

- The function $y = \frac{x^4}{8} + \frac{1}{4x^2}$ "works": $\frac{dy}{dx} = \frac{1}{2}(x^3 - 1/x^3)$, and

$$\begin{aligned}\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx &= \int \sqrt{1 + \frac{\left(x^3 - \frac{1}{x^3}\right)^2}{4}}\, dx = \int \sqrt{1 + \frac{x^6}{4} - \frac{1}{2} + \frac{1}{4x^6}}\, dx \\ &= \int \sqrt{\frac{1}{4}\left(x^3 + \frac{1}{x^3}\right)^2}\, dx = \int \frac{1}{2}\left(x^3 + \frac{1}{x^3}\right) dx \\ &= \left[\frac{x^4}{8} - \frac{1}{4x^2}\right] + C.\end{aligned}$$

- One more function that "works" is $y = \ln(\cos x)$; we have $\frac{dy}{dx} = -\sin x / \cos x$. Hence

$$\begin{aligned}\int \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\, dx. &= \int \sqrt{1 + \left(\frac{-\sin x}{\cos x}\right)^2}\, dx = \int \sqrt{1 + \frac{\sin^2 x}{\cos^2 x}}\, dx \\ &= \int \sqrt{\frac{\sin^2 x + \cos^2 x}{\cos^2 x}}\, dx = \int \sqrt{\frac{1}{\cos^2 x}}\, dx \\ &= \int \frac{1}{\cos x}\, dx = \frac{1}{2}\ln\left|\frac{\sin x + 1}{\sin x - 1}\right| + C,\end{aligned}$$

where the last integral comes from IV-22 of the integral tables.

69. (a) If $f(x) = \int_0^x \sqrt{g'(t)^2 - 1}\, dt$, then, by the Fundamental Theorem of Calculus, $f'(x) = \sqrt{g'(x)^2 - 1}$. So the arc length of f from 0 to x is

$$\begin{aligned}\int_0^x \sqrt{1 + (f'(t))^2}\, dt &= \int_0^x \sqrt{1 + (\sqrt{g'(t)^2 - 1})^2}\, dt \\ &= \int_0^x \sqrt{1 + g'(t)^2 - 1}\, dt \\ &= \int_0^x g'(t)\, dt = g(x) - g(0) = g(x).\end{aligned}$$

(b) If g is the arc length of any function f, then by the Fundamental Theorem of Calculus, $g'(x) = \sqrt{1 + f'(x)^2} \geq 1$. So if $g'(x) < 1$, g cannot be the arc length of a function.

(c) We find a function f whose arc length from 0 to x is $g(x) = 2x$. Using part (a), we see that

$$f(x) = \int_0^x \sqrt{(g'(t))^2 - 1}\, dt = \int_0^x \sqrt{2^2 - 1}\, dt = \sqrt{3}x.$$

This is the equation of a line. Does it make sense to you that the arc length of a line segment depends linearly on its right endpoint?

70. (a) For $n = 1$, we have

$$|x| + |y| = 1.$$

In the first quadrant, the equation is the line

$$x + y = 1.$$

By symmetry, the graph in the other quadrants gives the square in Figure 8.42.

For $n = 2$, the equation is of a circle of radius 1, centered at the origin:

$$x^2 + y^2 = 1.$$

For $n = 4$, the equation is

$$x^4 + y^4 = 1.$$

The graph is similar to a circle, but bulging out more. See Figure 8.42.

(b) For $n = 1$, the arc length is the perimeter of the square. Each side is the hypotenuse of a right triangle of sides $1, 1, \sqrt{2}$. Thus

$$\text{Arc length } = 4\sqrt{2} = 5.657.$$

For $n = 2$, the arc length is the perimeter of the circle of radius 1. Thus

$$\text{Arc length } = 2\pi \cdot 1 = 2\pi = 6.283.$$

For $n = 4$, we find the arc length using the formula

$$L = \int_a^b \sqrt{1 + (f'(x))^2}\, dx.$$

We find the arc length of the top half of the curve, given by $y = (1 - x^4)^{1/4}$, and double it. Since

$$\frac{dy}{dx} = \frac{1}{4}(1 - x^4)^{-3/4}(-4x^3) = \frac{-x^3}{(1 - x^4)^{3/4}},$$

$$\text{Arc length } = 2\int_{-1}^{1} \sqrt{1 + \left(\frac{-x^3}{(1 - x^4)^{3/4}}\right)^2}\, dx = 2\int_{-1}^{1} \sqrt{1 + \frac{x^6}{(1 - x^4)^{3/2}}}\, dx.$$

The integral is improper because the integral is not defined at $x = \pm 1$. Using numerical methods, we find

$$\text{Arc length } = 2\int_{-1}^{1} \sqrt{1 + \frac{x^6}{(1 - x^4)^{3/2}}}\, dx = 7.018.$$

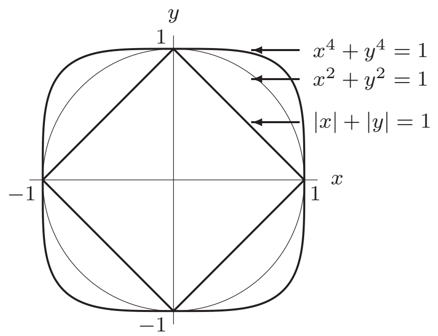

Figure 8.42

Strengthen Your Understanding

71. The volume is $\int_0^5 \left(\pi(3x)^2 - \pi(2x)^2\right)\, dx$, since the slices are disks-with-holes.

72. The arc length is given by $\int_0^{\pi/4} \sqrt{1 + (f'(x))^2}\, dx$ with $f(x) = \sin x$. Thus, the correct formula for the arc length is $\int_0^{\pi/4} \sqrt{1 + \cos^2 x}\, dx$.

73. The curve begins at the point $(0, 0)$ and ends at the point $(2, 32)$. The distance between these points is $\sqrt{2^2 + 32^2} > 32$. Since the arc length of any curve is greater than or equal to the length of the straight line connecting the points, the arc length of $y = x^5$ between $x = 0$ and $x = 2$ must be greater than 32.

74. The triangular region with vertices $(0, 0)$, $(0, 1)$ and $(1, 0)$ gives the exact same solid shape whether rotated about the x- or y-axis.

75. One example is the region bounded by $y = 2x$ and the x-axis for $0 \le x \le 1$. When the region is rotated about the x-axis, we get a cone of radius 2 and height 1. When it is rotated about the y-axis, we get a cone of radius 1 and height 2.

Since

$$\text{Volume around } x\text{-axis } = \frac{1}{3}\pi \cdot 2^2 \cdot 1 = \frac{4\pi}{3}$$
$$\text{Volume around } y\text{-axis } = \frac{1}{3}\pi \cdot 1^2 \cdot 2 = \frac{2\pi}{3},$$

the volume is greater around the x-axis than around the y-axis.

76. The circle of radius 5 centered at $(5, 0)$ goes through both the points $(0, 0)$ and $(10, 0)$. The upper semicircle and the lower semicircle are different curves between these two points that have the same arc length, namely half the circumference of the circle.

77. The distance from $(0, 0)$ to $(1, 1)$ is $\sqrt{2}$, so any curve other than a straight line between the points has an arc length greater than $\sqrt{2}$. One possible example is $f(x) = x^2$.

78. False. The volume also depends on how far away the region is from the axis of revolution. For example, let R be the rectangle $0 \le x \le 8, 0 \le y \le 1$ and let S be the rectangle $0 \le x \le 3, 0 \le y \le 2$. Then rectangle R has area greater than rectangle S. However, when you revolve R about the x-axis you get a cylinder, lying on its side, of radius 1 and length 8, which has volume 8π. When you revolve S about the x-axis, you get a cylinder of radius 2 and length 3, which has volume 12π. Thus the second volume is larger, even though the region revolved has smaller area.

79. False. Suppose that the graph of f starts at the point $(0, 100)$ and then goes down to $(1, 0)$ and from there on goes along the x-axis. For example, if $f(x) = 100(x-1)^2$ on the interval $[0, 1]$ and $f(x) = 0$ on the interval $[1, 10]$, then f is differentiable on the interval $[0, 10]$. The arc length of the graph of f on the interval $[0, 1]$ is at least 100, while the arc length on the interval $[1, 10]$ is 9.

80. True. Since f is concave up, f' is an increasing function, so $f'(x) \ge f'(0) = 3/4$ on the interval $[0, 4]$. Thus $\sqrt{1 + (f'(x))^2} \ge \sqrt{1 + 9/16} = 5/4$. Then we have:

$$\text{Arc length} = \int_0^4 \sqrt{1 + (f'(x))^2}\, dx \ge \int_0^4 \frac{5}{4}\, dx = 5.$$

81. False. Since f is concave down, this means that $f'(x)$ is decreasing, so $f'(x) \le f'(0) = 3/4$ on the interval $[0, 4]$. However, it could be that $f'(x)$ becomes negative so that $(f'(x))^2$ becomes large, making the integral for the arc length large also. For example, $f(x) = (3/4)x - x^2$ is concave down and $f'(0) = 3/4$, but $f(0) = 0$ and $f(4) = -13$, so the graph of f on the interval $[0, 4]$ has arc length at least 13.

Solutions for Section 8.3

Exercises

1. With $r = 1$ and $\theta = 2\pi/3$, we find $x = r\cos\theta = 1 \cdot \cos(2\pi/3) = -1/2$ and $y = r\sin\theta = 1 \cdot \sin(2\pi/3) = \sqrt{3}/2$.
The rectangular coordinates are $(-1/2, \sqrt{3}/2)$.

2. With $r = \sqrt{3}$ and $\theta = -3\pi/4$, we find $x = r\cos\theta = \sqrt{3}\cos(-3\pi/4) = \sqrt{3}(-\sqrt{2}/2) = -\sqrt{6}/2$ and $y = r\sin\theta = \sqrt{3}\sin(-3\pi/4) = \sqrt{3}(-\sqrt{2}/2) = -\sqrt{6}/2$.
The rectangular coordinates are $(-\sqrt{6}/2, -\sqrt{6}/2)$.

3. With $r = 2\sqrt{3}$ and $\theta = -\pi/6$, we find $x = r\cos\theta = 2\sqrt{3}\cos(-\pi/6) = 2\sqrt{3} \cdot \sqrt{3}/2 = 3$ and $y = r\sin\theta = 2\sqrt{3}\sin(-\pi/6) = 2\sqrt{3}(-1/2) = -\sqrt{3}$.
The rectangular coordinates are $(3, -\sqrt{3})$.

4. With $r = 2$ and $\theta = 5\pi/6$, we find $x = r\cos\theta = 2\cos(5\pi/6) = 2(-\sqrt{3}/2) = -\sqrt{3}$ and $y = r\sin\theta = 2\sin(5\pi/6) = 2(1/2) = 1$.
The rectangular coordinates are $(-\sqrt{3}, 1)$.

5. With $x = 1$ and $y = 1$, find r from $r = \sqrt{x^2 + y^2} = \sqrt{1^2 + 1^2} = \sqrt{2}$. Find θ from $\tan\theta = y/x = 1/1 = 1$. Thus, $\theta = \tan^{-1}(1) = \pi/4$. Since $(1, 1)$ is in the first quadrant this is a correct θ. The polar coordinates are $(\sqrt{2}, \pi/4)$.

6. With $x = -1$ and $y = 0$, find $r = \sqrt{x^2 + y^2} = \sqrt{(-1)^2 + 0^2} = 1$. Find θ from $\tan\theta = y/x = 0/(-1) = 0$. Thus, $\theta = \tan^{-1}(0) = 0$. Since $(-1, 0)$ is on the x-axis between the second and third quadrant, $\theta = \pi$. The polar coordinates are $(1, \pi)$.

7. With $x = \sqrt{6}$ and $y = -\sqrt{2}$, find $r = \sqrt{(\sqrt{6})^2 + (-\sqrt{2})^2} = \sqrt{8} = 2\sqrt{2}$. Find θ from $\tan\theta = y/x = -\sqrt{2}/\sqrt{6} = -1/\sqrt{3}$. Thus, $\theta = \tan^{-1}(-1/\sqrt{3}) = -\pi/6$. Since $(\sqrt{6}, -\sqrt{2})$ is in the fourth quadrant, this is the correct θ. The polar coordinates are $(2\sqrt{2}, -\pi/6)$.

8. With $x = -\sqrt{3}$ and $y = 1$, find $r = \sqrt{(-\sqrt{3})^2 + 1^2} = \sqrt{4} = 2$. Find θ from $\tan\theta = y/x = 1/(-\sqrt{3})$. Thus, $\theta = \tan^{-1}(-1/\sqrt{3}) = -\pi/6$. Since $(-\sqrt{3}, 1)$ is in the second quadrant, $\theta = -\pi/6 + \pi = 5\pi/6$. The polar coordinates are $(2, 5\pi/6)$.

9. (a) Table 8.5 contains values of $r = 1 - \sin\theta$, both exact and rounded to one decimal.

Table 8.5

θ	0	$\pi/3$	$\pi/2$	$2\pi/3$	π	$4\pi/3$	$3\pi/2$	$5\pi/3$	2π	$7\pi/3$	$5\pi/2$	$8\pi/3$
r	1	$1-\sqrt{3}/2$	0	$1-\sqrt{3}/2$	1	$1+\sqrt{3}/2$	2	$1+\sqrt{3}/2$	1	$1-\sqrt{3}/2$	0	$1-\sqrt{3}/2$
r	1	0.134	0	0.134	1	1.866	2	1.866	1	0.134	0	0.134

(b) See Figure 8.43.

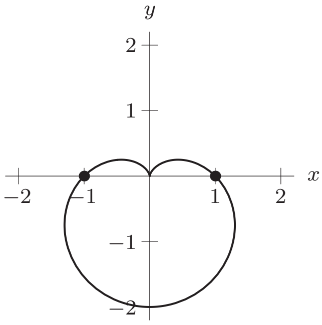

Figure 8.43

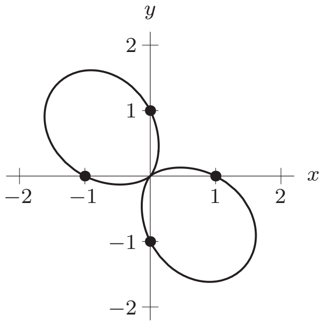

Figure 8.44

(c) The circle has equation $r = 1/2$. The cardioid is $r = 1 - \sin\theta$. Solving these two simultaneously gives

$$1/2 = 1 - \sin\theta,$$

or

$$\sin\theta = 1/2.$$

Thus, $\theta = \pi/6$ or $5\pi/6$. This gives the points $(x, y) = ((1/2)\cos\pi/6, (1/2)\sin\pi/6) = (\sqrt{3}/4, 1/4)$ and $(x, y) = ((1/2)\cos 5\pi/6, (1/2)\sin 5\pi/6) = (-\sqrt{3}/4, 1/4)$ as the location of intersection.

(d) The curve $r = 1 - \sin 2\theta$, pictured in Figure 8.44, has two regions instead of the one region that $r = 1 - \sin\theta$ has. This is because $1 - \sin 2\theta$ will be 0 twice for every 2π cycle in θ, as opposed to once for every 2π cycle in θ for $1 - \sin\theta$.

10. There will be n loops. See Figures 8.45-8.48.

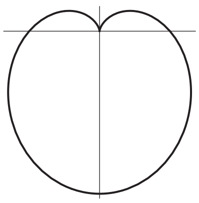

Figure 8.45: $n = 1$

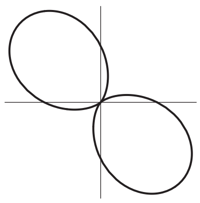

Figure 8.46: $n = 2$

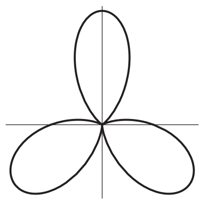

Figure 8.47: $n = 3$

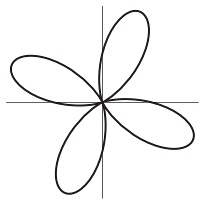

Figure 8.48: $n = 4$

11. The graph will begin to draw over itself for any $\theta \geq 2\pi$ so the graph will look the same in all three cases. See Figure 8.49.

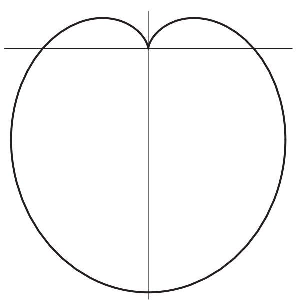

Figure 8.49

12. The curve will be a smaller loop inside a larger loop with an intersection point at the origin. Larger n values increase the size of the loops. See Figures 8.50-8.52.

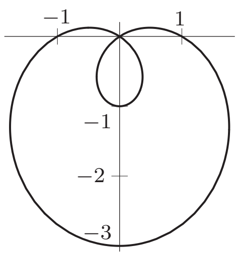

Figure 8.50: $n = 2$

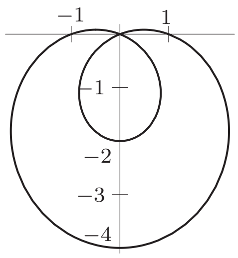

Figure 8.51: $n = 3$

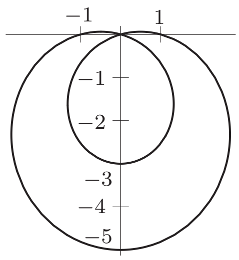

Figure 8.52: $n = 4$

13. See Figures 8.53 and 8.54. The first curve will be similar to the second curve, except the cardioid (heart) will be rotated clockwise by 90° ($\pi/2$ radians). This makes sense because of the identity $\sin\theta = \cos(\theta - \pi/2)$.

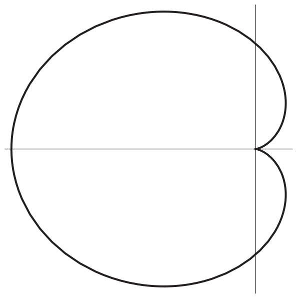

Figure 8.53: $r = 1 - \cos\theta$

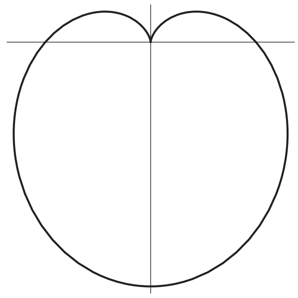

Figure 8.54: $r = 1 - \sin\theta$

14. Let $0 \le \theta \le 2\pi$ and $3/16 \le r \le 1/2$.

15. A loop starts and ends at the origin, that is, when $r = 0$. This happens first when $\theta = \pi/4$ and next when $\theta = 5\pi/4$. This can also be seen by using a trace mode on a calculator. Thus restricting θ so that $\pi/4 \le \theta \le 5\pi/4$ will graph the upper loop only. See Figure 8.55. To show only the other loop use $0 \le \theta \le \pi/4$ and $5\pi/4 \le \theta \le 2\pi$. See Figure 8.56.

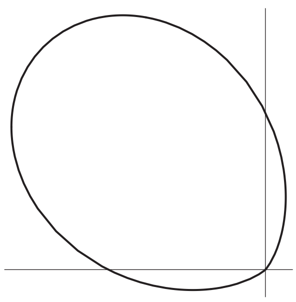

Figure 8.55: $\pi/4 \le \theta \le 5\pi/4$

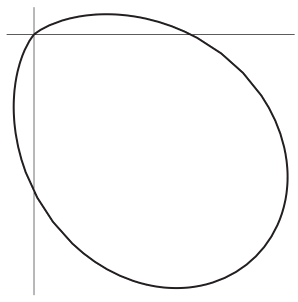

Figure 8.56: $0 \le \theta \le \pi/4$ and $5\pi/4 \le \theta \le 2\pi$

16. (a) Let $0 \le \theta \le \pi/4$ and $0 \le r \le 1$.
(b) Break the region into two pieces: one with $0 \le x \le \sqrt{2}/2$ and $0 \le y \le x$, the other with $\sqrt{2}/2 \le x \le 1$ and $0 \le y \le \sqrt{1-x^2}$.

17. The region is given by $\sqrt{8} \le r \le \sqrt{18}$ and $\pi/4 \le \theta \le \pi/2$.

18. The region is given by $0 \le r \le 2$ and $-\pi/6 \le \theta \le \pi/6$.

19. The circular arc has equation $r = 1$, for $0 \le \theta \le \pi/2$. the vertical line $x = 2$ has polar equation $r\cos\theta = 2$, or $r = 2/\cos\theta$. So the region is described by $0 \le \theta \le \pi/2$ and $1 \le r \le 2/\cos\theta$.

20. Expressing x and y in terms of θ, we have

$$x = 2\cos\theta \quad \text{and} \quad y = 2\sin\theta.$$

The slope is given by

$$\frac{dy}{dx} = \frac{-2\cos\theta}{2\sin\theta} = -\frac{\cos\theta}{\sin\theta}.$$

At $\theta = \pi/4$, we have

$$\left.\frac{dy}{dx}\right|_{\theta=\pi/4} = \frac{1/\sqrt{2}}{1/\sqrt{2}} = -1.$$

21. Expressing x and y in terms of θ, we have

$$x = e^{\theta}\cos\theta \quad \text{and} \quad y = e^{\theta}\sin\theta.$$

The slope is given by

$$\frac{dy}{dx} = \frac{e^{\theta}\sin\theta + e^{\theta}\cos\theta}{e^{\theta}\cos\theta - e^{\theta}\sin\theta} = \frac{\sin\theta + \cos\theta}{\cos\theta - \sin\theta}.$$

At $\theta = \pi/2$, we have $\sin\theta = 1$ and $\cos\theta = 0$, so

$$\left.\frac{dy}{dx}\right|_{\theta=\pi/2} = \frac{1+0}{0-1} = -1.$$

22. Expressing x and y in terms of θ, we have

$$x = (1-\cos\theta)\cos\theta \quad \text{and} \quad y = (1-\cos\theta)\sin\theta.$$

The slope is given by

$$\frac{dy}{dx} = \frac{-(1-\cos\theta)\cos\theta - \sin\theta\sin\theta}{(1-\cos\theta)\sin\theta - \sin\theta\cos\theta}.$$

At $\theta = \pi/2$, we have $\cos\theta = 0$ and $\sin\theta = 1$, so that

$$\left.\frac{dy}{dx}\right|_{\theta=\pi/2} = -1.$$

23. The curve is given parametrically by

$$x = e^{\theta}\cos\theta \quad \text{and} \quad y = e^{\theta}\sin\theta.$$

Thus, calculating $dx/d\theta$ and $dy/d\theta$, gives

$$\begin{aligned}
\text{Arc length } &= \int_{\pi/2}^{\pi} \sqrt{(e^{\theta}\cos\theta - e^{\theta}\sin\theta)^2 + (e^{\theta}\sin\theta + e^{\theta}\cos\theta)^2}\, d\theta \\
&= \int_{\pi/2}^{\pi} e^{\theta}\sqrt{(\cos\theta - \sin\theta)^2 + (\sin\theta + \cos\theta)^2}\, d\theta \\
&= \int_{\pi/2}^{\pi} e^{\theta}\sqrt{2}\, d\theta \\
&= \sqrt{2}(e^{\pi} - e^{\pi/2}).
\end{aligned}$$

24. The curve is given parametrically by

$$x = \theta^2 \cos\theta \quad \text{and} \quad y = \theta^2 \sin\theta.$$

Thus, calculating $dx/d\theta$ and $dy/d\theta$, gives

$$\begin{aligned}
\text{Arc length } &= \int_0^{2\pi} \sqrt{(2\theta\cos\theta - \theta^2\sin\theta)^2 + (2\theta\sin\theta + \theta^2\cos\theta)^2}\, d\theta \\
&= \int_0^{2\pi} \sqrt{4\theta^2 + \theta^4}\, d\theta \\
&= \int_0^{2\pi} \theta\sqrt{4+\theta^2}\, d\theta \\
&= \frac{1}{3}(4+4\pi^2)^{3/2} - \frac{1}{3}4^{3/2}.
\end{aligned}$$

Problems

25. The formula for area is

$$A = \frac{1}{2}\int_\alpha^\beta r^2\, d\theta$$

Therefore, since

$$A = \frac{1}{2}\int_0^{\pi/3} \sin^2(3\theta)\, d\theta = \frac{1}{2}\int_0^{\pi/3} (\sin 3\theta)^2\, d\theta,$$

we have $r = \sin 3\theta$. The integral represents the shaded area inside one petal of the three-petaled rose curve, $r = \sin 3\theta$, in Figure 8.57.

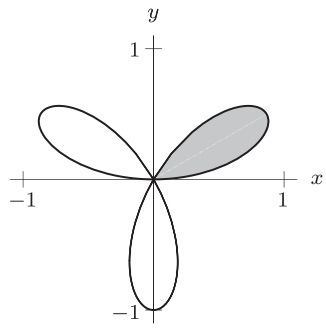

Figure 8.57: Graph of $r = \sin 3\theta$

26. The spiral is shown in Figure 8.58.

$$\text{Area } = \frac{1}{2}\int_0^{2\pi} \theta^2\, d\theta = \frac{1}{6}\theta^3\Big|_0^{2\pi} = \frac{8\pi^3}{6}.$$

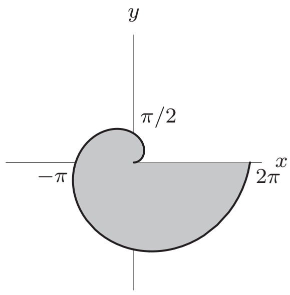

Figure 8.58: Spiral $r = \theta$

27. The region between the spirals is shaded in Figure 8.59.

$$\text{Area } = \frac{1}{2}\int_0^{2\pi} ((2\theta)^2 - \theta^2)\, d\theta = \frac{1}{2}\int_0^{2\pi} 3\theta^2\, d\theta = \frac{1}{2}\theta^3\Big|_0^{2\pi} = 4\pi^3.$$

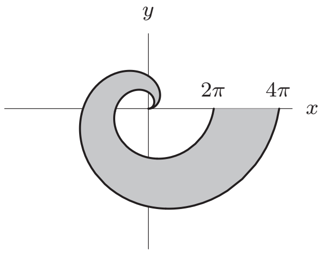

Figure 8.59: Region between the inner spiral, $r = \theta$, and the outer spiral, $r = 2\theta$

28. The cardioid is shown in Figure 8.60. The following integral can be evaluated using a calculator or by parts or using the table of integrals.

$$\begin{aligned}\text{Area } &= \frac{1}{2}\int_0^{2\pi} (1+\cos\theta)^2\, d\theta = \frac{1}{2}\int_0^{2\pi} \left(1 + 2\cos\theta + \cos^2\theta\right)\, d\theta \\ &= \frac{1}{2}\left(\theta + 2\sin\theta + \frac{1}{2}\cos\theta\sin\theta + \frac{1}{2}\theta\right)\Big|_0^{2\pi} = \frac{1}{2}(2\pi + 0 + 0 + \pi) = \frac{3\pi}{2}.\end{aligned}$$

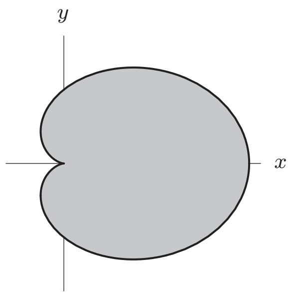

Figure 8.60: Cardioid $r = 1 + \cos\theta$

29. (a) See Figure 8.61. In polar coordinates, the line $x = 1$ is $r\cos\theta = 1$, so its equation is

$$r = \frac{1}{\cos\theta}.$$

The circle of radius 2 centered at the origin has equation

$$r = 2.$$

(b) The line and circle intersect where

$$\begin{aligned}\frac{1}{\cos\theta} &= 2 \\ \cos\theta &= \frac{1}{2} \\ \theta &= -\frac{\pi}{3}, \frac{\pi}{3}.\end{aligned}$$

Thus,

$$\text{Area } = \frac{1}{2}\int_{-\pi/3}^{\pi/3} \left(2^2 - \left(\frac{1}{\cos\theta}\right)^2\right)\, d\theta.$$

(c) Evaluating gives

$$\text{Area } = \frac{1}{2}\int_{-\pi/3}^{\pi/3}\left(4-\frac{1}{\cos^2\theta}\right)d\theta = \frac{1}{2}(4\theta-\tan\theta)\Big|_{-\pi/3}^{\pi/3} = \frac{4\pi}{3}-\sqrt{3}.$$

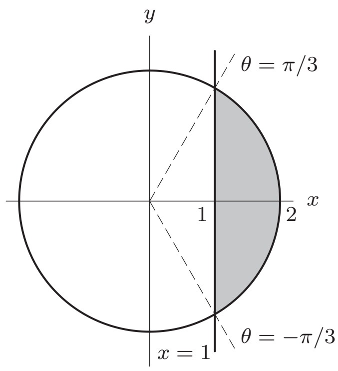

Figure 8.61

30. Using the formula Area$= (1/2)\int_\alpha^\beta (f(\theta))^2\,d\theta$ gives

$$\text{Area} = \frac{1}{2}\int_0^{2\pi} a^2\,d\theta = \frac{a^2}{2}\theta\Big|_0^{2\pi} = \pi a^2,$$

which is the formula for the area of a disk of radius a.

31. Using the formula Arc length $= \int_\alpha^\beta \sqrt{(dx/d\theta)^2+(dy/d\theta)^2}d\theta$, where $x = a\cos\theta$, $y = a\sin\theta$ and $a > 0$ gives

$$\text{Arc length} = \int_0^{2\pi}\sqrt{(-a\sin\theta)^2+(a\cos\theta)^2}\,d\theta = \int_0^{2\pi} a\,d\theta = a\theta|_0^{2\pi} = 2\pi a,$$

which is the formula for the circumference of a circle of radius a.

32. See Figure 8.62. Notice that the curves intersect at $(1,0)$, where $\theta = 0, 2\pi$, and at $(-1,0)$, where $\theta = \pi$, so

$$\text{Area } = \frac{1}{2}\int_\pi^{2\pi}(1^2-(1+\sin\theta)^2)\,d\theta = \frac{1}{2}\int_\pi^{2\pi}(-2\sin\theta-\sin^2\theta)\,d\theta.$$

Using a calculator, integration by parts, or formula IV-17 in the integral table, we have

$$\text{Area } = \frac{1}{2}\left(2\cos\theta+\frac{1}{2}\sin\theta\cos\theta-\frac{1}{2}\theta\right)\Big|_\pi^{2\pi} = \frac{1}{2}\left(2\cdot 2+0-\frac{1}{2}\pi\right) = 2-\frac{\pi}{4}.$$

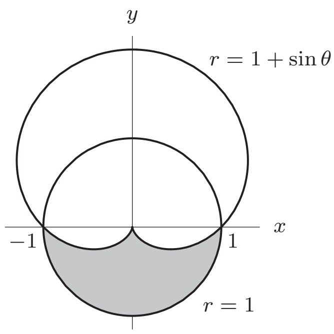

Figure 8.62

33. The two curves intersect where

$$\begin{aligned}1-\sin\theta &= \frac{1}{2}\\ \sin\theta &= \frac{1}{2}\\ \theta &= \frac{\pi}{6},\frac{5\pi}{6}.\end{aligned}$$

See Figure 8.63. We find the area of the right half and multiply that answer by 2 to get the entire area. The integrals can be computed numerically with a calculator or, as we show, using integration by parts or formula IV-17 in the integral tables.

$$\begin{aligned}\text{Area of right half } &= \frac{1}{2}\int_{-\pi/2}^{\pi/6}\left((1-\sin\theta)^2-\left(\frac{1}{2}\right)^2\right)d\theta\\ &= \frac{1}{2}\int_{-\pi/2}^{\pi/6}\left(1-2\sin\theta+\sin^2\theta-\frac{1}{4}\right)d\theta\\ &= \frac{1}{2}\int_{-\pi/2}^{\pi/6}\left(\frac{3}{4}-2\sin\theta+\sin^2\theta\right)d\theta\\ &= \frac{1}{2}\left(\frac{3}{4}\theta+2\cos\theta-\frac{1}{2}\sin\theta\cos\theta+\frac{1}{2}\theta\right)\Bigg|_{-\pi/2}^{\pi/6}\\ &= \frac{1}{2}\left(\frac{5\pi}{6}+\frac{7\sqrt{3}}{8}\right).\end{aligned}$$

Thus,

$$\text{Total area } = \frac{5\pi}{6}+\frac{7\sqrt{3}}{8}.$$

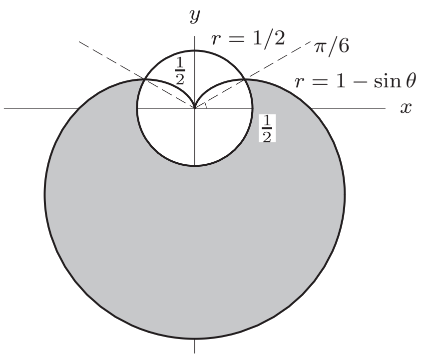

Figure 8.63

34. Figure 8.64 shows the curves which touch at $(2,0)$ and the origin. However, the circle lies entirely inside the cardioid, so we find the area by subtracting the area of the circle from that of the cardioid. To find the areas, we take the integrals.

The cardioid, $r=1+\cos\theta$, starts at $(2,0)$ when $\theta=0$ and traces the top half, reaching the origin when $\theta=\pi$. Thus

$$\text{Area of cardioid } = 2\cdot\frac{1}{2}\int_0^{\pi}(1+\cos\theta)^2\,d\theta.$$

The circle starts at $(2,0)$ when $\theta=0$ and traces the top half, reaching the origin when $\theta=\pi/2$. Thus

$$\text{Area of circle } = 2\cdot\frac{1}{2}\int_0^{\pi/2}(2\cos\theta)^2\,d\theta.$$

The area, A, we want is therefore

$$\begin{aligned}
\text{Area } &= 2\cdot\frac{1}{2}\int_0^{\pi}(1+\cos\theta)^2\,d\theta - 2\cdot\frac{1}{2}\int_0^{\pi/2}(2\cos\theta)^2\,d\theta\\
&= \int_0^{\pi}(1+2\cos\theta+\cos^2\theta)\,d\theta - \int_0^{\pi/2}4\cos^2\theta\,d\theta\\
&= \left(\theta+2\sin\theta+\frac{1}{2}(\sin\theta\cos\theta+\theta)\right)\Big|_0^{\pi} - \frac{4}{2}(\sin\theta\cos\theta+\theta)\Big|_0^{\pi/2}\\
&= \frac{3}{2}\pi - 2\cdot\frac{\pi}{2} = \frac{\pi}{2}.
\end{aligned}$$

Alternatively, we could compute the area of the cardioid and subtract the area of the circle of radius 1 from it.

The integrals can be computed numerically using a calculator, or, as we show, using integration by parts or formula IV-18 from the integral tables.

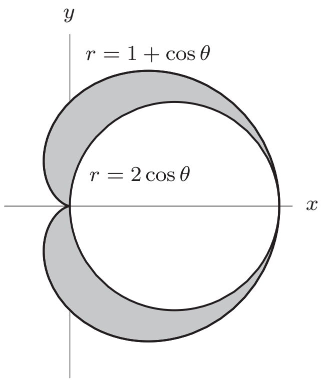

Figure 8.64

35. (a) The graph of $r = 2\cos\theta$ is a circle of radius 1 centered at $(1, 0)$; the graph of $r = 2\sin\theta$ is a circle of radius 1 centered at $(0, 1)$. See Figure 8.65.

(b) The Cartesian coordinates of the points of intersection are at $(0, 0)$ and $(1, 1)$.

The origin corresponds to $\theta = \pi/2$ on $r = 2\cos\theta$ and to $\theta = 0$ on $r = 2\sin\theta$. The point $(1, 1)$ has polar coordinates $r = \sqrt{2}, \theta = \pi/4$.

We find the area below the line $\theta = \pi/4$ and above $r = 2\sin\theta$ and double it:

$$\text{Area } = 2\cdot\frac{1}{2}\int_0^{\pi/4}(2\sin\theta)^2\,d\theta = 4\int_0^{\pi/4}\sin^2\theta\,d\theta.$$

Using a calculator, integration by parts or formula IV-17 from the integral tables,

$$\text{Area } = 4\left(-\frac{1}{2}\sin\theta\cos\theta+\frac{\theta}{2}\right)\Big|_0^{\pi/4} = -2\cdot\frac{1}{2}+2\frac{\pi}{4} = \frac{\pi}{2}-1.$$

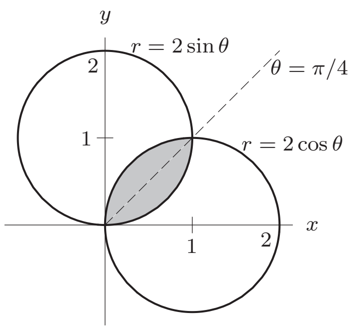

Figure 8.65

36. The area is

$$
\begin{aligned}
A = \frac{1}{2}\int_0^a r^2\,d\theta = \frac{1}{2}\int_0^a \theta^2\,d\theta &= 1 \\
\frac{1}{2}\left(\frac{\theta^3}{3}\right)\bigg|_0^a &= 1 \\
\frac{a^3}{6} &= 1 \\
a^3 &= 6 \\
a &= \sqrt[3]{6}.
\end{aligned}
$$

37. (a) See Figure 8.66.
(b) The curves intersect when $r^2 = 2$

$$
\begin{aligned}
4\cos 2\theta &= 2 \\
\cos 2\theta &= \frac{1}{2}.
\end{aligned}
$$

In the first quadrant:

$$2\theta = \frac{\pi}{3} \quad \text{so} \quad \theta = \frac{\pi}{6}.$$

Using symmetry, the area in the first quadrant can be multiplied by 4 to find the area of the total bounded region.

$$
\begin{aligned}
\text{Area } &= 4\left(\frac{1}{2}\right)\int_0^{\pi/6}(4\cos 2\theta - 2)\,d\theta \\
&= 2\left(\frac{4\sin 2\theta}{2} - 2\theta\right)\bigg|_0^{\pi/6} \\
&= 4\sin\frac{\pi}{3} - \frac{2}{3}\pi \\
&= 4\frac{\sqrt{3}}{2} - \frac{2}{3}\pi \\
&= 2\sqrt{3} - \frac{2}{3}\pi = 1.370.
\end{aligned}
$$

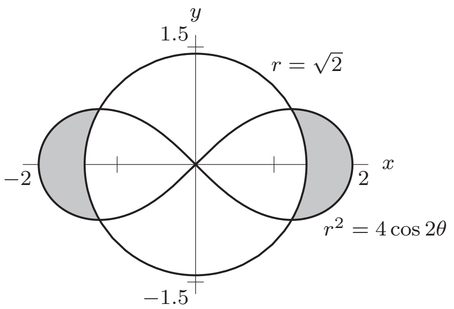

Figure 8.66

38. The slope of the tangent line at $\theta = \pi/3$ is $dy/dx = \sqrt{3}/5$. Since $x = 3\sin(2\theta)\cos\theta$ and $y = 3\sin(2\theta)\sin\theta$, when $\theta = \pi/3$, we have $x = 3\sqrt{3}/4$ and $y = 9/4$. Thus, the equation of the tangent line is

$$
\begin{aligned}
y - \frac{9}{4} &= \frac{\sqrt{3}}{5}\left(x - \frac{3\sqrt{3}}{4}\right) \\
y &= \frac{\sqrt{3}}{5}x - \frac{9}{20} + \frac{9}{4} \\
y &= \frac{\sqrt{3}}{5}x + \frac{9}{5}.
\end{aligned}
$$

39. We first find the points with horizontal and vertical tangents in the first quadrant and then use symmetry to obtain the points in other quadrants.

The slope of the tangent line is

$$\frac{dy}{dx} = \frac{6\cos(2\theta)\sin\theta + 3\sin(2\theta)\cos\theta}{6\cos(2\theta)\cos\theta - 3\sin(2\theta)\sin\theta}.$$

The curve has a horizontal tangent where

$$6\cos(2\theta)\sin\theta + 3\sin(2\theta)\cos\theta = 0.$$

Solving this equation numerically for $0 < \theta < \pi/2$, we have $\theta = 0.9553$; in addition $\theta = 0$ is a solution. Thus, there are horizontal tangents where $x = 1.633$ and $y = 2.309$ and where $x = 0$, $y = 0$. Thus, the five points with horizontal tangents are

$$(1.633, 2.309); \quad (-1.633, 2.309); \quad (-1.633, -2.309); \quad (1.633, -2.309); \quad (0, 0).$$

The curve has vertical tangents where

$$6\cos(2\theta)\cos\theta - 3\sin(2\theta)\sin\theta = 0.$$

Solving this equation numerically for $0 < \theta < \pi/2$, we have $\theta = 0.6155$; in addition $\theta = \pi/2$ is a solution. Thus, there are vertical tangents where $x = 2.309$, $y = 1.633$, and where $x = 0, y = 0$. Thus, there are five points with vertical tangents:

$$(2.309, 1.633); \quad (-2.309, 1.633); \quad (-2.309, -1.633); \quad (2.309, -1.633); \quad (0, 0).$$

40. We can express x and y in terms of θ as a parameter. Since $r = \theta$, we have

$$x = r\cos\theta = \theta\cos\theta \quad \text{and} \quad y = r\sin\theta = \theta\sin\theta.$$

Calculating the slope using the parametric formula,

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta},$$

we have

$$\frac{dy}{dx} = \frac{\sin\theta + \theta\cos\theta}{\cos\theta - \theta\sin\theta}.$$

Horizontal tangents occur where $dy/dx = 0$, so

$$\sin\theta + \theta\cos\theta = 0$$
$$\theta = -\tan\theta.$$

Solving this equation numerically gives

$$\theta = 0, 2.029, 4.913.$$

Vertical tangents occur where dy/dx is undefined, so

$$\cos\theta - \theta\sin\theta = 0$$
$$\theta = \frac{1}{\tan\theta} = \cot\theta.$$

Solving this equation numerically gives

$$\theta = 0.860, 3.426.$$

41. (a) Expressing x and y parametrically in terms of θ, we have

$$x = r\cos\theta = \frac{\cos\theta}{\theta} \quad \text{and} \quad y = r\sin\theta = \frac{\sin\theta}{\theta}.$$

The slope of the tangent line is given by

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \left(\frac{\theta\cos\theta - \sin\theta}{\theta^2}\right) \Big/ \left(\frac{-\theta\sin\theta - \cos\theta}{\theta^2}\right) = \frac{\sin\theta - \theta\cos\theta}{\cos\theta + \theta\sin\theta}.$$

At $\theta = \pi/2$, we have

$$\left.\frac{dy}{dx}\right|_{\theta=\pi/2} = \frac{1 - (\pi/2)0}{0 + (\pi/2)1} = \frac{2}{\pi}.$$

At $\theta = \pi/2$, we have $x = 0$, $y = 2/\pi$, so the equation of the tangent line is

$$y = \frac{2}{\pi}x + \frac{2}{\pi}.$$

(b) As $\theta \to 0$,

$$x = \frac{\cos\theta}{\theta} \to \infty \quad \text{and} \quad y = \frac{\sin\theta}{\theta} \to 1.$$

Thus, $y = 1$ is a horizontal asymptote. See Figure 8.67.

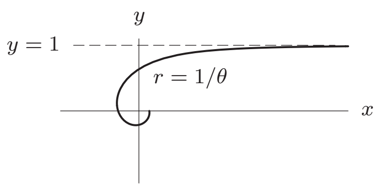

Figure 8.67

42. The limaçon is given by $r = 1 + 2\cos\theta$; see Figure 8.68. At $\theta = 0$, the graph is at $(3, 0)$; as θ increases, the graph sweeps out the top arc (on which the maximum value of y occurs), reaching the origin when

$$\begin{aligned} 1 + 2\cos\theta &= 0 \\ \cos\theta &= -\frac{1}{2} \\ \theta &= \frac{2\pi}{3}. \end{aligned}$$

Thus, we want to find the maximum value of y on the interval $0 \le \theta \le 2\pi/3$. Since $y = r\sin\theta$, we want to find the maximum value of

$$y = (1 + 2\cos\theta)\sin\theta = \sin\theta + 2\cos\theta\sin\theta.$$

At a critical point

$$\begin{aligned} \frac{dy}{d\theta} &= \cos\theta - 2\sin^2\theta + 2\cos^2\theta = 0 \\ \cos\theta - 2(1 - \cos^2\theta) + 2\cos^2\theta &= 0 \\ 4\cos^2\theta + \cos\theta - 2 &= 0 \\ \cos\theta &= \frac{-1 \pm \sqrt{33}}{8} = 0.593, -0.843. \end{aligned}$$

Thus, $\theta = \cos^{-1}(0.593) = 0.936$ and $\theta = \cos^{-1}(-0.843) = 2.574$ are the critical values. Since 2.574 is outside the interval $0 \le \theta \le 2\pi/3$, there is one critical point $\theta = 0.963$.

At the endpoints of the interval, $y = 0$. At $\theta = 0.936$, we have $y = 1.760$, which is the maximum value.

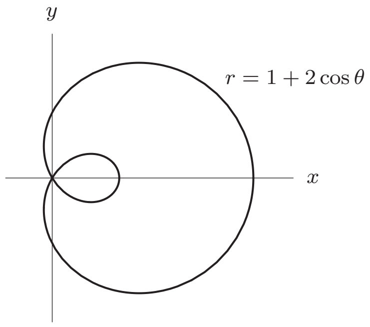

Figure 8.68: The inner loop has $r < 0$

43. Since $x = \theta\cos\theta$ and $y = \theta\sin\theta$, we have

$$\text{Arc length } = \int_0^{2\pi} \sqrt{(\cos\theta - \theta\sin\theta)^2 + (\sin\theta + \theta\cos\theta)^2}\, d\theta = \int_0^{2\pi} \sqrt{1+\theta^2}\, d\theta = 21.256.$$

44. Since $x = \cos\theta/\theta$ and $y = \sin\theta/\theta$, we have

$$\begin{aligned}\text{Arc length } &= \int_\pi^{2\pi} \sqrt{\left(\frac{-\theta\sin\theta - \cos\theta}{\theta^2}\right)^2 + \left(\frac{\theta\cos\theta - \sin\theta}{\theta^2}\right)^2}\, d\theta \\ &= \int_\pi^{2\pi} \sqrt{\frac{\theta^2+1}{\theta^4}}\, d\theta = 0.712.\end{aligned}$$

45. Parameterized by θ, the curve $r = f(\theta)$ is given by $x = f(\theta)\cos\theta$ and $y = f(\theta)\sin\theta$. Then

$$\begin{aligned}\text{Arc length } &= \int_\alpha^\beta \sqrt{\left(\frac{dx}{d\theta}\right)^2 + \left(\frac{dy}{d\theta}\right)^2}\, d\theta \\ &= \int_\alpha^\beta \sqrt{(f'(\theta)\cos\theta - f(\theta)\sin\theta)^2 + (f'(\theta)\sin\theta + f(\theta)\cos\theta)^2}\, d\theta \\ &= \int_\alpha^\beta \sqrt{(f'(\theta))^2\cos^2\theta - 2f'(\theta)f(\theta)\cos\theta\sin\theta + (f(\theta))^2\sin^2\theta} \\ &\qquad \overline{+(f'(\theta))^2\sin^2\theta + 2f'(\theta)f(\theta)\sin\theta\cos\theta + (f(\theta))^2\cos^2\theta}\, d\theta \\ &= \int_\alpha^\beta \sqrt{(f'(\theta))^2(\cos^2\theta + \sin^2\theta) + (f(\theta))^2(\sin^2\theta + \cos^2\theta)}\, d\theta \\ &= \int_\alpha^\beta \sqrt{(f'(\theta))^2 + (f(\theta))^2}\, d\theta.\end{aligned}$$

46. Let $f(\theta) = \theta$. Then $f'(\theta) = 1$. Using the formula derived in Problem 45, we have

$$\text{Arclength } = \int_0^{2\pi} \sqrt{1+\theta^2}\, d\theta = \left[\frac{1}{2}\theta\sqrt{1+\theta^2} + \frac{1}{2}\ln|\theta + \sqrt{1+\theta^2}|\right]_0^\pi = \frac{1}{2}\pi\sqrt{1+\pi^2} + \frac{1}{2}\ln|\pi + \sqrt{1+\pi^2}|$$

47. Let $f(\theta) = 1 + \cos\theta$. Then $f'(\theta) = -\sin\theta$. Using numerical methods, we have

$$\text{Arclength } = \int_0^{\pi/2} \sqrt{(-\sin\theta)^2 + (1+\cos\theta)^2}\, d\theta = \int_0^{\pi/2} \sqrt{2+2\cos\theta}\, d\theta = 2.828.$$

Strengthen Your Understanding

48. The formula $\theta = \tan^{-1}(y/x)$ is incorrect if $x \le 0$. If $x = 0$, then $\tan^{-1}(y/x)$ is not defined and so cannot be used. If $x < 0$, then the point (x, y) is in quadrant II or III, but $\tan^{-1}(y/x)$ is an angle in quadrant I or IV, because $-\pi/2 < \tan^{-1}(y/x) < \pi/2$.

49. The points on the polar curve with $\pi/2 < \theta < \pi$ are in quadrant IV, because $r = \sin(2\theta) < 0$.

50. Since $dr/d\theta$ is the rate of change of r with respect to θ, it cannot be interpreted as the slope of the polar curve. The circle $r = 1$ has positive slope at $\theta = 3\pi/4$, yet $dr/d\theta = 0$ everywhere, since the radius does not change as θ increases.

51. The rose with four petals, $r = 3\sin 2\theta$, shown in Figure 8.69 is symmetric about both axes.

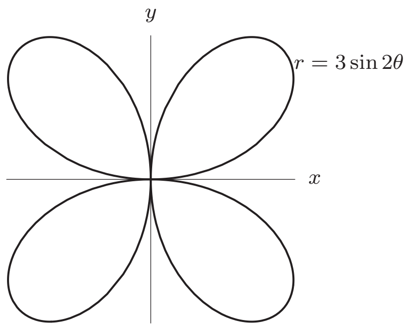

Figure 8.69

52. Changing the polar coordinate θ by adding 2π does not change the point. For example, $(r, \theta) = (10, \pi)$ and $(r, \theta) = (10, 3\pi)$ correspond to the same point $(x, y) = (-10, 0)$.

53. The circle of radius k centered at the origin has equation $r = k$. For example, $r = 100$.

54. One example is the Archimedean spiral $r = \theta$.

55. A polar curve is symmetric about the x-axis if replacing θ by $-\theta$ in its formula makes no difference, so any formula involving only $\cos\theta$ will work. One such example is the limaçon $r = 1 + \cos\theta$.

Solutions for Section 8.4

Exercises

1. Since density is e^{-x} gm/cm,

$$\text{Mass } = \int_0^{10} e^{-x}\,dx = -e^{-x}\Big|_0^{10} = 1 - e^{-10} \text{ gm.}$$

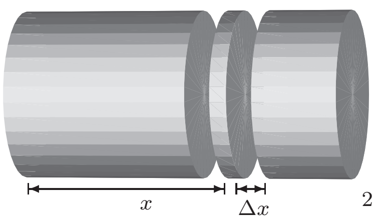
2. Strips perpendicular to the x-axis have length 3, area $3\Delta x$, and mass $5 \cdot 3\Delta x$ gm. Thus

$$\text{Mass } = \int_0^2 5 \cdot 3\,dx = \int_0^2 15\,dx.$$

Strips perpendicular to the y-axis have length 2, area $2\Delta y$, and mass $5 \cdot 2\Delta y$ gm. Thus

$$\text{Mass } = \int_0^3 5 \cdot 2\,dy = \int_0^3 10\,dy.$$

3. (a) Suppose we choose an x, $0 \le x \le 2$. If Δx is a small fraction of a meter, then the density of the rod is approximately $\delta(x)$ anywhere from x to $x + \Delta x$ meters from the left end of the rod (see below). The mass of the rod from x to $x + \Delta x$ meters is therefore approximately $\delta(x)\Delta x = (2 + 6x)\Delta x$. If we slice the rod into N pieces, then a Riemann sum is $\sum_{i=1}^{N}(2 + 6xi)\Delta x$.



(b) The definite integral is

$$M = \int_0^2 \delta(x)\,dx = \int_0^2 (2+6x)\,dx = (2x+3x^2)\Big|_0^2 = 16 \text{ grams.}$$

4. We have

$$\begin{aligned}\text{Moment} &= \int_0^2 x\delta(x)\,dx = \int_0^2 x(2+6x)\,dx \\ &= \int_0^2 (6x^2+2x)\,dx = (2x^3+x^2)\Big|_0^2 = 20 \text{ gram-meters.}\end{aligned}$$

Now, using this and Problem 3 (b), we have

$$\text{Center of mass} = \frac{\text{Moment}}{\text{Mass}} = \frac{20 \text{ gram-meters}}{16 \text{ grams}} = \frac{5}{4} \text{ meters (from its left end).}$$

5. (a) Figure 8.70 shows a graph of the density function.

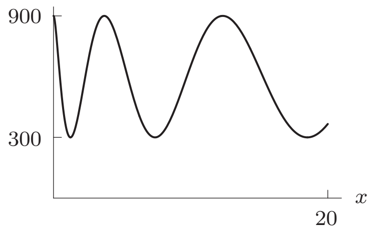


Figure 8.70

(b) Suppose we choose an x, $0 \le x \le 20$. We approximate the density of the number of the cars between x and $x+\Delta x$ miles as $\delta(x)$ cars per mile. Therefore, the number of cars between x and $x+\Delta x$ is approximately $\delta(x)\Delta x$. If we slice the 20 mile strip into N slices, we get that the total number of cars is

$$C \approx \sum_{i=1}^{N} \delta(x_i)\Delta x = \sum_{i=1}^{N} \left[600 + 300\sin(4\sqrt{x_i+0.15})\right]\Delta x,$$

where $\Delta x = 20/N$. (This is a right-hand approximation; the corresponding left-hand approximation is $\sum_{i=0}^{N-1} \delta(x_i)\Delta x$.)

(c) As $N \to \infty$, the Riemann sum above approaches the integral

$$C = \int_0^{20} (600 + 300\sin 4\sqrt{x+0.15})\,dx.$$

If we calculate the integral numerically, we find $C \approx 11513$. We can also find the integral exactly as follows:

$$\begin{aligned}C &= \int_0^{20} (600 + 300\sin 4\sqrt{x+0.15})\,dx \\ &= \int_0^{20} 600\,dx + \int_0^{20} 300\sin 4\sqrt{x+0.15}\,dx \\ &= 12000 + 300\int_0^{20} \sin 4\sqrt{x+0.15}\,dx.\end{aligned}$$

Let $w = \sqrt{x+0.15}$, so $x = w^2 - 0.15$ and $dx = 2w\,dw$. Then

$$\begin{aligned}\int_{x=0}^{x=20} \sin 4\sqrt{x+0.15}\,dx &= 2\int_{w=\sqrt{0.15}}^{w=\sqrt{20.15}} w\sin 4w\,dw, \text{ (using integral table III-15)} \\ &= 2\left[-\frac{1}{4}w\cos 4w + \frac{1}{16}\sin 4w\right]\Bigg|_{\sqrt{0.15}}^{\sqrt{20.15}} \\ &\approx -1.624.\end{aligned}$$

Using this, we have $C \approx 12000 + 300(-1.624) \approx 11513$, which matches our numerical approximation.

6. (a) Orient the rectangle in the coordinate plane in such a way that the side referred to in the problem—call it S—lies on the y-axis from $y = 0$ to $y = 5$, as shown in Figure 8.71. We may subdivide the rectangle into strips of width Δx and length 5. If the left side of a given strip is a distance x away from S (i.e., the y-axis), its density 2 is $1/(1+x^4)$. If Δx is small enough, the density of the strip is approximately constant—i.e., the density of the whole strip is about $1/(1+x^4)$. The mass of the strip is just its density times its area, or $5\Delta x/(1+x^4)$. Thus the mass of the whole rectangle is approximated by the Riemann sum

$$\sum \frac{5\Delta x}{1+x^4},$$

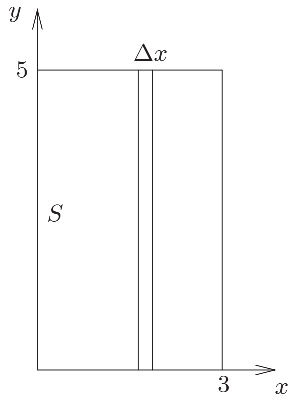

Figure 8.71

(b) The exact mass of the rectangle is obtained by letting $\Delta x \to 0$ in the Riemann sums above, giving us the integral

$$\int_0^3 \frac{5\,dx}{1+x^4}.$$

Since it is not easy to find an antiderivative of $5/(1+x^4)$, we evaluate this integral numerically, getting 5.5.

7. The total mass is 7 grams. The center of mass is given by

$$\overline{x} = \frac{2(-3)+5(4)}{7} = 2 \text{ cm to right of origin.}$$

8. The total mass is 9 gm, and so the center of mass is located at $\overline{x} = \frac{1}{9}(-10\cdot 5 + 1\cdot 3 + 2\cdot 1) = -5$.

9. We slice the block horizontally. A slice has area $10\cdot 3 = 30$ and thickness Δz. On such a slice, the density is approximately constant. Thus

$$\text{Mass of slice} \approx \text{Density} \cdot \text{Volume} \approx (2-z)\cdot 30\Delta z,$$

so we have

$$\text{Mass of block} \approx \sum (2-z)30\Delta z.$$

In the limit as $\Delta z \to 0$, the sum becomes an integral and the approximation becomes exact. Thus

$$\text{Mass of block} = \int_0^1 (2-z)30\,dz = 30\left(2z - \frac{z^2}{2}\right)\Bigg|_0^1 = 30\left(2-\frac{1}{2}\right) = 45.$$

Problems

10. According to the table, the number of bats/ha drops from 117 at 3 km to 85 at 4 km. To make an overestimate, we can assume there are 117 bats/ha everywhere between 3 and 4 km from the cave. We have

$$\text{Area of ring (km}^2) = \underbrace{\text{Area of outer circle}}_{\pi\cdot 4^2} - \underbrace{\text{Area of inner circle}}_{\pi\cdot 3^2} = 7\pi.$$

There are 100 ha per km^2, so the area is $7\pi(100) = 700\pi$ ha. Assuming 117 bats/ha, this gives

$$\text{Overestimate for number of bats} = \underbrace{\text{Area of ring (ha)}}_{700\pi} \times \underbrace{\text{Number bats per ha}}_{117} = 257{,}296.$$

11. According to the table, the number of bats/ha drops from 117 at 3 km to 85 at 4 km. To make an underestimate, we can assume there are 85 bats/ha everywhere between 3 and 4 km from the cave. We have

$$\text{Area of ring (km}^2) = \underbrace{\text{Area of outer circle}}_{\pi\cdot 4^2} - \underbrace{\text{Area of inner circle}}_{\pi\cdot 3^2} = 7\pi.$$

There are 100 ha per km^2, so the area is $7\pi(100) = 700\pi$ ha. Assuming 85 bats/ha, this gives

$$\text{Underestimate for number of bats} = \underbrace{\text{Area of ring (ha)}}_{700\pi} \times \underbrace{\text{Number bats per ha}}_{85} = 186{,}925.$$

12. The number of bats in a ring of inner radius r and width Δr is given by

$$\begin{aligned}\text{Number of bats} &= \text{Area of ring (ha)} \times \text{Bats per ha} \\ &\approx \underbrace{100 \cdot \overbrace{2\pi r\Delta r}^{\text{area (km}^2)}}_{\text{area (ha)}} \times \underbrace{f(r)}_{\text{bats per ha}} \\ &= 200\pi f(r) r\Delta r.\end{aligned}$$

Thus, adding up the contributions from each ring gives:

$$\text{Total number of bats} \approx \sum 200\pi f(r) r\Delta r.$$

Taking the limit of the sum as $\Delta r \to 0$, we get

$$\text{Total number of bats} = \int_0^5 200\pi f(r) r dr.$$

13. Since the density varies with x, the region must be sliced perpendicular to the x-axis. This has the effect of making the density approximately constant on each strip. See Figure 8.72. Since a strip is of height y, its area is approximately $y\Delta x$. The density on the strip is $\delta(x) = 1 + x$ gm/cm^2. Thus

$$\text{Mass of strip} \approx \text{Density} \cdot \text{Area} \approx (1 + x)y\Delta x \text{ gm}.$$

Because the tops of the strips end on two different lines, one for $x \geq 0$ and the other for $x < 0$, the mass is calculated as the sum of two integrals. See Figure 8.72. For the left part of the region, $y = x + 1$, so

$$\begin{aligned}\text{Mass of left part} &= \lim_{\Delta x\to 0} \sum (1 + x)y\Delta x = \int_{-1}^{0} (1 + x)(x + 1)\, dx \\ &= \int_{-1}^{0} (1 + x)^2\, dx = \left.\frac{(x + 1)^3}{3}\right|_{-1}^{0} = \frac{1}{3} \text{ gm}.\end{aligned}$$

From Figure 8.72, we see that for the right part of the region, $y = -x + 1$, so

$$\begin{aligned}\text{Mass of right part} &= \lim_{\Delta x\to 0} \sum (1 + x)y\Delta x = \int_{0}^{1} (1 + x)(-x + 1)\, dx \\ &= \int_{0}^{1} (1 - x^2)\, dx = x - \left.\frac{x^3}{3}\right|_{0}^{1} = \frac{2}{3} \text{ gm}.\end{aligned}$$

$$\text{Total mass} = \frac{1}{3} + \frac{2}{3} = 1 \text{ gm}.$$

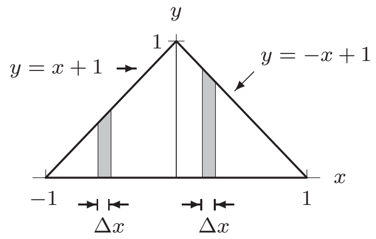

Figure 8.72

14. Since the density $\delta(y) = 2 + y^2$ is constant for fixed y, we take slices parallel to the x-axis of height Δy and length 2. Then a slice has area $= 2\Delta y$ and approximate mass of $(2 + y^2) \cdot 2\Delta y$. Adding the slices and letting $\Delta y \to 0$ gives

$$\text{Mass} = \int_0^3 2(2 + y^2)\, dy = 4y + \frac{2}{3}y^3 \Big|_0^3 = 30 \text{ gm}.$$

15. (a) We must find where the population density is zero. The density is given by the function

$$10{,}000(3 - r);$$

if $10{,}000(3 - r) = 0$, then we must have $r = 3$. We thus conclude that the radius of Circle City is 3 miles. (Note that for $r > 3$, $10{,}000(3 - r)$ becomes negative, so at that point, our function no longer gives a meaningful representation of population density.)

