The chart shows that true conditional power gradually climbs from below 20% to about 50% in the *unfavorable zone* ($CP(\text{Dsgn.Events, Est.HR}) < 0.3$). The true conditional power receives a substantial boost in the *promising zone* ($0.3 \leq CP(\text{Dsgn.Events, Est.HR}) < 0.9$), because the **Required Events** jump from 334 to 501 in this zone. Now the conditional power climbs from slightly below 80% to slightly above 90%. There is a slight decline in the true conditional power upon entering the *favorable zone* $CP(\text{Dsgn.Events, Est.HR}) \geq 0.9$, for now the **Required Events** drop back to 334. However in this zone the true conditional power starts out at 82% and rapidly climbs up to well over 90%.

The conditional power chart is useful because it provides a good idea of the type of power one can expect, conditional on falling in the unfavorable, promising and favorable zones, even before any simulations are performed. The simulation results, to be discussed next, provide additional insights.

Table of Simulation Results by Zone

We have already seen in the **Simulation Outputs Without Adaptation** that if the underlying hazard ratio is 0.77 and there is no adaptive change to the number of events then the study only has about 66% power. The power can be improved by increasing the number of events. The traditional approach is to commit up-front to an increase in the number of events. This was the approach used for creating Des 3. We saw in Section 54.5.2 that while Des 3 does indeed have 90% power to detect a hazard ratio of 0.77, it requires a considerably larger up-front commitment of resources; 539 events to be obtained from 823 subjects enrolled over 24 months with 6 additional months of follow-up. A commitment of this magnitude based solely on limited phase 2 data from other trials was not feasible for the sponsor of the current study.

We now consider an alternative approach that has lower overall power than Des 3 under a hazard ratio of 0.77, but might be more acceptable to the sponsor. This is the adaptive approach in which the commitment of resources occurs in two stages with the second stage commitment forthcoming only if the first stage results are in the promising zone. We will evaluate the operating characteristics of this approach by generating 10,000 simulated trials.

CP Computation Based on:

Accrual Rate After Adaptation:

These inputs imply that the data for each of the 10,000 simulated trials will be generated from exponential distributions with a hazard ratio of 0.77, with patients arriving at the rate of 20.08/month, and no drop-outs. At the interim analysis, when 167 events have been observed, there will be an increase of resources **only if** the stage 1 conditional power lies in the promising zone (between 0.3 and 0.9). In that case, the maximum number of events will increase by 50%, from 334 to 501, and the maximum number of subjects will also increase by 50%, from 483 to 724.

To run the simulations, click the **Simulate** button. Save the overall Simulation output in the **Library**. This will get saved as **CHWSim1**. The Table of Simulation Results by Zone gets filled in and is displayed below as Figure 54.1

Figure 54.1: Simulation Results for 10,000 Trials of Des 1 with Adaptation at Look 1

Promising Zone defined as 0.3 <= CP < 0.9

This table displays five rows for tracking the outcomes of the 10,000 simulated clinical trials zone by zone, plus a sixth row that combines the results across all five zones. The entries in the table are self-explanatory. For comparison purposes run the simulations again, this time without adaptation. One simple way to do this is to set the two multipliers equal to 1. Edit the Simulation node **CHWSim1** by selecting it and clicking the  icon.

Make the two multipliers equal to 1 as shown below:

Max. # of Events if Adapt (multiplier; total #):

Max. Sample Size if Adapt (multiplier; total #):

The results from 10,000 simulations are re-computed, this time without any adaptation of events or sample size and are displayed below as Figure 54.2.

54 The Cui, Hung and Wang Method

Promising Zone defined as $0.3 \leq CP < 0.9$

Figure 54.1 displays the simulation based operating characteristics of the Des 1 with the adaptive option enabled while Figure 54.2 displays corresponding operating characteristics of Des 1 with the adaptive option disabled. Although Des 1 was designed under the optimistic assumption that the true hazard ratio is 0.7, both sets of simulations are performed under the pessimistic assumption that the true hazard ratio is 0.77. In order to conveniently compare the operating characteristics of the non-adaptive and adaptive designs, we have combined the relevant data from Figures 54.1 and 54.2 into a single table, Table 54.11.

Table 54.11: Operating Characteristics of Optimistic Design (Powered to Detect HR=0.7) under the Pessimistic Scenario (true HR=0.77)

| 10,000 Simulations Under the Pessimistic Scenario that HR = 0.77 | | | | | | | |
|--|---------|---------|-------|-------------------|-------|---------------|-------|
| Zone | P(Zone) | Power | | Duration (months) | | # of Subjects | |
| | | NonAdpt | Adapt | NonAdpt | Adapt | NonAdpt | Adapt |
| Unf+Fut | 29% | 30% | 31% | 27.8 | 27.8 | 468 | 468 |
| Prom | 34% | 68% | 86% | 29.3 | 33.9 | 483 | 724 |
| Fav+Eff | 37% | 93% | 92% | 26.3 | 26.3 | 452 | 451 |
| Total | — | 66% | 72% | 27.7 | 29.3 | 467 | 550 |

The fourth row of Table 54.11 displays the overall simulation results combined across all zones. The non-adaptive design has 66% power, average study duration of 27.7 months and an average sample size of 467 subjects. In contrast the adaptive design boosts the power by 7 percentage points to 73%, but requires average study duration of 29.34 months and an average sample size of 550 subjects. This is to be expected. If additional study duration and sample size resources are allocated to a trial, its power must increase.

It is more instructive to compare the results Table 54.11 by zone rather than overall. In

this type of comparison it is seen that the adaptive and non-adaptive designs behave identically (up to Monte Carlo accuracy) in the **Unfavorable+Futility** zone as well as in the **Favorable+Efficacy** zone. Both designs end up in the **Unfavorable+Futility** zone about 29% of the time and in that case both designs have similar power of about 30% with identical average study duration, and average number of subjects. Again, both designs end up in the **Favorable+Efficacy** zone about 37% of the time, and in that case they have about 93% power with practically identical average study duration and average number of subjects. In other words the adaptive design produces the same power and consumes the same resources as the conventional design if the interim result falls in either of these two zones. However, 34% of the time both designs end up in the **Promising: $0.3 \leq CP < 0.9$** zone, and where the adaptive design produces about 86% power whereas the non-adaptive design produces only 68% power. To be sure the adaptive design consumes more resources in the promising zone (study duration = 34 months versus 29.3 months; average events = 501 versus 334; average number of subjects = 724 versus 483), but these additional resources are worth spending since they can boost the power by about 20% and might make all the difference between a successful trial and a failure. In summary the adaptive design calls up the additional event and sample size resources only when they are needed and not otherwise.

Although the tables in Figure 54.1 and Figure 54.2 have partitioned the simulation results into three zones there are in fact five zones in the East output. The simulations in the **Unfavorable+Futility** zone are further separated into those simulations that were terminated for futility at the interim analysis and those that were unfavorable but did not cross the futility boundary. Similarly the simulations in the **Favorable+Efficacy** zone are further separated into those that crossed the efficacy boundary at the interim look and those that were favorable but did not cross the efficacy boundary.

The Table of Simulation Results by Zone as seen above for adaptive design:

☰ Zone-wise Averages

| Zone | Simulations Rejecting H0 | | Simulations Rejecting H1 | | Total Simulations | | Average Sample Size | Average Number of Events | Average Accrual Duration | Average Study Duration |
|---------------|--------------------------|----------|--------------------------|----------|-------------------|----------|---------------------|--------------------------|--------------------------|------------------------|
| | Count | Row % | Count | Row % | Count | Column % | | | | |
| ☐ Futility | 0 | 0.000% | 362 | 100.000% | 362 | 3.620% | 364.417 | 167 | 18.101 | 18.15 |
| ☐ Unfavorable | 909 | 35.608% | 1642 | 64.392% | 2550 | 25.500% | 483 | 334 | 24.005 | 29.228 |
| ☐ Promising | 2958 | 86.365% | 467 | 13.635% | 3425 | 34.250% | 724 | 501 | 30.067 | 33.911 |
| ☐ Favorable | 2380 | 89.239% | 287 | 10.761% | 2667 | 26.670% | 483 | 334 | 24.004 | 29.233 |

| ☐ All Trials | 7242 | 72.420% | 2758 | 27.580% | 10000 | 100.000% | 549.533 | 368.519 | 25.282 | 29.347 |

Promising Zone defined as $0.3 \leq CP < 0.9$

Examined in this way, it is seen that of the 2912 simulations entering the

54 *The Cui, Hung and Wang Method*

Unfavorable+Futility zone, only 362 (3.62%) stop early for futility. Of the 3663 simulations entering the **Favorable+Efficiency** zone, only 996 (9.96%) cross the efficacy boundary and stop early.

Table of Zone wise Percentiles

The Table of Simulation Results by Zone reports only the average number of events, sample size, accrual duration and study duration. One can examine the percentiles of the distributions of these statistics from the Table of Zone-Wise Percentiles. Double click the node named **CHWSim2** to see the detailed simulation output for adaptive

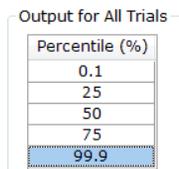

design.

| | Average | 368.519 | 549.533 | 25.282 | 29.347 | |

By default this table displays the 5th, 25th, 50th, 75th and 95th percentiles of the relevant distributions for all 10,000 trials. For example, the 95th percentile of the **Study Duration** for **all Trials** is displayed as 38.14 months.

54 The Cui, Hung and Wang Method

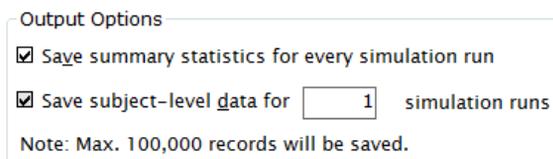

The 95% percentile of the study duration for trials that enter the promising zone, and therefore adapt, is 35.4 months. It might be of interest to know that how short and how long the study duration could be among the simulations that have entered the promising zone. To see this one may edit the **Percentile** column of small table named **Output for all Trials** on **Simulation Control Info** tab

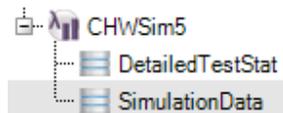

and run the simulations again. Observe the Promising zone table.

| | Zone | Percentile | Number of Events | Sample Size | Accrual Duration | Study Duration |
|---|-----------|------------|------------------|-------------|------------------|----------------|
| ⊖ | Promising | 0.100% | 501 | 724 | 27.855 | 31.172 |
| | | 25.000% | 501 | 724 | 29.583 | 33.343 |
| | | 50.000% | 501 | 724 | 30.06 | 33.925 |
| | | 75.000% | 501 | 724 | 30.537 | 34.561 |
| | | 99.900% | 501 | 724 | 32.243 | 36.942 |
| | | Average | 501 | 724 | 30.065 | 33.953 |

The 0.1 percentile of the study duration is 32 months while the 99.9 percentile is 37 months. East also provides the capability to store the summary statistics for every simulation run and the subject level data. This is achieved by checking off the following checkboxes

on the **Simulation Control Info** tab. When we keep this simulation output in the **Library**, two more nodes get saved under the simulation node as shown below:

Simulating Multiple Scenarios

The simulations that were performed in the earlier section were based on a multiplier of 1.5 for the maximum number of subjects, if an adaptation were to occur (cell 3 in the Table of Input Parameters). The choice of 1.5 was arbitrary. It is possible that a smaller multiplier might result in almost the same average study duration, and hence produce a more efficient design from the sponsor’s perspective. It would therefore be desirable to conduct several simulation experiments with different multipliers for the number of subjects. It is possible to conduct such multiple experiments from the **Sample Size Re-estimation** tab.

Edit the Simulations and click on **Sample Size Re-estimation** tab.

| | | | |

The inputs on this tab can be used to conduct simulation experiments over a range of multipliers for the maximum number of subjects, while keeping the multiplier for an adaptive increase in the number of events constant. The magnitude of the multiplier applied to the maximum number of subjects does not affect the power of the study but it does have a direct impact on the study duration. It is thus preferable to experiment with a range of multipliers so as to gain a better understanding of the relationship between maximum number of subjects and study duration in an adaptive design.

Suppose we wish to conduct simulation experiments over a range of sample sizes, with the **Max. Events if Adapt** multiplier fixed at 1.5.

54 The Cui, Hung and Wang Method

We may enter a range of multipliers for sample size into the field for **Max. Sample size if adapt** using the convention $x : y : z$ to denote entries ranging from x to y in steps of size z . Let us enter multiplier values for sample size ranging from 1.25 to 1.9 in steps of size 0.05. The complete input table will look like:

Adapt at:

Max. # of Events if Adapt (multiplier; total #):

Max. Sample Size if Adapt (multiplier; total #):

The above simulation output displays results for all 10,000 simulated trials. The column **Power** contains the overall power based on 10,000 simulated trials. It might be of greater interest to examine the results only for those trials that entered the promising zone and hence were adapted. The above simulation output also has some columns which correspond to the promising zone. These columns are **Power**

(Promising), Average Study Duration, Average Sample Size and Average Events.

These same simulation results for promising zone are also displayed graphically on the three charts shown below.

We have performed ten simulation runs with the **Maximum Number of Subjects if Adapt** input parameter ranging from 603 to 821. Let us analyze these outputs.

Power The **Power (Promising)** column show a relatively constant power of about 87% for the entire range of proposed values for **Maximum Number of Subjects if Adapt**. This is what one would expect in an event driven trial. The mild fluctuation in power that are observed are due to Monte Carlo sampling error.

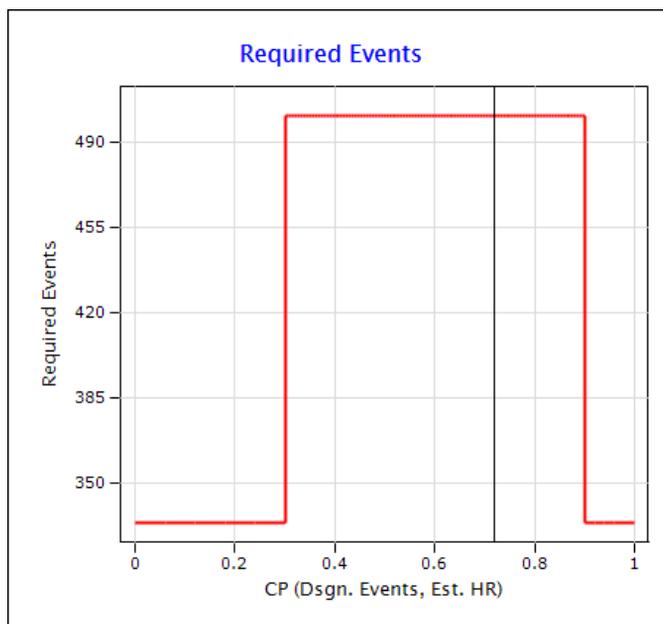

Average Number of Events The required number of events for trials that enter the promising zone is determined by the **Target CP**.

Target CP for Re-estimating # of Events:

Since the value of this parameter has been set to 0.99, the Required Events Chart displayed in the **Sample Size Re-estimation** tab is a step function with the

54 The Cui, Hung and Wang Method

constant value 501 for all value of conditional power in the promising zone.

Consequently the **Average Number of Events** for all trials in the promising zone is 501 regardless of the value of the **Maximum Number of Subjects if Adapt** parameter.

Average Sample Size Observe from the table of simulation results that the numbers in the **Maximum Sample Size if Adapt** column and the **Average Sample Size** are close to one another between 604 and 748. Thereafter the **Average Sample Size** level off to a constant value of 750 even though the **Maximum Sample Size if Adapt** continue to grow. The same behavior is evident in the Number of Subjects Chart which displays a 45 degree line for values between 603 and 748 on the X-axis and a horizontal line thereafter. This is so because the time that it takes for the 748 subjects to be enrolled is about 37 months and that is about the same as the average time that it takes for the required 501 events to arrive. Once 501 events have arrived, additional enrollment stops. Thus values on the Y-axis of the Number of Subjects Chart do not change after an average enrollment of 748 subjects.

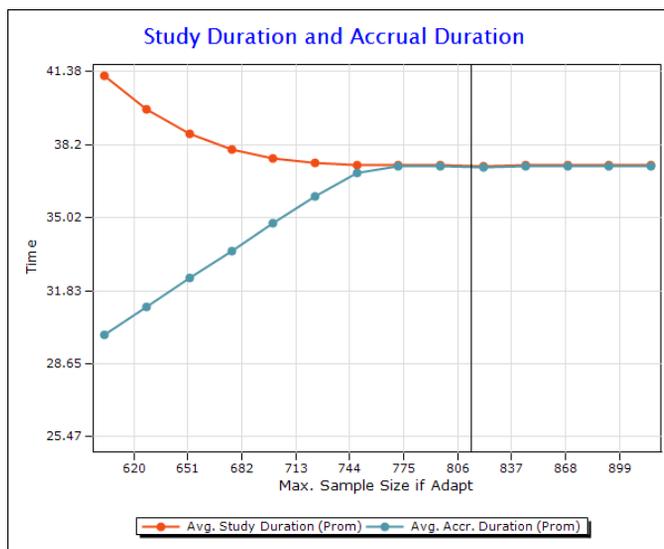

Average Study Duration As the magnitude of the **Maximum Number of**

Subjects if Adapt parameter increases, the **Average Study Duration** decreases. This is so because with increased accrual the required 501 events arrive earlier. Notice, however, from the Study Duration and Accrual Duration Chart as well as from the tabulated values in the **Average Study Duration** column that the rate of decrease in the average study duration continues to decline until it gradually comes to a halt at a value between 724 and 748 for the **Maximum Number of Subjects if Adapt** value on the X-axis. Thereafter the **Average Study Duration** value remains constant at 37 months even though the **Maximum Number of Subjects if Adapt** value continues to increase. This is so because on average by the time about 748 subjects have enrolled, the required 501 events will have arrived and the trial will be terminated.

Average Accrual Duration As the magnitude of the **Maximum Number of Subjects if Adapt** parameter increases, the **Average Accrual Duration** increase as well since more subject are being enrolled while the rate of accrual is constant. However, as seen from the Study Duration and Accrual Duration Chart, the rate of increase in **Average Accrual Duration** continues to decline until it comes to a halt at a value close to 748 for the **Maximum Number of Subjects if Adapt** value on the X-axis. Thereafter the **Average Accrual Duration** value remains constant at about 37 months even though the **Maximum Number of Subjects if Adapt** value continues to increase. This is so because on average by the time about 748 subjects have enrolled, the required 501 events will have arrived and further enrollment will be halted. Indeed, as can be seen on the Study Duration and Accrual Duration Chart, the graphs of **Average Study Duration** and **Average Accrual Duration** begin to converge and meet at a value of

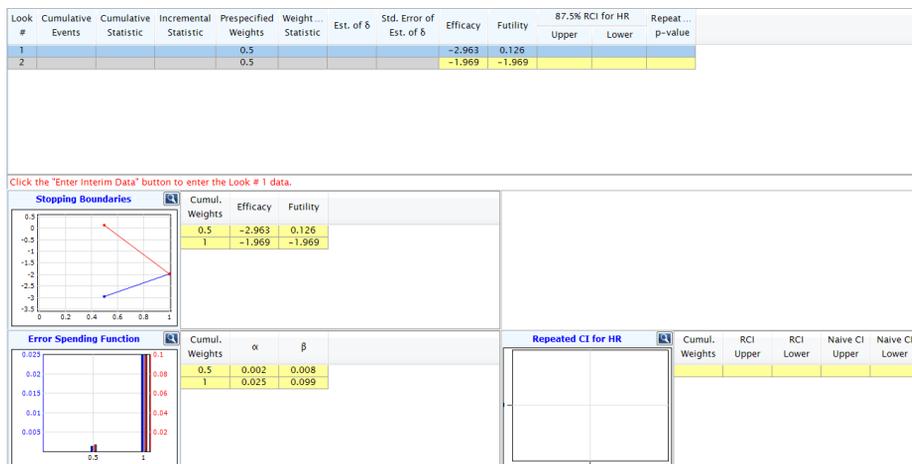

54 The Cui, Hung and Wang Method

about 772 subjects on the X-axis and 37 months on the Y-axis approximately.

54.5.4 Interim Monitoring

Now we will discuss the CHW interim monitoring procedure taking the example of Des 1. Select Des 1 in the **Library** and click on the icon  to create a CHW Interim Monitoring Dashboard for this design as shown below.

This dashboard differs from the usual interim monitoring dashboard for a classical group sequential trial in the following major ways: The Pre-specified Nominal Critical Points (stopping boundaries) are written into dashboard as soon as it is created, and are non-editable. Incremental Statistic value is derived at each look from Cumulative Events and Cumulative Statistic values of that look and the previous look, except at the first look, the Incremental Statistic value remains same as the Cumulative Statistic value. The weighted statistic is obtained by combining the incremental test statistics using Pre-specified Weights. In actual trial, the cumulative events at each look need not correspond to what was originally specified at the design stage. But if the cumulative events that correspond to the original study design are entered, then the weighted statistic is the same as the usual Wald statistic employed in conventional (non-adaptive) interim monitoring.

The values of cumulative test statistics $Z_{j,cum}^*$ at the interim look j are calculated by clicking on the **Enter Interim Data** button. This calculator uses as an input the estimates of the treatment effect $\hat{\delta}_j$ and estimated value of the standard error of $\hat{\delta}_j$. These values may be obtained by fitting a Cox proportional hazard model to the dataset available at look j or by calculating the Z-score based on the log-rank test statistics

54 The Cui, Hung and Wang Method

$Z_{j,LR}^*$ and using the following (approximating) expressions

$$\hat{\delta}_j^* = \frac{Z_{j,LR}^*}{\sqrt{r(1-r)D_j^*}} \quad (54.27)$$

$$Var(\hat{\delta}_j^*) = \frac{1}{r(1-r)D_j^*} \quad (54.28)$$

Here r is the proportion of subjects randomized to the active treatment group and D_j^* is the number of events observed at the look j .

Example: IM Inputs taken from the results of Cox proportional hazards model

Suppose the first look is taken as planned after an accrual of 167 events. Suppose we observe $\hat{\delta} = -0.288$ and a standard error of 0.236. The cumulative statistic at the first look is thus $(-0.288/0.236) = -1.220$. We enter these quantities into the Test statistic calculator as shown below. On pressing OK, the IM dashboard is updated with the first look computation.

 $\delta = \ln(\lambda_t / \lambda_c)$

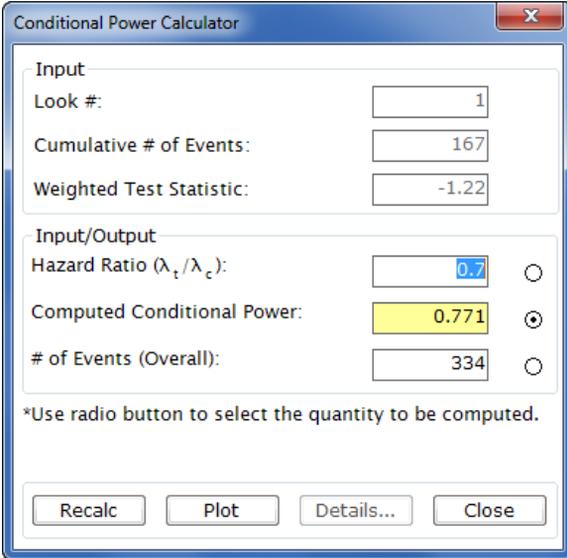

Standard Error of Estimate of δ :

Output

Weighted Statistic:
 Cumulative Statistic:

Recalc OK Cancel

Since the nominal critical value for early stopping is -2.963, the trial continues. We now need to decide on the sample size to use for the second and final look. We invoke the conditional power calculator to assist with this decision.

The screenshot shows a dialog box titled "Conditional Power Calculator". It has a blue title bar with a close button (X) in the top right corner. The dialog is divided into two main sections: "Input" and "Input/Output".

Input Section:

- Look #:
- Cumulative # of Events:
- Weighted Test Statistic:

Input/Output Section:

- Hazard Ratio (λ_t/λ_c):
- Computed Conditional Power:
- # of Events (Overall):

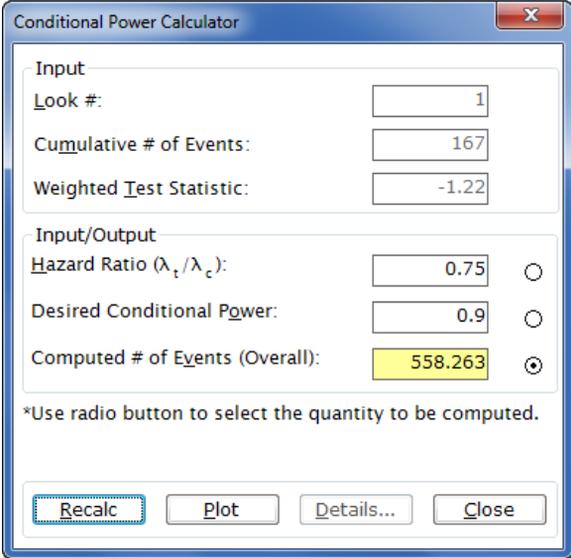

*Use radio button to select the quantity to be computed.

At the bottom of the dialog, there are four buttons: "Recalc", "Plot", "Details...", and "Close".

Suppose we specify to the calculator that we wish to obtain 90% conditional power to detect HR=0.75. Upon entering these terms into the calculator we obtain a final

54 The Cui, Hung and Wang Method

(overall) tally of 558.263 events.

The image shows a software dialog box titled "Conditional Power Calculator". It contains several input fields and radio buttons. The "Input" section has three fields: "Look #:" with value 1, "Cumulative # of Events:" with value 167, and "Weighted Test Statistic:" with value -1.22. The "Input/Output" section has three fields: "Hazard Ratio (λ_t/λ_c):" with value 0.75, "Desired Conditional Power:" with value 0.9, and "Computed # of Events (Overall):" with value 558.263. There are three radio buttons to the right of the Hazard Ratio, Desired Conditional Power, and Computed # of Events fields. A note below the radio buttons says "*Use radio button to select the quantity to be computed." At the bottom, there are four buttons: "Recalc", "Plot", "Details...", and "Close".

| Field | Value |
|---|---------|
| Look #: | 1 |
| Cumulative # of Events: | 167 |
| Weighted Test Statistic: | -1.22 |
| Hazard Ratio (λ_t/λ_c): | 0.75 |
| Desired Conditional Power: | 0.9 |
| Computed # of Events (Overall): | 558.263 |

Based on the guidance provided by the calculator, suppose we decide to continue the trial to observe 560 events by suitably increasing the sample size and the study duration.

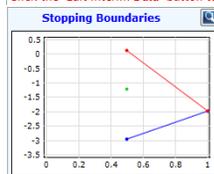

Suppose that, based on these 560 events, the estimate of delta is -0.272 corresponding to a HR value of 0.762 and the estimate of standard error of $\hat{\delta}$ as 0.135, leading to

cumulative test statistic of -2.015.

Upon pressing the OK button the cumulative statistic is entered into the interim monitoring dashboard, the incremental statistic and the weighted statistic are computed as -1.605 and -1.998 respectively. Since the weighted statistic exceeds the nominal critical value, the null hypothesis is rejected. The repeated confidence interval for HR is (0.697,0.996) and the repeated p-value is 0.023. These estimates are based on the methods described in Section 54.1 and are appropriately adjusted to preserve their validity in the face of adaptive sample size changes.

| Look # | Cumulative Events | Cumulative Statistic | Incremental Statistic | Prespecified Weights | Weight... Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | 87.5% RCI for HR | | Repeat... p-value |
|--------|-------------------|----------------------|-----------------------|----------------------|---------------------|-----------|-------------------------|----------|----------|------------------|-------|-------------------|
| | | | | | | | | | | Upper | Lower | |

| 2 | 560 | -2.015 | -1.605 | 0.5 | -1.998 | -0.272 | 0.135 | -1.969 | -1.969 | 0.996 | 0.697 | 0.023 |

Click the "Edit Interim Data" button to edit the Look # 2 data.

| Cumul. Weights | Efficacy | Futility |
|----------------|----------|----------|
| 0.5 | -2.963 | 0.126 |
| 1 | -1.969 | -1.969 |

54 The Cui, Hung and Wang Method

The above computations in the IM sheet were carried out using the formulas specified in section 54.2 as detailed below.

At the first look,

$$\hat{\delta}_1^* = -0.288, SE(\hat{\delta}_1^*) = 0.236, I_1^* = \frac{1}{[SE(\hat{\delta}_1^*)]^2} = 17.955, Z_{1,cum}^* = \frac{\hat{\delta}_1^*}{SE(\hat{\delta}_1^*)} = -1.22$$

By definition, for the first look, the incremental statistic and the weighted statistic are $Z^{*(1)} = Z_{1,CHW}^* = Z_{1,cum}^* = -1.22$

At the second look,

$$\hat{\delta}_2^* = -0.272, SE(\hat{\delta}_2^*) = 0.135, I_2^* = \frac{1}{[SE(\hat{\delta}_2^*)]^2} = 54.870, Z_{2,cum}^* = \frac{\hat{\delta}_2^*}{SE(\hat{\delta}_2^*)} = -2.015$$

The incremental statistic at the second look is

$$Z^{*(2)} = \frac{\sqrt{I_2^*} Z_{2,cum}^* - \sqrt{I_1^*} Z_{1,cum}^*}{\sqrt{I_2^* - I_1^*}} = -1.605$$

The weighted statistic

$$Z_{2,CHW}^* = \frac{\sqrt{w^{(1)}} Z^{*(1)} + \sqrt{w^{(2)}} Z^{*(2)}}{\sqrt{w^{(1)} + w^{(2)}}} = \frac{\sqrt{0.5}(-1.22) + \sqrt{0.5}(-1.605)}{\sqrt{0.5 + 0.5}} = -1.998$$

Example: IM Inputs taken from the results of Logrank test

Suppose the first look is taken after an accrual of 160 events. Further we apply Logrank test to the data, and obtain the value of χ_{1df}^2 to be 1.456 or equivalently $Z_1^* = \sqrt{1.456} = 1.2066$. The cumulative statistic at the first look is thus 1.2066. We will first estimate $\hat{\delta}$ and $SE(\hat{\delta})$ using the approximation formulas 54.27 and 54.28 and then use the test statistic calculator to post these values. Thus using the formulas,

$$\delta_1^* = \frac{Z_1^*}{\sqrt{r(1-r)D_1^*}} = \frac{1.2066}{\sqrt{0.5(1-0.5)160}} = \frac{1.2066}{6.3246} = 0.1908;$$

$$Var(\delta_1^*) = \frac{1}{r(1-r)D_1^*} = \frac{1}{0.5(1-0.5)160} = 0.025, SE(\delta_1^*) = \sqrt{0.025} = 0.1581.$$

Another way to estimate δ_1^* is

$$\delta_1^* = (Z_1^*)(SE(\delta_1^*)) = (1.2066)(0.1581) = 0.1908.$$

Now bring up CHW-IM dashboard, select the first look row and click on the **Enter Interim Data** button to input the look-wise information. Enter Cumulative Events as 160. Enter the value of $\hat{\delta}$ as -0.1908, the value of $SE(\hat{\delta})$ as 0.1581 and click on **Recalc** and then on **OK**. The values in the IM sheet for the first look will appear as shown below.

| Look # | Cumulative Events | Cumulative Statistic | Incremental Statistic | Prespecified Weights | Weight... Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | 87.5% RCI for HR | | Repeat ... p-value |
|--------|-------------------|----------------------|-----------------------|----------------------|---------------------|------------------|--------------------------------|----------|----------|------------------|-------|--------------------|
| | | | | | | | | | | Upper | Lower | |
| 1 | 160 | -1.207 | -1.207 | 0.5 | -1.207 | -0.191 | 0.158 | -2.963 | 0.126 | 1.32 | 0.567 | 0.263 |
| 2 | | | | 0.5 | | | | -1.969 | -1.969 | | | |

The values of cumulative, incremental and weighted statistics are all same as -1.207. Since the nominal critical value for early stopping is -2.963, the trial continues. We

now need to decide on the sample size to use for the second and final look. We invoke the conditional power calculator to assist with this decision.

The screenshot shows a dialog box titled "Conditional Power Calculator" with a close button (X) in the top right corner. The dialog is divided into two main sections: "Input" and "Input/Output".

Input Section:

- Look #: 1
- Cumulative # of Events: 160
- Weighted Test Statistic: -1.207

Input/Output Section:

- Hazard Ratio (λ_t/λ_c): 0.7 (radio button is unselected)
- Computed Conditional Power: 0.781 (radio button is selected, and the value is highlighted in yellow)
- # of Events (Overall): 334 (radio button is unselected)

Below the input/output section, there is a note: "*Use radio button to select the quantity to be computed."

At the bottom of the dialog, there are four buttons: "Recalc", "Plot", "Details...", and "Close".

Suppose we specify to the calculator that we wish to obtain 90% conditional power to detect HR=0.75. Upon entering these terms into the calculator we obtain a final

54 The Cui, Hung and Wang Method

(overall) tally of 555.0 events.

Based on the guidance provided by the calculator, suppose we decide to continue the trial to accrue 560 events by suitably increasing the number of subjects and the study duration. Suppose that, based on these 560 events, the estimate of Z_2^* from Logrank test is -2.135. Now as in the first look, we can estimate $SE(\hat{\delta})$ and $\hat{\delta}$ using the formulas 54.27 and 54.28.

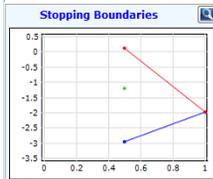

These estimates work out as

$SE(\hat{\delta}_2^*) = 0.0845$, the default value that appears in the test statistic calculator and $\hat{\delta}_2^* = (SE(\hat{\delta}_2^*))(Z_2^*) = (0.0845)(-2.135) = -0.1804$. Enter these values in the CHW IM dashboard. Now the cumulative statistic is entered into the interim monitoring dashboard, the incremental statistic and the weighted statistic are computed as -1.7624 and -2.0995 respectively. Since the weighted statistic exceeds the nominal critical value, the null hypothesis is rejected. The repeated confidence interval for HR is (0.6921, 0.9887) and the repeated p-value is 0.0182. These estimates are based on the methods described in Section 54.1 and are appropriately adjusted to preserve their

validity in the face of adaptive sample size changes.

| Look # | Cumulative Events | Cumulative Statistic | Incremental Statistic | Prespecified Weights | Weight... Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | 87.5% RCI for HR | | Repeat... p-value |
|--------|-------------------|----------------------|-----------------------|----------------------|---------------------|------------------|--------------------------------|----------|----------|------------------|-------|-------------------|
| | | | | | | | | | | Upper | Lower | |
| 1 | 160 | -1.207 | -1.207 | 0.5 | -1.207 | -0.191 | 0.158 | -2.963 | 0.126 | 1.32 | 0.567 | 0.263 |

| 1 | -1.969 | -1.969 |

East 6

Since the value of weighted statistic is \leq the critical point for efficacy, H_0 is rejected.

OK

55

The Chen, DeMets and Lan Method

Two objections are sometimes leveled at the CHW method discussed in Chapter 54. They both relate to the use of the CHW statistic (54.2) instead of the classical Wald statistic (54.3) or its variant (54.4) for performing the hypothesis tests. Specifically, it is felt by some statisticians that the incremental Wald statistics $(Z^{*(1)}, Z^{*(2)}, \dots, Z^{*(K)})$ generated at the K stages should be combined by utilizing weights derived from the actual sample sizes $(n_1^*, n_2^*, \dots, n_K^*)$ at each stage rather than by weights that depend on the pre-specified sample sizes (n_1, n_2, \dots, n_K) . There is a concern that if the actual number of subjects entering the trial differs from the number pre-specified at the start of the trial, then the use of pre-specified weights will distort the scientific contribution of each cohort entering the trial. This is a philosophical rather than statistical objection, since the use of pre-specified weights controls the type-1 error in the presence of sample size changes, whereas the use of actual weights, in general, does not. It has, however, led to some interesting theoretical research on the loss of efficiency resulting from use of the CHW statistic. (See, for example, Tsiatis and Mehta, 2003; Jennison and Turnbull, 2006). In practice, the magnitude of the adaptive sample size increase is seldom greater than two-fold and within this limit, the loss of efficiency is rather small. Indeed some of the EastAdapt tools described in the present chapter will show that in most practical settings, the loss of efficiency is negligible.

This chapter discusses a method proposed by Chen, DeMets and Lan (2004) (the CDL method) for making sample size modifications to an ongoing trial and then performing the interim monitoring and final analysis with the classical Wald statistic rather than the weighted CHW statistic. The method is further extended to a more general setting by Gao, Ware and Mehta (2008) (the extended CDL method). The main limitation of these two methods is that they are only applicable if the sample size is altered at the penultimate stage of a K -stage group sequential trial. Thus, for simplicity, we will illustrate the methods for two-stage trials only. Furthermore, in the current implementation of East, they are only applicable if the sample size is increased adaptively, but not if it is decreased.

This chapter pre-supposes familiarity with the CHW method and examples presented in Chapter 54. The same three designs, normal (schizophrenia example), binomial (acute coronary syndromes example) and survival (lung cancer example), that were used to illustrate the CHW method in Chapter 54 will be re-visited in the present chapter. Thus some of the steps used to construct these designs in East may be skipped since they will have already been presented in Chapter 54.

55.1 The CDL Method

55.1.1 Normal Endpoint

55.1.2 Binomial Endpoint

55.1.3 Survival Endpoint

Consider a two-sided level- α test of the null hypothesis

$$H_0: \delta = 0$$

versus the two-sided alternative hypothesis

$$H_1: \delta \neq 0$$

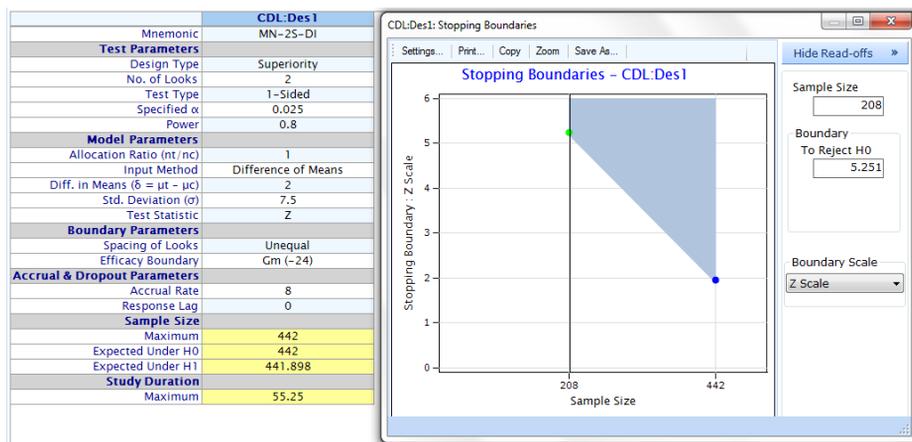

for a two-arm randomized clinical trial. We assume that the null hypothesis will be tested by a two-look group sequential trial with cumulative sample sizes (n_1, n_2) and stopping boundaries (b_1, b_2) derived from some level- α spending function. The data will be examined at the end of look 1 and the sample size for the remainder of the trial may then be changed. Ordinarily if the sample size is changed in a data dependent manner in the middle of a trial, we would be obliged to use the CHW weighted statistic (54.2) described in Chapter 54 instead of the conventional Wald statistic (54.3) for the final analysis, in order to preserve the type-1 error. Intuitively, however, it could be argued that if under the null hypothesis the interim value of the test statistic is large, then it would stand a better chance of regressing to the mean if the sample size of the second stage was increased. Therefore a sample size increase would make it more difficult to achieve statistical significance at the final analysis. Chen, DeMets and Lan (2006) have formalized this intuition by demonstrating mathematically that if the conditional power at the interim look, evaluated at the **estimated** value $\hat{\delta}$ obtained at the interim analysis, is at **least 50%**, one can increase the sample size for the remainder of the trial and still use the conventional Wald statistic for the final analysis, **and the type-1 error won't be inflated thereby**. This important result makes it possible to design two-stage adaptive trials in which the sample size may be increased in a data dependent manner at the interim look, but all the conventional methods of obtaining p-values, confidence intervals and point estimates, available in standard software packages, are applicable at the time of the final analysis.

The above CDL result applies only to a sample size increase and not to a sample size decrease. In order to use the conventional statistic under a sample size decrease the reverse condition must hold. That is, if the conditional power is **no greater than 50%** at the interim look, the sample size can be decreased and the conventional Wald statistic can be used for the final analysis without inflating the type-1 error. However, the discussion in this chapter focuses on sample size increases only. This is entirely in keeping with the recommendations in the FDA Guidance on Adaptive Design (2010) where the use of adaptive methods to decrease sample size is discouraged.

55 The Chen, DeMets and Lan Method

55.1.1 Normal Endpoint: Schizophrenia Trial

We will apply the CDL method to the Schizophrenia trial discussed in detail in Chapter 54. The starting point is a two-look design enrolling 442 subjects, with an interim look planned after obtaining data on 208 completers. The trial is designed to test the null hypothesis $\delta = 0$ versus the one-sided alternative that $\delta > 0$. The standard deviation is assumed to be $\sigma = 7.5$. As the only purpose of the interim analysis is to re-estimate the sample size, but not to stop early, we use the conservative $\gamma(-24)$ spending function (Hwang, Shih and DeCani, 1990) to obtain the efficacy stopping boundary for the interim look. Thereby the amount of type-1 error spent at the interim look is negligible and practically the entire $\alpha = 0.025$ is available for the final analysis. With these specification the trial has just over 80% power to detect $\delta = 2$.

As pointed out in Chapter 54, the true value of δ which might actually be less than 2. It is thus possible that this trial is underpowered at a sample size of 442. We can, however, examine the data at the interim look and estimate the conditional power, and increase the sample size if the conditional power falls in a promising zone. The approach is identical to that discussed in Chapter 54 for the CHW design. We partition the sample space into following zones - futility, unfavorable, promising, favorable and efficacy, based on the conditional power attained at the interim look. The sample size may then be increased if the interim results fall inside the promising zone, thereby recovering the lost power. The additional feature of the CDL design is, however, that if conditional power at the interim look is at least 50% it is not necessary to use the CHW statistic at the final analysis. The conventional Wald statistic may then be used without inflating the type-1 error. We shall study the operating characteristics of the above CDL design through simulation. The option for choosing CDL method for adaptation

is on the **Sample Size Re-estimation** tab. We call the CDL simulations by clicking on the radio-button for CDL, the resulting simulation input window will appear as shown below.

| | |
|--|--|
| Use Adaptation Method | |
| <input type="radio"/> CHW | <input checked="" type="radio"/> CDL |
| <input type="radio"/> Müller and Schäfer | |
| Adapt at: | Look # <input type="text" value="1"/> |
| Max. Sample Size if Adapt (multiplier; total #): | <input type="text" value="1"/> <input type="text" value="442"/> |
| Upper Limit on Study Duration: | <input type="text" value="165.75"/> |
| Target CP for Re-estimating Sample Size: | <input type="text" value="0.8"/> |
| Use Wald Stat. if CP >= | <input type="text" value="0.5"/> |
| Promising Zone Scale: | Cond. Power <input type="text" value="CP"/> |
| Promising Zone: | Min. CP: <input type="text" value="0.3"/> Max. CP: <input type="text" value="0.8"/> |
| CP Computation Based on: | Estimated δ/σ <input type="text"/> |
| Accrual Rate After Adaptation: | No Change <input type="text"/> |

The inputs on this window are almost the same as those for CHW simulations which was described in detail in Chapter 54.

Most of the entries are self-explanatory. Those that need special explanation are listed below. **All the conditional power calculations mentioned below will be performed at the estimated value, $\delta/\hat{\sigma}$, obtained at the time of the interim analysis.**

Min and Max CP: This range partitions the interim result into unfavorable, promising and favorable zones based on conditional power (CP). If the conditional power at the interim look, under the original sample size, falls in this range then the interim result is deemed to be promising and the sample size is re-estimated according to criteria specified in the remaining cells.

Max Sample Size if Adapt, multiplier : Use this cell to specify the cap for the re-estimated sample size. Since, we don't allow decrease in sample size after adaptation, the minimum sample size is the one coming from the study design. This interval [Min. Sample Size and Max. Sample Size] defines the range of re-estimated sample size after adaptation.

55 The Chen, DeMets and Lan Method

Use Wald Statistic if $CP(n_1) \geq$: The entry in this cell determines when to use the conventional Wald statistic and when to use the CHW statistic for the final analysis. The default entry is 0.5. Thus if the conditional power at the interim analysis is at least 50%, the simulations will use the conventional Wald statistic for the final analysis. Otherwise the CHW statistic will be used. The CDL method will preserve the type-1 error as long as this entry is at least 0.5. We shall show subsequently that by applying the Gao, Ware and Mehta (2008) extension, the probability in this cell can be lowered without inflating the type-1 error.

Target Conditional Power for Re-estimating Sample Size: This entry is the primary driver for the new sample size. It specifies what conditional power is desired at the end of the study. The sample size for the remainder of the trial is changed accordingly, subject to the constraints placed upon it by the **Max Sample Size if Adapt** cell.

Suppose, for example, that we wish to run 100,000 simulations at $\delta = 1.6$ and $\sigma = 7.5$, and to increase the sample size only if the conditional power at the interim analysis under the original sample size is between 0.5 and 0.9. And in that case suppose that we wish to increase the sample size by just the right amount so that the conditional power is boosted to 0.95. Furthermore suppose that the re-estimated sample size is constrained to remain between 442 and 884 subjects. To run the simulations with these specifications we would change the entries in the **Response Generation Info** tab, the **Sample Size Re-estimation** tab and the **Simulation Control Info** tab as shown below

The **Response Generation Info** tab:

|---------|-------------------------|-------------------|
| 1 | 208.001 | 25.943 |
| 2 | 530.321 | 66.142 |
| Average | 530.263 | 66.135 |

☉ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Efficacy | Count |
| 1 | 208 | 5.251 | 18 | 18 | 0.018% |
| 2 | 442 | 1.96 | 66445 | 99982 | 99.982% |
| Total | | | 66463 | 100000 | |
| % | | | 66.463% | | |

The null hypothesis was rejected 66,463 times in 100,000 trials for an overall power of 66.46%. The average sample size was 530.26. In contrast, if there is no sample size increase, the power would be 61% and the average sample size would be 442. This can be verified by setting the multiplier for Max. Sample Size if Adapt to 1 on **Sample Size Re-estimation** tab. This is not the full story, however. As discussed in Chapter 54, one of the major appeals of an adaptive design is the ability to invest in stages, with the additional sample size investment being required only if the interim result falls in the promising zone. From this point of view it is of interest to examine the power and expected sample size conditional on being in the unfavorable, promising and favorable zones. The top part of the simulation output shows that the trial falls into the promising zone, and thereby undergoes an adaptive sample size increase, in 25,030 of the of 100,000 simulations (25.03%). Moreover 90% of these simulated trials go on to reject the null hypothesis. This is a significant boost to the power of the study, conditional on having a favorable interim outcome. The simulation results are

displayed zone by zone as shown below.

☰ Zone-wise Averages

| | Promising | 22543 | 90.064% | 2487 | 9.936% | 25030 | 25.030% | 794.799 |
| ☰ | Favorable | 29503 | 90.256% | 3185 | 9.744% | 32688 | 32.688% | 442 |
| | Efficacy | 18 | 100.000% | 0 | 0.000% | 18 | 0.018% | 208 |
| | All Trials | 66463 | 66.463% | 33537 | 33.537% | 100000 | 100.000% | 530.263 |

Promising Zone defined as 0.5 <= CP < 0.9

The expected sample size of all the trials that undergo a sample size increase is 794.799. Although this is considerably greater than the overall average of 530.263, it is important to recognize that a sample size increase is only requested if a trial enters the promising zone at the interim look. In that case, the prospects of success become extremely promising (90 % power) and hence, the sponsor or investor might be willing to make the additional investment. The alternative approach, to commit a large sample size at the very beginning, before any interim results have been observed, might not be as attractive.

In the above figure, observe that trials fall into the favorable zone (conditional power at least 90%) 32.688% of the time. For such trials the success rate is 90.256%, and no sample size increase is called for. Trials fall into the unfavorable zone 42.264% of the time and only 34.069% of such trials go on to succeed. In this design, the adaptive option is invoked only 25.03% of the time, but once invoked, it greatly improves the chances of success. This example has highlighted the importance of evaluating any proposed adaptive strategy by simulation before adopting it. One should look at the operating characteristics of the proposed adaptive design over the entire range of plausible parameter values in order to determine if the rules for sample size increase are acceptable. If the operating characteristics are not satisfactory, it would be necessary to perform similar simulation experiments with a different adaptive strategy for sample size change. In this manner it is possible to converge to an acceptable design.

It is interesting to simulate the trial under the null hypothesis and verify that the type-1 error is indeed preserved. Accordingly set the **Mean Treatment** μ_t cell in

55 The Chen, DeMets and Lan Method

Response Generation Info tab to 0. The other simulation parameters are unchanged.

| | | |
|-----------------------------|--------------------------------|---|
| Generate Data Using: | Individual Means | <input checked="" type="checkbox"/> Common Standard Deviation |
| Mean Control (μ_c): | <input type="text" value="0"/> | SD Control (σ_c): <input type="text" value="7.5"/> |
| Mean Treatment (μ_t): | <input type="text" value="0"/> | SD Treatment (σ_t): <input type="text" value="7.5"/> |

The results based on 100,000 simulated trials are displayed below.

⊖ **Average Sample Size and Look Times**

| Look # | Average Sample Size (n) | Average Look Time |
|---------|-------------------------|-------------------|
| 1 | 208.001 | 25.941 |
| 2 | 466.652 | 58.199 |
| Average | 466.652 | 58.199 |

⊖ **Simulation Boundaries and Boundary Crossing Probabilities**

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|----------|
| | | Efficacy | Efficacy | Count | % |
| 1 | 208 | 5.251 | 0 | 0 | 0.000% |
| 2 | 442 | 1.96 | 2426 | 100000 | 100.000% |
| Total | | | 2426 | 100000 | |
| % | | | 2.426% | | |

It is seen that only 2426 of the 100,000 trials rejected the null hypothesis, for an overall type-1 error of 2.426%. The type-1 error was thus preserved.

Suppose, in order to provide the maximum opportunity to increase the sample size we set the **Promising Zone: Min.CP** to 0, in addition to setting **Mean**

55 The Chen, DeMets and Lan Method

CP (442) >= cell from 0.5 to 0.0 as shown below and run simulations.

| Total | | | 2590 | 100000 | |
| % | | | 2.590% | | |

Of 100,000 simulated trials a total of 2590 rejected the null hypothesis, for a type-1 error of 2.59%. This shows that the CDL constraint is indeed necessary.

55.1.2 Binomial Endpoint: Acute Coronary Syndromes Trial

Consider a two-arm, placebo controlled randomized clinical trial for subjects with acute cardiovascular disease undergoing percutaneous coronary intervention (PCI), which we discussed in Section 54.4. The primary endpoint in this study is a composite of death, myocardial infarction or ischemia-driven revascularization during the first 48 hours after randomization. We assume on the basis of prior knowledge that the event rate for the placebo arm is 8.7%. The investigational drug is expected to reduce the event rate by at least 20%. The investigators are planning to randomize a total of 8000 subjects in equal proportions to the two arms of the study.

As explained in the beginning of this chapter, for applying CDL method, a 2 look group sequential design will suffice, without loss of generality.

It is easy to show that a group sequential design enrolling a total of 8000 subjects with an interim look after 4000 subjects are enrolled (50% of total information), will have 82% power to detect a 20% risk reduction with a one-sided level-0.025 test of significance, and early stopping efficacy boundary derived from the Lan and DeMets (1983) O'Brien-Fleming type error spending function.

55 The Chen, DeMets and Lan Method

The actual risk reduction is expected to be larger, but could also be as low as 15%, a treatment effect that would still be of clinical interest given the severity and importance of the outcomes. In addition, there is some uncertainty about the magnitude of the placebo event rate. For these reasons the investigators wish to build into the trial design some flexibility for adjusting the sample size. Two options under consideration are, a group sequential design with the possibility of early stopping in case the risk reduction is large, and an adaptive design with the possibility of increasing the sample size in case the risk reduction is small. In the remainder of this section we shall discuss these two options and show how they may be combined into a single design that captures the benefits of both.

For this design, where the risk reduction is 20%; the probabilities of crossing boundary at Look1 (N=4000) is 0.181, and at Final Look 0.644; the overall power is 82%.

As we did in chapter 54, we partition the sample space into three important zones, unfavorable, promising and favorable, based on the conditional power attained at the interim look. The sample size may then be increased if the interim results fall inside the promising zone, thereby recovering the lost power. The additional feature of the CDL design is, however, that if conditional power at the interim look is at least 50% it is not necessary to use the CHW statistic at the final analysis. The conventional Wald statistic may then be used without inflating the type-1 error.

Adaptive Group Sequential Design We convert the two-look group sequential design Des 1 into an adaptive group sequential design to increase the sample size at look 1, when 4000 subjects have been enrolled. The rules governing the sample size increase similar to the rules specified in Section 55.1.1 for the schizophrenia trial. We shall study the operating characteristics of the above CDL design through simulation. The option for choosing CDL method for adaptation is on the **Sample Size Re-estimation** tab. We invoke the CDL simulation by clicking on the radio-button for

CDL, The resulting simulation input window will appear as shown below.

| | | | |
|--|--------------------------------------|--|----|
| Use Adaptation Method | | | |
| <input type="radio"/> CHW | <input checked="" type="radio"/> CDL | <input type="radio"/> Müller and Schäfer | |
| Adapt at: | Look # | 1 | |
| Max. Sample Size if Adapt (multiplier; total #): | 1 | 8000 | |
| Target CP for Re-estimating Sample Size: | 0.825 | | |

| Promising Zone: | Min. CP: | 0.3 | |
| | Max. CP: | 0.825 | |
| CP Computation Based on: | Estimated (n_c, n_t) | | |

The inputs on this window are almost the same as those for CHW simulations which was described in detail in Chapter 54.

Most of the entries are self-explanatory. Those that need special explanation are similar to what have been described in section 55.1.1 for schizophrenia example. **All the conditional power calculations mentioned below will be performed at the estimated value, π_c, π_t , obtained at the time of the interim analysis.**

Suppose, for example, that we wish to run 100,000 simulations at risk reduction $\rho = 0.15$ and to increase the sample size only if the conditional power at the interim analysis under the original sample size is between 0.5 and 0.9. And in that case suppose that we wish to increase the sample size by just the right amount so that the conditional power is boosted to 0.95. Furthermore suppose that the re-estimated sample size is constrained to remain between 8000 and 16000 subjects. To run the simulations with these specifications we would change the entries in the three tabs as shown below.

observe the detailed output.

⊖ Average Sample Size

| Look # | Average Sample Size (n) |
|---------|-------------------------|
| 1 | 4000 |
| 2 | 9731.685 |
| Average | 9318.603 |

⊖ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Count | % |
| | | Lower | Efficacy | | |
| 1 | 4000 | -2.963 | 7207 | 7207 | 7.207% |
| 2 | 8000 | -1.969 | 55185 | 92793 | 92.793% |
| Total | | | 62392 | 100000 | |
| % | | | 62.392% | | |

The null hypothesis was rejected 62,392 times in 100,000 trials for an overall power of 62.4%. The average sample size was 9318.60. In contrast, if there is no sample size increase, the power would be 57.2% and the average sample size would be 7703.1. Next, let us consider these results zone by zone. As discussed in Chapter 54, one of the major appeals of an adaptive design is the ability to invest in stages, with the additional sample size investment being required only if the interim result falls in the promising zone. From this point of view it is of interest to examine the power and expected sample size conditional on being in the unfavorable, promising and favorable zones. The bottom part of the simulation output shows that the trial falls into the promising zone, and thereby undergoes an adaptive sample size increase, in 24,944 of the of 100,000 simulations (24.94%). Moreover 87.98% of these simulated trials go on to reject the null hypothesis. This is a significant boost to the power of the study,

55 The Chen, DeMets and Lan Method

conditional on having a favorable interim outcome.

Zone-wise Averages

| Promising Zone defined as $0.5 \leq CP < 0.9$ | | | | | | | | |

The expected sample size of all the trials that undergo a sample size increase is 14,441.961. Although this is considerably greater than the overall average of 9,318.603, it is important to recognize that a sample size increase is only requested if a trial enters the promising zone at the interim look. In that case, the prospects of success become extremely promising (87.98% power) and hence, the sponsor or investor might be willing to make the additional investment. The alternative approach, to commit a large sample size at the very beginning, before any interim results have been observed, might not be as attractive. The simulation results are also displayed zone by zone as shown below.

Observe that trials fall into the Favorable + Efficacy zone (conditional power at least 90%) 29.97% of the time. For such trials the success rate is 82.19%, and no sample size increase is called for. Trials fall into the unfavorable zone 45.08% of the time and only 35.08% of such trials go on to succeed. In this design the adaptive option is invoked 24.94% of the time, and once invoked, it greatly improves the chances of success. This example has highlighted the importance of evaluating any proposed adaptive strategy by simulation before adopting it. One should look at the operating characteristics of the proposed adaptive design over the entire range of plausible parameter values in order to determine if the rules for sample size increase are acceptable. If the operating characteristics are not satisfactory it would be necessary to perform similar simulation experiments with a different adaptive strategy for sample size change. In this manner it is possible to converge to an acceptable design.

It is interesting to simulate the trial under the null hypothesis and verify that the type-1 error is indeed preserved. Accordingly set the **Proportion Under Treatment** cell in **Response Generation Info** tab to **Proportion Under Control**. The

other simulation parameters are unchanged.

Promising Zone defined as 0 <= CP < 0.9

Of 100,000 simulated trials a total of 2616 rejected the null hypothesis, for a type-1 error of 2.62% which is slightly inflated. This shows that the CDL constraint is indeed necessary.

55.1.3 Survival Endpoint: Lung Cancer Trial

Let us re-visit the non-small cell lung cancer trial introduced in Section 54.5 of Chapter 54. This is a two-arm multi-center randomized clinical trial for subjects with advanced metastatic non-small cell lung cancer comparing the current standard second line therapy (docetaxel+cisplatin) to a new docetaxel containing combination regimen. The primary endpoint is overall survival (OS). The study is required to have one-sided $\alpha = 0.025$, and 90% power to detect an improvement in median survival, from 8

months on the control arm to 11.4 months on the experimental arm, which corresponds to a hazard ratio of 0.7. We shall first create a group sequential design for this study in East, and shall then show how the design may be improved by permitting an increase in the number of events and sample size at the time of the interim analysis.

Following the steps exactly as outlined in Section 54.5.1 of Chapter 54 we create a 2-look group sequential design with an efficacy boundary derived from the Lan and DeMets (1983) O'Brien-Fleming type spending function, a futility boundary derived from the γ -spending function of Hwang, Shih and DeCani (1990) with parameter $\gamma = -5$, and an interim analysis at 50% of the total information. It is planned to enroll subjects over 24 months and extend the follow-up for six additional months, thereby completing the study in 30 months. This design is created in East and displayed below

| 1 | 24 | 100 |

Variable Follow-Up Design: All subjects are followed until failure, drop out or end of study.

Des1 requires an up-front commitment of 334 events to achieve 90% power. With an enrollment of 483 subjects over 24 months, the required 334 events are expected to arrive within 30 months. An interim analysis will be performed after 167 events are obtained (50% of the total information). Under the alternative hypothesis that the

hazard ratio is 0.7, the chance of crossing the efficacy boundary at the interim look is about 26% leading to an expected sample size of 454 subjects and an expected study duration of about 27 months.

⊖ Sample Size Information

| | Control Arm | Treatment Arm | Total |
|------------------------------|-------------|---------------|---------|
| Sample Size (n) | | | |

| Expected H1 | 162.827 | 135.155 | 290.11 |
| Expected H0 | 130.437 | 130.437 | 258.635 |
| Maximum Information (I):83.5 | | | |

⊖ Accrual and Study Duration

| | Accrual Duration | Study Duration |
|-------------|------------------|----------------|
| Maximum | 24 | 29.984 |
| Expected H1 | 22.543 | 26.954 |
| Expected H0 | 20.954 | 22.92 |

Although Des1 is adequately powered to detect a hazard ratio of 0.7, its power deteriorates from 90% to below 68% if the true hazard ratio is 0.77, an effect that is still considered clinically meaningful. To see this let us simulate Des1 under HR=0.77.

Select Des1 in the **Library** and click the **S** icon. You will be taken to the usual simulation input window. This has four tabs as below:

Simulation Parameters Response Generation Info Accrual/Dropout Info Sample Size Re-estimation Simulation Control Info

The use of four tabs **Simulation Parameters**, **Response Generation Info**, **Accrual/Dropout Info** and **Simulation Control Info** is exactly same as that explained

55 The Chen, DeMets and Lan Method

in sections of CHW Simulations.

You may refer to Chapter 54, Section 54.5.3 for a complete description of their functioning. The fourth tab, **Sample Size Re-estimation**, is almost identical to the corresponding tab for CHW simulations but contains **one** additional input parameter that distinguishes the CDL method from the CHW method for adaptive design. We will assume for the remainder of this section that the user is familiar with the CHW simulation worksheet. If not, please refer to Section 54.5.3 of Chapter 54 where this worksheet was fully discussed with a worked example.

Observe that the **Response Generation Info** tab currently displays a hazard ratio of 0.7, since this was the value specified at the design stage.

| Survival Information | | | | |
|--|-------------|--------------|-----------|--------------|
| <input checked="" type="radio"/> Using Hazard Rates <input type="radio"/> Using Cum. % Survival | | | | |
| # of Hazard Pieces <input type="text" value="1"/> | | | | |
| Piece | Starting At | Hazard Rates | | Hazard Ratio |
| | | Control | Treatment | |
| 1 | 0.000 | 0.0866 | 0.061 | 0.700 |

We know from the design of Des1 that a hazard ratio of 0.7 will yield 90% power. But what if the true hazard ratio was 0.77? The resultant deterioration in power can be evaluated by simulation. Accordingly we shall alter the Treatment cell, containing the hazard 0.0607, by replacing it with $0.77 * 0.0866 = 0.0667$.

| Survival Information | | | | |
|--|-------------|--------------|-----------|--------------|

| Total | | | | 6631 | 3369 | 10000 | |
| % | | | | 66.310% | 33.690% | | |

⊖ Response Generation Parameters

No. of Hazard Pieces: 1
Input Method: Median Survival Times

| Piece # | Control | Treatment | Ratio |
|---------|---------|-----------|-------|
| 1 | 8 | 10.39 | 0.77 |

⊖ Accrual/Dropout Parameters

Sample Size: 483
Subjects are Followed: Until End of Study
Accrual Duration: 24
Accrual Input Method: Cum. Accrual %

| Period # | By Time | Cum. % Accrued |
|----------|---------|----------------|
| 1 | 24 | 100 |

The overall power is only 66.31% suggesting that it might be useful to consider an adaptive increase in the number of events and sample size at the interim look.

The impact of an adaptive increase in the number of events and sample size on power and study duration can be evaluated by simulation. Accordingly click on the **Sample Size Re-estimation** tab and select the option of **CDL** on this tab. This will take you to

55 The Chen, DeMets and Lan Method

the input parameters for performing the adaptive simulations using CDL method.

| | |
|--|--|
| Use Adaptation Method | |
| <input type="radio"/> CHW | <input checked="" type="radio"/> CDL |
| <input type="radio"/> Müller and Schäfer | |

Target CP for Re-estimating # of Events:

Use Wald Stat. if CP >=

Promising Zone Scale:

Promising Zone: Min. CP: Max. CP:

CP Computation Based on:

Accrual Rate After Adaptation:

These inputs imply that there will be a 50% increase in the number of events for each simulation that enters the promising zone and up to a 50% increase in the sample size also. The promising zone is specified by conditional power (based on estimated HR) being between 0.3 and 0.9. These adaptation rules are the same as the adaptation rules applied in Section 54.5.3 of Chapter 54. However, the test statistic to be used for the final analysis will depend on the CP observed at the interim look. If this CP exceeds 0.5, the conventional Wald statistic (equation (54.3) in Chapter 54) will be used for the final analysis, whereas if this CP is below 0.5, the weighted CHW statistic (equation (54.2) in Chapter 54) will be used for the final analysis. Upon pressing the **Simulate** button the following outputs are obtained in the Table of Simulation Results by Zone

Zone-wise Averages

| All Trials | 7263 | 72.630% | 2737 | 27.370% | 10000 | 100.000% | 549.822 | 368.719 | 27.249 | 30.508 |

Promising Zone defined as 0.3 <= CP < 0.9

55 The Chen, DeMets and Lan Method

and in the Table of Output for all Trials.

⊖ Zone-Wise Percentiles

| | Zone | Percentile | Number of Events | Sample Size | Accrual Duration | Study Duration |
|---|-------------|------------|------------------|-------------|------------------|----------------|
| + | Futility | Average | 167 | 364.134 | 18.042 | 18.095 |
| + | Unfavorable | Average | 334 | 483 | 23.95 | 29.193 |
| + | Promising | Average | 501 | 723.946 | 35.874 | 37.344 |
| + | Favorable | Average | 334 | 483 | 23.95 | 29.261 |
| + | Efficacy | Average | 167 | 365.519 | 18.068 | 18.119 |
| ⊖ | All Trials | 5.000% | 167 | 360 | 17.791 | 17.834 |
| | | 25.000% | 334 | 483 | 23.925 | 28.544 |
| | | 50.000% | 334 | 483 | 23.981 | 29.678 |
| | | 75.000% | 501 | 724 | 35.849 | 36.941 |
| | | 95.000% | 501 | 724 | 35.941 | 38.026 |
| | | Average | 368.719 | 549.822 | 27.249 | 30.508 |

These results are almost the same as were obtained by use of the CHW method.

The main advantage of using the CDL method is that one can dispense with the use of the non-standard, weighted CHW statistic (54.2) as long as the conditional power at the interim analysis exceeds 0.5. Therefore, if the minimum CP for the promising zone is itself 0.5, one can dispense with the use of the CHW statistic altogether and always use the conventional Wald statistic at the time of the final analysis.

To see that the CDL condition ($CP \geq 0.5$) is necessary for preserving the type-1 error if the Wald statistic is always used for increasing the number of events, consider the following simulation experiment based on 10,000 simulated trials.

Set the hazard ratio to 1, so as to simulate under the null hypothesis.

Survival Information

of Hazard Pieces Input Method:

Hazard Ratio

Hazard Ratio (λ_t / λ_c):

| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
|-------|------------------|--------------|-----------|--------------|
| | | Control | Treatment | |
| 1 | 0.000 | 0.087 | 0.087 | 1.000 |

55 The Chen, DeMets and Lan Method

Row 6 of the Table of Simulation Results by Zone displays the results for all trials, combined across zones. Thus Column 3 of Row 6 of this table displays the magnitude of the type-1 error, 0.0317 which is seen to exceed 0.025 even after accounting for Monte Carlo error.

To be sure, the entries in the **Sample Size Re-estimation** tab are rather extreme and unrealistic. However this example serves to illustrate the point that control of type-1 error cannot be guaranteed if the Wald statistic replaces the CHW statistic inappropriately. On the other hand suppose we set the **Use Wald Stat. if CP >=** to 0.5.

| | | |
|--|--------------------------------------|--|
| Use Adaptation Method | | |
| <input type="radio"/> CHW | <input checked="" type="radio"/> CDL | <input type="radio"/> Müller and Schäfer |
| Adapt at: | Look # | 1 |

Promising Zone defined as 0 <= CP < 0.9

This time 249 of the 10,000 simulations rejected the null hypothesis, for an overall type-1 error of 0.0249. Thus the type-1 error is controlled.

55.2 Extension of CDL Method

55.2.1 Underlying Theory

55.2.2 Normal Endpoint

55.2.3 Binomial Endpoint

55.2.4 Survival Endpoint

We now describe an extension to the CDL method in which the 0.5 probability limit above which one is permitted to substitute the conventional Wald statistic for the CHW statistic can be lowered. The amount by which the CDL criterion can be lowered will depend on the other design parameters of the trial, and must be computed separately for each specific trial design. We have provided a table of cut-off values from which one may extrapolate for this purpose. The underlying theory is discussed next and provides some insight into why both, the CDL method and the extended CDL method are able to protect the type-1 error.

55.2.1 Underlying Theory

The results in this section are only valid for one-sided tests, and only for a sample size increase, but not for a sample size decrease. For simplicity we confine the discussion to tests of $H_0: \delta = 0$ against the one-sided alternative $\delta > 0$. However these results apply equally to tests against the one-sided alternative $\delta < 0$.

The ability to relax the criterion for using the conventional Wald statistic in an adaptive trial is based on a result due to Gao, Ware and Mehta (2008). Using the notation introduced in Chapter 54, let (n_1, n_2) be the **pre-specified** cumulative sample sizes for look 1 and look 2, respectively, and let (b_1, b_2) be corresponding one-sided level- α boundaries. Let

$$Z_1 = \hat{\delta}_1 \sqrt{I_1}$$

be the observed value of the Wald statistic at look 1, where I_1 is the Fisher information about δ based on the n_1 observations available at the time of the interim analysis. After observing $Z_1 = z_1$ suppose that the cumulative sample size for the final analysis is increased from n_2 to n_2^* . Using the notation developed in Chapter 54, we define the incremental Wald statistic

$$Z^{*(2)} = \hat{\delta}^{*(2)} \sqrt{I^{*(2)}},$$

55 The Chen, DeMets and Lan Method

where $I^{*(2)}$ is the Fisher information about δ based only on the additional $n_2^* - n_1$ observations obtained after the interim analysis. The CHW statistic (54.2) can be expressed as

$$Z_{2,\text{chw}}^* = \sqrt{\frac{n_1}{n_2}} Z_1 + \sqrt{\left(1 - \frac{n_1}{n_2}\right)} Z^{*(2)}$$

while the conventional Wald statistic (54.4) can be expressed as

$$Z_{2,\text{wald}}^* = \sqrt{\frac{n_1}{n_2^*}} Z_1 + \sqrt{\left(1 - \frac{n_1}{n_2^*}\right)} Z^{*(2)}.$$

Since the CHW statistic preserves the type-1 error it is clear that

$$P_0(Z_1 \geq b_1) + P_0(Z_1 < b_1, Z_{\text{chw}}^* \geq b_2) = \alpha. \quad (55.1)$$

However, due to the data dependent sample size change at look 1,

$$P_0(Z_1 \geq b_1) + P_0(Z_1 < b_1, Z_{2,\text{wald}}^* \geq b_2) \neq \alpha.$$

Therefore using the conventional Wald statistic for the final analysis will not protect the type-1 error. Gao, Ware and Mehta (2008) have shown that if, upon observing $Z_1 = z_1$ and increasing the total sample size from n_2 to n_2^* we change the final critical boundary from b_2 to

$$b_2(z_1, n_2^*) = (n_2^*)^{-0.5} \left[\sqrt{\frac{n_2^* - n_1}{n_2 - n_1}} (b_2 \sqrt{n_2} - z_1 \sqrt{n_1}) + z_1 \sqrt{n_1} \right] \quad (55.2)$$

then

$$P_0(Z_1 \geq b_1) + P_0(Z_1 < b_1, Z_{2,\text{wald}}^* \geq b_2(z_1, n_2^*)) = \alpha. \quad (55.3)$$

Thus we can use the conventional Wald statistic for the final analysis and also protect the type-1 error provided we replace the final critical boundary value b_2 by $b_2(z_1, n_2^*)$. The extended CDL method follows from this result.

The Extended CDL Method: Whenever $b_2(z_1, n_2^*) \leq b_2$, we may reject the null hypothesis $H_0: \delta = 0$ in favor of the one sided alternative that $\delta > 0$ if

$$(Z_1 \geq b_1) \text{ or } (Z_1 < b_1, Z_{2,\text{wald}}^* \geq b_2) \quad (55.4)$$

and the type-1 error will not exceed α notwithstanding the data dependent sample size increase from n_2 to n_2^* at the interim analysis. This result holds because $b_2(z_1, n_2^*) \leq b_2$ implies that

$$\alpha = P_0(Z_1 \geq b_1) + P_0(Z_1 < b_1, Z_{2,\text{wald}}^* \geq b_2(z_1, n_2^*)) \quad (55.5)$$

$$\geq P_0(Z_1 \geq b_1) + P_0(Z_1 < b_1, Z_{2,\text{wald}}^* \geq b_2) \quad (55.6)$$

Recall that the regular CDL method satisfies (55.6) only if the conditional power at the interim look is at least 0.5. We shall see that the extended CDL method satisfies (55.6) over a wider range of conditional powers. To show this we must investigate the behavior of the adjusted boundary $b_2(z_1, n_2^*)$ as a function of z_1 and n_2^* . We first reduce the dimensionality of the investigation by making the increased sample size n_2^* a function of z_1 . This is achieved by imposing the requirement that the new sample size, n_2^* , should be such that the conditional power given z_1 , evaluated at $\hat{\delta}_1$, reaches some pre-specified target value, subject however to an upper limit on the magnitude of the sample size increase. To be specific, define

$$CP_{\hat{\delta}_1}(z_1, n_2^*) = P_{\hat{\delta}_1}(Z_{2,\text{chw}}^* \geq b_2|z_1).$$

Under the extended CDL method, we pre-specify a *target value* for $CP_{\hat{\delta}_1}(z_1, n_2^*)$, say $1 - \beta$, and attempt to reach it by altering the sample size from n_2 to n_2^* . The first step is to find the sample size $n_2'(z_1)$ for each possible value of z_1 such that

$$CP_{\hat{\delta}_1}(z_1, n_2'(z_1)) = 1 - \beta. \tag{55.7}$$

A simplification of Gao, Ware and Mehta(2008, equation (5)) shows that (55.7) is satisfied by the function

$$n_2'(z_1) = \left[\frac{n_1}{z_1^2} \right] \left[\frac{b_2\sqrt{n_2} - z_1\sqrt{n_1}}{\sqrt{n_2} - n_1} + z_\beta \right]^2 + n_1. \tag{55.8}$$

There are, however, restrictions on the range of sample size alterations that are allowable at the interim analysis. At the lower end, the CDL and extended CDL methods do not permit the sample size to be decreased below the original sample size n_2 . At the upper end there is usually a limit to the magnitude of the sample size increase that the sponsor will permit. Denote this upper limit by N_{max}^* . Then the new sample size at the time of the interim analysis is computed by the formula

$$n_2^* = \max\{n_2, \min(n_2'(z_1), N_{\text{max}}^*)\}. \tag{55.9}$$

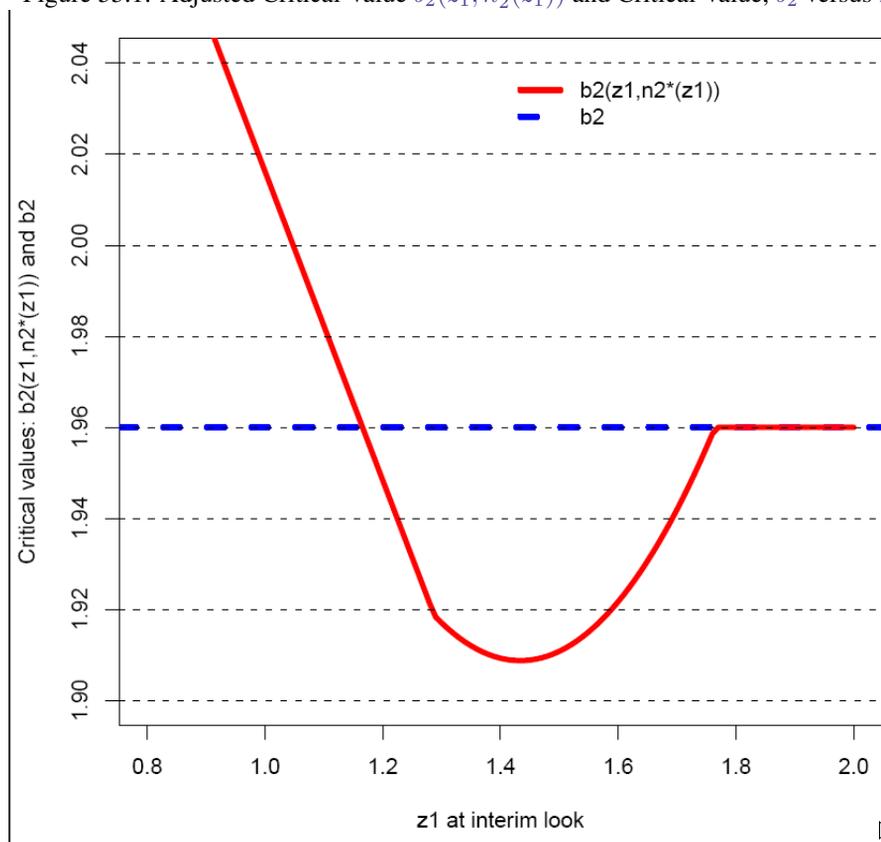

Note that $n_2^*(z_1)$ is a random variable at the start of the trial, its value being determined by the statistic z_1 obtained at the interim analysis.

By substituting (55.9) into (55.2) we can express the adjusted critical value $b_2(z_1, n_2^*)$ for the final analysis as a function of z_1 alone, and will hereafter denote it as $b_2(z_1, n_2^*(z_1))$ to show the explicit dependence of n_2^* on z_1 . Thus, we may use the criterion (55.4) for rejecting H_0 without inflating the type-1 error for the entire range of z_1 values that satisfy $b_2(z_1, n_2^*(z_1)) \leq b_2$, thereby utilizing the conventional group sequential hypothesis test at the final analysis despite a data dependent sample size

55 The Chen, DeMets and Lan Method

increase at the interim analysis. To obtain this range, it is convenient to plot $b_2(z_1, n_2^*(z_1))$ and b_2 against z_1 . Figure 55.1 displays such a plot for the two-look Schizophrenia trial that was discussed in Section 55.1.1. For this trial we have $n_1 = 208, n_2 = 442, N_{\max}^* = 884, b_1 = 5.25, b_2 = 1.96, \beta = 0.2$ and the sample size will be increased at look 1 from n_2 to $n_2^*(z_1)$ based on equation (55.9).

Figure 55.1: Adjusted Critical Value $b_2(z_1, n_2^*(z_1))$ and Critical Value, b_2 versus z_1

The curves of $b_2(z_1, n_2^*(z_1))$ and b_2 intersect at two places; at $z_{1,\min} = 1.1657$ and $z_{1,\max} = 1.7646$. Thus for all $1.0982 \leq z_1 \leq 1.7646$, we may use the conventional Wald test

$$Z_{2,\text{wald}}^* \geq b_2 \tag{55.10}$$

at the final analysis without inflating the type-1 error. To be sure we might lose some power because we are using (55.10) as our rejection criterion instead of using the less

restrictive rejection criterion

$$Z_{2,\text{wald}}^* \geq b_2(z_1, n_2^*(z_1)) \quad (55.11)$$

which also protects the type-1 error since, by (55.1) and (55.3),

$$\begin{aligned} & P_0(Z_1 \geq b_1) + P_0(Z_1 < b_1, Z_{2,\text{wald}}^* \geq b_2(z_1, n_2^*)) \\ &= P_0(Z_1 \geq b_1) + P_0(Z_1 < b_1, Z_{2,\text{chw}}^* \geq b_2) = \alpha. \end{aligned} \quad (55.12)$$

However, that is the price we must pay for using the conventional Wald test with guaranteed preservation of the type-1 error, instead of using the CHW test. In the next section we will show that the power loss is in fact negligible.

It is convenient re-scale the X-axis of Figure 55.1 in terms of conditional power. We can show that the conditional power given z_1 , evaluated at the estimated value $\hat{\delta}_1$, under the assumption that the final sample size remains unchanged at n_2 , is

$$\text{CP}_{\hat{\delta}_1}(z_1, n_2) = 1 - \Phi \left(\frac{b_2\sqrt{n_2} - z_1\sqrt{n_1}}{\sqrt{n_2 - n_1}} - \frac{z_1\sqrt{n_2 - n_1}}{\sqrt{n_1}} \right). \quad (55.13)$$

Accordingly we use equation (55.13) to transform the X-axis from z_1 to $\text{CP}_{\hat{\delta}_1}(z_1, n_2)$. Figure 55.2 is a plot of $b_2(z_1, n_2^*(z_1))$ and b_2 against $\text{CP}_{\hat{\delta}_1}(z_1, n_2)$. The curves intersect at two points which we denote as CP_{\min} and CP_{\max} . For the current example, $\text{CP}_{\min} = 0.36$ and $\text{CP}_{\max} = 0.8$. Thus for all $0.36 \leq \text{CP}_{\hat{\delta}_1}(z_1, n_2) \leq 0.8$, we may use the conventional Wald test (55.10) at the final analysis without inflating the type-1 error. The conventional Wald statistic may be used without inflating the type-1 error as long as $\text{CP}_{\hat{\delta}_1}(z_1, n_2) \geq \text{CP}_{\min}$, and the sample size is only permitted to increase (but never decreased) in accordance with (55.9).

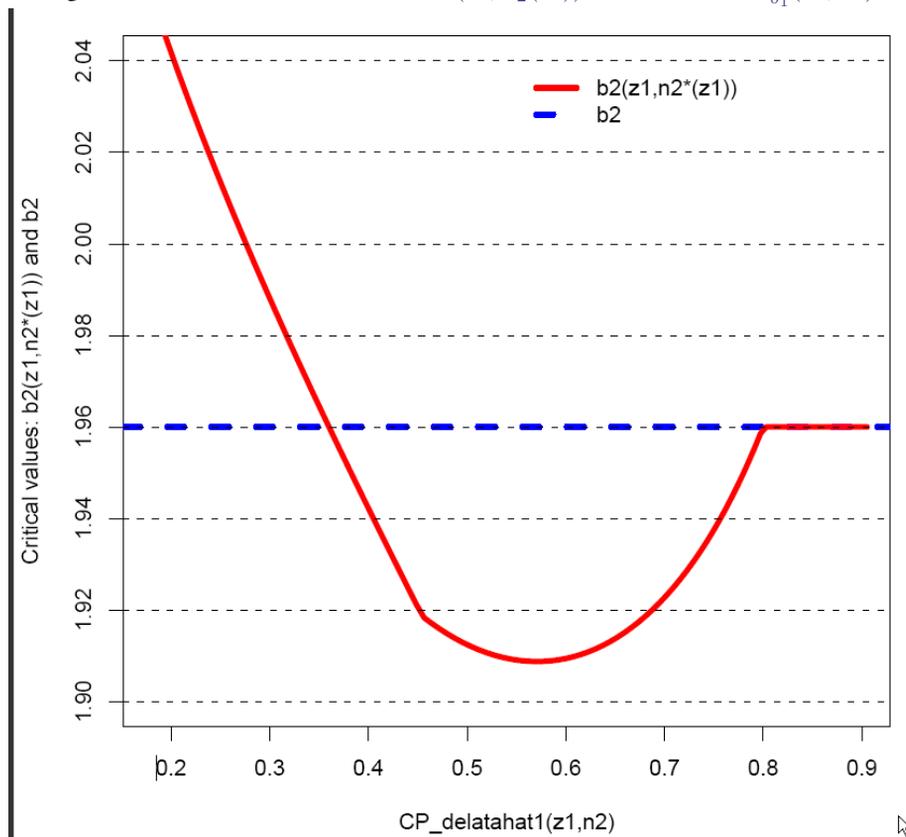

The extended CDL simulation module in the EastAdapt software accepts CP_{\min} as an input. The hypothesis test at the time of the final analysis of each simulated trial utilizes the conventional Wald criterion $Z_{2,\text{wald}}^* \geq b_2$ for rejecting H_0 if

$\text{CP}_{\hat{\delta}_1}(z_1, n_2) \geq \text{CP}_{\min}$ and utilizes the CHW criterion $Z_{2,\text{chw}}^* \geq b_2$ otherwise. Thus in all cases the type-1 error is preserved. The following is a summary of the extended CDL method:

1. Pre-specify the conditional power $1 - \beta$ that will be targeted at the time of the interim analysis
2. For a wide range of z_1 values, compute the new sample size $n_2^*(z_1)$ that would be needed to achieve the targeted conditional power, using equation (55.9)
3. Substitute $n_2^*(z_1)$ into equation (55.2) to obtain $b_2(z_1, n_2^*(z_1))$

55 The Chen, DeMets and Lan Method

Figure 55.2: Plots of Critical Values $b_2(z_1, n_2^*(z_1))$ and b_2 versus $CP_{\hat{\delta}_1}(z_1, n_2)$

4. Transform each z_1 into a corresponding conditional power $CP_{\hat{\delta}_1}(z_1, n_2)$ using equation (55.13)
5. Plot $b_2(z_1, n_2^*(z_1))$ and b_2 versus $CP_{\hat{\delta}_1}(z_1, n_2)$ and determine the value CP_{\min} where $b_2(z_1, n_2^*(z_1))$ first intersects with b_2 as shown in Figure 55.2.
6. Under the extended CDL method we can use the conventional Wald criterion $Z_{2, \text{wald}}^* \geq b_2$ to reject H_0 at the final analysis whenever $CP_{\hat{\delta}_1}(z_1, n_2) \geq CP_{\min}$.

For the convenience of the user we have pre-computed CP_{\min} cut-offs for some common two-stage, adaptive designs with no early stopping, and have displayed them in Table 55.1. All table entries are expressed as multiples of the initially proposed sample size n_2 and do not depend on the actual value of n_2 specified in the design.

One may conveniently refer to this table for suitable cut-offs instead of calculating them through the six-step procedure outlined above. For values of (n_1/n_2) or

Table 55.1: CP_{\min} Cut-Off Values for Some Typical Two-Stage Adaptive Designs with no Early Stopping either for Efficacy or Futility

| Sample Size Ratios | | CP_{\min} Values for Targeted Conditional Powers | | |
|---------------------------------------|--------------------------------|--|------|------|
| Maximum Allowed (N_{\max}^*/n_2) | At Interim Look (n_1/n_2) | 80% | 90% | 95% |
| 1.5 | 0.25 | 0.42 | 0.42 | 0.42 |
| 1.5 | 0.5 | 0.41 | 0.41 | 0.41 |
| 1.5 | 0.75 | 0.38 | 0.38 | 0.38 |
| 2 | 0.25 | 0.37 | 0.37 | 0.37 |
| 2 | 0.5 | 0.36 | 0.36 | 0.36 |
| 2 | 0.75 | 0.33 | 0.33 | 0.33 |
| 3 | 0.25 | 0.32 | 0.32 | 0.32 |
| 3 | 0.5 | 0.31 | 0.31 | 0.30 |
| 3 | 0.75 | 0.30 | 0.27 | 0.27 |
| ∞ | 0.25 | 0.32 | 0.28 | 0.26 |
| ∞ | 0.5 | 0.31 | 0.27 | 0.25 |
| ∞ | 0.75 | 0.30 | 0.25 | 0.23 |

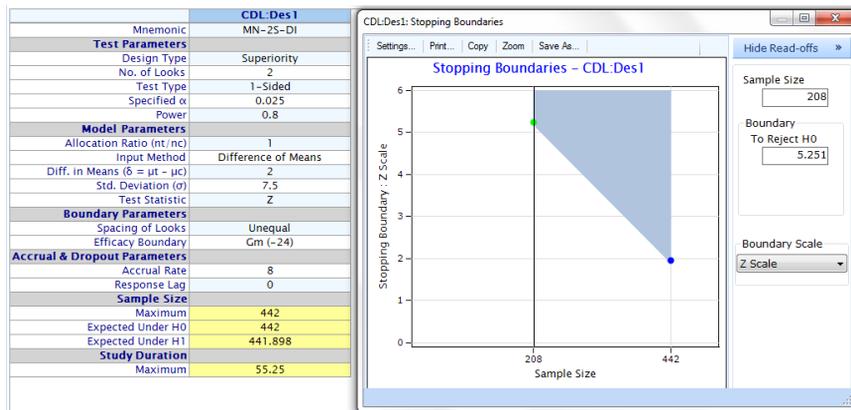

(N_{\max}^*/n_2) not included in the table, one may utilize the closest available cut-off value that guarantees conservative preservation of type-1 error. For example, for the Schizophrenia trial, $(N_{\max}^*/n_2) = 2$ and $(n_1/n_2) = 0.47$. Table 55.1 shows that the cut-off value $CP_{\min} = 0.37$ will preserve the type-1 error conservatively for targeted conditional powers of 80%, 90% or 95%. Observe that $CD_{\min} < 0.5$ for all the entries in Table 55.1 thus demonstrating that the extended CDL method is a relaxation of the original CDL method.

55.2.2 Normal Endpoint: Schizophrenia Trial

Consider again the Schizophrenia example introduced in Section 55.1.1. This is a two-look design with an initially specified sample size $n_2 = 442$ and one interim look after seeing data on $n_1 = 208$ completers. The stopping boundaries at the interim and final look are one-sided level-0.025 efficacy boundaries derived from the $\gamma(-24)$ spending function, which for all practical purposes implies that there will be no early stopping for efficacy. There is no futility boundary. This trial has slightly over 80% power to detect $\delta = 2$, given a standard deviation of $\sigma = 7.5$. The East design

55 The Chen, DeMets and Lan Method

screenshot is reproduced below.

Suppose that at the time of the interim analysis the sample size may be increased up to a maximum of $N_{\max}^* = 884$ in an attempt to attain a target conditional power of 95%. Assume that the sample size will only be increased (never decreased) if at the interim analysis the observed z_1 is such that $0.5 \leq CP_{\hat{\delta}_1}(z_1, 442) < 0.8$, identified as the *promising zone* for the interim results.

We will simulate the trial under different assumptions about δ and σ , using the extended CDL criterion instead of the original CDL criterion. To do this we need to know CP_{\min} , the value of $CP_{\hat{\delta}_1}(z_1, n_2)$ at which the adjusted critical value $b_2(z_1, n_2^*(z_1))$ starts to dip below the critical value $b_2 = 1.96$. To obtain the exact cut-off value we would have to manually execute the six-step procedure outlined at the end of Section 55.2.1. An easier alternative is to use the cut-off values provided in Table 55.1 for the standard two-stage designs. The difference in the operating characteristics of the design produced the two methods is negligible. Here $(N_{\max}^*/n_2) = 2$, $(n_1/n_2) = 0.47$ and the targeted conditional power is 0.95. Since there is no entry in Table 55.1 for this choice of parameters we use the more conservative choices, $(N_{\max}^*/n_2) = 2$ and $(n_1/n_2) = 0.25$, whereupon $CP_{\min} = 0.37$ for a targeted conditional power of 95%.

Suppose we wish to obtain the power of the above adaptive design under $\delta = 1.6$ and $\sigma = 7.5$. We therefore save the design in **Library**, insert Simulations for this design and enter the following parameters into different tabs: The **Response Generation Info**

tab:

| | |
|---------------------------------------|---|
| Generate Data Using: Individual Means | <input checked="" type="checkbox"/> Common Standard Deviation |

| Total | | | 68619 | 100000 | |
| % | | | 68.619% | | |

The null hypothesis was rejected a total of 68619 times in 100,000 trials for an overall power of 68.6%. The average sample size was 557.0. The top part of the simulation output, shows the zone by zone results and the results conditional on falling in the promising zone and thereby undergoing a sample size increase. This occurred 30,890 times out of 100,000 simulations. Moreover 27,805 of these trials rejected the null hypothesis for a power of 90.013%. The expected sample size of all trials that underwent a sample size increase was 814.413.

⊖ Zone-wise Averages

| Zone | Simulations Rejecting H0 | | Simulations Not Rejecting H0 | | Total Simulations | | Average Sample Size |

Promising Zone defined as $0.37 \leq CP < 0.9$

As before, it is of interest to verify that the type-1 error is preserved by the extended CDL method. Accordingly we set $\delta = 0$ in the **Mean Treatment** μ_t . Rest all

parameters are unchanged.

| | |
|---------------------------------------|---|
| Generate Data Using: Individual Means | <input checked="" type="checkbox"/> Common Standard Deviation |
| Mean Control (μ_c): 0 | SD Control (σ_c): 7.5 |
| Mean Treatment (μ_t): 0 | SD Treatment (σ_t): 7.5 |

The results from 100,000 simulations are shown below.

⊖ Average Sample Size and Look Times

| Look # | Average Sample Size (n) | Average Look Time |
|---------|-------------------------|-------------------|
| 1 | 208.001 | 25.939 |
| 2 | 479.899 | 59.852 |
| Average | 479.899 | 59.852 |

⊖ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|----------|
| | | Efficacy | | Efficacy | Count |
| 1 | 208 | 5.251 | 0 | 0 | 0.000% |
| 2 | 442 | 1.96 | 2356 | 100000 | 100.000% |
| Total | | | 2356 | 100000 | |
| % | | | 2.356% | | |

It is seen that only 2356 of the 100,000 simulations were able to reject the null hypothesis, for a type-1 error of 0.02356.

Now in addition to setting $\delta = 0$ in the **Difference of Means**, we set the **Promising Zone: Min CP** to zero as well, so as to provide the simulations with the largest possible opportunity to increase the sample size and thereby inflate the

55 The Chen, DeMets and Lan Method

type-1 error.

| 2 | 442 | 1.96 | 2267 | 100000 | 100.000% |
| Total | | | 2267 | 100000 | |
| % | | | 2.267% | | |

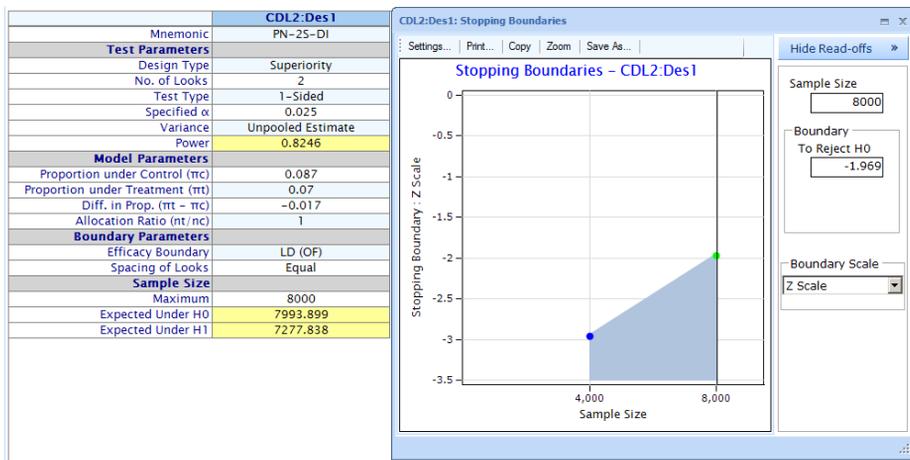

It is seen that only 2267 of the 100,000 simulations were able to reject the null hypothesis, for a type-1 error of 0.02267, preserving type-1 error of 0.025.

55.2.3 Binomial Endpoint: Acute Coronary Syndromes Trial

Consider again a two-arm, placebo controlled randomized clinical trial for subjects with acute cardiovascular disease undergoing percutaneous coronary intervention (PCI), which we discussed in Section 54.4. The primary endpoint in this study is a composite of death, myocardial infarction or ischemia-driven revascularization during the first 48 hours after randomization. We assume on the basis of prior knowledge that the event rate for the placebo arm is 8.7%. The investigational drug is expected to reduce the event rate by at least 20%. The investigators are planning to randomize a total of 8000 subjects in equal proportions to the two arms of the study.

As explained in the beginning of this chapter, for applying CDL method, a 2 look group sequential design will suffice, without loss of generality.

It is easy to show that a group sequential design enrolling a total of 8000 subjects with an interim look after 4000 subjects are enrolled (50% of total information), will have 82% power to detect a 20% risk reduction with a one-sided level-0.025 test of significance, and early stopping efficacy boundary derived from the Lan and DeMets (1983) O’Brien-Fleming type error spending function.

Suppose that at the time of the interim analysis the sample size may be increased up to a maximum of $N_{\max}^* = 16000$ in an attempt to attain a target conditional power of 95%. Assume that the sample size will only be increased (never decreased) if at the interim analysis the observed z_1 is such that $0.5 \leq CP_{\delta_1}(z_1, 8000) < 0.9$, identified as the *promising zone* for the interim results. We will simulate the trial under different assumptions about δ and σ , using the extended CDL criterion instead of the original

55 The Chen, DeMets and Lan Method

CDL criterion. To do this we need to know CP_{\min} , the value of $CP_{\delta_1}(z_1, n_2)$ at which the adjusted critical value $b_2(z_1, n_2^*(z_1))$ starts to hover above the critical value $b_2 = -1.9686$. To obtain the exact cut-off value we would have to manually execute the six-step procedure outlined at the end of Section 55.2.1. An easier alternative is to use the cut-off values provided in Table 55.1 for the standard two-stage designs. The difference in the operating characteristics of the design produced the two methods is negligible. Here $(N_{\max}^*/n_2) = 2$, $(n_1/n_2) = 0.50$ and the targeted conditional power is 0.95. There is an entry in Table 55.1 for this choice of parameters, $(N_{\max}^*/n_2) = 2$ and $(n_1/n_2) = 0.50$, whereupon $CP_{\min} = 0.36$ for a targeted conditional power of 95%. Suppose, we wish to obtain the power of the above adapted design, for example, at risk reduction $\rho = 0.15$ and to increase the sample size only if the conditional power at the interim analysis under the original sample size is between 0.36 and 0.9. And in that case suppose that we wish to increase the sample size by just the right amount so that the conditional power is boosted to 0.95. Furthermore suppose that the re-estimated sample size is constrained to remain between 8000 and 16000 subjects. To run the simulations with these specifications we would change the entries in simulation tabs as shown below.

The **Response Generation Info** tab:

| Specify Proportion | |
|------------------------------------|-------|
| Prop. under Control (π_c): | 0.087 |
| Prop. under Treatment (π_t): | 0.074 |

The **Sample Size Re-estimation** tab:

| | | |
|--|--------------------------------------|--|
| Use Adaptation Method | | |
| <input type="radio"/> CHW | <input checked="" type="radio"/> CDL | <input type="radio"/> Müller and Schäfer |
| Adapt at: | Look # | 1 |
| Max. Sample Size if Adapt (multiplier; total #): | 2 | 16000 |
| Target CP for Re-estimating Sample Size: | 0.95 | |
| Use Wald Stat. if CP >= | 0.36 | |
| Promising Zone Scale: | Cond. Power | CP |
| Promising Zone: | Min. CP: | 0.36 |
| | Max. CP: | 0.9 |
| CP Computation Based on: | Estimated (n_c, n_t) | |

and the **Simulation Control Info** tab:

| | |
|---|-------------------|
| Number of Simulations: | 100000 |
| Refresh Frequency: | 10000 |
| Random Number Seed | |
| <input checked="" type="radio"/> Clock | |
| <input type="radio"/> Fixed | 100 |
| Output Options | |
| Output Type: | Case Data |
| <input type="checkbox"/> Save summary statistics for every simulation run | |
| <input type="checkbox"/> Save subject-level data for | 1 simulation runs |
| Note: Max. 100,000 records will be saved. | |

We run the simulations by pressing the **Simulate** button. The results are as shown

55 The Chen, DeMets and Lan Method

below.

⊖ Average Sample Size

| Look # | Average Sample Size (n) |
|---------|-------------------------|
| 1 | 4000 |
| 2 | 10332.703 |
| Average | 9877.509 |

⊖ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Count | % |
| | | Lower | Efficacy | | |
| 1 | 4000 | -2.963 | 7188 | 7188 | 7.188% |
| 2 | 8000 | -1.969 | 57851 | 92812 | 92.812% |
| Total | | | 65039 | 100000 | |
| % | | | 65.039% | | |

The null hypothesis was rejected 65,039 times in 100,000 trials for an overall power of 65 %. The average sample size was 9877.5. In contrast, if there is no sample size increase, the power would be 57% and the average sample size would be 8000.

The top part of the simulation output displayed below, shows the zone by zone results as well as results conditional on falling in the promising zone and thereby undergoing a sample size increase. This occurred 31,855 times out of 100,000 simulations. Moreover 28,086 of these trials rejected the null hypothesis for a power of 88.2%. The expected sample size of all trials that underwent a sample size increase was 14,796.5.

⊖ Zone-wise Averages

| | Zone | Simulations Rejecting H0 | | Simulations Not Rejecting H0 | | Total Simulations | | Average Sample Size |
|---|-------------|--------------------------|----------|------------------------------|---------|-------------------|----------|---------------------|
| | | Count | Row % | Count | Row % | Count | Column % | |
| ⊖ | Futility | 0 | 0.000% | 0 | 0.000% | 0 | 0.000% | 0 |
| | Unfavorable | 9702 | 25.604% | 28191 | 74.396% | 37893 | 37.893% | 8000 |
| | Promising | 28086 | 88.168% | 3769 | 11.832% | 31855 | 31.855% | 14796.511 |
| ⊖ | Favorable | 20063 | 86.988% | 3001 | 13.012% | 23064 | 23.064% | 8000 |
| | Efficacy | 7188 | 100.000% | 0 | 0.000% | 7188 | 7.188% | 4000 |
| | All Trials | 65039 | 65.039% | 34961 | 34.961% | 100000 | 100.000% | 9877.509 |

Promising Zone defined as $0.36 \leq CP < 0.9$

As before, it is of interest to verify that the type-1 error is preserved by the extended

CDL method. Accordingly we set treatment proportion same as control proportion =0.087, thereby making $\delta = 0$. Rest all parameters are unchanged.

Specify Proportion

Prop. under Control (π_c):

Prop. under Treatment (π_t):

The results from 100,000 simulations are shown below.

⊖ Average Sample Size

| Look # | Average Sample Size (n) |
|---------|-------------------------|
| 1 | 4000 |
| 2 | 8678.491 |
| Average | 8670.958 |

⊖ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Count | % |
| | | Lower | Efficacy | | |
| 1 | 4000 | -2.963 | Efficacy | 161 | 0.161% |
| 2 | 8000 | -1.969 | Efficacy | 99839 | 99.839% |
| Total | | | Efficacy | 100000 | |
| % | | | Efficacy | 2320 | 2.320% |

It is seen that only 2320 of the 100,000 simulations were able to reject the null hypothesis and hence the simulated type-1 error is 0.0232.

On the other hand, suppose we perform the very same simulations but set the **Use Wald Stat. if CP(8000) >=** parameter to zero and **Promising Zone: Min CP** to zero as well. There is now no protection against type-1 error inflation. As seen below, 2679 of 100,000 simulations with this change rejected the null hypothesis

55 The Chen, DeMets and Lan Method

giving us a type-1 error of 0.02679.

⊖ Average Sample Size

| Look # | Average Sample Size (n) |
|---------|-------------------------|
| 1 | 4000 |
| 2 | 11690.227 |
| Average | 11679.23 |

⊖ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |

| 2 | 8000 | -1.969 | 2536 | 99857 | 99.857% |
| Total | | | 2679 | 100000 | |
| % | | | 2.679% | | |

55.2.4 Survival Endpoint: Lung Cancer Trial

The statistical methodology described in Section 55.2.1 for normal and binomial endpoints applies also to survival endpoints with appropriate changes in notation as described in Chapter 54, Section 54.2. To see this, carry out CDL simulations of Des 1, the lung cancer example discussed earlier in Section 55.1.3 of this chapter.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

| 2 | 1 | 493 | 334 | 149 | 29.984 | 0.645 | 0.092 |

Survival Information: Median Survival Times

| Median Survival Times | | Hazard Ratio |
|-----------------------|----------------|--------------|
| Control (Ac) | Treatment (AT) | Alt. (AT)/Ac |
| 8 | 11.429 | 0.7 |

Accrual Information

| Period # | Starting at Time | Cum. % Accrued |
|----------|------------------|----------------|
| 1 | 24 | 100 |

Variable Follow-Up Design: All subjects are followed until failure, drop out or end of study.

We will simulate this design using CDL method. To do this, insert simulations for this design and add the **Sample Size Re-estimation** tab.

In the **Response Generation Info** tab, set the hazard ratio to 1 as shown below, so as

55 The Chen, DeMets and Lan Method

to simulate under the null hypothesis.

| Survival Information | | | | |
|--|------------------|---------------|-----------|--------------|
| # of Hazard Pieces | 1 | Input Method: | | Hazard Rates |
| <input checked="" type="checkbox"/> Hazard Ratio | | | | |
| Hazard Ratio (λ_t/λ_c): | | 1 | | |
| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
| | | Control | Treatment | |
| 1 | 0.000 | 0.0866 | 0.0866 | 1.000 |

Now go to the **Sample Size Re-estimation** tab and enter the following values:

| | | | |
|--|--------------|---|-----------|
| Use Adaptation Method | | <input type="radio"/> CHW <input checked="" type="radio"/> CDL <input type="radio"/> Müller and Schäfer | |
| Adapt at: | Look # | 1 | |
| Max. # of Events if Adapt (multiplier; total #): | 10 | 3340 | |
| Max. Sample Size if Adapt (multiplier; total #): | 10 | 4830 | |
| Upper Limit on Study Duration: | 500 | | |
| Target CP for Re-estimating # of Events: | 0.9 | | |
| Use Wald Stat. if CP >= | 0 | | |
| Promising Zone Scale: | Cond. Power | | CP |
| Promising Zone: | Min. CP: | 0 | |
| | Max. CP: | 0.9 | |
| CP Computation Based on: | Estimated HR | | |
| Accrual Rate After Adaptation: | No Change | | |

We can verify by simulating 10,000 times with these input parameters that the type-1 error will not be preserved because the input parameter **Use Wald Statistic if CP >=** has been set to 0 instead of being at 0.5. Consequently the CDL condition, required for preserving the type-1 error if the conventional Wald statistic is being used with a data dependent increase in the number of events, is not satisfied. Hit the **Simulate** button to obtain the following output:

Row 6 of the table of Zone-wise Averages displays the results for all trials, combined across zones. Thus Column 4 of Row 6 of this table displays the magnitude of the type-1 error, 0.029 which is seen to exceed 0.025 even after accounting for Monte Carlo error.

⊖ Zone-wise Averages

| | Zone | Simulations Rejecting H0 | |
|---|-------------|--------------------------|----------|
| | | Count | Row % |
| ⊖ | Futility | 0 | 0.000% |
| | Unfavorable | 0 | 0.000% |
| | Promising | 211 | 3.996% |
| ⊖ | Favorable | 61 | 30.964% |
| | Efficacy | 17 | 100.000% |
| | All Trials | 289 | 2.890% |

Table 55.1 shows cut-off values of conditional power below 0.5 at which the use of the conventional Wald statistic will preserve the type-1 error. There is no entry in this table for a Sample Size Ratio (i.e., event multiplier) of 10. However a 10-fold multiplier is for all practical purposes the same as an infinite multiplier. Table 55.1 shows that for a Sample Size Ratio equal to ∞ (infinite multiplier), the cut-off for a trial powered at 90% with and interim analysis at 50% of the information is 0.27. Let us therefore use a

55 The Chen, DeMets and Lan Method

cut-off of 0.27 for the simulations instead of a zero cut-off as was done previously.

Use Adaptation Method CHW CDL Müller and Schäfer

Adapt at:

Max. # of Events if Adapt (multiplier; total #):

| Total | 208 | | | 208 | 9792 | 10000 | |
| % | | | 2.080% | 97.920% | | | |

Thus the extended CDL method permits a lower cut-off than 0.5 and may be used to design studies with a wider range of promising zones while permitting the use of a conventional Wald statistic for the final analysis without type-1 error inflation.

55.3 Efficiency Considerations

At the beginning of this chapter we cited some theoretical results by Tsiatis and Mehta (2003) and Jennison and Turnbull (2006) who demonstrated that the use of the CHW statistic instead of the conventional Wald statistic to perform hypothesis tests in a group sequential clinical trial with sample size changes can lead to loss of efficiency. These results, however, involved extremely large sample size increases (up to tenfold) and numerous interim looks at the accruing data. It would thus be of interest to determine whether the CHW statistic also loses power relative to the conventional Wald statistic for the more common situation of a two-stage clinical trial with at most a doubling of the sample size if the interim results fall in a promising zone. The CHW and CDL simulation worksheets provides us with the tools to make the relevant comparisons. We will accordingly compare the operating characteristics of the two-stage schizophrenia trial when the CHW test, the CDL test and the conventional Wald test are utilized for the final analysis. The design specifications for this trial were provided at the beginning of Section 55.1.1 of this chapter. The trial has a planned enrollment of 442 subjects and an interim analysis after seeing data on 208 completers. The main purpose of the interim analysis is to decide whether to increase the sample size, not to stop early for efficacy. Consequently the conservative $\gamma(-24)$ error spending function is utilized at the interim analysis. The sample size may be increased up to a maximum of 884 subjects so as to recover a target conditional power of 80%, provided the interim results fall in a promising zone. The promising zone is defined by $0.3 \leq \text{CP}(442) < 0.8$ where $\text{CP}(442)$ is the conditional power at the interim look (based on the estimated value of δ/σ) assuming no change in the initially specified sample size of 442 subjects.

We shall compare power and expected sample size of all three methods (CHW, CDL, conventional Wald) for $\delta = 0, 1, 1.6, 1.8, 2$ assuming $\sigma = 7.5$. The CHW method utilizes the CHW simulation worksheet. The following are the simulation parameters for simulating under $\delta = 0$.

By setting this CDL parameter to zero we have ensured that the conventional Wald statistic will be used for the final analysis all the time. In principle this should inflate the type-1 error. However, because the sample size is only increased in the promising zone, it is possible that the type-1 error might not be inflated in the current setting. This

turns out to be the case as is shown below for 1,000,000 simulated trials under $\delta = 0$.

The null hypothesis was rejected 25406 times in 1,000,000 trials allowing for Monte Carlo accuracy for a level 0.025 test. Simulation results for other values of δ are displayed in Table 55.2.

Having established that the CHW, CDL and conventional Wald tests have all preserved the type-1 error, it is now possible to have a meaningful comparison of their respective operating characteristics for other values of δ . These results are displayed in Table 55.2 for $\delta = 0, 1, 1.6, 1.8$ and 2. As noted above, the results for $\delta = 0$ were based on 1,000,000 simulated trials so as to leave no doubt that the type-1 error is preserved. The other results in Table 55.2 are all based on 100,000 simulated trials, which easily produces Monte Carlo accuracy to the nearest percentage point. The operating characteristics of the 442-subject fixed sample non-adaptive trial are also displayed so as to provide a benchmark for the comparisons.

Table 55.2 shows that all three adaptive methods preserve the type-1 error and are practically indistinguishable with respect to power or expected sample size for non-zero values of δ . This interesting finding suggests that for practical applications of adaptive sample size re-estimation in two-stage designs there is no loss of efficiency

55 The Chen, DeMets and Lan Method

due to the use of the CHW statistic, notwithstanding the theoretical results of Tsiatis and Mehta (2003) or Jennison and Turnbull (2006). Further investigation of this conjecture would be desirable.

56

Muller and Schafer Method

This chapter discusses the Müller and Schäfer (2001) method for adaptive design. This is the most general of the three methods provided by EastAdapt and permits many different types of data dependent changes to a study design in addition to sample size changes. These include data-dependent changes in the error spending function, changes in the number and spacing of the interim looks, and population enrichment via the selection of prospectively identified subgroups. The actual decision rule for making an adaptive change at an interim look can be selected after examining the data available at that look. Indeed the adaptation may be made on the basis of either internal data from the trial, externally available data at the time of the interim look, or a combination of the two. Furthermore, these adaptive changes can be made more than once in any group sequential design. The method is based on preserving the conditional type-1 error in effect at the time of the adaptive change. One can show that if the type-1 error is preserved conditionally for all possible interim results, then it is also preserved unconditionally. P-values, point estimates and confidence intervals adjusted for the adaptive change are produced by extending the work of Müller and Schäfer (2001). We have developed two methods for this extension. Method 1 generalizes the repeated confidence intervals of Jennison and Turnbull (2000, Chapter 9) and was developed by Mehta, Bauer, Posch and Brannath (2007). We refer to it as the RCI method. It is more general than the RCI method discussed in Chapter 54 in that it is valid with any type of adaptive design change whereas the latter is only valid for sample size changes. When only sample size changes are involved, the two RCI methods are the same. Both RCI methods produce confidence intervals with conservative coverage of the unknown δ . Method 2 is BWCI (Backward Image Confidence Interval) method, developed by Gao, Liu and Mehta (2013), provided for computing a two-sided confidence interval having exact coverage, along with a point estimate that is median unbiased for the primary efficacy parameter in a two-arm adaptive group sequential design. The possible adaptations are not only confined to sample size alterations but also include data-dependent changes in the number and spacing of interim looks and changes in the error spending function. The procedure is based on mapping the final test statistic obtained in the modified trial into a corresponding backward image in the original trial. This is an advance on previously available methods, which either produced conservative coverage and no point estimates or provided exact coverage for one-sided intervals only.

In Section 56.1 we provide a quick review of the theory underlying the Müller and Schäfer method for preserving the type-1 error and its extension for parameter estimation by the RCI and BWCI methods. For more details, refer to Müller and Schäfer (2001), Mehta, Bauer, Posch and Brannath (2007), and Gao, Liu and Mehta (2013). In Section 56.2, we illustrate the methods through a worked example using the

56 Muller and Schafer Method

EastAdapt software.

56.1 Statistical Method

56.1.1 Hypothesis Testing

56.1.2 Parameter Estimation

The original method published by Müller and Schäfer (2001) only provided a solution for the problem of preserving the type-1 error in an adaptive hypothesis test. Subsequently the method was extended by Gao, Liu and Mehta (2013) to cover the related inference problem of computing the point estimate, confidence intervals and p-value. Accordingly in Section 56.1.1 we will discuss hypothesis testing based on the original Müller and Schäfer (2001) method. In Section 56.1.2 we will generalize the approach so as to cover parameter estimation and p-value computation based on the method of Gao, Liu and Mehta (2013).

56.1.1 Hypothesis Testing

To understand how the Müller and Schäfer (2001) method works let us consider a one-sided, level- α test of the null hypothesis

$$H_0: \delta = 0$$

versus the one-sided alternative hypothesis

$$H_1: \delta > 0$$

for a two-arm randomized clinical trial. We assume that this is a group sequential trial, designed for K looks at the information fractions t_1, t_2, \dots, t_K . Let $\alpha_j, j = 1, 2, \dots, K$, denote the amount of type-1 error to be spent at the j th look. Let the corresponding stopping boundaries be denoted by $\{b_j: j = 1, 2, \dots, K\}$.

Now suppose that at some interim look L the investigators, having already seen the results for the first L looks, wish to alter one or more design parameters for the future course of the study. Such data-dependent alterations might include a change in the maximum sample size, a change in the rate of error spending for the remainder of the trial, a change in the number and spacing of the future interim looks, and even a refinement of the eligibility criteria for enrolling additional patients into the trial. Müller and Schäfer have shown that all such changes are permissible provided the remainder of the trial preserves the *conditional rejection probability* (CRP), or conditional probability of rejecting H_0 , that are in effect at look L . This needs further explanation. Let Z_j be the Wald statistic at any look j and suppose that z_L is its observed value at look L . Then the CRP, denoted by ϵ_0 , is the conditional probability given z_L that, under the null hypothesis H_0 , Z_j will cross the stopping boundary at some future look. Specifically,

$$\begin{aligned} \epsilon_0 = & P_0\{Z_{L+1} \geq b_{L+1}|z_L\} + P_0\{Z_{L+1} < b_{L+1} \text{ and } Z_{L+2} \geq b_{L+2}|z_L\} + \dots \\ & \dots + P_0\left\{\bigcap_{j=L+1}^{K-1} Z_j < b_j \text{ and } Z_K \geq b_K|z_L\right\} \end{aligned} \quad (56.1)$$

(56.2)

This CRP is calculated by applying the recursive integration algorithm of Armitage, McPherson and Rowe (1969).

Müller and Schäfer (2001) have shown that, no matter what data dependent changes one makes at look L , the overall **unconditional** type-1 error of the entire trial with respect to all possible trial modifications at look L will be preserved provided the CRP for the modified trial beyond look L , under H_0 , remain fixed at ϵ_0 . Moreover, as the trial proceeds, the same process can be repeated again with further trial modifications that also preserve the CRP of the remainder of the trial.

For practical implementation in East one would conduct the adaptive trial as though it consisted of two trials; one primary and the other secondary. The initial design, prior to any adaptation is known as the primary trial. Suppose that at some look L of the primary trial the decision is taken to make an adaptive change in the design. At that point one would invoke East's conditional power calculator from the interim monitoring worksheet to obtain ϵ_0 (56.1.1). One would then use East to design a one-sided secondary trial with ϵ_0 as the significance level. This secondary trial would incorporate all the desired adaptive changes such a sample size change, spending function change, etc. The secondary trial would then be monitored as though it were a completely a separate trial with no relationship to the primary trial except for carrying over the significance level ϵ_0 . Acceptance or rejection of the null hypothesis in the secondary trial would imply acceptance or rejection of the null hypothesis overall. We shall illustrate this approach with the help of a detailed example in Section 56.2

56.1.2 Parameter Estimation

The material in this section summarizes the paper by Mehta, Bauer, Posch and Brannath (2007). It is fairly technical and may be skipped if you simply wish to design, monitor and simulate an adaptive trial by the Müller and Schäfer method. In that case you may proceed directly to Section 56.2. A careful study of this section will, however, provide you with a deeper appreciation of the difficulties of parameter estimation.

We will only consider parameter estimation for adaptive designs with one-sided hypothesis testing and no futility boundaries, since this is the only setting in which

56 Muller and Schafer Method

East currently provides point and interval estimates by the extended Müller and Schäfer method. (For the two-sided case one may use the repeated confidence intervals and the repeated p-values discussed in Chapter 54, Section 54.1.2). Accordingly we consider a level- α test of

$$H_0: \delta = 0 \tag{56.3}$$

versus the one-sided alternative hypothesis that $\delta > 0$. We shall be interested in estimating $\underline{\delta}$, the lower confidence bound of the $100 \times (1 - \alpha)\%$ confidence set

$$C_\alpha = (\underline{\delta}, \infty) .$$

We shall also be interested in estimating $\tilde{\delta}$, a point estimate for δ , and p_1 , a one sided p-value for the test of H_0 .

A general way to construct a $100 \times (1 - \alpha)\%$ confidence set C_α , applicable to both non-adaptive and adaptive group sequential trials is by performing a level- α test of the hypothesis

$$H_h: \delta = h \tag{56.4}$$

versus the one-sided alternative hypothesis that $\delta > h$. The confidence set C_α will then consist of all values h having the property that the hypothesis (56.4) cannot be rejected by a level- α one-sided hypothesis test. The lower limit of the confidence set C_α is therefore the supremum of the set of all h for which (56.4) is rejected by a level- α one-sided hypothesis test . It remains only to find a way to perform such a test in the adaptive setting.

Let us first review the Müller and Schäfer method for performing the one-sided test of the null hypothesis (56.3) that $\delta = 0$ at level α in the adaptive setting. For $j = 1, 2, \dots K$, let Z_j denote the Wald statistics and b_j denote the efficacy boundaries of a K -look one-sided level- α group sequential test. At some interim look L , where $Z_L = z_L$, it is decided to alter the future course of the trial through an adaptive change. In order to preserve the type-1 error of the trial despite the adaptive change, the following steps must be followed:

1. Compute the conditional rejection probability

$$\epsilon = P_0 \left\{ \bigcup_{j=L+1}^K (Z_j \geq b_j) | z_L \right\} . \tag{56.5}$$

2. Use the ϵ so obtained as the significance level of a $K^{(2)}$ -look secondary trial with Wald statistics $Z_j^{(2)}$ and efficacy boundaries $b_j^{(2)}$, $j = 1, 2, \dots K^{(2)}$, in

which all the adaptive changes have been incorporated. Thus

$$P_0\{\cup_{j=1}^{K^{(2)}} (Z_j^{(2)} \geq b_j^{(2)})\} = \epsilon ,$$

where all quantities associated with the secondary trial are tagged with the superscript ⁽²⁾.

3. Monitor the secondary trial until it is terminated at some stage $L^{(2)} \leq K^{(2)}$. Compute the stage wise adjusted p-value (see for example, Jennison and Turnbull 2000, page 179)

$$p^{(2)} = P_0\left(\bigcup_{j=1}^{L^{(2)}-1} \{Z_j^{(2)} \geq b_j^{(2)}\} \cup \{Z_{L^{(2)}}^{(2)} \geq z_{L^{(2)}}^{(2)}\}\right) . \quad (56.6)$$

4. Reject H_0 if $p^{(2)} \leq \epsilon$. By the Müller and Schäfer principle this is a level- α test of H_0 .

Now consider how the procedure might be extended to produce a level- α test of H_h . Analogous to (56.5) and (56.6) we must compute the conditional rejection probability $\epsilon(h)$ and the secondary trial p-value $p^{(2)}(h)$ under the hypothesis that $\delta = h$. The expression for $p^{(2)}(h)$ is a straightforward extension of (56.6) and is given by

$$p^{(2)}(h) = P_h\left(\bigcup_{j=1}^{L^{(2)}-1} \{Z_j^{(2)} \geq b_j^{(2)}\} \cup \{Z_{L^{(2)}}^{(2)} \geq z_{L^{(2)}}^{(2)}\}\right) \quad (56.7)$$

where $P_h(\cdot)$ denotes probability under H_h .

RCI Method We have shown in Mehta, Bauer, Posch and Brannath (2007) that

$$\epsilon(h) = P_h \bigcup_{j=L+1}^K (Z_j - h\sqrt{I_j} \geq b_j | z_L) \quad (56.8)$$

where I_j is the Fisher information at look j .

BWCI method Please refer to Gao, Liu and Mehta (2013) for details of BWCI method.

56 Muller and Schafer Method

56.2 Implementation of Hypothesis Testing

56.2.1 Designing the Primary

Primary

56.2.2 Monitoring the Primary

Primary

56.2.3 Primary Trial

56.2.4 Secondary Trial

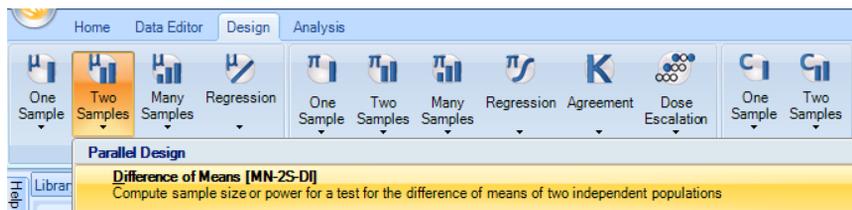

56.2.5 Combining Trial

56.2.6 Simulation

We illustrate the Müller and Schäfer method in this section through a worked example that includes the design of the trial, its adaptive re-design, and verification of its operating characteristics by simulation. Parameter estimation and p-value computation are presented separately in Section 56.3 since these capabilities are only available for one-sided tests.

56.2.1 Designing the Primary Trial

We begin with a one-sided, level 0.025, three look, group sequential design, with $LD(OF)$ spending function, for testing the difference of means, δ , in a two arm randomized clinical trial with a normally distributed primary endpoint. The study is designed to have 90% power to detect $\delta = 15$ at $\sigma = 50$. To design this study using EastAdapt, select as shown in the screen below.

Change the Number of Looks to 3. You will see a new tab **Boundary Info** added. Before we go to this tab, change **Input Method** to **Difference of Means, Diff. in Means** to 15 and **Std.Deviation** to 50. Keep other default selections without any change. Now, the input dialog box will look as shown below.

| | | | | | |
|---|---------------|--|---------------------|------------------------------|----|
| Test Type: | 1-Sided | Input Method: | Difference of Means | Test Statistic: | Z |

We see that the study will achieve the desired power at a maximum sample size of 473 subjects. However, the values of δ and σ on which these calculations rest were selected after considerable discussion and disagreement amongst the investigators. There was a scarcity of reliable data from previous studies about the treatment arm, the patient population and the primary endpoint. Thus the sample size of 473 was selected as a compromise, with the understanding that this important design parameter would be re-assessed at the first interim look, using data from the trial and possibly other external information that might become available at that time.

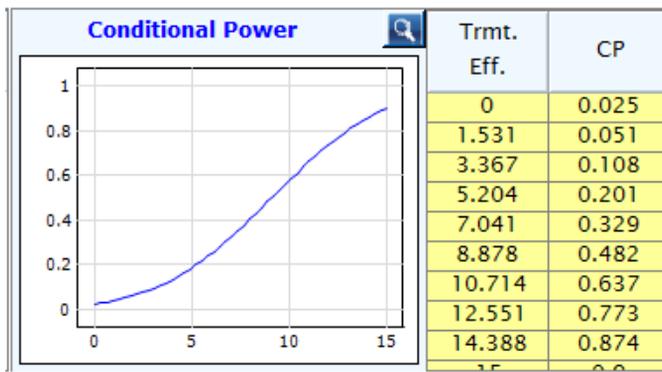

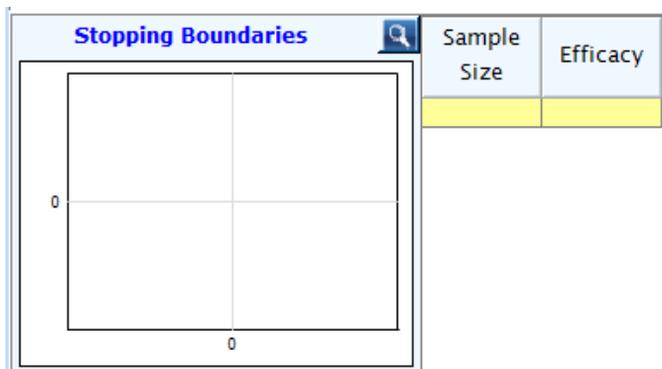

56.2.2 Monitoring the Primary Trial

To monitor this trial click on the 'Create Interim Monitoring' icon  to invoke the interim monitoring worksheet.

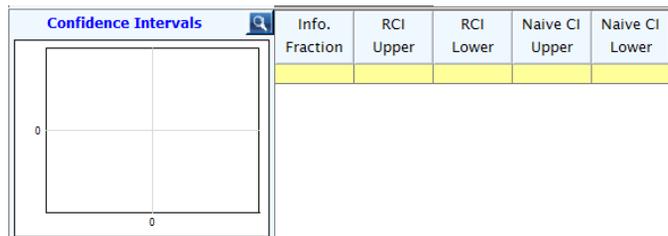

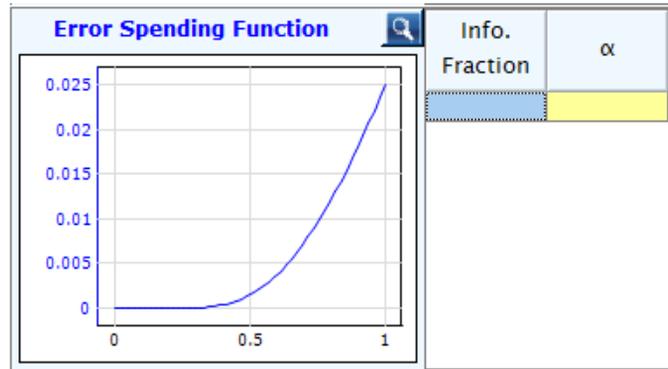

The parts of this sheet are shown, for visual clarity, in separate screen shots displayed

below.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeated p-value | CP | Predictive Power |

| | | | | | | | Upper | Lower | | | |
| 1 | | | | | | | | | | | |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

56 Muller and Schafer Method

The top portion of the Interim Monitoring sheet is where the inputs for the interim looks will be entered and is displayed here again.

In the IM sheet you are ready to enter values for Look 1. Click on the button

Enter Interim Data

to see the Test Statistic Calculator dialog box displayed as shown

below.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Cumulative Sample Size: 158

Input for Normal end point

Estimate of δ : 15
 $\delta = (\mu_t - \mu_c)$

Standard Error of Estimate of δ : 7.956

Output

Test Statistic: 1.885

Recalc OK Cancel

Some default values for Look 1 are already estimated and displayed in the calculator. You are free to change these values depending on your actual data. Suppose the first interim look is taken when data are available on $n_1 = 158$ subjects. Further, suppose that the observed difference of means is $\hat{\delta}_1 = 8$ and the observed standard deviation is $\hat{\sigma}_1 = 55$. Enter the value 8 for the estimate of δ and enter the square root of $(4 \times \hat{\sigma}_1^2 / 158) = 4 \times 55^2 / 158 = 8.751$ as the standard error of estimate of δ into the appropriate cells of this calculator. (Note that you can either type in a numerical value or a formula into the cells of any dialog box that accepts numerical values.)

56 Muller and Schafer Method

Click the **Recalc** button to see the output of test statistic value in the calculator.

Now click on **OK** to post these entries into the interim monitoring worksheet. The current information fraction is $t_1 = 158/473 = 0.334$. East populates the first row of the interim monitoring worksheet with the observed test statistic $z_1 = \hat{\delta}_1 / \text{se}(\hat{\delta}_1) = 0.914$, the corresponding efficacy stopping boundary = 3.706, the repeated 97.5% confidence interval limits for δ , and the repeated p-value.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat ... p-value | CP | Predicti... Power |

| | | | | | | | Upper | Lower | | | |
| 1 | 0.334 | 158 | 0.914 | 8 | 8.751 | 3.706 | Infinity | -24.432 | 0.439 | 0.311 | 0.388 |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

56.2.3 Making Adaptive Changes to Primary Trial

The observed value of the Wald statistic at the first look, is $z_1 = 0.914$ whereas the critical value for rejecting H_0 is $b_1 = 3.706$. Thus a traditional group sequential trial would continue on to the next interim monitoring time point. Here, however, we have built in the flexibility to re-assess the adequacy of the sample size specified at the start of the trial. How should this be done? There are two aspects to this question; logistical

and scientific. We have already mentioned the logistical difficulties in Section 53.5 of Chapter 53 and will not discuss them further here. The scientific question is, how should one decide on the new sample size? The observed treatment difference $\hat{\delta}_1 = 8$ is considerably smaller than the value $\delta = 15$ at which the trial was powered.