(b) We refer to Example 4 in this section, with $f(r) = 10{,}000(3 - r)$. The population is approximated by a sum

$$\text{Population} \approx \sum 2\pi r \cdot 10{,}000(3 - r)\Delta r.$$

Since the city radius is 3 miles, r ranges from 0 to 3. Hence as $\Delta r \to 0$, the sum is given by the integral

$$\text{Population} = \int_0^3 2\pi r \cdot 10{,}000(3 - r)\, dr.$$

This integral evaluates to $9\pi \cdot 10{,}000 \approx 282{,}743$. So we can say that the population of Circle City is approximately 282,743.

16. (a) Partition $[0, 10{,}000]$ into N subintervals of width Δr. The area in the i^{th} subinterval is $\approx 2\pi r_i \Delta r$. So the total mass in the slick $= M \approx \sum_{i=1}^{N} 2\pi r_i \left(\frac{50}{1+r_i}\right) \Delta r$.

(b) $M = \displaystyle\int_0^{10{,}000} 100\pi \frac{r}{1+r} dr$. We may rewrite $\dfrac{r}{1+r}$ as $\frac{1+r}{1+r} - \frac{1}{1+r} = 1 - \frac{1}{1+r}$, so that

$$M = \int_0^{10{,}000} 100\pi\left(1 - \frac{1}{1+r}\right) dr = 100\pi \left(r - \ln|1+r| \Big|_0^{10{,}000} \right)$$
$$= 100\pi(10{,}000 - \ln(10{,}001)) \approx 3.14 \times 10^6 \text{ kg}.$$

(c) We wish to find an R such that

$$\int_0^R 100\pi \frac{r}{1+r} dr = \frac{1}{2} \int_0^{10{,}000} 100\pi \frac{r}{1+r} dr \approx 1.57 \times 10^6.$$

So $100\pi(R - \ln|R + 1|) \approx 1.57 \times 10^6$; $R - \ln|R + 1| \approx 5000$. By trial and error, we find $R \approx 5009$ meters.

17. (a) We form a Riemann sum by slicing the region into concentric rings of radius r and width Δr. Then the volume deposited on one ring will be the height $H(r)$ multiplied by the area of the ring. A ring of width Δr will have an area given by

$$\begin{aligned}\text{Area} &= \pi(r + \Delta r)^2 - \pi(r^2) \\ &= \pi(r^2 + 2r\Delta r + (\Delta r)^2 - r^2) \\ &= \pi(2r\Delta r + (\Delta r)^2).\end{aligned}$$

Since Δr is approaching zero, we can approximate

$$\text{Area of ring} \approx \pi(2r\Delta r + 0) = 2\pi r\Delta r.$$

From this, we have

$$\Delta V \approx H(r) \cdot 2\pi r\Delta r.$$

Thus, summing the contributions from all rings we have

$$V \approx \sum H(r) \cdot 2\pi r\Delta r.$$

Taking the limit as $\Delta r \to 0$, we get

$$V = \int_0^5 2\pi r \left(0.115e^{-2r}\right) dr.$$

(b) We use integration by parts:

$$\begin{aligned} V &= 0.23\pi \int_0^5 \left(re^{-2r}\right) dr \\ &= 0.23\pi \left(\frac{re^{-2r}}{-2} - \frac{e^{-2r}}{4}\right)\Bigg|_0^5 \\ &\approx 0.181(\text{millimeters}) \cdot (\text{kilometers})^2 = 0.181 \cdot 10^{-3} \cdot 10^6 \text{ meters}^3 = 181 \text{ cubic meters.} \end{aligned}$$

18. Partition $a \le x \le b$ into N subintervals of width $\Delta x = \dfrac{(b-a)}{N}$; $a = x_0 < x_1 < \cdots < x_N = b$. The mass of the strip on the ith subinterval is approximately $m_i = \delta(x_i)[f(x_i) - g(x_i)]\Delta x$. If we use a right-hand Riemann sum, the approximation for the total mass is
$\displaystyle\sum_{i=1}^{N} \delta(x_i)[f(x_i) - g(x_i)]\Delta x$, and the exact mass is $M = \displaystyle\int_a^b \delta(x)[f(x) - g(x)]dx$.

19. (a) Use the formula for the volume of a cylinder:

$$\text{Volume} = \pi r^2 l.$$

Since it is only a half cylinder

$$\text{Volume of shed} = \frac{1}{2}\pi r^2 l.$$

(b) Set up the axes as shown in Figure 8.73. The density can be defined as

$$\text{Density} = ky.$$

Now slice the sawdust horizontally into slabs of thickness Δy as shown in Figure 8.74, and calculate

$$\text{Volume of slab} \approx 2xl\Delta y = 2l(\sqrt{r^2 - y^2})\Delta y.$$

$$\text{Mass of slab} = \text{Density} \cdot \text{Volume} \approx 2kly\sqrt{r^2 - y^2}\Delta y.$$

Finally, we compute the total mass of sawdust:

$$\text{Total mass of sawdust} = \int_0^r 2kly\sqrt{r^2 - y^2}\, dy = -\frac{2}{3}kl(r^2 - y^2)^{3/2}\Bigg|_0^r = \frac{2klr^3}{3}.$$

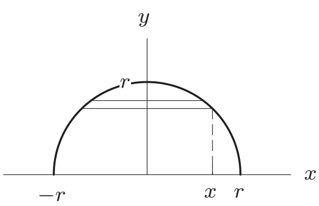

Figure 8.73

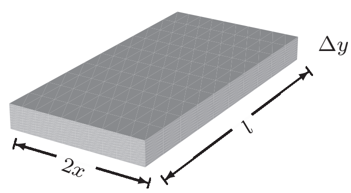

Figure 8.74

20. First we rewrite the chart, listing the density with the corresponding distance from the center of the earth (x km below the surface is equivalent to $6370 - x$ km from the center):

This gives us spherical shells whose volumes are $\frac{4}{3}\pi(r_i^3 - r_{i+1}^3)$ for any two consecutive distances from the origin. We will assume that the density of the earth is increasing with depth. Therefore, the average density of the i^{th} shell is between D_i and D_{i+1}, the densities at top and bottom of shell i. So $\frac{4}{3}\pi D_{i+1}(r_i^3 - r_{i+1}^3)$ and $\frac{4}{3}\pi D_i(r_i^3 - r_{i+1}^3)$ are upper and lower bounds for the mass of the shell.

Table 8.6

i	x_i	$r_i = 6370 - x_i$	D_i
0	0	6370	3.3
1	1000	5370	4.5
2	2000	4370	5.1
3	2900	3470	5.6
4	3000	3370	10.1
5	4000	2370	11.4
6	5000	1370	12.6
7	6000	370	13.0
8	6370	0	13.0

To get a rough approximation of the mass of the earth, we don't need to use all the data. Let's just use the densities at $x = 0$, 2900, 5000 and 6370 km. Calculating an upper bound on the mass,

$$M_U = \frac{4}{3}\pi[13.0(1370^3 - 0^3) + 12.6(3470^3 - 1370^3) + 5.6(6370^3 - 3470^3)] \cdot 10^{15} \approx 7.29 \times 10^{27} \text{ g}.$$

The factor of 10^{15} may appear unusual. Remember the radius is given in kilometers and the density is given in g/cm^3, so we must convert kilometers to centimeters: 1 km $= 10^5$ cm , so 1 km$^3 = 10^{15}$ cm^3.

The lower bound is

$$M_L = \frac{4}{3}\pi[12.6(1370^3 - 0^3) + 5.6(3470^3 - 1370^3) + 3.3(6370^3 - 3470^3)] \cdot 10^{15} \approx 4.05 \times 10^{27} \text{ g}.$$

Here, our upper bound is just under 2 times our lower bound.

Using all our data, we can find a more accurate estimate. The upper and lower bounds are

$$M_U = \frac{4}{3}\pi \sum_{i=0}^{7} D_{i+1}(r_i^3 - r_{i+1}^3) \cdot 10^{15} \text{ g}$$

and

$$M_L = \frac{4}{3}\pi \sum_{i=0}^{7} D_i(r_i^3 - r_{i+1}^3) \cdot 10^{15} \text{ g}.$$

We have

$$\begin{aligned} M_U &= \frac{4}{3}\pi[4.5(6370^3 - 5370^3) + 5.1(5370^3 - 4370^3) + 5.6(4370^3 - 3470^3) \\ &+ 10.1(3470^3 - 3370^3) + 11.4(3370^3 - 2370^3) + 12.6(2370^3 - 1370^3) \\ &+ 13.0(1370^3 - 370^3) + 13.0(370^3 - 0^3)] \cdot 10^{15} \text{ g} \\ &\approx 6.50 \times 10^{27} \text{ g} \end{aligned}$$

and

$$\begin{aligned} M_L &= \frac{4}{3}\pi[3.3(6370^3 - 5370^3) + 4.5(5370^3 - 4370^3) + 5.1(4370^3 - 3470^3) \\ &+ 5.6(3470^3 - 3370^3) + 10.1(3370^3 - 2370^3) + 11.4(2370^3 - 1370^3) \\ &+ 12.6(1370^3 - 370^3) + 13.0(370^3 - 0^3)] \cdot 10^{15} \text{ g} \\ &\approx 5.46 \times 10^{27} \text{ g}. \end{aligned}$$

21. We slice time into small intervals. Since t is given in seconds, we convert the minute to 60 seconds. We consider water loss over the time interval $0 \leq t \leq 60$. We also need to convert inches into feet since the velocity is given in ft/sec. Since 1 inch = $1/12$ foot, the square hole has area $1/144$ square feet. For water flowing through a hole with constant velocity v, the amount of water which has passed through in some time, Δt, can be pictured as the rectangular solid in Figure 8.75, which has volume

$$\text{Area} \cdot \text{Height} = \text{Area} \cdot \text{Velocity} \cdot \text{Time}.$$

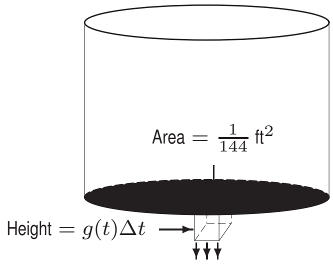

Figure 8.75: Volume of water passing through hole

Over a small time interval of length Δt, starting at time t, water flows with a nearly constant velocity $v = g(t)$ through a hole $1/144$ square feet in area. In Δt seconds, we know that

$$\text{Water lost } \approx \left(\frac{1}{144}\text{ ft}^2\right)(g(t)\text{ ft/sec})(\Delta t\text{ sec}) = \left(\frac{1}{144}\right) g(t)\,\Delta t\text{ ft}^3.$$

Adding the water from all subintervals gives

$$\text{Total water lost } \approx \sum \frac{1}{144} g(t)\,\Delta t\text{ ft}^3.$$

As $\Delta t \to 0$, the sum tends to the definite integral:

$$\text{Total water lost} = \int_0^{60} \frac{1}{144} g(t)\,dt\text{ ft}^3.$$

22. (a) Divide the atmosphere into spherical shells of thickness Δh. See Figure 8.76. The density on a typical shell, $\rho(h)$, is approximately constant. The volume of the shell is approximately the surface area of a sphere of radius $r_e + h$ meters times Δh, where $r_e = 6.4 \cdot 10^6$ meters is the radius of the earth,

$$\text{Volume of Shell } \approx 4\pi(r_e + h_i)^2 \Delta h.$$

A Riemann sum for the total mass is

$$\text{Mass } \approx \sum 4\pi(r_e + h)^2 \times 1.28e^{-0.000124h_i}\,\Delta h\text{ kg}.$$

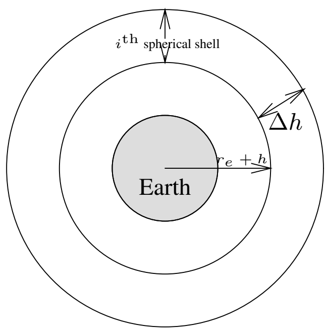

Figure 8.76

(b) This Riemann sum becomes the integral

$$\begin{aligned} \text{Mass } &= 4\pi \int_0^{100} (r_e + h)^2 \cdot 1.28e^{-0.000124h}\, dh \\ &= 4\pi \int_0^{100} (6.4 \cdot 10^6 + h)^2 \cdot 1.28e^{-0.000124h}\, dh. \end{aligned}$$

Evaluating the integral using numerical methods gives $M = 6.5 \cdot 10^{16}$ kg.

23. We need the numerator of $\overline{x}$, to be zero, i.e. $\sum x_i m_i = 0$. Since all of the masses are the same, we can factor them out and write $4\sum x_i = 0$. Thus the fourth mass needs to be placed so that all of the positions sum to zero. The first three positions sum to $(-6+1+3) = -2$, so the fourth mass needs to be placed at $x = 2$.

24. We have

$$\text{Total mass of the rod } = \int_0^3 (1+x^2)\, dx = \left[x + \frac{x^3}{3}\right]\Bigg|_0^3 = 12 \text{ grams.}$$

In addition,

$$\text{Moment } = \int_0^3 x(1+x^2)\, dx = \left[\frac{x^2}{2} + \frac{x^4}{4}\right]\Bigg|_0^3 = \frac{99}{4} \text{ gram-meters.}$$

Thus, the center of mass is at the position $\bar{x} = \frac{99/4}{12} = 2.06$ meters.

25. The center of mass is

$$\bar{x} = \frac{\int_0^\pi x(2+\sin x)\, dx}{\int_0^\pi (2+\sin x)\, dx}.$$

The numerator is $\int_0^\pi (2x + x\sin x)\, dx = (x^2 - x\cos x + \sin x)\Big|_0^\pi = \pi^2 + \pi$.

The denominator is $\int_0^\pi (2+\sin x)\, dx = (2x - \cos x)\Big|_0^\pi = 2\pi + 2$. So the center of mass is at

$$\overline{x} = \frac{\pi^2+\pi}{2\pi+2} = \frac{\pi(\pi+1)}{2(\pi+1)} = \frac{\pi}{2}.$$

26. (a) We find that

$$\text{Moment } = \int_0^1 x(1+kx^2)\, dx = \left(\frac{x^2}{2} + \frac{kx^4}{4}\right)\Bigg|_0^1 = \frac{1}{2} + \frac{k}{4} \text{ gram-meters,}$$

and that

$$\text{Total mass } = \int_0^1 (1+kx^2)\, dx = \left(x + \frac{kx^3}{3}\right)\Bigg|_0^1 = 1 + \frac{k}{3} \text{ grams.}$$

Thus, the center of mass is

$$\bar{x} = \frac{\frac{1}{2} + \frac{k}{4}}{1 + \frac{k}{3}} = \frac{3}{4}\left(\frac{2+k}{3+k}\right) \text{ meters.}$$

(b) Let $f(k) = \frac{3}{4}\left(\frac{2+k}{3+k}\right)$. Then $f'(k) = \frac{3}{4}\left(\frac{1}{(3+k)^2}\right)$, which is always positive, so f is an increasing function of k. Since $f(0) = 0.5$, this is the smallest value of f. As $k \to \infty$, $f(k) \to 3/4 = 0.75$. So $f(k)$ is always between 0.5 and 0.75.

27. (a) The density is minimum at $x = -1$ and increases as x increases, so more of the mass of the rod is in the right half of the rod. We thus expect the balancing point to be to the right of the origin.

(b) We need to compute

$$\begin{aligned} \int_{-1}^1 x(3-e^{-x})\, dx &= \left(\frac{3}{2}x^2 + xe^{-x} + e^{-x}\right)\Bigg|_{-1}^1 \quad \text{(using integration by parts)} \\ &= \frac{3}{2} + e^{-1} + e^{-1} - \left(\frac{3}{2} - e^1 + e^1\right) = \frac{2}{e}. \end{aligned}$$

We must divide this result by the total mass, which is given by

$$\int_{-1}^{1}(3-e^{-x})\,dx = (3x+e^{-x})\Big|_{-1}^{1} = 6-e+\frac{1}{e}.$$

We therefore have

$$\bar{x} = \frac{2/e}{6-e+(1/e)} = \frac{2}{1+6e-e^2} \approx 0.2.$$

28. Since the region is symmetric about the x-axis, $\bar{y}=0$.

To find $\bar{x}$, we first find the density. The area of the disk is $\pi/2$ m^2, so it has density $3/(\pi/2)=6/\pi$ kg/m^2. We find the mass of the small strip of width Δx in Figure 8.77. The height of the strip is $\sqrt{1-x^2}$, so

$$\text{Area of the small strip } \approx A_x(x)\Delta x = 2\cdot\sqrt{1-x^2}\Delta x \text{ m}^2.$$

When multiplied by the density $6/\pi$, we get

$$\text{Mass of the strip } \approx \frac{12}{\pi}\cdot\sqrt{1-x^2}\Delta x \text{ kg}.$$

We then sum the product of these masses with x, and take the limit as $\Delta x \to 0$ to get

$$\text{Moment } = \int_0^1 \frac{12}{\pi}x\sqrt{1-x^2}\,dx = -\frac{4}{\pi}(1-x^2)^{3/2}\Big|_0^1 = \frac{4}{\pi} \text{ meter}.$$

Finally, we divide by the total mass 3 kg to get the result $\bar{x}=4/(3\pi)$ meters.

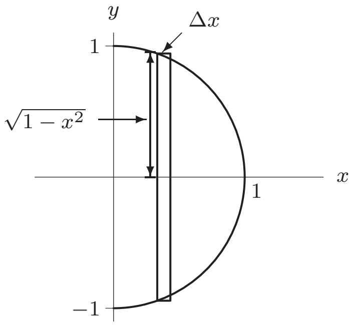

Figure 8.77: Area of a small strip

29. (a) Since the density is constant, the mass is the product of the area of the plate and its density.

$$\text{Area of the plate } = \int_0^1 x^2\,dx = \frac{1}{3}x^3\Big|_0^1 = \frac{1}{3}\text{ cm}^2.$$

Thus the mass of the plate is $2\cdot 1/3 = 2/3$ gm.

(b) See Figure 8.78. Since the region is "fatter" closer to $x=1$, $\bar{x}$ is greater than $1/2$.

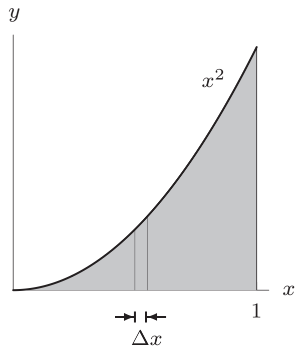

Figure 8.78

(c) To find the center of mass along the x-axis, we slice the region into vertical strips of width Δx. See Figure 8.78. Then

$$\text{Area of strip } = A_x(x)\Delta x \approx x^2\Delta x$$

Then, since the density is 2 gm/cm^2, we have

$$\overline{x} = \frac{\int_0^1 2x^3\,dx}{2/3} = \frac{3}{2}\cdot\left.\frac{2x^4}{4}\right|_0^1 = 3\left(\frac{1}{4}\right) = \frac{3}{4}\text{cm}.$$

This is greater than $1/2$, as predicted in part (b).

30. (a) Since the density is constant, the mass is the product of the area of the plate and its density.

$$\text{Area of the plate } = \int_0^1 \sqrt{x}\,dx = \left.\frac{2}{3}x^{3/2}\right|_0^1 = \frac{2}{3}\text{ cm}^2.$$

Thus the mass of the plate is $5\cdot 2/3 = 10/3$ gm.

(b) To find $\bar{x}$, we slice the region into vertical strips of width Δx. See Figure 8.79. Then

$$\text{Area of strip } = A_x(x)\Delta x \approx \sqrt{x}\Delta x\text{ cm}^2.$$

Then, since the density is 5 gm/cm^2, we have

$$\overline{x} = \frac{\int x\delta A_x(x)\,dx}{\text{Mass}} = \frac{\int_0^1 5x^{3/2}\,dx}{10/3} = \frac{3}{10}\left. 2x^{5/2}\right|_0^1 = \frac{3}{5}\text{ cm}.$$

To find $\bar{y}$, we slice the region into horizontal strips of width Δy

$$\text{Area of horizontal strip } = A_y(y)\Delta y \approx (1-x)\Delta y = (1-y^2)\Delta y\text{ cm}^2.$$

Then, since the density is 5 gm/cm^2, we have

$$\overline{y} = \frac{\int y\delta A_y(y)\,dy}{\text{Mass}} = \frac{\int_0^1 5(y-y^3)\,dy}{10/3} = \frac{3}{10}\,5\left.\left(\frac{y^2}{2}-\frac{y^4}{4}\right)\right|_0^1 = \frac{3}{10}\cdot\frac{5}{4} = \frac{3}{8}\text{ cm}.$$

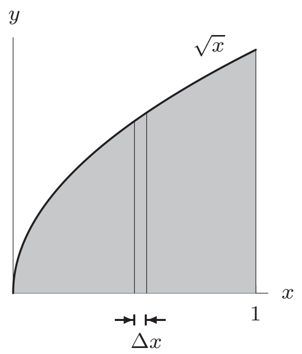

Figure 8.79

31. The triangle is symmetric about the x axis, so $\bar{y} = 0$.

To find $\bar{x}$, we first calculate the density. The area of the triangle is $ab/2$, so it has density $2m/(ab)$ where m is the total mass of the triangle. We need to find the mass of a small strip of width Δx located at x_i (see Figure 8.80).

$$\text{Area of the small strip } \approx A_x(x)\Delta x = 2\cdot\frac{b(a-x)}{2a}\Delta x.$$

Multiplying by the density $2m/(ab)$ gives

$$\text{Mass of the strip } \approx 2m\frac{(a-x)}{a^2}\Delta x.$$

We then sum the product of these masses with x_i, and take the limit as $\Delta x \to 0$ to get

$$\text{Moment } = \int_0^a \frac{2mx(a-x)}{a^2}\,dx = \frac{2m}{a^2}\left(\frac{ax^2}{2} - \frac{x^3}{3}\right)\Bigg|_0^a = \frac{2m}{a^2}\left(\frac{a^3}{2} - \frac{a^3}{3}\right) = \frac{ma}{3}.$$

Finally, we divide by the total mass m to get the desired result $\bar{x} = a/3$, which is independent of the length of the base b.

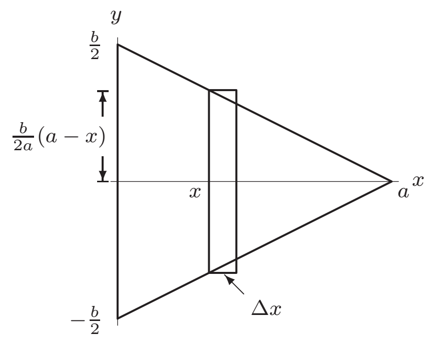

Figure 8.80

32. Stand the cone with the base horizontal, with center at the origin. Symmetry gives us that $\bar{x} = \bar{y} = 0$. Since the cone is fatter near its base we expect the center of mass to be nearer to the base.

Slice the cone into disks parallel to the xy-plane.

As we saw in Example 3 on page 416, a disk of thickness Δz at height z above the base has

$$\text{Volume of disk } = A_z(z)\Delta z \approx \pi(5-z)^2\Delta z \text{ cm}^3.$$

Thus, since the density is δ,

$$\overline{z} = \frac{\int z\delta A_z(z)\,dz}{\text{Mass}} = \frac{\int_0^5 z\cdot\delta\pi(5-z)^2\,dz}{\text{Mass}} \text{ cm}.$$

To evaluate the integral in the numerator, we factor out the constant density δ and π to get

$$\int_0^5 z\cdot\delta\pi(5-z)^2\,dz = \delta\pi\int_0^5 z(25-10z+z^2)\,dz = \delta\pi\left(\frac{25z^2}{2} - \frac{10z^3}{3} + \frac{z^4}{4}\right)\Bigg|_0^5 = \frac{625}{12}\delta\pi.$$

We divide this result by the total mass of the cone, which is $\left(\frac{1}{3}\pi 5^2\cdot 5\right)\delta$:

$$\overline{z} = \frac{\frac{625}{12}\delta\pi}{\frac{1}{3}\pi 5^3\delta} = \frac{5}{4} = 1.25\,\text{cm}.$$

As predicted, the center of mass is closer to the base of the cone than its top.

33. Since the density is constant, the total mass of the solid is the product of the volume of the solid and its density: $\delta\pi(1-e^{-2})/2$. By symmetry, $\bar{y} = 0$. To find $\bar{x}$, we slice the solid into disks of width Δx, perpendicular to the x-axis. See Figure 8.81. A disk at x has radius $y = e^{-x}$, so

$$\text{Volume of disk } = A_x(x)\Delta x = \pi y^2\Delta x = \pi e^{-2x}\Delta x.$$

Since the density is δ, we have

$$\overline{x} = \frac{\int_0^1 x\cdot\delta\pi e^{-2x}dx}{\text{Total mass}} = \frac{\delta\pi\int_0^1 xe^{-2x}dx}{\delta\pi(1-e^{-2})/2} = \frac{2}{1-e^{-2}}\int_0^1 xe^{-2x}\,dx.$$

The integral $\int xe^{-2x}\,dx$ can be done by parts: let $u = x$ and $v' = e^{-2x}$. Then $u' = 1$ and $v = e^{-2x}/(-2)$. So

$$\int xe^{-2x}\,dx = \frac{xe^{-2x}}{-2} - \int\frac{e^{-2x}}{-2}\,dx = \frac{xe^{-2x}}{-2} - \frac{e^{-2x}}{4}.$$

and then

$$\int_0^1 xe^{-2x}\,dx = \left(\frac{xe^{-2x}}{-2} - \frac{e^{-2x}}{4}\right)\Bigg|_0^1 = \left(\frac{e^{-2}}{-2} - \frac{e^{-2}}{4}\right) - \left(0 - \frac{1}{4}\right) = \frac{1-3e^{-2}}{4}.$$

The final result is:

$$\overline{x} = \frac{2}{1-e^{-2}} \cdot \frac{1-3e^{-2}}{4} = \frac{1-3e^{-2}}{2-2e^{-2}} \approx 0.343.$$

Notice that $\bar{x}$ is less that $1/2$, as we would expect from the fact that the solid is wider near the origin.

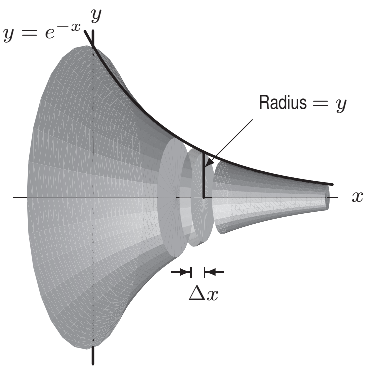

Figure 8.81

34. (a) Position the pyramid so that the center of its base lies at the origin on the xy-plane. Slice the pyramid into square slabs parallel to its base. We compute the mass of the pyramid by adding the masses of the slabs.

The mass of a slab is its volume multiplied by the density δ. To compute the volume of a slab, we need to get an expression for the side s of the slab in terms of its height z. Using the similar triangles in Figure 8.82, we see that

$$\frac{s}{40} = \frac{(10-z)}{10}.$$

Thus $s = 4(10-z)$. Since the area of the square slab's face is s^2,

$$\text{Volume of the slab } \approx A_z(z)\Delta z = s^2\Delta z = 16(10-z)^2\Delta z.$$

$$\text{Mass of slab } = 16\delta(10-z)^2\Delta z.$$

The mass of the pyramid can be found by summing all of the masses of the slabs, and letting the thickness Δz approach zero:

$$\text{Total mass } = \lim_{\Delta z\to 0}\sum 16\delta(10-z)^2\Delta z = \int_0^{10} 16\delta(10-z)^2\,dz = \frac{-16\delta(10-z)^3}{3}\Bigg|_0^{10} = \frac{16000\delta}{3}\text{gm.}$$

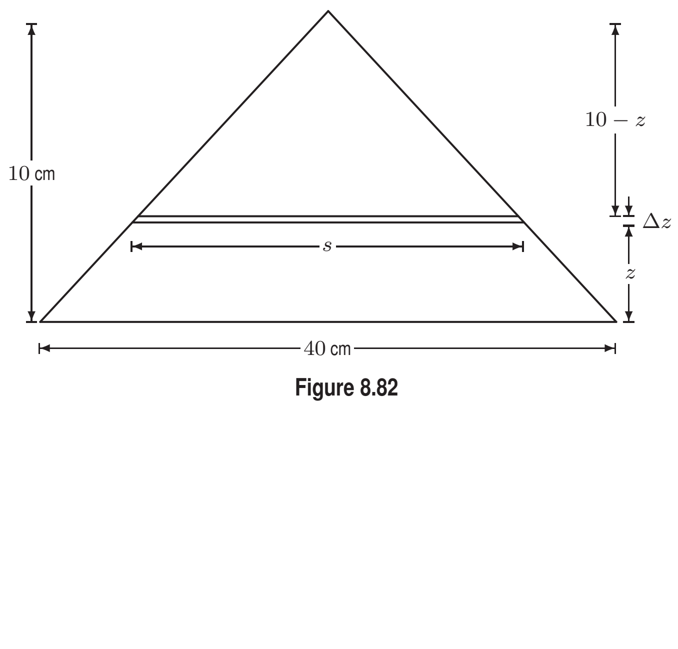

Figure 8.82

(b) From symmetry, we have $\bar{x} = \bar{y} = 0$. Since the pyramid is fatter near its base we expect the center of mass to be nearer to the base. Since

$$\text{Volume of slab } = A_z(z)\Delta z = 16(10-z)^2\Delta z,$$

$$\overline{z} = \frac{\int_0^{10} z \cdot 16\delta(10-z)^2\,dz}{\text{Total mass}}.$$

To evaluate the integral in the numerator, we factor out the constant 16δ and expand the integrand to get

$$16\delta \int_0^{10} (100z - 20z^2 + z^3)\,dz = 16\delta \left(50z^2 + \frac{-20z^3}{3} + \frac{z^4}{4}\right)\Bigg|_0^{10} = \frac{40000\delta}{3}.$$

We divide this result by the total mass $16000\delta/3$ of the pyramid

$$\overline{z} = \frac{40000\delta/3}{16000\delta/3} = \frac{40000}{16000} = 2.5\,\text{cm}.$$

As predicted, the center of mass is closer to the base of the pyramid than its top.

Strengthen Your Understanding

35. Mass density can never be negative, but $f(x) < 0$ for $0 < x < 5$.

36. The center of mass with density $\delta(x)$ for $0 \le x \le 10$ is given by

$$\text{Center of mass} = \frac{\int_0^{10} x\delta(x)\,dx}{\int_0^{10} \delta(x)\,dx}.$$

The correct formula for $\delta(x) = x^2$ is

$$\text{Center of mass} = \frac{\int_0^{10} x^3\,dx}{\int_0^{10} x^2\,dx}.$$

37. Any density function that is symmetric about the center of the rod will also give a center of mass in the center of the rod. For example, if a rod has ends at $x = -1$ and $x = 1$ and density $\delta(x) = x^2$ then its center of mass is at the origin.

38. When the density is constant, for example, if $\delta(r) = 3$ everywhere on the disk, the mass of the disk is the density times the area of the disk, or $3 \cdot 9\pi = 27\pi$ gm. Since the density is not constant and is less than 3 everywhere except at the center of the disk, the mass of the disk must be less than 27π gm.

39. Let the rod be the interval $0 \le x \le 10$. Suppose the density is given by

$$\delta(x) = \begin{cases} 5, & 0 \le x \le 1 \\ 1, & 1 < x < 5 \\ 4, & 5 \le x \le 10 \end{cases}.$$

The rod is denser at the end $x = 0$ than at the end $x = 10$.
We have

$$\int_0^{10} x\delta(x)\,dx = \int_0^1 5x\,dx + \int_1^5 x\,dx + \int_5^{10} 4x\,dx = 2.5 + 12 + 150 = 164.5$$
$$\int_0^{10} \delta(x)\,dx = \int_0^1 5\,dx + \int_1^5 1\,dx + \int_5^{10} 4\,dx = 5 + 4 + 20 = 29.$$

Therefore

$$\text{Center of Mass} = \frac{\int_0^{10} x\delta(x)\,dx}{\int_0^{10} \delta(x)\,dx} = \frac{164.5}{29} = 5.672.$$

The center of mass at $x = 5.672$ is nearer to the end $x = 10$ than to the end $x = 0$.

40. Any rod whose mass increases towards one end will skew the center of mass towards that end. As an example, if $\delta(x) = x$, then the total mass of the rod is

$$\text{Mass} = \int_0^2 x\,dx = 2$$

and the center of mass is

$$\text{Center of mass} = \frac{1}{2}\int_0^2 x \cdot \delta(x)\,dx = \frac{1}{2} \cdot \frac{x^3}{3}\bigg|_0^2 = \frac{4}{3}\text{ cm}$$

which is not at the center of the rod.

41. Taking a constant density $\delta(x) = 1$ gives the desired result, since then the center of mass is

$$\text{Center of mass} = \frac{\int_0^2 x \cdot \delta(x)\,dx}{\int_0^2 \delta(x)\,dx} = \frac{2}{2} = 1\text{ cm.}$$

42. False. The population density needs to be approximately constant on each ring. This is only true if the population density is a function of r, the distance from the center of the city.

43. False. Since the density varies with y, the region must be sliced perpendicular to the y-axis, along the lines of constant y.

44. False. Although the density is greater near the center, the area of the suburbs is much larger than the area of the inner city, and population is determined by both area and density. In fact, the population of the inner city:

$$\int_0^1 (10 - 3r)2\pi r\,dr = 2\pi(5r^2 - r^3)\bigg|_0^1 = 8\pi$$

is less than the population of the suburbs:

$$\int_1^2 (10 - 3r)2\pi r\,dr = 2\pi(5r^2 - r^3)\bigg|_1^2 = 16\pi.$$

45. True. One way to look at it is that the center of mass should not change if you change the units by which you measure the masses. If you double the masses, that is no different than using as a new unit of mass half the old unit. Alternatively, let the masses be m_1, m_2, and m_3 located at x_1, x_2, and x_3. Then the center of mass is given by:

$$\bar{x} = \frac{x_1m_1 + x_2m_2 + x_3m_3}{m_1 + m_2 + m_3}.$$

Doubling the masses does not change the center of mass, since it doubles both the numerator and the denominator.

46. False. The center of mass of a circular ring (for example, a coin with a hole in it) is at the center.

47. True. The density of particles hitting the target is approximately constant on concentric rings.

48. False. If the density were constant this would be true, but suppose that all the mass on the left half is concentrated at $x = 0$ and all the mass on the right side is concentrated at $x = 3$. In order for the rod to balance at $x = 2$, the weight on the left side must be half the weight on the right side.

Solutions for Section 8.5

Exercises

1. This is in British units, so the distance raised, d, is first converted to feet: $d = 0.75.$ feet.

$$\text{Work done } = F \cdot d = 40\text{ lb } \cdot 0.75\text{ ft } = 30\text{ ft-lb.}$$

2. This is in International units, so the distance raised, d, is first converted to meters: $d = 0.3$ m. The force due to gravity is $mg = (20\text{ kg})(g\text{ m/sec}^2)$, so

$$W = F \cdot d = [(20\text{ kg})(9.8\text{ m/sec}^2)] \cdot (0.3\text{ m}) = 58.8\text{ joules.}$$

3. Because the force is a function $F(x)$ of position x, then in moving from $x = a$ to $x = b$,

$$\text{Work done } = \int_a^b F(x)\,dx.$$

In this case

$$\text{Work done } = \int_0^1 x^2 + 2x\,dx = \frac{1}{3}x^3 + x^2\Big|_0^1 = 1.333 \text{ ft-lb.}$$

4. The work done is given by

$$W = \int_1^2 3x\,dx = \frac{3}{2}x^2\Big|_1^2 = \frac{9}{2} \text{ joules.}$$

5. The work done is given by

$$W = \int_0^3 3x\,dx = \frac{3}{2}x^2\Big|_0^3 = \frac{27}{2} \text{ joules.}$$

6. (a) For compression from $x = 0$ to $x = 1$,

$$\text{Work } = \int_0^1 3x\,dx = \frac{3}{2}x^2\Big|_0^1 = \frac{3}{2} = 1.5 \text{ joules.}$$

For compression from $x = 4$ to $x = 5$,

$$\text{Work } = \int_4^5 3x\,dx = \frac{3}{2}x^2\Big|_4^5 = \frac{3}{2}(25 - 16) = \frac{27}{2} = 13.5 \text{ joules.}$$

(b) The second answer is larger. Since the force increases with x, for a given displacement, the work done is larger for larger x values. Thus, we expect more work to be done in moving from $x = 4$ to $x = 5$ than from $x = 0$ to $x = 1$.

7. Since all parts of the plate are at the same depth, the force is constant on all parts of the plate. The force is the pressure, $62.4 \cdot 150$ lb/ft^2 multiplied by the area of the plate, 400π ft^2, so

$$\text{Force} = 1.176 \cdot 10^7 \text{pounds.}$$

8. Because the bottom of the fish tank is horizontal, the pressure is the same at every point on the bottom, so

$$\text{Pressure } = 62.4 \text{ lb/ft}^3 \cdot 1 \text{ ft } = 62.4 \text{ lb/ft}^2.$$

and

$$\text{Force } = \text{Pressure} \cdot \text{Area} = 62.4 \text{ lb/ft}^2 \cdot 2 \text{ ft} \cdot 1 \text{ ft} = 124.8 \text{ pounds.}$$

9. The only work is done by lifting the bucket initially, since the motion is parallel to the force of gravity, so the work is $2 \cdot 10 = 20$ ft-lb. When the child is walking and holding the bucket at a constant height, the force of gravity and the motion are at right angles, and the work done is zero. Thus, the total work done is 20 ft-lb.

10. Since the gravitational force is

$$F = \frac{4 \cdot 10^{14}}{r^2} \text{ newtons}$$

and r varies between $6.4 \cdot 10^6$ and $7.4 \cdot 10^6$ meters,

$$\begin{aligned}\text{Work done } &= \int_{6.4\cdot 10^6}^{7.4\cdot 10^6} \frac{4 \cdot 10^{14}}{r^2}\,dr = -4.10^{14}\frac{1}{r}\Big|_{6.4\cdot 10^6}^{7.4\cdot 10^6} \\ &= 4 \cdot 10^{14}\left(\frac{1}{6.4 \cdot 10^6} - \frac{1}{7.4 \cdot 10^6}\right) = 8.4 \cdot 10^6 \text{ joules.}\end{aligned}$$

Problems

11. The force exerted on the satellite by the earth (and vice versa!) is GMm/r^2, where r is the distance from the center of the earth to the center of the satellite, m is the mass of the satellite, M is the mass of the earth, and G is the gravitational constant. So the total work done is

$$\int_{6.4\cdot 10^6}^{8.4\cdot 10^6} F\,dr = \int_{6.4\cdot 10^6}^{8.4\cdot 10^6} \frac{GMm}{r^2}\,dr = \left(\frac{-GMm}{r}\right)\Bigg|_{6.4\cdot 10^6}^{8.4\cdot 10^6} \approx 1.489\cdot 10^{10} \text{ joules.}$$

12. Let x be the distance from ground to the bucket of cement. At height x, if the bucket is lifted by Δx, the work done is $500\Delta x + 0.5(75-x)\Delta x$. See Figure 8.83. The $500\Delta x$ term is due to the bucket of cement; the $0.5(75-x)\Delta x$ term is due to the remaining cable. So the total work, W, required to lift the bucket is

$$\begin{aligned} W &= \int_0^{30} 500dx + \int_0^{30} 0.5(75-x)dx \\ &= 500\cdot 30 + 0.5(75\cdot 30 - \frac{1}{2}30^2) \\ &= 15{,}900 \text{ ft-lb.} \end{aligned}$$

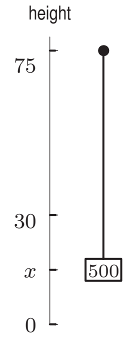

Figure 8.83

13. When the anchor has been lifted through h feet, the length of chain in the water is $25-h$ feet, so the total weight of the anchor and chain in the water is $50+3(25-h)$ lb. Then

$$\begin{aligned} \text{Work to lift the anchor and chain } \Delta h \text{ higher} &= \text{Weight}\cdot\text{Distance lifted} \\ &= (100+3(25-h))\Delta h. \end{aligned}$$

To find the total work, we integrate from $h=0$ to $h=25$:

$$W = \int_0^{25} (100+3(25-h))dh = \int_0^{25} (175-3h)dh = \left(175h - \frac{3h^2}{2}\right)\Bigg|_0^{25} = 3437.5\text{ft-lbs.}$$

14. To lift the weight an additional height Δh off the ground from a height of h, we must do work on the weight and the amount of rope not yet pulled onto the roof. Since the roof is 30 ft off the ground, there will be $30-h$ feet remaining of rope, for a weight of $4(30-h)$. So the work required to raise the weight and the rope a height Δh will be $\Delta h(1000+4(30-h))$. To find the total work, we integrate this quantity from $h=0$ to $h=10$:

$$\begin{aligned} \text{Work} &= \int_0^{10} (1000+4(30-h))\,dh \\ &= \int_0^{10} (1120-4h)\,dh \\ &= (1120h-2h^2)\Big|_0^{10} \\ &= 11{,}200-200 \\ &= 11{,}000 \text{ ft-lbs.} \end{aligned}$$

15. The bucket moves upward at $40/10 = 4$ meters/minute. If time is in minutes, at time t the bucket is at a height of $x = 4t$ meters above the ground. See Figure 8.84.

The water drips out at a rate of $5/10 = 0.5$ kg/minute. Initially there is 20 kg of water in the bucket, so at time t minutes, the mass of water remaining is

$$m = 20 - 0.5t \text{ kg.}$$

Consider the time interval between t and $t+\Delta t$. During this time the bucket moves a distance $\Delta x = 4\Delta t$ meters. So, during this interval,

$$\text{Work done} \approx mg\Delta x = (20 - 0.5t)g4\Delta t \text{ joules.}$$

$$\text{Total work done} = \lim_{\Delta t \to 0} \sum (20 - 0.5t)g4\Delta t = 4g\int_0^{10} (20 - 0.5t)\,dt$$
$$= 4g(20t - 0.25t^2)\Big|_0^{10} = 700g = 700(9.8) = 6860 \text{ joules.}$$

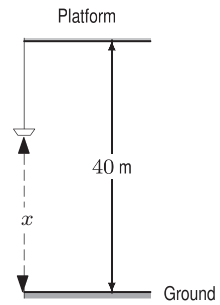

Figure 8.84

16. Let x be the height (in feet) from ground to the cube of ice. It follows that $0 \le x \le 100$. At height x, the ice cube w weighs $2000 - 4x$ since it's being lifted at a rate 1 ft./min. and it's melting at a rate of 4 lb/min. To lift it Δx more the work required is $(2000 - 4x)\Delta x$. So the total work done is

$$\begin{aligned} W &= \int_0^{100} (2000 - 4x)dx \\ &= \left(2000x - 2x^2\right)\Big|_0^{100} \\ &= 2000(100) - 2\cdot(100)^2 \\ &= 180{,}000 \quad \text{ft-lb.} \end{aligned}$$

17. Let y represent depth below the surface of the can. Slice the water in the can horizontally into cylinders of height Δy and radius 1. See Figure 8.85. To find the weight of such a slice, we multiply its volume by its weight per cubic foot: we obtain

$$\text{Weight} = \pi 1^2(\Delta y)(62.4) \approx 196.04\,\Delta y.$$

So the work required to lift a slice at depth y to the surface is $196.04y\,\Delta y$.

To find the total work required to empty the can, we integrate:

$$\text{Total Work} \approx \int_1^3 196.04y\,dy = 196.04\frac{y^2}{2}\Big|_1^3 \approx 784.14 \text{ ft-lb.}$$

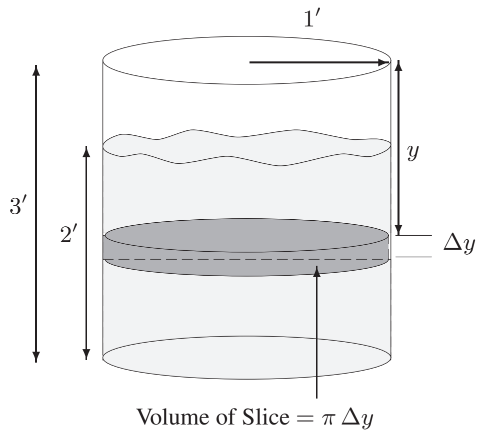

Figure 8.85

18. We slice the water horizontally and find the work required to pump each horizontal slice of water over the top. See Figure 8.86. At a distance h ft above the bottom, a slice of thickness Δh has

$$\text{Volume } \approx 50 \cdot 20\Delta h \text{ ft}^3.$$

Since the density of water is ρ lb/ft^3,

$$\text{Weight of the slice } \approx \rho(50 \cdot 20 \cdot \Delta h) \text{ lbs.}$$

The distance to lift the slice of water at height h ft is $10 - h$ ft, so

$$\begin{aligned}\text{Work to move one slice} &= \rho \cdot \text{Volume} \cdot \text{Distance lifted}\\ &\approx \rho(50 \cdot 20 \cdot \Delta h)(10-h)\\ &= 100\rho(10-h)\Delta h \text{ ft-lb.}\end{aligned}$$

The work done, W, to pump all the water is the sum of the work done on the pieces:

$$W \approx \sum 100\rho(10-h)\Delta h.$$

As $\Delta h \to 0$, we obtain a definite integral. Since h varies from $h = 0$ to $h = 9$ and $\rho = 62.4$ lb/ft^3, the total work is:

$$W = \int_0^9 100\rho(10-h)dh = 62400\left(10h - \frac{h^2}{2}\right)\Bigg|_0^9 = 62400(49.5) = 3{,}088{,}800.$$

The work to pump all the water out is $3{,}088{,}800$ ft-lbs.

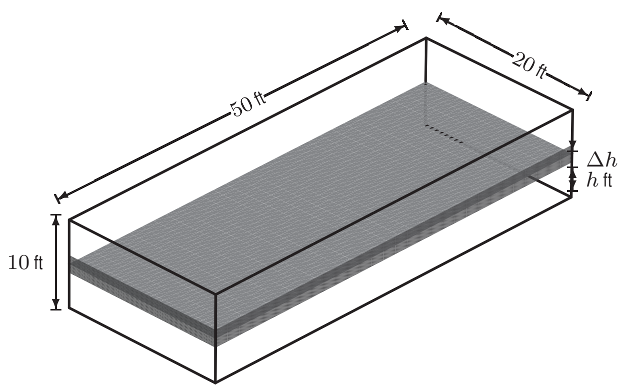

Figure 8.86

19. Let x be the distance measured from the bottom the tank. See Figure 8.87. To pump a layer of water of thickness Δx at x feet from the bottom, the work needed is

$$(62.4)\pi 6^2(20-x)\Delta x.$$

Therefore, the total work is

$$\begin{aligned} W &= \int_0^{10} 36\cdot(62.4)\pi(20-x)dx \\ &= 36\cdot(62.4)\pi(20x-\frac{1}{2}x^2)\Big|_0^{10} \\ &= 36\cdot(62.4)\pi(200-50) \\ &\approx 1{,}058{,}591.1 \text{ ft-lb.} \end{aligned}$$

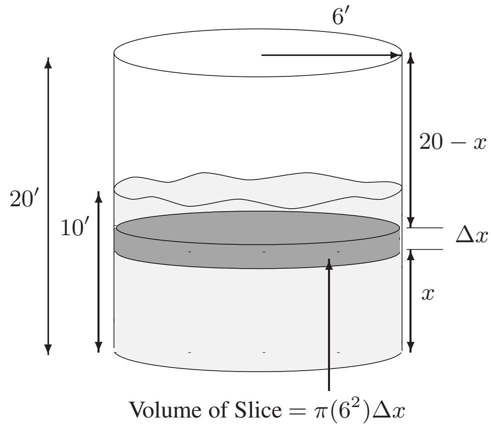

Figure 8.87

20. Let x be the distance from the bottom of the tank. See Figure 8.88. To pump a layer of water of thickness Δx at x feet from the bottom to 10 feet above the tank, the work done is $(62.4)\pi 6^2(30-x)\Delta x$. Thus the total work is

$$\begin{aligned} &\int_0^{20} 36\cdot(62.4)\pi(30-x)dx \\ &= 36\cdot(62.4)\pi\left(30x-\frac{1}{2}x^2\right)\Big|_0^{20} \\ &= 36\cdot(62.4)\pi(30(20)-\frac{1}{2}20^2) \\ &\approx 2{,}822{,}909.50 \text{ ft-lb.} \end{aligned}$$

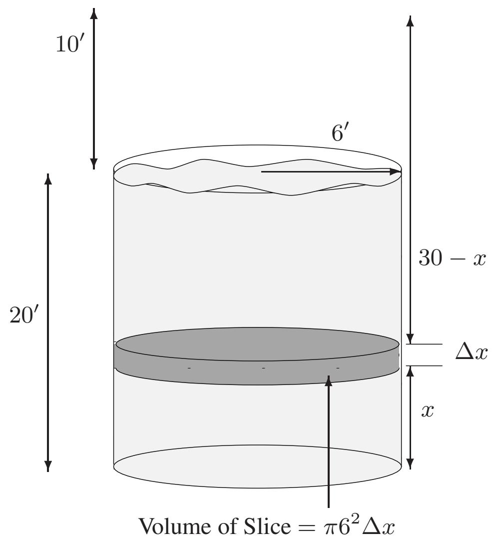

Figure 8.88

21. (a) We slice the water horizontally. Each slice is a cylindrical slab of radius 4 and thickness Δh, so

$$\text{Volume of each slab } \approx \pi 4^2\Delta h \text{ ft}^3.$$

See Figure 8.89. The density of water is δ lb/ft^3, so

$$\text{Weight of slab } \approx \delta\pi 4^2\Delta h \text{ lb.}$$

Water at a height of h ft must be lifted a distance of $10-h$ ft.

$$\begin{aligned} \text{Work to move one slice} &= \delta\cdot\text{Volume}\cdot\text{Distance lifted} \\ &\approx \delta(\pi(4)^2\Delta h)(10-h) \text{ ft-lb.} \end{aligned}$$

Since the density of water is $\delta = 62.4$ lb/ft^3 and since h varies from $h=0$ to $h=10$, the total work, W, is:

$$W = \int_0^{10}\delta(\pi 4^2)(10-h)dh = 16\delta\pi\int_0^{10}(10-h)dh = 998.4\pi\left(10h-\frac{h^2}{2}\right)\Big|_0^{10} = 156{,}828 \text{ ft-lb.}$$

The total work required is 156,828 ft-lbs.

(b) This is the same as part (a) except the water must be lifted a distance of $15 - h$ ft. The total work is:

$$W = \int_0^{10} \delta(\pi 4^2)(15-h)dh = 16\delta\pi \int_0^{10} (15-h)dh = 998.4\pi \left(15h - \frac{h^2}{2}\right)\Bigg|_0^{10} = 313{,}656 \text{ ft-lb.}$$

The total work required is 313,656 ft-lbs.

(c) This is the same as part (a) except that h varies from $h = 0$ to $h = 8$. The total work is:

$$W = \int_0^{8} \delta(\pi 4^2)(10-h)dh = 16\delta\pi \int_0^{8} (10-h)dh = 998.4\pi \left(10h - \frac{h^2}{2}\right)\Bigg|_0^{8} = 150{,}555.$$

The total work required is 150,555 ft-lbs.

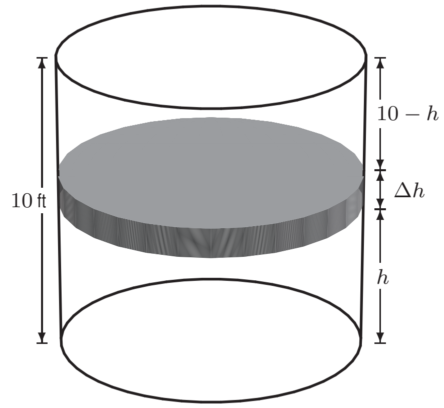

Figure 8.89

22.

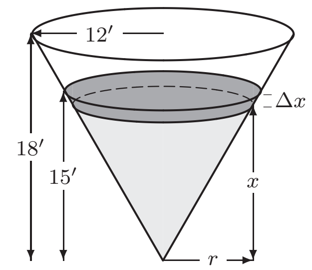

Figure 8.90

Let x be the depth of the water measured from the bottom of the tank. See Figure 8.90. It follows that $0 \le x \le 15$. Let r be the radius of the section of the cone with height x. By similar triangles, $\frac{r}{x} = \frac{12}{18}$, so $r = \frac{2}{3}x$. Then the work required to pump a layer of water with thickness of Δx at depth x over the top of the tank is $62.4\pi \left(\frac{2}{3}x\right)^2 \Delta x(18 - x)$. So the total work done by pumping the water over the top of the tank is

$$\begin{aligned} W &= \int_0^{15} 62.4\pi \left(\frac{2}{3}x\right)^2 (18-x)dx \\ &= \frac{4}{9}\, 62.4\pi \int_0^{15} x^2(18-x)dx \\ &= \frac{4}{9}\, 62.4\pi \left(6x^3 - \frac{1}{4}x^4\right)\Bigg|_0^{15} \\ &= \frac{4}{9}\, 62.4\pi(7593.75) \approx 661{,}619.41 \text{ ft-lb.} \end{aligned}$$

23. We slice the water horizontally as in Figure 8.91. We use similar triangles to find the radius r of the slice at height h in terms of h:

$$\frac{r}{h} = \frac{4}{12} \quad \text{so} \quad r = \frac{1}{3}h.$$

At height h,

$$\text{Volume of slice} \approx \pi r^2 \Delta h = \pi \left(\frac{1}{3}h\right)^2 \Delta h \text{ ft}^3.$$

The density of water is δ lb/ft^3, so

$$\text{Weight of slice } \approx \delta\pi \left(\frac{1}{3}h\right)^3 \Delta h \text{ lb}.$$

The water at height h must be lifted a distance of $12 - h$ ft, so

$$\begin{aligned}\text{Work to move slice} &= \delta \cdot \text{Volume} \cdot \text{Distance lifted}\\ &\approx \delta \left(\pi \left(\frac{1}{3}h\right)^2 \Delta h\right)(12-h) \text{ ft-lb}.\end{aligned}$$

The work done, W, to lift all the water is the sum of the work done on the pieces:

$$W \approx \sum \delta\pi(\frac{1}{3}h)^2 \Delta h(12-h) \text{ ft-lb}.$$

As $\Delta h \to 0$, we obtain a definite integral. Since h varies from $h = 0$ to $h = 9$, and $\delta = 62.4$, we have:

$$W = \int_0^9 \delta\pi(\frac{1}{3}h)^2(12-h)dh = \frac{62.4\pi}{9}\int_0^9 (12h^2 - h^3)dh = \frac{62.4\pi}{9}\left(4h^3 - \frac{h^4}{4}\right)\Bigg|_0^9 = 27{,}788 \text{ ft-lb}.$$

The work to pump all the water out is 27,788 ft-lbs.

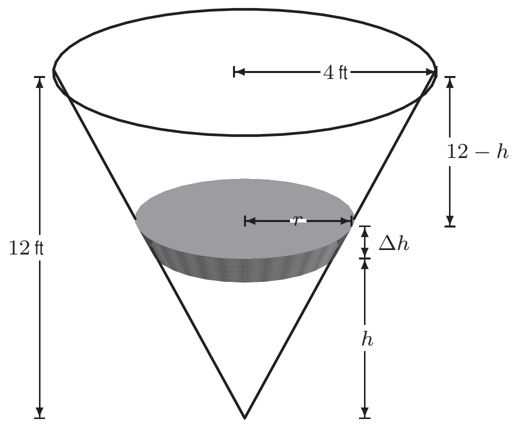

Figure 8.91

24. Let h represent distance below the surface in feet. We slice the tank up into horizontal slabs of thickness Δh. From looking at Figure 8.92, we can see that the slabs will be rectangular. The length of any slab is 12 feet. The width w of a slab h units below the ground will equal $2x$, where $(14-h)^2 + x^2 = 16$, so $w = 2\sqrt{4^2 - (14-h)^2}$. The volume of such a slab is therefore $12w\,\Delta h = 24\sqrt{16-(14-h)^2}\,\Delta h$ cubic feet; the slab weighs $42 \cdot 24\sqrt{16-(14-h)^2}\,\Delta h = 1008\sqrt{16-(14-h)^2}\,\Delta h$ pounds. So the total work done in pumping out all the gasoline is

$$\int_{10}^{18} 1008h\sqrt{16-(14-h)^2}\,dh = 1008\int_{10}^{18} h\sqrt{16-(14-h)^2}\,dh.$$

Substitute $s = 14 - h$, $ds = -dh$. We get

$$1008\int_{10}^{18} h\sqrt{16-(14-h)^2}\,dh = -1008\int_4^{-4} (14-s)\sqrt{16-s^2}\,ds$$

$$= 1008 \cdot 14 \int_{-4}^{4} \sqrt{16 - s^2}\, ds - 1008 \int_{-4}^{4} s\sqrt{16 - s^2}\, ds.$$

The first integral represents the area of a semicircle of radius 4, which is 8π. The second is the integral of an odd function, over the interval $-4 \le s \le 4$, and is therefore 0. Hence, the total work is $1008 \cdot 14 \cdot 8\pi \approx 354{,}673$ foot-pounds.

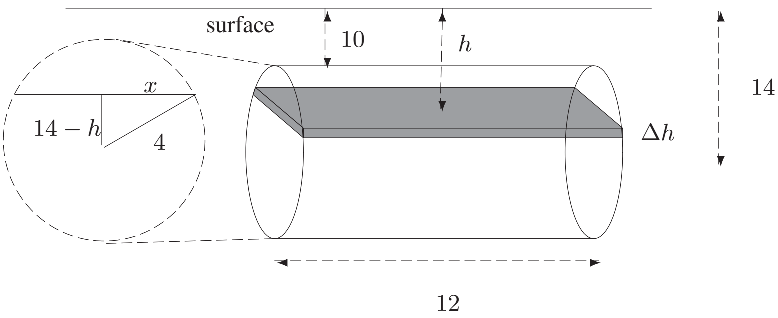

Figure 8.92

25. Divide the muddy water into horizontal slabs of thickness Δh. See Figure 8.93. Then for a typical slab

$$\text{Volume of slab} = \pi(0.5)^2 \Delta h \text{ m}^3$$
$$\text{Mass of slab} \approx \delta(h)\pi(0.5)^2 \Delta h = 0.25\pi(1 + kh)\Delta h \text{ kg}$$

The water in this slab is moved a distance of $h + 0.3$ meters to the rim of the barrel. Now

$$\text{Work done} = \text{Mass} \cdot g \cdot \text{Distance moved},$$

and work is measured in newtons if mass is in kilograms and distance is in meters, so

$$\text{Work done in moving slab} \approx 0.25\pi(1 + kh)g(h + 0.3)\Delta h \text{ joules}.$$

Since the slices run from $h = 0$ to $h = 1.5$, we have

$$\text{Total work done} = \int_0^{1.5} 0.25\pi(1 + kh)g(h + 0.3)\, dh$$
$$= 0.366(k + 1.077)g\pi \text{ joules}$$

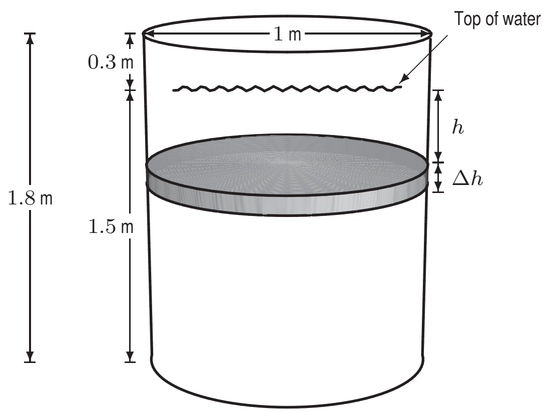

Figure 8.93

26. (a) We divide the triangular end into horizontal strips of thickness Δh. The length of a strip, s, depends on its height h from the bottom. See Figure 8.94. We use similar triangles to see that

$$\frac{s}{h} = \frac{2}{3} \quad \text{so} \quad s = \frac{2}{3}h.$$

Since each strip is approximately a rectangle, at height h,

$$\text{Area of strip } \approx \frac{2}{3}h\Delta h \text{ ft}^2.$$

Since the depth at height h is $3 - h$, writing δ for the density of water, we have:

$$\begin{aligned}\text{Force on one strip} &= \delta \cdot \text{Depth} \cdot \text{Area}\\ &\approx \delta(3-h)\left(\frac{2}{3}h\Delta h\right) \text{ lb.}\end{aligned}$$

To find the total force, F, we integrate the force on a strip from $h = 0$ to $h = 3$, using $\delta = 62.4$ lb/ft^3:

$$F = \int_0^3 \delta(3-h)\frac{2}{3}h dh = \frac{2}{3}\delta\int_0^3 (3h - h^2)dh = \frac{2}{3}62.4\left(\frac{3h^2}{2} - \frac{h^3}{3}\right)\Bigg|_0^3 = 187.2 \text{ lbs.}$$

(b) To find the work, we slice the water horizontally. Each slice is a rectangular slab with thickness Δh, length 15 ft, and width s as in Figure 8.95. As we saw in part (a), at a height of h we have $s = \frac{2}{3}h$. At height h,

$$\text{Volume of slab } \approx 15\left(\frac{2}{3}h\right)\Delta h \text{ ft}^3.$$

The distance to lift the slice at height h is $3 - h$, so if δ is the density of water, we have:

$$\begin{aligned}\text{Work to lift one slice} &= \delta \cdot \text{Volume} \cdot \text{Distance lifted}\\ &\approx \delta(15(\frac{2}{3}h)\Delta h)(3-h) \text{ ft-lb.}\end{aligned}$$

To find the total work, W, we integrate the work to lift a slice from $h = 0$ to $h = 3$, using $\delta = 62.4$ lb/ft^3.

$$W = \int_0^3 \delta 15\left(\frac{2}{3}h\right)(3-h)\,dh = 10\delta\int_0^3 (3h - h^2)dh = 10 \cdot 62.4\left(\frac{3h^2}{2} - \frac{h^3}{3}\right)\Bigg|_0^3 = 10\delta(4.5) = 2808 \text{ ft-lbs.}$$

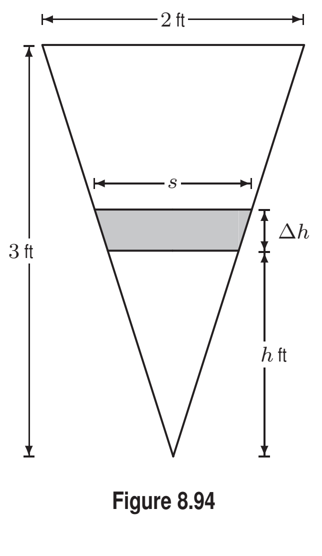

Figure 8.94

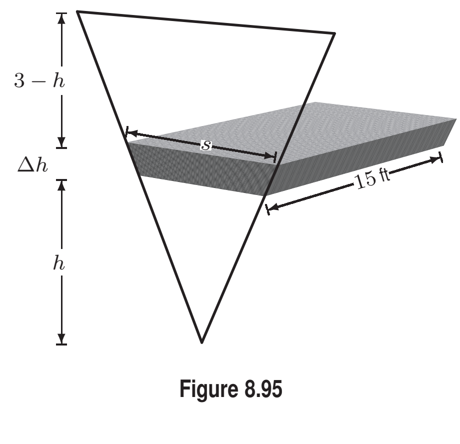

Figure 8.95

27. (a) Divide the wall into horizontal strips, each of height Δh. See Figure 8.96. The area of each strip is $1000\Delta h$, and the pressure at depth h is $62.4h$, so

$$\text{Force on strip } \approx 1000(62.4h)\Delta h$$
$$\text{Force on dam } \approx \sum 1000(62.4h)\Delta h.$$

(b) The force on the dam is given by the integral

$$\text{Force on dam } = \int_0^{50} 1000(62.4h)\,dh = 62400\frac{h^2}{2}\bigg|_0^{50} = 78{,}000{,}000 \text{ pounds.}$$

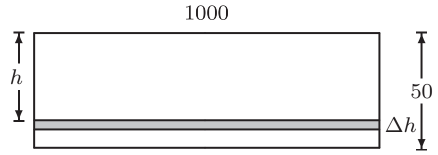

Figure 8.96

28. See Figure 8.97.

For the bottom: The bottom of the tank is at constant depth 15 feet, and therefore is under constant pressure, $15 \cdot 62.4 = 936$ lb/ft^2. The area of the base is 200 ft^2, so

$$\text{Total force on bottom } = 200 \text{ ft}^2 \cdot 936 \text{ lb/ft}^2 = 187200 \text{ lb.}$$

For the 15×10 side: The area of a horizontal strip of width dh is $10\,dh$ square feet, and the pressure at height h is $62.4h$ pounds per square foot. Therefore, the force on such a strip is $62.4h(10\,dh)$ pounds. Hence,

$$\text{Total force on the } 15 \times 10 \text{ side } = \int_0^{15} (62.4h)(10)\,dh = 624\frac{h^2}{2}\bigg|_0^{15} = 70200 \text{ lbs.}$$

For the 15×20 side: Similarly,

$$\text{Total force on the } 15 \times 20 \text{ side } = \int_0^{15} (62.4h)(20)\,dh = 1248\frac{h^2}{2}\bigg|_0^{15} = 140400 \text{ lbs.}$$

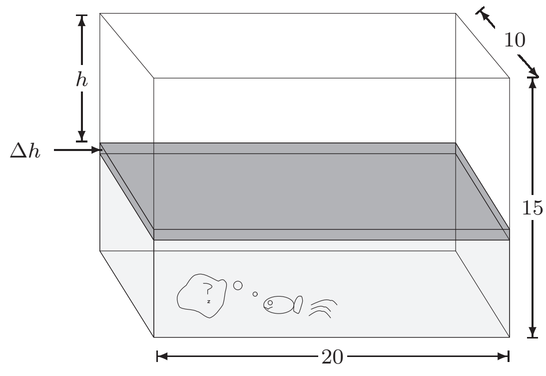

Figure 8.97

29. We divide the water against the dam into horizontal strips, each of thickness Δh and length 100.

$$\text{Area of each strip } \approx 100\Delta h \text{ ft}^2.$$

See Figure 8.98. The strip at height h ft from the bottom is at a water depth of $40-h$, so, if δ lb/ft^3 is the density of water, we have:

$$\begin{aligned}\text{Force of one strip} &= \delta \cdot \text{Depth} \cdot \text{Area}\\ &\approx \delta(40-h)(100\Delta h) \text{ lb.}\end{aligned}$$

To find the total force, F, we integrate the force on a strip from $h=0$ to $h=40$, using $\delta = 62.4$ lb/ft^3:

$$F = \int_0^{40} \delta(40-h)100dh = 100\cdot 62.4\left(40h - \frac{h^2}{2}\right)\Bigg|_0^{40} = 6240(800) = 4{,}992{,}000\text{lbs.}$$

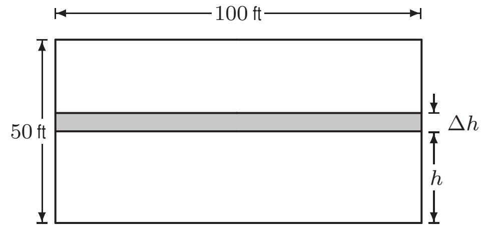

Figure 8.98

30. Bottom:

$$\text{Water force } = 62.4(2)(12) = 1497.6 \text{ lbs.}$$

Front and back:

$$\begin{aligned}\text{Water force } &= (62.4)(4)\int_0^2 (2-x)\,dx = (62.4)(4)(2x - \frac{1}{2}x^2)\Bigg|_0^2\\ &= (62.4)(4)(2) = 499.2 \text{ lbs.}\end{aligned}$$

Both sides:

$$\text{Water force} = (62.4)(3)\int_0^2 (2-x)\,dx = (62.4)(3)(2) = 374.4 \text{ lbs.}$$

31. (a) Since the density of water is $\delta = 1000$ kg/m^3, at the base of the dam, water pressure $\delta g h = 1000\cdot 9.8\cdot 180 = 1.76\cdot 10^6$ nt/m^2.

(b) To set up a definite integral giving the force, we divide the dam into horizontal strips. We use horizontal strips because the pressure along each strip is approximately constant, since each part is at approximately the same depth. See Figure 8.99.

$$\text{Area of strip } = 2000\Delta h \text{ m}^2.$$

Pressure at depth of h meters $= \delta g h = 9800h$ nt/m^2. Thus,

$$\text{Force on strip } \approx \text{ Pressure } \times \text{ Area } = 9800h\cdot 2000\Delta h = 1.96\cdot 10^7 h\Delta h \text{ nt.}$$

Summing over all strips and letting $\Delta h \to 0$ gives:

$$\text{Total force } = \lim_{\Delta h\to 0}\sum 1.96\cdot 10^7 h\Delta h = 1.96\cdot 10^7\int_0^{180} h\,dh \text{ newtons.}$$

Evaluating gives

$$\text{Total force } = 1.96\cdot 10^7 \frac{h^2}{2}\Bigg|_0^{180} = 3.2\cdot 10^{11} \text{ newtons.}$$

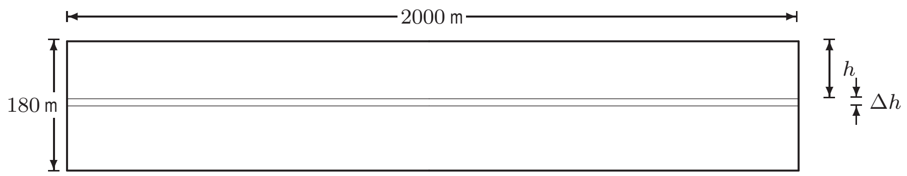

Figure 8.99

32. (a) At a depth of 350 feet,

$$\text{Pressure } = 62.4 \cdot 350 = 21{,}840 \text{ lb/ft}^2.$$

To imagine this pressure, we convert to pounds per square inch, giving a pressure of $21{,}840/144 = 151.7$ lb/in^2.

(b) (i) When the square is held horizontally, the pressure is constant at $21{,}840$ lbs/ft^2, so

$$\text{Force } = \text{ Pressure } \cdot \text{ Area } = 21{,}840 \cdot 5^2 = 546{,}000 \text{ pounds.}$$

(ii) When the square is held vertically, only the bottom is at 350 feet. Dividing into horizontal strips, as in Figure 8.100, we have

$$\text{Area of strip } = 5\Delta h \text{ ft}^2.$$

Since the pressure on a strip at a depth of h feet is $62.4h$ lb/ft^2,

$$\text{Force on strip } \approx 62.4h \cdot 5\Delta h = 312h\Delta h \text{ pounds.}$$

Summing over all strips and taking the limit as $\Delta h \to 0$ gives a definite integral. The strips vary between a depth of 350 feet and 345 feet, so

$$\text{Total force } = \lim_{\Delta h \to 0} \sum 312h\Delta h = \int_{345}^{350} 312h\, dh \text{ pounds.}$$

Evaluating gives

$$\text{Total force } = 312\frac{h^2}{2}\bigg|_{345}^{350} = 156(350^2 - 345^2) = 542{,}100 \text{ pounds.}$$

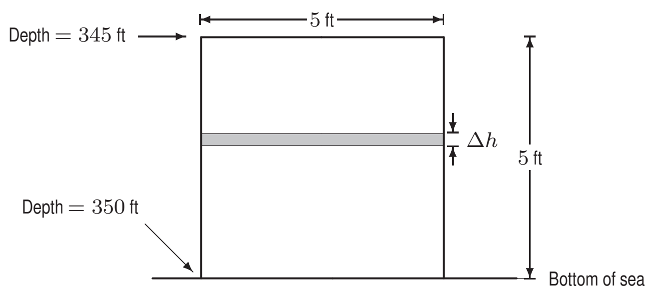

Figure 8.100

33. (a) Since water has density 62.4 lb/ft^3, at a depth of $12{,}500$ feet,

$$\text{Pressure } = \text{ Density } \times \text{ Depth } = 62.4 \cdot 12{,}500 = 780{,}000 \text{ lb/square foot.}$$

To imagine this pressure, observe that it is equivalent to $780{,}000/144 \approx 5400$ pounds per square inch.

(b) To calculate the pressure on the porthole (window), we slice it into horizontal strips, as the pressure remains approximately constant along each one. See Figure 8.101. Since each strip is approximately rectangular

$$\text{Area of strip } \approx 2r\Delta h \text{ ft}^2.$$

To calculate r in terms of h, we use the Pythagorean Theorem:

$$\begin{aligned} r^2 + h^2 &= 9 \\ r &= \sqrt{9 - h^2}, \end{aligned}$$

so

$$\text{Area of strip } \approx 2\sqrt{9 - h^2}\Delta h \text{ ft}^2.$$

The center of the porthole is at a depth of $12{,}500$ feet below the surface, so the strip shown in Figure 8.101 is at a depth of $(12{,}500 - h)$ feet. Thus, pressure on the strip is $62.4(12{,}500 - h)$ lb/ft^2, so

$$\begin{aligned} \text{Force on strip } = \text{ Pressure } \times \text{ Area } &\approx 62.4(12{,}500 - h)2\sqrt{9 - h^2}\Delta h \text{ lb} \\ &= 124.8(12{,}500 - h)\sqrt{9 - h^2}\Delta h \text{ lb.} \end{aligned}$$

To get the total force, we sum over all strips and take the limit as $\Delta h \to 0$. Since h ranges from -3 to 3, we get the integral

$$\begin{aligned}\text{Total force } &= \lim_{\Delta h\to 0}\sum 124.8(12{,}500-h)\sqrt{9-h^2}\Delta h\\ &= 124.8\int_{-3}^{3}(12{,}500-h)\sqrt{9-h^2}\,dh \text{ lb.}\end{aligned}$$

Evaluating the integral numerically, we obtain a total force of $2.2\cdot 10^7$ pounds.

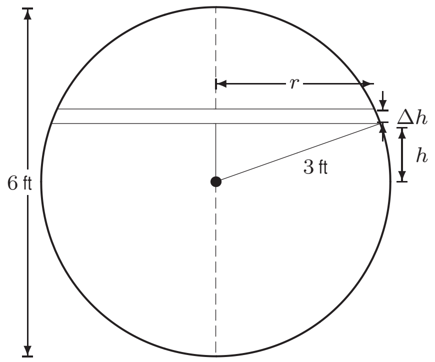

Figure 8.101: Center of circle is 12,500 ft below the surface of ocean

34. We divide the dam into horizontal strips since the pressure is then approximately constant on each one. See Figure 8.102.

$$\text{Area of strip } \approx w\Delta h \text{ m}^2.$$

Since w is a linear function of h, and $w = 3600$ when $h = 0$, and $w = 3000$ when $h = 100$, the function has slope $(3000 - 3600)/100 = -6$. Thus,

$$w = 3600 - 6h,$$

so

$$\text{Area of strip } \approx (3600-6h)\Delta h \text{ m}^2.$$

The density of water is $\delta = 1000$ kg/m^3, so the pressure at depth h meters $= \delta gh = 1000\cdot 9.8h = 9800h$ nt/m^2. Thus,

$$\text{Total force } = \lim_{\Delta h\to 0}\sum 9800h(3600-6h)\Delta h = 9800\int_0^{100} h(3600-6h)\,dh \text{ newtons.}$$

Evaluating the integral gives

$$\text{Total force } = 9800(1800h^2 - 2h^3)\Big|_0^{100} = 1.6\cdot 10^{11} \text{ newtons.}$$

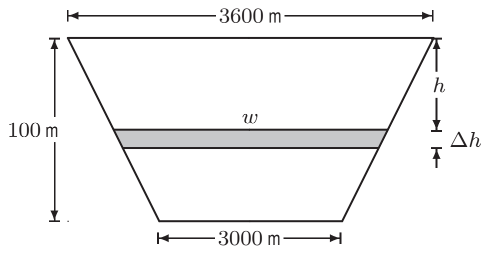

Figure 8.102

35. We need to divide the disk up into circular rings of charge and integrate their contributions to the potential (at P) from 0 to a. These rings, however, are not uniformly distant from the point P. A ring of radius z is $\sqrt{R^2+z^2}$ away from point P (see Figure 8.103).

The ring has area $2\pi z\,\Delta z$, and charge $2\pi z\sigma\,\Delta z$. The potential of the ring is then $\dfrac{2\pi z\sigma\,\Delta z}{\sqrt{R^2+z^2}}$ and the total potential at point P is

$$\int_0^a \frac{2\pi z\sigma\,dz}{\sqrt{R^2+z^2}} = \pi\sigma\int_0^a \frac{2z\,dz}{\sqrt{R^2+z^2}}.$$

We make the substitution $u=z^2$. Then $du=2z\,dz$. We obtain

$$\pi\sigma\int_0^a \frac{2z\,dz}{\sqrt{R^2+z^2}} = \pi\sigma\int_0^{a^2}\frac{du}{\sqrt{R^2+u}} = \pi\sigma(2\sqrt{R^2+u})\Big|_0^{a^2}$$
$$= \pi\sigma(2\sqrt{R^2+z^2})\Big|_0^a = 2\pi\sigma(\sqrt{R^2+a^2}-R).$$

(The substitution $u=R^2+z^2$ or $\sqrt{R^2+z^2}$ works also.)

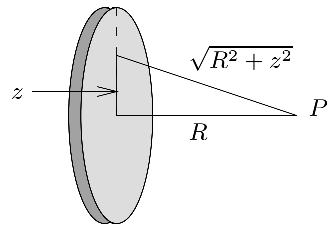

Figure 8.103

36. The density of the rod is $10\text{ kg}/6\text{ m} = \frac{5}{3}\frac{\text{kg}}{\text{m}}$. A little piece, dx m, of the rod thus has mass $5/3\,dx$ kg. If this piece has an angular velocity of 2 rad/sec, then its actual velocity is $2|x|$ m/sec. This is because a radian angle sweeps out an arc length equal to the radius of the circle, and in this case the little piece moves in circles about the origin of radius $|x|$. See Figure 8.104. The kinetic energy of the little piece is $mv^2/2 = (5/3\,dx)(2|x|)^2/2 = \frac{10}{3}x^2\,dx$.

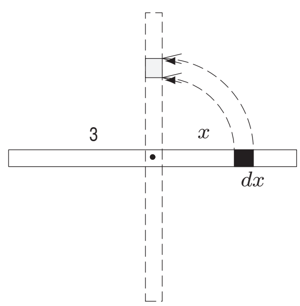

Figure 8.104

Therefore,

$$\text{Total Kinetic Energy} = \int_{-3}^{3}\frac{10x^2}{3}\,dx = \frac{20}{3}\left[\frac{x^3}{3}\right]\Big|_0^3 = 60\text{ kg}\cdot\text{m}^2/\text{sec}^2 = 60\text{ joules}.$$

37. We slice the record into rings in such a way that every point has approximately the same speed: use concentric circles around the hole. See Figure 8.105. We assume the record is a flat disk of uniform density: since its mass is 50 grams and its area is $\pi(10\text{cm})^2 = 100\pi\ \text{cm}^2$, the record has density $\frac{50}{100\pi} = \frac{1}{2\pi}\frac{\text{gram}}{\text{cm}^2}$. So a ring of width dr, having area about $2\pi r\, dr\ \text{cm}^2$, has mass approximately $(2\pi r\, dr)(1/2\pi) = r\, dr$ gm. At radius r, the velocity of the ring is

$$33\tfrac{1}{3}\,\frac{\text{rev}}{\text{min}}\cdot\frac{1\ \text{min}}{60\ \text{sec}}\cdot\frac{2\pi r\ \text{cm}}{1\ \text{rev}} = \frac{10\pi r}{9}\,\frac{\text{cm}}{\text{sec}}.$$

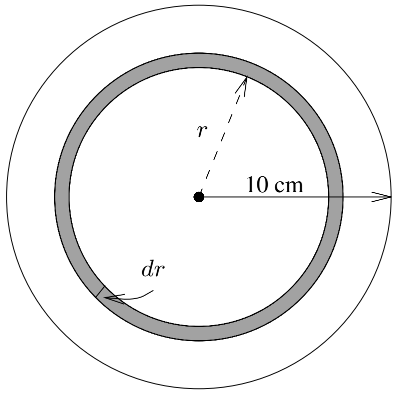

Figure 8.105

The kinetic energy of the ring is

$$\frac{1}{2}mv^2 = \frac{1}{2}(r\, dr\ \text{grams})\left(\frac{10\pi r}{9}\,\frac{\text{cm}}{\text{sec}}\right)^2 = \frac{50\pi^2 r^3\, dr}{81}\,\frac{\text{gram}\cdot\text{cm}^2}{\text{sec}^2}.$$

So the kinetic energy of the record, summing the energies of all these rings, is

$$\int_0^{10}\frac{50\pi^2 r^3\, dr}{81} = \left.\frac{25\pi^2 r^4}{162}\right|_0^{10} \approx 15231\,\frac{\text{gram}\cdot\text{cm}^2}{\text{sec}^2} = 15231\ \text{ergs}.$$

38. The density of the rod, in mass per unit length, is M/l (see Figure 8.106). So a slice of size dr has mass $\frac{M\, dr}{l}$. It pulls the small mass m with force $Gm\frac{M\, dr}{l}/r^2 = \frac{GmM\, dr}{lr^2}$. So the total gravitational attraction between the rod and point is

$$\begin{aligned}\int_a^{a+l}\frac{GmM\, dr}{lr^2} &= \frac{GmM}{l}\left(-\frac{1}{r}\right)\Bigg|_a^{a+l}\\ &= \frac{GmM}{l}\left(\frac{1}{a}-\frac{1}{a+l}\right)\\ &= \frac{GmM}{l}\,\frac{l}{a(a+l)} = \frac{GmM}{a(a+l)}.\end{aligned}$$

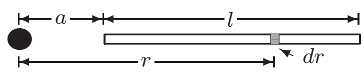

Figure 8.106

39. This time, let's split the second rod into small slices of length dr. See Figure 8.107. Each slice is of mass $\frac{M_2}{l_2}\, dr$, since the density of the second rod is $\frac{M_2}{l_2}$. Since the slice is small, we can treat it as a particle at distance r away from the end of the first rod, as in Problem 38. By that problem, the force of attraction between the first rod and particle is

$$\frac{GM_1\frac{M_2}{l_2}\, dr}{(r)(r+l_1)}.$$

So the total force of attraction between the rods is

$$\begin{aligned}\int_a^{a+l_2}\frac{GM_1\frac{M_2}{l_2}\, dr}{(r)(r+l_1)} &= \frac{GM_1M_2}{l_2}\int_a^{a+l_2}\frac{dr}{(r)(r+l_1)}\\ &= \frac{GM_1M_2}{l_2}\int_a^{a+l_2}\frac{1}{l_1}\left(\frac{1}{r}-\frac{1}{r+l_1}\right)dr.\end{aligned}$$

$$= \frac{GM_1M_2}{l_1l_2}(\ln|r| - \ln|r+l_1|)\bigg|_a^{a+l_2}$$
$$= \frac{GM_1M_2}{l_1l_2}[\ln|a+l_2| - \ln|a+l_1+l_2| - \ln|a| + \ln|a+l_1|]$$
$$= \frac{GM_1M_2}{l_1l_2}\ln\left[\frac{(a+l_1)(a+l_2)}{a(a+l_1+l_2)}\right].$$

This result is symmetric: if you switch l_1 and l_2 or M_1 and M_2, you get the same answer. That means it's not important which rod is "first," and which is "second."

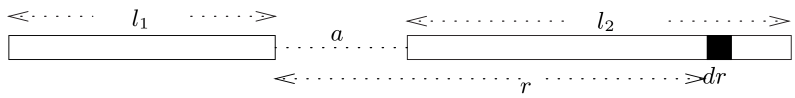

Figure 8.107

40. In Figure 8.108, consider a small piece of the ring of length Δl and mass

$$\Delta M = \frac{\Delta l M}{2\pi a}.$$

The gravitational force exerted by the small piece of the ring is along the line QP. As we sum over all pieces of the ring, the components perpendicular to the line OP cancel. The components of the force toward the point O are all in the same direction, so the net force is in this direction. The small piece of length Δl and mass $\Delta l M/2\pi a$ is at a distance of $\sqrt{a^2+y^2}$ from P, so

$$\text{Gravitational force from small piece} = \Delta F = \frac{G\frac{\Delta l M}{2\pi a}m}{(\sqrt{a^2+y^2})^2} = \frac{GMm\Delta l}{2\pi a(a^2+y^2)}.$$

Thus the force toward O exerted by the small piece is given by

$$\Delta F\cos\theta = \Delta F\frac{y}{\sqrt{a^2+y^2}} = \frac{GMm\Delta l}{2\pi a(a^2+y^2)}\frac{y}{\sqrt{a^2+y^2}} = \frac{GMmy\Delta l}{2\pi a(a^2+y^2)^{3/2}}.$$

The total force toward O is given by $F \approx \sum \Delta F\cos\theta$, so

$$F = \frac{GMmy\cdot\text{Total length}}{2\pi a(a^2+y^2)^{3/2}} = \frac{GMmy2\pi a}{2\pi a(a^2+y^2)^{3/2}} = \frac{GMmy}{(a^2+y^2)^{3/2}}.$$

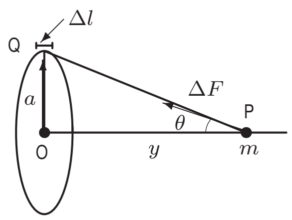

Figure 8.108

41. Divide the disk into rings of radius r, width Δr, as shown in Figure 8.109.
Then

$$\text{Area of ring} \approx 2\pi r\Delta r.$$

Since total area of disk is πa^2,

$$\text{Mass of ring} \approx \frac{2\pi r\Delta r}{\pi a^2}M = \frac{2rM}{a^2}\Delta r.$$

Thus, calculating the gravitational force due to the ring, we have

$$\begin{array}{c}\text{Gravitational force}\\ \text{on } m \text{ due to ring}\end{array} = G\left(\frac{2rM}{a^2}\Delta r\right)\frac{my}{(r^2+y^2)^{3/2}} = \frac{2GMmyr}{a^2(r^2+y^2)^{3/2}}\Delta r.$$

Summing over all rings, we get

$$\begin{array}{c}\text{Total gravitational force}\\ \text{on } m \text{ due to disk}\end{array} \approx \sum \frac{2GMmyr}{a^2(r^2+y^2)^{3/2}}\Delta r.$$

As $\Delta r \to 0$, we get

$$\begin{aligned}\begin{array}{c}\text{Gravitational force}\\ \text{on } m \text{ due to disk}\end{array} &= \int_0^a \frac{2GMmyr}{a^2(r^2+y^2)^{3/2}}dr = \frac{2GMmy}{a^2}\cdot\left.\frac{-1}{(r^2+y^2)^{1/2}}\right|_0^a\\ &= \frac{2GMmy}{a^2}\left(\frac{1}{y}-\frac{1}{(a^2+y^2)^{1/2}}\right).\end{aligned}$$

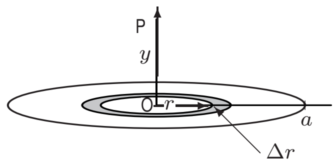

Figure 8.109

Strengthen Your Understanding

42. The calculation given is correct when the entire rope is lifted 20 m. But the portions of the rope nearer the top are raised a shorter distance, so less work is required.

43. It takes less work to pump the oil out of the top half of the tank than to pump it out of the bottom half of the tank because the oil in the top half has to be lifted a shorter distance. Emptying the full tank takes less than twice as much work as emptying the half-filled tank.

44. The force exerted lifting the rock is equal to 10 kg $\times$ 9.8 m/sec^2 $= 98$ nt. The work is

$$\text{Work } = \text{Force } \times \text{Distance} = 98\cdot 2 \text{ joules}.$$

45. Raising a 2 kg book 1 meter off the ground requires work Force $\times$ Distance where Force $= (2 \text{ kg})\left(9.8 \text{ m/sec}^2\right)$ and Distance $= 1$ meter .

46. Let tank A be a cylinder of radius 1 meter and height 4 meters and tank B be a cylinder of radius 2 meters and height 1 meter as shown in Figure 8.110. The volume of each tank is $4\pi = 12.56$ meters^3. All the water in tank B has to be pumped at least 9 meters, whereas the water in the top part of tank A has to be pumped a shorter distance. Therefore, it takes less work to pump the water from tank A to a height of 10 meters than the water from tank B.

Figure 8.110

47. False. Work is the product of force and distance moved, so the work done in either case is 200 ft-lb.

48. True. Displacement in the same direction as the force gives positive work; displacement in the opposite direction as the force gives negative work.

49. False. Since the water pressure increases with depth, the force on the lower half of the new dam is greater than the force on the upper half of the new dam, which is the same as the force on the old dam. Thus the force on the new dam is more than double the force on the old dam.

50. True. Since pressure increases with depth and we want the pressure to be approximately constant on each strip, we use horizontal strips.

51. False. The pressure is positive and when integrated gives a positive force.

52. True. Although work is expressed in an integral, the average value is also expressed in an integral. We have:

$$\text{Average value of the force} = \frac{1}{4-1}\int_1^4 F(x)\,dx.$$

Thus if we multiply the average force by 3, we get $\int_1^4 F(x)\,dx$, which is the work done.

Solutions for Section 8.6

Exercises

1. The future value, in dollars, is

$$C(1+0.03)^{25}.$$

2. The present value, in dollars, is

$$\frac{C}{(1+0.03)^{25}}.$$

3. The present value, in dollars, is

$$\frac{C}{e^{0.03(5)}}.$$

4. The present value, in dollars, is

$$\int_0^{15} C\,e^{-0.02t}\,dt.$$

5. The future value, in dollars, is

$$\int_0^{15} C\,e^{0.02(15-t)}\,dt.$$

6. The future value, in dollars, is

$$500e^{0.02(C)} + 500e^{0.02(C-1)} + 500e^{0.02(C-2)}.$$

7. We want

$$Ce^{r\cdot 30} = 25{,}000.$$

Thus,

$$e^{30r} = \frac{25{,}000}{C},$$

so, taking logs, we find the continuous interest rate is

$$r = \frac{\ln(25{,}000/C)}{30} \text{ per year.}$$

8. At any time t, in a time interval Δt, an amount of $1000\Delta t$ is deposited into the account. This amount earns interest for $(10-t)$ years giving a future value of $1000e^{(0.08)(10-t)}$. Summing all such deposits, we have

$$\text{Future value} = \int_0^{10} 1000e^{0.08(10-t)}\, dt = \$15{,}319.30.$$

9. (a)

$$\begin{aligned}\text{Future Value } &= \int_0^{20} 100e^{0.10(20-t)}\,dt \\ &= 100\int_0^{20} e^2 e^{-0.10t}\,dt \\ &= \frac{100e^2}{-0.10}e^{-0.10t}\Big|_0^{20} \\ &= \frac{100e^2}{0.10}(1-e^{-0.10(20)}) \approx \$6389.06.\end{aligned}$$

The present value of the income stream is

$$\begin{aligned}\int_0^{20} 100e^{-0.10t}\,dt &= 100\left(\frac{1}{-0.10}\right)e^{-0.10t}\Big|_0^{20} \\ &= 1000\left(1-e^{-2}\right) = \$864.66.\end{aligned}$$

Note that this is also the present value of the sum \$6389.06.

(b) Let T be the number of years for the balance to reach \$5000. Then

$$\begin{aligned}5000 &= \int_0^{T} 100e^{0.10(T-t)}\,dt \\ 50 &= e^{0.10T}\int_0^{T} e^{-0.10t}\,dt \\ &= \frac{e^{0.10T}}{-0.10}e^{-0.10t}\Big|_0^{T} \\ &= 10e^{0.10T}(1-e^{-0.10T}) = 10e^{0.10}T - 10.\end{aligned}$$

So, $60 = 10e^{0.10T}$, and $T = 10\ln 6 \approx 17.92$ years.

10. We compute the future value first: we have

$$\text{Future value} = \int_0^{5} 2000e^{0.08(5-t)}\,dt = \$12,295.62.$$

We can compute the present value using an integral and the income stream or using the future value. We compute the present value, P, from the future value:

$$12295.62 = Pe^{0.08(5)} \quad \text{so} \quad P = 8242.00.$$

The future value of this income stream is $\$12,295.62$ and the present value of this income stream is $\$8,242.00$.

11. (a) We compute the future value of this income stream:

$$\text{Future value} = \int_0^{20} 1000e^{0.07(20-t)}\,dt = \$43,645.71.$$

After 20 years, the account will contain $\$43,645.71$.

(b) The person has deposited \$1000 every year for 20 years, for a total of $\$20,000$.

(c) The total interest earned is $\$43,645.71 - \$20,000 = \$23,645.71$.

12. Since we want to have \$20,000 in 60 years starting with a single initial deposit of \$10,000, we have

$$20{,}000 = 10{,}000\, e^{r(60)}.$$

Solving for r, we get:

$$\begin{aligned} 2 &= e^{r(60)} \\ r &= \frac{\ln(2)}{60} \\ r &= 0.01155 \qquad \text{or} \qquad r = 1.155\% \text{ per year.} \end{aligned}$$

13. Since we want to have \$20,000 in 15 years starting with a single initial investment of \$10,000, we have

$$20{,}000 = 10{,}000e^{r(15)}.$$

Solving for r, we get:

$$\begin{aligned} 2 &= e^{r(15)} \\ r &= \frac{\ln(2)}{15} \\ r &= 0.04621 \qquad \text{or} \qquad r = 4.621\% \text{ per year.} \end{aligned}$$

14. Since we want to have \$20,000 in 5 years starting with a single initial deposit of \$10,000, we have

$$20{,}000 = 10{,}000e^{r(5)}.$$

Solving for r, we get:

$$\begin{aligned} 2 &= e^{r(5)} \\ r &= \frac{\ln(2)}{5} \\ r &= 0.13863 \qquad \text{or} \qquad r = 13.863\% \text{ per year.} \end{aligned}$$

Notice that the goal of doubling the initial \$10,000 deposit in a short period of time (5 years) leads to a high interest rate (13.863%).

15. A constant income stream that pays 20,000 in 5 years has a yearly rate amount of $20{,}000/5 = 4000$ dollars/year. Thus, the future value, B, of the stream at the end of 5 years is

$$B = \int_0^5 4000\, e^{0.02(5-t)}\, dt = 4000\, \frac{-e^{0.02(5-t)}}{0.02}\bigg|_0^5 = 200{,}000(e^{0.1} - 1) = 21{,}034.18 \text{ dollars.}$$

16. A constant income stream that pays 20,000 in 10 years has a yearly rate amount of $20{,}000/10 = 2000$ dollars/year. Thus, the future value, B, of the stream at the end of 10 years is

$$B = \int_0^{10} 2000\, e^{0.02(10-t)}\, dt = 2000\, \frac{-e^{0.02(10-t)}}{0.02}\bigg|_0^{10} = 100{,}000(e^{0.2} - 1) = 22{,}140.28 \text{ dollars.}$$

17. A constant income stream that pays 20,000 in 20 years has a yearly rate amount of $20{,}000/20 = 1000$ dollars/year. Thus, the future value, B, of the stream at the end of 20 years is

$$B = \int_0^{20} 1000\, e^{0.02(20-t)}\, dt = 1000\, \frac{-e^{0.02(20-t)}}{0.02}\bigg|_0^{20} = 50{,}000(e^{0.4} - 1) = 24{,}591.23 \text{ dollars.}$$

Problems

18. If $S(t) = S$ is the constant income stream, then we want

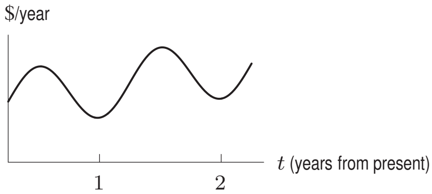
$$\text{Future value } = 20000 = \int_0^{10} Se^{0.03(10-t)}\, dt = S\int_0^{10} e^{0.03(10-t)}\, dt.$$

Evaluating the integral gives

$$\int_0^{10} e^{0.03(10-t)}\, dt = \frac{-1}{0.03}e^{0.03(10-t)}\bigg|_0^{10} = 11.662.$$

Then $S = 20000/11.662 = 1714.97$ dollars per year.

19.



The graph reaches a peak each summer, and a trough each winter. The graph shows sunscreen sales increasing from cycle to cycle. This gradual increase may be due in part to inflation and to population growth.

20. (a) The lump sum payment has a present value of 120 million dollars . We compute the present value of the other option at 6% and 3%. An award of \$195 million paid out continuously over 20 years works out to an income stream of 9.75 million dollars per year.

If the interest rate is 6%, compounded continuously, we have

$$\text{Present value at } 6\% = \int_0^{20} 9.75e^{-0.06t}\,dt = \frac{9.75}{-0.06}(e^{-0.06\cdot 20} - 1) = 113.556 \text{ million dollars.}$$

Since this amount is less than the lump sum payment of 120 million dollars, the lump sum payment is preferable if the interest rate is 6%.

If the interest rate is 3%, we have

$$\text{Present value at } 3\% = \int_0^{20} 9.75e^{-0.03t}\,dt = \frac{9.75}{-0.03}(e^{-0.03\cdot 20} - 1) = 146.636 \text{ million dollars.}$$

Since this amount is greater than the lump sum payment of 120 million dollars, taking payments continuously over 20 years is the better option if the interest rate is 3%.

(b) The assumption is that the interest rates would stay relatively high (closer to 6%). The interest rate at which the decision changes is the solution to the equation

$$\frac{9.75}{-x}(e^{-20x} - 1) = 120.$$

Using a graph or numerical methods gives $x = 5.3\%$. Thus if Mr. Nabors chooses the lump sum, he is assuming interests rates stay above 5.3%.

21. (a) Solve for $P(t) = P$.

$$\begin{aligned} 100000 &= \int_0^{10} Pe^{0.10(10-t)}\,dt = Pe\int_0^{10} e^{-0.10t}\,dt \\ &= \frac{Pe}{-0.10}e^{-0.10t}\Big|_0^{10} = Pe(-3.678 + 10) \\ &= P \cdot 17.183. \end{aligned}$$

So, $P \approx \$5820$ per year.

(b) To answer this, we'll calculate the present value of \$100,000:

$$\begin{aligned} 100000 &= Pe^{0.10(10)} \\ P &\approx \$36{,}787.94. \end{aligned}$$

22. (a) Let L be the number of years for the balance to reach \$10,000. Since our income stream is \$1000 per year, the future value of this income stream should equal (in L years) \$10,000. Thus

$$\begin{aligned} 10000 &= \int_0^{L} 1000e^{0.05(L-t)}\,dt = 1000e^{0.05L}\int_0^{L} e^{-0.05t}\,dt \\ &= 1000e^{0.05L}\left(-\frac{1}{0.05}\right)e^{-0.05t}\Big|_0^{L} = 20000e^{0.05L}\left(1 - e^{-0.05L}\right) \\ &= 20000e^{0.05L} - 20000 \\ \text{so}\quad e^{0.05L} &= \frac{3}{2} \\ L &= 20\ln\left(\frac{3}{2}\right) \approx 8.11 \text{ years.} \end{aligned}$$

(b) We want

$$10000 = 2000e^{0.05L} + \int_0^L 1000e^{0.05(L-t)}\,dt.$$

The first term on the right hand side is the future value of our initial balance. The second term is the future value of our income stream. We want this sum to equal \$10,000 in L years. We solve for L:

$$\begin{aligned}
10000 &= 2000e^{0.05L} + 1000e^{0.05L}\int_0^L e^{-0.05t}\,dt \\
&= 2000e^{0.05L} + 1000e^{0.05L}\left(\frac{1}{-0.05}\right)e^{-0.05t}\Big|_0^L \\
&= 2000e^{0.05L} + 20000e^{0.05L}\left(1 - e^{-0.05L}\right) \\
&= 2000e^{0.05L} + 20000e^{0.05L} - 20000.
\end{aligned}$$

So,

$$\begin{aligned}
22000e^{0.05L} &= 30000 \\
e^{0.05L} &= \frac{30000}{22000} \\
L &= 20\ln\frac{15}{11} \approx 6.203 \text{ years.}
\end{aligned}$$

23. You should choose the payment which gives you the highest present value. The immediate lump-sum payment of \$2800 obviously has a present value of exactly \$2800, since you are getting it now. We can calculate the present value of the installment plan as:

$$\begin{aligned}
\text{PV} &= 1000e^{-0.06(0)} + 1000e^{-0.06(1)} + 1000e^{-0.06(2)} \\
&\approx \$2828.68.
\end{aligned}$$

Since the installment payments offer a (slightly) higher present value, you should accept this option.

24. The initial \$9000 deposit earns interest for 20 years. Since we want to have \$18,000 in 20 years, we have:

$$18{,}000 = 9000e^{r(20)}.$$

Solving for r, we get:

$$\begin{aligned}
\frac{18{,}000}{9000} &= e^{r(20)} \\
r &= \frac{\ln\ 2}{20} \\
r &= 0.03466 \qquad \text{or} \qquad r = 3.466\% \text{ per year.}
\end{aligned}$$

25. The initial \$6000 deposit earns interest for 20 years. The second deposit only earns interest for 17 years. Since we want to have \$18,000 in 20 years, we have:

$$18{,}000 = 6000e^{r(20)} + 3000e^{r(17)},$$

or

$$\frac{18{,}000}{3000} = 2e^{r(20)} + e^{r(17)}.$$

We can solve for r numerically or by graphing the functions on the left- and right-hand sides of the equation, and finding the intersection point. This yields $r = 0.03641$, or $r = 3.641\%$ per year.

26. The initial \$3000 deposit earns interest for 20 years. The second deposit earns interest for 17 years. Since we want to have \$18,000 in 20 years, we have:

$$18{,}000 = 3000e^{r(20)} + 6000e^{r(17)},$$

or

$$\frac{18{,}000}{3000} = e^{r(20)} + 2e^{r(17)}.$$

We can solve for r numerically or by graphing the functions on the left- and right-hand sides of the equation, and finding the intersection point. This yields $r = 0.03843$, or $r = 3.843\%$ per year.

27. We want to reach a target of $18,000 in 20 years, so we have:

$$18{,}000 = \int_0^{20} 300\, e^{r(20-t)}\, dt.$$

In order to solve for r, we integrate, then solve the resulting equation graphically or numerically. We have:

$$\begin{aligned}\frac{18{,}000}{300} &= \left.\frac{-e^{r(20-t)}}{r}\right|_0^{20}\\ 60 &= \frac{e^{20r}-1}{r}.\end{aligned}$$

We can solve for r by graphing the functions on the left- and right-hand sides of the last equation, and finding the intersection point. This yields $r = 0.09519$, or $r = 9.519\%$ per year.

28. Since we want the future value of the income stream of 4800 per year to be 100,000 in 15 years, we have

$$100{,}000 = \int_0^{15} 4800 e^{r(15-t)}\, dt.$$

Evaluating the integral gives

$$100{,}000 = \left.\frac{4800}{-r} e^{r(15-t)}\right|_0^{15} = \frac{4800}{-r}(e^0 - e^{15r}) = \frac{4800}{r}(e^{15r}-1).$$

This equation is not solvable by algebraic means. However, using a computer or calculator to solve for r numerically or graphically we obtain $r = 0.0416$. So a continuous interest rate of 4.16% per year is required.

29. (a) We calculate the future values of the two options:

$$\begin{aligned}\text{FV}_1 &= 6e^{0.1(3)} + 2e^{0.1(2)} + 2e^{0.1(1)} + 2e^{0.1(0)}\\ &\approx 8.099 + 2.443 + 2.210 + 2\\ &= \$14.752 \text{ million.}\end{aligned}$$

$$\begin{aligned}\text{FV}_2 &= e^{0.1(3)} + 2e^{0.1(2)} + 4e^{0.1(1)} + 6e^{0.1(0)}\\ &\approx 1.350 + 2.443 + 4.421 + 6\\ &= \$14.214 \text{ million.}\end{aligned}$$

As we can see, the first option gives a higher future value, so he should choose Option 1.

(b) From the future value we can easily derive the present value using the formula $\text{PV} = \text{FV}e^{-rt}$. So the present value is

$$\text{Option 1: PV} = 14.752e^{0.1(-3)} \approx \$10.929 \text{ million.}$$

$$\text{Option 2: PV} = 14.214e^{0.1(-3)} \approx \$10.530 \text{ million.}$$

30. At any time t, the company receives income of $s(t)$ per year. It will then invest this money for a length of $2 - t$ years at 6% interest, giving it future value of $s(t)e^{(0.06)(2-t)}$ from this income. If we sum all such incomes over the two-year period, we can find the total value of the sales:

$$\begin{aligned}\text{Value} &= \int_0^2 s(t)e^{(0.06)(2-t)}\, dt = \int_0^2 \left[50e^{-t}e^{(0.06)(2-t)}\right] dt\\ &= \int_0^2 \left[50e^{0.12-1.06t}\right] dt = \left.\left(\frac{-53.1838}{e^{1.06t}}\right)\right|_0^2 = \$46{,}800.\end{aligned}$$

31. Price in future $= P(1+20\sqrt{t})$.
The present value V of price satisfies $V = P(1+20\sqrt{t})e^{-0.05t}$.
We want to maximize V. To do so, we find the critical points of $V(t)$ for $t \geq 0$. (Recall that $\sqrt{t}$ is nondifferentiable at $t = 0$.)

$$\begin{aligned}\frac{dV}{dt} &= P\left[\frac{20}{2\sqrt{t}}e^{-0.05t} + (1+20\sqrt{t})(-0.05e^{-0.05t})\right] \\ &= Pe^{-0.05t}\left[\frac{10}{\sqrt{t}} - 0.05 - \sqrt{t}\right].\end{aligned}$$

Setting $\frac{dV}{dt} = 0$ gives $\frac{10}{\sqrt{t}} - 0.05 - \sqrt{t} = 0$. Using a calculator, we find $t \approx 10$ years. Since $V'(t) > 0$ for $0 < t < 10$ and $V'(t) < 0$ for $t > 10$, we confirm that this is a maximum. Thus, the best time to sell the wine is in 10 years.

32. (a) Suppose the oil extracted over the time period $[0, M]$ is S. (See Figure 8.111.) Since $q(t)$ is the rate of oil extraction, we have:

$$S = \int_0^M q(t)dt = \int_0^M (a - bt)dt = \int_0^M (10 - 0.1t)\,dt.$$

To calculate the time at which the oil is exhausted, set $S = 100$ and try different values of M. We find $M = 10.6$ gives

$$\int_0^{10.6} (10 - 0.1t)\,dt = 100,$$

so the oil is exhausted in 10.6 years.

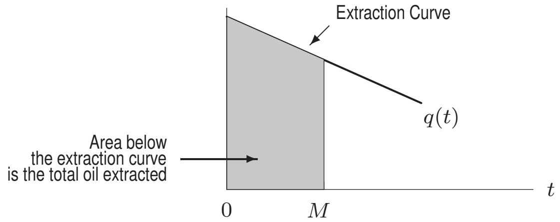


Figure 8.111

(b) Suppose p is the oil price, C is the extraction cost per barrel, and r is the interest rate. We have the present value of the profit as

$$\begin{aligned}\text{Present value of profit} &= \int_0^M (p - C)q(t)e^{-rt}dt \\ &= \int_0^{10.6} (20 - 10)(10 - 0.1t)e^{-0.1t}\,dt \\ &= 624.9 \text{ million dollars.}\end{aligned}$$

33. (a) Let's split the time interval into n parts, each of length Δt. During the interval from t_i to t_{i+1}, profit is earned at a rate of approximately $(2 - 0.1t_i)$ thousand dollars per year, or $(2000 - 100t_i)$ dollars per year. Thus during this period, a total profit of $(2000 - 100t_i)\Delta t$ dollars is earned. Since this profit is earned t_i years in the future, its present value is $(2000 - 100t_i)\Delta t e^{-0.1t_i}$ dollars. Thus

$$\text{Total present value} \approx \sum_{i=0}^{n-1}(2000 - 100t_i)e^{-0.1t_i}\Delta t.$$

(b) The Riemann sum corresponds to the integral:

$$\text{Present value} = \int_0^M e^{-0.10t}(2000 - 100t)\,dt.$$

(c) To find where the present value is maximized, we take the derivative of

$$P(M) = \int_0^M e^{-0.10t}(2000 - 100t)\,dt,$$

with respect to M, and obtain

$$P'(M) = e^{-0.10M}(2000 - 100M).$$

This is 0 when $2000 - 100M = 0$, that is, when $M = 20$ years. The value $M = 20$ maximizes $P(M)$, since $P'(M) > 0$ for $M < 20$, and $P'(M) < 0$ for $M > 20$. To determine what the maximum is, we evaluate the integral representation for $P(20)$ by III-14 in the integral table:

$$\begin{aligned} P(20) &= \int_0^{20} e^{-0.10t}(2000 - 100t)\,dt \\ &= \left[\frac{(2000 - 100t)}{-0.10}e^{-0.10t} + 10000e^{-0.10t}\right]\Bigg|_0^{20} \approx \$11353.35. \end{aligned}$$

34. One good way to approach the problem is in terms of present values. In 1980, the present value of Germany's loan was 20 billion DM. Now let's figure out the rate that the Soviet Union would have to give money to Germany to pay off 10% interest on the loan by using the formula for the present value of a continuous stream. Since the Soviet Union sends gas at a constant rate, the rate of deposit, $P(t)$, is a constant c. Since they don't start sending the gas until after 5 years have passed, the present value of the loan is given by:

$$\text{Present Value} = \int_5^\infty P(t)e^{-rt}\,dt.$$

We want to find c so that

$$\begin{aligned} 20{,}000{,}000{,}000 &= \int_5^\infty ce^{-rt}\,dt = c\int_5^\infty e^{-rt}\,dt \\ &= c\lim_{b\to\infty}(-10e^{-0.10t})\Big|_5^b = ce^{-0.10(5)} \\ &\approx 6.065c. \end{aligned}$$

Dividing, we see that c should be about 3.3 billion DM per year. At 0.10 DM per m^3 of natural gas, the Soviet Union must deliver gas at the constant, continuous rate of about 33 billion m^3 per year.

35. Measuring money in thousands of dollars, the equation of the line representing the demand curve passes through (50, 980) and (350, 560). Its slope is $(560 - 980)/(350 - 50) = -420/300$. See Figure 8.112. So the equation is $y - 560 = -\frac{420}{300}(x - 350)$, i.e. $y - 560 = -\frac{7}{5}x + 490$. Thus

$$\begin{aligned} \text{Consumer surplus } &= \int_0^{350}\left(-\frac{7}{5}x + 1050\right)dx - 350\cdot 560 = -\frac{7}{10}x^2 + 1050x\Big|_0^{350} - 196000 \\ &= 85{,}750. \end{aligned}$$

(Note that $85{,}750 = \frac{1}{2}\cdot 490\cdot 350$, the area of the triangle in Figure 8.112. We could have used this instead of the integral to find the consumer surplus.)

Recalling that our unit measure for the price axis is \$1000/car, the consumer surplus is \$85,750,000.

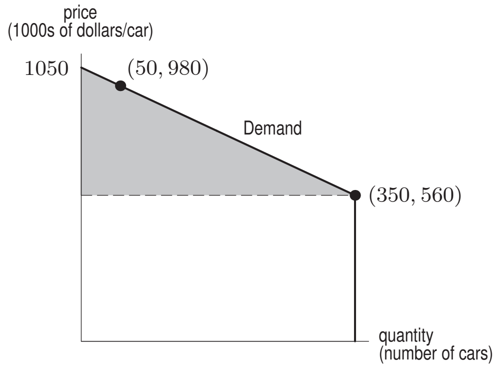

Figure 8.112

36. The supply curve, $S(q)$, represents the minimum price p per unit that the suppliers will be willing to supply some quantity q of the good for. See Figure 8.113. If the suppliers have q^* of the good and q^* is divided into subintervals of size Δq, then if the consumers could offer the suppliers for each Δq a price increase just sufficient to induce the suppliers to sell an additional Δq of the good, the consumers' total expenditure on q^* goods would be

$$p_1\Delta q + p_2\Delta q + \cdots = \sum p_i \Delta q.$$

As $\Delta q \to 0$ the Riemann sum becomes the integral $\int_0^{q^*} S(q)\,dq$. Thus $\int_0^{q^*} S(q)\,dq$ is the amount the consumers would pay if suppliers could be forced to sell at the lowest price they would be willing to accept.

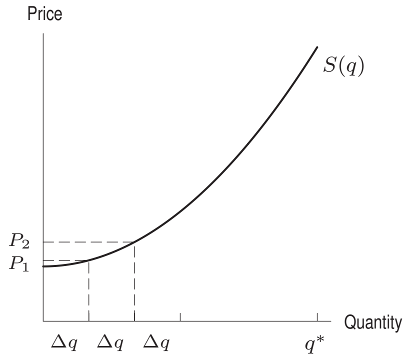

Figure 8.113

37.

$$\begin{aligned}\int_0^{q^*} (p^* - S(q))\,dq &= \int_0^{q^*} p^*\,dq - \int_0^{q^*} S(q)\,dq \\ &= p^*q^* - \int_0^{q^*} S(q)\,dq.\end{aligned}$$

Using Problem 36, this integral is the extra amount consumers pay (i.e., suppliers earn over and above the minimum they would be willing to accept for supplying the good). It results from charging the equilibrium price.

38. (a) p^*q^* = the total amount paid for q^* of the good at equilibrium. See Figure 8.114.

(b) $\int_0^{q^*} D(q)\,dq$ = the maximum consumers would be willing to pay if they had to pay the highest price acceptable to them for each additional unit of the good. See Figure 8.115.

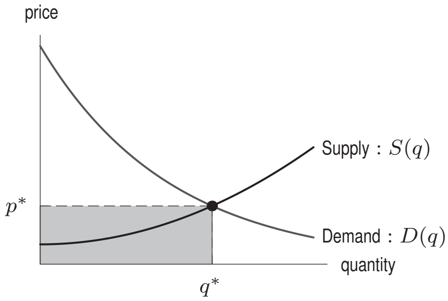

Figure 8.114

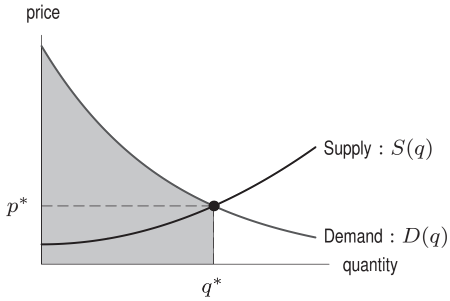

Figure 8.115

(c) $\int_0^{q^*} S(q)\,dq =$ the minimum suppliers would be willing to accept if they were paid the minimum price acceptable to them for each additional unit of the good. See Figure 8.116.

(d) $\int_0^{q^*} D(q)\,dq - p^*q^* =$ consumer surplus. See Figure 8.117.

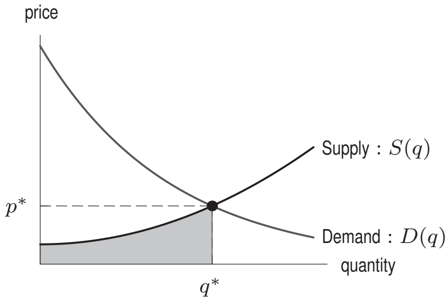

Figure 8.116

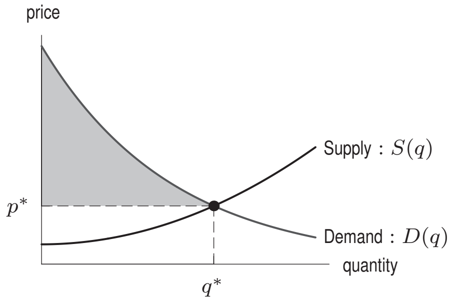

Figure 8.117

(e) $p^*q^* - \int_0^{q^*} S(q)\,dq =$ producer surplus. See Figure 8.118.

(f) $\int_0^{q^*} (D(q) - S(q))\,dq =$ producer surplus and consumer surplus. See Figure 8.119.

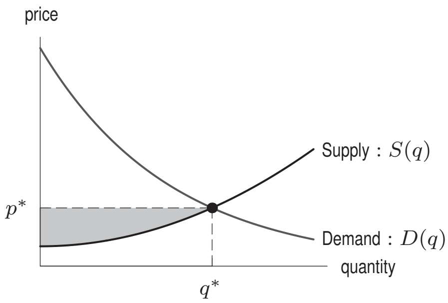

Figure 8.118

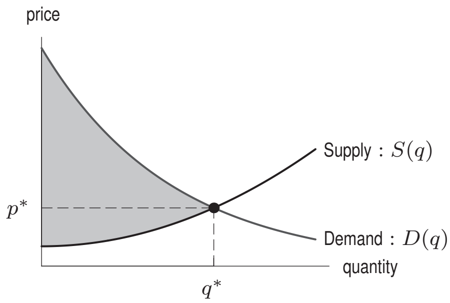

Figure 8.119

39.

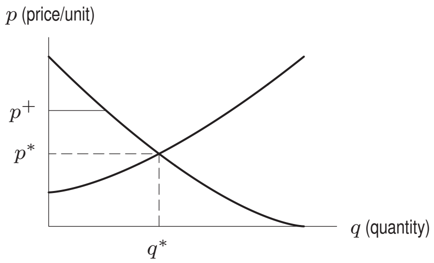

Figure 8.120: What effect does the artificially high price, p^+, have?