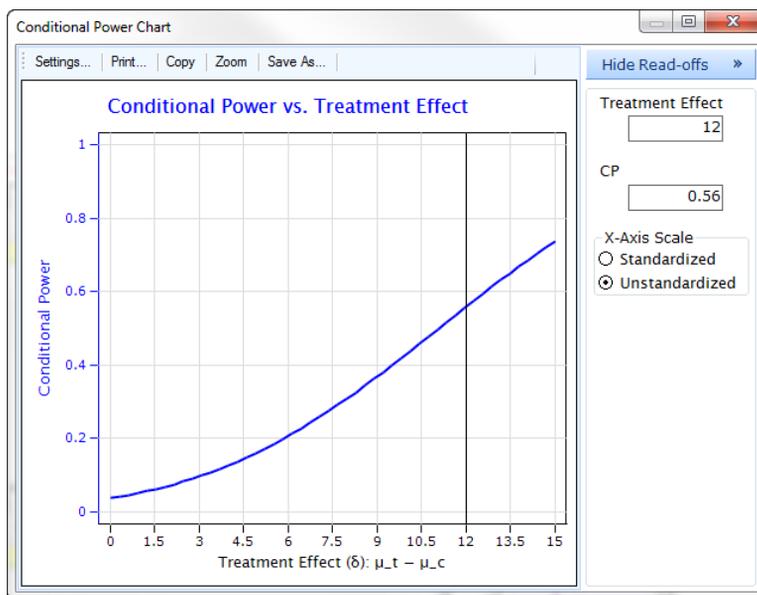

For an estimate of the conditional power that at any future look, that the test statistic value will cross the stopping boundary, click on the icon . You will see the following Conditional Power Calculator, displaying the conditional power as 0.311.

| Conditional Power Calculator | |
|--|-------|
| Input | |
| Look #: | 1 |
| Cumulative Sample Size: | 158 |
| Test Statistic: | 0.914 |
| Input/Output | |
| <input type="checkbox"/> Value of δ : | |
| Value of σ : | |
| <input checked="" type="checkbox"/> Value of δ/σ : | 0.145 |
| Computed Conditional Power: | 0.311 |
| Sample Size (Overall): | 473 |
| <input type="button" value="Recalc"/> <input type="button" value="Plot"/> <input type="button" value="Details..."/> <input type="button" value="Close"/> | |

You can also see the conditional power value for different assumed values of δ from

56 Muller and Schafer Method

the conditional power chart as shown below.

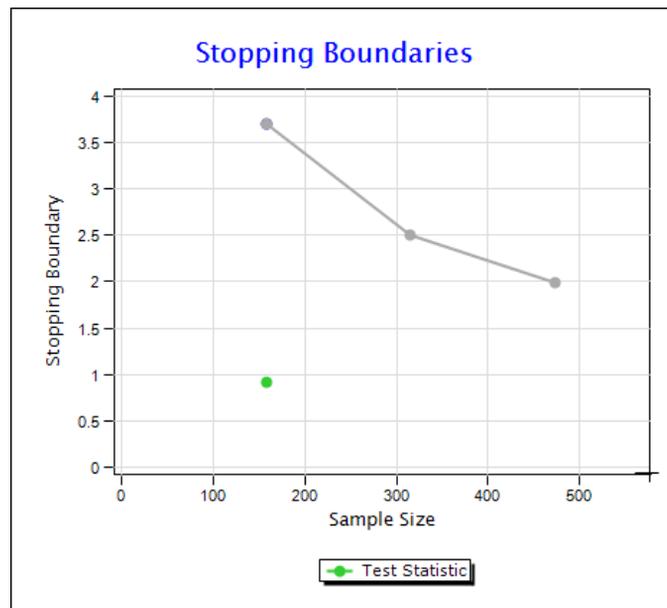

We shall shortly discuss the important role that conditional power plays in making an adaptive modification to the trial.

We would like to increase the sample size and thereby boost up the conditional power. The computation of conditional power, however, requires us to input a value for δ . Now, of course, the true value of δ cannot be known. While considerable weight should be given to the point estimate $\delta = 8$ obtained at the interim analysis, it might be wise to retain the flexibility to use this estimate in conjunction with other data from the trial, and other externally available data. The Müller and Schäfer method gives you this flexibility. You can revise the sample size in any manner that seems appropriate at the time of the interim analysis, without having to pre-specify a particular decision rule for determining the new sample size. (You may also decide that no sample size increase is warranted.) We will assume that the trial investigators have taken advantage of this flexibility to review the interim data, as well as all relevant external data, and have finally determined that the clinically meaningful value at which to power the study should be revised downwards to $\delta = 10$. Based on the observed data, the investigators continue to assume that $\sigma = 50$. Suppose therefore that they wish to increase the sample size so as to increase the conditional power to 90% at $\delta = 10$ and

$\sigma = 50$, while simultaneously preserving the type-1 error at 0.025 despite the data dependent change. The Müller and Schäfer method achieves this goal through a re-designed secondary trial as shown next.

The trial has so far only proceeded to the first interim look with 158 subjects enrolled, and the current value of the test statistic is $z_1 = 0.914$. Its current status can be depicted graphically in East by clicking on the ‘yellow up-arrow’ at the top of the thumbnail chart titled **Stopping Boundaries** in the interim monitoring worksheet, and checking off **Show Design** check box in the expanded chart that appears.

This chart displays the status quo. It shows us the current position of the test statistic in relation to the current and future stopping boundaries. Our objective is to re-design the continuation of this trial with appropriate changes to the sample size and stopping boundaries, and possibly also to the spending function, the number of remaining looks and their spacing. In effect, we wish to capitalize on having taken an unblinded look at the data from the 158 subjects already enrolled to re-design the trial so that it has a better chance of success and utilizes the data yet to be collected more efficiently. At the same time we do not wish to ignore the data already obtained when we perform the final analysis, and we do not want this trial to lose its pivotal status by failing to

56 Muller and Schafer Method

preserve the overall type-1 error. The Müller and Schäfer method makes this possible.

We stated in Section 56.1 that the unconditional type-1 error, over all possible design modifications, is preserved provided that each time a design modification is made, the remainder of the trial preserves the CRP, ϵ_0 . Here in our example with one-sided test, the first step is to compute ϵ_0 using equation (56.1.1). For example, in the above nominal critical point chart, $z_1 = 0.914$, the boundary at sample size $n_2 = 315$ is $(b_2) = 2.513$ and the boundary at sample size $n_3 = 473$ is $(b_3) = 1.993$. Therefore

$$\begin{aligned} \epsilon_0 &= P_0\{Z_2 \geq 2.513 | z_1 = 0.914\} \\ &\quad + P_0\{Z_2 < 2.513 \text{ and } Z_3 \geq 1.993 | z_1 = 0.914\} . \end{aligned}$$

The Müller and Schäfer calculator provided by EastAdapt can evaluate this CRP. With the cursor in any cell of the interim monitoring worksheet of Plan1, click on the icon

. The following Müller and Schäfer calculator dialog box appears,

revealing that at the first interim look the sample size is 158, the observed value of the test statistic is $z = 0.914$. The calculator permits the user to enter values for δ and σ , or for δ/σ , and computes conditional power assuming no change in the future course of the current group sequential design having a maximum sample size 473. The default values of δ and σ when this calculator is first invoked are the values that were entered into the interim monitoring worksheet through the test statistic calculator for the current look. In this case, the values were $\delta = 8$ and $\sigma = 55$, resulting in $\delta/\sigma = 0.145$. The conditional power if the trial proceeds without any design modification is shown to be 0.311. To obtain the conditional type-1 error (or conditional rejection

probability) we enter the value 0 in the δ/σ edit box and press the **Recalc** button.

| Conditional Power Calculator | |
|--|-------|
| Input | |
| Look #: | 1 |
| Cumulative Sample Size: | 158 |
| Test Statistic: | 0.914 |
| Input/Output | |
| <input type="checkbox"/> Value of δ : | |
| Value of σ : | |
| <input checked="" type="checkbox"/> Value of δ/σ : | 0 |
| Computed Conditional Power: | 0.038 |
| Sample Size (Overall): | 473 |
| <input type="button" value="Recalc"/> <input type="button" value="Plot"/> <input type="button" value="Details..."/> <input type="button" value="Close"/> | |

The conditional type-1 error is seen to be $\epsilon_0 = 0.038$.

We can make any desired modifications to the remainder of the trial, such as changing the remaining sample size, or the number of future interim look and their locations, provided we preserve the conditional rejection probability. Accordingly, it is decided that the trial should continue to be extended to two further looks but should utilize the **LD (PK)** (Pocock) spending function instead of the current **LD (OF)** (O'Brien-Fleming) spending function for the stopping boundary, so as to increase the chance of early termination. Additionally, the sample size should be increased appropriately to make the conditional power, given $z_1 = 0.914$ at $\delta = 10$ and $\sigma = 50$, equal to 90%. In keeping with the Müller and Schäfer principle, the new stopping boundaries should be such that if in fact $\delta = 0$, the probability of crossing the boundary is 0.038. That is, we must preserve the conditional type-1 error of the original unmodified trial in the modified trial.

56.2.4 Implementing Adaptive Changes through Secondary Trial

56 Muller and Schafer Method

At first sight, it appears complicated to modify the boundaries of the on-going trial in which $z_1 = 0.914$ so as to fulfill conditional type-1 error requirement, $\epsilon_0 = 0.038$, with a Pocock **LD (PK)** spending function for the boundary. The solution, however, is rather simple and can be accomplished very naturally within EastAdapt. The approach, proposed by Müller and Schäfer, is to step away from the actual trial (hereafter referred to as the primary trial) at its look $L = 1$, (where an adaptive change has been requested), and to instead design an independent secondary two-look trial that has 90% power to detect $\delta = 10$ at $\sigma = 50$, and utilizes the Pocock **LD (PK)** spending function to generate the boundary, with $\alpha = 0.038$. Note that this error probability is the only statistic that we are required to carry forward from the primary trial into the design of the secondary trial. The further progress of the primary trial may then be conveniently monitored by entering the observed values of the test statistic, **computed only from incremental data generated after trial modification** into the interim monitoring worksheet of this secondary trial. In particular, the value $z_1 = 0.914$ from the primary trial plays no role in the interim monitoring of the secondary trial, since this value was already factored into the computation of ϵ_0 . We illustrate below.

To design the secondary trial, click on Des1 node in the library, and then click on the icon . In the ensuing input dialog box, enter Number of Looks as 2, Test Type as 1-sided, Type I Error(α) as 0.038, power as 0.9, and Mean and SD values under alternative as 10 and 50 respectively as shown below.

| | | | | | |
|----------------------------|---------------|--|---------------------|------------------------------|----|
| Test Type: | 1-Sided | Input Method: | Difference of Means | Test Statistic: | Z |
| Type I Error (α): | 0.038 | Diff. in Means ($\delta = \mu_t - \mu_c$): | 10 | Std. Deviation (σ): | 50 |
| Power: | 0.9 | | | | |
| Sample Size (n): | Computed | | | | |
| Allocation Ratio: | 1 | | | | |
| | (n_t/n_c) | | | | |

Click on **Boundary Info** tab and change the efficacy boundary as PK, as shown below.

| | | | |
|--|-----------------------|---|--------------------------|
| Efficacy Boundary Family: <input type="text" value="Spending Functions"/> Spending Function: <input type="text" value="Lan-DeMets"/> Parameter: <input type="text" value="PK"/> Type I Error (α): 0.038 | | Futility Boundary Family: <input type="text" value="None"/> | |
| Spacing of Looks: <input checked="" type="radio"/> Equal <input type="radio"/> Unequal | | Efficacy Boundary: <input type="text" value="Z Scale"/> | |
| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
| 1 | 0.500 | 0.024 | 1.985 |
| 2 | 1.000 | 0.038 | 2.015 |

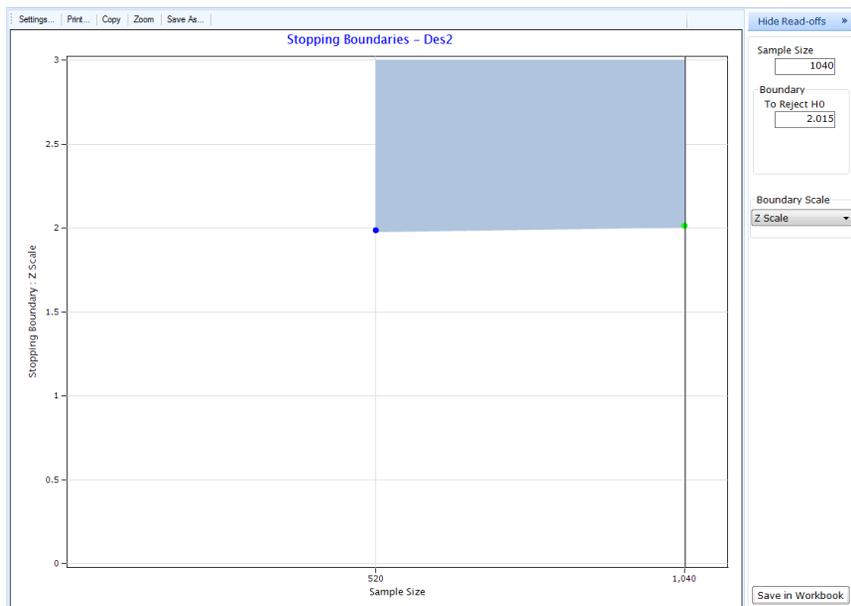

Now click on **Compute**. A new row will be added in the Output Preview window. Click on the row and save it in the library as Des2 node. Now select Des1 and Des2 nodes by holding ctrl key and then click Output Summary icon . You will see the following screen shot displaying the results for Des1 and Des2 side by side.

| | Wbk1:Des1 | Wbk1:Des2 |

| Power | 0.9 | 0.9 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Input Method | Difference of Means | Difference of Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 15 | 10 |
| Std. Deviation (σ) | 50 | 50 |
| Test Statistic | Z | Z |
| Boundary Parameters | | |
| Spacing of Looks | Equal | Equal |
| Efficacy Boundary | LD (OF) | LD (PK) |
| Sample Size | | |
| Maximum | 473 | 1040 |
| Expected Under H0 | 472.032 | 1027.747 |
| Expected Under H1 | 379.185 | 719.637 |

Des2 requires a maximum sample size of 1040 subjects and calls for two equally

56 Muller and Schafer Method

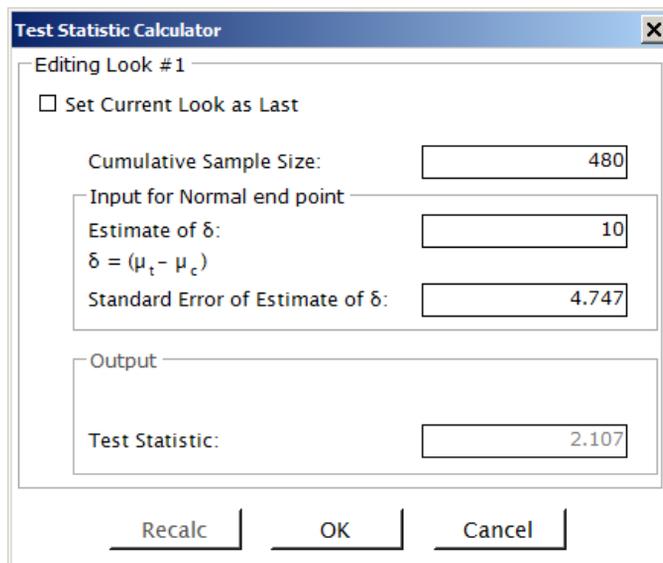

spaced looks, with a **LD (PK)** stopping boundary, as displayed below.

The further progress of the modified trial is now monitored on the interim monitoring worksheet of Plan2. Click on the **IM** tool to invoke the interim monitoring worksheet.

Suppose the data are monitored after 480 **new** subjects enter the trial. This corresponds to a total enrollment of $158 + 480 = 638$ subjects in the primary and secondary trials combined together. The secondary trial, however, only monitors the incremental data obtained from the 480 new subjects. Let us assume that these 480 new subjects provide the estimates $\hat{\delta} = 10$ and $\hat{\sigma} = 52$, so that $se(\hat{\delta}) = \sqrt{4 \times 52^2 / 480} = 4.747$. Enter these values into the Plan2 interim monitoring worksheet in the usual manner as shown

below.

The screenshot shows a dialog box titled "Test Statistic Calculator" with a close button (X) in the top right corner. The dialog is divided into several sections:

- Editing Look #1**: Contains a checkbox labeled "Set Current Look as Last" which is currently unchecked.
- Input for Normal end point**: A section containing three input fields:
 - "Cumulative Sample Size:" with the value 480.
 - "Estimate of δ :" with the value 10. Below this field is the formula $\delta = (\mu_t - \mu_c)$.
 - "Standard Error of Estimate of δ :" with the value 4.747.
- Output**: A section containing one output field:
 - "Test Statistic:" with the value 2.107.

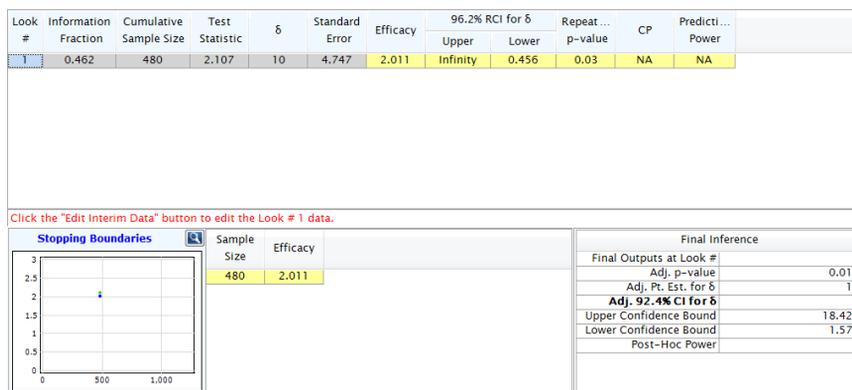

At the bottom of the dialog, there are three buttons: "Recalc", "OK", and "Cancel".

Click on **OK** to post these numbers into the interim monitoring worksheet. Now the observed value of the test statistic is 2.107 whereas the upper stopping boundary to reject H_0 is 2.011. Therefore you'll be notified by East that the stopping boundary has been crossed.

Click on the **Stop** button to terminate the trial and the Final Inference details are

56 Muller and Schafer Method

displayed as shown below.

Since the test statistic has crossed the upper boundary, the null hypothesis $\delta = 0$ is rejected. The requirement that the CRP be preserved no matter how the original trial is modified ensures that the unconditional type-1 error of the primary trial, taken over all possible trial modifications within any family of modifications under consideration, will always be preserved. We shall verify this fact through simulation in Section 56.2.6.

It should be noted that the confidence interval, point estimate and p-value displayed on the interim monitoring worksheet of the secondary trial are not valid for the overall trial. Those inferences must be made using the adaptive extension of the Müller and Schäfer (2001) procedure as described in Section 56.1.2. The implementation in EastAdapt is shown in Section 56.3.

56.2.5 Reconstructing a Combined Trial from the Primary and Secondary Trials

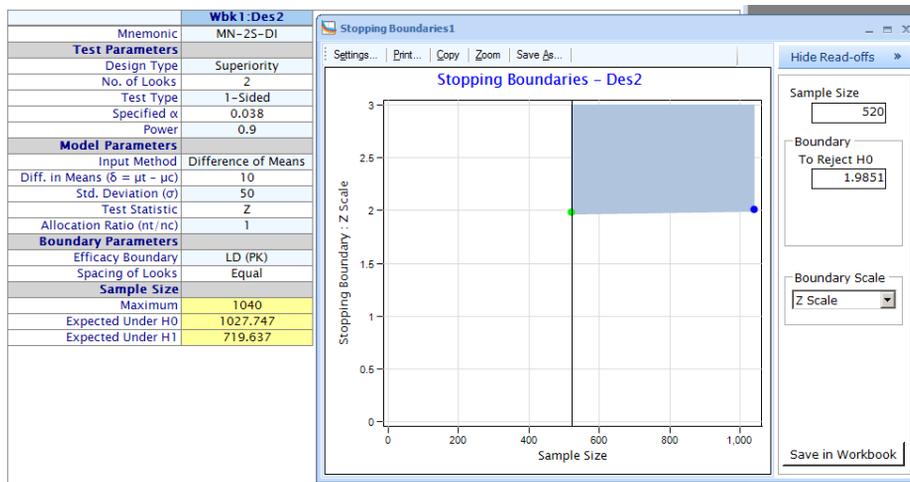

The secondary trial was terminated after a single look, taken at a sample size of 480 subjects. The interim monitoring worksheet of the secondary trial showed that the stopping boundary at this look was 2.011. Although not strictly necessary, it is instructive to transform these boundaries appropriately and attach them to the primary trial thereby recreating the combined trial in one piece. The path traced out by the test statistic in the secondary trial can likewise be appropriately transformed and attached to the test statistic generated in the primary trial before the trial was modified. The reconstruction is helpful for clarifying that it is the combined trial and not the secondary trial that is actually being monitored after an adaptive change in the design. The secondary trial is an artificial construct; a convenient way to obtain new stopping boundary satisfying the specification of the conditional rejection probability in the

combined trial.

Let us illustrate by reconstructing the combined trial for our example. In the discussion that follows, we shall distinguish between data from the primary and secondary trials by labeling the test statistics, stopping boundaries and sample sizes with superscripts. For example the sample size at look 1 in the primary trial is denoted by $n_1^{(1)}$ while the sample size of the secondary trial at look 1 is denoted by $n_1^{(2)}$. Now recall that the primary trial only proceeded up to the first interim look with a sample size $n_1^{(1)} = 158$ and corresponding stopping boundary 3.706. The mean and standard error of δ at look 1 were $\hat{\delta}_1^{(1)} = 8$ and $se(\hat{\delta}_1^{(1)}) = 8.751$, leading to the Wald statistic $z_1^{(1)} = 0.914$. At this point we implemented an adaptive change in the primary trial with the following requirements:

- Conditional rejection probability at $\delta = 0$ should be 0.038
- Conditional power at $\delta = 10, \sigma = 50$ should be 90%
- Two equally spaced additional looks with the **LD (PK)** spending function spending the type-1 error according to the CRP.

These requirements were incorporated into a secondary trial displayed below as Des2.

Although Des2 was designed for two equally spaced looks, at sample sizes 520 and 1040 respectively, the first look was actually taken at a sample size of $n_1^{(2)} = 480$. The information fraction at this look was $t_1^{(2)} = 480/1040 = 0.462$. By spending the appropriate amount of error at this information fraction the stopping boundaries was

56 Muller and Schafer Method

obtained as 2.011. We observed $\hat{\delta}_1^{(2)} = 10$, and $\text{se}(\hat{\delta}_1^{(2)}) = 4.747$, resulting in the Wald statistic $z_1^{(2)} = 2.107$.

We now show how to represent the stopping boundaries and test statistic values of the primary and secondary trials through a single combined trial. Suppose that a K -look primary trial is monitored up to and including look $L < K$, at which point an adaptive change takes effect. Suppose that all new data obtained after the adaptive change are monitored through a $K^{(2)}$ -look secondary trial which terminates at some look $K' \leq K^{(2)}$. It is possible to prove that monitoring the primary and secondary trials separately, as was done above, is equivalent to monitoring a single combined trial consisting of $L + K'$ looks. The stopping boundaries and test statistic values for the first L looks of this combined trial are identical to the corresponding values of the primary trial. The value of the test statistic at look $L + j$, $j = 1, 2, \dots, K'$, of the combined trial is

$$z_{L+j}^{(c)} = \frac{z_L^{(1)} \sqrt{n_L^{(1)}} + z_j^{(2)} \sqrt{n_j^{(2)}}}{\sqrt{n_L^{(1)} + n_j^{(2)}}}. \quad (56.9)$$

The value of the stopping boundary at look $L + j$ of the combined trial is

$$b_{L+j}^{(c)} = \frac{z_L^{(1)} \sqrt{n_L^{(1)}} + b_j^{(2)} \sqrt{n_j^{(2)}}}{\sqrt{n_L^{(1)} + n_j^{(2)}}}. \quad (56.10)$$

For more general settings, such as binomial or survival data, we would replace sample size by Fisher information in each of the above formulae.

Applying these formulae to the example under consideration we have $L = 1$ and $K' = 1$ so that the combined trial consists of $L + K' = 2$ looks. The boundaries and test statistics for the first look of the combined trial are identical to the corresponding values of the primary trial. The upper stopping boundary of the second look of the combined trial is obtained from equation (56.10) to be

$$b_2^{(c)} = \frac{0.914 \times \sqrt{158} + 2.011 \times \sqrt{480}}{\sqrt{158 + 480}} = 2.199$$

The value of the test statistic at the second look of the combined trial is obtained from equation (56.9) to be

$$z_2^{(c)} = \frac{0.9142 \times \sqrt{158} + 2.107 \times \sqrt{480}}{\sqrt{158 + 480}} = 2.282$$

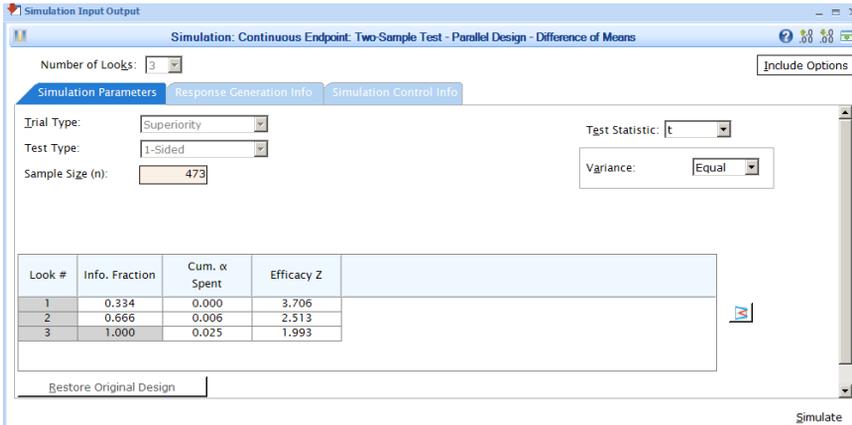

Since $z_2^{(c)} > b_2^{(c)}$, the combined trial is terminated.

56.2.6 Verifying Operating Characteristics by Simulation

Simulation is a very valuable tool for making adaptive decisions that suit the needs of the study. For example one might want to place an upper bound on the magnitude of the sample size increase following an adaptive look at the interim results, or one might want to place a lower bound on the estimated value of δ such that no sample size increase would be permitted should the estimate fall below the lower bound. These and other similar restrictions will affect the power of the study as well as the expected sample size in ways that might not be analytically tractable. One can, however, easily estimate power and expected sample size for various adaptive designs through simulation.

There is a second important reason for including a simulation tool in EastAdapt. We have made a major claim that by preserving the CRP after any type of adaptation, we will automatically preserve the unconditional type-1 error, taken over all possible adaptations, as well. A convincing way to demonstrate that this claim is correct is through simulation.

To illustrate how to use the simulation tool in EastAdapt, let us consider once again Des1 that we created in Section 56.2.1. With the cursor on Des1 node in the library, click on . You will see the following simulation input/output dialog box with three tabs **Simulation Parameters**, **Response Generation Info**, and **Simulation Control Info**. These are the same tabs you would have come across in the earlier chapters of the manual.

Now click on the button **Specify Stage II Design**. In the resulting dialog box, specify the Stage II Design details as described below.

The above dialog box has three sections.

Number of Looks Specify number of looks as 2.

Specification of α for Stage II This section of the dialog box asks you to specify how

56 Muller and Schafer Method

EastAdapt is to obtain the type-1 error for creating each simulated design of the Stage II or secondary trial . There are two choices. The default item is **Conditional Type-1 Error from Stage-1**. If you select this option, EastAdapt computes the conditional rejection probability ϵ_0 from each simulation of the primary trial at its look L , where an adaptive change has been requested. The secondary trial is then designed so as to spend $\alpha = \epsilon_0$. If you choose the **User Specified** item, then, you will have to specify how much α you would like to spend for the secondary trial. Ordinarily the default option should be selected as it ensures that the overall type-1 error of the adaptive trial will be preserved.

Specification of δ for Stage II This query of the dialog box asks you to specify how EastAdapt is to obtain the value of δ at which to power each simulation of the Stage II (secondary) trial. If you choose the **Estimated from Stage I** item, EastAdapt will use the value of δ estimated from the primary trial at its look L , where an adaptive change has been requested. If you choose the **User Specified** radio button, you will have to specify the value of δ at which to power the secondary trial. We stated in Section 56.2.3 that the secondary trial will be powered at $\delta = 10$. Therefore we select the **User Specified** radio button.

Specification of σ for Stage II This query of the dialog box asks you to specify how EastAdapt is to obtain the value of σ for each simulation of the Stage II (secondary) trial. If you choose the **Estimated from Stage I** radio button, EastAdapt will use the value of σ estimated from the primary trial at its look L , where an adaptive change has been requested. If you choose the **User Specified** radio button, you will have to specify the value of σ in a subsequent dialog box. We stated in Section 56.2.3 that the secondary trial will be powered at $\sigma = 50$. Therefore we select the **User Specified** radio button.

The dialog boxes will look as shown below.

Design Type: Superiority Number of Looks: 2 Specification of alpha: Cond. Type I Error From Stage-1

Now we are ready for carrying out our simulation of the trial. Let us call this as 'Experiment 1'.

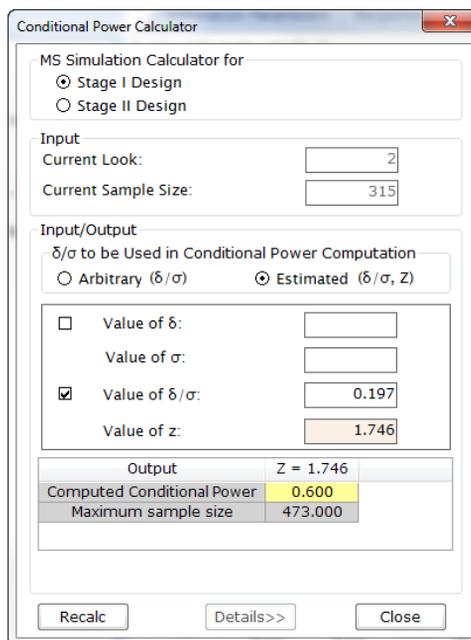

56 Muller and Schafer Method

Experiment 1: Explaining the Basics of the Simulation Tool

Suppose we specify simulation parameters as described below.

- Data for each simulation of the primary trial will be generated from a normal population with a difference of means $\delta = 12$ and population standard deviation $\sigma = 50$.
- In each simulation, the primary trial will proceed through $L = 2$ looks, each look being equally spaced with $473/3 = 158$ subjects. After look 2, there may be an adaptive change, depending on the simulated data obtained at look 2.
- At the end of the second look, when the sample size is 316, the conditional power will be computed. This computation will utilize the estimates $\hat{\delta}$ and $\hat{\sigma}$ obtained from the simulated data up to look L . The value of the conditional power estimate in relation to the re-design criteria **Min.CP** and **Max.CP** will determine whether or not the primary trial should undergo an adaptive change. If the conditional power obtained under the current design falls between 30% and 90%, then an adaptive change will be made to the primary trial. Alternatively, you can specify Promising Zone range in terms of Test Statistic or Estimated δ/σ , by making the choice in the drop down box. If adaptive change is decided, in that case:
 - As explained previously, the adaptive change to the primary trial will be implemented **indirectly** by invoking a secondary trial whose plan details are shown as **Specify Stage II Design** on this screen..
 - The secondary design is one-sided and spends its $\alpha = \epsilon_0$. The value assumed by this conditional rejection probability depends on the value of $z_L^{(1)}$ obtained in the primary trial.
 - There will be two equally spaced looks in the secondary trial with both α being spent according to the **LD (PK)** (Pocock) spending function.
 - The sample size of the secondary trial will be computed so that this trial can achieve $(1 - \beta) = 0.9$ power under the alternative hypothesis $\delta_1 = 10$ with $\sigma = 50$.
 - This indirect approach corresponds to modifying the primary trial in such a way that the **conditional power** for the remainder of the trial, given the observed value of $z_L^{(1)}$ is 90%.
- We have stated that EastAdapt will compute the sample size required in order for the secondary trial to achieve $(1 - \beta) = 0.9$ power at significance level of $\alpha = \epsilon_0$. Denote this sample size by $N_{\max}^{(2)}$, and denote the combined sample size, to be utilized by both the primary and secondary trials, by $N_{\max}^{(c)}$. In the present example, since $L = 2$, we must have $N_{\max}^{(c)} = 316 + N_{\max}^{(2)}$. More generally $N_{\max}^{(c)} = n_L^{(1)} + N_{\max}^{(2)}$

- In the present example, the field titled **Max. Sample Size if Adapt** has been set to 946 through a multiplier of 2 on primary trial max. sample size which is 473. This means that:
 - If $N_{\max}^{(c)} < 473$, EastAdapt will **extend** the combined sample size to $N_{\max}^c = 473$. In that case the sample size of the secondary trial will be correspondingly increased to $N_{\max}^{(2)} = 473 - 158 = 316$.
 - If $N_{\max}^c > 946$, East Adapt will **truncate** the combined sample size to $N_{\max}^{(c)} = 946$. In that case the sample size of the secondary trial will be correspondingly truncated to $N_{\max}^{(2)} = 946 - 316 = 630$.
- There is also a Conditional Power calculator available in this dialog box, which you can access by clicking on the button . This calculator will be useful to understand the simulation parameters and their impact on the simulation results. The calculator has two functions one for Stage I Design and the other for Stage II Design. By default, Stage I Design will appear selected as shown below.

You may enter any input values involving δ , σ , and z and can get the computed conditional power for the Stage I Design. In this example, the default values for δ/σ and z of 0.197 and 1.746 are displayed corresponding to conditional power of 0.6 which is a mid-value in the range specified for promising zone - 0.3 to

56 Muller and Schafer Method

0.9. You may change the input values to see their impact on computed conditional power in Stage I. Now select the radio button against Stage II Design as shown below.

| Sample Size (Integrated) | 886.401 |

* In promising zone and trial adapted

Recalc Details>> Close

Since at Stage I, the computed conditional power of 0.6 is in the Promising Zone, adaptation takes place. Further, the computations show that the maximum sample size for Stage II design is 571 and that for the integrated trial is 886 in order to achieve 90% power in Stage II. The implication is that we can choose a multiplier less than 2 in the specification for maximum sample size ($886/473 = 1.87$), provided the Stage I results assumption holds good. Now click on the button 'Details'. You will see the two Boundary Plots as shown

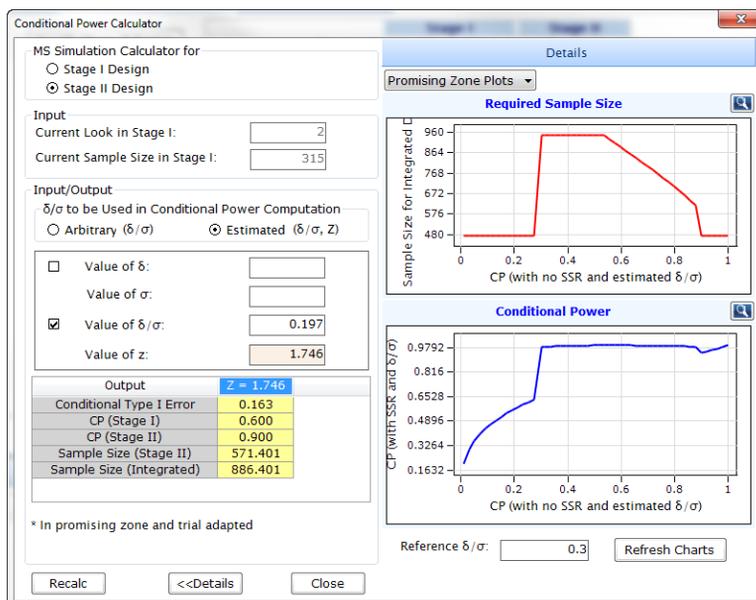

below.

In the Boundary Plot for the integrated design, the first and second looks boundaries correspond to those of Stage I design. The point plotted below the second look boundary value correspond to the z value estimated at that look. You may reach this point by different routes from the first look z value. For illustration, five different routes are shown, all joining the second look z value. Next, choose **Promising Zone Plots** in the drop down box under Details. You

56 Muller and Schafer Method

will see two plots -**Required Sample Size** and **Conditional Power** Plots.

The Required Sample Size plot shows that required sample size increases to a maximum of 946 at the start of promising zone, that is at CP=0.3 and gradually reduces when reaching the end of promising zone, that is at CP=0.9. Outside the promising zone, the required sample size remains steady at the stage I maximum sample size value of 473.

The Conditional Power plot shows the relationship between the conditional power without SSR and the conditional power with SSR, under a reference value of δ/σ . The conditional power with SSR increases to maximum values in the promising zone.

- There will be 10000 simulated trials and the screen will be refreshed after every 1000 simulations, and the starting seed for the simulations will be 100.

To run 10000 simulations of this adaptive design click on the **Simulate** button. After 10000 simulations are done click **Close**. East will add the results in a new row in Output Preview Window. Click on this row and add it to the library node under Des1. If you double-click on this node you will see the simulation results displayed in several small tables. You can collapse or expand each of these tables by clicking on down arrow or right arrow buttons at the top left hand side in each table.

First let us look at the table on the far left side of the screen.

The above tables show parameters of stage-I design, parameters for sample-size re-estimation, and the parameters for stage-II design.

Now let us look at the Tables on the right side.

Zone-wise Averages The first tables on the right-side is displayed below.

⊖ Zone-wise Averages

| | Zone | Simulations Rejecting H0 | | Simulations Not Rejecting H0 | | Total Simulations | | Average Sample Size |
|---|-------------|--------------------------|----------|------------------------------|---------|-------------------|----------|---------------------|
| | | Count | Row % | Count | Row % | Count | Column % | |
| ⊖ | Futility | 0 | 0.000% | 0 | 0.000% | 0 | 0.000% | 0 |
| | Unfavorable | 563 | 24.900% | 1698 | 75.100% | 2261 | 22.610% | 473 |
| | Promising | 2944 | 94.541% | 170 | 5.459% | 3114 | 31.140% | 625.946 |
| ⊖ | Favorable | 987 | 90.968% | 98 | 9.032% | 1085 | 10.850% | 473 |
| | Efficacy | 3540 | 100.000% | 0 | 0.000% | 3540 | 35.400% | 308.436 |
| | All Trials | 8034 | 80.340% | 1966 | 19.660% | 10000 | 100.000% | 462.372 |

Promising Zone defined as $0.3 \leq CP < 0.9$

The above results show the classification of simulations by the criterion used under **Sample Size Re-estimation parameters** section in the simulation sheet. Out of 10000 simulations carried out, as there was no futility

rule in the design, no simulation was stopped for futility. In 3540 simulations, H_0 was rejected at the first or second look itself (Efficacy). In 2261 simulations, the CP was less than 0.30 (unfavorable zone) and in 1085 simulations, the CP was greater than 0.90 (favorable zone) and in both these cases, no adaption was needed. In the remaining 3114 simulations, where CP was between 0.3 and 0.9 (promising zone), adaption might be needed.

You may also notice what eventually happened to the simulations under each of the three Zones. Of the 2261 simulations that fell under unfavorable zone where no adaption was made to the sample size, in 563 simulations (24.9%), H_0 was rejected eventually. In all the 1085 simulations that were classified into favorable zone, in 987 simulations (91.0%), H_0 was rejected. Compared to these, in the 3114 simulations that were in the promising zone and where adaption in sample size was made, in as much as 2944 (94.5%) simulations, H_0 was rejected. This result illustrates the positive impact, the sample size adaption can bring about in a trial.

Simulation Results for Integrated Trial This table for the integrated trial, shows, look by look, information on the average sample size, the number of simulations in which the boundary for efficacy was crossed and the total number of simulations. The last row shows that the power attained in the integrated trial is 80.34%.

Experiment 2: No Sample Size Increase

In Experiment 1, we permitted a sample size increase up to a maximum of 946 subjects. This sample size increase enabled the clinical trial to recover power even though the simulations were performed with $\delta = 12$ whereas the primary trial was actually a design to detect $\delta = 15$ with 90% power. If we were to impose the restriction that there should be no sample size increase in these simulations, we would expect to lose power. To see this, re-run the simulations with the **Simulation Parameters** as shown below.

Promising Zone defined as $0.3 \leq CP < 0.9$

This time only 7338 of the 10000 simulations of the combined trial rejected H_0 , yielding 73.38% unconditional power. Of the 10000 simulated trials, 3181 required a sample size increase and therefore activated the secondary trial. However, since no sample size increase was forthcoming, only 2282 of these trials were able to reject H_0 , resulting in 71.74% conditional power.

Experiment 3: Preserving the Unconditional Type-1 Error The statistical validity of the Müller and Schäfer adaptive procedure hinges on the claim that, despite making data dependent changes to the primary trial, the unconditional type-1 error is always preserved so long as the conditional rejection probability in effect at the time of the adaptive re-design is preserved. To verify this claim, edit Des1 by changing the type-1 error from 0.025 to 0.05, and by changing the spending function from **LD (OF)** (O’Brien-Fleming) to **LD (PK)** (Pocock), and save the edited design as Des3. These changes will exaggerate any possible inflation of type-1 error, and will thereby provide stronger empirical evidence for the validity of the Müller and Schäfer procedure. Des3 is displayed below as a group sequential design with three equally spaced looks and a

maximum sample size of 442 subjects.

| Wbk1:Des3 | |

| Sample Size | |
| Maximum | 442 |
| Expected Under H0 | 433.04 |
| Expected Under H1 | 269.098 |

Suppose we decided to convert Des3 into an adaptive design in the following manner:

1. Proceed with the primary group sequential trial up to and including look 2.
2. Let $z_2^{(1)}$ denote the observed value of the Wald statistic $Z_2^{(1)}$ at look 2 of the primary trial, and let $\hat{\delta}_2^{(1)}$ be the estimate of δ at look 2 of the primary trial.
3. Compute the sample size $N_{\max}^{(2)}$ for the secondary trial (i.e., for the remainder of the combined trial) so as to make the conditional power, given the observed value of $z_2^{(1)}$, equal to 90% under the assumption that $\delta = \hat{\delta}_2^{(1)}$.

Now let us simulate this adaptive design 10,000 times in two ways. First we will simulate the design **without** preserving the conditional rejection probability, ϵ_0 , obtained at the end of look 2 of the primary trial. We will, instead, run each simulation of the secondary trial at the 0.1 level.

56 Muller and Schafer Method

Fill in the ensuing dialog boxes as shown below.

The image displays three sequential dialog boxes from the EastAdapt software interface, configured for the Muller and Schafer adaptive design method.

Dialog 1: Response Generation Info
 - **Generate Data Using:** Individual Means (dropdown)
 - **Mean Control (μ_c):** 0 (input field)
 - **Mean Treatment (μ_t):** 0 (input field)
 - **Common Standard Deviation:**
 - **SD Control (σ_c):** 50 (input field)
 - **SD Treatment (σ_t):** 50 (input field)

Dialog 2: Adaptation Method
 - **Use Adaptation Method:** CHW, CDL, Müller and Schäfer
 - **Adapt at:** Look # (dropdown), 2 (dropdown)
 - **Max. Sample Size if Adapt (multiplier; total #):** 10 (input field), 4420 (input field)
 - **Promising Zone Scale:** Cond. Power (dropdown), CP (button)
 - **Promising Zone:** Min. CP: 0 (input field), Max. CP: 0.9 (input field)
 - **CP Computation Based on:** Estimated δ/σ (dropdown)
 - **Estimation Method:** None (dropdown)

Dialog 3: Specification of Stage II Design
 - **Design Type:** Superiority (dropdown)
 - **Number of Looks:** 1 (dropdown)
 - **Specification of alpha:** User Specified (dropdown)
 - **Specification of delta:** Estimated from Stage-I (dropdown)
 - **Specification of sigma:** Estimated from Stage-I (dropdown)

Dialog 4: Design Parameters
 - **Test Type:** 1-Sided (dropdown)
 - **Type I Error (α):** 0.05 (input field)
 - **Power:** 0.9 (input field)
 - **Sample Size (n):** Computed (input field)
 - **Allocation Ratio:** 1 (input field), (n_t/n_c)
 - **Input Method:** Individual Means (dropdown)
 - **Test Statistic:** Z (dropdown)
 - **Specify Mean Responses:** Mean Control (μ_c): Computed (input field), Mean Treatment (μ_t): Computed (input field)
 - **Std. Deviation (σ):** Computed (input field)

By selecting the **User Specified** radio button for the **Specification of alpha**, we have informed EastAdapt **not** to use the conditional rejection probability for the secondary trial. By selecting **Estimated from Stage-I** for δ and σ , we have asked EastAdapt to make data dependent sample size changes to the trial based on estimates of these parameters obtained from the primary trial. Click on **Simulate** button to generate 10,000 simulations of this adaptive design. Save the results in the library node. By double-clicking on the node or by clicking on 'Details' button, you

will the following results along with other results.

⊖ Simulation Results for Integrated Trial:

| Look # | Average Sample Size (n) | Stopping For | Total Simulations | |
|--------|-------------------------|--------------|-------------------|---------|
| | | Efficacy | Count | % |
| 1 | 147 | 229 | 229 | 2.290% |
| 2 | 295 | 152 | 152 | 1.520% |
| 3 | 1965.018 | 245 | 9619 | 96.190% |
| Total | 1898.002 | 626 | 10000 | |
| % | | 6.26 | | |

⊖ Simulation Results for Stage II Trial:

| Look # | Average Sample Size (n) | Stopping For | Total Simulations | |
|--------|-------------------------|--------------|-------------------|----------|
| | | Efficacy | Count | % |
| 1 | 3271.315 | 245 | 4689 | 100.000% |
| Total | 3271.315 | 245 | 4689 | |
| % | | 5.225 | | |

The **Simulation Results for Integrated Trial** panel shows that that 626 of the 10,000 simulations rejected the null hypothesis. Thus the type-1 error rate was 0.0626 which is excessive, even allowing for Monte Carlo error. We conclude that in these simulations the type-1 error was inflated.

Next we will simulate the adaptive design while also preserving the conditional rejection probability, ϵ_0 , obtained at the end of look 2 of the primary trial. Keeping cursor on the last simulation node, click on 'Edit' button and make selection for alpha as shown below.

56 Muller and Schafer Method

By selecting the **Conditional Type-I Error from Stage-I** radio button in the **Specification of alpha from Stage-I**, we are asking EastAdapt to use the conditional rejection probabilities obtained at the time of the adaptive change, for re-designing the trial. Therefore we would expect the unconditional type-1 error to be preserved. To see this, click on **OK** and then on **Simulate** to run 10,000 simulations. Now you will see the results as shown below.

⊖ Simulation Results for Integrated Trial:

| Look # | Average Sample Size (n) | Stopping For | Total Simulations | |
|--------|-------------------------|--------------|-------------------|---------|
| | | Efficacy | Count | % |
| 1 | 147 | 228 | 228 | 2.280% |
| 2 | 295 | 178 | 178 | 1.780% |
| 3 | 2031.773 | 118 | 9594 | 95.940% |
| Total | 1957.886 | 524 | 10000 | |
| % | | 5.24 | | |

⊖ Simulation Results for Stage II Trial:

| Look # | Average Sample Size (n) | Stopping For | Total Simulations | |
|--------|-------------------------|--------------|-------------------|----------|
| | | Efficacy | Count | % |
| 1 | 3391.477 | 118 | 4701 | 100.000% |
| Total | 3391.477 | 118 | 4701 | |
| % | | 2.51 | | |

The **Simulation Results for Integrated Trial** table shows that only 524 of the 10,000 simulations rejected H_0 , for an overall unconditional type-1 error rate of 0.0524. This demonstrates that the type-1 error of 0.05 was preserved up to Monte Carlo accuracy.

56.3 Implementation of Parameter Estimation

56.3.1 Parkinson's Disease

56.3.2 BWCI versus RCI

In this section we show how the generalization of the Müller and Schäfer (2001) method to the problem of parameter estimation has been implemented in EastAdapt. Results are presented for both the RCI method developed by Mehta, Bauer, Posch and Brannath (2007) and the BWCI (Backward Image Confidence Interval) method developed by Gao, Liu and Mehta (2013).

We shall see that the BWCI method has some advantages over the RCI method.

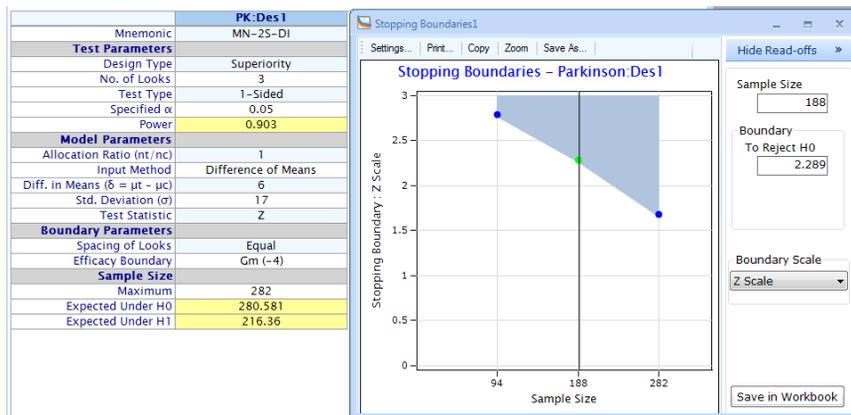

- The BWCI method produces confidence intervals with exact coverage, whereas the RCI method produces conservative coverage. The procedure is based on mapping the final test statistic obtained in the modified trial into a corresponding backward image in the original trial.
- The BWCI method produces a median unbiased point estimate, whereas the RCI method provides point estimates that can be severely negatively biased.

56.3.1 Parkinson's Disease Example

To illustrate how parameter estimation has been implemented, we consider a slight modification of an example discussed in Müller and Schäfer (2001). Müller and Schäfer consider a clinical trial comparing deep brain stimulation to conventional treatment for Parkinson's disease. The main outcome variable was the quality of life as measured by the 39-item Parkinson's Disease Questionnaire (the PDQ-39). Since no prior PDQ-39 data on deep brain stimulation were available, the study was planned based on the data from the pallidotomy trial of Martinez-Martin (2000). This led to the assumption of an improvement by $\delta = 6$ points in PDQ-39 for the treatment arm relative to the control arm. The standard deviation, also subject to considerable uncertainty, was assumed to be 17. We shall assume here that the trial was initially planned as a three-look group sequential design at the one-sided 0.05 level to test $H_0: \delta = 0$. A sample size of 282 subjects was selected with equally spaced interim monitoring after $n_1^{(1)} = 94$, $n_2^{(1)} = 188$, and $n_3^{(1)} = 282$ subjects, using the $\gamma(-4)$ error spending function of Hwang, Shih, and DeCani (1990). Upon entering these parameters into East we obtain the following design (Plan1) with slightly over 90% power to detect $\delta = 6$, and Wald stopping boundaries given by $b_1^{(1)} = 2.794$,

56 Muller and Schafer Method

$$b_2^{(1)} = 2.289, \text{ and } b_3^{(1)} = 1.680.$$

To illustrate our estimation procedure we implement a hypothetical (but realistic) scenario in which the first interim analysis is followed by an adaptive change to the design. Suppose that at the first interim analysis, when 94 subjects have been evaluated, the estimate of δ is $\hat{\delta}^{(1)} = 4.5$ with estimated standard deviation $\hat{\sigma} = 20$. We invoke the interim monitoring worksheet by pressing the **IM** icon.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|----------------------|-------|------------------|----|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | | | | | | | | | | | |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

Next click on 'Enter Interim Data' to bring up the test statistic calculator

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Cumulative Sample Size: 94

Input for Normal end point

Estimate of δ : 6
 $\delta = (\mu_1 - \mu_c)$

Standard Error of Estimate of δ : 3.507

Output

Test Statistic: 1.711

Recalc OK Cancel

Keep the cumulative sample size as 94. Enter $\hat{\delta} = 4.5$ and $se(\hat{\delta}) = \sqrt{4 \times 20^2 / 94}$ into

56 Muller and Schafer Method

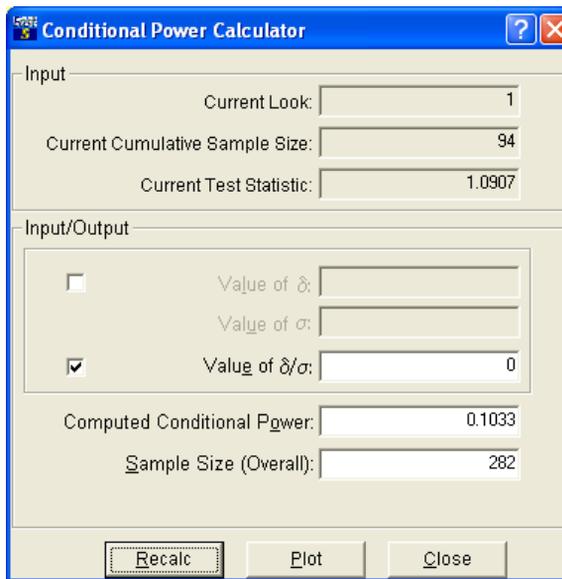

the test statistic calculator. Next, hit the **Recalc** button.

Now click **OK**. This completes the data entry for the first interim look.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|----------------------|--------|------------------|-------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.333 | 94 | 1.091 | 4.5 | 4.126 | 2.794 | Infinity | -7.026 | 1 | 0.606 | 0.562 |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

At this point it is decided to increase the sample size since, if in truth $\delta = 4.5$ and $\sigma = 20$, the conditional power is only about 60%, whereas we would prefer to proceed with at least 80% conditional power. The conditional rejection probability for the remainder of the trial is 0.1033. This can be seen by invoking the conditional power

calculator icon CP, setting $\delta/\sigma = 0$, and clicking on 'Recalc' button.

You can click on 'Close' and close the calculator. We may construct any suitable secondary trial to take over from the primary trial at the present look, as long as the significance level of the secondary trial is $\epsilon = 0.1033$.

How should the secondary trial be designed? The real benefit of an adaptive trial lies in the fact that all aspects of the original design can be re-visited at an interim look. All the observed efficacy and safety data, rather than just the summary statistics $\hat{\delta}$ and $\hat{\sigma}$, could be reviewed alongside any new external information that may also become available. Suitable design changes can then be made to the primary trial. In the present case we will assume that as a result of this type of review the investigators have determined that $\delta = 5$ rather than $\delta = 6$ would still constitute a clinically meaningful treatment benefit. Suppose then that the sponsor decides to re-design the study under the now more accurate assumption that $\delta = 5$ and $\sigma = 20$. To this end they decided to adopt a three-look secondary trial with $\gamma(-2)$ spending function and 80% power. The $\gamma(-2)$ spending function was selected because, under the new alternative hypothesis $\delta = 5$, it provides a reasonable chance of terminating for efficacy at the first or second interim looks. In keeping with the Müller and Schäfer principle the α for the secondary trial must be 0.1033. This secondary trial is constructed as shown below and displayed as Des2.

56 Muller and Schafer Method

Enter $\alpha = 0.1033$, 3 looks, 0.8 power, $\delta = 5$ and $\sigma = 20$ into the first dialog box of the design wizard.

Design Type: Superiority Number of Looks: 3

| 1 | | | | | | | | | | | |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

Suppose the following data are observed and the first and second interim looks, leading to termination of the trial at the second look.

| Look | SampSize | $\hat{\delta}$ | $\hat{\sigma}$ | $se(\hat{\delta})$ | $Z = \hat{\delta}/se(\hat{\delta})$ |
|------|----------|----------------|----------------|--------------------|-------------------------------------|
| 1 | 100 | 5.8 | 20.5 | 4.1 | 1.4146 |
| 2 | 200 | 6.1 | 19.5 | 2.7577 | 2.212 |

56 Muller and Schafer Method

After these values are entered into the interim monitoring worksheet, it looks as shown below

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 89.67% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|-------------------------|--------|------------------|--------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.338 | 100 | 1.415 | 5.8 | 4.1 | 2.154 | Infinity | -3.033 | 0.52 | 0.9174 | 0.7937 |
| 2 | 0.676 | 200 | 2.212 | 6.1 | 2.758 | 1.768 | Infinity | 1.223 | 0.038 | NA | NA |

Boundary Crossed

Since the value of Test Statistic is \geq the critical point for efficacy, H_0 is rejected.

Although boundary has been crossed, East gives you choice either to stop the study or to continue entering further looks. Please make your decision.

stop the study and bar further looks input

allow the study to continue

| Final Inference | |
|---|-------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0.025 |
| Adj. Pt. Est. for δ | 5.824 |
| Adj. 79.34% CI for δ | |
| Upper Confidence Bound | 9.396 |
| Lower Confidence Bound | 2.147 |
| Post-Hoc Power | |

The stopping boundary at the second look was crossed and statistical significance has been achieved. The point and interval estimates of δ and the p-value displayed at the bottom right corner of the interim monitoring worksheet are, however, only valid for the secondary trial and not for the overall trial that combines the data from the first and second stages.

56.3.2 Evaluating the BWCI and RCI Methods by Simulation

In the previous section we designed and monitored a clinical trial comparing deep brain stimulation and conventional therapy for Parkinson's disease. EastAdapt provides a simulation tool for evaluating the properties of the two methods of estimation - RCI and BWCI. This tool can be invoked for any one-sided design. We shall demonstrate its utility by applying it to the Parkinson's disease example.

Return to the Des1 design that was created in the previous section for the Parkinson's

disease trial.

| PK:Des 1 | |

With the choices made, the design parameters of the secondary trial in each simulation will be estimated from the data generated from the primary trial at the time of the adaptation. The significance level (α) for this trial will be determined from the data of the primary trial, in keeping with the Müller and Schäfer principle. The sample size will be determined by the values of δ and σ that are estimated from the data of the primary trial. Click on 'Simulate' button. After 10,000 simulations are carried out, click 'Close' to get results in the Output Preview and add it a library node. With the

cursor on this node, click 'Details' icon. In the resulting output at the bottom you will see the results RCI Estimation method as shown below.

| [25.057,27.779) | 4 | 0.04 | 0.04 |

You can choose from the plot icon menu, the item 'Distribution of Confidence Bounds' to get the following histogram.

The results obtained so far help to evaluate the properties of the BWCI and RCI methods with respect to coverage. Similarly we can carry out simulations to evaluate bias, by specifying in the simulation parameters confidence coefficient as 0.5 for both

56 Muller and Schafer Method

the methods. Under BWCI method, the option 'Compute MUE' also can be chosen. These simulation results are summarized in Table 56.1.

Table 56.1: Comparison of BWCI and RCI methods for Parkinson's Disease example with 3-look $\gamma(-4)$ boundary for primary trial, adaptation at first look, and 3-look $\gamma(-2)$ boundary for secondary trial.

| True δ | Actual Coverage of 95% CI | | Median of $\hat{\delta}_{0.5}$ | |
|---------------|---------------------------|-------|--------------------------------|--------|
| | BWCI | RCI | BWCI | RCI |
| 6 | 0.949 | 0.995 | 5.939 | 1.929 |
| 3 | 0.95 | 0.985 | 3.028 | 0.438 |
| 0 | 0.948 | 0.95 | 0.021 | -3.336 |

The results in the above table shows that while the coverage property of the two methods are similar, the bias in estimation is markedly more in RCI method compared to BWCI method.

We know from the design surv-01 that a hazard ratio of 0.7 will yield 90% power. But what if the true hazard ratio was 0.77? The resultant deterioration in power can be evaluated by simulation. Accordingly we shall alter the Treatment cell, containing the hazard 0.0607, by replacing it with $0.77 * 0.0866 = 0.0667$.

Survival Information

of Hazard Pieces Input Method:

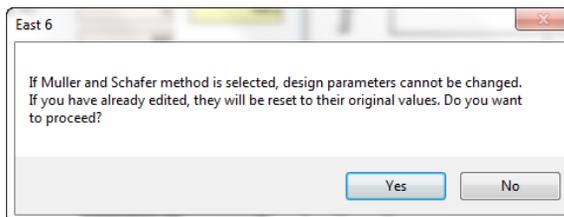

Hazard Ratio

| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
|-------|------------------|--------------|-----------|--------------|
| | | Control | Treatment | |
| 1 | 0.000 | 0.087 | 0.067 | 0.770 |

The "Sample Size Re-Estimation" Tab

The impact of an adaptive increase in the number of events and sample size on power and study duration can be evaluated by simulation. Click the **Sample Size Re-estimation** tab. This tab contains the input parameters for performing the adaptive simulations and sample size re-estimation in the on-going trial. Select **Muller and**

Schafer button in the dialog box. You will see the following message on the screen:

Click on **Yes**.

Now you see the dialog box shown below.

The **Sample Size Re-estimation** tab is the main location from which you will be using East to design adaptive time-to-event trials.

Input Parameters for Sample Size Re-estimation

This window consists of 10 input fields into which one may enter various design parameters.

56 Muller and Schafer Method

| | | | |
|---|----------|-------------------------|-----|

| 50 | | | | | | | |
| 75 | | | | | | | |
| 95 | | | | | | | |

On running the simulations, an entry for Simulation output gets added in the **Output Preview** pane and the detailed output can be seen in the Output Summary of Simulations.

The input quantities in the **Sample Size Re-estimation** tab are described below in detail.

1. **Adaptation at:** For a K -look group sequential design, one can decide the time at which conditions for adaptations are to be checked and actual adaptation is to be carried out. This can be done either at some intermediate look or after accumulating data on specified number of events or after some specified information fraction. The value of this parameter depends upon the choice of the user. If it is **Look no.** then this parameter can be any integer number from 1 to $K - 1$. If the adaptation is to be carried out after observing specified events then this parameter can be some integer between [4, No. of events at design stage] and so on. The default choice in East is **look number** to decide the time of adaptation.

Adapt at:

| | |
|----------------|---|
| Look # | ▼ |
| Look # | |
| Events | |
| Info. Fraction | |

2. **Max Number of Events if Adapt :** This quantity is a multiplier with value ≥ 1 for specifying the upper limit (or cap) on the increase in the number of events, should an adaptive increase be called for based on the target conditional power. Notice that, in keeping with the FDA Guidance on Adaptive Clinical Trials (2010), East does not permit an adaptive decrease in the number of events. Therefore multipliers less than 1 are not accepted in this cell. For example, if you use the multiplier 1.5 and if adaptation takes place, the modified number of events is capped at 501. The 501-event cap becomes effective only if the increased number of events (as calculated by the criteria of cells 4, 5 and 6) exceed 501.

Max. # of Events if Adapt (multiplier; total #):

| | |
|-----|-----|
| 1.5 | 501 |
|-----|-----|

3. **Max Subjects if Adapt :** This quantity is a multiplier with value ≥ 1 for specifying the upper limit (or cap) on the number of subjects to be enrolled in the study. Although the power of the trial is determined by the number of events and not the number of subjects, the number of subjects play a role in determining how long it will take to observe the required number of events, and hence for determining the study duration. The number of subjects may only be increased, never decreased. Therefore multipliers less than 1 are not accepted in this cell. For example, if you use the multiplier 1.5 and if adaptation takes place,

56 Muller and Schafer Method

the modified number of subjects is capped at 724 subjects. The trial will continue to enroll subjects until either the required number of events is reached or the cap on the number of subjects is reached.

Max. Sample Size if Adapt (multiplier; total #):

- Upper Limit on Study Duration :** An event driven trial ordinarily continues until the required number of events arrive. This input parameter is provided merely as a safety factor in order to prevent the trial from being prolonged excessively should the required number of events be very large or their rate of arrival be very slow. Its default value is set at three times the expected study duration obtained from the initial design of the trial. Consequently, if the scenarios being simulated are realistic, the required number of events will almost always be attained much before this upper limit parameter becomes operational. It is recommended to leave this parameter unchanged at least for the initial set of simulation experiments since it would interfere with the operating characteristics of the study if it were to become operational.

Upper Limit on Study Duration:

- Target Conditional Power for Re-estimating Events :** This parameter ranges between 0 and 1 and is the *target conditional power* desired at the end of the study. Suppose, for example that the Target CP is set at 0.9.

Target CP for Re-estimating # of Events:

Let the value of the test statistic obtained in the current simulation be z_L at

look L , where an adaptive increase in the number of events is being considered. Then, by setting the left hand side of equation (54.21) to 0.9 we have:

$$0.9 = 1 - \Phi \left\{ b_K \sqrt{1 + \frac{D_L}{D_K - D_L}} - z_L \sqrt{\frac{D_L}{D_K - D_L}} - \delta \sqrt{r(1-r)} \sqrt{D_K^* - D_L} \right\}. \quad (56.11)$$

Upon solving equation (56.11) for D_K^* we obtain the increased number of events

that are needed to achieve the target conditional power of 0.9 in this simulation. Let us illustrate with Des 1. In Des 1 $K = 2, L = 1, r = 0.5$ and the critical value for declaring statistical significance at the end of the trial is $b_2 = -1.9687$, as can be seen by examining the stopping boundaries displayed in the **Simulation Parameters** tab. The interim analysis is performed when $D_1 = 167$ events are obtained. In the absence of any adaptive change, the trial will terminate when $D_2 = 334$ events are obtained. Suppose the current simulation generates a value $z_1 = 1.5$ for the logrank statistic at look 1. Since the target conditional power is 0.9, equation (56.11) takes the form

$$0.9 = 1 - \Phi \left\{ -1.9687 \sqrt{1 + \frac{167}{334 - 167}} - 1.5 \sqrt{\frac{167}{334 - 167}} - 0.5\delta \sqrt{D_2^* - 167} \right\}. \quad (56.12)$$

In order to evaluate D_2^* , however, it is necessary to specify a value for the log hazard ratio δ in equation (56.12). This parameter is of course unknown. East gives you the option to perform simulations with either the current estimate $\hat{\delta}_1$ or to use the value of δ specified under the alternative hypothesis at the design stage. The choice can be made by selecting **Estimated HR** or **Design HR** from a drop-down list of the quantity **CP Computation Based on** of the **Sample Size Re-estimation** tab.

The default value is **Estimated HR**, (or equivalently $\hat{\delta}_1 = \ln \hat{HR}_1$) and we recommend using this default until you have gained some experience with the simulation output and can judge for yourselves which option provides better operating characteristics for your studies. East uses the formula

$$\hat{\delta}_1 = \frac{z_1}{\sqrt{r(1-r)D_1}}$$

to obtain the current estimate of δ . Upon substituting $z_1 = 1.5, D_1 = 167$ and $r = 0.5$ in the above expression we obtain $\hat{\delta}_1 = 0.232$, or equivalently a hazard ratio estimate of $\exp(0.232) = 1.2611$. Substituting the estimate of $\hat{\delta}_1$ into equation (56.12) and solving for D_2^* yields $D_2^* = 656$. Since the maximum number of events has been capped at 501, this simulation will terminate the trial when the number of events reaches 501 instead of going all the way to 656 events. In this case the desired target conditional power of 0.9 will not be met. Indeed in this case the conditional power (with $\hat{\delta}_1$ being used in place of the unknown true δ) is only

$$1 - \Phi \left\{ 1.9687 \sqrt{1 + \frac{167}{333 - 167}} - 1.5 \sqrt{\frac{333}{333 - 167}} - 0.5\delta \sqrt{500 - 167} \right\} = 0.798$$

For a more detailed discussion of conditional power, including the use of a special conditional power calculator that computes conditional power accurately

56 Muller and Schafer Method

without relying on the approximate assumption that the next look will be the last one, see Chapter 57.

6. **Promising Zone Scale :** Promising Zone is such that the number of events will only be increased if the conditional power at the interim look falls in this zone. East asks you to select the scale on which the promising zone is to be defined. It can be defined based on the conditional power or the test statistic or the estimated effect size and should be specified by entering the minimum and maximum of these quantities.
Let us go ahead with the default option which is Conditional Power.
7. **Promising Zone – Min CP :** In this cell you specify the minimum conditional power (in the absence of any adaptive change) at which you will entertain an increase in the number of events. That is, you specify the lower limit of the promising zone.
8. **Promising Zone – Max CP :** In this cell you specify the maximum conditional power (in the absence of any adaptive change) at which you will entertain an increase in the number of events. That is, you specify the upper limit of the promising zone.

Suppose, for example, that the number of events is only increased in a promising zone specified by the range $0.45 \leq CP < 0.8$, and suppose that in that case, the number of events is re-estimated so as to achieve a target conditional power of 0.99. Then the Input Parameters Table will contain the entries shown below.

| | | | | | |
|--|---|----------|------|----------|-----|
| <u>T</u> arget CP for Re-estimating # of Events: | 0.99 | | | | |
| <u>P</u> romising Zone Scale: | Cond. Power ▾ | | | | |
| Promising Zone: | <table style="border-collapse: collapse; width: 100%;"> <tr> <td style="padding-right: 10px;">Min. CP:</td> <td style="border: 1px solid #ccc; padding: 2px 10px; text-align: center;">0.45</td> </tr> <tr> <td style="padding-right: 10px;">Max. CP:</td> <td style="border: 1px solid #ccc; padding: 2px 10px; text-align: center;">0.8</td> </tr> </table> | Min. CP: | 0.45 | Max. CP: | 0.8 |
| Min. CP: | 0.45 | | | | |
| Max. CP: | 0.8 | | | | |

The zone to the left of the *promising zone* ($CP < 0.45$) is known as the *unfavorable zone*. The zone to the right of the *promising zone* ($CP \geq 0.8$) is known as the *favorable zone*. In a group sequential design that includes early stopping boundaries for futility and efficacy, the unfavorable zone contains within it an even more extreme region for early futility stopping and the favorable zone contains within it an even more extreme region for early efficacy

stopping.

9. **HR Used in CP Computations:** In this cell you specify whether the simulations should utilize conditional power based on $\hat{\delta}_L$ estimated at the time of the interim analysis or should utilize the value of δ specified under the alternative hypothesis, in equations (54.21) and (56.11). The adaptive design will have rather different operating characteristics in each case. The default is to use the estimated value $\hat{\delta}_L$.

CP Computation Based on:

Estimated HR ▼

10. **Accrual Rate After Adaptation :** East gives you the option to alter the rate of enrollment after an adaptive increase in the number of events. This feature would be useful, for example, to evaluate the extent to which the follow-up time and hence the total study duration can be shortened if the rate of enrollment is increased after the adaptive change is implemented.
11. **Estimation Method** East gives you the choice of None, RCI, or BWCI methods for parameter estimation.
12. **Specify Stage II Design** Clicking on this button will bring up the following dialog box. Here you specify the desired choices for Stage-II design. The specification of alpha for the Stage-II design is the most important component for Muller and Schafer method. We will keep the default choice. The other choice is **user Specified**.
Keep all other default choices in this dialog box and click **OK**.

56 Muller and Schafer Method

The dialog box will now look as shown below.

Click on **Simulate** button. Store the simulation results in the library and see the details as shown below.

Zone-wise Averages

| Zone | Simulations Rejecting H0 | | Simulations Rejecting H1 | | Total Simulations | | Average Sample Size | Average Number of Events | Average Accrual Duration | Average Study Duration |

Promising Zone defined as 0.3 <= CP < 0.9

Average Sample Size and Look Times (Integrated Trial)

| Look # | Average Sample Size | Average Events | Average Events | | Average Look Time | Average Follow up |
|---------|---------------------|----------------|----------------|-----------|-------------------|-------------------|
| | | | Control | Treatment | | |
| 1 | 364.657 | 167 | 90.587 | 76.413 | 18.103 | 6.002 |
| 2 | 568.347 | 386.406 | 204.764 | 181.642 | 31.694 | 8.964 |
| Average | 540.487 | 356.347 | | | 29.837 | |

Simulation Results for Integrated Trial

| Look # | Events | Stopping For | | Total Simulations | |
|--------|---------|--------------|----------|-------------------|---------|
| | | Efficacy | Futility | Count | % |
| 1 | 167 | 1010 | 360 | 1370 | 13.700% |
| 2 | 386.406 | 6221 | 1883 | 8630 | 86.300% |
| Total | 366.347 | 7231 | 2243 | 10000 | |
| % | | 72.310% | 22.430% | | |

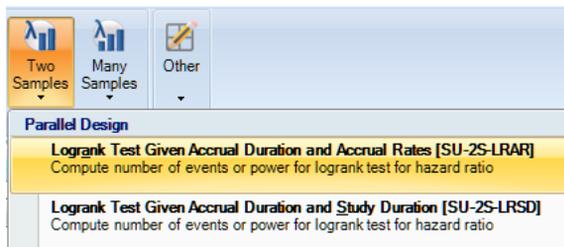

The interpretation of these results is very similar to what was described in CHW chapter section 54.5. Please also see the example for parameter estimation by BWCI and RCI methods given in section 56.3.1.

56.4 Survival Endpoint: Pancreatic Cancer Trial

A multi-center, double-blind, placebo-controlled randomized clinical trial is planned for subjects with advanced pancreatic cancer with the goal of comparing the current standard of care (gemcitabine + nap-paclitaxel) to an experimental regimen containing the two standard of care drugs plus a recombinant human enzyme. The primary endpoint is Overall Survival (OS). The study is required to have one-sided $\alpha = 0.025$, and 90% power to detect an improvement in median survival, from 8.5 months on the control arm to 12.744 months on the experimental arm, which corresponds to a hazard ratio of 0.667. The average enrollment is expected to be 15 subjects/month. We shall first create a two-look group sequential design for this study in East, and shall then show how the design may be improved by permitting an increase in the number of events and sample size at the time of the interim analysis.

56.4.1 Base Design

The base design is a two look group sequential design with a Lan and DeMets O’Brien-Fleming LD(OF) efficacy boundary, and a futility boundary for terminating if the estimated hazard ratio exceeds 1.0. To enter these design parameters into East select the design option for the **Logrank Test Given Accrual Duration and Accrual Rates** from the Tab on the menu bar as shown below.

56 Muller and Schafer Method

Enter the design inputs as shown in the **Test Parameters** tab.

Design Type: Superiority Number of Looks: 2

Test Parameters Boundary Accrual / Dropouts

Change the number of simulations to 100000 for greater Monte Carlo accuracy.

Thus far the only change that we have made the original design is to increase the hazard ratio from 0.67 to 0.72 for the simulations. We can simulate the design with the increased hazard ratio by clicking on the **Simulate** button. Notice that the power, based on 100000 simulated trials with HR=0.72, is only 74.47%.

Press the **Close** button, then move the simulated design from the **Output Preview** window to the **Library** and save the simulated design in the library.

Rename it as **Sim-0.72**.

56.4.3 Adaptive Simulation

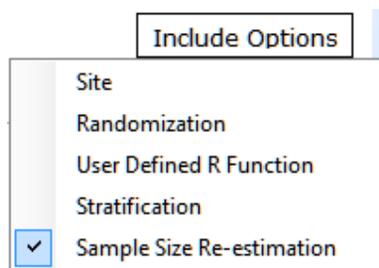

There is some uncertainty about the hazard ratio at which to power this study. A hazard ratio of 0.72 is still clinically meaningful. But as we just showed, the power at that hazard ratio is only about 75%. We can recover the lost power by implementing an adaptive increase to the number of events and sample size at the interim analysis time point. We shall do this by simulation using the Müller and Schäfer method. Return to the simulation input window. The easiest way to do this is to click on the Input icon

 located on the task bar at the bottom of the current window. This action will always open the input window that was most recently used. Alternatively, you can open the input window by selecting **Sim-0.72** in the library and clicking on the **Edit Simulation** icon . Either way you will be taken back to the

56 Muller and Schafer Method

Simulation Inputs window with the four tabs.

At the far right corner of this window is the **Include Options** button. Click on this button and select **Sample Size Re-estimation** from the drop-down list.

An additional tab labelled **Sample Size Re-Estimation** is created. Select that tab and choose the **Muller and Schafer** radio button. You'll be taken to the **Sample Size Re-estimation** window.

Let us examine this window carefully, for it conveys a large amount of information. It

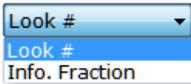

is convenient separate this window into two panels; a *Left Panel* and a *Right Panel*. The Left Panel, displayed below, is primarily for specifying the criteria that will be used to determine whether or not the current design should be adapted.

The Right Panel, displayed below, is for specifying how the original design will be adapted if indeed the criteria for adaptation that have been entered into the left panel are satisfied. At present only the original design (i.e., the **Base** design saved in the library) is shown in the Right Panel. For simulation purposes it is referred to as the **Stage I** design. If, in any simulation round, the adaptation criteria specified in the Left Panel are not met, only the **Stage I** design that will be simulated.

Now we have stipulated on the top line of the Left Panel that the Stage I design would be adapted at look 1.

Therefore, if the the adaptation criteria specified in the Left Panel are met, then the remainder of the **Stage I** design beyond look 1 will be adapted in accordance with specifications that will be provided through the creation of a Stage II design. We shall explain how the **Stage II** design is created shortly.

Left Panel: Specification of Criteria for Adaptation We first we enter the inputs into the Left Panel. At the top of the Left Panel we specify when the adaptation will take place. This may either be specified in terms of the **Look #** or **Information Fraction**

Adapt at: 

For this example, we will make the adaptation after completing Look 1.

Adapt at:  

We next specify the maximum allowable number of events and the maximum allowable sample size should the trial be adapted. This is achieved by specifying an appropriate multiplier in the **Max. # of Events** and **Max. Sample Size** edit boxes. We will use a multiplier of 1.5 for both the events and the sample size.

| | | |
|--|-----|-----|
| Max. # of Events if Adapt (multiplier; total #): | 1.5 | 390 |
| Max. Sample Size if Adapt (multiplier; total #): | 1.5 | 540 |

56 Muller and Schafer Method

By this specification we have placed a cap on the magnitude of the increase in events and sample size. For example, if in any simulation round the decision rule used to re-estimate events produces the value 400, the re-estimated number of events will be nevertheless be truncated to 390.

The next specification is the **Upper Limit on Study Duration**. By default it is three times the maximum study duration of the **Stage I** design. It is provided as a precaution against excessive prolongation of a simulated trial in case of very slow arrival of events and its default value is typically not altered. The **Stage I** design displayed on the Right Panel shows a maximum study duration of 32.925 months.

| Study Duration | |
|-------------------|--------|
| Maximum | 32.925 |
| Expected Under H0 | 23.853 |
| Expected Under H1 | 29.361 |

Therefore the **Upper Limit on Study Duration** is $3 \times 32.925 = 98.776$.

Upper Limit on Study Duration: 98.776

The next three entries describe the criteria for trial adaptation.

Promising Zone Scale: Cond. Power CP

| | | |
|-----------|----------|-----|
| Promising | Min. CP: | 0.3 |
| Zone: | Max. CP: | 0.9 |

The adaptation criteria in East are based on the promising zone design proposed by Mehta and Pocock (2011). The interim analysis results are partitioned into three zones; **Unfavorable**, **Promising** and **Favorable**. If the interim results fall in the unfavorable or favorable zones, there is no adaptation. But if they fall in the promising zone, the trial is adapted. In the Müller and Schäfer method permits the permissible adaptations go beyond mere sample size re-estimation. One may, in addition increase the number and spacing of the future looks and also alter the spending function. The partitioning of the interim sample space into zones can be based on three different scales – **Conditional Power**, **Test Statistic** or **Estimated HR**. One

can pick the desired scale from a drop-down list as shown below.

Promising Zone Scale: Cond. Power ▾
Cond. Power
Test Statistic
Estimated HR

The three scales are in one-to-one correspondence, so that the selection of the scale is simply a matter of choosing the one that is easiest to interpret in a given situation. In the current example the **Conditional Power** scale has been chosen. Accordingly the promising zone is defined as the region of the interim analysis sample space in which the conditional power is between 0.3 and 0.9.

To see this same zone on the hazard ratio scale, choose **Estimated Hazard** form the drop-down choice of scales for the promising zone.

Promising Zone Scale: Estimated HR ▾

| | |
|-----------------|---|
| Promising Zone: | Min. HR: 0.7001 |
| | Max. HR: 0.8202 |

It is seen that on the estimated HR scale the same promising zone corresponds to the interim estimate of the hazard ratio lying between 0.8202 and 0.7001. On the test statistic (or Wald statistic, or Z-statistic) scale the promising zone corresponds to $-2.0328 \leq Z \leq -1.1298$.

Promising Zone Scale: Test Statistic ▾

| | |
|-----------------|--|
| Promising Zone: | Min. Test Stat.: -2.0328 |
| | Max. Test Stat.: -1.1298 |

If the promising zone is defined in terms of conditional power, one needs to specify what hazard ratio will be assumed for computing conditional power. The conditional power calculations may be performed either with the interim estimate of hazard ratio or with the value of hazard ratio that was used to create the base design (i.e., 0.667). The default choice is **Estimated HR**. We will use the default specification.

CP Computation Based on: Estimated HR ▾

The next entry is used to specify the rate of accrual after the adaptation. We shall

56 Muller and Schafer Method

assume that there will be no change in the accrual rate.

Accrual Rate After Adaptation:

The final entry in the Left Panel is a specification of the method for estimating the hazard ratio at the final analysis that adjusts for the fact that an adaptive group sequential design was used. There are three choices; none, RCI method and BWCI method.

Estimation Method:
None
RCI
BWCI

The purpose of this input is to verify by simulation the properties of the RCI method (Mehta, Bauer, Posh, Brannath, *Statistics in Medicine*, 2007) and the BWCI method (Gao, Liu, Mehta, *Statistics in Medicine*, 2013) for computing point estimates and confidence intervals that adjust for having used an adaptive group sequential design. We shall use the **None** option for the present since the RCI and BWCI options are intended as tools for methodological research rather than for the actual design of a trial.

Right Panel: Specification of the Stage II Design Next we consider the Right Panel. At present it displays the **Stage I** or **Base** design in summary form. The Stage I design has 2 looks and we have indicated that we will be altered if the adaptation criterion of being in the promising zone is met. We must, however, specify to East precisely how the remainder of the trial beyond look 1 will be adapted if the adaptation criterion is satisfied. As we have explained in Section 56.1.1, although we are dealing with a single trial that is adapted at an interim analysis, it is more convenient to specify the portion of this trial that is implemented after the adaptation as a separate **Stage II** trial having a type-1 error equal to the conditional type-1 error of the Stage I trial obtained at the time of the adaptation. This is the essence of the Müller and Schäfer method of adapting an on-going study while preserving the overall type-1 error. Accordingly, click on the

button. You are now taken to the following dialog box where you must specify the

design parameters of the Stage II design.

You must specify the Stage II design in this dialog box. The complete design specification consists of type-1 error, power, number of looks, hazard ratio and efficacy/futility boundaries. East will then compute the number of events that are needed to attain the specified power. Because this dialog box is used for simulation only power and number of looks are specified explicitly. All other quantities depend on the data that are obtained from the Stage I trial at the time of the adaptive look, and therefore vary from simulation to simulation. Let us illustrate by simulating an adaptive trial in which we will adapt at look 1 of the Stage I design. The adaptation will consist of an increase in the number of events and sample size, and one additional interim look, resulting in a two-look Stage II design with a Pocock error spending function for the efficacy boundary and a hazard ratio of 1 for the futility boundary. We enter the appropriate inputs as follows:

- Specify that the Stage II design has two looks.
This specification causes a **Boundary** tab to appear.
- Enter the Pocock efficacy boundary and the HR=1 futility boundary in the

56 Muller and Schafer Method

Boundary tab as shown.

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Futility HR |
|--------|----------------|-------------------------------------|-------------------------------------|---------------------|-------------------|-------------|
| 1 | 0.500 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | Computed | Computed | 1.000 |
| 2 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | Computed | Computed | Computed |

The actual amount of α available for spending and the actual efficacy boundary cannot be displayed. These design parameters depend on the conditional type-1 error of the Stage I trial at the time of the adaptation and will therefore vary from simulation to simulation in accordance with the Müller and Schäfer method.

- Return to the **Test Parameters** tab. This input dialog box requires the following specifications:
 1. Specification of alpha: There are two choices.

Specification of alpha:

For a Müller and Schäfer design the correct choice is **Cond. Type 1 Error From Stage-I**. Only this choice will ensure that the overall type-1 error of the adaptive design is preserved. The alternative choice, **User Specified**, has been included simply for illustrative purposes, to demonstrate that if a fixed type-1 error is specified in an adaptive trial, it would not be preserved. Thus select **Cond. Type 1 Error from Stage -I** and note that it will vary from simulation to simulation depending on the value of the test statistic obtained in the **Stage I** trial at look 1.

2. Specification of HR: Here too there are two choices

Specification of HR

In this case the choice depends on the user's preference. If **Estimated from Stage-I** is selected the sample size will be computed by

assuming that the hazard ratio that was obtained at Stage I at the time of the adaptive interim look is the true hazard ratio. Therefore it will vary from simulation to simulation. Alternatively one might desire to simulate the adaptive design with a fixed hazard ratio, say the HR that was specified for the original design. Here we will select the **Estimated from Stage-I** option thereby letting the data from the first stage determine the value of HR from simulation to simulation.

3. Power. This is the desired power for the Stage II trial. However this power may not be attainable in every simulated trial. Depending on the type-1 error and hazard ratio that have been estimated from Stage I, East will compute the number of events, say D_r , that are *required* to attain the desired power in the **Stage II** trial. Now you have already specified in the Left Panel of the **Sample Size Re-estimation** tab the maximum number of events if the trial is adapted – in this case 390 events: Therefore if, in any simulation, $D_r > 390$, East will only generate 390 events, and the desired power will not be attained. More generally let D_{max} denote the *maximum* allowable number of events specified in the **Sample Size Re-estimation** tab. Then D_a , the *actual* number of events that East will generate in any simulation, is given by

$$D_a = \min(D_r, D_{max})$$

Let N_{max} denote the maximum sample size if the trial is adapted, in this case 540.

East will generate patient arrivals until either the D_a events have arrived or N_{max} subjects have arrived. In the latter case East will follow the N_{max} subjects until D_a events have arrived.

For the current simulation experiment enter the value 0.999 into the edit box for power.

Power:

0.999

By selecting such a high value for power we are assured that in every simulated trial the required number of events, D_r , will hit the cap $D_{max} = 390$; that is, $D_a = D_{max} = 390$ in every simulation. Thus this choice for power is an implicit way of specifying that there will be a one-time 50% increase in the number of events if the Stage I results fall in the promising zone at the time of the interim analysis.

- The inputs in the **Test Parameters** tab for the specification of the Stage II design now look as follows.

56 Muller and Schafer Method

To complete the specification, press the **OK** button. East will return you to the **Sample Size Re-estimation** tab and will display both the Stage I and Stage II designs side by side in the Right Panel.

Displaying Stage I and Stage II as Single Integrated Design Although we are dealing with a single integrated design we have regarded the remainder of the trial after the adaptive look at Stage I as a separate Stage II trial whose type-1 error is equal to the conditional type-1 error of the Stage I design. This is extremely convenient for

design purposes because we can use all the functionality that already exists in East to design a separate Stage II trial without considering how it will be integrated with the existing Stage I design. On the other hand, this artificial separation of a single design into two separate designs makes it difficult to visualize the stopping boundaries of the integrated design or the trajectory traced by the test statistic during the interim monitoring phase of the study. Thus, although it is technically correct to monitor the Stage II design independently, with the test statistic starting out at the value zero, it is not very intuitive to do so. To gain a better understanding of the how the Stage I and Stage II designs are integrated in to a single design we have provided the **CP+–** button to the right of **Cond. Power**.

Clicking on this button will open up a conditional power calculator. By default, the calculator will open with the radio button for the Stage I design selected

and the radio button for specifying that the **HR to be Used in Conditional Power Computation** will be estimated from the data rather than specified separately by the user.

With this choice the observed value of the test statistic Z and the estimate of HR, say \hat{HR} , at the time of the adaptive look in the Stage I trial are in one to one correspondence through the relationship due to Schoenfeld (Biometrika, 1981)

$$Z = \ln(HR) \sqrt{Dr(1-r)}$$

where D is the number of events at the time of the adaptive look (here $D = 130$) and r is the randomization fraction for allocating subjects to the two treatment arm (here $r = 0.5$). We can specify either \hat{HR} or Z in the appropriate edit box and the calculator will output the corresponding value of conditional power. If the conditional power falls in the promising zone, the trial will be adapted through the creation of a Stage II design. Otherwise the trial will continue as planned. Below we provide three examples to show how different values of Z result in different Stage II designs and how the two Stages may be viewed as a single integrated adaptive design.

Example 1: $Z = -1.5187$ In the view below, if $Z = -1.5187$, then $HR = 0.7661$ (by Schoenfeld's formula above) and the conditional power is computed as 0.6.

Recalc Details>> Close

This would imply that the interim result has fallen in the promising zone (CP between 0.3 and 0.9) and hence the remainder of the Stage I trial should be adapted. To obtain the conditional type-1 error, (also referred to as the Conditional Error Rate (CER) or the conditional Rejection Probability (CRP)) of the remainder of the Stage I trial, select the **Arbitrary HR** radio button. Now HR and Z are no longer in one to one correspondence so that we can set **Value of HR** to 1 and separately set **Value of**

z to -1.5187 as shown below.

The calculator reveals that the conditional type-1 error at $HR = 1$ and $Z = -1.5187$ is 0.1029. Since $HR = 1$ corresponds to the null hypothesis, 0.1029 is the conditional type-1 error of the Stage I trial if $Z = -1.5187$ is observed at look1. Thus the amount of α we would use for the Stage II design is 0.1029. Now set the radio button for HR back to **Estimated HR**, z and set $Z = -1.5187$. Once again, Z and HR are in one to one correspondence via Schoenfeld's formula so that $HR = 0.7661$. Now

56 Muller and Schafer Method

select the **Stage II Design** radio button.

| Events (Stage II) | 260.0000 |
| Events (Integrated) | 390.0000 |

* In promising zone and trial adapted

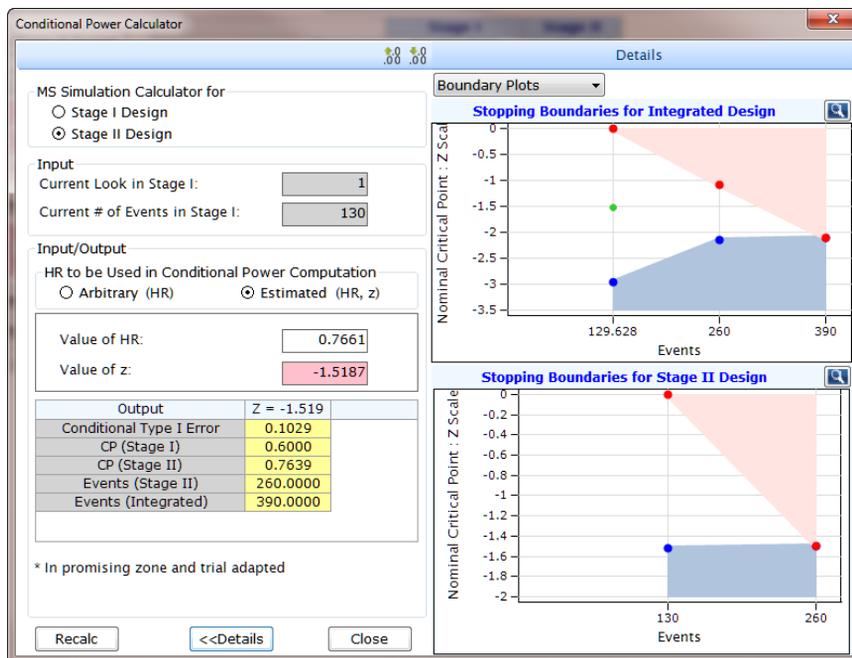

Recalc Details>> Close

The following output is obtained:

- Conditional Type I Error = 0.1029. This is the amount of α or conditional error rate that will be available for the Stage II design
- CP(Stage I) = 0.6. This is the conditional power of the Stage I design if the observed value at look 1 is $Z = -1.5187$ and $HR = 0.7661$. This puts the look 1 result in the promising zone so that the trial may be adapted
- CP(Stage II) = 0.7639; Events(Stage II) = 260; Events(Integrated) = 390. These outputs show that the interim analysis of the Stage I trial is in the promising zone and therefore the Stage II design is invoked. Although the Stage II design is intended to achieve 99% power at the estimated value of $HR = 0.7661$, it

cannot do so because of the cap of 390 events on the integrated design (or 260 events on the Stage II design). Because the number of events cannot be increased further, the power of the Stage II design is 0.7639 and not 0.999.

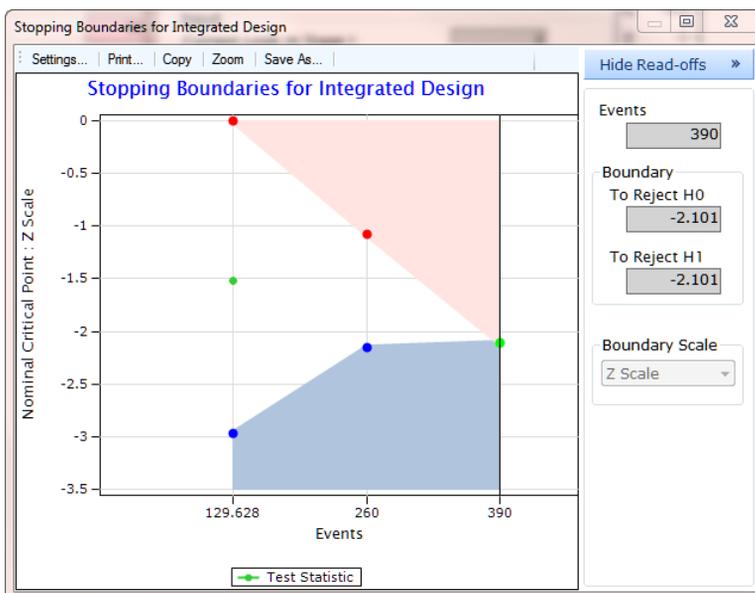

If we click on the **Details** button we get more insight into the Stage II and integrated designs.

Each of the charts in the right panel can be magnified by clicking in its icon. The top panel shows the integrated design in which the Stage I design was adapted after 130

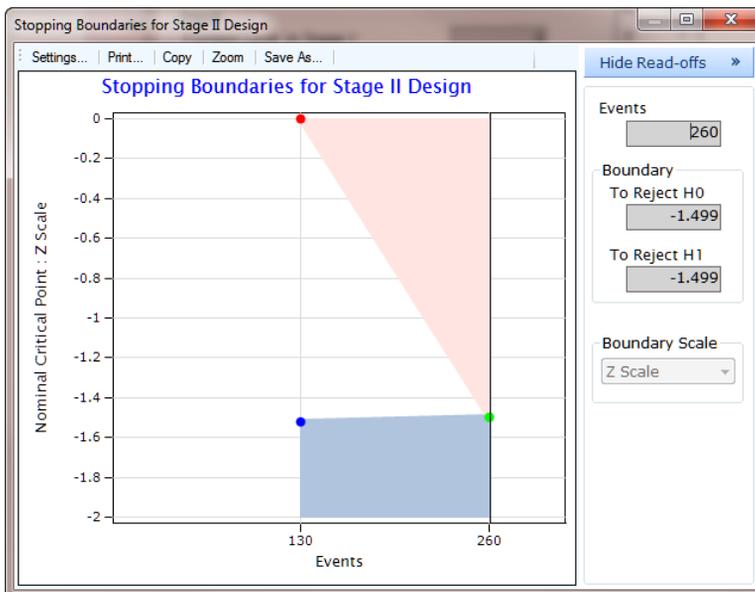

56 Muller and Schafer Method

events were observed.

The green dot is the observed value of the test statistic at look 1, $Z = -1.519$. It falls in the promising zone. The lower panel shows the two-look Stage II design with the Pocock efficacy boundary and the HR=1 futility boundary. The type-1 error of the Stage II design is 0.1029, which corresponds to the conditional type-1 error from Stage

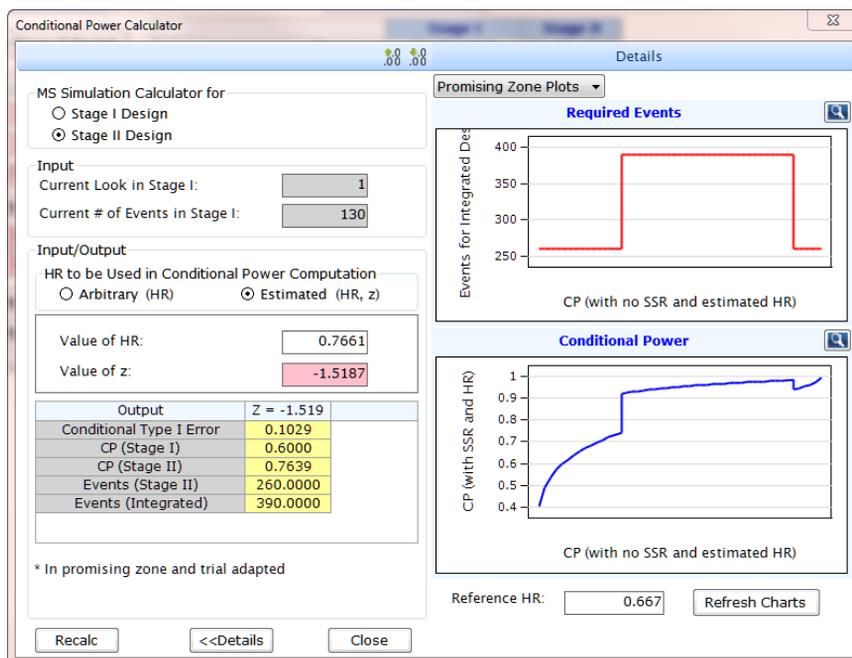

I.

It is instructive to view the adaptation rule and its impact on conditional power graphically. This can be achieved by switching from **Boundary Plots** to

56 Muller and Schafer Method

Promising Zone Plots from the drop-down list as shown below.

These are the familiar **Promising Zone Plots** that have been well documented in Chapter 54. The top plot displays the promising zone (CP between 0.3 and 0.9) on the X-axis and the number of events for the integrated design on the Y-axis. Outside the

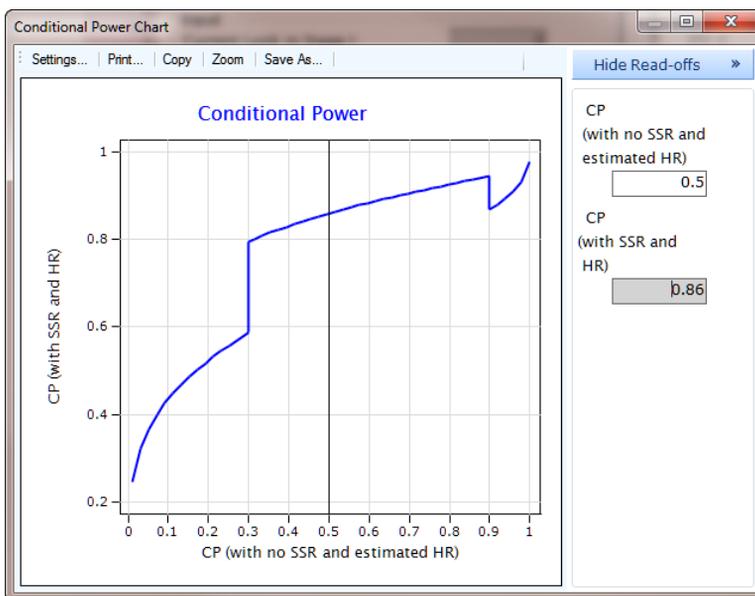

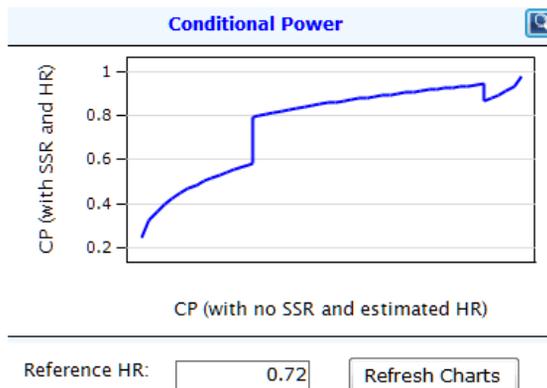

promising zone the number of events is 260, rising to 390 in the promising zone.

The X-axis of the bottom plot is the same as for the top plot and shows, the conditional power based on the current value of the test statistic and the current estimate of the hazard ratio. The Y-axis shows the conditional power if the number of events are increased in accordance with the rule implied by the top plot, and under the hazard

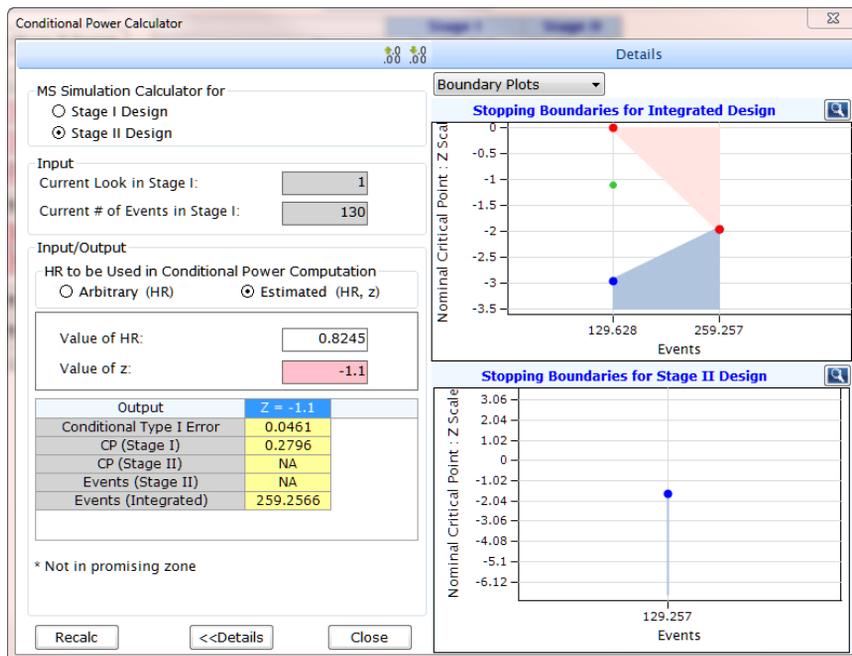

56 Muller and Schafer Method

ratio specified in the **Reference HR** edit box.

Example 2: $Z = -1.1$ For additional insight enter the value $Z = -1.1$ into the CP calculator and press the **Recalc** button. This time the result from the Stage I design is not in the promising zone. Therefore the integrated design and the Stage I design are identical with a total of 260 events. The Stage II design is simply the continuation of the Stage I design for an additional 130 events and has the same final critical value of

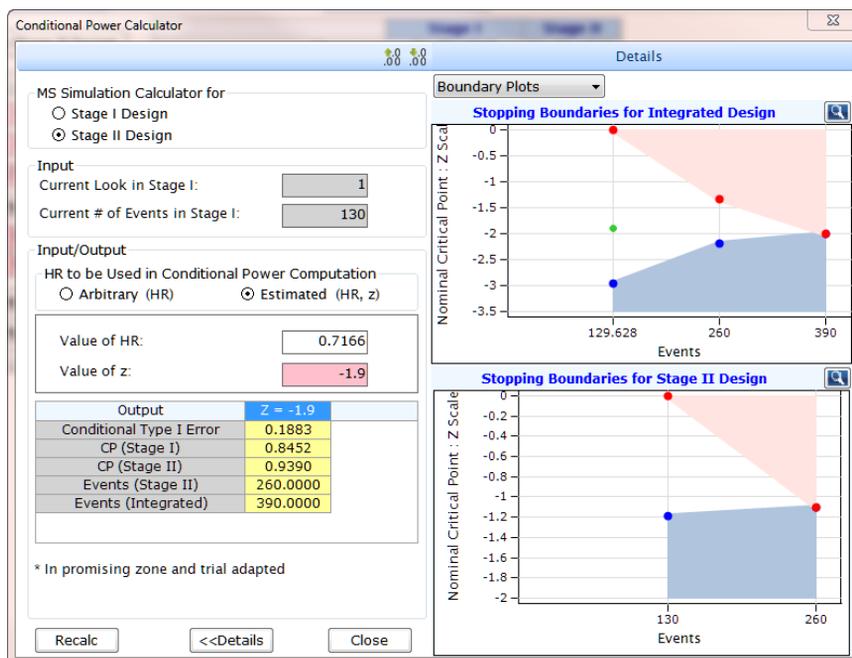

-1.9686.

Example 3: $Z = -1.9$ Finally, enter the value $Z = -1.9$ (corresponding to $HR = 0.7166$) into the calculator. Now $CP = 0.8452$ which is in the promising zone.

56 Muller and Schafer Method

Thus the trial is adapted.

The conditional type-1 error from stage I that is utilized in the Stage II design is 0.1883. Unlike Example 1, the Stage II design achieves the full 90% power with 260 events. The pre-specified cap of 360 events for the integrated design (or 260 events for the stage II design) was not exceeded in the computation of events required to obtain 90% power for the Stage II design.

To further your understanding of the adaptive design you might find it helpful to enter additional values of Z or HR into the conditional power calculator and view the resulting numerical and graphical outputs. When you are done with exploring the properties of the integrated and Stage II design in this manner, press the **Close** button to return to the **Sample Size Re-estimation** tab of the simulation inputs window.

Now that you have completed the specification of the adaptive design through the Stage I and Stage II specification in the **Sample Size Re-estimation** tab, let us evaluate its operating characteristics by simulation. The design is shown below.

This two-stage design will be simulated 100,000 times. In each simulation, look 1 of the Stage I design will be taken after 130 events and if the resulting conditional power based on the estimated hazard ratio lies in the promising zone (conditional power of the Stage I design between 30

Test Parameters

Response Generation

Accrual / Dropouts

Survival Information

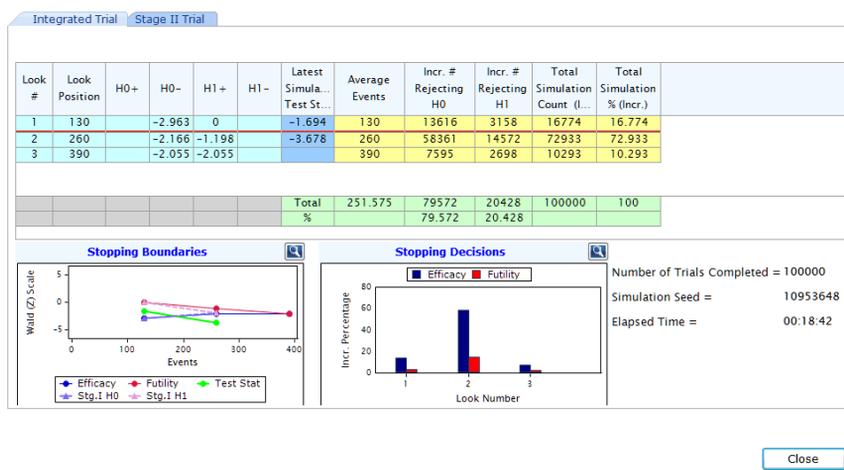

of Hazard Pieces Input Method:

| Med.Surv.Time | | Hazard Ratio |
|----------------------------------|-------------------------------------|-----------------------------------|
| Control | Treatment | |
| <input type="text" value="8.5"/> | <input type="text" value="11.806"/> | <input type="text" value="0.72"/> |

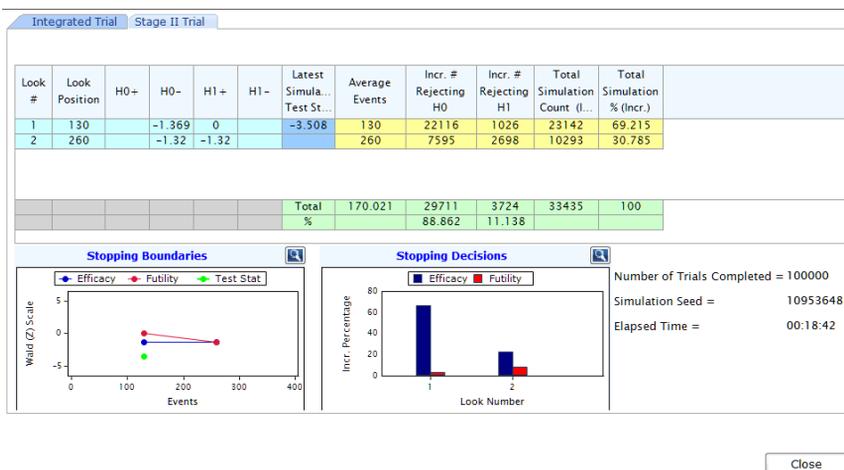

To simulate this design press the **Simulate** button at the bottom right of the screen.

56 Muller and Schafer Method

East will generate 100000 simulated trials with a hazard ratio of 0.72, the value that we entered in the **Response Generation** tab. The simulation results may be viewed in the temporary tables shown below for the Integrated Trial

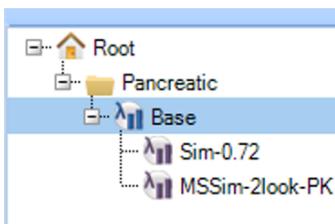

and the Stage II Trial

Press the **Close** to move the simulation results to the Output Preview.

Then press the  button to move the simulation results to the library where you can view the detailed output. Name the saved library node as **MSSim-2look-PK**.

Open MSSim-2look-PK with the tool and examine the output. Notice that the overall power is 79.57% while in the promising zone is 88.86%. The cost in terms of average study duration is 30.304 months for all trials and 30.292 months in the promising zone. The average sample size in the promising zone, however, is 478 compared to 388 for all trials.

Zone-wise Averages

| Zone | Simulations Rejecting H0 | | Simulations Rejecting H1 | | Total Simulations | | Average Sample Size | Average Number of Events | Average Accrual Duration | Average Study Duration |
|-------------|--------------------------|----------|--------------------------|----------|-------------------|----------|---------------------|--------------------------|--------------------------|------------------------|

Promising Zone defined as $0.3 \leq CP < 0.9$

Notice that the power in the Promising Zone is only 74.71%. And the average cost in terms of study duration 32.139 in the promising zone and 30.001 months for all trials, about the same as for MSSim-2look-PK. On the other hand the average sample size in the promising zone is only 360 subjects for MSSim-1look-noSSR, compared to 478 subjects for MSSim-2look-PK. This is the cost associated with increasing the power from 74.58% to 88.86% and it is only incurred if the interim results are promising.

It would be interesting to compare the adaptive design obtained by the Müller and Schäfer method with the adaptive design obtained by the CHW method. The main limitation of the CHW method is that the only adaptation permitted is an increase in events and sample size. There is no flexibility to alter the number or spacing of the future looks after the adaptation. To run the CHW design make the changes shown below in the **Sample Size Re-estimation** tab. (Notice that that **Target CP for Re-estimating # of Events** is set to 0.999 so as to ensure a one-time

56 Muller and Schafer Method

therefore expect that if we were to construct a Müller and Schäfer design with only one look for the Stage II portion, it would have similar operating characteristics to the CHW design. To verify this conjecture create such a design by using the following inputs.

Use Adaptation Method
 CHW CDL Müller and Schäfer

Promising Zone defined as 0.3 <= CP < 0.9

As we anticipated, the CHWSim-1look, the MSSim-1look designs have similar operating characteristics; about the same power and same study duration in all zones. This confirms the claim by Mehta and Liu (2016) that for the special case of a single future look following an interim analysis the CHW and Müller and Schäfer methods are equivalent. These examples show that the Müller and Schäfer method has greater flexibility for trading off power versus study duration in an adaptive setting than the CHW method; it permits more complex adaptations for the Stage II design, without sacrificing power or study duration in the special case of a single-look adaptation.

56.4.4 Interim Monitoring

We will now use East to monitor the Base design. With cursor on **Base** in the library window, click on the interim monitoring icon **IM**. You will be taken to the interim monitoring worksheet.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | Rep. Conf. Bounds for HR | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|----------|--------------------------|--------------|------------------|----|------------------|
| | | | | | | | | Upper (1...) | Lower (2...) | | | |
| 1 | | | | | | | | | | | | |
| 2 | | | | | | | | | | | | |

The First Interim Look In order to populate this worksheet with interim data you must click on the **Enter Interim Data** button on the tool bar at the top of the worksheet. Thereby a form, titled **Test Statistic Calculator**, appears and you are requested to enter the interim number of events, the interim estimate of δ and its standard error into this form.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Read from Analysis Node

Select Workbook: [Dropdown]

Select Analysis Node: [Dropdown]

Cumulative Events: [Input: 130]

Input for Survival end point

Estimate of δ : [Input: -0.405]

$\delta = \ln(\lambda_t / \lambda_c)$

Standard Error of Estimate of δ : [Input: 0.1754]

Output

Test Statistic: [Output: -2.3087]

Recalc OK Cancel

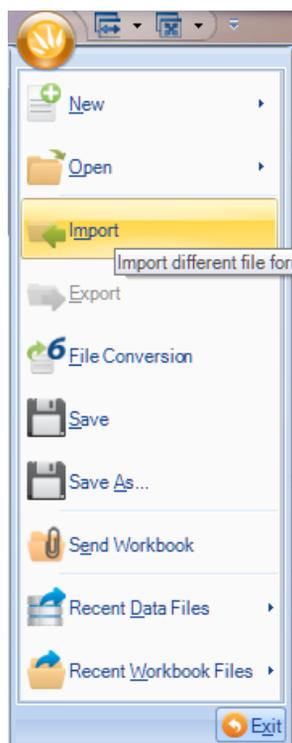

You now have two options.

56 Muller and Schafer Method

Option 1 Enter the requested quantities directly into the **Test Statistic Calculator** for the current look and click the **OK** button at the bottom. East will then perform the necessary calculations and post the interim results in the worksheet as shown below.

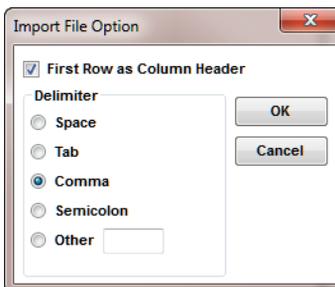

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of... | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | Rep. Conf. Bounds for HR | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|-------------------|----------------|------------|------------------|--------------------------------|----------|----------|--------------------------|--------------|------------------|--------|------------------|
| | | | | | | | | | Upper (1...) | Lower (2...) | | | |
| 1 2 | 0.5 | 130 | -2.3087 | 0.667 | -0.405 | 0.1754 | -2.9626 | 0 | 1.1215 | 0.4449 | 0.0703 | 0.9666 | 0.9026 |

Option 2 If the actual patient level data are saved as a file in one of the acceptable file formats, you can import the file into East through the **File > Import**.

In this example there is a file titled Pancreatic-Look1.csv in the sub-folder **Samples** in your East installation folder containing the data required for the interim analysis at look 1. When you select this file with **File > Import > ~Pancreatic-Look1.csv** you will be asked to select the appropriate

Delimiter from the **Import File Format Option** dialog box.

Choose the default **Comma** delimiter and attach the file to the **Pancreatic** workbook. East will then display the data in its **Data Editor**.

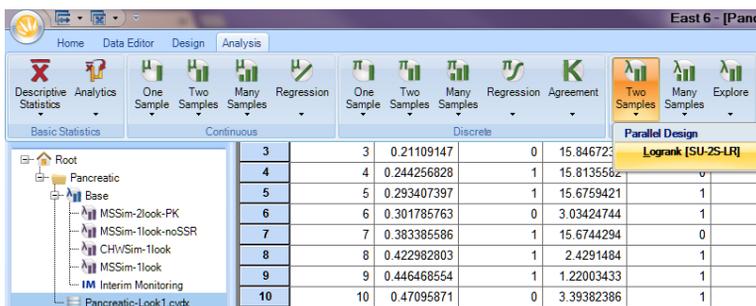

| | SubjectID | ArrivalTime | TreatmentID | TimeOnStud | CensorInd | Status |
|----|-----------|-------------|-------------|-------------|-----------|--------|
| 1 | 1 | 0.091101201 | 0 | 15.9667138 | 0 | 0 |
| 2 | 2 | 0.136753868 | 0 | 0.736892474 | 1 | 1 |
| 3 | 3 | 0.21109147 | 0 | 15.8467236 | 0 | 0 |
| 4 | 4 | 0.244256828 | 1 | 15.8135582 | 0 | 0 |
| 5 | 5 | 0.293407397 | 1 | 15.6759421 | 1 | 1 |
| 6 | 6 | 0.301785763 | 0 | 3.03424744 | 1 | 1 |
| 7 | 7 | 0.383385586 | 1 | 15.6744294 | 0 | 0 |
| 8 | 8 | 0.422982803 | 1 | 2.4291484 | 1 | 1 |
| 9 | 9 | 0.446468554 | 1 | 1.22003433 | 1 | 1 |
| 10 | 10 | 0.47095871 | 0 | 3.39382386 | 1 | 1 |
| 11 | 11 | 0.632641096 | 0 | 11.9518103 | 1 | 1 |

This file must contain, at a minimum, the above six variables, **Subject ID**, **ArrivalTime**, **TreatmentID**, **TimeOnStudy**, **CensorInd**, **Status**, although it may contain many other variables as well. The names of these variables may differ in your data set from the ones given in this example, but they must carry the same meaning above. The variable names used in this example are mostly self-explanatory. However there is a distinction between **CensorInd** and **Status**. **CensorInd** assumes the value 1 if the event (in this case death) has occurred, and assumes the value 0 if the observation is administratively censored while the subject is still in follow-up. **Status** assumes the value 1 if the event (in this case death) has occurred, assumes the value 0 if the observation is administratively censored, and assumes the value -1 if the subject has dropped out of the study. In this example **CensorInd** and **Status** are the same, because there are no drop-outs.

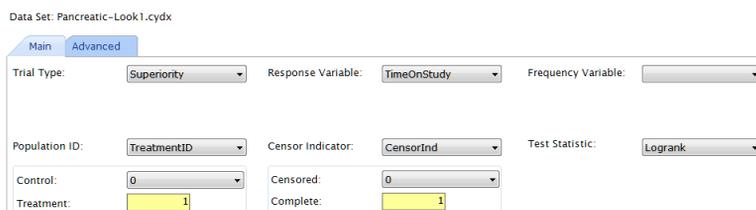

Before East can populate the interim analysis worksheet it is necessary to create an **Analysis Node** from this data set. Accordingly select the

56 Muller and Schafer Method

Analysis>Two Sample>Logrank options from the top-level menu

and complete the entries in the ensuing form as shown.

Upon clicking the OK button East will create the following **Analysis of Time to Event Response** node.

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | | Average Follow-up Time |
|--------------|-----------------|------------|----------------|------------|----------------|------------------------|
| | | Count | % | Count | % | |
| 0 | 133 | 69 | 51.880% | 64 | 48.120% | 5.1962 |
| 1 | 130 | 61 | 46.923% | 69 | 53.077% | 6.2139 |
| Total | 263 | 130 | 49.430% | 133 | 50.570% | 5.6992 |

Test of Hypothesis:

| Log Rank Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|----------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| -8.9569 | 5.672 | -1.5792 | L.E. | 0.0572 | 0.1143 |

Parameter Estimates from Cox Model:

| Hazard Ratio (HR) | ln(Hazard Ratio) (δ) | Std. Error of Estimate of δ | Wald Statistic | 95% Confidence Interval of HR(2-Sided) | |
|-------------------|-------------------------------|------------------------------------|----------------|--|-------------|
| | | | | Lower Limit | Upper Limit |
| 0.7579 | -0.2772 | 0.1761 | -1.5741 | 0.5366 | 1.0703 |

Estimated Hazard Rates:

| | |
|--------------------------------|--------|
| Control (λ_c) | 0.0998 |
| Treatment ($\lambda_c * HR$) | 0.0757 |

Four tables are created. The **Summary of Observed Data** table shows

that 130 events have been observed from 263 enrolled subjects. The **Parameter Estimates from Cox Model** table displays the current estimate of hazard ratio (HR=0.7579), and other related output from the Cox model including the estimate of δ (-0.2772), its standard error (0.1761), and the corresponding Wald statistic (-1.5741). This information can now be utilized to populate the interim analysis worksheet.

Select the interim monitoring node from the library and click the edit button from the library menu to retrieve the worksheet.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | Rep. Conf. Bounds for HR | | Repeated p-value | CP | Predictive Power | |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|----------|--------------------------|--------------|------------------|--------|------------------|--------|
| | | | | | | | | Upper (1...) | Lower (2...) | | | | |
| 1 | 0.5 | 130 | -2.3087 | 0.667 | -0.405 | 0.1754 | -2.9626 | 0 | 1.1215 | 0.4449 | 0.0703 | 0.9666 | 0.9028 |
| 2 | | | | | | | | | | | | | |

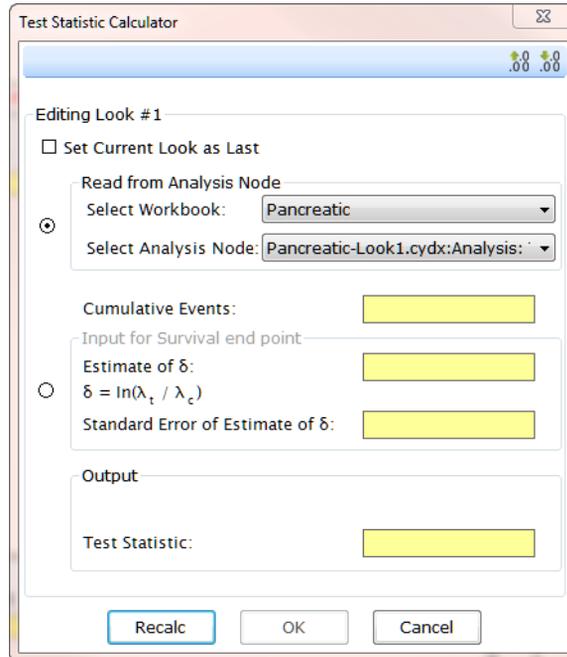

If any row of the worksheet is already populated clear away the entries by selecting that row and clicking on the **Delete Look** button

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | Rep. Conf. Bounds for HR | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|----------|--------------------------|--------------|------------------|----|------------------|
| | | | | | | | | Upper (1...) | Lower (2...) | | | |
| 1 | | | | | | | | | | | | |
| 2 | | | | | | | | | | | | |

Now click on the **Enter Interim Data** button and select the **Read from**

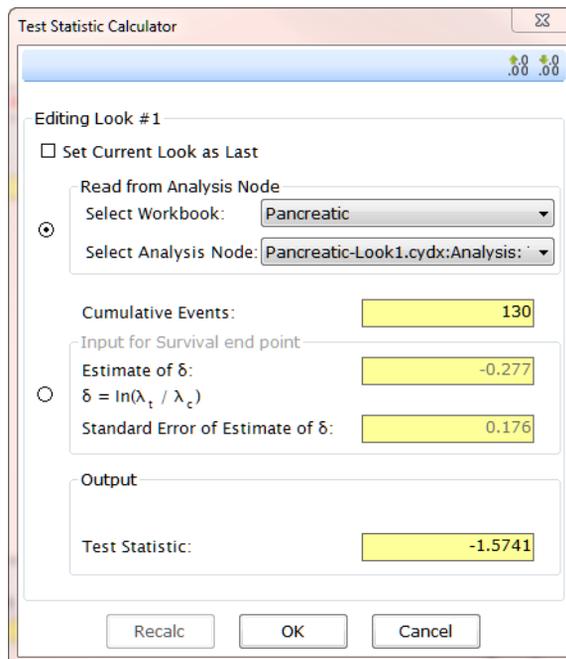

56 Muller and Schafer Method

Analysis Node radio button.

Make sure that the appropriate **Workbook** and **Analysis Node** are selected

in this dialog box. Then click the **Recalc** button.

Upon clicking **OK Look 1** of the **Interim Analysis Worksheet** gets populated with the results of the first interim analysis.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of... | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | Rep. Conf. Bounds for HR | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|-------------------|----------------|------------|------------------|--------------------------------|----------|----------|--------------------------|-------------|------------------|--------|------------------|
| | | | | | | | | | Upper (1... | Lower (2... | | | |
| 1 | 0.5 | 130 | -1.5741 | 0.758 | -0.2772 | 0.1761 | -2.9626 | 0 | 1.277 | 0.5055 | 0.1796 | 0.6421 | 0.6016 |
| 2 | | | | | | | | | | | | | |

We observe that the test statistic, -1.5741 has not crossed the efficacy boundary, -2.9626. However, the conditional power, 0.6421, is in the promising zone. Thus an adaptive increase in number of events and sample size is indicated. This can be confirmed by simulation as we show next.

The Predictive Interval Plot (Note: The Predictive Interval Plots (PIPs) are introduced and fully described with examples in Chapter 65.) Clicking on the **PIP** button on the menu bar will enable you to simulate the future course of the trial conditional on the current data. You will be requested in fill in the names of required

56 Muller and Schafer Method

variables from the **Pancreatic-Look1** data set.

Select the appropriate variables from the respective drop-down menus as shown.

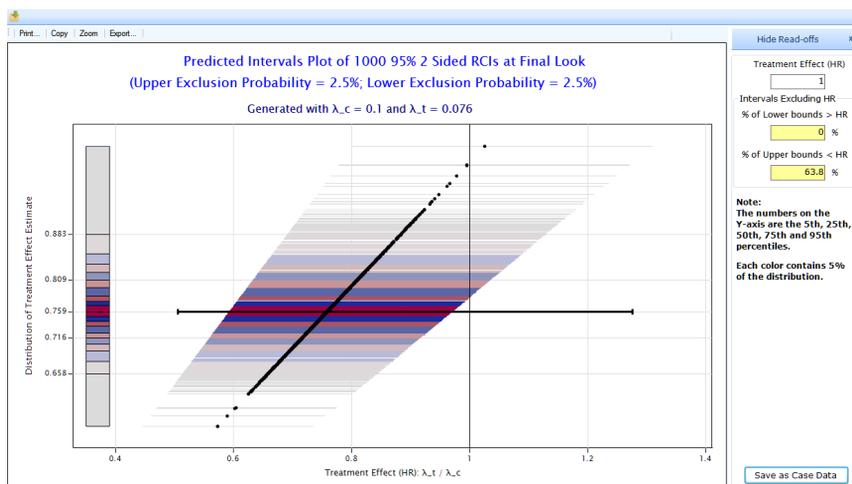

Click on the **Optional: Estimate Parameters from Data** button so that East can estimate the individual hazards and hazard ratio and can input the sample size and number of events

from the **Pancreatic-Look1** data set.

If you now click on the **Simulate** button you will simulate the future course of the trial from the current data in **Pancreatic-Look1** and obtain 1000 repeated confidence intervals (RCIs) each representing a possible final analysis for the trial. These RCIs are sorted and stacked on top of one another to provide an intuitive plot called a Predicted Interval Plot (see, for example, Li, Evans, Uno and Wei, Statistics in

56 Muller and Schafer Method

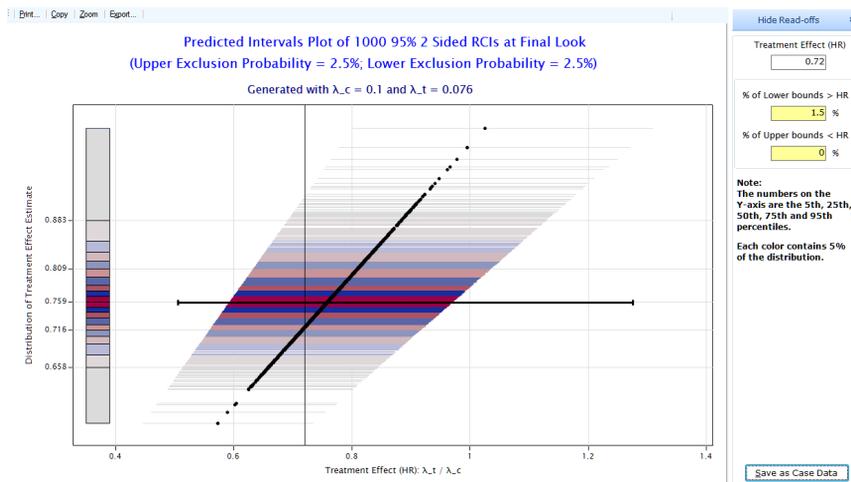

Biopharmaceutical Research, 2009).

The black dot at the center of each RCI is the estimate of hazard ratio for that simulation. The X-axis displays a range of possible hazard ratios with a vertical cursor positioned by default at HR=1. The vertical cursor can be dragged to the left or right or be moved to a specific location by entering a value in the **Treatment Effect** edit box at the top right of the window.

It is seen that 63.8% of these RCI's have their upper bounds to the left of HR=1, thereby demonstrating the estimated conditional power of 64.2%. The color coded vertical bar on the right of the graph is a heat plot representing the distribution of the 1000 hazard ratios. Each color represents 5% of the observed hazard ratios. For example, the lowest 5% of hazard ratios have values less than or equal to 0.658, the lowest 25% of hazard ratios have values less than 0.716, and so on. The PIP plot is more informative than a conditional power calculation. To see this let us suppose that only hazard ratios that are smaller than 0.72 are considered to be clinically meaningful. If we move the vertical cursor to 0.72, we find that only 1.5% of the 1000 simulated future

trial have a clinically meaningful hazard ratio.

To save this PIP plot in the library for future use click on the **Save in Workbook** icon at the top of the window

A snapshot of the current entries in the interim monitoring worksheet is saved in the library along with the PIP plot.

One can examine the contents of these newly created nodes by double-clicking or by selecting and the clicking on the **Details** tool in the library tool bar.

Adaptive Increase in Events and Number of Looks Since the conditional power (64%) is in the promising zone we decide to make an adaptive change. In keeping with the simulations that were performed at the design stage, let us alter the future course of the trial in two ways:

1. Increase the total number of events by 50%. Thus the total number of events will be increased from the 260 to 390.
2. Increase the number for future looks from 1 to 2 and alter the efficacy spending function from LD(OF) to LD(PK).

In order to make these changes click on the **Adapt** button on the tool bar at the top of

56 Muller and Schafer Method

the interim monitoring worksheet.

Specification of Stage II Design

Design Type: Superiority Number of Looks: 1

Test Parameters Accrual / Dropouts

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Median Survival Times

Conditional Error Rate: 0.1132 Hazard Ratio (Optional)

Power: 0.9 Hazard Ratio (λ_1/λ_2) Alternative: 0.75788

Incremental Ratio of Medians (m_1/m_2) Alternative: 1.31947

Recalc OK Cancel

Change the **Number of Looks** to 2 and the **Incremental Number of Events** to 260 as shown. (Note: to change the events rather than the power, you will

have to switch the selection of the radio button.). Press the **Recalc** button when done.