(a) A graph of possible demand and supply curves for the milk industry is given in Figure 8.120, with the equilibrium price and quantity labeled p^* and q^* respectively. Suppose that the price is fixed at the artificially high price labeled p^+ in Figure 8.120. Recall that the consumer surplus is the difference between the amount the consumers did pay (p^+) and the amount they would have been willing to pay (given on the demand curve). This is the area shaded in Figure 8.121(i). Notice that this consumer surplus is clearly less than the consumer surplus at the equilibrium price, shown in Figure 8.121(ii).

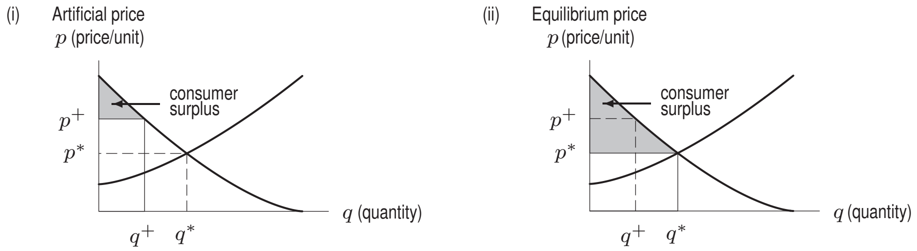

Figure 8.121: Consumer surplus for the milk industry

(b) At a price of p^+, the quantity sold, q^+, is less than it would have been at the equilibrium price. The producer surplus is the area between p^+ and the supply curve *at this reduced demand*. This area is shaded in Figure 8.122(i). Compare this producer surplus (at the artificially high price) to the producer surplus in Figure 8.122(ii) (at the equilibrium price). It appears that in this case, producer surplus is greater at the artificial price than at the equilibrium price. (Different supply and demand curves might have led to a different answer.)

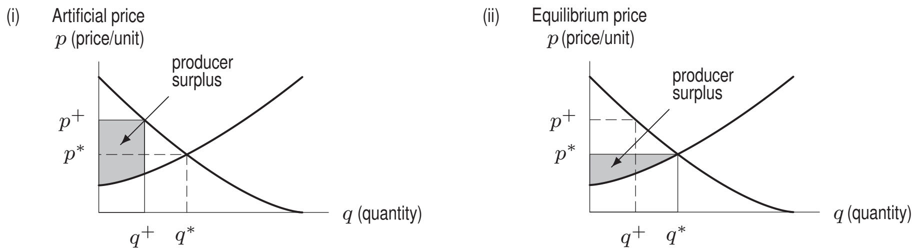

Figure 8.122: Producer surplus for the milk industry

(c) The total gains from trade (Consumer surplus + Producer surplus) at the artificially high price of p^+ is the area shaded in Figure 8.123(i). The total gains from trade at the equilibrium price of p^* is the area shaded in Figure 8.123(ii). It is clear that, under artificial price conditions, total gains from trade go down. The total financial effect of the artificially high price on all producers and consumers combined is a negative one.

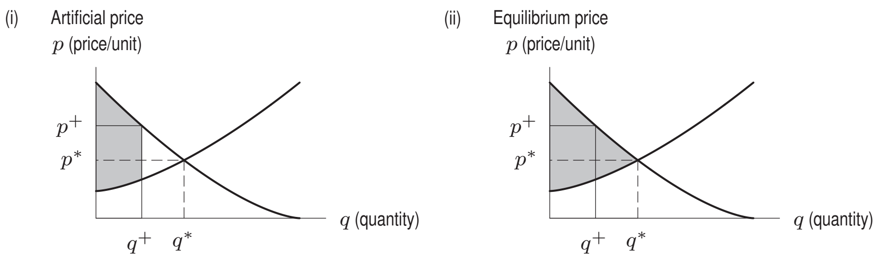

Figure 8.123: Total gains from trade

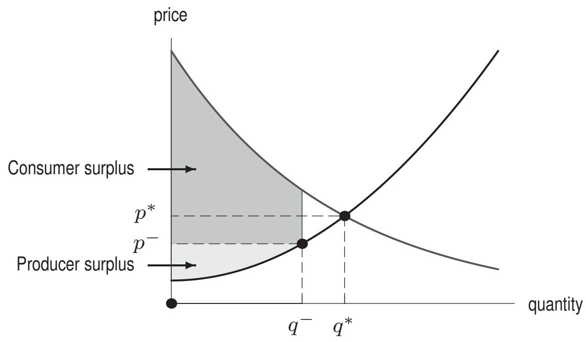
40.



(a) The producer surplus is the area on the graph between p^- and the supply function. Lowering the price also lowers the producer surplus.

(b) Note that the consumer surplus—the area between the line p^- and the supply curve—increases or decreases depending on the functions describing the supply and demand and on the lowered price. (For example, the consumer surplus seems to be increased in the graph above, but if the price were brought down to \$0 then the consumer surplus would be zero, and hence clearly less than the consumer surplus at equilibrium.)

(c) The graph above shows that the total gains from the trade are decreased.

Strengthen Your Understanding

41. With no interest, the future value of the stream is equal to the total amount deposited over 10 years, which is \$20,000. So the future value is more than \$20,000.

42. The present value of S at a 4% interest rate, compounded annually, is

$$PV = \frac{S}{1.04}.$$

The present value of S at a 3% interest rate, compounded annually, is

$$PV = \frac{S}{1.03}.$$

Thus, the present value is smaller with a 4% interest rate.

43. The present value of a continuous stream of payments is found using an integral:

$$\text{PV} = \int_0^2 Pe^{-rt}dt = -\frac{P}{r}e^{-rt}\Big|_0^2 = \frac{P}{r}(1 - e^{-2r}).$$

44. Producer surplus is measured in dollars.

45. See Figure 8.124.

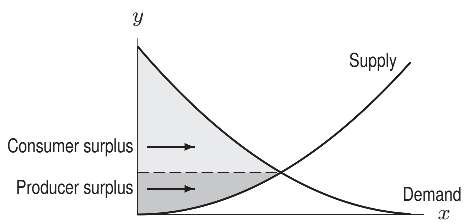


Figure 8.124

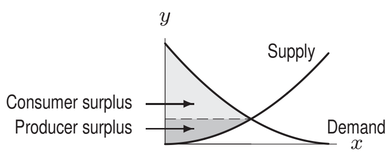

46. We want $10{,}000e^{-r\cdot 10} < 5000$. Solving

$$e^{-10r} = 0.5$$
$$r = -\frac{1}{10}\ln(0.5) = 0.0693.$$

We want an interest rate larger than 0.0693, such as 7% or larger.
Larger than 6.93%/ yr

47. A present value of A with an interest rate r, compounded annually, has future value $A(1+r)$ after one year. Since we want the future value to be \$5000, we have

$$A(1+r) = 5000$$

or

$$A = \frac{5000}{1+r}.$$

Every choice of r gives a choice of A. For example, a 5% interest rate corresponds to $r = 0.05$ and gives $A = 5000/1.05 = 4761.90$. If the annual interest rate is 5%, then \$4761.90 now has future value \$5000 one year from now.

48. Suppose there is an annual interest rate of 10%. Then the present value, A, of the \$10,000 is:

$$A = \frac{10,000}{(1+0.10)^{10}} = 3855.$$

Thus, a deposit of roughly \$3855 is needed now to have 10,000 dollars in 10 years, assuming a 10% interest rate.

There are two ways to think about the remaining values in the table. We can ask how much the amount needed now, \$3855, will grow to in t years. This means the remaining values in the table arise by calculating:

$$3855(1+0.10)^t \quad \text{for} \quad t = 1, 2, 3, 4.$$

Alternatively, we realize that a single deposit made t years from now would have $10 - t$ years to grow to reach our target investment of \$10,000 in 10 years. This means the remaining values in the table arise by calculating:

$$\frac{10,000}{(1+0.10)^{10-t}}, \quad \text{for} \quad t = 1, 2, 3, 4.$$

If we ignore rounding errors, we see that two approaches yield the same table values:

t (years from now)	0	1	2	3	4
\$ (dollars)	3855	4241	4665	5131	5644

Other possible answers to this problem can arise from alternate interest rate choices.

Solutions for Section 8.7

Exercises

1. The two humps of probability in density (a) correspond to two intervals on which its cumulative distribution function is increasing. Thus (a) and (II) correspond.

A density function increases where its cumulative distribution function is concave up, and it decreases where its cumulative distribution function is concave down. Density (b) matches the distribution with both concave up and concave down sections, which is (I). Density (c) matches (III) which has a concave down section but no interval over which it is concave up.

2.

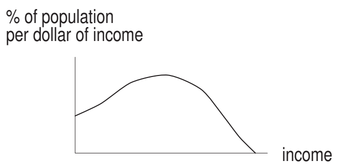

Figure 8.125: Density function

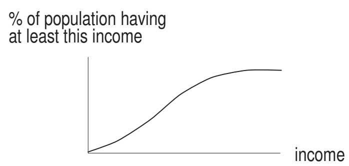

Figure 8.126: Cumulative distribution function

3.

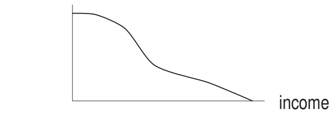

Figure 8.127: Density function

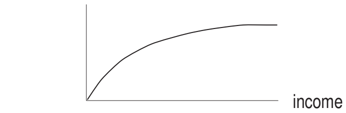

Figure 8.128: Cumulative distribution function

4.

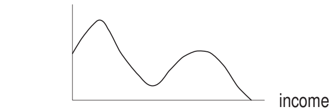

Figure 8.129: Density function

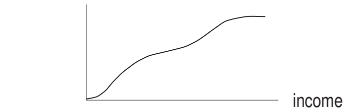

Figure 8.130: Cumulative distribution function

5. Since the function takes on the value of 4, it cannot be a cdf (whose maximum value is 1). In addition, the function decreases for $x > c$, which means that it is not a cdf. Thus, this function is a pdf. The area under a pdf is 1, so $4c = 1$ giving $c = \frac{1}{4}$. The pdf is $p(x) = 4$ for $0 \le x \le \frac{1}{4}$, so the cdf is given in Figure 8.131 by

$$P(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ 4x & \text{for} \quad 0 \le x \le \dfrac{1}{4} \\ 1 & \text{for} \quad x > \dfrac{1}{4} \end{cases}$$

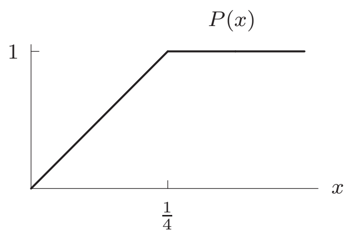

Figure 8.131

6. Since the function is decreasing, it cannot be a cdf (whose values never decrease). Thus, the function is a pdf.

The area under a pdf is 1, so, using the formula for the area of a triangle, we have

$$\frac{1}{2}4c = 1, \quad \text{giving} \quad c = \frac{1}{2}.$$

The pdf is

$$p(x) = \frac{1}{2} - \frac{1}{8}x \quad \text{for} \quad 0 \le x \le 4,$$

so the cdf is given in Figure 8.132 by

$$P(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ \dfrac{x}{2} - \dfrac{x^2}{16} & \text{for} \quad 0 \le x \le 4 \\ 1 & \text{for} \quad x > 4. \end{cases}$$

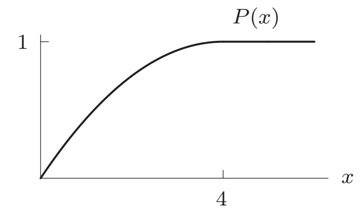

Figure 8.132

7. Since the function levels off at the value of c, the area under the graph is not finite, so it is not 1. Thus, this function cannot be a pdf.

It is a cdf and $c = 1$. The cdf is given by

$$P(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ \dfrac{x}{5} & \text{for} \quad 0 \le x \le 5 \\ 1 & \text{for} \quad x > 5. \end{cases}$$

The pdf in Figure 8.133 is given by

$$p(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ 1/5 & \text{for} \quad 0 \le x \le 5 \\ 0 & \text{for} \quad x > 5. \end{cases}$$

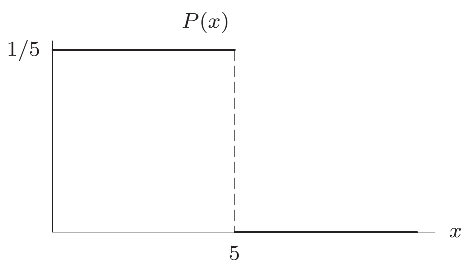

Figure 8.133

8. This function decreases, so it cannot be a cdf. Since the graph must represent a pdf, the area under it is 1. The region consists of two rectangles, each of base 0.5, and one of height $2c$ and one of height c, so

$$\text{Area} = 2c(0.5) + c(0.5) = 1$$
$$c = \frac{1}{1.5} = \frac{2}{3}$$

The pdf is therefore

$$p(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ 4/3 & \text{for} \quad 0 \le x \le 0.5 \\ 2/3 & \text{for} \quad 0.5 < x \le 1 \\ 0 & \text{for} \quad x > 1. \end{cases}$$

The cdf $P(x)$ is the antiderivative of this function with $P(0) = 0$. See Figure 8.134. The formula for $P(x)$ is

$$P(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ 4x/3 & \text{for} \quad 0 \le x \le 0.5 \\ 2/3 + (2/3)(x - 0.5) & \text{for} \quad 0.5 < x \le 1 \\ 1 & \text{for} \quad x > 1. \end{cases}$$

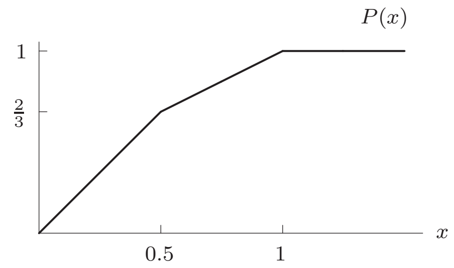

Figure 8.134

9. This function increases and levels off to c. The area under the curve is not finite, so it is not 1. Thus, the function must be a cdf, not a pdf, and $3c = 1$, so $c = 1/3$.

The pdf, $p(x)$ is the derivative, or slope, of the function shown, so, using $c = 1/3$,

$$p(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ (1/3 - 0)/(2 - 0) = 1/6 & \text{for} \quad 0 \le x \le 2 \\ (1 - 1/3)/(4 - 2) = 1/3 & \text{for} \quad 2 < x \le 4 \\ 0 & \text{for} \quad x > 4. \end{cases}$$

See Figure 8.135.

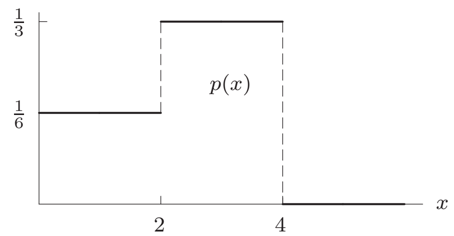

Figure 8.135

10. This function does not level off to 1, and it is not always increasing. Thus, the function is a pdf. Since the area under the curve must be 1, using the formula for the area of a triangle,

$$\frac{1}{2} \cdot c \cdot 1 = 1 \quad \text{so} \quad c = 2.$$

Thus, the pdf is given by

$$p(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ 4x & \text{for} \quad 0 \le x \le 0.5 \\ 2 - 4(x - 0.5) = 4 - 4x & \text{for} \quad 0.5 < x \le 1 \\ 0 & \text{for} \quad x > 0. \end{cases}$$

To find the cdf, we integrate each part of the function separately, making sure that the constants of integration are arranged so that the cdf is continuous.

Since $\int 4x dx = 2x^2 + C$ and $P(0) = 0$, we have $2(0)^2 + C = 0$ so $C = 0$. Thus $P(x) = 2x^2$ on $0 \le x \le 0.5$. At $x = 0.5$, the cdf has value $P(0.5) = 2(0.5)^2 = 0.5$. Thus, we arrange that the integral of $4 - 4x$ goes through the point $(0.5, 0.5)$. Since $\int (4 - 4x)\, dx = 4x - 2x^2 + C$, we have

$$4(0.5) - 2(0.5)^2 + C = 0.5 \quad \text{giving} \quad C = -1.$$

Thus

$$P(x) = \begin{cases} 0 & \text{for} \quad x < 0 \\ 2x^2 & \text{for} \quad 0 \le x \le 0.5 \\ 4x - 2x^2 - 1 & \text{for} \quad 0.5 < x \le 1 \\ 1 & \text{for} \quad x > 1. \end{cases}$$

See Figure 8.136.

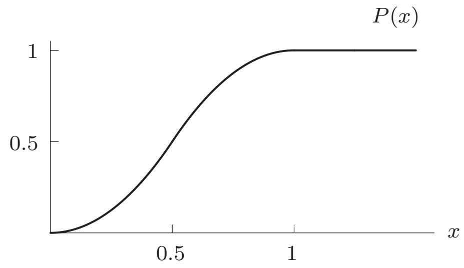

Figure 8.136

11. The statement $p(70) = 0.05$ means that for some small interval Δx around 70, the fraction of families with incomes in that interval around \$70,000 is about $0.05\Delta x$.

12. We need to find a nonnegative function $p(x)$ for which the area between $y = p(x)$ and the x axis is 1. One example is a decreasing linear function $p(x) = b + mx$ with $m < 0$. We choose b and m so that $p(5) = 0$ and the triangular area under the graph of $p(x)$ for $0 \le x \le 5$ is 1. Since b is the height of the triangle, we have

$$\text{Area} = \frac{1}{2} b \cdot 5 = 1$$

or $b = 2/5$. Then $p(5) = 0$ gives

$$\frac{2}{5} + 5m = 0$$

or $m = -2/25$. Thus

$$p(x) = \frac{2}{5} - \frac{2}{25}x \quad \text{when} \quad 0 \le x \le 5 \quad \text{and} \quad p(x) = 0 \text{ otherwise.}$$

Problems

13. For a given energy E, Figure 8.137 shows that the area under the graph to the right of E is larger for graph B than it is for graph A. Therefore graph B has more molecules at higher kinetic energies, so it is the hotter gas. So graph A corresponds to 300 kelvins and graph B corresponds to 500 kelvins.

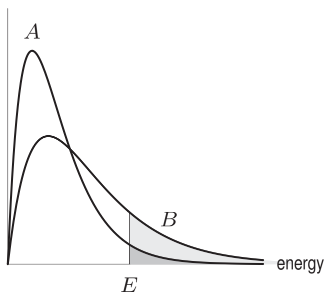

Figure 8.137

14. No. Though the density function has its maximum value at 50, this does not mean that a large fraction of the population receives scores near 50. The value $p(50)$ can not be interpreted as a probability. Probability corresponds to *area* under the graph of a density function. Most of the area in this case is in the broad hump covering the range $0 \le x \le 40$, very little in the peak around $x = 50$. Most people score in the range $0 \le x \le 40$.

15. (a) Let $P(x)$ be the cumulative distribution function of the heights of the unfertilized plants. As do all cumulative distribution functions, $P(x)$ rises from 0 to 1 as x increases. The greatest number of plants will have heights in the range where $P(x)$ rises the most. The steepest rise appears to occur at about $x = 1$ m. Reading from the graph we see that $P(0.9) \approx 0.2$ and $P(1.1) \approx 0.8$, so that approximately $P(1.1) - P(0.9) = 0.8 - 0.2 = 0.6 = 60\%$ of the unfertilized plants grow to heights between 0.9 m and 1.1 m. Most of the plants grow to heights in the range 0.9 m to 1.1 m.

(b) Let $P_A(x)$ be the cumulative distribution function of the plants that were fertilized with A. Since $P_A(x)$ rises the most in the range 0.7 m $\leq x \leq$ 0.9 m, many of the plants fertilized with A will have heights in the range 0.7 m to 0.9 m. Reading from the graph of P_A, we find that $P_A(0.7) \approx 0.2$ and $P_A(0.9) \approx 0.8$, so $P_A(0.9) - P_A(0.7) \approx 0.8 - 0.2 = 0.6 = 60\%$ of the plants fertilized with A have heights between 0.7 m and 0.9 m. Fertilizer A had the effect of stunting the growth of the plants.

On the other hand, the cumulative distribution function $P_B(x)$ of the heights of the plants fertilized with B rises the most in the range 1.1 m $\leq x \leq$ 1.3 m, so most of these plants have heights in the range 1.1 m to 1.3 m. Fertilizer B caused the plants to grow about 0.2 m taller than they would have with no fertilizer.

16. (a) $F(7) = 0.6$ tells us that 60% of the trees in the forest have height 7 meters or less.

(b) $F(7) > F(6)$. There are more trees of height less than 7 meters than trees of height less than 6 meters because every tree of height ≤ 6 meters also has height ≤ 7 meters.

17. For a small interval Δx around 68, the fraction of the population of American men with heights in this interval is about $(0.2)\Delta x$. For example, taking $\Delta x = 0.1$, we can say that approximately $(0.2)(0.1) = 0.02 = 2\%$ of American men have heights between 68 and 68.1 inches.

18. We want to find the cumulative distribution function for the age density function. We see that $P(10)$ is equal to 0.15 since the table shows that 15% of the population is between 0 and 10 years of age. Also,

$$P(20) = \frac{\text{Fraction of the population}}{\text{between 0 and 20 years old}} = 0.15 + 0.14 = 0.29$$

and

$$P(30) = 0.15 + 0.14 + 0.14 = 0.43.$$

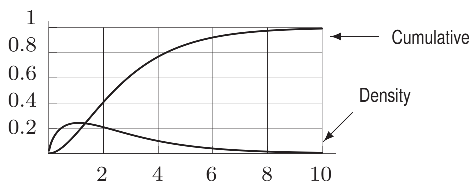
Continuing in this way, we obtain the values for $P(t)$ shown in Table 8.7.

Table 8.7 *Cumulative distribution function of ages in the US*

t	0	10	20	30	40	50	60	70	80	90	100
$P(t)$	0	0.15	0.29	0.43	0.60	0.74	0.84	0.92	0.97	0.99	1.00

19. (a) The two functions are shown below. The choice is based on the fact that the cumulative distribution does not decrease.

(b) The cumulative distribution levels off to 1, so the top mark on the vertical scale must be 1.



The total area under the density function must be 1. Since the area under the density function is about 2.5 boxes, each box must have area $1/2.5 = 0.4$. Since each box has a height of 0.2, the base must be 2.

20. (a) The area under the graph of the height density function $p(x)$ is concentrated in two humps centered at 0.5 m and 1.1 m. The plants can therefore be separated into two groups, those with heights in the range 0.3 m to 0.7 m, corresponding to the first hump, and those with heights in the range 0.9 m to 1.3 m, corresponding to the second hump. This grouping of the grasses according to height is probably close to the species grouping. Since the second hump contains more area than the first, there are more plants of the tall grass species in the meadow.

(b) As do all cumulative distribution functions, the cumulative distribution function $P(x)$ of grass heights rises from 0 to 1 as x increases. Most of this rise is achieved in two spurts, the first as x goes from 0.3 m to 0.7 m, and the second as x goes from 0.9 m to 1.3 m. The plants can therefore be separated into two groups, those with heights in the range 0.3 m to 0.7 m, corresponding to the first spurt, and those with heights in the range 0.9 m to 1.3 m, corresponding to the second spurt. This grouping of the grasses according to height is the same as the grouping we made in part (a), and is probably close to the species grouping.

(c) The fraction of grasses with height less than 0.7 m equals $P(0.7) = 0.25 = 25\%$. The remaining 75% are the tall grasses.

21. (a) The percentage of calls lasting from 1 to 2 minutes is given by the integral

$$\int_1^2 p(x)\,dx \int_1^2 0.4e^{-0.4x}\,dx = e^{-0.4} - e^{-0.8} \approx 22.1\%.$$

(b) A similar calculation (changing the limits of integration) gives the percentage of calls lasting 1 minute or less as

$$\int_0^1 p(x)\,dx = \int_0^1 0.4e^{-0.4x}\,dx = 1 - e^{-0.4} \approx 33.0\%.$$

(c) The percentage of calls lasting 3 minutes or more is given by the improper integral

$$\int_3^\infty p(x)\,dx = \lim_{b\to\infty} \int_3^b 0.4e^{-0.4x}\,dx = \lim_{b\to\infty} (e^{-1.2} - e^{-0.4b}) = e^{-1.2} \approx 30.1\%.$$

(d) The cumulative distribution function is the integral of the probability density; thus,

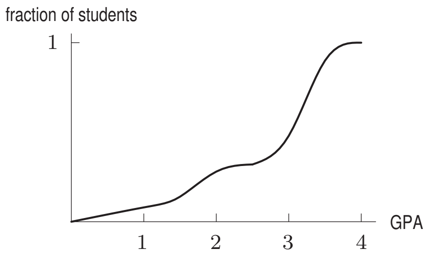
$$C(h) = \int_0^h p(x)\,dx = \int_0^h 0.4e^{-0.4x}\,dx = 1 - e^{-0.4h}.$$

22. (a) The fraction of students passing is given by the area under the curve from 2 to 4 divided by the total area under the curve. This appears to be about $\frac{2}{3}$.

(b) The fraction with honor grades corresponds to the area under the curve from 3 to 4 divided by the total area. This is about $\frac{1}{3}$.

(c) The peak around 2 probably exists because many students work to get just a passing grade.

(d)



23. (a) Most of the earth's surface is below sea level. Much of the earth's surface is either around 3 miles below sea level or exactly at sea level. It appears that essentially all of the surface is between 4 miles below sea level and 2 miles above sea level. Very little of the surface is around 1 mile below sea level.

(b) The fraction below sea level corresponds to the area under the curve from -4 to 0 divided by the total area under the curve. This appears to be about $\frac{3}{4}$.

24. (a) We must have $\displaystyle\int_0^\infty f(t)dt = 1$, for even though it is possible that any given person survives the disease, everyone eventually dies. Therefore,

$$\int_0^\infty cte^{-kt}dt = 1.$$

Integrating by parts gives

$$\begin{aligned}
\int_0^b cte^{-kt}dt &= -\frac{c}{k}te^{-kt}\Big|_0^b + \int_0^b \frac{c}{k}e^{-kt}dt \\
&= \left(-\frac{c}{k}te^{-kt} - \frac{c}{k^2}e^{-kt}\right)\Big|_0^b \\
&= \frac{c}{k^2} - \frac{c}{k}be^{-kb} - \frac{c}{k^2}e^{-kb}.
\end{aligned}$$

As $b \to \infty$, we see

$$\int_0^{\infty} cte^{-kt} dt = \frac{c}{k^2} = 1 \quad \text{so} \quad c = k^2.$$

(b) We are told that $\displaystyle\int_0^5 f(t)dt = 0.4$, so using the fact that $c = k^2$ and the antiderivatives from part (a), we have

$$\begin{aligned}\int_0^5 k^2 te^{-kt} dt &= \left(-\frac{k^2}{k}te^{-kt} - \frac{k^2}{k^2}e^{-kt}\right)\Big|_0^5 \\ &= 1 - 5ke^{-5k} - e^{-5k} = 0.4\end{aligned}$$

so

$$5ke^{-5k} + e^{-5k} = 0.6.$$

Since this equation cannot be solved exactly, we use a calculator or computer to find $k = 0.275$. Since $c = k^2$, we have $c = (0.275)^2 = 0.076$.

(c) The cumulative death distribution function, $C(t)$, represents the fraction of the population that have died up to time t. Thus,

$$\begin{aligned}C(t) &= \int_0^t k^2 xe^{-kx} dx = \left(-kxe^{-kx} - e^{-kx}\right)\Big|_0^t \\ &= 1 - kte^{-kt} - e^{-kt}.\end{aligned}$$

Strengthen Your Understanding

25. The fact that $p(1) = 0.02$ tells us that the probability that x falls in a small interval of length Δx around 1 is $0.02\Delta x$.

26. The cumulative distribution gives the probability that x is less than some value. Thus, $P(5) = 0.4$ means that the probability that x is less that 5 is 0.4.

27. Every density function $p(t)$ satisfies the equation $\int_{-\infty}^{\infty} p(t)\,dt = 1$. Since $\int_{-\infty}^{\infty} t^2\,dt = \infty$, the function $p(t) = t^2$ is not a density function.

28. Since this function is increasing for $x > 0$, the area under its graph increases without bound. So the area under the graph of this function is not equal to 1.

29. As $x \to \infty$ the function $P(x) = x^2 e^x$ grows without bound, whereas a cumulative distribution function must approach 1.

30. Every cumulative distribution is a nondecreasing function, but $P(t) = e^{-t^2}$ is decreasing for $t > 0$.

31. A cumulative distribution function is increasing for all values of x; a probability density function is not.

32. We can take

$$p(x) = \begin{cases} 1/20, & 0 \le x \le 20 \\ 0, & \text{otherwise.} \end{cases}$$

It is a density function because $p(x) \ge 0$ for $0 \le x \le 20$ and $\int_{-\infty}^{\infty} p(x)\,dx = 1$.

33. We can use

$$P(t) = \begin{cases} 0, & t < 0 \\ t, & 0 \le t \le 1 \\ 1, & t > 1. \end{cases}$$

It is a cumulative distribution function because $P(t)$ is an increasing function that increases from 0 to 1.

34. One possible density function is given by

$$p(x) = \begin{cases} 0 & x < 2 \\ 1/5 & 2 \le x \le 7 \\ 0 & 7 < x. \end{cases}$$

This function is nonzero only between $x = 2$ and $x = 7$ and has $\int_{-\infty}^{\infty} p(x)\,dx = 1$.

35. The cumulative distribution function increases between $x = 3$ and $x = 7$. One possible cumulative distribution function is

$$P(x) = \begin{cases} 0 & x < 3 \\ 1/4(x-3) & 3 \le x \le 7 \\ 1 & x > 7. \end{cases}$$

36. False. Since $p(x) < 0$ for $x < 0$, it cannot be a probability density function.

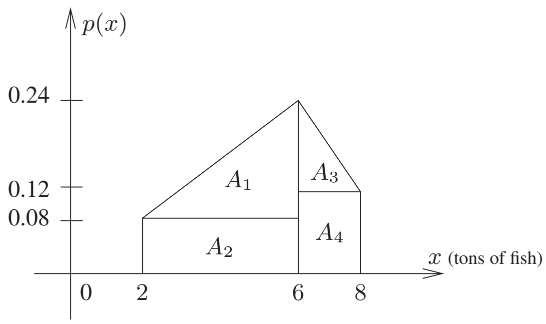
37. False. It is true that $p(x) \ge 0$ for all x, but we also need $\int_{-\infty}^{\infty} p(x)dx = 1$. Since $p(x) = 0$ for $x \le 0$, we need only check the integral from 0 to ∞. We have

$$\int_0^\infty xe^{-x^2}dx = \lim_{b\to\infty}\left(-\frac{1}{2}e^{-x^2}\right)\Bigg|_0^b = \frac{1}{2}.$$

Solutions for Section 8.8

Exercises

1.



Splitting the figure into four pieces, we see that

$$\begin{aligned}\text{Area under the curve} &= A_1 + A_2 + A_3 + A_4 \\ &= \frac{1}{2}(0.16)4 + 4(0.08) + \frac{1}{2}(0.12)2 + 2(0.12) \\ &= 1.\end{aligned}$$

We expect the area to be 1, since $\displaystyle\int_{-\infty}^{\infty} p(x)\,dx = 1$ for any probability density function, and $p(x)$ is 0 except when $2 \le x \le 8$.

2. Recall that the mean is $\displaystyle\int_{-\infty}^{\infty} xp(x)\,dx$. In the fishing example, $p(x) = 0$ except when $2 \le x \le 8$, so the mean is

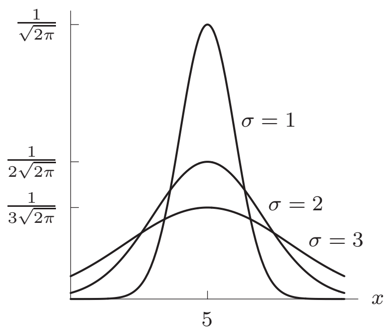
$$\int_2^8 xp(x)\,dx.$$

Using the equation for $p(x)$ from the graph,

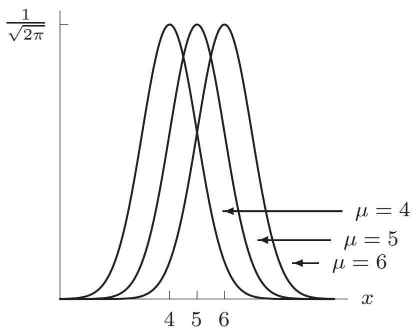
$$\begin{aligned}\int_2^8 xp(x)\,dx &= \int_2^6 xp(x)\,dx + \int_6^8 xp(x)\,dx \\ &= \int_2^6 x(0.04x)\,dx + \int_6^8 x(-0.06x + 0.6)\,dx \\ &= \frac{0.04x^3}{3}\Bigg|_2^6 + \left(-0.02x^3 + 0.3x^2\right)\Bigg|_6^8 \\ &\approx 5.253 \text{ tons.}\end{aligned}$$

3. (a)

(i)



(ii)



(b) Recall that the mean is the "balancing point." In other words, if the area under the curve was made of cardboard, we'd expect it to balance at the mean. All of the graphs are symmetric across the line $x = \mu$, so μ is the "balancing point" and hence the mean.

As the graphs also show, increasing σ flattens out the graph, in effect lessening the concentration of the data near the mean. Thus, the smaller the σ value, the more data is clustered around the mean.

Problems

4. The mean is the value of the integral

$$\int_0^2 x \cdot 0.5(2-x)\,dx = \frac{2}{3}.$$

The median is the value of T such that

$$\int_0^T 0.5(2-x)\,dx = 0.5.$$

Integrating gives the equation

$$x - 0.5\frac{x^2}{2}\bigg|_0^T = T - \frac{T^2}{4} = 0.5$$

which is a quadratic with solutions $T = 2 \pm \sqrt{2}$. Since the median must be between 0 and 2, the solution we want is $T = 2 - \sqrt{2} = 0.586$.

5. The median is the value of T such that $P(T) = 0.5$, so we solve

$$T - \frac{T^2}{4} = \frac{1}{2}$$

to get $T = 2 \pm \sqrt{2}$. Since the median is between 0 and 2 we discard the larger solution, so the median is $T = 2 - \sqrt{2}$.
To find the mean, we first calculate the probability density

$$\text{Density } = p(x) = P'(x) = 1 - \frac{x}{2}$$

and then evaluate the integral

$$\text{Mean } = \int_0^2 xp(x)\,dx = \int_0^2 x - \frac{x^2}{2}\,dx = \frac{2}{3}.$$

So the mean is $2/3$.

6. (a) Since $d(e^{-ct})/dt = ce^{-ct}$, we have

$$c\int_0^6 e^{-ct}dt = -e^{-ct}\Big|_0^6 = 1 - e^{-6c} = 0.1,$$

so

$$c = -\frac{1}{6}\ln 0.9 \approx 0.0176.$$

(b) Similarly, with $c = 0.0176$, we have

$$c\int_6^{12} e^{-ct}dt = -e^{-ct}\Big|_6^{12}$$
$$= e^{-6c} - e^{-12c} = 0.9 - 0.81 = 0.09,$$

so the probability is 9%.

7. (a) We can find the proportion of students by integrating the density $p(x)$ between $x = 1.5$ and $x = 2$:

$$P(2) - P(1.5) = \int_{1.5}^{2} \frac{x^3}{4}\,dx$$
$$= \frac{x^4}{16}\Big|_{1.5}^{2}$$
$$= \frac{(2)^4}{16} - \frac{(1.5)^4}{16} = 0.684,$$

so that the proportion is $0.684 : 1$ or 68.4%.

(b) We find the mean by integrating x times the density over the relevant range:

$$\text{Mean} = \int_0^2 x\left(\frac{x^3}{4}\right)\,dx$$
$$= \int_0^2 \frac{x^4}{4}\,dx$$
$$= \frac{x^5}{20}\Big|_0^2$$
$$= \frac{2^5}{20} = 1.6 \text{ hours.}$$

(c) The median will be the time T such that exactly half of the students are finished by time T, or in other words

$$\frac{1}{2} = \int_0^T \frac{x^3}{4}\,dx$$
$$\frac{1}{2} = \frac{x^4}{16}\Big|_0^T$$
$$\frac{1}{2} = \frac{T^4}{16}$$
$$T = \sqrt[4]{8} = 1.682 \text{ hours.}$$

8. (a) Since $\int_0^\infty p(x)\,dx = 1$, we have

$$1 = \int_0^\infty ae^{-0.122x}\,dx$$
$$= \frac{a}{-0.122}e^{-0.122x}\Big|_0^\infty = \frac{a}{0.122}.$$

So $a = 0.122$.

(b)

$$P(x) = \int_0^x p(t)\,dt$$
$$= \int_0^x 0.122e^{-0.122t}\,dt$$
$$= -e^{0.122t}\Big|_0^x = 1 - e^{-0.122x}.$$

(c) Median is the x such that

$$P(x) = 1 - e^{-0.122x} = 0.5.$$

So $e^{-0.122x} = 0.5$. Thus,

$$x = -\frac{\ln 0.5}{0.122} \approx 5.68 \text{ seconds}$$

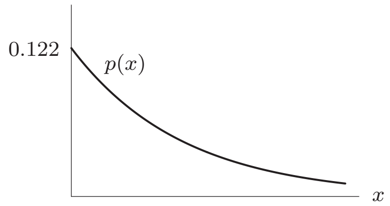
and

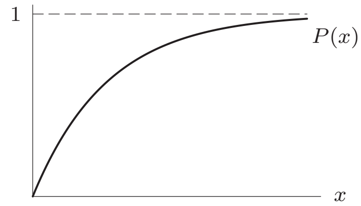
$$\text{Mean} = \int_0^\infty x(0.122)e^{-0.122x}\,dx = -\int_0^\infty x\left(-0.122e^{-0.122x}\right)\,dx.$$

We now use integration by parts. Let $u = -x$ and $v' = -0.122e^{-0.122x}$. Then $u' = -1$, and $v = e^{-0.122x}$. Therefore,

$$\text{Mean} = -xe^{-0.122x}\Big|_0^\infty + \int_0^\infty e^{-0.122x}\,dx = \frac{1}{0.122} \approx 8.20 \text{ seconds.}$$

(d)





9. (a) The cumulative distribution function

$$\begin{aligned} P(t) = \int_0^t p(x)dx &= \text{Area under graph of density function } p(x) \text{ for } 0 \le x \le t \\ &= \text{Fraction of population who survive } t \text{ years or less after treatment} \\ &= \text{Fraction of population who survive up to } t \text{ years after treatment.} \end{aligned}$$

(b) The probability that a randomly selected person survives for at least t years is the probability that he lives t years or longer, so

$$\begin{aligned} S(t) &= \int_t^\infty p(x)\,dx = \lim_{b\to\infty}\int_t^b Ce^{-Ct}\,dx \\ &= \lim_{b\to\infty} -e^{-Ct}\Big|_t^b = \lim_{b\to\infty} -e^{-Cb} - (-e^{-Ct}) = e^{-Ct}, \end{aligned}$$

or equivalently,

$$S(t) = 1 - \int_0^t p(x)\,dx = 1 - \int_0^t Ce^{-Ct}\,dx = 1 + e^{-Ct}\Big|_0^t = 1 + (e^{-Ct} - 1) = e^{-Ct}.$$

(c) The probability of surviving at least two years is

$$S(2) = e^{-C(2)} = 0.70$$

so

$$\begin{aligned} \ln e^{-C(2)} &= \ln 0.70 \\ -2C &= \ln 0.7 \\ C &= -\frac{1}{2}\ln 0.7 \approx 0.178. \end{aligned}$$

10. (a) The probability you dropped the glove within a kilometer of home is given by

$$\int_0^1 2e^{-2x}dx = -e^{-2x}\Big|_0^1 = -e^{-2}+1 \approx 0.865.$$

(b) Since the probability that the glove was dropped within y km $= \int_0^y p(x)dx = 1-e^{-2y}$, we solve

$$\begin{aligned} 1-e^{-2y} &= 0.95 \\ e^{-2y} &= 0.05 \\ y &= \frac{\ln 0.05}{-2} \approx 1.5 \text{ km.} \end{aligned}$$

11. (a) Since $\mu = 100$ and $\sigma = 15$:

$$p(x) = \frac{1}{15\sqrt{2\pi}} e^{-\frac{1}{2}\left(\frac{x-100}{15}\right)^2}.$$

(b) The fraction of the population with IQ scores between 115 and 120 is (integrating numerically)

$$\begin{aligned} \int_{115}^{120} p(x)\,dx &= \int_{115}^{120} \frac{1}{15\sqrt{2\pi}} e^{-\frac{(x-100)^2}{450}}\,dx \\ &= \frac{1}{15\sqrt{2\pi}} \int_{115}^{120} e^{-\frac{(x-100)^2}{450}}\,dx \\ &\approx 0.067 = 6.7\% \text{ of the population.} \end{aligned}$$

12. (a) The normal distribution of car speeds with $\mu = 58$ and $\sigma = 4$ is shown in Figure 8.138.

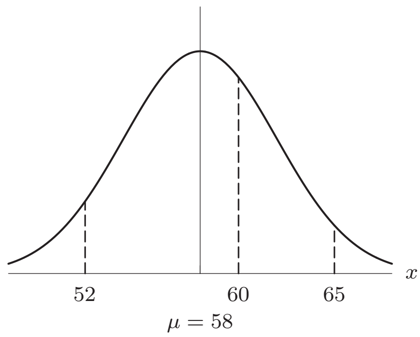


Figure 8.138

The probability that a randomly selected car is going between 60 and 65 is equal to the area under the curve from $x = 60$ to $x = 65$,

$$\text{Probability} = \frac{1}{4\sqrt{2\pi}} \int_{60}^{65} e^{-(x-58)^2/(2\cdot 4^2)}\,dx \approx 0.2685.$$

We obtain the value 0.2685 using a calculator or computer.

(b) To find the fraction of cars going under 52 km/hr, we evaluate the integral

$$\text{Fraction} = \frac{1}{4\sqrt{2\pi}} \int_0^{52} e^{-(x-58)^2/32} dx \approx 0.067.$$

Thus, approximately 6.7% of the cars are going less than 52 km/hr.

13. (a) First, we find the critical points of $p(x)$:

$$\begin{aligned}\frac{d}{dx}p(x) &= \frac{1}{\sigma\sqrt{2\pi}}\left[\frac{-2(x-\mu)}{2\sigma^2}\right]e^{-\frac{(x-\mu)^2}{2\sigma^2}}\\ &= -\frac{(x-\mu)}{\sigma^3\sqrt{2\pi}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}.\end{aligned}$$

This implies $x=\mu$ is the only critical point of $p(x)$.

To confirm that $p(x)$ is maximized at $x=\mu$, we rely on the first derivative test. As $-\frac{1}{\sigma^3\sqrt{2\pi}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}$ is always negative, the sign of $p'(x)$ is the opposite of the sign of $(x-\mu)$; thus $p'(x)>0$ when $x<\mu$, and $p'(x)<0$ when $x>\mu$.

(b) To find the inflection points, we need to find where $p''(x)$ changes sign; that will happen only when $p''(x)=0$. As

$$\frac{d^2}{dx^2}p(x) = -\frac{1}{\sigma^3\sqrt{2\pi}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}\left[-\frac{(x-\mu)^2}{\sigma^2}+1\right],$$

$p''(x)$ changes sign when $\left[-\frac{(x-\mu)^2}{\sigma^2}+1\right]$ does, since the sign of the other factor is always negative. This occurs when

$$\begin{aligned}-\frac{(x-\mu)^2}{\sigma^2}+1 &= 0,\\ -(x-\mu)^2 &= -\sigma^2,\\ x-\mu &= \pm\sigma.\end{aligned}$$

Thus, $x=\mu+\sigma$ or $x=\mu-\sigma$. Since $p''(x)>0$ for $x<\mu-\sigma$ and $x>\mu+\sigma$ and $p''(x)<0$ for $\mu-\sigma\le x\le\mu+\sigma$, these are in fact points of inflection.

(c) μ represents the mean of the distribution, while σ is the standard deviation. In other words, σ gives a measure of the "spread" of the distribution, i.e., how tightly the observations are clustered about the mean. A small σ tells us that most of the data are close to the mean; a large σ tells us that the data is spread out.

14. The fraction of the population within one standard deviation of the mean is given by

$$\text{Fraction within } \sigma \text{ of mean } = \int_{-\sigma}^{\sigma}\frac{1}{\sqrt{2\pi}\sigma}e^{-x^2/(2\sigma^2)}dx.$$

Let us substitute $w=\frac{x}{\sigma}$ so that $dw=\frac{1}{\sigma}dx$, and when $x=\pm\sigma$, $w=\pm1$. Then we have

$$\text{Fraction } = \int_{-\sigma}^{\sigma}\frac{1}{\sqrt{2\pi}\sigma}e^{-x^2/(2\sigma^2)}dx = \int_{-1}^{1}\frac{1}{\sqrt{2\pi}\sigma}e^{-w^2/2}\cdot\sigma dw = \int_{-1}^{1}\frac{1}{\sqrt{2\pi}}e^{-w^2/2}dw.$$

This integral is independent of σ. Evaluating the integral numerically gives 0.68, showing that about 68% of the population lies within one standard deviation of the mean.

15. It is not (a) since a probability density must be a non-negative function; not (c) since the total integral of a probability density must be 1; (b) and (d) are probability density functions, but (d) is not a good model. According to (d), the probability that the next customer comes after 4 minutes is 0. In real life there should be a positive probability of not having a customer in the next 4 minutes. So (b) is the best answer.

16. (a) Since P is the cumulative distribution function, the percentage of households that made between \$40,000 and \$60,000 is

$$P(60)-P(40) = 66.8\% - 50.1\% = 16.7\%.$$

Therefore 16.7% of the households made between \$40,000 and \$60,000.

The percentage of households making over \$100,000 is $100\% - 87.1\% = 12.9\%$.

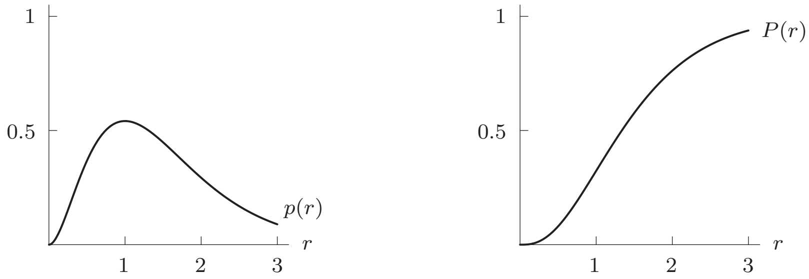
(b) The median income is the income such that half the households make less than this amount. Looking at the table, we see that the 50% mark occurs between \$20,000 and \$40,000. Since $P(20)=29.5\%$, we know 29.5% of the households made less than \$20,000. Assuming local linearity we calculate the slope of the line connecting $(20, 29.5)$ with $(40, 50.1)$ as $(50.1-29.5)/20 = 1.03$. If x is the additional income it takes to achieve the median, then $1.03x = 50.0-29.5$, so $x=19.90$. Since $20+19.90=39.90$, the median income is approximately \$39,900. This looks sensible since just over 50% of the population earn \$40,000.

(c) The percentage of households that made between \$40,000 and \$75,000 is $76.2-50.1=26.1$. Since this percentage is less than $1/3$, the statement is false.

17. (a) Let the $p(r)$ be the density function. Then $P(r) = \int_0^r p(x)\,dx$, and from the Fundamental Theorem of Calculus, $p(r) = \frac{d}{dr}P(r) = \frac{d}{dr}(1-(2r^2+2r+1)e^{-2r}) = -(4r+2)e^{-2r} + 2(2r^2+2r+1)e^{-2r}$, or $p(r) = 4r^2e^{-2r}$.

We have that $p'(r) = 8r(e^{-2r}) - 8r^2e^{-2r} = e^{-2r}\cdot 8r(1-r)$, which is zero when $r=0$ or $r=1$, negative when $r>1$, and positive when $r<1$. Thus $p(1) = 4e^{-2} \approx 0.54$ is a relative maximum.

Here are sketches of $p(r)$ and the cumulative position $P(r)$:



(b) The median distance is the distance r such that $P(r) = 1-(2r^2+2r+1)e^{-2r} = 0.5$, or equivalently, $(2r^2+2r+1)e^{-2r} = 0.5$.

By experimentation with a calculator, we find that $r \approx 1.33$ Bohr radii is the median distance.

The mean distance is equal to the value of the integral $\int_0^\infty rp(r)\,dr = \lim_{x\to\infty}\int_0^x rp(r)\,dr$. We have that $\int_0^x rp(r)\,dr = \int_0^x 4r^3e^{-2r}\,dr$. Using the integral table, we get

$$\begin{aligned}\int_0^x 4r^3e^{-2r}\,dr &= \left[\left(-\frac{1}{2}\right)4r^3 - \frac{1}{4}(12r^2) - \frac{1}{8}(24r) - \frac{1}{16}(24)\right]e^{-2x}\Bigg|_0^x \\ &= \frac{3}{2} - \left[2x^3+3x^2+3x+\frac{3}{2}\right]e^{-2x}.\end{aligned}$$

Taking the limit of this expression as $x\to\infty$, we see that all terms involving (powers of x or constants) $\cdot\, e^{-2x}$ have limit 0, and thus the mean distance is 1.5 Bohr radii.

The most likely distance is obtained by maximizing $p(r) = 4r^2e^{-2r}$; as we have already seen this corresponds to $r=1$ Bohr unit.

(c) Because it is the most likely distance of the electron from the nucleus.

Strengthen Your Understanding

18. A median satisfies $P(T) = 0.5$ where P is the cumulative distribution function.

19. The median is the value which divides the area under the density function graph into halves. The median of this function cannot be 1 since all of the area is to the left of $x=1$. The median is between 0 and 1.

20. We can use the normal distribution

$$p(x) = \frac{1}{\sigma\sqrt{2\pi}}e^{-(x-\mu)^2/(2\sigma^2)}$$

with $\mu = \sigma = 1/2$ to get

$$p(x) = \frac{2}{\sqrt{2\pi}}e^{-2(x-1/2)^2}.$$

21. We can take a constant, or uniform distribution

$$p(x) = \begin{cases} 0 & \text{for} \quad x<0 \\ 1 & \text{for} \quad 0\le x\le 1 \\ 0 & \text{for} \quad x>1. \end{cases}$$

Since

$$\int_0^1 x\,dx = \frac{1}{2}, \quad \text{the mean is } \frac{1}{2}.$$

Since

$$\int_0^{1/2} p(x)\,dx = \int_0^{1/2} 1\,dx = \frac{1}{2}, \quad \text{the median is also } \frac{1}{2}.$$

22. False. Note that p is the density function for the population, not the cumulative density function. Thus $p(10) = 1/2$ means that the probability of x lying in a small interval of length Δx around $x = 10$ is about $(1/2)\Delta x$.

23. True. This follows directly from the definition of the cumulative density function.

24. True. The interval from $x = 9.98$ to $x = 10.04$ has length 0.06. Assuming that the value of $p(x)$ is near $1/2$ for $9.98 < x < 10.04$, the fraction of the population in that interval is $\int_{9.98}^{10.04} p(x)\,dx \approx (1/2)(0.06) = 0.03$.

25. False. Note that p is the density function for the population, not the cumulative density function. Thus $p(10) = p(20)$ means that x values near 10 are as likely as x values near 20.

26. True. By the definition of the cumulative distribution function, $P(20) - P(10) = 0$ is the fraction of the population having x values between 10 and 20.

Solutions for Chapter 8 Review

Exercises

1. Vertical slices are circular. Horizontal slices would be similar to ellipses in cross-section, or at least ovals (a word derived from *ovum*, the Latin word for egg).

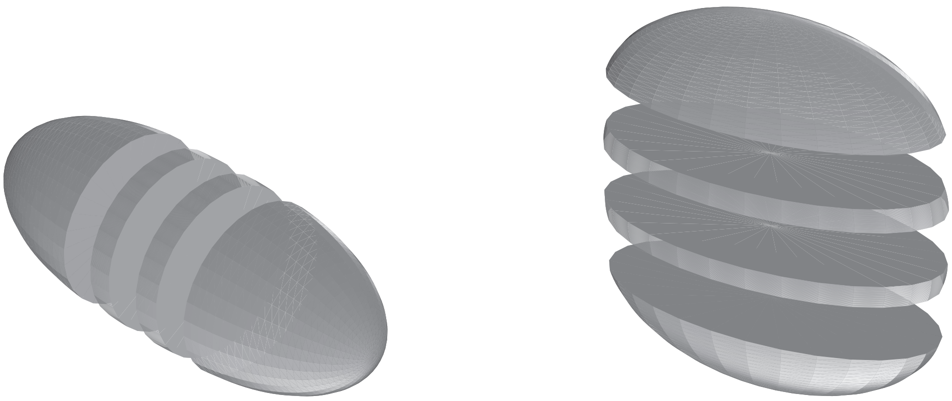


Figure 8.139

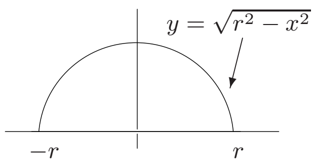
2. The limits of integration are 0 and b, and the rectangle represents the region under the curve $f(x) = h$ between these limits. Thus,

$$\text{Area of rectangle} = \int_0^b h\,dx = hx\Big|_0^b = hb.$$

3. The circle $x^2 + y^2 = r^2$ cannot be expressed as a function $y = f(x)$, since for every x with $-r < x < r$, there are two corresponding y values on the circle. However, if we consider the top half of the circle only, as shown below, we have $x^2 + y^2 = r^2$, or $y^2 = r^2 - x^2$, and taking the positive square root, we have that $y = \sqrt{r^2 - x^2}$ is the equation of the top semicircle.



Then

$$\text{Area of Circle} = 2(\text{Area of semicircle}) = 2\int_{-r}^{r} \sqrt{r^2 - x^2}\,dx$$

We evaluate this using integral table formula 30.

$$\begin{aligned}2\int_{x=-r}^{x=r}\sqrt{r^2-x^2}\,dx &= 2\left[\frac{1}{2}\left(x\sqrt{r^2-x^2}+r^2\arcsin\frac{x}{r}\right)\right]\Bigg|_{-r}^{r}\\ &= r^2(\arcsin 1-\arcsin(-1))\\ &= r^2\left(\frac{\pi}{2}-\left(-\frac{\pi}{2}\right)\right)=\pi r^2.\end{aligned}$$

4. Name the slanted line $y = f(x)$. Then the triangle is the region under the line $y = f(x)$ and between the lines $y = 0$ and $x = b$. Thus,

$$\text{Area of triangle} = \int_0^b f(x)\,dx.$$

Since $f(x)$ is a line of slope h/b which passes through the origin, its equation is $f(x) = hx/b$. Thus,

$$\text{Area of triangle} = \int_0^b \frac{hx}{b}\,dx = \frac{hx^2}{2b}\Bigg|_0^b = \frac{hb^2}{2b} = \frac{hb}{2}.$$

5. We slice the region vertically. Each rotated slice is approximately a cylinder with radius $y = x^2 + 1$ and thickness Δx. See Figure 8.140. The volume of a typical slice is $\pi(x^2+1)^2\Delta x$. The volume, V, of the object is the sum of the volumes of the slices:

$$V \approx \sum \pi(x^2+1)^2\Delta x.$$

As $\Delta x \to 0$ we obtain an integral.

$$V = \int_0^4 \pi(x^2+1)^2dx = \pi\int_0^4 (x^4+2x^2+1)dx = \pi\left(\frac{x^5}{5}+\frac{2x^3}{3}+x\right)\Bigg|_0^4 = \frac{3772\pi}{15} = 790.006.$$

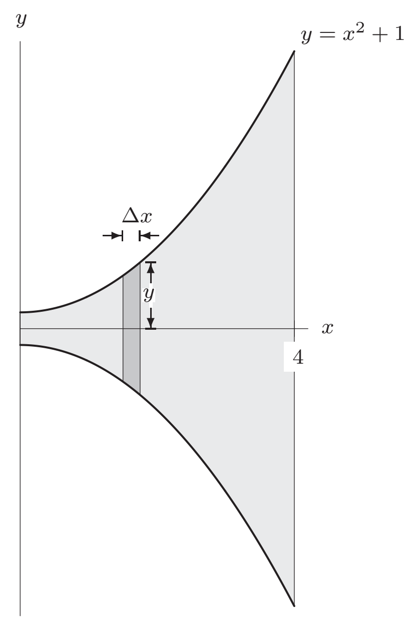


Figure 8.140

6. We slice the region vertically. Each rotated slice is approximately a cylinder with radius $y = \sqrt{x}$ and thickness Δx. See Figure 8.141. The volume of a typical slice is $\pi(\sqrt{x})^2\Delta x$. The volume, V, of the object is the sum of the volumes of the slices:

$$V \approx \sum \pi(\sqrt{x})^2\Delta x.$$

As $\Delta x \to 0$ we obtain an integral.

$$V = \int_1^2 \pi(\sqrt{x})^2 dx = \pi \int_1^2 x dx = \pi \left(\frac{x^2}{2}\right)\bigg|_1^2 = \frac{3\pi}{2} = 4.712.$$

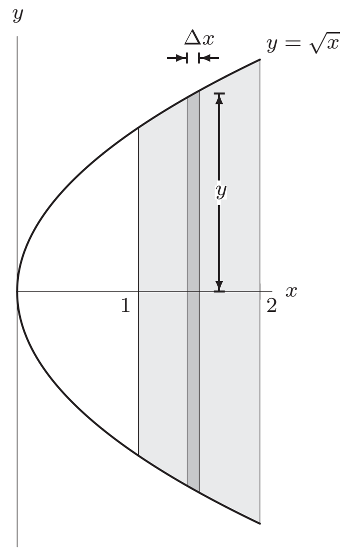

Figure 8.141

7. We slice the region vertically. Each rotated slice is approximately a cylinder with radius $y = e^{-2x}$ and thickness Δx. See Figure 8.142. The volume of a typical slice is $\pi(e^{-2x})^2\Delta x$. The volume, V, of the object is the sum of the volumes of the slices:

$$V \approx \sum \pi(e^{-2x})^2 \Delta x.$$

As $\Delta x \to 0$ we obtain an integral.

$$V = \int_0^1 \pi(e^{-2x})^2 dx = \pi \int_0^1 e^{-4x} dx = \pi\left(-\frac{1}{4}\right)(e^{-4x})\bigg|_0^1 = -\frac{\pi}{4}(e^{-4} - 1) = 0.771.$$

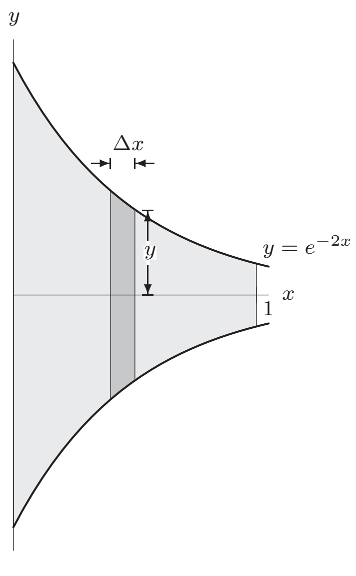

Figure 8.142

8. We slice the region vertically. Each rotated slice is approximately a cylinder with radius $y = 4 - x^2$ and thickness Δx. See Figure 8.143. The volume, V, of a typical slice is $\pi(4-x^2)^2\Delta x$. The volume of the object is the sum of the volumes of the slices:

$$V \approx \sum \pi(4 - x^2)^2\Delta x.$$

As $\Delta x \to 0$ we obtain an integral. Since the region lies between $x = -2$ and $x = 2$, we have:

$$V = \int_{-2}^{2} \pi(4-x^2)^2 dx = \pi \int_{-2}^{2} (16 - 8x^2 + x^4)dx = \pi \left(16x - \frac{8x^3}{3} + \frac{x^5}{5}\right)\Bigg|_{-2}^{2} = \frac{512\pi}{15} = 107.233.$$

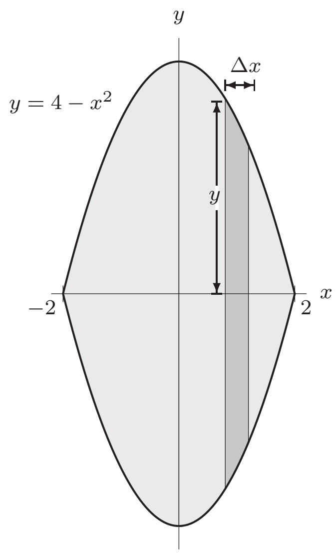

Figure 8.143

9. We divide the region into vertical strips of thickness Δx. As a slice is rotated about the x-axis, it creates a disk of radius r_{out} from which has been removed a smaller circular disk of inside radius r_{in}. We see in Figure 8.144 that $r_{\text{out}} = 2x$ and $r_{\text{in}} = x$. Thus,

$$\text{Volume of a slice } \approx \pi(r_{\text{out}})^2\Delta x - \pi(r_{\text{in}})^2\Delta x = \pi(2x)^2\Delta x - \pi(x)^2\Delta x.$$

To find the total volume, V, we integrate this quantity between $x = 0$ and $x = 3$:

$$V = \int_0^3 (\pi(2x)^2 - \pi(x)^2)dx = \pi \int_0^3 (4x^2 - x^2)\, dx = \pi \int_0^3 3x^2 dx = \pi x^3\Big|_0^3 = 27\pi = 84.823.$$

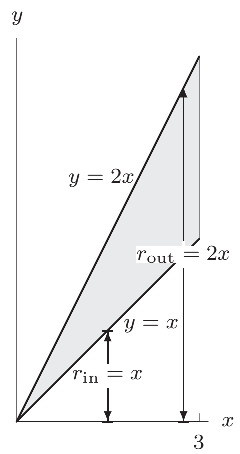

Figure 8.144

10. The two functions intersect at $(0,0)$ and $(8,2)$. We slice the volume with planes perpendicular to the x-axis. This divides the solid into thin washers with

$$\text{Volume of slice } = \pi r_{out}^2 \Delta x - \pi r_{in}^2 \Delta x.$$

The inner radius is the vertical distance from the x-axis to the curve $y = \frac{1}{4}x$. Similarly, the outer radius is the vertical distances from the x-axis to the curve $y = \sqrt[3]{x}$. Integrating from $x = 0$ to $x = 8$ we have

$$V = \int_0^8 \left[\pi(\sqrt[3]{x})^2 - \pi(\frac{1}{4}x)^2\right] dx.$$

11. The region is bounded by $y = 2$, the y-axis and $y = x^{1/3}$. The two functions $y = 2$ and $y = x^{1/3}$ intersect at $(8,2)$. We slice the volume with planes that are perpendicular to the y-axis. This divides the solid into thin cylinders with

$$\text{Volume } \approx \pi r^2 \Delta y.$$

The radius is the distance from the y-axis to the curve $x = y^3$. Integrating from $y = 0$ to $y = 2$ we have

$$V = \int_0^2 \pi(y^3)^2 \, dy.$$

12. The region is bounded by $y = 2$, the y-axis and $y = x^{1/3}$. The two functions $y = 2$ and $y = x^{1/3}$ intersect at $(8,2)$. We slice the volume with planes that are perpendicular to the line $y = -2$. This divides the solid into thin washers with

$$\text{Volume } \approx \pi r_{out}^2 \Delta x - \pi r_{in}^2 \Delta x.$$

The inner radius is the distance from the line $y = -2$ to the curve $y = x^{1/3}$ and the outer radius is the distance from the line $y = -2$ to the line $y = 2$. Integrating from $x = 0$ to $x = 8$ we have

$$V = \int_0^8 \left[\pi(2-(-2))^2 - \pi(x^{1/3} - (-2))^2\right] dx.$$

13. The region is bounded by $x = 4y$, the x-axis and $x = 8$. The two lines $x = 4y$ and $x = 8$ intersect at $(8,2)$. We slice the volume with planes that are perpendicular to the line $x = 10$. This divides the solid into thin washers with

$$\text{Volume } \approx \pi r_{out}^2 dy - \pi r_{in}^2 dy.$$

The inner radius is the distance from the line $x = 10$ to the line $x = 8$ and the outer radius is the distance from the line $x = 10$ to the line $x = 4y$. Integrating from $y = 0$ to $y = 2$ we have

$$V = \int_0^2 \left[\pi(10 - 4y)^2 - \pi(2)^2\right] dy.$$

14. The region is bounded by $y = \frac{1}{4}x$, the x-axis and $x = 8$. The two lines $y = \frac{1}{4}x$ and $x = 8$ intersect at $(8,2)$. We slice the volume with planes that are perpendicular to the line $y = 3$. This divides the solid into thin washers with

$$\text{Volume } \approx \pi r_{out}^2 \Delta x - \pi r_{in}^2 \Delta x.$$

The inner radius is the distance from the line $y = 3$ to the line $y = \frac{1}{4}x$ and the outer radius is the distance from the line $y = 3$ to the x-axis. Integrating from $x = 0$ to $x = 8$ we have

$$V = \int_0^8 \left[\pi(1 - \frac{1}{4}x)^2 - \pi(3)^2\right] dx.$$

15. The region is bounded by $x = 4x$ and $x = y^3$. The two functions intersect at $(0,0)$ and $(8,2)$. We slice the volume with planes that are perpendicular to the line $x = -3$. This divides the solid into thin washers with

$$\text{Volume } = \pi r_{out}^2 \Delta y - \pi r_{in}^2 \Delta y.$$

The inner radius is the distance from the line $x = -3$ to $x = y^3$ and the outer radius is the distance from the line $x = -3$ to the line $x = 4y$. Integrating from $y = 0$ to $y = 2$ we have

$$V = \int_0^2 \left[\pi(4y + 3)^2 - \pi(y^3 + 3)^2\right] dx.$$

16. Each slice is a circular disk. The radius, r, of the disk increases with h and is given in the problem by $r = \sqrt{h}$. Thus

$$\text{Volume of slice } \approx \pi r^2 \Delta h = \pi h \Delta h.$$

Summing over all slices, we have

$$\text{Total volume } \approx \sum \pi h \Delta h.$$

Taking a limit as $\Delta h \to 0$, we get

$$\text{Total volume } = \lim_{\Delta h \to 0} \sum \pi h \Delta h = \int_0^{12} \pi h \, dh.$$

Evaluating gives

$$\text{Total volume } = \pi \frac{h^2}{2} \bigg|_0^{12} = 72\pi.$$

17.

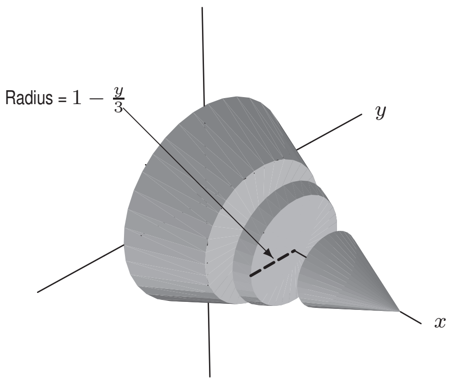

Figure 8.145

Slice parallel to the base of the cone, or, equivalently, rotate the line $x = (3 - y)/3$ about the y–axis. (One can also slice the other way.) See Figure 8.145. The volume V is given by

$$\begin{aligned} V &= \int_{y=0}^{y=3} \pi x^2 \, dy = \int_0^3 \pi \left(\frac{3-y}{3}\right)^2 dy \\ &= \pi \int_0^3 \left(1 - \frac{2y}{3} + \frac{y^2}{9}\right) dy \\ &= \pi \left(y - \frac{y^2}{3} + \frac{y^3}{27}\right) \bigg|_0^3 = \pi. \end{aligned}$$

18. (a) We slice the pyramid horizontally. See Figure 8.146. Each slice is a square slab of thickness Δh, so the volume of a slice at height h is $s^2 \Delta h$, where s is the length of a side. We use the similar triangles in Figure 8.147 to write s as a function of h:

$$\frac{s}{10-h} = \frac{8}{10} \quad \text{so} \quad s = 0.8(10-h).$$

The volume of the slice at height h is $(0.8(10-h))^2 \Delta h$. To find the total volume, we integrate this quantity from $h = 0$ to $h = 10$.

$$V = \int_0^{10} (0.8(10-h))^2 dh = 0.64 \int_0^{10} (h-10)^2 dh = \frac{16}{75}(h-10)^3 \bigg|_0^{10} = \frac{640}{3} = 213.333 \text{ m}^3.$$

(b) As in part (a),

$$\text{Volume of a slice at height } h \approx s^2 \Delta h = (0.8(10-h))^2 \Delta h.$$

The height h ranges from $h = 0$ to $h = 6$. We have

$$V = \int_0^6 (0.8(10-h))^2 dh = 0.64 \int_0^6 (h-10)^2 \, dh = \frac{16}{75}(h-10)^3 \bigg|_0^6 = \frac{4992}{25} = 199.680 \text{ m}^3.$$

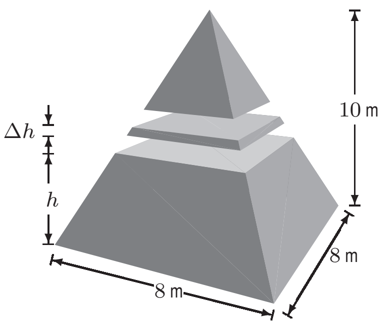

Figure 8.146

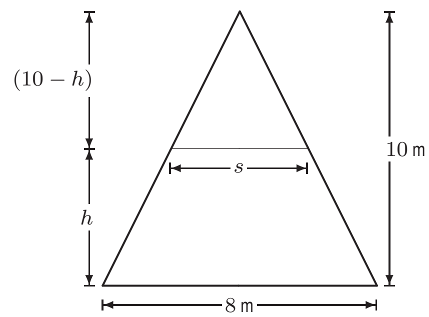

Figure 8.147

19. We slice the tank horizontally. There is an outside radius r_{out} and an inside radius r_{in} and, at height h,

$$\text{Volume of a slice } \approx \pi(r_{\text{out}})^2\Delta h - \pi(r_{\text{in}})^2\Delta h.$$

See Figure 8.148. We see that $r_{\text{out}} = 3$ for every slice. We use similar triangles to find r_{in} in terms of the height h:

$$\frac{r_{\text{in}}}{h} = \frac{3}{6} \quad \text{so} \quad r_{\text{in}} = \frac{1}{2}h.$$

At height h,

$$\text{Volume of slice } \approx \pi(3)^2\Delta h - \pi\left(\frac{1}{2}h\right)^2\Delta h.$$

To find the total volume, we integrate this quantity from $h = 0$ to $h = 6$.

$$V = \int_0^6 \left(\pi(3)^2 - \pi\left(\frac{1}{2}h\right)^2\right) dh = \pi\int_0^6 \left(9 - \frac{1}{4}h^2\right) dh = \pi\left(9h - \frac{h^3}{12}\right)\Bigg|_0^6 = 36\pi = 113.097 \text{ m}^3.$$

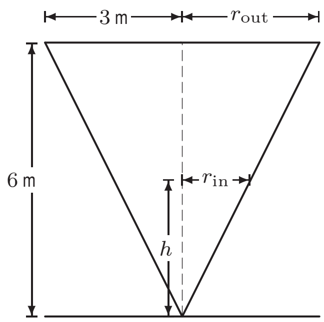

Figure 8.148

20. Since $f(x) = \sin x$, $f'(x) = \cos(x)$, so

$$\text{Arc Length} = \int_0^\pi \sqrt{1 + \cos^2 x}\, dx.$$

21. We'll find the arc length of the top half of the ellipse, and multiply that by 2. In the top half of the ellipse, the equation $(x^2/a^2) + (y^2/b^2) = 1$ implies

$$y = +b\sqrt{1 - \frac{x^2}{a^2}}.$$

Differentiating $(x^2/a^2) + (y^2/b^2) = 1$ implicitly with respect to x gives us

$$\frac{2x}{a^2} + \frac{2y}{b^2}\frac{dy}{dx} = 0,$$

so

$$\frac{dy}{dx} = \frac{\frac{-2x}{a^2}}{\frac{2y}{b^2}} = -\frac{b^2x}{a^2y}.$$

Substituting this into the arc length formula, we get

$$\begin{aligned}\text{Arc Length} &= \int_{-a}^{a} \sqrt{1 + \left(-\frac{b^2x}{a^2y}\right)^2}\, dx \\ &= \int_{-a}^{a} \sqrt{1 + \left(\frac{b^4x^2}{a^4(b^2)(1 - \frac{x^2}{a^2})}\right)}\, dx \\ &= \int_{-a}^{a} \sqrt{1 + \left(\frac{b^2x^2}{a^2(a^2 - x^2)}\right)}\, dx.\end{aligned}$$

Hence the arc length of the entire ellipse is

$$2\int_{-a}^{a}\sqrt{1+\left(\frac{b^2x^2}{a^2(a^2-x^2)}\right)}\,dx.$$

22. Since $f'(x)=\cos x$, we have

$$L=\int_0^3\sqrt{1+(f'(x))^2}\,dx=\int_0^3\sqrt{1+\cos^2 x}\,dx=3.621.$$

We see in Figure 8.149 that the length of the curve is slightly longer than the length of the x-axis from $x=0$ to $x=3$, so the answer of 3.621 makes sense.

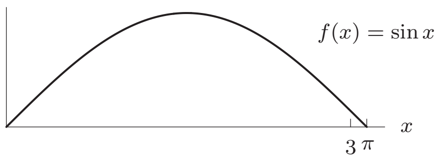

Figure 8.149

23. Since $f'(x)=10x$, we have

$$L=\int_0^3\sqrt{1+(f'(x))^2}\,dx=\int_0^3\sqrt{1+(10x)^2}\,dx=\int_0^3\sqrt{1+100x^2}\,dx=45.230.$$

We see in Figure 8.150 that the length of the curve is definitely longer than 45 and slightly longer than $\sqrt{45^2+3^2}=45.10$, so the answer of 45.230 is reasonable.

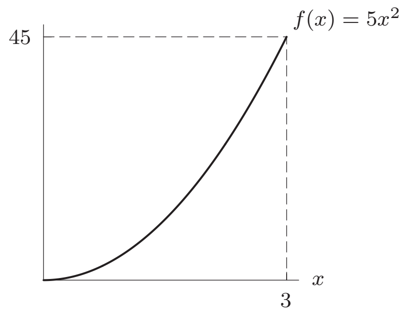

Figure 8.150

24. The arc length of $\sqrt{1-x^2}$ from $x=0$ to $x=1$ is one quarter of the perimeter of the unit circle. Hence the length is $\frac{2\pi}{4}=\frac{\pi}{2}$.

25. The arc length is given by

$$L=\int_1^2\sqrt{1+e^{2x}}\,dx\approx 4.785.$$

Note that $\sqrt{1+e^{2x}}$ does not have an obvious elementary antiderivative, so we use an approximation method to find an approximate value for L.

26. The arc length is given by

$$L=\int_1^2\sqrt{1+\left(x^4+\frac{1}{(16x^4)}-\frac{1}{2}\right)}\,dx=\int_1^2\sqrt{\left(x^2+\frac{1}{(4x^2)}\right)^2}\,dx$$

$$=\int_1^2\left(x^2+\frac{1}{4}x^{-2}\right)dx=\left[\frac{x^3}{3}-\frac{1}{4x}\right]\Bigg|_1^2=\frac{59}{24}.$$

27. We have $dx/dt = -3\sin t$, $dy/dt = 2\cos t$, so, evaluating the integral numerically, we have

$$\text{Arc length } = \int_0^{2\pi} \sqrt{9\cos^2 t + 4\sin^2 t}\, dt = 15.865.$$

The curve is a ellipse.

28. We have $dx/dt = -2\sin(2t)$, $dy/dt = 2\cos(2t)$, so, simplifying the integrand, we have

$$\text{Arc length } = \int_0^{\pi} \sqrt{4\sin^2(2t) + 4\cos^2(2t)}\, dt = 2\int_0^{\pi} dt = 2\pi.$$

The curve is a circle of radius 1.

29.
- $\int_0^1 f(x)\, dx$ gives the area under the graph of f from 0 to 1.
- The graph of f is concave up and passes through the points $(0,0)$ and $(1,1)$, so it lies below the line $y = x$.
- The area under $y = x$ from 0 to 1 is half the area of a square of side 1, or $1/2$. Thus, $\int_0^1 f(x)\, dx < \frac{1}{2}$.

30.
- Since $f(0) = 0$, the Fundamental Theorem gives $\int_0^{0.5} f'(x)\, dx = f(0.5) - f(0) = f(0.5)$.
- The graph of f is concave up and passes through the points $(0,0)$ and $(1,1)$, so it lies below the line $y = x$. This means $f(x) < x$ for $0 < x < 1$.
- Since $f(x) < x$, we have $f(0.5) < 0.5$. Hence $\int_0^{0.5} f'(x)dx < \frac{1}{2}$.

31.
- Since $f(x) = x^p$, we know $f^{-1}(x) = x^{1/p}$, because $(x^p)^{1/p} = \left(x^{1/p}\right)^p = x$.
- Since $f(0) = 0$ and $f(1) = 1$, we know $f^{-1}(0) = 0$ and $f^{-1}(1) = 1$. Likewise, since f is increasing, so is f^{-1}.
- Since $p > 1$, we know $0 < 1/p < 1$, so the graph of f^{-1} is concave down, and therefore lies above the line $y = x$ on $0 < x < 1$.
- $\int_0^1 f^{-1}(x)\, dx$ gives the area under f^{-1} from 0 to 1, so, since the graph lies above $y = x$ on this interval, we have $\int_0^1 f^{-1}(x)\, dx > \frac{1}{2}$.

32.
- $\int_0^1 \pi\left(f(x)\right)^2\, dx$ gives the volume of the region formed by rotating the graph of f on $0 \le x \le 1$ about the x-axis.
- The graph of f is concave up and contains $(0,0)$ and $(1,1)$, so it lies below the line $y = x$ on $0 < x < 1$.
- This means the region formed by rotating the graph of f lies within the region formed by rotating the line segment $y = x$, which is a cone of base $r = 1$ and height $h = 1$. The volume of this cone is $(1/3)\pi r^2 h = \pi/3$.
- Since this cone contains the region formed by rotating the graph of f, we have $\int_0^1 \pi\left(f(x)\right)^2\, dx < \frac{\pi}{3}$.

33.
- $\int_0^1 \sqrt{1 + (f'(x))^2}\, dx$ gives the arc length of the graph of f from $x = 0$ to $x = 1$.
- The graph of f is concave up and contains $(0,0)$ and $(1,1)$, so it lies below the line $y = x$ on $0 < x < 1$. The arc length of the line between $(0,0)$, and $(1,1)$ is $\sqrt{1^2 + 1^2} = \sqrt{2}$.
- The line segment between $(0,0)$ and $(1,1)$ is shorter than the arc length of f, so $\int_0^1 \sqrt{1 + (f'(x))^2}\, dx > \sqrt{2}$.

Problems

34. (a) The points of intersection are $x = 0$ to $x = 2$, so we have

$$\text{Area} = \int_0^2 (2x - x^2)dx = x^2 - \frac{x^3}{3}\bigg|_0^2 = \frac{4}{3} = 1.333.$$

(b) The outside radius is $2x$ and the inside radius is x^2, so we have

$$\text{Volume} = \int_0^2 (\pi(2x)^2 - \pi(x^2)^2)dx = \pi\int_0^2 (4x^2 - x^4)dx = \frac{\pi}{15}(20x^3 - 3x^5)\bigg|_0^2 = \frac{64\pi}{15} = 13.404.$$

(c) The length of the perimeter is equal to the length of the top plus the length of the bottom. Using the arclength formula, and the fact that the derivative of $2x$ is 2 and the derivative of x^2 is $2x$, we have

$$L = \int_0^2 \sqrt{1+2^2}dx + \int_0^2 \sqrt{1+(2x)^2}dx = 4.4721 + 4.6468 = 9.119.$$

35. There are at least two possible answers. Since $\sqrt{4-x^2} - (-\sqrt{4-x^2}) \geq 0$ when $0 \leq x \leq 2$, one possibility is that the integral gives the area between the curve $y = 2\sqrt{4-x^2}$ and the line $y = 0$ as shown in Figure 8.151.

Alternatively, since $\sqrt{4-x^2} \geq -\sqrt{4-x^2}$ when $0 \leq x \leq 2$, the integral gives the area between the quarter circles $y = \sqrt{4-x^2}$ and $y = -\sqrt{4-x^2}$, as shown in Figure 8.152.

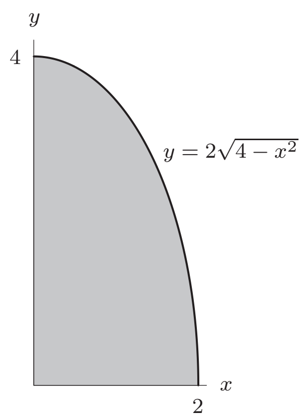

Figure 8.151

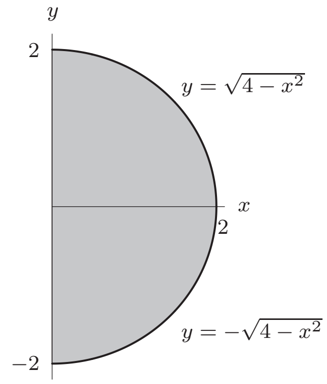

Figure 8.152

36. The two functions intersect at $(0, 0)$ and $(5, 25)$. We slice the volume with planes perpendicular to the horizontal line $y = 30$. This divides the solid into thin washers with volume

$$\text{Volume of slice } = \pi((r_{out})^2 - (r_{in})^2)\Delta x.$$

The outer radius is the vertical distance from the line $y = 30$ to the curve $y = x^2$, so $r_{out} = 30 - x^2$. Similarly, the inner radius is the vertical distance from the line $y = 30$ to the curve $y = 5x$, so $r_{in} = 30 - 5x$. Integrating from $x = 0$ to $x = 5$ we have

$$V = \int_0^5 \pi((30-x^2)^2 - (30-5x)^2)\, dx.$$

37. The two functions intersect at $(0, 0)$ and $(5, 25)$. We slice the volume with planes perpendicular to the vertical line $x = 8$. This divides the solid into thin washers with volume

$$\text{Volume of slice } = \pi((r_{out})^2 - (r_{in})^2)\Delta y.$$

The outer radius is the horizontal distance from the line $x = 8$ to the curve $x = y/5$, so $r_{out} = 8 - y/5$. Similarly, the inner radius is the horizontal distance from the line $x = 8$ to the curve $x = \sqrt{y}$, so $r_{in} = 8 - \sqrt{y}$. Integrating from $y = 0$ to $y = 25$ we have

$$V = \int_0^{25} \pi((8-y/5)^2 - (8-\sqrt{y})^2)\, dy.$$

38. (a) See Figure 8.153

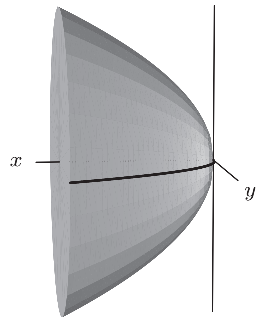

Figure 8.153: Rotated Region

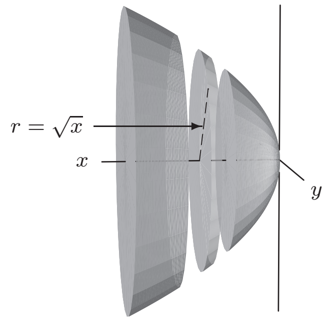

Figure 8.154: Cutaway View

(b) Divide [0,1] into N subintervals of width $\Delta x = \frac{1}{N}$. The volume of the i^{th} disc is $\pi(\sqrt{x_i})^2 \Delta x = \pi x_i \Delta x$. So, $V \approx \sum_{i=1}^{N} \pi x_i \Delta x$. See Figure 8.154

(c)

$$\text{Volume} = \int_0^1 \pi x \, dx = \frac{\pi}{2} x^2 \Big|_0^1 = \frac{\pi}{2} \approx 1.57.$$

39. (a) See Figure 8.155.

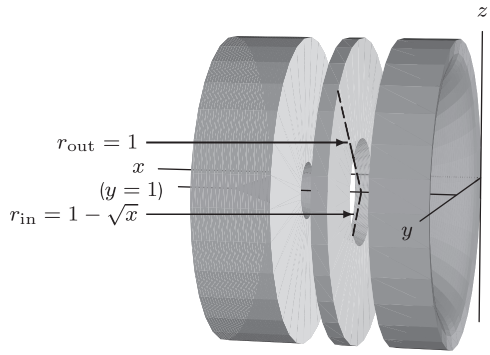

Figure 8.155

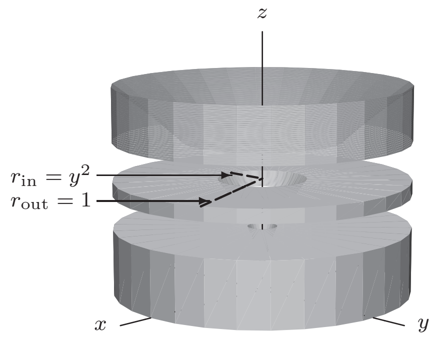

Figure 8.156

Slice the figure perpendicular to the x–axis. One gets washers of inner radius $1 - \sqrt{x}$ and outer radius 1. Therefore,

$$\begin{aligned} V &= \int_0^1 \left(\pi 1^2 - \pi(1-\sqrt{x})^2\right) dx \\ &= \pi \int_0^1 (1 - [1 - 2\sqrt{x} + x]) \, dx \\ &= \pi \left[\frac{4}{3} x^{\frac{3}{2}} - \frac{1}{2} x^2\right]_0^1 = \frac{5\pi}{6} \approx 2.62. \end{aligned}$$

(b) See Figure 8.156. Note that $x = y^2$. We now integrate over y instead of x, slicing perpendicular to the y–axis. This gives us washers of inner radius x and outer radius 1. So

$$\begin{aligned} V &= \int_{y=0}^{y=1} (\pi 1^2 - \pi x^2) \, dy \\ &= \int_0^1 \pi(1 - y^4) dy \\ &= \left(\pi y - \frac{\pi}{5} y^5\right) \Big|_0^1 = \pi - \frac{\pi}{5} = \frac{4\pi}{5} \approx 2.51. \end{aligned}$$

40. (a) Since $y = ax^2$ is non-negative, we integrate to find the area:

$$\text{Area} = \int_0^2 (ax^2)dx = a\frac{x^3}{3}\bigg|_0^2 = \frac{8a}{3}.$$

(b) Each slice of the object is approximately a cylinder with radius ax^2 and thickness Δx. We have

$$\text{Volume} = \int_0^2 \pi(ax^2)^2 dx = \pi a^2 \frac{x^5}{5}\bigg|_0^2 = \frac{32}{5}a^2\pi.$$

41. (a) Since $y = e^{-bx}$ is non-negative, we integrate to find the area:

$$\text{Area} = \int_0^1 (e^{-bx})dx = \frac{-1}{b}e^{-bx}\bigg|_0^1 = \frac{1}{b}(1 - e^{-b}).$$

(b) Each slice of the object is approximately a cylinder with radius e^{-bx} and thickness Δx. We have

$$\text{Volume} = \int_0^1 \pi(e^{-bx})^2 dx = \pi\int_0^1 e^{-2bx}dx = \frac{-\pi}{2b}e^{-2bx}\bigg|_0^1 = \frac{\pi}{2b}(1 - e^{-2b}).$$

42. (a) We divide the region into vertical strips of thickness Δx. As a slice is rotated about the x-axis, it creates a disk of radius r_{out} from which has been removed a smaller circular disk of radius r_{in}. We see in Figure 8.157 that $r_{\text{out}} = \sin x$ and $r_{\text{in}} = 0.5x$. Thus,

$$\text{Volume of a slice } \approx \pi(r_{\text{out}})^2\Delta x - \pi(r_{\text{in}})^2\Delta x = \pi(\sin x)^2\Delta x - \pi(0.5x)^2\Delta x.$$

To find the total volume, we integrate this quantity between the points of intersection $x = 0$ and $x = 1.9$:

$$V = \int_0^{1.9} (\pi(\sin x)^2 - \pi(0.5x)^2)dx = \pi\left(-\frac{\sin x\cos x}{2} - \frac{x^3}{12} + x\right)\bigg|_0^{1.9} = 1.669.$$

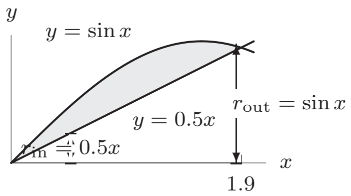

Figure 8.157

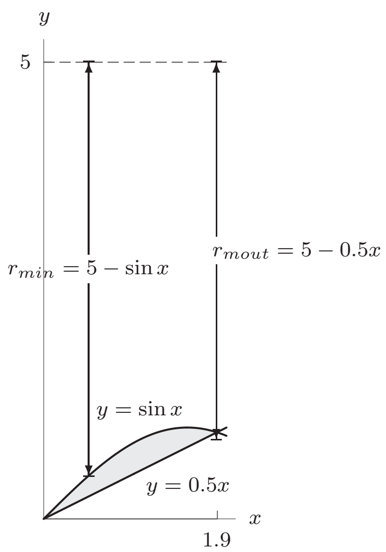

Figure 8.158

(b) We see in Figure 8.158 that $r_{\text{out}} = 5 - 0.5x$ and $r_{\text{in}} = 5 - \sin x$. Thus,

$$\text{Volume of a slice } \approx \pi(r_{\text{out}})^2\Delta x - \pi(r_{\text{in}})^2\Delta x = \pi(5 - 0.5x)^2\Delta x - \pi(5 - \sin x)^2\Delta x.$$

To find the total volume, V, we integrate this quantity between the points of intersection $x = 0$ and $x = 1.9$:

$$V = \int_0^{1.9} \left(\pi(5 - 0.5x)^2 - \pi(5 - \sin x)^2\right)dx = \frac{\pi}{12}(6(\sin x - 20)\cos x + x(x^2 - 30x - 6))\bigg|_0^{1.9} = 11.550.$$

43. We divide the region into vertical strips of thickness Δx. As a slice is rotated about the x-axis, it creates a disk of radius r_{out} from which has been removed a disk of radius r_{in}. We see in Figure 8.159 that $r_{\text{out}} = 5 + 2x$ and $r_{\text{in}} = 5$. Thus,

$$\text{Volume of a slice } \approx \pi(r_{\text{out}})^2\Delta x - \pi(r_{\text{in}})^2\Delta x = \pi(5+2x)^2\Delta x - \pi(5)^2\Delta x.$$

To find the total volume, V, we integrate this quantity between $x = 0$ and $x = 4$:

$$V = \int_0^4 (\pi(5+2x)^2 - \pi(5)^2)dx = \pi\int_0^4 ((5+2x)^2 - 25)\,dx = \pi\left(\frac{4}{3}x^3 + 10x^2\right)\Bigg|_0^4 = \frac{736\pi}{3} = 770.737.$$

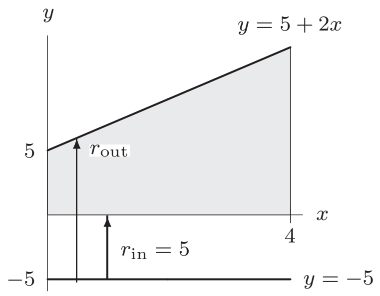

Figure 8.159

44. (a) We divide the region into vertical strips of thickness Δx. As a slice is rotated about the x-axis, it creates a disk of radius r_{out} from which has been removed a disk of radius r_{in}. We see in Figure 8.160 that $r_{\text{out}} = 2 + x^2$ and $r_{\text{in}} = 2$. Thus,

$$\text{Volume of a slice } \approx \pi(r_{\text{out}})^2\Delta x - \pi(r_{\text{in}})^2\Delta x = \pi(2+x^2)^2\Delta x - \pi(2)^2\Delta x.$$

To find the total volume, V, we integrate this quantity between $x = 0$ and $x = 3$:

$$V = \int_0^3 (\pi(2+x^2)^2 - \pi(2)^2)dx = \pi\int_0^3 ((2+x^2)^2 - 4)\,dx = \frac{\pi}{15}(3x^5 + 20x^3)\Bigg|_0^3 = \frac{423\pi}{5} = 265.778.$$

(b) We see in Figure 8.161 that $r_{\text{out}} = 10$ and $r_{\text{in}} = 10 - x^2$. Thus,

$$\text{Volume of a slice } \approx \pi(r_{\text{out}})^2\Delta x - \pi(r_{\text{in}})^2\Delta x = \pi(10)^2\Delta x - \pi(10-x^2)^2\Delta x.$$

To find the total volume, V, we integrate this quantity between $x = 0$ and $x = 3$:

$$V = \int_0^3 (\pi(10)^2 - \pi(10-x^2)^2)dx = \pi\int_0^3 (100 - (10-x^2)^2)\,dx = \frac{\pi}{15}(100x^3 - 3x^5)\Bigg|_0^3 = \frac{657\pi}{5} = 412.805.$$

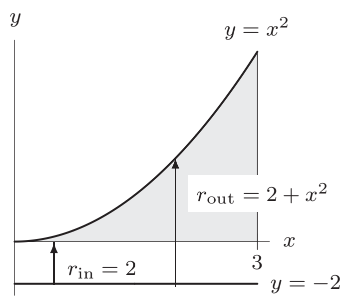

Figure 8.160

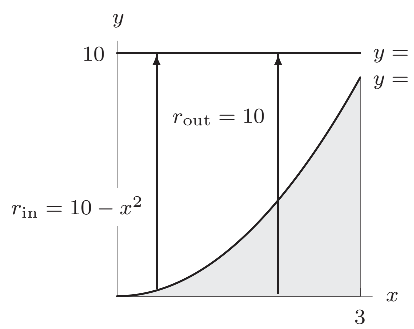

Figure 8.161

45. Slice the object into disks vertically, as in Figure 8.162. A typical disk has thickness Δx and radius $y = \sqrt{1-x^2}$. Thus

$$\text{Volume of disk } \approx \pi y^2 \Delta x = \pi(1-x^2)\,\Delta x.$$

$$\text{Volume of solid } = \lim_{\Delta x \to 0} \sum \pi(1-x^2)\,\Delta x = \int_0^1 \pi(1-x^2)\,dx = \pi\left(x - \frac{x^3}{3}\right)\Bigg|_0^1 = \frac{2\pi}{3}.$$

Note: As we expect, this is the volume of a half sphere.

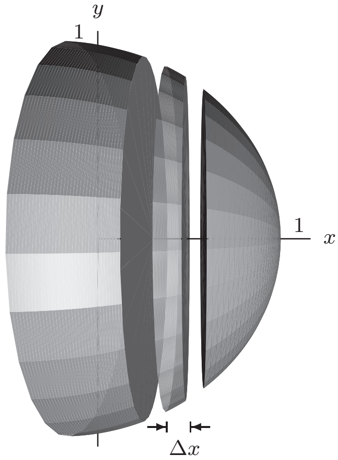

Figure 8.162

46. Slice the object into rings horizontally, as in Figure 8.163. A typical ring has thickness Δy, inner radius 2 and outer radius $2 + x = 2 + \sqrt{1-y^2}$. Thus,

$$\text{Volume of ring } \approx \pi(2+\sqrt{1-y^2})^2\Delta y - \pi 2^2 \Delta y = \pi(4\sqrt{1-y^2} + 1 - y^2)\,\Delta y.$$

$$\begin{aligned}
\text{Volume of solid } &= \int_0^1 \pi(4\sqrt{1-y^2} + 1 - y^2)\,dy \\
&= 4\pi \int_0^1 \sqrt{1-y^2}\,dy + \pi \int_0^1 1\,dy - \pi \int_0^1 y^2\,dy \\
&= 4\pi\left(\frac{1}{2}\left(y\sqrt{1-y^2}\Big|_0^1 + \int_0^1 \frac{1}{\sqrt{1-y^2}}\,dy\right)\right) + \pi y\Big|_0^1 - \frac{\pi y^3}{3}\Big|_0^1 \\
&= 2\pi y\sqrt{1-y^2} + 2\pi \arcsin y + \pi y - \frac{\pi y^3}{3}\Big|_0^1 \\
&= 0 + 2\pi \arcsin 1 + \pi - \frac{\pi}{3} - 0 - 2\pi \arcsin 0 - 0 + 0 \\
&= \pi^2 + \frac{2\pi}{3} = 11.964.
\end{aligned}$$

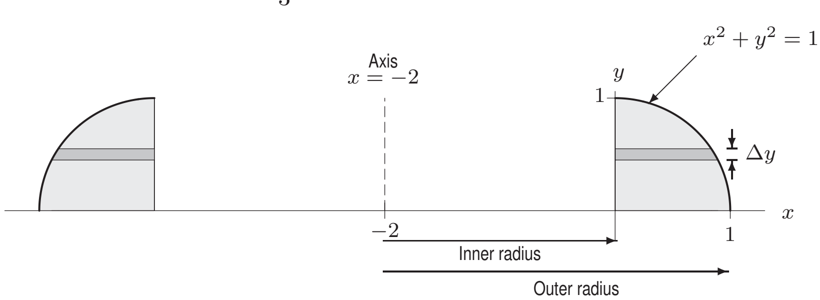

Figure 8.163: Cross-section of solid

47. Slice the object into rings horizontally, as in Figure 8.164. A typical ring has thickness Δy, outer radius 1, and inner radius $1 - x = 1 - \sqrt{1-y^2}$. Thus,

$$\text{Volume of ring } \approx \pi 1^2 \Delta y - \pi(1 - \sqrt{1-y^2})^2 \Delta y = \pi(2\sqrt{1-y^2} - (1-y^2))\,\Delta y.$$

$$\begin{aligned}
\text{Volume of solid } &= \int_0^1 \pi(2\sqrt{1-y^2} - 1 + y^2)\,dy \\
&= 2\pi \int_0^1 \sqrt{1-y^2}\,dy - \pi \int_0^1 1\,dy + \pi \int_0^1 y^2\,dy \\
&= 2\pi \cdot \frac{1}{2}\left(y\sqrt{1-y^2}\Big|_0^1 + 1^2 \int_0^1 \frac{1}{\sqrt{1-y^2}}\,dy \right) - \pi y\Big|_0^1 + \frac{\pi y^3}{3}\Big|_0^1 \\
&= \pi y\sqrt{1-y^2} + \pi \arcsin y - \pi y + \frac{\pi y^3}{3}\Big|_0^1 \\
&= 0 + \frac{\pi^2}{2} - \pi + \frac{\pi}{3} - 0 - 0 + 0 - 0 \\
&= \frac{\pi^2}{2} - \frac{2\pi}{3} = 2.840.
\end{aligned}$$

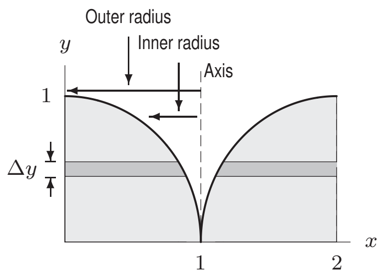

Figure 8.164: Cross-section of solid

48. Slicing perpendicularly to the x-axis gives squares whose thickness is Δx and whose side is $y = \sqrt{1-x^2}$. See Figure 8.165. Thus,

$$\text{Volume of square slice } \approx (\sqrt{1-x^2})^2 \Delta x = (1-x^2)\,\Delta x.$$

$$\text{Volume of solid } = \int_0^1 (1-x^2)\,dx = x - \frac{x^3}{3}\Big|_0^1 = \frac{2}{3}.$$

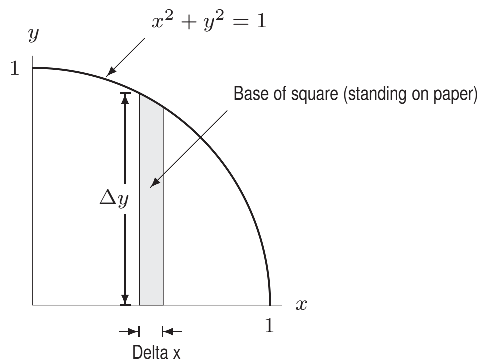

Figure 8.165: Base of solid

49. Slicing perpendicularly to the y-axis gives semicircles whose thickness is Δy and whose diameter is $x = \sqrt{1-y^2}$. See Figure 8.166. Thus

$$\text{Volume of semicircular slice } \approx \frac{\pi}{2}\left(\frac{\sqrt{1-y^2}}{2}\right)^2 \Delta y = \frac{\pi}{8}(1-y^2)\,\Delta y.$$

$$\text{Volume of solid } = \int_0^1 \frac{\pi}{8}(1-y^2)\,dy = \frac{\pi}{8}\left(y - \frac{y^3}{3}\right)\Bigg|_0^1 = \frac{\pi}{8}\cdot\frac{2}{3} = \frac{\pi}{24}.$$

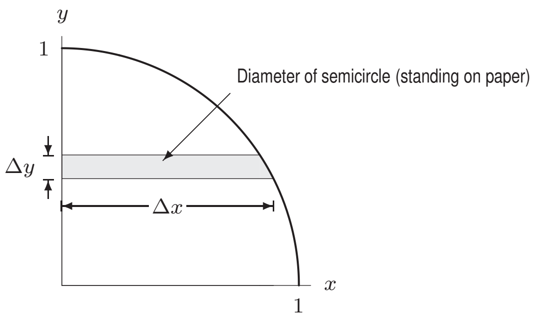

Figure 8.166: Base of Solid

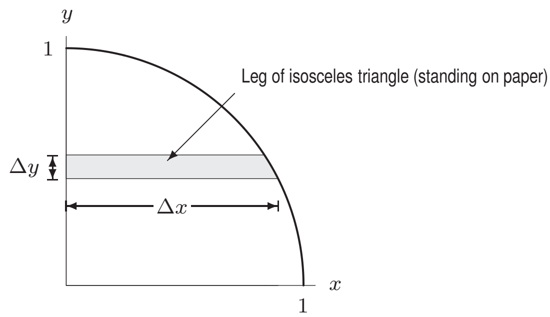

Figure 8.167: Base of solid

50. An isosceles triangle with legs of length s has

$$\text{Area } = \frac{1}{2}s^2.$$

Slicing perpendicularly to the y-axis gives isosceles triangles whose thickness is Δy and whose leg is $x = \sqrt{1-y^2}$. See Figure 8.167. Thus

$$\text{Volume of triangular slice } \approx \frac{1}{2}(\sqrt{1-y^2})\,\Delta y = \frac{1}{2}(1-y^2)\,\Delta y.$$

$$\text{Volume of solid } = \int_0^1 \frac{1}{2}(1-y^2)\,dy = \frac{1}{2}\left(y - \frac{y^3}{3}\right)\Bigg|_0^1 = \frac{1}{3}.$$

51. The curve $y = x(x-3)^2$ has x-intercepts at $x = 0, 3$ and lies above the x-axis on this interval.

Thus, $\int_0^3 x(x-3)^2\,dx$ gives the area under the graph of f from $x = 0$ to $x = 3$.

52. The curve $y = x(x-3)^2$ has x-intercepts at $x = 0, 3$ and lies above the x-axis on this interval. Rotating the curve about the x-axis forms a solid of revolution with

$$\text{Volume} = \int_0^3 \pi\,(f(x))^2\;dx = \int_0^3 \pi\left(x(x-3)^2\right)^2\;dx = \int_0^3 \pi x^2(x-3)^4\,dx.$$

Thus, this expression represents a volume of revolution about the x-axis between $x = 0$ and $x = 3$.

53. Since $y = (e^x + e^{-x})/2$, $y' = (e^x - e^{-x})/2$. The length of the catenary is

$$\begin{aligned}\int_{-1}^1 \sqrt{1+(y')^2}\,dx &= \int_{-1}^1 \sqrt{1+\left[\frac{e^x - e^{-x}}{2}\right]^2}\,dx = \int_{-1}^1 \sqrt{1+\frac{e^{2x}}{4} - \frac{1}{2} + \frac{e^{-2x}}{4}}\,dx \\ &= \int_{-1}^1 \sqrt{\left[\frac{e^x+e^{-x}}{2}\right]^2}\,dx = \int_{-1}^1 \frac{e^x+e^{-x}}{2}\,dx \\ &= \left[\frac{e^x - e^{-x}}{2}\right]\Bigg|_{-1}^1 = e - e^{-1}.\end{aligned}$$

54. (a) Slice the headlight into N disks of height Δx by cutting perpendicular to the x–axis. The radius of each disk is y; the height is Δx. The volume of each disk is $\pi y^2 \Delta x$. Therefore, the Riemann sum approximating the volume of the headlight is

$$\sum_{i=1}^{N} \pi y_i^2 \Delta x = \sum_{i=1}^{N} \pi \frac{9x_i}{4} \Delta x.$$

(b)

$$\pi \int_0^4 \frac{9x}{4}\, dx = \pi \frac{9}{8} x^2 \bigg|_0^4 = 18\pi.$$

55. (a) The line $y = ax$ must pass through (l, b). Hence $b = al$, so $a = b/l$.

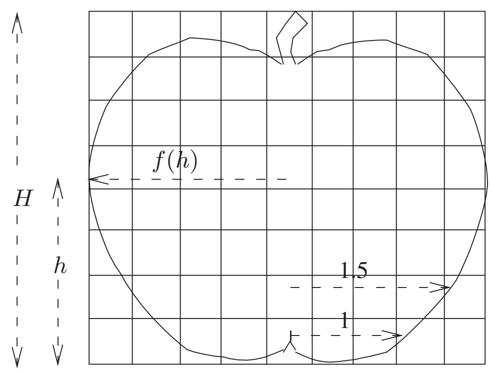
(b) Cut the cone into N slices, slicing perpendicular to the x–axis. Each piece is almost a cylinder. The radius of the ith cylinder is $r(x_i) = \frac{bx_i}{l}$, so the volume

$$V \approx \sum_{i=1}^{N} \pi \left(\frac{bx_i}{l}\right)^2 \Delta x.$$

Therefore, as $N \to \infty$, we get

$$\begin{aligned} V &= \int_0^l \pi b^2 l^{-2} x^2 dx \\ &= \pi \frac{b^2}{l^2} \left[\frac{x^3}{3}\right]_0^l = \left(\pi \frac{b^2}{l^2}\right)\left(\frac{l^3}{3}\right) = \frac{1}{3}\pi b^2 l. \end{aligned}$$

56. (a) If you slice the apple perpendicular to the core, you expect that the cross section will be approximately a circle.



If $f(h)$ is the radius of the apple at height h above the bottom, and H is the height of the apple, then

$$\text{Volume} = \int_0^H \pi f(h)^2\, dh.$$

Ignoring the stem, $H \approx 3.5$. Although we do not have a formula for $f(h)$, we can estimate it at various points. (Remember, we measure here from the bottom of the *apple*, which is not quite the bottom of the graph.)

h	0	0.5	1	1.5	2	2.5	3	3.5
$f(h)$	1	1.5	2	2.1	2.3	2.2	1.8	1.2

Now let $g(h) = \pi f(h)^2$, the area of the cross-section at height h. From our approximations above, we get the following table.

h	0	0.5	1	1.5	2	2.5	3	3.5
$g(h)$	3.14	7.07	12.57	13.85	16.62	13.85	10.18	4.52

We can now take left- and right-hand sum approximations. Note that $\Delta h = 0.5$ inches. Thus

$$\text{LEFT}(9) = (3.14 + 7.07 + 12.57 + 13.85 + 16.62 + 13.85 + 10.18)(0.5) = 38.64.$$
$$\text{RIGHT}(9) = (7.07 + 12.57 + 13.85 + 16.62 + 13.85 + 10.18 + 4.52)(0.5) = 39.33.$$

Thus the volume of the apple is ≈ 39 cu.in.

(b) The apple weighs $0.03 \times 39 \approx 1.17$ pounds, so it costs about 94¢.

57.

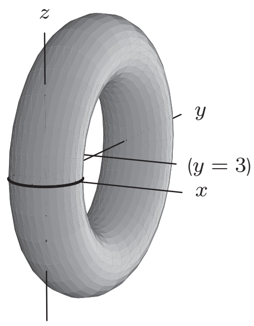


Figure 8.168: The Torus

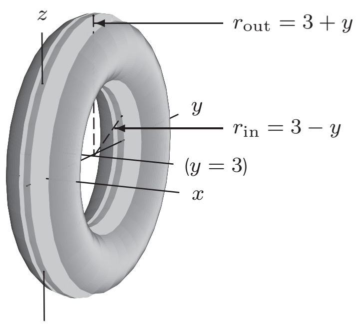

Figure 8.169: Slice of Torus

As shown in Figure 8.169, we slice the torus perpendicular to the line $y = 3$. We obtain washers with width dx, inner radius $r_{\text{in}} = 3 - y$, and outer radius $r_{\text{out}} = 3 + y$. Therefore, the area of the washer is $\pi r_{\text{out}}^2 - \pi r_{\text{in}}^2 = \pi[(3+y)^2 - (3-y)^2] = 12\pi y$. Since $y = \sqrt{1-x^2}$, the volume is gotten by summing up the volumes of the washers: we get

$$\int_{-1}^{1} 12\pi\sqrt{1-x^2}\,dx = 12\pi \int_{-1}^{1} \sqrt{1-x^2}\,dx.$$

But $\int_{-1}^{1} \sqrt{1-x^2}\,dx$ is the area of a semicircle of radius 1, which is $\frac{\pi}{2}$. So we get $12\pi \cdot \frac{\pi}{2} = 6\pi^2 \approx 59.22$. (Or, you could use

$$\int \sqrt{1-x^2}\,dx = \left[x\sqrt{1-x^2} + \arcsin(x)\right],$$

by VI-30 and VI-28.)

58. The arc length of the curve $y = f(t)$ from $t = 3$ to $t = 8$ is $\int_3^8 \sqrt{1 + (f'(t))^2}\,dt$. Thus, we want a function f such that

$$\int_3^8 \sqrt{1 + (f'(t))^2}\,dt = \int_3^8 \sqrt{1 + e^{6t}}\,dt.$$

Thus, we have

$$\left(f'(t)\right)^2 = e^{6t}.$$

One possibility is

$$f'(t) = e^{3t}$$
$$f(t) = \frac{1}{3}e^{3t} + C.$$

For any constant C, the original integral is the arc length of the curve $y = \frac{1}{3}e^{3t} + C$ from $t = 3$ to $t = 8$.

Another solution to $\left(f'(t)\right)^2 = e^{6t}$ is $f'(t) = -e^{3t}$, which gives $f(t) = -\frac{1}{3}e^{3t} + C$.

59. We take a cross-section of the pipe and cut it up in such a way that the speed of the water is nearly uniform on each slice. See Figure 8.170.

We use thin rings around the pipe's center; if a given ring is narrow enough, all points on it will be roughly equidistant from the center. Since the water speed is a function of the distance from the center, the speed is nearly constant on the entire ring.

Let r be the distance from the center to the inner boundary of the ring, and let Δr be the width of the ring, as in Figure 8.170. By straightening the ring into a thin rectangle, we find that its area is approximately given by the quantity $2\pi r\Delta r$. The speed across any part of the ring is roughly equal to the speed across the inner boundary, $10(1-r^2)$ inches per second. The flow is defined as the speed times the area; thus on any given ring we have

$$\text{Flow} \approx 10(1-r^2)\cdot 2\pi r\Delta r.$$

The total flow across the pipe cross-section is approximated by a Riemann sum incorporating all of the rings:

$$\text{Total Flow} \approx 20\pi \sum (1-r^2)r\Delta r,$$

where r is in between 0 and 1. Letting $\Delta r \to 0$, we obtain the exact solution:

$$\text{Total Flow} = 20\pi \int_0^1 (1-r^2)r\,dr = 20\pi\left(\frac{r^2}{2}-\frac{r^4}{4}\right)\Bigg|_0^1 = 5\pi \text{ cubic inches/second.}$$

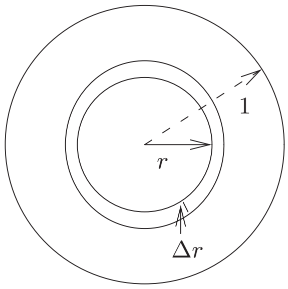

Figure 8.170

60. Multiplying $r = 2a\cos\theta$ by r, converting to Cartesian coordinates, and completing the square gives

$$\begin{aligned} r^2 &= 2ar\cos\theta \\ x^2+y^2 &= 2ax \\ x^2-2ax+a^2+y^2 &= a^2 \\ (x-a)^2+y^2 &= a^2. \end{aligned}$$

This is the standard form of the equation of a circle with radius a and center $(x,y)=(a,0)$.

To check the limits on θ note that the circle is in the right half plane, where $-\pi/2 \le \theta \le \pi/2$. Rays from the origin at all these angles meet the circle because the circle is tangent to the y-axis at the origin.

61. The area is given by

$$\int_{-\pi/2}^{\pi/2} \frac{1}{2}r^2\,d\theta = \int_{-\pi/2}^{\pi/2} \frac{1}{2}\left(2a\cos\theta\right)^2\,d\theta = 2a^2\int_{-\pi/2}^{\pi/2}\cos^2\theta\,d\theta = 2a^2\left(\frac{1}{2}\cos\theta\sin\theta+\frac{\theta}{2}\right)\Bigg|_{-\pi/2}^{\pi/2} = \pi a^2.$$

(We have used formula IV-18 from the integral table. The integral can also be done using a calculator or integration by parts.)

62. See Figure 8.171. The circles meet where

$$\begin{aligned} 2a\cos\theta &= a \\ \cos\theta &= \frac{1}{2} \\ \theta &= \pm\frac{\pi}{3}. \end{aligned}$$

The area is obtained by subtraction:

$$\begin{aligned}
\text{Area} &= \int_{-\pi/3}^{\pi/3} \left(\frac{1}{2}(2a\cos\theta)^2 - \frac{1}{2}a^2\right) d\theta \\
&= \int_{-\pi/3}^{\pi/3} \left(2a^2\cos^2\theta - \frac{1}{2}a^2\right) d\theta \\
&= \left(2a^2\left(\frac{1}{2}\cos\theta\sin\theta + \frac{\theta}{2}\right) - \frac{a^2}{2}\theta\right)\Bigg|_{-\pi/3}^{\pi/3} \\
&= \left(\frac{\pi}{3} + \frac{\sqrt{3}}{2}\right)a^2.
\end{aligned}$$

Since

$$\frac{\left(\pi/3 + \sqrt{3}/2\right)a^2}{\pi a^2} = 61\%$$

the shaded region covers 61% of circle C.

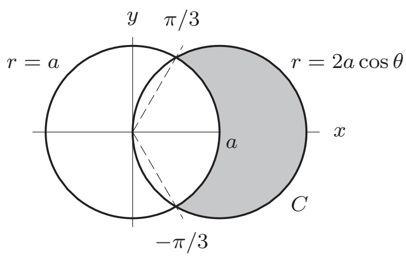

Figure 8.171

63. (a) Writing C in parametric form gives

$$x = 2a\cos^2\theta \quad \text{and} \quad y = 2a\cos\theta\sin\theta,$$

so the slope is given by

$$\frac{dy}{dx} = \frac{dy/d\theta}{dx/d\theta} = \frac{-2a\sin^2\theta + 2a\cos^2\theta}{-4a\cos\theta\sin\theta} = \frac{\sin^2\theta - \cos^2\theta}{2\cos\theta\sin\theta}.$$

(b) The maximum y-value occurs where $dy/dx = 0$, so

$$\begin{aligned}
\sin^2\theta - \cos^2\theta &= 0 \\
\theta &= \pm\frac{\pi}{4}.
\end{aligned}$$

The value $\theta = \pi/4$ gives the maximum y-value; $\theta = -\pi/4$ gives the minimum y-value.

64. Writing C in parametric form gives

$$x = 2a\cos^2\theta \quad \text{and} \quad y = 2a\cos\theta\sin\theta,$$

so

$$\begin{aligned}
\text{Arc length} &= \int_{-\pi/2}^{\pi/2} \sqrt{(-4a\cos\theta\sin\theta)^2 + (-2a\sin^2\theta + 2a\cos^2\theta)^2}\, d\theta \\
&= 2a\int_{-\pi/2}^{\pi/2} \sqrt{4\cos^2\theta\sin^2\theta + \sin^4\theta - 2\sin^2\theta\cos^2\theta + \cos^4\theta}\, d\theta \\
&= 2a\int_{-\pi/2}^{\pi/2} \sqrt{\sin^4\theta + 2\sin^2\theta\cos^2\theta + \cos^4\theta}\, d\theta \\
&= 2a\int_{-\pi/2}^{\pi/2} \sqrt{(\sin^2\theta + \cos^2\theta)^2}\, d\theta \\
&= 2a\int_{-\pi/2}^{\pi/2} d\theta = 2\pi a.
\end{aligned}$$

65. This function has zeros at $x = -2$ and $x = 1$. The bounded region lies between these two zeros. Thus,

$$\text{Volume} = \int_{-2}^{1} \pi \left((x-1)^2(x+2)\right)^2 \, dx.$$

66. The total mass is 12 gm, so the center of mass is located at $\overline{x} = \frac{1}{12}(-5\cdot 3 - 3\cdot 3 + 2\cdot 3 + 7\cdot 3) = \frac{1}{4}$.

67. (a) Since the density is constant, the mass is the product of the area of the plate and its density.

$$\text{Area of the plate } = \int_0^1 (\sqrt{x} - x^2)\, dx = \left(\frac{2}{3}x^{3/2} - \frac{1}{3}x^3\right)\Big|_0^1 = \frac{1}{3}\text{ cm}^2.$$

Thus the mass of the plate is $2\cdot 1/3 = 2/3$ gm.

(b) See Figure 8.172. Since the region is "fatter" closer to the origin, $\bar{x}$ is less than $1/2$.

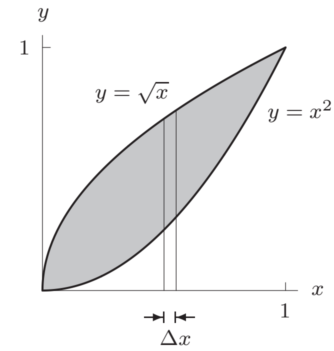

Figure 8.172

(c) To find $\bar{x}$, we slice the region into vertical strips of width Δx. See Figure 8.172.

$$\text{Area of strip } = A_x(x)\Delta x \approx (\sqrt{x} - x^2)\Delta x \text{ cm}^2.$$

Then we have

$$\overline{x} = \frac{\int x\delta A_x(x)\, dx}{\text{Mass}} = \frac{\int_0^1 2x(\sqrt{x} - x^2)\, dx}{2/3} = \frac{3}{2}\int_0^1 2(x^{3/2} - x^3)\, dx = \frac{3}{2}\cdot 2\left(\frac{2}{5}x^{5/2} - \frac{1}{4}x^4\right)\Big|_0^1 = \frac{9}{20}\text{ cm}.$$

This is less than $1/2$, as predicted in part (b). So $\bar{x} = \bar{y} = 9/20$ cm.

68. Let x be the height from ground to the weight. It follows that $0 \le x \le 20$. At height x, to lift the weight Δx more, the work needed is $200\Delta x + 2(20 - x)\Delta x = (240 - 2x)\Delta x$. So the total work is

$$W = \int_0^{20} (240 - 2x)dx = (240x - x^2)\Bigg|_0^{20} = 240(20) - 20^2 = 4400 \text{ ft-lb}.$$

69. Imagine the pole is divided into n segments of length Δx. The heights of the segments are given by $x_1, x_2, \ldots, x_i, \ldots x_n$. A segment of length Δx weighs $\dfrac{20\text{ lb}}{10\text{ ft}} \cdot \Delta x = 2\Delta x$. The work required to raise a segment a vertical distance of x_i ft is

$$\text{Work to raise segment } x_i \text{ ft} = \underbrace{\text{Weight}}_{2\Delta x} \cdot \underbrace{\text{Distance}}_{x_i} = 2x_i\Delta x.$$

The total work is therefore

$$\begin{aligned}\text{Total work} &= \lim_{n\to\infty} \sum_{i=1}^{n} 2x_i\Delta x \\ &= \int_0^{10} 2x\, dx = x^2\Bigg|_0^{10} = 100 \text{ ft-lbs}.\end{aligned}$$

To check our answer, notice that the work required to raise the entire 20 lb pole so that it is suspended horizontally 10 ft above the ground is:

$$\text{Work} = \underbrace{\text{Weight}}_{20\text{ lbs}} \cdot \underbrace{\text{Distance}}_{10\text{ ft}} = 200 \text{ ft-lbs}.$$

This is more than 100 lbs, because it should take more work to raise the entire pole 10 ft than to stand it upright.