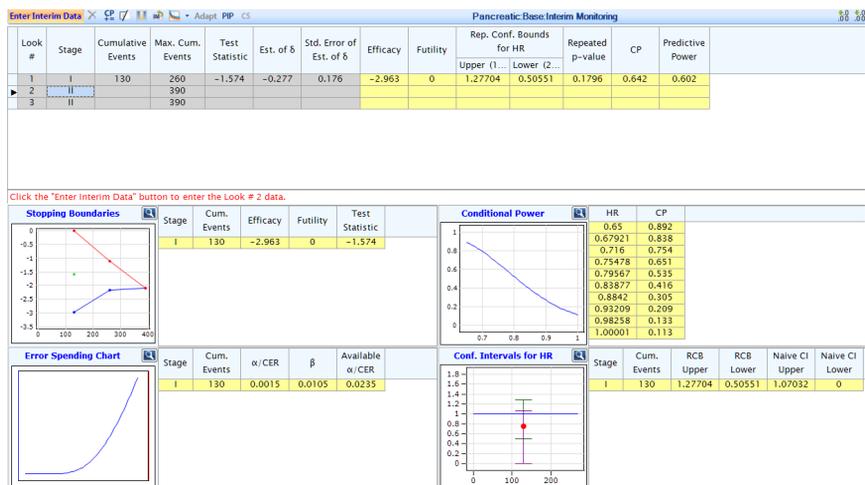

Next go to the **Boundary** tab and change the error spending function for efficacy from LD(OF) to LD(PK). Also change the HR for early stopping for futility to 1.0. Press **Recalc** when done.

Finally examine the **Accrual/Dropouts** tab and leave these entries unchanged and

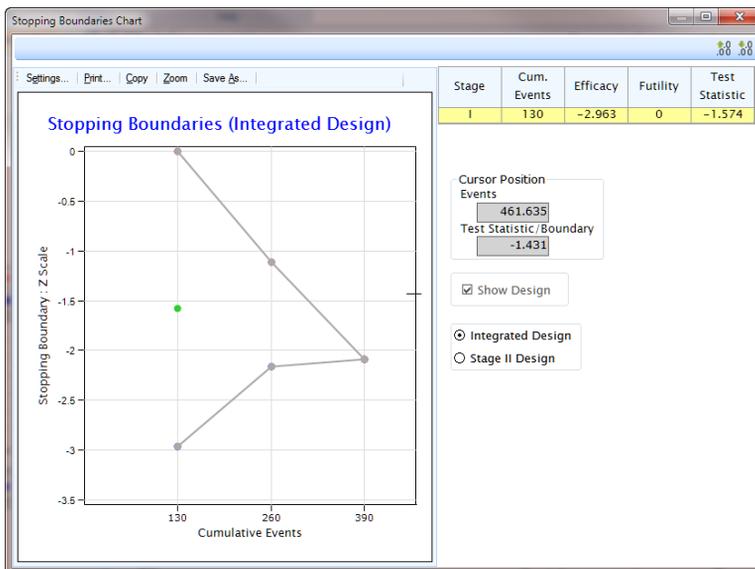

56 Muller and Schafer Method

click **OK**.

With these adaptations, the study will enroll an additional 209 subjects for a total of 472 subjects, and will follow them until 390 total events are obtained. Two additional interim looks are planned, one at 260 events and one at 390, with a Pocock spending function efficacy boundary and a HR=1 futility boundary. The interim monitoring worksheet has been modified to reflect these changes. Below is a screenshot of the

integrated 3-look adaptive design.

The Second Interim Look Import the data set for the second interim analysis into East with the **File>Import>~Pancreatic-Look2.csv** commands.

57 *Conditional Power for Decision Making*

In the course of conducting an adaptive clinical trial, many decisions that are to be made on matters such as determining sample size, stopping the trial for futility, and whether or not and when and how to adapt the trial design, depend primarily on the values of ‘power estimates’. East provides facilities to compute or use different types of ‘power estimates’ while designing, simulating, or monitoring a trial.

This chapter describes the special conditional power calculators that EastAdapt and EastSurvAdapt have provided for computing conditional power either in the interim monitoring worksheets or in the simulation worksheets. Informally, conditional power is the probability, given the current data, that the trial will ultimately achieve statistical significance. For a more formal definition refer to Chapter 54, Section 54.1.3. Conditional power calculations depend on assumptions that you make about the unknown parameters δ and σ . The conditional power calculators in East accept as inputs either user-specified values of δ and σ , or estimates of δ and σ obtained at the interim analysis. This will be illustrated through several examples in this chapter.

This chapter is arranged into the following sections:

- CP Calculator-CHW:Interim Monitoring
 - Normal Endpoint
 - Binomial Endpoint
 - Time to Event Endpoint
- CP Calculator-CHW:Simulation
 - Normal Endpoint
 - Binomial Endpoint
 - Time to Event Endpoint

57.1 CP Calculator - CHW: Interim Monitoring

57.1.1 Normal Endpoint

57.1.2 Binomial Endpoint

57.1.3 Time to Event Endpoint

This section explains the use of conditional power calculator while performing Interim Monitoring.

57.1.1 Normal Endpoint

Consider a two-arm trial to determine if there is an efficacy gain for an experimental drug relative to the industry standard treatment for negative symptoms schizophrenia. The primary endpoint is the improvement from baseline to week 26 in the Negative Symptoms Assessment (NSA), a 16-item clinician-rated instrument for measuring the negative symptomatology of schizophrenia. The trial is designed for one-sided

alternative hypothesis that $\delta > 0$. It is expected, from limited data on related studies, that the difference of mean is expected to be 10 with a standard deviation of 50.

Create a design worksheet as shown below.

| CPower1:Des1 | |
|---|---------------------|
| Mnemonic | MN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 5 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.9 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Input Method | Difference of Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 10 |
| Std. Deviation (σ) | 50 |
| Test Statistic | Z |
| Boundary Parameters | |
| Spacing of Looks | Equal |
| Efficacy Boundary | LD (OF) |
| Sample Size | |
| Maximum | 1075 |
| Expected Under H0 | 1071.471 |
| Expected Under H1 | 797.168 |

We will now monitor the trial. Invoke the CHW interim monitoring by clicking  icon which will appear as displayed below.

| CHW Interim Monitoring: Des1 | | | | | | | | | | | |
|------------------------------|-------------------------|-----------------------|------------------------|----------------------|----------------------|----------|----------------|----------|------------------------|-------|--------------------|
| Look # | Incremental Sample Size | Incremental Statistic | Cumulative Sample Size | Prespecified Weights | Weight ... Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat ... p-value |
| | | | | | | | | | Upper | Lower | |
| 1 | | | | 0.2 | | | | 4.877 | | | |
| 2 | | | | 0.2 | | | | 3.357 | | | |
| 3 | | | | 0.2 | | | | 2.68 | | | |
| 4 | | | | 0.2 | | | | 2.29 | | | |
| 5 | | | | 0.2 | | | | 2.031 | | | |

Click on the  icon and in the ensuing Test Statistic Calculator, enter sample size as 215, δ as 8, and SE as 7.2291. Click OK. The incremental test

57 Conditional Power for Decision Making

statistic, will be computed as 1.1066 ($\hat{\delta}/\hat{SE} = 8/7.2291 = 1.1066$).

Similarly, for the second look, click on the **Enter Interim Data** icon and then enter the estimates of the incremental accrual, δ and SE as 220, 9.2 and 7.4162 respectively in the Test Statistic Calculator. Click OK. The computed values will be posted in the interim monitoring sheet as shown below.

| Look # | Incremental Sample Size | Incremental Statistic | Cumulative Sample Size | Prespecified Weights | Weight ... Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat ... p-value |
|--------|-------------------------|-----------------------|------------------------|----------------------|----------------------|----------|----------------|----------|------------------------|---------|--------------------|
| | | | | | | | | | Upper | Lower | |
| 1 | 215 | 1.107 | 215 | 0.2 | 1.107 | 8 | 7.229 | 4.877 | Infinity | -27.255 | 0.503 |
| 2 | 220 | 1.241 | 435 | 0.2 | 1.66 | 9.2 | 7.416 | 3.357 | Infinity | -8.787 | 0.216 |
| 3 | | | | 0.2 | | | | 2.68 | | | |
| 4 | | | | 0.2 | | | | 2.29 | | | |
| 5 | | | | 0.2 | | | | 2.031 | | | |

After any interim look, based on the observed values of δ and σ , you will be able to use conditional power calculator to estimate either conditional power or sample size using appropriate inputs as shown in Table 57.1.

Let us examine the use of conditional power calculator with a few examples. From the interim monitoring sheet, click on the **Conditional Power Calculator** icon

Table 57.1: Conditional Power Calculator Use

| Estimate | Input |
|-------------------|--|
| conditional power | observed δ/σ design sample size |
| conditional power | observed δ/σ user specified sample size |
| conditional power | user specified δ/σ design sample size |
| conditional power | user specified δ/σ user specified sample size |
| sample size | observed δ/σ desired conditional power |
| sample size | user specified δ/σ desired conditional power |

 to invoke the conditional power calculator as displayed below.

57 Conditional Power for Decision Making

The calculator is divided into two parts. The first part is the input part. The values for the cells in this part are automatically filled using the interim monitoring sheet values. The calculator indicates that the second interim look has been taken, the cumulative sample size is 435 and the weighted z statistic after the second interim look is 1.66.

The second part is the input/output part. Here you may decide to estimate either conditional power or sample size by clicking on the appropriate radio button, and then specifying the required input as detailed in Table 57.1. By default, the calculator is showing the value of δ/σ as 0.2, which is the estimate obtained from the incremental data of the second look. The interpretation is that if the hypothesized value of δ/σ is 0.2, then the conditional power to reach significance at any future look with a maximum sample size of 1075 is 0.905.

Computing Conditional Power for Specified Sample Size Now, suppose, you estimate, using cumulated data, that δ/σ is likely to be 0.1593, then enter this value in the calculator and click on **Recalc** button. The calculator will display the new estimate for conditional power, which is 0.789.

To view a plot of **conditional power vs. delta**, click on the **Plot** button

57 Conditional Power for Decision Making

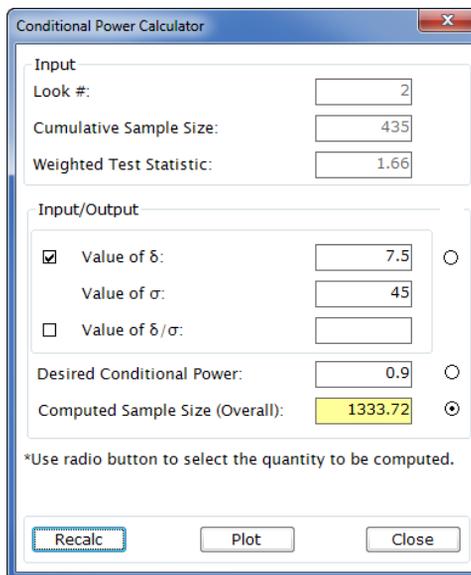

and a plot will appear as shown below.

In the above plot, if you click on the radio button against **sample size**, you will get the **conditional power vs. sample size** plot displayed below.

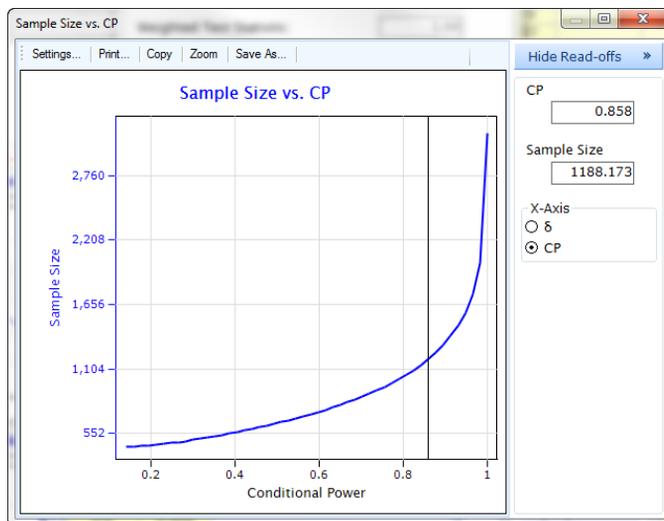

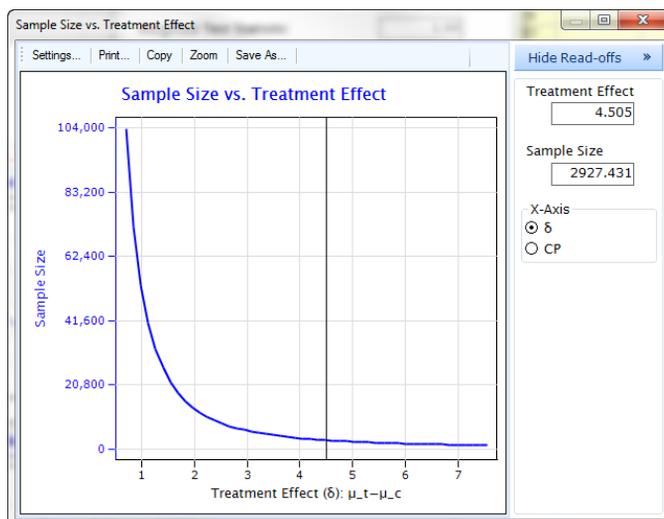

Computing Sample Size for Desired Conditional Power With the values of $\delta = 7.5$, $\sigma = 45.0$, and $sample\ size = 1075$, we obtained the conditional power estimate as 0.815. Now, keeping the same values for δ and σ , if you want to estimate the sample size for a desired conditional power of 0.90, you can proceed like this: Click on the radio button against **sample size** input box, enter the value of 0.90 for conditional power and then click on **Recalculate** button. You will get the estimate of sample size to be 1334 as displayed in the screen shot below.

With the above setting in the conditional power calculator, you can click on the **Plot** button to get the **sample size vs. delta** and **sample size vs.**

57 Conditional Power for Decision Making

conditional power plots as displayed below.

57.1.2 Binomial Endpoint

Consider a two-arm, placebo controlled randomized clinical trial for subjects with acute cardiovascular disease undergoing percutaneous coronary intervention (PCI).

The primary endpoint is a composite of death, myocardial infarction or ischemia-driven revascularization during the first 48 hours after randomization. We assume on the basis of prior knowledge that the event rate for the placebo arm is 8.7%. The investigational drug is expected to reduce the event rate by at least 20%. The investigators are planning to randomize a total of 8000 subjects in equal proportions to the two arms of the study. Let us design with help of East that a group sequential 3 looks design to detect a 20% risk reduction with a one-sided level-0.025 test of significance (with 0.087 on the control arm and $0.8 \times 0.087 = 0.0696$ on the treatment arm). It is also decided that two interim looks, one after 4000 subjects are enrolled (50% of total information) and the second after 5600 subjects are enrolled (70% of total information) will be taken. Early stopping efficacy boundaries are derived from the Lan and DeMets (1983) O'Brien-Fleming type error spending function.

With the above specifications, create a plan in East as shown below.

| | Bin:Des 1 |
|--|-------------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 3 |

| Efficacy Boundary | LD (OF) |
| Sample Size | |
| Maximum | 8000 |
| Expected Under H0 | 7979.837 |
| Expected Under H1 | 6535.034 |

We will now monitor the trial. Select  icon to invoke the CHW interim monitoring sheet. You will then be taken to the interim monitoring worksheet

57 Conditional Power for Decision Making

displayed below.

| Look # | Incremental Sample Size | Incremental Statistic | Cumulative Sample Size | Prespecified Weights | Weight ... Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat ... p-value |
|--------|-------------------------|-----------------------|------------------------|----------------------|----------------------|----------|----------------|----------|------------------------|-------|--------------------|
| | | | | | | | | | Upper | Lower | |
| 1 | | | | 0.5 | | | | -2.963 | | | |
| 2 | | | | 0.2 | | | | -2.462 | | | |
| 3 | | | | 0.3 | | | | -2.002 | | | |

The first interim look was taken after accruing 4000 patients, 2000 per treatment arm. We input this number in the Incremental accrual number in the row corresponding to the first look. To calculate the incremental statistic, we utilize the test statistic calculator. There are 174 events in the control arm and 147 events in the treatment arm. Based on these data the estimate of δ is $(147/2000) - (174/2000) = -0.0135$ and the estimate of $SE = 0.0086$. So the value of the test statistic is $SE/\text{estimate of } \delta = -1.5718$. These values are entered in the test statistic calculator as shown below.

Test Statistic Calculator

| 1 | 4000 | -1.572 | 4000 | 0.5 | -1.572 | -0.014 | 0.009 | -2.963 | 0.012 | -1 | 0.18 |
| 2 | | | | 0.2 | | | | -2.462 | | | |
| 3 | | | | 0.3 | | | | -2.002 | | | |

Conditional Power Calculator After each look during interim monitoring the decision to alter the sample size can be made using the conditional power calculator. After any interim look, based on the observed data, you will be able to use conditional power calculator to estimate any one of the three quantities - conditional power or sample size or π_t -given the estimates of other two and any specified value of π_c .

Computing Power for a pre specified sample size Click on the icon  from the IM toolbar to invoke the conditional power calculator as shown below.

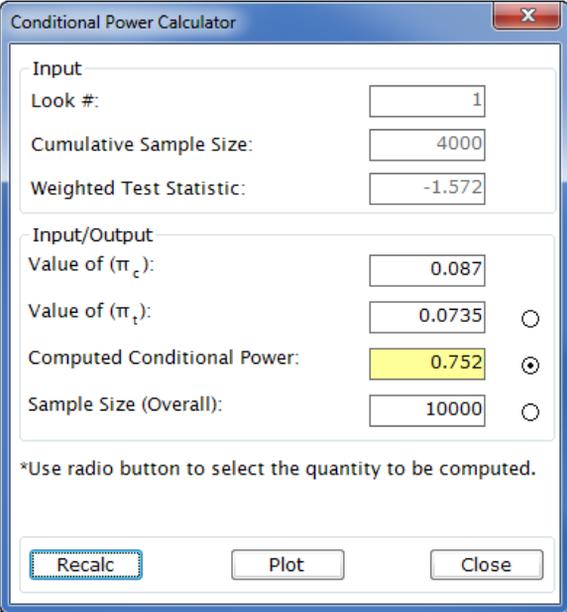

The calculator is divided into 2 parts. The first part displays the inputs that are used in the interim monitoring sheet till the current look. The Cumulative accrual is 4000 and the current weighted test statistic is -1.5718.

57 Conditional Power for Decision Making

The second part helps the user to estimate the value of a desired parameter by selecting the radio button against the parameter and then entering the values for other parameters and clicking on **Recalc** button.

In the current scenario, for a final overall size of 8000, and the hypothesized values of $\pi_c = 0.087$ and $\pi_t = 0.0735$, the conditional power is estimated to be 0.629.

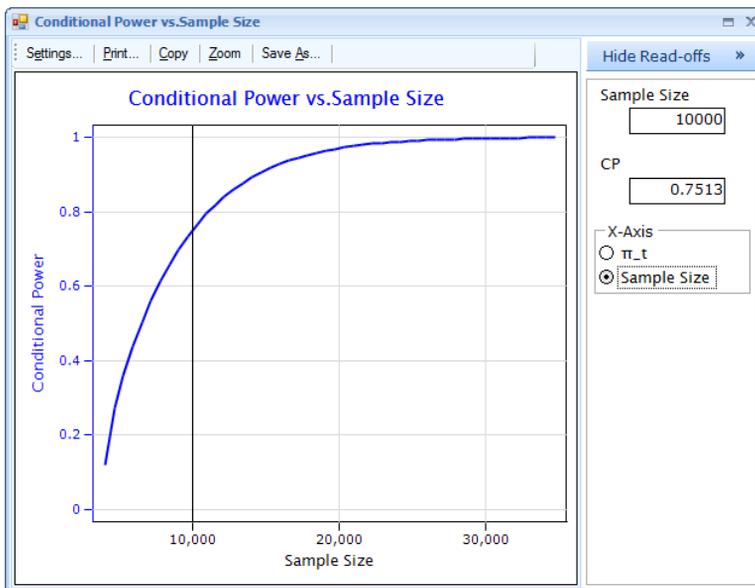

Now keeping the values of π_c , and π_t same, if you want to estimate the conditional power for an increased sample size of 10,000, then enter this value and click on **Recalc** button to see the conditional power estimate to be 0.752.

The image shows a software dialog box titled "Conditional Power Calculator". It contains several input fields and radio buttons. The "Input" section has fields for "Look #:" (value 1), "Cumulative Sample Size:" (value 4000), and "Weighted Test Statistic:" (value -1.572). The "Input/Output" section has fields for "Value of (π_c):" (value 0.087), "Value of (π_t):" (value 0.0735), "Computed Conditional Power:" (value 0.752, highlighted in yellow), and "Sample Size (Overall):" (value 10000). There are radio buttons next to the π_t and Sample Size fields. A note at the bottom says "*Use radio button to select the quantity to be computed." At the bottom of the dialog are three buttons: "Recalc", "Plot", and "Close".

Now you may click on the **Plot** button and choose x-axis to represent sample size, to see the graph of conditional power vs. sample size, assuming $\pi_t = 0.0735$,

$$\pi_c = 0.087.$$

Re-estimating Sample Size for a desired power

If a final overall sample size is to be estimated for a desired value of conditional power, the user can do so by selecting the sample size radio button in the calculator. Suppose, the user wants to estimate the increase required in the final sample size for a desired conditional power of 80%. The user can select the radio button next to the **Final Sample Size** input box and enter the value of 0.8 for conditional power and then click on **Recalc** button. The result in the conditional power calculator will appear as

57 Conditional Power for Decision Making

shown below.

The image shows a software dialog box titled "Conditional Power Calculator". It is divided into two main sections: "Input" and "Input/Output".

Input Section:

- Look #: 1
- Cumulative Sample Size: 4000
- Weighted Test Statistic: -1.572

Input/Output Section:

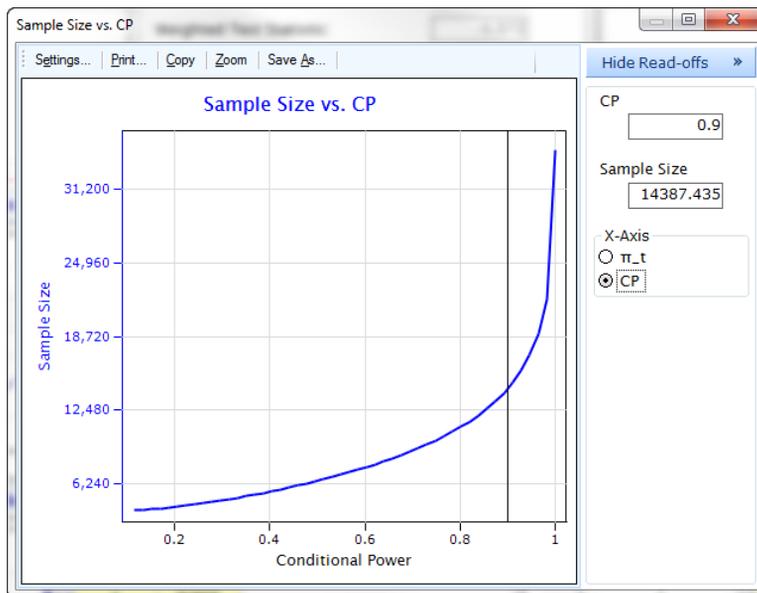

- Value of (π_c): 0.087
- Value of (π_t): 0.0735 (radio button is unselected)
- Desired Conditional Power: 0.8 (radio button is unselected)
- Computed Sample Size (Overall): 11057.84 (radio button is selected, and the value is highlighted in yellow)

Below the input/output section, there is a note: "*Use radio button to select the quantity to be computed."

At the bottom of the dialog box, there are three buttons: "Recalc", "Plot", and "Close".

The calculator estimates a final sample size of 11058 for a desired conditional power of 0.8 for the values of $\pi_t = 0.0735$ and $\pi_c = 0.087$. After clicking on the **Plot**

button, the user can view the plot of sample size vs. conditional power as shown below.

57.1.3 Time to Event Endpoint

A two-arm multi-center randomized clinical trial is planned for subjects with advanced metastatic non-small cell lung cancer with the goal of comparing the current standard second line therapy (docetaxel+cisplatin) to a new docetaxel containing combination regimen. The primary endpoint is overall survival (OS). The study is required to have one-sided $\alpha = 0.025$, and 90% power to detect an improvement in median survival, from 8 months on the control arm to 11.4 months on the experimental arm, which corresponds to a hazard ratio of 0.7. Accrual duration is 24 months and the study duration 30 months. We shall first create a three look group sequential design for

57 Conditional Power for Decision Making

this study in East as shown below.

| Surv:Des 1 | |
|---|--------------------|
| Mnemonic | SU-2S-LRSD |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 3 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.9008 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Hazard Ratio (Alt.) | 0.702 |
| Var (Log HR) | Null |
| Boundary Parameters | |
| Spacing of Looks | Equal |
| Efficacy Boundary | LD (OF) |
| Accrual & Dropout Parameters | |
| Subjects are Followed | Until End of Study |
| No. of Accrual Periods | 1 |
| No. of Dropout Pieces | 0 |
| Sample Size | |
| Maximum | 492 |
| Expected Under H0 | 491.5725 |
| Expected Under H1 | 464.4281 |
| Events | |
| Maximum | 340 |
| Expected Under H0 | 339.3008 |
| Expected Under H1 | 272.5305 |
| Study Duration | |
| Maximum | 30 |
| Expected Under H0 | 27.523 |
| Expected Under H1 | 25.25 |
| Accrual Duration | |
| Maximum | 24 |
| Expected Under H0 | 23.979 |
| Expected Under H1 | 22.655 |

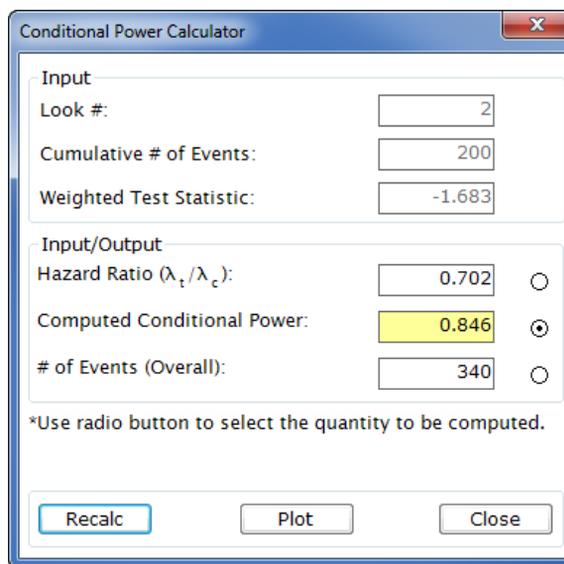

We will now monitor the trial. Invoke the CHW interim monitoring sheet. Enter at the first look, the cumulative events as 110 and the cumulative test statistic, using test statistic calculator, as 1.220 ($\hat{\delta}/\hat{SE} = -0.288/0.236 = -1.220$). At the second look, enter the incremental accrual as 200 and again use the test calculator to enter ($\hat{\delta}/\hat{SE} = -0.324/0.195 = -1.662$).

Now the interim monitoring sheet will appear as displayed below.

| Look # | Cumulative Events | Cumulative Statistic | Incremental Statistic | Prespecified Weights | Weight... Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | 97.5% RCI for HR | | Repeated p-value |
|--------|-------------------|----------------------|-----------------------|----------------------|---------------------|------------------|--------------------------------|----------|------------------|-------|------------------|
| | | | | | | | | | Upper | Lower | |
| 1 | 110 | -1.22 | -1.22 | 0.332 | -1.22 | -0.288 | 0.236 | -3.716 | 1.802 | 0 | 0.358 |
| 2 | 200 | -1.662 | -1.16 | 0.335 | -1.683 | -0.324 | 0.195 | -2.509 | 1.178 | 0 | 0.106 |
| 3 | | | | 0.332 | | | | -1.993 | | | |

After any interim look, based on the observed values of δ and its SE, you will be able to use conditional power calculator to estimate either conditional power or number of events using appropriate inputs.

Let us examine the use of conditional power calculator with a few examples. From the interim monitoring sheet, click on the icon  to invoke the conditional power calculator as displayed below.

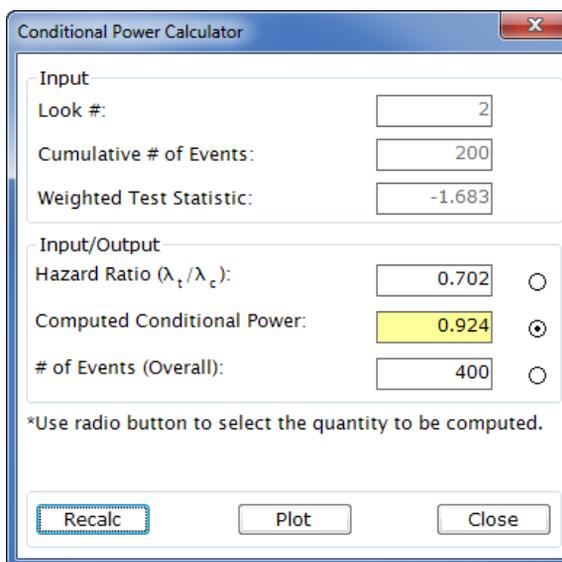

The calculator is divided into two parts. The first part is the input part. The values for the cells in this part are automatically filled using the interim monitoring sheet values. The calculator indicates that the second interim look has been taken, the cumulative number of events is 200 and the weighted z statistic after the second interim look is -1.683 .

The second part is the input/output part. Here you may decide to estimate any of the three quantities - required HR, conditional power, number of events by clicking on the appropriate radio button, and then specifying the input for the other two quantities.

Computing Conditional Power for Specified Number of Events Now, suppose, you estimate that with the available budget you can extend the study to cover 400 events. In that scenario you may want to know the effect on the conditional power. With the radio

57 Conditional Power for Decision Making

button selected to compute conditional power, enter the value of 400 as the number of events and click on **Recalc** button. The calculator will display the new estimate for conditional power, which is 0.9239.

The image shows a software dialog box titled "Conditional Power Calculator". It contains two main sections: "Input" and "Input/Output".

Input Section:

- Look #:
- Cumulative # of Events:
- Weighted Test Statistic:

Input/Output Section:

- Hazard Ratio (λ_t / λ_c):
- Computed Conditional Power:
- # of Events (Overall):

*Use radio button to select the quantity to be computed.

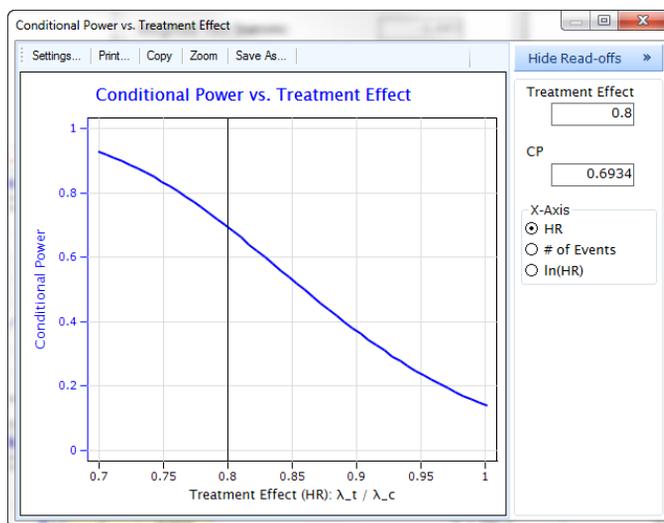

At the bottom, there are three buttons: "Recalc" (highlighted with a dashed border), "Plot", and "Close".

To view a plot of **conditional power vs. number of events**, click on the **Plot** button, select number of events as the x-axis variable and a plot will appear

as shown below.

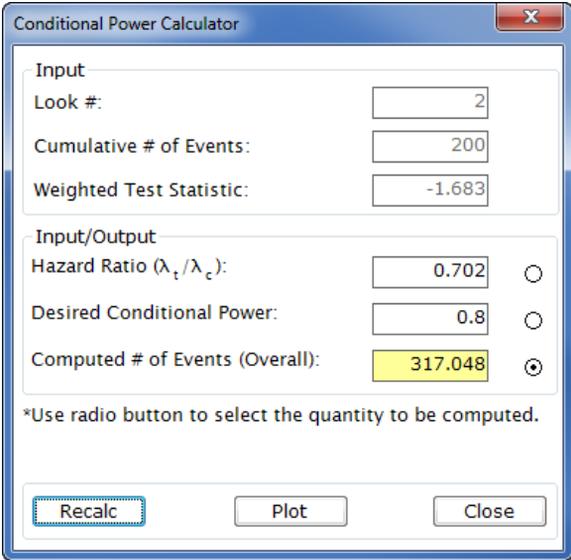

In the above plot, if you click on the radio button against **HR**, you will get the **conditional power vs. HR** plot displayed below.

57 Conditional Power for Decision Making

Computing Sample Size for Desired Conditional Power If you would like to estimate the number of events required for a specified conditional power, say 0.80, you can click on the radio button against # of events, enter 0.80 as conditional power, and then click on **Recalc** button. The calculator will display the estimate for number of events, which is 317.

The image shows a software dialog box titled "Conditional Power Calculator". It contains two main sections: "Input" and "Input/Output".

Input Section:

- Look #: 2
- Cumulative # of Events: 200
- Weighted Test Statistic: -1.683

Input/Output Section:

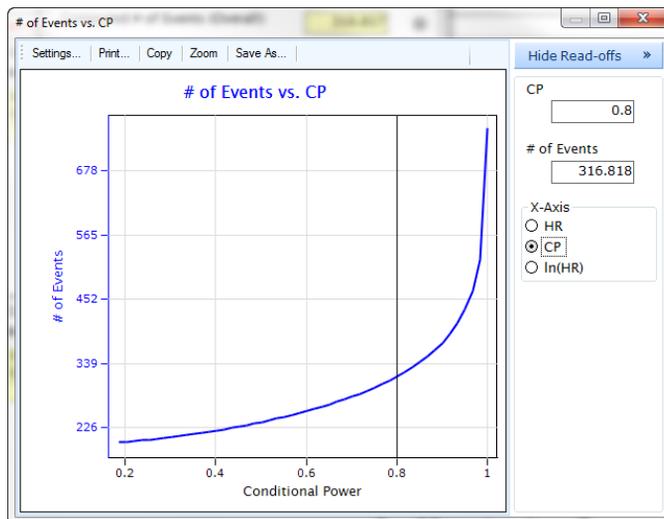

- Hazard Ratio (λ_t / λ_c): 0.702
- Desired Conditional Power: 0.8
- Computed # of Events (Overall): 317.048

Below the radio buttons, there is a note: "*Use radio button to select the quantity to be computed."

At the bottom of the dialog, there are three buttons: "Recalc", "Plot", and "Close".

To view a plot of **number of events vs. conditional power**, click on the **Plot** button, select conditional power as the x-axis variable and a plot will appear

as shown below.

57.2 CP Calculator - CHW: Simualtion

This section explains the use of conditional power calculator while performing adaptive simulations. Simulation capabilities can be useful in verifying the operating characteristics of the design.

57.2.1 Normal Endpoint

Let us use the design for normal endpoint that we discussed in section 57.1.1 which is

57 Conditional Power for Decision Making

shown below.

| | Wbk1:Des1 |
|---|---------------------|
| Mnemonic | MN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 5 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.9 |
| Model Parameters | |
| Input Method | Difference of Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 10 |
| Std. Deviation (σ) | 50 |
| Test Statistic | Z |
| Allocation Ratio (nt/nc) | 1 |
| Boundary Parameters | |
| Efficacy Boundary | LD (OF) |
| Spacing of Looks | Equal |
| Sample Size | |
| Maximum | 1075 |
| Expected Under H0 | 1071.4709 |
| Expected Under H1 | 797.1678 |

Save this design in the library and then click on the icon  to get the simulation worksheet. In this sheet, in the **Include Options** button, choose **Sample Size Re-estimation**. You will get the a simulation worksheet. Click on the tab **Sample Size**

Re-estimation to see the simulation sheet with this tab opened.

Keep the simulation parameters displayed in other tabs without any change. The default values for simulation suggest that the difference of means to be 10.0 and the standard deviation to be 50. The maximum sample size to be used till look $L=4$, is $N_{max} = 1075$. Let us change this max value to 2150 by modifying the multiplier value from 1 to 2. Also the criterion for when to adapt the sample size is specified by a range of conditional power value from 0.3 to 0.9. Thus after the second look, if the conditional power computed lies between 0.3 and 0.9, the simulation will increase the sample size to a maximum of 2150, so that the conditional power can rise to the desired level of 0.9. In order to assess and observe the effect of varying the values of these simulation parameters, we use the conditional power calculator. Based on the results we get from the conditional power calculator, we decide on a set of values for the simulation parameters and then carry out the simulation.

Open the conditional power calculator by clicking on the icon  and the

57 Conditional Power for Decision Making

calculator will appear as shown below.

The image shows a software dialog box titled "Conditional Power Calculator". It is divided into two main sections. The first section, "Input", contains two text input fields: "Current Look:" with the value "4" and "Current Sample Size:" with the value "860". The second section, "Input/Output", is titled " δ/σ to be Used in Conditional Power Computation" and contains two radio buttons: "Arbitrary (δ/σ)" (unselected) and "Estimated ($\delta/\sigma, Z$)" (selected). Below these are two groups of input fields. The first group, under the "Arbitrary" option, has a checkbox (unchecked) and three input fields: "Value of δ :" (empty), "Value of σ :" (empty), and "Value of δ/σ :" (containing "0.131"). The second group, under the "Estimated" option, has a checkbox (checked) and two input fields: "Value of δ/σ :" (containing "0.131") and "Value of z :" (containing "1.918"). At the bottom of the dialog, there are two more input fields: "Computed Conditional Power:" (containing "0.6") and "Sample Size (Overall):" (containing "1075"). A note at the bottom reads: "* Use radio button to select the quantity to be computed." At the very bottom are two buttons: "Recalc" and "Close".

The conditional power calculator is divided into two parts. The first part lists the inputs and gives the current look position and the sample size at the current look.

The second part is used to compute either conditional power or sample size given the other quantity and appropriate values among δ/σ , z , δ , and σ depending on the choice made between the options **Arbitrary** and **Estimated**. For example if you want to estimate the conditional power for the estimated values of $\delta = 8$ and $\sigma = 70$ and for a maximum sample size of 2150, enter these values in the calculator and click on **Recalc** button. The calculator will compute the values of z and the conditional

power as shown below.

Conditional Power Calculator

Input
 Current Look:
 Current Sample Size:

Input/Output
 δ/σ to be Used in Conditional Power Computation
 Arbitrary (δ/σ) Estimated ($\delta/\sigma, Z$)

Value of δ :
 Value of σ :
 Value of δ/σ :
 Value of z :

Computed Conditional Power:
 Sample Size (Overall):

* Use radio button to select the quantity to be computed.

The estimated conditional power of 0.8058 indicates that even with a maximum sample size of 2150, the conditional power cannot reach the desired level of 0.90, if the estimated values of $\delta = 8$ and $\sigma = 70$ represent the true values of the population.

The quantity δ/σ can either be estimated or design values, using the drop down box against **CP Computation Based on:**. For this simulation, we will use the estimated value of δ/σ and Z . Select the option **Estimated $\delta/\sigma, Z$** .

Computing overall Sample Size

Suppose we wish to compute the overall sample size required for a conditional power of 0.9. Select the radio button next to the overall sample size and enter the value of 0.9

57 Conditional Power for Decision Making

for conditional power. Press **Recalc** to obtain the result as shown below

Conditional Power Calculator

Input
 Current Look:
 Current Sample Size:

Input/Output
 δ/σ to be Used in Conditional Power Computation
 Arbitrary (δ/σ) Estimated ($\delta/\sigma, Z$)

Value of δ :
 Value of σ :
 Value of δ/σ :
 Value of z :

Conditional Power:
 Computed Sample Size (Overall):

* Use radio button to select the quantity to be computed.

The calculator shows that the overall sample size for the desired conditional power of 0.90 is 2730.8. You may enter this sample size as the **Max. Usable sample size** by specifying the multiplier as $2730.8/1075 = 2.5403$ in the simulation sheet along with appropriate values for other simulation parameters and then carry out the simulation.

57.2.2 Binomial Endpoint

This section looks at the use of conditional power calculator during the adaptive simulation of trials with binomial endpoints.

Let us use the design for binomial endpoint that we discussed in section 57.1.2 which

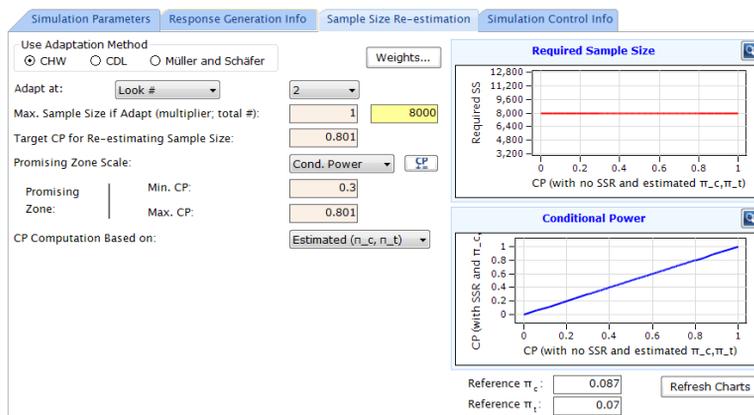

is shown below.

| | Bin:Des 1 |
|--|-------------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 3 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.82 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Proportion under Control (π_c) | 0.087 |
| Proportion under Treatment (π_t) | 0.07 |
| Diff. in Prop. ($\pi_t - \pi_c$) | -0.017 |
| Variance | Unpooled Estimate |
| Boundary Parameters | |
| Spacing of Looks | Unequal |
| Efficacy Boundary | LD (OF) |
| Sample Size | |
| Maximum | 8000 |
| Expected Under H0 | 7979.8367 |
| Expected Under H1 | 6535.0339 |

We will now simulate this plan using adaptive simulation in East. click on the icon  to get the simulation worksheet. In this sheet, in the **Include Options** button, choose **Sample Size Re-estimation**. You will get the a simulation worksheet. Click on

57 Conditional Power for Decision Making

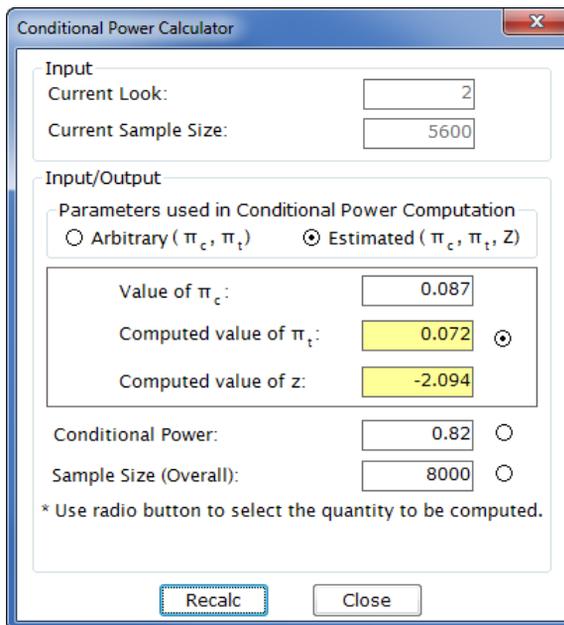

the tab **Sample Size Re-estimation** to see the simulation sheet with this tab opened.

Keep the simulation parameters displayed in other tabs without any change. The default values indicate that the proportion of response for control arm to be 0.087 and for the treatment arm to be 0.0696. The criterion for when to adapt the sample size is specified by a range of conditional power value from 0.3 to 0.82. Change the multiplier value from 1 to 2, so as to get maximum sample size if adapt to become 16000. Thus, after the second look, if the estimated conditional power lies between 0.3 and 0.82, then the simulation process will increase the sample size to a maximum of 16000, so as to raise the conditional power to the desired level of 0.82. In order to assess and observe the effect of varying the values of these simulation parameters, you may use the conditional power calculator. Based on the results you get from the conditional power calculator, you may decide on a set of values for the simulation parameters and then carry out the simulation.

Open the conditional power calculator by clicking on the icon  and the

calculator will appear as shown below.

The conditional power calculator is divided into two parts. The first part lists the inputs and gives the current look position and the current sample size.

The second part is used to compute either conditional power or sample size given the other quantity and appropriate values among π_c , π_t , and z , depending on the choice made between the options **Arbitrary** and **Estimated**.

Computing conditional power for a specified sample size For example if you want to estimate the conditional power for the estimated values of $\pi_c = 0.085$ and $\pi_t = 0.074$ and for a maximum sample size of 16,000, enter these values in the calculator and click on **Recalc** button. The calculator will compute the values of z

57 Conditional Power for Decision Making

and the conditional power as shown below.

The image shows a software dialog box titled "Conditional Power Calculator". It contains several input fields and radio buttons. Under "Input", "Current Look" is set to 2 and "Current Sample Size" is 5600. Under "Input/Output", the "Parameters used in Conditional Power Computation" section has two radio buttons: "Arbitrary (π_c, π_t)" (unselected) and "Estimated (π_c, π_t, Z)" (selected). Below this, "Value of π_c " is 0.085, "Value of π_t " is 0.074 (with an unselected radio button), and "Value of z" is -1.522. The "Computed Conditional Power" is 0.771 (with a selected radio button), and "Sample Size (Overall)" is 16000 (with an unselected radio button). A note at the bottom states: "* Use radio button to select the quantity to be computed." At the bottom of the dialog are "Recalc" and "Close" buttons.

The computed conditional power of 0.7715 indicates that the maximum usable sample size of 16,000 may have to be increased in order to attain the desired conditional power of 0.82.

Computing overall Sample Size for a desired conditional power Now suppose we wish to compute the overall sample size required for a conditional power of 0.82. Select the radio button next to the overall sample size and enter the value of 0.82 for Computed conditional power. Press **Recalc** button to obtain the result as shown

below.

Conditional Power Calculator

Input
Current Look: 2
Current Sample Size: 5600

Input/Output
Parameters used in Conditional Power Computation
 Arbitrary (π_c, π_t) Estimated (π_c, π_t, Z)

Value of π_c : 0.085
Value of π_t : 0.074
Value of z: -1.522

Conditional Power: 0.82
Computed Sample Size (Overall): 17793.723

* Use radio button to select the quantity to be computed.

Recalc Close

East computes that the required over all sample size for the desired conditional power is 17793.7. Now you may enter this value for **Max. Sample Size** in the simulation sheet and then carry out simulation.

57.2.3 Time to Event Endpoint

Let us use the design for survival endpoint that we discussed in section 57.1.3 which is

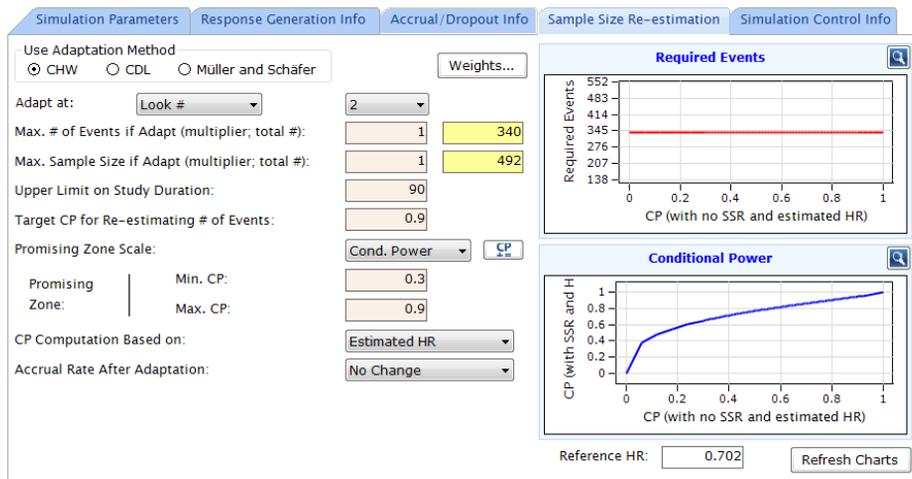

57 Conditional Power for Decision Making

shown below.

| | Surv:Des 1 |
|---|--------------------|
| Mnemonic | SU-25-LRSD |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 3 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.9008 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Hazard Ratio (Alt.) | 0.702 |
| Var (Log HR) | Null |
| Boundary Parameters | |
| Spacing of Looks | Equal |
| Efficacy Boundary | LD (OF) |
| Accrual & Dropout Parameters | |
| Subjects are Followed | Until End of Study |
| No. of Accrual Periods | 1 |
| No. of Dropout Pieces | 0 |
| Sample Size | |
| Maximum | 492 |
| Expected Under H0 | 491.5725 |
| Expected Under H1 | 464.4281 |
| Events | |
| Maximum | 340 |
| Expected Under H0 | 339.3008 |
| Expected Under H1 | 272.5305 |
| Study Duration | |
| Maximum | 30 |
| Expected Under H0 | 27.523 |
| Expected Under H1 | 25.25 |
| Accrual Duration | |
| Maximum | 24 |
| Expected Under H0 | 23.979 |
| Expected Under H1 | 22.655 |

We will now simulate this plan using adaptive simulation in East. click on the icon  to get the simulation worksheet. In this sheet, in the **Include Options** button, choose **Sample Size Re-estimation**. You will get the a simulation worksheet. Click on

the tab **Sample Size Re-estimation** to see the simulation sheet with this tab opened.

Keep the simulation parameters displayed in other tabs without any change. The default values for simulation suggest that the hazard rates for control and treatment arms as 0.0866 and 0.0607 respectively with the resulting Hazard Ratio of 0.70. The maximum number of events to be used till look $L=2$, is $MaxEvents = 340$ with the multiplier at the default value of 1.0. Also the criterion for when to adapt the number of events is specified by a range of conditional power value from 0.3 to 0.9. The target CP is at the default value of 0.90. In order to assess and observe the effect of varying the values of these simulation parameters, we use the conditional power calculator. Based on the results we get from the conditional power calculator, we decide on a set of values for the simulation parameters and then carry out the simulation.

Open the conditional power calculator by clicking on the icon  and the

57 Conditional Power for Decision Making

calculator will appear as shown below.

The screenshot shows a dialog box titled "Conditional Power Calculator" with a close button (X) in the top right corner. The dialog is divided into two main sections: "Input" and "Input/Output".

Input Section:

- Current Look:
- Current # of Events:

Input/Output Section:

HR to be Used in Conditional Power Computation

Arbitrary (HR) Estimated (HR, z)

Value of HR:

Value of z:

Computed Conditional Power:

of Events (Overall):

* Use radio button to select the quantity to be computed.

Buttons: Recalc, Close

The conditional power calculator is divided into two parts. The first part lists the inputs and gives the current look position and the number of events at the current look.

The second part is used to compute either conditional power or number of events given the other quantity and appropriate values of HR, and z , depending on the choice made between the options **Arbitrary** and **Estimated**. For example if you want to estimate the conditional power for the estimated value of HR = 0.8 and for a maximum no.of events of 500, enter these values in the calculator and click on **Recalc** button.

The calculator will compute the values of z and the conditional power as shown below.

The estimated conditional power of 0.779 indicates that even with the number of events at a maximum of 500, the conditional power cannot reach the desired level of 0.90, if the estimated Hazard Ratio of 0.80 represents the true value of the population.

The quantity of Hazard Ratio can either be defined by the user or estimated or design values. For this simulation, we will use the estimated value of Hazard Ratio. Select the radio button next to **Estimated (HR, Z)**.

Computing Number of Events (Overall)

Suppose we wish to compute the number of events (overall) required for a conditional power of 0.9. Select the radio button next to the # of Events (Overall) and enter the

57 Conditional Power for Decision Making

value of 0.9 for conditional power. Press **Recalc** to obtain the result as shown below

The image shows a dialog box titled "Conditional Power Calculator". It contains several input fields and radio buttons. The "Input" section has "Current Look:" set to 2 and "Current # of Events:" set to 227. The "Input/Output" section has "HR to be Used in Conditional Power Computation" with "Arbitrary (HR)" unselected and "Estimated (HR, z)" selected. Below this, "Value of HR:" is 0.8 and "Value of z:" is -1.681. The "Conditional Power:" is 0.9 and "Computed # of Events (Overall):" is 673.089. A note at the bottom says "* Use radio button to select the quantity to be computed." There are "Recalc" and "Close" buttons at the bottom.

| Field | Value |
|--------------------------------|---------|
| Current Look | 2 |
| Current # of Events | 227 |
| Value of HR | 0.8 |
| Value of z | -1.681 |
| Conditional Power | 0.9 |
| Computed # of Events (Overall) | 673.089 |

The calculator shows that the overall sample size for the desired conditional power of 0.90 is 673. You may specify this number as the **Max. Events if Adapt (multiplier, total #)** by entering the multiplier as $673/340 = 1.9794$ in the simulation sheet. You may then specify appropriate values for other simulation parameters and then carry out the simulation.

58 *Introduction to Volume 8*

This volume contains Chapters 58 through 69. These chapters describe special design and monitoring tools that, rather than being end-point specific, cut across all different types of group sequential designs.

Chapter 59 deals with the design and monitoring of trials on an information scale rather than on a sample size scale. By fixing the maximum information but allowing the sample size to float one can ensure that a study will be adequately powered despite poor initial guesses about nuisance parameters like σ^2 .

Chapter 60 describes how one can convert any fixed sample design into a group sequential design. Suppose, for example, that you wish to run a three period cross-over study as a group sequential design with interim looks for early stopping for efficacy and futility. Since East does not at present support this type of design you may first obtain the necessary sample size for a single look design on your own, perhaps with other commercial software. This sample size would be input to East and the single look design would then be converted into a group sequential design with stopping boundaries and a corresponding inflated sample size.

Chapter 61 discusses early stopping for futility.

Chapter 62 describes all the different types of stopping boundary families that are available in East, such as Haybittle-Peto, Wang-Tsiatis, Lan-DeMets etc.

Chapter 63 illustrates through several examples how East may be used to obtain sample sizes that are based on the desired width of a confidence interval for the parameter of interest rather than being based on the desired power of a hypothesis test.

Chapter 64 discusses the various types of simulation tools provided by East.

Chapter 65 explains the concept of predicting the future course of a trial with Predictive Interval Plots.

Chapter 66 discusses the Enrollment/Events Prediction At Design Stage.

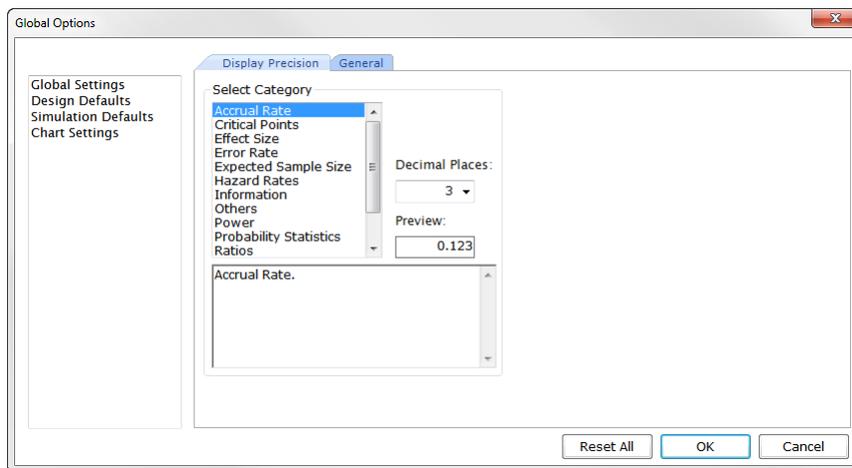

Chapter 67 discusses the Enrollment/Events Prediction At Interim Monitoring Stage using conditional simulations.

Chapter 69 discusses the interaction of East 6 with East PROCs.

58.1 Settings

Click the **Global Options** icon in the **Home** menu to adjust default values in East 6.

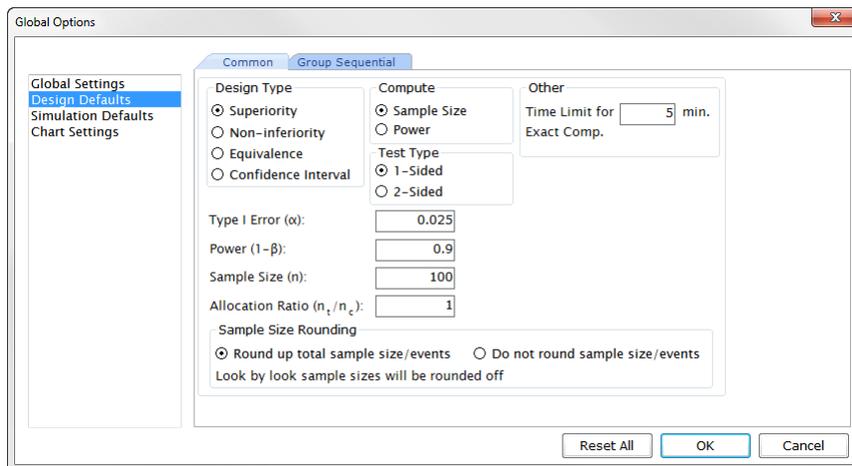

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

58 Introduction to Volume 8

The **Design Defaults** is where the user can change the settings for trial design:

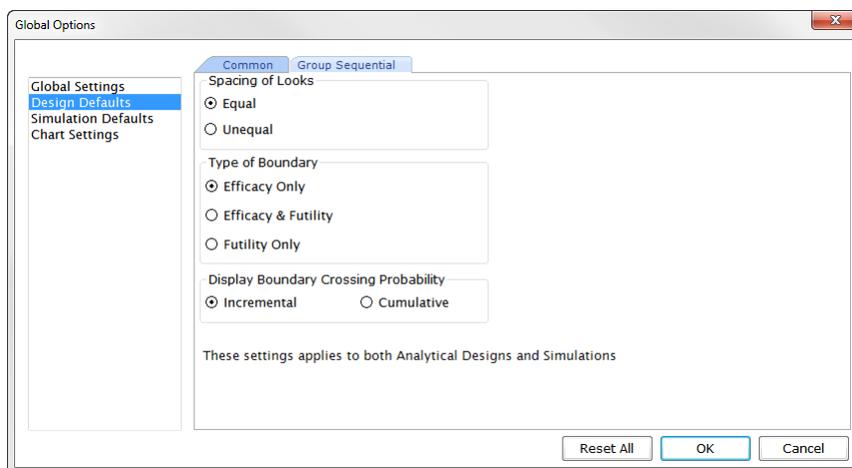

Under the **Common** tab, default values can be set for input design parameters.

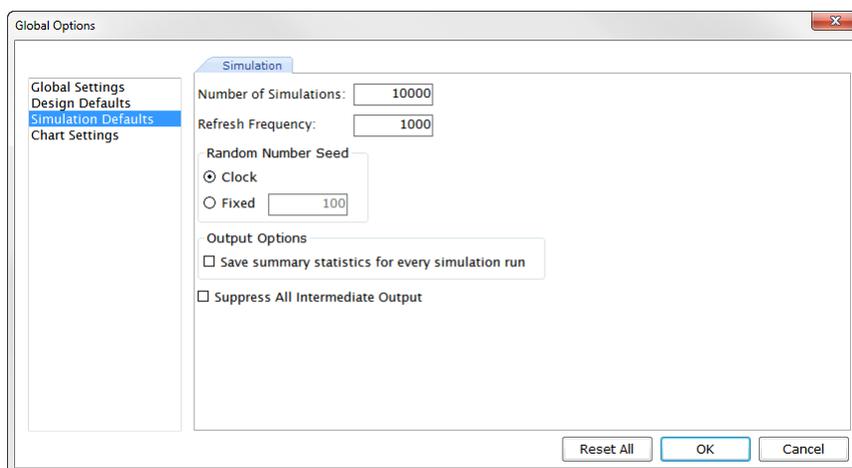

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

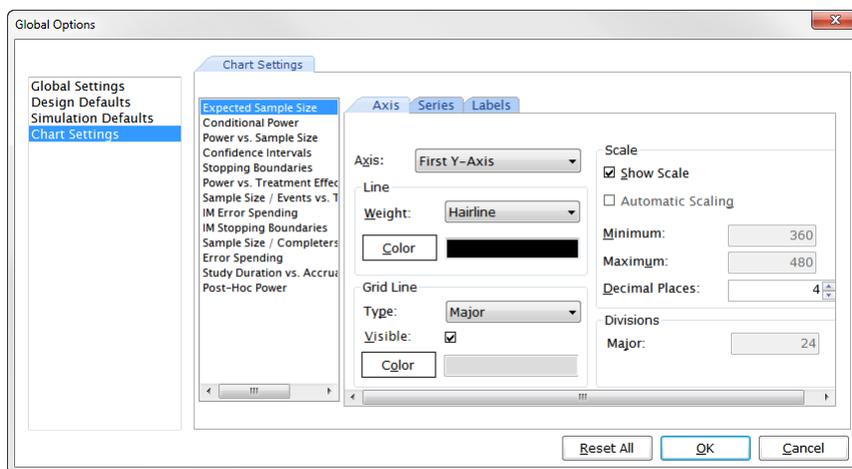

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

58 Introduction to Volume 8

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

We suggest that you do not alter the defaults until you are quite familiar with the software.

59 *Design and Monitoring of Maximum Information Studies*

This chapter discusses the use of a general tool for designing and monitoring studies on the "information" scale rather than on the "sample size" scale. It is based on the work of Lan and Zucker (1993), Scharfstein, Tsiatis and Robins (1997), Jennison and Turnbull (1997), and Mehta and Tsiatis (2001). It permits a general methodology for group-sequential inference, applicable to any data-generating process with or without covariates. Suppose we wish to detect an effect of magnitude δ with power $1 - \beta$ using a two-sided level- α , K -look group sequential test. The parameter δ may be a binomial probability, a mean from a normal distribution, a difference of two means, a difference of two binomial probabilities, an odds ratio, a hazard ratio, a ratio of Poisson rates, the coefficient of interest in a regression model, or any other univariate "effect size" parameter of interest. The fundamental idea is that no matter what parameter δ we wish to make inferences about, the maximum amount of statistical information, I_{\max} , needed to make the inference is always obtained in the same manner. It is computed by the formula

$$I_{\max} = \left[\frac{z_{\alpha/2} + z_{\beta}}{\delta} \right]^2 \times IF(\alpha, \beta, K, \text{boundary}) \quad (59.1)$$

where $IF(\cdot)$ is an inflation factor that depends on α, β, K and the stopping boundary, but does not depend on δ .

Equation (59.1) tells us, at the design stage, how much information about δ we **need** in order to achieve $1 - \beta$ power. It is applicable in all types of designs, ranging from simple 1-sample normal or binomial designs to more complicated designs based on generalized linear models for discrete categorical or continuous data, parametric survival models, proportional hazard models, mixed effects models, and semi-parametric models for longitudinal data. However, once the trial is underway we need to know how much information about δ has already been accumulated, so as to determine if it is time to terminate the trial. If $\hat{\delta}_j$ is an estimate of δ at the j th interim analysis, the information about δ is estimated by the relationship

$$I_j \approx \text{var}[\hat{\delta}_j]^{-1} \quad (59.2)$$

One could therefore adopt a common design and monitoring strategy for all types of group sequential trials, regardless of the endpoint or the model generating the data.

1. Use equation (59.1) to determine the maximum required information, I_{\max} .
2. At the j -th interim look, estimate I_j , the amount of information currently available about δ , using equation (59.2).
3. If either $I_j \geq I_{\max}$ or the stopping boundary is crossed at information fraction $t_j = I_j/I_{\max}$, terminate the trial. Otherwise continue.

59 Design and Monitoring of Maximum Information Studies

This strategy is appealing both because of its general applicability and because it does not require a priori specification of unknown nuisance parameters. In practice, however, we would be obliged to provide at least an initial estimate of the maximum sample size so that the sponsor of the clinical trial could have some idea of the resources to be committed up-front. For example, suppose that $X_t \sim N(\mu_t, \sigma^2)$, $X_c \sim N(\mu_c, \sigma^2)$ and $\delta = \mu_t - \mu_c$. Then $\hat{\delta}(K) = \bar{X}_t - \bar{X}_c$ and $\text{var}(\hat{\delta}_K) = 4\sigma^2/n_{\max}$, so that finally,

$$n_{\max} = 4\sigma^2 I_{\max} . \tag{59.3}$$

If we were designing the study on the basis of maximum information there would not be any nuisance parameters, whereas if we design the study on the basis of maximum sample size, we would need to know the value of σ^2 . One possibility would be to fix a tentative value for n_{\max} at the design stage, based on our best initial guess at the value of σ^2 . In the previous chapters the group-sequential approach has been utilized exclusively to monitor a study with a view to early stopping. It would seem reasonable, however, to take advantage of the data available at each interim monitoring time-point also to revise our initial estimate of σ^2 and thereby improve the study design adaptively.

Here we will illustrate the procedure with three examples: 1) comparing two binomial distributions where the control response rate is unknown, 2) comparing two normal distributions where the variance is unknown, and 3) comparison of two poisson rates. These examples are intended to demonstrate that the sample size of a study may be revised as data for estimating nuisance parameters become available at the interim monitoring time-points.

59.1 Two Binomials with Unknown Control Response

59.1.1 Information Based Design

59.1.2 Information Based Monitoring

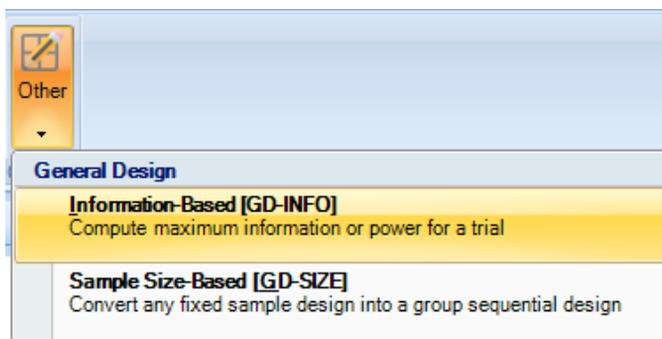

Consider the information based design and monitoring of a randomized clinical trial comparing an experimental therapy with a control therapy based on a dichotomous outcome and equal treatment allocation. Let π_c be the response rate for the control arm, π_t be the response rate for the experimental arm, and $\delta = \pi_t - \pi_c$. We will now design and monitor this study on the information scale.

59.1.1 Information Based Design

Consider a phase III group sequential clinical trial for evaluating the effect of a new drug for prevention of myocardial infarction in patients undergoing coronary artery bypass graft surgery. The study is designed to test the null hypothesis $H_0 : \delta = 0$ against the alternative hypothesis $H_0 : \delta < 0$ using a two sided test at significance level $\alpha = 0.05$. We plan the study to detect a 15% reduction in incidence compared to placebo with 90% power. At the time of designing the study we don't have any reliable estimate of incidence of myocardial infarction in placebo. Therefore, we prefer

information based design that does not rely on the incidence rate of myocardial infarction in placebo.

Single look study Click **Other** on the **Design** tab, and then click **Information Based** as shown below.

A new input window will appear. We will design a study without any interim look. Leave the **Number of Looks** as 1 only. Select **2-Sided** for **Test Type** and enter the values of **Type I Error (α)** and **Power ($1-\beta$)** as 0.05 and 0.9, respectively. Change **Treatment Effect** to -0.15 .

Number of Looks: 1

Test Parameters

Test Type: 2-Sided

Type I Error (α): 0.05 Treatment Effect (δ): -0.15

Power: 0.9

Max. Information: Computed

Click **Compute**. The output is shown as a row in the **Output Preview** located in the

59 Design and Monitoring of Maximum Information Studies

lower pane, with the computed maximum information displayed.

| | ID | No. of Looks | Test Type | Specified α | Power | Max. Information | δ |
|---|------|--------------|-----------|--------------------|-------|------------------|----------|
|  | Des1 | 1 | 2-Sided | 0.05 | 0.9 | 466.996 | -0.15 |

East tells us that the total information required to achieve the operating characteristics of the above study with a fixed sample design is 467 units. This quantity, denoted by I_1 (see Appendix B, Section B.3 for details), was computed by the equation

$$I_1 = \left[\frac{z_{\alpha/2} + z_{\beta}}{\delta_1} \right]^2. \quad (59.4)$$

The subscript ‘1’ indicates that I_1 is the required information for a single look study. Information is approximately equal to the square inverse of the standard error of the estimate of δ . Thus, in a fixed sample trial, the desired power can be achieved if we go on accruing patients until $[\text{se}(\hat{\delta})]^{-2} = 466.996$.

This design has default name Des 1. Save this design in the current workbook by selecting the row corresponding to Des 1 in **Output Preview** and clicking  on the **Output Preview** toolbar.

Multi look study Suppose we actually intend to monitor the study four times. In order to do this, create a new design by selecting Des 1 in the **Library**, and clicking the  icon on the **Library** toolbar. First, change the **Number of Looks** from 1 to 4, to generate a study with three interim looks and a final analysis. Click the **Boundary Info** tab.

Suppose, you have decided to go for a design with 4 interim looks that allows to reject H_0 for efficacy. In order to do this, select **Spending Functions** for **Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in **Efficacy**

box. Select **None** for **Boundary Family** in **Futility** box.

Number of Looks: 4

Test Parameters

Boundary

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks: Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|--------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.250 | 0.000 | 4.333 | -4.333 |
| 2 | 0.500 | 0.003 | 2.963 | -2.963 |
| 3 | 0.750 | 0.019 | 2.359 | -2.359 |
| 4 | 1.000 | 0.050 | 2.014 | -2.014 |

Click **Compute**. A new row will be added in the **Output Preview**.

| ▲ | ID | No. of Looks | Test Type | Specified α | Power | Max. Information | δ | Spacing of Looks | Efficacy Boundary | Expected Info. (H0) | Expected Info. (H1) |
|---|------|--------------|-----------|-------------|-------|------------------|-------|------------------|-------------------|---------------------|---------------------|
| | Des1 | 1 | 2-Sided | 0.05 | 0.9 | 466.996 | -0.15 | | | | |
| | Des2 | 4 | 2-Sided | 0.05 | 0.9 | 475.533 | -0.15 | Unequal | LD (OF) | 472.874 | 362.996 |

Save this design in the current workbook by selecting the row corresponding to Des 2 in **Output Preview** and clicking on the **Output Preview** toolbar.

East has inflated the maximum information of the single-look study by an appropriate inflation factor to compensate for the power loss of monitoring four times instead of once. The new maximum information, I_K , for a K -look study is shown in Appendix B, Section B.3 to be

$$I_K = I_1 \times \text{IF}(\alpha, \beta, K, \text{boundary})$$

where $\text{IF}(\alpha, \beta, K)$ is an inflation factor that depends on α, β, K and the type of stopping boundary used. The new maximum information is 475.5 units, instead of 467 units. The monitoring strategy for the above sequential trial calls for accruing subjects onto the study until the total information, as measured by $[\text{se}(\hat{\delta})]^{-2}$, equals 475.5 units or until a stopping boundary is crossed, whichever comes first. Now it is difficult to know how long to accrue subjects when the accrual goals are expressed in units of

59 Design and Monitoring of Maximum Information Studies

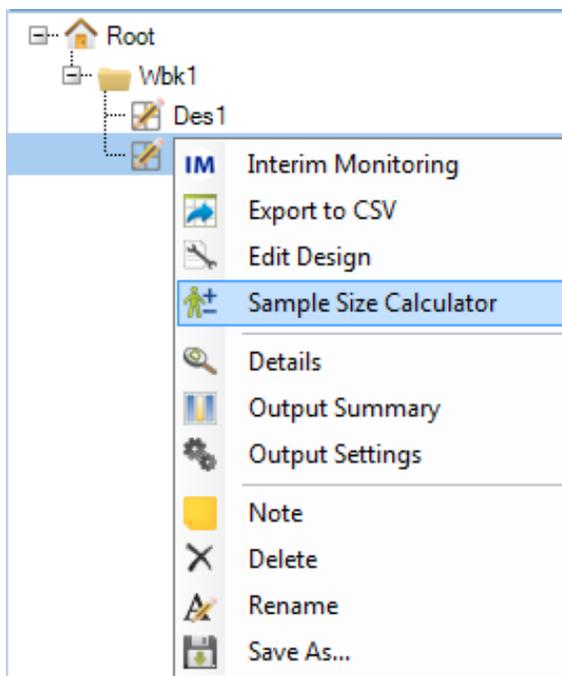

square inverse standard error instead of being expressed in terms of a physical quantity like sample size. We need to translate units of information into sample size units. This is easy to do since the variance of $\hat{\delta}$ is a simple function of the π_c, δ_1 , and the total sample size, n_K . Thus

$$I_K \approx [\text{se}(\hat{\delta})]^{-2} = \left[\frac{(\pi_c)(1 - \pi_c)}{n_K/2} + \frac{(\pi_c + \delta_1)(1 - \pi_c - \delta_1)}{n_K/2} \right]^{-1}.$$

Now since East has already computed $I_K = 475.533$ for $K = 4$, we obtain

$$n_K = 2 \times 475.533 \times [(\pi_c + \delta_1)(1 - (\pi_c + \delta_1)) + (\pi_c)(1 - \pi_c)]. \quad (59.5)$$

East provides you with a convenient sample size calculator for converting the 475.533 units of Fisher information into a sample size, based on equation (38.5). To invoke this calculator, right click on Des2 in the **Library** and select **Sample Size Calculator** from the list.

And select **Difference of Proportions** from the dropdown of *Translate Information From*. The calculator appears as shown below:

The dialog box 'Sample Size Calculator' shows the following settings and results:

- Current Design : Wbk1:Des2
- Translate Information From : Difference of Proportions
- Proportion Control : 0.1

| | Information | Sample Size |
|---------------------|-------------|-------------|
| Maximum : | 475.533 | |
| Expected Under H0 : | 472.874 | |
| Expected Under H1 : | 362.996 | |

Buttons: Recalc, Close

You can alter the control binomial probability in the top cell of the dialog box, and East will compute the corresponding maximum sample size based on maximum Fisher information of 475.533 units. For example, if the baseline response probability is 0.25, the 475.533 units translates into a maximum sample size of 264 subjects (both treatments combined).

The dialog box 'Sample Size Calculator' shows the following settings and results:

- Current Design : Wbk1:Des2
- Translate Information From : Difference of Proportions
- Proportion Control : 0.25

| | Information | Sample Size |
|---------------------|-------------|-------------|
| Maximum : | 475.533 | 264 |
| Expected Under H0 : | 472.874 | 262.524 |
| Expected Under H1 : | 362.996 | 201.505 |

Buttons: Recalc, Close

Based on historical data we assume that the control response rate is 0.3. When you enter 0.3 into the top cell of the dialog box and press the **Recalc** button, East reveals

59 Design and Monitoring of Maximum Information Studies

that the maximum sample size needed for this sequential study is 321.

| | Information | Sample Size |
|---------------------|-------------|-------------|
| Maximum : | 475.533 | 321 |
| Expected Under H0 : | 472.874 | 319.201 |
| Expected Under H1 : | 362.996 | 244.963 |

Thus on the assumption that the control response rate is 0.3, we require an up-front commitment of 321 subjects to meet the operating characteristics of this study. (We can verify this independently by designing a 4-look binomial study using the unpooled

estimate of standard error as shown below. See Section 23.1 for further details.)

| | Des3 |
|--|-------------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 4 |
| Test Type | 2-Sided |
| Specified α | 0.05 |
| Power | 0.9 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Proportion under Control (π_c) | 0.15 |
| Proportion under Treatment (π_t) | 0.3 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0.15 |
| Variance | Unpooled Estimate |
| Boundary Parameters | |
| Spacing of Looks | Unequal |
| Efficacy Boundary | LD (OF) |
| Sample Size | |
| Maximum | 321 |
| Expected Under H0 | 319.201 |
| Expected Under H1 | 244.963 |

Of course, if the assumption that the control response rate is 0.30 is incorrect, 321 subjects will not produce the desired operating characteristics. Depending on the actual value of the control response rate, we might have either an under-powered or over-powered study. We shall show in the next section that one of the major advantages of the information based approach is that we can use all the data accrued at any interim monitoring time point to re-estimate the control response rate and, if it differs from what was assumed initially, re calculate the sample size.

59.1.2 Information Based Monitoring

Select Des 2 in the **Library**, and click **IM** from the **Library** toolbar. This will open a interim monitoring dashboard.

If we monitor the data at any chronological time τ , an efficient estimator of δ is $\hat{\delta}(\tau) = \hat{\pi}_t(\tau) - \hat{\pi}_c(\tau)$ and the standard error of this estimator is

$$se(\hat{\delta}(\tau)) = [(\hat{\pi}_t(\tau))(1 - \hat{\pi}_t(\tau))/n_1(\tau) + (\hat{\pi}_c(\tau))(1 - \hat{\pi}_c(\tau))/n_2(\tau)]^{1/2},$$

59 Design and Monitoring of Maximum Information Studies

where $\hat{\pi}_i(\tau)$ is the sample proportion responding to treatment i among the $n_i(\tau)$ individuals assigned to treatment i by time τ , $i = 1, 2$. The information accrued at this time point is

$$I(\tau) = (\text{se}(\hat{\delta}(\tau)))^{-2}$$

and the value of the Wald test statistic is

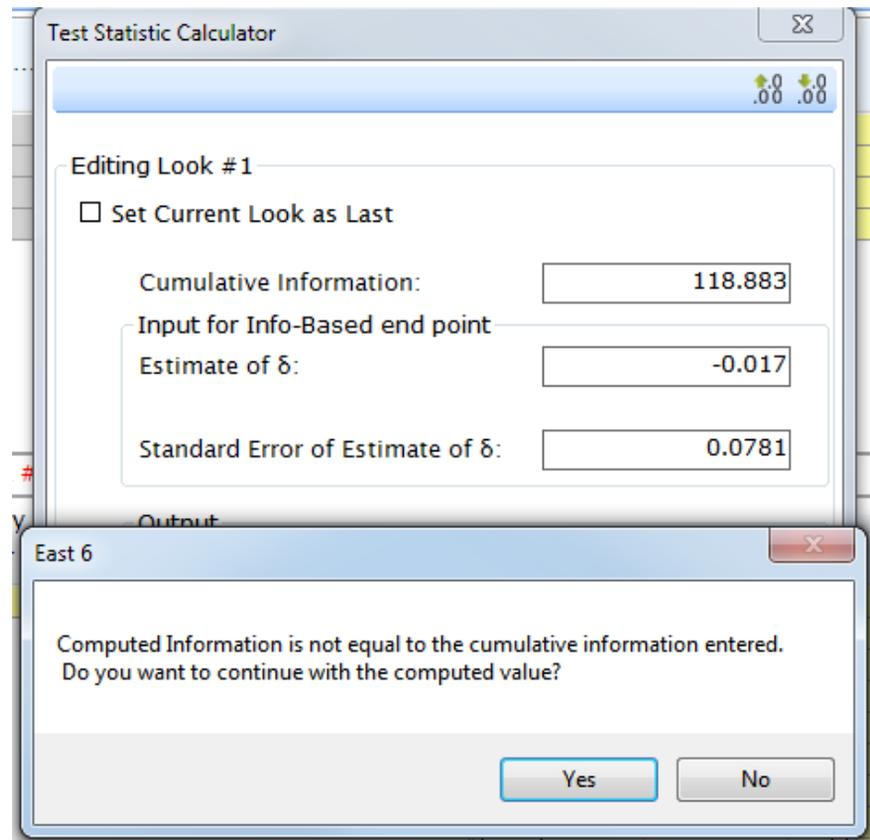

$$T(\tau) = \hat{\delta}(\tau)/\text{se}(\hat{\delta}(\tau)) .$$

The information fraction at chronological time τ is $t(\tau) = I(\tau)/475.5327$. We will stop the study if the test statistic crosses the **LD (OF)** stopping boundary at this information fraction. For future reference, we will also refer to the information fraction as “process time”. In contrast, the time τ will also be referred to as “calendar time”.

Results at the First Interim Monitoring Time Point

Suppose that at the first interim monitoring time point, τ_1 , we observe 15/60 responders on placebo and 14/60 responders on treatment. Then $\hat{\delta}(\tau_1) = -0.017$, $\text{se}(\hat{\delta}(\tau_1)) = 0.0781$. To pass these values to East, click **Enter Interim Data** from the toolbar to invoke the **Test Statistic Calculator**. Enter the information above, and click

Recalc:

Saying ‘Yes’ to this message will update that the current information to 163.945 units and the current value of the test statistic to -0.218. Now click **OK** to continue.

East displays the information fraction, $t(\tau_1) = 163.945/475.533 = 0.345$, and computes the appropriate stopping boundary at that process time. The value of the stopping boundary is ± 3.643 . Since our test statistic did not exceed this boundary, we

59 Design and Monitoring of Maximum Information Studies

continue to the next interim monitoring time point.

| Look # | Information Fraction | Cumulative Info. | Test Statistic | Effect... | Standard Error | Efficacy | | 95% RCI for Effect Si... | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|------------------|----------------|-----------|----------------|----------|--------|--------------------------|--------|-------------------|-------|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.345 | 163.945 | -0.218 | -0.017 | 0.078 | 3.643 | -3.643 | 0.267 | -0.301 | 1 | 0.024 | 0.16 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |
| 4 | | | | | | | | | | | | |

We have accrued 120 subjects out of the 321 required under the design assumption that the nuisance parameter is $\pi_c = 0.30$. The information fraction under this design assumption is thus $120/321 = 0.374$, while the actual information fraction is 0.345. Thus the information appears to be coming in a little slower than anticipated, but this difference does not seem serious enough to alter the sample size requirements of the study.

Results at the Second Interim Monitoring Time Point

Suppose that at the second interim monitoring time point, τ_2 , we observe 29/120 responders on treatment and 41/120 responders on placebo. Therefore, the estimate of $\hat{\delta}$ is -0.1 with standard error as 0.058. Click [Enter Interim Data](#) to bring up **Test Statistic Calculator**. Enter -0.1 for **Estimate of δ** and 0.058 for **Standard Error of**

Estimate of δ .

Click **Recalc**, and then click **Yes**. The information accrued at this time point is 297.265 and the observed value of the test statistic is $T(\tau_2) = -1.724$. Upon pressing the **OK** button, these values are pasted into the interim monitoring dashboard.

The information fraction is 0.625. The required stopping boundary is 2.609. Since the absolute value of test statistic is smaller than 2.609, the stopping boundary is not crossed and, once more, the study continues.

This time the anticipated information fraction under the assumption that $\pi_c = 0.30$ is $240/321 = 0.748$, which is considerably larger than the actual information fraction 0.625. Thus, there is considerable evidence that the information is coming in slower than anticipated. In fact, the data suggest that the value of π_c is close to 0.34, as the

59 Design and Monitoring of Maximum Information Studies

estimate at the first look $14/60 = 0.238$ and the estimate at the second look is $29/120 = 0.242$. It might therefore be prudent to re-estimate the sample size of the study. The new maximum sample size can be obtained by the relationship

$$\frac{n(\tau_2)}{n_{\max}} = \frac{I(\tau_2)}{I_{\max}}.$$

Thus the maximum sample size (rounded up to the nearest integer) is

$$n_{\max} = n(\tau_2) \times \frac{I_{\max}}{I(\tau_2)} = 240 \times \frac{475.533}{297.265} = 389.$$

Therefore we need to commit 389 subjects to the study, not 321 as originally estimated. We see that the original design with 321 subjects would have led to a seriously under-powered study.

Results at the Third Interim Monitoring Time-Point

We continue to accrue subjects beyond the 321 in the original design, and reach the third interim monitoring time point at time τ_3 with 61/180 responders on placebo and 41/180 responders on treatment. Therefore, the estimate of $\hat{\delta}$ is -0.111 with standard error as 0.047. Click on the **Enter Interim Data** icon, and enter -0.111 for

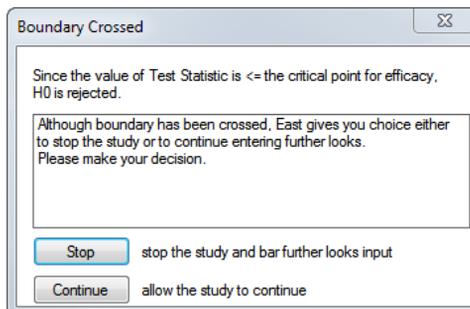

Estimate of δ and 0.047 for Standard Error of Estimate of δ .

The screenshot shows a dialog box titled "Test Statistic Calculator". At the top right, there are two small green arrows and the number ".00". Below the title bar, the text "Editing Look #3" is displayed. A checkbox labeled "Set Current Look as Last" is present and unchecked. The "Input for Info-Based end point" section contains three input fields: "Cumulative Information:" with the value 452.694, "Estimate of δ :" with the value -0.111, and "Standard Error of Estimate of δ :" with the value 0.047. The "Output" section contains one input field: "Test Statistic:" with the value -2.362. At the bottom of the dialog, there are three buttons: "Recalc", "OK", and "Cancel". The "OK" button is highlighted with a dashed border.

Click **Recalc**, and then click **OK**. The information accrued at this time point is 452.69 and the observed value of the test statistic is $T(\tau_2) = -2.362$. Now click **OK** to update the charts and tables in the dashboard. Now the stopping boundary is crossed

59 Design and Monitoring of Maximum Information Studies

and the following dialog box appears.

Click **Stop**. At this look, the total information accrued is 452.694 and the observed value of the test statistic is $T(\tau_3) = -2.362$. Since the absolute value of the test statistic exceeds the corresponding stopping boundary, 2.05, the stopping boundary is crossed and the study terminates with a statistically significant outcome.

You see the IM sheet results as shown below.

| Look # | Information Fraction | Cumulative Info. | Test Statistic | Effect... | Standard Error | Efficacy | | 95% RCI for Effect Si... | | Repeat... p-value | CP | Predicti... Power |

The adjusted p-value is 0.023, with a final adjusted estimate of the difference of

−0.109.

This example highlights the fundamental difference between information based sequential monitoring and conventional sequential monitoring. Had the study been monitored by the conventional method, the maximum sample size would have been fixed from the start at 321 subjects and there would have been no flexibility to change the level of this physical resource over the course of the study. But in an information based approach the maximum information is fixed, not the maximum amount of a physical resource. Thus, the maximum sample size could be altered over the course of the study from 321 subjects to 389 subjects, while the maximum information stayed constant. Without this flexibility, the power of the study would be severely compromised.

59.2 Two Normals with Unknown Variance

59.2.1 Info Based Design

59.2.2 Info Based Monitoring

In this section we will consider the PRIMO study (Pritchett et al., 2011). This was a multinational, multicenter randomized controlled trial to assess the effects of paricalcitol (a selective vitamin D receptor activator) on mild to moderate left ventricular hypertrophy in patients with chronic kidney disease. The primary endpoint was change in left ventricular mass (LVM) index. Let μ_t and μ_c be the change in LVM index in paricalcitol and placebo, respectively. $\delta = \mu_t - \mu_c$ denotes the difference in change in LVM index in paricalcitol compared to placebo. We want to test the hypothesis $H_0 : \delta = 0$ against $H_0 : \delta < 0$. A mean difference of 2.7g/m in LVM index change was considered clinically meaningful. Therefore, we will design a study to detect $\delta_1 = -2.7$ with 90% power.

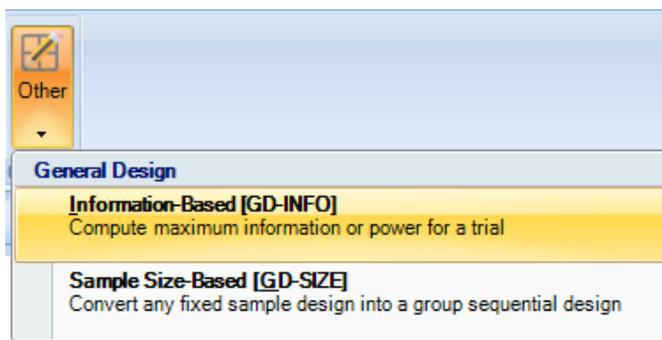

59.2.1 Information Based Design

There is no reliable estimate available for the standard deviation (σ). Therefore, an information based design that does not rely on the standard deviation would be preferable in this case. An unblinded interim analysis was conducted for early termination and to make an informative decision with respect to sample size adjustment. Interim analysis was planned when 90% of subjects are enrolled.

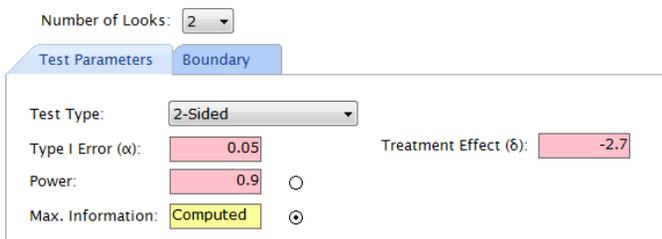

First, click **Other** on the **Design** tab, and then click **Information Based** as shown

59 Design and Monitoring of Maximum Information Studies

below.

Change the **Number of Looks** to 2. This will add a tab with label **Boundary Info**. We will come back to this tab later. In the **Design Parameters** tab, select **Test Type** as **2-Sided** and enter **Type I Error (α)** and **Power ($1-\beta$)** as 0.05 and 0.9, respectively. Change **Effect Size** to -2.7 . The **Design Parameters** tab should appear as below:

Now click **Boundary Info**. Select **Spending Functions** for **Boundary Family**, **Gamma Family** for **Spending Function** and -8 for **Parameter (γ)** in the **Efficacy** box. In the **Futility** box, select **None** for **Boundary Family**. Since we want to have a interim look at 90% of sample size, specify 0.9 for 'Info. Fraction at Interim Look'.

The **Boundary Info** tab should appear as below.

Number of Looks: 2

Test Parameters
Boundary

Efficacy

Boundary Family: Spending Functions

Spending Function: Gamma Family

Parameter (γ): -8

Type I Error (α): 0.05

Futility

Boundary Family: None

Info. Fraction at Interim Look: 0.9 Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|--------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.900 | 0.022 | 2.283 | -2.283 |
| 2 | 1.000 | 0.050 | 1.981 | -1.981 |

Click **Compute**. The output is shown as a row in the **Output Preview** located in the lower pane. The computed maximum information is highlighted in yellow.

| ▲ | ID | No. of Looks | Test Type | Specified α | Power | Info. Fraction at Interim Look | Efficacy Boundary | Max. Information | Expected Info. (H0) | Expected Info. (H1) | δ |
|---|------|--------------|-----------|-------------|-------|--------------------------------|-------------------|------------------|---------------------|---------------------|------|
| | Des1 | 2 | 2-Sided | 0.05 | 0.9 | 0.9 | Gm (-8) | 1.448 | 1.445 | 1.334 | -2.7 |

East tells us that the total information required to achieve the operating characteristics of the above study is 1.448 units. The monitoring strategy for the above 2-look sequential trial calls for accruing subjects onto the study until the total information, as measured by $[se(\hat{\delta})]^{-2}$, equals 1.448 units or until a stopping boundary is crossed, whichever comes first. Now we can translate this information into sample size using the following relationship:

$$n_{\max} = 4\sigma^2 I_{\max} .$$

In the PRIMO study the initial estimate of σ is assumed as 6.39. Save this design in the current workbook by selecting the row corresponding to Des 1 in **Output Preview** and clicking on the **Output Preview** toolbar. Right click on the design node to invoke the **Sample Size Calculator**. Plug in this value in the calculator, the 1.448 units

59 Design and Monitoring of Maximum Information Studies

translates into a maximum sample size of 237 (total sample size).

| | Information | Sample Size |
|---------------------|-------------|-------------|
| Maximum : | 1.448 | 237 |
| Expected Under H0 : | 1.445 | 236.466 |
| Expected Under H1 : | 1.334 | 218.106 |

This calculator should only be used for Difference of Means and Difference of Proportions (Unpooled variance) Superiority designs.

If we design the study for a maximum sample size of 237 patients, we will achieve 90% power so long as our estimate of σ , 6.39, is correct. On the other hand we gain more flexibility by designing the study for maximum information of 1.448 units. This design parameter remains the same whether the standard deviation is 6.39 or something different. As the data accumulate during the interim monitoring phase, we will obtain more accurate estimates of the standard deviation and can revise the sample size on that basis. We shall show in the next section that one of the major advantages of the information based approach is that we can use all the data accrued at any interim monitoring time point to re-estimate the σ and, if it differs from what was assumed initially, re-calculate the sample size.

59.2.2 Information Based Monitoring

We will monitor the study on the information scale. Select Des 1 in the **Library**, and click **IM** from the **Library** toolbar. This will open an interim monitoring dashboard.

Results at the First Interim Monitoring Time-Point

Recall that the study is planned to have an interim look when 90% of sample size are accrued. Therefore a interim look can be planned when 237×0.9 or 214 subjects are evaluated. Suppose that at the first interim monitoring time-point, there were 107

subjects on the placebo arm, and 107 subjects on the treatment arm, $\delta = -2.85$, $s_c = 7.5$ and $s_t = 7.4$. Based on the sample standard deviation, the pooled standard deviation is 7.45 and $[se(\hat{\delta})] = 1.019$.

Click on the **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. Enter -2.85 for **Estimate of δ** and 1.019 for **Standard Error of Estimate of δ** . Click **Recalc**, and then click **Yes**. The information accrued at this time point is 0.963 and the observed value of the test statistic is $T(\tau_1) = -2.797$. Pres OK to update the IM dashboard.

| Look # | Information Fraction | Cumulative Info. | Test Statistic | Effect... | Standard Error | Efficacy | | 95% RCI for Effect Si... | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|------------------|----------------|-----------|----------------|----------|--------|--------------------------|--------|-------------------|-------|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.665 | 0.963 | -2.797 | -2.85 | 1.019 | 2.927 | -2.927 | 0.133 | -5.833 | 0.076 | 0.995 | 0.983 |
| 2 | | | | | | | | | | | | |

The information fraction is 0.665 . The required stopping boundary is 2.927 . Since the absolute value of test statistic is smaller than 2.927 , the stopping boundary is not crossed and the study continues.

This time the anticipated information fraction under the assumption that $\sigma = 6.4$ is $214/237 = 0.903$, which is considerably larger than the actual information fraction 0.665 . Thus, there is considerable evidence that the information is coming in slower than anticipated. In fact, the data suggest that the value of σ is close to 7.45 . It might therefore be prudent to re-estimate the sample size of the study. The new maximum sample size can be obtained by the relationship

$$\frac{n(\tau_1)}{n_{\max}} = \frac{I(\tau_1)}{I_{\max}}.$$

Thus the maximum sample size (rounded up to the nearest integer) is

$$n_{\max} = n(\tau_1) \times \frac{I_{\max}}{I(\tau_1)} = 214 \times \frac{0.903}{0.665} = 291.$$

Therefore we need to commit 291 subjects to the study, not 237 as originally estimated. Thus it is clear that unless we increase patient accrual from the initial specification of 237, we will have a seriously underpowered study. Let us assume then that the investigators agree at this stage to increase the sample size to 291 patients.

Results at the Final Look

Suppose that at the final look we have accrued 291 patients of which 145 are allocated to placebo and 146 are allocated to new drug paricalcitol. Based on these subjects,

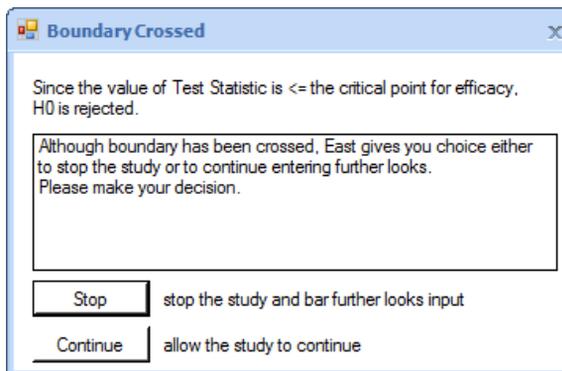

59 Design and Monitoring of Maximum Information Studies

$\delta = -2.93$, $s_c = 7.43$ and $s_t = 7.41$. Thus, the pooled standard deviation is 7.42 and $[se(\hat{\delta})] = 0.870$. Click on the **Enter Interim Data** icon. In the **Test Statistic Calculator**, tick the checkbox of **Set Current Look as Last**. Enter -2.93 for **Estimate of δ** and 0.870 for **Standard Error of Estimate of δ** . Click **Recalc**, and then click **Yes**. The information accrued at this time point is 1.321 and the observed value of the test statistic is $T(\tau_2) = -3.368$. The **Test Statistic Calculator** should look as below.

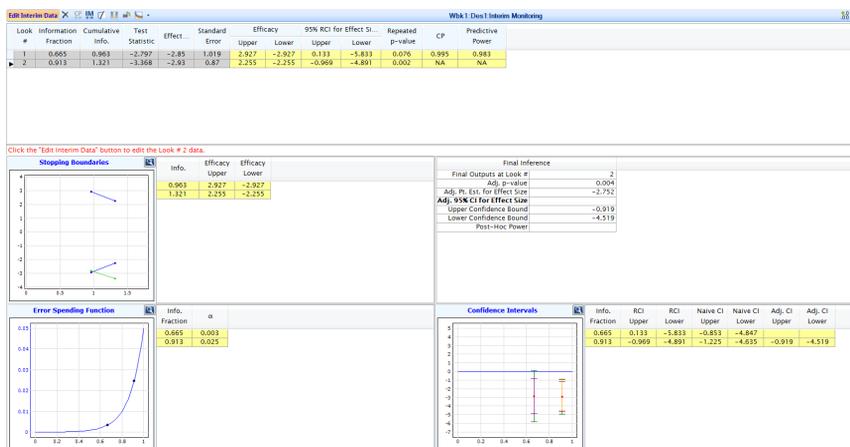

The screenshot shows a dialog box titled "Test Statistic Calculator". At the top right, there are zoom in (+) and zoom out (-) icons. The main content area is titled "Editing Look #2" and contains a checkbox labeled "Set Current Look as Last" which is currently unchecked. Below this are three input fields: "Cumulative Information:" with the value 1.321, "Estimate of δ :" with the value -2.93, and "Standard Error of Estimate of δ :" with the value 0.87. An "Output" section at the bottom shows "Test Statistic:" with the value -3.368 highlighted in yellow. At the very bottom of the dialog are three buttons: "Recalc", "OK", and "Cancel".

Upon pressing the **OK** button a pop-up window will appear notifying you that H_0 is

rejected as the test statistic exceeds the critical boundary.

Click **Stop**. This time East tells us that the stopping boundary of 1.962 has been crossed and the study terminates with the conclusion that the paricalcitol does indeed lower the change in LVM index relative to the placebo.

The adjusted estimate of the difference is -2.752 and the adjusted p-value is 0.004. The 95% adjusted confidence interval for the reduction is [-4.519, -0.919].

59 Design and Monitoring of Maximum Information Studies

59.3 Equality of Two Poisson Rates

59.3.1 Trial Design

59.3.2 Interim Monitoring

We will use an information-based approach to design a stroke prevention study that was previously discussed in detail in Chapter 60, Section 60.1.1. The goal is to design a balanced two arm randomized clinical trial for high risk patients with atrial fibrillation in which the standard treatment (adjusted dose warfarin) has a Poisson event rate of 1.8% per year (i.e., 1.8 ischaemic stroke events per 100 people per year). If the experimental treatment (low-dose warfarin plus aspirin) has a Poisson event rate in excess of 3% per year, we wish to detect this with 90% power using a one sided test conducted at the 5% level of significance. Let λ_c and λ_t denote the Poisson event rates for the control and treatment arms, respectively, and define the risk ratio

$$\gamma = \frac{\lambda_t}{\lambda_c}.$$

59.3.1 Trial Design

We wish to test the null hypothesis that $\gamma = 1$ against the one-sided alternative hypothesis that $\gamma > 1$ using a test at significance at level $\alpha = 0.05$. The test is required to have power $1 - \beta = 0.9$ at the alternative $\gamma = 3/1.8 = 1.667$. In Section 60.1.1, we designed and monitored this study using traditional large-sample methods of unconditional inference. In the present section, we will use an alternative conditional method of inference for comparison purposes. Although there have been no formal studies comparing the conditional and unconditional approaches for Poisson data it is generally believed that the conditional approach has greater accuracy. For example, Breslow and Day (1987) utilize the conditional approach in their monograph on cohort studies.

Suppose that X_c is the number of events observed on the control arm, X_t is the number of events observed on the treatment arm and $N = X_c + X_t$. Then it is well known that the conditional distribution of X_t given N is binomial with parameters (π, N) where

$$\pi = \frac{n_t \gamma}{n_c + n_t \gamma} \tag{59.6}$$

and n_c is the number of person years of follow-up on the control arm and n_t is the number of person years of follow-up on the treatment arm. The present study was designed for equal amounts of follow-up on each arm. Thus, at the design stage we may assume that $n_c = n_t$. The protocol specifies that $\gamma = 1$ under the null hypothesis, and $\gamma = 1.667$ under the alternative hypothesis. Therefore, by equation 59.6, the null and alternative hypotheses may be stated as:

$$H_0: \pi = 0.5 \text{ versus } H_1: \pi = 0.625 .$$

The design has now been formulated in terms of testing the mean of a binomial random variable.

Hence with N , the total number

$$\delta = \pi - 0.5$$

playing the role of effect size. The null and alternative hypotheses can now be specified in terms of δ as

$$H_0: \delta = 0 \text{ versus } H_1: \delta = 0.125 .$$

The maximum value of N for a K look group sequential design is thus

$$N_{\max} = \pi(1 - \pi)I_{\max} \tag{59.7}$$

where I_{\max} is computed by equation (59.1) and can be obtained from East.

Click **Other** on the **Design** tab, and then click **Information Based**. In the ensuing input dialog box, in the **Design Parameters** tab, select **1-Sided** for **Test Type**. Specify **Type I Error (α)** as 0.05, and **Power ($1-\beta$)** as 0.9, respectively. Change **Treatment Effect** to 0.125.

Number of Looks: 1

Test Parameters

Test Type: 1-Sided

Type I Error (α): 0.05 Treatment Effect (δ): 0.125

Power: 0.9

Max. Information: Computed

Click **Compute**. The output is shown as a row in the **Output Preview** located in the lower pane.

| ▲ | ID | No. of Looks | Test Type | Specified α | Power | Max. Information | δ |
|----|------|--------------|-----------|--------------------|-------|------------------|----------|
| 🗑️ | Des1 | 1 | 1-Sided | 0.05 | 0.9 | 548.086 | 0.125 |

59 Design and Monitoring of Maximum Information Studies

This design has default name Des 1. Save this design in the current workbook by selecting the row corresponding to Des 1 in **Output Preview** and clicking  on the **Output Preview** toolbar. For Des 1 $I_{\max} = 548.09$. Equation (59.7) converts I_{\max} to N_{\max} . In applying this equation, we must specify the value of π at which 90% power is desired. With $\pi = 0.625$, we have $N_{\max} = 0.625 \times 0.375 \times 548.09 = 128$ events. This is somewhat lower than the 135 events computed in the general design of Chapter 60, and suggests that the conditional approach used here is more efficient than the unconditional approach.

Suppose we wish to take two interim looks and a final look at the accruing data and utilize the usual Lan and DeMets (1983) α -spending function **LD (OF)**. Now create a new design by right-clicking Des 1 in the **Library**, and edit it by clicking  icon. Change the **Number of Looks** from 1 to 3. In the **Boundary Info** tab, select **Spending Functions** for **Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in the **Efficacy** box. In the **Futility** box, select **None** for **Boundary Family**.

Click **Compute** to generate output for this design. A new row will be added in the **Output Preview**.

| ID | No. of Looks | Test Type | Specified α | Power | Max. Information | δ | Spacing of Looks | Efficacy Boundary | Expected Info. (H0) | Expected Info. (H1) |
|------|--------------|-----------|--------------------|-------|------------------|----------|------------------|-------------------|---------------------|---------------------|
| Des1 | 1 | 1-Sided | 0.05 | 0.9 | 548.086 | 0.125 | | | | |
| Des2 | 3 | 1-Sided | 0.05 | 0.9 | 558.362 | 0.125 | Unequal | LD (OF) | 555.187 | 432.696 |

The maximum information is inflated to $I_{\max} = 558.36$ and the corresponding maximum number of events is inflated to $N_{\max} = 131$. Save this design in the current workbook by selecting the row corresponding to Des 2 in **Output Preview** and clicking  on the **Output Preview** toolbar.

Observe that although the maximum information is slightly inflated, the expected information under H_1 is only 432.696. If H_1 is true then $\pi = 0.625$ so that the corresponding expected number of events is $0.625 \times (.375) \times 432.696 = 101$, a considerable saving over the single look design.

59.3.2 Interim Monitoring

Let us monitor this study using the interim monitoring data published in JAMA (vol 279, No. 16, Table 2). According to this report, the study was monitored after $N = 55$ events were observed. There were $X_c = 11$ events on the control arm over $n_c = 581$

person years of observation. And there were $X_t = 44$ events on the treatment arm over $n_t = 558$ person years of observation. We can estimate γ from the data as

$$\hat{\gamma} = \frac{X_t/n_t}{X_c/n_c} = \frac{44/558}{11/581} = 4.1649$$

whereupon the estimate of π is

$$\hat{\pi} = \frac{558 \times 4.1649}{581 + 558 \times 4.1649} = 0.8,$$

the estimate of effect size is

$$\hat{\delta} = 0.8 - 0.5 = 0.3.$$

and its standard error is

$$\text{se}(\hat{\delta}) = \sqrt{\frac{\hat{\pi}(1 - \hat{\pi})}{N}} = 0.054.$$

The current information is thus $I = 0.053936^{-2} = 343.75$. We enter this value into the interim monitoring worksheet as described below.

Select Des 2 in the **Library**, and click **IM** from the **Library** toolbar. This will open a interim monitoring dashboard. Click on the **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. Enter 0.3 for **Estimate of δ** and 0.054 for **Standard Error of Estimate of δ** . Click **Recalc**, and then click **Yes**. The information accrued at this

59 Design and Monitoring of Maximum Information Studies

time point is 342.936 and the observed value of the test statistic is $T(\tau_1) = 5.556$.

Finally, click **OK** to paste this information in the monitoring dashboard. Now, the stopping boundary is crossed, and a dialog box appears. Click **Stop**. Since the test statistic, $Z = 0.3/0.054 = 5.556$ exceeds the upper stopping boundary, the trial is terminated. A table for **Final Inference** will appear in the dashboard.

| Final Inference | |
|------------------------------------|-------|
| Final Outputs at Look # | 1 |
| Adj. p-value | 0 |
| Adj. Pt. Est. for Effect Size | 0.3 |
| Adj. 90% CI for Effect Size | |
| Upper Confidence Bound | 0.389 |
| Lower Confidence Bound | 0.211 |
| Post-Hoc Power | |

The lower confidence bound of the adjusted confidence interval for δ is 0.211 implying that π is at least $0.5 + 0.211 = 0.711$ with 95% confidence. Thus the risk ratio γ is

estimated to be at least $\pi/(1 - \pi) = 0.711/0.289 = 2.46$. The risk of stroke is at least 2.46 times greater on the treatment arm than on the control arm. If the event rate on the control arm is 1.8% per year, then the corresponding event rate on the treatment arm is at least 2.46×1.8 , or 4.428% per year.

59.4 Some Non-Statistical Concerns

This chapter demonstrated the monitoring clinical trials which is statistically sound and ensures that the trials will be adequately powered despite inaccurate initial estimates of nuisance parameters that crucially affect the sample size. Provided we are prepared to remain flexible about the final sample size, we can learn as we go, and make appropriate sample size adjustments along the way. The pay-off for adopting this approach is high, both ethically and economically. Many industry trials are over-powered in order to compensate for ignorance about the variability of the data, thereby raising the cost of the trial unnecessarily. Some trials are underpowered because of overly optimistic initial estimates of variability. A promising new therapy might remain undetected despite incurring the high cost running the trial. The information-based approach ensures that we will neither randomize too many subjects nor too few subjects, but just the right number to meet the goals of the trial.

A number of factors, unrelated to the statistical methodology, will determine whether or not this idea is adopted in practice. Here is a list of unresolved issues that must be addressed:

- The time between the intermediate data base lock and the performance of the interim analysis must be shortened, so as to minimize the number of patients being enrolled while the decision to continue or terminate accrual is being made.
- Institutional Review Boards must be educated on the benefits of these trials. They need to understand that an information-based design with a flexible sample size is, in some situations, more ethical than a design that fixes the sample size up-front, despite considerable uncertainty about its adequacy to achieve the desired power.
- When the sample size is a random variable, the sponsor may face logistical challenges related to ensuring that sites have sufficient quantities of the drugs or biologics on hand.
- The sponsor will have to re-think the manner in which the budget is prepared for a trial. Rather than having a fixed budget for each individual trial, it might be necessary to envisage a fixed overall budget for a portfolio of trials which can be allocated to the individual trials in a flexible manner.
- These information-based trials might be subject to additional regulatory scrutiny. The burden will be on the sponsor to demonstrate that the statistical methodology is sound and, by the manner in which the trial was conducted, the

59 *Design and Monitoring of Maximum Information Studies*

interim results were not prematurely unblinded.

60 *Design and Interim Monitoring with General Endpoints*

In the previous chapters, we have shown how to use East to design and monitor group-sequential studies with normal, binomial and survival endpoints. In this chapter, we show how to extend East to design and monitor studies with any general endpoint, including longitudinal studies, equivalence studies, and studies where the endpoint is specified as one of the covariates in a generalized linear regression model. In all these settings, we use East in conjunction with some other design package that is capable of computing the sample-size for the end-point in question when there is no interim monitoring. The fixed sample-size thus obtained is then used as an input to the General Design module provided by East. East inflates this fixed sample-size appropriately based on the planned number of interim analyses, the type of stopping boundary, the desired type-1 error and the desired power. The derivation of the appropriate inflation factor for this purpose is discussed in Appendix B, Section B.3. The resulting group-sequential design may then be monitored flexibly using East's interim monitoring dashboard. We illustrate below with an example involving Poisson data.

60.1 *Poisson Model*

For Stroke Prevention in Atrial Fibrillation, investigators conducted a two arm randomized clinical trial of adjusted-dose warfarin versus low-intensity fixed-dose warfarin plus aspirin for high-risk patients with atrial fibrillation (AF). (See, Lancet, 1996, 348(9028):633-8, for details.) Adjusted-dose warfarin is known to be highly efficacious for prevention of ischaemic stroke in AF patients, with an event rate of only 1.8% per year. This treatment, however, carries a risk of bleeding and requires frequent monitoring. The objective of the study was to determine if low-intensity fixed-dose warfarin plus aspirin, which is safer and easier to administer, might be substituted for adjusted-dose warfarin without resulting in an unacceptably high relative risk of stroke. An event rate in excess of 3% per year with the low-intensity warfarin would be considered unacceptable. We will use East to design and monitor a group-sequential study with two interim looks and one final look.

60.1.1 *Design of Stroke Prevention Study*

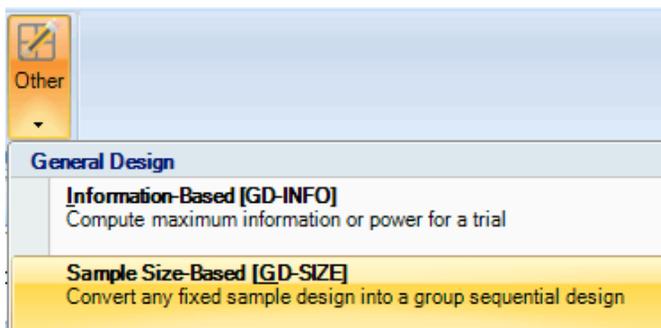

The goal is to design a balanced two-arm randomized clinical trial for high-risk patients with AF in which the standard treatment (adjusted-dose warfarin) has a Poisson event rate of 1.8% per year. If the experimental treatment (low-dose warfarin plus aspirin) has a Poisson event rate in excess of 3% per year, we wish to detect this with 90% power using a one-sided test conducted at the 5% level of significance. One can use a standard sample-size package like **Egret Siz** to determine the total number of events of ischaemic stroke that one must observe in order to detect a difference in Poisson rates of 1.8% per year versus 3% per year (i.e., a risk ratio of $3/1.8 = 1.667$) with 90% power using a one-sided fixed-sample Wald test conducted at the 5% significance level. The desired number works out to be 135 events. More direct

60 Design and Interim Monitoring with General Endpoints

methods of determining the required number of events, rather than relying on output from a statistical software package, are available through the information based approach discussed in Chapter 59, Section 59.3.

The above requirement of 135 events assumed that there would be no interim monitoring for early stopping. This study, however, was intended to be monitored twice during execution, and a third time at the end, each look being taken after equal increments of information. The group-sequential strategies implemented in East are applicable to this problem, and East can determine the amount by which the required number of events for the fixed-sample study should be inflated for the group-sequential design, and then allow to properly monitor the study. The first step is to provide East with the appropriate design parameters.

First, click **Other** on the **Design** tab and then click **General Design: Sample-Size Based** as shown below.

The upper pane displays the several fields with default values. First, change the **Number of Looks** to 3, to generate a study with two interim looks and a final analysis. In the **Design Parameters** tab, select **1-Sided** for **Test Type**. Specify **Type I Error (α)** as 0.05 and **Power ($1-\beta$)** as 0.9, respectively. Enter 135 for **Total SS for Fixed-Sample Study**. The **Design Parameters** tab in the upper pane should appear as

below:

Design: Other: General Design - Sample Size-Based

Number of Looks: 3

Test Parameters | Boundary

Test Type: 1-Sided

Type I Error (α): 0.05

Power: 0.9

Sample Size (n): Computed

Total SS for Fixed-Sample Study: 135

Click **Boundary Info**. In this tab, you will see **Efficacy** and **Futility** boxes. Select **Spending Functions** for **Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in **Efficacy** box. Select **None** for **Boundary Family** in **Futility** boxes. The **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The **Boundary Info** tab should appear as below.

Number of Looks: 3

Test Parameters | Boundary

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks: Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|---------------------|-------------------|

| 2 | 0.667 | 0.016 | 2.141 |
| 3 | 1.000 | 0.050 | 1.695 |

Click **Compute** to generate output for this design. A new row will be added in the **Output Preview** with label Des 1.

| ID | No. of Looks | Test Type | Specified α | Power | Spacing of Looks | Efficacy Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | Fixed SS |
|------|--------------|-----------|--------------------|-------|------------------|-------------------|-------------|------------------|------------------|----------|
| Des1 | 3 | 1-Sided | 0.05 | 0.9 | Equal | LD (OF) | 138 | 137.215 | 106.941 | 135 |

60 Design and Interim Monitoring with General Endpoints

In order to preserve the power of this study at 90% while monitoring the data three times, we must inflate the number of events required for a fixed sample size study from 135 to 138 events. That is, we must commit up front to keeping the study open until 138 ischaemic events are observed. On the other hand, since we will be monitoring the data sequentially, we expect to cross the stopping boundary and stop early after only 107 events, on average, if the alternative hypothesis is true. Thus, the increase in sample size corresponds to a small price to pay in order to benefit from the advantages of potential early stopping.

Save Des 1 in the current workbook by selecting the row corresponding to Des 1 in **Output Preview** and clicking  on the **Output Preview** toolbar. For any chosen design, the study has a certain probability of stopping at any of the looks. In order to see the stopping probabilities select Des 1 in the **Library**, and click .

Design: Other: General Design - Sample Size-Based

| Test Parameters | |
|---------------------------------|----------|
| Design ID | Des1 |
| Number of Looks | 3 |
| Test Type | 1- Sided |
| Specified α | 0.05 |

Sample Size Information

| | Total |
|-------------------------|---------|
| Sample Size (n) | |
| Maximum | 138 |
| Expected H1 | 106.941 |
| Expected H0 | 137.215 |
| Maximum Information (I) | 96.938 |

Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries Efficacy Z | Boundary Crossing Probability (Cumulative) | |
|--------|--------------------------|-----------------|---------------------------|-----------------------|--|----------|
| | | | | | Under H0 | Under H1 |
| | | | | | Efficacy | Efficacy |
| 1 | 0.333 | 46 | 6.869E-4 | 3.2 | 6.869E-4 | 0.067 |
| 2 | 0.667 | 92 | 0.016 | 2.141 | 0.016 | 0.608 |
| 3 | 1 | 138 | 0.05 | 1.695 | 0.05 | 0.9 |

The clear advantage of this sequential design resides in the high probability of stopping by the second look, if the alternative is true, with a sample size of 92 patients, which is well below the requirements for a fixed sample study (135 patients). Close the Output window before continuing.

A less conservative approach would be to use stopping boundaries in the spirit of Pocock (1977). To generate stopping boundaries in the spirit of Pocock (1977), create a new design by right-clicking Des 1 in the **Library**, and selecting **Edit Design**. Go to the **Boundary Info** tab. As before, keep **Spending Functions** for **Boundary Family** and **Lan-DeMets** for **Spending Function**. Change the **Parameter** to **PK** in **Efficacy** boxes. Click **Compute**. A new row will be added in the **Output Preview**

with label Des 2.

| ▲ | ID | No. of Looks | Test Type | Specified α | Power | Spacing of Looks | Efficacy Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | Fixed SS |
|---|------|--------------|-----------|--------------------|-------|------------------|-------------------|-------------|------------------|------------------|----------|
|  | Des1 | 3 | 1-Sided | 0.05 | 0.9 | Equal | LD (OF) | 138 | 137.215 | 106.941 | 135 |
|  | Des2 | 3 | 1-Sided | 0.05 | 0.9 | Equal | LD (PK) | 157 | 153.815 | 95.597 | 135 |

Under this sequential scheme, we must commit up front to 157 events, but the expected number of events upon stopping the study is only 96 under the alternative hypothesis. Des 1 requires a smaller up front commitment, but Des 2 will stop with a smaller number of events, on average, if the alternative hypothesis is true. Now select Des 2 in

Output Preview and click  on the **Output Preview** toolbar to save in the **Library**.

The two designs considered can also be compared in terms of the actual stopping probabilities. In order to see the stopping probabilities with the boundaries with the spirit of Pocock, select Des 2 in the **Library**, and click .

The comparison of stopping probabilities across alternative design options can help in choosing the one with the most desirable properties. In particular, designs that require a larger maximum sample size are usually those that have rather high stopping probabilities at early analyses. Indeed, although Des 2 may require as many as 157 events if the alternative hypothesis is indeed true, there is a higher chance of stopping at the first analysis with this design (stopping probability = 0.428 with 52 events) than with Des 1 (stopping probability = 0.067 with 46 events).

Although the trial report did not mention which monitoring strategy, we will assume

60 Design and Interim Monitoring with General Endpoints

that the decision was made to use Des 1, with stopping boundaries in the spirit of O'Brien and Fleming, and we shall now proceed with the interim monitoring of the study. The inflation factor, $IF(\alpha, \beta, K, \text{boundaries})$, for Des 1 is

$$\frac{N_{max}}{N_1} = \frac{138}{135} = 1.022$$

The $IF = IF(\alpha, \beta, K, \text{boundaries})$ and $\eta = \eta(\alpha, \beta, K, \text{boundaries})$ are related as

$$IF = \left(\frac{\eta}{z_\alpha + z_\beta}\right)^2$$

With $IF = 1.022$, $\alpha = 0.05$ and $\beta = 0.1$, $\eta = 2.958$. We have obtained η through back calculation. In fact, East calculates IF and N_{max} from η . Although this parameter was not specified at the design stage, it is implied by the choice of power, type 1 error, number and spacing of looks and spending function. Specifically, a process of independent increments of the form $W(t) \sim N(\eta t, t)$ (as defined by equations (B.8), (B.9), and (B.10) in Section B.1 of Appendix B) in which $\eta = 2.958$, will cross the stopping boundary of the above study design at one of the three equally spaced monitoring times ($t_1 = 1/3, t_2 = 2/3$, or $t_3 = 1$) with probability $1 - \beta = 0.9$. The parameter η generated at the design stage is an abstract quantity of no inherent interest to the end user. However, as we shall see in the next two sections, point and interval estimates of η obtained from the data at the interim monitoring stage can be of great interest to the end user, for they can be transformed into corresponding estimates of the relevant treatment difference δ .

60.1.2 Interim Monitoring of Stroke Prevention Study

Select Des 1 in the **Library**, and click **IM** from the **Library** toolbar. Alternatively, right-click on Des 1 and select **Interim Monitoring**.

60.1.3 First Interim Analysis

The report does not mention how many events were observed at the first interim analysis and what the value of the test statistic was at that time. We shall suppose that the study was first monitored after 25 events. Suppose in addition that the treatment group was followed for 210 person years producing 20 events, and the control group was followed for 218 person years producing 5 events. With these data, we can test the null hypothesis that the event rate for ischaemic stroke is the same in the treatment and control groups. Before proceeding with this test, however, it is useful to review some basic theory about the Poisson distribution. Let (λ_c, λ_t) be the Poisson event rates for the treatment and control groups, respectively. It is convenient to characterize the treatment difference in terms of the logarithm of the risk ratio

$$\delta = \ln\left(\frac{\lambda_t}{\lambda_c}\right).$$

Then the test statistic of interest for testing $H_0: \delta = 0$ is the Wald statistic

$$Z = \frac{\hat{\delta}}{\text{se}(\hat{\delta})}. \tag{60.1}$$

This statistic is $N(0, 1)$ under the null hypothesis and has the appropriate covariance structure for group sequential inference provided $\hat{\delta}$ is an efficient estimate of δ . At the time of the interim analysis, let n_c denote the number of person years of follow-up in the control group, and let x_c be the corresponding number of events that are observed in the control group. Similarly, let n_t denote the number of person years of follow-up in the treatment group and let x_t be the corresponding number of events that are observed in the treatment group. An efficient estimator for δ is now given by

$$\hat{\delta} = \ln(x_t/n_t) - \ln(x_c/n_c). \tag{60.2}$$

In order to compute the standard error, $\text{se}(\hat{\delta})$, we need to derive the variance of the random variable

$$\ln(T_n) = \ln\left(\frac{X}{n}\right)$$

where X is a Poisson random variable with density

$$f(x) = \frac{(\lambda n)^x e^{-\lambda n}}{x!}.$$

By Poisson theory,

$$E(T_n) = \lambda$$

and

$$\text{var}(T_n) = \frac{\lambda}{n}.$$

Thus, under the null hypothesis $H_0: \delta = 0$,

$$\sqrt{n}(T_n - \lambda) \xrightarrow{d} N(0, \lambda).$$

Therefore, by the delta method (see for example, Agresti, 1990, page 420)

$$\sqrt{n}[g(T_n) - g(\lambda)] \xrightarrow{d} N(0, \lambda[g'(\lambda)]^2).$$

Here $g(\lambda) = \ln(\lambda)$. Therefore

$$\lambda[g'(\lambda)]^2 = \frac{1}{\lambda}$$

and hence

$$\sqrt{n}[\ln(T_n) - \ln(\lambda)] \xrightarrow{d} N\left(0, \frac{1}{\lambda}\right).$$

60 Design and Interim Monitoring with General Endpoints

It follows that

$$\text{var}[\ln(T_n)] = \frac{1}{n\lambda}. \quad (60.3)$$

Substituting this result into equation (60.2) we have

$$\text{var}(\hat{\delta}) = \frac{1}{n_c \lambda_c} + \frac{1}{n_t \lambda_t}.$$

Replacing the Poisson event rates λ_c and λ_t by their corresponding maximum likelihood estimates x_c/n_c and x_t/n_t we finally obtain

$$\text{se}(\hat{\delta}) = \sqrt{\frac{1}{x_c} + \frac{1}{x_t}} \quad (60.4)$$

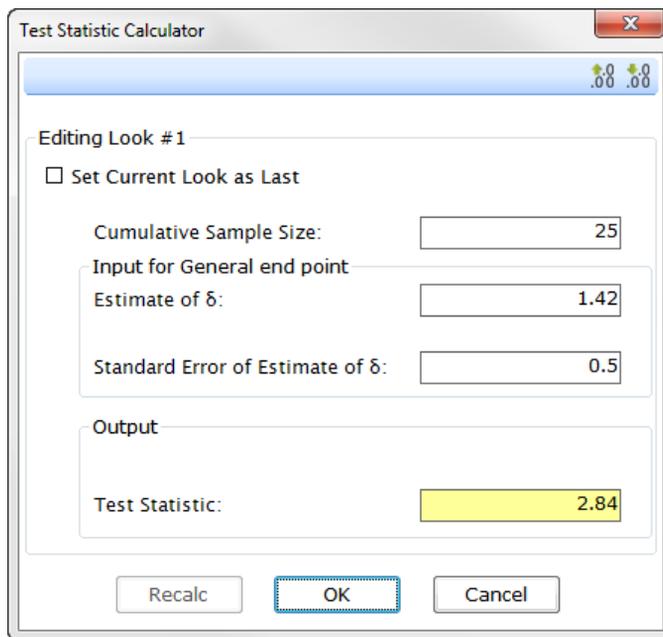

so that the test statistic (60.1) becomes

$$Z = \frac{\ln\left(\frac{x_t}{n_t}\right) - \ln\left(\frac{x_c}{n_c}\right)}{\sqrt{\frac{1}{x_c} + \frac{1}{x_t}}}. \quad (60.5)$$

Substituting the observed values of x_c, x_t, n_c, n_t into equation (60.2) and (60.4), we obtain $\hat{\delta} = 1.423682$ and $\text{se}(\hat{\delta}) = 0.5$. Thus the first interim analysis is performed after observing 55 events with the value of the test statistic being $1.42/0.5 = 2.84$.

At the top of the Interim Monitoring sheet, click [Enter Interim Data](#) from the toolbar to invoke the **Test Statistic Calculator**. In this dialog box, enter 25 in **Cumulative Sample Size**, 1.42 for **Estimate of δ** and 0.5 for **Standard Error of Estimate of δ** .

Then, click **Recalc**.

Click **OK**. East displays the information fraction, $t(\tau_1) = 25/135 = 0.181$, test statistic, $T(\tau_1) = 1.42/0.5 = 2.84$ and efficacy boundary as 4.458. Thus, we can stop the study if the value of test statistic exceeds 4.458. Since this is not the case, we continue to the next interim monitoring time point.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeat ... p-value | CP | Predicti... Power |
|--------|----------------------|------------------------|----------------|------|----------------|----------|---------------|--------|--------------------|----|-------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.181 | 25 | 2.84 | 1.42 | 0.5 | 4.458 | Infinity | -0.809 | 0.194 | 1 | 0.992 |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

The lower 95% confidence bound on η is -3.803. We can convert this estimate into a lower 95% confidence bound for δ by using the relationship

$$\eta = \delta \sqrt{I_{\max}}$$

derived in Section B.1 of Appendix B. Now observe that

$$I_{\max} = \frac{I_{\max}}{I_1} I_1 = t_1^{-1} [\text{se}(\hat{\delta}_1)]^{-2} .$$

60 Design and Interim Monitoring with General Endpoints

Therefore

$$\delta = \eta \sqrt{t_1} [\text{se}(\hat{\delta}_1)] \quad (60.6)$$

Thus, the lower confidence bound for δ is $-3.803 \times \sqrt{0.181} \times 0.5 = -0.809$. We can conclude that based on the current data, the ratio of treatment event rate to control event rate is at least $\exp(-0.809) = 0.445$. There is not yet sufficient evidence to exclude a ratio of 1.0.

60.1.4 Second Interim Analysis

A published report (JAMA, vol 279, No 16, Table 2) shows that this study was indeed monitored after 55 events were observed. There were only 11 events on the adjusted dose arm (control) with 581 patient years of observation. On the other hand there were 44 events on the fixed dose plus aspirin arm (treatment) with 558 patient years of observation. Entering these data into equations (60.2), (60.4) and (60.5) we obtain $\hat{\delta} = 1.427$, $\text{se}(\hat{\delta}) = 0.337$ and $Z = 4.234$.

In the top part of the IM dashboard, enter 55 for **Cumulative Sample Size**, 1.427 for **Estimate of δ** , and 0.337 for **Standard Error of Estimate of δ** . Click **OK**.

Recalc OK Cancel

Click **OK** to update the charts and tables in the dashboard. Now, the stopping

boundary is crossed, and the following window appears.

Click **Stop**. The left side of the dashboard will show the stopping boundaries and the error spending function.

The right side of the dashboard will show a table for final inference, and the confidence intervals:

With 39.9% of the information, East was able to reach an early decision in favor of the alternative hypothesis, that fixed-dose warfarin plus aspirin is insufficient for stroke prevention.

61 *Early Stopping for Futility*

Group sequential methods were developed originally for early stopping if the experimental treatment showed a statistically significant therapeutic advantage at an interim look. In many clinical trials, however, there is limited interest in stopping early for a positive efficacy outcome. This is usually because the investigators wish to continue the trial all the way to the end and gather additional safety data for the experimental arm. Nevertheless, there is a great deal of interest in stopping early for futility if the interim analysis reveals that, with high probability, the trial will end up negative. In that case, the investigators might wish to cut their losses and possibly divert their resources to a more promising study.

East provides two ways to stop early for futility: (a) informal – based on conditional power and (b) formal – based on futility stopping boundaries. Industry trials have typically adopted the informal approach, stopping early if the conditional power at an interim analysis is extremely low. We consider this approach to be informal because it is not necessary to specify ahead of time how low the conditional power should be in order to declare futility and terminate the study. The futility threshold can be determined at the time of the interim analysis itself, possibly using both internal data from the trial and external information about other similar trials. It is easy to see that the informal approach will not inflate the type-1 error, provided the only decisions possible at each interim monitoring time point are to either continue the study or stop and declare futility. On the other hand, the informal approach may not preserve the type-2 error (and thus, the study may lose power) as the decision to stop for futility is based on an ad hoc determination that the conditional power is too low. In contrast, the use of a futility boundary guarantees the preservation of power. This is because the boundary is constructed by using the spending function methodology of Lan and DeMets (1983). However, in this case one spends β , the type-2 error, rather than spending α , the type-1 error. The technical details are available in Appendix B.