70. Let x be the distance from the bucket to the surface of the water. It follows that $0 \le x \le 40$. At x feet, the bucket weighs $(30 - \frac{1}{4}x)$, where the $\frac{1}{4}x$ term is due to the leak. When the bucket is x feet from the surface of the water, the work done by raising it Δx feet is $(30 - \frac{1}{4}x)\,\Delta x$. So the total work required to raise the bucket to the top is

$$\begin{aligned} W &= \int_0^{40} (30 - \frac{1}{4}x)dx \\ &= \left(30x - \frac{1}{8}x^2\right)\Big|_0^{40} \\ &= 30(40) - \frac{1}{8}40^2 = 1000 \text{ ft-lb.} \end{aligned}$$

71. Consider lifting a rectangular slab of water h feet from the top up to the top. See Figure 8.173. The area of such a slab is $(10)(20) = 200$ square feet; if the thickness is Δh, then the volume of such a slab is $200\,\Delta h$ cubic feet. This much water weighs 62.4 pounds per ft^3, so the weight of such a slab is $(200\,\Delta h)(62.4) = 12480\,\Delta h$ pounds. To lift that much water h feet requires $12480h\,\Delta h$ foot-pounds of work. To lift the whole tank, we lift one plate at a time; integrating over the slabs yields

$$\int_0^{15} 12480h\,dh = \frac{12480h^2}{2}\Big|_0^{15} = \frac{12480 \cdot 15^2}{2} = 1{,}404{,}000 \text{ foot-pounds.}$$

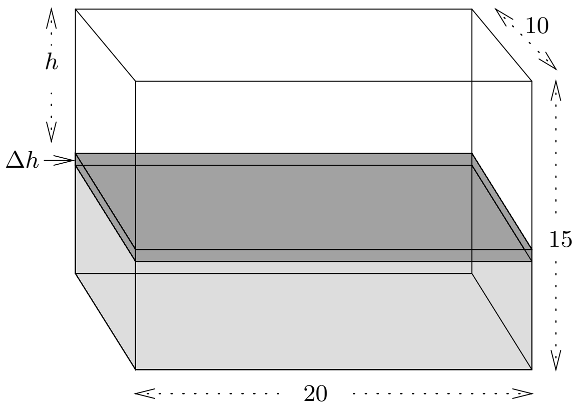

Figure 8.173

72. We begin by slicing the oil into slabs at a distance h below the surface with thickness Δh. We can then calculate the volume of the slab and the work needed to raise this slab to the surface, a distance of h.

$$\begin{aligned} \text{Volume of } \Delta h \text{ disk} &= \pi r^2 \Delta h = 25\pi\Delta h \\ \text{Weight of } \Delta h \text{ disk} &= (25\pi)(50)\Delta h \\ \text{Distance to raise} &= h \\ \text{Work to raise} &= (25\pi)(50)(h)\Delta h. \end{aligned}$$

Integrating the work over all such slabs, we have

$$\begin{aligned} \text{Work} &= \int_{19}^{25} (50)(25\pi)(h)\,dh \\ &= 625\pi h^2 \Big|_{19}^{25} \\ &= 390{,}625\pi - 225{,}625\pi \\ &\approx 518{,}363 \text{ ft-lbs.} \end{aligned}$$

A diagram of this tank is shown in Figure 8.174.

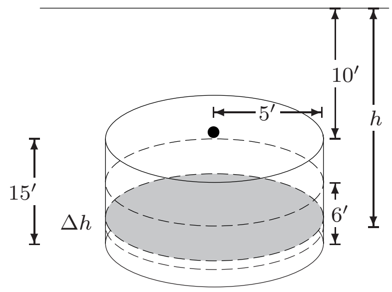

Figure 8.174

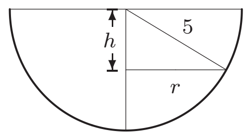

Figure 8.175

73. We slice the gasoline horizontally. At a distance h feet below the surface, the horizontal slab is a cylinder with radius r and thickness Δh, so

$$\text{Volume of one slab } \approx \pi r^2 \Delta h.$$

To find the radius r at a depth h from the top as in Figure 8.175, we note that $h^2 + r^2 = 5^2$, so $r = \sqrt{25 - h^2}$. At depth h

$$\text{Volume of one slice} \approx \pi(\sqrt{25 - h^2})^2 \Delta h = \pi(25 - h^2)\Delta h \text{ ft}^3.$$

The gasoline at depth h must be lifted a distance of h ft, so

$$\begin{aligned}\text{Work to move one slice} &= \rho \cdot \text{Volume} \cdot \text{Distance lifted} \\ &\approx \rho(\pi(25 - h^2)\Delta h)(h) \text{ ft-lb.}\end{aligned}$$

The work done, W, to lift all the gasoline is the sum of the work done on the pieces:

$$W \approx \sum \rho(\pi(25 - h^2)\Delta h)h \text{ ft-lb..}$$

As $\Delta h \to 0$, we obtain a definite integral. Since h varies from $h = 0$ to $h = 5$ and $\rho = 42$, we have:

$$W = \int_0^5 \rho\pi(25h - h^3)dh = 42\pi \left(25\frac{h^2}{2} - \frac{h^4}{4}\right)\Bigg|_0^5 = \frac{13125\pi}{2} = 20{,}617 \text{ ft-lb.}$$

The work to pump all the gasoline out is 20,617 ft-lbs.

74. Let h be height above the bottom of the dam. Then

$$\begin{aligned}\text{Water force } &= \int_0^{25} (62.4)(25 - h)(60)\, dh \\ &= (62.4)(60)\left(25h - \frac{h^2}{2}\right)\Bigg|_0^{25} \\ &= (62.4)(60)(625 - 312.5) \\ &= (62.4)(60)(312.5) \\ &= 1{,}170{,}000 \text{ lbs.}\end{aligned}$$

75. If the weight of the chain were negligible, the work required would be $1000 \cdot 20 = 20{,}000$ ft-lbs. Because of the chain, the total work is slightly more than 20,000 ft-lbs. When the object is h ft off the ground, the length of chain is $50 - h$ so the total weight being lifted is $1000 + 2(50 - h)$ lb. See Figure 8.176. Thus

$$\begin{aligned}\text{Work to lift the weight an addition } \Delta h \text{ higher} &= \text{Weight} \cdot \text{Distance lifted} \\ &\approx (1000 + 2(50 - h))\Delta h \text{ ft-lb.}\end{aligned}$$

To find the total work, we integrate this quantity from $h = 0$ to $h = 20$:

$$W = \int_0^{20} (1000 + 2(50 - h))dh = \int_0^{20} (1100 - 2h)dh = (1100h - h^2)\Big|_0^{20} = 21{,}600\text{ft-lbs}.$$

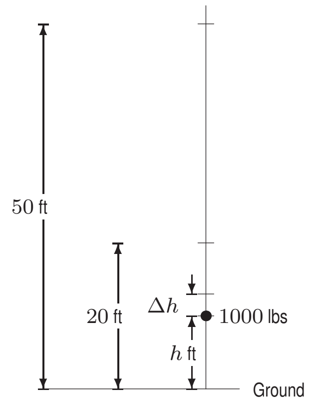

Figure 8.176

76.

$$\begin{aligned}\text{Future Value } &= \int_0^{15} 3000e^{0.06(15-t)}\,dt = 3000e^{0.9}\int_0^{15} e^{-0.06t}dt \\ &= 3000e^{0.9}\left(\frac{1}{-0.06}e^{-0.06t}\right)\Big|_0^{15} = 3000e^{0.9}\left(\frac{1}{-0.06}e^{-0.9} + \frac{1}{0.06}e^{0}\right) \\ &\approx \$72{,}980.16\end{aligned}$$

$$\begin{aligned}\text{Present Value } &= \int_0^{15} 3000e^{-0.06t}\,dt = 3000\left(-\frac{1}{0.06}\right)e^{-0.06t}\Big|_0^{15} \\ &\approx \$29{,}671.52.\end{aligned}$$

There's a quicker way to calculate the present value of the income stream, since the future value of the income stream is (as we've shown) \$72,980.16, the present value of the income stream must be the present value of \$72,980.16. Thus,

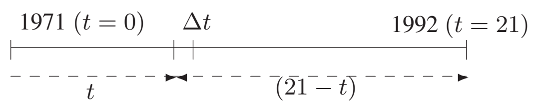
$$\begin{aligned}\text{Present Value} &= \$72{,}980.16(e^{-.06\cdot 15}) \\ &\approx \$29{,}671.52,\end{aligned}$$

which is what we got before.

77. We divide up time between 1971 and 1992 into intervals of length Δt, and calculate how much of the strontium-90 produced during that time interval is still around.

Strontium-90 decays exponentially, so if a quantity S_0 was produced t years ago, and S is the quantity around today, $S = S_0e^{-kt}$. Since the half-life is 28 years, $\frac{1}{2} = e^{-k(28)}$, giving $k = -\ln(1/2)/28 \approx 0.025$.

We measure t in years from 1971, so that 1992 is $t = 21$.



Since strontium-90 is produced at a rate of 3 kg/year, during the interval Δt, a quantity $3\Delta t$ kg was produced. Since this was $(21 - t)$ years ago, the quantity remaining now is $(3\Delta t)e^{-0.025(21-t)}$. Summing over all such intervals gives

$$\begin{matrix}\text{Strontium remaining} \\ \text{in 1992}\end{matrix} \approx \int_0^{21} 3e^{-0.025(21-t)}\,dt = \frac{3e^{-0.025(21-t)}}{0.025}\Big|_0^{21} = 49\text{ kg}.$$

[Note: This is like a future value problem from economics, but with a negative interest rate.]

78. (a) Slice the mountain horizontally into N cylinders of height Δh. The sum of the volumes of the cylinders will be

$$\sum_{i=1}^{N} \pi r^2 \Delta h = \sum_{i=1}^{N} \pi \left(\frac{3.5 \cdot 10^5}{\sqrt{h+600}}\right)^2 \Delta h.$$

(b)

$$\begin{aligned}
\text{Volume} &= \int_{400}^{14400} \pi \left(\frac{3.5 \cdot 10^5}{\sqrt{h+600}}\right)^2 dh \\
&= 1.23 \cdot 10^{11} \pi \int_{400}^{14400} \frac{1}{(h+600)} dh \\
&= 1.23 \cdot 10^{11} \pi \ln(h+600)\Big|_{400}^{14400} dh \\
&= 1.23 \cdot 10^{11} \pi \left[\ln 15000 - \ln 1000\right] \\
&= 1.23 \cdot 10^{11} \pi \ln(15000/1000) \\
&= 1.23 \cdot 10^{11} \pi \ln 15 \approx 1.05 \cdot 10^{12} \text{ cubic feet.}
\end{aligned}$$

79. Look at the disc-shaped slab of water at height y and of thickness Δy in Figure 8.177. The rate at which water is flowing out when it is at depth y is $k\sqrt{y}$ (Torricelli's Law, with k constant). Then, if $x = g(y)$, we have

$$\Delta t = \begin{pmatrix}\text{Time for water to} \\ \text{drop by this amount}\end{pmatrix} = \frac{\text{Volume}}{\text{Rate}} = \frac{\pi (g(y))^2 \Delta y}{k\sqrt{y}}.$$

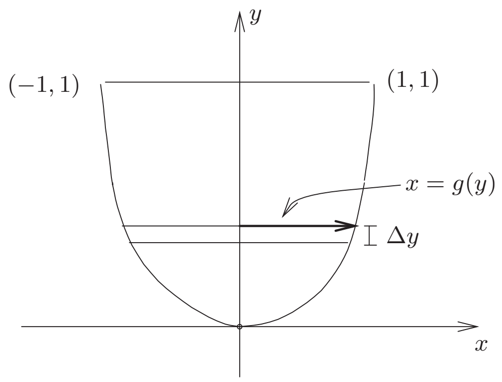


Figure 8.177

If the rate at which the depth of the water is dropping is constant, then dy/dt is constant, so we want

$$\frac{\pi (g(y))^2}{k\sqrt{y}} = \text{constant},$$

so $g(y) = c\sqrt[4]{y}$, for some constant c. Since $x = 1$ when $y = 1$, we have $c = 1$ and so $x = \sqrt[4]{y}$, or $y = x^4$.

80. The statement $P(70) = 0.76$ means that 76% of the population has ages less than 70.

81. Graph B is more spread out to the right, and so it represents a gas in which more of the molecules are moving at faster velocities. Thus the average velocity in gas B is larger.

82. Every photon which falls a given distance from the center of the detector has the same probability of being detected. This suggests that we divide the plate up into concentric rings of thickness Δr. Consider one such ring having inner radius r and outer radius $r + \Delta r$. For this ring,

$$\text{Number of photons hitting ring per unit time } \approx N \cdot \text{ Area of ring } \approx N \cdot 2\pi r \Delta r.$$

Then,

$$\text{Number of photons detected on ring per unit time} \approx \text{Number hitting} \cdot S(r) \approx N \cdot 2\pi r\Delta r \cdot S(r).$$

Summing over all rings gives us

$$\text{Total number of photons detected per unit time} \approx \sum 2\pi NrS(r)\Delta r.$$

Taking the limit as $\Delta r \to 0$ gives

$$\text{Total number of photons detected per unit time} = \int_0^R 2\pi NrS(r)dr.$$

83. The number of houses in a ring of width Δr a distance r_i from the city center is given by:

$$\begin{aligned}\text{Number houses} &= 1000 \text{ houses/mi}^2 \times \text{Area of ring}\\ &= 1000 \cdot 2\pi r_i \Delta r = 2000\pi r_i \Delta r.\end{aligned}$$

The value of the houses in this ring is given by:

$$\begin{aligned}\text{Value} &= \text{Price per house} \times \text{Number of houses}\\ &= p(r_i) \cdot 1000 \cdot 2\pi r_i \Delta r = 2000\pi r_i p(r_i)\Delta r.\end{aligned}$$

The total value of the houses within 7 miles of the city center is therefore

$$\begin{aligned}\text{Total value} &= \lim_{n\to\infty} \sum_{i=1}^{n} 2000\pi r_i p(r_i)\Delta r\\ &= \int_0^7 2000\pi r p(r)\,dr\\ &= 2000\pi \int_0^7 400e^{-0.2r^2} r dr\\ &= 800{,}000\pi \int_{r=0}^{r=7} e^{w^2}(-2.5)\ dw \qquad \text{let } w = -0.2r^2, dw = -0.4rdr\\ &= -2{,}000{,}000\pi \int_{r=0}^{r=7} e^{w}\,dw\\ &= -2{,}000{,}000\pi e^{-0.2r^2}\Big|_0^7\\ &= -2{,}000{,}000\pi\left(e^{-0.2(7)^2} - e^{-0.2(0)^2}\right) = 6{,}282{,}837.\end{aligned}$$

This figure is in \$1000s, so the total value of homes is approximately \$6.2828 billion.

84. (a) Divide the cross-section of the blood into rings of radius r, width Δr. See Figure 8.178.

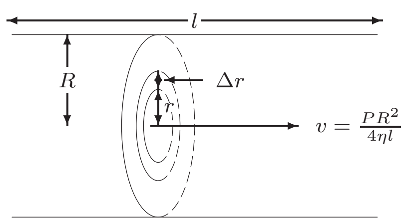

Figure 8.178

Then

$$\text{Area of ring} \approx 2\pi r\Delta r.$$

The velocity of the blood is approximately constant throughout the ring, so

$$\begin{aligned}\text{Rate blood flows through ring} &\approx \text{Velocity}\cdot\text{Area}\\ &= \frac{P}{4\eta l}(R^2-r^2)\cdot 2\pi r\Delta r.\end{aligned}$$

Thus, summing over all rings, we find the total blood flow:

$$\text{Rate blood flowing through blood vessel} \approx \sum \frac{P}{4\eta l}(R^2-r^2)2\pi r\Delta r.$$

Taking the limit as $\Delta r \to 0$, we get

$$\text{Rate blood flowing through blood vessel} = \int_0^R \frac{\pi P}{2\eta l}(R^2 r - r^3)dr$$

$$= \frac{\pi P}{2\eta l}\left(\frac{R^2r^2}{2}-\frac{r^4}{4}\right)\Big|_0^R = \frac{\pi P R^4}{8\eta l}.$$

(b) Since

$$\text{Rate of blood flow} = \frac{\pi P R^4}{8\eta l},$$

if we take $k = \pi P/(8\eta l)$, then we have

$$\text{Rate of blood flow} = kR^4,$$

that is, rate of blood flow is proportional to R^4, in accordance with Poiseuille's Law.

85. Pick a small interval of time Δt which takes place at time t. Fuel is consumed at a rate of $(25+0.1v)^{-1}$ gallons per mile. In the time Δt, the car moves $v\,\Delta t$ miles, so it consumes $v\,\Delta t/(25+0.1v)$ gallons during the instant Δt. Since $v = 50\frac{t}{t+1}$, the car consumes

$$\frac{v\,\Delta t}{25+0.1v} = \frac{50\frac{t}{t+1}\,\Delta t}{25+0.1\left(50\frac{t}{t+1}\right)} = \frac{50t\,\Delta t}{25(t+1)+5t} = \frac{10t\,\Delta t}{6t+5}$$

gallons of gas, in terms of the time t at which the instant occurs. To find the total gas consumed, sum up the instants in an integral:

$$\text{Gas consumed } = \int_2^3 \frac{10t}{6t+5}dt \approx 1.25 \text{ gallons.}$$

86. (a) Slicing horizontally, as shown in Figure 8.179, we see that the volume of one disk-shaped slab is

$$\Delta V \approx \pi x^2\Delta y = \frac{\pi y}{a}\Delta y.$$

Thus, the volume of the water is given by

$$V = \int_0^h \frac{\pi}{a} y dy = \frac{\pi}{a}\frac{y^2}{2}\Big|_0^h = \frac{\pi h^2}{2a}.$$

(b) The surface of the water is a circle of radius x. Since at the surface, $y = h$, we have $h = ax^2$. Thus, at the surface, $x = \sqrt{(h/a)}$. Therefore the area of the surface of water is given by

$$A = \pi x^2 = \frac{\pi h}{a}.$$

(c) If the rate at which water is evaporating is proportional to the surface area, we have

$$\frac{dV}{dt} = -kA.$$

(The negative sign is included because the volume is decreasing.) By the chain rule, $\frac{dV}{dt} = \frac{dV}{dh}\cdot\frac{dh}{dt}$. We know $\frac{dV}{dh} = \frac{\pi h}{a}$ and $A = \frac{\pi h}{a}$ so

$$\frac{\pi h}{a}\frac{dh}{dt} = -k\frac{\pi h}{a} \quad \text{giving} \quad \frac{dh}{dt} = -k.$$

(d) Integrating gives

$$h = -kt + h_0.$$

Solving for t when $h = 0$ gives

$$t = \frac{h_0}{k}.$$

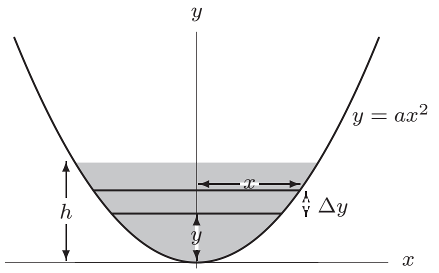

Figure 8.179

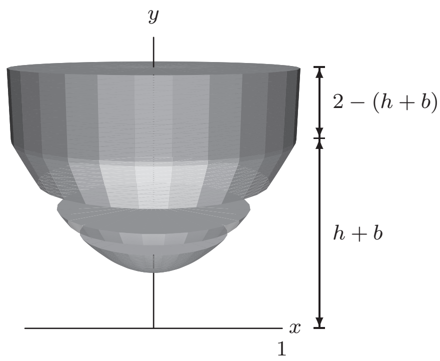

Figure 8.180

87. (a) The volume of water in the centrifuge is $\pi(1^2)\cdot 1 = \pi$ cubic meters. The centrifuge has total volume 2π cubic meters, so the volume of the air in the centrifuge is π cubic meters. Now suppose the equation of the parabola is $y = h + bx^2$. We know that the volume of air in the centrifuge is the volume of the top part (a cylinder) plus the volume of the middle part (shaped like a bowl). See Figure 8.180.

To find the volume of the cylinder of air, we find the maximum water depth. If $x = 1$, then $y = h + b$. Therefore the height of the water at the edge of the bowl, 1 meter away from the center, is $h + b$. The volume of the cylinder of air is therefore $[2 - (h + b)] \cdot \pi \cdot (1)^2 = [2 - h - b]\pi$.

To find the volume of the bowl of air, we note that the bowl is a volume of rotation with radius x at height y, where $y = h + bx^2$. Solving for x^2 gives $x^2 = (y - h)/b$. Hence, slicing horizontally as shown in the picture:

$$\text{Bowl Volume} = \int_h^{h+b} \pi x^2\, dy = \int_h^{h+b} \pi \frac{y-h}{b}\, dy = \left.\frac{\pi(y-h)^2}{2b}\right|_h^{h+b} = \frac{b\pi}{2}.$$

So the volume of both pieces together is $[2 - h - b]\pi + b\pi/2 = (2 - h - b/2)\pi$. But we know the volume of air should be π, so $(2 - h - b/2)\pi = \pi$, hence $h + b/2 = 1$ and $b = 2 - 2h$. Therefore, the equation of the parabolic cross-section is $y = h + (2 - 2h)x^2$.

(b) The water spills out the top when $h + b = h + (2 - 2h) = 2$, or when $h = 0$. The bottom is exposed when $h = 0$. Therefore, the two events happen simultaneously.

88. Any small piece of mass ΔM on either of the two spheres has kinetic energy $\frac{1}{2}v^2\Delta M$. Since the angular velocity of the two spheres is the same, the actual velocity of the piece ΔM will depend on how far away it is from the axis of revolution. The further away a piece is from the axis, the faster it must be moving and the larger its velocity v. This is because if ΔM is at a distance r from the axis, in one revolution it must trace out a circular path of length $2\pi r$ about the axis. Since every piece in either sphere takes 1 minute to make 1 revolution, pieces farther from the axis must move faster, as they travel a greater distance.

Thus, since the thin spherical shell has more of its mass concentrated farther from the axis of rotation than does the solid sphere, the bulk of it is traveling faster than the bulk of the solid sphere. So, it has the higher kinetic energy.

89. Any small piece of mass ΔM on either of the two hoops has kinetic energy $\frac{1}{2}v^2\Delta M$. Since the angular velocity of the two hoops is the same, the actual velocity of the piece ΔM will depend on how far away it is from the axis of revolution. The further away a piece is from the axis, the faster it must be moving and the larger its velocity v. This is because if ΔM is at a distance r from the axis, in one revolution it must trace out a circular path of length $2\pi r$ about the axis. Since every piece in either hoop takes 1 minute to make 1 revolution, pieces farther from the axis must move faster, as they travel a greater distance.

The hoop rotating about the cylindrical axis has all of its mass at a distance R from the axis, whereas the other hoop has a good bit of its mass close (or on) the axis of rotation. So, since the bulk of the hoop rotating about the cylindrical axis is traveling faster than the bulk of the other hoop, it must have the higher kinetic energy.

CAS Challenge Problems

90. (a) We need to check that the point with the given coordinates is on the curve, i.e., that

$$x = a\sin^2 t, \quad y = \frac{a\sin^3 t}{\cos t}$$

satisfies the equation

$$y = \sqrt{\frac{x^3}{a-x}}.$$

This can be done by substituting into the computer algebra system and asking it to simplify the difference between the two sides, or by hand calculation:

$$\begin{aligned}\text{Right-hand side} &= \sqrt{\frac{(a\sin^2 t)^3}{a - a\sin^2 t}} = \sqrt{\frac{a^3\sin^6 t}{a(1-\sin^2 t)}} \\ &= \sqrt{\frac{a^3\sin^6 t}{a\cos^2 t}} = \sqrt{\frac{a^2\sin^6 t}{\cos^2 t}} \\ &= \frac{a\sin^3 t}{\cos t} = y = \text{Left-hand side.}\end{aligned}$$

We chose the positive square root because both $\sin t$ and $\cos t$ are nonnegative for $0 \le t \le \pi/2$. Thus the point always lies on the curve. In addition, when $t = 0$, $x = 0$ and $y = 0$, so the point starts at $x = 0$. As t approaches $\pi/2$, the value of $x = a\sin^2 t$ approaches a and the value of $y = a\sin^3 t/\cos t$ increases without bound (or approaches ∞), so the point on the curve approaches the vertical asymptote at $x = a$.

(b) We calculate the volume using horizontal slices. See the graph of $y = \sqrt{x^3/(a-x)}$ in Figure 8.181.

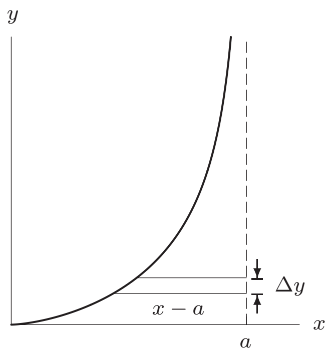

Figure 8.181

The slice at y is a disk of thickness Δy and radius $x - a$, hence it has volume $\pi(x-a)^2\Delta y$. So the volume is given by the improper integral

$$\text{Volume} = \int_0^\infty \pi(x-a)^2\,dy.$$

(c) We substitute

$$x = a\sin^2 t, \quad y = \frac{a\sin^3 t}{\cos t}$$

and

$$dy = \frac{d}{dt}\left(\frac{a\sin^3 t}{\cos t}\right)dt = a\left(3\sin^2 t + \frac{\sin^4 t}{\cos^2 t}\right)dt.$$

Since $t = 0$ where $y = 0$ and $t = \pi/2$ at the asymptote where $y \to \infty$, we get

$$\begin{aligned}\text{Volume} &= \int_0^{\pi/2} \pi(a\sin^2 t - a)^2 a\left(3\sin^2 t + \frac{\sin^4 t}{\cos^2 t}\right)dt \\ &= \pi a^3 \int_0^{\pi/2}(3\sin^2 t\cos^4 t + \sin^4 t\cos^2 t)\,dt = \frac{\pi^2 a^3}{8}.\end{aligned}$$

You can use a CAS to calculate this integral; it can also be done using trigonometric identities.

91. (a) The expression for arc length in terms of a definite integral gives

$$A(t) = \int_0^t \sqrt{1+4x^2}\,dx = \frac{2\,t\,\sqrt{1+4\,t^2} + \operatorname{arcsinh}(2\,t)}{4}.$$

The integral was evaluated using a computer algebra system; different systems may give the answer in different forms. Here arcsinh is the inverse function of the hyperbolic sine function.

(b) Figure 8.182 shows that the graphs of $A(t)$ and t^2 look very similar. This suggests that $A(t) \approx t^2$.

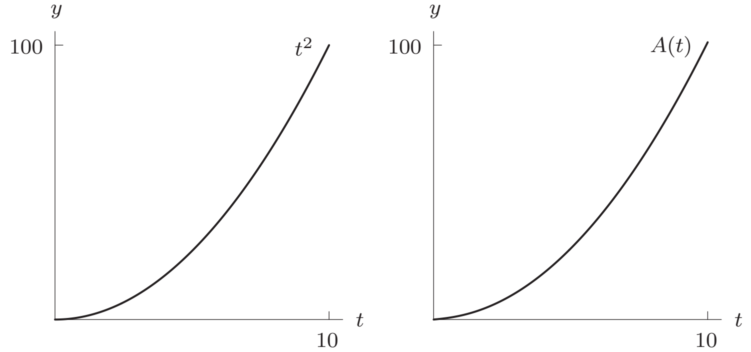

Figure 8.182

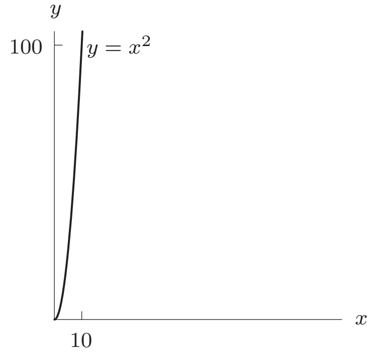

Figure 8.183

(c) The graph in Figure 8.183 is approximately vertical and close to the y axis. Thus, if we measure the arc length up to a certain y-value, the answer is approximately the same as if we had measured the length straight up the y-axis. Hence

$$A(t) \approx y = f(t) = t^2.$$

So

$$A(t) \approx t^2.$$

92. (a) The expression for arc length in terms of a definite integral gives

$$A(t) = \int_0^t \sqrt{1+\left(\frac{1}{2\sqrt{x}}\right)^2}\,dx = \frac{2\sqrt{t}\sqrt{1+4t} + \operatorname{arcsinh}(2\sqrt{t})}{4}.$$

The integral was evaluated using a computer algebra system; different systems may give the answer in different forms. Some may involve ln instead of arcsinh, which is the inverse function of the hyperbolic sine function.

(b) Figure 8.185 shows that the graphs of $A(t)$ and the graph of $y = t$ look very similar. This suggests that $A(t) \approx t$.

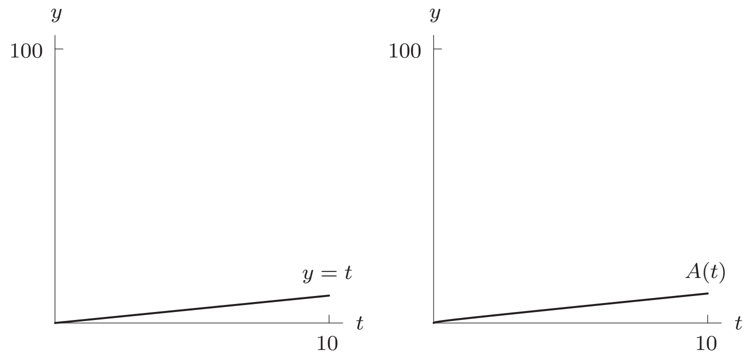

Figure 8.184

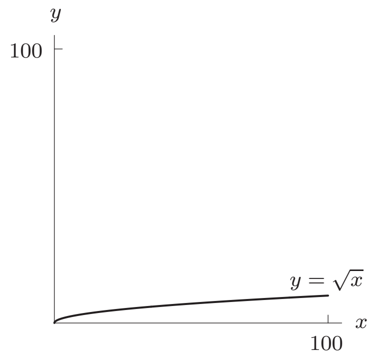

Figure 8.185

(c) The graph in Figure 8.185 is approximately horizontal and close to the x-axis. Thus, if we measure the arc length up to a certain x-value, the answer is approximately the same as if we had measured the length straight along the x-axis. Hence

$$A(t) \approx x = t.$$

So

$$A(t) \approx t.$$

93. (a) Slice the sphere at right angles to the axis of the cylinder. Consider a slice of thickness Δx at distance x from the center of the sphere. The cross-section is an annulus (ring) with internal radius $r_i = a$ and outer radius $r_o = \sqrt{r^2 - x^2}$. Thus

$$\text{Area of annulus } = \pi {r_o}^2 - \pi {r_i}^2 = \pi\left(\sqrt{r^2 - x^2}\right)^2 - \pi a^2 = \pi(r^2 - x^2 - a^2).$$

$$\text{Volume of slice} \approx \pi(r^2 - x^2 - a^2)\Delta x.$$

The lower and upper limits of the integral are where the cylinder meets the sphere, i.e., where $x^2 + a^2 = r^2$, or $x = \pm\sqrt{r^2 - a^2}$. Thus

$$\text{Volume of bead} = \int_{-\sqrt{r^2-a^2}}^{\sqrt{r^2-a^2}} \pi(r^2 - x^2 - a^2)\,dx.$$

(b) Using a computer algebra system to evaluate the integral, we have

$$\text{Volume of bead} = \frac{4\pi}{3}\left(r^2 - a^2\right)^{3/2}.$$

PROJECTS FOR CHAPTER EIGHT

1. (a) The hydrostatic pressure p_h is a linear function of distance x, so $p_h = b + mx$. At the artery end, $x = 0$, and $p_h = 35$. At the vein end, $x = L = 0.1$ and $p_h = 15$. This means the points $(0, 35)$ and $(0.1, 15)$ are on the graph of p_h, so the slope is given by

$$m = \frac{15 - 35}{0.1 - 0} = -200\,\frac{\text{mm Hg}}{\text{cm}}.$$

We know that $b = 35$, so $p_h = 35 - 200x$ mm Hg.

(b) The net pressure, p, is the difference between the hydrostatic pressure and the oncotic pressure. Using part (a), we have

$$p = p_h - p_o = (35 - 200x) - 23 = 12 - 200x \text{ mm Hg}.$$

(c) Since $j = k \cdot p$, we have

$$j \text{ units} = (k \text{ units}) \times (p \text{ units}) = \frac{\text{cm}}{\text{sec} \cdot \text{mm Hg}} \times \text{mm Hg} = \frac{\text{cm}}{\text{sec}}.$$

In addition

$$\text{Volume/time/area units} = \frac{\text{Volume units}}{\text{Time units}} \times \frac{1}{\text{Area units}} = \frac{\text{cm}^3}{\text{sec}} \times \frac{1}{\text{cm}^2} = \frac{\text{cm}}{\text{sec}}.$$

Thus, j has units of volume per time per area.

(d) To find the flow rate through a small section of length Δx of the capillary, we multiply j, the flow rate per capillary wall area, by the area, $A = 2\pi r\,\Delta x$ of the section. To find the flow through the wall of the entire capillary, we integrate. Thus,

$$\text{Flow rate } = \int_0^L j \cdot 2\pi r\,dx = \int_0^L kp \cdot 2\pi r\,dx$$

Using the formula for p from part (b), and the values $L = 0.1$ cm, $r = 0.0004$ cm, and $k = 10^{-7}$ cm/(sec$\cdot$ mm Hg), evaluating the integral symbolically or numerically, we have

$$\text{Flow rate } = \int_0^{0.1} 2\pi(10^{-7})(0.0004)(12 - 200x)\,dx = 8 \cdot 10^{-11}\pi(12x - 100x^2)\Big|_0^{0.1} = 5.03 \cdot 10^{-11}\frac{\text{cm}^3}{\text{sec}}.$$

2. (a) The volume of a cylinder of radius r and height h is $V = \pi r^2 h$. Since the total volume of the urine sample is 2000 ml and the diameter is 10 cm (so the radius is 5 cm), we have:

$$\pi r^2 h = \pi 5^2 h = 2000$$
$$h = \frac{2000}{25\pi} = 25.46 \text{ cm.}$$

Thus, the depth of urine in the cylinder is 25.46 cm.

(i) The protein concentration c is a linear function of height y, so $c = b + my$. At the bottom of the sample, $y = 0$, and $c = 0.96$. At the top, $y = 25.46$ and $c = 0.14$. This means the points $(0, 0.96)$ and $(25.46, 0.14)$ are on the graph of c, so the slope is given by

$$m = \frac{0.14 - 0.96}{25.46 - 0} = -0.0322 \, \frac{\text{mg}}{\text{ml} \cdot \text{cm}}.$$

We know that $b = 0.96$, so $c = 0.96 - 0.0322y$ mg/ml.

(ii) A cross sectional slice of the cylinder has volume $5^2\pi\Delta y = 25\pi\Delta y$. This means the quantity of protein in a given slice is

$$\Delta Q = \underbrace{\text{Volume}}_{25\pi\Delta y} \times \underbrace{\text{Concentration}}_{0.96-0.0322y} = 25\pi\Delta y\,(0.96 - 0.0322y) \text{ mg.}$$

(iii) To find the total quantity of protein, we integrate:

$$\begin{aligned}\text{Total mass} &= \int_{y=0}^{25.46} 25\pi\,(0.96 - 0.0322y)\,dy \\ &= 25\pi\left(0.96y - 0.0161y^2\right)\Big|_0^{25.46} \\ &= 1099.98 \text{ mg.}\end{aligned}$$

Thus, the patient excreted approximately 1100 mg, or 1.1 gm, of protein during the 24 hour period in which urine was collected. This is above the threshold of 1 gm per 24 hour period at which active treatment is recommended.

(b) Let the radius of the collection container be r, the volume of the urine be V, and the concentrations of protein at the top and bottom of the collected fluid be c_t and c_b. We compute the quantity of protein by following the procedure of part (a).

If h is the depth of the sample, we have

$$V = \pi r^2 h.$$

Assuming that protein concentration, c, is a linear function of the distance, y, from the bottom of the container, we have

$$c = c_b + my$$

where the slope m is given by

$$m = \frac{c_t - c_b}{h}.$$

The quantity of protein in a horizontal slice is

$$\Delta Q = \text{Volume} \times \text{Concentration} = \pi r^2 \Delta y \cdot c.$$

To find the total quantity of protein in the container, we integrate:

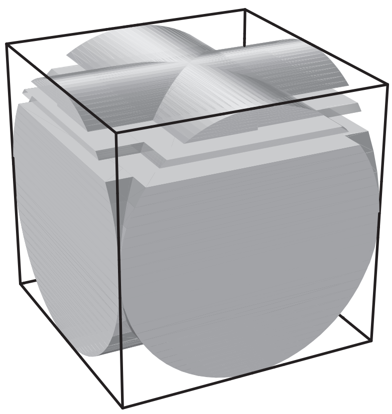
$$\text{Total mass} = \int_0^h \pi r^2 c(y)\,dy = \int_0^h \pi r^2 (c_b + my)\,dy$$

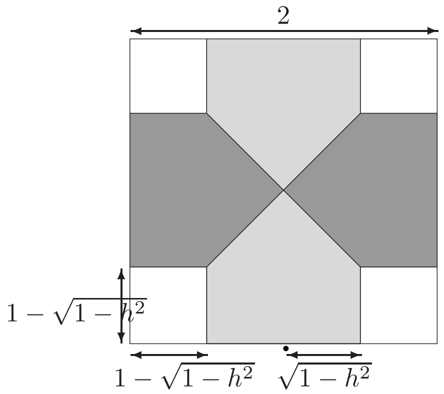
$$= \pi r^2 \left(c_b y + m\frac{y^2}{2} \right) \bigg|_0^h = \pi r^2 \left(c_b h + m\frac{h^2}{2} \right)$$
$$= \pi r^2 \left(c_b h + \frac{c_t - c_b}{h} \cdot \frac{h^2}{2} \right) = \pi r^2 h \left(c_b + \frac{c_t - c_b}{2} \right)$$
$$= \frac{c_t + c_b}{2} V.$$

Thus, the quantity of protein in the sample is the product of the average of the top and bottom protein concentrations by the volume of urine collected.

3. Let us make coordinate axes with the origin at the center of the box. The x and y axes will lie along the central axes of the cylinders, and the (height) axis will extend vertically to the top of the box. If one slices the cylinders horizontally, one gets a cross. The cross is what you get if you cut out four corner squares from a square of side length 2. If h is the height of the cross above (or below) the xy plane, the equation of a cylinder is $h^2 + y^2 = 1$ (or $h^2 + x^2 = 1$). Thus the "armpits" of the cross occur where $y^2 - 1 = -h^2 = x^2 - 1$ for some fixed height h—that is, out $\sqrt{1-h^2}$ units from the center, or $1 - \sqrt{1-h^2}$ units away from the edge. Each corner square has area $(1 - \sqrt{1-h^2})^2 = 2 - h^2 - 2\sqrt{1-h^2}$. The whole big square has area 4. Therefore, the area of the cross is

$$4 - 4(2 - h^2 - 2\sqrt{1-h^2}) = -4 + 4h^2 + 8\sqrt{1-h^2}.$$





We integrate this from $h = -1$ to $h = 1$, and obtain the volume, V:

$$V = \int_{-1}^{1} -4 + 4h^2 + 8\sqrt{1-h^2}\, dh$$
$$= \left[-4h + \frac{4h^3}{3} + 8 \cdot \frac{1}{2} \left(h\sqrt{1-h^2} + \arcsin h \right) \right] \bigg|_{-1}^{1}$$
$$= -8 + \frac{8}{3} + 4\pi = 4\pi - \frac{16}{3} \approx 7.23.$$

This is a reasonable answer, as the volume of the cube is 8, and the volume of one cylinder alone is $2\pi \approx 6.28$.

4. (a) Let y represent height, and let x represent horizontal distance from the lowest point of the cable. Then the stretched cable is a parabola of the form $y = kx^2$ passing through the point $(1280/2, 143) = (640, 143)$. Therefore, $143 = k(640)^2$ so $k \approx 3.491 \times 10^{-4}$. To find the arc length of the parabola, we take twice the arc length of the part to the right of the lowest point. Since $dy/dx = 2kx$,

$$\text{Arc Length} = 2\int_0^{640} \sqrt{1 + (2kx)^2}\, dx = 2\int_0^{640} \sqrt{1 + 4k^2x^2}\, dx.$$

The easiest way to find this integral is to substitute the value of k and find the integral's value numerically, giving

$$\text{Arc Length} \approx 1321.4 \text{ meters.}$$

Alternatively, we can make the substitution $w = 2kx$:

$$\begin{aligned}\text{Arc Length} &= \frac{2}{2k}\int_0^{1280k}\sqrt{1+w^2}\,dw\\ &= \frac{1}{k}\int_0^{1280k}\sqrt{1+w^2}\,dw\\ &= \frac{1}{2k}\left(w\sqrt{1+w^2}\Big|_0^{1280k}\right)+\frac{1}{2k}\left(\int_0^{1280k}\frac{1}{\sqrt{1+w^2}}\,dw\right)\\ &\quad\text{[Using the integral table, Formula VI-29, or substitute } w=\tan\theta]\\ &= \frac{1}{2k}\left(1280k\sqrt{1+(1280k)^2}\right)+\frac{1}{2k}\left(\ln\left|x+\sqrt{1+x^2}\right|\Big|_0^{1280k}\right)\\ &= \frac{1}{2k}\left(1280k\sqrt{1+(1280k)^2}\right)+\frac{1}{2k}\left(\ln\left|1280k+\sqrt{1+(1280k)^2}\right|\right)\\ &\approx 1321.4 \text{ meters.}\end{aligned}$$

(b) Adding 0.05% to the length of the cable gives a cable length of $(1321.4)(1.0005) = 1322.1$. We now want to calculate the new shape of the parabola; that is, we want to find a new k so that the arc length is 1322.1. Since

$$\text{Arc Length} = 2\int_0^{640}\sqrt{1+4k^2x^2}\,dx$$

we can find k numerically by trial and error. Trying values close to our original value of k, we find $k \approx 3.52 \times 10^{-4}$. To find the sag for this new k, we find the height $y = kx^2$ for which the cable hangs from the towers. This is

$$y = k(640)^2 \approx 144.2.$$

Thus the cable sag is 144.2 meters, over a meter more than on a cold winter day. Notice, though, that although the length increases by 0.05%, the sag increases by more:$144.2/143 \approx 1.0084$, an increase of 0.84%.

5. (a) Revolving the semi-circle $y = \sqrt{r^2 - x^2}$ around the x-axis yields the sphere of radius r. See Figure 8.186. Differentiating yields:

$$\frac{dy}{dx} = \frac{-1}{\sqrt{r^2-x^2}}\cdot x = -\frac{x}{y}.$$

Thus, substituting $-x/y$ for $f'(x)$, we get

$$\begin{aligned}\text{Surface area} &= 2\pi\int_{-r}^{r} y\sqrt{1+\frac{x^2}{y^2}}\,dx = 2\pi\int_{-r}^{r}\sqrt{x^2+y^2}\,dx\\ &= 2\pi r\int_{-r}^{r}dx = 4\pi r^2.\end{aligned}$$

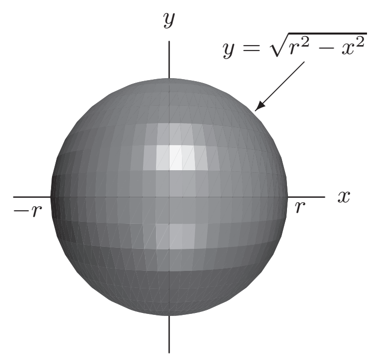


Figure 8.186

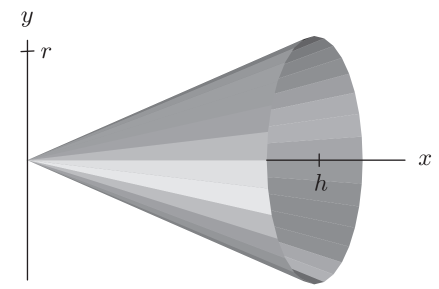

Figure 8.187

(b) Revolving the line $y = rx/h$ around the x-axis yields the cone. The base of the cone is a circle with area πr^2. See Figure 8.187. The area of the rest of the cone is

$$\begin{aligned}\text{Surface area} &= 2\pi \int_0^h y\sqrt{1+\frac{r^2}{h^2}}\,dx = 2\pi\sqrt{1+\frac{r^2}{h^2}}\left(\frac{r}{h}\int_0^h x\,dx\right)\\ &= 2\pi\frac{r}{h}\frac{h^2}{2}\sqrt{1+\frac{r^2}{h^2}} = \pi r\sqrt{r^2+h^2}\end{aligned}$$

Adding the area of the base, we get

$$\text{Total surface area of cone } = \pi r^2 + \pi r\sqrt{r^2+h^2}.$$

(c) We find the volume of $y = 1/x$ revolved about the x-axis as x runs from 1 to ∞. See Figure 8.188.

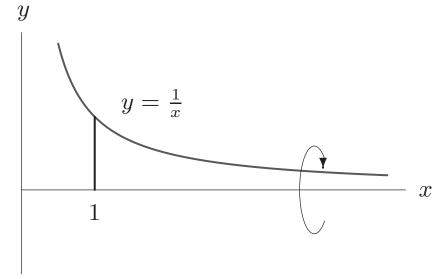

Figure 8.188

$$\text{Volume } = \int_1^\infty \pi y^2\,dx = \pi\int_1^\infty \frac{1}{x^2}\,dx = \pi\lim_{b\to\infty}\int_1^b \frac{dx}{x^2} = \pi\lim_{b\to\infty}\left.\frac{-1}{x}\right|_1^b = \pi$$

Thus, the volume of this solid is finite and equal to π.

(d) Now we show the surface area of this solid is unbounded. We have

$$\text{Surface area } = 2\pi\int_1^\infty y\sqrt{1+\left(\frac{dy}{dx}\right)^2}\,dx = 2\pi\int_1^\infty \frac{1}{x}\sqrt{1+\frac{1}{x^4}}\,dx$$

We cannot easily compute the antiderivative of $\frac{1}{x}\sqrt{1+\frac{1}{x^4}}$, so we bound the integral from below by noticing that

$$\sqrt{1+\frac{1}{x^4}} \geq 1.$$

Thus we see that

$$\text{Surface area } \geq 2\pi\int_1^\infty \frac{1}{x}\,dx = 2\pi\lim_{b\to\infty}\int_1^b\frac{dx}{x} = 2\pi\lim_{b\to\infty}\left.\ln x\right|_1^b.$$

Since $\ln x$ goes to infinity as x goes to infinity, the surface area is unbounded.

Alternatively, we can try calculating

$$2\pi\int_1^b \frac{1}{x}\sqrt{1+\frac{1}{x^4}}\,dx$$

for larger and larger values of b. We would see that the integral seems to diverge.

(e) For a solid generated by the revolution of a curve $y = f(x)$ for $a \le x \le b$,

$$\text{Volume} = \int_a^b \pi y^2\, dx$$

and

$$\text{Surface area} = \int_a^b 2\pi y \sqrt{1 + (f'(x))^2}\, dx.$$

The volume and the surface area will be equal if

$$f(x) = 2\sqrt{1 + (f'(x))^2}.$$

We find a function $y = f(x)$ which satisfies this relation:

$$\begin{aligned}
y &= 2\sqrt{1 + \left(\frac{dy}{dx}\right)^2} \\
\frac{y^2}{4} &= 1 + \left(\frac{dy}{dx}\right)^2 \\
\frac{dy}{dx} &= \sqrt{\frac{y^2}{4} - 1} \\
\frac{dy}{\sqrt{y^2 - 4}} &= \frac{1}{2}\, dx \\
\int \frac{dy}{\sqrt{y^2 - 4}} &= \int \frac{1}{2}\, dx \\
\ln|y + \sqrt{y^2 - 4}| &= \frac{x}{2} + C \\
y + \sqrt{y^2 - 4} &= Ae^{x/2}
\end{aligned}$$

Notice in the third line we have used the fact that $dy/dx \ge 0$. Any function, $y = f(x)$, which satisfies this relationship has the required property.

6. (a) We want to find a such that $\int_0^\infty p(v)\, dv = \lim_{r\to\infty} a \int_0^r v^2 e^{-mv^2/2kT}\, dv = 1$. Therefore,

$$\frac{1}{a} = \lim_{r\to\infty} \int_0^r v^2 e^{-mv^2/2kT}\, dv.$$

To evaluate the integral, use integration by parts with the substitutions $u = v$ and $w' = ve^{-mv^2/2kT}$:

$$\begin{aligned}
\int_0^r \underbrace{v}_{u} \underbrace{ve^{-mv^2/2kT}}_{w'}\, dv &= \underbrace{v}_{u} \underbrace{\frac{e^{-mv^2/2kT}}{-m/kT}}_{w}\Bigg|_0^r - \int_0^r \underbrace{1}_{u'} \underbrace{\frac{e^{-mv^2/2kT}}{-m/kT}}_{w}\, dv \\
&= -\frac{kTr}{m} e^{-mr^2/2kT} + \frac{kT}{m}\int_0^r e^{-mv^2/2kT}\, dv.
\end{aligned}$$

From the normal distribution we know that $\displaystyle\int_0^\infty \frac{1}{\sqrt{2\pi}} e^{-x^2/2}\, dx = \frac{1}{2}$, so

$$\int_0^\infty e^{-x^2/2}\, dx = \frac{\sqrt{2\pi}}{2}.$$

Therefore in the above integral, make the substitution $x = \sqrt{\frac{m}{kT}}v$, so that $dx = \sqrt{\frac{m}{kT}}\, dv$, or $dv = \sqrt{\frac{kT}{m}}\, dx$. Then

$$\frac{kT}{m}\int_0^r e^{-mv^2/2kT}\, dv = \left(\frac{kT}{m}\right)^{3/2} \int_0^{\sqrt{\frac{m}{kT}}r} e^{-x^2/2}\, dx.$$

Substituting this into Equation 6a we get

$$\frac{1}{a} = \lim_{r\to\infty}\left(-\frac{kTr}{m}e^{-mr^2/2kT} + \left(\frac{kT}{m}\right)^{3/2}\int_0^{\sqrt{\frac{m}{kT}}r} e^{-x^2/2}\,dx\right) = 0 + \left(\frac{kT}{m}\right)^{3/2}\cdot\frac{\sqrt{2\pi}}{2}.$$

Therefore, $a = \frac{2}{\sqrt{2\pi}}(\frac{m}{kT})^{3/2}$. Substituting the values for k, T, and m gives $a \approx 3.4\times 10^{-8}$.

(b) To find the median, we wish to find the speed x such that

$$\int_0^x p(v)\,dv = \int_0^x av^2e^{-\frac{mv^2}{2kT}}\,dv = \frac{1}{2},$$

where $a = \frac{2}{\sqrt{2\pi}}(\frac{m}{kT})^{3/2}$. Using a calculator, by trial and error we get $x \approx 441$ m/sec.

To find the mean, we find

$$\int_0^\infty vp(v)\,dv = \int_0^\infty av^3e^{-\frac{mv^2}{2kT}}\,dv.$$

This integral can be done by substitution. Let $u = v^2$, so $du = 2vdv$. Then

$$\begin{aligned}\int_0^\infty av^3e^{-\frac{mv^2}{2kT}}\,dv &= \frac{a}{2}\int_{v=0}^{v=\infty} v^2e^{-\frac{mv^2}{2kT}}2v\,dv\\ &= \frac{a}{2}\int_{u=0}^{u=\infty} ue^{-\frac{mu}{2kT}}\,du\\ &= \lim_{r\to\infty}\frac{a}{2}\int_0^r ue^{-\frac{mu}{2kT}}\,du.\end{aligned}$$

Now, using the integral table, we have

$$\begin{aligned}\int_0^\infty av^3e^{-\frac{mv^2}{2kT}}\,dv &= \lim_{r\to\infty}\frac{a}{2}\left[-\frac{2kT}{m}ue^{-\frac{mu}{2kT}} - \left(-\frac{2kT}{m}\right)^2e^{-\frac{mu}{2kT}}\right]\Bigg|_0^r\\ &= \frac{a}{2}\left(-\frac{2kT}{m}\right)^2\\ &\approx 457.7 \text{ m/sec.}\end{aligned}$$

The maximum for $p(v)$ will be at a point where $p'(v) = 0$.

$$\begin{aligned}p'(v) &= a(2v)e^{-\frac{mv^2}{2kT}} + av^2\left(-\frac{2mv}{2kT}\right)e^{-\frac{mv^2}{2kT}}\\ &= ae^{-\frac{mv^2}{2kT}}\left(2v - v^3\frac{m}{kT}\right).\end{aligned}$$

Thus $p'(v) = 0$ at $v = 0$ and at $v = \sqrt{\frac{2kT}{m}} \approx 405$. It's obvious that $p(0) = 0$, and that $p \to 0$ as $v \to \infty$. So $v = 405$ gives us a maximum: $p(405) \approx 0.002$.

(c) The mean, as we found in part (b), is $\frac{a}{2}\frac{4k^2T^2}{m^2} = \frac{4}{\sqrt{2\pi}}\frac{k^{1/2}T^{1/2}}{m^{1/2}}$. It is clear, then, that as T increases so does the mean. We found in part (b) that $p(v)$ reached its maximum at $v = \sqrt{\frac{2kT}{m}}$. Thus

$$\begin{aligned}\text{The maximum value of } p(v) &= \frac{2}{\sqrt{2\pi}}\left(\frac{m}{kT}\right)^{3/2}\frac{2kT}{m}e^{-1}\\ &= \frac{4}{e\sqrt{2\pi}}\frac{m^{1/2}}{kT^{1/2}}.\end{aligned}$$

Thus as T increases, the maximum value decreases.

CHAPTER NINE

Solutions for Section 9.1

Exercises

1. The first term is $2^1 + 1 = 3$. The second term is $2^2 + 1 = 5$. The third term is $2^3 + 1 = 9$, the fourth is $2^4 + 1 = 17$, and the fifth is $2^5 + 1 = 33$. The first five terms are $3, 5, 9, 17, 33$.

2. The first term is $1 + (-1)^1 = 1 - 1 = 0$. The second term is $2 + (-1)^2 = 2 + 1 = 3$. The third term is $3 - 1 = 2$ and the fourth is $4 + 1 = 5$. The first five terms are $0, 3, 2, 5, 4$.

3. The first term is $2 \cdot 1/(2 \cdot 1 + 1) = 2/3$. The second term is $2 \cdot 2/(2 \cdot 2 + 1) = 4/5$. The first five terms are

$$2/3, 4/5, 6/7, 8/9, 10/11.$$

4. The first term is $(-1)^1(1/2)^1 = -1/2$. The second term is $(-1)^2(1/2)^2 = 1/4$. The first five terms are

$$-1/2, 1/4, -1/8, 1/16, -1/32.$$

5. The first term is $(-1)^2(1/2)^0 = 1$. The second term is $(-1)^3(1/2)^1 = -1/2$. The first five terms are

$$1, -1/2, 1/4, -1/8, 1/16.$$

6. The first term is $(1 - 1/(1 + 1))^{(1+1)} = (1/2)^2$. The second term is $(1 - 1/3)^3 = (2/3)^3$. The first five terms are

$$(1/2)^2, (2/3)^3, (3/4)^4, (4/5)^5, (5/6)^6.$$

7. The terms look like powers of 2 so we guess $s_n = 2^n$. This makes the first term $2^1 = 2$ rather than 4. We try instead $s_n = 2^{n+1}$. If we now check, we get the terms $4, 8, 16, 32, 64, \ldots$, which is right.

8. We compare with positive powers of 2, which are $2, 4, 8, 16, 32, \ldots$. Each term is one less, so we take $s_n = 2^n - 1$.

9. We observe that if we subtract 1 from each term of the sequence, we get $1, 4, 9, 16, 25, \ldots$, namely the squares $1^2, 2^2, 3^2, 4^2, 5^2, \ldots$. Thus $s_n = n^2 + 1$.

10. First notice that $s_n = 2n - 1$ is a formula for the general term of the sequence

$$1,\ 3,\ 5,\ 7,\ 9, \ldots.$$

To obtain the alternating signs in the original sequence, we try multiplying by $(-1)^n$. However, checking $(-1)^n(2n-1)$ for $n = 1, 2, 3, \ldots$ gives

$$-1,\ 3,\ -5,\ 7,\ -9, \ldots.$$

To get the correct signs, we multiply by $(-1)^{n+1}$ and take

$$s_n = (-1)^{n+1}(2n - 1).$$

11. The numerator is n. The denominator is then $2n + 1$, so $s_n = n/(2n + 1)$.

12. The denominators are the even numbers, so we try $s_n = 1/(2n)$. To get the signs to alternate, we try multiplying by $(-1)^n$. That gives

$$-1/2, 1/4, -1/6, 1/8, -1/10, \ldots,$$

so we multiply by $(-1)^{n+1}$ instead. Thus $s_n = (-1)^{n+1}/(2n)$.

Problems

13. Since 2^n increases without bound as n increases, the sequence diverges.

14. Since $\lim_{n\to\infty} x^n = 0$ if $|x| < 1$ and $|0.2| < 1$, we have $\lim_{n\to\infty} (0.2)^n = 0$, so the sequence converges to 0

15. Since $\lim_{n\to\infty} x^n = 0$ if $|x| < 1$ and $|e^{-2}| < 1$, we have $\lim_{n\to\infty} (e^{-2n}) = \lim_{n\to\infty} (e^{-2})^n = 0$, so $\lim_{n\to\infty} (3+e^{-2n}) = 3+0 = 3$, so the sequence converges to 3.

16. Since $\lim_{n\to\infty} x^n = 0$ if $|x| < 1$ and $|-0.3| < 1$, we have $\lim_{n\to\infty} (-0.3)^n = 0$, so the sequence converges to 0.

17. We have:
$$\lim_{n\to\infty}\left(\frac{n}{10}+\frac{10}{n}\right) = \lim_{n\to\infty}\frac{n}{10} + \lim_{n\to\infty} 10n.$$
Since $n/10$ gets arbitrarily large and $10/n$ approaches 0 as $n \to \infty$, the sequence diverges.

18. Since $\lim_{n\to\infty} x^n = 0$ if $|x| < 1$ and $\left|\frac{2}{3}\right| < 1$, we have $\lim_{n\to\infty}\left(\frac{2^n}{3^n}\right) = \lim_{n\to\infty}\left(\frac{2}{3}\right)^n = 0$, so the sequence converges to 0.

19. We have
$$\lim_{n\to\infty}\frac{2n+1}{n} = \lim_{n\to\infty}\left(2+\frac{1}{n}\right) = 2,$$
so the sequence converges to 2.

20. We have:
$$\lim_{n\to\infty}\left(\frac{1}{n}\right) = 0.$$
The terms of the sequence alternate in sign, but they approach 0, so the sequence converges to 0.

21. Since $1/n$ approaches zero and $\ln n$ becomes arbitrarily large as $n \to \infty$, the sequence diverges.

22. As n increases, the term $2n$ is much larger in magnitude than $(-1)^n 5$ and the term $4n$ is much larger in magnitude than $(-1)^n 3$. Thus dividing the numerator and denominator by n and using the fact that $\lim_{n\to\infty} 1/n = 0$, we have
$$\lim_{n\to\infty}\frac{2n+(-1)^n 5}{4n-(-1)^n 3} = \lim_{n\to\infty}\frac{2+(-1)^n 5/n}{4-(-1)^n 3/n} = \frac{1}{2}.$$
Thus, the sequence converges to $1/2$.