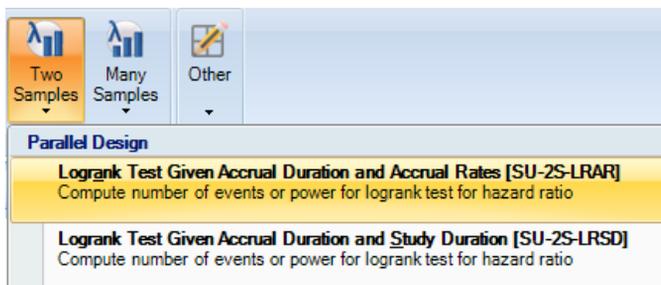

61.1 *Example: Survival in patients with advanced melanoma*

A phase III trial was conducted to compare overall survival (OS) in Tremelimumab, a fully human anti-cytotoxic T lymphocyte-associated antigen 4 (CTLA4) monoclonal antibody with standard, single-agent chemotherapy (Ribas et. al., 2008). Primary endpoint was OS. Let λ_t and λ_c be the overall survival rate in Tremelimumab and standard chemotherapy, respectively. Here, the treatment effect δ is represented in terms of $\ln(\lambda_t/\lambda_c)$ or the log hazard ratio. Therefore, $\delta < 0$ indicates the beneficial effect of new treatment, Tremelimumab. The study was designed to provide 90% power to detect a 33% improvement in true median OS with an unstratified log-rank test at overall 2-sided significance level of 0.05. Two equally spaced interim analyses were planned based on the group sequential design using the Lan-DeMets alpha and beta spending approach to an O'Brien-Fleming boundary. Improvement of 33% in true

median OS can be translated to ratio of medians as 1.33. In other words, we are considering a hazard ratio of $\ln \frac{1}{1+0.33}$ or 0.752. In the study, a median survival time of 10.7 months was observed in the standard chemotherapy group.

61.2 Single-Look Design with No Early Stopping

Suppose initially that no interim monitoring is contemplated. First, click **Survival: Two Samples** on the **Design** tab, and then click **Parallel Design: Logrank Test Given Accrual Duration and Accrual Rates**.

In the input window, leave the **Number of Looks** as 1. In the **Design Parameters** tab, select **Design Type** as **Superiority**, **Test Type** as **2-Sided**, and the values for **Type I Error (α)** and **Power ($1-\beta$)** as 0.05 and 0.9, respectively. Select **# of Hazard Pieces** as 1 which implies that hazard rates remain constant over time in both Tremelumab and standard chemotherapy. Select the **Input Method** as **Median Survival Times**. Tick the check box for **Hazard Ratio (Optional)** and select the radio-button **Ratio of Medians (m_t/m_c)**. Enter 1.33 for **Ratio of Medians (m_t/m_c)**. In the table below, enter 10.7 for **Med. Surv. Time (Control)**. The **Design**

61 Early Stopping for Futility

Parameters tab should now appear as below:

Design Type: Number of Looks:

Test Parameters **Accrual / Dropouts**

Test Type: # of Hazard Pieces: Input Method:

Type I Error (α): Hazard Ratio (Optional) Alternative

Click on the icon  to go back to the **Output Preview** window. Select Des 1 by clicking anywhere along the row in the **Output Preview** and click  to save this design in the **Library**. Des 1 shows that, in order to achieve the desired 90% power, we must keep the study open until 517 events are observed. Half of these events need to be observed in Tremeliumab arm, and another half in the standard chemotherapy arm. You can see the exact number of events required in each arm by double-clicking on Des 1 in the **Library**. In this design, there is no provision for interim monitoring to stop the trial early.

61.3 Group Sequential Design with Early Stopping for Efficacy

Recall from section 61.1 that the study was originally planned with two interim looks with the Lan-DeMets spending approach to an O'Brien-Fleming boundary. In this section, we will consider early stopping boundaries for efficacy only. Create a new design by selecting Des 1 in the **Library**, and clicking the  icon on the **Library** toolbar. First, change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab with label **Boundary Info** will appear. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. Select **Spending Functions** for **Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in **Efficacy** box. Select **None** for **Boundary Family** in **Futility** box. Select **None** for **Boundary Family** in **Futility** box.

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary Accrual / Dropouts

| Expected Under H0 | 17.333 | 17.332 |
| Expected Under H1 | 17.333 | 17.178 |

In order to achieve the desired 90% power, the study in Des 2 should be kept open until 523 events are obtained. However, under H_1 , the required number of events is 420 with expected study duration of 22 months only, compared to 517 events and 26.6 months for Des 1. To see the probability of crossing the stopping boundaries at one of the interim looks, and thus terminating the study earlier, double-click on Des 2 in the

Library.

|--------|--------------------------|-----------------|------------|----------------|---------------|--|-------|
| | | | | | | Efficacy | |
| | | | | | | Upper | Lower |
| 1 | 0.333 | 609 | 174 | 435 | 12.678 | 1.103E-8 | 0.033 |
| 2 | 0.667 | 832 | 349 | 483 | 19.014 | 1.251E-7 | 0.561 |
| 3 | 1 | 832 | 523 | 309 | 27.003 | 1.914E-7 | 0.9 |

You can increase the decimal precision by clicking on the  icon and displaying Probability Statistics up to four decimal places. Under H_1 there is a 3.34% chance of crossing a boundary at the first look, and 56% chance of crossing at the second look (this column is cumulative). This is why the expected study duration is about 4.5 months less than the study duration with Des 1. However, Des 2 has no formal mechanism for stopping the trial early if the two treatments are similar. Under the null hypothesis, the expected study duration under H_0 is nearly the same as for a single look design.

61.4 Informal Use of Conditional Power for Futility Stopping

One can use conditional power as an informal guide for terminating a study at an interim monitoring time point. To see how this works, recall that the study has been designed for two interim looks: first, when one-third of deaths are observed and second, when two-thirds of deaths are observed.

Right-click Des 2 in the **Library**, and select **Interim Monitoring**.

First interim monitoring

Click **Enter Interim Data** from the toolbar to invoke the **Test Statistic Calculator**. In this dialog box, enter 175 for **Cumulative Events**, 0.143 as **Estimate of δ** and 0.477 as **Standard Error of Estimate of δ** . Click **Recalc**. The test statistic value is computed and is displayed as 0.3. This appears to be a rather disappointing value for the test statistic half-way through the study, and suggests that the study might not end

61 Early Stopping for Futility

up positive after all.

| 2 | | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | | |

Examine the **Conditional Power** section of the monitoring sheet.

Conditional powers are calculated at different effect sizes. The conditional power corresponding to HR of 0.1.2 (which is very close to observed HR of 1.1545) is only 0.047. This means that if we were to perform an analysis of the data at 523 events, there is only a 4.7% chance of crossing the upper stopping boundary and declaring statistical significance. Is this chance sufficiently small to warrant terminating the study? There are no objective criteria for making this determination. Recall that the conditional power approach to stopping early for futility is informal. Thus, the low conditional power would have to be considered by the DMC, along with other factors such as toxicity, rate of accrual and parallel developments in other trials.

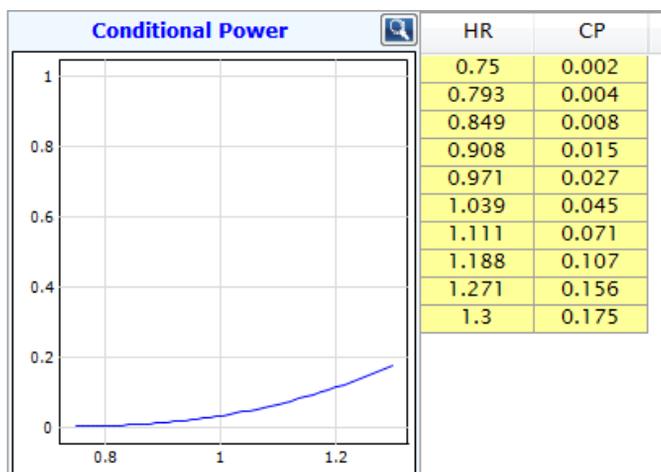

Second interim monitoring Suppose the trial continues and a second interim analysis is performed when almost two-thirds of the events are observed. Assume that the total number of events is 350, and the estimates of $\hat{\delta}=0.237$ and $SE(\hat{\delta})=0.206$. Enter these values in the test statistic calculator to post the results into the interim monitoring dashboard.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of HR | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for HR | | Repeat... p-value | CP | Predict... Power |
|--------|----------------------|-------------------|----------------|------------|------------------|--------------------------------|----------|--------|----------------|-------|-------------------|-------|------------------|

| 1 | 0.335 | 175 | 0.3 | 1.154 | 0.143 | 0.477 | 3.703 | -3.703 | 6.747 | 0.197 | 1 | 0.037 | 0.186 |
| 2 | 0.669 | 350 | 1.15 | 1.267 | 0.237 | 0.206 | 2.506 | -2.506 | 2.124 | 0.756 | 0.443 | 0.154 | 0.202 |
| 3 | | | | | | | | | | | | | |

Although the value of the test statistic has increased considerably from the value at the previous look, the conditional power has only marginally increased, from 0.047 to

61 Early Stopping for Futility

0.175. Because we are very close to the end of the study, there is only a 17.5% chance of crossing the upper stopping boundary at the final look. Should the study continue or be terminated? Again, the decision is a subjective one.

61.5 Combined Efficacy and Futility Stopping Boundaries

61.5.1 Two-Sided Tests

61.5.2 One-Sided Test

61.5.3 Conservative Futility Boundaries

One way to remove the subjectivity from the decision to stop early based on low conditional power is to use formal futility stopping boundaries. East has the provision to simultaneously create efficacy boundaries for rejecting H_0 and futility boundaries for rejecting H_1 . The efficacy boundaries are generated by an α -spending function that spends the type-1 error. The futility boundaries are generated by a β -spending function that spends the type-2 error. Moreover the two sets of boundaries are forced to meet at the last look so as to ensure that either H_0 or H_1 is rejected.

61.5.1 Two-Sided Tests

Recall that the advanced melanoma study we are considering in this section was implemented using the Lan-DeMets alpha and beta spending approach to an O'Brien-Fleming boundary. We will first consider a two-sided design with both efficacy and futility boundaries. In order to do this, create a new design by selecting Des 2 in the **Library**, and clicking the  icon on the **Library** toolbar. Click the **Boundary Info** tab. Select **Spending Functions** for **Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in both **Efficacy** and **Futility** boxes. In the right of the **Futility** box there is a field where you have to choose either **Non-Binding** or **Binding**. Binding futility boundary refers to a situation where the trial must be terminated once the test statistic falls within the futility

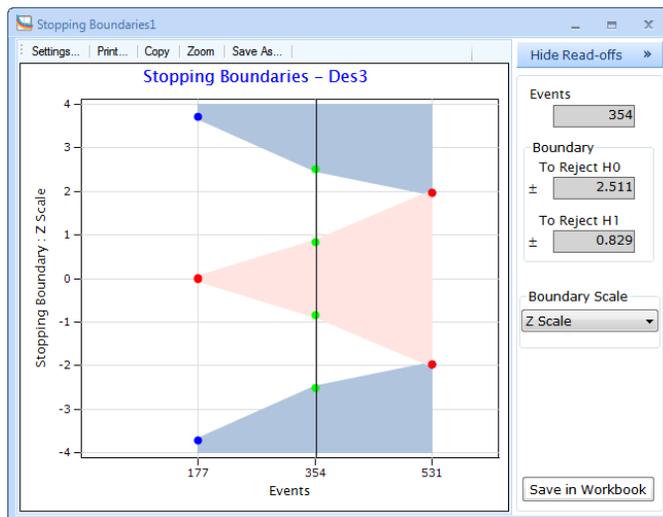

boundaries; otherwise overall type I error might be inflated. Non-Binding futility boundaries do not have this constraint. For now, select the radio-button corresponding to **Binding**. The cumulative α and β spent along with the boundary values are shown in the table in the **Boundary Info** tab. The columns **Stop for Efficacy** and **Stop for Futility** in the table provide the flexibility of excluding either efficacy of futility boundaries in certain interim looks, by unchecking the corresponding cells. For this example, leave all the boxes in columns **Stop for Efficacy** and **Stop for Futility** checked. Click **Compute**.

A new row will be added in the **Output Preview** labeled as Des 3. Save this design in the current workbook by selecting the row corresponding to Des 3 in **Output Preview** and clicking  on the **Output Preview** toolbar. To compare Des 1, Des 2, and Des 3, select all three rows in **Output Preview** using the Ctrl key and click  icon. All three designs will be displayed in the **Output Summary**.

61 Early Stopping for Futility

Select Des 3 in the **Library**, and click  , then select **Stopping Boundaries**.

Des 3 requires a commitment to keep the study open until either 531 events are observed or a boundary is crossed. However, by providing upper and lower stopping boundaries and an inner wedge, Des 3 has lower expected study durations under both the null and alternative hypotheses. If the test statistic enters:

- the pink zone (the inner wedge), the trial stops, the alternative hypothesis is rejected, and futility is declared.
- the lower blue zone, the trial stops, the null hypothesis is rejected, and the new treatment Tremelimumb is declared to be beneficial relative to the standard chemotherapy.
- the upper blue zone, the trial stops, the null hypothesis is rejected, and the Tremelimumb is declared to be harmful relative to the standard chemotherapy.

These boundaries are constructed in such a way that:

- if the null hypothesis is true (i.e., $\delta = \ln \lambda_t / \lambda_c = 0$), the test statistic will enter the pink inner wedge region with probability $1 - \alpha = 0.95$, the upper blue zone with probability 0.025 and the lower blue zone with probability 0.025.
- if the alternative hypothesis is true with $\delta = \ln \lambda_t / \lambda_c \leq \ln 0.752 = -0.285$, the test statistic will enter the pink zone with probability $\beta = 0.1$ and the lower blue zone with probability almost equal to 0.9.
- if the alternative hypothesis is true with $\delta \geq 0.285$ the test statistic will enter the

pink zone with probability $\beta = 0.1$ and the upper blue zone with probability almost equal to 0.9.

The inner wedge boundaries give us the chance to stop early if H_0 is true. Notice that with Des 3, the expected study duration under H_0 is only 20.639 months, as compared to 24.668 months with Des 2. Close this chart before continuing.

61.5.2 One-Sided Test

In Des 3 we utilized a total of four boundaries – two-sided upper and lower boundaries for rejecting H_0 , and two-sided upper and lower boundaries for rejecting H_1 . Such boundaries are only necessary if we wish to actually continue the trial until we have demonstrated that the new treatment is significantly worse than the standard treatment; i.e., until the test statistic enters the lower blue zone and rejects H_0 in favor of $H_1 : \delta \leq 0$. If, however, we are willing to stop the study early if equivalence rather than actual harm is demonstrated, a more efficient design consisting of only two boundaries can be devised. Create a new design by selecting Des 3 in the **Library**, and clicking the  icon on the **Library** toolbar. Click the **Design Parameters** tab. Replace **2-Sided** by **1-Sided**, and replace the significance level, $\alpha = 0.05$ by $\alpha = 0.025$.

| Test Parameters | Boundary | Accrual / |
|----------------------------|---------------|-----------|
| Test Type: | 1-Sided | |
| Type I Error (α): | 0.025 | |
| Power: | 0.9 | |
| No. of Events: | Computed | |
| Allocation Ratio: | 1 | |
| | (n_t / n_c) | |

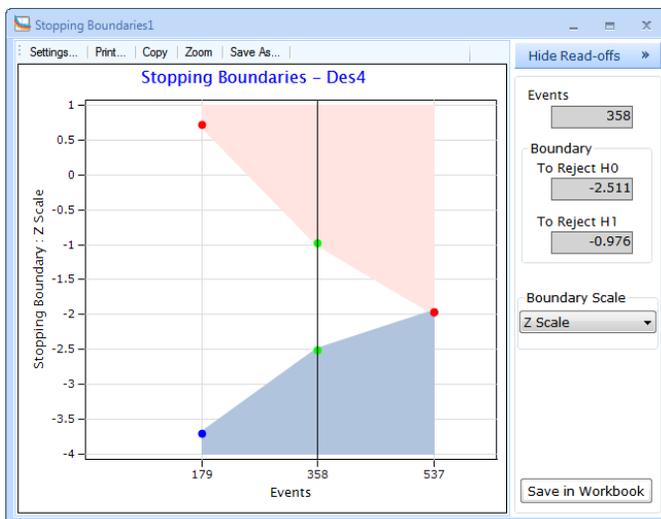

Go to the **Boundary Info** tab. Select **Spending Functions** for **Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in both

61 Early Stopping for Futility

Efficacy and **Futility** boxes. Select the radio-button corresponding to the **Binding**.

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Cum. β Spent | Futility Boundary |
|--------|----------------|-------------------------------------|-------------------------------------|---------------------|-------------------|--------------------|-------------------|
| 1 | 0.333 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.000 | -3.710 | 0.004 | 0.713 |
| 2 | 0.667 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.006 | -2.511 | 0.044 | -0.976 |
| 3 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.025 | -1.959 | 0.100 | -1.959 |

Click **Compute**. This will add a new row to the **Output Preview**. Save this design in the current workbook by selecting the row corresponding to Des 4 in **Output Preview** and clicking  on the **Output Preview** toolbar. Select Des 4 in the **Library**, and then click , and select **Stopping Boundaries**.

Des 4 requires a commitment to keep the study open until either 537 events are observed or one of the two boundaries is crossed. If the test statistic crosses:

- the upper boundary and enters the pink zone the trial stops, the alternative

- hypothesis is rejected, and futility is declared.
- the lower boundary and enters the blue zone the trial stops, the null hypothesis is rejected, and the new treatment is declared to be beneficial over the standard chemotherapy.

These boundaries are forced to meet at the end of 537 events, thus ensuring that either H_0 or H_1 will be rejected. They are constructed so that:

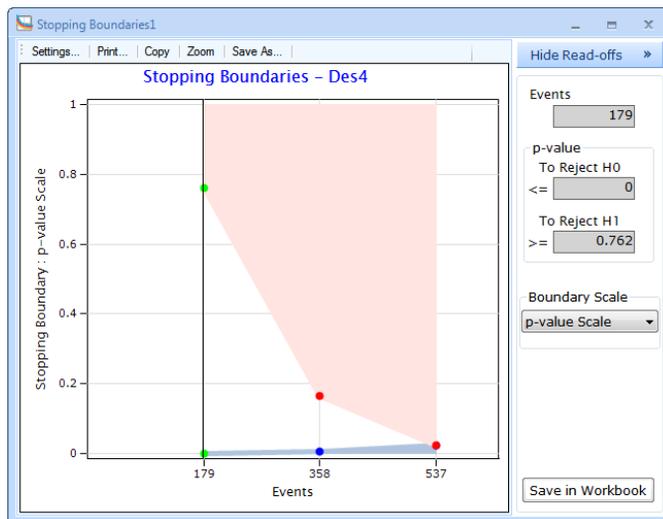

- if the null hypothesis is true (i.e., $\delta = \ln \lambda_t / \lambda_c = 0$), the test statistic will enter the pink zone with probability $1 - \alpha = 0.975$ and the blue zone with probability 0.025
- if the alternative hypothesis is true (i.e., $\delta = \ln \lambda_t / \lambda_c = -0.285$), the test statistic will enter the pink zone with probability $\beta = 0.1$ and the blue zone with probability 0.9.

Des 4 therefore meets the regulatory requirement that the false positive rate for a one sided test should not exceed 0.025. It also meets the sponsor's requirement that the study be designed for 90% power. In terms of shortening the expected study duration, however, Des 4 completely dominates the other three designs. Under H_0 the expected study duration is less than 18 months, a saving of over 6.5 months compared to Des 1. There is also over 4.5 months of expected saving relative to Des 1 if H_1 is true.

Unlike the informal approach, based on conditional power, Des 4 utilizes a formal futility boundary. Since the futility boundary is derived from a β -spending function, the type-2 error (and hence the power of the study) is fully controlled. A drawback of this approach is the loss of flexibility to keep the study open if the futility boundary is crossed. In this case, we must terminate the study. If we keep on accruing patients even after crossing a futility boundary, we are no longer assured of preserving the type-1 error. For this reason, it is important to examine the futility boundary from every angle before making the commitment. Accordingly, let us examine the stopping boundaries again, this time on the p-value scale. To display the boundaries on the p-value scale

61 Early Stopping for Futility

you must select this scale from the drop-down list in the Stopping Boundaries chart.

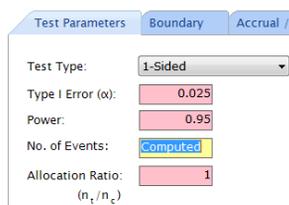

If the p-value (one-sided) at the first look exceeds 0.7622 the study should be terminated for futility. At the second look the futility criterion is $p = 0.1646$ and at the final look it is $p = 0.0251$. These values reveal several psychological drawbacks of the selected futility boundary. For instance, even though the overall power of the study is preserved, most investigators would be unwilling to terminate a study and declare futility at an interim analysis where the p-value was 0.1646; they would prefer to complete the study in hopes of a further decline in the p-value. Also, since the boundaries meet at the final look, one could technically reject the null hypothesis and claim that the trial is a success if the final p-value is less than 0.0251. This could appear counter-intuitive because one expects to pay a penalty for having taken multiple looks at the data. Usually the penalty amounts to requiring the cut-off for the final p-value to be less than $\alpha = 0.025$ in order to declare significance and reject H_0 . Here, however, the cut-off for the final p-value exceeds 0.025. It appears that we have been rewarded rather than penalized for having designed a multiple-look study.

The reason is that the presence of a futility boundary reduces the risk of crossing the efficacy stopping boundary. If the study were designed with an efficacy boundary only, it would be at risk of crossing the efficacy boundary at each interim look. This would elevate the overall type-1 error unless we imposed a suitable penalty on the final p-value to compensate. On the other hand if the study were designed with a futility boundary only, it would be at risk of crossing the futility boundary at each interim

look. This would reduce the overall type-1 error unless we rewarded the final look p-value by a suitable amount to compensate. When both efficacy and futility boundaries are present, the efficacy boundaries tend to lower the cut-off for the final p-value to below α whereas the futility boundaries tend to increase the cut-off for the final p-value to above α . Depending on the choice of stopping boundaries the number and timing of the looks and the values of α and β , one or other of these opposing forces dominates, resulting in a cut-off for the final p-value that is sometimes greater than α and sometimes less.

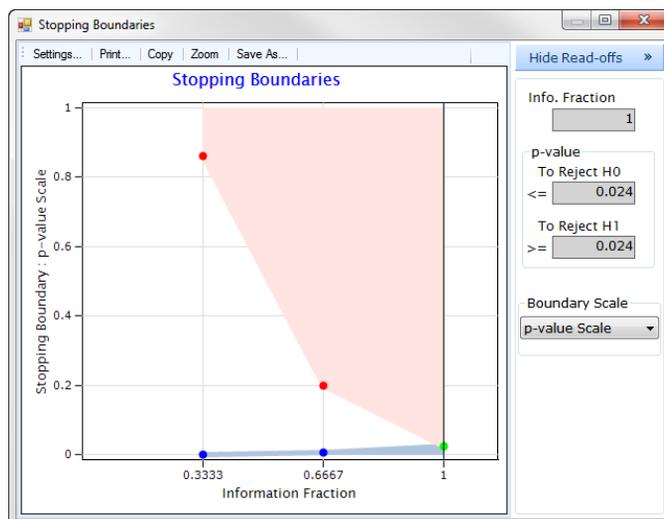

Select Des 4 in the **Library**, and click the  icon on the **Library** toolbar. Change the power from 90% to 95% in the **Design Parameters** tab.

Now go to the **Boundary Info** tab, and click  . Change the **Boundary Scale** to **p-value**. Look at the display of the stopping boundary in p-value scale. In this case the penalty imposed by the efficacy boundary has overcome the reward imposed by the futility boundary and the cut-off for the final p-value required to reject H_0 and declare

61 Early Stopping for Futility

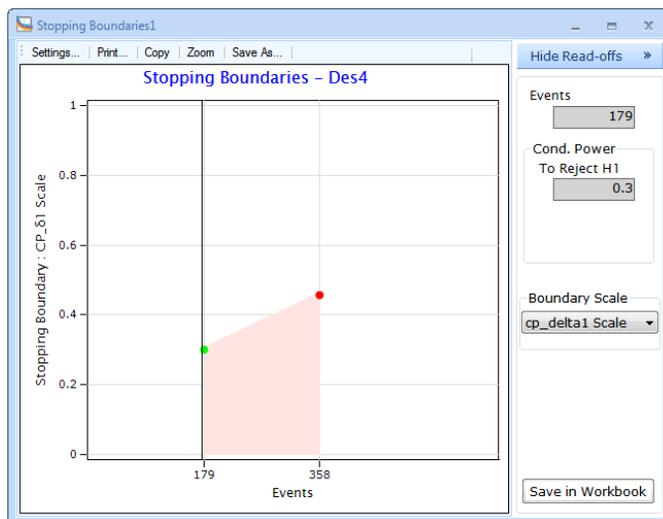

statistical significance is less than $\alpha = 0.025$.

61.5.3 More Conservative Futility Boundaries

It is useful to view futility stopping boundaries on a conditional power scale since that permits us to directly compare a formal futility boundary with an alternative informal early stopping criterion where both criteria are based on low conditional power. Select Des 4 in the **Library**, and then select **Stopping Boundaries** after clicking the 

icon. Select **cp_delta1 Scale**.

We are required to terminate the study at the first interim look if the conditional power is less than 0.2999, and at the second interim look if the conditional power is less than 0.4581. These are fairly large conditional power values. The trial investigators might not be willing to commit in advance to stop the study and declare futility if the conditional power is as high as 45%. Consequently, they might prefer to adopt an informal approach to early stopping for futility. However, as we have already discussed, the informal approach cannot ensure that the type-2 error will be preserved and the study might lose power.

The availability of a rich family of flexible spending functions in East enables us to pick formal futility boundaries with substantially lower conditional power for futility stopping, within the range of conditional power values that we might use with the informal approach. For example, suppose that the trial investigators do not wish to terminate this trial for futility unless the conditional power is less than 20% at the first interim look, and less than 10% at the second interim look. These rather conservative criteria for early stopping are more realistic than the 30% and 45% conditional power criteria implied by the stopping boundaries of Des 4. Close this chart before continuing.

Gamma family β spending function Create a new design by selecting Des 4 in the

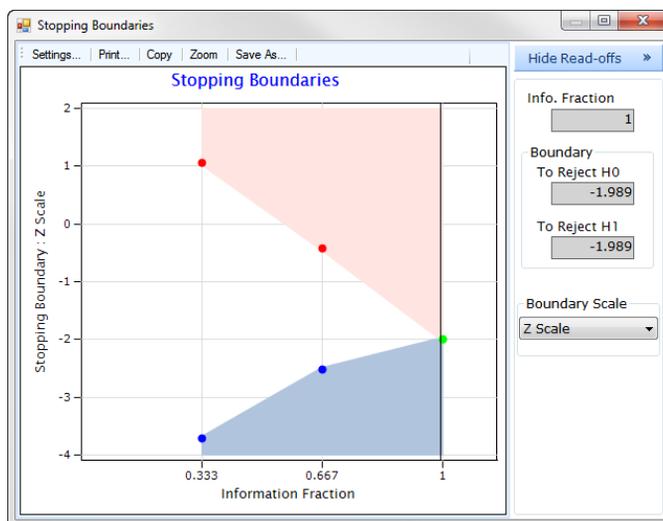

61 Early Stopping for Futility

Library, and then by clicking the  icon on the **Library** toolbar. Click the **Boundary Info** tab. In the **Futility** box, change the **Spending Function** to **Gamma Family** from the drop-down list.

We must choose a parameter value, γ , to identify a specific member of this family. The value $\gamma = -4$ will yield a spending function roughly similar to the **LD (OF)** spending function. Smaller values of γ will yield more conservative spending functions. Since the **LD (OF)** function (which was used to spend type-2 error in Des 4) yielded unsatisfactory futility boundaries on the conditional power scale, let us be more conservative. Type in -6 as the value of **Parameter** γ . Select the radio-button next for **Binding**.

| Test Parameters | Boundary | Accrual / Dropouts |
|----------------------------|---|--------------------|
| Efficacy | | |
| Boundary Family: | Spending Functions | |
| Spending Function: | Lan-DeMets | |
| Parameter: | OF | |
| Type I Error (α): | 0.025 | |
| Futility | | |
| Boundary Family: | Spending Functions | |
| Spending Function: | Gamma Family | |
| Parameter (γ): | -6 | |
| Type II Error (β): | 0.1 | |
| | <input type="radio"/> Non-Binding <input checked="" type="radio"/> Binding | |

Click  to show the boundary chart.

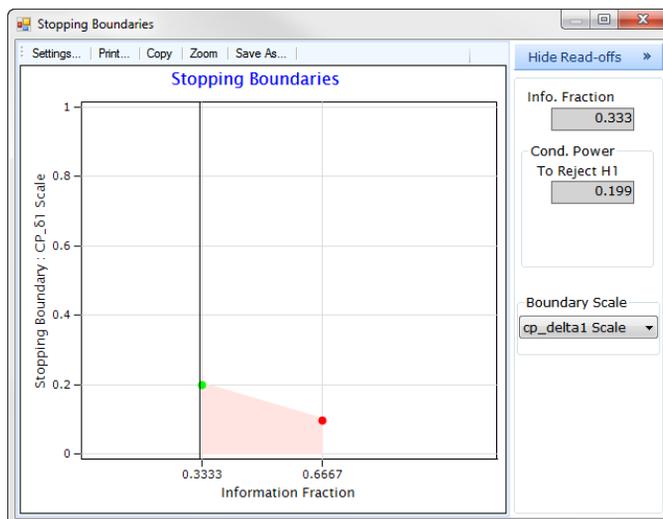

The stopping boundary for rejecting H_0 at the final look is now -1.9889 . As this value

is smaller than -1.96 there is indeed a penalty being paid for the multiple looks. Thus, the psychological difficulty encountered in Des 4, where the final stopping boundary for rejecting H_0 was less than -1.96, has been resolved. Click **Compute** to generate Des 5.

We can try to be more conservative in terms of β spending function. Change the parameter for the Gamma spending function from $\gamma = -6$ to $\gamma = -8$

Click  and change the **Boundary Scale** to the **cp_delta1 Scale**.

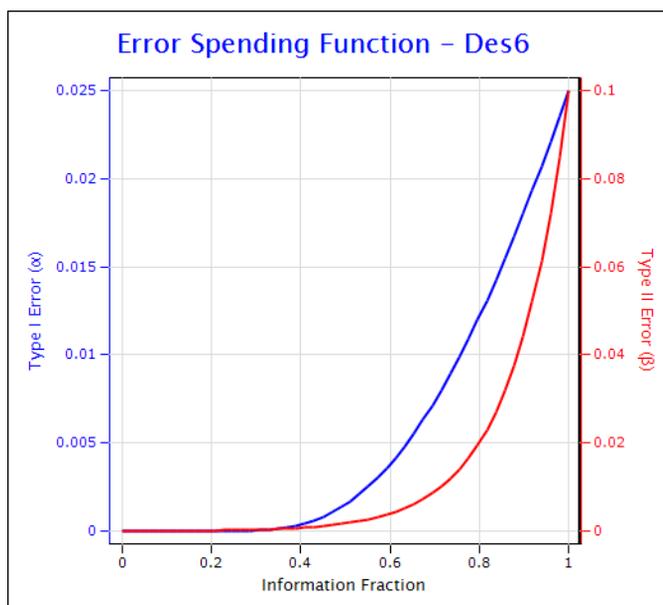

By viewing the futility boundary on the cp delta scale, the first and second-look values of conditional power required to stop early are, respectively, 0.1991 and 0.0973. These values are within a range where the trial investigators would be willing to guarantee in advance that they would stop the trial and declare futility. The advantage of using the formal futility boundary is, of course, that the type-2 error (and hence the power) is guaranteed to be preserved. Click **Compute**. This will add a new row to the **Output Preview** labeled as Des 6. Save this design in the current workbook by selecting the row corresponding to Des 6 in **Output Preview** and clicking  on the **Output Preview** toolbar.

61 Early Stopping for Futility

61.6 Early Stopping for Futility Only

Under Des 6 there is the possibility of rejecting H_0 and stopping early for efficacy if the upper stopping boundary is crossed. The α -spending function used to generate the upper efficacy stopping boundary is the **LD (OF)** spending function proposed by Lan and DeMets (1983). This function is popular because it spends the type-1 error conservatively in the beginning, but still provides a reasonable opportunity for premature termination once the trial gets underway. In contrast, the **Gm (-8)** β -spending function used by Des 6 to generate the futility boundary is much more conservative and provides considerably less opportunity for premature termination until the study close to completion. To examine these two spending functions together, first select Des 6 in **Library**. Click  in the **Library** toolbar and then select **Error Spending**.

For the first 40% of the trial, both spending functions are extremely conservative, spending a negligible amount of error. Thereafter, however, the α -spending function starts to spend the type-1 error at a much faster rate making it easier to stop early for efficacy. Let us examine the stopping probabilities for Des 6 under H_0 and H_1 . Select

Des 6 in the **Library** and double-click on it.

⊖ Events, Sample Size, Pipeline and Analysis Times: Look by Look (Under H0)

| Look # | Info. Fraction (s/s_max) | Sample Size (n) | Events (s) | Pipeline (n-s) | Analysis Time | Boundary Crossing Probability (Cumulative) | |

| | | | | | | Efficacy | Futility |
| 1 | 0.334 | 575 | 175 | 400 | 11.977 | 1.051E-4 | 0.076 |
| 2 | 0.666 | 840 | 349 | 491 | 17.857 | 0.006 | 0.576 |
| 3 | 1 | 840 | 524 | 316 | 24.66 | 0.025 | 0.975 |

⊖ Events, Sample Size, Pipeline and Analysis Times: Look by Look (Under H1)

| Look # | Info. Fraction (s/s_max) | Sample Size (n) | Events (s) | Pipeline (n-s) | Analysis Time | Boundary Crossing Probability (Cumulative) | |
|--------|--------------------------|-----------------|------------|----------------|---------------|--|----------|
| | | | | | | Efficacy | Futility |
| 1 | 0.334 | 611 | 175 | 436 | 12.718 | 0.034 | 4.501E-4 |
| 2 | 0.666 | 840 | 349 | 491 | 18.989 | 0.56 | 0.007 |
| 3 | 1 | 840 | 524 | 316 | 26.87 | 0.9 | 0.1 |

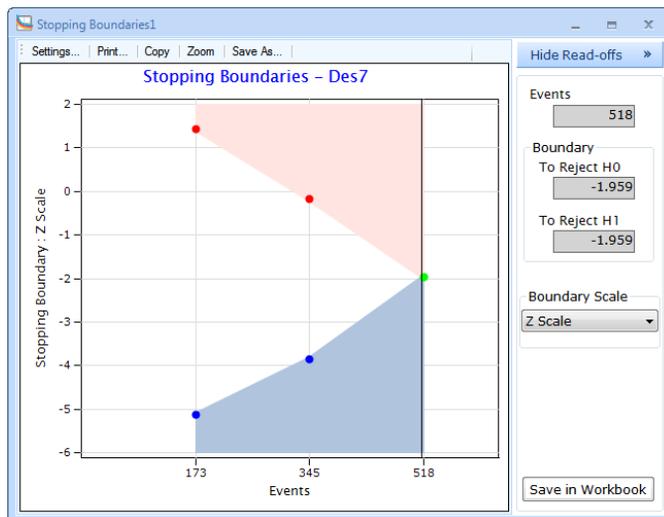

Under H_1 , the efficacy boundary would be crossed with probability 0.034 at the first interim analysis, one-third-way through the trial. By the time two-thirds of the trial has been completed, the probability of early stopping for efficacy under H_1 at the second look is 0.56 (cumulative). In some studies, however, the investigators have no desire to stop early for efficacy, but only wish to stop early for futility. Early efficacy stopping for a promising new therapy might not be desirable, for instance, if the investigators wish to continue the trial and monitor safety. Early futility stopping under H_0 , on the other hand, is desirable since it is better to kill a study that is going nowhere and spend the resources elsewhere. We can discourage early efficacy stopping by using stopping boundaries that are considerably more conservative than the **LD (OF)** boundary used in Des 6. Let us consider using the Gamma spending function with parameter $\gamma = -18$.

Create a new design by selecting Des 6 in the **Library**, and clicking the  icon on the **Library** toolbar. Click the **Boundary Info** tab. In the **Efficacy** box, change the **Spending Function** to **Gamma Family** from the drop-down list. Type in -18 as the value of **Parameter** (γ), and click **Compute**

This will add a row in the **Output Preview** with label Des 7. Select Des 7 by clicking anywhere along the row in the **Output Preview** and click  to save this design in the **Library**. Select Des 7 in the **Library**, and click , then select **Stopping**

61 Early Stopping for Futility

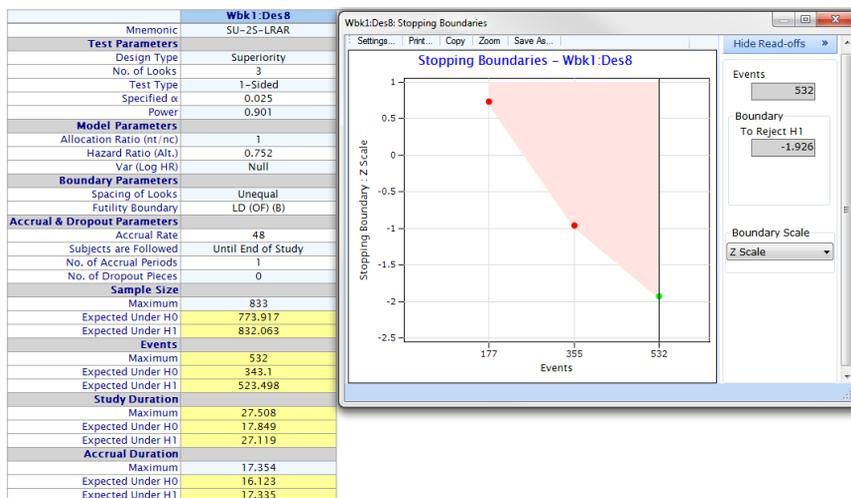

Boundaries.

Notice how hard it is to stop early for efficacy. Even as late as the second interim look the efficacy boundary value is -3.841 on the standardized difference scale. We would need to see a one-sided p-value smaller than 0.0001 in order to stop early for efficacy. Thus, except in very extreme situations, Des 7 will not permit early stopping for efficacy. An interesting feature of Des 7 is that the p-value required at the final look in order to reject the null hypothesis and declare statistical significance is 0.0251 . Although we have designed the study for multiple looks at the data, the cut-off p-value for rejecting H_0 at the final look is greater than $\alpha = 0.025$; i.e., we have been rewarded rather than penalized for the multiple looks. We explained the reason for this seeming anomaly in Section 61.5.2. The final cut-off p-value required to preserve the type-1 error is determined by balancing the penalty due to the presence of an efficacy boundary against the reward due to the presence of a futility boundary. Because of the specific choice of γ parameters, this balance ended up favoring a tiny reward. It might however be important, in an industry trial, to obtain the approval of the regulatory reviewers for using 0.0252 as the final cut-off for rejecting H_0 . The simulation tools of East may be used to demonstrate that this cut-off does indeed preserve the type-1 error. Close the chart before continuing.

It would be interesting to compare Des 7 with a design that has the same futility boundary but no efficacy boundary whatsoever. To achieve this aim create a new design by selecting Des 7 in the **Library**, and clicking the  on the **Library**

toolbar. Click the **Boundary Info** tab. In the **Efficacy** box, change the **Boundary Family** to **None** from the drop-down list, and click **Compute**. This will add a row in the **Output Preview** with label Des 8. The design summary and stopping boundaries (futility only) of this design are displayed below.

In this design, the trial stops for futility if the value of the test statistic is less than the corresponding boundary value. The value of the boundary at the final look is -1.9264. Therefore if the value of the test statistic is less than -1.9264 at the final look one could technically reject H_0 and claim efficacy. The type-1 error of this procedure is 0.025 even though this final boundary value is greater than -1.96. This follows from the same reasoning as we provided in Section 61.5.2. The type-1 error is decreased because there is a chance of being absorbed into the futility boundary at an earlier look. To compensate, the critical value of the test statistic for rejecting H_0 at the final look is determined to be -1.9264 rather than -1.96.

62 *Flexible Stopping Boundaries in East*

East provides considerable flexibility for generating stopping boundaries with different shapes and varying levels of conservatism for early stopping for efficacy, safety or futility. Suppose, for instance that a trial will be monitored at regular intervals for safety. For ethical reasons, one might wish to choose safety stopping boundaries that possess a very low threshold for early stopping. On the other hand, there might be some reluctance to stopping a trial early for efficacy. If the new treatment looks promising there is often a desire to go to completion and thereby gather overwhelmingly strong evidence of treatment benefit rather than stopping prematurely. In that case, one might wish to choose extremely conservative stopping boundaries with a high threshold for early stopping at the early interim looks. The boundaries that are available in East run the gamut between extreme conservatism and extreme liberality for early stopping. They fall into three main categories: p-value boundaries, power boundaries and spending function boundaries. Furthermore, a boundary may serve either to stop a trial and reject the null hypothesis or to stop a trial and reject the alternative hypothesis. Boundaries that facilitate early stopping to reject the null hypothesis are by far the more common of the two types. They are further classified into efficacy boundaries and safety boundaries. Boundaries that facilitate early stopping to reject the alternative hypothesis are known as futility boundaries. They play a role in early termination of trials in which the treatment effect is too small to confer a therapeutic advantage to the experimental arm. They may be used either in conjunction with, or as an alternative to, conditional power for futility stopping.

P-value boundaries are discussed in Section [62.1](#). Power boundaries are discussed in Section [62.2](#). As originally conceived of, p-value boundaries offer less flexibility than power boundaries in terms of boundary shape. However, as described in Section [62.1](#), p-value boundaries have been generalized in this version of East to accommodate many more situations. Still, spending function boundaries offer the most flexibility for trial design. They are discussed in Section [62.3](#). Our recommendation is to use the spending function boundaries whenever possible.

The theory underlying the actual construction of stopping boundaries is developed in Appendix [B](#). The purpose of the present chapter is to document how the various boundaries can be invoked in East and to demonstrate, through examples, the flexibility they confer for trial design.

62.1 P-Value (or Haybittle-Peto) Boundaries

62.1.1 Use of Haybittle-Peto boundaries

62.1.2 SPARCL trial

P-value boundaries, also known as Haybittle-Peto boundaries, have a very simple structure. One specifies a fairly small p-value, say 0.0001, for early stopping at the first $K - 1$ looks. East then uses recursive integration to compute the last-look p-value needed to achieve an overall type-1 error of α . Historically these boundaries were conceived by Haybittle (1971) as a fairly straightforward way of being permitted to take interim looks without having any substantial impact on the final p-value one would need in order to attain a statistically significant outcome.

In East, we have generalized the original Haybittle-Peto boundaries so that the p-values specified at the first $K - 1$ looks need not be equal. We call such boundaries Generalized Haybittle-Peto boundaries. The following two examples illustrate how to use the original and the generalized Haybittle-Peto boundaries in East. In addition to designing a trial with these types of boundaries, the second example shows how such a trial can be simulated and monitored using East.

62.1.1 Use of Haybittle-Peto boundaries in a hypertension trial

A randomized, placebo-controlled trial were conducted to evaluate the efficacy of arthroscopy for osteoarthritis of the knee (Moseley et al., 2002). Primary endpoint was patient-reported pain in the study knee 24 months after intervention on a scale range from 0 to 100, with higher score indicating the more sever pain. Let $X_{ic} \sim N(\mu_c, \sigma^2)$ be the pain score for the i th subject in the placebo group, $X_{it} \sim N(\mu_t, \sigma^2)$ be the pain score for the i th subject in the treatment group, and $\delta = \mu_t - \mu_c$. Null hypothesis was that the patients in the two groups report the same amount of knee pain after two years. That is, $H_0 : \mu_t = \mu_c$. The trial was designed to detect a moderate effect size $\delta_1 = 0.55$ with 90% power with a two-sided level-0.04 test. This was the group-sequential design with Haybittle-Peto stopping boundaries of $p=0.001$ for the interim analyses. For this study, the standard deviation for placebo arm was reported as 18.5 and we will use this as common standard deviation for both the group. We will illustrate designing of this study considering maximum of $K=4$ equally spaced looks.

First, click **Continuous: Two Samples** on the **Design** tab, and then click **Parallel Design: Difference of Means**. The upper pane of this window displays several fields with default values. First, change the **Number of Looks** to 4. This will add a tab with label **Boundary Info**. We will come back to this tab later. In the **Design Parameters** tab, select **Superiority** for **Design Type** and **2-Sided** for **Test Type**. Since the study was planned to detect a moderate effect size of 0.55, select **Standardized Diff. of Means** for **Input Method** and specify **Standardized Diff.** $((\mu_t - \mu_c)/\sigma)$ as 0.55. Enter 0.04 for **Type I Error (α)**, and 0.9 for **Power ($1-\beta$)**. The

62 Flexible Stopping Boundaries in East

Design Parameters tab should appear as below:

Design Type: Superiority Number of Looks: 4

Test Parameters Boundary

Test Type: 2-Sided Input Method: Standardized Diff. of Means Test Statistic: Z

Type I Error (α): 0.04 Specify Alternative Hypothesis

Power: 0.9 Standardized Diff. $((\mu_t - \mu_c)/\sigma)$: 0.55

Sample Size (n): Computed

Allocation Ratio: 1

(n_t/n_c)

Click the **Boundary Info** tab. In this tab, you will see **Efficacy** and **Futility** boxes, where you can select efficacy and futility boundary families. Select **Haybittle Peto (p-value)** for **Boundary Family** in the **Efficacy** box and select **None** for **Boundary Family** in the **Futility** box.

For the Haybittle Peto boundary family, East allows you to fix either overall type I error or the p-value at the final look. In both the cases, p-values for the interim looks need to be specified. To use the original Haybittle-Peto boundaries, all the interim looks should have equal p-value.

Fixed p-value at final look First we will illustrate how to fix the p-value at the final look instead of overall type I error (α). This is the case when one would like to specify a constant p-value boundary at the first 3 looks as well as any desired final p-value boundary for the 4th look. Suppose, for example, that we specify 0.001 at each of the first 3 looks and 0.04 at the 4th look. Select the radio-buttons corresponding to the **Last Look p-value**, and **Unequal p-values at looks**. The **Boundary Info** tab should

appear as below:

Test Parameters | **Boundary**

Efficacy

Boundary Family: Haybittle Peto (p-value)

Fix

Total Type I Error (α) p-values at looks Equal

Last Look p-value Unequal

Type I Error (α): 0.041

Spacing of Looks

Equal Unequal

| Look # | Info. Fraction | Efficacy p-value |
|--------|----------------|------------------|
| 1 | 0.250 | 0.001 |
| 2 | 0.500 | 0.001 |
| 3 | 0.750 | 0.001 |
| 4 | 1.000 | 0.04 |

Click **Compute**. This will add a row to the **Output Preview** with label Des 1.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | Input Method | Standardized Diff. | Test Statistic |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|-------------|------------------|------------------|-----------------------------|--------------------|----------------|
| Des1 | Superiority | 4 | 2-Sided | 0.041 | 0.9 | 1 | Unequal | HP | 147 | 146.801 | 124.507 | Standardized Diff. of Means | 0.55 | Z |

The overall type I error is now 0.041, which is slightly higher than the desired type I error of 0.04. The increase in overall power is due to the 3 interim looks. Maximum sample size required for this design is 147.

Fixed overall type I error Recall that the study we are considering in this section was designed to maintain an overall type I error of 0.04 with constant Haybittle-Peto boundaries of $p=0.001$ for the interim analyses. In **Boundary Info** tab, select the radio-buttons corresponding to the **Total Type I Error (α)**, and **Unequal p-values at looks**. Then go to the **Design Parameters** tab and set the **Type I error (α)** at 0.04.

62 Flexible Stopping Boundaries in East

The **Boundary Info** tab should appear as below:

Boundary

Efficacy

Boundary Family: Haybittle Peto (p-value) ▾

Fix

Total Type I Error (α) p-values at looks

Last Look p-value Unequal

Type I Error (α): 0.04

Spacing of Looks

Equal Unequal

| Look # | Info. Fraction | Efficacy p-value |
|--------|----------------|------------------|
| 1 | 0.250 | 0.001 |
| 2 | 0.500 | 0.001 |
| 3 | 0.750 | 0.001 |
| 4 | 1.000 | 0.039 |

The p-value corresponding to final look has been updated to 0.0391. Upon clicking the **Compute** button, we will see that a maximum sample size of 148 would be needed.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | Input Method | Standardized Diff. | Test Statistic |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|-------------|------------------|------------------|-----------------------------|--------------------|----------------|
| Des1 | Superiority | 4 | 2-Sided | 0.041 | 0.9 | 1 | Unequal | HP | 147 | 146.801 | 124.507 | Standardized Diff. of Means | 0.55 | Z |
| Des2 | Superiority | 4 | 2-Sided | 0.04 | 0.901 | 1 | Unequal | HP | 148 | 147.799 | 125.148 | Standardized Diff. of Means | 0.55 | Z |

It is more common to use Haybittle-Peto boundaries as shown in Des 2 – to specify a common p value for the first $K - 1$ looks, and adjust the final p value to satisfy an overall α . To see the sample size required for a single look design, change the **Number of Looks** to 1. Click **Compute** to obtain the fixed sample size.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | Input Method | Standardized Diff. | Test Statistic |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|-------------|------------------|------------------|-----------------------------|--------------------|----------------|
| Des1 | Superiority | 4 | 2-Sided | 0.041 | 0.9 | 1 | Unequal | HP | 147 | 146.801 | 124.507 | Standardized Diff. of Means | 0.55 | Z |
| Des2 | Superiority | 4 | 2-Sided | 0.04 | 0.901 | 1 | Unequal | HP | 148 | 147.799 | 125.148 | Standardized Diff. of Means | 0.55 | Z |
| Des3 | Superiority | 1 | 2-Sided | 0.04 | 0.902 | 1 | | | 148 | | | Standardized Diff. of Means | 0.55 | Z |

The sample size for Des 2 and that of Des 3, the fixed sample plan, are nearly the same as shown above. This was the original motivation for Haybittle-Peto boundaries. They are easy to specify, permit interim looks with very little chance of stopping the trial, and resemble the fixed sample trial at the final look.

62.1.2 Use of the Generalized Haybittle-Peto boundaries in the SPARCL

trial

The Stroke Prevention by Aggressive Reduction in Cholesterol Levels (SPARCL) group of investigators conducted a large multi-center placebo-controlled trial to evaluate the safety and efficacy of High-Dose Avorstatin after Stroke or Transient Ischemic Attack (TIA) (SPARCL, 2006). The primary hypothesis of the study was that treatment with 80 mg of Avorstatin per day would reduce the risk of fatal or non-fatal stroke among patients with a history of stroke or TIA. The study was designed to have a statistical power of 90% to detect an absolute one third increase in the primary endpoint (time to first fatal or non-fatal stroke) in the Avorstatin group as compared with the placebo group during a median follow-up of five years with a two-sided significance level of 5%. The assumed annual rate in the placebo group was 3.5% or a cumulative survival rate of 96.5%. Seven interim analyses of efficacy were planned with a stopping boundary corresponding to a two-sided significance level of $p_1 = 0.0001$ for the first analysis and $p_j = 0.001, j = 2, \dots, 7$ thereafter. Patients were enrolled between September 1998 and March 2001 for a total of 4200 (implying an accrual rate of 140 patients per month).

Trial Design

Using the generalized Haybittle-Peto boundaries available in East, we will now design this trial.

Start East afresh. Click **Survival: Two Samples** on the **Design** tab and then click **Parallel Design: Logrank Test Given Accrual Duration and Accrual Rates**. Set the **Number of Looks** to 8, to generate a study with seven interim looks and a final analysis.

In the **Design Parameters** tab, select **Design Type** as **Superiority**, **Test Type** as **2-Sided**, and enter **Type I Error (α)** and **Power ($1-\beta$)** as 0.05 and 0.9, respectively. Leave the **# of Hazard Pieces** as 1, which implies that hazard rates remain constant overtime in both Avorstatin and placebo groups. Change the **Input Method** to **Cum. % Survival**. Tick the check box for **Hazard Ratio (Optional)**, select the radio-button for **Hazard Ratio (λ_t/λ_c)** and enter 0.75. Finally, the **Cum. % Survival (Control)**

62 Flexible Stopping Boundaries in East

should be 96.5 at 12 months. The **Design Parameters** tab should appear as below:

Design Type: Superiority Number of Looks: 8

Test Parameters Boundary Accrual / Dropouts

Test Type: 2-Sided # of Hazard Pieces: 1 Input Method: Cum. % Survival

Type I Error (α): 0.05 Hazard Ratio (Optional) Alternative

Power: 0.9 Hazard Ratio (λ_1/λ_2) 0.75

No. of Events: Computed Ratio of % Survivals at Period # 1 (S_1/S_2) 1.009

Allocation Ratio: 1 (n_1/n_2)

| | Cum. % Survival | |
|----|-----------------|-----------------|
| | Control | Treatment: Alt. |
| 12 | 96.5 | 97.363 |

Note: Period 1 hazard rates apply after time 12.

Variance of Log Hazard Ratio

Null Alternative

Move to the **Boundary Info** tab. Select **Haybittle Peto (p-value)** for **Boundary Family in Efficacy**, and the radio-buttons corresponding to the **Total Type I Error (α)**, and **Unequal p-values at looks**. Enter the p-value as 0.0001 for the first look, and 0.001 for the next six looks, and click **Recalc**. The **Boundary Info** tab should appear as below:

Test Parameters Boundary Accrual / Dropouts

Efficacy Futility

Boundary Family: Haybittle Peto (p-value)

Fix p-values at looks

Total Type I Error (α) Equal

Last Look p-value Unequal

Type I Error (α): 0.05

Spacing of Looks Equal Unequal

| Look # | Info. Fraction | Efficacy p-value |
|--------|----------------|------------------|
| 1 | 0.125 | 0.0001 |
| 2 | 0.250 | 0.001 |
| 3 | 0.375 | 0.001 |
| 4 | 0.500 | 0.001 |
| 5 | 0.625 | 0.001 |
| 6 | 0.750 | 0.001 |
| 7 | 0.875 | 0.001 |
| 8 | 1.000 | 0.0488 |

The p-value corresponding to the final look has been updated to 0.0488.

Finally, move to the **Accrual / Dropout Info** tab. Select 1 for **# of Accrual Periods**, and enter 140 in the **Accrual Rate** column, and change the **Comtd.** number of subjects to 4200.

| Accrual | | | |
|--|------|--------|------------|
| | Min. | Comtd. | Sugg. Max. |
| <input type="radio"/> Duration: | 3.65 | 30 | 54.221 |
| <input checked="" type="radio"/> Subjects: | 511 | 4200 | 7591 |

Click **Compute**. Select Des 1 in **Output Preview** and click the  icon. This will

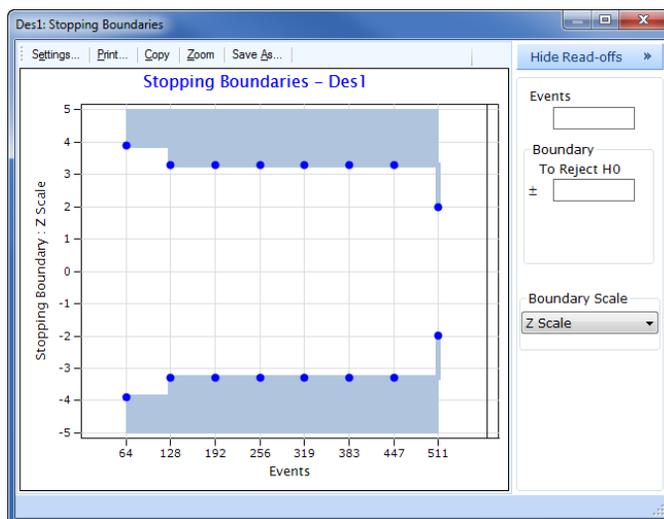

62 Flexible Stopping Boundaries in East

display the design details in the **Output Summary**.

| Maximum | 30 |
| Expected Under H0 | 29.994 |
| Expected Under H1 | 29.821 |

According to this design, 511 events are needed to appropriately power the study. Select Des 1 in **Output Summary**, click  , and select **Stopping Boundaries**.

The boundaries on the Z-scale are shown below:

62.2 Power Boundaries

62.2.1 Wang-Tsiatis Boundaries

62.2.2 Pampallona-Tsiatis Boundaries

East provides two types of power boundaries – Wang-Tsiatis boundaries (Wang and Tsiatis, 1987) for early rejection of H_0 , and Pampallona-Tsiatis boundaries (Pampallona and Tsiatis, 1994) for early rejection of H_0 or H_1 .

62.2.1 Wang-Tsiatis Boundaries

The Wang-Tsiatis boundaries permit early stopping to reject H_0 . They are used to stop a trial early for efficacy only (1-sided boundaries), safety only (1-sided boundaries) or to stop early either for efficacy or safety (two-sided case).

Group sequential boundaries of this type were first proposed by Pocock (1977) and O’Brien and Fleming (1979). Subsequently Wang and Tsiatis (1987) incorporated both the Pocock and O’Brien-Fleming boundaries into a family of “power boundaries” characterized by a shape parameter Δ . For a K -look group sequential trial the power boundary for the standardized test statistic Z_j at look j is of the form

$$c_j = C(\Delta, \alpha, K)t_j^{\Delta-0.5}, \quad j = 1, 2, \dots, K,$$

where $t_j = n_j/n_{\max}$, n_j is the sample size at look j , and n_{\max} is the maximum sample size we must commit up-front to this study in order to achieve the desired power. For technical details on the computation of $C(\Delta, \alpha, K)$ refer to Appendix B. The study is terminated, and the null hypothesis rejected, the first time that $Z_j > c_j$ for

62 Flexible Stopping Boundaries in East

one-sided tests and $|Z_j| > |c_j|$ for two-sided tests. The constant $C(\Delta, \alpha, K)$ is computed by recursive integration as described in Appendix F. When $\Delta = 0$, the stopping boundaries decrease in proportion to the square root of the current information fraction, these are the O'Brien-Fleming boundaries. When $\Delta = 0.5$, the stopping boundaries are constant at each look, these are the Pocock boundaries.

East permits shape parameters in the range $-0.5 < \Delta < 0.5$. The smaller the value of Δ , the more difficult it is to stop the trial at an interim look. The maximum sample size requirements increase progressively with increasing values of the shape parameter Δ . On the other hand, the expected sample sizes under the alternative hypothesis decrease with increasing values of Δ . Depending on availability of patients and the importance to the trial sponsor of trading off a larger maximum sample size commitment in exchange for a smaller expected sample size, one can select an appropriate value of Δ .

62.2.2 Pampallona-Tsiatis Boundaries

The Wang-Tsiatis power boundaries were developed for early stopping to reject H_0 . Subsequently Pampallona and Tsiatis (1994) extended these power boundaries to cover the case of early stopping to reject either H_0 or H_1 . The Pampallona-Tsiatis boundaries are characterized by two shape parameters, Δ_1 for the boundaries that facilitate early rejection of H_0 and Δ_2 for the boundaries that facilitate early rejection of H_1 . At the j th look the boundaries for early stopping to reject of H_0 are of the form

$$c_j = C_1(\Delta_1, \alpha, \beta, K),$$

and the boundaries for early stopping to reject H_1 are of the form

$$c_j = C_2(\Delta_2, \alpha, \beta, K) - \delta_1 \sqrt{n_j}$$

where $1 - \beta$ is the power and δ_1 is the treatment effect under H_1 . For technical details on the computation of $C_1(\cdot)$ and $C_2(\cdot)$ refer to Appendix B.

The one-sided version consists of a pair of boundaries that meet at the last look. In their most common application, one member of the pair facilitates stopping early for efficacy by rejecting H_0 and the other member facilitates stopping early for futility by rejecting H_1 . The two-sided version consists of a pair of outer boundaries and an inner wedge. Usually one outer boundary is for early stopping to reject H_0 in favor of efficacy and the other outer boundary is used for early stopping to reject H_0 and conclude that the new treatment is worse than the standard, hence that it is unsafe. If the test statistic enters the inner wedge, the alternative hypothesis H_1 is rejected and the trial stops for futility. We shall discuss efficacy, safety and futility stopping boundaries in greater detail in the next section where we introduce the spending function boundaries.

62.3 Spending Function Boundaries

The most general way to generate stopping boundaries is through α - and β -spending functions. The idea of using an α -spending function to derive stopping boundaries for early rejection of H_0 was first introduced in a landmark paper by Lan and DeMets (1983). Subsequently, Pampallona, Tsiatis and Kim (1995), (2001) developed the notion of a β -spending function to derive stopping boundaries for early rejection of H_1 . In East, one may use an α -spending function to generate efficacy, safety or non-inferiority boundaries and a β -spending function to generate futility boundaries. Also one may combine both α - and β -spending in a single trial, with one-sided or two-sided boundaries. All these options are discussed in the sections below. The theory underlying these spending functions is given in Appendix C.

62.3.1 The Alpha Spending Function

Suppose the type-1 error of a trial is fixed at α . An α -spending function is any monotone function of the information fraction $t \in [0, 1]$, with $\alpha(t) = 0$ and $\alpha(1) = \alpha$. The value $\alpha(t)$ may be interpreted as the probability, under H_0 , of crossing a stopping boundary by time t ; i.e., of committing a type-1 error by time t . Thus one can think of the α -spending function as a way of budgeting how the overall type-1 error is to be spent over the course of the trial.

Lan-DeMets Spending Functions

A conservative spending function will spend the type-1 error very sparingly in the beginning but will rapidly increase the pace of spending as the trial nears completion. An example of such a spending function, proposed by Lan and DeMets (1983) for two-sided tests, has the functional form

$$\alpha(t) = 4 - 4\Phi\left(\frac{z_{\alpha/4}}{\sqrt{t}}\right). \quad (62.1)$$

We shall see that this spending function generates stopping boundaries that are very similar to the O'Brien-Fleming boundaries. The function is displayed below. Notice how slowly the α is spent in the early phase of the trial. In East we use the mnemonic **LD (OF)** to denote this spending function where **LD** stands for Lan-DeMets and **OF** stands for O'Brien-Fleming.

Lan and DeMets (1983) proposed the following function for spending the type-1 error more aggressively.

$$\alpha(t) = \alpha \ln\{1 + (e - 1)t\} \quad (62.2)$$

This function is displayed below. Notice that it is a concave function. We shall see that this function generates stopping boundaries that closely resemble the Pocock boundaries. In East we use the mnemonic **LD (PK)** to denote this spending function where **LD** stands for Lan-DeMets and **PK** stands for Pocock.

62 Flexible Stopping Boundaries in East

At any time t that an interim look is taken, it is possible to invert the corresponding value of the $\alpha(t)$ and thereby generate the stopping boundary. Suppose, for instance, that a study is designed for two interim looks and one final look, at information fractions t_1, t_2 and $t_3 = 1$, not necessarily equally spaced. The two-sided symmetric boundary $\pm c_1$ at look-1 is obtained as the solution to

$$P_0(|Z(t_1)| \geq |c_1|) = \alpha(t_1)$$

Having already utilized $\alpha(t_1)$ of the total available error to compute c_1 , one can generate c_2 recursively as the solution to

$$\alpha(t_1) + P_0(|Z(t_1)| < |c_1|, |Z(t_2)| \geq |c_2|) = \alpha(t_2)$$

At the time of the last look, we will have utilized $\alpha(t_2)$ of the total available error and will know the values of the first two stopping boundaries, c_1 and c_2 . Thus, the final stopping boundary, c_3 , is obtained recursively as the solution to

$$\alpha(t_2) + P_0(|Z(t_1)| < |c_1|, (|Z(t_2)| < |c_2|, |Z(t_3)| \geq |c_3|) = \alpha.$$

Notice from the above that the probability of crossing a boundary for the first time at either the first, second or third looks is

$$\alpha(t_1) + [\alpha(t_2) - \alpha(t_1)] + [\alpha - \alpha(t_2)] = \alpha \quad (62.3)$$

In other words, this strategy for generating the stopping boundaries is guaranteed to preserve the type-1 error.

We will now see how to obtain stopping boundaries in East based on α spending. Suppose we want to generate two-sided stopping boundaries based on three equally spaced looks, derived from the **LD (OF)** spending function specified by equation (62.1).

Start East afresh. Click **Continuous: Two Samples** on the **Design** tab, and then click **Parallel Design: Difference of Means**. Change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. Accept the default values in **Design Parameters** tab. Move to the **Boundary Info** tab. Select **Spending Functions** for **Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in **Efficacy** box. In the **Futility** box, select **None** for **Boundary**

Family. Stopping boundaries will be displayed in the table below in this tab.

Design Parameters
Boundary Info

| 1 | 0.333 | 0.000 | 3.710 |
| 2 | 0.667 | 0.006 | 2.511 |
| 3 | 1.000 | 0.025 | 1.993 |

Click the  icon. This will show the boundary chart on the Z scale.

The stopping boundaries closely resemble the O’Brien-Fleming boundaries discussed in Section 62.2.1. East allows us to see stopping boundaries on different scales: Select from different options in the drop-down list under **Boundary Scale**.

Now compare these charts with those from Pocock-like boundaries. Change the

62 Flexible Stopping Boundaries in East

Parameter to **PK** in **Boundary Info** tab, and click  . The stopping boundaries derived from the **LD (PK)** spending function specified by equation (62.2) closely resemble the Pocock stopping boundaries.

Although one usually specifies the number and timing of the interim looks at the design stage, it might not be administratively convenient to adhere to these two design parameters at the interim monitoring stage. The great appeal of the spending function approach for regulatory purposes is that it gives us the freedom to alter both the number and timing of the interim looks while still preserving the overall type-1 error, α . Suppose, for instance that we were to introduce an unplanned interim analysis in between the second and third looks. Thus, suppose that a total of four looks were taken, even though the study was designed for only three looks. Let these looks be taken at times t'_1, t'_2, t'_3 , and t'_4 , where these times need not be the same as any of the three time points t_1, t_2, t_3 specified at the design stage. If we use the above recursive method to compute the stopping boundaries c'_1, c'_2, c'_3 , and c'_4 at the four looks, the probability of crossing a stopping boundary must be

$$\alpha(t'_1) + [\alpha(t'_2) - \alpha(t'_1)] + [\alpha(t'_3) - \alpha(t'_2)] + [\alpha(t'_4) - \alpha(t'_3)] = \alpha(t'_4) \leq \alpha$$

For further details and for a discussion of how to compute sample size for a given power using spending function boundaries, refer to Appendix B.

Published Spending Function Families

Two single-parameter spending function families are available in East. One such family is the ρ -family (Kim and DeMets, 1987; Jennison and Turnbull, 2000) whose spending functions are given by

$$\alpha(t) = \alpha t^\rho, \quad \rho > 0. \tag{62.4}$$

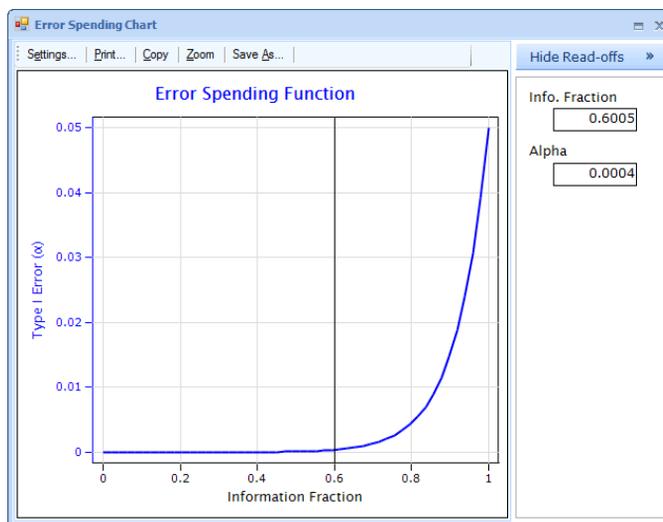

When $\rho = 1$, the corresponding stopping boundaries resemble the Pocock stopping boundaries. When $\rho = 3$, the boundaries resemble the O'Brien-Fleming boundaries. Larger values of ρ yield increasingly conservative boundaries.

Even greater flexibility is available through γ -family of spending functions (Hwang, Shih and DeCani, 1990) whose spending functions are given by

$$\alpha(t) = \begin{cases} \alpha \frac{(1-e^{-\gamma t})}{(1-e^{-\gamma})}, & \text{if } \gamma \neq 0 \\ \alpha t & \text{if } \gamma = 0. \end{cases} \tag{62.5}$$

Here negative values of γ yield convex spending functions that increase in conservatism as γ decreases, while positive values of γ yield concave spending

functions that increase in aggressiveness as γ increases. The choice $\gamma = 0$ spends the type-1 error linearly. The choice $\gamma = -4$ produces stopping boundaries that resemble the O'Brien-Fleming boundaries. The choice $\gamma = 1$ produces stopping boundaries that resemble the Pocock boundaries. The spending function below was produced with $\gamma = -12$.

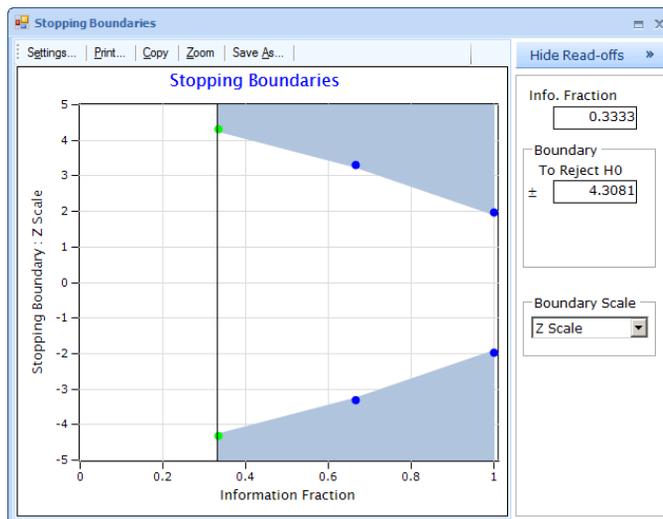

Notice that hardly any error is spent until the study has progressed 80% of the way through.

Below we display the 3-look stopping boundary on the standardized Z -statistic scale for a 2-sided design. Go to **Test Parameters** tab and change the **Test Type** to s-Sided, **Alpha** to 0.05. Also change the Spending Function to Gamma (-12) on **Boundary** tab. Notice that the test statistic must equal ± 4.3 standard deviations to stop at the first look and ± 3.32 standard deviations at the second look. This might be an appropriate stopping boundary for situations in which it is desirable to take interim looks primarily

62 Flexible Stopping Boundaries in East

for safety, but it is not desirable to stop the trial early for efficacy.

We stated that large values of γ result in spending functions that spend the error very aggressively. For example if we were to select $\gamma = 4$, we would obtain a spending function that is even more aggressive at the first look than the **LD (PK)** function

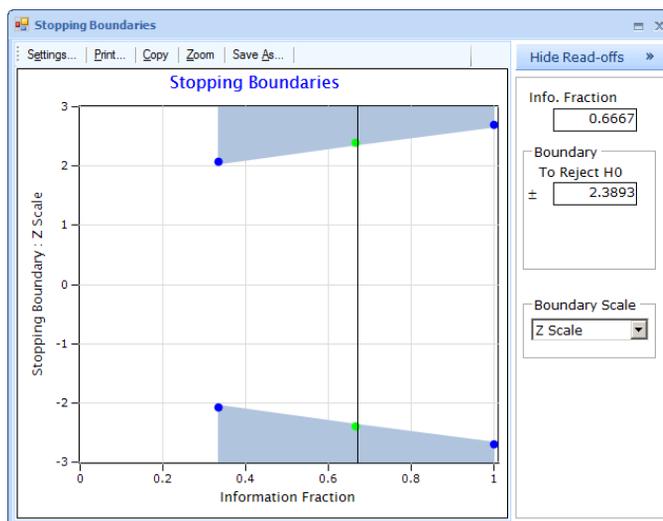

proposed by Lan and DeMets (1983).

The stopping boundaries generated by this spending function are displayed below. These boundaries actually widen over succeeding looks, unlike the Pocock boundaries that stay constant, or the O'Brien-Fleming boundaries that decrease. These might be

62 Flexible Stopping Boundaries in East

appropriate boundaries for stopping early for serious adverse events.

Interpolated Spending Functions

East permits users to specify arbitrary spending functions of their own choosing by defining the amount of α to be spent at various time points and interpolating linearly in between the time points. Interpolated spending functions can be used when it is of interest to use a published spending function and modify it. For instance, some trials use a truncated Lan and DeMets O'Brien-Fleming alpha spending function where the early boundary values are more aggressive than that generated by a regular Lan and DeMets (O'Brien-Fleming) alpha spending function. Suppose we want to take 4 equally spaced looks at the data and use a truncated Lan and DeMets O'Brien-Fleming boundary, which sets the first 2 boundary points close to each other.

Go back to **Test Parameters** tab. Change the **Number of Looks** to 4. In the **Boundary** tab, select **Spending Functions for Boundary Family**, **Lan-DeMets** for **Spending Function** and **OF** for **Parameter** in **Efficacy** box.

Choose **Spacing of Looks** as **Equal**.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|---------|
| | | | Upper | Lower |
| 1 | 0.25 | 0 | 4.3326 | -4.3326 |
| 2 | 0.5 | 0.0031 | 2.9631 | -2.9631 |
| 3 | 0.75 | 0.0193 | 2.3590 | -2.3590 |
| 4 | 1 | 0.05 | 2.0141 | -2.0141 |

The cumulative α spent in the second look is 0.0031. As we want to spend equal amount of α in the first two looks, the α to be spent in the first look is $0.0031/2 = 0.00165$. That is, we are looking for a interpolated spending function with 4 equally spaced looks like below:

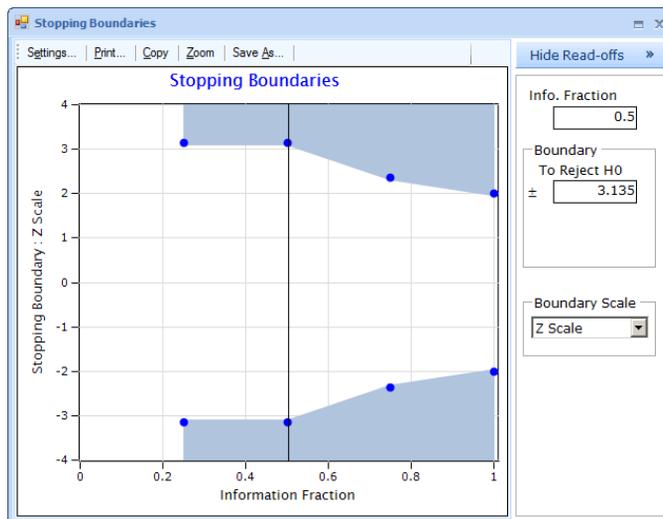

| t | $\alpha(t)$ |
|------|-------------|
| 0.25 | 0.00165 |
| 0.50 | 0.0031 |
| 0.75 | 0.0193 |
| 1.0 | 0.05 |

Change the **Spending Functions** to **Interpolated** and enter the values 0.00165, 0.0031 and 0.0193 in the first 3 cells of **Cum. α Spent**. Click **Recalc**.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|---------|
| | | | Upper | Lower |
| 1 | 0.25 | 0.00165 | 3.1469 | -3.1469 |
| 2 | 0.5 | 0.0031 | 3.1350 | -3.1350 |
| 3 | 0.75 | 0.0193 | 2.3698 | -2.3698 |
| 4 | 1 | 0.05 | 2.0169 | -2.0169 |

62 Flexible Stopping Boundaries in East

To see the stopping boundaries for this modified α -spending function, click .

These boundaries as you can observe are more aggressive at the first look than a regular Lan and DeMets O'Brien-Fleming boundary.

Spending the α Error Asymmetrically

It is sometimes desirable to spend the total type-1 error asymmetrically. Thus, suppose that we wish to split the total type-1 error, α , of a two-sided test into two components α_l and α_u , with $\alpha_l + \alpha_u = \alpha$ in such a way that the probability, under H_0 , of crossing the upper boundary is α_u and the probability, under H_0 , of crossing the lower boundary is α_l . The algorithm for constructing these asymmetric boundaries is given in Section B.2.4 of Appendix B.

We will now illustrate the use of these asymmetric two-sided α -spending function boundaries through an example. The CRASH trial (Lancet, 2004) was a very large multicenter clinical trial to determine the efficacy and safety of administering intravenous corticosteroids to subjects with significant head injury. Subjects with a Glasgow Coma Score of 14 or less were randomized to placebo or corticosteroids. The primary endpoint was death within 14 days. The public health implications of the conclusions from this study were expected to be significant. On the one hand, there was evidence from previous randomized studies that the use of corticosteroids is beneficial. On the other hand, evidence from meta-analysis suggested the possibility of

harm. The CRASH trial was intended to settle this issue. A large sample size was needed because any benefit was likely to be small. The risk of death in patients allocated to placebo was expected to be around 15%. Because even a 2% survival difference would be clinically important, the trial had to be large enough to detect a difference of this size. Accordingly, the trial planned to enroll a maximum of 20,000 patients. A sample size this large would be able to detect a 2% benefit with over 90% power while limiting the (two-sided) type-1 error to 0.01. A five-look group sequential design with a Lan-DeMets (O'Brien-Fleming) spending function was adopted since it would be desirable to terminate the trial early if a statistically significant result emerged.

First, click **Discrete: Two Samples** on the **Design** tab, and then click **Parallel Design: Difference of Proportions**. Change the **Number of Looks** to 5. In the **Design Parameters** tab, select **Superiority** as **Design Type** and **2-Sided (Asymmetric)** for **Test Type**. East will ask you to specify the upper and lower α . This is where we can specify that we wish to spend the total type-1 error asymmetrically. Suppose that we split the 0.01 type-1 error into two components each equal to 0.005. This implies that we are equally interested in detecting harm or detecting benefit. Therefore, enter 0.005 for both upper and lower α . Select the radio-button corresponding to **Power (1- β)** and enter 20000 for **Sample Size (n)**. Specify **Prop. under Control (π_c)** as 0.15 and **Prop. under Treatment (π_t)** as 0.13. The **Design Parameters** tab should appear as below:

Design Type: Superiority Number of Looks: 5

Test Parameters Boundary

Test Type: 2-Sided (Asymmetric)

Type I Error (α): Upper 0.005 Lower 0.005

Power: 0.9

Sample Size (n): Computed

Allocation Ratio: 1 (n_1/n_2)

Specify Proportion Response

Prop. under Control (π_c): 0.15

Specify Alternative Hypothesis

Prop. under Treatment (π_t): 0.13

Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): -0.02

Specify Variance

Pooled Estimate

Unpooled Estimate

Use Casagrande-Pike-Smith Correction (Ignored if alloc. ratio is not 1)

Click the **Boundary Info** tab. It is reasonable to suppose that if the corticosteroids are harmful, one would wish to detect this fact early in the trial, and terminate it before half of the 20,000 subjects are randomized to a harmful product. Therefore, one might prefer to spend the available type-1 error aggressively, using, say a Pocock type spending function, for the upper stopping boundary. On the other hand, if the corticosteroids are beneficial, it might be desirable to apply the more conservative O'Brien-Fleming type spending function for the lower stopping boundary so that

62 Flexible Stopping Boundaries in East

stronger evidence of benefit is obtained before the trial is terminated. Select **Spending Functions** for **Efficacy Boundary Family**. Choose **Lan-DeMets** as **Spending Function** in both **Upper Efficacy Boundary** and **Lower Efficacy Boundary** boxes. For **Parameter**, select **PK** and **OF** in **Upper Efficacy Boundary** and **Lower Efficacy Boundary** boxes, respectively.

Although the design requires an up-front commitment of 18,109 patients, if in fact the corticosteroids do reduce the mortality rate by 2%, then the trial is likely to terminate early with an expected sample size of 14246. To see the stopping boundaries, select this Design, click  in the **Output Summary** toolbar and then select **Stopping**

62 Flexible Stopping Boundaries in East

Boundaries.

The asymmetry in the lower and upper stopping boundaries ensures that if corticosteroids are harmful, this fact will be detected more quickly than would be the case with symmetric two sided boundaries.

62.3.2 The Beta Spending Function

Suppose we wish to design a group sequential trial with α as the type-1 error and β as the type-2 error; i.e., with $1 - \beta$ as the power. Just as we can use an α -spending function to generate efficacy boundaries, we can use a β -spending function to generate futility boundaries, or boundaries for early stopping in favor of the null hypothesis. The idea of designing trials with futility boundaries was developed by Pampallona and Tsiatis (1994). The further idea of using β -spending functions to create such boundaries both at the design and interim monitoring stages was developed by Pampallona, Tsiatis and Kim (2001). These boundaries are crossed with probability β under the alternative hypothesis. Moreover, the probability of crossing these boundaries increases as the treatment effect decreases towards the null hypothesis until, at the null hypothesis itself, the probability of crossing is $1 - \alpha$. Futility boundaries may be used either by themselves or in conjunction with efficacy boundaries. When an efficacy boundary and a futility boundary are both present in the same study, they are forced to meet at the last look, so that either H_0 is rejected or H_1 is rejected by the end of the study. Refer to Appendix B, Section B.2.4 for the technical details concerning the use of β -spending functions and the construction of futility boundaries.

Trials with Early Stopping for Efficacy or Futility

Consider a hypothetical two-arm hypertension clinical trial in which $X_{ic} \sim N(\mu_c, 1)$ is the blood pressure reduction for the i th subject in the control group, $X_{it} \sim N(\mu_t, 1)$ is the blood pressure reduction for the i th subject in the treatment group, and $\delta = \mu_t - \mu_c$. The trial should have 90% power to detect $\delta_1 = 0.3$ using a maximum of $K=5$ equally spaced looks, and we will assume that all measurements are made on a standardized scale so that $\sigma^2 = 1$. We wish to construct a one-sided level-0.025 test with both an efficacy and a futility boundary. These boundaries should be such that if H_1 is true ($\delta = \delta_1 = 0.3$) the upper efficacy boundary will be crossed with probability 0.9, whereas if H_0 is true ($\delta = 0$), the lower futility boundary will be crossed with probability $1 - 0.025 = 0.975$. The efficacy boundary is generated by specifying an α -spending function. The futility boundary is generated by specifying a β -spending function.

Start East afresh. First, click **Continuous: Two Samples** on the **Design** tab, and then click **Parallel Design: Difference of Means**. Change the **Number of Looks** to 5. In the **Design Parameters** tab, select **Superiority** as **Design Type** and **1-Sided** as **Test Type**. Select **Difference of Means** for **Input Method** and specify **Difference in Means ($\mu_t - \mu_c$)** as 0.3. Enter 1 for **Std. Deviation (σ)**. Enter values for **Type I Error (α)** and **Power (1- β)** as 0.025 and 0.9, respectively. The **Design Parameters** tab should appear as below:

Design Type: Superiority Number of Looks: 5

Test Parameters Boundary

Test Type: 1-Sided Input Method: Difference of Means Test Statistic: Z

Type I Error (α): 0.025

Power: 0.9

Sample Size (n): Computed

Allocation Ratio: 1 (n_t/n_c)

Diff. in Means ($\delta = \mu_t - \mu_c$): 0.3

Std. Deviation (σ): 1

Click the **Boundary Info** tab. In this tab, we must specify both the α - and β -spending functions. Select **Spending Functions** for **Boundary Family** in both **Efficacy** and **Futility** boxes. The next field asks you choose the type of spending function. There is complete flexibility to select any member of any of the four available spending function families (**Rho Family**, **Gamma Family**, **Lan-DeMets Family**, **Power Family**) for spending α and independently for spending β . Suppose we decide that we will use the **Gm (-8)** spending function for spending α and the **Gm (-4)** spending function for spending the β . This might be a good choice, for instance, if the sponsor wants to set a very high hurdle for early stopping for efficacy,

62 Flexible Stopping Boundaries in East

but wants to have a reasonable chance of pulling out early if the trial is going nowhere. Select **Gamma Family** as a type of **Spending Function** in both **Efficacy** and **Futility** boxes. Specify **Parameter (γ)** as -8 and -4 for efficacy and futility, respectively. Notice that in the **Futility** box you are given a further choice between **Binding** and **Non Binding** radio-buttons. The default selection is **Non Binding** and implies that the futility boundary will be constructed in such a way that it can be overruled if desired without inflating the type-1 error. This flexibility is important, since the sponsor or the data monitoring committee might well prefer to keep the trial going to gather additional information, despite crossing the futility boundary. A **Binding** futility boundary is generally not recommended. It interacts with the corresponding efficacy boundary in such a way that unless it is strictly enforced (i.e., unless the trial is terminated if the futility boundary is crossed) the type-1 error might be inflated. Thus, for the present, select the default **Non Binding** radio button. We will compare the operating characteristics of binding and non binding futility boundaries at the end of the present section. A more detailed technical discussion is available in Appendix B, Section B.2.4. The **Boundary Info** tab will look as shown below:

Test Parameters

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Cum. β Spent | Futility Boundary |
|--------|----------------|-------------------------------------|-------------------------------------|---------------------|-------------------|--------------------|-------------------|
| 1 | 0.200 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.000 | 3.989 | 0.002 | -1.362 |
| 2 | 0.400 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.000 | 3.581 | 0.007 | -0.436 |
| 3 | 0.600 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.001 | 3.121 | 0.019 | 0.384 |
| 4 | 0.800 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.005 | 2.596 | 0.044 | 1.169 |
| 5 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.025 | 1.971 | 0.100 | 1.971 |

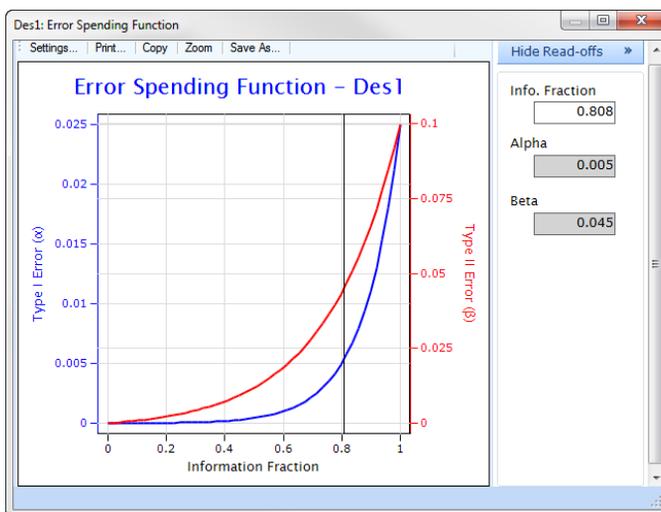

Note - In the **Spacing of Looks** table of the **Boundary Info** tab, notice that there are ticked checkboxes under the columns **Stop for Efficacy** and **Stop for Futility**. East gives you the flexibility to remove one of the stopping boundaries at certain looks, subject to the following constraints: (1) both boundaries must be included at the final two looks, (2) at least one boundary, either efficacy or futility, must be present at each look, (3) once a boundary has been selected all subsequent looks must include this boundary as well and (4) efficacy boundary for the penultimate look cannot be absent.

Click **Compute**. Select Des 1 by clicking anywhere along the row in the **Output Preview** and click the icon to save this design in the **Library**. Select Des 1 in

Output Preview or in **Library** and click the  icon. This will display the design details in the **Output Summary**.

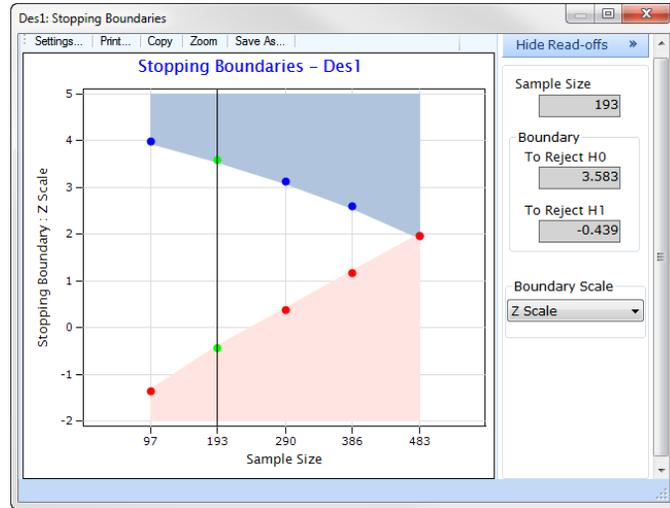

| Des 1 | |

To see the spending functions, click on the  icon from the **Output Summary** toolbar and then select **Error Spending**.

62 Flexible Stopping Boundaries in East

Notice how much slower the **Gm (-8)** function spends the α error than the **Gm (-4)** function spends the β error. Close the spending function chart and select **Stopping Boundaries** after clicking on the  icon.

An important feature of the stopping boundaries in Des 1 is that they meet at the final look. East forces this property on all **H0 or H1** boundaries. The computational details are given in Appendix B. By forcing the boundaries to meet, one is guaranteed to decide to either reject H_0 or reject H_1 . There is no area of indecision. This leads to a slight increase in the maximum sample size relative to a boundary corresponding to H_0 rejection. For comparison purposes, create a new design by right-clicking Des 1 in the **Library**, and clicking  icon. Go to the **Boundary Info** tab and change the **Boundary Family** to **None** in the **Futility** box. Click **Compute**. Select both Des 1

and Des 2 in the **Output Preview** and click .

For a very small increase in the up-front sample size commitment, Des 1 produces about the same saving in expected sample size as Des 2 if $\delta = 0.3$ and a considerably larger saving if $\delta = 0$. Moreover, as stated earlier, the futility boundary of Des 1 is non-binding; it can be overruled whenever desired without causing the type-1 error to exceed α , and without decreasing the power. Thus, all in all, Des 1 would appear to be superior to Des 2.

Futility boundaries derived from β -spending functions were introduced initially by Pampallona, Tsiatis and Kim (1995), (2001). The boundaries proposed in those papers had the serious drawback of being mandatory or binding. They interacted with the corresponding efficacy boundaries in such a way that one could not overrule them without the risk of inflating the type-1 error. For this reason, they were not very practical. Data monitoring committees (DMCs) prefer to use group sequential boundaries as guidance rather than as mandatory stopping rules. Efficacy boundaries pose no difficulty in this regard. If an efficacy boundary is crossed but the DMC votes nevertheless to keep the trial going to gain some additional information (on a secondary endpoint, say), there might be some loss of power, but there is no risk of inflating the type-1 error. Futility boundaries, as derived by Pampallona, Tsiatis and Kim (2001) are a different matter. They cannot be overruled without the risk of inflating the type-1 error. The modification to these boundaries that we have proposed

62 Flexible Stopping Boundaries in East

in Appendix B, Section B.2.4 overcomes this difficulty.

To compare non-binding and binding futility boundaries, create a new design by right-clicking Des 1 in the **Output Preview**, and clicking  icon. Go to the **Boundary Info** tab, and select the radio button corresponding to **Binding** in the **Futility** box, and click **Compute**. Select both Des 1 and Des 3 and click .

Des 3 is very similar to Des 1 in terms of maximum and expected sample sizes. The two designs differ in one important respect, however. The upper efficacy boundary of Des 3 is different from the upper efficacy boundary of Des 1, whereas the upper efficacy boundary of Des 1 is identical to the upper efficacy boundary of Des 2. Thus, the attained α for Des 1 is slightly lower than the specified α : the futility boundary will capture a small proportion of trials that would otherwise have crossed the efficacy boundary as type-1 errors.

Trials with Early Stopping for Futility Only

Let us consider, once again, the hypertension clinical trial introduced at the beginning of the ongoing subsection. Suppose the trial is designed for a test of $H_0 : \mu_t - \mu_c = 0$ at one-sided significance level $\alpha = 0.025$ and 90% power at the alternative hypothesis $H_1 : \mu_t - \mu_c = 0.3$ with an assumed variance $\sigma^2 = 1$. There will be five equally spaced looks at the data with a futility boundary for terminating the trial early with the declaration that H_0 cannot be rejected. The futility boundary is required to have the

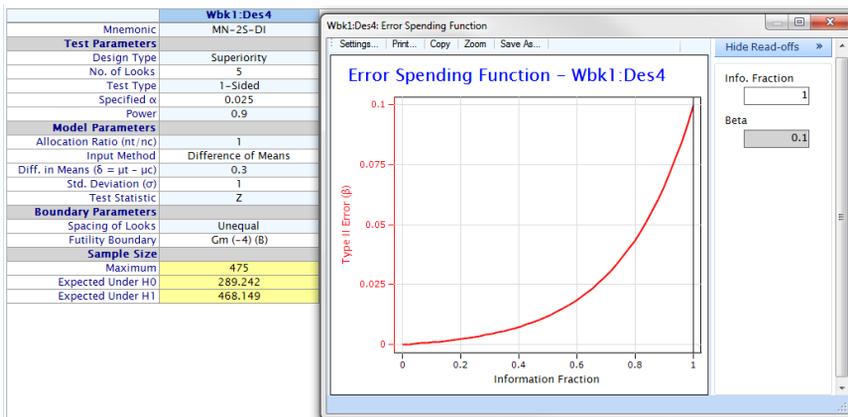

property that the overall boundary crossing probability under H_1 is 0.1. There is no intention to stop the trial early for efficacy.

Create a new design by right-clicking Des 1 in the **Library**, and clicking  icon. Go to the **Boundary Info** tab. In the **Efficacy** box, change the **Boundary Family** to **None** from the drop-down list. In the **Futility** box, set the **Boundary Family** to **Spending Function** and select **Gamma Family** in the ensuing field. Type in -4 as the value of **Parameter (γ)**. Select the radio-button corresponding to **Binding**.

| Look # | Info. Fraction | Cum. β Spent | Futility Boundary |
|--------|----------------|--------------------|-------------------|
| 1 | 0.200 | 0.0023 | -1.3742 |
| 2 | 0.400 | 0.0074 | -0.4538 |
| 3 | 0.600 | 0.0187 | 0.3621 |
| 4 | 0.800 | 0.0439 | 1.1437 |
| 5 | 1.000 | 0.1000 | 1.9370 |

Click **Compute** to obtain size for this 'Futility only' design. East will create this design with label Des 4. A summary of Des 4 and the associated β spending function are displayed below.

62 Flexible Stopping Boundaries in East

Edit Des 4 to create a corresponding a **Single-look** study (Des 5), designed for the same effect size, type-1 error and power. In Des 5, we are forced to continue until the maximum sample size is reached, unless it is terminated due to low conditional power. We have pointed out in Chapter 61 that use of low conditional power to terminate a trial early is rather ad hoc, and gives us no assurance that the overall unconditional power of the study will be preserved.

Des 5 requires a commitment of 467 patients. However, there is no option under Des 5 to stop the trial early if the effect size is smaller than was anticipated at the design stage. In contrast Des 4 requires an up-front commitment of 475 patients, five more than Des 5. But this is a small price to pay for the flexibility to take interim looks and stop early if the futility boundary is crossed. The expected sample size of Des 1 is 289 patients if H_0 is true.

63 Confidence Interval Based Design

During the design of an experiment such as a clinical trial, when researchers consider a hypothesis test for a parameter of interest, say δ , either the unknown sample size for the desired power or the unknown power for a fixed sample size must be determined. A confidence interval based design calculates the sample size based on the desired width of a confidence interval for the parameter of interest rather than the power of the hypothesis test. In previous versions of East, a user could employ a confidence interval based approach only via a labor intensive process of trial and error by generating repeated confidence interval charts. East now allows the computation of such a sample size for many single look designs based on analytical methods without the need to use such charts. The result is a quick and efficient way to compute the sample size required to achieve a desired width for a confidence interval for δ , given the confidence level $1 - \alpha$.

Definitions

- $1 - \alpha$ denotes the confidence level
- ω is the measure of precision for δ (width of confidence interval)
- $\hat{\delta}$ is the empirical estimate of δ

The estimated sample size n must satisfy the following:

For a two-sided confidence interval

$$P(\hat{\delta} - \omega \leq \delta \leq \hat{\delta} + \omega) = 1 - \alpha$$

For a one-sided confidence interval

$$P(\delta \geq \hat{\delta} - \omega) = 1 - \alpha$$

or

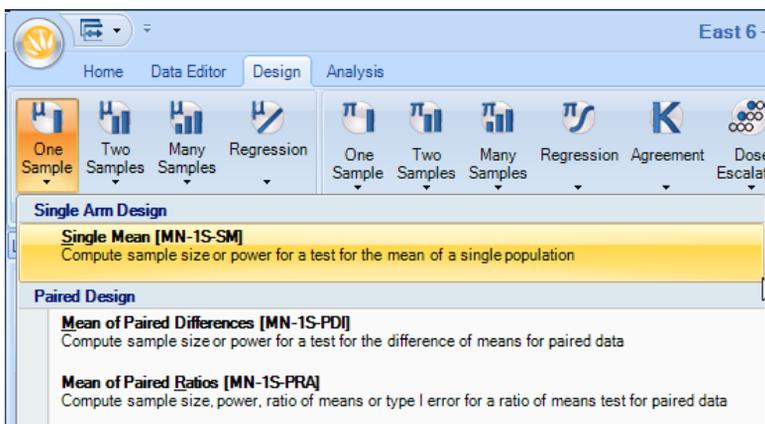

$$P(\delta \leq \hat{\delta} + \omega) = 1 - \alpha$$

63.1 One Sample Test for a Single Mean for Continuous Data

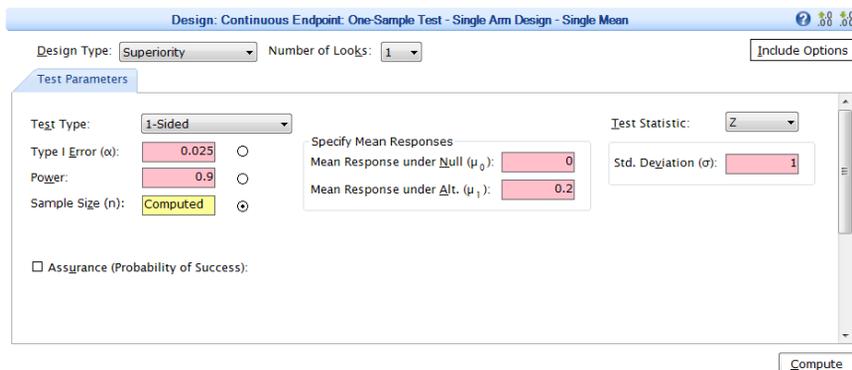

Consider the problem of comparing the mean of the distribution of observations from a single random sample of continuous data to a specified constant. Suppose it is required to estimate the sample size for obtaining a 95% two-sided confidence interval for the population mean with a precision of 5 units, when the population standard deviation is known to be 20 units.

63 Confidence Interval Based Design

To illustrate this example, in East under the **Design** ribbon for **Continuous** data, click **One Sample** and then click **Single Arm Design: Single Mean** as shown:

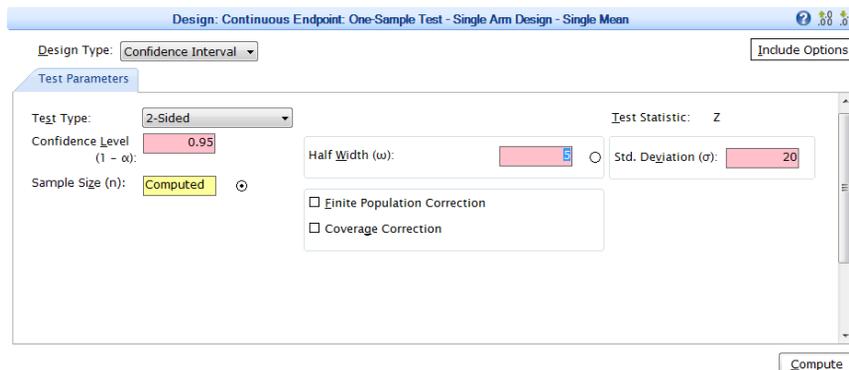

This will launch the following input window:

Choose **Confidence Interval** in the **Design Type** dropdown box and enter the following design parameters:

- Test Type: 2 sided
- Confidence Level ($1 - \alpha$): 0.95
- Sample Size (n): Computed (select radio button)
- Half Width (ω): 5.0
- Standard Deviation (σ): 20

The Confidence Interval based design for this particular test also allows the user to specify whether or not a **Finite Population Correction** for a fixed **Population Size** is used. In addition, the user can also determine if a **Coverage Correction** is to be used for a given **Coverage Probability**. This coverage correction may become necessary when the population standard deviation is unknown and is to be estimated from the sample. For now leave these boxes unchecked and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

| ID | Design Type | Test Type | Sample Size | ω | $(1 - \alpha)$ | σ | Test Statistic |
|------|---------------------|-----------|-------------|----------|----------------|----------|----------------|
| Des1 | Confidence Interval | 2-Sided | 62 | 5 | 0.95 | 20 | Z |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design summary will be displayed labeled **Output**

63 Confidence Interval Based Design

Summary.

| Des 1 | |
|-----------------------------|---------------------|
| Mnemonic | MN-1S-SM |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 2-Sided |
| Confidence Level | 0.95 |
| Model Parameters | |
| Width (ω) | 5 |
| Std. Deviation (σ) | 20 |
| Test Statistic | Z |
| Sample Size | |
| Maximum | 62 |

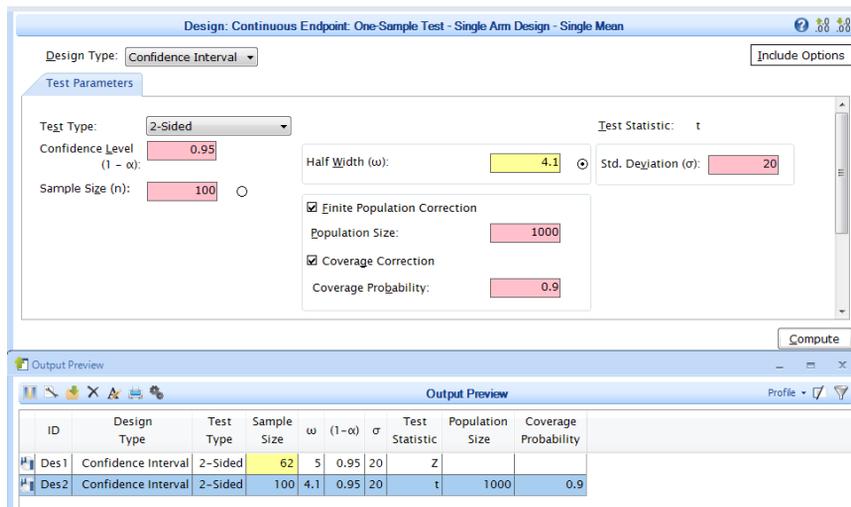

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for ω and σ , as well as any desired differences in **Population Size** and **Coverage Probability**.

| | |
|--|-----------------------------------|
| <input checked="" type="checkbox"/> Finite Population Correction | |
| Population Size: | <input type="text" value="1000"/> |
| <input checked="" type="checkbox"/> Coverage Correction | |
| Coverage Probability: | <input type="text" value="0.9"/> |

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 100$.

Enter the following in the **Design Input** screen and click **Compute**:

Test Type: 2 sided
 Confidence Level ($1 - \alpha$): 0.95
 Sample Size (n): 100
 Half Width (ω): Computed (select radio button)
 Standard Deviation (σ): 20

The precision parameter ω is calculated to be 4.1. As the sample size is increased the resulting estimate of precision increases, which is to say the precision limit decreases, providing a tighter confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East.

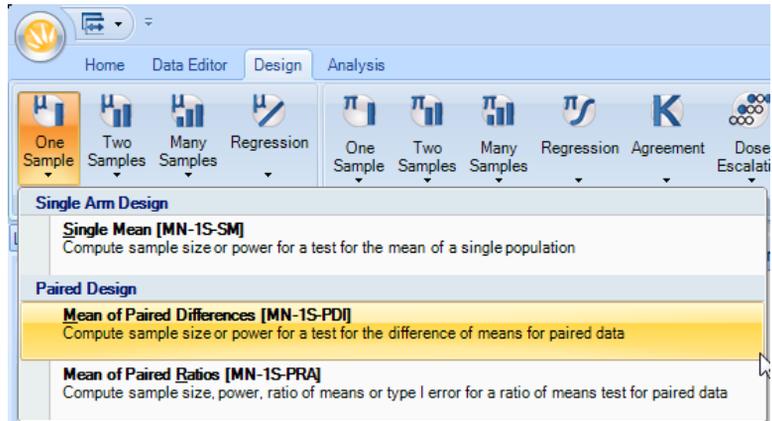

63.2 One Sample Test for the Mean of Paired Differences for Continuous Data

Consider the problem of comparing the means of two normal distributions when each observation in the random sample from one distribution is matched with a unique observation from the other distribution. Suppose it is required to estimate the sample size for obtaining a 99% two-sided confidence interval for the difference of means with a precision of 1.0 units, when the population standard deviation is known to be 3.4 units.

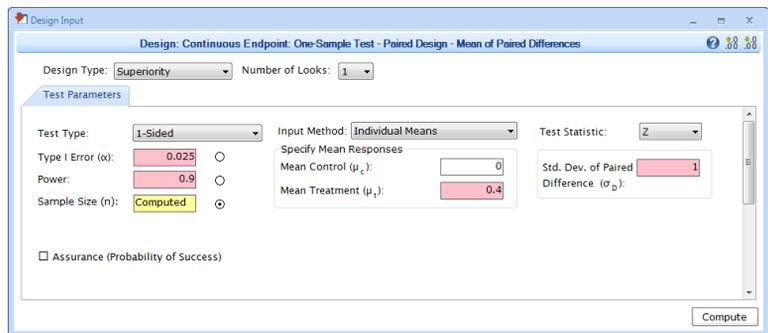

To illustrate this example, in East under the **Design** ribbon for **Continuous** data, click

63 Confidence Interval Based Design

One Sample and then click **Paired Design: Mean of Paired Differences** as shown:

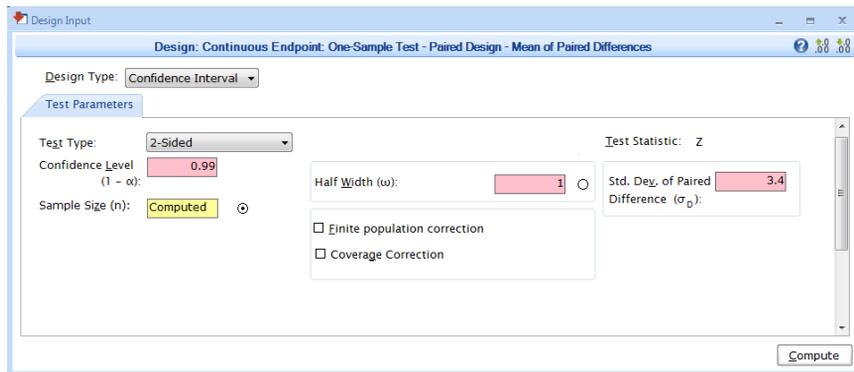

This will launch the following input window:

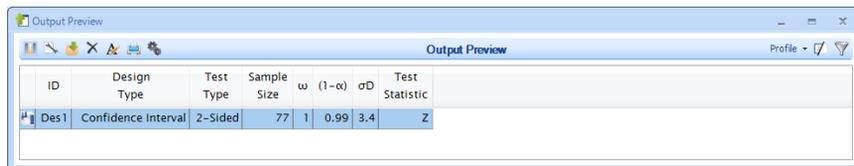

Choose **Confidence Interval** in the **Design Type** dropdown box and enter the following design parameters:

- Test Type: 2 sided
- Confidence Level ($1 - \alpha$): 0.99
- Sample Size (n): Computed (select radio button)
- Half Width (ω): 1.0
- Standard deviation of Paired Difference (σ_D): 3.4

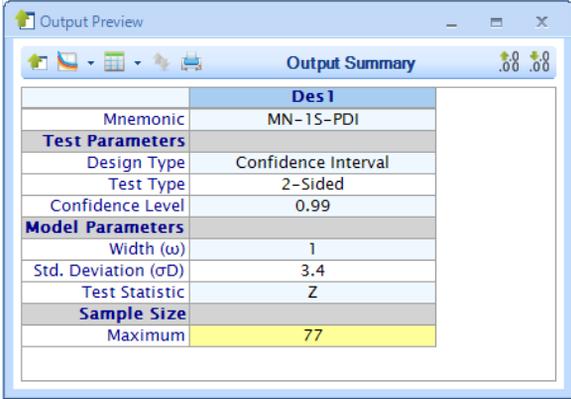

The Confidence Interval based design for this particular test also allows the user to specify whether or not a **Finite Population Correction** for a fixed **Population Size** is used. In addition, the user can also determine if a **Coverage Correction** is to be used for a given **Coverage Probability**. This coverage correction may become necessary when the population standard deviation is unknown and is to be estimated from the sample. For now leave these boxes unchecked and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

63 Confidence Interval Based Design

Summary.

| Des 1 | |
|-------------------------------|---------------------|

| Std. Deviation (σ_D) | 3.4 |
| Test Statistic | Z |
| Sample Size | |
| Maximum | 77 |

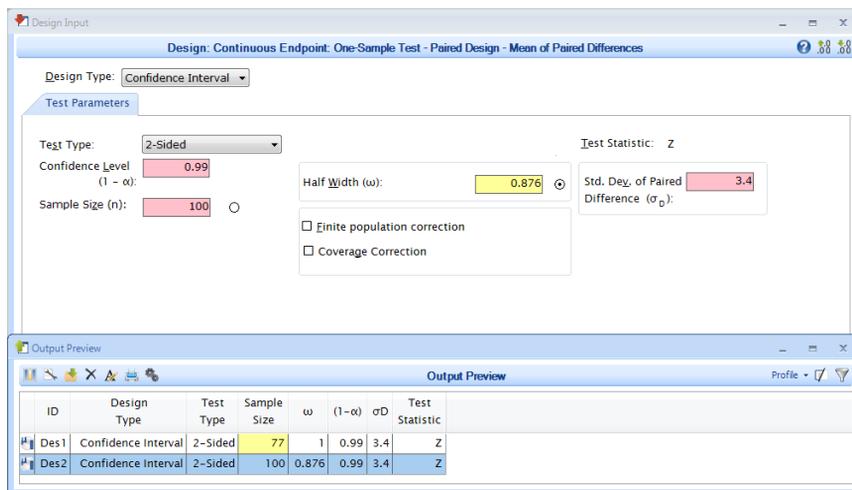

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for ω and σ_D , as well as any desired differences in **Population Size** and **Coverage Probability**.

| | |
|--|-----------------------------------|
| <input checked="" type="checkbox"/> Finite Population Correction | |
| Population Size: | <input type="text" value="1000"/> |
| <input checked="" type="checkbox"/> Coverage Correction | |
| Coverage Probability: | <input type="text" value="0.9"/> |

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 100$.

Enter the following in the **Design Input** screen and click **Compute**:

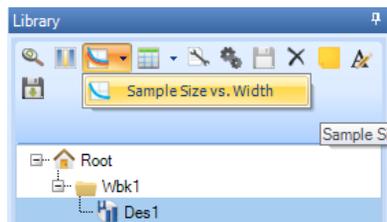

Test Type: 2 sided
 Confidence Level ($1 - \alpha$): 0.99
 Sample Size (n): 100
 Half Width (ω): Computed (select radio button)
 Standard deviation of Paired Difference (σ_D): 3.4

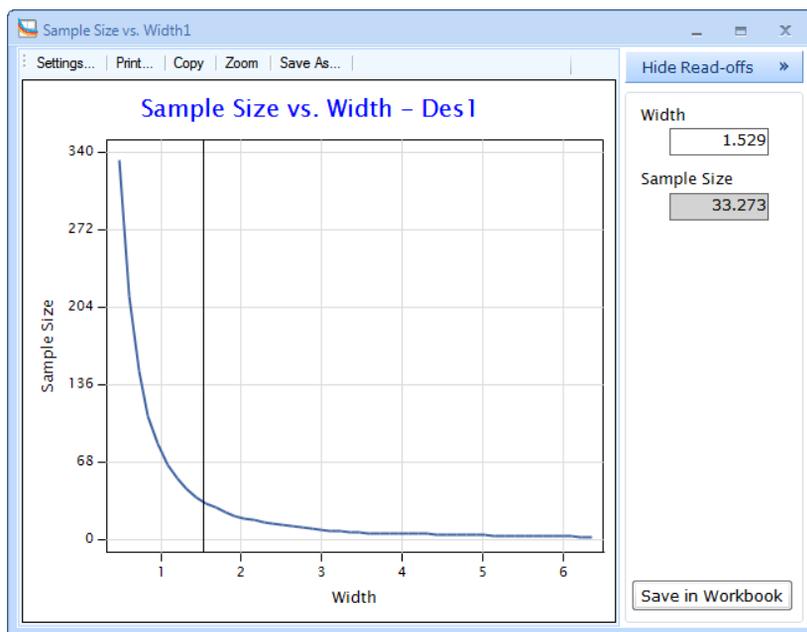

The precision parameter ω is calculated to be 0.876. As the sample size is increased the resulting estimate of precision increases, which is to say the precision limit decreases, providing a tighter confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From there, a summary of the design can be generated using the details  icon. East also provides a very useful **Sample Size vs. Width** plot. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. From the **Library** choose **Sample Size vs. Width** from the

63 Confidence Interval Based Design

Plots menu.

Here, the user can move the cursor horizontally back and forth to change the interval width and immediately view the resulting sample size.

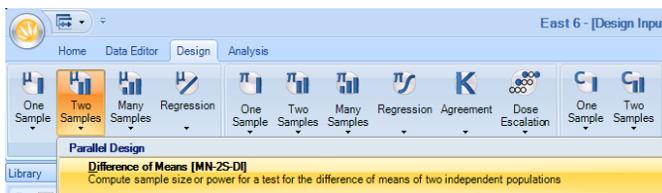

A table of **Sample Size vs. Width** values can be generated using the **Tables**  menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

63.3 Two Sample Test for the Difference of Means for Continuous Data

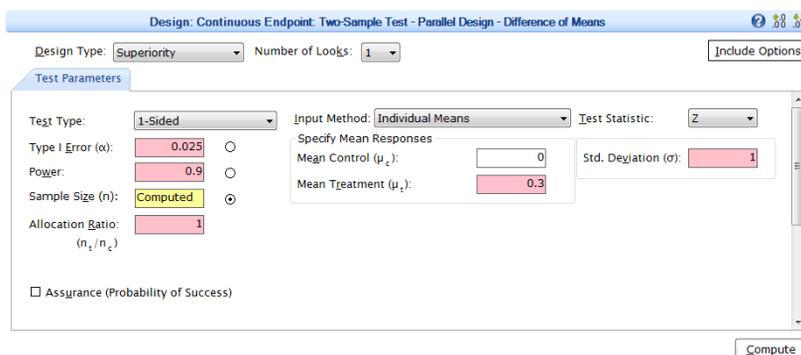

Consider the problem of comparing a new treatment to a standard protocol. It is often necessary to randomize subjects to the control and treatment arms, and then determine if the group-dependent means of the outcome variables are significantly different. The following example illustrates a confidence interval based design for such a trial when the outcomes from both groups follow a normal distribution.

Suppose it is required to estimate the sample size for obtaining a 95% two-sided confidence interval for the difference of two means with a precision of 3.0 units. Assume that the common standard deviation of the observations is 8.

In East under the **Design** ribbon for **Continuous** data, click **Two Sample** and then click **Parallel Design: Difference of Means** as shown:

This will launch the following input window:

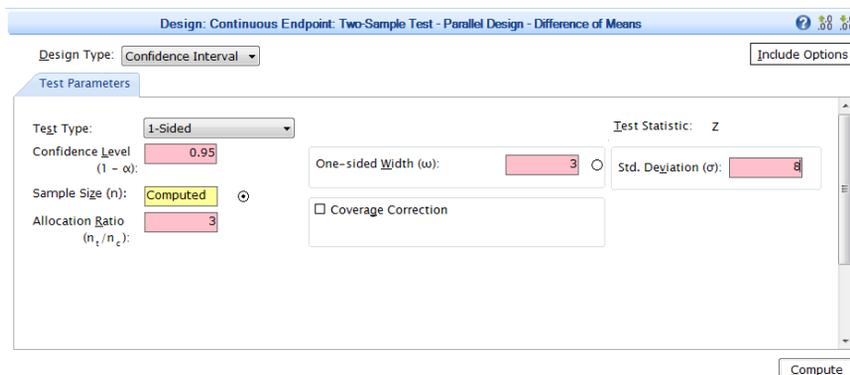

Choose **Confidence Interval** in the **Design Type** dropdown box. Consider a one sided test with 5% significance level, and an Allocation Ratio ($n_t : n_c$) of 3:1, that is, 75% of the patients are randomized to the treatment arm. Enter the following design

63 Confidence Interval Based Design

parameters:

Test Type: 1 sided
 Confidence Level ($1 - \alpha$): 0.95
 Sample Size (n): Computed (select radio button)
 Allocation Ratio: 3
 One-sided Width (ω): 3.0
 Standard Deviation (σ): 8

The Confidence Interval based design for this particular test also allows the user to specify whether or not a **Coverage Correction** is to be used for a given **Coverage Probability**. This coverage correction may become necessary when the population standard deviation is unknown and is to be estimated from the sample. For now leave this box unchecked and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

| ID | Design Type | Test Type | Sample Size | ω | $(1-\alpha)$ | σ | nt/nc | Test Statistic |
|------|---------------------|-----------|-------------|----------|--------------|----------|-------|----------------|
| Des1 | Confidence Interval | 1-Sided | 103 | 3 | 0.95 | 8 | 3 | Z |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

Summary.

| Des 1 | |
|-----------------------------|---------------------|
| Mnemonic | MN-2S-DI |
| Test Parameters | |

| Model Parameters | |
| Width (ω) | 3 |
| Std. Deviation (σ) | 8 |
| Allocation Ratio (nt/nc) | 3 |
| Test Statistic | Z |
| Sample Size | |
| Maximum | 103 |

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **Two-sided** confidence interval and with various values for **Allocation Ratio**, ω and σ , as well as any desired differences in **Coverage Probability**.

Coverage Correction
 Coverage Probability:

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 80$.

Enter the following in the **Design Input** screen and click **Compute**:

- Test Type: 1 sided
- Confidence Level ($1 - \alpha$): 0.95
- Sample Size (n): 80
- Allocation Ratio: 3
- One-sided Width (ω): Computed (select radio button)
- Standard Deviation (σ): 8

63 Confidence Interval Based Design

Design Input

Design: Continuous Endpoint: Two-Sample Test - Parallel Design - Difference of Means

Design Type: Confidence Interval

Test Parameters

Test Type: 1-Sided

Confidence Level (1 - α): 0.95

Sample Size (n): 80

Allocation Ratio (n_1/n_2): 3

One-sided Width (ω): 3.398

Std. Deviation (σ): 8

Test Statistic: Z

Coverage Correction

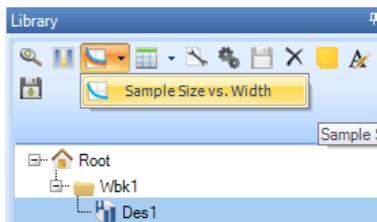

Output Preview

| ID | Design Type | Test Type | Sample Size | ω | (1- α) | σ | nt/nc | Test Statistic |
|------|---------------------|-----------|-------------|----------|----------------|----------|-------|----------------|
| Des1 | Confidence Interval | 1-Sided | 103 | 3 | 0.95 | 8 | 3 | Z |
| Des2 | Confidence Interval | 1-Sided | 80 | 3.398 | 0.95 | 8 | 3 | Z |

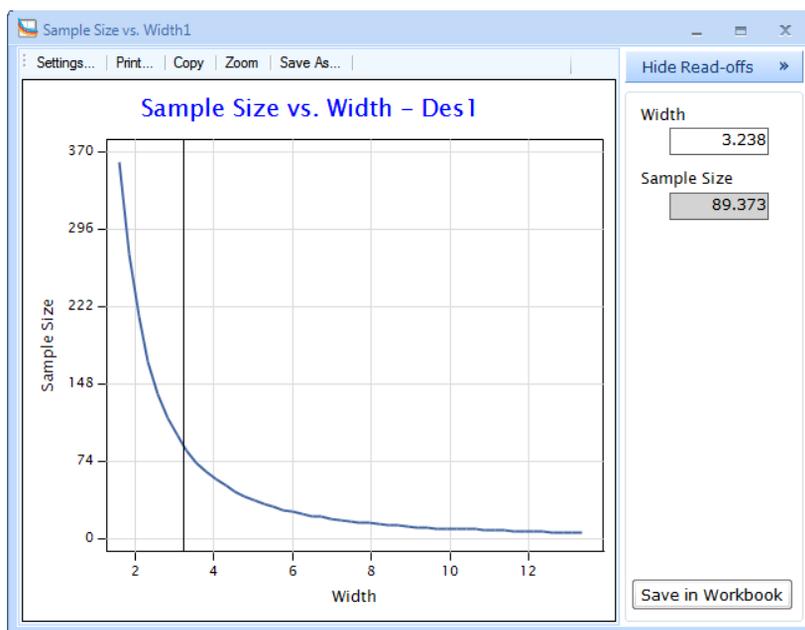

The precision parameter ω is calculated to be 3.398. As the sample size is decreased, the resulting value of ω increases. In other words, the precision limit increases, resulting in a wider confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From

there, a summary of the design can be generated using the details  icon. East also provides a very useful **Sample Size vs. Width** plot. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. From the **Library** choose **Sample Size vs. Width** from the **Plots**

menu.

Here, the user can move the cursor horizontally back and forth to change the interval width and immediately view the resulting sample size.

A table of **Sample Size vs. Width** values can be generated using the **Tables**  menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

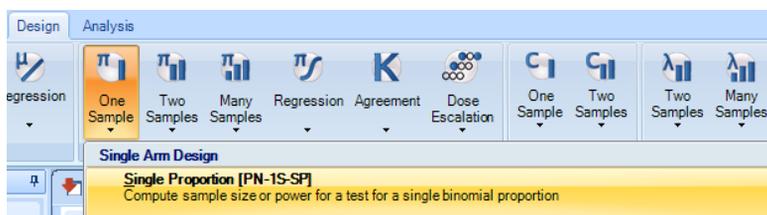

63 Confidence Interval Based Design

63.4 One Sample Test for a Single Binomial Proportion

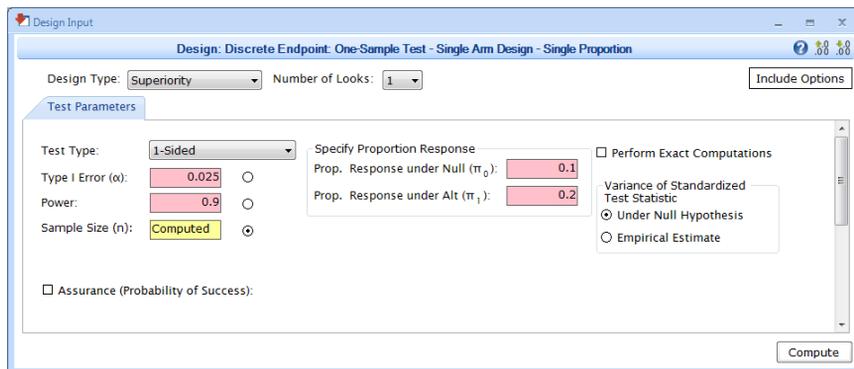

Consider the experimental situation in which an observed treatment response rate is compared to a fixed response rate derived from historical data, where the variable of interest has a binomial distribution. It is therefore of interest to determine whether the response rate π differs from a fixed value π_0 . The following example illustrates a confidence interval based design for a one arm trial having a binomial response rate, where a single binomial proportion is tested against a fixed value.

Suppose it is required to estimate the sample size to obtain a 95% two-sided confidence interval for π with a precision of 0.01 units. The sample size is determined for a specified value of π which is consistent with the alternative hypothesis, denoted π_1 . The design is a single-arm trial in which we wish to determine if the response rate of a new therapy is at least 15%. Thus, it is desired to test the null hypothesis $H_0: \pi = 0.15$ against the one-sided alternative hypothesis $H_1: \pi > 0.15$. Assume $\pi = \pi_1 = 0.25$ and a type one error rate of 0.05.

In East under the **Design** ribbon for **Discrete** data, click **One Sample** and then click **Single Arm Design: Single Proportion** as shown:

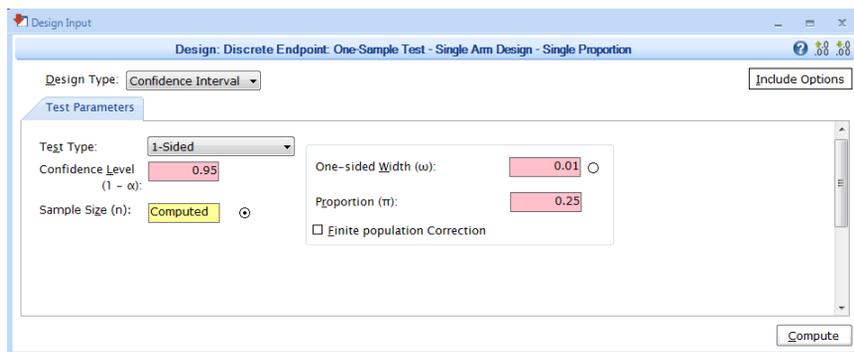

This will launch the following Design Input window:

Choose **Confidence Interval** in the **Design Type** dropdown box. Consider a one sided test with 5% significance level and fixed value of $\pi = 0.25$. Enter the following design parameters:

- Test Type: 1 sided
- Confidence Level $(1 - \alpha)$: 0.95
- Sample Size (n): Computed (select radio button)
- One-sided Width (ω): 0.01
- Proportion (π): 0.25

The Confidence Interval based design for this particular test also allows the user to specify whether or not a **Finite population Correction** is to be used for a given **Population Size**. For now leave this box unchecked and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output**

63 Confidence Interval Based Design

Preview window:

| ID | Design Type | Test Type | Sample Size | ω | $(1-\alpha)$ | Proportion (π) |
|------|---------------------|-----------|-------------|----------|--------------|----------------------|
| Des1 | Confidence Interval | 1-Sided | 5073 | 0.01 | 0.95 | 0.25 |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the icon in the Output Preview toolbar. The design details will be displayed, labeled **Output Summary**.

| Des 1 | |
|-------------------------|---------------------|
| Mnemonic | PN-1S-SP |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 1-Sided |
| Confidence Level | 0.95 |
| Model Parameters | |
| Width (ω) | 0.01 |
| Proportion (π) | 0.25 |
| Sample Size | |
| Maximum | 5073 |

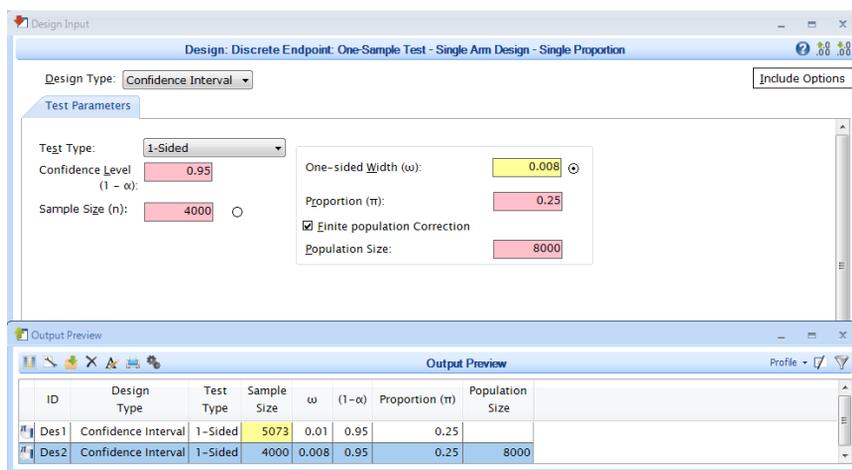

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the icon. This test can easily be repeated for a **Two-sided** confidence interval and with various values for ω and π , as well as any desired differences in **Finite Population Correction**.

| | | |
|--|-----------------------------------|-----------------------|
| Half Width (ω): | <input type="text" value="0.01"/> | <input type="radio"/> |
| Proportion (π): | <input type="text" value="0.25"/> | |
| <input checked="" type="checkbox"/> Finite population Correction | | |
| Population Size: | <input type="text" value="8000"/> | |

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 4000$ with a finite population correction of size 8000.

Enter the following in the **Design Input** screen and click **Compute**:

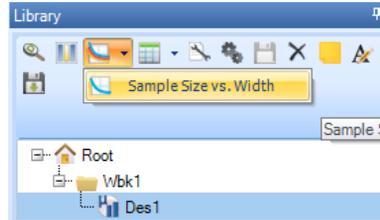

- Test Type: 1 sided
- Confidence Level ($1 - \alpha$): 0.95
- Sample Size (n): 4000
- One-sided Width (ω): Computed (select radio button)
- Proportion (π): 0.25
- Finite Population Correction: box checked
- Population Size: 8000

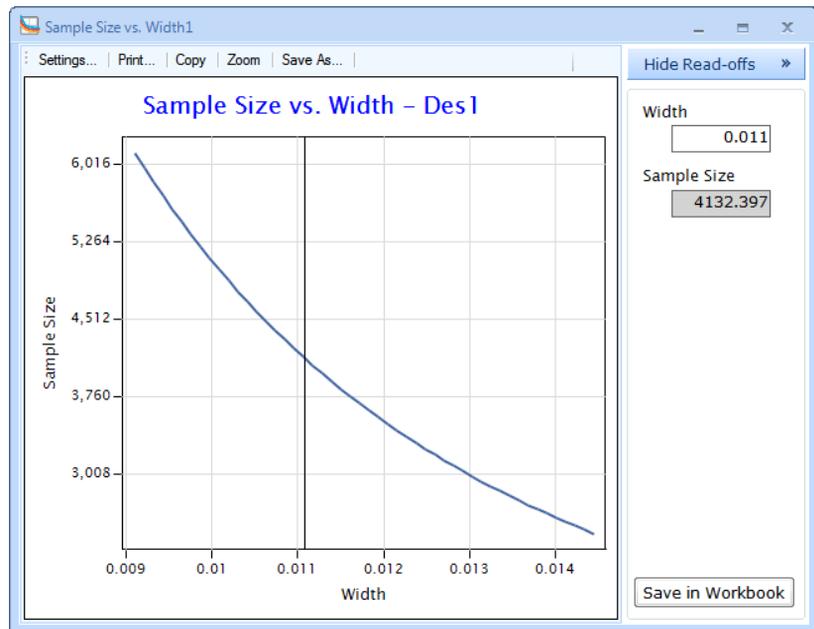

For a sample size of 4000 the precision parameter ω is calculated to be 0.008. As the sample size is decreased, the resulting value of ω decreases. For binomial data, this results in a wider confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From there, a summary of the design can be generated using the details  icon. East also provides a very useful **Sample Size vs. Width** plot. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the

63 Confidence Interval Based Design

confidence interval. From the **Library** choose **Sample Size vs. Width** from the **Plots** menu.

Here, the user can move the cursor horizontally back and forth to change the interval width and immediately view the resulting sample size.

A table of **Sample Size vs. Width** values can be generated using the **Tables**  menu, also found in the **Library**. This feature allows the user to input a range of

values to generate multiple confidence intervals and the corresponding sample sizes.

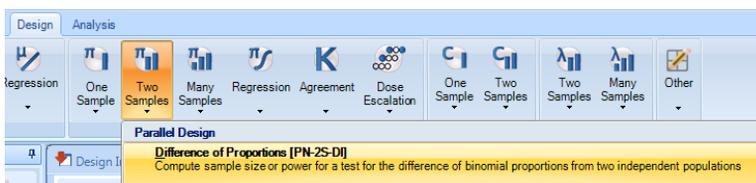

63.5 Two Sample Test for the Difference of Binomial Proportions

In medical research, outcomes dealing with the proportion of patients responding to a therapy, developing a certain side effect or requiring specialized care, are experiments based on binomial data designs. In these situations the goal is to compare independent samples from two populations in terms of the proportion of patients presenting the characteristic or outcome. East supports a Confidence Interval based approach to the design of clinical trials, independent of the power of the test, in which treatment comparison is based on the difference of such proportions.

For example, in a prospective randomized trial of placebo versus treatment for patients with a heart condition, the endpoint may be reduction in death or MI within a certain period of time after entering the study. It is of interest to detect a reduction in the event rate from 15% on the placebo arm to 10% on the treatment arm. In other words the goal is to test the null hypothesis that the treatment and placebo arms both have an event rate of 15%, versus the alternative that the treatment reduces the event rate by 5% (from 15% to 10%).

Let π_c and π_t denote the binomial probabilities for the control and treatment arms, respectively, and let $\delta = \pi_t - \pi_c$. The interest is therefore in testing the null hypothesis $H_0 : \delta = 0$, for a two-sided test with a type-1 error of 5%. Consider a confidence interval based design to estimate the sample size with a precision of $\omega = 0.05$.

In East under the **Design** ribbon for **Discrete** data, click **Two Samples** and then click **Parallel Design: Difference of Proportions** as shown:

63 Confidence Interval Based Design

[Compute]

The Allocation Ratio ($n_t : n_c$) describes the ratio of patients to each arm. For example, an allocation ratio of 3:1 indicates that 75% of the patients are randomized to the treatment arm as opposed to 25% to the control.

In binomial designs, the variance of a random variable is dependent on its mean. The maximum sample size required for a study will be affected by how the differences of binomial response rates are standardized when computing the test statistic, regardless of the other design parameters. There are two options for determining how the test statistic will be standardized, using either the **Unpooled** or **Pooled** specification for variance. The difference becomes important when planning a binomial study with unbalanced randomization. In this case, both pooled and unpooled designs should be considered and the one that produces a tighter confidence interval (measure of ω) with fewer patients should be chosen. This will depend on the response rates of the control and treatment arms as well as the value of the fraction assigned to the treatment arm. More information on this can be found in Section 23.1.

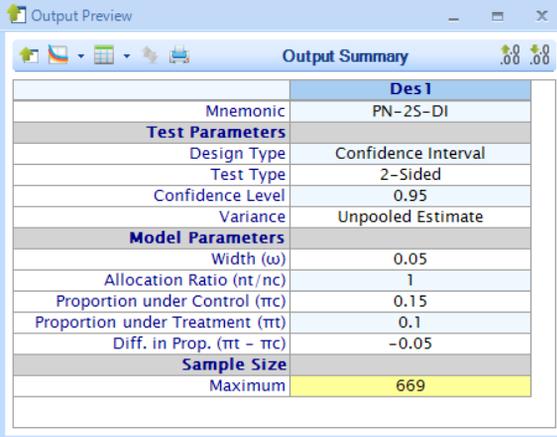

For this example, keep the default settings (Allocation Ratio = 1 and **Unpooled Estimate** selected) and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

| ID | Design Type | Test Type | Sample Size | ω | (1- α) | n_t/n_c | π_c | Prop. Treatment (Alt.) | δ_1 | Variance |
|------|---------------------|-----------|-------------|----------|----------------|-----------|---------|------------------------|------------|-------------------|
| Des1 | Confidence Interval | 2-Sided | 669 | 0.05 | 0.95 | 1 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

63 Confidence Interval Based Design

Summary.

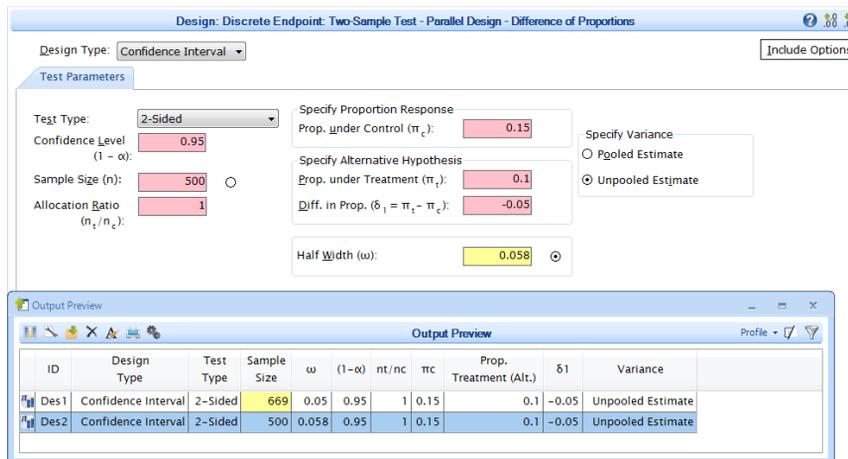

| Des 1 | |
|--|---------------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 2-Sided |
| Confidence Level | 0.95 |
| Variance | Unpooled Estimate |
| Model Parameters | |
| Width (ω) | 0.05 |
| Allocation Ratio (n_t/n_c) | 1 |
| Proportion under Control (π_c) | 0.15 |
| Proportion under Treatment (π_t) | 0.1 |
| Diff. in Prop. ($\pi_t - \pi_c$) | -0.05 |
| Sample Size | |
| Maximum | 669 |

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for ω , proportions of responses for treatment and control groups (π_t and π_c), and different specifications for variance estimates.

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 500$.

Enter the following in the **Design Input** screen and click **Compute**:

Test Type: 2 sided
 Confidence Level ($1 - \alpha$): 0.95
 Sample Size (n): 500
 Allocation Ratio (n_t/n_c): 1
 Prop. under Control (π_c): 0.15
 Prop. under Treatment (π_t): 0.10
 Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): -0.05 (this will be calculated)
 Half Width (ω): Computed (select radio button)
 Specify Variance: Select **Unpooled Estimate** radio button

For a sample size of 500 the precision parameter ω is calculated to be 0.058. As the sample size is decreased, the resulting value of ω slightly increases. For binomial data, this results in a wider confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From there, a summary of the design can be generated using the details  icon. East also provides a very useful **Sample Size vs. Width** plot, found in the plots  menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs. Width** values can be generated using the **Tables**  menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

63.6 Two Sample Test for the Ratio of Binomial Proportions

In experiments based on binomial data, independent samples from different populations are compared in terms of the proportion of participants presenting a particular trait or outcome of interest. For example, outcomes such as the proportion of

63 Confidence Interval Based Design

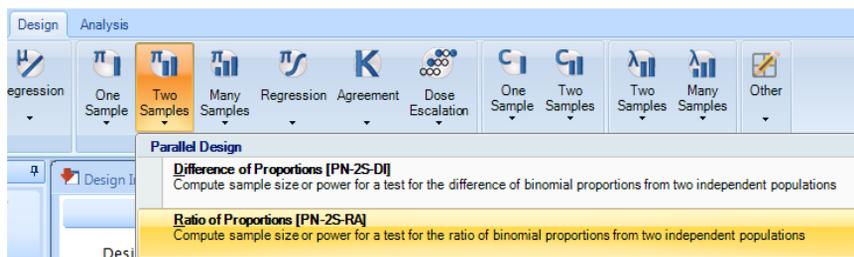

patients responding to a treatment, developing an adverse reaction, or requiring specialized care could be of interest in medical research. East supports a Confidence Interval based approach to the design of clinical trials in which this comparison is based on the ratio of proportions.

For example, consider a prospective randomized trial of a standard treatment (control arm) versus a new combination treatment (therapy arm) for patients with a heart condition, where the endpoint is either death or MI within a certain period of time after randomization. Suppose it is of interest to determine the sample size required for a trial to detect a 25% decline in the rate of such outcomes. It can be assumed that the control arm has a 30% event rate.

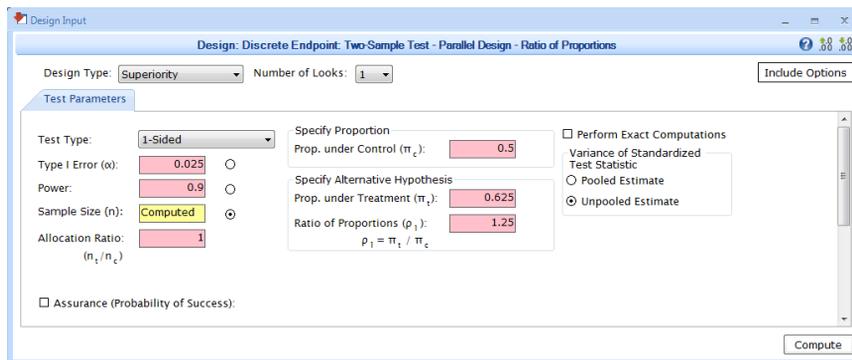

Let π_c and π_t denote the binomial probabilities for the control and treatment arms, respectively, and let $\rho = \pi_t/\pi_c$. Under H_0 , $\pi_t = \pi_c = 0.3$. A 25% decline in the event rate is thus $\rho = \pi_t/\pi_c = 0.75$. It is of interest to test the null hypothesis that $\rho = 1$ against one or two-sided alternatives. When dealing with ratios, it is mathematically more convenient to express this hypothesis in terms of the difference of the (natural) logarithms. Defining $\delta = \ln(\pi_t) - \ln(\pi_c)$ leads to the equivalent of testing $H_0: \delta = 0$. More information on this design can be found in Section 23.2

Consider a confidence interval based design of a two-arm study that compares the control arm to the combination therapy arm, where the sample size required for obtaining a 95% two-sided confidence interval for the ratio of proportions with a precision (width) of $\omega = 0.35$ must be determined.

In East under the **Design** ribbon for **Discrete** data, click **Two Samples** and then click **Parallel Design: Ratio of Proportions** as shown:

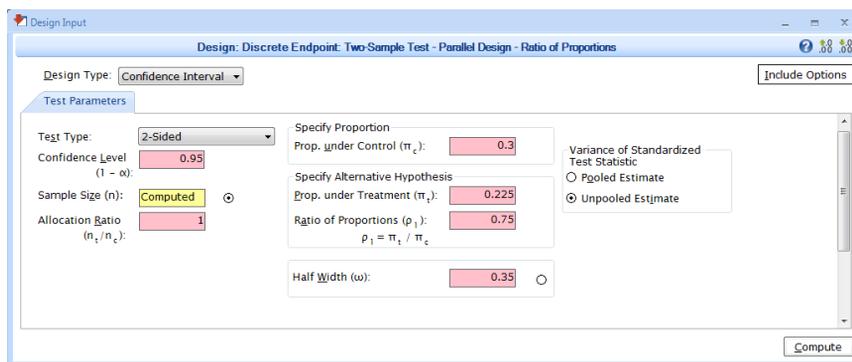

This will launch the following input window:

Choose **Confidence Interval** in the **Design Type** dropdown box and enter the following design parameters:

- Test Type: 2 sided
- Confidence Level $(1 - \alpha)$: 0.95
- Sample Size (n): Computed (select radio button)
- Allocation Ratio (n_t/n_c) : 1
- Prop. under Control (π_c) : 0.3
- Ratio of Proportions $(\rho_1 = \pi_t/\pi_c)$: 0.75
- Prop. under Treatment (π_t) : 0.225 (this will be calculated)
- Half-Width (ω) : 0.35
- Variance of Standardized Test Statistic: Select **Unpooled Estimate** radio button

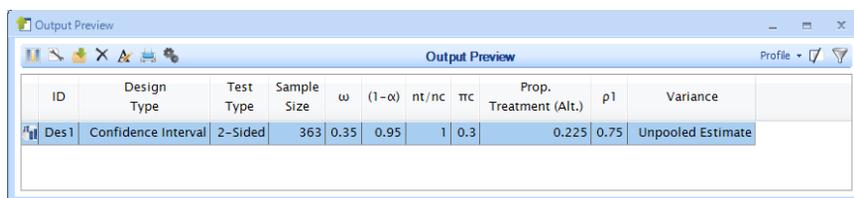

63 Confidence Interval Based Design

The Allocation Ratio ($n_t : n_c$) describes the ratio of patients to each arm. For example, an allocation ratio of 3:1 indicates that 75% of the patients are randomized to the treatment arm as opposed to 25% to the control.

In binomial designs, the variance of a random variable is dependent on its mean. The maximum sample size required for a study will be affected by how the differences of binomial response rates are standardized when computing the test statistic, regardless of the other design parameters. There are two options for determining how the test statistic will be standardized, using either the **Unpooled** or **Pooled** specification for variance. The difference becomes important when planning a binomial study with unbalanced randomization. In this case, both pooled and unpooled designs should be considered and the one that produces a tighter confidence interval (measure of ω) with fewer patients should be chosen. This will depend on the response rates of the control and treatment arms as well as the value of the fraction assigned to the treatment arm. More information on this can be found in Section 23.1.

For this example, keep the default settings (Allocation Ratio = 1 and **Unpooled Estimate** selected) and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

| ID | Design Type | Test Type | Sample Size | ω | (1- α) | nt/nc | π_c | Prop. Treatment (Alt.) | ρ_1 | Variance |
|------|---------------------|-----------|-------------|----------|----------------|-------|---------|------------------------|----------|-------------------|
| Des1 | Confidence Interval | 2-Sided | 363 | 0.35 | 0.95 | 1 | 0.3 | 0.225 | 0.75 | Unpooled Estimate |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

Summary.

| ID | Design Type | Test Type | Sample Size | ω | (1 - α) | nt/nc | π_c | Prop. Treatment (Alt.) | ρ_1 | Variance |
|------|---------------------|-----------|-------------|----------|-----------------|-------|---------|------------------------|----------|-------------------|
| Des1 | Confidence Interval | 2-Sided | 363 | 0.35 | 0.95 | 1 | 0.3 | 0.225 | 0.75 | Unpooled Estimate |
| Des2 | Confidence Interval | 2-Sided | 500 | 0.298 | 0.95 | 1 | 0.3 | 0.225 | 0.75 | Unpooled Estimate |

For a sample size of 500 the precision parameter ω is calculated to be 0.298. As the sample size is increased, the resulting value of ω slightly decreases. For binomial data, this results in a tighter confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From there, a summary of the design can be generated using the details icon. East also provides a very useful **Sample Size vs. Width** plot, found in the plots menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs. Width** values can be generated using the **Tables** menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

63.7 Two Sample Test for the Odds Ratio of Proportions

It is often of interest to compare two independent samples from different populations in terms of the proportion of participants presenting a particular response. For example, outcomes such as the proportion of patients responding to a therapy, developing a certain side effect, or requiring specialized care are common in clinical research. East supports a Confidence Interval based approach to the design of clinical

trials for such experiments based on binomial data, in which the relationship between the odds ratio of the two populations is to be investigated.

For example, consider a prospective randomized trial where the hope is that a new experimental treatment can triple the odds ratio of exhibiting a positive outcome. The standard treatment (control arm) is compared to the new treatment (therapy arm). Suppose the goal is for the 10% response rate of the standard treatment (control) to increase to 25% for the new therapy arm.

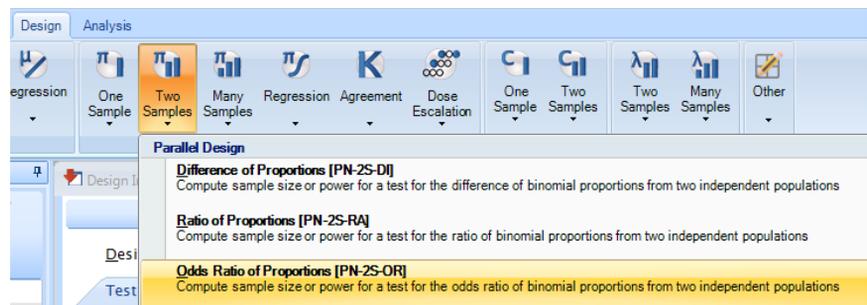

Let π_t and π_c denote the two binomial probabilities associated with the treatment and the control, respectively. The odds ratio is defined as:

$$\psi = \frac{\pi_t / (1 - \pi_t)}{\pi_c / (1 - \pi_c)} = \frac{\pi_t (1 - \pi_c)}{\pi_c (1 - \pi_t)}. \tag{63.1}$$

The problem reduces to testing $H_0: \psi = 1$ against the two-sided alternative $H_1: \psi \neq 1$ or against a one-sided alternative $H_1: \psi < 1$ or $H_1: \psi > 1$. Similar to tests dealing with the ratio of proportions, it is mathematically convenient to express the hypothesis testing of odds ratios in terms of the (natural) logarithm of ψ . Information regarding the specific details of parameter estimation for this test can be found in section 23.3

Consider a confidence interval based design for a study that compares the odds ratio of proportions between the control and experimental therapy arms. Use a two-sided test to determine the sample size required given $\pi_c = 0.1$ and $\psi_1 = 3$ with a precision parameter (width) of $\omega = 0.35$.

In East under the **Design** ribbon for **Discrete** data, click **Two Samples** and then click **Parallel Design: Odds Ratio of Proportions** as shown:

63 Confidence Interval Based Design

This will launch the following input window:

Choose **Confidence Interval** in the **Design Type** dropdown box and enter the following design parameters:

- Test Type: 2 sided
- Confidence Level ($1 - \alpha$): 0.95
- Sample Size (n): Computed (select radio button)
- Allocation Ratio (n_t/n_c): 1
- Prop. under Control (π_c): 0.1
- Prop. under Treatment (π_t): 0.25(this will be calculated)
- Odds Ratio of Proportions (ψ_1): 3
- Half Width (ω): 0.5

The Allocation Ratio ($n_t : n_c$) describes the ratio of patients to each arm. For example,

an allocation ratio of 3:1 indicates that 75% of the patients are randomized to the treatment arm as opposed to 25% to the control. For this example, keep the default Allocation Ratio = 1 and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

| ID | Design Type | Test Type | Sample Size | ω | $(1-\alpha)$ | nt/nc | π_c | Prop. Treatment (Alt.) | ψ_1 |
|-------|---------------------|-----------|-------------|----------|--------------|-------|---------|------------------------|----------|
| Des 1 | Confidence Interval | 2-Sided | 506 | 0.5 | 0.95 | 1 | 0.1 | 0.25 | 3 |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output Summary**.

| Des 1 | |
|--|---------------------|
| Mnemonic | PN-2S-OR |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 2-Sided |
| Confidence Level | 0.95 |
| Model Parameters | |
| Width (ω) | 0.5 |
| Allocation Ratio (nt/nc) | 1 |
| Proportion under Control (π_c) | 0.1 |
| Proportion under Treatment (π_t) | 0.25 |
| Odds Ratio of Proportions (ψ_1) | 3 |
| Sample Size | |
| Maximum | 506 |

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for ω , different proportions of responses for treatment and control groups (π_t and π_c), and desired odds ratios of proportions (ψ_1).

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the

63 Confidence Interval Based Design

user has to only enter the desired value, for example $n = 300$.

Enter the following in the **Design Input** screen and click **Compute**:

- Test Type: 2 sided
- Confidence Level ($1 - \alpha$): 0.95
- Sample Size (n): 300
- Allocation Ratio (n_t/n_c): 1
- Prop. under Control (π_c): 0.1
- Prop. under Treatment (π_t): 0.25(this will be calculated)
- Odds Ratio of Proportions (ψ_1): 3
- Half Width (ω): Computed (select radio button)

| ID | Design Type | Test Type | Sample Size | ω | (1- α) | n_t/n_c | π_c | Prop. Treatment (Alt.) | ψ_1 |
|------|---------------------|-----------|-------------|----------|----------------|-----------|---------|------------------------|----------|
| Des1 | Confidence Interval | 2-Sided | 506 | 0.5 | 0.95 | 1 | 0.1 | 0.25 | 3 |
| Des2 | Confidence Interval | 2-Sided | 300 | 0.649 | 0.95 | 1 | 0.1 | 0.25 | 3 |

For a sample size of 300 the precision parameter ω is calculated to be 0.649. As the sample size is decreased, the resulting value of ω increases. For binomial data, this results in a wider confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From

there, a summary of the design can be generated using the details  icon. East

also provides a very useful **Sample Size vs. Width** plot, found in the plots  menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs.**

Width values can be generated using the **Tables**  menu, also found in the

Library. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

63.8 One Sample Test for McNemar’s Test for Comparing Matched Pairs

Often two binary response measurements are made on each subject, from either two different treatments or from two different time points. For example, in a comparative clinical trial, subjects are matched on baseline demographics and disease characteristics and then randomized with one subject in the pair receiving the experimental treatment and the other subject receiving the control. Another example is the cross over clinical trial in which each subject receives both treatments. By random assignment, some subjects receive the experimental treatment followed by the control while others receive the control followed by the experimental treatment. **McNemar’s Test** is used in experimental situations where such paired comparisons are observed. More specific theoretical detail about this method with examples can be found in section 22.2

The probability parameters for McNemar’s test are displayed in the following table where π_c and π_t denote the response probabilities for the control and experimental treatments, respectively.

Table 63.1: A 2 x 2 Table of Probabilities for McNemar’s Test

| Control | Experimental | | Total Probability |
|-------------------|--------------|------------|-------------------|
| | No Response | Response | |
| No Response | π_{00} | π_{01} | $1 - \pi_c$ |
| Response | π_{10} | π_{11} | π_c |
| Total Probability | $1 - \pi_t$ | π_t | 1 |

The following example taken from Section 22.2 illustrates how a confidence interval based approach to the trial design can be applied to McNemar’s test for comparing matched pairs of binomial responses. Consider a trial in which we wish to determine whether a transdermal delivery system (TDS) can be improved with a new adhesive. Subjects are to wear the old TDS (control) and new TDS (experimental) in the same area of the body for one week each. A response is said to occur if the TDS remains on for the entire one week observation period. From historical data, it is known that control has a response rate of 85% ($\pi_c = 0.85$). It is hoped that the new adhesive will increase this to 95% ($\pi_t = 0.95$). Furthermore, of the 15% of the subjects who did not respond on the control, it is hoped that 87% will respond on the experimental system.

63 Confidence Interval Based Design

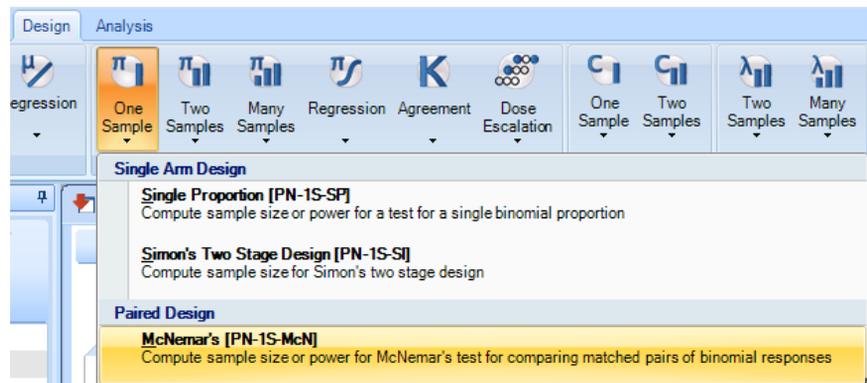

That is, $\pi_{01} = 0.87 \times 0.15 = 0.13$. Based on these data, we can fill in all the entries of Table 63.1 as follows:

Table 63.2: McNemar Probabilities for the TDS Trial

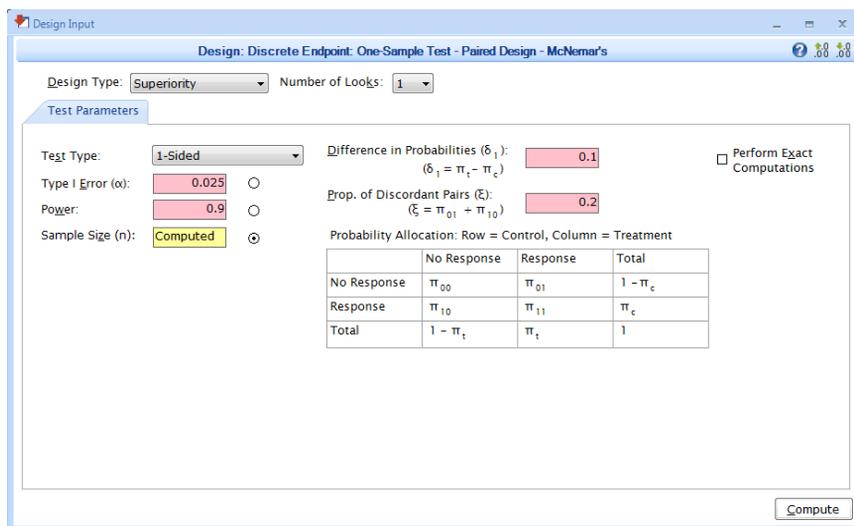

| Control | Experimental | | Total Probability |
|-------------------|--------------|----------|-------------------|
| | No Response | Response | |
| No Response | 0.02 | 0.13 | 0.15 |
| Response | 0.03 | 0.82 | 0.85 |
| Total Probability | 0.05 | 0.95 | 1 |

Although it is expected that the new adhesive will increase the adherence rate, the comparison is posed as a two-sided testing problem, testing $H_0: \pi_c = \pi_t$ against $H_1: \pi_c \neq \pi_t$ at the 0.05 level. We wish to determine the sample size for the values displayed in the above table using a Confidence Interval based design.

In East under the **Design** ribbon for **Discrete** data, click **One Sample** and then click **Paired Design: McNemar's** as shown:

This will launch the following input window:

Choose **Confidence Interval** in the **Design Type** dropdown box. Consider a two sided test with 5% significance level and specify $\delta_1 = \pi_t - \pi_c = 0.1$ and $\xi = \pi_{01} + \pi_{10} = 0.16$ with a precision (width) of 0.5 units.

Enter the following design parameters:

- Test Type: 2 sided
- Confidence Level $(1 - \alpha)$: 0.95
- Sample Size (n): Computed (select radio button)
- Half Width (ω) : 0.5
- Difference in Probabilities (δ_1) : 0.1
- Proportion of Discordant Pairs ξ : 0.16

| Sample Size | |
| Maximum | 631 |

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. From there, a summary of the design can be generated using the details  icon. East also provides a very useful **Sample Size vs. Width** plot, found in the plots  menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs. Width** values can be generated using the **Tables**  menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

This test can easily be repeated for a **one-sided** confidence interval and with various values for ω and difference in probabilities (δ_1) or proportion of discordant pairs (ξ). East can also compute the precision level ω for a given fixed sample size using a confidence interval based design for McNemar’s test. Following the example above, the precision of the estimate (ω) of population parameter can easily be determined.

63.9 Many Sample Test - One Way ANOVA

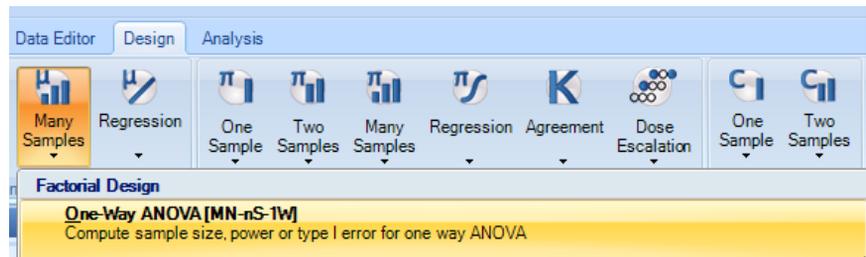

East offers the capability to design trials comparing more than two continuous means. A **One-Way ANOVA** tests the equality of means across R independent groups. The two sample difference of means test for independent data is a one-way ANOVA test for 2 groups. More information, including the following example which is modified here to illustrate a confidence interval based approach to the trial design, can be found in Section 22.2.

63 Confidence Interval Based Design

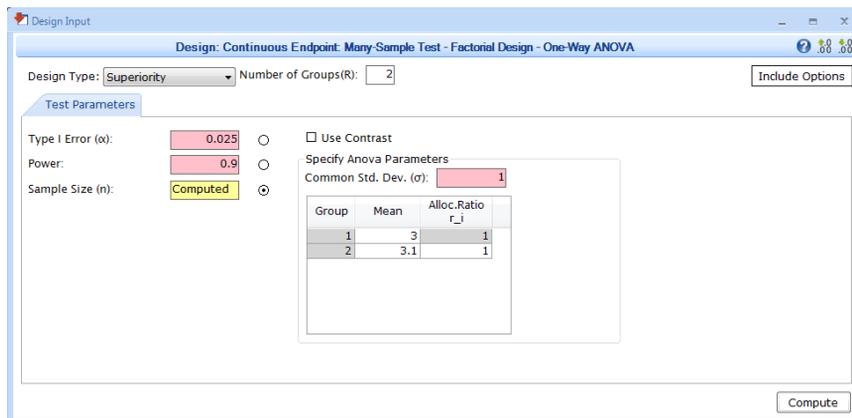

Suppose n patients have been allocated randomly to R treatments. We assume that the data of the R treatment groups comes from R normally distributed populations with the same variance σ^2 , and with population means $\mu_1, \mu_2, \dots, \mu_R$. The null hypothesis $H_0 : \mu_1 = \mu_2 = \dots = \mu_R$ is tested against the alternative hypothesis H_1 : for at least one pair (i, j) , $\mu_i \neq \mu_j$, where $i, j = 1, 2, \dots, R$.

Consider a clinical trial with four groups of patients where the goal is to study the efficacy of a treatment protocol. Three different doses of a drug are being compared against placebo in patients with Alzheimer’s disease. Suppose, based on historical data, the expected mean responses are 0, 1.5, 2.5, and 2, for Groups 1 to 4, respectively. The common standard deviation within each group is $\sigma = 3.5$. We wish to compute the required sample size using a confidence interval based design with a type-1 error of 5% and precision estimate of $\omega = 2$.

In East under the **Design** ribbon for **Continuous** data, click **Many Samples** and then click **Factorial Design: One Way ANOVA** as shown:

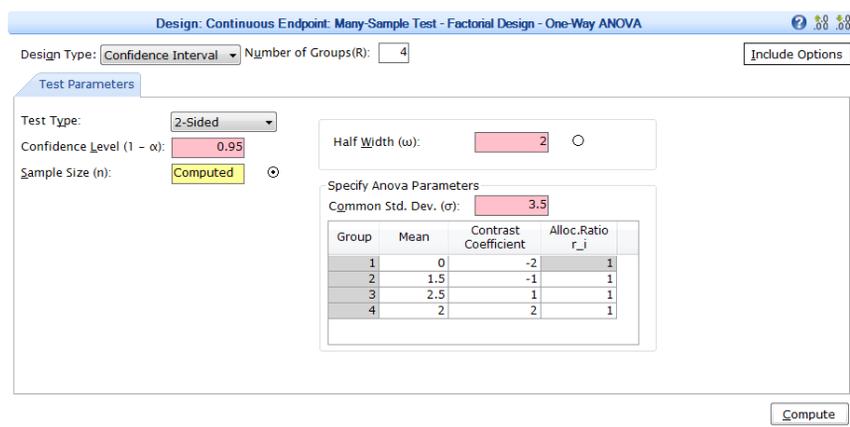

This will launch the following input window:

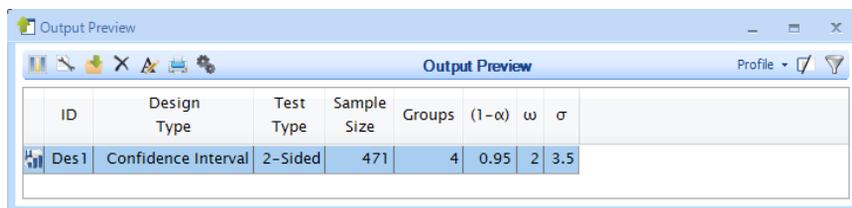

Choose **Confidence Interval** in the **Design Type** dropdown box and enter the following design parameters:

- Number of Groups(R): 4
- Test type: 2 sided
- Confidence level $(1 - \alpha)$: 0.95
- Sample size (n): Computed (select radio button)
- One-sided Width(ω): 2
- Common Standard Deviation (σ): 3.5
- Group 1: Mean= 0
- Group 2: Mean= 1.5
- Group 3: Mean= 2.5
- Group 4: Mean= 2

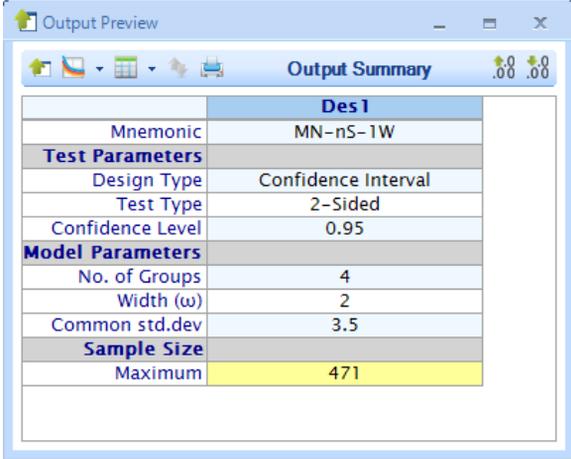

63 Confidence Interval Based Design

Leave all other Group values (Contrast Coefficients and Allocation Ratios) as defaults and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

Summary.

| Des 1 | |
|-------------------------|---------------------|
| Mnemonic | MN-nS-1W |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 2-Sided |
| Confidence Level | 0.95 |
| Model Parameters | |
| No. of Groups | 4 |
| Width (w) | 2 |
| Common std.dev | 3.5 |
| Sample Size | |
| Maximum | 471 |

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for w and σ , as well as any desired differences in group means, contrast coefficients or group allocation ratios.

Alternatively East can compute the precision level w given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 300$.

In the **Design Window** the parameters now become:

Number of Groups(R): 4
 Test type: 2 sided
 Confidence level ($1 - \alpha$): 0.95
 Sample size (n): 300
 Half Width(w): Computed (select radio button)
 Common Standard Deviation (σ): 3.5
 Group 1: Mean= 0
 Group 2: Mean= 1.5
 Group 3: Mean= 2.5
 Group 4: Mean= 2

63 Confidence Interval Based Design

Enter the above in the **Design Input** screen and click **Compute**:

The screenshot shows the 'Design Input' screen for a 'Confidence Interval' based design. The 'Design Type' is set to 'Confidence Interval' and the 'Number of Groups (R)' is 4. The 'Test Parameters' section shows a '2-Sided' test with a 'Confidence Level (1 - alpha)' of 0.95 and a 'Sample Size (n)' of 300. The 'Half Width (omega)' is 2.505. The 'Specify Anova Parameters' section shows a 'Common Std. Dev. (sigma)' of 3.5 and a table of Contrast Coefficients and Alloc. Ratio for four groups.

| Group | Mean | Contrast Coefficient | Alloc. Ratio r _j |
|-------|------|----------------------|-----------------------------|
| 1 | 0 | -2 | 1 |
| 2 | 1.5 | -1 | 1 |
| 3 | 2.5 | 1 | 1 |
| 4 | 2 | 2 | 1 |

The 'Output Preview' window shows the following table:

| ID | Design Type | Test Type | Sample Size | Groups | (1-α) | ω | σ |
|------|---------------------|-----------|-------------|--------|-------|-------|-----|
| Des1 | Confidence Interval | 2-Sided | 471 | 4 | 0.95 | 2 | 3.5 |
| Des2 | Confidence Interval | 2-Sided | 300 | 4 | 0.95 | 2.505 | 3.5 |

The precision parameter ω is calculated to be 2.505. As the sample size is decreased, the resulting value of ω increases. In other words, the precision limit increases, resulting in a wider confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From

there, a summary of the design can be generated using the details  icon. East

also provides a very useful **Sample Size vs. Width** plot, found in the plots  menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs.**

Width values can be generated using the **Tables**  menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

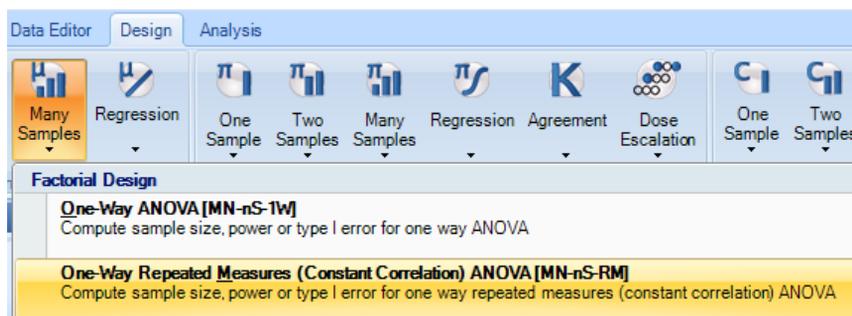

63.10 Many Sample Test - One Way Repeated Measures

The **One Way Repeated ANOVA** tests for equality of means in a repeated measures setting. As the patient population is exposed to each treatment, the measurement of the dependent variable is repeated, resulting in correlation between observations from the same patient. Constant correlation assumes that the correlation between observations from the same patient is constant for all patients. This correlation parameter (ρ) needs

to be specified in the one way repeated measures study design.

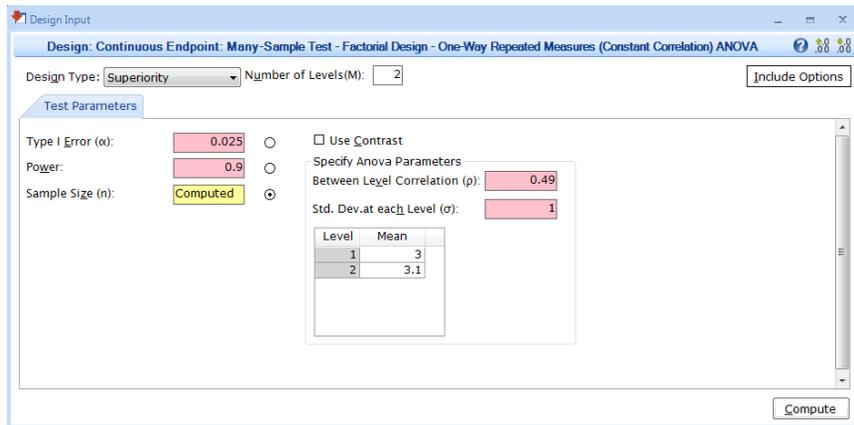

Consider a hypothetical longitudinal study that investigates the effect of a dietary intervention on weight loss, where the endpoint is decrease in weight (in kilograms) from baseline. Data is collected at four time points: baseline, 4 weeks, 8 weeks, and 12 weeks and are measured to be 0 kg, 10.5 kg, 25kg, and 20kg respectively. Assume the common standard deviation within each group (i.e. at each level) is $\sigma = 3.5$ and the constant correlation (between level) $\rho = 0.2$. We wish to compute the required sample size for this study, using a two-sided confidence interval based design with a type-1 error of 5% and precision estimate (width) of $\omega = 2$.

In East under the **Design** ribbon for **Continuous** data, click **Many Samples** and then click **Factorial Design: One Way Repeated Measures (Constant Correlation) ANOVA** as shown:

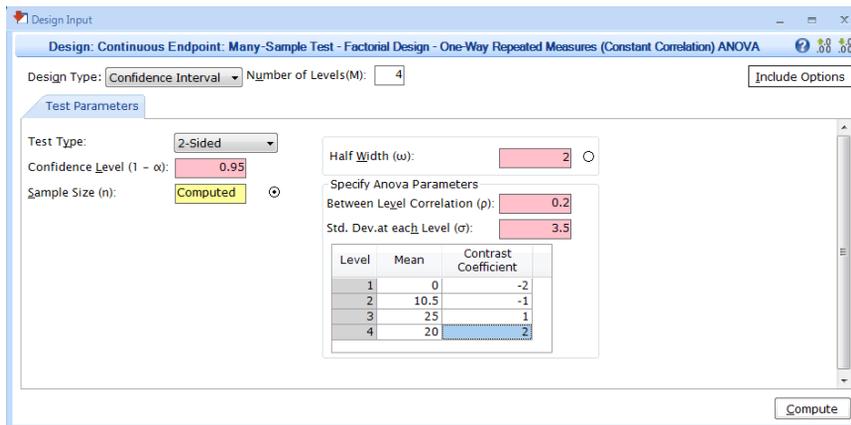

63 Confidence Interval Based Design

This will launch the following input window:

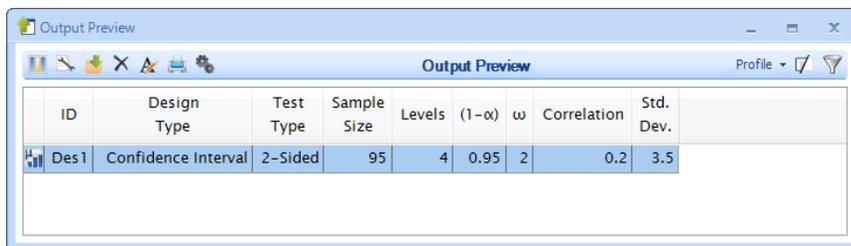

Choose **Confidence Interval** in the **Design Type** dropdown box and enter the following design parameters:

- Number of Levels (M): 4
- Test type: 2 sided
- Confidence level ($1 - \alpha$): 0.95
- Sample size (n): Computed (select radio button)
- Half Width(ω): 2
- Between Level Correlation (ρ): 0.2
- Standard Deviation at each Level (σ): 3.5
- Group 1: Mean= 0
- Group 2: Mean= 10.5
- Group 3: Mean= 25
- Group 4: Mean= 20

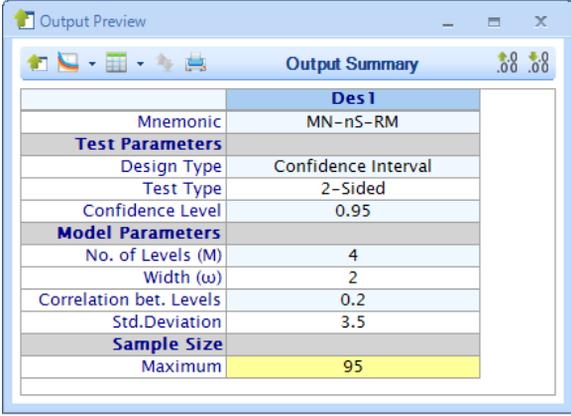

Leave all other Group level values (Contrast coefficients) as defaults and click **Compute**. The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

63 Confidence Interval Based Design

Summary.

| Des 1 | |
|-------------------------|---------------------|
| Mnemonic | MN-nS-RM |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 2-Sided |
| Confidence Level | 0.95 |
| Model Parameters | |
| No. of Levels (M) | 4 |
| Width (ω) | 2 |
| Correlation bet. Levels | 0.2 |
| Std.Deviation | 3.5 |
| Sample Size | |
| Maximum | 95 |

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for ω , ρ and σ , as well as any desired differences in group information.

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example increase n from 95 to $n = 200$.

In the **Design Window** the parameters now become:

Number of Levels(M): 4
 Test type: 2 sided
 Confidence level ($1 - \alpha$): 0.95
 Sample size (n): 200
 Half Width(ω): Computed (radio button selected)
 Between Level Correlation (ρ): 0.2
 Standard Deviation at each Level (σ): 3.5
 Group 1: Mean= 0
 Group 2: Mean= 10.5
 Group 3: Mean= 25
 Group 4: Mean= 20

Enter the above in the **Design Input** screen and click **Compute**:

The screenshot shows the 'Design: Continuous Endpoint - Many-Sample Test - Factorial Design - One-Way Repeated Measures (Constant Correlation) ANOVA' interface. The 'Design Type' is 'Confidence Interval' and 'Number of Levels(M)' is 4. Under 'Test Parameters', 'Test Type' is '2-Sided', 'Confidence Level (1 - α)' is 0.95, and 'Sample Size (n)' is 200. Under 'Specify Anova Parameters', 'Half Width (ω)' is 1.372, 'Between Level Correlation (ρ)' is 0.2, and 'Std. Dev. at each Level (σ)' is 3.5. A table below shows levels 1-4 with means 0, 10.5, 25, 20 and contrast coefficients -2, -1, 1, 2. The 'Output Preview' window at the bottom shows a table with two rows: Des1 (Sample Size 95, Levels 4, (1-α) 0.95, ω 2, Correlation 0.2, Std. Dev. 3.5) and Des2 (Sample Size 200, Levels 4, (1-α) 0.95, ω 1.372, Correlation 0.2, Std. Dev. 3.5).

The precision parameter ω is calculated to be 1.372. As the sample size is increased, the resulting value of ω decreases. In other words, the precision limit decreases, resulting in a tighter confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From there, a summary of the design can be generated using the details icon. East also provides a very useful **Sample Size vs. Width** plot, found in the plots menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs. Width** values can be generated using the **Tables** menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

63.11 Normal Test for Linear Regression - Single Slope

Regression models are often used to examine the relationship between a response and one or more explanatory variables. A simple linear regression model tests a single slope for one continuous covariate when the relationship with response is linear. The assumption is that the observed value of a response variable Y is a linear function of the explanatory variable X , plus some random noise.

63 Confidence Interval Based Design

For $i = 1, \dots, n$ subjects in a study the model can be written as:

$$Y_i = \gamma + \theta X_i + \epsilon_i$$

where each ϵ_i is an independent normal random variable with $E(\epsilon_i) = 0$ and $Var(\epsilon_i) = \sigma_\epsilon^2$. X_i (subject i) is a random variable with a variance σ_x^2 . More information on simple linear regression models, including distinctions between different types of studies and details on the calculation of the test statistic can be found in Section 19.1.

A dose-response relationship describes the effect of an exposure on an outcome (positive or negative) and is a crucial consideration in the development of a drug or other treatment. The relationship is often determined by estimating the slope of a regression model such as the one above, where Y is the appropriate response variable and the explanatory variable X is a set of specified doses. Consider a hypothetical clinical trial involving different doses of a medication under study. Assume that the doses and randomization of subjects across the doses have been chosen so that the standard deviation $\sigma_x = 9$. Based on information gained from prior studies, it can be assumed that $\sigma_\epsilon = 15$.

When the slope of the linear regression model is 0, the relationship between the outcome and covariate is flat. In other words, there is no evidence of a dose-response relationship. It therefore of interest to test the null hypothesis $H_0: \theta = 0$ against a two-sided alternative $H_1: \theta \neq 0$.

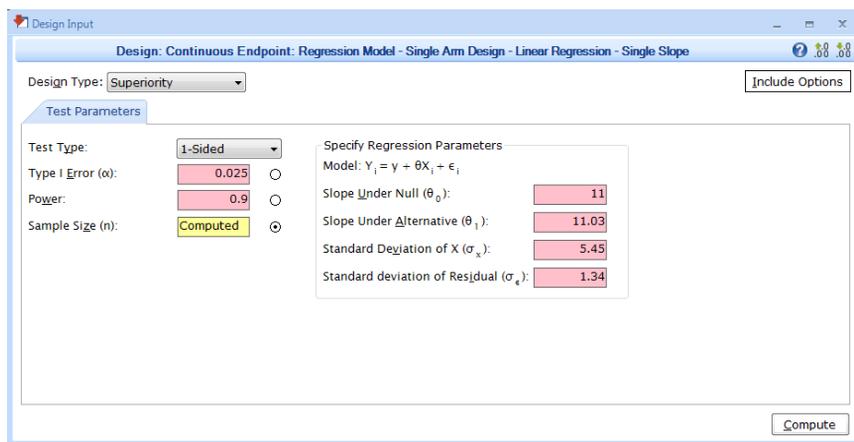

Consider a confidence interval based design for the above study to determine if a dose-response relationship exists between the patient outcome and dose level of a drug. Use a two-sided test with a type-1 error rate of 5% to compute the sample size required using a precision parameter (width) of $\omega = 0.15$.

To illustrate this example, in East under the **Design** ribbon for **Continuous** data, click **Regression** and then click **Single Arm Design: Linear Regression - Single Slope** as

shown:

This will launch the following input window:

Choose **Confidence Interval** in the **Design Type** dropdown box, enter the following design parameters and click **Compute**:

- Test type: 2 sided
- Confidence level $(1 - \alpha)$: 0.95
- Sample size (n): Computed (select radio button)
- Half Width (ω): 0.15
- Standard Deviation of $X(\sigma_X)$: 9
- Standard Deviation of Residuals $X(\sigma_\epsilon)$: 15

63 Confidence Interval Based Design

Design: Continuous Endpoint: Regression Model - Single Arm Design - Linear Regression - Single Slope

Design Type: Confidence Interval

Test Parameters

Test Type: 2-Sided

Confidence Level (1 - α): 0.95

Sample Size (n): Computed

Half Width (ω): 0.15

Standard Deviation of X (σ_x): 9

Standard Deviation of Residuals (σ_e): 15

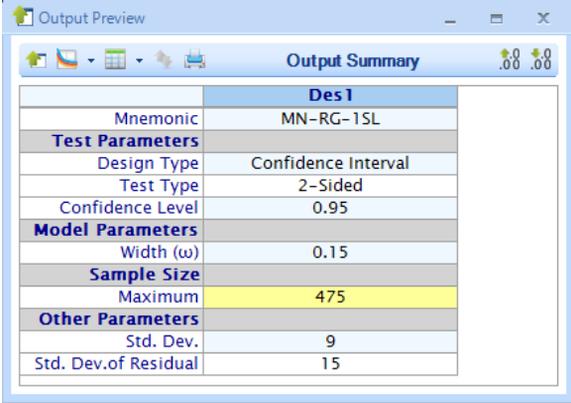

Compute

The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

| ID | Design Type | Test Type | Sample Size | (1- α) | ω | Std. Dev. | Std. Dev. of Residual |
|-------|---------------------|-----------|-------------|----------------|----------|-----------|-----------------------|
| Des 1 | Confidence Interval | 2-Sided | 475 | 0.95 | 0.15 | 9 | 15 |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

Summary.

| Des 1 | |
|-------------------------|---------------------|
| Mnemonic | MN-RG-1SL |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 2-Sided |
| Confidence Level | 0.95 |

| Width (ω) | 0.15 |
| Sample Size | |
| Maximum | 475 |
| Other Parameters | |
| Std. Dev. | 9 |
| Std. Dev. of Residual | 15 |

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for ω , σ_X , and σ_ϵ .

Alternatively East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 200$.

In the **Design Window** the parameters now become:

Test type: 2 sided
 Confidence level ($1 - \alpha$): 0.95
 Sample size (n): 200
 Half Width (ω): Computed (select radio button)
 Standard Deviation of $X(\sigma_X)$: 9
 Standard Deviation of Residuals $X(\sigma_\epsilon)$: 15

63 Confidence Interval Based Design

Enter the following in the **Design Input** screen and click **Compute**:

Design: Continuous Endpoint: Regression Model - Single Arm Design - Linear Regression - Single Slope

Design Type: Confidence Interval

Test Parameters

Test Type: 2-Sided

Confidence Level (1 - α): 0.95

Sample Size (n): 200

Half Width (ω): 0.231

Standard Deviation of X (σ_x): 9

Standard Deviation of Residuals (σ_e): 15

Output Preview

| ID | Design Type | Test Type | Sample Size | (1 - α) | ω | Std. Dev. | Std. Dev. of Residual |
|------|---------------------|-----------|-------------|-----------------|----------|-----------|-----------------------|
| Des1 | Confidence Interval | 2-Sided | 475 | 0.95 | 0.15 | 9 | 15 |
| Des2 | Confidence Interval | 2-Sided | 200 | 0.95 | 0.231 | 9 | 15 |

Compute

The precision parameter ω is calculated to be 0.231. When the sample size is decreased the estimate of the precision limit increases leading to a wider confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From there, a summary of the design can be generated using the details icon. East also provides a very useful **Sample Size vs. Width** plot, found in the plots menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs. Width** values can be generated using the **Tables** menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

63.12 Normal Test for Linear Regression - Difference of Slopes

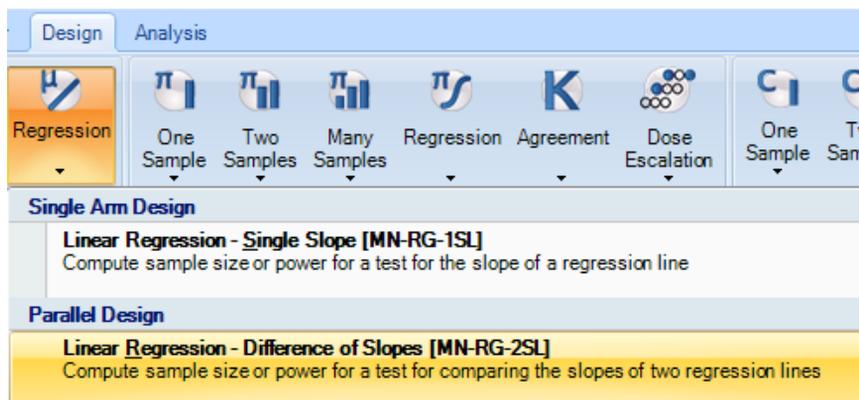

Linear regression models are used to examine the relationship between a response variable and one or more explanatory variables assuming that the relationship is linear. One type of linear regression tests the equality of two slopes in a model with only one observation per subject. In such experimental situations, it is of interest to compare the slopes of two regression lines.

The regression model relates the response variable Y to the explanatory variable X using the model $Y_{il} = \gamma + \theta_i X_{il} + \epsilon_{il}$, where the error ϵ_{il} has a normal distribution with mean zero and an unknown variance σ_ϵ^2 for Subject l in Treatment i , $i = c, t$ and $l = 1, \dots, n_i$. Let σ_{xc}^2 and σ_{xt}^2 denote the variance of the explanatory variable X for control (c) and treatment (t), respectively. More information on linear regression models for comparing two slopes and details on the calculation of the test statistic can be found in Section 19.2.

Suppose a treatment response depends on the level of a certain laboratory parameter. A new formulation is to be developed to decrease this interaction between the response and the level. The explanatory variable is the baseline value of the laboratory parameter. The study is designed with $\sigma_{xc} = \sigma_{xt} = 6$ and $\sigma_\epsilon = 10$. It is of interest to test the equality of the slopes θ_c and θ_t under the null hypothesis $H_0: \theta_t = \theta_c$ against the two-sided alternative $H_1: \theta_t \neq \theta_c$.

Consider a confidence interval based design for the above study to determine if there exists a difference between the slopes of the two regression lines. Use a two-sided test with a type-1 error rate of 5% to compute the sample size required using a precision parameter (width) of $\omega = 0.5$.

To illustrate this example, in East under the **Design** ribbon for **Continuous** data, click **Regression** and then click **Parallel Design: Linear Regression - Difference of Slopes** as shown:

63 Confidence Interval Based Design

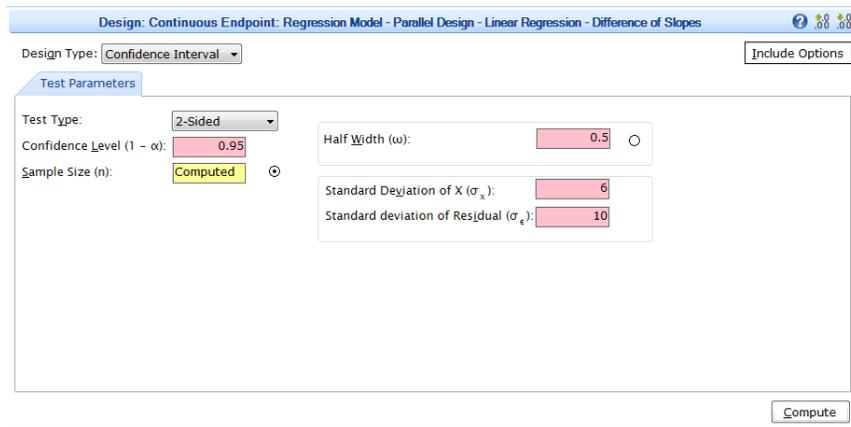

This will launch the following input window:

Choose **Confidence Interval** in the **Design Type** dropdown box, enter the following design parameters and click **Compute**:

- Test type: 2 sided
- Confidence level $(1 - \alpha)$: 0.95
- Sample size (n): Computed (select radio button)
- Allocation Ratio (n_t/n_c) : 1
- Half Width (ω) : 0.5
- Standard Deviation of $X(\sigma_x)$: 6
- Standard Deviation of Residual $X(\sigma_\epsilon)$: 10

The Allocation Ratio $(n_t : n_c)$ describes the ratio of patients to each arm. For example, an allocation ratio of 3:1 indicates that 75% of the patients are randomized to the treatment arm as opposed to 25% to the control. Keep the default allocation

ratio(n_t/n_c)= 1.

The sample size for this design is calculated and the output is shown as a row in the **Output Preview** window:

| ID | Design Type | Test Type | Sample Size | (1-α) | ω | Std. Dev. of X | Std. Dev. of Residual |
|------|---------------------|-----------|-------------|-------|-----|----------------|-----------------------|
| Des1 | Confidence Interval | 2-Sided | 171 | 0.95 | 0.5 | 6 | 10 |

As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details will be displayed, labeled **Output**

63 Confidence Interval Based Design

Summary.

| Des 1 | |
|-------------------------|---------------------|
| Mnemonic | MN-RG-2SL |
| Test Parameters | |
| Design Type | Confidence Interval |
| Test Type | 2-Sided |
| Confidence Level | 0.95 |
| Model Parameters | |
| Width (ω) | 0.5 |
| Sample Size | |
| Maximum | 171 |
| Other Parameters | |
| Std. Dev. | 6 |
| Std. Dev. of Residual | 10 |

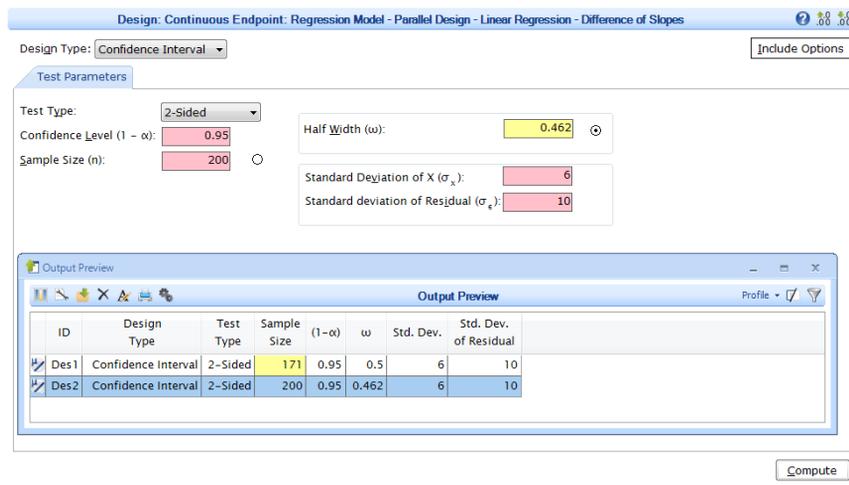

This design can be saved to the **Library** by selecting the **Des 1** in the **Output Preview** window and clicking the  icon. This test can easily be repeated for a **One-sided** confidence interval and with various values for ω , σ_x , and σ_ϵ .

Alternatively, East can compute the precision level ω given a fixed sample size using a confidence interval based design. Following the example above, to determine the precision of the estimate of population parameter where the sample size is fixed, the user has to only enter the desired value, for example $n = 200$.

In the **Design Window** the parameters now become:

Test type: 2 sided
 Confidence level ($1 - \alpha$): 0.95
 Sample size (n): 200
 Allocation Ratio (n_t/n_c): 1
 Half Width (ω): Computed (select radio button)
 Standard Deviation of X (σ_x): 6
 Standard Deviation of Residual X (σ_ϵ): 10

Enter the following in the **Design Input** screen and click **Compute**:

The precision parameter ω is calculated to be 0.462. As the sample size increases the precision limit decreases, providing a tighter confidence interval for the parameter of interest. The output for all parameters is again shown as a row in the **Output Preview** window and the design can be saved to the **Library** using the standard method as with all tests in East. From there, a summary of the design can be generated using the details  icon. East also provides a very useful **Sample Size vs. Width** plot, found in the plots  menu. This dynamic visual can immediately assess how changing the sample size effects the resulting width of the confidence interval. A table of **Sample Size vs. Width** values can be generated using the **Tables**  menu, also found in the **Library**. This feature allows the user to input a range of values to generate multiple confidence intervals and the corresponding sample sizes.

64 Simulation in East

East lets you simulate studies that were created by its design module. This chapter describes the simulations that are available in East. Through these simulation capabilities, you can repeatedly generate the entire path traced out by a test statistic under user-specified assumptions about treatment effects. Thereby you can verify various operating characteristics of your designs.

64.1 Normal Studies

To begin let us design a study. Click **Continuous: Two Samples** on the **Design** tab and then click **Parallel Design: Difference of Means**. Enter the design parameters as shown below.

Use the default boundary information and click **Compute** to create the design. The output summary is shown below.

| | Des1 |
|---|---------------------|
| Mnemonic | MN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 5 |
| Test Type | 2-Sided |
| Specified α | 0.05 |
| Power | 0.909 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Input Method | Difference of Means |
| Diff. in Means ($\delta = \mu_1 - \mu_2$) | 60 |
| Std. Deviation (σ) | 45 |
| Test Statistic | Z |
| Boundary Parameters | |
| Spacing of Looks | Unequal |
| Efficacy Boundary | LD (OF) |
| Sample Size | |
| Maximum | 25 |
| Expected Under H0 | 24.836 |
| Expected Under H1 | 18.347 |

The study is designed for up to 5 looks with the $LD(OF)$ spending function, and a

two-sided α of 0.05. At most 25 patients are needed in order to achieve 90% power with this large standardized treatment effect of $60/45 = 1.333$. Save the design to the workbook and click the **S** icon. You will be taken to the following simulation worksheet.

Number of Looks: 5

Test Parameters Response Generation Simulation Controls

Trial Type: Superiority Test Statistic: t

Test Type: 2-Sided Variance: Equal

Sample Size (n): 25

| Look # | Info. Fraction | Cum. α Spent | | Efficacy Z | |

| 3 | 0.600 | 0.004 | 0.004 | 2.680 | -2.680 |
| 4 | 0.800 | 0.012 | 0.012 | 2.290 | -2.290 |
| 5 | 1.000 | 0.025 | 0.025 | 2.031 | -2.031 |

Restore Original Design

Notice the **Test Statistic** option on the right. For normally distributed data with known variance one would select the **z-test** option from the drop down menu. These simulations are accurate regardless of sample size.

However, for normally distributed responses with unknown variance, selecting the **z-test** option will result in simulations that may not be valid for designs with small sample sizes. This is because with small samples, the Wald test statistic at any monitoring time-point has a student-t distribution rather than a standard normal distribution. The stopping boundaries in East exhibit type-1 error and power exactly as specified only if the sequentially computed test statistic is normally distributed and has independent increments. To the extent that the test statistic relies on large sample theory for its distributional behavior, there may be some loss of accuracy in the operating characteristics of the stopping boundaries. For sample sizes exceeding 100, the loss of accuracy is scarcely noticeable. However when the sample size is of the order of 20, there is indeed a noticeable loss of accuracy and the study must be re-designed and simulated repeatedly until, by trial and error, it possesses the required type-1 error and power.

Let us now illustrate this with an example. At the interim monitoring stage we will be

64 Simulation in East

tracking the Wald statistic. Thus we should simulate the behavior of this statistic ahead of time and verify that the type-1 error and power of the study are indeed as specified. Suppose we have accrued a total of n_j subjects by the j th look. We have two choices for computing the test statistic and checking if it has crossed a stopping boundary.

1. Use the value of $\sigma = 45$ specified at the design stage and compute

$$Z_j = \frac{\bar{X}_{tj} - \bar{X}_{cj}}{\sqrt{\frac{4\sigma^2}{n_j}}} . \tag{64.1}$$

This statistic is normally distributed with variance 1 and a known correlation structure across different values of j . Consequently, it should produce the precise type 1 error and power specified in the study design even though the maximum sample size is only 24. To do this select **z-test** from the drop down menu next to **Test Statistic**. Next, click on the **Response Generation Info** tab and enter the parameters as shown below.

Next, click the **Simulate** button. The simulation intermediate window will appear as shown below:

| Look # | Look Position | H0+ | H0- | H1+ | H1- | Latest Simul ... Test S... | Average Info. | Average Sample Size | Cum. # Rejecting... Up(H0+) | Cum. # Rejecting... Low(H0-) | Cum. # Unable... Reject... | Total Simulati... Count (...) | Total Simulati... % (Cum.) |
|--------|---------------|-------|--------|-----|-----|----------------------------|---------------|---------------------|-----------------------------|------------------------------|----------------------------|-------------------------------|----------------------------|
| 1 | 5 | 4.877 | -4.877 | | | -0.293 | | 5 | 0 | 0 | 0 | 0 | 0 |
| 2 | 10 | 3.357 | -3.357 | | | 0.681 | | 10 | 0 | 0 | 0 | 0 | 0 |
| 3 | 15 | 2.68 | -2.68 | | | -0.361 | | 15 | 6 | 4 | 0 | 10 | 1 |
| 4 | 20 | 2.29 | -2.29 | | | -0.324 | | 20 | 13 | 11 | 0 | 24 | 2.4 |
| 5 | 25 | 2.031 | -2.031 | | | -0.6 | | 25 | 10 | 17 | 939 | 966 | 96.6 |
| Total | | | | | | | | 24.78 | | | | | |
| % | | | | | | | | | 2.9 | 3.2 | 93.9 | | |

In the actual trial we would have to know the value of σ^2 in order to compute Z_j . If the estimate $\sigma = 45$ is incorrect the power and type-1 error of the trial will not match the simulation results. Even worse, we have no way of knowing if the simulation results are correct or not, since it is difficult to verify the value of σ from a small data set. Thus it might be preferable to use an estimate of σ in the definition of the test statistic. This is discussed next.

2. Estimate σ^2 by s_j^2 from the interim data and compute

$$T_j = \frac{\bar{X}_{tj} - \bar{X}_{cj}}{\sqrt{\frac{4s_j^2}{n_j}}} . \tag{64.2}$$

It is more common to monitor a group sequential, normal endpoints trial with the test statistic T_j given by equation (64.2) than with the test statistic Z_j given (64.1). If we use (64.1) in the interim monitoring phase of a trial, we imply that we know the value of σ^2 with certainty, since it is needed in the computation. But the value of σ^2 that we use for this purpose may only be an informed guess with no data to back it up. At the interim monitoring stage, we have the opportunity to actually estimate σ^2 from the data and use the estimate, s_j^2 say, in the computation of the test statistic (64.2). This might be a more reliable approach than making a strong assumption that σ^2 is known with certainty. Now the distribution of T_j is only asymptotically normal. In small samples T_j has a student-t distribution under the null hypothesis. Thus use of T_j does not by itself ensure that the study will have the power and type-1 error that were implied by the sample size and stopping boundaries specified in the study design. This is where the simulations can help. Since the test statistic T_j is computed entirely from the data, and contains no unknown nuisance parameters, we can obtain the true power and type-1 error of any design that uses T_j for the interim monitoring, by means of simulation.

To do this open the simulation worksheet and select the following options:

Number of Looks: 5

Test Parameters | Response Generation | Simulation Controls

Trial Type: Superiority | Test Statistic: t

Test Type: 2-Sided | Variance: Equal

Sample Size (n): 25

| 4 | 0.800 | 0.012 | 0.012 | 2.290 | -2.290 |
| 5 | 1.000 | 0.025 | 0.025 | 2.031 | -2.031 |

Next, click on the **Response Generation Info** tab. You will notice that we do not have the option to select how the data are generated. We must use **Individual Means**. This is because when East calculates the t-statistic it needs to estimate the variance in each group. This is not possible if East generates the data using the **Difference of Means** option since East is only simulating differences of the means and not the actual means themselves. Thus, East cannot estimate the variance in each group. It is for this reason that the **Individual**

64 Simulation in East

Means option is selected.

Again we wish to simulated under the null hypothesis, $\mu_t - \mu_c = 0$. Enter the parameters in this tab as shown below.

Number of Looks: 5

| Test Parameters | Response Generation | Simulation Controls |
|---------------------------------------|---------------------|---|
| Generate Data Using: Individual Means | | <input checked="" type="checkbox"/> Common Standard Deviation |
| Mean Control (μ_c): 60 | | SD Control (σ_c): 45 |
| Mean Treatment (μ_t): 60 | | SD Treatment (σ_t): 45 |

Next, click the **Simulate** button. The simulation results will appear in the output preview window. Save this simulation to the workbook and then double click on Sim2 in the Library. A portion of the results are shown below.

Simulation Boundaries and Cumulative Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | | Stopping For | | Total Simulations | |
|---------|-----------------|------------|--------|----------------|----------------|-------------------|----------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 5 | 4.877 | -4.877 | 96 | 76 | 172 | 1.720% |
| 2 | 10 | 3.357 | -3.357 | 129 | 126 | 255 | 2.550% |
| 3 | 15 | 2.68 | -2.68 | 194 | 207 | 401 | 4.010% |
| 4 | 20 | 2.29 | -2.29 | 320 | 313 | 633 | 6.330% |
| 5 | 25 | 2.031 | -2.031 | 451 | 448 | 10000 | 100.000% |
| Total % | | | | 4.510% | 4.480% | | |

We observe that this small study does not preserve the type-1 error.

64.2 Binomial Studies

When computing a design for binomially distributed responses, East relies on the normal approximation to the binomial distribution. Thus, these designs may not be as accurate for small sample sizes. As in the previous section, the study should be re-designed and simulated repeatedly until, by trial and error, it possesses the required type-1 error and power. The simulations in East, as opposed to the designs, generate data from the actual binomial model specified instead of relying on a normal approximation. Thus, the simulations might provide a more realistic assessment of power and type-1 error for designs involving binomial endpoints and small sample sizes.

To illustrate, consider the following binomial design. Click **Discrete: Two Samples** on the **Design** tab and then click **Parallel Design: Difference of Proportions** and enter

the design parameters as shown below.

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Design Type: Superiority Number of Looks: 5

Test Parameters Boundary

Test Type: 2-Sided

Type I Error (α): 0.05

Power: 0.9

Sample Size (n): Computed

Allocation Ratio: 1 (n_1/n_2)

Specify Proportion Response

Prop. under Control (π_c): 0.1

Specify Alternative Hypothesis

Prop. under Treatment (π_t): 0.65

Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): 0.55

Specify Variance

Pooled Estimate

Unpooled Estimate

Use Casagrande-Pike-Smith Correction (Ignored if alloc. ratio is not 1)

Next click on the **Boundary Info** tab and enter the parameters as shown below.

Design Type: Superiority Number of Looks: 5

Test Parameters Boundary

Efficacy

Boundary Family: Spending Functions

Spending Function: Gamma Family

Parameter (γ): 1

Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.200 | 0.014 | 2.449 | -2.449 |
| 2 | 0.400 | 0.026 | 2.419 | -2.419 |
| 3 | 0.600 | 0.036 | 2.398 | -2.398 |
| 4 | 0.800 | 0.044 | 2.391 | -2.391 |
| 5 | 1.000 | 0.050 | 2.395 | -2.395 |

64 Simulation in East

Click **Compute** to create the design. The output summary is shown below.

| Des 1 | |
|--|-----------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 5 |
| Test Type | 2-Sided |
| Specified α | 0.05 |
| Power | 0.908 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Proportion under Control (π_c) | 0.1 |
| Proportion under Treatment (π_t) | 0.65 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0.55 |
| Variance | Pooled Estimate |
| Boundary Parameters | |
| Spacing of Looks | Unequal |
| Efficacy Boundary | Gm (1) |
| Sample Size | |
| Maximum | 36 |
| Expected Under H0 | 35.139 |
| Expected Under H1 | 21.832 |

The study is designed for up to 5 looks and a two-sided α of 0.05. At most 36 patients are needed in order to achieve 90% power. Save the design to the workbook and click the **S** icon. You will be taken to the following simulation worksheet.

Number of Looks:

Test Parameters

Trial Type:

Test Type:

Sample Size (n):

Simulation Controls

Specify Variance

Pooled Estimate

Unpooled Estimate

| Look # | Info. Fraction | Cum. α Spent | | Efficacy Z | |
|--------|----------------|---------------------|-------|------------|--------|
| | | Upper | Lower | Upper | Lower |
| 1 | 0.194 | 0.007 | 0.007 | 2.458 | -2.458 |
| 2 | 0.389 | 0.013 | 0.013 | 2.427 | -2.427 |
| 3 | 0.611 | 0.018 | 0.018 | 2.382 | -2.382 |
| 4 | 0.806 | 0.022 | 0.022 | 2.393 | -2.393 |
| 5 | 1.000 | 0.025 | 0.025 | 2.398 | -2.398 |

Next, click **Simulate**. A portion of the results is shown below.

Simulation Boundaries and Cumulative Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | | Stopping For | | Total Simulations | |
|---------|-----------------|------------|--------|----------------|----------------|-------------------|----------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 7 | 2.458 | -2.458 | 0 | 0 | 0 | 0.000% |
| 2 | 14 | 2.427 | -2.427 | 118 | 0 | 118 | 11.800% |
| 3 | 22 | 2.382 | -2.382 | 589 | 0 | 589 | 58.900% |
| 4 | 29 | 2.393 | -2.393 | 795 | 0 | 795 | 79.500% |
| 5 | 36 | 2.398 | -2.398 | 898 | 0 | 1000 | 100.000% |
| Total % | | | | 89.800% | 0.000% | | |

Notice that the simulated power this design is (up to Monte Carlo accuracy) and slightly lower than 90%.

It is worth noting that by the time the sample size exceeds 100, the normal approximation should be sufficiently accurate. To see this, create a new design Des2 by editing Des1 and changing π_t value to 0.35. The Des2 summary will be as follows

| Des2 | |
|--|-----------------|
| Mnemonic | PN-25-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 5 |
| Test Type | 2-Sided |
| Specified α | 0.05 |
| Power | 0.901 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Proportion under Control (π_c) | 0.1 |
| Proportion under Treatment (π_t) | 0.35 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0.25 |
| Variance | Pooled Estimate |
| Boundary Parameters | |
| Spacing of Looks | Unequal |
| Efficacy Boundary | Gm (1) |
| Sample Size | |
| Maximum | 137 |
| Expected Under H0 | 133.721 |
| Expected Under H1 | 79.609 |

Save this design to the workbook and open the simulation worksheet by clicking on the  icon in the Library. Again, click **Simulate**. A portion of the results is shown

64 Simulation in East

below.

Simulation Boundaries and Cumulative Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | | Stopping For | | Total Simulations | |
|---------|-----------------|------------|--------|----------------|----------------|-------------------|----------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 27 | 2.453 | -2.453 | 85 | 0 | 85 | 8.500% |
| 2 | 55 | 2.415 | -2.415 | 402 | 0 | 402 | 40.200% |
| 3 | 82 | 2.4 | -2.4 | 631 | 0 | 631 | 63.100% |
| 4 | 110 | 2.389 | -2.389 | 808 | 0 | 808 | 80.800% |
| 5 | 137 | 2.396 | -2.396 | 898 | 0 | 1000 | 100.000% |
| Total % | | | | 89.800% | 0.000% | | |

This confirms that the power is indeed preserved (up to Monte Carlo accuracy) for group sequential designs based on the normal approximation to the binomial with large sample sizes. In general, whenever a small binomial study is contemplated it is a good idea to verify its operating characteristics through simulations.

64.3 Description of Simulation Output Columns

Following are the output quantities computed while simulating ‘Subject Data’.

| Column Name | Description | Applicability |
|---------------------|---|--|
| Scenario ID | Identification number of scenarios when multiple values are provided for a parameter(s) | All Simulations |
| Simulation ID | Identification number of simulations | All Simulations |
| Subject ID | Identification number of subjects | All Simulations |
| Arrival Time | Arrival Time of a particular subject | All Simulations |
| Treatment ID | Treatment given to a particular subject | All Simulations |
| Survival Time | Survival Time of a particular subject | SU-2S-LRAR, SU-2S-LRSD |
| DPN-2S-RAOut Time | Time when a particular subject dPN-2S-RAs out from the study | All Simulations |
| Stratum_Var_< i > | Variable which stratifies the subjects into different levels | SU-2S-LRAR, SU-2S-LRSD |
| CensorInd | Indicator variable (flag) denoting whether a particular subject is censored or not | Enhanced Simulations |
| Response | Response corresponding to a particular subject after given a particular treatment | MN-2S-DI, PN-2S-DI, PN-2S-RA, SU-2S-LRAR, SU-2S-LRSD |
| Endpoint_< i > | Response of endpoint_< i > | All Simulations |
| Survival Time_Weeks | Survival Time of a particular subject in time unit weeks | Survival Designs |
| Site ID | Identification number of sites | MN-2S-DI,PN-2S-DI, PN-2S-RA,SU-2S-LRAR, SU-2S-LRSD |

64 Simulation in East

Following are the output quantities computed while simulating ‘Summary Statistics’.

| Column Name | Description | Applicability |
|---------------------|---|--|
| Scenario ID | Identification number of scenarios when multiple values are provided for a parameter(s) | All simulations |
| SimIndex | An identifier for the simulation | All simulations |
| Look Index | Identifier for the look number | Multi Look Simulations |
| Status | Variable denoting whether a simulation was successfully executed | All simulations |
| BdryStopCode | Lookwise stopping decision | Multi Look simulations (0=Continue, 1= lower efficacy stop, 2= Upper Efficacy stop, 3= Futility) |
| Accruals 0 | Total accrued subjects under control for a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| DPN-2S-RAOuts0 | Total dPN-2S-RApedout subjects under control for a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| Pendings0 | Number of pending subjects under control for a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| Events0 | Total number of events happened for control | SU-2S-LRAR, SU-2S-LRSD |
| Accruals_< i > | Total accrued subjects under treatment i for a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| DPN-2S-RAOuts_< i > | Total dPN-2S-RApedout subjects under treatment i for a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |

| Column Name | Description | Applicability |
|-----------------------|---|--|
| Pendings_< <i>i</i> > | Number of pending subjects under treatment <i>i</i> for a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| Events_< <i>i</i> > | Total number of events happened for treatment <i>i</i> | SU-2S-LRAR, SU-2S-LRSD |
| TotAccruals | Total accruals for all the treatments together in a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| TotDPN-2S-RAOuts | Total dPN-2S-RA outs for all the treatments together in a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| Tot Pendings | Total pending subjects for all treatments together | Enhanced simulations with accrual dPN-2S-RAout |
| Tot Events | Total events for all the treatments together in a particular simulation | SU-2S-LRAR, SU-2S-LRSD |
| Look Time | At what time a particular look was taken | Enhanced simulations with accrual dPN-2S-RAout |
| Avg FollowUp Time | Average followup time for a particular simulation | Enhanced simulations with accrual dPN-2S-RAout |
| LogRankScore | Numerator of log rank statistic | SU-2S-LRAR, SU-2S-LRSD |
| HRfMN-2S-RALRStat | HR estimated fMN-2S-RA Log Rank statistic | SU-2S-LRAR, SU-2S-LRSD |

64 Simulation in East

| Column Name | Description | Applicability |
|----------------------------------|---|--|
| StdError | Standard Error | All simulations |

Predictive Interval Plots

65.1 Predicting the Future Course of a Trial with Predictive Interval Plots (PIPS)

At the design stage of clinical trial, when no data are available, one relies on initial assumptions about the efficacy of the treatment arms to perform power calculations. Once the trial is underway, however, data begin to accrue and can be utilized to make predictions about the future course of the trial. These predictions fall into two categories; predictions from data pooled by treatment arm and predictions from unpooled data. For the trial sponsor, who must remain blinded to the results while the trial is on-going one, predictions from pooled data are the only option. A data monitoring committee on the other hand does have access to data broken out by treatment arm and is thus in a position to make predictions about the future course of the trial in an unblinded manner. In this chapter, we focus only on predictions from unblinded data. A popular way to make such predictions is through the use of conditional power. We have provided numerous examples of conditional power throughout this manual and hence will not dwell on it here. In this chapter we present an alternative graphical approach to prediction, utilizing predictive interval plots (PIPS) proposed by Evans, Li and Wei (2007) and Li, Evans, Uno and Wei (2009). These plots provide us with a visual display of the possible future outcomes for the trial by generating a series of repeated confidence intervals for future time points that are conditional on the current data. Conditional power is an automatic by-product of these plots, which provide additional insights about the magnitude of the treatment effect and its associated uncertainty. Please see Appendix L for details on input, output, and formulas relating to Predictive Interval Plots.

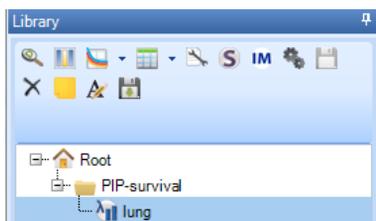

65.2 Example 1: PIP for Time to Event Data

A clinical trial of non small cell lung cancer was designed for 80% power to detect a hazard ratio of 0.8 at $\alpha = 0.05$ (two-sided) with three equally spaced looks using a Lan-DeMets O'Brien-Fleming type (**LD (OF)**) spending function. The primary endpoint was overall survival (OS). With these inputs, 641 OS events are needed to achieve 80% power. The median OS for the control arm was assumed to be 10 months. Based on 18 months of enrollment and an additional 12 months of follow-up this 30-month trial requires 639 events from a sample size of 897 patients.

The workbook **PIP-survival** containing this design named **lung** is already available to you in the sub-folder **Samples** in the East 6.4 installation folder in your computer. A typical path for this sub-folder is: **C:\Program Files (x86) \Cytel\Cytel Architect\East 6.4\Samples**. Open this workbook from File or Home menu.

65 Predictive Interval Plots

The Library nodes will appear as shown below.

Click on the design node **lung** and click on  icon to get the details of the design as shown below.

| Test Parameters | |

Stopping Boundaries: Look by Look

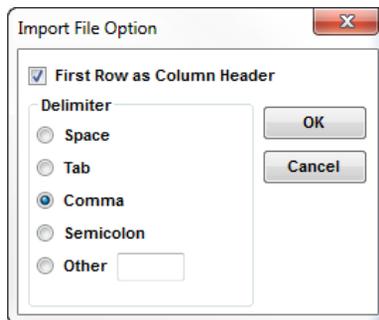

| Look # | Info. Fraction (s/s_max) | Events (s) | Cumulative α Spent | Boundaries Efficacy Z | |
|--------|--------------------------|------------|---------------------------|-----------------------|--------|
| | | | | Upper | Lower |
| 1 | 0.333 | 213 | 2.07E-4 | 3.71 | -3.71 |
| 2 | 0.667 | 426 | 0.012 | 2.511 | -2.511 |
| 3 | 1 | 639 | 0.05 | 1.993 | -1.993 |

The First Interim Analysis Although the first interim analysis was planned after 213 events, due to rapid enrollment it occurred earlier, after only 119 events. The dataset containing the data from the first interim analysis is saved in a .csv file named **PIP-Lung-Look01.csv** in the **Samples** folder. To illustrate the role of the PIPs at this interim analysis, you need this dataset. While you are on the design node **lung**, you can bring up this dataset into the workbook by clicking on the menu item File >

Import or Home > Import and locating the sub-folder Samples.

After clicking on the menu item **Import** and locating **Samples** sub-folder, you click on the dataset name **PIP-Lung-Look01.csv**. You will be presented with the following dialog box.

Keep the default choices selected, click OK, and keep the imported dataset in the workbook **PIP-survival**. Now a new node with the name **PIP-Lung-Look01.cydx** will appear under the design node **lung**. The data also

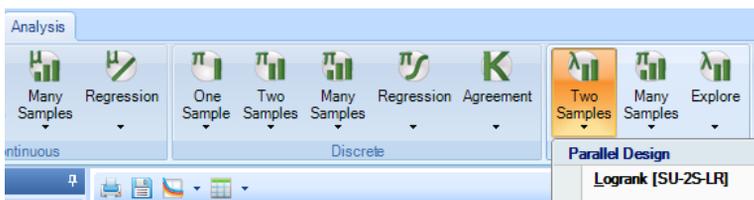

65 Predictive Interval Plots

will be displayed in the right side window.

| TrtmntID: 1 | | Value: 2 | | | | |
|-------------|----------|------------|-------------|---------|---------|-----|
| | TrtmntID | SRVMON | ArrivalTime | Censor1 | Censor2 | var |
| 1 | 2 | 1.4 | 0.033333333 | 1 | 1 | |
| 2 | 2 | 1.4 | 0.066666667 | 1 | 1 | |
| 3 | 2 | 22.6333333 | 0.066666667 | 0 | 0 | |
| 4 | 2 | 3.3 | 0.2 | 1 | 1 | |
| 5 | 2 | 5.3 | 0.533333333 | -1 | 0 | |
| 6 | 1 | 4 | 0.866666667 | 1 | 1 | |
| 7 | 1 | 2.8 | 1.166666667 | 1 | 1 | |
| 8 | 2 | 2.8 | 1.6 | 1 | 1 | |
| 9 | 2 | 3.4 | 1.933333333 | 1 | 1 | |
| 10 | 1 | 20.6666667 | 2.033333333 | 0 | 0 | |

The dataset is saved in the library as a Cytel file with extension **.cydx**. Examine this dataset. It contains five variables: TrtmntID (1=control, 2=experimental); SRVMON (time since entering the trial in months); ArrivalTime (time of entry into the trial), Censor1 (1=alive; 0=dead, -1=lost to follow up); Censor2 (1=alive, 0=dead or lost to follow up). Note the presence of two censor variables. Censor1, indicating drop-outs with -1, is utilized by the program that generates the PIPs. Censor2, indicating either drop-outs or administratively censored patients, is utilized by the Analysis program computing the Logrank test. This can be seen in the choice of the variables in the Analysis dialog box and PIP dialog box detailed below.

Before we can perform the first interim analysis, we must estimate the hazard ratio and its standard error from this interim analysis dataset. To that end, select the **Two Samples > Logrank** from the **Analysis** tab.

Enter the appropriate variables into the input dialog box.

Analysis: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank

Data Set: PIP-Lung-Look01.cyx

Main Advanced

Trial Type: Superiority Response Variable: SRVMON Frequency Variable:

Population ID: TrtmntID

Control: 1 Censor Indicator: Censor2

Treatment: 2 Censored: 0 Complete: 1

and click on the **OK** button at the bottom right side of the screen. You will get the analysis results with a summary as shown below.

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | | Average Follow-up Time |
|--------------|-----------------|------------|----------------|------------|----------------|------------------------|
| | | Count | % | Count | % | |
| 1 | 256 | 61 | 23.828% | 195 | 76.172% | 11.353 |
| 2 | 261 | 58 | 22.222% | 203 | 77.778% | 11.699 |
| Total | 517 | 119 | 23.017% | 398 | 76.983% | 11.528 |

Test of Hypothesis:

| Log Rank Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|----------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| -2.509 | 5.441 | -0.461 | L.E. | 0.322 | 0.645 |

Parameter Estimates from Cox Model:

| Hazard Ratio (HR) | ln(Hazard Ratio) (δ) | Std. Error of Estimate of δ | Wald Statistic | 95% Confidence Interval(2-Sided) | |
|-------------------|-------------------------------|------------------------------------|----------------|----------------------------------|-------------|
| | | | | Lower Limit | Upper Limit |
| 0.919 | -0.084 | 0.183 | -0.46 | 0.642 | 1.317 |

Estimated Hazard Rates:

| | |
|--------------------------------|---------|
| Control (λ_c) | 0.02099 |
| Treatment ($\lambda_c * HR$) | 0.01929 |

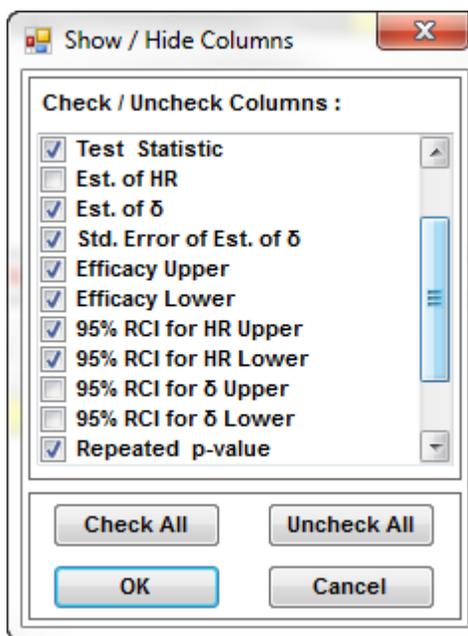

The hazard ratio is 0.919 and the total number of events is 119. These are the summary statistics we need to perform the first interim analysis. With the design node **lung** selected in the library, bring up the Interim Monitoring worksheet by clicking on the

65 Predictive Interval Plots

IM icon on the library toolbar.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for HR | | Repeat... p-value | CP | Predictive Power |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|-------|----------------|-------|-------------------|----|------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | | | | | | | | | | | | |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

East gives you a facility to choose the columns to display in the IM sheet, by clicking on the show/hide icon  and choosing from the list displayed.

For convenient entry of the summary data into the interim monitoring worksheet, you can display the Interim Monitoring worksheet and the logrank analysis side by side in two windows, with the use of the menu item Home>Arrange>View Selected

Windows:

The screenshot displays the 'IM Interim Monitoring Dashboard' window. At the top, there is a table for 'Look #', 'Information Fraction', 'Cumulative Events', 'Test Statistic', 'Est. of δ ', 'Std. Error of Est. of δ ', and 'Efficacy' (Upper, Lower, U). Below this, a red instruction reads: 'Click the "Enter Interim Data" button to enter the Look # 1 data.' The dashboard includes several interactive panels: 'Stopping' (Cum. Events, Efficacy Upper/Lower), 'Conditions' (HR, CP), 'Error' (Info. Fraction, α), and 'Conf.' (Info. Fraction, RCI Upper/Lower). To the right, the 'Analysis: Time to Event Response: Logrank Test' window is open, showing the following text:

Let $\delta = \ln(A_1/A_2)$
 $H_0: \delta = 0$ Vs. $H_1: \delta \neq 0$ for 2-Sided test
 Either $H_1: \delta > 0$ Or $H_1: \delta < 0$ for 1-Sided test

Data File: PIP-Lung-Look01.cyx
 Trial Type: Superiority
 Population ID: TrtmntID(Treatment=2, Control=1)
 Response Variable: SRVMON
 Censor: Censor2(Censor Value=0, Complete=1)
 Confidence Level: 0.95

Output

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | |
|--------------|-----------------|--------|---------|----------|---------|
| | | Count | % | Count | % |
| 1 | 256 | 61 | 23.828% | 195 | 76.172% |
| 2 | 261 | 58 | 22.222% | 203 | 77.778% |
| Total | 517 | 119 | 23.017% | 398 | 76.983% |

| Hazard Ratio (HR) | 95% Confidence Interval(2-Sided) | | |
|-------------------|----------------------------------|-------------|--|
| | Lower Limit | Upper Limit | |
| 0.919 | 0.641 | 1.317 | |

Click on the **Enter Interim Data** button and the **Test Statistic Calculator** will appear. Here you have two options, either you can read and transfer directly from the results of analysis node or enter the estimate and SE of delta manually. Let us follow the first option. Click on the Recalc button and it will transfer the results from

65 Predictive Interval Plots

the analysis node to the test statistic calculator.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Read from Analysis Node

Select Workbook: PIP-survival

Select Analysis Node: PIP-Lung-Look01.cydx:Analysis:

Cumulative Events: 119

Input for Survival end point

Estimate of δ : -0.084

$\delta = \ln(\lambda_t / \lambda_c)$

Standard Error of Estimate of δ : 0.183

Output

Test Statistic: -0.46

Recalc OK Cancel

If you had chosen the second option in the test statistic calculator, you would enter 119 for the cumulative number of events, $\ln(0.919)$ for $\hat{\delta}$ and $2/\sqrt{119}$ for the standard error of $\hat{\delta}$.

Click **OK** to enter the first-look data into the interim monitoring worksheet.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for HR | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|--------|----------------|-------|-------------------|-------|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.186 | 119 | -0.46 | -0.084 | 0.183 | 5.063 | -5.063 | 2.326 | 0.363 | 1 | 0.156 | 0.403 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

The results at this first interim analysis are not very promising. The conditional power under the current trend (HR=0.919) is only 0.156 and the predictive power is only 0.403. The predictive interval plots (PIPs) can provide some additional insights by simulating the future course of the trial conditional on the data already obtained and assumptions about the hazard rates of the two survival curves. To generate these plots select the **Look # 1** row. Then click on the **PIP** icon to open the PIP dialog box. Enter the inputs into the left panel of the dialog box as shown below.

PIP for Look: Required No. of Events:

Specify Subject Info

Select Workbook:

Select Subject Data:

Choose Variables

Population ID: Status Indicator:

Control: 1=Complete

Treatment: 0=Censored

Arrival Time: Response Variable:

-1 = Dropout

The information in the PIP-Lung-Look01.cyx is now available to East.

Entries into the right hand panel of the PIP inputs dialog box may either be user specified or estimated directly from the PIP-Lung-Look01.cyx dataset. To begin with, let us estimate the entries from the data. Accordingly click on the **Optional: Estimate Parameters from Data** button. The right hand panel fills up as

65 Predictive Interval Plots

shown below.

Parameters of Current Dataset (Editable)

| | | |
|---|---------|-----------|
| Sample Size: | 517 | |
| No. of Events: | 119 | |
| Accrual Rate: | 44.957 | |
| Hazard Ratio (λ_t/λ_c): | 0.919 | |
| | Control | Treatment |
| Hazard Rate (λ): | 0.021 | 0.019 |
| Dropout Hazard Rate (γ): | 0.002 | 0.001 |

We are now in a position to generate the predictive interval plots. As stated earlier these are repeated confidence intervals based on the data already observed and estimates of the hazard ratio for future looks. Since the first interim look was taken earlier than planned, there are still three additional interim looks (looks, 2, 3, or 4) to be encountered.

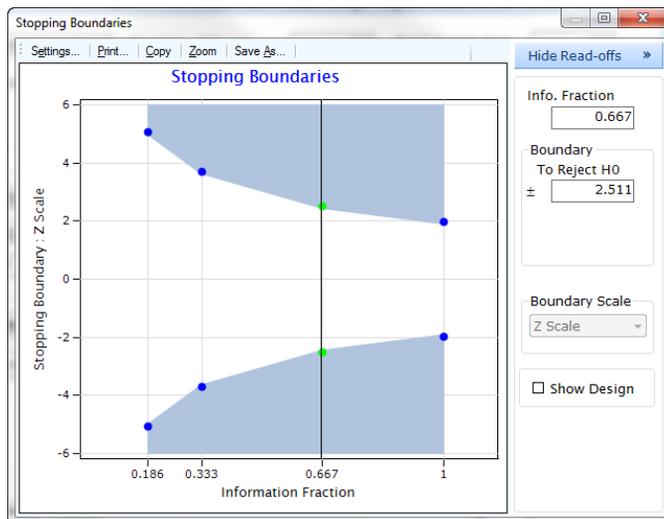

Input for Predicted Intervals Plot

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

PIP for Look: Any Future Look Total No. of Events: 639 Total Sample Size: 897

The boundaries for these future looks have been re-computed based on the specified error spending function. To view the re-computed 4-look design, click on the 

icon at the top right of the input dialog box.

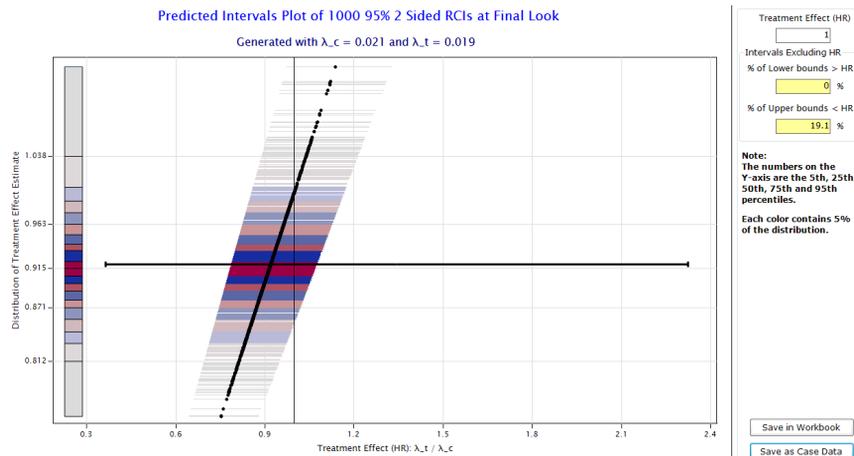

Suppose we wish to generate 1000 PIPs for look 4, ignoring the intermediate looks. Select Final Look from the drop-down box .

The dialog box is titled "Input for Predicted Intervals Plot" and contains the following information:

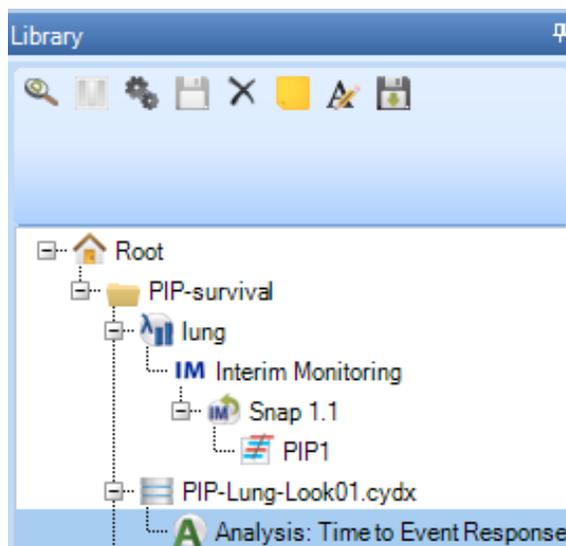

- Simulation: Survival Endpoint - Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration
- PIP for Look: Final Look (selected in a dropdown)
- Required No. of Events: 639
- Total Sample Size: 897

65 Predictive Interval Plots

and press the **Simulate** button. The following plot is generated.

One thousand repeated confidence intervals (RCIs) are generated for look 4, sorted in increasing order of their corresponding estimated hazard ratios, and stacked on top of each other. Save this PIP in the library by clicking on the **Save in Workbook** button on the bottom right of the plot. The library should now look as shown below.

Let us examine the generated PIP. The black horizontal line is the RCI for the current look (look 1). Notice how much narrower the RCIs for look 4 are compared to the current RCI. By default, the vertical cursor is positioned at HR=1 on the X-axis. In this position it is seen that 19.1% of the RCI's have upper bounds that are less than 1, suggesting that under the current trend with HR=0.919, the probability of a successful outcome for this trial at look 4 (ignoring all intermediate looks) is 0.191.

One can drag the vertical cursor to the right or left to see what percentage of trials will successfully cut-off hazard ratios other than 1. For the present let us leave the vertical cursor at HR=1. Notice the thick vertical bar with colored bands near the Y-axis. This band displays quantiles of the distribution of the hazard ratios generated by the simulations. Each color on either side of the median contains 5% of the generated hazard ratios. Thus, for example, the lowest five bands on the bar, ending at HR=0.871 represent 25% of the generated hazard ratios. In other words, the lower 25-th quantile of the hazard ratios is 0.871.

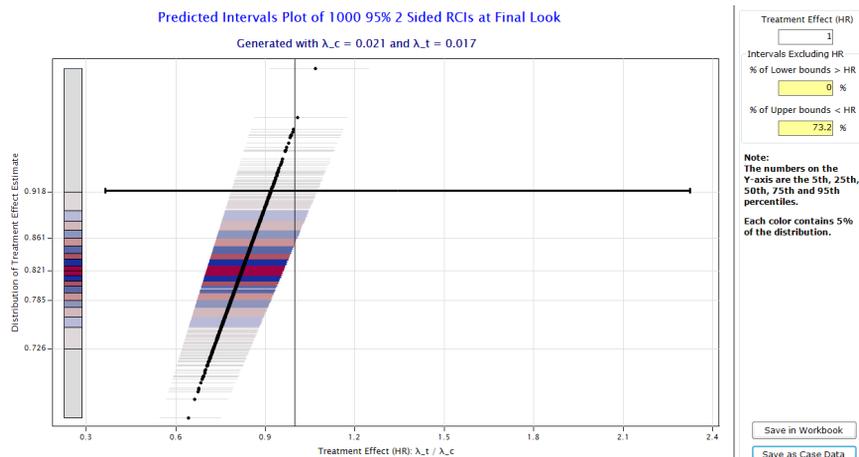

Since only 19.1% of the RCIs in this PIP resulted in a statistically significant outcome (upper bound of RCI less than 1), one might weigh the option of terminating the trial for futility. The above PIP was, however, generated under the assumption that the hazard ratio is 0.919, estimated from the look 1 data, is the actual hazard ratio. There is uncertainty associated with this estimate. Thus it would be desirable to take a conservative approach to futility termination and re-run the PIPs under the assumption, made at the design stage, that the underlying HR=0.8. To that end, we retrieve the input dialog box that was used for the current PIP by clicking on **PIP1** in the library and clicking on the **Edit** tool in the library toolbar. While on the node **PIP1**, click on . In the ensuing dialog box, change the value of the hazard rate for the Treatment arm from the current $\lambda(Treatment)$ value to $0.8 \times \lambda(Control)$.

| | Control | Treatment |
|-----------------------------------|---------|---------------|
| Hazard Rate (λ): | 0.021 | $0.8 * 0.021$ |
| Dropout Hazard Rate (γ): | 0.002 | 0.001 |

Now generate a new PIP by clicking on the **Simulate** button and save it in the

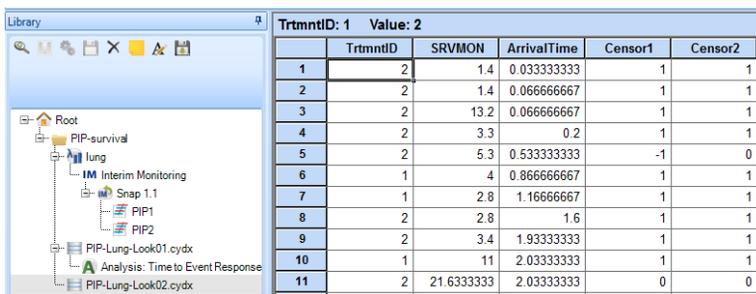

65 Predictive Interval Plots

workbook.

In this PIP, 73.2% of the RCIs have upper bounds that exclude HR=1. Therefore, given the uncertainty about the true value of the HR, it is premature to terminate this trial for futility and the trial continues to the next interim analysis.

The Second Interim Analysis The dataset for the second interim analysis is contained in a .csv file named **PIP-Lung-02.csv** on your computer. Import this .csv into East as shown below.

Next perform the logrank test on the look 2 data by invoking it from the Analysis tab in the same manner as you did for look 1.

The results will appear as shown below.

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | |
|--------------|-----------------|--------|---------|----------|---------|
| | | Count | % | Count | % |
| 1 | 395 | 126 | 31.899% | 269 | 68.101% |
| 2 | 403 | 132 | 32.754% | 271 | 67.246% |
| Total | 798 | 258 | 32.331% | 540 | 67.669% |

Parameter Estimates:

| Hazard Ratio (HR) | 95% Confidence Interval(2-Sided) | |
|-------------------|----------------------------------|-------------|
| | Lower Limit | Upper Limit |
| 1.019 | 0.799 | 1.301 |

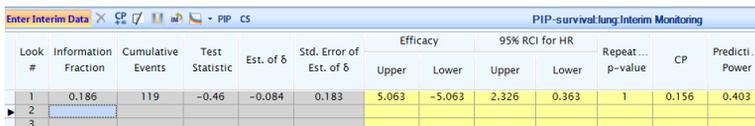

Test of Hypothesis:

| Log Rank Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|----------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| 1.231 | 8.008 | 0.154 | G.E. | 0.439 | 0.878 |

Estimated Hazard Rates:

| | |
|--------------------------------|-------|
| Control (λ_c) | 0.033 |
| Treatment ($\lambda_c * HR$) | 0.034 |

At this look, taken after 258 events, the hazard ratio estimate is 1.019. We must enter this information into the interim monitoring worksheet. Select the node **Interim Monitoring** from the library and click on the  icon in the library toolbar. You will see the IM worksheet as shown below.

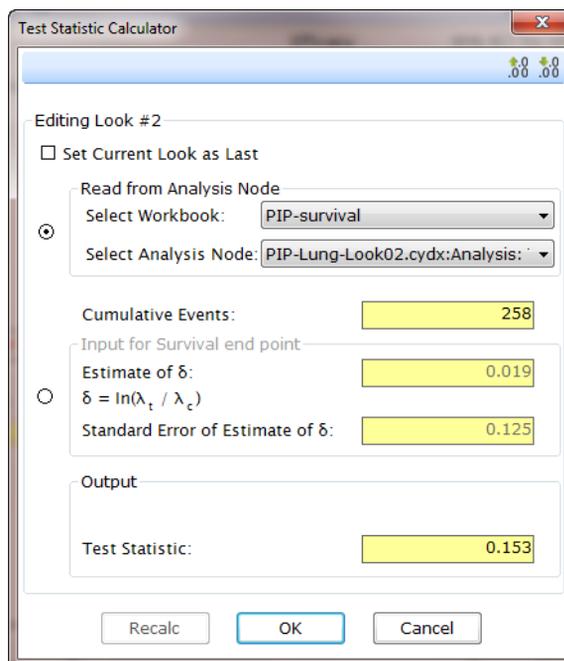

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of 6 | Std. Error of Est. of 6 | Efficacy | | 95% RCI for HR | | Repeat p-value | CP | Predicted Power |
|--------|----------------------|-------------------|----------------|-----------|-------------------------|----------|-------|----------------|-------|----------------|----|-----------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| | | | | | | 1 | 0.186 | 119 | -0.46 | | | |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

With **Look #2** selected, click on the **Enter Interim Data** button and choose the option to read values from look 2 analysis node. Click on Recalc button to see the test

65 Predictive Interval Plots

calculator computations as shown below.

enter in the resulting **Test Statistic Calculator**, the values for **Cumulative Events = 258**, **Estimate of delta = $\ln(1.019)$** , and **Standard Error of Estimate of delta = $2/\sqrt{258}$** , and click the **OK** button. The interim monitoring worksheet gets updated.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for HR | | Repeat ... p-value | CP | Predicti... Power |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|-------|----------------|--------|--------------------|-------|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| | | | | | | 1 | 0.186 | 119 | -0.461 | | | |
| 2 | 0.404 | 258 | 0.151 | 0.019 | 0.125 | 3.34 | -3.34 | 1.544 | 0.672 | 1 | 0.013 | 0.108 |
| 3 | | | | | | | | | | | | |

Now the conditional power under the current trend is only 0.014 and the predictive power is only 0.108. It is very unlikely that the trial will succeed and termination for futility appears to be a reasonable option. Before taking a final decision, however, it may be advisable to obtain a PIP for the future course of the trial under the assumption that HR=0.8 is still correct and the observed value HR=1.019 is due to variability in the data. Accordingly we invoke the PIP dialog box, enter a value of 0.8 for the hazard

ratio, and simulate the remainder of the trial 1000 times.

We observe that 32.2% of the RCIs have upper bounds that are below 1. This suggests that if the trial continued and the true hazard ratio was indeed 0.8 the chance of a successful trial is 0.322. But how many of these successful outcomes would be considered clinically meaningful? Suppose that trials with observed values of HR that exceed 0.85 are not of any interest to the sponsor since there are other compounds on

65 Predictive Interval Plots

the market for this therapeutic area that have had smaller hazard ratios. Then the question becomes, how many of the 1000 RCIs would have upper bounds that are below 0.85. To answer this question, move the vertical cursor to 0.85 on the X-axis. This can be done either by dragging the cursor or (more conveniently) by entering the value 0.85 in the edit box at the top of the **Read-offs** panel of the PIP.

It is seen that 0.2% of the RCIs have upper bounds that are below 0.85 even though we generated the PIP under the optimistic assumption that the true HR=0.8. It is clearly desirable to terminate the trial for futility.

This example has shown that the RCIs provide more information than can be obtained from a conditional power calculation. The PIP may be used to determine whether a clinically meaningful treatment effect can be ruled out.

65.3 Example 2: PIP for Binomial Data

CAPTURE (Lancet, 1997; 349: 1429-35) was a randomized placebo-controlled trial of abciximab before and during coronary intervention in refractory unstable angina. After angiography, patients received a randomly assigned infusion of abciximab or placebo followed by percutaneous transluminal coronary intervention (PTCA). The primary endpoint was death from any cause within 30 days after the PTCA. The planned enrollment was 1400 patients with four equally spaced looks and stopping boundaries generated by the LD(OF) spending function. This study has 80% power to detect a 5% difference in mortality rates, from 15% on the placebo arm to 10% on the abciximab arm, at two sided $\alpha = 0.05$.

The workbook **PIP-binomial** containing this design named **capture** is already available to you in the sub-folder **Samples** in the East 6.4 installation folder in your computer. Open the **PIP-binomial** workbook in the East library. The design details are shown below.

| Test Parameters | |
|-----------------------------------|-------------------|
| Design ID | Capture |
| Design Type | Superiority |
| Number of Looks | 4 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.802 |

Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|------------|---|----------|
| | | | | | Under H0 | Under H1 |
| | | | | | Efficacy Z | Efficacy |
| 1 | 0.25 | 350 | 7.367E-6 | -4.333 | 7.367E-6 | 0.002 |
| 2 | 0.5 | 700 | 0.002 | -2.963 | 0.002 | 0.167 |
| 3 | 0.75 | 1050 | 0.01 | -2.359 | 0.008 | 0.373 |
| 4 | 1 | 1400 | 0.025 | -2.014 | 0.015 | 0.26 |

The table below displays the results observed at each interim look.

Table 65.1: Results Observed At Each Interim Look

| Look Number | Sample Size | Placebo | Abciximab | p-value |
|-------------|-------------|----------------|----------------|---------|
| 1 | 350 | 30/175 (17.2%) | 14/175 (8%) | 0.010 |
| 2 | 700 | 55/353 (15.6%) | 37/347 (10.6%) | 0.047 |
| 3 | 1050 | 84/532 (15.8%) | 55/518 (10.6%) | 0.010 |

The stopping boundary was crossed and the Data Monitoring Committee stopped the trial

Let us enter the data from the first two looks into the interim monitoring worksheet. Select the CAPTURE design in the workbook library and click on the **IM** tool from the library toolbar.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat ... p-value | CP | Predicted ... Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|------------------------|-------|--------------------|----|---------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | | | | | | | | | | | |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |
| 4 | | | | | | | | | | | |

Now enter the data for the first two looks into the IM dashboard. For each look you

65 Predictive Interval Plots

will have to click on the **Enter Interim Data** button to invoke the test statistic calculator and enter the data look by look as described below.

For the first look, enter the data in the test statistic calculator, click on **Recalc** and **OK** buttons.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Sample Size and Responses

| | Control | Treatment |
|-------------------------|---------|-----------|
| Cumulative Sample Size: | 175 | 175 |
| Cumulative Response: | 30 | 14 |

Cumulative Sample Size: 350

Input for Binomial end point

Estimate of δ : -0.091

$\delta = (\pi_1 - \pi_2)$

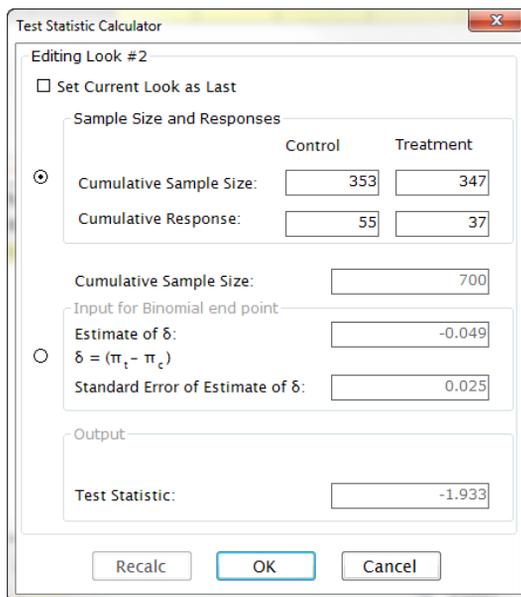

Standard Error of Estimate of δ : 0.035

Output

Test Statistic: -2.605

Recalc OK Cancel

Similarly post the data for the second look into the IM worksheet.

Now you will see the computed results posted into the IM worksheet as shown below.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat ... p-value | CP | Predicti... Power |
|--------|----------------------|------------------------|----------------|--------|----------------|----------|-----------------|-------|--------------------|-------|-------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.25 | 350 | -2.605 | -0.091 | 0.035 | -4.333 | 0.061 | -1 | 0.157 | 1 | 0.971 |
| 2 | 0.5 | 700 | -1.933 | -0.049 | 0.025 | -2.963 | 0.026 | -1 | 0.118 | 0.858 | 0.778 |
| 3 | | | | | | | | | | | |
| 4 | | | | | | | | | | | |

It is evident from the above results that new drug looks promising. The conditional power is 0.858 and the predictive power is 0.778. It might be instructive at this stage to run a PIP for the future course of the trial. The data for the first two looks are stored on your computer in a .csv file named "PIP-Capture-Look02.csv". Import this file into

65 Predictive Interval Plots

East. It will be added to the library with the name "PIP-Capture-Look02.cydx".

| | Trtmnt_ID | Response |
|----|-----------|----------|
| 1 | 1 | 0 |
| 2 | 1 | 1 |
| 3 | 0 | 0 |
| 4 | 0 | 0 |
| 5 | 1 | 0 |
| 6 | 0 | 1 |
| 7 | 0 | 0 |
| 8 | 0 | 0 |
| 9 | 0 | 0 |
| 10 | 1 | 1 |

Now return to the IM dashboard by selecting Interim Monitoring node in the library. To produce the PIP for the next look (look 3), select the Look 2 row on the IM dashboard and click on the **PIP** button. Complete the Input dialog box as shown below. (Remember to click on the **Optional: Estimate Parameters from Data** button if you want East to compute the sample size and estimate the event rates from the look 2 dataset and post these parameters directly into the dialog box.)

Simulate Cancel

Click on the **Simulate** button to generate the PIP for look 3 with 1000 repeated confidence intervals.

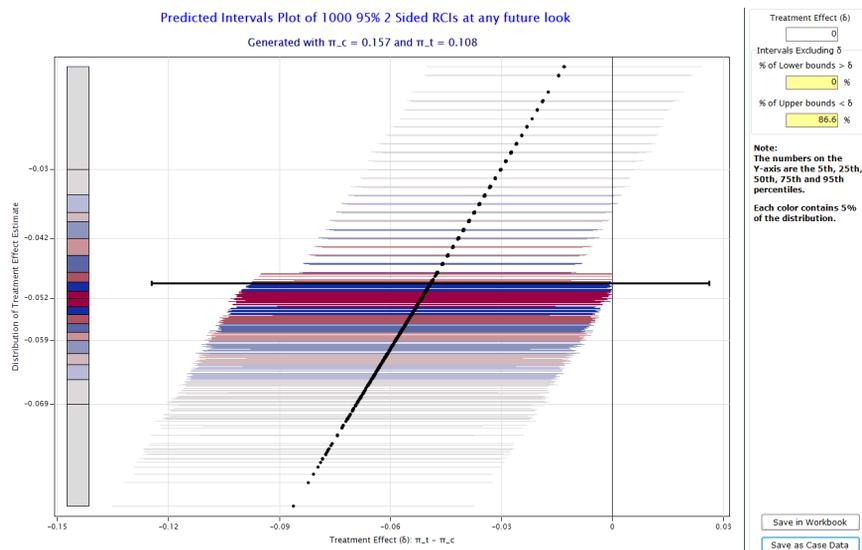

Observe that for 49.8% of the RCIs have upper bounds that exclude 0. Thus, conditional on current data and the current estimates of the event rates, there is a 49.8% chance of crossing the early-stopping boundary at the very next look. Save this PIP in the library. This can be done by clicking on the **Save in Workbook** button at the bottom right of the screen.

Suppose we wish to generate a PIP for any future look, not simply the next one. With the cursor on the PIP1 node in the library, click on the edit tool, and specify in the

65 Predictive Interval Plots

resulting input dialog box that you wish to create a PIP for "any future look".

Upon clicking the **Simulate** button the requested PIP is generated.

Overall, 86.6% of the RCIs have upper confidence bounds that are less than 0. The wider intervals are generated at Look 3 and the narrower ones are generated at Look 4. This PIP shows that the overall probability that this trial will be a success, conditional on current trends, is 0.866. The vertical rectangle with the colored bands displays the distribution of the estimated risk reductions, From this PIP we see that only the 5% of the estimated risk reductions will be less than 0.029. We now return to the IM dashboard and enter the data for look 3.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat ... p-value | CP | Predicti... Power |

Test Statistic: -2.485

Click **OK** on the test statistic calculator to post the computed values for third look. Now

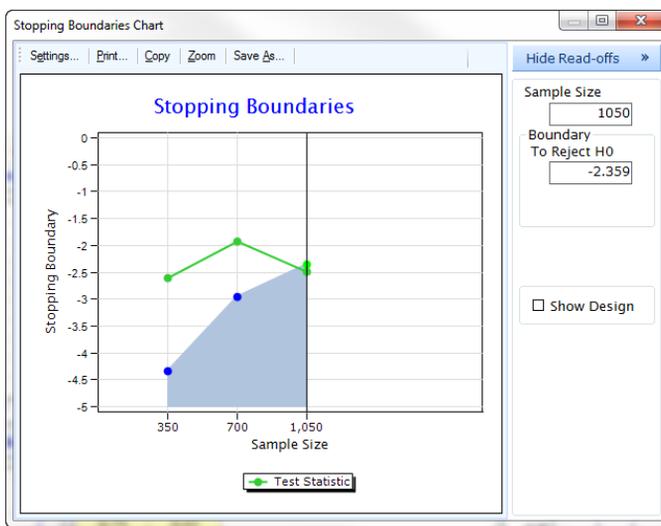

65 Predictive Interval Plots

the boundary is crossed and you are presented with the message on boundary crossing.

You have to decide now, on the choice of either stopping or continuing the trial. In the actual trial the data monitoring committee (DMC) recommended that the trial be terminated and the sponsor agreed with the recommendation. Thus abciximab was declared to be superior to placebo in this class of patients with respect to all causes mortality, at the two-sided 5% level of significance.

Notice, however, that the stopping boundary was barely crossed.

The efficacy boundary is -2.359 while the corresponding test statistic is -2.485. Had there been one less event on the Control arm and one more on the Treatment arm, the efficacy boundary would not have been crossed and the study would have continued to the final look after enrolling 1400 patients. Now the DMC is charged with examining the totality of evidence, including safety issues and consistency across secondary endpoints before recommending that a trial be terminated. Therefore sometimes, in close situations like this one, the DMC might well recommend that the trial not be terminated prematurely but rather that it continue to the end so as to achieve a robust result that can alter medical practice. In such a situation the DMC might find a PIP for the final look to be a valuable additional piece of information to help it with the decision making. In order to illustrate this, now stop the trial first. Next, click on PIP button while on the third look in the IM worksheet. You will be presented with PIP dialog box where you fill in the details. The dialog box will look as shown below.

Input for Predicted Intervals Plot

65 Predictive Interval Plots

Click on **Simulate** button. The PI plot will be generated as shown below.

We see that 95.8% of the RCIs have upper confidence bounds that are below zero. Thus the trial were to continue to look 4, there is only a 4% chance that it would fail to achieve statistical significance. Moreover, the vertical bar near the Y-axis displaying the distribution of the estimates of treatment effect shows in 95% of the simulations the absolute risk reduction is at least -0.037. This is the type of robust result that the trial needs to obtain in order to alter medical practice. Thus the DMC might weigh the trade-off between terminating the trial immediately with a relatively marginal result or proceeding to take one more look with a high probability of achieving a stronger result.

65.4 Example 3: PIP for Continuous Outcome Data

We thank the AIDS Clinical Trials Group (ACTG) for permitting us to use this dataset. NARC 009 was a prospective, randomized, double-blind, placebo-controlled, multicenter, clinical trial of Prosaptide (PRO) conducted by the Neurologic AIDS Research Consortium for the treatment of HIV-associated neuropathic pain. Subjects were randomized to a daily dose of 2, 4, 8 or 16 mg PRO or placebo via subcutaneous injection. The primary endpoint was the 6-week reduction from baseline in the weekly average of random daily Gracely pain scale prompts, collected using an electronic diary. The trial randomized a total of 390 subjects in equal proportion to the five treatment arms. With 78 patients/arm the trial is capable of detecting a difference (treatment minus control) in the change from baseline of $\delta = -0.2$ Gracely units with

93% power, for each dose versus placebo comparison, assuming a common $\sigma = 0.35$, two-sided $\alpha = 0.05$, and no correction for multiplicity. One interim analysis was planned when about half the patients had enrolled.

In this example, we will only consider the comparison of the 2 mg dose and placebo. The design is saved in the East workbook named PIP-normal. Please bring up this workbook into your East library.

Design: Continuous Endpoint: Two-Sample Test - Parallel Design - Difference of Means

Test Parameters

| | |

| 8 | 8 | 0 | -0.533261905 |
| 9 | 9 | 0 | -0.416964286 |
| 10 | 10 | 0 | -0.356419048 |

Then perform the **Two Samples > Difference of Means** test on the

65 Predictive Interval Plots

imported dataset.

Click on **OK** at the bottom of Analysis input dialog box. You will get the following analysis results.

Output

Response Variable: CFBPAIN
 Total Number of Records: 65
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|--------|-------|--------|--------|---------|----|
| 0 | -1.178 | 0.238 | -0.086 | -0.231 | 0.333 | 31 |
| 1 | -1.36 | 0.366 | -0.174 | -0.251 | 0.366 | 34 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-------|----|---------|------|---------|----------------------------------|-------------|
| | | | | | | p-value | Tail | | p-value | Lower Limit |
| 65 | -0.019 | -0.055 | 0.087 | -0.22 | 63 | 0.413 | L.E. | 0.826 | -0.193 | 0.155 |

The observed value of δ is only -0.019 with a standard error of 0.087. We will enter these results into the interim monitoring worksheet. Select the NARC009 node in the library and click on the **IM** tool in the library toolbar. Then click on the **Enter Interim Data** button and enter the sample size, estimate of δ and standard error

into the test statistic calculator and press **OK**.

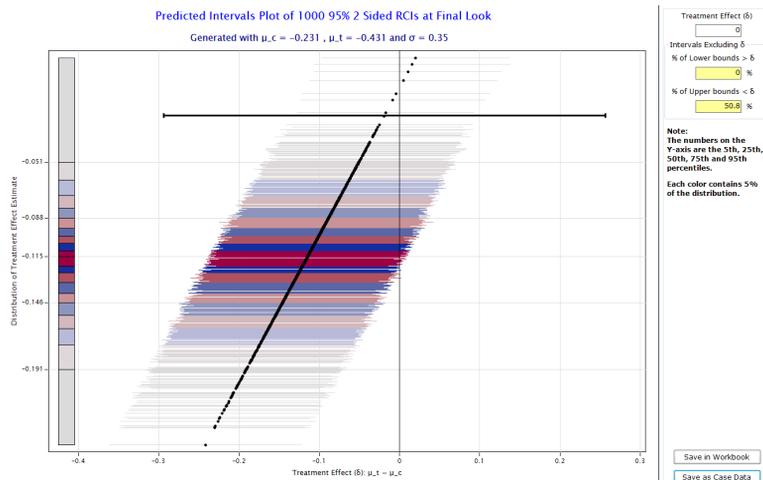

The computed values will now be posted in the IM worksheet.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | | 95% RCI for δ | | Repeat ... p-value | CP | Predicti... Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|--------|----------------------|--------|--------------------|-------|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.445 | 65 | -0.218 | -0.019 | 0.087 | 3.163 | -3.163 | 0.256 | -0.294 | 1 | 0.015 | 0.091 |
| 2 | | | | | | | | | | | | |

These interim results are rather poor. With a conditional power of only 0.015 and a predictive power of only 0.091 under the current trend, this trial is likely to fail. Before terminating the trial for futility, however, it would be useful to generate a PIP with 1000 RCIs generated under the design assumption that the true value of $\delta = -0.2$. With the Look 1 row selected on the Interim Monitoring worksheet, click on the PIP button, click on 'Optional: Estimate Parameters from Data' button, and complete the

65 Predictive Interval Plots

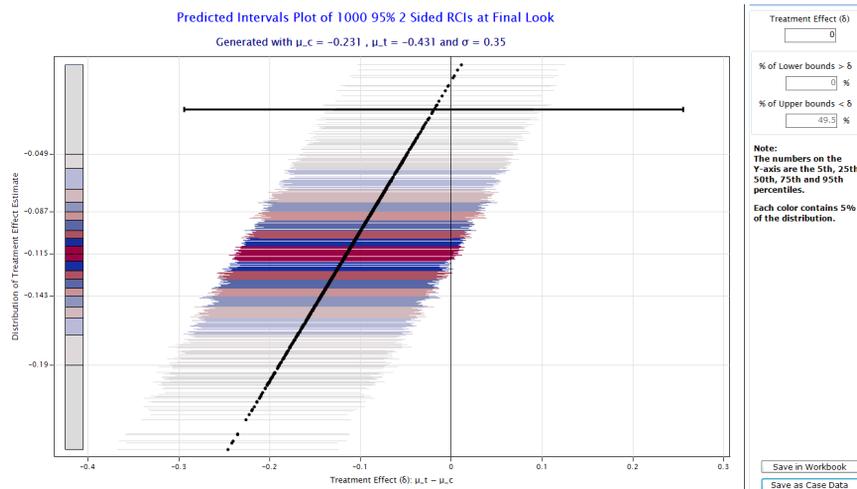

dialog box as shown.

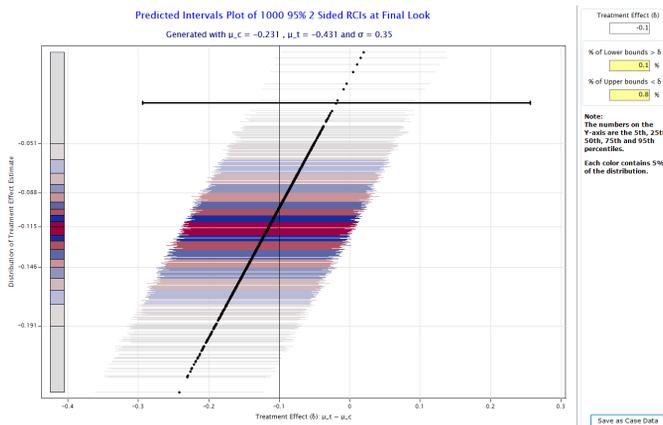

Notice that the PIP is generated for final look is for look 3, not for look 2.

Since look 1 was taken earlier than scheduled, after 65 subjects, the look that was actually designated as look 1 with 73 subjects, is becomes look 2. Thus the final look, with 146 subjects becomes look 3. Also the value of $\mu_t = \mu_c - 0.2 = -0.431$.

Click on the **Simulate** button to generate the PIP.

Under the optimistic assumption that the true value of $\delta = -0.2$ we see that 50.8% of the RCIs have upper bounds that are less than 0. This would suggest that the trial continue to the next look. It is important to point out, however, that the smallest value of δ that would be considered clinically meaningful is $\delta = -0.1$. Accordingly, drag the cursor to -0.1 on the X-axis (or type -0.1, in the edit box at the top of the Read-offs panel).

65 *Predictive Interval Plots*

It is now seen that only 1% of the RCI's have upper bounds that are less than -0.1. Moreover, these RCI's were generated under the optimistic assumption that the true $\delta = -0.2$. We may thus feel confident that terminating the trial for futility is the correct decision.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

EastPredict is an enrollment/events prediction procedure that models the subject enrollment process. In general, the enrollment rate for a specific trial can be estimated based on past experience and any relevant information on that trial. However, this rate is only an estimate and the actual enrollment in a period needs to be treated as a random variable with a certain probability distribution. EastPredict module models this uncertainty in enrollment through the assumption that the subject arrival pattern follows a known probability distribution. In this chapter, we demonstrate the features of EastPredict (henceforth ‘East’) using examples of studies with normal, binomial, and survival endpoints.

Important Note: In this chapter, we will use four examples for three endpoints - normal (Orlistat trial), binomial (Capture trial), and survival (Rales trial and Oncox trial) to illustrate enrollment/events prediction procedures. The main purpose of these procedures is to predict at any time point of the study, the likely cumulative enrollment/completers/dropouts for normal and binomial studies and enrollment/events/dropouts for survival studies. A study may be terminated at a particular time point, because of a decision as per group sequential procedure. In that case, any prediction made for a subsequent time point will have no meaning. So the procedures described in this and the next chapter, predict what would materialize if the study reaches any particular time point, ignoring the possibility of earlier termination by crossing a group sequential boundary. In this way, the predictive procedures cover all possible scenarios, whether the study is likely to terminate earlier or later.