23. Since $\lim_{n\to\infty} 1/n = 0$ and $-1 \le \sin n \le 1$, the terms approach zero and the sequence converges to 0.

24. Since $s_n = \cos(\pi n) = 1$ if n is even and $s_n = \cos(\pi n) = -1$ if n is odd, the values of s_n alternate between 1 and -1, so the limit does not exist. Thus, the sequence diverges.

25. (a) matches (IV), since the sequence increases toward 1.
(b) matches (III), since the odd terms increase toward 1 and the even terms decrease toward 1.
(c) matches (II), since the sequence decreases toward 0.
(d) matches (I), since the sequence decreases toward 1.

26. (a) matches (II), since $\lim_{n\to\infty}(n(n+1)-1) = \infty$.
(b) matches (III), since $\lim_{n\to\infty}(1/(n+1)) = 0$ and $1/(n+1)$ is always positive.
(c) matches (I), since $\lim_{n\to\infty}(1-n^2) = -\infty$.
(d) matches (IV), since $\lim_{n\to\infty}\cos(1/n) = \cos 0 = 1$.
(e) matches (V), since $\sin n$ is bounded above and below by ± 1, so $\lim_{n\to\infty}((\sin n)/n) = 0$ and the sign of $\sin n$ varies as $n \to \infty$.

27. (a) matches (II), since the sequence increases toward 2.
(b) matches (III), since the even terms decrease toward 2 and odd terms decrease toward -2.
(c) matches (IV), since the even terms decrease toward 2 and odd terms increase toward 2.
(d) matches (I), since the sequence decreases toward 2.
(e) matches (V), since the even terms decrease toward 2 and odd terms increase toward -2.

28. We have $s_2 = 2s_1 + 3 = 2\cdot 1 + 3 = 5$ and $s_3 = 2s_2 + 3 = 2\cdot 5 + 3 = 13$. Continuing, we get
$$1, 5, 13, 29, 61, 125.$$

29. We have $s_2 = s_1 + 2 = 3$ and $s_3 = s_2 + 3 = 6$. Continuing, we get
$$1,\ 3,\ 6,\ 10,\ 15,\ 21.$$

30. We have $s_2 = s_1 + 1/2 = 0 + (1/2)^1 = 1/2$ and $s_3 = s_2 + (1/2)^2 = 1/2 + 1/4 = 3/4$. Continuing, we get

$$0,\ \frac{1}{2},\ \frac{3}{4},\ \frac{7}{8},\ \frac{15}{16},\ \frac{31}{32}.$$

31. We have $s_3 = s_2 + 2s_1 = 5 + 2 \cdot 1 = 7$ and $s_4 = s_3 + 2s_2 = 7 + 2 \cdot 5 = 17$. Continuing, we get

$$1,\ 5,\ 7,\ 17,\ 31,\ 65.$$

32. We have

$$\begin{aligned} a_2 &= a_{2-1} + 3 \cdot 2 = a_1 + 6 &&= 8 + 6 &&= 14 \\ a_3 &= a_{3-1} + 3 \cdot 3 = a_2 + 9 &&= 14 + 9 &&= 23 \\ a_4 &= a_{4-1} + 3 \cdot 4 = a_3 + 12 &&= 23 + 12 &&= 35. \end{aligned}$$

33. We have

$$\begin{aligned} a_2 &= a_{2-1} + 3 \cdot 2 = a_1 + 6 = 8 + 6 = 14 \\ a_3 &= a_{3-1} + 3 \cdot 3 = a_2 + 9 = 14 + 9 = 23 \\ a_4 &= a_{4-1} + 3 \cdot 4 = a_3 + 12 = 23 + 12 = 35 \end{aligned}$$

$$\begin{aligned} b_2 &= b_{2-1} + a_{2-1} = b_1 + a_1 = 5 + 8 = 13 \\ b_3 &= b_{3-1} + a_{3-1} = b_2 + a_2 = 13 + 14 = 27 \\ b_4 &= b_{4-1} + a_{4-1} = b_3 + a_3 = 27 + 23 = 50 \\ b_5 &= b_{5-1} + a_{5-1} = b_4 + a_4 = 50 + 35 = 85. \end{aligned}$$

34. We have:

$$\begin{aligned} s_1 & &&= 0 \\ s_2 & &&= 0 \\ s_3 & &&= 1 \\ s_4 &= s_3 + s_2 + s_1 = 1 + 0 + 0 &&= 1 \\ s_5 &= s_4 + s_3 + s_2 = 1 + 1 + 0 &&= 2 \\ s_6 &= s_5 + s_4 + s_3 = 2 + 1 + 1 &&= 4 \\ s_7 &= s_6 + s_5 + s_4 = 4 + 2 + 1 &&= 7 \\ s_8 &= s_7 + s_6 + s_5 = 7 + 4 + 2 &&= 13 \\ s_9 &= s_8 + s_7 + s_6 = 13 + 7 + 4 &&= 24 \\ s_{10} &= s_9 + s_8 + s_7 = 24 + 13 + 7 &&= 44. \end{aligned}$$

35. The first 6 terms of the sequence for the sampling is

$$(-0.5)^2,\ (0.0)^2,\ (0.5)^2,\ (1.0)^2,\ (1.5)^2,\ (2.0)^2,$$
$$= 0.25,\ 0.00,\ 0.25,\ 1.00,\ 2.25,\ 4.00.$$

36. The first 6 terms of the sequence for the sampling is

$$\cos 0.5,\ \cos 1.0,\ \cos 1.5,\ \cos 2.0,\ \cos 2.5,\ \cos 3.0$$
$$= 0.878,\ 0.540,\ 0.071,\ -0.416,\ -0.801,\ -0.990.$$

37. The first 6 terms of the sequence for the sampling are

$$\frac{\sin 1}{1},\ \frac{\sin 2}{2},\ \frac{\sin 3}{3},\ \frac{\sin 4}{4},\ \frac{\sin 5}{5},\ \frac{\sin 6}{6}$$
$$= 0.841,\ 0.455,\ 0.047,\ -0.189,\ -0.192,\ -0.047.$$

38. The first smoothing gives

$$0,\ 6,\ -6,\ 6,\ -6,\ 6, \ldots$$

The second smoothing gives

$$3,\ 0,\ 2,\ -2,\ 2, \ldots$$

The smoothing process diminishes the peaks and valleys of this alternating sequence.

39. The first smoothing gives

$$0,\ 0,\ 6,\ 6,\ 6,\ 0,\ 0 \ldots$$

The second smoothing gives

$$0,\ 2,\ 4,\ 6,\ 4,\ 2 \ldots$$

The smoothing process spreads out the spike at the fourth term to the neighboring terms.

40. The first smoothing gives

$$1.5,\ 2,\ 3,\ 4,\ 5,\ 6,\ 7 \ldots$$

The second smoothing gives

$$1.75,\ 2.17,\ 3,\ 4,\ 5,\ 6 \ldots$$

Terms which are already the same as their average with their neighbors are not changed.

41. Each term is 2 more than the previous term, so a recursive definition is $s_n = s_{n-1} + 2$ for $n > 1$ and $s_1 = 1$.

42. Each term is 2 more than the previous term, so a recursive definition is $s_n = s_{n-1} + 2$ for $n > 1$ and $s_1 = 2$. Notice that the even positive integers and odd positive integers have the same recursive definition except for the starting term.

43. Each term is twice the previous term minus one, so a recursive definition is $s_n = 2s_{n-1} - 1$ for $n > 1$ and $s_1 = 3$. We also notice that the differences of consecutive terms are powers of 2, so $s_2 = s_1 + 2$, $s_3 = s_2 + 2^2$, and so on. Thus another recursive definition is $s_n = s_{n-1} + 2^{n-1}$ for $n > 1$ and $s_1 = 3$.

44. The differences between consecutive terms are $4, 9, 16, 25$, so, for example, $s_2 = s_1 + 4$ and $s_3 = s_2 + 9$. Thus, a possible recursive definition is $s_n = s_{n-1} + n^2$ for $n > 1$ and $s_1 = 1$.

45. The differences are $2, 3, 4, 5$, so, for example, $s_2 = s_1 + 2$, $s_3 = s_2 + 3$, and $s_4 = s_3 + 4$. Thus, a recursive definition is $s_n = s_{n-1} + n$ for $n > 1$ and $s_1 = 1$.

46. The numerator and denominator of each term are related to the numerator and denominator of the previous term. The denominator is the previous numerator and the numerator is the sum of the previous numerator and previous denominator. For example,

$$\frac{5}{3} = \frac{2+3}{3} \text{ and } \frac{8}{5} = \frac{3+5}{5}.$$

If we simplify, we get

$$\frac{5}{3} = \frac{2}{3} + 1, \text{ and } \frac{8}{5} = \frac{3}{5} + 1.$$

In words, we turn the previous term upside down and add 1. Thus, a recursive definition is $s_n = \dfrac{1}{s_{n-1}} + 1$ for $n > 1$ and $s_1 = 1$.

47. For $n > 1$, if $s_n = 3n - 2$, then $s_{n-1} = 3(n-1) - 2 = 3n - 5$, so

$$s_n - s_{n-1} = (3n-2) - (3n-5) = 3,$$

giving

$$s_n = s_{n-1} + 3.$$

In addition, $s_1 = 3 \cdot 1 - 2 = 1$.

48. For $n > 1$, if $s_n = n(n+1)/2$, then $s_{n-1} = (n-1)(n-1+1)/2 = n(n-1)/2$. Since

$$s_n = \frac{1}{2}(n^2 + n) = \frac{n^2}{2} + \frac{n}{2} \quad \text{and} \quad s_{n-1} = \frac{1}{2}(n^2 - n) = \frac{n^2}{2} - \frac{n}{2},$$

we have

$$s_n - s_{n-1} = \frac{n}{2} + \frac{n}{2} = n,$$

so

$$s_n = s_{n-1} + n.$$

In addition, $s_1 = 1(2)/2 = 1$.

49. For $n > 1$, if $s_n = 2n^2 - n$, then $s_{n-1} = 2(n-1)^2 - (n-1) = 2n^2 - 5n + 3$, so

$$s_n - s_{n-1} = (2n^2 - n) - (2n^2 - 5n + 3) = 4n - 3,$$

giving

$$s_n = s_{n-1} + 4n - 3.$$

In addition, $s_1 = 2 \cdot 1^2 - 1 = 1$.

50. The sequence seems to converge. By the 25^{th} term it stabilizes to four decimal places at $L = 0.7391$.

51. The sequence oscillates up and down, but by the 20^{th} term it stabilizes to 4 decimal places at $L = 0.5671$.

52. The sequence appears to be decreasing toward 0, but at a slower and slower rate. Even after 100 terms, it is hard to guess what the series will eventually do. It can be shown that it converges to 0.

53. The sequence converges to 1. By the tenth term, it stabilizes to three decimal places at 1.000.

54. (a) Since month 10 is October, V_{10} is the number of SUVs sold in the US in October 2004.
(b) The difference $V_n - V_{n-1}$ represents the increase in sales between month $(n-1)$ and month n.
(c) The sum $\sum_{i=1}^{12} V_i$ represents the total sales of SUVs in the year 2004 (twelve months). The sum $\sum_{i=1}^{n} V_i$ represents the total sales in the n months starting from January 1, 2004.

55. (a) Since you have two parents and four grandparents, $s_1 = 2$ and $s_2 = 4$. In general, $s_n = 2^n$.
(b) Solving $s_n = 6 \cdot 10^9$ gives

$$\begin{aligned} 2^n &= 6 \cdot 10^9 \\ n &= \frac{\ln(6 \cdot 10^9)}{\ln 2} = 32.482. \end{aligned}$$

Thus, 33 or more generations ago, the number of ancestors is greater than the current population of the world. Since the population of the world 33 generations ago was much smaller than it is now, there must have been overlap among our ancestors.

56. In year 1, the payment is

$$p_1 = 10{,}000 + 0.05(100{,}000) = 15{,}000.$$

The balance in year 2 is $100{,}000 - 10{,}000 = 90{,}000$, so

$$p_2 = 10{,}000 + 0.05(90{,}000) = 14{,}500.$$

The balance in year 3 is 80,000, so

$$p_3 = 10{,}000 + 0.05(80{,}000) = 14{,}000.$$

Thus,

$$\begin{aligned} p_n &= 10{,}000 + 0.05(100{,}000 - (n-1) \cdot 10{,}000) \\ &= 15{,}500 - 500n. \end{aligned}$$

57. (a) The bottom row contains k cans, the next one contains $(k-1)$ cans, then $(k-2)$ and so on. Thus, there are k rows. Since the top row contains 1 can, the second contains 2 cans, etc, we have $a_n = n$.
(b) Since the n^{th} row contains n cans, $a_n = n$,

$$T_n = T_{n-1} + a_n$$

gives

$$T_n = T_{n-1} + n, \quad \text{for } n > 1.$$

In addition, $T_1 = 1$.
(c) If $T_n = \frac{1}{2}n(n+1)$, then $T_{n-1} = \frac{1}{2}(n-1)n$, so

$$T_n - T_{n-1} = \frac{1}{2}n(n+1) - \frac{1}{2}n(n-1) = \frac{n}{2}(n+1-(n-1)) = n.$$

In addition, $T_1 = \frac{1}{2} \cdot 1(2) = 1$.

58. (a) In the first year, $d_1 = 20{,}000(0.12)$, so the car's value at the end of the first year is \$$20{,}000(0.88)$. In the second year, $d_2 = 20{,}000(0.88)(0.12)$, so the car's value at the end of the second year is \$$20{,}000(0.88)^2$. Similarly, $d_3 = 20{,}000(0.88)^2(0.12)$. In general

$$d_n = 20{,}000(0.88)^{n-1}(0.12).$$

(b) The first year $r_1 = 400$; the second year $r_2 = 400(1.18)$, the third year $r_3 = 400(1.18)^2$. In general, $r_n = 400(1.18)^{n-1}$.

(c) We have

$$\begin{aligned}\text{Total cost} &= d_1 + d_2 + d_3 + r_1 + r_2 + r_3 \\ &= 20{,}000(0.12)(1 + 0.88 + (0.88)^2) + 400(1 + 1.18 + (1.18)^2) \\ &= 7799.52 \text{ dollars.}\end{aligned}$$

(d) A two-year old car has the same pattern of expenses except that the initial price is \$$20{,}000(0.88)^2$ instead of \$20,000 and that the repair costs start at \$$400(1.18)^2$ instead of \$400. Then

$$\begin{aligned}\text{Total cost} &= 20{,}000(0.88)^2(0.12)(1 + 0.88 + (0.88)^2) + 400(1.18)^2(1 + 1.18 + (1.18)^2) \\ &= 6923.05 \text{ dollars.}\end{aligned}$$

Thus, the two-year-old car costs you less and you should buy it.

59. (a) The first 12 terms are

$$1,\ 1,\ 2,\ 3,\ 5,\ 8,\ 13,\ 21,\ 34,\ 55,\ 89,\ 144.$$

(b) The sequence of ratios is

$$1,\ 2,\ \frac{3}{2},\ \frac{5}{3},\ \frac{8}{5},\ \frac{13}{8},\ \frac{21}{13},\ \frac{34}{21},\ \frac{55}{34},\ \frac{89}{55},\ldots.$$

To three decimal places, the first ten ratios are

$$1,\ 2,\ 1.500,\ 1.667,\ 1.600,\ 1.625,\ 1.615,\ 1.619,\ 1.618,\ 1.618.$$

It appears that the sequence of ratios is converging to $r = 1.618$. We find $(1.618)^2 = 2.618 = 1.618 + 1$ so r seems to satisfy $r^2 = r + 1$. Alternatively, by the quadratic formula, the positive root of $x^2 - x - 1 = 0$ is $(1 + \sqrt{5})/2 = 1.618$.

(c) If we multiply both sides of the equation $r^2 = r + 1$ by Ar^{n-2}, we obtain

$$Ar^n = Ar^{n-1} + Ar^{n-2}.$$

Thus, if $s_n = Ar^n$, then $s_{n-1} = Ar^{n-1}$ and $s_{n-2} = Ar^{n-2}$, so the sequence satisfies $s_n = s_{n-1} + s_{n-2}$.

60. (a) Since $25/8 = 3 + 1/8$, we have $f(25/8) = 3 + (1 - 1/8) = 3 + 7/8 = 31/8$.
Since $13/9 = 1 + 4/9$, we have $f(13/9) = 1 + (1 - 4/9) = 1 + 5/9 = 14/9$.
Since $\pi = 3 + (\pi - 3)$, we have $f(\pi) = 3 + (1 - (\pi - 3)) = 7 - \pi$.

(b) The terms are given by

$$\begin{aligned}s_1 &= 1 \\ s_2 &= \frac{1}{f(1)} = \frac{1}{1 + (1 - 0)} = \frac{1}{2} \\ s_3 &= \frac{1}{f(1/2)} = \frac{1}{0 + (1 - 1/2)} = 2 \\ s_4 &= \frac{1}{f(2)} = \frac{1}{2 + (1 - 0)} = \frac{1}{3} \\ s_5 &= \frac{1}{f(1/3)} = \frac{1}{0 + (1 - 1/3)} = \frac{3}{2} \\ s_6 &= \frac{1}{f(3/2)} = \frac{1}{1 + (1 - 1/2)} = \frac{2}{3}.\end{aligned}$$

The first six terms of the sequence are

$$1, \frac{1}{2}, 2, \frac{1}{3}, \frac{3}{2}, \frac{2}{3}.$$

61. We want to define $\lim_{n\to\infty} s_n = L$ so that s_n is as close to L as we please for all sufficiently large n. Thus, the definition says that for any positive ϵ, there is a value N such that

$$|s_n - L| < \epsilon \quad \text{whenever} \quad n \geq N.$$

62. We use Theorem 9.1, so we must show that s_n is bounded. Since t_n converges, it is bounded so there is a number M, such that $t_n \leq M$ for all n. Therefore $s_n \leq t_n \leq M$ for all n. Since s_n is increasing, $s_1 \leq s_n$ for all n. Thus if we let $K = s_1$, we have $K \leq s_n \leq M$ for all n, so s_n is bounded. Therefore, s_n converges.

Strengthen Your Understanding

63. A decreasing sequence does not have to converge to 0; in fact, it does not have to converge at all (consider the sequence $s_n = -n$, for example). In this case, the limit of the sequence is

$$\lim_{n\to\infty} \frac{3n+10}{7n+3} = \lim_{n\to\infty} \frac{3+10/n}{7+3/n} = \frac{3+0}{7+0} = \frac{3}{7}.$$

64. Even though each term of the sequence is greater than 2, the terms could be getting progressively closer to 2 and the limit could equal 2. For example, consider the sequence

$$s_n = 2 + \frac{1}{n}.$$

The limit of this sequence is

$$\lim_{n\to\infty} \left(2 + \frac{1}{n}\right) = 2 + 0 = 2.$$

Thus, the limit of the sequence could be 2.

65. Since we want our sequence to be increasing and converging to 0, all of the terms of the sequence must be negative. So we need to find a sequence whose terms are negative and approaching zero. An example is $s_n = -1/n$.

66. One example is the sequence $s_n = n$. This sequence is increasing and therefore monotone, but it does not converge because the terms do not get closer and closer to any specific finite value.

67. False. The first 1000 terms could be the same for two different sequences and yet one sequence converges and the other diverges. For example, $s_n = 0$ for all n is a convergent sequence, but

$$t_n = \begin{cases} 0 & \text{if } n \leq 1000 \\ n & \text{if } n > 1000 \end{cases}$$

is a divergent sequence.

68. False. The limit could be zero. For example, $s_n = 1/n$ is a convergent sequence of positive terms and $\lim_{n\to\infty} s_n = 0$.

69. True. If there is no term greater than a million, then the sequence is bounded by $0 < s_n < 10^6$ for all n.

70. True. If there is only a finite number of terms greater than a million, then we can choose the largest of them to be an upper bound M for the sequence. Thus the sequence is bounded by $0 < s_n \leq M$ for all n.

71. False. The terms s_n tend to the limit of the sequence which may not be zero. For example, $s_n = 1 + 1/n$ is a convergent sequence and s_n tends to 1 as n increases.

72. False. For example the sequence $-2, -1, 0, 1, 2, 3, \ldots$ with $s_n = n - 3$ is monotone increasing and has both positive and negative terms.

73. True. If a monotone sequence does not converge, then it is unbounded. If moreover the sequence contains only positive terms then it is bounded below by zero. Thus it is not bounded above, and in particular it is not bounded above by a million.

74. False. The decreasing sequence $-1, -2, -3, \ldots$ has all terms less than a million, but it has no lower bound. Thus it is unbounded.

75. (b). Sequence (I) is monotone increasing, bounded between 9 and 10.

Sequence (II) is monotone decreasing and bounded between 10 and 11.

Sequence (III) is bounded between -1 and 1 but it is not monotone because it begins $0.54, -0.42, -0.99, -0.65, \ldots$, which contains both a jump down, from 0.54 to -0.42 and a jump up, from -0.99 to -0.65. Terms in a monotone sequence always jump in the same direction.

Sequence (IV) is monotone increasing but is not bounded.

Solutions for Section 9.2

Exercises

1. Sequence, because the terms are not added together.
2. Series, because the terms are added together.
3. Sequence, because the terms are not added together.
4. Sequence, because the terms are not added together.
5. Series, because the terms are added together.
6. Series, because the terms are added together.
7. Series, because the terms are added together.
8. Yes, $a = 5$, ratio $= -2$.
9. No. Ratio between successive terms is not constant: $\dfrac{1/3}{1/2} = 0.66\ldots$, while $\dfrac{1/4}{1/3} = 0.75$.
10. Yes, $a = 2$, ratio $= 1/2$.
11. Yes, $a = 1$, ratio $= -1/2$.
12. No. Ratio between successive terms is not constant: $\dfrac{2x^2}{x} = 2x$, while $\dfrac{3x^3}{2x^2} = \dfrac{3}{2}x$.
13. Yes, $a = 1$, ratio $= 2z$.
14. No. Ratio between successive terms is not constant: $\dfrac{6z^2}{3z} = 2z$, while $\dfrac{9z^3}{6z^2} = \dfrac{3}{2}z$.
15. Yes, $a = 1$, ratio $= -x$.
16. Yes, $a = 1$, ratio $= -y^2$.
17. Yes, $a = y^2$, ratio $= y$.
18. No. Ratio between successive terms is not constant: $\dfrac{-z^4}{z^2} = -z^2$, while $\dfrac{z^8}{-z^4} = -z^4$.
19. The series has 26 terms. The first term is $a = 2$ and the constant ratio is $x = 0.1$, so

$$\text{Sum } = \frac{a(1-x^{26})}{(1-x)} = \frac{2(1-(0.1)^{26})}{0.9} = 2.222.$$

20. The series has 10 terms. The first term is $a = 0.2$ and the constant ratio is $x = 0.1$, so

$$\text{Sum } = \frac{0.2(1-x^{10})}{(1-x)} = \frac{0.2(1-(0.1)^{10})}{0.9} = 0.222.$$

21. The series has 9 terms. The first term is $a = 0.00002$ and the constant ratio is $x = 0.1$, so

$$\text{Sum } = \frac{0.00002(1-x^{9})}{(1-x)} = \frac{0.00002(1-(0.1)^{9})}{0.9} = 0.0000222.$$

22. The series has 14 terms. The first term is $a = 8$ and the constant ratio is $x = 1/2 = 0.5$, so

$$\text{Sum } = \frac{8(1-x^{14})}{(1-x)} = \frac{8(1-(0.5)^{14})}{0.5} = 15.999$$

23. We have

$$\begin{aligned}\text{Sum} &= 36 + 12 + 4 + \frac{4}{3} + \frac{4}{9} + \cdots \\ &= 36 + 36\cdot\frac{1}{3} + 36\left(\frac{1}{3}\right)^2 + 36\left(\frac{1}{3}\right)^3 + \cdots \\ &= \frac{36}{1-1/3} = 54.\end{aligned}$$

24. We have

$$\begin{aligned}\text{Sum} &= -810 + 540 - 360 + 240 - 160 + \cdots \\ &= -810 + (-810)\cdot\left(-\frac{2}{3}\right) + (-810)\cdot\left(-\frac{2}{3}\right)^2 + (-810)\cdot\left(-\frac{2}{3}\right)^3 + \cdots \\ &= \frac{-810}{1-(-2/3)} = -486.\end{aligned}$$

25. We have

$$\begin{aligned}\text{Sum} &= 80 + \frac{80}{\sqrt{2}} + 40 + \frac{40}{\sqrt{2}} + 20 + \frac{20}{\sqrt{2}} + \cdots \\ &= 80 + 80\left(\frac{1}{\sqrt{2}}\right) + 80\left(\frac{1}{\sqrt{2}}\right)^2 + +80\left(\frac{1}{\sqrt{2}}\right)^3 + \cdots \\ &= \frac{80}{1-1/\sqrt{2}} = 273.137.\end{aligned}$$

26. This is a geometric series with first term 1 and ratio $z/2$:

$$1 + \frac{z}{2} + \frac{z^2}{4} + \frac{z^3}{8} + \cdots = 1 + \frac{z}{2} + \left(\frac{z}{2}\right)^2 + \left(\frac{z}{2}\right)^3 + \cdots = \frac{1}{1-(z/2)}.$$

This series converges for $|z/2| < 1$, that is for $-2 < z < 2$.

27. This is a geometric series with first term 1 and ratio $3x$:

$$1 + 3x + 9x^2 + 27x^3 + \cdots = 1 + (3x) + (3x)^2 + (3x)^3 + \cdots = \frac{1}{1-(3x)}.$$

This series converges for $|3x| < 1$, that is for $-1/3 < x < 1/3$.

28. This is a geometric series with first term y and ratio $-y$:

$$y - y^2 + y^3 - y^4 + \cdots = \frac{y}{1-(-y)} = \frac{y}{1+y}.$$

This series converges for $|-y| < 1$, that is for $-1 < y < 1$.

29. This is a geometric series with first term 2 and ratio $-2z$,

$$2 - 4z + 8z^2 - 16z^3 + \cdots = \frac{2}{1-(-2z)} = \frac{2}{1+2z}.$$

This series converges for $|-2z| < 1$, that is for $-1/2 < z < 1/2$.

30. We can rewrite the series as $3 + (x + x^2 + x^3 + \cdots)$. The terms after the first term define a geometric series with first term x and ratio x. Therefore, we have

$$3 + x + x^2 + x^3 + \cdots = 3 + (x + x^2 + x^3 + \cdots) = 3 + \frac{x}{1-x}.$$

This series converges for $|x| < 1$, that is for $-1 < x < 1$.

31. We can rewrite the series as $4 + (y + y^2/3 + y^3/9 + \cdots)$. The terms after the first term define a geometric series with first term y and ratio $y/3$. Therefore, we have

$$4 + y + y^2/3 + y^3/9 + \cdots = 4 + (y + y^2/3 + y^3/9 + \cdots) = 4 + \frac{y}{1-(y/3)}.$$

This series converges for $|y/3| < 1$, that is for $-3 < y < 3$.

Problems

32. Since the amount of ampicillin excreted during the time interval between tablets is 250 mg, we have

$$\begin{aligned}\text{Amount of ampicillin excreted} &= \text{Original quantity} - \text{Final quantity} \\ 250 &= Q - (0.04)Q.\end{aligned}$$

Solving for Q gives, as before,

$$Q = \frac{250}{1-0.04} \approx 260.42.$$

33. (a)

$$\begin{aligned}P_1 &= 0\\ P_2 &= 250(0.04)\\ P_3 &= 250(0.04) + 250(0.04)^2\\ P_4 &= 250(0.04) + 250(0.04)^2 + 250(0.04)^3\\ &\vdots\\ P_n &= 250(0.04) + 250(0.04)^2 + 250(0.04)^3 + \cdots + 250(0.04)^{n-1}\end{aligned}$$

(b) $P_n = 250(0.04)\left(1 + (0.04) + (0.04)^2 + (0.04)^3 + \cdots + (0.04)^{n-2}\right) = 250\dfrac{0.04(1-(0.04)^{n-1})}{1-0.04}$

(c)

$$\begin{aligned}P &= \lim_{n\to\infty} P_n\\ &= \lim_{n\to\infty} 250\frac{0.04(1-(0.04)^{n-1})}{1-0.04}\\ &= \frac{(250)(0.04)}{0.96} = 0.04Q \approx 10.42\end{aligned}$$

Thus, $\lim_{n\to\infty} P_n = 10.42$ and $\lim_{n\to\infty} Q_n = 260.42$. We would expect these limits to differ because one is right before taking a tablet, one is right after. We would expect the difference between them to be 250 mg, the amount of ampicillin in one tablet.

34. (a) The quantity of atenolol in the blood is given by $Q(t) = Q_0e^{-kt}$, where $Q_0 = Q(0)$ and k is a constant. Since the half-life is 6.3 hours,

$$\frac{1}{2} = e^{-6.3k}, \quad k = -\frac{1}{6.3}\ln\frac{1}{2} \approx 0.11.$$

After 24 hours

$$Q = Q_0e^{-k(24)} \approx Q_0e^{-0.11(24)} \approx Q_0(0.07).$$

Thus, the percentage of the atenolol that remains after 24 hours $\approx 7\%$.

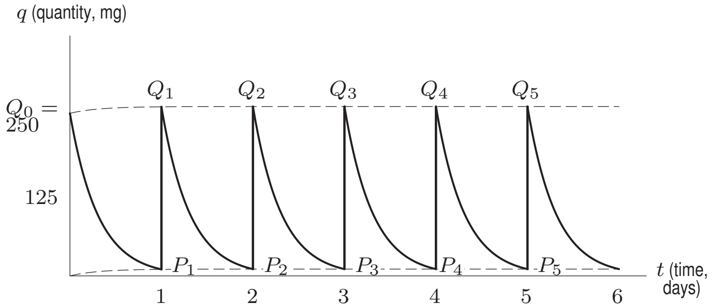
(b)

$$\begin{aligned}Q_0 &= 50\\ Q_1 &= 50 + 50(0.07)\\ Q_2 &= 50 + 50(0.07) + 50(0.07)^2\\ Q_3 &= 50 + 50(0.07) + 50(0.07)^2 + 50(0.07)^3\\ &\vdots\\ Q_n &= 50 + 50(0.07) + 50(0.07)^2 + \cdots + 50(0.07)^n = \frac{50(1-(0.07)^{n+1})}{1-0.07}\end{aligned}$$

(c)

$$\begin{aligned}P_1 &= 50(0.07)\\ P_2 &= 50(0.07) + 50(0.07)^2\\ P_3 &= 50(0.07) + 50(0.07)^2 + 50(0.07)^3\\ P_4 &= 50(0.07) + 50(0.07)^2 + 50(0.07)^3 + 50(0.07)^4\\ &\vdots\\ P_n &= 50(0.07) + 50(0.07)^2 + 50(0.07)^3 + \cdots + 50(0.07)^n\\ &= 50(0.07)\left(1 + (0.07) + (0.07)^2 + \cdots + (0.07)^{n-1}\right) = \frac{0.07(50)(1-(0.07)^n)}{1-0.07}\end{aligned}$$

35.



36. Let n be the number of days elapsed. As $n \to \infty$, the amount of pollutants right after a dump is given by the sum of an infinite geometric series:

$$B = 8 + 8(0.75) + 8(0.75)^2 + 8(0.75)^3 + \cdots = \frac{8}{1 - 0.75} = 32.$$

Thus, the level of pollutants in the bay approaches 32 tons over time.

37. (a) In the first year, consumption is 25 million tons. In the second year this grows to $25(1.01)$ million tons, and in subsequent years the consumption grows by a factor of 1.01. During the next n years

$$\text{Total consumption} = 25 + 25(1.01) + 25(1.01)^2 + \cdots 25(1.01)^{n-1}\text{million tons.}$$

This is a geometric series with $a = 25$ and $x = 1.01$, thus we have

$$\text{Total consumption} = 25\left(\frac{1.01^n - 1}{1.01 - 1}\right).$$

The reserves are exhausted when the total consumption reaches 400 so we find n by solving the equation

$$25\left(\frac{1.01^n - 1}{1.01 - 1}\right) = 400.$$

Simplifying, gives

$$\frac{1.01^n - 1}{0.01} = 16$$

so

$$1.01^n - 1 = 0.16$$

and

$$1.01^n = 1.16.$$

Taking natural logs of both sides gives

$$\ln 1.01^n = \ln 1.16$$

so

$$n \ln 1.01 = \ln 1.16$$

and

$$n = \frac{\ln 1.16}{\ln 1.01} = 14.916.$$

The reserves are exhausted after 15 years.

(b) If an $r\%$ annual reduction is imposed then

$$\text{Total consumption} = 25 + 25\left(1 - \frac{r}{100}\right) + 25\left(1 - \frac{r}{100}\right)^2 + \cdots \text{million tons.}$$

This is an infinite geometric series with $a = 25$ and $x = 1 - r/100$, thus we have

$$\begin{aligned}\text{Total consumption} &= 25\frac{1}{1 - (1 - r/100)} \\ &= \frac{2500}{r}.\end{aligned}$$

For existing reserves never to be exhausted, we need $2500/r < 400$, which gives $r > 6.25\%$. Consumption must be reduced by at least 6.25% annually.

38.

$$\begin{aligned}\text{Total present value, in dollars} &= 1000 + 1000e^{-0.01} + 1000e^{-0.01(2)} + 1000e^{-0.01(3)} + \cdots \\ &= 1000 + 1000(e^{-0.01}) + 1000(e^{-0.01})^2 + 1000(e^{-0.01})^3 + \cdots\end{aligned}$$

This is an infinite geometric series with $a = 1000$ and $x = e^{(-0.01)}$, and sum

$$\text{Total present value, in dollars} = \frac{1000}{1 - e^{-0.01}} = 100{,}500.833.$$

39. (a) (i) On the night of December 31, 1999:

First deposit will have grown to $2(1.04)^7$ million dollars.
Second deposit will have grown to $2(1.04)^6$ million dollars.
...
Most recent deposit (Jan.1, 1999) will have grown to $2(1.04)$ million dollars.

Thus

$$\begin{aligned}\text{Total amount} &= 2(1.04)^7 + 2(1.04)^6 + \cdots + 2(1.04) \\ &= 2(1.04)\underbrace{(1 + 1.04 + \cdots + (1.04)^6)}_{\text{finite geometric series}} \\ &= 2(1.04)\left(\frac{1-(1.04)^7}{1-1.04}\right) \\ &= 16.43 \text{ million dollars.}\end{aligned}$$

(ii) Notice that if 10 payments were made, there are 9 years between the first and the last. On the day of the last payment:

First deposit will have grown to $2(1.04)^9$ million dollars.
Second deposit will have grown to $2(1.04)^8$ million dollars.
...
Last deposit will be 2 million dollars.

Therefore

$$\begin{aligned}\text{Total amount} &= 2(1.04)^9 + 2(1.04)^8 + \cdots + 2 \\ &= 2\underbrace{(1 + 1.04 + (1.04)^2 + \cdots + (1.04)^9)}_{\text{finite geometric series}} \\ &= 2\left(\frac{1-(1.04)^{10}}{1-1.04}\right) \\ &= 24.01 \text{ million dollars.}\end{aligned}$$

(b) In part (a) (ii) we found the future value of the contract 9 years in the future. Thus

$$\text{Present Value} = \frac{24.01}{(1.04)^9} = 16.87 \text{ million dollars.}$$

Alternatively, we can calculate the present value of each of the payments separately:

$$\begin{aligned}\text{Present Value} &= 2 + \frac{2}{1.04} + \frac{2}{(1.04)^2} + \cdots + \frac{2}{(1.04)^9} \\ &= 2\left(\frac{1-(1/1.04)^{10}}{1-1/1.04}\right) = 16.87 \text{ million dollars.}\end{aligned}$$

Notice that the present value of the contract (\$16.87 million) is considerably less than the face value of the contract, \$20 million.

40. The first \$200 is invested for 24 months so it has a future value of $\$200(1+0.5/100)^{24} = \$200 \cdot 1.005^{24}$. The second installment has a future value of $\$\ 200 \cdot 1.005^{23}$, since it is invested for only 23 months. The final installment, paid after 23 months, has a future value of $\$\ 200 \cdot 1.005$. So,

$$\begin{aligned}\text{Total investment} &= 200 \cdot 1.005^{24} + 200 \cdot 1.005^{23} + \ldots + 200 \cdot 1.005 \\ &= 200 \cdot 1.005\left(1.005^{23} + 1.005^{22} + \ldots + 1\right) \\ &= 200 \cdot 1.005\left(\frac{1-1.005^{24}}{1-1.005}\right) \\ &= 200 \cdot 1.005 \cdot 25.432 \\ &= \$5111.82.\end{aligned}$$

41. To get \$20,000 the day he retires he needs to invest a present value P such that $P(1+5/100)^{20} = \$20{,}000$. Solving for P gives the present value $P = \$20{,}000 \cdot 1.05^{-20}$. To fund the second payment he needs to invest $\$\ 20{,}000 \cdot 1.05^{-21}$, and so on. To fund the payment 10 years after his retirement he needs to invest $\$\ 20{,}000 \cdot 1.05^{-30}$. There are 11 payments in all, so

$$\begin{aligned}\text{Total investment} &= 20{,}000 \cdot 1.05^{-20} + 20{,}000 \cdot 1.05^{-21} + \ldots + 20{,}000 \cdot 1.05^{-30} \\ &= 20{,}000 \cdot 1.05^{-20}\left(1 + 1.05^{-1} + \ldots + 1.05^{-10}\right) \\ &= 20{,}000 \cdot 1.05^{-20}\left(\frac{1-1.05^{-11}}{1-1.05^{-1}}\right) \\ &= 20{,}000 \cdot 1.05^{-20} \cdot 8.7217 \\ &= \$65{,}742.60.\end{aligned}$$

42. If the half-life is T hours, then the exponential decay formula $Q = Q_0e^{-kt}$ gives $k = \ln 2/T$. If we start with $Q_0 = 1$ tablet, then the amount of drug present in the body after $5T$ hours is

$$Q = e^{-5kT} = e^{-5\ln 2} = 0.03125,$$

so 3.125% of a tablet remains. Thus, immediately after taking the first tablet, there is one tablet in the body. Five half-lives later, this has reduced to $1 \cdot 0.03125 = 0.03125$ tablets, and immediately after the second tablet there are $1 + 0.03125$ tablets in the body. Continuing this forever leads to

$$\text{Number of tablets in body } = 1 + 0.03125 + (0.03125)^2 + \cdots + (0.03125)^n + \cdots.$$

This is an infinite geometric series, with common ratio $x = 0.03125$, and sum $1/(1-x)$. Thus

$$\text{Number of tablets in body } = \frac{1}{1-0.03125} = 1.0323.$$

43. The amount of additional income generated directly by people spending their extra money is $\$100(0.8) = \$80$ million. This additional money in turn is spent, generating another $(\$100(0.8))\,(0.8) = \$100(0.8)^2$ million. This continues indefinitely, resulting in

$$\text{Total additional income} = 100(0.8) + 100(0.8)^2 + 100(0.8)^3 + \cdots = \frac{100(0.8)}{1-0.8} = \$400 \text{ million}$$

44. (a)

$$\begin{aligned}\text{Present value of first coupon } &= \frac{50}{1.05} \\ \text{Present value of second coupon } &= \frac{50}{(1.05)^2}, \text{ etc.}\end{aligned}$$

$$\begin{aligned}\text{Total present value} &= \underbrace{\frac{50}{1.05} + \frac{50}{(1.05)^2} + \cdots + \frac{50}{(1.05)^{10}}}_{\text{coupons}} + \underbrace{\frac{1000}{(1.05)^{10}}}_{\text{principal}} \\ &= \frac{50}{1.05}\left(1 + \frac{1}{1.05} + \cdots + \frac{1}{(1.05)^9}\right) + \frac{1000}{(1.05)^{10}} \\ &= \frac{50}{1.05}\left(\frac{1-\left(\frac{1}{1.05}\right)^{10}}{1-\frac{1}{1.05}}\right) + \frac{1000}{(1.05)^{10}} \\ &= 386.087 + 613.913 \\ &= \$1000\end{aligned}$$

(b) When the interest rate is 5%, the present value equals the principal.
(c) When the interest rate is more than 5%, the present value is smaller than it is when interest is 5% and must therefore be less than the principal. Since the bond will sell for around its present value, it will sell for less than the principal; hence the description *trading at discount*.
(d) When the interest rate is less than 5%, the present value is more than the principal. Hence the bond will be selling for more than the principal, and is described as *trading at a premium*.

45. The total of the spending and respending of the additional income is given by the series: Total additional income $= 100(0.9) + 100(0.9)^2 + 100(0.9)^3 + \cdots = \frac{100(0.9)}{1-0.9} = \$900$ million.
Notice the large effect of changing the assumption about the fraction of money spent has: the additional spending more than doubles.

46. (a) Let h_n be the height of the n^{th} bounce after the ball hits the floor for the n^{th} time. Then from Figure 9.1,

$$\begin{aligned} h_0 &= \text{height before first bounce } = 10 \text{ feet}, \\ h_1 &= \text{height after first bounce } = 10\left(\frac{3}{4}\right) \text{ feet}, \\ h_2 &= \text{height after second bounce } = 10\left(\frac{3}{4}\right)^2 \text{ feet}. \end{aligned}$$

Generalizing gives

$$h_n = 10\left(\frac{3}{4}\right)^n.$$

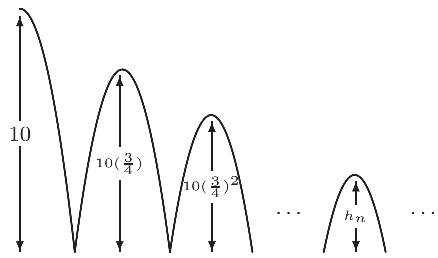


Figure 9.1

(b) When the ball hits the floor for the first time, the total distance it has traveled is just $D_1 = 10$ feet. (Notice that this is the same as $h_0 = 10$.) Then the ball bounces back to a height of $h_1 = 10\left(\frac{3}{4}\right)$, comes down and hits the floor for the second time. See Figure 9.1. The total distance it has traveled is

$$D_2 = h_0 + 2h_1 = 10 + 2\cdot 10\left(\frac{3}{4}\right) = 25 \text{ feet}.$$

Then the ball bounces back to a height of $h_2 = 10\left(\frac{3}{4}\right)^2$, comes down and hits the floor for the third time. It has traveled

$$D_3 = h_0 + 2h_1 + 2h_2 = 10 + 2\cdot 10\left(\frac{3}{4}\right) + 2\cdot 10\left(\frac{3}{4}\right)^2 = 25 + 2\cdot 10\left(\frac{3}{4}\right)^2 = 36.25 \text{ feet}.$$

Similarly,

$$\begin{aligned} D_4 &= h_0 + 2h_1 + 2h_2 + 2h_3 \\ &= 10 + 2\cdot 10\left(\frac{3}{4}\right) + 2\cdot 10\left(\frac{3}{4}\right)^2 + 2\cdot 10\left(\frac{3}{4}\right)^3 \\ &= 36.25 + 2\cdot 10\left(\frac{3}{4}\right)^3 \\ &\approx 44.69 \text{ feet.} \end{aligned}$$

(c) When the ball hits the floor for the n^{th} time, its last bounce was of height h_{n-1}. Thus, by the method used in part (b), we get

$$\begin{aligned} D_n &= h_0 + 2h_1 + 2h_2 + 2h_3 + \cdots + 2h_{n-1} \\ &= 10 + \underbrace{2\cdot 10\left(\frac{3}{4}\right) + 2\cdot 10\left(\frac{3}{4}\right)^2 + 2\cdot 10\left(\frac{3}{4}\right)^3 + \cdots + 2\cdot 10\left(\frac{3}{4}\right)^{n-1}}_{\text{finite geometric series}} \\ &= 10 + 2\cdot 10\cdot\left(\frac{3}{4}\right)\left(1 + \left(\frac{3}{4}\right) + \left(\frac{3}{4}\right)^2 + \cdots + \left(\frac{3}{4}\right)^{n-2}\right) \\ &= 10 + 15\left(\frac{1-\left(\frac{3}{4}\right)^{n-1}}{1-\left(\frac{3}{4}\right)}\right) \\ &= 10 + 60\left(1-\left(\frac{3}{4}\right)^{n-1}\right). \end{aligned}$$

47. (a) The acceleration of gravity is 32 ft/sec^2 so acceleration $= 32$ and velocity $v = 32t + C$. Since the ball is dropped, its initial velocity is 0 so $v = 32t$. Thus the position is $s = 16t^2 + C$. Calling the initial position $s = 0$, we have $s = 6t$. The distance traveled is h so $h = 16t$. Solving for t we get $t = \frac{1}{4}\sqrt{h}$.

(b) The first drop from 10 feet takes $\frac{1}{4}\sqrt{10}$ seconds. The first full bounce (to $10\cdot(\frac{3}{4})$ feet) takes $\frac{1}{4}\sqrt{10\cdot(\frac{3}{4})}$ seconds to rise, therefore the same time to come down. Thus, the full bounce, up and down, takes $2(\frac{1}{4})\sqrt{10\cdot(\frac{3}{4})}$ seconds. The next full bounce takes $2(\frac{1}{4})10\cdot(\frac{3}{4})^2 = 2(\frac{1}{4})\sqrt{10}\left(\sqrt{\frac{3}{4}}\right)^2$ seconds. The n^{th} bounce takes $2(\frac{1}{4})\sqrt{10}\left(\sqrt{\frac{3}{4}}\right)^n$ seconds. Therefore the

$$\begin{aligned} &\text{Total amount of time} \\ &= \frac{1}{4}\sqrt{10} + \underbrace{\frac{2}{4}\sqrt{10}\sqrt{\frac{3}{4}} + \frac{2}{4}\sqrt{10}\left(\sqrt{\frac{3}{4}}\right)^2 + \frac{2}{4}\sqrt{10}\left(\sqrt{\frac{3}{4}}\right)^3}_{\text{Geometric series with } a = \frac{2}{4}\sqrt{10}\sqrt{\frac{3}{4}} = \frac{1}{2}\sqrt{10}\sqrt{\frac{3}{4}} \text{ and } x = \sqrt{\frac{3}{4}}} + \cdots \\ &= \frac{1}{4}\sqrt{10} + \frac{1}{2}\sqrt{10}\sqrt{\frac{3}{4}}\left(\frac{1}{1-\sqrt{3/4}}\right) \text{ seconds.} \end{aligned}$$

Strengthen Your Understanding

48. The formula $4/(1-1/4)$ used is for computing the sum of a geometric series, not the limit of a sequence. The sequence is given by the formula

$$s_n = 4\left(\frac{1}{4}\right)^{n-1}, \quad n \geq 1,$$

so since $(1/4)$ is between 0 and 1, the sequence converges to 0.

49. The formula for the sum of an infinite geometric series does not apply because the common ratio is not between -1 and 1.

50. If the common ratio, x, of a geometric series satisfies $|x| \geq 1$ then the series diverges. If $x = 3$ then the series $3 + 6 + 12 + 24 + \cdots$ diverges.

51. Two possible examples are the series $1+1+1+1+\ldots$, which has common ratio 1, and the series $1+(-1)+1+(-1)+\ldots$, which has common ratio -1.

52. One way to find an example is to start with a geometric series with four distinct terms, and then rescale the terms so that their sum is 10.

For example, we might start with the series

$$1+\frac{1}{2}+\frac{1}{4}+\frac{1}{8},$$

whose sum is $15/8$. Since we want a sum of 10, we scale these terms up by a factor of

$$\frac{10}{15/8}=\frac{16}{3}.$$

This gives the series

$$\frac{16}{3}+\frac{8}{3}+\frac{4}{3}+\frac{2}{3}=10.$$

This series is geometric with common ratio $1/2$.

53. We know that $\sum_{n=0}^{\infty} ax^n = \frac{a}{1-x}$ for $|x|<1$. Letting $x=1/2$ we have $\frac{a}{1-1/2}=2a$. Thus $a=5$ gives a limit of 10 for the geometric series.

54. (c). The common ratio in series (I) and (IV) is between -1 and 1. The common ratio in (II) and (III) is greater than one.

Solutions for Section 9.3

Exercises

1. The series is $1+2+3+4+5+\cdots$. The sequence of partial sums is

$$S_1=1,\quad S_2=1+2,\quad S_3=1+2+3,\quad S_4=1+2+3+4,\quad S_5=1+2+3+4+5,\ldots$$

which is

$$1,\quad 3,\quad 6,\quad 10,\quad 15\ldots.$$

2. The series is $-1+1/2-1/3+1/4-1/5+\cdots$. The sequence of partial sums is

$$S_1=-1,\quad S_2=-1+\frac{1}{2},\quad S_3=-1+\frac{1}{2}-\frac{1}{3},\quad S_4=-1+\frac{1}{2}-\frac{1}{3}+\frac{1}{4},\quad S_5=-1+\frac{1}{2}-\frac{1}{3}+\frac{1}{4}-\frac{1}{5},\ldots$$

which is

$$-1,\quad -\frac{1}{2},\quad -\frac{5}{6},\quad -\frac{7}{12},\quad -\frac{47}{60},\ldots.$$

3. The series is $1/2+1/6+1/12+1/20+1/30+\cdots$. The sequence of partial sums is

$$S_1=\frac{1}{2},\quad S_2=\frac{1}{2}+\frac{1}{6},\quad S_3=\frac{1}{2}+\frac{1}{6}+\frac{1}{12},\quad S_4=\frac{1}{2}+\frac{1}{6}+\frac{1}{12}+\frac{1}{20},\quad S_5=\frac{1}{2}+\frac{1}{6}+\frac{1}{12}+\frac{1}{20}+\frac{1}{30},\ldots$$

which is

$$\frac{1}{2},\quad \frac{2}{3},\quad \frac{3}{4},\quad \frac{4}{5},\quad \frac{5}{6}.$$

4. We use the integral test to determine whether this series converges or diverges. To do so we determine whether the corresponding improper integral $\int_1^\infty \frac{1}{(x+2)^2}\,dx$ converges or diverges:

$$\begin{aligned}\int_1^\infty \frac{1}{(x+2)^2}\,dx &= \lim_{b\to\infty}\int_1^b \frac{1}{(x+2)^2}\,dx \\ &= \lim_{b\to\infty}\int_3^b \frac{1}{w^2}\,dw \qquad \text{(Substitute } w = x+2\text{)} \\ &= \lim_{b\to\infty} -\frac{1}{w}\bigg|_3^b \\ &= \lim_{b\to\infty}\left(-\frac{1}{b}+\frac{1}{3}\right) = \frac{1}{3}.\end{aligned}$$

Since the integral $\int_1^\infty \frac{1}{(x+2)^2}\,dx$ converges, we conclude from the integral test that the series $\sum_{n=1}^\infty \frac{1}{(n+2)^2}$ converges.

5. We use the integral test with $f(x) = x/(x^2+1)$ to determine whether this series converges or diverges. We determine whether the corresponding improper integral $\int_1^\infty \frac{x}{x^2+1}dx$ converges or diverges:

$$\int_1^\infty \frac{x}{x^2+1}dx = \lim_{b\to\infty}\int_1^b \frac{x}{x^2+1}dx = \lim_{b\to\infty}\frac{1}{2}\ln(x^2+1)\bigg|_1^b = \lim_{b\to\infty}\left(\frac{1}{2}\ln(b^2+1) - \frac{1}{2}\ln 2\right) = \infty.$$

Since the integral $\int_1^\infty \frac{x}{x^2+1}dx$ diverges, we conclude from the integral test that the series $\sum_{n=1}^\infty \frac{n}{n^2+1}$ diverges.

6. We use the integral test with $f(x) = 1/e^x$ to determine whether this series converges or diverges. To do so we determine whether the corresponding improper integral $\int_1^\infty \frac{1}{e^x}dx$ converges or diverges:

$$\int_1^\infty \frac{1}{e^x}dx = \lim_{b\to\infty}\int_1^b e^{-x}dx = \lim_{b\to\infty} -e^{-x}\bigg|_1^b = \lim_{b\to\infty}\left(-e^{-b}+e^{-1}\right) = e^{-1}.$$

Since the integral $\int_1^\infty \frac{1}{e^x}dx$ converges, we conclude from the integral test that the series $\sum_{n=1}^\infty \frac{1}{e^n}$ converges. We can also observe that this is a geometric series with ratio $x = 1/e < 1$, and hence it converges.

7. We use the integral test with $f(x) = 1/(x(\ln x)^2)$ to determine whether this series converges or diverges. We determine whether the corresponding improper integral $\int_2^\infty \frac{1}{x(\ln x)^2}dx$ converges or diverges:

$$\int_2^\infty \frac{1}{x(\ln x)^2}dx = \lim_{b\to\infty}\int_2^b \frac{1}{x(\ln x)^2}dx = \lim_{b\to\infty}\frac{-1}{\ln x}\bigg|_2^b = \lim_{b\to\infty}\left(\frac{-1}{\ln b}+\frac{1}{\ln 2}\right) = \frac{1}{\ln 2}.$$

Since the integral $\int_2^\infty \frac{1}{x(\ln x)^2}dx$ converges, we conclude from the integral test that the series $\sum_{n=2}^\infty \frac{1}{n(\ln n)^2}$ converges.

8. The improper integral $\int_1^\infty x^{-3}\,dx$ converges to $\frac{1}{2}$, since

$$\int_1^b x^{-3}\,dx = \frac{x^{-2}}{-2}\bigg|_1^b = \frac{b^{-2}}{-2} - \frac{1^{-2}}{-2} = \frac{1}{-2b^2}+\frac{1}{2}$$

and

$$\lim_{b\to\infty}\left(\frac{1}{-2b^2}+\frac{1}{2}\right) = \frac{1}{2}.$$

The terms of the series $\sum_{n=2}^{\infty} n^{-3}$ form a right hand sum for the improper integral; each term represents the area of a rectangle of width 1 fitting completely under the graph of the function x^{-3}. (See Figure 9.2.) Thus the sequence of partial sums is bounded above by $1/2$. Since the partial sums are increasing (every new term added is positive) the series is guaranteed to converge to some number less than or equal to $1/2$ by Theorem 9.1.

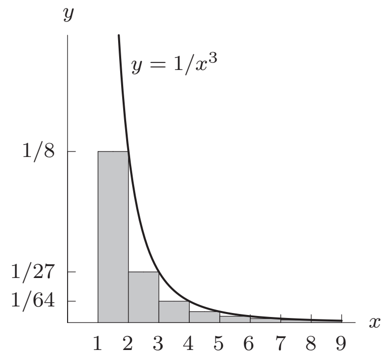

Figure 9.2

9. The improper integral $\int_0^\infty \frac{1}{x^2+1}\,dx$ converges to $\frac{\pi}{2}$, since

$$\int_0^b \frac{1}{x^2+1}\,dx = \arctan x\big|_0^b = \arctan b - \arctan 0 = \arctan b,$$

and $\lim_{b\to\infty} \arctan b = \frac{\pi}{2}$. The terms of the series $\sum_{n=1}^{\infty} \frac{1}{n^2+1}$ form a right hand sum for the improper integral; each term represents the area of a rectangle of width 1 fitting completely under the graph of the function $\frac{1}{x^2+1}$. (See Figure 9.3.) Thus the sequence of partial sums is bounded above by $\frac{\pi}{2}$. Since the partial sums are increasing (every new term added is positive), the series is guaranteed to converge to some number less than or equal to $\pi/2$ by Theorem 9.1.

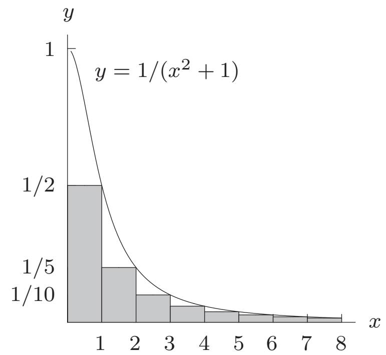

Figure 9.3

10. The integral test requires that $f(x) = x^2$, which is not decreasing.

11. The integral test requires that $f(x) = (-1)^x/x$. However $(-1)^x$ is not defined for all x.

12. The integral test requires that $f(x) = e^{-x}\sin x$, which is not positive, nor is it decreasing.

Problems

13. Using the integral test, we compare the series with

$$\int_0^\infty \frac{3}{x+2}\,dx = \lim_{b\to\infty}\int_0^b \frac{3}{x+2}\,dx = 3\ln|x+2|\Big|_0^b.$$

Since $\ln(b+2)$ is unbounded as $b\to\infty$, the integral diverges and therefore so does the series.

14. Since the terms in the series are positive and decreasing, we can use the integral test. We calculate the corresponding improper integral:

$$\int_0^\infty \frac{4}{2x+1}\,dx = \lim_{b\to\infty}\int_0^b \frac{4}{2x+1}\,dx = \lim_{b\to\infty} 2\ln(2x+1)\Big|_0^b = \lim_{b\to\infty} 2\ln(2b+1).$$

Since the limit does not exist, the integral diverges, so the series $\sum_{n=0}^{\infty}\frac{4}{2n+1}$ diverges.

15. We use the integral test and calculate the corresponding improper integral, $\int_0^\infty 2/\sqrt{2+x}\,dx$:

$$\int_0^\infty \frac{2}{\sqrt{2+x}}\,dx = \lim_{b\to\infty}\int_0^b \frac{2\,dx}{\sqrt{2+x}} = \lim_{b\to\infty} 4(2+x)^{1/2}\Big|_0^b = \lim_{b\to\infty} 4\left((2+b)^{1/2}-2^{1/2}\right).$$

Since the limit does not exist, the integral diverges, so the series $\sum_{n=1}^{\infty}\frac{2}{\sqrt{2+n}}$ diverges.

16. Since the terms in the series are positive and decreasing, we can use the integral test. We calculate the corresponding improper integral using the substitution $w=x^2$

$$\int_0^\infty \frac{2x}{1+x^4}\,dx = \lim_{b\to\infty}\int_0^b \frac{2x}{1+x^4}\,dx = \lim_{b\to\infty}\arctan x^2\Big|_0^b = \lim_{b\to\infty}\arctan b^2 = \frac{\pi}{2}.$$

Since the limit exists, the integral converges, so the series $\sum_{n=0}^{\infty}\frac{2n}{1+n^4}$ converges.

17. Since the terms in the series are positive and decreasing, we can use the integral test. We calculate the corresponding improper integral using the substitution $w=1+x^2$:

$$\int_0^\infty \frac{2x}{(1+x^2)^2}\,dx = \lim_{b\to\infty}\int_0^b \frac{2x}{(1+x^2)^2}\,dx = \lim_{b\to\infty}\frac{-1}{(1+x^2)}\Big|_0^b = \lim_{b\to\infty}\left(\frac{-1}{1+b^2}+1\right) = 1.$$

Since the limit exists, the integral converges, so the series $\sum_{n=0}^{\infty}\frac{2n}{(1+n^2)^2}$ converges.

18. The terms in this series do not tend to 0. We have

$$\lim_{n\to\infty}\frac{2n}{\sqrt{4+n^2}} = \lim_{n\to\infty}\frac{2}{\sqrt{4/n^2+1}} = 2.$$

Thus the series diverges. It is also possible (although much slower) to use the integral test. We calculate the corresponding improper integral using the substitution $w=x^2$

$$\int_0^\infty \frac{2x}{\sqrt{4+x^2}}\,dx = \lim_{b\to\infty}\int_0^b \frac{2x}{\sqrt{4+x^2}}\,dx = \lim_{b\to\infty} 2\sqrt{4+x^2}\Big|_0^b = \lim_{b\to\infty}(2\sqrt{4+b^2}-4).$$

Since the limit does not exist, the integral diverges, so the series $\sum_{n=0}^{\infty}\frac{2n}{\sqrt{4+n^2}}$ diverges.