66.1 Normal Design

66.1.1 The Orlistat Trial: Initial Design

66.1.2 Simulating the Orlistat Trial

66.1.3 Output

This section uses inputs from the Orlistat trial described in Chapter 10 and extends the example by adding site information and accrual information to the simulation design.

66.1.1 The Orlistat Trial: Initial Design

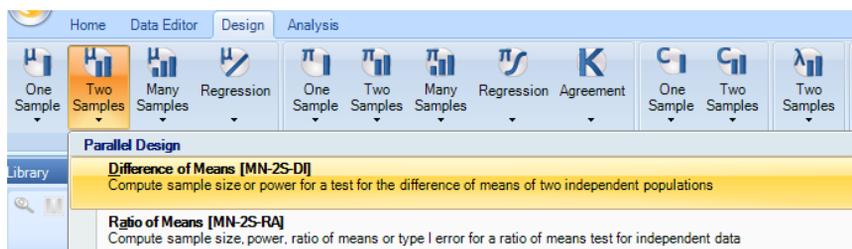

The drug Orlistat was developed to treat obesity by promoting weight loss. Its efficacy was tested by randomizing patients into the treatment group or the control group according to the ratio 3:1, and comparing the resulting weight loss of the two groups after one year. The following assumptions were made:

- Expected mean weight loss in the treatment group: 9 kg
- Expected mean weight loss in the control group: 6 kg
- Standard deviation of weight change: 8 kg

Eighteen sites participated in the trial. The accrual rate was expected to be 100 subjects per year with a dropout rate of 10% and a response lag of 1 year.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

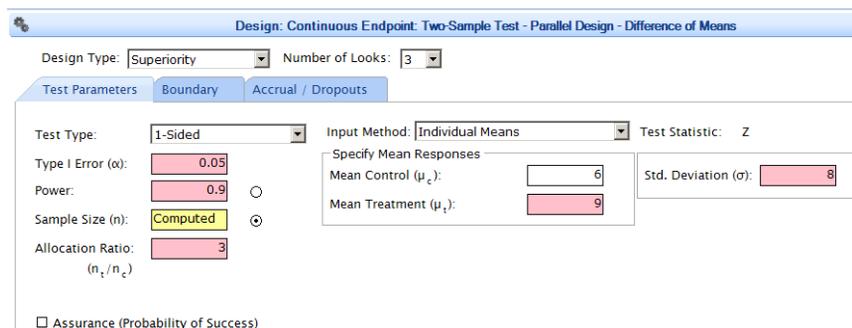

To design this trial navigate to the Design ribbon and select **Two Samples** under the Continuous tab and then **Difference of Means**, the first option under Parallel Designs.

This will open an input dialog box, where you enter the following design parameters of the Orlistat trial in the corresponding fields:

- Design Type: Superiority
- Number of Looks: 3
- Test Type: 1-Sided
- Type-1 Error: 0.05
- Power: 0.9
- Allocation Ratio (n_t/n_c): 3
- Mean Control (μ_c): 6
- Mean Treatment (μ_t): 9
- Std. Deviation (σ): 8

Click on the **Include Options** button in the top right-hand corner and select **Accrual/Dropouts** which opens a third tab of the same name. The design window then appears as follows:

In the **Boundary** tab, we specify the details for the **Efficacy** boundary, and the spacing of the looks. We keep the spending function as the default Lan DeMets (OF) function. The spacing of the looks is defined in the column **Info. Fraction** which has a range of (0, 1.000]. When set to **Equal** the looks are distributed equidistantly across this range. Setting the spacing of looks to **Unequal** allows us to define at which points the looks occur by changing the corresponding information fractions.

Let us assume that in the Orlistat trial all three looks are equally spaced and the dialog box will appear as shown below.

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary Accrual / Dropouts

Efficacy

Boundary Family: Spending Functions
 Spending Function: Lan-DeMets
 Parameter: OF
 Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks: Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|---------------------|-------------------|
| 1 | 0.333 | 0.001 | 3.200 |
| 2 | 0.667 | 0.016 | 2.141 |
| 3 | 1.000 | 0.050 | 1.695 |

The final step is to add the accrual/dropout information. Click on the **Accrual/Dropouts** tab and set **Accrual Rate** to 100, **Response Lag** to 1 and **Probability of Dropout** to 0.1. Note that East does not require the unit of time to be specified explicitly as long as consistency is maintained in the parameters given. In other words, we may choose the unit of analysis to be years, months or weeks as long as all time-related data (overall accrual rate, response lag, dropout rate, individual site accrual rates, etc.) is also expressed in terms of the same unit. Later examples will

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

demonstrate the use of months and weeks as units of analysis.

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary Accrual / Dropouts

Accrual Info
Accrual Rate: 100

Response Lag Info
Response Lag: 1

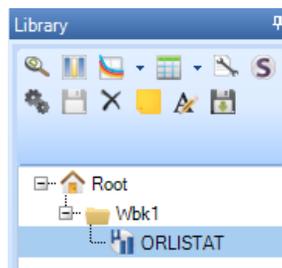

Dropout Info
Probability of Dropout: 0.1

We have entered all the parameters required for East to determine the sample size. Click **Compute** in the bottom right-hand corner of the design window. The following output preview is displayed in the lower panel when the computation is complete.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Accrual Rate | Response Lag | Dropout Prob. | Study Duration | Sample Size |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|--------------|--------------|---------------|----------------|-------------|
| Des1 | Superiority | 3 | 1-Sided | 0.05 | 0.9 | 3 | Equal | LD (OP) | 100 | 1 | 0.1 | 4.68 | 368 |

East has determined that a sample size of 368 subjects is required to attain a power of 0.9. The trial is expected to be around 4.68 years long. In the next section we introduce the simulation feature to explore the enrollment process of this trial given information about the sites over which it will be conducted.

Rename the design 'ORLISTAT' using the button in the **Output Preview** pane and then save it using . It will then appear in the **Library** pane on the left-hand side of the East interface in a workbook named 'Wbk1', which you can rename as 'Orlistat'.

66.1.2 Simulating the Orlistat Trial

The primary input in the simulation is the enrollment plan which contains the following information for each site:

- Site initiation period: the time period over which the site is expected to be initialized so that it is ready to begin enrolling subjects
- Site accrual rate: the number of subjects expected to arrive at the site over the unit of time chosen (in this case, 'year')
- Enrollment cap: the maximum number of subjects that may be enrolled at the site. This enrollment cap also applies to the entire study. This means that no single site or all the sites put together can enroll more than this enrollment cap.

The table below shows a sample enrollment plan for Orlistat.

| Site Name | Site Initiation (Start) | Site Initiation (End) | Accrual Rate | Enrollment Cap |
|-----------|-------------------------|-----------------------|--------------|----------------|
| Site 1 | 0 | 0 | 10 | 368 |
| Site 2 | 0 | 0.25 | 10 | 368 |
| Site 3 | 0 | 0.25 | 10 | 368 |
| Site 4 | 0 | 0.25 | 10 | 368 |
| Site 5 | 0 | 0.25 | 10 | 368 |
| Site 6 | 0 | 0.25 | 5 | 368 |
| Site 7 | 0 | 0.25 | 5 | 368 |
| Site 8 | 0 | 0.25 | 5 | 368 |
| Site 9 | 0 | 0.25 | 5 | 368 |
| Site 10 | 0 | 0.25 | 5 | 368 |
| Site 11 | 0 | 0.25 | 5 | 368 |
| Site 12 | 0 | 0.25 | 5 | 368 |
| Site 13 | 0 | 0.25 | 5 | 368 |
| Site 14 | 0 | 0.25 | 2 | 368 |
| Site 15 | 0 | 0.25 | 2 | 368 |
| Site 16 | 0 | 0.25 | 2 | 368 |
| Site 17 | 0 | 0.25 | 2 | 368 |
| Site 18 | 0 | 0.25 | 2 | 368 |

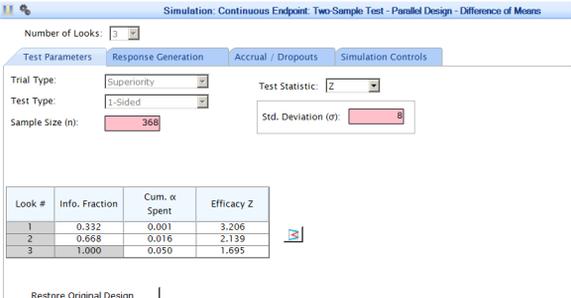

Recall that all parameters in this example are in annual terms, thus a site initiation end time of 0.25 for Sites 2 to 18 indicates that these sites must be initiated within 3 months. In the case of Site 1, the start and end times of '0' indicate that the site is ready to begin enrolling subjects immediately. In addition, note that the individual site accrual rates must sum up to the overall accrual rate specified during the design time,

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

such as in the plan above where all the site accrual rates sum to 100. Lastly, the enrollment cap for each site is generally set to the sample size.

Let us simulate the enrollment process of the Orlistat trial under this enrollment plan.

Select ‘ORLISTAT’ in the **Library** pane and click . This opens the simulation input dialog box containing four tabs: **Test Parameters**, **Response Generation**, **Accrual/Dropouts**, and **Simulation Controls**. Select the **Test Statistic Z**.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z |
|--------|----------------|---------------------|------------|
| 1 | 0.332 | 0.001 | 3.206 |
| 2 | 0.668 | 0.016 | 2.139 |
| 3 | 1.000 | 0.050 | 1.695 |

The first three tabs contain the trial details we had entered in the initial design phase. In the **Simulation Controls** tab we can specify the number of simulation runs we wish to make as well as general output options.

The enrollment plan is to be specified in the **Accrual/Dropouts** tab. Click on **Include Options** in the upper right-hand corner and select **Site**. The **Accrual/Dropouts** tab then provides an option to select the accrual model and a grid in which the enrollment plan can be filled in:

Accrual Model East models the variation in accrual rate by assuming that subjects arrive according to one of two probability distributions: Uniform or Poisson. Under the uniform model, the arrival times of subjects are sampled from a uniform distribution over the given time interval. The Poisson model assumes that subjects arrive according to a Poisson process and thus their inter-arrival times are sampled from an exponential distribution. Experience suggests that arrivals follow a Poisson process and so for all examples in this chapter we select the Poisson accrual model.

Enrollment Plan When entering the enrollment plan we must select whether we will specify it by region or by site. When we select **Sites by Region** it is assumed that all sites within a region have the same parameters (site initiation periods, accrual rates and enrollment caps), while selecting **Sites** allows us to specify enrollment parameters

individually by site. The enrollment plan of Orlistat shown above was specified by site, thus we select **Sites**.

The site parameters can be entered manually in the grid after specifying Number of Sites. Alternatively, you may create a spreadsheet such as the one shown below and save it as a comma-separated values (CSV) file and then import it.

| | A | B | C | D | E |
|----|--------|----------|--------|-------|------|
| 1 | SiteID | SIPstart | SIPend | Arate | Ecap |
| 2 | SITE1 | 0 | 0 | 10 | 368 |
| 3 | SITE2 | 0 | 0.25 | 10 | 368 |
| 4 | SITE3 | 0 | 0.25 | 10 | 368 |
| 5 | SITE4 | 0 | 0.25 | 10 | 368 |
| 6 | SITE5 | 0 | 0.25 | 10 | 368 |
| 7 | SITE6 | 0 | 0.25 | 5 | 368 |
| 8 | SITE7 | 0 | 0.25 | 5 | 368 |
| 9 | SITE8 | 0 | 0.25 | 5 | 368 |
| 10 | SITE9 | 0 | 0.25 | 5 | 368 |
| 11 | SITE10 | 0 | 0.25 | 5 | 368 |
| 12 | SITE11 | 0 | 0.25 | 5 | 368 |
| 13 | SITE12 | 0 | 0.25 | 5 | 368 |
| 14 | SITE13 | 0 | 0.25 | 5 | 368 |
| 15 | SITE14 | 0 | 0.25 | 2 | 368 |
| 16 | SITE15 | 0 | 0.25 | 2 | 368 |
| 17 | SITE16 | 0 | 0.25 | 2 | 368 |
| 18 | SITE17 | 0 | 0.25 | 2 | 368 |
| 19 | SITE18 | 0 | 0.25 | 2 | 368 |

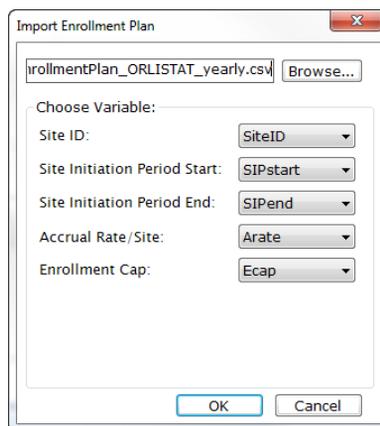

In the above data, ‘SiteID’ corresponds to the site name, ‘SIPstart’ refers to the Site Initiation Start and ‘SIPend’ to Site Initiation End. ‘Arate’ and ‘Ecap’ refer to the site accrual rate and enrollment cap respectively.

For your convenience, this CSV file is already created and stored in **Samples** subfolder in your East installation folder, under the name **EnrollmentPlan_ORLISTAT_yearly.csv**. You may import this CSV file by clicking on **Home** -- > **Import** menu item and choosing the CSV file from **Samples** subfolder. This imported CSV file will appear as a node under ORLISTAT workbook with the extension .cydx which is the format for East data files.

Click on **Specify Enrollment Plan...** button and select the workbook and the imported CSV file, now with the extension .cydx. Next, use the dropdown boxes in the **Choose Variable** panel to match the header names in your .cydx file to the column names shown in the East interface. In our example the final Import **Enrollment Plan**

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

window would appear as follows:

When all these inputs are entered correctly the **Accrual/Dropouts** tab appears as shown below:

Test Parameters Response Generation **Accrual/Dropout** Simulation Controls

Accrual Model:

Sites By Regions Sites

Number of Sites:

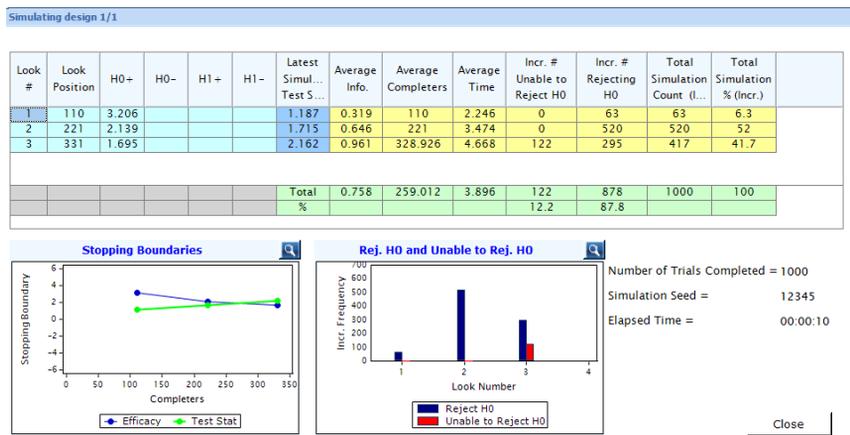

Response Lag Info
Response Lag:

Dropout Info
Probability of Dropout:

| Site ID | Site Initiation Period | | Accrual Rate /Site | Enrollment Cap |
|---------|------------------------|------|--------------------|----------------|
| | Start | End | | |
| SITE1 | 0 | 0 | 10 | 368 |
| SITE2 | 0 | 0.25 | 10 | 368 |
| SITE3 | 0 | 0.25 | 10 | 368 |
| SITE4 | 0 | 0.25 | 10 | 368 |
| SITE5 | 0 | 0.25 | 10 | 368 |
| SITE6 | 0 | 0.25 | 5 | 368 |
| SITE7 | 0 | 0.25 | 5 | 368 |

As a final step, let us navigate to the **Simulation Controls** and set the number of simulations to 1000. Choose the **Fixed** seed as 12345. We can now simulate this design by clicking the **Simulate** button in the lower right-hand corner. East displays

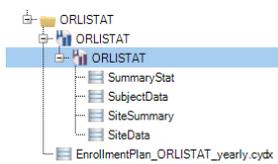

the following window after it carries out the required simulation runs:

Once the specified number of simulations has been run we can close the simulating design window and see a one-line summary of the output in the **Output Preview** pane with the ID Sim1:

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Accrual Rate | Response Lag | Dropout Prob. | Study Duration | Sample Size |
|----------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|--------------|--------------|---------------|----------------|-------------|
| Orlistat | Superiority | 3 | 1-Sided | 0.05 | 0.9 | 3 | Equal | LD (OF) | 100 | 1 | 0.1 | 4.68 | 368 |
| Sim1 | Superiority | 3 | 1-Sided | | 0.878 | | User Specified | User Specified | | 1 | 0.1 | | |

Then save Sim1 by clicking on the button. It will appear as a sub-node of the design in 'Orlistat' in the **Library** pane on the left-hand side of the East interface along with four spreadsheets containing detailed information from the simulation runs. Click on the Sim1 node and rename it 'ORLISTAT' using the . Note that East uses the blue icon to denote designs and the brown icon to denote simulations.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

66.1.3 Output

All outputs from the simulation can be accessed from the **Library** pane. Double-clicking on the 'ORLISTAT' simulation opens a general summary page containing four output tables.

The first output table, **Average Sample Size, Dropouts and Look Times**, displays the average over all 1000 simulations of the sample size (the number of subjects enrolled in the study), completers (subjects who completed the one year period till follow-up), dropouts (subjects who dropped out of the study) and pipeline (subjects who enrolled but did not complete or drop out of the system formally). The table also contains the average look time for all three looks, for instance we observe that on average the first look took place at 2.336 years.

The table **Simulation Boundaries and Boundary Crossing Probabilities** displays the efficacy boundary at each look and the number of simulations in which the boundary was crossed. In total, the trial was stopped for efficacy in 878 simulations resulting in the average power at termination of 0.878.

Average Sample Size, Dropouts and Look Times

| Look # | Average Sample Size (n) | Average Completers (s) | Average Dropouts (d) | Average Pipeline (n-s-d) | Average Look Time | Final Analysis For (Incr.) |
|---------|-------------------------|------------------------|----------------------|--------------------------|-------------------|----------------------------|
| | | | | | | Efficacy (%) |
| 1 | 222.205 | 110 | 12.262 | 99.943 | 2.336 | 4.7 |
| 2 | 345.271 | 221 | 24.662 | 99.609 | 3.572 | 50 |
| 3 | 368 | 328.926 | 36.144 | 2.93 | 4.779 | 30 |
| Average | 347.356 | 259.012 | 28.753 | 59.591 | 3.996 | |
| % | | | | | | 84.700% |

Simulation Boundaries and Incremental Boundary Crossing Probabilities

| Look # | Completers | Boundaries | Stopping For | Total Simulations | |
|--------|------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Count | % |
| | | | Efficacy | | |
| 1 | 110 | 3.206 | 63 | 63 | 6.300% |
| 2 | 221 | 2.139 | 520 | 520 | 52.000% |
| 3 | 331 | 1.695 | 295 | 417 | 41.700% |
| Total | | | 878 | 1000 | |
| % | | | 87.800% | | |

The third table summarizes the enrollment plan, and the final table **Overall Look-Wise Output** shows the number of completers, accruals and dropouts over a

range of percentiles at each look.

Enrollment Plan

Accrual Model: Poisson

Number of Sites: 18

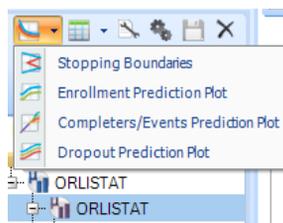

| Site ID | Site Initiation Period Start | Site Initiation Period End | Accrual Rate /Site | Enrollment Cap |

| | | 75% | | 18 | 230 | 15 |
| | | 95% | | 18 | 240 | 19 |
| | | Average | | 18 | 222.205 | 12.262 |
| - | 2 | 5% | 221 | 18 | 326 | 16 |
| | | 25% | | 18 | 338 | 21 |
| | | 50% | | 18 | 346 | 24 |
| | | 75% | | 18 | 353 | 28 |
| | | 95% | | 18 | 363 | 33 |
| | | Average | | 18 | 345.271 | 24.662 |
| - | 3 | 5% | 331 | 18 | 368 | 25 |
| | | 25% | | 18 | 368 | 32 |
| | | 50% | | 18 | 368 | 37 |
| | | 75% | | 18 | 368 | 41 |
| | | 95% | | 18 | 368 | 46 |
| | | Average | | 18 | 368 | 36.144 |

In addition, East generates a series of plots depicting the timelines of enrollment, completers and dropouts. These plots can be accessed by selecting the ‘ORLISTAT’ simulation in the **Library** pane and clicking the  button.

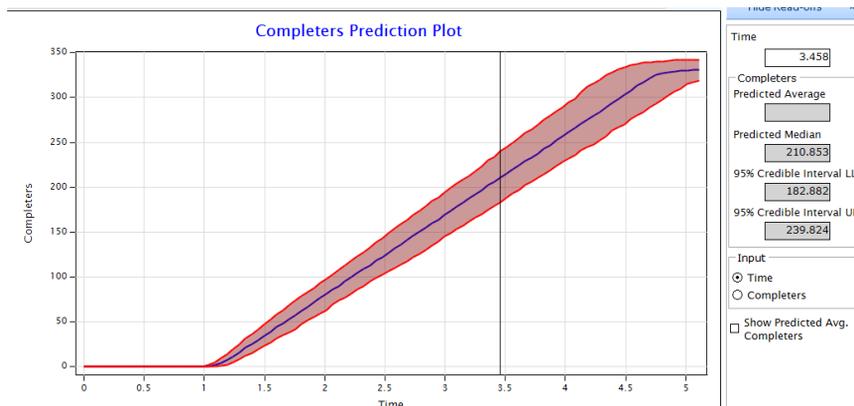

The **Enrollment Prediction Plot** displays the number of enrollments against time. It shows the predicted median and average enrollments across all simulations as well as the 95% confidence interval. For instance, at the time 2.651, indicated by the vertical marker the number of enrollments reached 253 in 97.5% of the simulations, while in 2.5% of the simulations the number of enrollments was below 224. Overall, East predicts a maximum accrual duration of around 4.2 years to enroll 368 subjects.

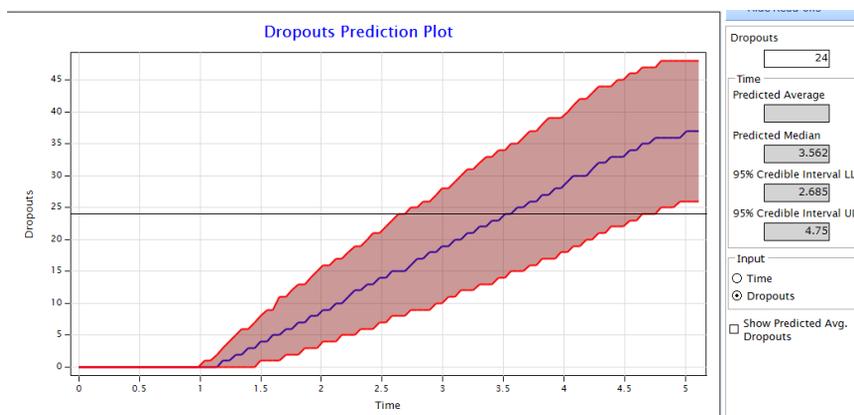

The **Completers Prediction Plot** displays the number of completers over time in terms of the 95% confidence interval, mean and median. In the case of normal and binomial designs the shape of the **Completers Prediction Plot** resembles that of the **Enrollment Prediction Plot**, with the main difference being that it is off-set to the right corresponding to the length of the response lag (one year, in the case of Orlistat). In addition, the prediction lines of the completers are slightly lower than the

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

enrollments due to the number of dropouts.

The **Dropout Prediction Plot** shows the fairly steady increase in dropouts as the trial progresses. The median number of dropouts by the end of the study is 36, as we would expect given the 10% dropout rate.

Lastly, there are four output files nested below the 'ORLISTAT' simulation node containing the full details of all the simulation runs. These files, named **SummaryStat**, **SubjectData**, **SiteSummary**, and **SiteData**, are the source of the data displayed in the tables and plots described above.

66.2 Binomial Design

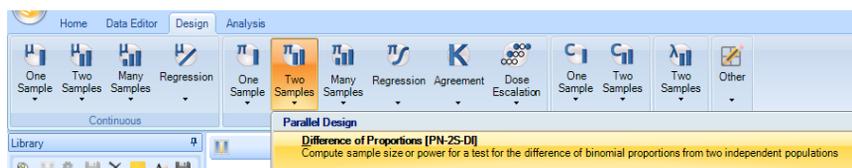

- 66.2.1 The CAPTURE Trial: Initial Design
- 66.2.2 Simulating the CAPTURE Trial
- 66.2.3 Output

In the following section we simulate the CAPTURE trial introduced in Chapter 3. It is an example of a binomial design, where the aim was to compare two independent samples in terms of the difference of proportions in event rate.

66.2.1 The CAPTURE Trial: Initial Design

The CAPTURE trial compared the performance of the drug Abciximab and a placebo on event rate. The null hypothesis H_0 stated that both the drug and the placebo had an event rate of 15%, versus the alternative hypothesis H_1 that Abciximab reduces the event rate from 15% to 10%. The study was 2-sided with a power of 0.8 and an α of 0.05. The accrual rate was 12 subjects/week, the probability of dropout was 5% and the response lag was 4 weeks.

To design this trial, click on the Design ribbon and select ‘Two Samples’ under the Discrete tab and then click on ‘Difference of Proportions’:

This opens an input dialog box:

In the relevant fields of the dialog box, fill in the design parameters of the CAPTURE trial that are summarized below:

- Design Type: Superiority
- Number of Looks: 3
- Test Type: 2-Sided
- Type-1 Error: 0.05
- Power: 0.8
- Prop. Under Control (π_c): 0.15
- Prop. Under Treatment (π_t): 0.1
- Allocation Ratio : 1

Next, click on the **Include Options** button, in the top right-hand corner and select **Accrual/Dropouts**. This opens an additional tab in which we can specify the accrual rate, response lag and the probability of subjects dropping out of the trial.

When the design parameters are filled in correctly the Test Parameters window appears

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

as follows:

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary Accrual / Dropouts

Test Type: 2-Sided

Type I Error (α): 0.05

Power: 0.8

Sample Size (n): Computed

Allocation Ratio: 1 (n_1/n_2)

Specify Proportion Response
Prop. under Control (π_c): 0.15

Specify Alternative Hypothesis
Prop. under Treatment (π_t): 0.1
Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): -0.05

Specify Variance
 Pooled Estimate
 Unpooled Estimate

Use Casagrande-Pike-Smith Correction (Ignored if alloc. ratio is not 1)

Assurance (Probability of Success):

In the **Boundary** tab we specify the details for the **Efficacy** boundary, the spacing of the looks, the boundary families and spending functions. We keep the default spending function of Lan DeMets (OF) for this design. The spacing of the looks is defined in the column **Info. Fraction** which has a range of (0, 1.000]. When the spacing of the looks is set to **Equal** the values of the information fraction are distributed equally across the range. If we wish specify when each interim look will be taken we can set the spacing of looks to **Unequal** and then enter the desired information fractions corresponding to the time points at which the interim looks shall occur. For this example let us assume all three looks are equally spaced.

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary Accrual / Dropouts

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: None

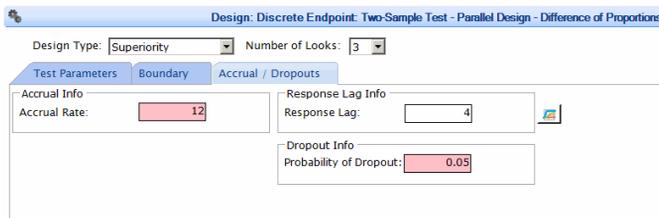

Spacing of Looks Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.333 | 0.000 | 3.710 | -3.710 |
| 2 | 0.667 | 0.012 | 2.511 | -2.511 |
| 3 | 1.000 | 0.050 | 1.993 | -1.993 |

In the **Accrual/Dropouts** tab, set **Accrual Rate** to 12, **Response Lag** to 4 and

Probability of Dropout to 0.05.

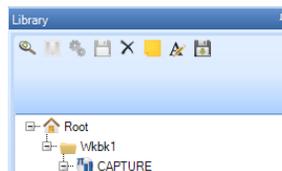

We have entered all the parameters required for East to determine the sample size. Click **Compute** to obtain a preview of the output.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Accrual Rate | Response Lag | Dropout Prob. | Study Duration | Sample Size |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|--------------|--------------|---------------|----------------|-------------|
| Des1 | Superiority | 3 | 2-Sided | 0.05 | 0.8 | 1 | Equal | LD (OF) | 12 | 4 | 0.05 | 125.333 | 1456 |

East has determined that a sample size of 1456 subjects is required to attain a power of 0.8. The trial is expected to be approximately 125 weeks long. Let us simulate this trial to explore its enrollment timeline.

Rename the design ‘CAPTURE’ using the  tool in the **Output Preview** pane. It will then appear in the **Library** pane on the left-hand side of the East interface in a workbook named ‘Wkbk1’, which also you can rename as ‘CAPTURE’.

66.2.2 Simulating the CAPTURE Trial

The primary input in the simulation is the enrollment plan which contains the following information for each site:

- Site initiation period: the time period over which the site is expected to be initialized so that it is ready to begin enrolling subjects
- Site accrual rate: the number of subjects expected to arrive at the site over the unit of time chosen (in this case, ‘week’)

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

- Enrollment cap: the maximum number of subjects that may be enrolled at the site. This enrollment cap also applies to the entire study. This means that no single site or all the sites put together can enroll more than this enrollment cap.

The table below shows a sample enrollment plan for the CAPTURE trial.

| Site Name | Site Initiation (Start) | Site Initiation (End) | Accrual Rate | Enrollment Cap |
|-----------|-------------------------|-----------------------|--------------|----------------|
| Site 1 | 0 | 0 | 1 | 1456 |
| Site 2 | 0 | 10 | 1 | 1456 |
| Site 3 | 0 | 10 | 1 | 1456 |
| Site 4 | 0 | 10 | 1 | 1456 |
| Site 5 | 0 | 10 | 1 | 1456 |
| Site 6 | 0 | 10 | 0.75 | 1456 |
| Site 7 | 0 | 10 | 0.75 | 1456 |
| Site 8 | 0 | 10 | 0.75 | 1456 |
| Site 9 | 0 | 10 | 0.75 | 1456 |
| Site 10 | 0 | 10 | 0.75 | 1456 |
| Site 11 | 0 | 10 | 0.5 | 1456 |
| Site 12 | 0 | 10 | 0.5 | 1456 |
| Site 13 | 0 | 10 | 0.5 | 1456 |
| Site 14 | 0 | 10 | 0.25 | 1456 |
| Site 15 | 0 | 10 | 0.25 | 1456 |
| Site 16 | 0 | 10 | 0.25 | 1456 |
| Site 17 | 0 | 10 | 0.25 | 1456 |
| Site 18 | 0 | 10 | 0.25 | 1456 |
| Site 19 | 0 | 10 | 0.25 | 1456 |
| Site 20 | 0 | 10 | 0.25 | 1456 |

Under this enrollment plan, Site1 initiates immediately and the remaining 19 sites must initiate within 10 weeks of the start time. The accrual rates are given per site per week and sum up to the overall accrual rate of 12. The enrollment cap of each site is set to the estimated total sample size of the study. We shall simulate the CAPTURE trial using this enrollment plan.

To access the simulation tool select 'CAPTURE' in the **Library** pane and click . This opens the simulation input dialog box containing four tabs: **Test Parameters**, **Response Generation**, **Accrual/Dropouts** and **Simulation Controls**.

The **Simulation Controls** tab is where we specify the number of simulation runs. The remaining three tabs contain the trial details we had entered in the initial design phase.

Click on **Include Options** in the upper right-hand corner and select **Site** to add information about the number of sites and their enrollment parameters.

Accrual Model We have the choice to specify whether the arrival times of subjects are to be sampled under a uniform model or a Poisson model. Under the uniform model,

the arrival times of subjects are sampled from a uniform distribution over the given time interval. The Poisson model assumes that subjects arrive according to a Poisson process and thus their inter-arrival times are sampled from an exponential distribution. Let us use the Poisson accrual model as it is known to be a more realistic representation of the subject arrival process.

Enrollment Plan We must choose whether to specify the enrollment plan by region or by site. Under **Sites by Region** East assumes that all sites within a region have the same parameters (site initiation periods, accrual rates and enrollment caps), while selecting **Sites** allows us to specify enrollment parameters individually. Let us specify the CAPTURE enrollment plan by **Sites**.

Enter the parameters in the enrollment plan grid either manually or by creating a spreadsheet such as the one shown below, saving it as a CSV file, import it using **Home** -- > **Imports** menu item to appear as a node with extension .cydx, and then select it using the **Specify Enrollment Plan...** button.

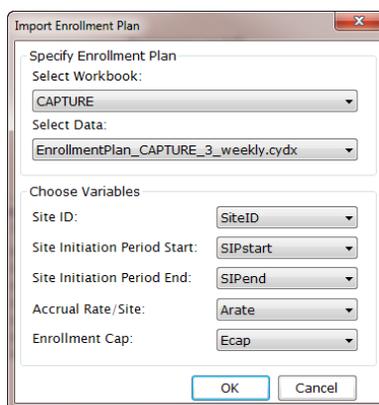

| Site Name | Site Initiation (Start) | Site Initiation (End) | Accrual Rate | Enrollment Cap |
|-----------|-------------------------|-----------------------|--------------|----------------|
| Site 1 | 0 | 0 | 1 | 1456 |
| Site 2 | 0 | 10 | 1 | 1456 |
| Site 3 | 0 | 10 | 1 | 1456 |
| Site 4 | 0 | 10 | 1 | 1456 |
| Site 5 | 0 | 10 | 1 | 1456 |
| Site 6 | 0 | 10 | 0.75 | 1456 |
| Site 7 | 0 | 10 | 0.75 | 1456 |
| Site 8 | 0 | 10 | 0.75 | 1456 |
| Site 9 | 0 | 10 | 0.75 | 1456 |
| Site 10 | 0 | 10 | 0.75 | 1456 |
| Site 11 | 0 | 10 | 0.5 | 1456 |
| Site 12 | 0 | 10 | 0.5 | 1456 |
| Site 13 | 0 | 10 | 0.5 | 1456 |
| Site 14 | 0 | 10 | 0.25 | 1456 |
| Site 15 | 0 | 10 | 0.25 | 1456 |
| Site 16 | 0 | 10 | 0.25 | 1456 |
| Site 17 | 0 | 10 | 0.25 | 1456 |
| Site 18 | 0 | 10 | 0.25 | 1456 |
| Site 19 | 0 | 10 | 0.25 | 1456 |
| Site 20 | 0 | 10 | 0.25 | 1456 |

For your convenience this CSV file is already created and stored in the **Samples** subfolder in your East installation folder, under the name **EnrollmentPlan_CAPTURE_3_weekly.csv**. In this CSV file, ‘SiteID’ corresponds to the site name, ‘SIPstart’ refers to the Site Initiation Start and ‘SIPend’ to Site Initiation End. ‘Arate’ and ‘Ecap’ refer to the site accrual rate and enrollment cap respectively. You may import this CSV file by clicking on **Home** -- > **Import** menu item and choosing the CSV file from **Samples** subfolder. This imported CSV

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

file will appear as a node under CAPTURE workbook with the extension .cydx which is the format for East data files.

Click on **Specify Enrollment Plan...** button and specify the workbook and the imported CSV file, now with the extension .cydx. After selecting the .cydx file, use the dropdown boxes in the **Choose Variable** panel to match the header names in your .cydx file to the column names shown in the East interface. Using the names in our .cydx file the final **Specify Enrollment Plan** window would appear as follows:

After clicking **OK** the grid should contain the CAPTURE enrollment plan and the complete **Accrual/Dropout** tab should appear as shown below:

Simulation: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Number of Looks: 3

Test Parameters | Response Generation | **Accrual / Dropouts** | Simulation Controls

Accrual Model: Poisson

Sites By Regions Sites

Specify Enrollment Plan...

Number of Sites: 20

Response Lag Info
Response Lag: 4

Dropout Info
Probability of Dropout: 0.05

| Site ID | Site Initiation Period Start | Site Initiation Period End | Accrual Rate /Site | Enrollment Cap |
|---------|------------------------------|----------------------------|--------------------|----------------|
| SITE1 | 0 | 0 | 1 | 1456 |
| SITE2 | 0 | 10 | 1 | 1456 |
| SITE3 | 0 | 10 | 1 | 1456 |
| SITE4 | 0 | 10 | 1 | 1456 |
| SITE5 | 0 | 10 | 1 | 1456 |

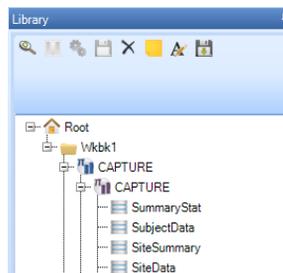

Set the number of simulations to 1000 in the **Simulation Control Info** tab; select **Random Number Seed** as **Fixed** equal to 12345 and then simulate the design by clicking the **Simulate** button in the lower right-hand corner.

Once the simulation is complete and we close the simulating window a one-line summary of the output is shown in the **Output Preview** pane:

| ID | Design Type | Test Type | Sample Size | Completers | Power | πc (Data) | πt (Data) | No. of Looks |
|------|-------------|-----------|-------------|------------|-------|----------------|----------------|--------------|
| Sim1 | Superiority | 2-Sided | 1456 | 1383 | 0.811 | 0.15 | 0.1 | 3 |

Click on the summary, rename it ‘CAPTURE’ using the  button and then save it by clicking on the  button.

It will appear as a sub-node of the design in ‘Wkbk1’ in the **Library** pane on the left-hand side of the East interface along with four spreadsheets containing detailed information from the simulation runs.

Note that East uses the blue icon  to denote designs and the brown icon  to denote simulations.

66.2.3 Output

The **Library** pane contains all the output from the simulation of the CAPTURE trial. The general summary is accessed by double-clicking on the ‘CAPTURE’ simulation. The first table, **Average Sample Size, Dropouts and Look Times**, shows us the average over all 1000 simulations of the sample size (the number of subjects enrolled in the study), completers (subjects who completed the one year period till follow-up), dropouts (subjects who dropped out of the study) and pipeline (subjects who enrolled but did not complete or drop out of the system formally). In addition it provides the

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

average look time for all three looks. For instance, the first look took place on average at around 49.0 weeks, the second look at 89.4 weeks and the final look at 129.428 weeks. These interim looks are approximately 40 weeks apart, reflecting the equally spaced look times we specified in the **Boundary Info** tab.

In the table **Simulation Boundaries and Boundary Crossing Probabilities** we can see the efficacy boundary and number of completers at each look. By end of the study the null hypothesis was rejected in 818 out of 1000 simulations, resulting in the power of 0.818.

Average Sample Size, Dropouts and Look Times

| Look # | Average Sample Size (n) | Average Completers (s) | Average Dropouts (d) | Average Pipeline (n-s-d) | Average Look Time | Final Analysis For (Incr.) | |

| % | | | | 0.000% | 81.800% | | |

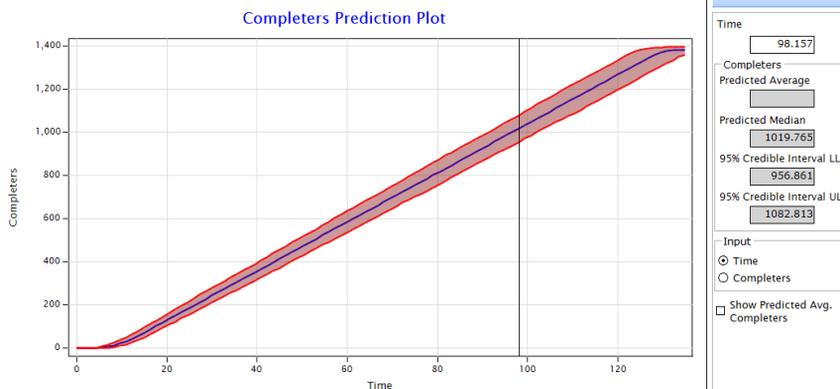

East aggregates the data contained in these data files to generate plots showing the enrollment process over time. These plots can be accessed by clicking the  button in the **Library** pane.

The **Enrollment Prediction Plot** displays the number of enrollments against time and shows us how long it is expected to take for the target number of enrollments to be reached. In this case the predicted median enrollment of 1456 was completed at

around 129 weeks, closer to the initial computation of 125 weeks.

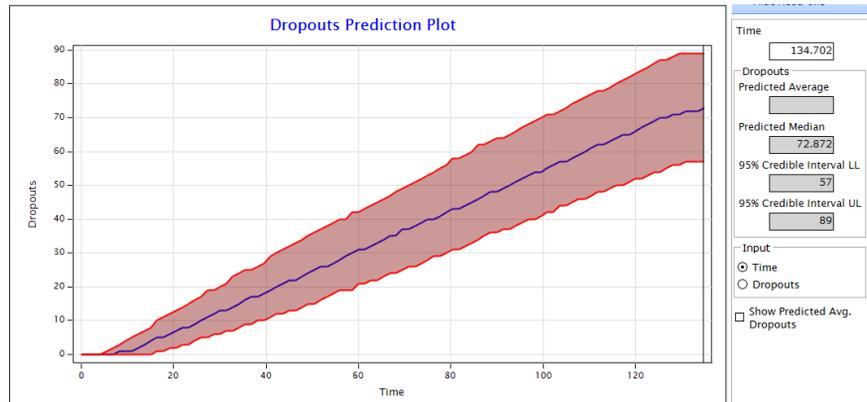

In the **Completers Prediction Plot** we can see the number of completers over time. While the number of subjects is lower due to dropouts, the plot itself is very similar to the **Enrollment Prediction Plot** owing to the relatively short response lag of 4 weeks.

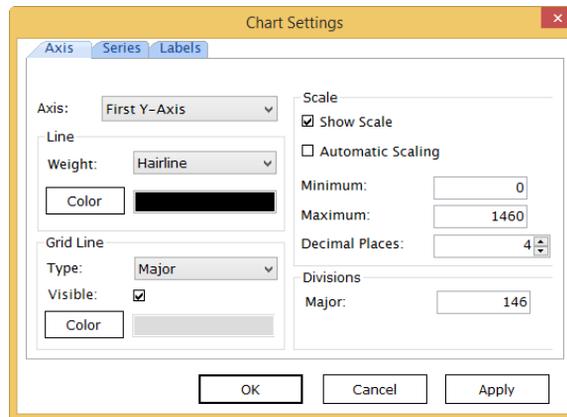

Lastly, the **Dropout Prediction Plot** shows the cumulative number of dropouts over the accrual duration and indicates that the median number of dropouts at the end of the

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

trial was about 73.

For all the plots, the axes and labels can be adjusted using the  button which invokes the **Chart Settings** menu:

Finally, East produces four files containing the full data generated in the simulations. These files, named **SummaryStat**, **SubjectData**, **SiteSummary**, and **SiteData** are the source of the data displayed in the tables and plots described above and can be accessed from the **Library**.

66.3 Survival Design- Example 1

- 66.3.1 The RALES Trial:
Initial Design
- 66.3.2 Simulating the
RALES Trial
- 66.3.3 Output

The next example is based on the RALES trial described in Chapter 43. The aim of this trial was to compare survival in two groups: a treatment group receiving Aldactone for heart failure, and a control group. As in the previous examples, we extend the RALES simulation to incorporate accrual information and study the enrollment and events prediction.

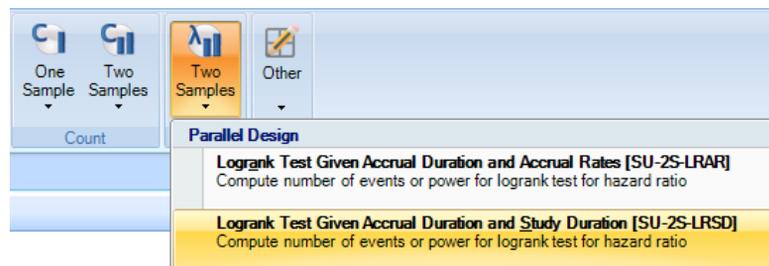

66.3.1 The RALES Trial: Initial Design

Aldactone was developed to treat patients with severe heart failure. The randomized aldactone evaluation study (RALES) was a six-year double blind trial comparing survival rates of a treatment group that was administered Aldactone and a control group that received a placebo. The placebo group was known to have a mortality rate of 38%, and the aim of RALES was to ascertain with a power of 0.9 whether Aldactone was successful in reducing that mortality rate by 17% (from 38% to 31.54%) in the treatment group. The study was a two-sided test with $\alpha = 0.05$ and an expected dropout rate of 5% in both groups. Subjects were enrolled over a period of 1.7 years and there were 6 interim looks scheduled over the duration of the study.

Suppose we wish to design this trial using ‘months’ as our unit of analysis instead of ‘years’. In that case, the relevant parameters would be adjusted as follows:

- Accrual rate: $960/12 = 80$ subjects/month
- Accrual duration: $1.7 \times 12 = 20.4$ months
- Study duration: $6 \times 12 = 72$ months
- Hazard rate (treatment): $0.3154/12 = 0.0263$
- Hazard rate (control): $0.38/12 = 0.0317$

Let us implement this design in East. Click on the **Two Sample** button in the Survival category on the Design ribbon and select **Logrank Test Given Accrual Duration and Study Duration**.

This opens the survival design dialog box with default values.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

Enter the following design parameters of the RALES trial in the corresponding fields:

- Design Type: Superiority
- Number of Looks: 6
- Test Type: 2-Sided
- Type-1 Error: 0.05
- Power: 0.9
- Allocation Ratio: 1

The next step is to enter the survival information in the right-hand portion of the **Test Parameters** tab. Set **# of Hazard Pieces** to '1' and let **Input Method** be 'Hazard Rates'. Fill in **Hazard Rate (Control)** as '0.0317' and **Hazard Rate (Treatment)** as '0.0263'. The **Hazard Ratio** is then automatically computed as 0.83:

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Design Type: Superiority Number of Looks: 6

Test Parameters Boundary Accrual / Dropouts

Test Type: 2-Sided # of Hazard Pieces: 1 Input Method: Hazard Rates

Hazard Ratio (Optional) Alternative

Hazard Ratio (λ_t / λ_c) 0.83

Log Hazard Ratio $\ln(\lambda_t / \lambda_c)$ -0.187

| Hazard Rate | |
|-------------|-----------------|
| Control | Treatment: Alt. |
| 0.0317 | 0.0263 |

Variance of Log Hazard Ratio

Null Alternative

Assurance (Probability of Success)

In the **Boundary** tab we specify the details for the **Efficacy** boundary and the spacing of the interim looks. We keep the default spending function of Lan DeMets (OF). When set to **Equal** the looks are distributed equidistantly across the (0, 1.000] range of the **Info. Fraction**. Setting the spacing of looks to **Unequal** allows us to choose when the interim looks take place by setting the information fractions accordingly. For this example let us assume all looks are equally spaced.

Design Parameters Boundary Info **Accrual / Dropout Info**

Efficacy
 Boundary Family: Spending Functions
 Spending Function: Lan-DeMets
 Parameter: OF
 Type I Error (α): 0.05

Futility
 Boundary Family: None

Spacing of Looks Efficacy Boundary: Z Scale

Equal Unequal

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|--------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.167 | 0.000 | 5.367 | -5.367 |
| 2 | 0.333 | 0.000 | 3.710 | -3.710 |
| 3 | 0.500 | 0.003 | 2.970 | -2.970 |
| 4 | 0.667 | 0.012 | 2.539 | -2.539 |
| 5 | 0.833 | 0.028 | 2.252 | -2.252 |

In the final tab we can enter the accrual and dropout information. Recall that RALES had an accrual duration of 20.4 months (1.7 years) and a total study duration of 72 months (6 years). Enter these values in their respective fields while leaving **# of Accrual Periods** as '1'. Also, in the RALES trial 5% of the subjects are expected to drop out. This can be specified in the **Piecewise Dropout Information** panel either in terms of hazard rates or probability. Achieving the 5% dropout is a trial and error process as described in Chapter 50. Set **# of Pieces** to '1' and **Input Method** to 'Prob. of Dropout'. Set both **Prob. of Dropout (Control)** and **Prob. of Dropout (Treatment)** to 0.05 and initially set **By Time** to 12 (months). The final **Accrual/Dropout** tab should appear as follows:

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Design Type: Superiority Number of Looks: 6

Test Parameters Boundary **Accrual / Dropouts**

Subjects are followed: Until End of Study

Accrual Info
 Accrual Duration: 20.4 Study Duration: 72
 # of Accrual Periods: 1

| Period # | By Time | Cum. % Accrued |
|----------|---------|----------------|
| 1 | 20.400 | 100.000 |

Piecewise Dropout Information
 # of Pieces: 1 Input Method: Prob. of Dropout
 By Time: 12
 Prob. of Dropout (Control): 0.05
 Prob. of Dropout (Treatment): 0.05

Note: Period 1 hazard rates apply after time 12.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

Click **Compute** to determine the required accruals and events for this trial.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | Maximum Events |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|-------------|------------------|------------------|----------------|
| Des1 | Superiority | 6 | 2-Sided | 0.05 | 0.9 | 1 | Equal | LD (OF) | 1638 | 1637.996 | 1637.987 | 1238 |

Rename this design 'RALES' using  and then save it in the library using . Let us simulate this trial to study its enrollment process.

66.3.2 Simulating the RALES Trial

The primary input in the simulation is the enrollment plan which contains the following information for each site:

- Site initiation period: the time period over which the site is expected to be initialized so that it is ready to begin enrolling subjects
- Site accrual rate: the number of subjects expected to arrive at the site over the unit of time chosen (in this case, 'month')
- Enrollment cap: the maximum number of subjects that may be enrolled at the site. This enrollment cap also applies to the entire study. This means that no single site or all the sites put together can enroll more than this enrollment cap.

The table below shows a sample enrollment plan for the RALES trial.

| Site Name | Site Initiation (Start) | Site Initiation (End) | Accrual Rate | Enrollment Cap |
|-----------|-------------------------|-----------------------|--------------|----------------|
| SITE1 | 0 | 0 | 8 | 1000 |
| SITE2 | 0 | 1 | 8 | 1000 |
| SITE3 | 0 | 1 | 4 | 1000 |
| SITE4 | 0 | 1 | 4 | 1000 |
| SITE5 | 0 | 1 | 4 | 1000 |
| SITE6 | 0 | 1 | 4 | 1000 |
| SITE7 | 0 | 1 | 4 | 1000 |
| SITE8 | 0 | 1 | 4 | 1000 |
| SITE9 | 0 | 1 | 4 | 1000 |
| SITE10 | 0 | 1 | 4 | 1000 |
| SITE11 | 0 | 1 | 4 | 1000 |
| SITE12 | 0 | 1 | 4 | 1000 |
| SITE13 | 0 | 1 | 4 | 1000 |
| SITE14 | 0 | 1 | 4 | 1000 |
| SITE15 | 0 | 1 | 4 | 1000 |
| SITE16 | 0 | 1 | 4 | 1000 |
| SITE17 | 0 | 1 | 2 | 1000 |
| SITE18 | 0 | 1 | 2 | 1000 |
| SITE19 | 0 | 1 | 2 | 1000 |
| SITE20 | 0 | 1 | 2 | 1000 |

We see from this enrollment plan that there are 20 sites participating in the study and each site may enroll a maximum of 1000 subjects. Site 1 initiates immediately and the remaining 19 sites must initiate within 1 month of the start of the study. The accrual rates are given in terms of subjects arriving per site per month and sum up to the overall monthly accrual rate of 80. We shall use this enrollment plan in our simulation of the RALES trial.

Select 'RALES' in the **Library** pane and click  to open the simulating design window containing the tabs **Simulation Parameters**, **Response Generation**, **Accrual/Dropouts**, and **Simulation Controls**. The first three tabs contain the trial details we had entered in the initial design phase. The **Simulation Controls** tab is

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

where we specify the number of runs.

The main inputs we must provide in the **Accrual/Dropouts** tab are the accrual model and the enrollment plan.

Accrual Model We have the choice to specify whether the arrival times of subjects are to be sampled from a uniform distribution or from an exponential distribution under the Poisson process. Let us use the Poisson accrual model as it is known to be a more realistic representation of the subject arrival process. Furthermore, let us specify the enrollment plan in terms of **Sites**; when we specify in terms of **Sites by Region** it is assumed that all sites within a region have the same parameters, which is not the case

in our enrollment plan.

Accrual Model: ▾

Sites By Regions Sites

Enrollment Plan Enter the parameters of the RALES enrollment plan in the grid manually. Alternatively, create a spreadsheet such as the one shown below and save it as a CSV file, import it using the menu item **Home-->Import** to add it as a node with the extension .cydx, and then select it using the **Specify Enrollment Plan...** button.

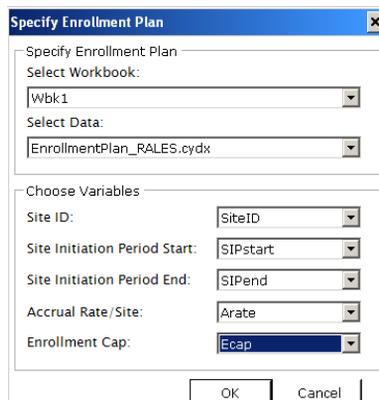

| | A | B | C | D | E |
|----|--------|----------|--------|-------|------|
| 1 | SiteID | SIPstart | SIPend | Arate | Ecap |
| 2 | SITE1 | 0 | 0 | 8 | 1000 |
| 3 | SITE2 | 0 | 1 | 8 | 1000 |
| 4 | SITE3 | 0 | 1 | 4 | 1000 |
| 5 | SITE4 | 0 | 1 | 4 | 1000 |
| 6 | SITE5 | 0 | 1 | 4 | 1000 |
| 7 | SITE6 | 0 | 1 | 4 | 1000 |
| 8 | SITE7 | 0 | 1 | 4 | 1000 |
| 9 | SITE8 | 0 | 1 | 4 | 1000 |
| 10 | SITE9 | 0 | 1 | 4 | 1000 |
| 11 | SITE10 | 0 | 1 | 4 | 1000 |
| 12 | SITE11 | 0 | 1 | 4 | 1000 |
| 13 | SITE12 | 0 | 1 | 4 | 1000 |
| 14 | SITE13 | 0 | 1 | 4 | 1000 |
| 15 | SITE14 | 0 | 1 | 4 | 1000 |
| 16 | SITE15 | 0 | 1 | 4 | 1000 |
| 17 | SITE16 | 0 | 1 | 4 | 1000 |

| 20 | SITE19 | 0 | 1 | 2 | 1000 |
| 21 | SITE20 | 0 | 1 | 2 | 1000 |

For your convenience this CSV file is already created and stored in the **Samples** subfolder in your East installation folder, under the name **EnrollmentPlan RALES.csv**. In this CSV file, ‘SiteID’ corresponds to the site name, ‘SIPstart’ refers to the Site Initiation Start and ‘SIPend’ to Site Initiation End. ‘Arate’ and ‘Ecap’ refer to the site accrual rate and enrollment cap respectively.

Click the **Specify Enrollment Plan...** button to load the file into the enrollment plan grid using **Browse**:

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

Ensure that the header names in your CSV file match the column names indicated in the **Specify Enrollment Plan** window by selecting the corresponding variable names in the dropdown boxes:

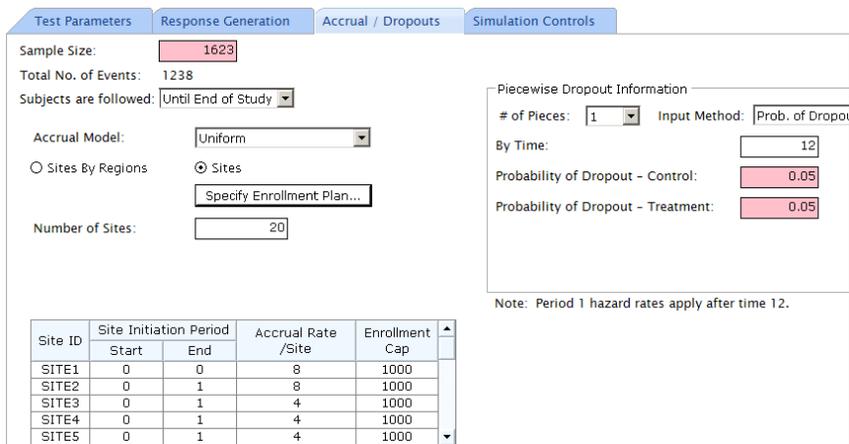

The 'Specify Enrollment Plan' dialog box contains the following fields:

- Select Workbook:** Wbk 1
- Select Data:** EnrollmentPlan_RALES.cydx
- Choose Variables:**
 - Site ID: SiteID
 - Site Initiation Period Start: SIPstart
 - Site Initiation Period End: SIPend
 - Accrual Rate / Site: Arate
 - Enrollment Cap: Ecap

Buttons: OK, Cancel

Click **OK**. When the final **Accrual/Dropouts** tab appears as displayed below we can set the number of simulations to 1000 in the **Simulation Control** tab and then simulate the design by clicking **Simulate**.

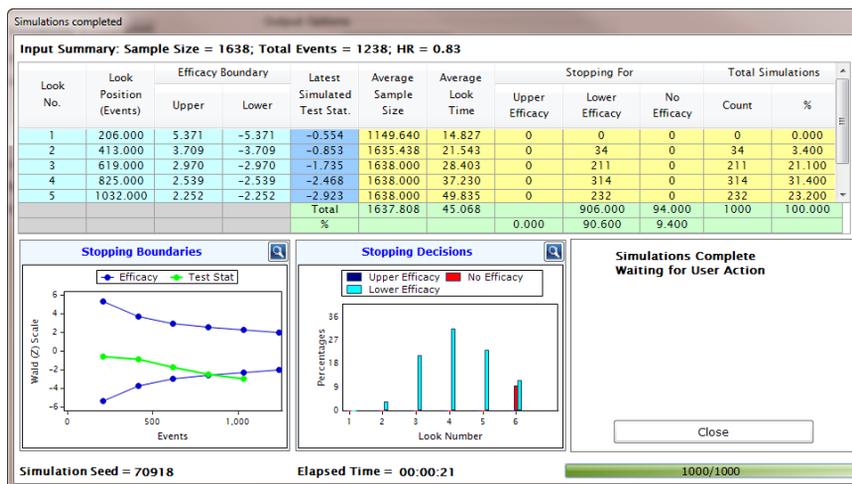

The 'Simulation Control' dialog box shows the following settings:

- Sample Size:** 1623
- Total No. of Events:** 1238
- Subjects are followed:** Until End of Study
- Accrual Model:** Uniform
- Sites By Regions:** Sites
- Number of Sites:** 20
- Piecewise Dropout Information:**
 - # of Pieces: 1
 - Input Method: Prob. of Dropout
 - By Time: 12
 - Probability of Dropout - Control: 0.05
 - Probability of Dropout - Treatment: 0.05

Note: Period 1 hazard rates apply after time 12.

| Site ID | Site Initiation Period Start | Site Initiation Period End | Accrual Rate /Site | Enrollment Cap |
|---------|------------------------------|----------------------------|--------------------|----------------|
| SITE1 | 0 | 0 | 8 | 1000 |
| SITE2 | 0 | 1 | 8 | 1000 |
| SITE3 | 0 | 1 | 4 | 1000 |
| SITE4 | 0 | 1 | 4 | 1000 |
| SITES | 0 | 1 | 4 | 1000 |

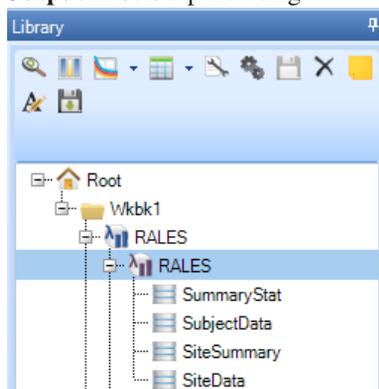

East displays the following window as it carries out the simulation runs:

Once the specified number of simulations has been run we can close the simulating design window and see a one-line summary of the output in the **Output Preview** pane:

| ID | Design Type | Test Type | Sample Size | Maximum Events | Power | No. of Looks | Spacing of Looks | Efficacy Boundary | No. of Hazard Pieces | Test Statistic | Followup Duration | Average Study Duration | Average Sample Size |
|------|-------------|-----------|-------------|----------------|-------|--------------|------------------|-------------------|----------------------|----------------|--------------------|------------------------|---------------------|
| Sim1 | Superiority | 2-Sided | 1638 | 1238 | 0.906 | 6 | User Specified | User Specified | 1 | Logrank | Until End of Study | 45.068 | 1637.808 |

Save the output from the **Output Preview** pane using

Note that East uses the blue icon  to denote designs and the brown icon  to denote simulations.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

66.3.3 Output

Double-click on the 'RALES' simulation node in the **Library** pane to open the output summary. Here we can see data such as the estimations of the average sample size, number of events and dropouts at each look. In the table **Simulation Boundaries and Boundary Crossing Probabilities** we observe that by the end of the trial in 906 out of 1000 simulations we are able to reject the null hypothesis that the hazard rates of the treatment and control group are equal. In other words, Aldactone was effective in reducing the mortality rate by 17% as hypothesized.

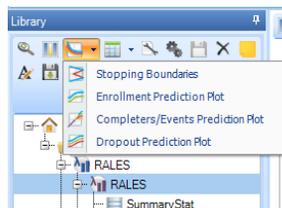

Average Sample Size, Dropouts and Look Times

| Look # | Average Sample Size | Average Events | | Average Dropouts | | Average Look Time | Average Follow up |
|---------|---------------------|----------------|-----------|------------------|-----------|-------------------|-------------------|
| | | Control | Treatment | Control | Treatment | | |
| 1 | 1149.64 | 111.552 | 94.448 | 14.889 | 15.492 | 14.827 | 6.167 |

| % | | | | 0.000% | 90.600% | | |

Click on the  button in the **Library** pane and select **Enrollment Prediction Plot**.

The **Enrollment Prediction Plot** displays the cumulative enrollments over time. It shows the predicted median and average enrollments along with the 95% confidence

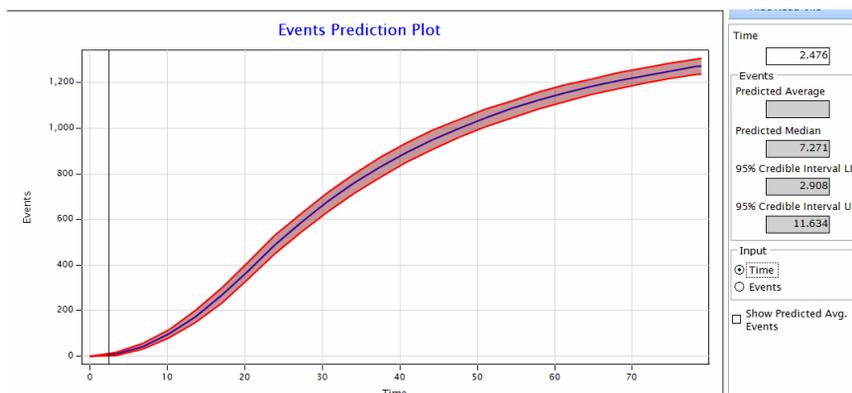

interval over all simulations.

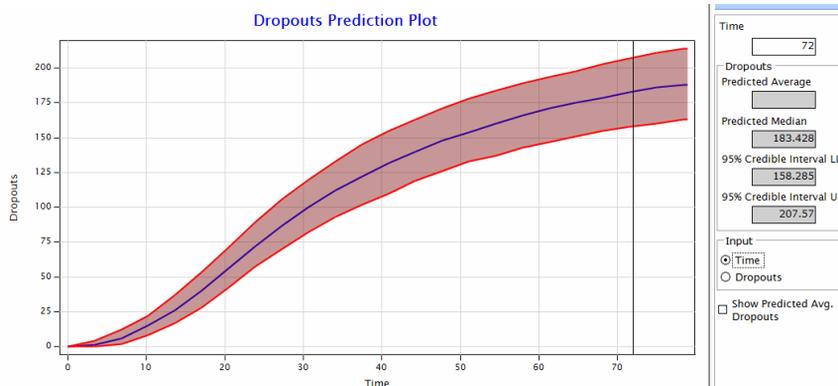

From our simulation of the RALES trial, it is expected that the full sample size will be enrolled earliest by about 20 months and latest by about 22 months. Furthermore, the confidence interval band is fairly narrow; indicating that there is not expected to be a great degree of variation in the predicted enrollment.

In the **Events Prediction Plot** we can observe the timeline of the events throughout the study period of around 72 months and beyond, while the **Enrollment Prediction Plot** only covered the accrual duration of about 20 months. From the graph, we may conclude that it is likely that the study will take the estimated length of a median of about 73 months and a maximum of 79 months.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

Lastly, the **Dropouts Prediction Plot** shows the progression of dropouts over the study duration. The predicted median dropouts by the end of the study period of 72 months is about 182, with the 95% confidence interval spanning a range of 158 to 208.

Lastly, four output files nested below the ‘RALES’ simulation node in the **Library** pane contain the full details of all the simulation runs. These files, named **SummaryStat**, **SubjectData**, **SiteSummary**, and **SiteData**, are the source of the data displayed in the tables and plots described above.

SummaryStat contains the look-wise details of each of the 1000 simulation runs including the number of accruals, completers, dropouts, look times, average follow-up

times and so on.

| | ScenarioID | SimIndex | LookIndex | Status | BdryStopCod | Accruals0 | DropOuts0 | Pendings0 | Events0 | Accruals1 |

| 7 | 1 | 2 | 3 | SUCCESS | 0 | 819 | 47 | 445 | 327 | 819 |
| 8 | 1 | 2 | 4 | SUCCESS | 1 | 819 | 56 | 325 | 438 | 819 |
| 9 | 1 | 3 | 1 | SUCCESS | 0 | 617 | 13 | 491 | 113 | 624 |
| 10 | 1 | 3 | 2 | SUCCESS | 0 | 819 | 29 | 573 | 217 | 819 |

The **SubjectData** sheet displays the following data corresponding to each subject:

- ScenarioID: it is possible to simulate a design under different scenarios by entering multiple parameter values in certain fields (refer to Section 3.7). East then assigns an identification number to each scenario. In this example we simulated a single design without varying the parameters and so the ScenarioID is always '1'.
- SimulationID: the identification number of the simulation.
- PatientID: a unique identification number assigned to each subject.
- SiteID: the identification number of the site at which the subject arrived.
- ArrivalTime: the time at which the subject arrived.
- TreatmentID: the type of treatment the patient received.
- SurvivalTime: the observed survival time of the subject over the course of the study duration
- DropOutTime: the time at which the subject dropped out of the study.
- CensorInd: this variable corresponds to censoring information. '1' represents completers and '0' represents dropouts and subjects in the pipeline.

| | ScenarioID | SimulationID | SubjectID | SiteID | ArrivalTime | TreatmentID | SurvivalTime | DropOutTime | CensorInd |
|----|------------|--------------|-----------|--------|-------------|-------------|--------------|-------------|-----------|

SiteSummary contains the site-level data:

- SiteID: the identification number of the site.
- RegionID (if applicable): the ID of the region to which the site belongs. In this

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

example there is no RegionID column because we chose to define the enrollment plan by individual sites.

- AvgInitiationTime: the average initiation time of this site over all simulations in which this site was opened.
- AvgLastSubjectArrTime: the average time at which the last subject was enrolled at this site over all simulations in which this site was opened.
- AvgNumOfSubj: the average number of subjects enrolled at this site over all simulations in which this site was opened.
- AvgAccrualDuration: the average of the accrual duration for the site computed in every simulation in which the site was opened. The accrual duration is calculated as the last subject randomization time - site initiation time of that site.
- AvgAccrualRate: the average of the observed accrual rate computed in each simulation in which the site was opened.
- SiteOpenedSimCount: the number of simulations in which the site was opened.

| | SiteID | AvgInitiation | AvgLastSubj | AvgNumOfSu | AvgAccrualD | AvgAccrualR | SiteOpenedS |
|----|--------|---------------|-------------|------------|-------------|-------------|-------------|
| 1 | SITE1 | 0 | 20.8234621 | 167.702 | 20.9368551 | 8.01436138 | 1000 |

The final output file, **SiteData**, contains the following information for each site:

- SimulationID: the identification number of the simulation.
- SiteOpenFlag: indicates whether the site has been initiated. The flag is '1' if the site has been initiated and '0' if it has not.
- SiteID: the identification number of the site.
- RegionID (if applicable): the ID of the region to which the site belongs. In this example there is no RegionID column because we chose to define the enrollment plan by individual sites.
- SiteReadyTime: the site initiation time generated as part of the simulations.
- SiteAccrRate: the site accrual rate specified in the enrollment plan.
- SubjectsAccrued: the number of subjects accrued at the site.
- LastSubjectRand: the randomization time of the last subject arriving at the site.
- AccrualDuration: if SiteOpenFlag = 1 for the ith site the accrual duration is computed as follows: AccrualDuration = maximum of the LastSubjRand times

across all sites - SiteReadyTime of the ith site. If SiteOpenFlag = 0 for the site then the AccrualDuration field will be blank.

- ObsrvdAccrualRate: the observed accrual rate for the site. It is computed as follows: $\text{ObsrvdAccrualRate} = \text{SubjectsAccrued} / \text{AccrualDuration}$.

| | SimulationID | SiteOpenFla | SiteID | SiteInitiation | SiteAccrRate | SubjectsAccr | LastSubjectR | AccrualDurat | ObsrvdAccru |

66.4 Survival Design-Example 2

The final example is based on the ONCOX time to event trial. The aim of this trial was to compare survival in two groups: a treatment group receiving a new drug for cancer, and a control group. As in the previous examples, we extend the ONCOX simulation to incorporate accrual information and study the enrollment and events prediction.

66.4.1 The ONCOX Trial: Initial Design

The randomized ONCOX study was a 30 months double blind efficacy and futility trial comparing survival rates of a treatment group and a control group with one interim look. The control group was known to have a median survival period of 5 months and the aim of ONCOX was to ascertain with a power of 0.9 that the median survival in the treatment group would be a longer period of 7 months. The study was a one-sided test with $\alpha = 0.025$ and an expected annualized dropout rate of 4% in both the groups. The efficacy and futility boundaries were to be based on spending function of $\gamma(-5)$. Subjects were enrolled over a period of 24 months. The sample size was fixed to be 460.

Let us implement this design in East. Click on the **Two Sample** button in the Survival category on the Design ribbon and select **Logrank Test Given Accrual Duration and Study Duration**.

This opens the survival design dialog box with default values.

Enter the following design parameters of the ONCOX trial in the corresponding fields Design Parameters tab:

- Design Type: Superiority

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

- Number of Looks: 2
- Test Type: 1-Sided
- Type-1 Error: 0.025
- Sample Size: 460
- Power: (to be computed)
- No.of Events (to be computed)
- # of Hazard Pieces: 1
- Median Survival Time
- Input Method: Median Survival Time (Control): 5
- Input Method: Median Survival Time (Treatment): 7
- Allocation Ratio: 1

The dialog box will appear as shown below.

Design Type: Superiority Number of Looks: 2

Test Parameters Boundary Accrual / Dropouts

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Median Survival Times

Type I Error (α): 0.025

Power: Computed

Sample Size (n): 460

No. of Events: Computed

Allocation Ratio: 1 (n_1/n_2)

Hazard Ratio (Optional) Alternative

Hazard Ratio (λ_1/λ_2) 0.714

Ratio of Medians (m_1/m_2) 1.4

| Med.Surv.Time | |
|---------------|-----------------|
| Control | Treatment: Alt. |
| 5 | 7 |

Variance of Log Hazard Ratio

Null Alternative

Assurance (Probability of Success)

Notice that the hazard ratio is computed to 0.714.

Next, in the **Boundary** tab we specify the details for the **Efficacy** boundary, **Futility** boundary, and the spacing of the interim looks. As indicated in the beginning of this chapter, we modify the spending function from the default Lan DeMets (OF) to Gamma family(-5). Set the spacing of looks as **Equal**. Futility boundary Non-binding Gamma family with parameter -5 is chosen.

Now the **Test Parameters** tab will appear as shown below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Design Type: Superiority Number of Looks: 2

Test Parameters Boundary Accrual / Dropouts

Efficacy
Boundary Family: Spending Functions
Spending Function: Gamma Family
Parameter (γ): -5
Type I Error (α): 0.025

Futility
Boundary Family: Spending Functions
Spending Function: Gamma Family
Parameter (γ): -5
Type II Error (β): 0.101

Info. Fraction at Interim Look: 0.5 Boundary Scale: Z Scale

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Cum. β Spent | Futility Boundary |
|--------|----------------|-------------------------------------|-------------------------------------|--------------|-------------------|--------------|-------------------|
| 1 | 0.500 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.002 | -2.895 | 0.008 | 0.125 |
| 2 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.025 | -1.972 | 0.100 | -1.972 |

In the final tab, we can enter the accrual duration (24 months), study duration (30 months) and dropout information (prob.of dropout as 0.04 in a 12 month survival period). Now the **Accrual/Dropouts** tab should appear as follows:

Test Parameters Boundary **Accrual / Dropouts**

Subjects are followed: Until End of Study

Accrual Info
Accrual Duration: 24 Study Duration: 30
of Accrual Periods: 1

| Period # | By Time | Cum. % Accrued |
|----------|---------|----------------|
| 1 | 24.000 | 100.000 |

Piecewise Dropout Information
of Pieces: 1 Input Method: Prob. of Dropo
By Time: 12
Prob. of Dropout (Control): 0.04
Prob. of Dropout (Treatment): 0.04

Note: Period 1 hazard rates apply after time 12.

Click **Compute** to determine the required events and the power attained for this trial.

| ID | Design Type | No. of Looks | Test Type | Specified α | Attained α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Futility Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | Maximum Events |

Rename this design 'ONCOX' using and then save it in the library using . Let us simulate this trial to study its enrollment process.

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

66.4.2 Simulating the ONCOX Trial

The primary input in the simulation is the enrollment plan which contains the following information for each site:

- Site initiation period: the time period over which the site is expected to be initialized so that it is ready to begin enrolling subjects
- Site accrual rate: the number of subjects expected to arrive at the site over the unit of time chosen (in this case, ‘month’)
- Enrollment cap: the maximum number of subjects that may be enrolled for the entire country as well for each site within the country. Thus, one site in a country can enroll number of subjects equal to the cap, provided all other sites in the country enroll none.

The table below shows a sample enrollment plan for the ONCOX trial.

| Country | No.ofSites | Site Initiation | | Accrual Rate | Enrollment Cap |
|------------|------------|-----------------|-------|--------------|----------------|
| | | (Start) | (End) | | |
| Austria | 4 | 3 | 6 | 0.3835 | 64 |
| Belgium | 6 | 5 | 6 | 0.3185 | 72 |
| CZ | 3 | 4 | 6 | 0.247 | 36 |
| France | 9 | 4 | 5 | 0.4485 | 168 |
| Germany | 10 | 4 | 5 | 0.3965 | 164 |
| Hungary | 4 | 6 | 8 | 0.1755 | 28 |
| ITALY | 7 | 5 | 7 | 0.2665 | 73 |
| Poland | 4 | 4 | 5 | 0.481 | 65 |
| Spain | 7 | 4 | 6 | 0.1755 | 47 |
| UK | 8 | 4 | 6 | 0.2795 | 92 |
| Australia | 11 | 4 | 6 | 0.299 | 181 |
| NewZealand | 4 | 5 | 6 | 0.2535 | 55 |
| Canada | 5 | 6 | 7 | 0.234 | 64 |
| US | 39 | 0 | 11 | 0.2535 | 544 |

We see from this enrollment plan that there are 14 countries each with different number of sites, participating in the study and each site may enroll a maximum of the number of subjects specified as ‘Enrollment Cap’. Sites in US initiates immediately and the remaining sites in remaining 13 countries must initiate within a maximum of 8 months of the start of the study. The accrual rates are given in terms of subjects arriving per site per month. We shall use this enrollment plan in our simulation of the ONCOX trial.

Select ‘ONCOX’ design in the **Library** pane and click  to open the simulating design window containing the tabs **Test Parameters**, **Response Generation**, **Accrual/Dropouts**, and **Simulation Controls**. The first three tabs contain the trial details we had entered in the initial design phase. The **Simulation Controls** tab is

where we specify the number of runs.

| Test Parameters | Response Generation | Accrual/Dropout | Simulation Controls | |
|----------------------|---------------------|---------------------|---------------------|------------|
| Trial Type: | Superiority | | | |
| Test Type: | 1-Sided | | | |
| Fix at Each Look: | Total No. of Events | | | |
| Total No. of Events: | 374 | | | |
| Look # | Info. Fraction | Cum. α Spent | Efficacy Z | Futility Z |
| 1 | 0.500 | 0.002 | -2.895 | 0.121 |
| 2 | 1.000 | 0.025 | -1.972 | -1.972 |

Click on the **Include Options** box to add **Site Info**:

Include Options

- Site
- Randomization
- User Defined R Function
- Stratification
- Sample Size Re-estimation

The main inputs we must provide in the **Accrual/Dropouts** tab are the accrual model and the enrollment plan.

Accrual Model We have the choice to specify whether the arrival times of subjects are to be sampled from a uniform distribution or from an exponential distribution under the Poisson process. Let us use the Poisson accrual model as it is known to be a more realistic representation of the subject arrival process. Furthermore, let us specify the enrollment plan in terms of **Sites by Regions**; when we specify in terms of **Sites by**

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

Region it is assumed that all sites within a region have the same parameters.

Accrual Model:

Sites By Regions Sites

Enrollment Plan Enter the parameters of the ONCOX enrollment plan in the grid manually. Alternatively, create a spreadsheet such as the one shown below and save it as a CSV file so that it can be imported using the menu item **Home-->Import** to appear as a node with extension .cydx.

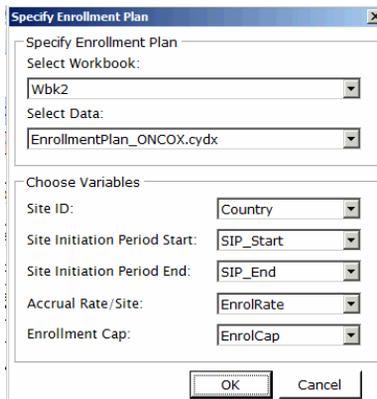

| | A | B | C | D | E | F |
|----|-----------|--------|-----------|---------|-----------|----------|
| 1 | Country | Nsites | SIP_Start | SIP_End | EnrolRate | EnrolCap |
| 2 | Austria | 4 | 3 | 6 | 0.3835 | 64 |

| 4 | CZ | 3 | 4 | 6 | 0.247 | 36 |
| 5 | France | 9 | 4 | 5 | 0.4485 | 168 |
| 6 | Germany | 10 | 4 | 5 | 0.3965 | 164 |
| 7 | Hungary | 4 | 6 | 8 | 0.1755 | 28 |
| 8 | ITALY | 7 | 5 | 7 | 0.2665 | 73 |
| 9 | Poland | 4 | 4 | 5 | 0.481 | 65 |
| 10 | Spain | 7 | 4 | 6 | 0.1755 | 47 |
| 11 | UK | 8 | 4 | 6 | 0.2795 | 92 |
| 12 | Australia | 11 | 4 | 6 | 0.299 | 181 |
| 13 | NewZeala | 4 | 5 | 6 | 0.2535 | 55 |
| 14 | Canada | 5 | 6 | 7 | 0.234 | 64 |
| 15 | US | 39 | 0 | 11 | 0.2535 | 544 |

For your convenience this CSV file is already created and stored in the **Samples** subfolder in your East installation folder, under the name **EnrollmentPlan.ONCOX.csv**. In this CSV file, the column titles are self explanatory.

Click the **Specify Enrollment Plan...** button to specify the .cydx file and get it into the enrollment plan grid.

Ensure that the header names in your CSV file which is now a .cydx file, match the column names indicated in the **Specify Enrollment Plan** dialog box by selecting the

corresponding variable names in the dropdown boxes:

Click **OK**. When the final **Accrual/Dropouts** tab appears as displayed below we can set the number of simulations to 1000 in the **Simulation Controls** tab. Fix the seed at 12345 and then simulate the design by clicking **Simulate**.

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

East displays the following window as it carries out the simulation runs:

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

Once the specified number of simulations has been run we can close the simulating design window and see a one-line summary of the output in the **Output Preview** pane:

| ID | Design Type | No. of Looks | Test Type | Power | Efficacy Boundary | Sample Size | Maximum Events | Futility Boundary | Spacing of Looks | No. of Hazard Pieces | Hazard Ratio | Test Statistic |
|------|-------------|--------------|-----------|-------|-------------------|-------------|----------------|-------------------|------------------|----------------------|--------------|----------------|
| Sim1 | Superiority | 2 | 1-Sided | 0.9 | User Specified | 460 | 374 | User Specified | User Specified | 1 | 0.714 | Logrank |

Save the simulation output from the **Output Preview** pane to the library. Note that East uses the blue icon  to denote designs and the brown icon  to denote simulations.

66.4.3 Output

Double-click on the 'ONCOX' simulation node in the **Library** pane to open the output summary. Here we can see data such as the estimations of the average sample size, number of events and dropouts at each look. In the table **Simulation Boundaries and Boundary Crossing Probabilities** we observe that by the end of the trial in 900 out of 1000 simulations we are able to reject the null hypothesis that the hazard rates of the

treatment and control group are equal, matching with the 90% power of the study.

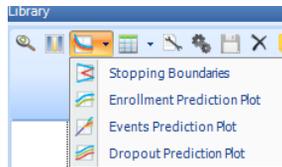

☰ Average Sample Size, Dropouts and Look Times

| Look # | Average Sample Size | Average Events | | Average Dropouts | | Average Look Time | Average Follow up |
|---------|---------------------|----------------|-----------|------------------|-----------|-------------------|-------------------|
| | | Control | Treatment | Control | Treatment | | |
| 1 | 227.726 | 96.448 | 90.552 | 2.476 | 3.045 | 59.227 | 7.052 |
| 2 | 420.22 | 190.439 | 183.561 | 4.865 | 6.132 | 104.726 | 7.622 |
| Average | 366.101 | 164.277 | 156.989 | 4.163 | 5.279 | 91.919 | 7.49 |

☰ Simulation Boundaries and Incremental Boundary Crossing Probabilities

| Look # | Events | Boundaries | | Stopping For | | Total Simulations | |
|--------|--------|------------|----------|--------------|----------|-------------------|---------|
| | | Efficacy | Futility | Efficacy | Futility | Count | % |
| 1 | 187 | -2.895 | 0.125 | 271 | 11 | 282 | 28.200% |
| 2 | 374 | -1.972 | -1.972 | 629 | 89 | 718 | 71.800% |
| Total | | | | 900 | 100 | 1000 | |
| % | | | | 90.000% | 10.000% | | |

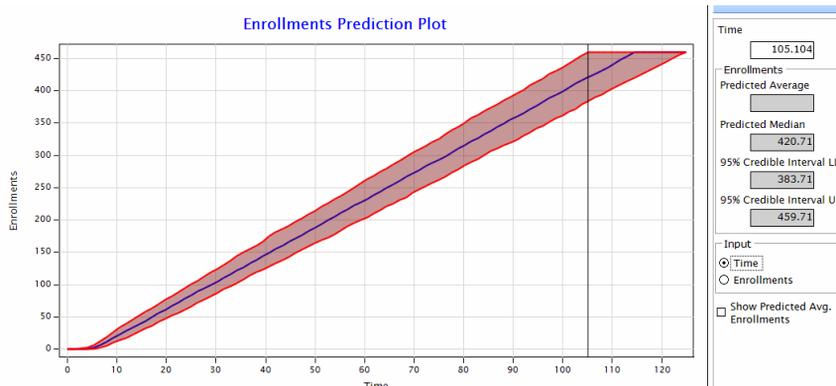

Click on the  button in the **Library** pane and select **Enrollment Prediction Plot**.

The **Enrollment Prediction Plot** displays the cumulative enrollments over time. It shows the predicted median and average enrollments along with the 95% confidence

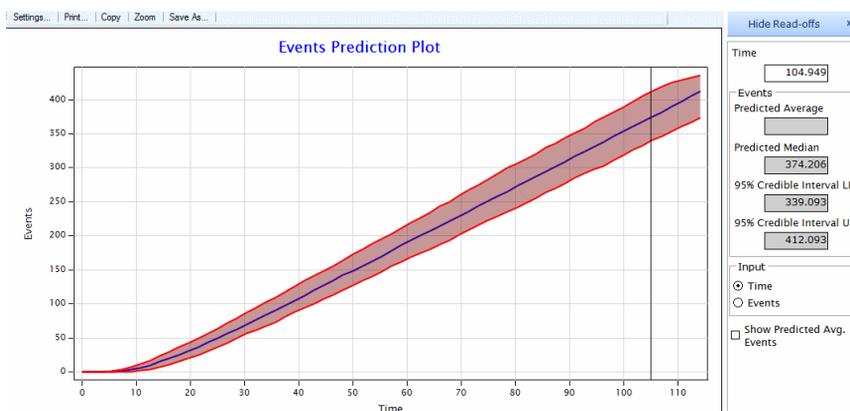

66 Enrollment/Events Prediction - At Design Stage (By Simulation)

interval over all simulations.

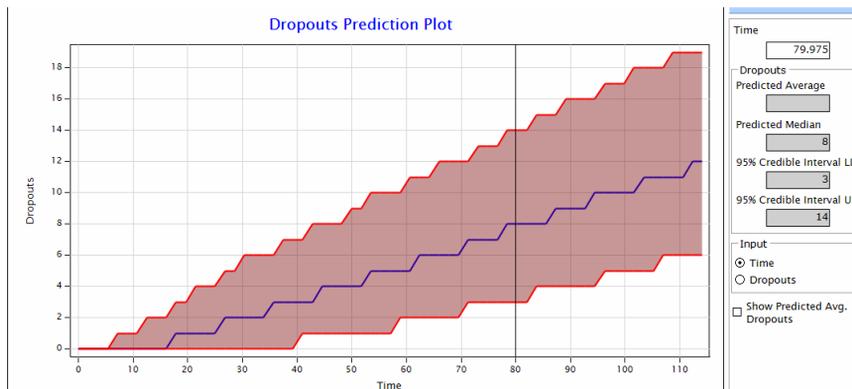

From our simulation of the ONCOX trial, it is expected that the full sample size will be enrolled earliest by about 105 months and latest by about 125 months.

In the **Events Prediction Plot**, we may observe that it is likely that the study will take the targeted median of 374 events in about 105 months and latest by 112 months with 95% confidence.

Lastly, the **Dropouts Prediction Plot** shows the progression of dropouts over the study

duration.

Lastly, four output files nested below the 'ONCOX' simulation node in the **Library** pane contain the full details of all the simulation runs. These files, named **SummaryStat**, **SubjectData**, **SiteSummary**, and **SiteData**, are the source of the data displayed in the tables and plots described above.

67 *Conditional Simulation*

During the design stage in the previous chapter we used simulation to explore the enrollment timeline and event prediction. The inputs of the design stage simulations were based on estimates of accrual rates and other parameters. In the case of Survival designs, once the trial begins and we obtain data on the realized enrollments, we can use the interim monitoring (IM) feature of EastPredict to update the parameters and generate new predictions about the enrollment and event timelines.

67.1 Survival Design- Example 1

67.1.1 Interim Data Preparation

67.1.2 Interim Analysis

67.1.3 Simulation

67.1.4 Output

The simulation of the RALES trial in the previous chapter indicated a required sample size of 1638 subjects with an expected accrual period of around 20 months. The total duration of the study was around 72 months. This example continues from the unconditional simulation performed in the previous chapter and assumes that the **Rales.cyx** workbook which is available in the **Samples** folder is open in East. In this section we perform a conditional simulation at the first interim look.

67.1.1 Interim Data Preparation

Data preparation for conditional simulation involves compiling the required data from various sources at a certain cut-off point as described below:

Subject Data Subject data refers to information collected about each subject accrued so far, namely:

- Arrival time: the time at which the subject arrived at the site.
- Censor information: whether the subject is a completer, a dropout or still in the pipeline.
- Treatment information: whether the subject was randomized to the treatment arm or the placebo arm.
- Survival information: the survival time of the subject.

For our example, we prepare the data on the basis of a simulated trial which was the output of our design time (unconditional) simulation.

The file **RALES_iLook1_SubjectData** contains a list of subjects accrued so far and the following data for each subject:

- **ArrivalTime**: the time at which the subject arrived.
- **TreatmentID**: a variable indicating which group the subject was randomized to ('1' for treatment, '0' for placebo).
- **TimeOnStudy**: the length of time the subject has been in the study, corresponding to survival time.

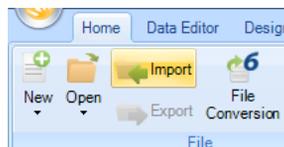

- CensorIndicator: a variable indicating whether the subject is a completer ('1'), a dropout ('-1') or in the pipeline ('0').
- CensorInd: a variable indicating whether the subject is a completer ('1') or a non-completer ('0'). A non-completer can be either a dropout or in the pipeline.

A portion of the RALES_iLook1_SubjectData file is shown below:

| | A | B | C | D | E | F | G |
|----|-----------|--------|------------|-----------|-----------------|----------|-----------|
| 1 | PatientID | SiteID | ArrivalTim | Treatment | CensorIndicator | TimeOnSt | CensorInd |
| 2 | 1 | SITE9 | 0.033264 | 1 | 0 | 15.52795 | 0 |
| 3 | 2 | SITE9 | 0.083005 | 1 | 0 | 15.47821 | 0 |
| 4 | 3 | SITE3 | 0.123138 | 0 | 1 | 7.790942 | 1 |
| 5 | 4 | SITE1 | 0.129578 | 0 | 0 | 15.43164 | 0 |
| 6 | 5 | SITE9 | 0.187238 | 0 | 1 | 4.249194 | 1 |
| 7 | 6 | SITE1 | 0.191141 | 1 | 1 | 0.05485 | 1 |
| 8 | 7 | SITE1 | 0.218275 | 1 | 0 | 15.34294 | 0 |
| 9 | 8 | SITE9 | 0.287513 | 1 | 1 | 2.748406 | 1 |
| 10 | 9 | SITE1 | 0.295866 | 1 | 1 | 10.83515 | 1 |

For your convenience the **Rales_iLook1_subjectdata.csv** has already been created and available in **Samples** subfolder in your East installation folder.

This data file can be imported into East using the **Import** button in the Home ribbon:

Once imported, the file will appear in the **Library** pane as a node in the active workbook, with extension **.cydx**.

67.1.2 Interim Analysis

Click on the node **RALES_iLook1_SubjectData.cydx** and choose the menu item **Analysis>Two Samples>Logrank**. In the resulting dialog box, select the

67 Conditional Simulation

variables as shown in the screen shots below.

Analysis: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank

Data Set: RALES_iLook1_SubjectData.cydx

| | |

Click on the first blank row in the upper panel corresponding to Look #1 and click on the  button. This invokes the **Test Statistic Calculator** for recalculating the test statistic value based on the interim data. We saw from the interim analysis, the first look was taken at 206 events and the data was as follows: **Estimate of $\delta = \ln(0.743) = -0.29706$** and **Standard Error of Estimate of $\delta = \sqrt{4/206} = 0.139347$** . Enter these results in the relevant fields and then click on **Recalc** to obtain

67 Conditional Simulation

the updated test statistic:

The test statistic is updated to -2.132. After clicking **OK** the table in the dashboard is updated according to the new information:

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for HR | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|--------|----------------|-------|-------------------|----|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.166 | 206 | -2.132 | -0.297 | 0.139 | 5.371 | -5.371 | 1.57 | 0.352 | 0.656 | 1 | 0.929 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |
| 4 | | | | | | | | | | | | |
| 5 | | | | | | | | | | | | |
| 6 | | | | | | | | | | | | |

The next step is to enter the observed data for the first look. In the IM Dashboard select the first row corresponding to Look #1 and click the **CS** button. This opens an input dialog window.

Specify Subject Info In this pane, use the drop-down menus next to **Select Workbook** and **Select Subject Data** to select the active workbook and the

RALES_iLook1_SubjectData file we imported earlier.

Next, in the **Choose Variables** tab, match the variables names to the corresponding headers in RALES_iLook1_SubjectData using the drop-down menus. In our example the matching would appear as follows:

- Population ID = TreatmentID
- Control = 0
- Treatment = 1
- Status Indicator = CensorIndicator
- Arrival Time = ArrivalTime
- Time on Study = TimeOnStudy

Estimate Parameters from Data...

Specify Subject Info

Select Workbook: RALES

Select Subject Data: RALES_iLook1_SubjectData.cydx

Choose Variables

1=Complete
0=Censored
-1 = Dropout

Arrival Time: ArrivalTime

Response Variable: TimeOnStudy

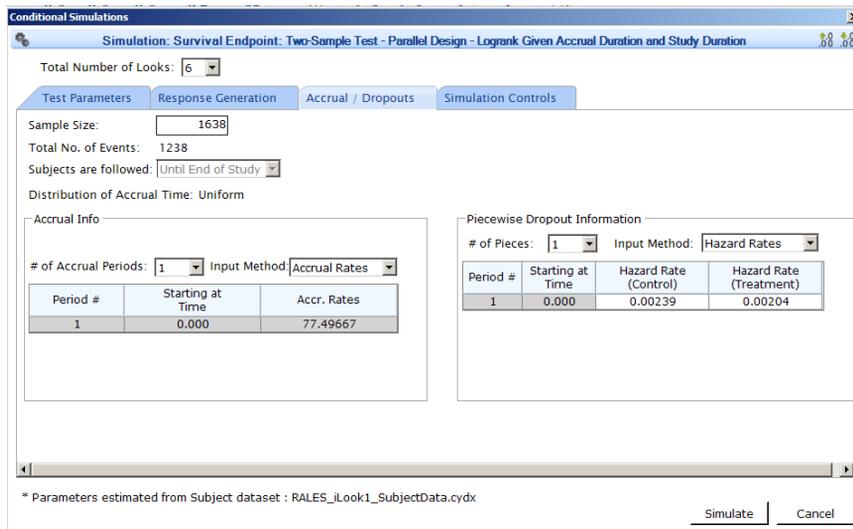

OK Cancel

Click on **OK** to obtain the input dialog window for conditional simulation:

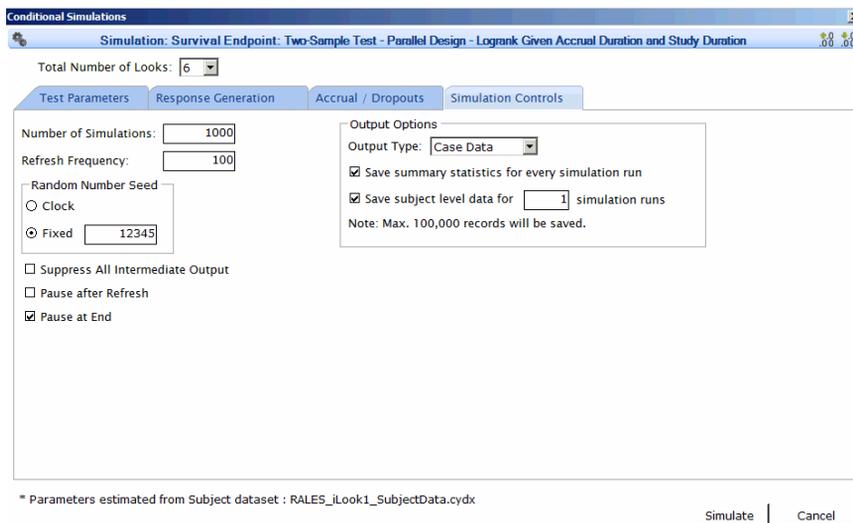

The simulation input dialog window consists of four tabs: **Test Parameters**, **Response Generation**, **Accrual/Dropouts**, and **Simulation Controls**. The first three tabs contain the parameters specified in the previous step. Navigate to the **Accrual/Dropouts** tab. Note that the parameters are estimated from the subject data

67 Conditional Simulation

RALES_iLook1_SubjectData.cydx

Lastly, in the **Simulation Controls** tab set the number of simulations to 1000, select the Fixed Random Seed 12345, check all the output options to save the data

Click **Simulate**. After the simulation is complete the results appear in the **Library** as a sub-node of the RALES design:

Under this sub-node, there is a snapshot of the initial interim data entered (**Snap 1.1**), an output summary of the conditional simulation (**CS:Sim1**) and the updated versions of the output files generated during the initial (unconditional) simulation.

67.1.4 Output

Double-click 'CS:Sim1' in the Library to open a detailed summary of the conditional simulation. The first and third tables, **Actuals: Sample Size and Look Times** and **Actuals: Events and Boundaries**, contain the interim data pertaining to the first look (1205 subjects accrued, 206 events out of which 116 were in the control group and 90 were in the treatment group) and the time of the interim look (15.561 months). The second table named **Conditional Simulation: Average Sample Size and Look Times** displays the projections of these parameters for the remaining five looks. From the fourth table, we can see the boundary crossing probabilities in the remaining five looks. For instance, by the 3rd look, 619 events have been observed and the efficacy boundary has been crossed in 671 out of 1000 simulations.

67.2 Survival Design-Example 2

The ONCOX trial in the previous chapter was designed with a sample size of 460 subjects with an expected accrual period of around 24 months and targeted 374 events within a study period of around 30 months. This example continues from the unconditional simulation performed in the previous chapter and assumes that the workbook **OncoX.cyx** is open in East. You may open it from the Samples folder. In this section we perform a conditional simulation at the first interim look.

67.2.1 Interim Data Preparation

Data preparation for conditional simulation involves compiling the required data from various sources at a certain cut-off point. The data required is **Subject Data** which consist of the following information.

Subject Data Subject data refers to information collected about each subject accrued so far, namely:

- Country: Country ID.
- Arrival time: the time at which the subject arrived at the site.
- Censor information: whether the subject is a completer, a dropout or still in the pipeline.
- Treatment information: whether the subject was randomized to the treatment arm or the control arm.

- Survival information: the survival time of the subject.

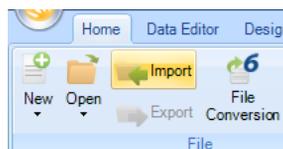

The file ONCOX_iLook1_SubjectData contains a list of subjects accrued so far and the following data for each subject:

- Country: Country ID.
- ArrivalTime: the time at which the subject arrived.
- TreatmentID: a variable indicating which group the subject was randomized to ('1' for treatment, '0' for placebo).
- TimeOnStudy: the length of time the subject has been in the study, corresponding to survival time.
- Status: a variable indicating whether the subject is a completer ('1'), a dropout ('-1') or in the pipeline ('0').
- Censor: a variable indicating whether the subject is a completer ('1') or a non-completer ('0'). A non-completer can be either a dropout or in the pipeline.

A portion of the ONCOX_iLook1_SubjectData file is shown below:

| | A | B | C | D | E | F | G |
|----|-----------|---------|------------|----------|--------|-------|--------|
| 1 | Country | Site_Id | ArrivalTim | TimeOnSt | Status | Trtmt | Censor |
| 2 | United_St | 103 | 0.493421 | 20.23026 | | 0 | 0 |
| 3 | United_St | 103 | 1.085526 | 8.322368 | | 1 | 1 |
| 4 | United_St | 108 | 1.513158 | 6.743421 | | 1 | 0 |
| 5 | United_St | 108 | 1.644737 | 3.75 | | 1 | 1 |
| 6 | United_St | 108 | 1.973684 | 5.953947 | | 1 | 0 |
| 7 | United_St | 103 | 2.5 | 4.934211 | | 1 | 0 |
| 8 | United_St | 103 | 2.565789 | 5 | | 1 | 0 |
| 9 | United_St | 104 | 2.894737 | 9.309211 | | 1 | 0 |
| 10 | United_St | 106 | 2.960526 | 14.70395 | | -1 | 0 |

The data file can be imported into East using the **Import** button in the Home ribbon:

Once imported, the file will appear in the **Library** pane as a node in the active workbook, with extension .cydx.

67.2.2 Simulation

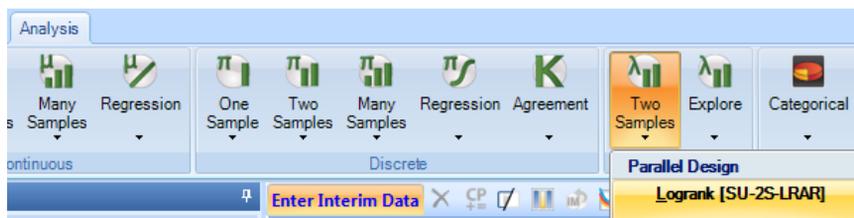

To open the IM design window, select the 'ONCOX' design (represented by the blue

67 Conditional Simulation

icon  in the **Library** pane and click . This opens the IM dashboard:

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | Futility | 88.421% RCI for HR | | Repeat ... p-value | CP | Predicti... Power |
|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|----------|--------------------|-------|--------------------|----|-------------------|
| | | | | | | | | Upper | Lower | | | |
| 1 | | | | | | | | | | | | |
| 2 | | | | | | | | | | | | |

First we need to compute hazard ratio from the interim subject data. For this, click on 'ONCOX_iLook1_SubjectData.cydx' node in the library and then click on **Analysis** > **Two Samples** > **Parallel Design** > **Logrank** menu item.

In the resulting dialog box fill up items as shown below and click OK.

Data Set: ONCOX_iLook1_SubjectData.cydx

Main | Advanced

Superiority | Response Variable: TimeOnStudy | Frequency Variable:

Trtmt | Censor Indicator: Censor | Test Statistic: Logrank

0 | Censored: 0

1 | Complete: 1

Now you will get the following results.

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | |
|--------------|-----------------|--------|---------|----------|---------|
| | | Count | % | Count | % |
| 0 | 203 | 106 | 52.217% | 97 | 47.783% |
| 1 | 199 | 81 | 40.704% | 118 | 59.296% |
| Total | 402 | 187 | 46.517% | 215 | 53.483% |

Parameter Estimates:

| Hazard Ratio (HR) | 95% Confidence Interval(2-Sided) | |
|-------------------|----------------------------------|-------------|
| | Lower Limit | Upper Limit |
| 0.743 | 0.556 | 0.994 |

Test of Hypothesis:

| Log Rank Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|----------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| -13.782 | 6.819 | -2.021 | L.E. | 0.022 | 0.043 |

Estimated Hazard Rates:

| | |
|--------------------------------|-------|
| Control (λ_c) | 0.108 |
| Treatment ($\lambda_c * HR$) | 0.081 |

The number of events is 187 and the estimated hazard ratio is 0.743. Now go to IM dashboard and click on the first blank row in the upper panel corresponding to Look #1 and click on the **Enter Interim Data** button. This invokes the **Test Statistic Calculator** for recalculating the test statistic values based on the interim data. Enter the cumulative events as 187, Estimate of δ as $\ln(0.743)$, and Standard Error as

67 Conditional Simulation

$\sqrt{4/187}$). Click Recalculate. You will see the Test Statistic computed as -2.031.

|--------|----------------------|-------------------|----------------|------------------|--------------------------------|----------|----------|--------------------|-------|--------------------|-------|-------------------|
| | | | | | | | | Upper | Lower | | | |
| 1 | 0.5 | 187 | -2.031 | -0.297 | 0.146 | -2.895 | 0.121 | 1.135 | 0.518 | 0.278 | 0.899 | 0.816 |
| 2 | | | | | | | | | | | | |

In the IM Dashboard select the first row corresponding to Look #1 and click the **CS** button. This opens an input dialog window.

Specify Subject Info In this pane, use the drop-down menus next to **Select Workbook** and **Select Subject Data** to select the active workbook and the ONCOX_iLook1_SubjectData file we imported earlier.

Next, in the **Choose Variables** tab, match the variables names to the corresponding headers in ONCOX_iLook1_SubjectData using the drop-down menus. In our example the matching would appear as follows:

- Population ID = TreatmentID
- Control = 0
- Treatment = 1
- Status Indicator = Status
- Arrival Time = ArrivalTime
- Time on Study = TimeOnStudy

Click on **OK** to obtain the input dialog window for conditional simulation:

The simulation input dialog window consists of four tabs: **Test Parameters**, **Response Generation**, **Accrual/Dropouts** and **Simulation Controls**. The first three tabs contain the parameters specified in the previous step. Navigate to the

67 Conditional Simulation

Accrual/Dropouts tab. Note that the parameters are estimated from the subject data.

Conditional Simulations
Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Total Number of Looks: 2

Test Parameters | Response Generation | **Accrual / Dropouts** | Simulation Controls

Sample Size: 460
Total No. of Events: 374
Subjects are followed: Until End of Study
Distribution of Accrual Time: Uniform

Accrual Info

* Parameters estimated from Subject dataset : ONCOX_iLook1_SubjectData.cyx

Simulate Cancel

Click **Simulate**. After the simulation is complete the results appear in the **Library** as a sub-node of the ONCOX design:

Under this sub-node, there is a snapshot of the initial interim data entered (**Snap 1.1**), an output summary of the conditional simulation (**CS:Sim1**) and the updated versions of the output files generated during the initial (unconditional) simulation.

67.2.3 Output

Double-click 'CS:Sim1' in the Library to open a detailed summary of the conditional simulation. The first table, **Actuals: Sample Size and Look Times**, contains the interim data pertaining to the first look (402 subjects accrued, 187 events out of which 106 were in the control group and 81 were in the treatment group) and the time of the interim look (20.724 months). The second table named **Conditional Simulation: Average Sample Size and Look Times** displays the projections of these parameters for the second and last look.

Actuals: Sample Size and Look Times

| Look # | Sample Size | Events | | Dropouts | | Look Time | Average Follow up |
|--------|-------------|---------|-----------|----------|-----------|-----------|-------------------|
| | | Control | Treatment | Control | Treatment | | |
| 1 | 402 | 106 | 81 | 1 | 2 | 20.724 | 4.908 |

Conditional Simulation: Average Sample Size and Look Times

| Look # | Average Sample Size | Average Events | | Average Dropouts | | Average Look Time | Average Follow up |
|---------|---------------------|----------------|-----------|------------------|-----------|-------------------|-------------------|
| | | Control | Treatment | Control | Treatment | | |
| 2 | 460 | 199.87 | 174.13 | 1.908 | 4.306 | 34.016 | 8.679 |
| Average | 460 | 199.87 | 174.13 | 1.908 | 4.306 | 34.016 | 8.679 |

Actuals: Events and Boundaries

| % | | | | 86.400% | 13.600% | | |

Interim Data Information: Subject Data

Subject Dataset: ONCOX_iLook1_SubjectData.cyx
 Population ID: Trtmt (Treatment=1, Control=0)
 Response Variable: TimeOnStudy
 Status Indicator: Status
 Arrival Time: ArrivalTime

Simulation Seed and Elapsed Time

Starting Seed: 12345
 Total Number of Simulations: 1000
 Elapsed Time: 00:00:09

The table **Simulation Boundaries and Boundary Crossing Probabilities** shows the number of simulations in which the efficacy boundary is crossed at each look. For instance, by the second look, 374 events have been observed and the efficacy boundary has been crossed in 864 out of 1000 simulations.

68 *Enrollment/Events Prediction - Analysis*

Prediction is useful even in fixed sample trials, that is, trials in which the user is not interested in stopping early for efficacy or futility. Even in such trials, the user or authorized person(s) may have access to the interim subject and site data or at least the summarized trial data and may want to predict the future enrollment and event milestones in the trial. There may be situations where a group sequential trial might not have been designed using East, or might not possess an access to Interim Monitoring module of East. The investigator is still interested in predicting the Accrual Duration and Study Duration based on an interim subject data. Catering to the needs of all such studies, the **Predict** feature is developed in the current version of East. We make the prediction functionality available through **Analysis** menu.

During the design stage in chapter 66 we used simulation to explore the enrollment timeline and event prediction of four trials: Orlistat (normal design), CAPTURE (binomial design) and RALES and ONCOX (survival designs). The inputs for the design stage simulations were based on estimates of accrual rates and other parameters. Once the trial begins and we obtain data on the realized enrollment, we can use the **Predict** module to update the parameters and generate new predictions about the enrollment and event timelines.

In this chapter, we introduce the Predict feature available in Analysis menu of East 6.4 and demonstrate its use for normal, binomial and survival designs considering data arising from the respective studies. The Predict feature in Analysis can play a vital role in assisting the Data Monitoring Committee (DMC) statistician as well as sponsor statistician in the following manner.

A DMC statistician typically has access to unblinded trial data. With this, she can use Predict feature to forecast how long the subject enrollment is likely to take and how long the study will take to complete by predicting the time by which required number of events would be achieved separately on the treatment and control drug.

The sponsor statistician generally has access to the blinded trial data. She can use Predict feature to forecast enrollment duration as well as study duration based on the available blinded subject and/or events data.

The option of providing summary data as input makes the use of **Predict** feature possible whenever individual subject data are not available. The **Summary Data** may consist of information on number of subjects enrolled, number of events occurred, number of drop outs observed so far etc. In addition to these, estimates of parameters

68 Enrollment/Events Prediction - Analysis

such as hazard rates for events, hazard rates of drop outs also might be available based on the interim or prior data.

In this chapter, we will use four examples for three endpoints - normal (Orlistat trial), binomial (Capture trial), and survival (Rales trial and Oncox trial) to illustrate enrollment/events prediction procedures. The main purpose of these procedures is to predict at any time point of the study, the likely cumulative enrollment for normal, binomial and survival studies and events/dropouts for survival studies.

68.1 Enrollment Only

68.1.1 Subject-level Data

68.1.2 Subject Data with Site Information

68.1.3 Summary Data

Suppose we have a partial data on enrollments of subjects for the Orlistat trial described in chapter 11. The trial is still ongoing and we want to predict the time when the target enrollment would be complete. The enrollment data till the current calendar time are stored in the **ORLISTAT_iLook1_SubjectData.csv** file which is available in the **Samples** folder of East 6.4 installation.

68.1.1 Enrollment Only: Subject-level Data

Data preparation for the **Enrollment Only** menu of **Predict** involves compiling the required data from various sources at a certain cut-off point. The enrollment can be across number of sites or at a single center. For the **Enrollment Only** feature, arrival times of the subjects are required. In this illustration, we assume that there is only Subject data available which comprises of the following variables.

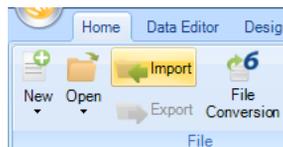

Subject Data Subject data refers to information collected about each subject accrued so far, namely:

- PatientID : Subject ID of the patient.
- Arrival time: the time at which the subject arrived.

For our example we prepare the data on the basis of the subjects enrolled so far. The data in **ORLISTAT_iLook1_SubjectData.csv** contains PatientID and Arrival Time. Note that the data contains some additional variables which are not required for this illustration but will be required later.

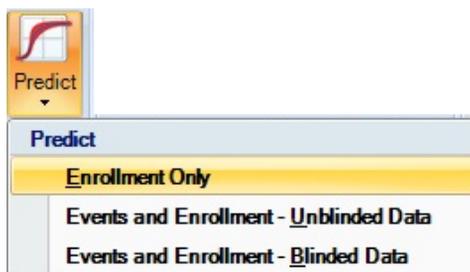

Import the **ORLISTAT_iLook1_SubjectData.csv** file into East using the

Import button in the Home ribbon:

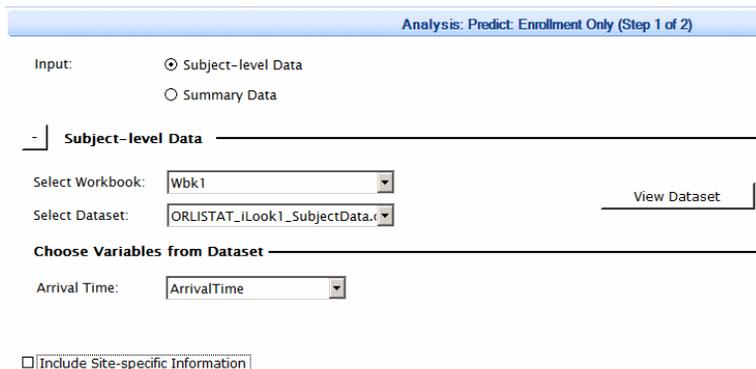

Once imported, the file will appear in the **Library** pane as a node in the active workbook, with extension `.cydx`.

Click on the node `ORLISTAT_iLook1_SubjectData.cydx` and choose the menu item `Analysis>Predict>Enrollment Only`.

In the resulting dialog box, select **Arrival Time** as shown below.

68 Enrollment/Events Prediction - Analysis

Since the default value for Input is **Subject-level Data** we leave it as it is. You may click the **View Dataset** button to view the data.

- Subject-level Data

Selected Dataset: ORLISTAT_iLook1_SubjectData.cydx

| PatientID: 1 Value: 1 | | | | | |
|-----------------------|-----------|--------|-------------|-------------|-------------|
| | PatientID | SiteID | ArrivalTime | TreatmentID | Response |
| 1 | 1 | SITE1 | 0.025987927 | 1 | 13.7118018 |
| 2 | 2 | SITE1 | 0.042236098 | 1 | 5.41314876 |
| 3 | 3 | SITE1 | 0.110120225 | 0 | -3.59692722 |
| 4 | 4 | SITE5 | 0.127380897 | 1 | -10.5383905 |
| 5 | 5 | SITE4 | 0.169874146 | 1 | 2.78465282 |

Click **Hide Dataset** to restore the dialog. Since we are not considering any Site information, leave the check box **Include Site-specific information** blank.

Click **Next**. This will invoke the next input dialog, **Accrual/Dropouts**.

Analysis: Predict: Enrollment Only (Step 1 of 2)

Target Sample Size:

Accrual / Dropouts | Simulation Controls

Current Sample Size: 212
Current Calendar Time: 2.224

Accrual Information

of Accrual Periods: Input Method:

| Period # | Starting at Time | Accrual Rate |
|----------|------------------|--------------|
| 1 | 0.0000 | 95.30998 |
| 2 | 2.2243 | 47.65499 |

You will see some default values already filled in. The **Current Sample Size** is the number of records (number of arrivals) in the data file which is 212 in this case. The **Target Sample Size** default value is 318 which is $1.5 * CurrentSampleSize$. You may change the **Target Sample Size** value. This is the value of targeted enrollment in the trial. The objective is to find out on an average how long will the trial take to enroll these many subjects. The **Current Calendar Time** is accrual time of the last subject in the data which is 2.224. The **Accrual Information** input is meant for simulating the additional, that is

$318 - 212 = 106$ accruals. There are two options for **Input Method**. For the **Accrual Rates** option, East considers the accrual process comprised of two periods. The first period is assumed to be the one presented in the data. Starting time for this period is assumed to be 0 whereas the accrual rate for this period is computed as $(CurrentSampleSize)/(CurrentCalendarTime)$. In this case it is $212/2.2243 = 95.31$. Both the starting time and Accrual Rate fields are uneditable as these are estimated from the data. The second period is the one which starts after the last accrual in the first period. As a result, the **Starting At** time default value is the last arrival time in the data which is also the **Current Calendar Time**. For the second period, the default accrual rate is computed as: $(TargetSampleSize - CurrentSampleSize)/(CurrentCalendarTime)$ which is $(318 - 212)/2.2243 = 47.65499$ for the current example. You can edit both the Starting Time and Accrual Rate for the second period. Accrual may vary over time. To reflect this assumption, one can specify the number of time periods, each having different accrual rates. An alternate way to give accrual input is **Cum Accrual %**. If you choose this option, the input dialog will be

Analysis: Predict: Enrollment Only (Step 1 of 2)

Target Sample Size:

Accrual / Dropouts | Simulation Controls

Current Sample Size: 212
Current Calendar Time: 2.224

Accrual Information

of Accrual Periods: Input Method:

| Period # | By Time | Accr. % |
|----------|---------|-----------|
| 1 | 2.224 | 66.66667 |
| 2 | 4.449 | 100.00000 |

As before, East treats the accruals in two pieces. The default value of **By Time** for the first period is the *CalendarTime* while for the second, it is $2 * CalendarTime$. Default values of **Accr %** for Period 1 and Period 2 are $100 * (CurrentSampleSize/TargetSampleSize)$ and 100% respectively. Both these values are uneditable. If you choose more than two accrual periods, the table expands and allows you to specify the values of **By Time** and **Accr %** fixing the **Accr %** for the last period to 100%.

For this study, let us use the option of **Accrual Rates** and use the default values.

68 Enrollment/Events Prediction - Analysis

Go to the **Simulation Controls** tab. It will show the following screen.

Analysis: Prediction of Enrollment Timeline (Step 2 of 2)

Sample Size:

Accrual / Dropouts | **Simulation Controls**

Number of Simulations:
 Refresh Frequency:

Random Number Seed
 Clock
 Fixed

Suppress All Intermediate Output
 Pause after Refresh
 Stop at End

Output Options
 Output Type:
 Save summary statistics for every simulation run
 Save subject level data for simulation runs
 Note: Max. 100,000 records will be saved.

Output for All Trials

| Percentile (%) |
|----------------|
| 5 |
| 25 |
| 50 |
| 75 |
| 95 |

The default number of simulation runs is 10000. Set the number of simulations to 1000 and the Random Number Seed to 12345. The simulation output can be saved either in a .csv file or as a Case Data. You can save **Summary Statistics** for every simulation run and the **Subject level data** for a few simulation runs. Suppose we want to save the **Summary Statistics** and the **Subject level data** for say, 5 simulation runs. Check both the check boxes and specify 5 simulation runs as indicated in the following screen shot. You can also modify the percentile values available in the **Output for All Trials** table. For now, let us keep them as they are. The **Simulation Controls** dialog will look as shown below:

Sample Size:

Accrual / Dropouts | **Simulation Controls**

Number of Simulations:
 Refresh Frequency:

Random Number Seed
 Clock
 Fixed

Suppress All Intermediate Output
 Pause after Refresh
 Stop at End

 Save subject level data for simulation runs
 Note: Max. 100,000 records will be saved.

Output for All Trials

| Percentile (%) |
|----------------|
| 5 |
| 25 |
| 50 |
| 75 |
| 95 |

Click the **Simulate** button available at the bottom. East simulates the arrival of

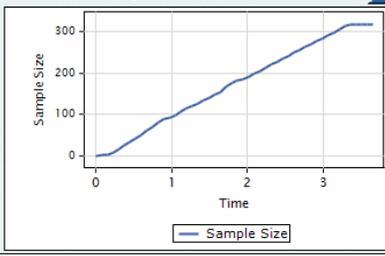

subjects according to the Poisson Arrival process. After a few seconds East will display the message that **Simulations complete. Waiting for User's action.**

Simulations in progress

Input Summary: Accrual: Ongoing, Sample Size = 318

| Current Time | Average Accrual Duration | Average Sample Size |
|--------------|--------------------------|---------------------|
| 2.224 | 3.326 | 318.000 |

Sample Size vs. Time

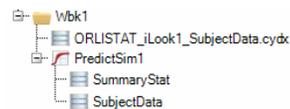

— Sample Size

**Simulations Complete
Waiting for User Action**

Close

Simulation Seed = 12345 Elapsed Time = 00:00:06 1000/1000

Click **Close**. This will save the **Predict Simulation** in the Output Preview window first. Once you save it in the Workbook, it will create a node **PredictSim1** with sub-nodes for **SummaryStat** and **SubjectData** in the **Library**.

Open the **SummaryStat** data by double clicking the sub node. You will see the

68 Enrollment/Events Prediction - Analysis

following display of data.

| ScenarioID | SimIndex | Stage | Status | TotAccruals | TotPendings | TotEvents | AccrDurtn |
|------------|----------|---------|---------|-------------|-------------|-----------|------------|
| 1 | 1 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 1 | Final | SUCCESS | 318 | 0 | 318 | 4.35719694 |
| 1 | 2 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 2 | Final | SUCCESS | 318 | 0 | 318 | 4.7111913 |
| 1 | 3 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 3 | Final | SUCCESS | 318 | 0 | 318 | 4.23758069 |
| 1 | 4 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 4 | Final | SUCCESS | 318 | 0 | 318 | 4.52927409 |
| 1 | 5 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 5 | Final | SUCCESS | 318 | 0 | 318 | 4.42808236 |
| 1 | 6 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 6 | Final | SUCCESS | 318 | 0 | 318 | 4.36122242 |
| 1 | 7 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 7 | Final | SUCCESS | 318 | 0 | 318 | 4.28554977 |
| 1 | 8 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 8 | Final | SUCCESS | 318 | 0 | 318 | 4.58337695 |

Observe that for every simulation East calls the **Current Sample Size** available data as **First Interim** while the **Target Sample Size** as **Final**.

The column **SUCCESS** indicates that the simulation was successful. The variable **TotEvents** is synonymous to Sample Size.

The last column **AccrDurtn** specifies the accrual duration required to enroll the 318 subjects in the respective simulation run. For instance, in the first simulation, the 318th subject arrived at the time epoch 4.35719 and so on. Now double click the

SubjectData sub node in the library. You will see the following display of data.

| ScenarioID | SimulationID | SubjectID | ArrivalTime |
|------------|--------------|-----------|-------------|
| 1 | 1 | 1 | 0.025987927 |
| 1 | 1 | 2 | 0.042236098 |
| 1 | 1 | 3 | 0.110120225 |
| 1 | 1 | 4 | 0.127380897 |
| 1 | 1 | 5 | 0.169874146 |
| 1 | 1 | 6 | 0.174202349 |
| 1 | 1 | 7 | 0.190352212 |
| 1 | 1 | 8 | 0.212313918 |
| 1 | 1 | 9 | 0.223044303 |
| 1 | 1 | 10 | 0.242310384 |
| 1 | 1 | 11 | 0.251971183 |
| 1 | 1 | 12 | 0.263265167 |
| 1 | 1 | 13 | 0.270861527 |
| 1 | 1 | 14 | 0.272797233 |
| 1 | 1 | 15 | 0.291490085 |
| 1 | 1 | 16 | 0.295691405 |
| 1 | 1 | 17 | 0.30714988 |
| 1 | 1 | 18 | 0.310955834 |
| 1 | 1 | 19 | 0.313170244 |
| 1 | 1 | 20 | 0.322496136 |

It shows arrival times of each and every subject in the study for five simulation runs. This is because we have asked to save the data for five runs. The first simulation id is 1. If you scroll down you will be able to see that East has chosen the simulation runs 4, 9,12 and 17 to save the data. This selection is arbitrary on the part of the software. Obviously, if we would have asked for saving data for 1000 runs, East would have chosen all the **SimulationIds** for saving the data (with the restriction that East can store at the most 100,000 records.)

To view the detailed summary output of the simulations, double click the node

68 Enrollment/Events Prediction - Analysis

`PredictSim1` in the Library. The following output is displayed.

Conditional Simulation: Prediction of Enrollment Timelines

Subject-level Data

Subject Dataset: ORLISTAT_iLook1_SubjectData.cydx

Arrival Time: ArrivalTime

Simulation Seed and Elapsed Time

Starting Seed: 12345

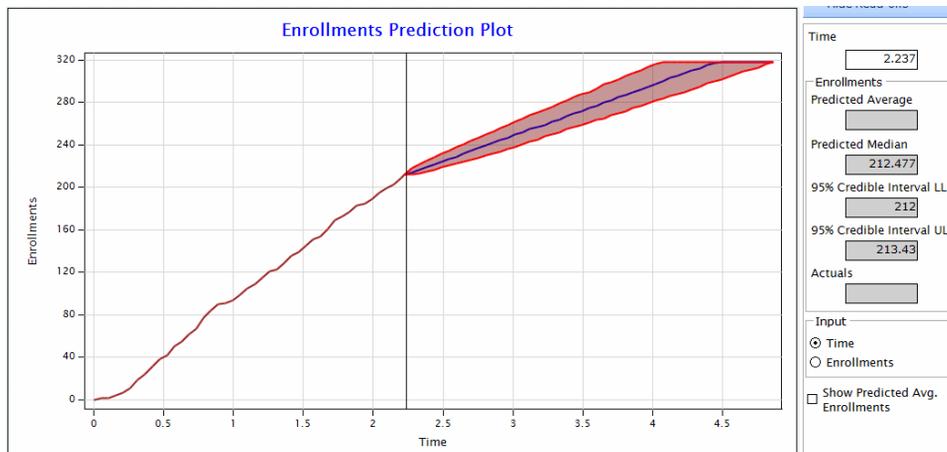

Total Number of Simulations: 1000

Elapsed Time: 00:00:09

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed and the simulated results for the remaining arrivals in the second period. The table **Overall Output** presents the information on the percentiles of the (simulated) total accrual duration. For example, almost 50% simulations have been completed by 4.447 units of time etc. The mean accrual duration of all the simulations is 4.448.

In addition, we can view the enrollment prediction plot using the  tool in the **Library** pane:

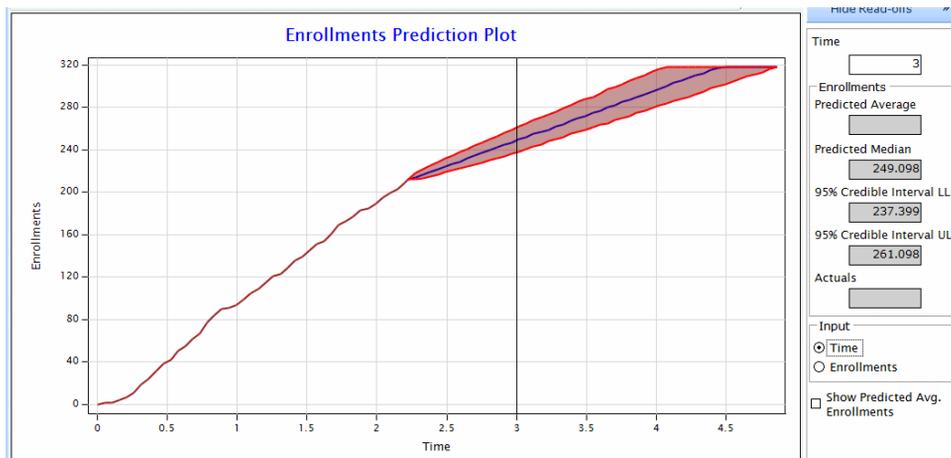

The **Enrollment Prediction Plot** displays the timeline of the observed accruals until 2.234 by which in all 212 subjects have been enrolled. This is as per the observed data.

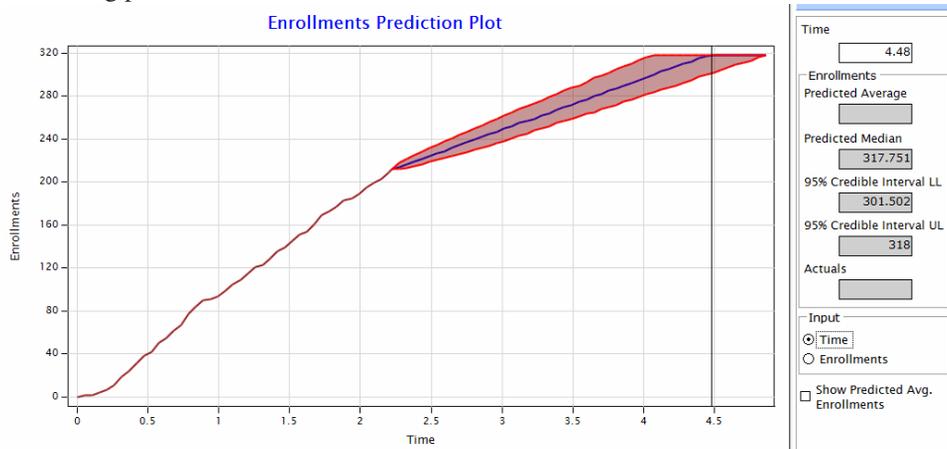

After that point it displays the projected enrollments based on the observed accrual data we specified and the revised **Accrual Rate** in the second period. For example, at year 3 the predicted median enrollments reach the sample size of 249 subjects with

68 Enrollment/Events Prediction - Analysis

95% Confidence Interval as (237.399, 261.098). Please see the plot below.

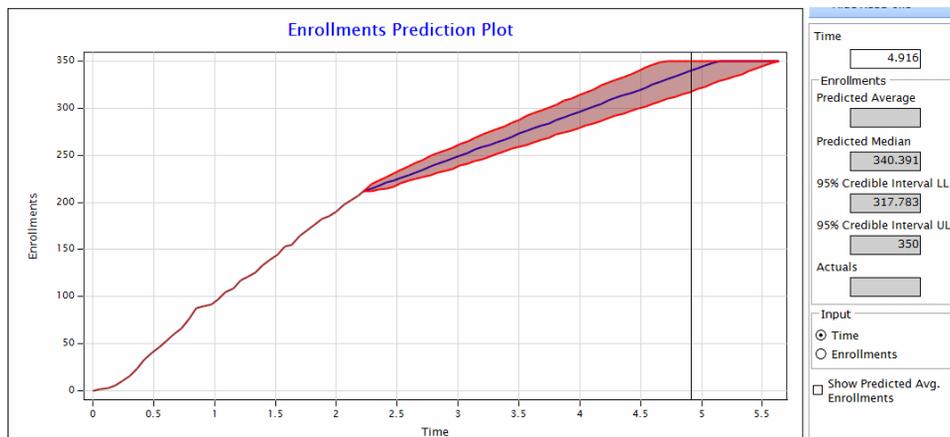

For the targeted 318 subjects it will take 4.48 units of time as is clear from the following plot.

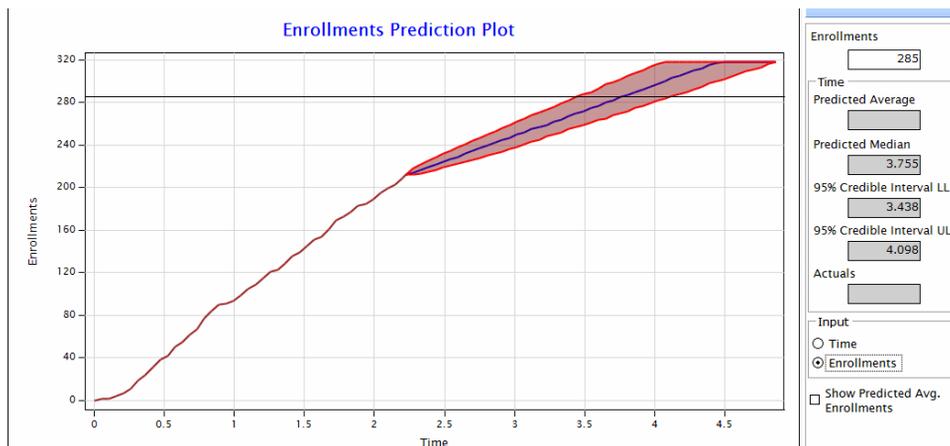

The problem here is that median and upper limit coincide and equal to 318. To envisage the true situation we suggest a workaround to the users. You can rerun the simulations with targeted sample size sufficiently greater than the true targeted sample size. For instance, if you consider the target sample size as say 350, and simulate

keeping rest of the things as previous, you get the **Enrollment Prediction Plot** as shown below:

Try to find out the **Time** so that the 95% lower limit is around 318 as shown in the picture above. This gives the latest time to get 318 events. From the plot, one can say that the latest time by which 318 accruals will happen is 4.916.

In the earlier plot (for 318 targeted sample size), if you want to find out how long will it take to enroll say, 285 subjects. Select the Input > Enrollments option on the plot and type 285 in the **Enrollments** textbox as shown in the following plot.

68 Enrollment/Events Prediction - Analysis

From the read-offs it is clear that the median accrual duration for accruing 285 subjects would be 3.755 with 95% confidence interval (3.438, 4.098).

68.1.2 Enrollment Only: Subject-level Data with Site-specific Information

In the case of a multi-center trial, accrual rates vary across sites. It is necessary to incorporate this information in the study to come up with a better estimate of total accrual duration on a whole. East provides a way to use this information by accepting the following information on different sites. Suppose for the Orlistat trial we also have the site data stored in a .csv file named **ORLISTAT_iLook1_SiteData.csv** which is available in the **Samples** folder of East installation directory. Import this file in East 6. Once imported, the file will appear in the **Library** pane as a node in the active workbook, with extension .cydx. The Site data comprises of the following variables.

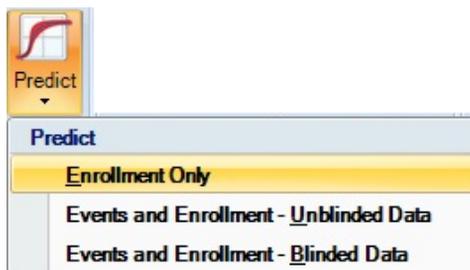

Site Data

Site data refers to information collected about each subject accrued so far, at each of the sites in a multi-center trial.

- Site ID: Site ID of the site.
- Site Accrual Rate: Site specific enrollment rate
- Enrollment Cap: This is the maximum number of subjects the site can enroll.
- Site Initiation: Unopened Sites
 - Start Time: It is the time at which the unopened site will open and start accepting accruals.
 - End Time: It is the time at which the site will stop accepting accruals and close.
- Site Initiation: Opened Sites
 - Site Initiation Time: It is the time at which the site was open and started accepting accruals.

Click on the node **ORLISTAT_iLook1_SubjectData.cydx** and choose the

menu item Analysis>Predict>Enrollment Only.

In the resulting dialog box, select the variable **ArrivalTime** in the drop down for **Arrival Time**. Since we want to include the Site information for this study, check the **Include Site-specific Information** check box. As soon as you check this option, the Input screen enables input for **Site ID** for Subject data as well as some more information about Site data such as workbook, dataset and some variables. Scroll down to see the complete Input dialog. Select **Site ID** for subject-level data and the data set **ORLISTAT_iLook1_SiteData.cyx** for the input of Site-level Data and map the variables from the Site data to the respective inputs as shown in the following screen which shows the necessary part of the input dialog.

Choose Variables from Dataset

Arrival Time: Site ID:

 Site-level Data: ORLISTAT_iLook1_SiteData.cydx

Click **Simulate**. After a few seconds East will display the message **Simulations complete. Waiting for User's action**. Click **Close**. This will save the **Predict Simulation** in the Output Preview window first.

| ID | Average Sample Size | Average Accrual Duration |
|-------------|---------------------|--------------------------|
| PredictSim3 | 318 | 3.265 |

Once you save it in the Workbook, it will create a node **PredictSim3** with subnodes for the simulation outputs. To view the detailed output, double click the node

68 Enrollment/Events Prediction - Analysis

PredictSim3 in **Library**. You will see the following output.

Conditional Simulation: Prediction of Enrollment Timelines

| Test Parameters | |
|-------------------------------|--------------------|
| Simulation ID | PredictSim3 |
| Accrual | Ongoing |
| Input | Subject-level Data |
| Include Site Info | Yes |
| Target Sample Size | 318 |
| Accrual / Dropouts Parameters | |
| Accrual Model | Poisson |
| Total No. of Sites | 18 |
| Simulation Control Parameters | |
| Starting Seed | Fixed |
| Number of Simulations | 1000 |

Actuals from Interim Trial Data: Sample Size

| Sample Size | Current Accrual Duration |
|-------------|--------------------------|
| 212 | 2.224 |

Conditional Simulation: Average Sample Size

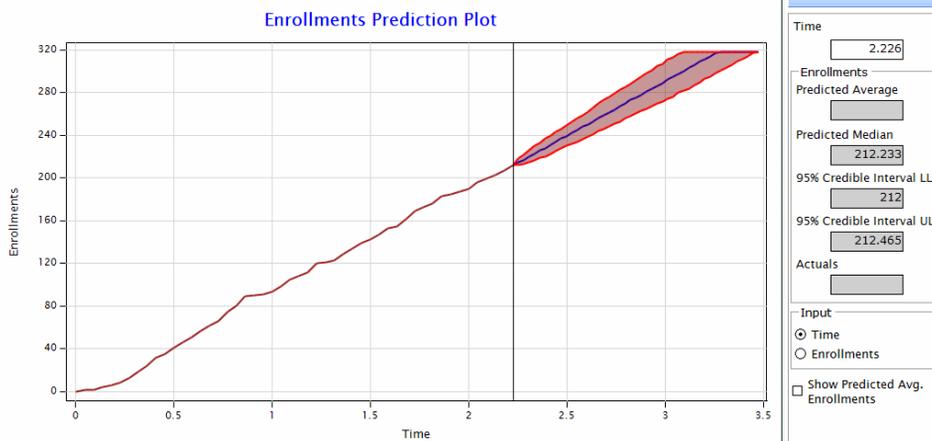

| Average Sample Size | Average Accrual Duration |
|---------------------|--------------------------|
| 318 | 3.265 |

Overall Output

| | Stage | Percentile | No. of Sites Opened | No. of Accruals | Accrual Duration |
|---|--------------|------------|---------------------|-----------------|------------------|
| | Interim | Actuals | 0 | 212 | 2.224 |
| - | End of Trial | 5% | 18 | 318 | 3.107 |
| | | 25% | 18 | 318 | 3.2 |
| | | 50% | 18 | 318 | 3.261 |
| | | 75% | 18 | 318 | 3.335 |
| | | 95% | 18 | 318 | 3.423 |
| | | Average | 18 | 318 | 3.265 |

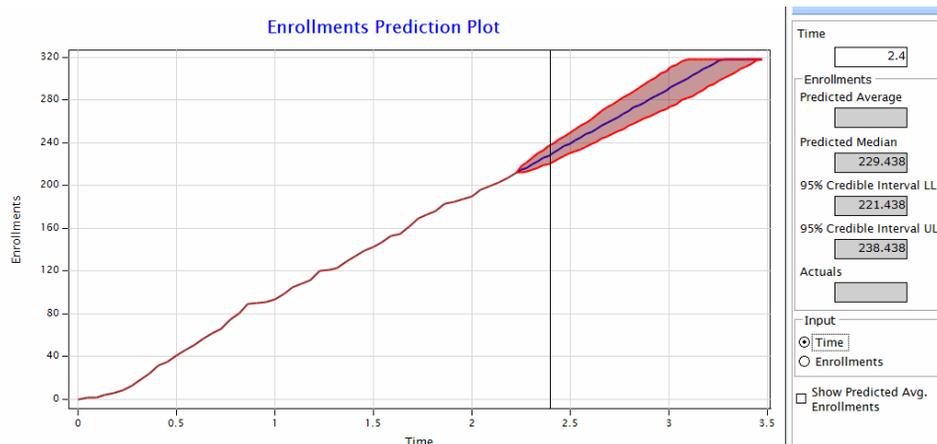

The **Average Accrual Duration** across all the simulations is 3.265. The **Accrual Duration** column in the **Overall Summary** table indicates the frequency distribution of **Accrual Duration**. Accordingly, median accrual duration is 3.261, whereas 75% of the simulations have total Accrual Duration 3.335.

To view the **Enrollments Simulation Plot** click the **PredictSim1** node in the **Library**; use the  tool in the **Library** pane.

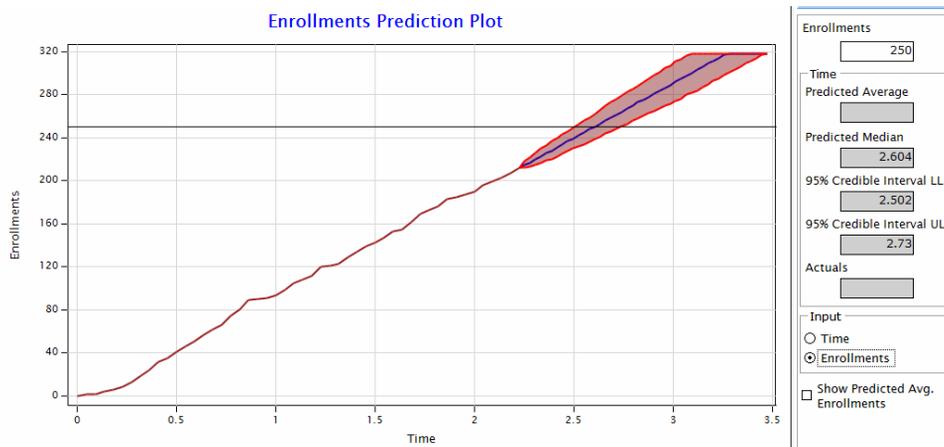

The **Enrollment Prediction Plot** displays the timeline of the observed accruals until 2.226 by which in all 212 subjects have been enrolled. This is as per the observed data.

After that point it displays the projected enrollments based on the observed accrual data we specified and the revised **Accrual Rate** in the second period. For example, at year 2.4 the predicted median enrollments reach the sample size of 229 subjects with the 95% Confidence Interval as (221.438, 238.438). Please see the plot below.

68 Enrollment/Events Prediction - Analysis

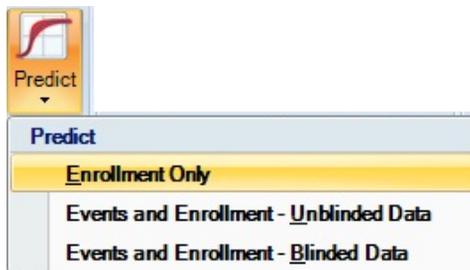

On similar lines, if you want to find out how long will it take to enroll say, 250 subjects. Select the Input> Enrollments option on the plot and type 250 in the **Enrollments** textbox as shown in the following plot.

From the read-offs it is clear that the median accrual duration for accruing 250 subjects would be 2.604 with 95% confidence interval (2.502, 2.73).

The **Predict** feature of East can also handle situations where the sites are initially closed, but would open later and start accruing the subjects subsequently. We will illustrate this feature now.

Import the **ORLISTAT_EnrollmentOnly_SubjectData.csv** and **ORLISTAT_EnrOnly_SiteData.csv** which will create data nodes in the library. As before, choose the menu item Analysis>Predict>Enrollment Only.

In the resulting dialog box, give the inputs as shown below:

Input: Subject-level Data
 Summary Data

- | **Subject-level Data** _____

Select Workbook:

Site Initiation: Opened Sites

Site Initiation Time:

68 Enrollment/Events Prediction - Analysis

Click **View Site Dataset**

Selected Dataset: ORLISTAT_EnrOnly_SiteData.cydx

| SiteOpenFlag: 1 | | Value: 1 | | | | |
|-----------------|-------------|----------|-------------|--------------|-----------|--|
| | SiteOpenFla | SiteID | SiteReadyTi | SiteAccrRate | SIP_Start | |
| 1 | 1 | SITE1 | 0 | 10 | 0 | |
| 2 | 1 | SITE2 | 0.186156561 | 10 | 0 | |
| 3 | 1 | SITE3 | 0.230253726 | 10 | 0 | |
| 4 | 0 | SITE4 | . | 10 | 2 | |
| 5 | 1 | SITE5 | 0.122660027 | 10 | 0 | |

Note that the **Site Ready Time** for sites 4 and 10 are missing. Note that the two sites can be opened anytime during the time interval (2, 9). Accordingly, the **SIP_Start** and **SIP_End** values are 2 and 9 respectively.

Click **Hide Dataset**. Click **Next**. This will invoke the **Accrual/Dropouts Information** dialog. The **Current Sample Size** is 183 as the subjects at the sites 4 and 10 have not yet been enrolled. East gives two options for generating arrivals: Poisson or Uniform. Select the option of **Poisson** arrivals. Scroll down a little for the middle table to view the **Unopened Sites** information. The values of **Site Initiation Period Start** and **End** are **NA** as these sites are already open whereas for the sites 4 and 10, **Start** and periods are specified which will be used to generate the **Site Initiation Times** for these two sites. The column **Accrual Rate/Site** depicts the accrual rates calculated from the existing data. These will be used to simulate the remaining $274 - 183 = 91$ accruals. You may change the values of **Accrual rate/Site**. Suppose henceforth the sites 13 and 17 are expected to enroll the subjects pretty fast. We want to change the accrual rates for the sites 13 and 17 to 20 and 40 respectively. Change the corresponding values. The **Planned Accrual Rate** are the values read from the data in the variable **SiteAcrrRate**. These values can't be edited. Now the input screen showing the lower part of the table scrolled down would look as shown below:

Target Sample Size:

Current Sample Size: 183
 Current Calendar Time: 2.224

Total Number of Sites: Accrual Model:

Number of Sites Opened: 16

| Site ID | Site Initiation Period | | Accrual Rate/Site | Enrollment Cap | Planned Accrual Rate/Site | Site Initiation Time | No. of Accruals |
|---------|------------------------|-----|-------------------|----------------|---------------------------|----------------------|-----------------|
| | Start | End | | | | | |
| SITE11 | NA | NA | 5.5078 | 368 | 5 | 0.046 | 12 |
| SITE12 | NA | NA | 4.20469 | 368 | 5 | 0.084 | 9 |
| SITE13 | NA | NA | 20 | 368 | 5 | 0.104 | 11 |
| SITE14 | NA | NA | 2.36288 | 368 | 2 | 0.108 | 5 |
| SITE15 | NA | NA | 2.32135 | 368 | 2 | 0.07 | 5 |
| SITE16 | NA | NA | 2.70295 | 368 | 2 | 0.005 | 6 |

| SITE10 | 2 | 9 | 5 | 368 | 5 | NA | NA |

Subject-level Data: ORLISTAT_EnrollmentOnly_SubjectData.cydx
 Site-level Data: ORLISTAT_EnrOnly_SiteData.cydx

Go to the **Simulation Controls** tab. You can change the simulation parameters here as per your wish. Suppose you want to have the outputs stored in .csv format. Select the **Output Type** as CSV file. Either you can already create the files in local folders and select them using the **Browse** button or you may create the files while you are browsing.

Suppose the **Summary.csv**, **SubjectData.csv**, **SitewiseSummary.csv** and **SitewisePara.csv** are the files which would store the Summary statistics for every simulation run, Subject level data for 1 simulation run, Sitewise summary for every simulation run and Sitewise parameter data for 1 simulation run respectively. All these files are to be stored on say the local drive *G*. Choose the **Random Number Seed** as **Fixed** with its value 12345. The input screen for simulation will be seen as

68 Enrollment/Events Prediction - Analysis

shown below:

Target Sample Size:

Accrual / Dropouts | Simulation Controls

Number of Simulations:
 Refresh Frequency:

Save subject level data for simulation runs

Save site-wise summary for every simulation run

Save site parameters data for simulation runs

Output for All Trials

Subject-level Data: ORLISTAT_EnrollmentOnly_SubjectData.cydx
 Site-level Data: ORLISTAT_EnrOnly_SiteData.cydx

Click **Simulate**. After a few seconds East will display the message **Simulations complete. Waiting for User's action**. Click **Close**. This will save the **Predict Simulation** in the Output Preview window first.

| ID | Average Sample Size | Average Accrual Duration |
|-------------|---------------------|--------------------------|
| PredictSim4 | 274 | 2.866 |

Once you save it in the Workbook, it will create a node **PredictSim1**. This time no sub nodes will be created as we have asked the output to be saved in .CSV files at the specified locations on the machine. To view the detailed output, double click the node

PredictSim1 in **Library**. You will see the following output.

Conditional Simulation: Prediction of Enrollment Timelines

| Test Parameters | |
|-------------------------------|--------------------|
| Simulation ID | PredictSim4 |
| Accrual | Ongoing |
| Input | Subject-level Data |
| Include Site Info | Yes |
| Target Sample Size | 274 |
| Accrual / Dropouts Parameters | |
| Accrual Model | Poisson |
| Total No. of Sites | 18 |
| Simulation Control Parameters | |
| Starting Seed | Fixed |
| Number of Simulations | 1000 |

Actuals from Interim Trial Data: Sample Size

| Sample Size | Current Accrual Duration |
|-------------|--------------------------|
| 183 | 2.224 |

Conditional Simulation: Average Sample Size

| Average Sample Size | Average Accrual Duration |
|---------------------|--------------------------|
| 274 | 2.866 |

Overall Output

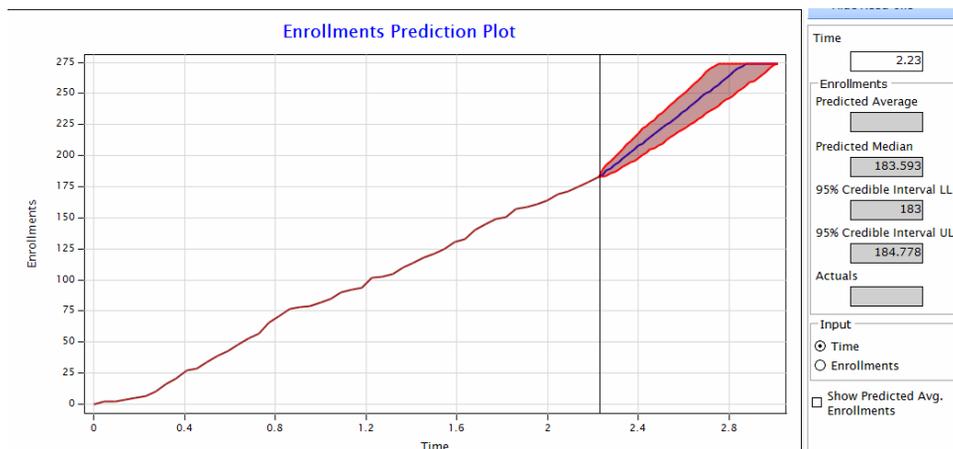

| | Stage | Percentile | No. of Sites Opened | No. of Accruals | Accrual Duration |
|--|--------------|------------|---------------------|-----------------|------------------|
| | Interim | Actuals | 0 | 183 | 2.224 |
| | End of Trial | 5% | 16 | 274 | 2.759 |
| | | 25% | 16 | 274 | 2.818 |
| | | 50% | 16 | 274 | 2.864 |
| | | 75% | 16 | 274 | 2.91 |
| | | 95% | 17 | 274 | 2.979 |
| | | Average | 16.194 | 274 | 2.866 |

The **Average Accrual Duration** across all the simulations is 2.866. The **Accrual Duration** column in the **Overall Summary** table indicates the frequency distribution of **Accrual Duration**. Accordingly, median accrual duration is 2.864, whereas 75% of the simulations have total Accrual Duration 2.91.

To view the **Enrollments Simulation Plot** click the **PredictSim1** node in

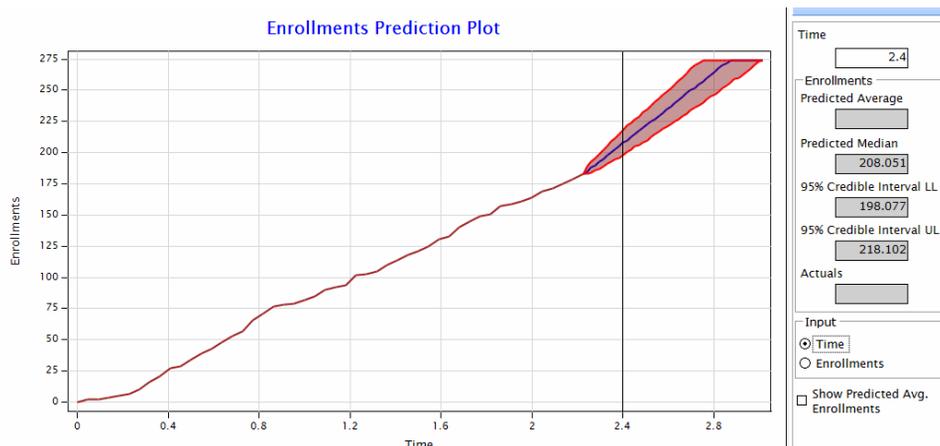

68 Enrollment/Events Prediction - Analysis

the Library; use the  tool in the **Library** pane.

The **Enrollment Prediction Plot** displays the timeline of the observed accruals until 2.23 by which in all 183 subjects have been enrolled. This is as per the observed data.

After that point it displays the projected enrollments based on the observed accrual data we specified and the revised **Accrual Rate** in the second period. For example, at year 2.4 the predicted median enrollments reach the sample size of 208 subjects with the 95% Confidence Interval as (198.077, 218.102). Please see the plot below.

Let us investigate further the output of the simulations run. Below is repeated the **Overall Output** from the detail output.

Overall Output

| | Stage | Percentile | No. of Sites Opened | No. of Accruals | Accrual Duration |
|--------------|---------|------------|---------------------|-----------------|------------------|
| | Interim | Actuals | 0 | 183 | 2.224 |
| End of Trial | | 5% | 16 | 274 | 2.759 |
| | | 25% | 16 | 274 | 2.818 |
| | | 50% | 16 | 274 | 2.864 |
| | | 75% | 16 | 274 | 2.91 |
| | | 95% | 17 | 274 | 2.979 |
| | | Average | | 16.194 | 274 |

Subject-level Data

Subject Dataset: ORLISTAT_EnrollmentOnly_SubjectData.cydx
 Arrival Time: ArrivalTime
 Site ID: SiteID

Site-level Data

Dataset: ORLISTAT_EnrOnly_SiteData.cydx
 Site ID: SiteID
 Accrual Rate / Site: SiteAccrRate
 Enrollment Cap: Ecap
 Unopened Sites: Start SIP_Start
 Unopened Sites: End SIP_End
 Opened Sites: Site Initiation Time: SiteReadyTime

If you have a close look at the column **No of Sites Opened**, you will notice that till the 75th percentile of the Accrual duration, that is by 2.91, only 16 sites were open as was the situation in the beginning. One more site has got opened during 2.91 and 2.979. Let us see what all has happened during this time period.

We have saved the outputs in .CSV files. Open the file **Summary.csv** which stores summary statistics for every simulation run. You will see the data as shown below:

68 Enrollment/Events Prediction - Analysis

| ScenarioID | SimIndex | Stage | Status | TotAccruals | TotPendings | TotEvents | AccrDurtn |
|------------|----------|---------|---------|-------------|-------------|-----------|-----------|
| 1 | 1 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 1 | Final | SUCCESS | 274 | 0 | 274 | 2.804084 |
| 1 | 2 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 2 | Final | SUCCESS | 274 | 0 | 274 | 3.015385 |
| 1 | 3 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 3 | Final | SUCCESS | 274 | 0 | 274 | 2.732081 |
| 1 | 4 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 4 | Final | SUCCESS | 274 | 0 | 274 | 2.860316 |
| 1 | 5 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 5 | Final | SUCCESS | 274 | 0 | 274 | 2.91049 |
| 1 | 6 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 6 | Final | SUCCESS | 274 | 0 | 274 | 2.809429 |
| 1 | 7 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 7 | Final | SUCCESS | 274 | 0 | 274 | 2.834545 |
| 1 | 8 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 8 | Final | SUCCESS | 274 | 0 | 274 | 2.883579 |
| 1 | 9 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 9 | Final | SUCCESS | 274 | 0 | 274 | 2.912459 |
| 1 | 10 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 10 | Final | SUCCESS | 274 | 0 | 274 | 2.882488 |
| 1 | 11 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 11 | Final | SUCCESS | 274 | 0 | 274 | 2.815699 |
| 1 | 12 | Interim | SUCCESS | 183 | 0 | 183 | |
| 1 | 12 | Final | SUCCESS | 274 | 0 | 274 | 2.97942 |

Observe that for every simulation East calls the **Current Sample Size** available data as **Interim** while the **Target Sample Size** as **Final**.

The column **SUCCESS** indicates that the simulation was successful. The variable **TotEvents** is synonymous to Sample Size.

The last column **AccrDurtn** specifies the accrual duration required to enroll the 274 subjects in the respective simulation run. For instance, in the first simulation, the 274th subject arrived at the time epoch 2.80408 and so on. Now open the **Subject.csv** file which stores arrival times of each subject for one simulation. You will see the

following display of data.

| ScenarioID | Simulation | SubjectID | SiteID | ArrivalTime |
|------------|------------|-----------|--------|-------------|
| 1 | 4 | 1 | SITE1 | 0.025988 |
| 1 | 4 | 2 | SITE1 | 0.042236 |
| 1 | 4 | 3 | SITE1 | 0.11012 |
| 1 | 4 | 4 | SITE5 | 0.127381 |
| 1 | 4 | 5 | SITE1 | 0.174202 |
| 1 | 4 | 6 | SITE11 | 0.190352 |
| 1 | 4 | 7 | SITE18 | 0.223044 |
| 1 | 4 | 8 | SITE1 | 0.24231 |
| 1 | 4 | 9 | SITE14 | 0.251971 |
| 1 | 4 | 10 | SITE13 | 0.270862 |
| 1 | 4 | 11 | SITE9 | 0.272797 |
| 1 | 4 | 12 | SITE6 | 0.29149 |
| 1 | 4 | 13 | SITE1 | 0.295691 |
| 1 | 4 | 14 | SITE8 | 0.30715 |
| 1 | 4 | 15 | SITE16 | 0.310956 |
| 1 | 4 | 16 | SITE11 | 0.31317 |
| 1 | 4 | 17 | SITE3 | 0.322496 |
| 1 | 4 | 18 | SITE5 | 0.323448 |
| 1 | 4 | 19 | SITE1 | 0.330773 |
| 1 | 4 | 20 | SITE7 | 0.343222 |
| 1 | 4 | 21 | SITE9 | 0.354224 |
| 1 | 4 | 22 | SITE3 | 0.366509 |
| 1 | 4 | 23 | SITE8 | 0.368021 |
| 1 | 4 | 24 | SITE14 | 0.377406 |

Note that the data are ordered according to the arrival times of all the subjects across all the sites. The first three subjects arrive at Site 1 in succession, whereas the fourth subject arrives at Site 5 and so on. You can sort the data on sites and see that the sites 4 and 10 are not opened in this particular simulation, that is simulation 4. The last subject arrived in Simulation 1 at time point 2.8603 at Site 12. The question is when the sites 4 and 10 finally opened and started accepting subjects. Since these sites don't occur in the **Summary** data, they must have got opened after the last arrival. To verify this, open the file **SitewisePara.csv** which stores the site parameter data for one simulation run.

68 Enrollment/Events Prediction - Analysis

The data are as follows:

| SimulationID | SiteOpenFlag | SiteAlreadyOpened | SiteID | SiteInitiationTime | SiteAccrRate | SubjectsAccrued | LastSubjectRand | AccrualDuration | ObsrvdAccrualRate |
|--------------|--------------|-------------------|--------|--------------------|--------------|-----------------|-----------------|-----------------|-------------------|

This file gives site wise details of the accrual process. The columns **SiteInitiationTime** and **SubjectsAccrued** specify the time at which the site was opened and the number of subjects it accrued in that simulation. The column **LastSubjectRand** shows the time at which the last subject arrived at that site. Since the accrual rates of different sites are different, some sites would accrue more subjects than the ones having low accrual rates. Also the **SiteInitiation time** matters for accruing a few or more subjects. Note that from the last two rows, the **SiteInitiationTime** for Site 4 is 3.5685 and for Site 10, it is 7.9575. However, the last subject arrived in the study at 2.8603 at Site 12. As a result, both the sites 4 and 10 got opened after the accruals in the study on a whole were complete.

The columns **Accrual Duration** and **ObsrvdAccrualRate** specify the site wise accrual duration and the rate at which the site accrued subjects. Now open the

SitewiseSummary.csv file. It will display the following information.

| SiteID | AvgInitiationTime | AvgLastSubjArrTi | AvgNumOfSubj | AvgAccrualDuration | AvgAccrualRate | SiteOpenedSimCount |

Averages across all the simulations for the quantities, **Initiation Time, last Subject Arrival Time, Number of Subjects Enrolled, Accrual Duration, Accrual Rate** are provided for individual sites. From the last two rows, it should be noted that only in 97 simulations out of 1000, the two sites 4 and 10 have got opened during the accrual duration.

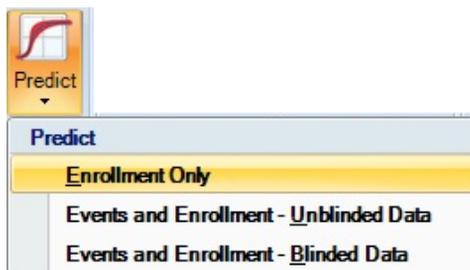

We suggest you to try with different input subject data and/ or site data with varying accrual rates, site initiation intervals, enrollment cap to develop better insight of the accrual process.

68.1.3 Enrollment Only: Summary Data

In the earlier section we saw how to simulate the accruals and estimate the average accrual duration when an interim subject-level data is available. However, sometimes, the subject-level data may not be available. What can be available is the summary of the accruals that have happened till date. For example, in the case of Orlistat trial considered above, the DMC statistician may have the information that there have been 212 subjects accrued so far and the last subject arrived at time 2.224. The DMC statistician is interested in knowing the total accrual duration for say 318 accruals. East through its Predict feature makes it possible to still come up with an estimate of average accrual duration based on arrival simulations for these additional $318 - 212 = 106$ arrivals. To see this, choose the menu item

68 Enrollment/Events Prediction - Analysis

Analysis>Predict>Enrollment Only.

In the ensuing dialog box, select the **Input** option, **Summary Data**. Fill in the Sample Size as 212 and the **Current Calendar Time** as 2.224. The screen will look as shown below.

Analysis: Predict: Enrollment Only (Step 1 of 2)

Input: Subject-level Data
 Summary Data

Summary Data

Sample Size:

Current Calendar Time:

* Click 'Next' to specify other parameters.

Click **Next**. The next input dialog appears as shown here:

Analysis: Predict: Enrollment Only (Step 2 of 2)

Target Sample Size:

Accrual / Dropouts

Simulation Controls

Current Sample Size: 212

Current Calendar Time: 2.224 Accrual Model: Poisson

Accrual Information

of Accrual Periods: Input Method:

| Period # | Starting at Time | Accrual Rate |
|----------|------------------|--------------|
| 1 | 0.000 | 95.324 |
| 2 | 2.224 | 47.662 |

As before, default values for **Current Sample Size** and the **Target Sample Size** are 212 and 318 respectively, default for the **target Sample Size** being $1.5 * CurrentSampleSize$. You may change the **Target Sample Size** value. This is the value of targeted enrollment in the trial. The objective is to find out on an average how long will the trial take to enroll these many subjects. The **Current Calendar Time** is accrual time of the last subject in the data which is 2.224. The **Accrual Information** input is meant for simulating the additional, that is $318 - 212 = 106$ accruals. There are two options for **Input Method**. For the **Accrual Rates** option, East considers the accrual process comprised of two periods. The first period is assumed to be the one presented in the data. Starting time for this period is assumed to be 0 whereas the accrual rate for this period is computed as $(CurrentSampleSize)/(CurrentCalendarTime)$. In this case it is $212/2.2243 = 95.31$. Both the starting time and Accrual Rate fields are uneditable as these are estimated from the data. The second period is the one which starts after the last subject in the first period has arrived. As a result, the **Starting At** time default value is the last arrival time in the data which is also the **Current Calendar Time**. For the second period, the default accrual rate is computed as: $(TargetSampleSize - CurrentSampleSize)/(CurrentCalendarTime)$ which is $(318 - 212)/2.2243 = 47.65499$ for the current example. You can edit both the Starting Time and Accrual Rate for the second period. Accrual may vary over time. To reflect this assumption, one can specify the number of time periods, each having different accrual rates. Go to the **Simulation Controls** tab. Let us fix the Random Number Seed to 12345. Check the Output options, **Save the summary statistics for every simulation run** and **Save subject-level**

68 Enrollment/Events Prediction - Analysis

data for 1 simulation run. The input screen will be as shown below:

Simulation Seed and Elapsed Time

Starting Seed: 12345
 Total Number of Simulations: 1000
 Elapsed Time: 00:00:09

The table at the left describes the Simulation scenario. This summary contains an

68 Enrollment/Events Prediction - Analysis

overview of the actual data we observed and the simulated results for the remaining arrivals in the second period. The table **Overall Output** presents the information on the percentiles of the (simulated) total accrual duration. For example, almost 50% simulations have completed by 4.433 units of time etc. The mean accrual duration of all the simulations is 4.427.

Open the **SummaryStat** data by double clicking the sub node. You will see the following display of data.

| ScenarioID | SimIndex | Stage | Status | TotAccruals | TotPendings | TotEvents | AccrDurtn |
|------------|----------|---------|---------|-------------|-------------|-----------|------------|
| 1 | 1 | Interim | SUCCESS | 212 | 0 | 212 | . |

| 1 | 7 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 7 | Final | SUCCESS | 318 | 0 | 318 | 4.40053653 |
| 1 | 8 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 8 | Final | SUCCESS | 318 | 0 | 318 | 4.43956756 |
| 1 | 9 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 9 | Final | SUCCESS | 318 | 0 | 318 | 4.44045153 |
| 1 | 10 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 10 | Final | SUCCESS | 318 | 0 | 318 | 4.43619724 |
| 1 | 11 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 11 | Final | SUCCESS | 318 | 0 | 318 | 4.41786203 |

Observe that for every simulation East calls the **Current Sample Size** available data as **First Interim** while the **Target Sample Size** as **Final**.

The column **SUCCESS** indicates that the simulation was successful. The variable **TotEvents** is synonymous to Sample Size.

The last column **AccrDurtn** specifies the accrual duration required to enroll the 318 subjects in the respective simulation run. For instance, in the first simulation, the 318th subject arrived at the time epoch 4.34938 and so on. Now double click the **SubjectData** sub node in the library. You will see the following display of data.

| ScenarioID | SimulationID | SubjectID | ArrivalTime |
|------------|--------------|-----------|-------------|
| 1 | 1 | 213 | 2.23154614 |
| 1 | 1 | 214 | 2.23830539 |

| 1 | 1 | 217 | 2.28054916 |
| 1 | 1 | 218 | 2.30184938 |
| 1 | 1 | 219 | 2.3080157 |
| 1 | 1 | 220 | 2.31911506 |
| 1 | 1 | 221 | 2.34185009 |
| 1 | 1 | 222 | 2.35918468 |
| 1 | 1 | 223 | 2.3594013 |
| 1 | 1 | 224 | 2.37968859 |
| 1 | 1 | 225 | 2.39830855 |
| 1 | 1 | 226 | 2.40411586 |
| 1 | 1 | 227 | 2.45398704 |
| 1 | 1 | 228 | 2.47648728 |
| 1 | 1 | 229 | 2.48733738 |
| 1 | 1 | 230 | 2.51316958 |
| 1 | 1 | 231 | 2.5820502 |
| 1 | 1 | 232 | 2.62757609 |
| 1 | 1 | 233 | 2.62920135 |
| 1 | 1 | 234 | 2.64162236 |

It shows arrival times of each and every subject in the study for one simulation. This is because we have asked to save the data for one run. To view the detailed summary output of the simulations, Open the **SummaryStat** data by double clicking the sub

68 Enrollment/Events Prediction - Analysis

node. You will see the following display of data.

| ScenarioID | SimIndex | Stage | Status | TotAccruals | TotPendings | TotEvents | AccrDurtn |
|------------|----------|---------|---------|-------------|-------------|-----------|------------|
| 1 | 1 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 1 | Final | SUCCESS | 318 | 0 | 318 | 4.35719694 |
| 1 | 2 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 2 | Final | SUCCESS | 318 | 0 | 318 | 4.7111913 |
| 1 | 3 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 3 | Final | SUCCESS | 318 | 0 | 318 | 4.23758069 |
| 1 | 4 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 4 | Final | SUCCESS | 318 | 0 | 318 | 4.52927409 |
| 1 | 5 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 5 | Final | SUCCESS | 318 | 0 | 318 | 4.42808236 |
| 1 | 6 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 6 | Final | SUCCESS | 318 | 0 | 318 | 4.36122242 |
| 1 | 7 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 7 | Final | SUCCESS | 318 | 0 | 318 | 4.28554977 |
| 1 | 8 | Interim | SUCCESS | 212 | 0 | 212 | . |
| 1 | 8 | Final | SUCCESS | 318 | 0 | 318 | 4.58337695 |

Observe that for every simulation East calls the **Current Sample Size** available data as **First Interim** while the **Target Sample Size** as **Final**.

The column **SUCCESS** indicates that the simulation was successful. The variable **TotEvents** is synonymous to Sample Size.

The last column **AccrDurtn** specifies the accrual duration required to enroll the 318 subjects in the respective simulation run. For instance, in the first simulation, the 318th subject arrived at the time epoch 4.35001 and so on. Now double click the **SubjectData** sub node in the library. You will see the following display of data.

| ScenarioID | SimulationID | SubjectID | ArrivalTime |
|------------|--------------|-----------|-------------|
| 1 | 1 | 213 | 2.23154614 |
| 1 | 1 | 214 | 2.23830539 |
| 1 | 1 | 215 | 2.24938829 |
| 1 | 1 | 216 | 2.25249941 |
| 1 | 1 | 217 | 2.28054916 |
| 1 | 1 | 218 | 2.30184938 |

| 1 | 1 | 220 | 2.31911506 |
| 1 | 1 | 221 | 2.34185009 |
| 1 | 1 | 222 | 2.35918468 |
| 1 | 1 | 223 | 2.3594013 |
| 1 | 1 | 224 | 2.37968859 |
| 1 | 1 | 225 | 2.39830855 |
| 1 | 1 | 226 | 2.40411586 |
| 1 | 1 | 227 | 2.45398704 |
| 1 | 1 | 228 | 2.47648728 |
| 1 | 1 | 229 | 2.48733738 |
| 1 | 1 | 230 | 2.51316958 |
| 1 | 1 | 231 | 2.5820502 |
| 1 | 1 | 232 | 2.62757609 |
| 1 | 1 | 233 | 2.62920135 |
| 1 | 1 | 234 | 2.64162236 |

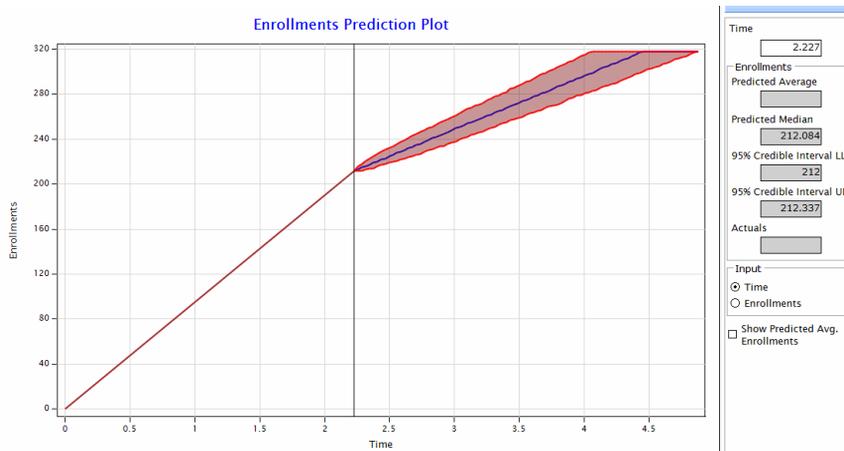

It shows arrival times for the subjects in the study for one simulation run. Note that the first subject id is 213 as the summary data input was for 212 subjects. If you scroll down, you can see that the last subject id is 318 which is the target sample size. This

68 Enrollment/Events Prediction - Analysis

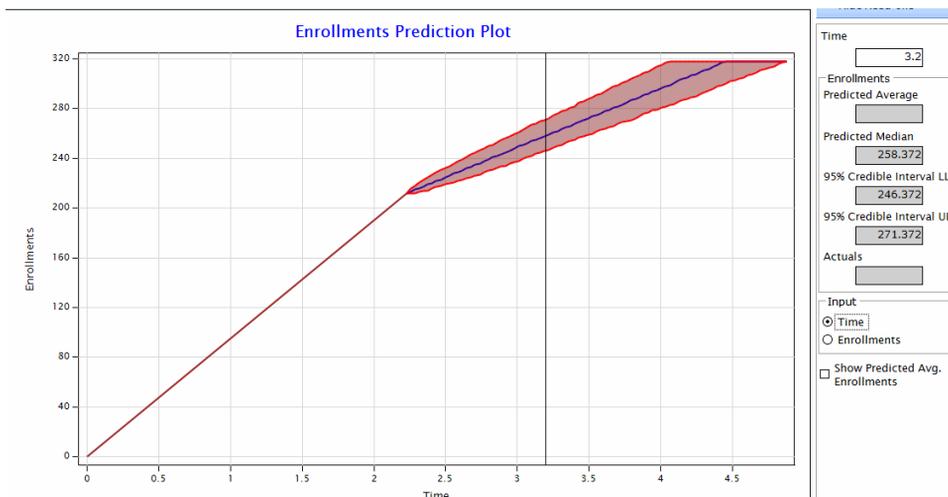

subject was accrued at 4.34938.

In addition, you can view the enrollment prediction plot using the  tool in the **Library** pane:

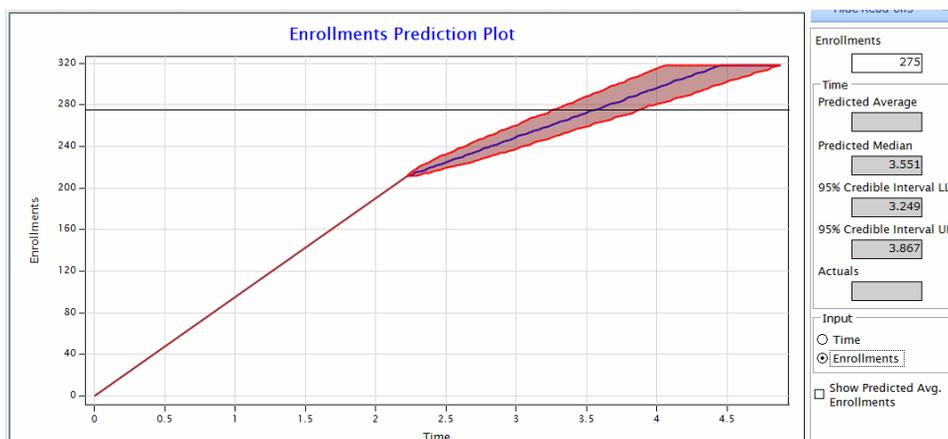

The **Enrollment Prediction Plot** displays the timeline of the observed accruals until 2.234 by which in all 212 subjects have been enrolled. This is as per the observed data.

After that point it displays the projected enrollments based on the observed accrual data we specified and the revised **Accrual Rate** in the second period. For example, at year 3.2 the predicted median enrollments reach the sample size of 258 subjects with the 95% Confidence Interval as (246.372, 271.372). Please see the plot below.

On similar lines, if you want to find out how long will it take to enroll say, 275 subjects. Select the Input > Enrollments option on the plot and type 275 in the **Enrollments** textbox as shown in the following plot.

From the read-offs it is clear that the median accrual duration for accruing 275 subjects would be 3.551 with 95% confidence interval (3.249, 3.867).

68 Enrollment/Events Prediction - Analysis

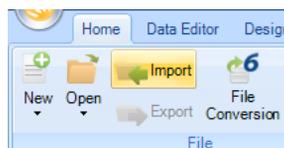

68.2 Events and Enrollment- Unblinded Data

- 68.2.1 Accrual Complete
- 68.2.2 Accrual Ongoing

A DMC statistician typically has access to unblinded trial data. In survival studies, the prediction of enrollments as well as of events is of interest. As it is important to know how long the accruals will take to complete, it is equally important to know how much time it will take to get the required number of events. With the use of predict feature, providing the inputs such as accrual rate, hazard rates, drop-out rates for the treatment and control arms you can forecast how long the subject enrolment is likely to take, and how long the trial is likely to take to complete. With PREDICT, one is able to simulate the accrual process and the follow up time, so as to predict the average accrual duration, average follow up time and average study duration (by predicting when the required number of events are likely to be achieved). We will treat the cases unblinded and blinded data separately. In unblinded situation, the user is expected to know the subject data or summary data for both the control and treatment arms separately. For instance, the control and treatment have different hazard and drop out rates and this information can be provided to East by giving different inputs for the two arms. In the case of blinded, the user is supposed to know the common hazard rate which is utilized to generate the events for control and treatment both. We will illustrate the feature with the help of Oncox (for unblinded) and Rales (for blinded) trials explained in chapter 44.

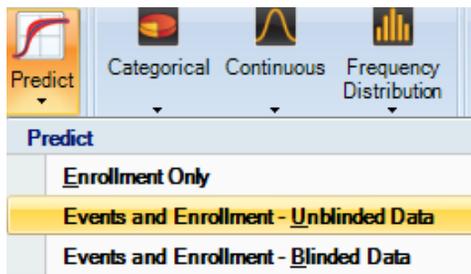

68.2.1 Events and Enrollment- Unblinded Data: Accrual Complete

Subject-level Data Assume that the study has already accrued all the subjects and we are interested in forecasting only the follow up time and study duration. The trial has accrued in all 402 subjects and stopped accruing anymore. The Subject data are available in the file **ONCOX_iLook1_SubjectData.csv** in the Samples folder of East installation directory. The data file can be imported into East using the **Import** button in the Home ribbon:

Once imported, the file will appear in the **Library** pane as nodes in the active workbook, with extension **.cydx**. Choose the menu item

Analysis>Predict>Events and Enrollment-Unblinded Data.

In the ensuing dialog box, select the **Accrual** option, **Complete**. Select data set **ONCOX_iLook1_SubjectData.cyx** . Map the variables from the data to the ones shown below:

Analysis: Predict: Events and Enrollment - Unblinded Data (Step 1 of 2)

Input: Subject-level Data Accrual: Complete
 Summary Data Ongoing

Subject-level Data

Select Workbook:

Select Dataset:

Choose Variables from Dataset

Arrival Time: Time on Study Variable:

Control: (1 = complete, 0 = censored, -1 = dropout)

Treatment: 1

Include Site-specific Information

68 Enrollment/Events Prediction - Analysis

Click **Next**. The next input dialog appears as shown here:

Analysis: Predict: Events and Enrollment - Unblinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation **Accrual / Dropouts** Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Ratio:

Hazard Rate - Control (λ_c):

Hazard Rate - Treatment (λ_t):

The default values for **Hazard Rate - Control** and **Hazard Rate - Treatment** are estimated from the subject data. You can verify this by running the LogRank Test from **Analysis > Events > Two Samples > LogRank [SU-2S-LR]**. The input dialog for the same would be

Data Set: Oncox_EventsOnly_SubjectData.cyx

Main **Advanced**

Trial Type: Response Variable: Frequency Variable:

Population ID: Censor Indicator: Test Statistic:

Control: Censored:

Treatment: Complete:

Choose the variables as shown in the dialog. Click **OK**. A partial output is shown

below:

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | | Average Follow-up Time |
|--------------|-----------------|--------|---------|----------|---------|------------------------|
| | | Count | % | Count | % | |
| 0 | 203 | 106 | 52.217% | 97 | 47.783% | 4.814 |
| 1 | 199 | 81 | 40.704% | 118 | 59.296% | 5.004 |
| Total | 402 | 187 | 46.517% | 215 | 53.483% | 4.908 |

Test of Hypothesis:

| Log Rank Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|----------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| -13.782 | 6.819 | -2.021 | L.E. | 0.022 | 0.043 |

Parameter Estimates from Cox Model:

| Hazard Ratio (HR) | ln(Hazard Ratio) (δ) | Std. Error of Estimate of δ | Wald Statistic | 95% Confidence Interval(2-Sided) | |
|-------------------|-------------------------------|------------------------------------|----------------|----------------------------------|-------------|
| | | | | Lower Limit | Upper Limit |
| 0.743 | -0.297 | 0.148 | -2.01 | 0.556 | 0.993 |

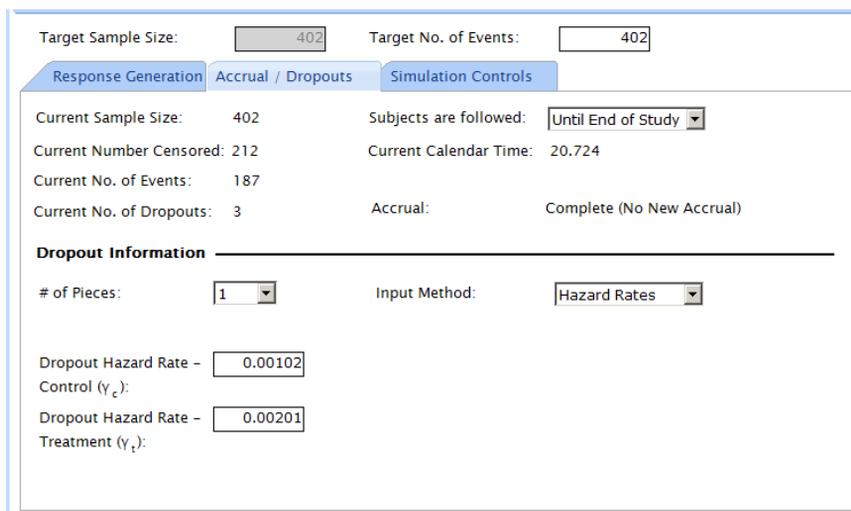

Estimated Hazard Rates:

| | |
|--------------------------------|---------|
| Control (λ_c) | 0.10847 |
| Treatment ($\lambda_c * HR$) | 0.08062 |

Observe that the **Hazard Ratio** is 0.743 and the **Estimated Hazard Rates** table gives the Hazard Rate for Control 0.10847 and that for treatment 0.08062. These are the same as the ones East chose while predicting the events. Please refer to the second input dialog for **Predict**. Continuing the **Predict** for the Oncox subject data, go to the **Accrual/ DropOuts** tab. In the ensuing dialog, you will see

68 Enrollment/Events Prediction - Analysis

almost all values filled in.

The screenshot shows a simulation control interface with the following parameters:

| | | | | | |
|--|---------|------------------------|---------------------------|---------------------|--|
| Target Sample Size: | 402 | Target No. of Events: | 402 | | |
| Response Generation | | Accrual / Dropouts | | Simulation Controls | |
| Current Sample Size: | 402 | Subjects are followed: | Until End of Study | | |
| Current Number Censored: | 212 | Current Calendar Time: | 20.724 | | |
| Current No. of Events: | 187 | Accrual: | Complete (No New Accrual) | | |
| Current No. of Dropouts: | 3 | | | | |
| Dropout Information | | | | | |
| # of Pieces: | 1 | Input Method: | Hazard Rates | | |
| Dropout Hazard Rate - Control (y_c): | 0.00102 | | | | |
| Dropout Hazard Rate - Treatment (y_t): | 0.00201 | | | | |

The **Current Calendar Time** is accrual time of the last subject in the data which is 20.724.

The drop out hazard rates for Control and Treatment are estimated from the subject data. The **Target Sample Size** is disabled as we have chosen the option **Accruals complete**. However, the **Target Number of Events** default value is 402, the same as in the data. This value can be edited. You can edit the values of hazard rates, target number of events etc. You can choose a specific follow up period as well by selecting **For Fixed Period** in the **Subjects are followed** textbox. The number of hazard pieces in the Drop out information also can be increased to specify different hazard rates for different time periods. The **Number of pieces** equal to 0 will assume that there aren't going to be any drop outs. For now, let us proceed further with all the default values. Go to **Simulation Controls**

tab. Check the Output Options for saving the outputs.

| | Average | 395.345 | 402 | 6.655 | 86.765 |

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. Since the accruals were complete, the **Target Sample Size** and the **Target Number of Events** are the same and equal to 402. The table **Actuals from Interim Trial Data: Sample Size and Events** presents the detailed information of the subject data such as events on control and treatment arms, drop outs, average follow up etc. Observe that at the end of the current time, the subjects in pipeline are 212. These are followed till the end of the study. The study is complete when all the subjects in pipeline either experience events or drop out. The table **Average Sample Size and Events** provide information about the average study duration, average number of events on control and treatment, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 86.765 units of time to complete the study. The number of events on control arm and treatment arm would be around 201 and 194. Average follow up time for an individual is 10.609. The **Overall Output** table describes the details of the distribution of **Average Study Duration** across 1000 simulations. Note that the column **No of Accruals** has all values 402 since the accruals were complete and only events are being forecasted. Since there are a few drop outs, we expect lesser, say around 395 events to occur out of 402 subjects. It is worth noting that the 5th percentile of the Average Study Duration is going to give 392 events pretty early, by the time 67.981. The 95th percentile is 111.235 which is the maximum duration the study can take. You could have changed the percentiles input, if you want to be more specific. For instance

you can input 100% to get the value of maximum study duration. Let us have a look at the individual files stored in the **Library**.

Open the **SummaryStat** data by double clicking the sub node. You will see the following display of data (shown in parts).

| ScenarioID | SimIndex | Stage | Status | Accruals0 | DropOuts0 | Pendings0 | Events0 | Accruals1 | DropOuts1 | Pendings1 | Events1 | TotAccruals |

| 3 | 212 | 187 | 20.7236842 | 4.90802566 | . |
| 11 | 0 | 391 | 88.0893703 | 10.6308622 | 20.7236842 |

Accruals0 and **Accruals1** specify the total subjects accrued on Control and Treatment arms respectively. Similar convention is used for naming the various

68 Enrollment/Events Prediction - Analysis

quantities for Control and Treatment. As before, **Interim** refers to the available data whereas **Final** refers to the simulated data. Observe that although the **TotAccruals** for every simulation is 402, the **TotEvents** may differ from simulation to simulation. Total number of events occurred in simulations 1, 2 and 3 are 398, 395 and 396 respectively. This is because of varying number of drop outs which are 4, 7 and 6 respectively for these three runs. The column **AvgFollowUp** indicates the average follow-up time of subjects by this stage, interim or Final. It is worth noting that the **LookTime** corresponding to the Final stage is essentially the study duration observed in that particular simulation. In other words, all the 402 subjects were accrued and followed in a period of 118.44 time units in simulation 1, while 78.207 for simulation 2 and so on.

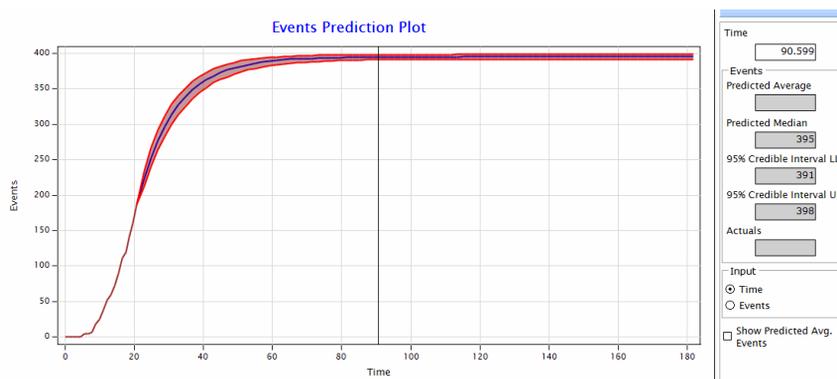

Open the **Subject Data** file which stores detailed information about one simulation.

| ScenarioID | SimulationID | SubjectID | ArrivalTime | TreatmentID | SurvivalTime | DropOutTime | CensorInd_1 |
|------------|--------------|-----------|-------------|-------------|--------------|-------------|-------------|

TreatmentID equal to 0 means the subject is on Control while 1 indicates Treatment. **Arrival Time** is the calendar time, **Survival Time** is the duration for which the subject was alive in the study. **DropOutTime** is the duration of time the subject was present in the study before dropping out. These are generated using the specified drop out hazard rates for control and treatment. For the first subject in the data, the **DropOutTime** is 237.9819 which is greater than the survival time. The time on study is the time subject was present in the study, which is **Accrual Time** plus **Survival Time** or **Accrual Time** plus **Drop Out Time** whichever is

minimum. In this case it is, 28.645. This means that the subject will not drop out till the study is completed. Accordingly, the value of **CensorInd_1** is 1 as it results in a complete observation for survival. On the other hand, observe that for the SubjectID 9, the **DropOutTime** is 14.7039, and survival time is not displayed. It means that the generated survival time was more than the drop out time. As a result, the drop out will happen before the event. The subject drops out resulting into a censored observation(**CensorInd_1** =0).

The **Events Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of events 395 are reached in a duration of 90.599 units of time.

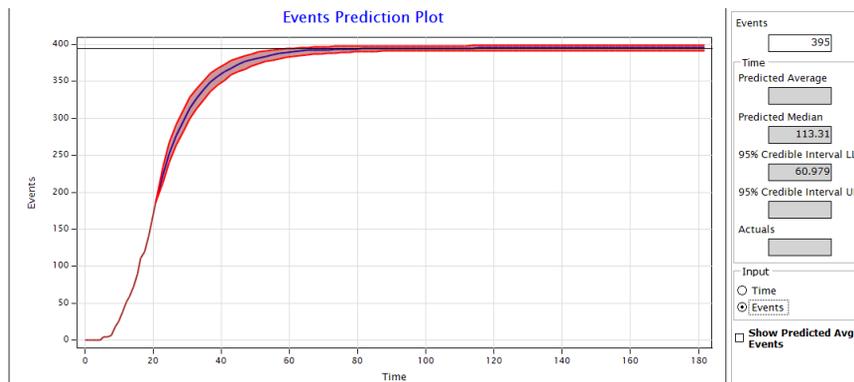

The earliest time to reach this target may be by 59.264 by looking at the upper 95% confidence limit at this time. The screens shot shown below illustrate this result.

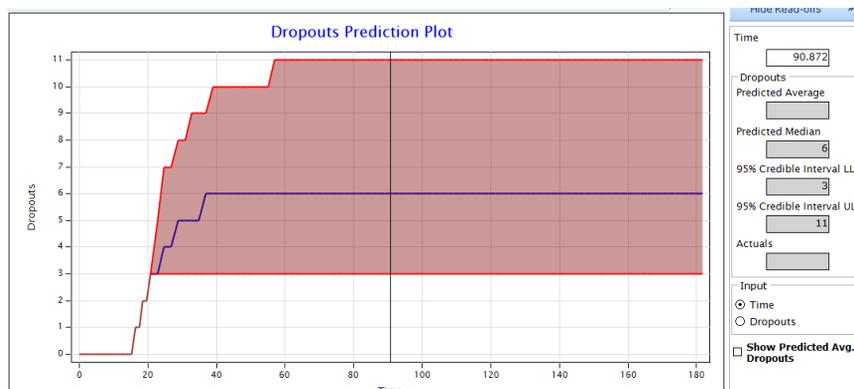

68 Enrollment/Events Prediction - Analysis

In order to find the average study duration for getting the median number of events, select the Input option **Events** in the plot. Enter 395 for Events.

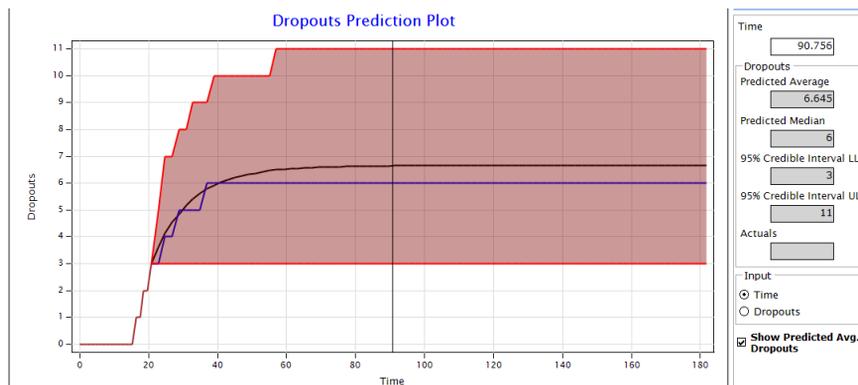

The median study duration is 113.31. Since the 95% upper limit does not exist, one can not forecast the latest time to reach the target.

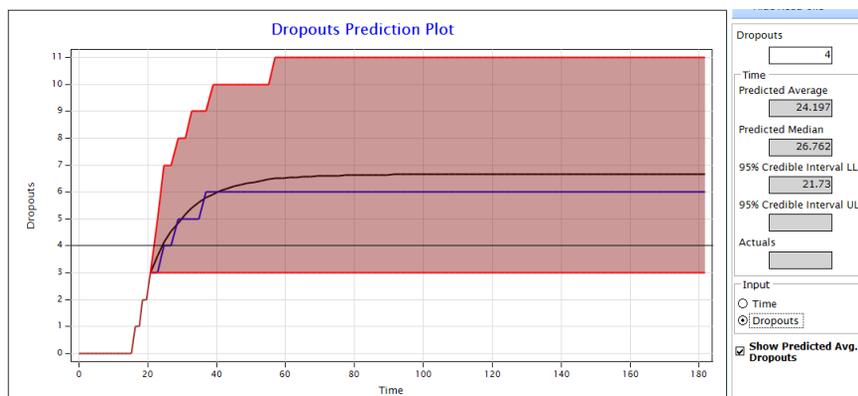

Invoke the **(Dropout Prediction Plot)** using the  tool in the **Library** pane.

In this plot, the simulation results indicate that by the end of 90.87, the median number of dropouts in both the control and treatment arms would be 6 in a 95% confidence interval of 3 to 11. If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

To find out the duration by which there will be specified number of drop outs, select the **Input** option **Dropouts**. Suppose we are interested in knowing by what time there will be 4 drop outs, give this input for **Events**. Click **Enter**.

Note that the predicted median time for getting 4 dropouts is 26.762.

Summary Data In the earlier section we saw how to generate the events and follow all subjects till they experience either events or drop out. We estimated the study duration with the help of Predict feature in East. For this to use, we assumed that an interim subject-level data was available which had information on individual arrival time, status etc. However, many a times, the subject-level data may not be available. What can be available is the summary of the accruals that have happened till date. For

Click **Next**. The next input dialog appears as shown here:

Analysis: Predict: Events and Enrollment - Unblinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation | **Accrual / Dropouts** | Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Ratio:

Hazard Rate - Control (λ_c):

Hazard Rate - Treatment (λ_t):

The default values for **Hazard Rate - Control** and **Hazard Rate - Treatment** are shown in the dialog. Note that these are not estimated from any data as we don't have the individual subject data as input. Nonetheless, use the same hazard rates 0.10847 for Control and 0.08062 for treatment, input as in the previous section. Can we consider Target No of events as 500? If you give this input, you will get an error **Value range for target no. of events should be [188, 402]**. This is because the accruals are complete and it won't accept any further accruals. The 187 events are already occurred. Suppose you are interested in 385 events. Input this value for **Target No. of Events**

Analysis: Predict: Events and Enrollment - Unblinded Data (Step 2 of 2)

Simulation Seed and Elapsed Time

Starting Seed: 12345

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. Since the accruals were complete, the **Target Sample Size** and the **Target Number of Events** are 402 and 385 respectively. The table **Actuals from Interim Trial Data: Sample**

68 Enrollment/Events Prediction - Analysis

Size and Events presents the detailed information of the subject data such as events on control and treatment arms, drop outs, average follow up etc. Observe that at the end of the current time, the subjects in pipeline are 212. These are followed till the end of the study. The study is complete when in all 385 events occur. A few simulations may give lesser number of events as there can be more drop outs. The table **Average Sample Size and Events** provide information about the average study duration, average number of events on control and treatment, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 50.946 units of time to complete the study. The number of events on control arm and treatment arm would be around 197 and 187. The **Overall Output** table describes the details of the distribution of **Average Study Duration** across 1000 simulations. Note that the column **No of Accruals** has all values 402 since the accruals were complete and only events are being forecasted. Since the targeted number of events was 385, the **No of Events** column show the value 385 in almost all the cases. It is worth noting that the 5th percentile of the Average Study Duration is going to give 381 events pretty early, by the time 52.755. The 95th percentile is 98.407 by which almost in all cases the target would be achieved. Let us have a look at the individual files stored in the **Library**.

Open the **SummaryStat** data by double clicking the sub node. You will see the

following display of data (shown in parts).

| ScenarioID | SimIndex | Stage | Status | Accruals0 | DropOuts0 | Pendings0 | Events0 | Accruals1 | DropOuts1 | Pendings1 |

| 81 | 402 | 3 | 212 | 187 | 20.7236 |
| 188 | 402 | 14 | 3 | 385 | 65.8378117 |
| 81 | 402 | 3 | 212 | 187 | 20.7236 |
| 186 | 402 | 19 | 0 | 383 | 88.0853607 |

Accruals0 and **Accruals1** specify the total subjects accrued on Control and Treatment arms respectively. Similar convention is used for naming the various quantities for Control and Treatment. As before, **Interim** refers to the available data whereas **Final** refers to the simulated data. Observe that although the **TotAccruals** for every simulation is 402, and the **TotEvents** is 385. The **TotPending** values for **Final Look** are the subjects which have neither experienced events nor have dropped out till the end of the study. This is because the study is concluded after getting 385 events and does not proceed till all the subjects experience the event as was the case in the previous section. It is worth noting that the **LookTime**

68 Enrollment/Events Prediction - Analysis

corresponding to the Final stage is essentially the study duration observed in that particular simulation.

Open the **Subject Data** file which stores detailed information about one simulation.

| 1 | 1 | 206 | 1 | 1.04244909 | 518.242629 | 1 |

The **SubjectID** starts from 191 as there were 187 events occurred earlier and 3 had dropped out. For the initial 190 subjects the detail information such as arrival time, drop out time etc is not available. **TreatmentID** 0 means the subject is on Control while 1 indicates Treatment. For the 191 subject onwards, the survival times and drop out times are generated. **Survival Time** is the duration for which the subject was alive in the study. **DropOutTime** is the duration of time the subject was present in the study before dropping out. These are generated using the specified drop out probabilities for control and treatment. Note that the data is sorted on Survival Times. Key points to observe:

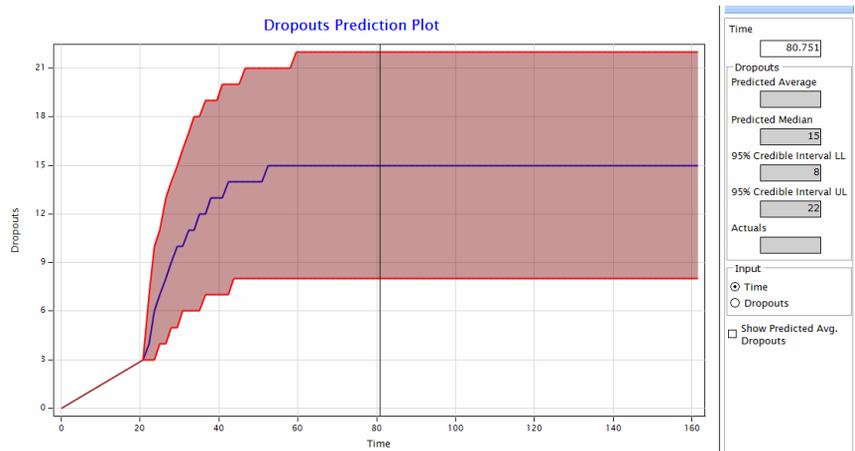

- Since out of targeted 385 events, 187 were observed earlier, the required number of events is essentially 198.
- Subject 289 drops out as its generated survival time is greater than its drop out time.
- The subjects having SubjectID 401 and 402 are not followed as the requirement of 385 events has been satisfied. They just form the group of **pending** subjects which are 4 in number.
- For the subjects which are either dropped out or form a pending observation, the

value of **CensorInd_1** is 0.

The **Events Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of events 385 are reached in a duration of 68.129 units of time.

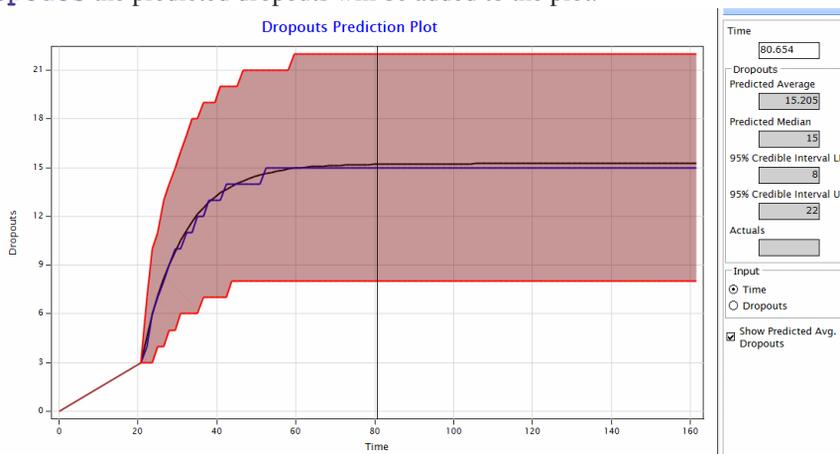

Invoke the **(Dropout Prediction Plot)** using the  tool in the **Library** pane.

In this plot, the simulation results indicate that by the end of 80.751, the median

68 Enrollment/Events Prediction - Analysis

number of dropouts in both the control and treatment arms would be 15 in a 95% confidence interval of 8 to 22. If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

68.2.2 Events and Enrollment- Unblinded Data: Accrual Ongoing

Subject-level Data The ONCOX trial in the earlier chapters was designed with a sample size of 460 subjects with an expected accrual period of around 24 months and targeted 374 events within a study period of around 30 months. Assume that an interim look has been taken and subject data are available at this time point. The trial is still accruing subjects and we are interested in forecasting Accrual duration as well as the Study Duration. The trial has accrued in all 402 subjects so far. The Subject data are available in the file **ONCOX_iLook1_SubjectData.csv** in the Samples folder of East installation directory. The file ONCOX_iLook1_SubjectData contains a list of subjects accrued so far and the following data for each subject:

- Country: Country ID.
- SiteID: the site at which the subject arrived.
- ArrivalTime: the time at which the subject arrived.
- TreatmentID: a variable indicating which group the subject was randomized to ('1' for treatment, '0' for placebo).
- TimeOnStudy: the length of time the subject has been in the study, corresponding to survival time.
- Status: a variable indicating whether the subject is a completer ('1'), a dropout

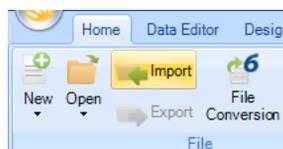

(‘-1’) or in the pipeline (‘0’).

- Censor: a variable indicating whether the subject is a completer (‘1’) or a non-completer (‘0’). A non-completer can be either a dropout or in the pipeline.

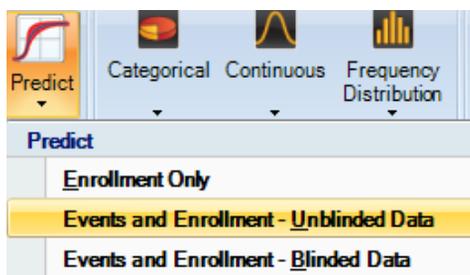

The trial is assumed to enroll subjects from several sites, the information about which is provided in the file **ONCOX_iLook1_SiteData** also available in **Samples** folder. The file contains the following data for each site:

- Country: Country ID.
- SiteID: the identification number of the site.
- SiteReadyTime: the time at which the site was initiated.
- SiteAccrRate: the site accrual rate specified in the enrollment plan.
- SubjectsAccrued: the number of subjects accrued at the site.
- LastSubjectRand: the randomization time of the last subject arriving at the site.
- ObsrvdAccrualRate: the observed accrual rate at the site.
- PosteriorAccrualRate: the updated site accrual rate.
- SIP_Start: the start of the initiation period of the site.
- SIP_End: the end of the initiation period of the site.
- Ecap: the enrollment cap, representing the maximum number of subjects that can be enrolled at the site.

Both these files can be imported into East using the **Import** button in the Home ribbon:

Once imported, the files will appear in the **Library** pane as nodes in the active workbook, with extension .cydx. Choose the menu item **Analysis>Predict>Events and Enrollment-Unblinded Data**.

68 Enrollment/Events Prediction - Analysis

In the ensuing dialog box, select the **Accrual** option, **Ongoing**. Select data set **ONCOX_iLook1_SubjectData.cydx** . Tick the check box **Include Site-specific Information**. Map the variables from the data to the ones shown below:

<< Back Simulate

The default values for **Hazard Rate - Control** and **Hazard Rate -Treatment** are estimated from the subject data. You can verify this by running the LogRank Test from **Analysis > Events > Two Samples > LogRank [SU-2S-LR]**. The input dialog for the same would be

Data Set: Oncox_EventsOnly_SubjectData.cydx

Main | **Advanced**

Trial Type: Response Variable: Frequency Variable:

Population ID: Censor Indicator: Test Statistic:

Control: Censored:

Treatment: Complete:

Choose the variables as shown in the dialog. Click **OK**. A partial output is shown

68 Enrollment/Events Prediction - Analysis

below:

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | | Average Follow-up Time |
|--------------|-----------------|--------|---------|----------|---------|------------------------|
| | | Count | % | Count | % | |
| 0 | 203 | 106 | 52.217% | 97 | 47.783% | 4.814 |
| 1 | 199 | 81 | 40.704% | 118 | 59.296% | 5.004 |
| Total | 402 | 187 | 46.517% | 215 | 53.483% | 4.908 |

Test of Hypothesis:

| Log Rank Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|----------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| -13.782 | 6.819 | -2.021 | L.E. | 0.022 | 0.043 |

Parameter Estimates from Cox Model:

| Hazard Ratio (HR) | ln(Hazard Ratio) (δ) | Std. Error of Estimate of δ | Wald Statistic | 95% Confidence Interval(2-Sided) | |
|-------------------|-------------------------------|------------------------------------|----------------|----------------------------------|-------------|
| | | | | Lower Limit | Upper Limit |
| 0.743 | -0.297 | 0.148 | -2.01 | 0.556 | 0.993 |

Estimated Hazard Rates:

| | |
|--------------------------------|---------|
| Control (λ_c) | 0.10847 |
| Treatment ($\lambda_c * HR$) | 0.08062 |

Observe that the **Hazard Ratio** is 0.743 and the **Estimated Hazard Rates** table gives the Hazard Rate for Control 0.10847 and that for treatment 0.08062. These are the same as the ones East chose while predicting the events. Please refer to the second input dialog for **Predict**. Continuing the **Predict** for the Oncox subject data, go to the **Accrual/ Dropouts** tab. In the ensuing dialog, you will see almost all values filled in. Change the **Accrual Model** to **Poisson**.

Dropout Information

of Pieces: Input Method:

Dropout Hazard Rate - Control (γ_c):

Dropout Hazard Rate - Treatment (γ_t):

Subject-level Data: ONCOX_ILook1_SubjectData.cydx
Site-level Data: ONCOX_ILook1_SiteData.cydx

The **Current Calendar Time** is accrual time of the last subject in the data which is 20.724.

The drop out hazard rates for Control and Treatment are estimated from the subject data. The **Target Sample Size** is 603 which is $1.5 * SampleSize$. You are free to change the **Target Sample Size** as we are assuming that the study is still accepting enrolments. The **Target Number of Events** default value is 402, the same as in the data. This value can be edited. You can edit the values of hazard rates, target number of events etc. You can choose a specific follow up period as well by selecting **For Fixed Period** in the **Subjects are followed** textbox. The number of hazard pieces in the Drop out information also can be increased to specify different hazard rates for different time periods. The **Number of pieces** equal to

68 Enrollment/Events Prediction - Analysis

0 will assume that there aren't going to be any drop outs. For now, let us proceed further with all the default values. Go to **Simulation Controls** tab. Give a fixed seed 12345. Check the Output Options for saving the outputs.

| | 95% | 402 | 127 | 603 | 10 | 26.678 | 30.932 |
| | Average | 402 | 127 | 603 | 6.648 | 26.009 | 30.027 |

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. The table **Actuals from Interim Trial Data: Sample Size and Events** presents the detailed information of the subject data such as events on control and treatment arms, drop outs, average follow up etc. The table **Average Sample Size and Events** provide information about the average study duration, average number of events on control and treatment, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 30 units of time to complete the study. The number of events on control arm and treatment arm would be around 219 and 183. Average follow up time for an individual is 7.102. The **Average Accrual Duration** is 26. The **Overall Output** table describes the details of the distribution of **Accrual Duration** and **Study Duration** across 1000 simulations. It is worth noting that the 5th percentile of the Average Study Duration is going to give 402 events, by the time 29.109. The 95th percentile is 30.931 which is the maximum duration the study can take. You could have changed the percentiles input, if you want to be more specific. For instance you can input 100% to get the value of maximum study duration. Let us have a look at the individual files stored in the **Library**. Open the **SummaryStat** data by double clicking the sub node. You

68 Enrollment/Events Prediction - Analysis

will see the following display of data (shown in parts).

Accruals0 and **Accruals1** specify the total subjects accrued on Control and Treatment arms respectively. Similar convention is used for naming the various quantities for Control and Treatment. As before, **Interim** refers to the available data whereas **Final** refers to the simulated data. Observe that although the **TotAccruals** for every simulation is 603, and the **TotEvents** is 402. The **TotPending** values for **Final Look** are the subjects which have neither experienced events nor have dropped out till the end of the study. This is because the study is concluded after getting 402 events and does not proceed till all the subjects experience the event. Note that the **LookTime** corresponding to the Final stage is essentially the study duration observed in that particular simulation.

TreatmentID 0 means the subject is on Control while 1 indicates Treatment. For all the subjects, the survival times and drop out times are generated. **Survival Time** is the duration for which the subject was alive in the study. **DropOutTime** is the duration of time the subject was present in the study before dropping out. For the existing data, the **Drop out times** are generated. These are generated using the specified drop out probabilities for control and treatment. For the new arrivals, accrual times, Survival time as well as drop out time are generated. Open the **SiteSummary** file which stores detailed information about one simulation.

Click on the **PredictSim** node. The **Enrollments Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of enrollments 603 are reached in a duration of 26.055 units of time.

Invoke the **(Events Prediction Plot)** using the  tool in the **Library** pane.

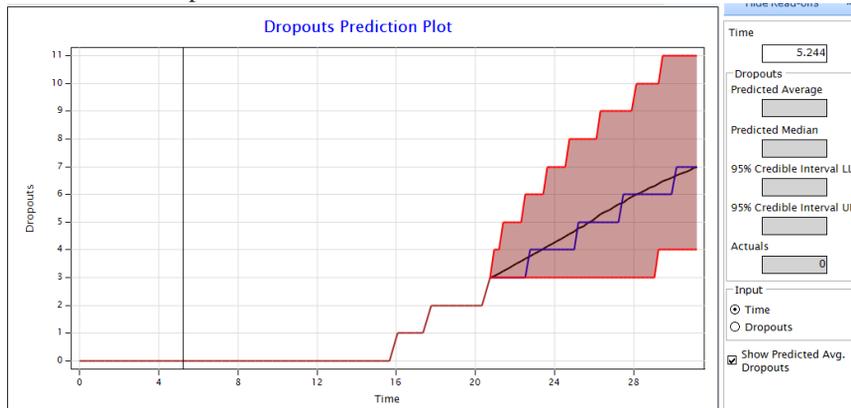

In this plot, the simulation results indicate that by the end of 30.076, the median number of events in both the control and treatment arms would be 402 in a 95% confidence interval of 382.75 to 422. Invoke the **(Dropouts Prediction Plot)** using the  tool in the **Library** pane.

In this plot, the simulation results indicate that by the end of 29.48, the median number of drop outs in both the control and treatment arms would be 6 in a 95% confidence interval of 4 to 11.

68 Enrollment/Events Prediction - Analysis

If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

Summary Data In the earlier section we saw how to generate the enrollment and follow them till the required number of events occur or the target sample size is reached. We estimated the study duration with the help of Predict feature in East. For this to use, we assumed that an interim subject-level data was available which had information on individual arrival time, status etc. However, many a times, the subject-level data may not be available. What can be available is the summary of the accruals that have happened till date. For example, in the case of Oncox trial considered above, the DMC statistician may have the information that there have been 402 subjects accrued so far, 203 on Control and 199 on Treatment. The number of events occurred so far on Control and Treatment are 106 and 81 respectively. The subjects dropped out are 1 on Control and 2 on Treatment arm. The last subject arrived at time 20.7236. The DMC statistician is interested in knowing the total study duration when all the accrued 402 subjects are followed till end. East through its Predict feature makes it possible to still come up with an estimate of average study duration based on simulating events from Poisson process based on the specified or default hazard rates. Accruals are simulated till the target sample size is reached or the target number of events are observed. To see this, choose the menu item

68 Enrollment/Events Prediction - Analysis

Click **Next**. The next input dialog appears as shown here:

Analysis: Predict: Events and Enrollment - Unblinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation | **Accrual / Dropouts** | Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Ratio:

Hazard Rate - Control (λ_c):

Hazard Rate - Treatment (λ_t):

The default values for **Hazard Rate - Control** and **Hazard Rate - Treatment** are shown in the dialog. Note that these are not estimated from any data as we don't have the individual subject data as input. Let us use the same hazard rates input as in the previous section. Hazard Rate for Control 0.10847 and that for treatment 0.08062 are these values. The default Target No of events is 402. The 188 events are already occurred. This means that the accrual will continue till we get 402 events in all. After filling all these values, the input dialog looks as shown below:

Analysis: Predict: Events and Enrollment - Unblinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation | **Accrual / Dropouts** | Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Ratio:

Hazard Rate - Control (λ_c):

Hazard Rate - Treatment (λ_t):

Go to the **Accruals/Dropouts** tab. Suppose instead of drop out hazard rates, the information is available on the probabilities of drop out. Suppose the probability of drop out for a subject receiving Control is 0.5% and Treatment is 0.6% and these are applicable from the current calendar time onwards which is 20. 724. Give all these

inputs.

Target Sample Size: Target No. of Events:

Click on **Simulate**. East simulates the events according to Poisson Arrival process with inter-arrival times following exponential distribution. The parameters are derived from the specified hazard rates for Control and Treatment. For details refer to the

68 Enrollment/Events Prediction - Analysis

Appendix M.

After a few seconds East will display the message **Simulations complete. Waiting for User's action.** Click **Close**. This will save the **Predict Simulation** in the Output Preview window first. Once you save it in the Workbook, it will create a node **PredictSim3** with sub-nodes for **SummaryStat** and **SubjectData** in the **Library**.

To view the detailed summary output of the simulations, double click the node **PredictSim3** in the Library. The following output is displayed.

Conditional Simulation: Unblinded Prediction of Enrollment and Event Timelines

Simulation Seed and Elapsed Time

Starting Seed: 12345
 Total Number of Simulations: 1000
 Elapsed Time: 00:00:13

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. The table **Actuals from Interim Trial Data: Sample Size and Events** presents the summary data input. The study is complete when in all 402 events occur. The table **Average Sample Size and Events** provide information about the average study duration, average number of events on control and treatment, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 35.31 units of time to complete the study. The number of events on control arm and treatment arm would be around 215 and 187. The **Overall Output** table describes the details of the distribution of **Average Study Duration** across 1000 simulations. Note that the column **No of Events** has all values 402 (except for actuals) meaning thereby the target sample size of 603 was adequate in giving the required number of events. The values in the column **Number of Accruals** vary since any simulated study concludes as soon as the target number of events are achieved. It is worth noting that the 5th percentile of the Average Study Duration is going to give 402 events pretty early, by the time 33.872. The 95th percentile is 36.815 by which almost in all cases the target would be achieved.

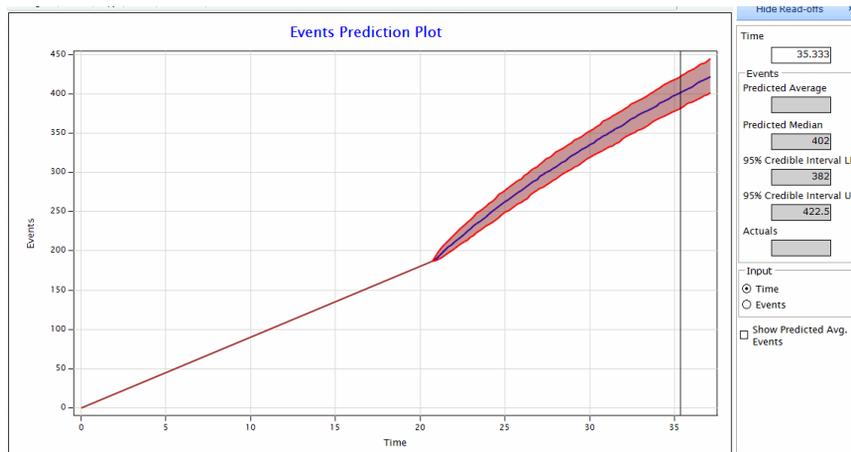

The **Enrollments Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of accruals 603 are reached in a duration of 41.469 units of time.

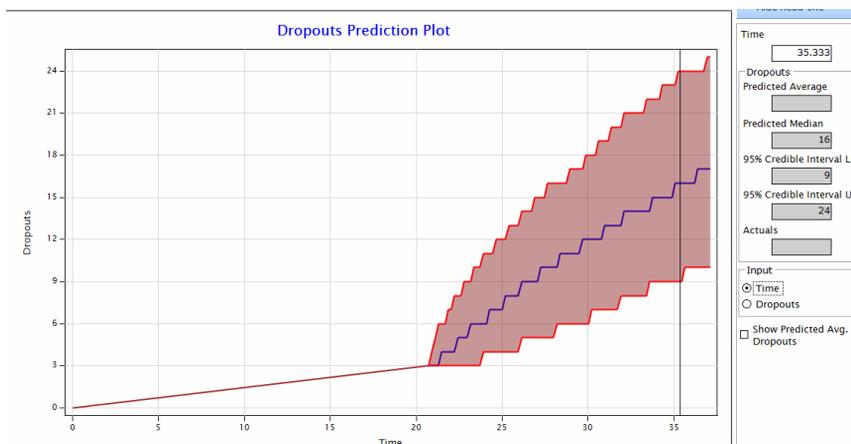

The **Events Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of events 402 are reached in a duration of 35.333 units

68 Enrollment/Events Prediction - Analysis

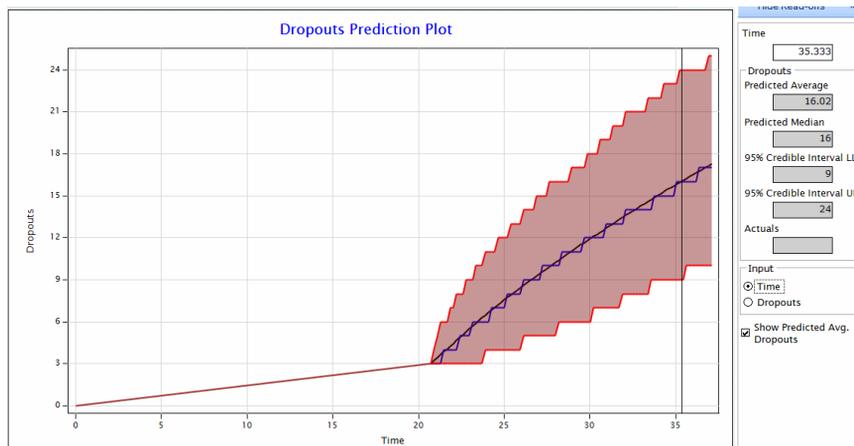

of time.

Invoke the **(Dropout Prediction Plot)** using the  tool in the **Library** pane.

In this plot, the simulation results indicate that by the end of 35.333, the median number of dropouts in both the control and treatment arms would be 16 in a 95% confidence interval of 9 to 24. If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

68.3 Events and Enrollment-Blinded Data

68.3.1 Events and Enrollment-Blinded Data: Accrual Complete

In the case of blinded data, information on the individual responses on the treatment and control arms is not available. Instead, common hazard rate and common dropout rate are available. We will explain the Predict feature for blinded data with the help of RALES Trial for Time to Event end point.

Subject-level Data The simulation of the RALES trial in Chapter 66 indicated a required sample size of 1638 subjects with an expected accrual period of around 20 months. The total duration of the study was around 72 months. Assume that an interim look has been taken and subject data are available at this time point. The trial is still accruing subjects and we are interested in forecasting Accrual Duration as well as the Study Duration. The trial has accrued in all 1205 subjects so far. The Subject data are available in the file **RALES_iLook1_SubjectData.csv** in the **Samples** folder of East installation directory. The file **RALES_iLook1_SubjectData.csv** contains a list of subjects accrued so far and the following data for each subject:

- SiteID: the site at which the subject arrived.
- ArrivalTime: the time at which the subject arrived.
- TreatmentID: a variable indicating which group the subject was randomized to ('1' for treatment, '0' for placebo).
- TimeOnStudy: the length of time the subject has been in the study, corresponding to survival time.

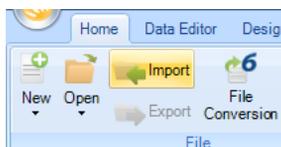

68 Enrollment/Events Prediction - Analysis

- **CensorIndicator**: a variable indicating whether the subject is a completer ('1'), a dropout ('-1') or in the pipeline ('0').
- **CensorInd**: a variable indicating whether the subject is a completer ('1') or a non-completer ('0'). A non-completer can be either a dropout or in the pipeline.

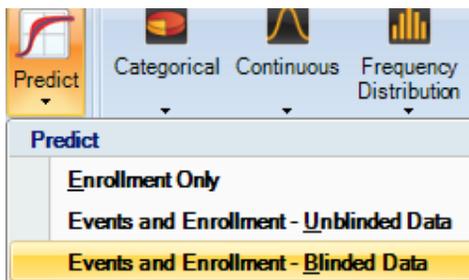

A portion of the **RALES_iLook1_SubjectData.csv** file is shown below:

| | A | B | C | D | E | F | G |
|----|-----------|--------|------------|----------|-----------------|----------|-----------|
| 1 | PatientID | SiteID | ArrivalTim | Treatmen | CensorIndicator | TimeOnSt | CensorInd |
| 2 | 1 | SITE9 | 0.033264 | 1 | 0 | 15.52795 | 0 |
| 3 | 2 | SITE9 | 0.083005 | 1 | 0 | 15.47821 | 0 |
| 4 | 3 | SITE3 | 0.123138 | 0 | 1 | 7.790942 | 1 |
| 5 | 4 | SITE1 | 0.129578 | 0 | 0 | 15.43164 | 0 |
| 6 | 5 | SITE9 | 0.187238 | 0 | 1 | 4.249194 | 1 |
| 7 | 6 | SITE1 | 0.191141 | 1 | 1 | 0.05485 | 1 |
| 8 | 7 | SITE1 | 0.218275 | 1 | 0 | 15.34294 | 0 |
| 9 | 8 | SITE9 | 0.287513 | 1 | 1 | 2.748406 | 1 |
| 10 | 9 | SITE1 | 0.295866 | 1 | 1 | 10.83515 | 1 |

The subject data file can be imported into East using the **Import** button in the Home ribbon:

Once imported, the file will appear in the **Library** pane as nodes in the active workbook, with extension **.cydx**. Choose the menu item **Analysis>Predict>Events and Enrollment-Blinded Data**.

In the ensuing dialog box, select the **Accrual** option, **Complete**. Select data set **RALES_iLook1_SubjectData.cydx**. Map the variables from the data to the

68 Enrollment/Events Prediction - Analysis

| # of Pieces: <input type="text" value="1"/> | Input Method: <input type="text" value="Hazard Rates"/> |
| Dropout Hazard Rate: <input type="text" value="0.00221"/> | |

Subject-level Data: RALES_iLook1_SubjectData.cyx

The **Current Calendar Time** is accrual time of the last subject in the data which is 15.561.

You can edit the values of hazard rate, targeted number of events etc. You can choose a specific follow up period as well by selecting **For Fixed Period** in the **Subjects are followed** textbox. The number of hazard pieces in the Drop out information also can be increased to specify different hazard rates for different time periods. The **Number of pieces** equal to 0 will assume that there aren't going to be any drop outs. For now, let us proceed further with all the default values. Go to **Simulation Controls** tab. Check the Output Options for saving the outputs.

⊖ Overall Output

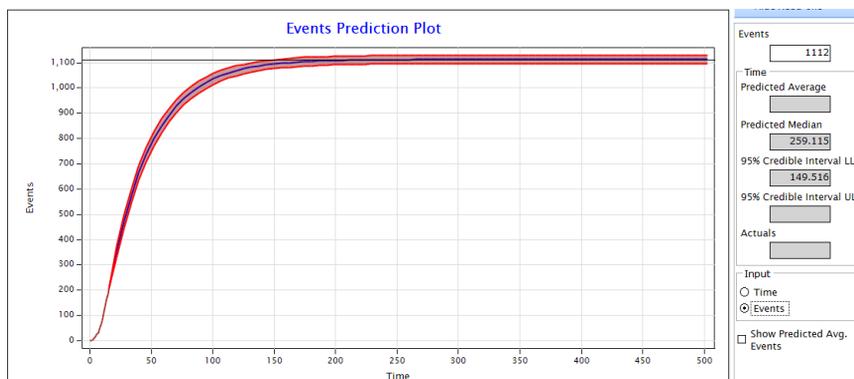

| | Stage | Percentile | No. of Events | No. of Accruals | No. of Dropouts | Study Duration |
|---|--------------|------------|---------------|-----------------|-----------------|----------------|
| | Interim | Actuals | 206 | 1205 | 17 | 15.561 |
| ⊖ | End of Trial | 5% | 1099 | 1205 | 79 | 216.232 |
| | | 25% | 1107 | 1205 | 86 | 242.356 |
| | | 50% | 1113 | 1205 | 92 | 268.125 |
| | | 75% | 1119 | 1205 | 98 | 296.104 |
| | | 95% | 1126 | 1205 | 106 | 351.112 |
| | | Average | 1113.103 | 1205 | 91.897 | 273.185 |

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. Since the accruals were complete, the **Target Sample Size** and the **Target Number of Events** are the same and equal to 1205. The table **Actuals from Interim Trial Data: Sample Size and Events** presents the detailed information of the subject data such as events, drop outs, average follow up etc. Observe that at the end of the current time, the subjects in pipeline are 982. These are followed till the end of the study. The study is complete when all the subjects in pipeline either experience events or drop out. The table **Average Sample Size and Events** provide information about the average study duration, average number of events, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 273.185 units of time to complete the study. Average follow up time for an individual is 34.443. The **Overall Output** table describes the details of the distribution of **Average Study Duration** across 1000 simulations. Note that the column **No of Accruals** has all values 1205 since the accruals were complete and only events are being forecasted. Since there are a few drop outs, we expect on an average a lesser, say around 1113 events to occur out of 1205 subjects. It is worth noting that the 5th percentile of the Average Study Duration is going to give 1099 events by the time 216.232. The 95th percentile is 351.112 which is the maximum duration the study can take. You could have changed the percentiles input, if you want to be more specific.

For instance you can input 100% to get the value of maximum study duration. Let us have a look at the individual files stored in the **Library**. The **Events Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of events 1112 are reached in a duration of 251.335 units of time.

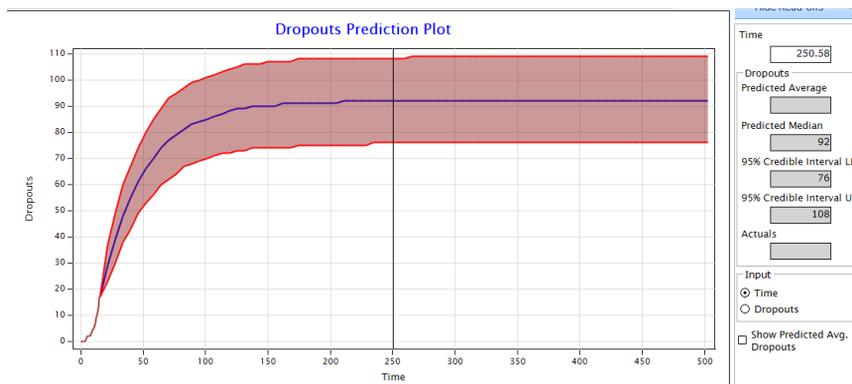

In order to find the average study duration for getting the median number of events, select the Input option **Events** in the plot. Enter 1112 for Events.

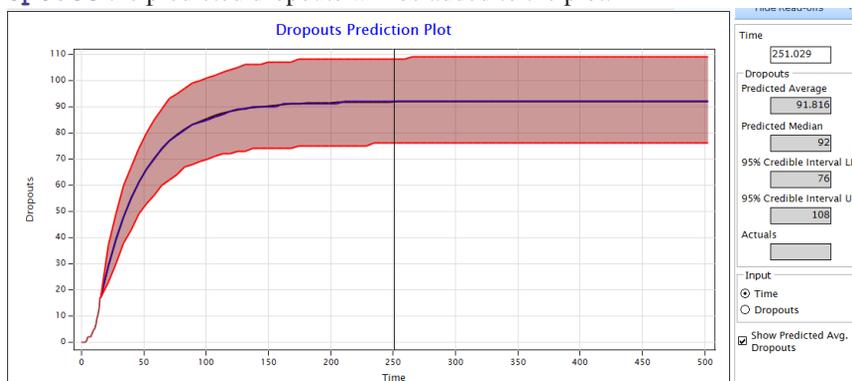

The median study duration is 259.115. Since the 95% upper limit does not exist, one can not forecast the latest time to reach the target.

68 Enrollment/Events Prediction - Analysis

Invoke the (**Dropout Prediction Plot**) using the  tool in the **Library** pane.

In this plot, the simulation results indicate that by the end of 250.58, the median number of dropouts in both the control and treatment arms would be 92 in a 95% confidence interval of 76 to 108. If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

Summary Data In the earlier section we saw how to generate the events and follow all subjects till they experience either events or drop out. We estimated the study duration with the help of Predict feature in East. For this to use, we assumed that an interim subject-level data was available which had information on individual arrival time, status etc. However, many a times, the subject-level data may not be available. Instead, the summary of the accruals that have happened till date can be available. For

68 Enrollment/Events Prediction - Analysis

Click **Next**. The next input dialog appears as shown here:

Analysis: Predict: Events and Enrollment - Blinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation | **Accrual / Dropouts** | Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Rate (λ):

The default value for **Hazard Rate** is shown in the dialog. Note that this is not estimated from any data as we don't have the individual subject data as input. Let us use the same hazard rate input as in the previous section, namely 0.02683.

Analysis: Predict: Events and Enrollment - Blinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation | **Accrual / Dropouts** | Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Rate (λ):

Go to the **Accruals/Dropouts** tab. Suppose instead of drop out hazard rates, the information is available on the probabilities of drop out. Suppose the probability of drop out for a subject receiving any of the Control or Treatment is 0.5% which is

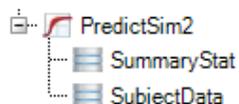

applicable from the current calendar time onwards 15.55. Give all these inputs.

Go to **Simulation Controls** tab. Give a fixed seed 12345. Save the outputs for Summary and Subject data.

Click on **Simulate**. East simulates the events according to Poisson Arrival process with inter-arrival times following exponential distribution. The parameters are derived from the specified hazard rates for Control and Treatment. For details refer to the Appendix M. After a few seconds East will display the message **Simulations complete. Waiting for User's action**. Click **Close**. This will save the **Predict Simulation** in the Output Preview window first. Once you save it in the Workbook, it will create a node **PredictSim2** with sub-nodes for

68 Enrollment/Events Prediction - Analysis

SummaryStat and SubjectData in the Library.

To view the detailed summary output of the simulations, double click the node **PredictSim2** in the Library. The following output is displayed.

Conditional Simulation: Blinded Prediction of Event Timelines

| Test Parameters | |
|--------------------------------|--------------------|
| Simulation ID | PredictSim2 |
| Accrual | Complete |
| Input | Summary Data |
| Target Sample Size | 1205 |

Actuals from Interim Trial Data: Sample Size and Events

| Sample Size | Events | Dropouts | Pipeline | Current Time |
|-------------|--------|----------|----------|--------------|
| 1205 | 206 | 17 | 982 | 15.55 |

Conditional Simulation: Average Sample Size and Events

| Average Sample Size | Average Events | Average Dropouts | Average Study Duration |
|---------------------|----------------|------------------|------------------------|
| 1205 | 1033.55 | 171.45 | 249.489 |

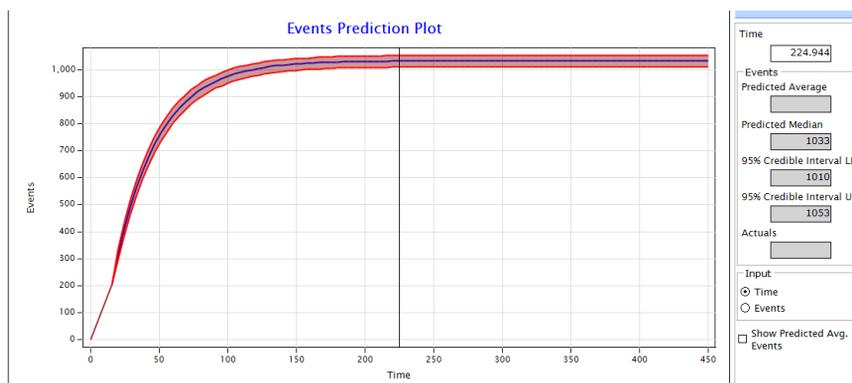

Overall Output

| Stage | Percentile | No. of Events | No. of Accruals | No. of Dropouts | Study Duration |
|--------------|------------|---------------|-----------------|-----------------|----------------|
| Interim | Actuals | 206 | 1205 | 17 | 15.55 |
| | 5% | 1014 | 1205 | 154 | 199.048 |
| End of Trial | 25% | 1026 | 1205 | 164 | 222.563 |
| | 50% | 1034 | 1205 | 171 | 244.173 |
| | 75% | 1041 | 1205 | 179 | 270.544 |
| | 95% | 1051 | 1205 | 191 | 315.872 |
| | Average | 1033.55 | 1205 | 171.45 | 249.489 |

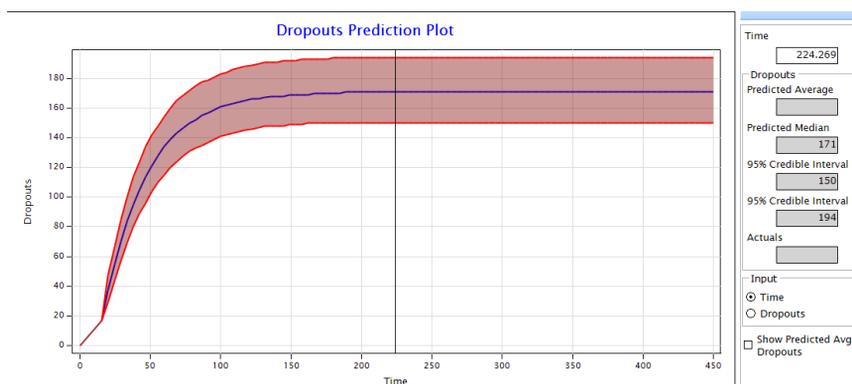

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. Since the accruals were complete, the **Target Sample Size** and the **Target Number of Events** are 1205. The table **Actuals from Interim Trial Data: Sample Size and Events** presents the detailed information of the subject data such as number of events, drop outs, average follow up etc. Observe that at the end of the current time, the subjects in pipeline are 982. These are followed till the end of the study. The study is complete when in all 1205 events occur. The table **Average Sample Size and Events** provide information about the average study duration, average number of events, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 249.489 units of time to complete the study. The **Overall Output** table describes the details of the distribution of **Average Study Duration** across 1000 simulations. Note that the column **No of Accruals** has all values 1205 since the accruals were complete and only events are

being forecasted. Although the targeted number of events was 1205, the **No of Events** column shows different values less than 1205 as the accruals were complete and only these subjects were followed till they produce events or drop out. It is worth noting that the 5th percentile of the Average Study Duration is going to give 1014 events, by the time 199.048 and the 95th percentile is 315.872 by which again only 1051 events have been occurred. The investigator has to decide whether to wait for a longer time for getting a few more events.

The **Events Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of events 1033 are reached in a duration of 224.944 units of time.

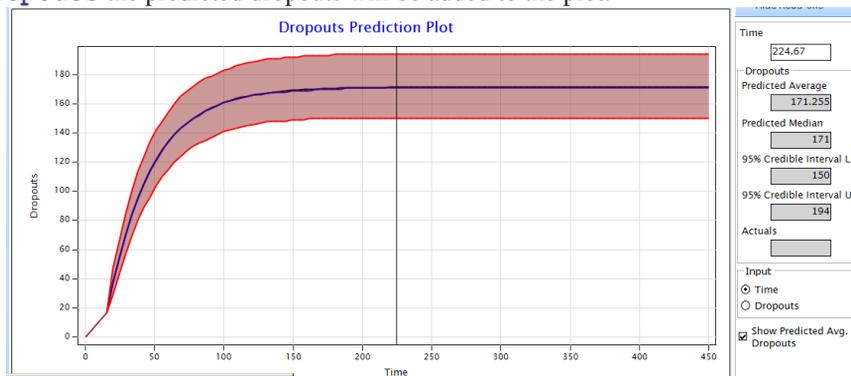

Invoke the **(Dropout Prediction Plot)** using the  tool in the **Library** pane.

68 Enrollment/Events Prediction - Analysis

In this plot, the simulation results indicate that by the end of 224.269, the median number of dropouts in both the control and treatment arms would be 171 in a 95% confidence interval of 150 to 194. If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

68.3.2 Events and Enrollment-Blinded Data: Accrual Ongoing

Subject-level Data The simulation of the RALES trial in Chapter 66 indicated a required sample size of 1638 subjects with an expected accrual period of around 20 months. The total duration of the study was around 72 months. Assume that an interim look has been taken and subject data are available at this time point. The trial is still accruing subjects and we are interested in forecasting Accrual Duration as well as Study Duration. The trial has accrued in all 1205 subjects so far. The Subject data are available in the file **RALES_iLook1_SubjectData.csv** in the Samples folder of East installation directory. The file RALES_iLook1_SubjectData.csv contains a list of subjects accrued so far and the following data for each subject:

- SiteID: the site at which the subject arrived.
- ArrivalTime: the time at which the subject arrived.
- TreatmentID: a variable indicating which group the subject was randomized to ('1' for treatment, '0' for placebo).
- TimeOnStudy: the length of time the subject has been in the study, corresponding to survival time.
- CensorIndicator: a variable indicating whether the subject is a completer ('1'), a dropout ('-1') or in the pipeline ('0').
- CensorInd: a variable indicating whether the subject is a completer ('1') or a non-completer ('0'). A non-completer can be either a dropout or in the pipeline.

A portion of the RALES_iLook1_SubjectData file is shown below:

| | A | B | C | D | E | F | G |
|----|-----------|--------|------------|----------|-----------------|----------|-----------|
| 1 | PatientID | SiteID | ArrivalTim | Treatmen | CensorIndicator | TimeOnSt | CensorInd |
| 2 | 1 | SITE9 | 0.033264 | 1 | 0 | 15.52795 | 0 |
| 3 | 2 | SITE9 | 0.083005 | 1 | 0 | 15.47821 | 0 |
| 4 | 3 | SITE3 | 0.123138 | 0 | 1 | 7.790942 | 1 |
| 5 | 4 | SITE1 | 0.129578 | 0 | 0 | 15.43164 | 0 |
| 6 | 5 | SITE9 | 0.187238 | 0 | 1 | 4.249194 | 1 |
| 7 | 6 | SITE1 | 0.191141 | 1 | 1 | 0.05485 | 1 |
| 8 | 7 | SITE1 | 0.218275 | 1 | 0 | 15.34294 | 0 |
| 9 | 8 | SITE9 | 0.287513 | 1 | 1 | 2.748406 | 1 |
| 10 | 9 | SITE1 | 0.295866 | 1 | 1 | 10.83515 | 1 |

The trial is assumed to enroll subjects from several sites, the information about which is provided in the file **RALES_iLook1_SiteData .csv** also available in **Samples** folder. The file contains the following data for each site:

- SiteID: the identification number of the site.
- SiteReadyTime: the time at which the site was initiated.
- SiteAccrRate: the site accrual rate specified in the enrollment plan.
- SubjectsAccrued: the number of subjects accrued at the site.
- LastSubjectRand: the randomization time of the last subject arriving at the site.
- ObsrvdAccrualRate: the observed accrual rate at the site.
- PosteriorAccrualRate: the updated site accrual rate.
- SIP_Start: the start of the initiation period of the site.
- SIP_End: the end of the initiation period of the site.
- Ecap: the enrollment cap, representing the maximum number of subjects that can be enrolled at the site.

Site-level Data

Select Workbook:

Select Dataset:

Choose Variables from Dataset

Site ID: **Site Initiation: Unopened Sites**

Accrual Rate/Site: Start Time:

Enrollment Cap: End Time:

Site Initiation: Opened Sites

Site Initiation Time:

Click **Next**. The next input dialog appears as shown here:

Analysis: Predict: Events and Enrollment - Blinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation **Accrual / Dropouts** Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Rate (λ):

Subject-level Data: RALES_iLook1_SubjectData.cydx
 Site-level Data: RALES_iLook1_SiteData.cydx

The default value for **Hazard Rate** is estimated from the subject data. Note that this is estimation of common hazard rate ignoring whether the event is occurring on the treatment arm or control arm. Go to the **Accrual/ Dropouts** tab. In the ensuing dialog, you will see almost all values filled in. Change the **Accrual Model** to **Poisson**.

Dropout Information

of Pieces: Input Method:

Dropout Hazard Rate:

Subject-level Data: RALES_iLook1_SubjectData.cydx

Site-level Data: RALES_iLook1_SiteData.cydx

The **Current Calendar Time** is accrual time of the last subject in the data which is 15.561. Again, the drop out hazard rate is estimated from the subject data assuming that the data are blinded on treatments. The **Target Sample Size** is 1807 which is $1.5 * SampleSize$. You are free to change the **Target Sample Size** as we are assuming that the study is still accepting enrollment. The **Target Number of Events** default value is 1205, the same as in the data. This value can be edited. You can edit the values of hazard rate, target number of events etc. You can choose a specific follow up period as well by selecting **For Fixed Period** in the **Subjects are followed** textbox. The number of hazard pieces in the Drop out information also can be increased to specify different hazard rates for different time periods. The **Number of pieces** equal to 0 will assume that there aren't going to be any drop outs. For now, let us proceed further with all the default values. Go to **Simulation Controls** tab. Give a fixed seed 12345. Check the Output Options

for saving the outputs.

Analysis: Predict: Events and Enrollment - Blinded Data (Step 2 of 2)

| 50.000 |
| 75.000 |

Subject-level Data: RALES_iLook1_SubjectData.cydx
 Site-level Data: RALES_iLook1_SiteData.cydx

Click **Simulate**. East simulates the arrival of subjects according to Poisson Arrival process with inter-arrival times following exponential distribution. After a few seconds East will display the message **Simulations complete. Waiting for User's action**. Click **Close**. This will save the **Predict Simulation** in the Output Preview window first. Once you save it in the Workbook, it will create a node **PredictSim1** with sub-nodes for **SummaryStat**, **SubjectData**, **SiteSummary** and **SitePara** in the **Library**.

To view the detailed summary output of the simulations, double click the node

68 Enrollment/Events Prediction - Analysis

PredictSim1 in the Library. The following output is displayed.

| Average Sample Size | Average Events | Average Dropouts | Average Follow up | Average Accrual Duration | Average Study Duration |
|---------------------|----------------|------------------|-------------------|--------------------------|------------------------|
| 1807 | 1205 | 99.064 | 24.855 | 23.058 | 56.573 |

Overall Output

| Stage | Percentile | No. of Events | No. of Sites Opened | No. of Accruals | No. of Dropouts | Accrual Duration | Study Duration |
|--------------|------------|---------------|---------------------|-----------------|-----------------|------------------|----------------|
| Interim | Actuals | 206 | 0 | 1205 | 17 | 15.549 | 15.561 |
| | 5% | 1205 | 20 | 1807 | 84 | 22.542 | 54.29 |
| End of Trial | 25% | 1205 | 20 | 1807 | 93 | 22.86 | 55.647 |
| | 50% | 1205 | 20 | 1807 | 99 | 23.059 | 56.503 |
| | 75% | 1205 | 20 | 1807 | 105 | 23.245 | 57.453 |
| | 95% | 1205 | 20 | 1807 | 115 | 23.556 | 58.866 |
| | Average | 1205 | 20 | 1807 | 99.064 | 23.058 | 56.573 |

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. The table **Actuals from Interim Trial Data: Sample Size and Events** presents the detailed information of the subject data such as events, drop outs, average follow up etc. The table **Average Sample Size and Events** provide information about the average study duration, average number of events considering both the arms together, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 56.573 units of time to complete the study getting all the 1205 events. Average follow up time for an individual is 24.855. The **Average Accrual Duration** is 23.058. The **Overall Output** table describes the details of the distribution of **Accrual Duration** and **Study Duration** across 1000 simulations. It is worth noting that the 5th percentile of the Average Study Duration is going to give 1205 events pretty early, by the time 54.29. The 95th percentile is 58.866 which is the maximum duration the study can take. You could have changed the percentiles input, if you want to be more specific. For instance, you can input 100% to get the value of maximum study duration. Open the **SummaryStat** data by double clicking the sub node. You will see the following display of data (shown in parts).

68 Enrollment/Events Prediction - Analysis

Note that the file contains overall information and not on individual treatment since the data are blinded. Observe that the **TotAccruals** for every simulation is 1807, and the **TotEvents** is 1205. The

tt TotPending values for **Final Look** are the subjects which have neither experienced events nor have dropped out till the end of the study. This is because the study is concluded after getting 1205 events and does not proceed till all the subjects experience the event as was the case in the previous section. It is worth noting that the **LookTime** corresponding to the Final stage is essentially the study duration observed in that particular simulation.

Open the **Subject Data** file which stores detailed information about one simulation.

For all the subjects, the survival times and drop out times are generated. **Survival Time** is the duration for which the subject was alive in the study. **DropoutTime** is the duration of time the subject was present in the study before dropping out. For the existing interim data, the **Drop out times** are generated. These are generated using the specified drop out probability. For the new arrivals, accrual times, survival times as well as drop out times are generated. Open the **SiteSummary** file which stores detailed information about one simulation.

Click on the **PredictSim** node. The **Enrollments Prediction Plot** (invoked using the  tool in the **Library** pane) shows that the median number of enrollments 1807 are reached in a duration of 23.209 units of time.

Invoke the **(Events Prediction Plot)** using the  tool in the **Library** pane.

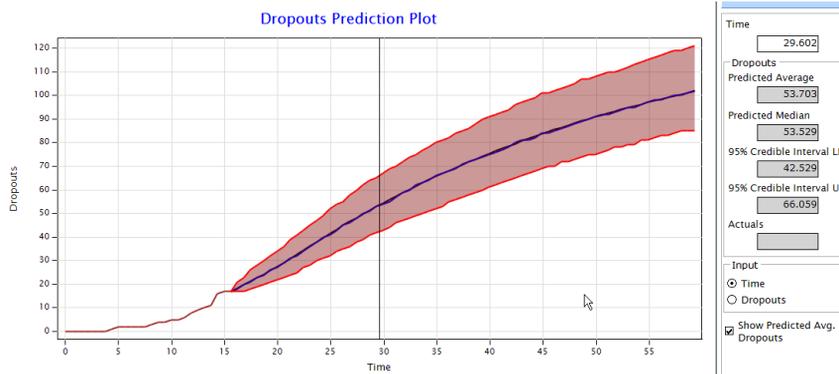

In this plot, the simulation results indicate that by the end of 56.556, the median number of events in both the control and treatment arms would be 1205 in a 95% confidence interval of 1169 to 1242. Invoke the **(Dropouts Prediction Plot)** using the  tool in the **Library** pane.

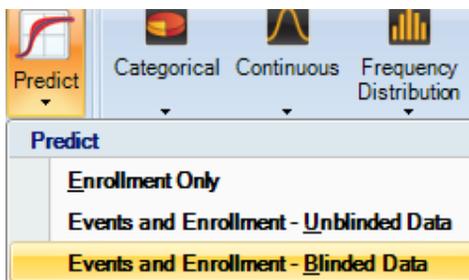

In this plot, the simulation results indicate that by the end of 29.549, the median number of drop outs in both the control and treatment arms would be 53 in a 95% confidence interval of 42 to 65.

If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

68 Enrollment/Events Prediction - Analysis

Summary Data In the earlier section we saw how to generate the events and follow them till the required number of events occur or the target sample size is reached. We estimated the study duration with the help of Predict feature in East. For this to use, we assumed that an interim subject-level data was available which had information on individual arrival time, status etc. However, many a times, the subject-level data may not be available. What can be available is the summary of the accruals that have happened till date. For example, in the case of Rales trial considered above, the DMC statistician may have the information that there have been 1205 subjects accrued so far. The number of events occurred so far 206 considering both Control and Treatment. In all 17 subjects have dropped out. The last subject arrived at time 15.55. The DMC statistician is interested in knowing the total study duration when all the accrued 1205 subjects are followed till end. East through its Predict feature makes it possible to still come up with an estimate of average study duration based on simulating events from Poisson process based on the specified or default hazard rate. To see this, choose the menu item **Analysis>Predict>Events and Enrollment-Blinded Data**.

68 Enrollment/Events Prediction - Analysis

values, the input dialog looks as shown below:

Analysis: Predict: Events and Enrollment - Blinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation | **Accrual / Dropouts** | Simulation Controls

Survival Information

of Hazard Pieces: Input Method:

Hazard Rate (λ):

Go to the **Accruals/Dropout** tab. Suppose instead of drop out hazard rates, the information is available on the probability of drop out. Suppose the probability of drop out for a subject is 0.5% and is applicable from the current calendar time onwards which is 15.55. Give all these inputs.

Analysis: Predict: Events and Enrollment - Blinded Data (Step 2 of 2)

Target Sample Size: Target No. of Events:

Response Generation | **Accrual / Dropouts** | Simulation Controls

Current Sample Size: 1205 Subjects are followed:

Current Number Censored: 982 Current Calendar Time: 15.55

Current No. of Events: 206

Current No. of Dropouts: 17 Accrual Model: Poisson

Accrual Information

of Accrual Periods: Input Method:

| 50.000 |
| 75.000 |
| 95.000 |

Click on **Simulate**. East simulates the events according to Poisson Arrival process with inter-arrival times following exponential distribution. The parameter is derived from the specified hazard rate. For details refer to the Appendix M. After a few seconds East will display the message **Simulations complete. Waiting for User's action**. Click **Close**. This will save the **Predict Simulation** in the Output Preview window first. Once you save it in the Workbook, it will create a node **PredictSim4** with sub-nodes for **SummaryStat** and **SubjectData** in the **Library**.

To view the detailed summary output of the simulations, double click the node

68 Enrollment/Events Prediction - Analysis

PredictSim4 in the Library. The following output is displayed.

Conditional Simulation: Blinded Prediction of Enrollment and Event Timelines

Simulation Seed and Elapsed Time

Starting Seed: 12345
 Total Number of Simulations: 1000
 Elapsed Time: 00:00:33

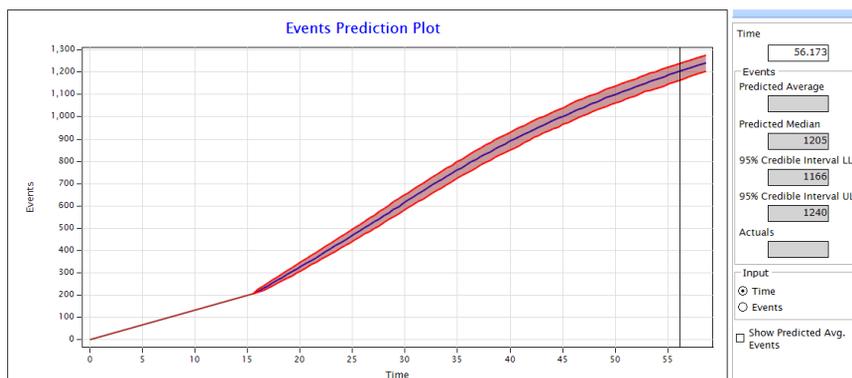

The table at the left describes the Simulation scenario. This summary contains an overview of the actual data we observed. The table **Actuals from Interim Trial Data: Sample Size and Events** presents the summary data input. The study is complete when in all 1205 events occur. The table **Average Sample Size and Events** provide information about the average study duration, average number of events, average drop outs, average follow up time etc. From this table it should be noted that it will take on an average 56.187 units of time to complete the study. The **Overall Output** table describes the details of the distribution of

Average Study Duration across 1000 simulations. Note that the column **No of Events** has all values 1205(except for actuals) meaning thereby the target sample size of 1807 was adequate in giving the required number of events. It is worth noting that the 5th percentile of the Average Study Duration is going to give 1205 events pretty early, by the time 54.231. The 95th percentile is 58.321 by which almost in all cases the target would be achieved. Click on the **PredictSim4** node. The

Enrollments Prediction Plot (invoked using the  tool in the **Library** pane) shows that the median number of enrollments 1807 are reached in a duration of 31.104 units of time.

Invoke the **(Events Prediction Plot)** using the  tool in the **Library** pane.

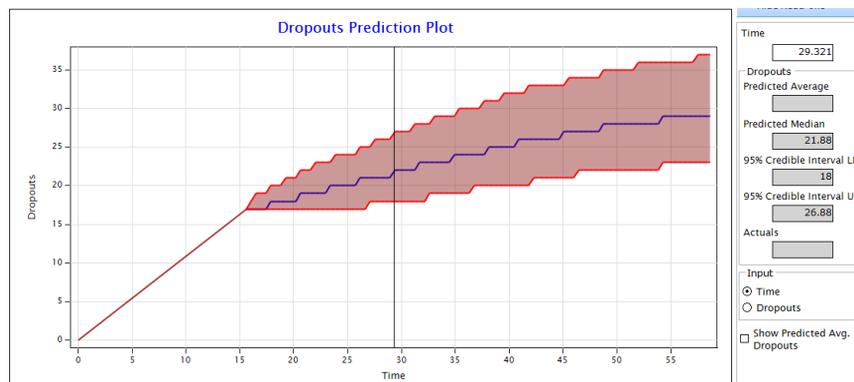

In this plot, the simulation results indicate that by the end of 56.173, the median

68 Enrollment/Events Prediction - Analysis

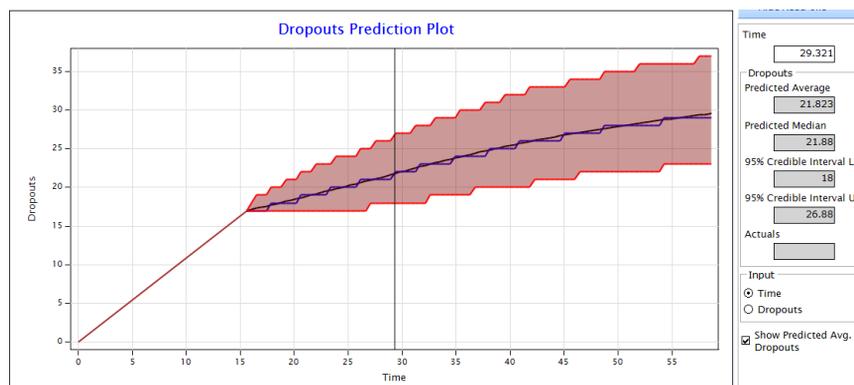

number of events in both the control and treatment arms would be 1205 in a 95% confidence interval of 1166 to 1240. Invoke the (**Dropouts Prediction Plot**) using the

 tool in the **Library** pane.

In this plot, the simulation results indicate that by the end of 29.321, the median number of drop outs in both the control and treatment arms would be 22 in a 95% confidence interval of 18 to 27.

If you select the **Show Predicted Avg. Dropouts** the predicted dropouts will be added to the plot.

69 *Interfacing with East PROCs*

69.1 *What is East PROCs*

East PROCs is a special version of **East 6.3** developed specially for *SAS*^(R) users. **East PROCs** contains an external SAS procedure for Interim Monitoring of a design created in **East 6.3**. While it has all the capabilities of **East** Interim Monitoring, it requires *SAS*^(R) system on your machine.

Proc EASTMONITOR from **East PROCs**, through its various options can perform monitoring of the following group sequential designs in **East**.

1. Continuous Endpoints
 - One Sample: Single mean
 - One Sample: Mean of paired differences
 - Two Samples: Difference of means from independent populations
2. Discrete Endpoints
 - One Sample: Single binomial proportion
 - One Sample: McNemar's for matched pairs of binomial responses
 - Two Samples: Difference of binomial proportions from independent populations
 - Two Samples: Ratio of binomial proportions from independent populations
 - Two Samples: Odds ratio of proportions from independent populations
 - Two Samples: Common odds ratio for stratified 2x2 tables
3. Survival Endpoints
 - Two Samples: Logrank test given accrual duration and accrual rates
 - Two Samples: Logrank test given accrual duration and study duration
4. General
 - Information based
 - Sample Size based

The trials can be Superiority or Noninferiority with either or both efficacy and futility boundaries. For details of combinations of efficacy and futility boundaries, boundary families etc allowed per test, the user is referred to **East 6** user manual.

Apart from Interim Monitoring of the above mentioned group sequential designs, **Proc EastMonitor** can also monitor Adaptive Trials created in **East 6** based on the following tests:

- Continuous: Difference of means from two independent populations

69 Interfacing with East PROCs

- Binary: Difference of proportions from two independent populations
- Binary: Ratio of proportions from two independent populations
- Survival: Logrank test given accrual duration and accrual rates
- Survival: Logrank test given accrual duration and study duration

The syntax for each of the above mentioned interim monitoring is described in the **East PROCs** user manual.

69.2 Why Proc EastMonitor

Clinical trial data are generally analyzed using SAS. **Proc EastMonitor** has been developed to enable the interim analysis of clinical trial data using SAS considering that the **East** has been used for designing the study. In other words, you don't need **East** to be available for interim monitoring. What you need is a design created in **East**. This design and interim look data are inputs to **Proc EastMonitor**. **Proc EastMonitor** then performs the interim analysis exactly the same way as East Interim Monitoring module would have done it. This is possible because **Proc EastMonitor** calls the East interim monitoring programs internally. The resulting output is available in SAS data sets as well as in the list files which include the decisions of the interim analysis regarding the continuation of the trial or otherwise. The generated output data sets can be subjected to SAS' graphical and reporting tools for creating reports as per requirement.

East being the pioneering software in designing of phase 3 clinical trials, encompasses numerous combinations of efficacy and futility boundaries and other features such as accrual, drop out etc. The boundaries that are available in **East** run the gamut between extreme conservatism and extreme liberality for early stopping. It can also handle the designs with missing efficacy or futility boundaries at some looks. All these designs can be monitored using **Proc EastMonitor**. Besides the non-adaptive designs, **East** can formulate adaptive designs following Cui, Hung and Wang (1999). This adaptive design allows modification of sample size and effect size at an interim look. In effect, the adaptive designs are also amenable for interim monitoring in SAS through Proc EastMonitor.

As a result, with **Proc EastMonitor** as an add on to SAS, the whole interim monitoring capability of **East** becomes available in SAS and will continue to be so for further new designs in **East**.

69.3 Continuous Endpoint: Orlistat Trial

Consider the Orlistat trial described in Section 10.1.1 where we would like to test the null hypothesis that treatment does not lead to weight loss, $H_0: \delta = 0$, against the alternative hypothesis that the treatment does result in a loss of weight, $H_1: \delta = 3$. Suppose we have designed this trial in East 6 and following is the detailed output of this design.