19. We use the integral test and calculate the corresponding improper integral, $\int_1^\infty 3/(2x-1)^2\,dx$:

$$\int_1^\infty \frac{3\,dx}{(2x-1)^2} = \lim_{b\to\infty}\int_1^b \frac{3\,dx}{(2x-1)^2} = \lim_{b\to\infty} \frac{-3/2}{(2x-1)}\bigg|_1^b = \lim_{b\to\infty}\left(\frac{-3/2}{(2b-1)} + \frac{3}{2}\right) = \frac{3}{2}.$$

Since the integral converges, the series $\sum_{n=1}^{\infty} \frac{3}{(2n-1)^2}$ converges.

20. We use the integral test and calculate the corresponding improper integral, $\int_1^\infty 4/(2x+1)^3\,dx$. Using the substitution $w = 2x+1$, we have

$$\int_1^\infty \frac{4\,dx}{(2x+1)^3} = \lim_{b\to\infty}\int_1^b \frac{4\,dx}{(2x+1)^3} = \lim_{b\to\infty} -\frac{1}{(2x+1)^2}\bigg|_1^b = \lim_{b\to\infty}\left(-\frac{1}{(2b+1)^2} + \frac{1}{9}\right) = \frac{1}{9}.$$

Since the integral converges, the series $\sum_{n=1}^{\infty} \frac{4}{(2n+1)^3}$ converges.

21. Using the integral test, we compare the series with

$$\int_0^\infty \frac{3}{x^2+4}\,dx = \lim_{b\to\infty}\int_0^b \frac{3}{x^2+4}\,dx = \frac{3}{2}\lim_{b\to\infty} \arctan\left(\frac{x}{2}\right)\bigg|_0^b = \frac{3}{2}\lim_{b\to\infty}\arctan\left(\frac{b}{2}\right) = \frac{3\pi}{4},$$

by integral table V-24. Since the integral converges so does the series.

22. Since the terms in the series are positive and decreasing, we can use the integral test. We calculate the corresponding improper integral using the substitution $w = 2x$:

$$\int_0^\infty \frac{2}{1+4x^2}\,dx = \lim_{b\to\infty}\int_0^b \frac{2}{1+4x^2}\,dx = \lim_{b\to\infty}\arctan(2x)\bigg|_0^b = \lim_{b\to\infty}\arctan(2b) = \pi/2.$$

Since the limit exists, the integral converges, so the series $\sum_{n=0}^{\infty} \frac{2}{1+4n^2}$ converges.

23. Writing $a_n = n/(n+1)$, we have $\lim_{n\to\infty} a_n = 1$ so the series diverges by Property 3 of Theorem 9.2.

24. Writing $a_n = (n+1)/(2n+3)$, we have $\lim_{n\to\infty} a_n = 1/2$, so the limit of individual terms is not 0. The series diverges by Property 3 of Theorem 9.2.

25. Both $\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^n$ and $\sum_{n=1}^{\infty}\left(\frac{2}{3}\right)^n$ are convergent geometric series. Therefore, by Property 1 of Theorem 9.2, the series $\sum_{n=1}^{\infty}\left(\frac{1}{2}\right)^n + \left(\frac{2}{3}\right)^n$ converges.

26. The series $\sum_{n=1}^{\infty}\left(\frac{3}{4}\right)^n$ is a convergent geometric series, but $\sum_{n=1}^{\infty}\frac{1}{n}$ is the divergent harmonic series.
If $\sum_{n=1}^{\infty}\left(\left(\frac{3}{4}\right)^n + \frac{1}{n}\right)$ converged, then $\sum_{n=1}^{\infty}\left(\left(\frac{3}{4}\right)^n + \frac{1}{n}\right) - \sum_{n=1}^{\infty}\left(\frac{3}{4}\right)^n = \sum_{n=1}^{\infty}\frac{1}{n}$ would converge by Theorem 9.2. Therefore $\sum_{n=1}^{\infty}\left(\left(\frac{3}{4}\right)^n + \frac{1}{n}\right)$ diverges.

27. The series can be written as

$$\sum_{n=1}^{\infty}\frac{n+2^n}{n2^n} = \sum_{n=1}^{\infty}\left(\frac{1}{2^n} + \frac{1}{n}\right).$$

If this series converges, then $\sum_{n=1}^{\infty}\left(\frac{1}{2^n} + \frac{1}{n}\right) - \sum_{n=1}^{\infty}\frac{1}{2^n} = \sum_{n=1}^{\infty}\frac{1}{n}$ would converge by Theorem 9.2. Since this is the harmonic series, which diverges, then the series $\sum_{n=1}^{\infty}\frac{n+2^n}{n}$ diverges.

28. Let $a_n = (\ln n)/n$ and $f(x) = (\ln x)/x$. We use the integral test and consider the improper integral

$$\int_c^{\infty} \frac{\ln x}{x} dx.$$

Since

$$\int_c^R \frac{\ln x}{x} dx = \frac{1}{2}(\ln x)^2\Big|_c^R = \frac{1}{2}\left((\ln R)^2 - (\ln c)^2\right),$$

and $\ln R$ grows without bound as $R \to \infty$, the integral diverges. Therefore, the integral test tells us that the series, $\sum_{n=1}^{\infty} \frac{\ln n}{n}$, also diverges.

29. Since the terms in the series are positive and decreasing, we can use the integral test. We calculate the corresponding improper integral using the substitution $w = 1 + \ln x$:

$$\int_1^{\infty} \frac{1}{x(1+\ln x)} dx = \lim_{b\to\infty} \int_1^b \frac{1}{x(1+\ln x)} dx = \lim_{b\to\infty} \ln(1+\ln x)\Big|_1^b = \lim_{b\to\infty} \ln(1+\ln b).$$

Since the limit does not exist, the integral diverges, so the series $\sum_{n=1}^{\infty} \frac{1}{n(1+\ln n)}$ diverges.

30. We use the integral test and calculate the corresponding improper integral, $\int_3^{\infty} (x+1)/(x^2+2x+2)\, dx$:

$$\int_3^{\infty} \frac{x+1}{x^2+2x+2} dx = \lim_{b\to\infty} \int_3^b \frac{x+1}{x^2+2x+2} dx = \lim_{b\to\infty} \frac{1}{2} \ln|x^2+2x+2|\Big|_3^b = \lim_{b\to\infty} \frac{1}{2}(\ln(b^2+2b+2) - \ln 17).$$

Since the limit does not exist (it is ∞), the integral diverges, so the series $\sum_{n=3}^{\infty} \frac{n+1}{n^2+2n+2}$ diverges.

31. Since the terms in the series are positive and decreasing, we can use the integral test. We calculate the corresponding improper integral using the substitution $w = 1 + x$:

$$\int_0^{\infty} \frac{1}{x^2+2x+2} dx = \lim_{b\to\infty} \int_0^b \frac{1}{x^2+2x+2} dx = \lim_{b\to\infty} \frac{1}{1+(x+1)^2} dx$$

$$= \lim_{b\to\infty} \arctan(x+1)\Big|_0^b = \lim_{b\to\infty} (\arctan(b+1) - \arctan 1) = \pi/2 - \arctan 1.$$

Since the limit exists, the integral converges, so the series $\sum_{n=0}^{\infty} \frac{1}{n^2+2n+2}$ converges.

32. Since the terms in the series are positive and decreasing, we can use the integral test. We calculate the corresponding improper integral:

$$\int_2^{\infty} \frac{x\ln x + 4}{x^2} dx = \lim_{b\to\infty} \int_2^b \frac{x\ln x+4}{x^2} dx = \lim_{b\to\infty} \left[\int_2^b \frac{\ln x}{x} dx + \int_2^b \frac{4}{x^2} dx\right].$$

Using the substitution $w = \ln x$ on the first integral, we have

$$\lim_{b\to\infty} \int_2^b \frac{x\ln x+4}{x^2} dx = \lim_{b\to\infty} \left(\frac{(\ln x)^2}{2} - \frac{4}{x}\right)\Big|_2^b = \lim_{b\to\infty} \frac{(\ln b)^2}{2} - \frac{4}{b} - \frac{(\ln 2)^2}{2} + 2.$$

Since the limit does not exist, the integral diverges, so the series $\sum_{n=2}^{\infty} \frac{n\ln n + 4}{n^2}$ diverges.

33. Using $\ln(2^n) = n\ln 2$, we see that

$$\sum \frac{1}{\ln(2^n)} = \sum \frac{1}{(\ln 2)n}.$$

The series on the right is the harmonic series multiplied by $1/\ln 2$. Since the harmonic series diverges, $\sum_{n=1}^{\infty} 1/\ln(2^n)$ diverges.

34. Using $\ln(2^n) = n\ln 2$, we see that
$$\sum_{n=1}^{\infty} \frac{1}{(\ln(2^n))^2} = \sum_{n=1}^{\infty} \frac{1}{(\ln 2)^2 n^2}.$$
Since $\sum 1/n^2$ converges, $\sum 1/((\ln(2))^2 n^2)$ converges by property 1 of Theorem 9.2.

35. (a) With $a_n = \ln((n+1)/n)$ we have
$$\begin{aligned} S_n &= a_1 + a_2 + a_3 + \cdots + a_{n-1} + a_n \\ &= \ln(2/1) + \ln(3/2) + \ln(4/3) + \cdots + \ln(n/(n-1)) + \ln((n+1)/n) \\ &= \ln\left(\frac{2}{1}\cdot\frac{3}{2}\cdot\frac{4}{3}\cdots\frac{n}{n-1}\cdot\frac{n+1}{n}\right) = \ln(n+1). \end{aligned}$$
(b) Since the limit of the partial sums, $\lim_{n\to\infty} S_n = \lim_{n\to\infty}\ln(n+1)$, does not exist, the series diverges.

36. (a) Using $r = e^{\ln r}$ and $n = e^{\ln n}$ we have $r^{\ln n} = e^{(\ln r)(\ln n)} = n^{\ln r}$.
(b) By part (a) we have $r^{\ln n} = n^{\ln r} = 1/n^{-\ln r}$. Since the p-series $\sum 1/n^p$ converges if and only if $p > 1$, the series $\sum_{n=1}^{\infty} 1/n^{-\ln r}$ converges if and only if $-\ln r > 1$, which is equivalent to $\ln r < -1$ or $r < 1/e$. Thus $\sum_{n=1}^{\infty} r^{\ln n}$ converges if $0 < r < 1/e$ and diverges if $r \geq 1/e$.

37. (a) A common denominator is $k(k+1)$ so
$$\frac{1}{k} - \frac{1}{k+1} = \frac{k+1}{k(k+1)} - \frac{k}{k(k+1)} = \frac{k+1-k}{k(k+1)} = \frac{1}{k(k+1)}.$$
(b) Using the result of part (a), the partial sum can be written as
$$S_3 = \frac{1}{1\cdot 2} + \frac{1}{2\cdot 3} + \frac{1}{3\cdot 4} = \frac{1}{1} - \frac{1}{2} + \frac{1}{2} - \frac{1}{3} + \frac{1}{3} - \frac{1}{4} = 1 - \frac{1}{4}.$$
All of the intermediate terms cancel out, leaving only the first and last terms. Thus $S_{10} = 1 - \frac{1}{11}$ and $S_n = 1 - \frac{1}{n+1}$.
(c) The limit of S_n as $n \to \infty$ is $\lim_{n\to\infty}\left(1 - \frac{1}{n+1}\right) = 1 - 0 = 1$. Thus the series $\sum_{k=1}^{\infty}\frac{1}{k(k+1)}$ converges to 1.

38. (a) The partial sum
$$S_3 = \ln\left(\frac{1\cdot 3}{2\cdot 2}\right) + \ln\left(\frac{2\cdot 4}{3\cdot 3}\right) + \ln\left(\frac{3\cdot 5}{4\cdot 4}\right).$$
Using the property $\ln(A) + \ln(B) = \ln(AB)$, we get
$$S_3 = \ln\left(\frac{1\cdot 3\cdot 2\cdot 4\cdot 3\cdot 5}{2\cdot 2\cdot 3\cdot 3\cdot 4\cdot 4}\right).$$
The intermediate factors cancel out, leaving only $\ln\left(\frac{1\cdot 5}{2\cdot 4}\right)$, so $S_3 = \ln\left(\frac{5}{8}\right)$.
(b) For the partial sum S_n, similar steps yield
$$S_n = \ln\left(\frac{1\cdot 3\cdot 2\cdot 4\cdot 3\cdot 5\cdots n(n+2)}{2\cdot 2\cdot 3\cdot 3\cdot 4\cdot 4\cdots(n+1)\cdot(n+1)}\right).$$
As before, most of the factors cancel, leaving $S_n = \ln\left(\frac{n+2}{2(n+1)}\right)$.
(c) The limit of $S_n = \ln\left(\frac{n+2}{2(n+1)}\right)$ as $n\to\infty$ is $\lim_{n\to\infty}\ln\left(\frac{n+2}{2(n+1)}\right) = \ln\left(\frac{1}{2}\right)$. Thus the series $\sum_{k=1}^{\infty}\ln\left(\frac{k(k+2)}{(k+1)^2}\right)$ converges to $\ln\left(\frac{1}{2}\right)$.

39. Let S_n be the n^{th} partial sum for $\sum a_n$ and let T_n be the n^{th} partial sum for $\sum b_n$. Then the n^{th} partial sums for $\sum(a_n + b_n)$, $\sum(a_n - b_n)$, and $\sum ka_n$ are $S_n + T_n$, $S_n - T_n$, and kS_n, respectively. To show that these series converge, we have to show that the limits of their partial sums exist. By the properties of limits,
$$\begin{aligned} \lim_{n\to\infty}(S_n + T_n) &= \lim_{n\to\infty} S_n + \lim_{n\to\infty} T_n \\ \lim_{n\to\infty}(S_n - T_n) &= \lim_{n\to\infty} S_n - \lim_{n\to\infty} T_n \\ \lim_{n\to\infty} kS_n &= k\lim_{n\to\infty} S_n. \end{aligned}$$
This proves that the limits of the partial sums exist, so the series converge.

40. Let S_n be the n-th partial sum for $\sum a_n$ and let T_n be the n-th partial sum for $\sum b_n$. Suppose that $S_N = T_N + k$. Since $a_n = b_n$ for $n \geq N$, we have $S_n = T_n + k$ for $n \geq N$. Hence if S_n converges to a limit, so does T_n, and vice versa. Thus, $\sum a_n$ and $\sum b_n$ either both converge or both diverge.

41. We have $a_n = S_n - S_{n-1}$. If $\sum a_n$ converges, then $S = \lim_{n\to\infty} S_n$ exists. Hence $\lim_{n\to\infty} S_{n-1}$ exists and is equal to S also. Thus

$$\lim_{n\to\infty} a_n = \lim_{n\to\infty} (S_n - S_{n-1}) = \lim_{n\to\infty} S_n - \lim_{n\to\infty} S_{n-1} = S - S = 0.$$

42. From Property 1 in Theorem 9.2, we know that if $\sum a_n$ converges, then so does $\sum ka_n$.

Now suppose that $\sum a_n$ diverges and $\sum ka_n$ converges for $k \neq 0$. Thus using Property 1 and replacing $\sum a_n$ by $\sum ka_n$, we know that the following series converges:

$$\sum \frac{1}{k}(ka_n) = \sum a_n.$$

Thus, we have arrived at a contradiction, which means our original assumption, that $\sum_{n=1}^{\infty} ka_n$ converged, must be wrong.

43. A typical partial sum of the series $\sum_{n=1}^{\infty}(a_{n+1} - a_n)$, say S_5, shows what happens in the general case:

$$S_5 = (a_2 - a_1) + (a_3 - a_2) + (a_4 - a_3) + (a_5 - a_4) + (a_6 - a_5) = a_6 - a_1$$

as all of the intermediate terms cancel out. The same thing will happen in the general partial sum: $S_n = a_{n+1} - a_1$.

Now the series $\sum_{n=1}^{\infty}(a_{n+1} - a_n)$ converges if the sequence of partial sums S_n has a limit as $n \to \infty$. Since we're assuming that the original series $\sum_{n=1}^{\infty} a_n$ converges, we know that $\lim_{n\to\infty} a_n = \lim_{n\to\infty} a_{n+1} = 0$ by property 3 of Theorem 9.2. Thus

$$\lim_{n\to\infty} S_n = \lim_{n\to\infty} (a_{n+1} - a_1) = 0 - a_1 = -a_1.$$

Since the sequence of partial sums converges (to $-a_1$), the series $\sum_{n=1}^{\infty}(a_{n+1} - a_n)$ converges (also to $-a_1$).

44. If $a_n = 1$ for all n, then $\sum a_n$ diverges but $\sum(a_{n+1} - a_n) = \sum 0$ converges. If $a_n = n$ for all n, then $\sum a_n$ diverges, and $\sum a_{n+1} - a_n = \sum 1$ diverges

45. (a) Suppose $\displaystyle\int_c^{\infty} f(x)\,dx$ diverges. In Figure 9.4 we see that for each positive integer k

$$\int_N^{N+k+1} f(x)\,dx \leq f(N) + f(N+1) + \cdots + f(N+k).$$

Since $f(n) = a_n$ for all n, we have

$$\int_N^{N+k+1} f(x)\,dx \leq a_N + a_{N+1} + \cdots + a_{N+k}.$$

Since $f(x)$ is defined for all $x \geq c$, if $\int_c^{\infty} f(x)\,dx$ is divergent, then $\int_N^{\infty} f(x)\,dx$ is divergent. So as $k \to \infty$, the integral $\int_N^{N+k+1} f(x)\,dx$ diverges, so the partial sums of the series $\sum_{i=N}^{\infty} a_i$ diverge. Thus, the series $\sum_{i=1}^{\infty} a_i$ diverges.

More precisely, suppose the series converged. Then the partial sums would be bounded. (The partial sums would be less than the sum of the series, since all the terms in the series are positive.) But that would imply that the integral converged, by Theorem 9.1 on Convergence of Monotone Bounded Sequences. This contradicts the assumption that $\int_N^{\infty} f(x)\,dx$ is divergent.

(b) Suppose $\int_c^\infty f(x)\,dx$ converges. Let N an integer with $N \geq c$. Consider the series $\sum_{i=N+1}^\infty a_i$. The partial sums of this series are increasing because all the terms in the series are positive. We show the partial sums are bounded using the right-hand sum in Figure 9.5. We see that for each positive integer k

$$f(N+1)+f(N+2)+\cdots+f(N+k) \leq \int_N^{N+k} f(x)\,dx.$$

Since $f(n) = a_n$ for all n, and $c \leq N$, we have

$$a_{N+1}+a_{N+2}+\cdots+a_{N+k} \leq \int_c^{N+k} f(x)\,dx.$$

Since $f(x)$ is a positive function, $\int_c^{N+k} f(x)\,dx \leq \int_c^b f(x)\,dx$ for all $b \geq N+k$. Since f is positive and $\int_c^\infty f(x)\,dx$ is convergent, $\int_c^{N+k} f(x)\,dx < \int_c^\infty f(x)\,dx$, so we have

$$a_{N+1}+a_{N+2}+\cdots+a_{N+k} \leq \int_c^\infty f(x)\,dx \quad \text{for all } k.$$

Thus, the partial sums of the series $\sum_{i=N+1}^\infty a_i$ are bounded and increasing, so this series converges by Theorem 9.1.

Now use Theorem 9.2, property 2, to conclude that $\sum_{i=1}^\infty a_i$ converges.

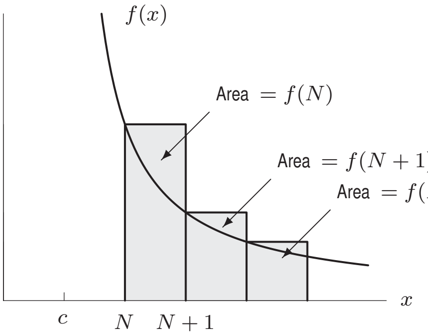

Figure 9.4

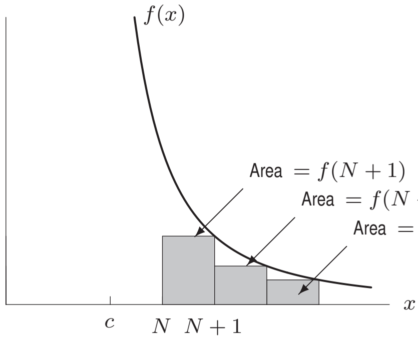

Figure 9.5

46. (a) Show that the sum of each group of fractions is more than $1/2$.
(b) Explain why this shows that the harmonic series does not converge.

(a) Notice that

$$\frac{1}{3}+\frac{1}{4} > \frac{1}{4}+\frac{1}{4} = \frac{2}{4} = \frac{1}{2}$$
$$\frac{1}{5}+\frac{1}{6}+\frac{1}{7}+\frac{1}{8} > \frac{1}{8}+\frac{1}{8}+\frac{1}{8}+\frac{1}{8} = \frac{4}{8} = \frac{1}{2}$$
$$\frac{1}{9}+\frac{1}{10}+\cdots+\frac{1}{16} > \frac{1}{16}+\frac{1}{16}+\cdots+\frac{1}{16} = \frac{8}{16} = \frac{1}{2}.$$

In the same way, we can see that the sum of the fractions in each grouping is greater than $1/2$.

(b) Since the sum of the first n groups is greater than $n/2$, it follows that the partial sums of the harmonic series are not bounded. Thus, the harmonic series diverges.

47. (a) Since for $x > 0$,

$$\int \frac{1}{x \ln x} dx = \ln(\ln x) + C$$

we have

$$\int_2^\infty \frac{1}{x \ln x} dx = \lim_{b\to\infty} \int_2^b \frac{1}{x \ln x} dx = \lim_{b\to\infty} (\ln(\ln b) - \ln(\ln 2)) = \infty.$$

The series diverges by the integral test.

(b) The terms in each group are decreasing so we can bound each group as follows:

$$\frac{1}{3\ln 3} + \frac{1}{4 \ln 4} > \frac{1}{4\ln 4} + \frac{1}{4\ln 4} = \frac{1}{2\ln 4}$$

and

$$\frac{1}{5\ln 5} + \frac{1}{6\ln 6} + \frac{1}{7\ln 7} + \frac{1}{8\ln 8} > 4\frac{1}{8\ln 8} = \frac{1}{2\ln 8}.$$

Similarly, the group whose final term is $1/(2^n \ln(2^n))$ is greater than $1/(2\ln(2^n)) = 1/(2(\ln 2)n)$. Thus

$$\sum_{n=2}^{2^N} \frac{1}{n \ln n} > \sum_{n=1}^{N} \frac{1}{2(\ln 2)n}.$$

The series on the right is the harmonic series multiplied by the constant $1/(2\ln 2)$. Since the harmonic series diverges, $\sum 1/(n \ln n)$ diverges.

48. (a) See Figure 9.6. We draw the left-hand sum approximation to $\int_1^{n+1}(1/x)\,dx$ using $\Delta x = 1$. Since the rectangles lie everywhere above the curve, for every positive integer k, we conclude that

$$\int_k^{k+1} \frac{dx}{x} < \frac{1}{k}.$$

We see that

$$a_{n+1} - a_n = \frac{1}{n+1} - \ln(n+2) + \ln(n+1) = \frac{1}{n+1} - \int_{n+1}^{n+2} \frac{dx}{x},$$

so we see that $a_n < a_{n+1}$ for every positive integer n.

(b) For every positive integer n, the value of a_n represents the difference between the left-hand approximation of $\int_1^{n+1}(1/x)\,dx$ and the integral itself.

This difference can be viewed as a sum of areas of n roughly triangular pieces, with the k^{th} piece having a vertical side running from $y = 1/k$ to $y = 1/(k+1)$. Each piece has width 1. All the pieces can be moved to the left and stacked up to fit inside the first rectangle of the left-hand approximation, which runs from $x = 1$ to $x = 2$ and from $y = 0$ to $y = 1$. Thus the sum of all these stacked areas is less than 1, so $a_n < 1$ for all n. See Figure 9.7.

(c) Since a_n is an increasing sequence bounded above by 1, Theorem 9.1 ensures that $\lim_{n\to\infty} a_n$ exists.

(d) The sequence converges slowly, but a calculator or computer gives $a_{200} = 0.5747$. For comparison, $a_{100} = 0.5723$, $a_{500} = 0.5762$. Thus, $\gamma \approx 0.58$. More extensive calculations show that $\gamma \approx 0.577216$.

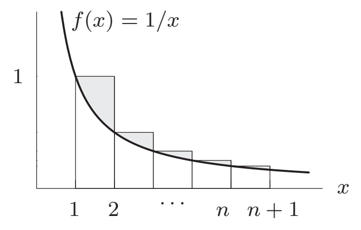

Figure 9.6

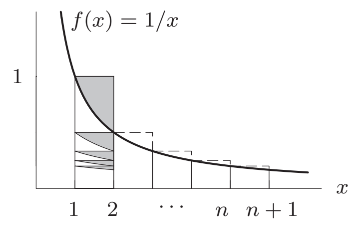

Figure 9.7

49. (a) A calculator or computer gives

$$\sum_{1}^{20} \frac{1}{n^2} = \frac{1}{1^2} + \frac{1}{2^2} + \cdots + \frac{1}{20^2} = 1.596.$$

(b) Since $\sum_{1}^{\infty} \frac{1}{n^2} = \frac{\pi^2}{6}$, the answer to part (a) gives

$$\frac{\pi^2}{6} \approx 1.596$$
$$\pi \approx \sqrt{6 \cdot 1.596} = 3.09$$

(c) A calculator or computer gives

$$\sum_{1}^{100} \frac{1}{n^2} = \frac{1}{1^2} + \frac{1}{2^2} + \cdots + \frac{1}{100^2} = 1.635,$$

so

$$\frac{\pi^2}{6} \approx 1.635$$
$$\pi \approx \sqrt{6 \cdot 1.635} = 3.13.$$

(d) The error in approximating $\pi^2/6$ by $\sum_1^{20} 1/n^2$ is the tail of the series $\sum_{21}^{\infty} 1/n^2$. From Figure 9.8, we see that

$$\sum_{21}^{\infty} \frac{1}{n^2} < \int_{20}^{\infty} \frac{dx}{x^2} = -\frac{1}{x}\bigg|_{20}^{\infty} = \frac{1}{20} = 0.05.$$

A similar argument leads to a bound for the error in approximating $\pi^2/6$ by $\sum_1^{100} 1/n^2$ as

$$\sum_{101}^{\infty} \frac{1}{n^2} < \int_{100}^{\infty} \frac{dx}{x^2} = -\frac{1}{x}\bigg|_{100}^{\infty} = \frac{1}{100} = 0.01.$$

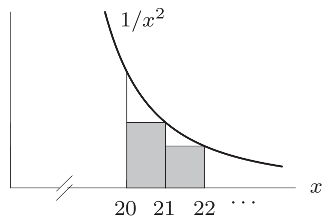

Figure 9.8

50. (a) We have $e > 1 + 1 + 1/2 + 1/6 + 1/24 = 65/24 = 2.708$.

(b) We have

$$\frac{1}{n!} = \frac{1}{1 \cdot 2 \cdot 3 \cdot 4 \cdots n} \leq \frac{1}{1 \cdot 2 \cdot 2 \cdot 2 \cdots 2} = \frac{1}{2^{n-1}}.$$

(c) The inequality in part (b) can be used to replace the given series with a geometric series that we can sum.

$$e = \sum_{n=0}^{\infty} \frac{1}{n!} = 1 + \sum_{n=1}^{\infty} \frac{1}{n!} < 1 + \sum_{n=1}^{\infty} \frac{1}{2^{n-1}} = 1 + \frac{1}{1 - 1/2} = 3.$$

51. (a) The right-hand sum for $\int_0^N x^N dx$ with $\Delta x = 1$ is the sum $1^5 \cdot 1 + 2^5 \cdot 1 + 3^5 \cdot 1 + \cdots + N^5 \cdot 1 = S_N$. This sum is greater than the integral because the integrand x^5 is increasing on the interval $0 < x < N$. Since $\int_0^N x^5 dx = N^6/6$, we have $S_N > N^6/6$.

(b) The left-hand sum for $\int_1^{N+1} x^N dx$ with $\Delta x = 1$ is the sum $1^5 \cdot 1 + 2^5 \cdot 1 + 3^5 \cdot 1 + \cdots + N^5 \cdot 1 = S_N$. This sum is less than the integral because the integrand x^5 is increasing on the interval $1 < x < N+1$. Since $\int_1^{N+1} x^5 dx = ((N+1)^6 - 1)/6$, we have $S_N < ((N+1)^6 - 1)/6$.

(c) By parts (a) and (b) we have

$$\frac{N^6/6}{N^6/6} = 1 < \frac{S_N}{N^6/6} < \frac{((N+1)^6 - 1)/6}{N^6/6} = (1 + \frac{1}{N})^6 - \frac{1}{N^6}.$$

Since both $\lim_{N\to\infty} 1 = 1$ and $\lim_{N\to\infty}((1+\frac{1}{N})^6 - \frac{1}{N^6}) = 1$, we conclude that the limit in the middle also equals 1, $\lim_{N\to\infty} S_N/(N^6/6) = 1$.

52. (a) Neglecting signs, the table reveals a regular pattern reminiscent of a linear function with slope 4. We see that term n is given by $4n - 3$:

Term	1	2	3	4	n
Value	1	5	9	13	$4n-3$

The odd-numbered terms are positive and the even-numbered terms are negative, so

$$c_n = \begin{cases} 4n - 3 & \text{for } n \text{ odd} \\ -1 \cdot (4n-3) & \text{for } n \text{ even.} \end{cases}$$

Notice that $-(-1)^n$ is negative if n is even, and positive if n is odd. Thus we can write $c_n = -(-1)^n(4n-3)$. Since $-(-1)^n = (-1)^1(-1)^n = (-1)^{n+1}$, we can also write this $c_n = (-1)^{n+1}(4n-3)$.

(b) Using double factorial (!!) notation, we can write: $b_2 = \left(\frac{1!!}{2!!}\right)^3, b_3 = \left(\frac{3!!}{4!!}\right)^3, b_4 = \left(\frac{5!!}{6!!}\right)^3, b_5 = \left(\frac{7!!}{8!!}\right)^3, \ldots$. Focusing on the patterns in the table of $1, 3, 5, 7$ in the numerator and $2, 4, 6, 8$ in the denominator, we see that both are reminiscent of linear functions with slope 2:

Term	2	3	4	5	n
Numerator	1	3	5	7	$2n-3$
Denominator	2	4	6	8	$2n-2$

This means we can write $b_n = \left(\frac{(2n-3)!!}{(2n-2)!!}\right)^3$.

(c) Putting together our answers for parts (a) and (b), we have $a_n = -(-1)^n(4n-3)\left(\frac{(2n-3)!!}{(2n-2)!!}\right)^3$, or (equivalently) $a_n = (-1)^{n+1}(4n-3)\left(\frac{(2n-3)!!}{(2n-2)!!}\right)^3$. Checking our answer, we have:

$$\begin{aligned}
a_1 &= -(-1)^1(4\cdot 1 - 3)\left(\frac{(2\cdot 1-3)!!}{(2\cdot 1-2)!!}\right)^3 = 1\left(\frac{(-1)!!}{0!!}\right)^3 = 1 && \text{since } (-1)!! = 0!! = 1 \\
a_2 &= -(-1)^2(4\cdot 2 - 3)\left(\frac{(2\cdot 2-3)!!}{(2\cdot 2-2)!!}\right)^3 = -5\left(\frac{1!!}{2!!}\right)^2 = -5\left(\frac{1}{2}\right)^3 && \text{since } 1!! = 1 \text{ and } 2!! = 2 \\
a_3 &= -(-1)^3(4\cdot 3 - 3)\left(\frac{(2\cdot 3-3)!!}{(2\cdot 3-2)!!}\right)^3 = 9\left(\frac{3!!}{4!!}\right)^2 = 9\left(\frac{1\times 3}{2\times 4}\right)^3 \\
s_4 &= -(-1)^4(4\cdot 4 - 3)\left(\frac{(2\cdot 4-3)!!}{(2\cdot 4-2)!!}\right)^3 = -13\left(\frac{5!!}{6!!}\right)^2 = -13\left(\frac{1\times 3\times 5}{2\times 4\times 6}\right)^3,
\end{aligned}$$

and so on, as required.

Strengthen Your Understanding

53. If the terms of a series do not approach zero, the series does not converge. But just because the terms approach zero does not mean the series converges. For example, $\sum(1/n)$ diverges even though the terms approach zero.

54. The integral $\int_1^\infty 1/x^3\,dx$ converges to $\frac{1}{2}$, because

$$\int_1^\infty \frac{dx}{x^3} = \lim_{b\to\infty}\int_1^b \frac{dx}{x^3} = \lim_{b\to\infty}\left(-\frac{1}{2b^2}+\frac{1}{2}\right) = \frac{1}{2}.$$

However, the series $\sum_{n=1}^\infty 1/n^3 = 1 + 1/2^3 + 1/3^3 + \cdots$ has a sum which is larger than 1 as its first term is 1 and all the subsequent terms are positive. Thus, the sum of the series is not $\frac{1}{2}$.

In general, the sum of a series and the value of an improper integral used to test it for convergence are not the same. Both converge or both diverge, but if they converge, usually they converge to different values.

55. The series $\sum_{n=1}^\infty 1/n$ is an example. The terms of the series converge to zero, but the series is a p-series with $p \le 1$, and therefore the series diverges.

56. One example is the series $\displaystyle\sum_{n=1}^\infty \frac{1}{n^2}$. This series is convergent because it is a p-series with $p = 2 > 1$.

If $a_n = 1/n^2$, then $\sqrt{a_n} = 1/n$, and the series $\sum_{n=1}^\infty 1/n$ diverges because it is a p-series with $p = 1$.

57. True. Writing out the terms of this series, we have

$$\begin{aligned}&(1+(-1)^1)+(1+(-1)^2)+(1+(-1)^3)+(1+(-1)^4)+\cdots\\ &=(1-1)+(1+1)+(1-1)+(1+1)+\cdots\\ &=0+2+0+2+\cdots.\end{aligned}$$

58. True. The definition of convergence of a series is that its partial sums are a convergent sequence.

59. False. For example, if $a_n = 1/n$ and $b_n = -1/n$, then $|a_n + b_n| = 0$, so $\sum |a_n + b_n|$ converges. However $\sum |a_n|$ and $\sum |b_n|$ are the harmonic series, which diverge.

60. False. The terms in the series do not go to zero:

$$\begin{aligned}2^{(-1)^1}+2^{(-1)^2}+2^{(-1)^3}+2^{(-1)^4}+2^{(-1)^5}+\cdots &= 2^{-1}+2^1+2^{-1}+2^1+2^{-1}+\cdots\\ &= 1/2+2+1/2+2+1/2+\cdots.\end{aligned}$$

61. True. If the terms do not tend to zero, the partial sums do not tend to a limit. For example, if the terms are all greater than 0.1, the partial sums will grow without bound.

62. False. Consider the series $\displaystyle\sum_{n=1}^\infty 1/n$. This series does not converge, but $1/n \to 0$ as $n \to \infty$.

63. False. If $a_n = b_n = 1/n$, then $\sum a_n$ and $\sum b_n$ do not converge. However, $a_n b_n = 1/n^2$, so $\sum a_n b_n$ does converge.

64. False. If $a_n b_n = 1/n^2$ and $a_n = b_n = 1/n$, then $\sum a_n b_n$ converges, but $\sum a_n$ and $\sum b_n$ do not converge.

65. (d)

Solutions for Section 9.4

Exercises

1. Let $a_n = 1/(n-3)$, for $n \ge 4$. Since $n - 3 < n$, we have $1/(n-3) > 1/n$, so

$$a_n > \frac{1}{n}.$$

The harmonic series $\displaystyle\sum_{n=4}^\infty \frac{1}{n}$ diverges, so the comparison test tells us that the series $\displaystyle\sum_{n=4}^\infty \frac{1}{n-3}$ also diverges.

2. Let $a_n = 1/(n^2+2)$. Since $n^2+2 > n^2$, we have $1/(n^2+2) < 1/n^2$, so

$$0 < a_n < \frac{1}{n^2}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges, so the comparison test tells us that the series $\sum_{n=1}^{\infty} \frac{1}{n^2+2}$ also converges.

3. Let $a_n = e^{-n}/n^2$. Since $e^{-n} < 1$, for $n \geq 1$,we have $\frac{e^{-n}}{n^2} < \frac{1}{n^2}$, so

$$0 < a_n < \frac{1}{n^2}.$$

The series $\sum_{n=1}^{\infty} \frac{1}{n^2}$ converges, so the comparison test tells us that the series $\sum_{n=1}^{\infty} \frac{e^{-n}}{n^2}$ also converges.

4. As n gets large, polynomials behave like the leading term, so for large n,

$$\frac{n^3+1}{n^4+2n^3+2n} \quad \text{behaves like} \quad \frac{n^3}{n^4} = \frac{1}{n}.$$

Since the series $\sum_{n=1}^{\infty} 1/n$ diverges, we predict that the given series will diverge.

5. As n gets large, polynomials behave like the leading term, so for large n,

$$\frac{n+4}{n^3+5n-3} \quad \text{behaves like} \quad \frac{n}{n^3} = \frac{1}{n^2}.$$

Since the series $\sum_{n=1}^{\infty} 1/n^2$ converges, we predict that the given series will converge.

6. As n gets large, polynomials behave like the leading term, so for large n,

$$\frac{1}{n^4+3n^3+7} \quad \text{behaves like} \quad \frac{1}{n^4}.$$

Since the series $\sum_{n=1}^{\infty} 1/n^4$ converges, we predict that the given series will converge.

7. As n gets large, polynomials behave like the leading term, so for large n,

$$\frac{n-4}{\sqrt{n^3+n^2+8}} \quad \text{behaves like} \quad \frac{n}{n^{3/2}} = \frac{1}{n^{1/2}}.$$

Since the series $\sum_{n=1}^{\infty} 1/n^{1/2}$ diverges, we predict that the given series will diverge.

8. Let $a_n = 1/(3^n+1)$. Since $3^n+1 > 3^n$, we have $1/(3^n+1) < 1/3^n = \left(\frac{1}{3}\right)^n$, so

$$0 < a_n < \left(\frac{1}{3}\right)^n.$$

Thus we can compare the series $\sum_{n=1}^{\infty} \frac{1}{3^n+1}$ with the geometric series $\sum_{n=1}^{\infty} \left(\frac{1}{3}\right)^n$. This geometric series converges since $|1/3| < 1$, so the comparison test tells us that $\sum_{n=1}^{\infty} \frac{1}{3^n+1}$ also converges.

9. Let $a_n = 1/(n^4+e^n)$. Since $n^4+e^n > n^4$, we have

$$\frac{1}{n^4+e^n} < \frac{1}{n^4},$$

so

$$0 < a_n < \frac{1}{n^4}.$$

Since the p-series $\sum_{n=1}^{\infty} \frac{1}{n^4}$ converges, the comparison test tells us that the series $\sum_{n=1}^{\infty} \frac{1}{n^4+e^n}$ also converges.

10. Since $\ln n \le n$ for $n \ge 2$, we have $1/\ln n \ge 1/n$, so the series diverges by comparison with the harmonic series, $\sum 1/n$.

11. Let $a_n = n^2/(n^4+1)$. Since $n^4+1 > n^4$, we have $\dfrac{1}{n^4+1} < \dfrac{1}{n^4}$, so

$$a_n = \frac{n^2}{n^4+1} < \frac{n^2}{n^4} = \frac{1}{n^2},$$

therefore

$$0 < a_n < \frac{1}{n^2}.$$

Since the p-series $\sum_{n=1}^{\infty} \dfrac{1}{n^2}$ converges, the comparison test tells us that the series $\sum_{n=1}^{\infty} \dfrac{n^2}{n^4+1}$ converges also.

12. We know that $|\sin n| < 1$, so

$$\frac{n\sin^2 n}{n^3+1} \le \frac{n}{n^3+1} < \frac{n}{n^3} = \frac{1}{n^2}.$$

Since the p-series $\sum_{n=1}^{\infty} \dfrac{1}{n^2}$ converges, comparison gives that $\sum_{n=1}^{\infty} \dfrac{n\sin^2 n}{n^3+1}$ converges.

13. Let $a_n = (2^n+1)/(n2^n-1)$. Since $n2^n - 1 < n2^n + n = n(2^n+1)$, we have

$$\frac{2^n+1}{n2^n-1} > \frac{2^n+1}{n(2^n+1)} = \frac{1}{n}.$$

Therefore, we can compare the series $\sum_{n=1}^{\infty} \dfrac{2^n+1}{n2^n-1}$ with the divergent harmonic series $\sum_{n=1}^{\infty} \dfrac{1}{n}$. The comparison test tells us that $\sum_{n=1}^{\infty} \dfrac{2^n+1}{n2^n-1}$ also diverges.

14. Since $a_n = \dfrac{n}{2^n}$, replacing n by $n+1$ gives $a_{n+1} = \dfrac{n+1}{2^{n+1}}$. Thus

$$\frac{|a_{n+1}|}{|a_n|} = \frac{(n+1)/2^{n+1}}{n/2^n} = \frac{n+1}{2n},$$

so

$$L = \lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \lim_{n\to\infty} \frac{n+1}{2n} = \lim_{n\to\infty} \frac{1+1/n}{2} = \frac{1}{2}.$$

Since $L < 1$, the ratio test tells us that $\sum_{n=1}^{\infty} \dfrac{n}{2^n}$ converges.

15. Since $a_n = 1/(2n)!$, replacing n by $n+1$ gives $a_{n+1} = 1/(2n+2)!$. Thus

$$\frac{|a_{n+1}|}{|a_n|} = \frac{\frac{1}{(2n+2)!}}{\frac{1}{(2n)!}} = \frac{(2n)!}{(2n+2)!} = \frac{(2n)!}{(2n+2)(2n+1)(2n)!} = \frac{1}{(2n+2)(2n+1)},$$

so

$$L = \lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \lim_{n\to\infty} \frac{1}{(2n+2)(2n+1)} = 0.$$

Since $L = 0$, the ratio test tells us that $\sum_{n=1}^{\infty} \dfrac{1}{(2n)!}$ converges.

16. Since $a_n = (n!)^2/(2n)!$, replacing n by $n+1$ gives $a_{n+1} = ((n+1)!)^2/(2n+2)!$. Thus,

$$\frac{|a_{n+1}|}{|a_n|} = \frac{\frac{((n+1)!)^2}{(2n+2)!}}{\frac{(n!)^2}{(2n)!}} = \frac{((n+1)!)^2}{(2n+2)!} \cdot \frac{(2n)!}{(n!)^2}.$$

However, since $(n+1)! = (n+1)n!$ and $(2n+2)! = (2n+2)(2n+1)(2n)!$, we have

$$\frac{|a_{n+1}|}{|a_n|} = \frac{(n+1)^2(n!)^2(2n)!}{(2n+2)(2n+1)(2n)!(n!)^2} = \frac{(n+1)^2}{(2n+2)(2n+1)} = \frac{n+1}{4n+2},$$

so

$$L = \lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \frac{1}{4}.$$

Since $L < 1$, the ratio test tells us that $\sum_{n=1}^{\infty} \frac{(n!)^2}{(2n)!}$ converges.

17. Since $a_n = n!(n+1)!/(2n)!$, replacing n by $n+1$ gives $a_{n+1} = (n+1)!(n+2)!/(2n+2)!$. Thus,

$$\frac{|a_{n+1}|}{|a_n|} = \frac{\frac{(n+1)!(n+2)!}{(2n+2)!}}{\frac{n!(n+1)!}{(2n)!}} = \frac{(n+1)!(n+2)!}{(2n+2)!} \cdot \frac{(2n)!}{n!(n+1)!}.$$

However, since $(n+2)! = (n+2)(n+1)n!$ and $(2n+2)! = (2n+2)(2n+1)(2n)!$, we have

$$\frac{|a_{n+1}|}{|a_n|} = \frac{(n+2)(n+1)}{(2n+2)(2n+1)} = \frac{n+2}{2(2n+1)},$$

so

$$L = \lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \frac{1}{4}.$$

Since $L < 1$, the ratio test tells us that $\sum_{n=1}^{\infty} \frac{n!(n+1)!}{(2n)!}$ converges.

18. Since $a_n = 1/(r^n n!)$, replacing n by $n+1$ gives $a_{n+1} = 1/(r^{n+1}(n+1)!)$. Thus

$$\frac{|a_{n+1}|}{|a_n|} = \frac{\frac{1}{r^{n+1}(n+1)!}}{\frac{1}{r^n n!}} = \frac{r^n n!}{r^{n+1}(n+1)!} = \frac{1}{r(n+1)},$$

so

$$L = \lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \frac{1}{r} \lim_{n\to\infty} \frac{1}{n+1} = 0.$$

Since $L = 0$, the ratio test tells us that $\sum_{n=1}^{\infty} \frac{1}{r^n n!}$ converges for all $r > 0$.

19. Since $a_n = 1/(ne^n)$, replacing n by $n+1$ gives $a_{n+1} = 1/(n+1)e^{n+1}$. Thus

$$\frac{|a_{n+1}|}{|a_n|} = \frac{\frac{1}{(n+1)e^{n+1}}}{\frac{1}{ne^n}} = \frac{ne^n}{(n+1)e^{n+1}} = \left(\frac{n}{n+1}\right)\frac{1}{e}.$$

Therefore

$$L = \lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = \frac{1}{e} < 1.$$

Since $L < 1$, the ratio test tells us that $\sum_{n=1}^{\infty} \frac{1}{ne^n}$ converges.

20. Since $a_n = 2^n/(n^3+1)$, replacing n by $n+1$ gives $a_{n+1} = 2^{n+1}/((n+1)^3+1)$. Thus

$$\frac{|a_{n+1}|}{|a_n|} = \frac{\frac{2^{n+1}}{(n+1)^3+1}}{\frac{2^n}{n^3+1}} = \frac{2^{n+1}}{(n+1)^3+1} \cdot \frac{n^3+1}{2^n} = 2\frac{n^3+1}{(n+1)^3+1},$$

so

$$L = \lim_{n\to\infty} \frac{|a_{n+1}|}{|a_n|} = 2.$$

Since $L > 1$ the ratio test tells us that the series $\sum_{n=0}^{\infty} \frac{2^n}{n^3+1}$ diverges.

21. Even though the first term is negative, the terms alternate in sign, so it is an alternating series.

22. Since $\cos(n\pi) = (-1)^n$, this is an alternating series.

23. Since $(-1)^n \cos(n\pi) = (-1)^{2n} = 1$, this is not an alternating series.

24. Since $a_n = \cos n$ is not always positive, this is not an alternating series.

25. Let $a_n = 1/\sqrt{n}$. Then replacing n by $n+1$ we have $a_{n+1} = 1/\sqrt{n+1}$. Since $\sqrt{n+1} > \sqrt{n}$, we have $\frac{1}{\sqrt{n+1}} < \frac{1}{\sqrt{n}}$, hence $a_{n+1} < a_n$. In addition, $\lim_{n\to\infty} a_n = 0$ so $\sum_{n=0}^{\infty} \frac{(-1)^n}{\sqrt{n}}$ converges by the alternating series test.

26. Let $a_n = 1/(2n+1)$. Then replacing n by $n+1$ gives $a_{n+1} = 1/(2n+3)$. Since $2n+3 > 2n+1$, we have

$$0 < a_{n+1} = \frac{1}{2n+3} < \frac{1}{2n+1} = a_n.$$

We also have $\lim_{n\to\infty} a_n = 0$. Therefore, the alternating series test tells us that the series $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{2n+1}$ converges.

27. Let $a_n = 1/(n^2+2n+1) = 1/(n+1)^2$. Then replacing n by $n+1$ gives $a_{n+1} = 1/(n+2)^2$. Since $n+2 > n+1$, we have

$$\frac{1}{(n+2)^2} < \frac{1}{(n+1)^2}$$

so

$$0 < a_{n+1} < a_n.$$

We also have $\lim_{n\to\infty} a_n = 0$. Therefore, the alternating series test tells us that the series $\sum_{n=1}^{\infty} \frac{(-1)^{n-1}}{n^2+2n+1}$ converges.

28. Let $a_n = 1/e^n$. Then replacing n by $n+1$ we have $a_{n+1} = 1/e^{n+1}$. Since $e^{n+1} > e^n$, we have $\frac{1}{e^{n+1}} < \frac{1}{e^n}$, hence $a_{n+1} < a_n$. In addition, $\lim_{n\to\infty} a_n = 0$ so $\sum_{n=1}^{\infty} \frac{(-1)^n}{e^n}$ converges by the alternating series test. We can also observe that the series is geometric with ratio $x = -1/e$ can hence converges since $|x| < 1$.

29. Both $\sum \frac{(-1)^n}{2^n} = \sum \left(\frac{-1}{2}\right)^n$ and $\sum \frac{1}{2^n} = \sum \left(\frac{1}{2}\right)^n$ are convergent geometric series. Thus $\sum \frac{(-1)^n}{2^n}$ is absolutely convergent.

30. The series $\sum \frac{(-1)^n}{2n}$ converges by the alternating series test. However $\sum \frac{1}{2n}$ diverges because it is a multiple of the harmonic series. Thus $\sum \frac{(-1)^n}{2n}$ is conditionally convergent.

31. Since

$$\lim_{n\to\infty} \frac{n}{n+1} = 1 \neq 0$$

the series $\sum (-1)^n \frac{n}{n+1}$ does not converge. It is a divergent series.

32. The series $\sum \frac{(-1)^n}{n^4+7}$ converges by the alternating series test. Moreover, the series $\sum \frac{1}{n^4+7}$ converges by comparison with the convergent p-series $\sum \frac{1}{n^4}$. Thus $\sum \frac{(-1)^n}{n^4+7}$ is absolutely convergent.

33. We first check absolute convergence by deciding whether $\sum 1/(n \ln n)$ converges by using the integral test. Since

$$\int_2^{\infty} \frac{dx}{x \ln x} = \lim_{b\to\infty} \int_2^b \frac{dx}{x \ln x} = \lim_{b\to\infty} \ln(\ln(x))\Big|_2^b = \lim_{b\to\infty} (\ln(\ln(b)) - \ln(\ln(2))),$$

and since this limit does not exist, $\sum \frac{1}{n \ln n}$ diverges.

We now check conditional convergence. The original series is alternating so we check whether $a_{n+1} < a_n$. Consider $a_n = f(n)$, where $f(x) = 1/(x \ln x)$. Since

$$\frac{d}{dx}\left(\frac{1}{x \ln x}\right) = \frac{-1}{x^2 \ln x}\left(1 + \frac{1}{\ln x}\right)$$

is negative for $x > 1$, we know that a_n is decreasing for $n \geq 2$. Thus, for $n \geq 2$

$$a_{n+1} = \frac{1}{(n+1)\ln(n+1)} < \frac{1}{n \ln n} = a_n.$$

Since $1/(n \ln n) \to 0$ as $n \to \infty$, we see that $\sum \frac{(-1)^{n-1}}{n \ln n}$ is conditionally convergent.

34. Although $\cos n$ is sometimes positive and sometimes negative, the series is not alternating because is does not change sign every term. For example $\cos 1 > 0$, whereas $\cos 2$ and $\cos 3$ are negative. If we use the comparison test on

$$\sum_{n=1}^{\infty} \left|\frac{\cos n}{n^2}\right|,$$

we find

$$\left|\frac{\cos n}{n^2}\right| \leq \frac{1}{n^2}.$$

The series $\sum_{n=1}^{\infty} 1/n^2$ is a p-series with $p = 2$, and therefore converges. Thus the original series is absolutely convergent.

35. This is an alternating series that converges by the alternating series test. However

$$\sum_{n=1}^{\infty} \left|\frac{(-1)^{n-1}}{\sqrt{n}}\right| = \sum_{n=1}^{\infty} \frac{1}{\sqrt{n}},$$

which is a p-series with $p = 1/2$, so this series diverges. Thus the original series is conditionally convergent.

36. We first check absolute convergence by deciding whether $\sum \arcsin(1/n)$ converges. Since $\sin\theta \approx \theta$ for small angles θ, writing $x = \sin\theta$ we see that

$$\arcsin x \approx x.$$

Since $\arcsin x$ "behaves like" x for small x, we expect $\arcsin(1/n)$ to "behave like" $1/n$ for large n. To confirm this we calculate

$$\lim_{n\to\infty} \frac{\arcsin(1/n)}{1/n} = \lim_{x\to 0} \frac{\arcsin x}{x} = \lim_{\theta\to 0} \frac{\theta}{\sin\theta} = 1.$$

Thus $\sum \arcsin(1/n)$ diverges by limit comparison with the harmonic series $\sum 1/n$.

We now check conditional convergence. The original series is alternating, so we check whether $a_{n+1} < a_n$. Consider $a_n = f(n)$, where $f(x) = \arcsin(1/x)$. Since

$$\frac{d}{dx} \arcsin \frac{1}{x} = \frac{1}{\sqrt{1 - (1/x)^2}}\left(-\frac{1}{x^2}\right)$$

is negative for $x > 1$, we know that a_n is decreasing for $n > 1$. Therefore, for $n > 1$

$$a_{n+1} = \arcsin(1/(n+1)) < \arcsin(1/n) = a_n.$$

Since $\arcsin(1/n) \to 0$ as $n \to \infty$, we see that $\sum(-1)^{n-1}\arcsin(1/n)$ is conditionally convergent.

37. We first check absolute convergence by deciding whether $\sum \frac{\arctan(1/n)}{n^2}$ converges. Since $\arctan x$ is the angle between $-\pi/2$ and $\pi/2$, we have $\arctan(1/n) < \pi/2$ for all n. We compare

$$\frac{\arctan(1/n)}{n^2} < \frac{\pi/2}{n^2},$$

and conclude that since $(\pi/2)\sum 1/n^2$ converges, $\sum \frac{\arctan(1/n)}{n^2}$ converges. Thus $\sum \frac{(-1)^{n-1}\arctan(1/n)}{n^2}$ is absolutely convergent.

38. We have

$$\frac{a_n}{b_n} = \frac{(5n+1)/(3n^2)}{1/n} = \frac{5n+1}{3n},$$

so

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{5n+1}{3n} = \frac{5}{3} = c \neq 0.$$

Since $\sum_{n=1}^{\infty} \frac{1}{n}$ is a divergent harmonic series, the original series diverges.

39. We have

$$\frac{a_n}{b_n} = \frac{((1+n)/(3n))^n}{(1/3)^n} = \left(\frac{n+1}{n}\right)^n = \left(1+\frac{1}{n}\right)^n,$$

so

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \left(1+\frac{1}{n}\right)^n = e = c \neq 0.$$

Since $\sum_{n=1}^{\infty} \left(\frac{1}{3}\right)^n$ is a convergent geometric series, the original series converges.

40. The n^{th} term is $a_n = 1 - \cos(1/n)$ and we are taking $b_n = 1/n^2$. We have

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1-\cos(1/n)}{1/n^2}.$$

This limit is of the indeterminate form $0/0$ so we evaluate it using l'Hopital's rule. We have

$$\lim_{n\to\infty} \frac{1-\cos(1/n)}{1/n^2} = \lim_{n\to\infty} \frac{\sin(1/n)(-1/n^2)}{-2/n^3} = \lim_{n\to\infty} \frac{1}{2}\frac{\sin(1/n)}{1/n} = \lim_{x\to 0} \frac{1}{2}\frac{\sin x}{x} = \frac{1}{2}.$$

The limit comparison test applies with $c = 1/2$. The p-series $\sum 1/n^2$ converges because $p = 2 > 1$. Therefore $\sum(1-\cos(1/n))$ also converges.

41. The n^{th} term $a_n = 1/(n^4 - 7)$ behaves like $1/n^4$ for large n, so we take $b_n = 1/n^4$. We have

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{1/(n^4-7)}{1/n^4} = \lim_{n\to\infty} \frac{n^4}{n^4-7} = 1.$$

The limit comparison test applies with $c = 1$. The p-series $\sum 1/n^4$ converges because $p = 4 > 1$. Therefore $\sum 1/(n^4-7)$ also converges.

42. The n^{th} term $a_n = (n+1)/(n^2+2)$ behaves like $n/n^2 = 1/n$ for large n, so we take $b_n = 1/n$. We have

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{(n+1)/(n^2+2)}{1/n} = \lim_{n\to\infty} \frac{n^2+n}{n^2+2} = 1.$$

The limit comparison test applies with $c = 1$. Since the harmonic series $\sum 1/n$ diverges, the series $\sum(n+1)/(n^2+2)$ also diverges.

43. The n^{th} term $a_n = (n^3 - 2n^2 + n + 1)/(n^4 - 2)$ behaves like $n^3/n^4 = 1/n$ for large n, so we take $b_n = 1/n$. We have

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{(n^3-2n^2+n+1)/(n^4-2)}{1/n} = \lim_{n\to\infty} \frac{n^4-2n^3+n^2+n}{n^4-2} = 1.$$

The limit comparison test applies with $c = 1$. The harmonic series $\sum 1/n$ diverges. Thus $\sum \left(n^3 - 2n^2 + n + 1\right) / \left(n^4 - 2\right)$ also diverges.

44. The n^{th} term $a_n = 2^n/(3^n - 1)$ behaves like $2^n/3^n$ for large n, so we take $b_n = 2^n/3^n$. We have

$$\lim_{n\to\infty} \frac{a_n}{b_n} = \lim_{n\to\infty} \frac{2^n/(3^n-1)}{2^n/3^n} = \lim_{n\to\infty} \frac{3^n}{3^n-1} = \lim_{n\to\infty} \frac{1}{1-3^{-n}} = 1.$$

The limit comparison test applies with $c = 1$. The geometric series $\sum 2^n/3^n = \sum(2/3)^n$ converges. Therefore $\sum 2^n/(3^n-1)$ also converges.

45. The n^{th} term $a_n = 1/(2\sqrt{n}+\sqrt{n+2})$ behaves like $1/(3\sqrt{n})$ for large n, so we take $b_n = 1/(3\sqrt{n})$. We have

$$\begin{aligned}\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{1/(2\sqrt{n}+\sqrt{n+2})}{1/(3\sqrt{n})} &= \lim_{n\to\infty}\frac{3\sqrt{n}}{2\sqrt{n}+\sqrt{n+2}}\\ &= \lim_{n\to\infty}\frac{3\sqrt{n}}{\sqrt{n}\left(2+\sqrt{1+2/n}\right)}\\ &= \lim_{n\to\infty}\frac{3}{2+\sqrt{1+2/n}} = \frac{3}{2+\sqrt{1+0}}\\ &= 1.\end{aligned}$$

The limit comparison test applies with $c = 1$. The series $\sum 1/(3\sqrt{n})$ diverges because it is a multiple of a p-series with $p = 1/2 < 1$. Therefore $\sum 1/(2\sqrt{n}+\sqrt{n+2})$ also diverges.

46. The n^{th} term,

$$a_n = \frac{1}{2n-1} - \frac{1}{2n} = \frac{1}{4n^2-2n},$$

behaves like $1/(4n^2)$ for large n, so we take $b_n = 1/(4n^2)$. We have

$$\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{1/(4n^2-2n)}{1/(4n^2)} = \lim_{n\to\infty}\frac{4n^2}{4n^2-2n} = \lim_{n\to\infty}\frac{1}{1-1/(2n)} = 1.$$

The limit comparison test applies with $c = 1$. The series $\sum 1/(4n^2)$ converges because it is a multiple of a p-series with $p = 2 > 1$. Therefore $\sum\left(\frac{1}{2n-1} - \frac{1}{2n}\right)$ also converges.

47. The n^{th} term,

$$a_n = \frac{n}{\cos n + e^n},$$

behaves like n/e^n for large n, so we take $b_n = n/e^n$. We have

$$\lim_{n\to\infty}\frac{a_n}{b_n} = \lim_{n\to\infty}\frac{n/\left(\cos n + e^n\right)}{n/e^n} = \lim_{n\to\infty}\frac{e^n}{\cos n + e^n} = \lim_{n\to\infty}\frac{1}{\cos n/e^n + 1} = \frac{1}{0+1} = 1.$$