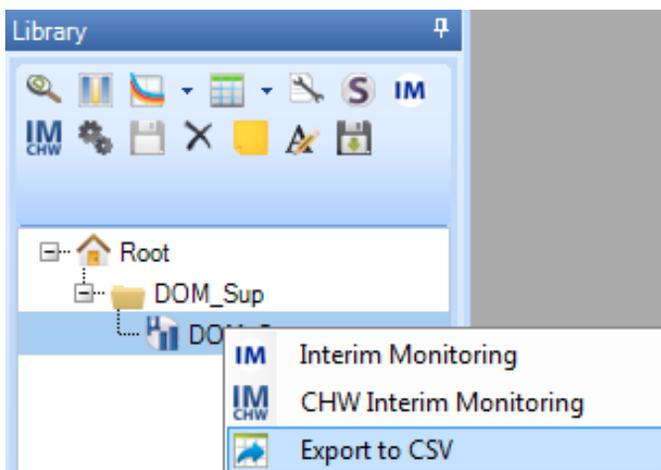

Design: Continuous Endpoint: Two-Sample Test - Parallel Design - Difference of Means

| Test Parameters | | | |
|--------------------------------|------------------|-------------|--|
| Design ID | DOM_Sup | Superiority | |
| Design Type | Superiority | | |
| Number of Looks | 3 | | |
| Test Type | 1-Sided | | |
| Specified α | 0.05 | | |

| Model Parameters | | | |
| Test Statistic | Z | | |
| Input Method | Individual Means | | |
| Mean Control (μ_c) | 6 | | |
| Mean Treatment (μ_t) | 9 | | |
| $\delta = \mu_t - \mu_c$ | | | |
| Under H_0 | 0 | | |
| Under H_1 | 3 | | |
| Std. Deviation (σ) | 8 | | |
| Allocation Ratio (n_t/n_c) | 3 | | |
| Boundary Parameters | | | |
| Spacing of Looks | Equal | | |
| Efficacy Boundary | LD (OF) | | |

| Sample Size Information | | | |
|------------------------------|-------------|---------------|---------|
| | Control Arm | Treatment Arm | Total |
| Sample Size (n) | | | |
| Maximum | 83 | 248 | 331 |
| Expected H_1 | 64.143 | 192.448 | 256.591 |
| Expected H_0 | 82.521 | 246.594 | 329.115 |
| Maximum Information (I) 0.97 | | | |

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries Efficacy Z | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|-----------------------|---|-------------|
| | | | | | Under H_0 | Under H_1 |
| 1 | 0.332 | 110 | 6.741E-4 | 3.205 | 6.741E-4 | 0.066 |
| 2 | 0.668 | 221 | 0.016 | 2.139 | 0.016 | 0.543 |
| 3 | 1 | 331 | 0.05 | 1.695 | 0.034 | 0.291 |

Let us monitor this trial using PROC EASTMONITOR. Save the design details into the CSV format. Right click on the design node in the Library and select Export to CSV.

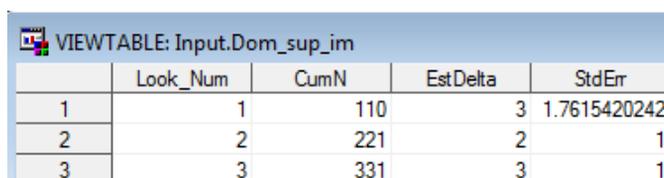

This CSV file will serve as an input to the PROC EASTMONITOR.

69 Interfacing with East PROCs

Launch East PROCs and import the above CSV file in SAS. The code in SAS to import the file may look like as shown below:

```
PROC IMPORT OUT= INPUT.orlistat_des
            DATAFILE= "D:\Work\EAST6.3\ProcIM\Orlistat\Orlistat.csv"
            DBMS=CSV REPLACE;
            GETNAMES=YES;
            DATAROW=2;
RUN;
```

Now suppose you have the data to be used for interim monitoring in a SAS file.

| | Look_Num | CumN | EstDelta | StdErr |
|---|----------|------|----------|--------------|
| 1 | 1 | 110 | 3 | 1.7615420242 |
| 2 | 2 | 221 | 2 | 1 |
| 3 | 3 | 331 | 3 | 1 |

The following code reads the design information from the dataset **orlistat_des**; IM data from the dataset **Orlistat_im**; monitors the trial; computes the look-by-look output quantities and saves the output in the form of a SAS datasets.

```
libname input "D:\Work\EAST6.3\ProcIM\Orlistat";run;
libname out "D:\Work\EAST6.3\ProcIM\Orlistat\out";run;

options nodate nonumber;
PROC EASTMONITOR DESIGN=input.Orlistat_Des DATA=input.Orlistat_im;
CONDPower OUT=out.cp_Orlistat ;
PHP OUT=out.php_Orlistat ;
ERRSPEND OUT=out.errspd_Orlistat ;
CI OUT=out.ci_Orlistat;
BOUNDARY OUT=out.bdd_Orlistat ;
OUTPUT OUT=out.IM_INFO_Orlistat ;
run;
```

The output from PROC EASTMONITOR can be seen in the Output window of SAS. It is divided into two parts - Design Output and IM Output. The Design Output part contains all the information exported from East 6. The IM output is actually the output we are interested in.

Final Inference

```
Final Outputs at Look          : 3
Adj. p-value                   : 0.0167
Adj. Pt. Est. for Effect Size  : 2.5047

Adj. 90.00% CI for Effect Size

Upper confidence bound         : 4.3144
Lower confidence bound         : 0.5825
Post-Hoc Power                 : 0.9001
```

Notice that the **PROC EASTMONITOR** prints the decision which was taken at the end of the trial. In the end, it prints the final inference as well.

One can also see this output back in the East6. To do that, export the output from SAS to a CSV file. The code to export the output dataset may look like as shown below:

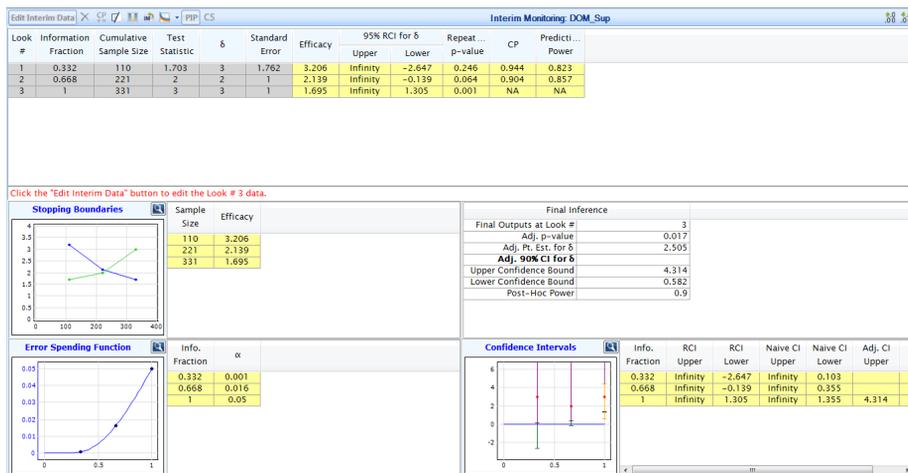

```
PROC EXPORT DATA= OUT.Im_info_orlistat
             OUTFILE= "D:\Work\EAST6.3\ProcIM\Orlistat\out\imout_orlistat.csv"
             DBMS=CSV REPLACE;
             PUTNAMES=YES;
RUN;
```

Activate East 6 and go back to the design node in **Library**. Insert a new IM dashboard by clicking the **IM** icon. Right click on the Interim Monitoring node and select **Import PROC EM Output**. Import the CSV file **imout_orlistat.csv**.

The Interim Monitoring dashboard gets updated with the output from **PROC**

70 *Introduction to Volume 9*

This volume describes the procedures for analyzing data for continuous, binary, discrete and survival endpoints. Analysis of data arising from clinical trials with one arm, two arm as well as multiple arms is possible with the help of the **Analysis** module of **East**. The procedures include **Basic Statistics** and **Plots** used for exploratory analysis of data and at higher level, Logistic and Probit regression as well as tests for handling analysis of crossover data. Exact Inference tests for two by two categorical data and multiple comparison tests for continuous and discrete data also belong to the Analysis menu. For a few tests, a link to SAS[®] is provided which enable user to perform analysis in SAS and display the output in **East**.

Chapter 4 introduces the data editor features such as creating a new data, manipulating existing data, sorting, filtering, transforming variables, generating random numbers from distributions etc. **East** caters to Case Data and Crossover Data.

Chapter 71 explains the workflow in Analysis used for analyzing any data. This chapter describes how you can use the data editor capabilities effectively and perform the statistical test you want.

Chapter 72 deals with preliminary exploration of data using elementary tools such as computation of summary measures, classification, cross tabulation of the data. Descriptive Statistics helps statisticians to choose statistical analysis techniques to arrive at meaningful inference.

Chapter 73 describes some of the commonly used univariate procedures: t-test (paired and independent), one-way and two-way (without interaction) analysis of variance (*ANOVA*) and multiple linear regression. The topics of correlations and Multivariate Analysis of Variance (*MANOVA*) are also included in this chapter.

Chapter 74 deals with data exploration plots for case data and crossover data.

Chapter 75 demonstrates how **East** can be used to perform inferences on data collected from a single-sample superiority study with continuous endpoint. This may consist of a random sample of observations from either a single treatment or paired observations from two treatments.

Chapter 76 explores how we can use **East** to perform inference on continuous data collected from a paired-sample noninferiority study.

Chapter 77 demonstrates how inference on continuous data collected from a paired-sample equivalence study can be performed.

Chapter 78 deals with analysis of continuous data coming from two independent samples and crossover superiority studies.

Chapter 79 deals with analysis of continuous data coming from two independent samples and crossover noninferiority studies.

Chapter 80 explains how we can use **East** to perform analysis of continuous data that comes from two independent samples and crossover equivalence studies.

Chapter 81 describes analysis using Wilcoxon-Mann-Whitney nonparametric test for parallel as well as crossover designs. Analysis of data from both superiority and noninferiority studies is possible.

Chapter 82 focuses on Analysis of Variance (*ANOVA*). The technique is useful in clinical trial data analysis whenever there are multiple responses or multiple doses of an experimental drug being compared with placebo. The chapter deals with **One way**, **Two way** and **One way repeated measures ANOVA** with SAS connection.

Chapter 83 demonstrates how to run regression analysis in **East**. East can perform multiple linear regression, repeated measure regression and fit linear mixed effect (LME) model on data obtained from 2×2 crossover design. Link to SAS is also available for the repeated measures regression and linear mixed effects model.

Chapter 84 deals with multiple comparison procedures in which multiple treatments are compared against a placebo or active control. The response is of continuous type. The procedures included are parametric and p-value based. For multiple comparison procedures in **East** we can either provide the dataset containing the observations under each arm or the raw p-values to obtain the adjusted p-values.

Chapter 86 demonstrates how to perform inferences on data collected from a single-sample superiority study when the observations on a binary variable have an unknown probability of success. You need to either test a null hypothesis about the probability, or compute an exact confidence interval for the probability of success. The section also discusses the analysis of paired data on a binary random variable. The chapter also discusses Exact test for paired samples.

Chapter 87 explores how to analyze data from two independent binomial samples

70 *Introduction to Volume 9*

generated while conducting a superiority trial. This comparison is based on difference of response probabilities, ratio of proportions or odds ratio of the two populations. Exact inference in case of difference of proportions and ratio of proportions is described.

Chapter 88 deals with noninferiority trials involving data from two independent binomial samples. This comparison is based on difference of proportions, ratio of proportions or odds ratio of the two populations. For difference of proportions and ratio of proportions exact inference is supported which is described in this chapter.

Chapter 89 explains how we can use **East** to perform analysis of data that comes from two independent binomial samples equivalence studies. Both asymptotic and Exact options are described.

Chapter 90 deals with situations for discrete data, where the data are either coming from many binomial populations or the responses are from multinomial distribution. In case of multiple binomial populations, the interest lies in testing whether the success probability differs across several binomial populations, in particular does it increase or decrease with reference to an index variable. For data coming from multinomial distributions, one is interested in testing if the cell probabilities are according to some theoretical law. **East** can be used to analyze both these types of data. Chi-square tests, Wilcoxon rank sum test for ordered categorical data, trend in R ordered populations are some of the tests described in this chapter.

Chapter 91 focuses on how to run binary regression analysis. **East** provides logistic, probit, and complementary log-log regression models for data with a binary response variable. Along with regular maximum likelihood inference for logistic model, **East** provides Firth bias-correction for asymptotic estimates for unstratified logistic regression. Profile likelihood based confidence intervals for estimates are available for unstratified data.

Chapter 92 explains how to analyze data arising out of multiple comparison studies where more than one treatment are compared against a placebo or active control. The procedures included are parametric and p-value based. For multiple comparison procedures in **East** we can either provide the dataset containing the observations under each arm or the raw p-values to obtain the adjusted p-values.

Chapter 93 deals with comparison of different multiple testing procedures for continuous end point through an illustrative example.

Chapter 95 discusses Cohen's Kappa and the Weighted Kappa measures. These two measures are used to assess the level of agreement between two observers classifying a sample of objects on the same categorical scale.

Chapter 96 deals with comparison of two survival curves using Logrank Test in superiority and noninferiority studies. The chapter also demonstrates how one can obtain a plot of multi-arm Kaplan Meier Estimator in **East**.

Chapter 97 explains how to analyze data arising out of multiple comparison studies with survival endpoint where more than one treatment are compared against a placebo or active control.

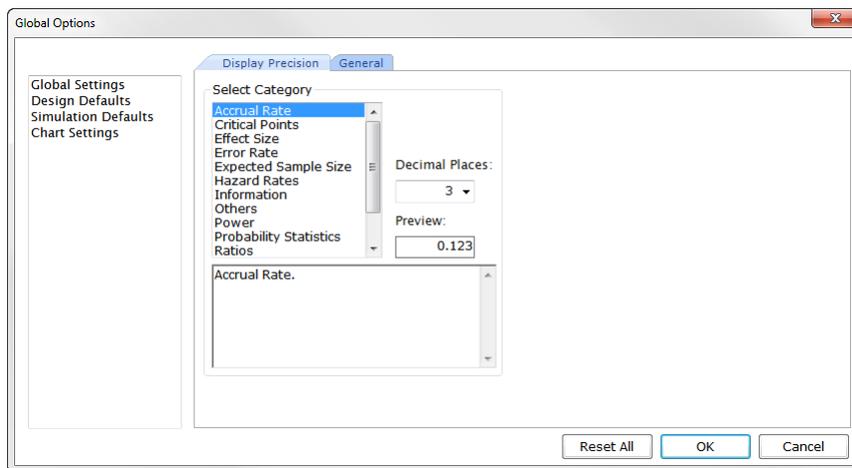

The following section discusses the Global Options in East 6. Most of them are not applicable to Analysis menu but some options like Data Path or Display Precision settings for analysis can be set.

70 Introduction to Volume 9

70.1 Settings

Click the **Global Options** icon in the **Home** menu to adjust default values in East 6.

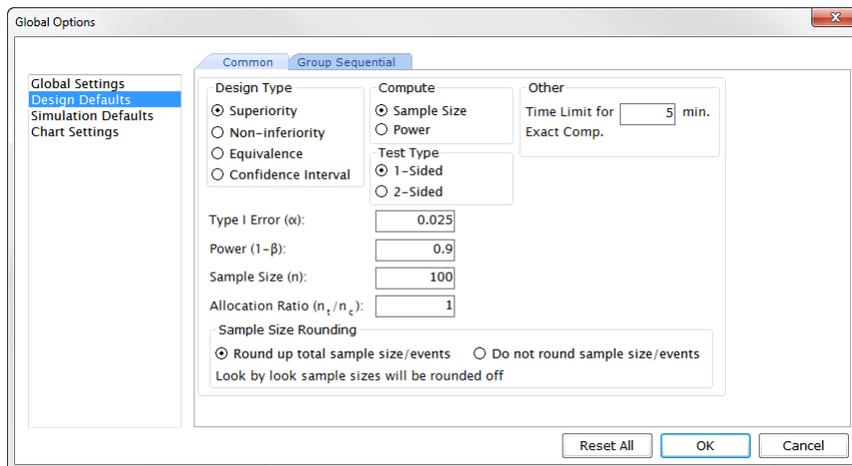

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

The **Design Defaults** is where the user can change the settings for trial design:

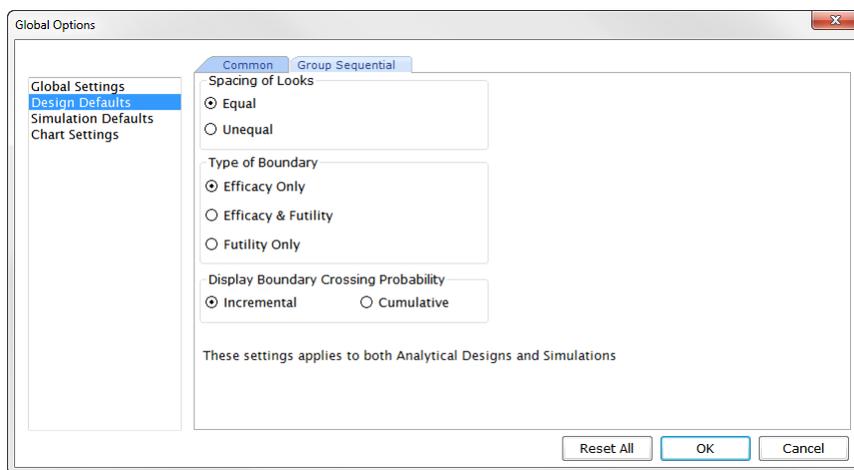

Under the **Common** tab, default values can be set for input design parameters.

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

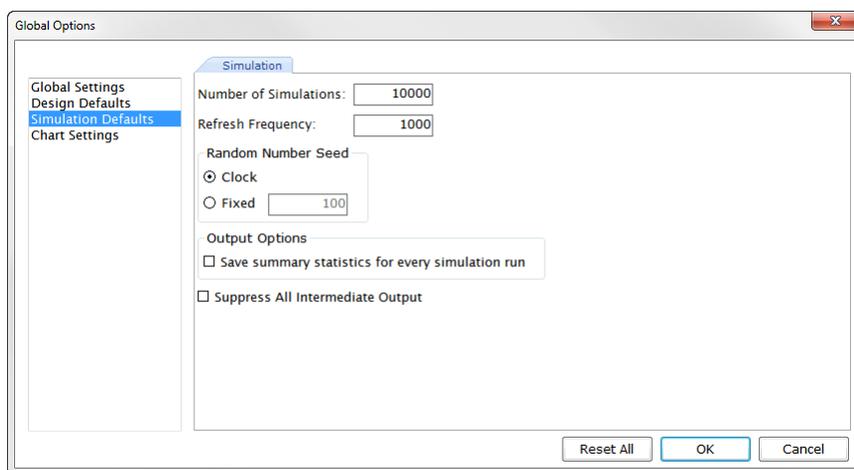

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

70 Introduction to Volume 9

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

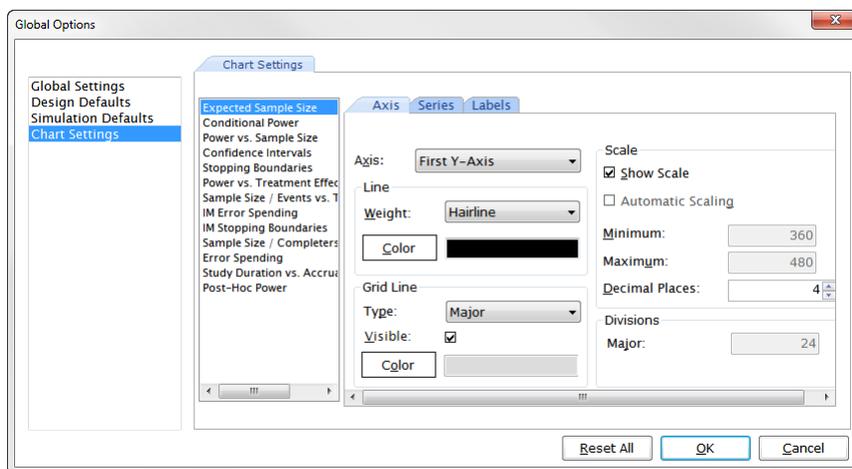

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

We suggest that you do not alter the defaults until you are quite familiar with the software.

71 *Tutorial: Analysis*

The Analysis menu of **East 6.3** contains various procedures for analyzing data. The procedures include **Basic Statistics** and **Plots** used for exploratory analysis of data and at higher level, Logistic and Probit regression as well as tests for handling analysis of crossover data. Exact Inference tests for two by two categorical data and multiple comparison tests for continuous and discrete data belong to the Analysis menu.

For a few tests, we provide a link to SAS[®] for invoking SAS[®] procedure or user's SAS program which will do the analysis in SAS[®] and display the results on **East** screen.

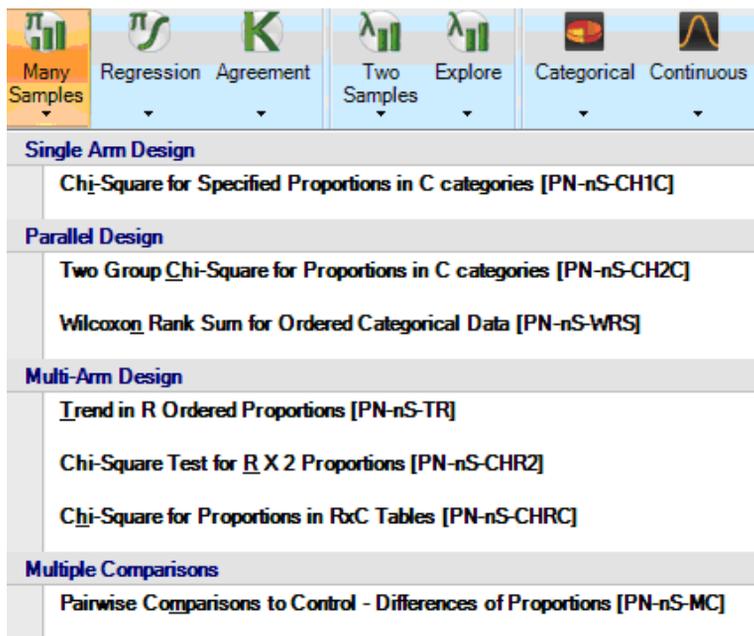

All the procedures in the Analysis menu are broadly grouped under the following categories.

- Basic Statistics
- Continuous
- Discrete
- Events
- Basic Plots
- Crossover Plots

Each of these categories is further divided into several sub menus consisting of the procedures related to that particular category. For example, if you traverse

Analysis > (Discrete) Many Samples

You will see the following list of available procedures.

Note that the procedures are grouped under **Single Arm Design**, **Parallel Design** etc. In this tutorial, we will take you on a tour of Analysis procedures available in **East**.

71.1 DataTypes

East can do analysis on data in **Case Data** or **Crossover Data** formats. Except for the procedures specifically marked for crossover analysis, all other procedures can be carried out on **Case Data**. **Case data** can be viewed and modified using the **case data editor**. The case data editor displays case data in the form of a sheet where Rows represent records and Columns represent variables. The variables can be of binary, string, categorical or continuous types. You can create a new Case Data sheet by clicking **New Data** on **File menu**. For more details about **Case Data Editor** and **Cross over Data Editor** refer to the Chapter 4.

For illustrative purposes we have included Data files in the **Samples** folder available in the **Installation Directory** of **East**. A typical **Case data file** in a case data editor looks as shown below:

71 Tutorial: Analysis

| | Dose | Animal | Week | Weight | var |
|----|------|--------|------|--------|-----|
| 1 | No | 1 | 1 | 455 | |
| 2 | No | 1 | 3 | 460 | |
| 3 | No | 1 | 4 | 510 | |
| 4 | No | 1 | 5 | 504 | |
| 5 | No | 1 | 6 | 436 | |
| 6 | No | 1 | 7 | 466 | |
| 7 | No | 2 | 1 | 467 | |
| 8 | No | 2 | 3 | 565 | |
| 9 | No | 2 | 4 | 610 | |
| 10 | No | 2 | 5 | 596 | |
| 11 | No | 2 | 6 | 542 | |
| 12 | No | 2 | 7 | 587 | |
| 13 | No | 3 | 1 | 445 | |
| 14 | No | 3 | 3 | 530 | |
| 15 | No | 3 | 4 | 580 | |
| 16 | No | 3 | 5 | 597 | |
| 17 | No | 3 | 6 | 582 | |
| 18 | No | 3 | 7 | 619 | |
| 19 | No | 4 | 1 | 485 | |
| 20 | No | 4 | 3 | 542 | |
| 21 | No | 4 | 4 | 594 | |
| 22 | No | 4 | 5 | 583 | |

This is a view of **Body_weight.cyd** data opened in **East**. These data contain 22 records on four variables: Dose, Animal, Week and Weight. While **Dose** is string variables, all others are of numeric type.

A typical **Crossover Data file** in crossover data editor looks as follows:

No. of Groups:

No. of Periods:

Treatment Assignment Table

| | P1 | P2 |
|----|----|----|
| G1 | T | R |
| G2 | R | T |

| | PatientId | GroupId | P1_Resp | P2_Resp | var |
|----|-----------|---------|---------|---------|-----|
| 1 | 1 | G1 | 228.04 | 288.79 | |
| 2 | 2 | G2 | 339.03 | 329.76 | |
| 3 | 3 | G1 | 288.21 | 343.37 | |
| 4 | 4 | G2 | 242.64 | 258.19 | |
| 5 | 5 | G2 | 249.94 | 201.56 | |
| 6 | 6 | G1 | 217.97 | 225.77 | |
| 7 | 7 | G1 | 133.13 | 235.89 | |
| 8 | 8 | G2 | 184.32 | 249.64 | |
| 9 | 9 | G1 | 213.78 | 215.14 | |
| 10 | 10 | G1 | 248.98 | 245.48 | |
| 11 | 11 | G1 | 163.93 | 134.89 | |
| 12 | 12 | G2 | 209.3 | 231.98 | |
| 13 | 13 | G2 | 207.4 | 234.19 | |
| 14 | 14 | G1 | 245.92 | 223.39 | |
| 15 | 15 | G2 | 239.84 | 241.25 | |
| 16 | 16 | G2 | 211.24 | 255.6 | |

The above is a view of the **Euphylong.cyd file**, that contains 2x2 crossover data on two drugs T and R administered in two sequences G1=T,R and G2=R,T. The variables P1_Resp and P2_Resp are the variables representing responses of patients in the first and second periods respectively.

71 Tutorial: Analysis

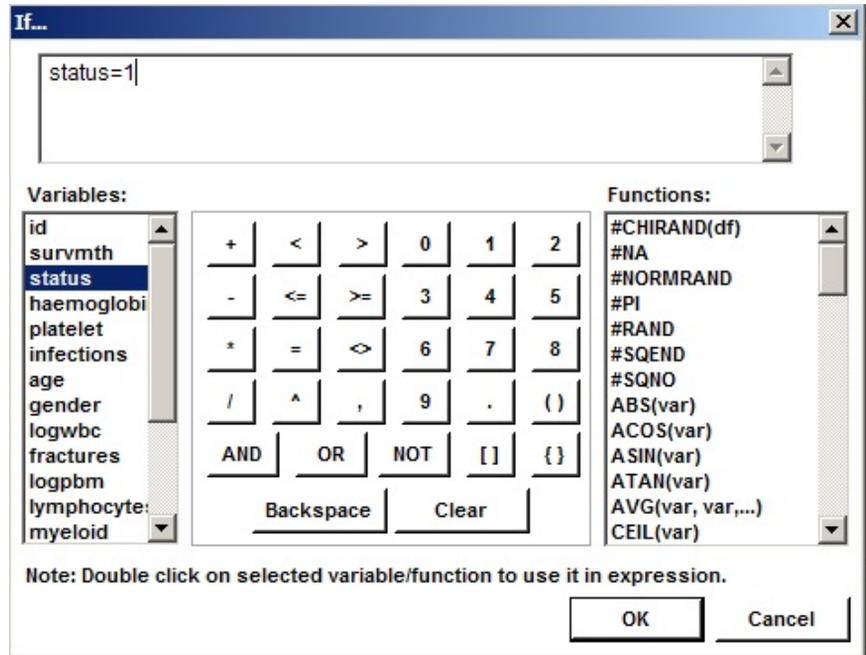

71.2 Using Case Data Editor Features

There are a whole lot of capabilities available with the **Case Data editor**. You can sort, filter transform variables, etc., and perform the analysis on the modified data. For instance, suppose you open the data set **Leukemia.cyd** from **Samples** folder. The data consist of three variables **Drug**, **Time** and **Status**, a part of which is shown below.

| | Drug | Time | Status |
|----|---------|------|--------|
| 1 | Placebo | 1 | 1 |
| 2 | 6-MP | 10 | 1 |
| 3 | Placebo | 22 | 1 |
| 4 | 6-MP | 7 | 1 |
| 5 | Placebo | 3 | 1 |
| 6 | 6-MP | 32 | 0 |
| 7 | Placebo | 12 | 1 |
| 8 | 6-MP | 23 | 1 |
| 9 | Placebo | 8 | 1 |
| 10 | 6-MP | 22 | 1 |
| 11 | Placebo | 17 | 1 |
| 12 | 6-MP | 6 | 1 |
| 13 | Placebo | 2 | 1 |
| 14 | 6-MP | 16 | 1 |

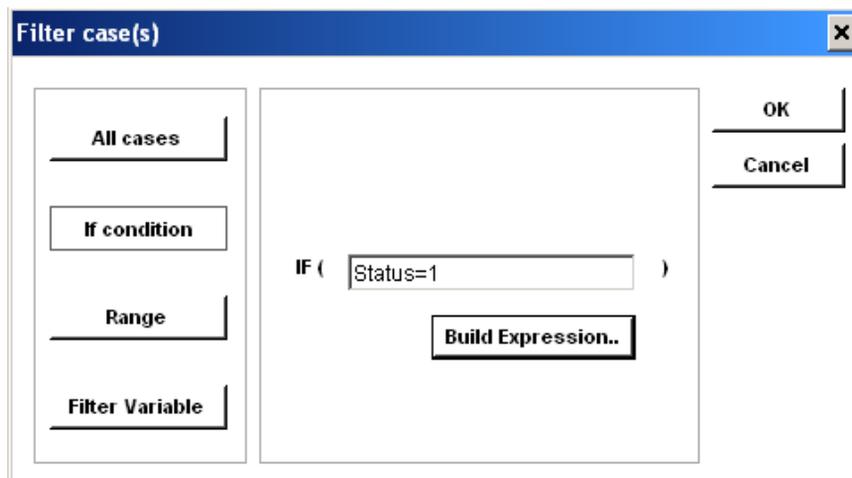

Suppose you want to consider data only for **Status =1**. This is possible by filtering the data using filter command as described below.

Click on the  filter icon on the **Data Editor** menu. In the ensuing dialog box, press **If Condition** and then **Build expression** button. You will see the following dialog box.

71 Tutorial: Analysis

Use the selections available to build the expression as shown below.

Press **OK**. This will select the data on **Status =1** as active. All other inactive records in

the data will be displayed in blue color. A partial data is shown in the following figure.

| Drug | Time | Status |
|---------|------|--------|
| Placebo | 1 | 1 |
| 6-MP | 10 | 1 |
| Placebo | 22 | 1 |
| 6-MP | 7 | 1 |
| Placebo | 3 | 1 |
| 6-MP | 32 | 0 |
| Placebo | 12 | 1 |
| 6-MP | 23 | 1 |
| Placebo | 8 | 1 |
| 6-MP | 22 | 1 |
| Placebo | 17 | 1 |
| 6-MP | 6 | 1 |
| Placebo | 2 | 1 |
| 6-MP | 16 | 1 |
| Placebo | 11 | 1 |
| 6-MP | 34 | 0 |

Let us perform the Difference of Means Test on the filtered data. Select Difference of Means Test as:

Analysis > (Continuous) Two Samples > (Parallel Design) Difference of Means

In the ensuing dialog box, select **Drug** as **Population Id**, **Placebo** as **Control** and **Time** as **Response variable**. No need to select any variable as **Frequency Variable**.

71 Tutorial: Analysis

The Input dialog box will look as follows:

Analysis: Continuous Endpoint Two-Sample Test - Parallel Design - Difference of Means

Data Set: leukemia.cyd

Main Advanced

Trial Type: Superiority Test Type: t-test Frequency Variable:

Variance Type: Equal Response Variable: Time

Population Id: Drug

Control: Placebo

Treatment: 6-MP

Click **OK**. You will see the following output.

Analysis: Continuous Response: Difference of Means for Independent Data

Hypothesis

$H_0 : \mu_t - \mu_c = 0$ Vs. $H_1 : \mu_t - \mu_c \neq 0$ for 2-Sided test

Either $H_1 : \mu_t - \mu_c < 0$

Or $H_1 : \mu_t - \mu_c > 0$ for 1-Sided test

Input Parameters

Data File: leukemia.cyd
 Trial Type: Superiority
 Drug(Treatment=6-MP,
 Population Id: MP,
 Control=Placebo)
 Response Variable: Time
 Variance Type: Equal
 Test Type: t-test
 Confidence Level: 0.95

Response Variable: Time
 Total Number of Records: 42
 Number of Records Rejected: 12

Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|--------|---------|----|
| Placebo | 1 | 23 | 8 | 8.667 | 6.468 | 21 |
| 6-MP | 6 | 23 | 10 | 12.111 | 6.846 | 9 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-------|----|---------|------|---------|----------------------------------|-------------|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit |
| 30 | 3.444 | 0.524 | 2.621 | 1.314 | 28 | 0.1 | G.E. | 0.199 | -1.924 | 8.813 |

The output is displayed in three parts. The **first part** specifies the **Null** as well as **Alternative hypotheses** to be tested. **East** considers testing of both one sided and two sided alternative hypotheses and computes the corresponding p- values.

In the **second part**, Input details such as **data file name**, **Population Id** and the **test to be performed** are mentioned.

In the **last part**, the output contains number of records in the data, number of record rejected, summary of data and the Inference. From the above output, it is clear that there are in all 42 records, out of which 12 are rejected by filtering and the t test is applied on the remaining 30 records. Both one sided and two sided p-values indicate that the null hypothesis Ho cannot be rejected at 5% level of significance.

71.3 Sub-Group Analysis using By variable

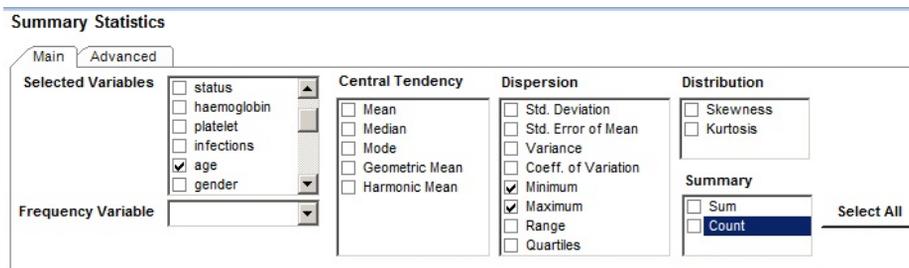

In almost every data analysis feature, **East** provides facility for doing sub-group analysis on maximum of two variables. For instance, consider running 'One way analysis of variance (ANOVA)' procedure on the **Myeloma.cyd** data set available in the **Samples** folder of the installation directory of the product. The authors Krall, Uthoff and Harley (1975) provide data of a survival study that include the survival times, in months, of 65 multiple myeloma patients with data on 15 concomitant variables. In this example, we like to perform one way ANOVA on the variable 'survmth' in subgroups of Males and Females separately.

Suppose we want to see if average survival is different across age groups, we would first like to categorize variable age into a factor. This we can do using the **RCODE** function available in **Transform Variable** in **Case Data Editor**. Open **Myeloma.cyd** from the **Samples** folder of **East**. In order to know the Minimum and Maximum value of age, choose from the menu:

Analysis > (Basic Statistics) Descriptive Statistics > Summary Statistics

71 Tutorial: Analysis

Select the variable **age** and **Minimum** and **Maximum** as shown in the following dialog box.

Click **OK**. You will see the following output.

Analysis: Summary Statistics

Input Parameters

Data File: Myeloma.cyd
Selected Variable (s): age
Statistics: Minimum, Maximum

Output

| | Min | Max |
|-----|-----|-----|
| age | 27 | 82 |

Accordingly let us form the age groups as follows:

1. AgeCode=1 for Age from 21 to 40
2. AgeCode=2 for Age from 41 to 60
3. AgeCode=3 for Age from 61 to 80
4. AgeCode=4 for Age not less than 81

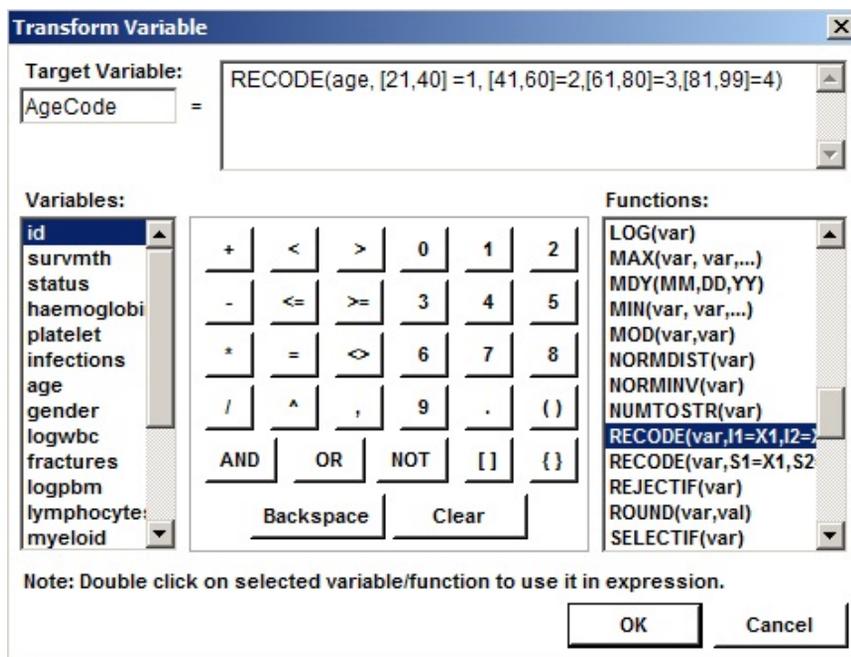

This grouping can be done using **RCODE** function. Here we show how to accomplish this. For demonstrating the grouping capability, we would use **Myeloma** dataset. This dataset when opened looks like this:

| | id | survmth | status | haemoglobin | platelet | infections |
|----|----|---------|--------|-------------|----------|------------|
| 2 | 2 | 1.25 | 1 | 12 | 1 | 1 |
| 3 | 3 | 2 | 1 | 9.8 | 1 | 1 |
| 4 | 4 | 2 | 1 | 11.3 | 0 | 0 |
| 5 | 5 | 2 | 1 | 5.1 | 0 | 0 |
| 6 | 6 | 3 | 1 | 6.7 | 1 | 1 |
| 7 | 7 | 5 | 1 | 10.1 | 1 | 0 |
| 8 | 8 | 5 | 1 | 6.5 | 1 | 0 |
| 9 | 9 | 6 | 1 | 9 | 1 | 1 |
| 10 | 10 | 6 | 1 | 10.2 | 0 | 0 |
| 11 | 11 | 6 | 1 | 9.7 | 1 | 0 |
| 12 | 12 | 6 | 1 | 10.4 | 1 | 0 |
| 13 | 13 | 7 | 1 | 9.5 | 1 | 0 |
| 14 | 14 | 7 | 1 | 5.1 | 0 | 0 |
| 15 | 15 | 7 | 1 | 11.4 | 1 | 0 |
| 16 | 16 | 9 | 1 | 8.2 | 1 | 0 |
| 17 | 17 | 11 | 1 | 14 | 1 | 0 |
| 18 | 18 | 11 | 1 | 12 | 1 | 0 |
| 19 | 19 | 11 | 1 | 13.2 | 1 | 0 |
| 20 | 20 | 11 | 1 | 7.5 | 1 | 0 |
| 21 | 21 | 11 | 1 | 9.6 | 1 | 0 |

In the next column after sercalcium (which is the last variable in the dataset) construct a new variable by clicking the Transform icon  on the **Data Editor menu**. In the

71 Tutorial: Analysis

ensuing dialog box, type the **Transform command** as shown below.

Click **OK**. This will generate a new variable **AgeCode** with values from 1 to 4. To run **One way ANOVA** procedure, follow the steps:

Analysis > (Continuous) Many Samples > One way ANOVA

You will see the following input dialog box. In it select **AgeCode** as **Factor** and **survmth** as **Response**.

Data Set: Myeloma.cyd

The screenshot shows a software interface with two tabs: 'Main' and 'Advanced'. The 'Main' tab is selected. Below the tabs, there are two dropdown menus. The first is labeled 'Factor:' and contains the text 'age'. The second is labeled 'Response:' and contains the text 'survmth'. To the right of these dropdowns is a checkbox labeled 'Contrast' which is currently unchecked.

Click **Advanced Tab**. Select **gender** in **By variable 1** drop down box.

The screenshot shows the same software interface but with the 'Advanced' tab selected. The 'By Variable 1:' dropdown menu now contains the text 'gender'. The 'By Variable 2:' dropdown menu is currently empty.

Click **OK**. The output obtained is as shown below.

71 Tutorial: Analysis

Analysis: ANOVA: One Way

Hypothesis

$H_0 : \mu_1 = \mu_2 = \dots = \mu_r$

Vs.

$H_1 : \text{At least one } \mu_i \text{ differs, for } i=1,2,3 \dots r \text{ where } r \text{ is the number of treatment groups}$

Input Parameters

Data File: Myeloma.cyd

Factor: AgeCode

Response: survmth

By Variable (s): gender

By: gender =
1

Total Number of Records: 38

Number of Records Rejected: 0

ANOVA Table:

| Source | DF | Sum of Squares | Mean Square | F Statistic | p-value |
|-----------|----|----------------|-------------|-------------|---------|
| AgeCode | 3 | 1515.209 | 505.07 | 0.878 | 0.462 |
| Residuals | 34 | 19568.593 | 575.547 | | |
| Total | 37 | 21083.803 | | | |

Summary Table:

| Overall Mean | Root MSE | R-Square | Adjusted R-Square | Coeff. of Variation |
|--------------|----------|----------|-------------------|---------------------|
| 24.908 | 23.991 | 0.072 | -0.01 | 96.317 |

By: gender =
2

Total Number of Records: 27

Number of Records Rejected: 0

ANOVA Table:

| Source | DF | Sum of Squares | Mean Square | F Statistic | p-value |
|-----------|----|----------------|-------------|-------------|---------|
| AgeCode | 3 | 1101.185 | 367.062 | 0.617 | 0.611 |
| Residuals | 23 | 13672 | 594.435 | | |
| Total | 26 | 14773.185 | | | |

Summary Table:

| Overall Mean | Root MSE | R-Square | Adjusted R-Square | Coeff. of Variation |
|--------------|----------|----------|-------------------|---------------------|
| 22.741 | 24.381 | 0.075 | -0.046 | 107.213 |

Notice that **East** has performed one way ANOVA procedure on the two subgroups formed by **gender=1** and **gender=2** respectively. There is no significant effect of **Age** on the survival. This is true in case of both male and female patients.

71.4 Workflow for Analysis

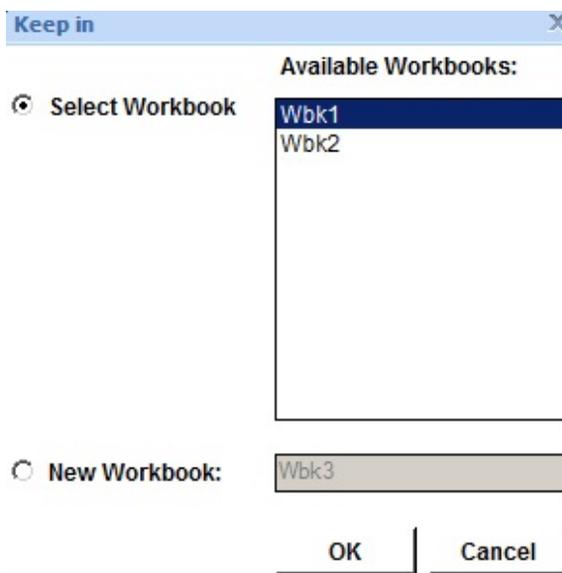

In this section we will walk you through the steps that will be generally followed while performing any analysis in **East**.

71.4.1 Getting Data into East

Data may be entered into **East** as case data or as crossover data, read in as a previously saved East file (.cydx) through the **Open** command in the **File** menu, or read in from another software package through the **Import command**. In this tutorial, you will read in a previously saved data file using the **Open** command.

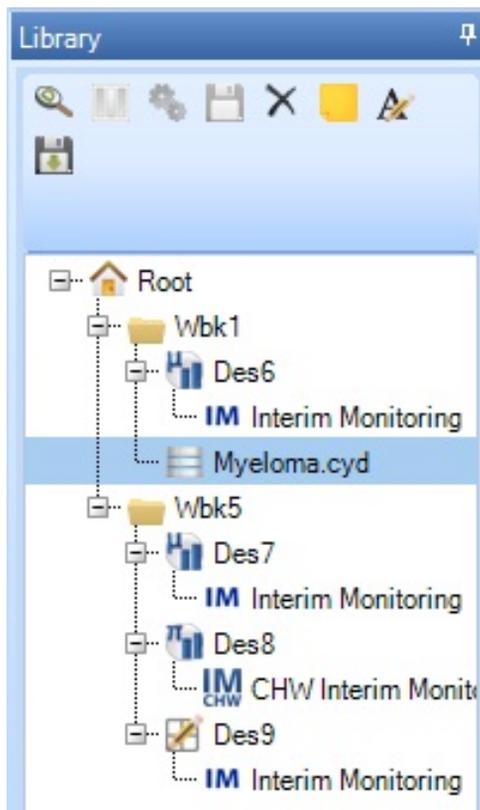

For illustrative purposes, let us consider performing **Difference of Means Test** on the data **Myeloma.cyd** available in the **Samples** folder.

Open the data set **Myeloma.cyd** from **Samples** folder. If there are several workbooks in Library, **East** will ask for the workbook you would like to store the data as shown in the following dialog:

71 Tutorial: Analysis

Suppose you choose **Wbk1**. A node named **Myeloma.cydx** will be created in **Wbk1** as shown below:

You may rename the data node by right clicking on it.

71.4.2 Choose the Test

Choose the test from the appropriate submenu of Analysis. In this case, select;

Analysis > (Continuous) Two Samples > (Parallel Designs) Difference of Means.

In the ensuing dialog, select the variables as shown below.

Data Set: Myeloma.cyd

Main Advanced

Trial Type: Superiority Test Type: t-test Frequency Variable:

Variance Type: Equal

Population Id: status Response Variable: platelet

Control: 0

Treatment: 1

Click **OK** to execute the test. You will see the following output.

71.4.3 Output

Analysis: Continuous Response: Difference of Means for Independent Data

Hypothesis

$H_0 : \mu_t - \mu_c = 0$ Vs. $H_1 : \mu_t - \mu_c \neq 0$ for 2-Sided test

Either $H_1 : \mu_t - \mu_c < 0$

Or $H_1 : \mu_t - \mu_c > 0$ for 1-Sided test

Input Parameters

Data File: Myeloma.cyd
 Trial Type: Superiority
 Population Id: status(Treatment=1, Control=0)
 Response Variable: platelet
 Variance Type: Equal
 Test Type: t-test
 Confidence Level: 0.95

Response Variable: platelet

Total Number of Records: 65

Number of Records Rejected: 0

Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|-------|---------|----|
| 0 | 0 | 1 | 1 | 0.941 | 0.243 | 17 |
| 1 | 0 | 1 | 1 | 0.833 | 0.377 | 48 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|------|----|---------|------|---------|-------------|----------------------------------|--|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 65 | -0.108 | -0.31 | 0.098 | -1.1 | 63 | 0.138 | L.E. | 0.276 | -0.304 | 0.088 | |

The output is divided into three sections. The first one is the **Hypothesis** where the null and alternative hypothesis for 2 sided and 1-sided tests are stated.

The next section is the **Input Parameters** section. This section tells us the name of

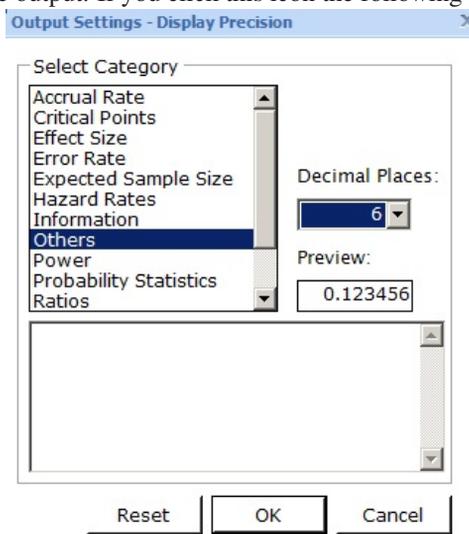

71 Tutorial: Analysis

data file and response variable used in the analysis, type of test performed, confidence level set for the analysis and other parameter(s) used in the analysis. This section is very important to review to make sure that we specified all the input correctly.

The last section is **Output**. First part of the output is the **Summary of the observed Data**. It contains descriptive statistics such as minimum, maximum, mean, median and standard deviation of the response variable within the two treatments groups. The remaining part of the output contains **inference for t test**. The standardized effect size is **-0.31** with t statistic value as **-1.1** which with **63 d.f.** is non-significant. Accordingly, the test fails to reject the null hypothesis at 5% level of significance. This is substantiated by observing that the 95 % confidence interval includes value 0.

You will see three icons at the top of the Analysis output. Using  icon you can print the output. The  icon is used to save the output as HTML.

With  icon you can readily change the display settings, in particular the number of decimal points on the output. If you click this icon the following dialog comes up.

Change the display precision for '**Others**' category to 6 decimals as shown in the above dialog box and click **OK**. You will see the following output with, other than

Beta and p- values, all values are displayed up to 6 decimals.

Analysis: Continuous Response: Difference of Means for Independent Data

Hypothesis

$H_0 : \mu_t - \mu_c = 0$ Vs. $H_1 : \mu_t - \mu_c \neq 0$ for 2-Sided test
 Either $H_1 : \mu_t - \mu_c < 0$
 Or $H_1 : \mu_t - \mu_c > 0$ for 1-Sided test

Input Parameters

Data File: Myeloma.cyd
 Trial Type: Superiority
 Population Id: status(Treatment=1, Control=0)
 Response Variable: platelet
 Variance Type: Equal
 Test Type: t-test
 Confidence Level: 0.95

Response Variable: platelet
 Total Number of Records: 65
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|-------|---------|----|
| 0 | 0 | 1 | 1 | 0.941 | 0.243 | 17 |
| 1 | 0 | 1 | 1 | 0.833 | 0.377 | 48 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-----------|----|---------|------|---------|----------------------------------|-------------|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit |
| 65 | -0.108 | -0.31 | 0.098 | -1.099564 | 63 | 0.138 | L.E. | 0.276 | -0.303837 | 0.08815 |

71.4.4 Links to SAS

The Analysis module of **East** facilitates analysis using SAS Procedures on the data in two ways.

1. Invoking **SAS** through SAS link '**Run Using SAS**' provided on the **Advanced tab** for the tests **Linear Mixed Effects Model: Difference of Means and Ratio of Means**. These tests are part of the **Regression** menu from **Analysis: Continuous**. By doing this, **East** will invoke Mixed procedure of **SAS**. You can also choose not to use **SAS**. If you use **SAS**, you will have the option of including covariates in your model. Without **SAS**, your model will not include covariates.
2. Using **SAS** command option available in the tests for 2x2 crossover tests in the **Regression** menu **Analysis: Continuous**. With this option, you can use your own data set and **SAS** commands. This will utilize the data in **East** and run the **PROC** specified in your **SAS** code. The output will be displayed in the **East's** main window. The flexibility offered allows you to write any **SAS** code. The only exception is that your code should not contain **SAS** graphics.

71 *Tutorial: Analysis*

For more details of these aspects you are referred to the respective chapters.

72 *Analysis-Descriptive Statistics*

Descriptive Statistics, under the **Basic Statistics** menu, deals with preliminary exploration of data using elementary tools such as computation of summary measures, classification, cross tabulation of the data. Descriptive Statistics helps statisticians to choose statistical analysis techniques to arrive at meaningful inference.

In this Chapter, Section (72.1) describes the descriptive statistical measures available in **East**. Section (72.2) describes the procedure for obtaining frequency distribution for one or more variables in a data set. Section (72.3) details the procedure for obtaining a cross-tabulation of any two variables in a case data file. All these procedures are available only for case data.

Note: All measures are computed after dropping observations with missing values.

72.1 *Summary Statistics*

72.1.1 *Example: Summary Statistics*

East provides results for a set of 16 predefined univariate summary measures for numeric variables in a data set. These measures help you to select the type of analysis to carry out later.

The following Descriptive Statistics or Univariate Summary Measures are available.

| Central Tendency | Dispersion | Distribution | Summary |
|---------------------------|--------------------------|--------------|---------|
| Mean (Std. Error of Mean) | Standard Deviation | Skewness | Count |
| Median | Variance | Kurtosis | Sum |
| Mode | Coefficient of variation | | |
| Geometric Mean | Maximum | | |
| Harmonic Mean | Minimum | | |
| | Range | | |

72.1.1 *Example: Summary Statistics*

Dataset: Myeloma.cydx

Data Description:

The authors Krall, Uthoff and Harley (1975) have provided data of a survival study. It included the survival times in months of 65 multiple myeloma patients with data on 15 concomitant variables.

72 Analysis-Descriptive Statistics

Purpose of the Analysis:

To compute summary measures for the variables **survmth**, **haemoglobin** and **bjprotein** grouped based on the survival status **status** and gender **gender**.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Descriptive Statistics > Summary Statistics

3. In the **Main** tab, select the variables of interest. In this example select the following variables: **survmth**, **haemoglobin** and **bjprotein**. Click the **Select All** button to get the results for all the summary measures.

4. Thereafter, under the **Advanced** tab choose the variables as shown below:

5. Click **OK**. You will see the Analysis results as shown below.

| | | Mean | Std.Error | Median | Mode | GeoMean |
|--------------------|--------|--------|-----------|--------|------|---------|
| survmth | | | | | | |
| status | gender | | | | | |
| 0 | 1 | 33.25 | 9.697 | 28.5 | N.A. | 21.578 |
| 0 | 2 | 13.556 | 2.467 | 12 | 12 | 11.741 |
| 1 | 1 | 22.683 | 4.168 | 14.5 | 11 | 12.829 |
| 1 | 2 | 27.333 | 6.567 | 17 | 6 | 16.921 |
| haemoglobin | | | | | | |
| status | gender | | | | | |
| 0 | 1 | 12.338 | 0.525 | 12.65 | 10.2 | 12.256 |
| 0 | 2 | 9.856 | 0.854 | 10 | N.A. | 9.498 |
| 1 | 1 | 10.277 | 0.458 | 10.1 | 9 | 9.961 |
| 1 | 2 | 9.3 | 0.616 | 10.1 | 7.5 | 8.917 |
| bjprotein | | | | | | |
| status | gender | | | | | |
| 0 | 1 | 1.625 | 0.183 | 2 | 2 | 1.542 |
| 0 | 2 | 2 | 0 | 2 | 2 | 2 |
| 1 | 1 | 1.6 | 0.091 | 2 | 2 | 1.516 |
| 1 | 2 | 1.556 | 0.121 | 2 | 2 | 1.47 |

72.2 Example: Frequency Distribution

The procedure **Frequency Distribution** displays a separate frequency distribution table for each of the variables specified in a list. The default display includes the values of the variable in sorted order in the first column and the frequencies in the second column. Additional display can be obtained by choosing one or more of the options Percentage, Cumulative<=, Cumulative >= or Compute Percentiles.

Dataset: *Myeloma.cydx* as described in Section 72.1.1.

Purpose of the Analysis:

To obtain Frequency Distribution table for the variables **haemoglobin**, **age**, **fractures**, and **bjprotein**.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:
Analysis > (Basic Statistics) Descriptive Statistics > Frequency Distribution

72 Analysis-Descriptive Statistics

- In the ensuing dialog box (under the **Main** tab), select the variables of interest in the **Selected Variables** box. For this example, select the variables: **haemoglobin**, **age**, **fractures**, and **bjprotein**. In the **Frequency Output** select all the three checkboxes and select the **Compute Percentile** check box.

Frequency Distribution

Main | Advanced

Selected Variables

- logpbm
- lymphocytes
- myeloid
- uria
- bjprotein
- totserprotein

Frequency Variable

Frequency Output

- Percentage
- Cumulative <=
- Cumulative >=

Compute Percentile

- Thereafter, under the **Advanced** tab choose the By Variables as shown below:

Frequency Distribution Data :

Main | Advanced

By Variable

| Total | 38 | 100 | | | | |

72.3 Example: Tabulate

The **Tabulate** procedure allows cross-tabulation of any two specified variables of a data set. It also allows specification of a **Frequency variable** and a **By Variable** for subgroup analysis. The optional output from this procedure includes row, column, and overall percentages, expected values and chi-square statistics with p-values.

Dataset: Job-case.cyx

Data Description:

This example refers to the data obtained in a general social survey conducted by National Opinion Research Center (1991) among black American women and men. The data is in case data form. For exploratory analysis and presentation, it is useful to summarize these data into a tabular form.

The data consist of the following annual income levels:

- <\$5,000
- 5,000-15,000
- 15,000-25,000
- > 25,000

and job satisfaction levels:

- Very Dissatisfied
- A little satisfied
- Moderately satisfied
- Very satisfied

for 64 women and 40 men.

Purpose of the Analysis:

To cross tabulate the data for the variables **Incomegrp** and **Jobsatis** grouped by gender.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Descriptive Statistics > Tabulate

3. In the ensuing dialog box, choose the variables as shown below.

Tabulate

Main | Advanced

Row Variable: Incomegrp Column Variable: Jobsatis Display: Chi-Square Test

Frequency Variable: Persons

Row Percent
 Column Percent
 Overall Percent
 Expected Value

4. Thereafter, under the **Advanced** tab choose the variables as shown below.

Tabulate

Main | Advanced

By Variable: Gender

5. Click **OK**. You will see the Analysis results as shown below.

72 Analysis-Descriptive Statistics

Analysis: Tabulate

73 *Analysis-Analytcs*

This chapter describes some of the commonly used univariate procedures: t-test (paired and independent), one-way and two-way (without interaction) analysis of variance (ANOVA) and multiple linear regression. The topic of correlations is also included in this chapter. References for the procedures covered in this chapter are provided in the table shown below:

| Test | References |
|--|---|
| t-tests | Snedecor & Cochran (1989) |
| ANOVA | Kreyszig (1970) |
| Pearson’s Product-Moment Correlation Spearman’s Product-Moment Correlation Kendall’s Tau | Siegel & Castellan (1988) |
| Regression procedures Collinearity diagnostics Residuals and Influence | Maindonald J (1984) Belsley, Kuh, & Welsh (1980) Cook & Weisberg (1982) |

Note: Any observation with a missing value for a variable that is included in the model is excluded from the analysis.

73.1 Example: t-test
 73.1.1 Independent t-test
 73.1.2 Paired t-test

This section describes t-test procedures for analyzing data of **independent** and **paired** samples.

73.1.1 Independent t-test

Dataset: *Myeloma.cyx* as described in Section 72.1.1.

Purpose of the Analysis:

To compare mean **Uria** level between two groups indicated by the variable **status** (0-alive, 1-dead).

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Analytcs > (t-test) Independent t-test

73 Analysis-Analytics

3. In the ensuing dialog box, choose the variables as shown below.

The screenshot shows the 'Independent t-Test' dialog box with the following settings:

- Tab: Main
- Population: status
- Response: uria
- Equal Variance:
- Unequal Variance:

4. Click **OK**. The results will appear as shown below.

Analysis: Two Sample t-test (Equal Variance)

Input Parameters

Data File: Myeloma.cyd

Population: status

Response: uria

| N | Difference | Standard Error | 95% C.I.(Lower Limit) | 95% C.I.(Upper Limit) | t | DF | P-Value |
|----|------------|----------------|-------------------------|-------------------------|--------|----|---------|
| 65 | -3.521 | 1.654 | -6.826 | -0.215 | -2.129 | 63 | 0.037 |

You can try running the t-test with unequal variance by selecting the **Unequal Variance** option on the main tab.

73.1.2 Paired t-test

Dataset: Azt1.cyd

Data Description:

The data from Makuch and Parks (1988) documents the response of serum antigen level to AZT in 20 AIDS patients. Two sets of antigen levels are provided for each patient:

- Pre-treatment
- Post-treatment

Purpose of the Analysis:

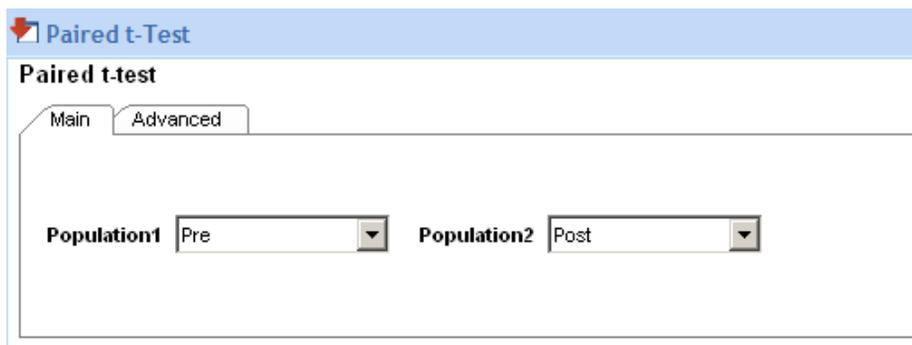

To compare the mean antigen level among patients after administering the treatment with the mean antigen level before administering the treatment.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Analytics >(t-test) Paired t-test

3. In the ensuing dialog box, choose the variables as shown below.

4. Click **OK**. You will see the analysis results as shown below.

Analysis: Paired t test

Input Parameters

Data File: Azt1.cyd
 Population1: Pre
 Population2: Post

| N | Difference | Standard Error | 95% C.I.(Lower Limit) | 95% C.I.(Upper Limit) | t | DF | P-Value |
|----|------------|----------------|-------------------------|-------------------------|-----|----|---------|

73 Analysis-Analytcs

73.2 Analysis of Variance

73.2.1 One-way Analysis of Variance

73.2.2 Two-way Analysis of Variance

The ANOVA procedure available under **Analytcs** menu can perform simple **one-way** and **two-way** analysis of variance, described in this section.

73.2.1 One-way Analysis of Variance

Dataset: Leukocyte.cyd

Data Description:

This data comes from a study done by Kontula et al. (1980) (1982) in which the Glucocorticoid Receptor (GR) Sites per Leukocyte Cell in normal subjects (Group 1) were compared to those in patients with hairy-cell leukemia (Group 2), chronic lymphatic leukemia (Group 3), chronic myelocytic leukemia (Group 4) or acute leukemia (Group 5). One of the aims of the study was to find whether there were any significant differences in the mean number of GR sites per leukocyte cells between these five groups.

Purpose of the Analysis:

To test whether the mean GR sites per Leukocyte Cell is the same across all groups.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Analytcs > ANOVA

3. In the ensuing dialog box, choose the variables as shown below.

ANOVA

ANOVA

Value GR Factor1 Group Factor2

4. Click **OK**. You will see the analysis results as shown below.

Analysis: One way ANOVA

Input Parameters

Data File: leukocyte.cyd

Value: GR

Factor1: Group

Output

| Source | Sum of Squares | DF | Mean Square | F | P-Value |
|-----------|----------------|----|--------------|-------|---------|
| Group | 353735187.391 | 4 | 88433796.848 | 4.308 | 0.007 |
| Residuals | 656834693.69 | 32 | 20526084.178 | | |

| | |
|--------------|----------|
| Overall Mean | 7107.568 |
| Root MSE | 4530.572 |
| R-Square | 0.35 |
| Coeff Var | 63.743 |

73.2.2 Two-way Analysis of Variance

Dataset: swine.cyd

Data Description:

The data for this example is a subset of the data that comes from a study reported by Snedecor and Cochran (1989). This data relates to dressing percentages of 20 swine that have been classified by breed (5 categories) and sex (2 categories) with 2 swine under each combination of breed and sex categories.

Purpose of the Analysis:

The aim of this study is to test for the effect of breed and sex on the study measure taken on the animals.

73 Analysis-Analytics

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Analytics > ANOVA

3. In the ensuing dialog box, choose the variables as shown below.

The screenshot shows a dialog box titled "ANOVA". Inside the dialog, there are three dropdown menus. The first is labeled "Value" and is set to "Measure". The second is labeled "Factor1" and is set to "Breed". The third is labeled "Factor2" and is set to "Sex".

4. Click **OK**. You will see the Analysis results as shown below.

Analysis: Two way ANOVA

Input Parameters

Data File: swine.cyd

Value: Measure

Factor1: Breed

Factor2: Sex

Output

| Source | Sum of Squares | DF | Mean Square | F | P-Value |
|-----------|----------------|----|-------------|-------|---------|
| Breed | 39.932 | 4 | 9.983 | 1.346 | 0.302 |
| Sex | 27.613 | 1 | 27.613 | 3.724 | 0.074 |
| Residuals | 103.805 | 14 | 7.415 | | |

| | |
|-----------------------|--------|
| Max no. of Replicates | 2 |
| Overall Mean | 12.405 |
| Root MSE | 2.723 |
| R-Square | 0.394 |
| Coeff Var | 21.951 |

73.3 Correlations

73.3.1 When to Use Each Measure

73.3.2 Example: Correlations

The **Correlations** procedure under **Analytcs** can be used to compute the following correlation measures for pairs of variables in a data set:

- Pearson's Correlation
- Spearman's Rho
- Kendall's Tau

All these measures of correlation range between -1 and +1 with:

- 0 signifying no association
- -1 signifying perfect negative association
- +1 signifying perfect positive association.

73.3.1 When to Use Each Measure

All the measures of correlation or association in this section capture in a single number

73 Analysis-Analytics

the relationship between two ordered data series. But one measure might be more appropriate than the others under different assumptions about the data. Here are some guidelines on when to use each measure.

Pearson: Use the Pearson product-moment correlation coefficient when you can assume that two correlated data series follow a bivariate normal distribution.

Spearman: Use the Spearman rank-order correlation coefficient when you cannot make a normality assumption about the two data series.

Kendall's Tau: Use Kendall's Tau to capture the association between two data series that are ordered implicitly but not numerically.

73.3.2 Example: Correlations

Dataset: **Myeloma.cyd** as described in Section 72.1.1.

Purpose of the Analysis:

To compute correlations among all pairs of variables from the variables **age**, **bjprotein**, **haemoglobin**, and **survmth**.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Analytics > Correlation

3. In the ensuing dialog box, select **age**, **bjprotein**, **haemoglobin**, and **survmth** as the **Selected Variables** and select all the three checkboxes inside the

Correlation box.

73.4 Multiple Linear Regression

73.4.1 Available procedures

73.4.2 Example: Multiple Linear Regression

This section describes the method of fitting a multiple linear regression model for a selected data set. The regression procedures are performed using a variance-covariance updating procedure described in Maindonald, J (1984). The least squared solution is facilitated by using Cholesky decomposition.

73.4.1 Available procedures

The procedure available in this section fits a linear model of the form $Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k + \varepsilon$ where Y is the dependent variable (response) and X_1, \dots, X_k are the independent variables (predictors) and ε is a random error with a normal distribution having mean=0 and variance= σ^2 . The multiple linear regression algorithm computes the estimates $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k$, of the regression coefficients $\beta_0, \beta_1, \dots, \beta_k$, so as to minimize the sum of squares of residuals.

The regression procedure

- Calculates the estimates of the regression coefficients, their standard errors, p-values, R^2 , and the contribution of each variable to reducing the total sum of squares.
- Performs the Wald test on groups of specified variables.
- Allows control of multicollinearity criterion (default 0.05) and number of components for collinearity diagnostics to be displayed (default 8).
- Computes the fitted values, ANOVA table and covariance matrix of the coefficients estimates.
- Computes various types of residuals-unstandardized, standardized, studentized and deleted.
- Computes influence statistics-Cook's distance, DFFIT's, covariance ratios and hat matrix diagonals.

73.4.2 Example: Multiple Linear Regression

Dataset: Werner.cyx

Data Description:

In this example, consider the data from a blood chemistry study described by Werner, et al (1985). Eight variables were recorded for n=188 women. The data includes the information on age, weight, birth pill (1=user, 2=nonuser), cholesterol, albumin and calcium. One of the aims of this study is to find the relationship between the variable **Cholesterol** and other variables.

Purpose of the Analysis:

To fit multiple linear regression model to the data with **Cholesterol** as dependent variable and **Age, Height, Weight, Birthpill, Albumin, Calcium, and Uric Acid** as

73 Analysis-Analytcs

independent variables. Also to obtain collinearity diagnostics and perform Wald test for **Albumin**, **Calcium**, and **Uric_Acid**.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

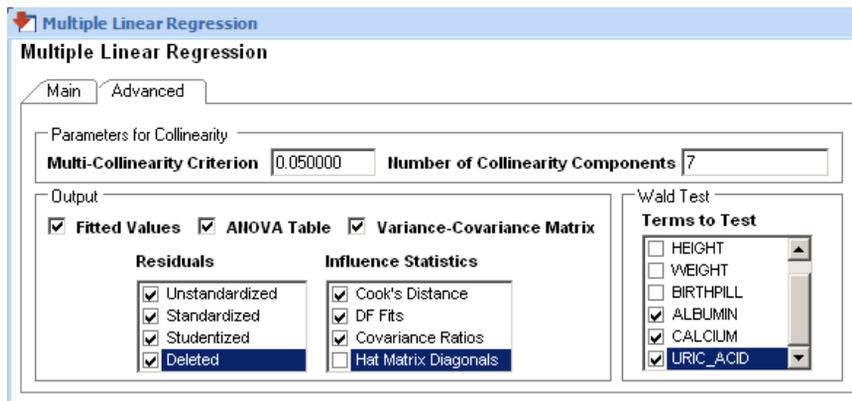

Analysis > (Basic Statistics) Analytics > Multiple Linear Regression

3. In the **Main** tab, select **Cholesterol** as the **Dependent Variable** and select the checkboxes against the remaining 7 variables, **Age**, **Height**, **Weight**, **Birthpill**, **Albumin**, **Calcium**, and **Uric_Acid** as independent variables. Click the **Wald Test** and **Collinearity Diagnostics** checkboxes.

The screenshot shows the 'Multiple Linear Regression' dialog box in SPSS, with the 'Main' tab selected. The 'Dependent Variable' is set to 'CHOLESTEROL'. The 'Independent Variables' list includes 'AGE', 'HEIGHT', 'WEIGHT', 'BIRTHPILL', and 'ALBUMIN', all of which are checked. The 'Wald Test' and 'Collinearity Diagnostics' checkboxes are also checked. The 'No Intercept Term' checkbox is unchecked. The 'Weightage Variable' field is empty.

4. In the **Advanced** tab, enter 7 as the **Number of Collinearity Components**. In the **Wald Test** box select the variables **albumin**, **calcium**, and **uric acid** for carrying out the Wald Test. In the **Output** box select all the checkboxes except

Hat Matrix Diagonals.

5. Click **OK**. You will see the Analysis results as shown below.

The **Terms dropped due to** table refers to some essential pre-processing of the data. If a particular independent variable assumes the same value throughout the data set, it is not really a ‘variable’ and has to be dropped. Its presence creates ‘singularity’ in the so called X matrix. In the present data set we do not have the problem and hence the entry is ‘none’. Multicollinearity is another similar feature of the data which makes the

problem unstable. Again, in the present dataset, no such difficulty is encountered and hence the entry 'None'. The **Summary Statistics** table gives an overview of the results. If the residual degrees of freedom are not adequate, we have too many independent variables. In the present case, the residual df value is 173. The data size is large, relative to the number of independent variables. Multiple R-squared indicates the fraction of the total variation explained by the selected set of independent variables. In this case, the value is 0.2523. If the data under study have high multicollinearity, estimates of regression coefficients become volatile and less dependable. To check this, examine the 'condition numbers'. (They indicate extent of spread in eigen-values of $X'X$). A very large number is a warning. Montgomery et al recommend use of 100 as indicative of moderate concern while a value of 1000 is an alarm trigger (Montgomery, Peck, and Vining, 2003, page 339). For this model, the number is 114.32. Thus, it may be pertinent to take corrective step such as centering the data. The next table is ANOVA. Our data has 181 observations and total degrees of freedom are 180 (one degree being spent on fitting an intercept in the model). There are 7 independent variables giving rise to 7 df for regression and remaining 173 df are assigned to error. The very low p-value shows that the model fitted is 'significant'. We have to reject the null hypothesis that all regression coefficients are zero. Lastly, we can test if a subset of the regression coefficients is zero. A test is carried out to check if coefficients of three independent variables (Albumin, calcium and uric acid) are zero. Here also, the p-value is very small and the hypothesis stands discredited.

73.5 *Multivariate Analysis of Variance*

This section describes various methods for analyzing a data set in which each observation consists of multiple measurements on the same experimental unit. As an example, if our study concerns the size of babies, we may measure length, chest girth, head girth and weight. In that case, there will be four measurements on each baby. We can of course study every measurement separately. However, the fact that they are correlated makes it necessary that they are studied together. All ideas applicable to analysis of univariate data are relevant here too. However, some aspects absent in univariate data arise in multivariate data. Procedures available in **East** for multivariate analysis include Multiple Linear Regression and Multivariate Analysis of Variance (MANOVA). References for the procedures covered in this section are provided in Johnson & Wichern (1998).

Multivariate Analysis of Variance (MANOVA) procedure is a generalization of univariate Analysis of Variance (ANOVA) procedure. When we have samples of observations from different multivariate normal populations having a common variance covariance matrix, we can use the MANOVA procedure to check for the equality of mean vectors.

73 Analysis-Analytcs

73.5.1 Available procedures

The available procedures under MANOVA are:

- One-way MANOVA
- Profile analysis

73.5.2 Example: Multivariate Analysis

Dataset: Root.cyx

Data Description:

The following Example is taken from Rencher (1995). In a classical experiment carried out from 1918 to 1934, apple trees of different rootstocks were compared (Andrews and Herzberg, 1985). The data for eight trees from each of six rootstocks are available. The variables in the data are:

y1 = trunk girth at 4 years (mm x 100)

y2 = extension growth at 4 years (m)

y3 = trunk girth at 15 years (mm x 100)

y4 = weight of tree above ground at 15 years (lb x 1000)

The table of mean vectors of the six rootstocks is shown below:

| Rootstock | Y1 | Y2 | Y3 | Y4 |
|-----------|--------|--------|--------|--------|
| 1 | 1.1375 | 2.9771 | 3.7388 | 0.8711 |
| 2 | 1.1575 | 3.1091 | 4.515 | 1.2805 |
| 3 | 1.1075 | 2.8152 | 4.455 | 1.3914 |
| 4 | 1.0975 | 2.8798 | 3.9063 | 1.039 |
| 5 | 1.08 | 2.5572 | 4.3125 | 1.181 |
| 6 | 1.0362 | 2.2146 | 3.5962 | 0.735 |

Purpose of the Analysis:

To perform One Way Multivariate Analysis of Variance (MANOVA) on the data with ROOTBOX as the group variable and Y1, Y2, Y3, Y4 as the response vector.

Analysis Steps:

1. Open the dataset from Samples folder.
2. Choose the menu item:

Analysis > (Basic Statistics) Analytics > Multiple Analysis of Variance

3. Select **ROOTBOX** in the **Group Variable**. Select all the checkboxes in the **Dependant Variable** box.

Multivariate Analysis of Variance

Group Variable ROOTSTOCK **Dependent Variable**

- Y1
- Y2
- Y3
- Y4

4. Click **OK**. You will see the Analysis results as shown below.

Analysis: Multivariate Analysis of Variance (MANOVA)

Input Parameters

Data File: Root.cyd
 Selected Variable (s): Y1,Y2,Y3,Y4
 Group Variable: ROOTSTOCK
 # Groups: 6
 Number of Obs. in Data File: 48
 No. of obs. Analysed: 48
 Number of Observations Rejected: 0

Output

| | Wilks' Lambda | F-Statistic | Num DF | Den DF | P-value |
|----------------------------|---------------|-------------|--------|--------|-----------|
| Test for equality of means | 0.154 | 4.937 | 20 | 131 | 0 |
| Test for parallel profiles | 0.17 | 6.662 | 15 | 111 | 4.779E-10 |

The p-values are very small and hence we reject the null hypothesis of equality of means as well as the hypothesis of parallel profile.

74 *Analysis-Plots*

The plotting capabilities available in the **Analysis** menu of **East** are of two types.

- Basic Plots
- Crossover Plots

These are essentially data exploration charts for the two types of data, case data and crossover data respectively.

This chapter discusses in detail the various types of basic plots and crossover plots . .

The following types of plots provide data exploration capabilities in **East**:

- Area
- Box
- Bubble
- Cumulative: (Left or Right)
- Density
- Histogram
- Simple Scatter
- Stem and Leaf
- Step Function
- Bar: (simple Bar, Stacked Bar, Horizontal Bar, or Stacked Horizontal Bar)
- Pie
- P-P Normal
- Q-Q Normal

74.1 *Data Exploration Plots*

The plots are further classified into Categorical, Continuous and Frequency Distribution. To generate a data exploration plot, open a data file and then choose from the menu:

Analysis> Basic Plots

Then you can select:

- **Categorical,**
- **Continuous,**
- **Frequency Distribution**

74.2 Categorical

74.2.1 Bar Chart

74.2.2 Pie chart

74.2.1 Bar Chart

Bar chart provides a choice of following graphical displays of the frequencies of the categories of a variable:

- Simple Bar
- Stacked Bar
- Horizontal Bar
- Horizontal Stacked Bar.

The display is in the form of vertical or horizontal bars, the height or length of the bars are proportional to the frequency of the categories shown in the X-axis.

Simple Bar

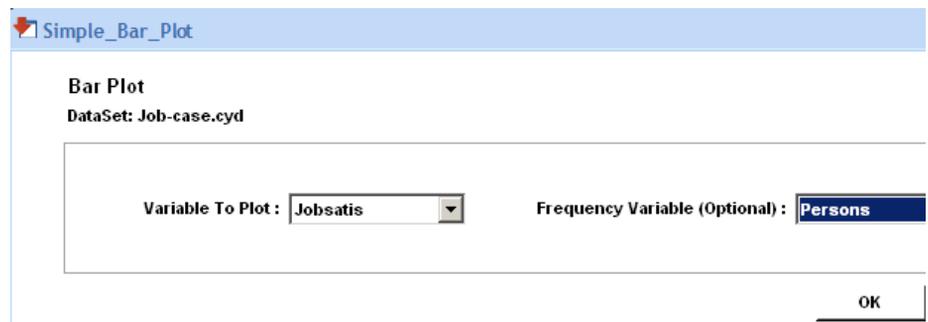

Dataset: Job-Case.cyx as described in Section 72.3.

Purpose of Plot :

For exploratory analysis and presentation, it is useful to summarize these data into a tabular form. The purpose is to generate and display a **Simple Bar** chart for the variable **Jobsatis**.

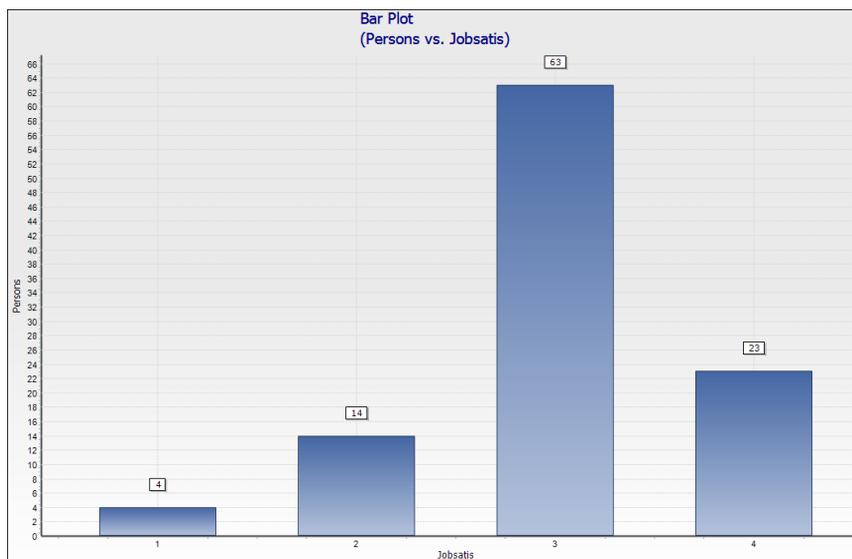

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Categorical > Bar Chart > Simple Bar
3. In the ensuing dialog box, select **Jobsatis** as the **Variable to Plot** and **Persons** as the **Frequency Variable (Optional)**.

74 Analysis-Plots

4. Click **OK**. The following **Simple Bar** chart is displayed in the main window.

Stacked Bar

Dataset: Job-Case.cydx as described in Section 72.3

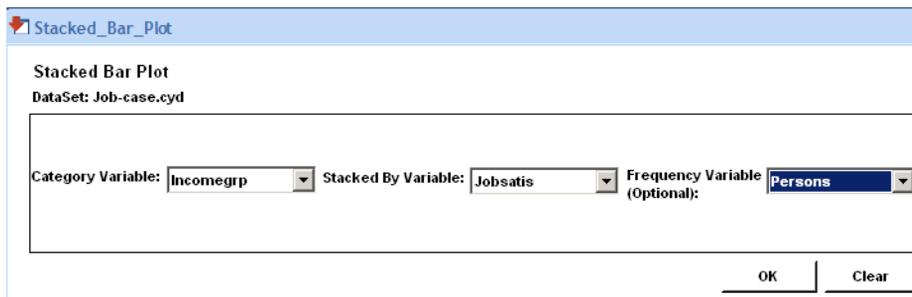

Purpose of Plot :

To generate and display a **Stacked Bar** chart for the variable **Incomegrp** stacked by **Jobsatis** based on the selected dataset.

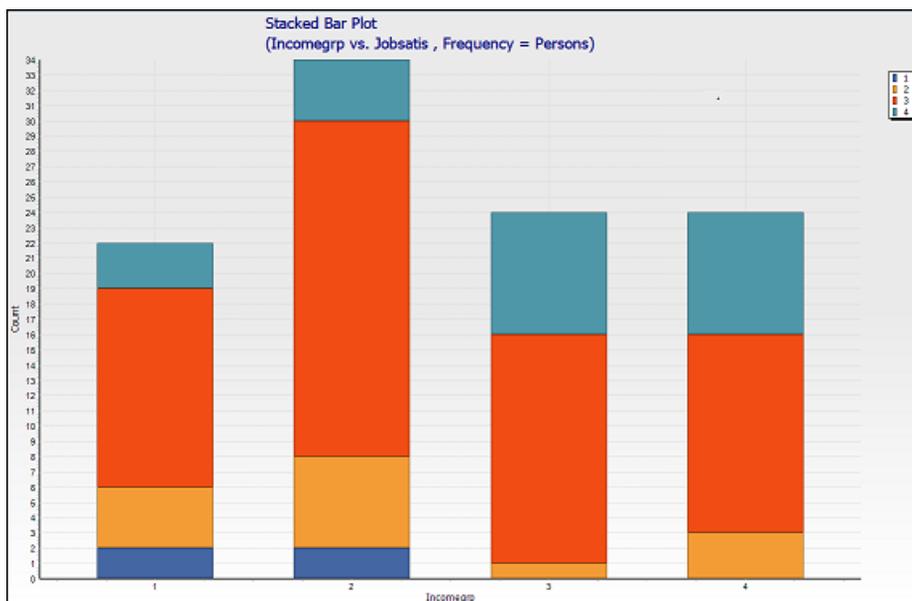

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Categorical > Bar Chart > Stacked Bar
3. In the ensuing dialog box, select **Incomegrp** as the **Category Variable**, **Jobsatis**

as the **Stacked By Variable** and **Persons** as the **Frequency Variable (Optional)**

4. Click **OK**. The following **Stacked Bar** chart is displayed in the main window.

Horizontal Bar

Dataset: Job-Case.cydx as described in Section 72.3.

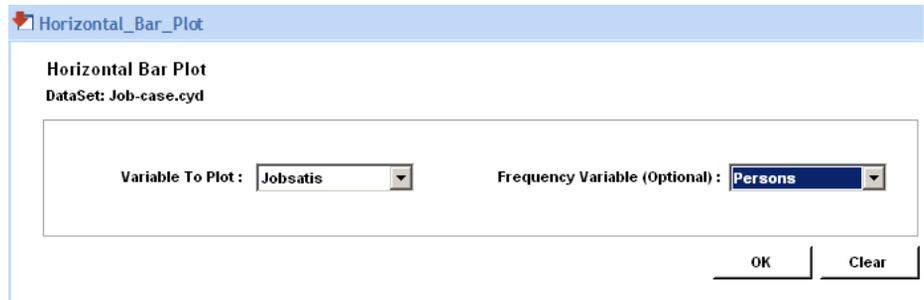

Purpose of Plot :

To generate a **Horizontal Bar** chart for the variable **Jobsatis**.

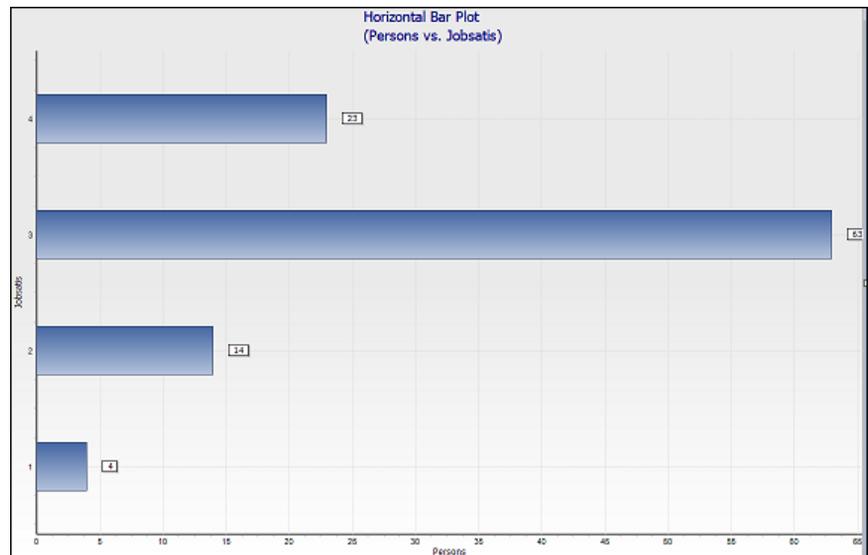

74 Analysis-Plots

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Categorical > Bar Chart > Horizontal Bar
3. In the ensuing dialog box, select **Jobsatis** as the **X axis variable** and **Persons** as the **Frequency Variable (Optional)**.

4. Click **OK**. The following **Horizontal** Bar chart is displayed in the main window.

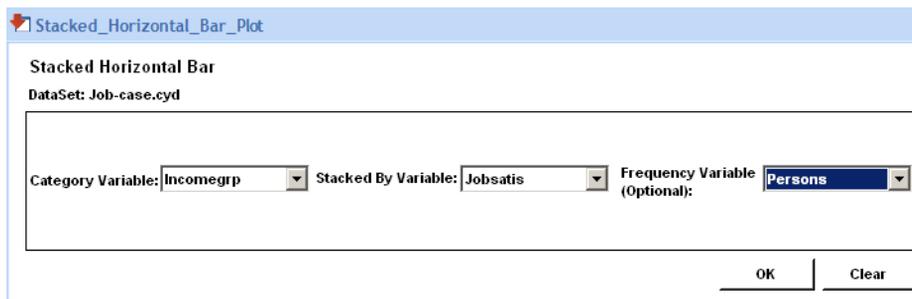

Horizontal Stacked Bar

Dataset: Job-Case.cyx as described in Section 72.3.

Purpose of the Analysis: To generate and display a **Horizontal Stacked Bar** chart for the variable **Incomegrp** stacked by **Jobsatis** based on the selected dataset. . **Steps:**

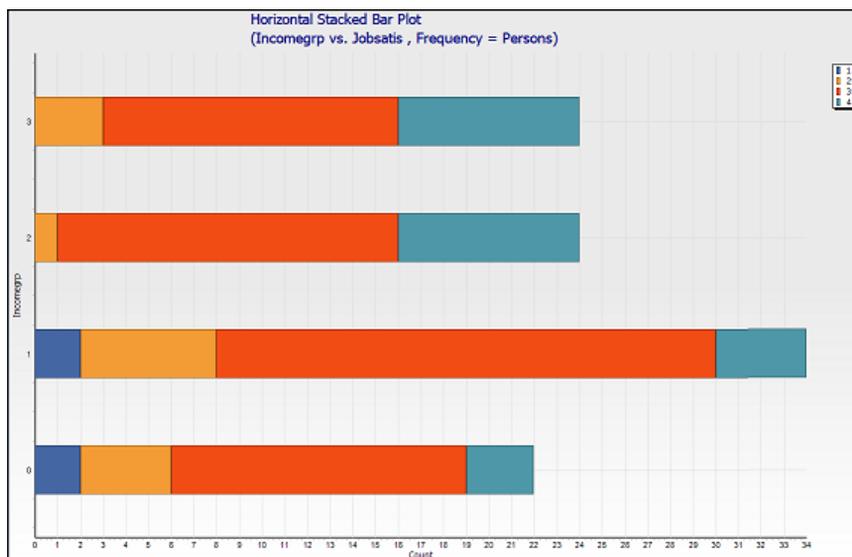

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Categorical > Bar Chart > Horizontal Stacked Bar
3. In the ensuing dialog box, Select **Incomegrp** as the **Category Variable**, **Jobsatis** as the **Stacked By Variable** and **Persons** as the **Frequency Variable (Optional)**.

4. Click **OK**. The following **Horizontal Stacked Bar** chart is displayed in the

74 Analysis-Plots

main window.

74.2.2 Pie chart

Pie provides a circle graph divided into slices, each displaying the frequency of the category of a variable. The size of each slice is proportional to the relative frequency of the values.

Dataset: Socio.cydx

Data Description

This dataset contains measurements on 11 variables. There are 40 subjects in the study. The first 6 variables are concerned with the performance of the subject in the past while the last 5 variables reflect current performance and future plan.

Purpose of Plot :

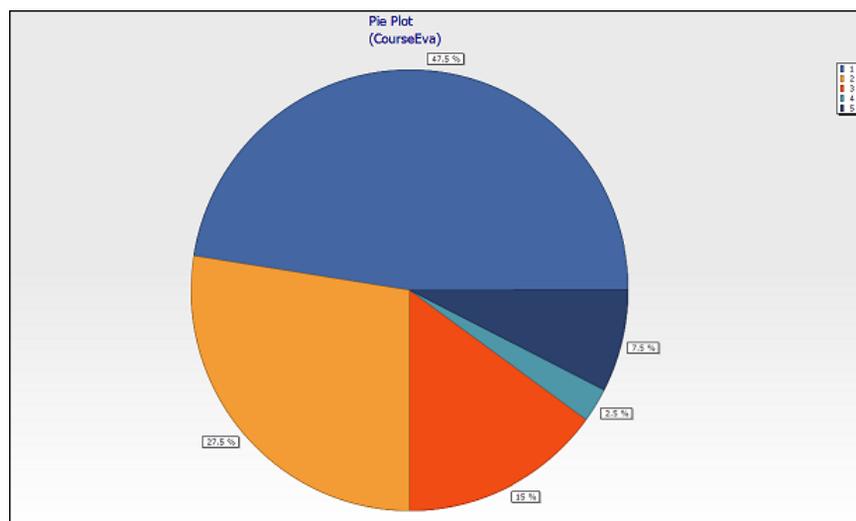

To generate and display a **Pie chart** for the variable **CourseEva**. **Steps:**

1. Open the dataset from **Samples** folder of the **East** Installation directory.
2. Choose the menu item:
Analysis > (Basic Plots) Categorical > Pie Chart
3. In the ensuing dialog box, select **CourseEva** as the **Variable To Plot** and leave

the **Summary Variable (optional)** blank.

4. Click **OK**. The following **Pie chart** is displayed in the main window.

74.3 Continuous

74.3.1 Area

74.3.2 Box

74.3.3 Bubble

74.3.4 Simple Scatter

74.3.5 Normality

74.3.1 Area

Area provides a graphical display of the trend of values of Y variable(s) over categories of an X variable. The display is in the form of shaded area(s) under the curve(s).

74 Analysis-Plots

Dataset: *Myeloma.cydx* as described in Section 72.1.1.

Purpose of Plot :

To generate and display an **Area chart** for the variable **haemoglobin** over **id**.

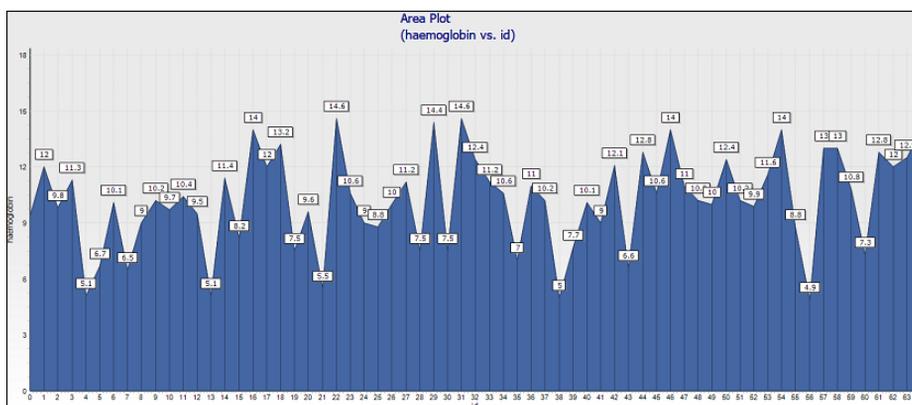

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Continuous > Area
3. In the ensuing dialog box, select **id** as the **Variable To Plot** and **haemoglobin** as the **Frequency Variable (Optional)**.

Area Plot
DataSet: Myeloma.cydx

Variable To Plot : Frequency Variable (Optional) :

4. Click **OK**. The following **Area chart** is displayed in the main window.

74.3.2 Box

Box provides a data display that shows the 25th and 75th percentiles of the data (using the outline of the box), the median value (the large dashed line in the box), the mean value (smaller dashed line), and the largest and smallest data points (endpoints of the

vertical line going through the box).

Dataset: *Myeloma.cydx* as described in Section 72.1.1.

Purpose of Plot :

To generate and display a **Box chart** for the variable **haemoglobin** across different values of **status** based on the selected dataset.

Steps:

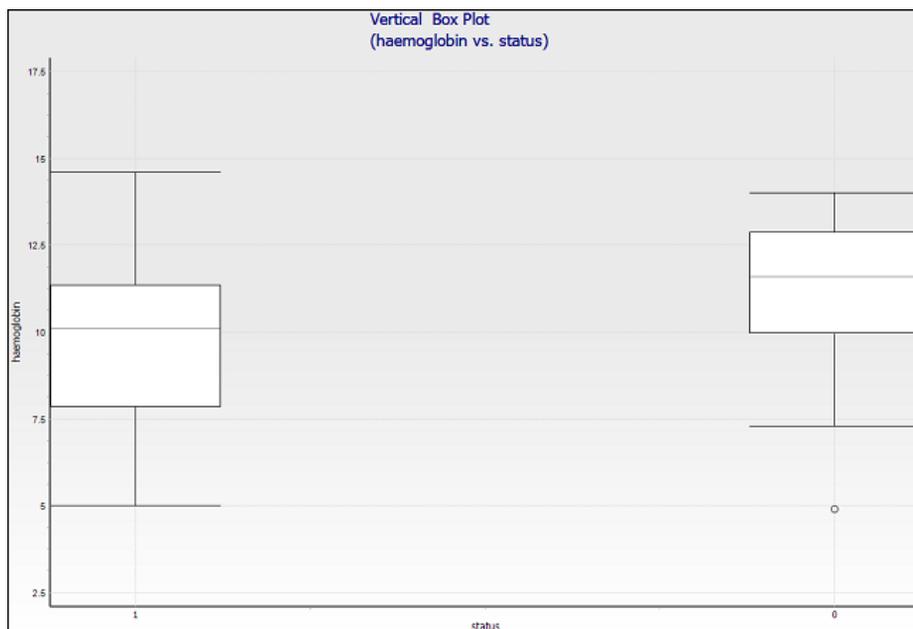

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Continuous > Box
3. In the ensuing dialog box, select **status** as the **Category Axis (optional)** and **haemoglobin** as the **Variable Axis**.

The image shows a dialog box titled "Box Plot" with the following fields and options:

- DataSet:** Myeloma.cydx
- Category Axis (Optional):** status
- Variable Axis:** haemoglobin
- Frequency Variable (Optional):** (empty)
- Vertical Box:**
- Horizontal Box:**

74 Analysis-Plots

4. Click **OK**. The following **Box chart** is displayed in the main window.

74.3.3 Bubble

Bubble provides an X versus Y data display that shows the number of points at a particular x, y value with proportional size bubbles, to allow the user to gauge the relative amounts of information at discrete points.

Dataset: **Myeloma.cydx** as described in Section 72.1.1.

Purpose of Plot:

To generate and display a **Bubble chart** for **status** over **gender** based on the selected dataset.

Steps:

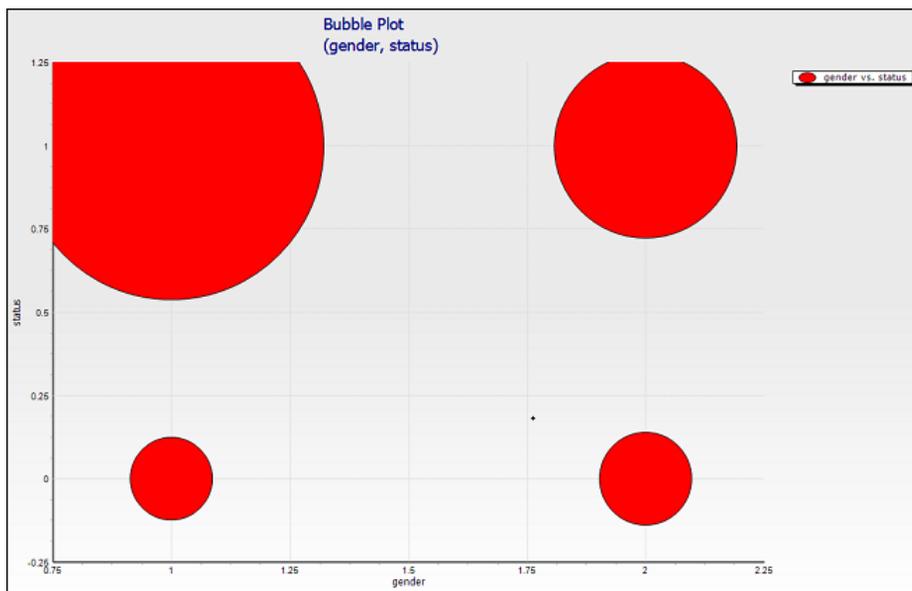

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Continuous > Bubble
3. In the ensuing dialog box, select **gender** as the **Variable on X-Axis** and **status**

as the **Variable on Y-Axis** variable. Leave the **Frequency Variable (optional)** blank.

Bubble Plot
 DataSet: Myeloma.cyd

Variable on X-Axis: Variable on Y-Axis: Frequency Variable: (Optional)

4. Click **OK**. The following **Bubble chart** is displayed in the main window.

74.3.4 Simple Scatter

Simple Scatter provides an X versus Y scatter plot.

Dataset: Myeloma.cydx as described in Section 72.1.1.

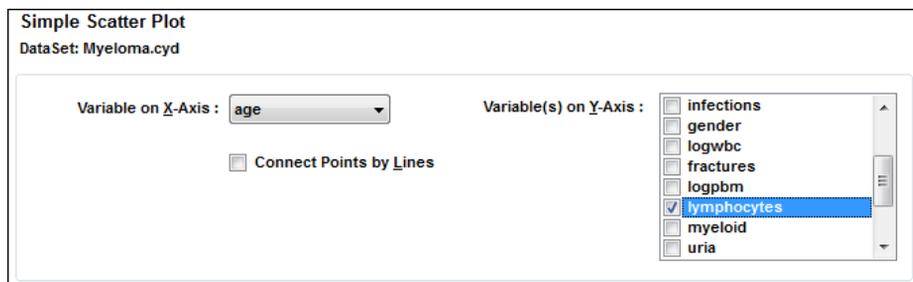

Purpose of Plot :

To generate and display a **Simple Scatter** chart for **lymphocytes** versus **age** based on the selected dataset.

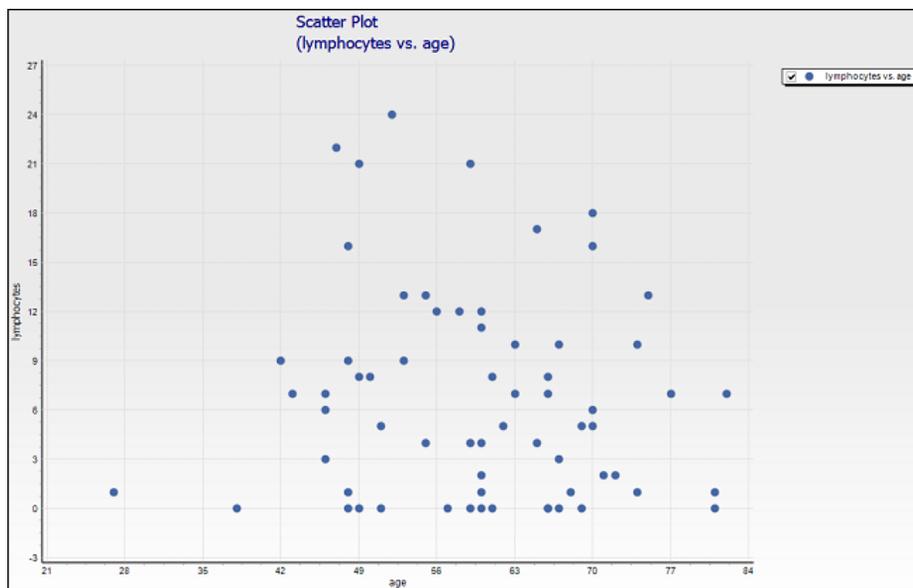

74 Analysis-Plots

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Continuous > Simple Scatter
3. In the ensuing dialog box, select **age** as the **Variable on X-Axis** and **lymphocytes** as the **Variable on Y-Axis**.

4. Click **OK**. The following **Simple Scatter** chart is displayed in the main window.

74.3.5 Normality

PP Normal :

PP Normal provides a probability-probability (P-P) plot to see if the selected variable follows a normal distribution. The X-axis displays the observed cumulative probability and the Y-axis displays the expected cumulative probability. The plot should be approximately linear if the normal distribution is the correct model.

Dataset: **Socio.cydx** as described in Section 74.2.2.

Purpose of Plot :

To generate and display a **PP Normal** chart for the variable **FinalExam** based on the selected dataset.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Continuous > Normality > PP Normal
3. In the ensuing dialog box, select **FinalExam** as the **Variable To Plot**.

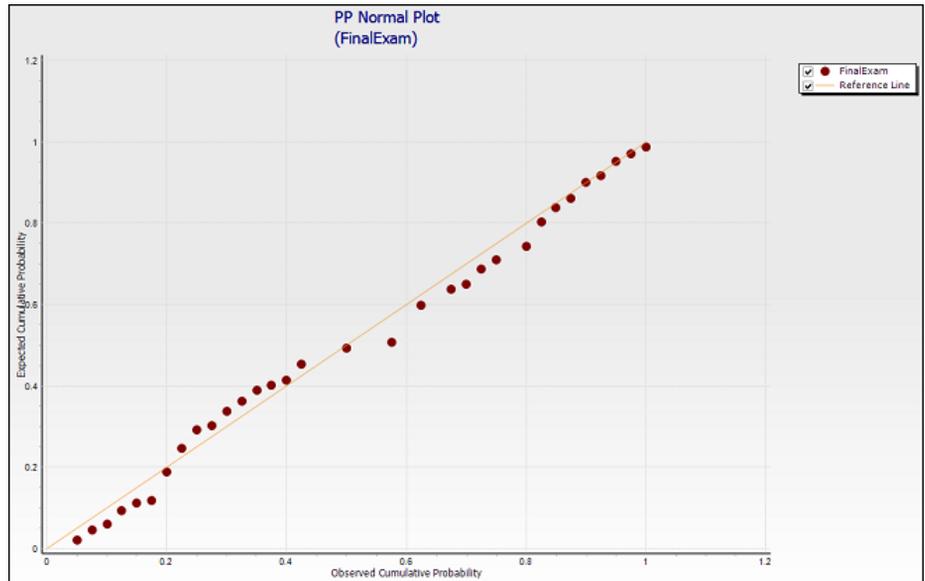

PP-Normal Plot

DataSet: Socio.cyd

Variable To Plot : FinalExam ▼

74 Analysis-Plots

4. Click **OK**. The following **PP Normal** chart is displayed in the main window.

QQ Normal :

QQ Normal provides a quantile-quantile (Q-Q) plot to see if the selected variable follows a normal distribution. The X-axis displays the observed normal value and the Y-axis displays the expected normal value. The plot should be approximately linear if the normal distribution is the correct model.

Dataset: **Socio.cyx** as described in Section 74.2.2.

Purpose of Plot :

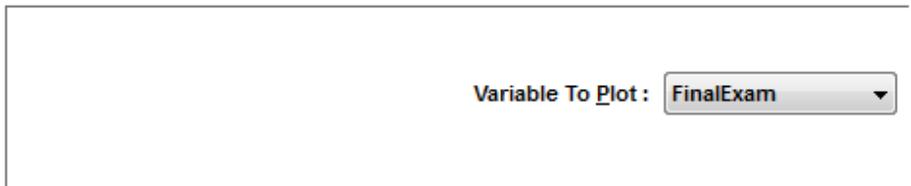

To generate and display a **QQ Normal** chart for the variable **FinalExam** based on the selected dataset.

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Continuous > Normality > QQ Normal
3. In the ensuing dialog box, select **FinalExam** as the **Variable To Plot**.

QQ-Normal Plot

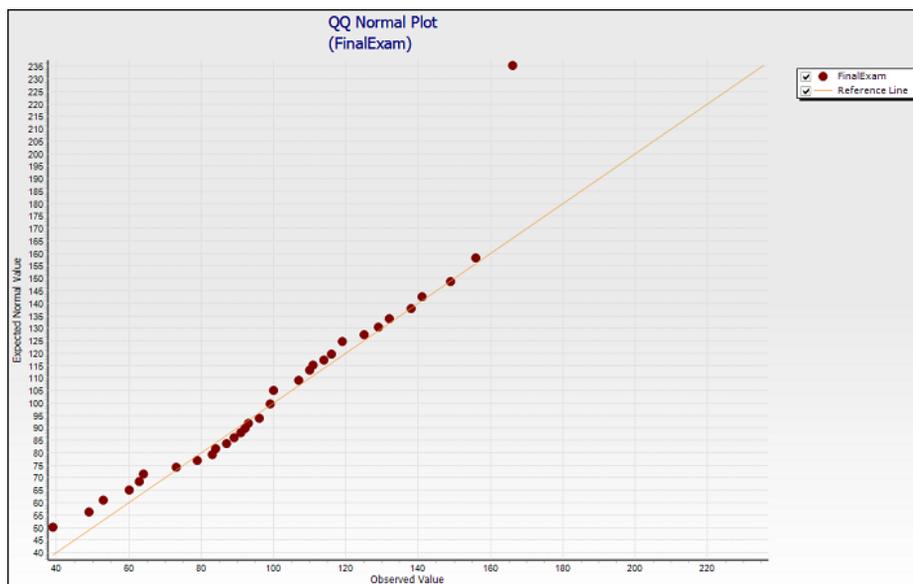

DataSet: **Socio.cyx**

Variable To Plot : FinalExam

74 Analysis-Plots

4. Click **OK**. The following **QQ Normal** chart is displayed in the main window.

74.4 Frequency Distribution

74.4.1 Cumulative Plot

74.4.2 Histogram

74.4.3 Stem and Leaf

74.4.4 Step Function

74.4.1 Cumulative Plot

Left cumulative

A left cumulative frequency plot is a way to display cumulative information graphically. It shows the number of observations that are less than or equal to particular values.

Dataset: Vari.cydx

Data Description:

A randomized clinical trial of Interferon and placebo was conducted on 44 children infected with childhood chicken pox (varicella) (Arvin, et al., 1982). One of the end points of the study was to determine whether Interferon is more effective than placebo in preventing adverse effects.

The dataset has three variables **Group**, **Category** and **Freq**. The **Group** variable

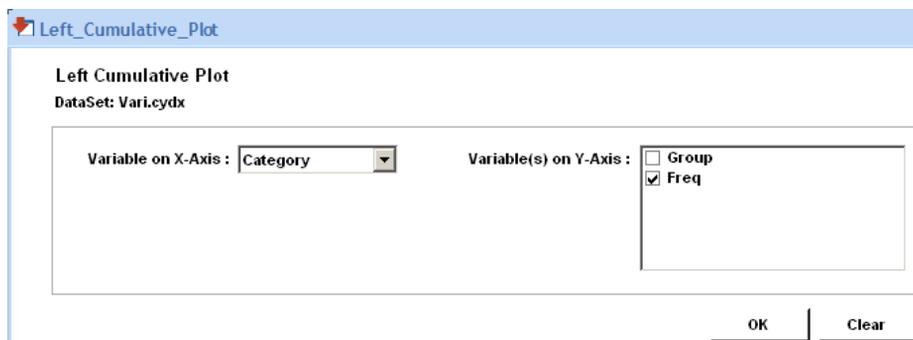

contains values 1 and 2 specifying the two groups **Interferon** and **Placebo**, respectively. The **Category** variable has four categories, representing the adverse effect starting from 'none' to 'death in less than a week' with values from 1 to 4 in increasing order. The number of children falling in each category, by treatment, is available in the variable **Freq**

Purpose of Plot :

To generate and display a **Left Cumulative** chart for **Freq** over the **Category** of adverse effects.

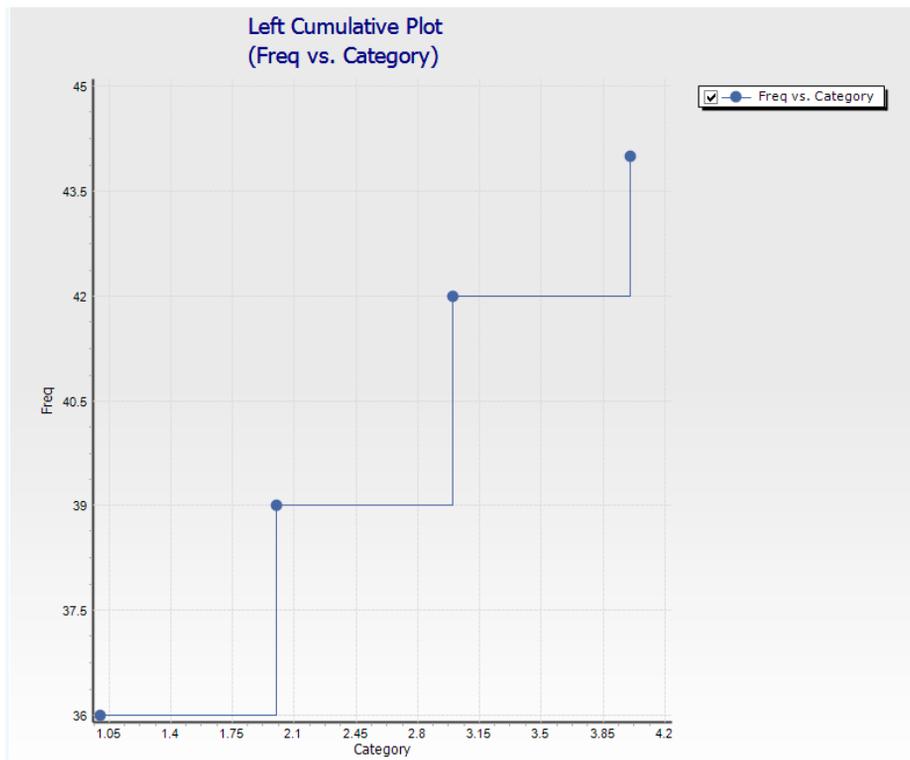

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Frequency Distribution > Cumulative > Left Cumulative
3. In the ensuing dialog box, select **Category** as the **Variable on X-Axis** and **Freq** as the **Variable on Y-Axis**.

74 Analysis-Plots

4. Click **OK**. The following **Left Cumulative** chart is displayed.

Right cumulative

Dataset: **Vari.cydx** as described in Section [74.4.1](#).

Purpose of Plot :

To generate and display a **Right Cumulative** chart for **Freq** over the **Category** of adverse effects.

Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Frequency Distribution > Cumulative > Right Cumulative

3. In the ensuing dialog box, select **Category** as the **variable on X-Axis** and **Freq** as the **Variable on Y-Axis**.

Right_Cumulative_Plot

Right Cumulative Plot
DataSet: Vari.cydx

Variable on X-Axis : Category

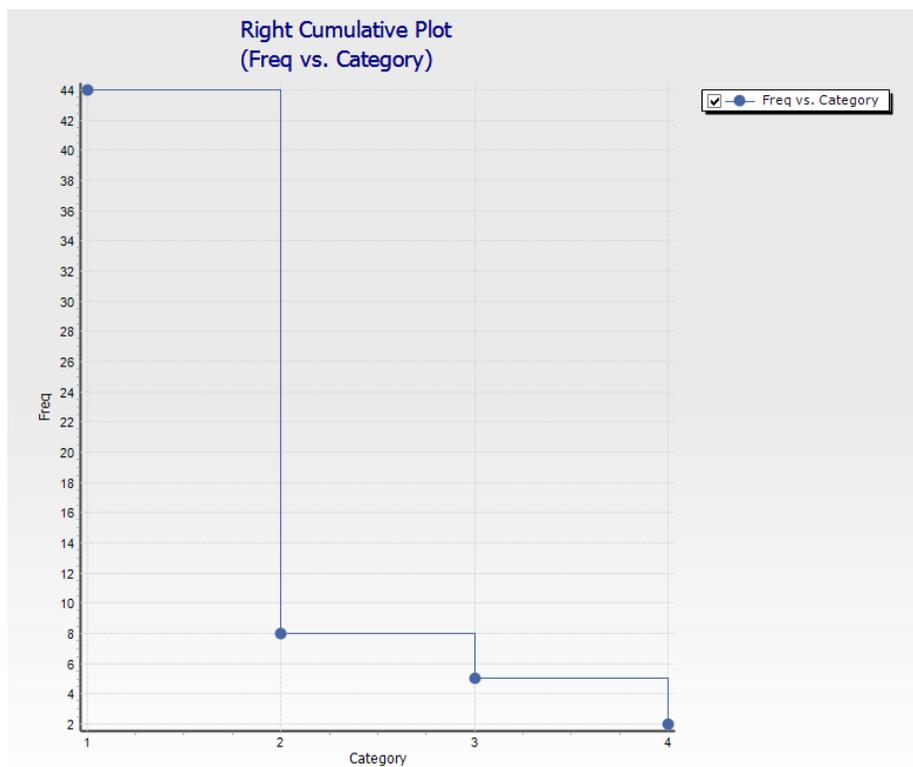

Variable(s) on Y-Axis : Group
 Freq

OK Clear

4. Click **OK**. The following **Right Cumulative** chart is displayed in the main

74 Analysis-Plots

window.

74.4.2 Histogram

Histogram provides a graphical display of the frequencies of the consecutive values of a variable. The display is in the form of contiguous bars, the height of the bars being proportional to the frequency of the values shown on the X-axis.

Dataset: [Myeloma.cydx](#) as described in Section [72.1.1](#).

Purpose of Plot :

To generate and display a **Histogram** chart for **age** based on the selected dataset.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

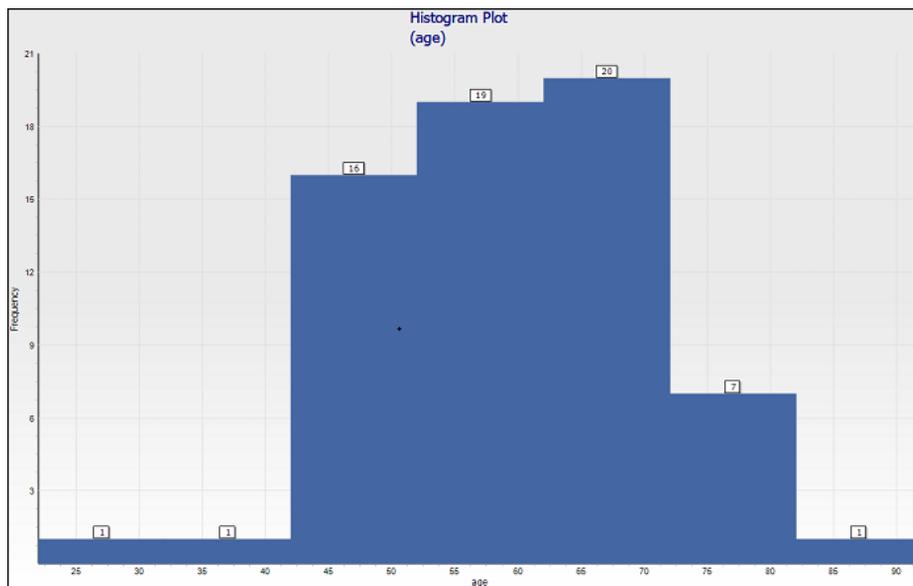

Analysis > (Basic Plots) Frequency Distribution > Histogram

- In the ensuing dialog box, select **age** as the **Variable To Plot**. Leave the **Frequency Variable** blank.

Histogram Plot
DataSet: Myeloma.cyd

Variable To Plot: age Frequency Variable (Optional):

- Click **OK**. The following **Histogram** chart is displayed in the main window.

74.4.3 Stem and Leaf

Stem and Leaf provides a way to form a diagrammatic display of data using data's number themselves.

Dataset: Myeloma.cydx as described in Section 72.1.1.

74 Analysis-Plots

Purpose of Plot :

To generate and display a **Stem and Leaf** chart for haemoglobin.

Steps:

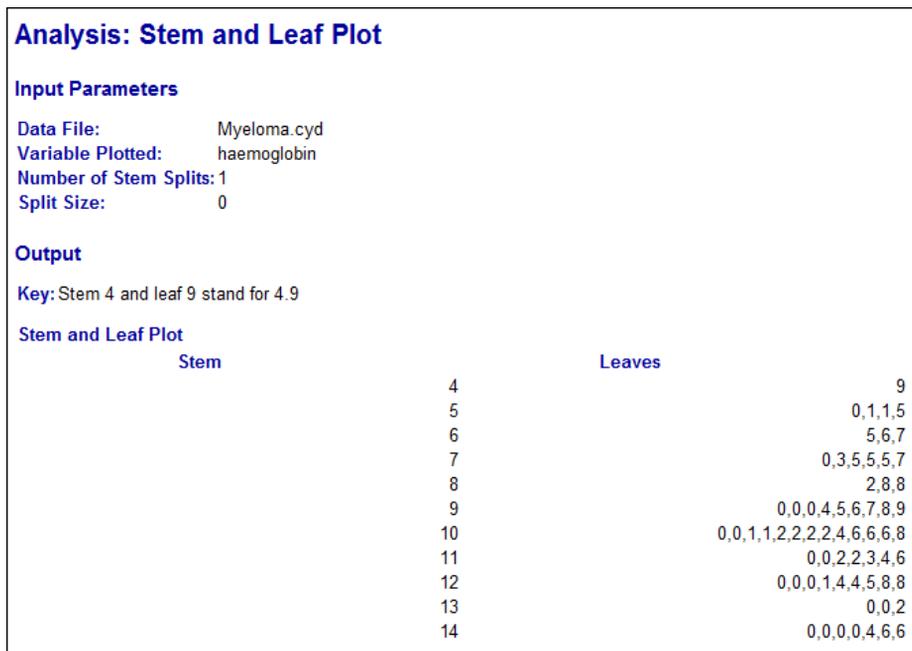

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Frequency Distribution > Stem and Leaf
3. In the ensuing dialog box, select **haemoglobin** as the **Variable To Plot** and 1 as **Number of Stem Splits**. Enter 0 for **Stem Split Size**. Leave the **Frequency Variable (optional)** field blank.

Stem and Leaf Plot
DataSet: Myeloma.cyd

Variable To Plot: Frequency Variable (Optional):

Number Of Stem Splits: 1 2 5 Stem Split Size:

4. Click **OK**. The following **Stem and Leaf** chart is displayed in the main window.

5. Basically it is histogram type of plot, a histogram turned on its side. It resembles right half of a leaf with the stem on the left.

74.4.4 Step Function

Step Function provides a data display for a variable that changes its value at discrete intervals. **Dataset: Survival.cyx**

Purpose of Plot:

To generate and display a **Step Function** chart for the variable **SurvPer** based on the selected dataset.

Steps:

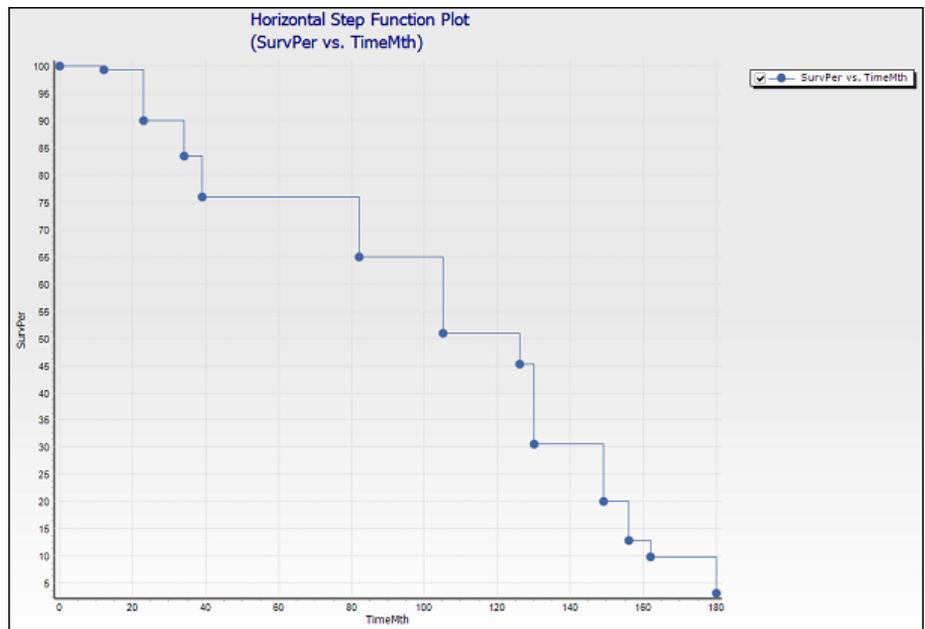

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Basic Plots) Frequency Distribution > Step Function

74 Analysis-Plots

- In the ensuing dialog box, select **TimeMth** as the **Variable on X-Axis** and **SurvPer** as the **Variable on Y-Axis**.

- Click **OK**. The following **Step Function** chart is displayed in the main window.

74.5 Crossover Plots

In this section, we consider data obtained from a 2x2 cross over trial. We also assume that the response measured in each period of the trial has been recorded on a continuous scale. The data may either be in the form of a regular case data in bf East or a Crossover Patients Continuous Data generated using the crossover data editor. Plotting of crossover data helps in understanding the data well and also in getting an idea about the difference in treatment or period effects. Three important plots used specifically for crossover data are described here.

- Period_2 Vs. Period_1 Plot
- Subject Profile Plot
- Treatment-by-Periods Plot

We will first address drawing of these plots using case data related to a 2x2 crossover trial. To generate a crossover plot, open a case data file and then choose from the menu:

Analysis > (Crossover Plots) Subject Plots

Then you can choose any of the three plots, **Period_2 Vs. Period_1 Plot**, **Subject Profile Plot**, **Convex Hull**.

74.5.1 Period_2 Vs. Period_1 Plot

Period_2 Vs. Period_1 Plot provides a scatter plot of points for each patient where the response in period 1 is on X axis and the response in period 2 is taken on Y axis.

Dataset: PEFR.cyd

Data Description:

Data from a single-centre, randomized, placebo-controlled, double-blind study carried out to evaluate the efficacy and safety of an inhaled drug (A) given to patients with chronic obstructive pulmonary disease on mean morning expiratory flow rate (PEFR) compared with a placebo B. In all 56 patients were involved in the study, 27 in the < AB > group who received treatment A in the first period and B in the second and 29 in the < BA > group who received treatment B in the first period and A in the second. The data are taken from Jones and Kenward (1989).

Steps

- Open the data file **PEFR.CYD**.
- Choose the menu item:
Analysis > (Crossover Plots) Subject Plots > Period 2 Vs. Period 1 Plot

74 Analysis-Plots

- In the ensuing dialog box, select **Group_ID** as the **Group ID**, **Period_ID** as **Period ID**, **Patient_ID** as **Subject ID** and **PEFR** as **Response**. The dialog box will now look as shown below.

Period_2_Vs_Period_1_Plot

Period_2 vs. Period_1 Plot
DataSet: PEFR.eyd

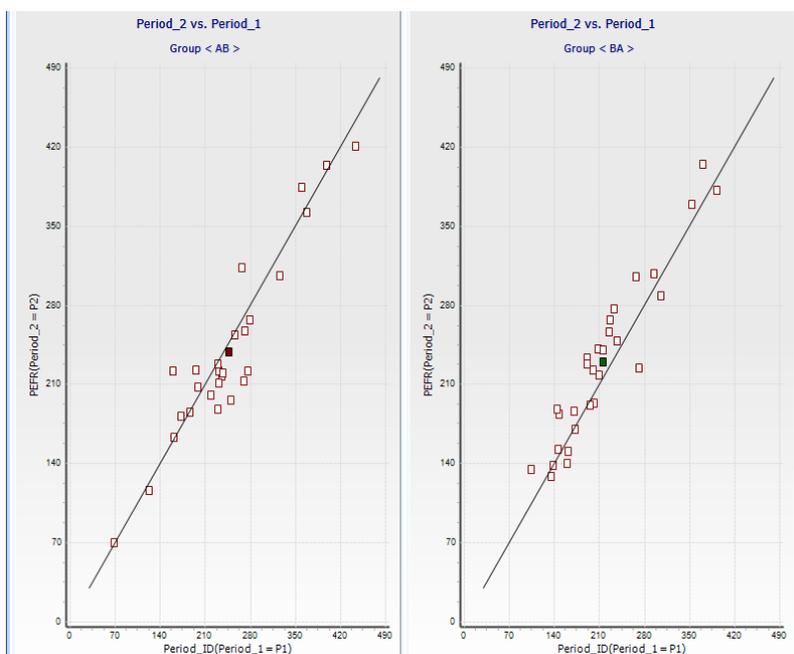

Group ID: Period ID:

Subject ID: Response:

Combine Groups Use Log Transform of Responses

OK Clear

- Click on **OK**. The following graph is produced.

The filled points represent the means of data called 'Centroids'. The line $Y=X$ is a line with slope 1 and intercept 0. Note that there is tendency for the plotted points to be

below the line in Group < AB > and above it in Group < BA >. Thus observations on treatment A tend to be greater than those on the placebo B. This is observed in both the groups. The points for each group are quite spread out, indicating high between-patient variability. We can also see that one of the patients has a very low mean PEFR values. You can take the cursor to the lowest point in Group < AB > and read the values which are (67.778, 70.278). The fact that the points from the two groups are almost symmetrically placed in relation to the diagonal is evidence for the absence of a period effect. To determine evidence for a direct treatment effect, we will plot a combined plot for both the groups. To do this, choose Period_2 Vs. Period_1 Plot from the **Cross Over Plots** menu and select the variables. This time select the check box for **Combined Groups**.

The dialog box will now look as shown below.

Period_2 Vs. Period_1 Plot

Period_2 vs. Period_1 Plot
DataSet: PEFR.cyd

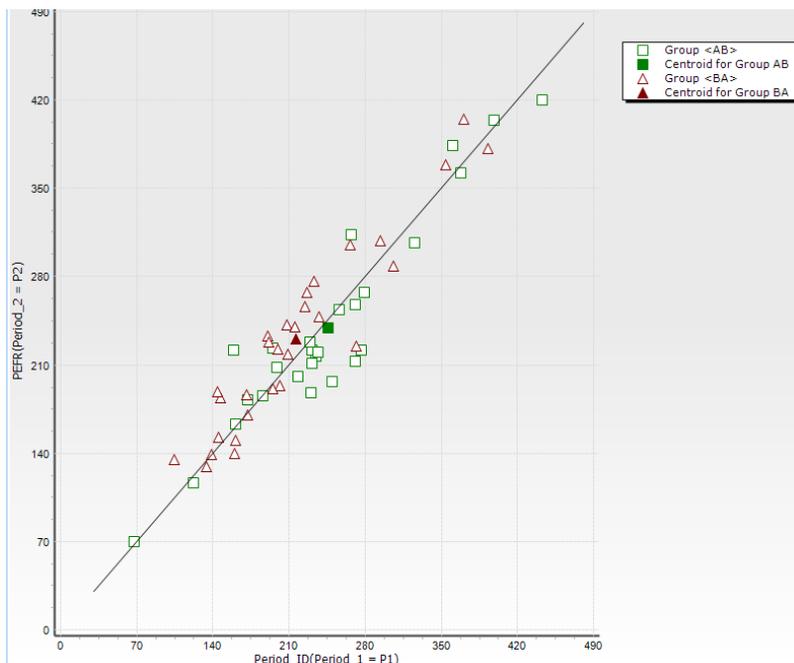

Group ID : Group_ID Period ID : Period_ID
Subject ID : Patient_ID Response : PEFR

Combine Groups Use Log Transform of Responses

OK Clear

74 Analysis-Plots

Click on **OK**. The following graph is produced.

Again, the filled points represent the centroids of the respective groups. The fact that the centroids are placed either side of the line with some vertical separation is evidence of a direct treatment effect.

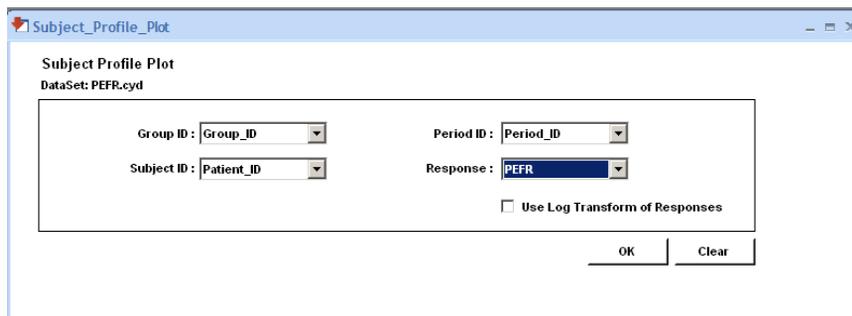

74.5.2 Subject Profile Plot

The objective of a crossover trial is to focus attention on within-patient treatment differences. A good plot for displaying these differences is the subject-profiles plot. In this plot, the change in each patient's response over the two treatment periods is plotted for each group. To draw the Subject Profile Plot, choose the menu item,

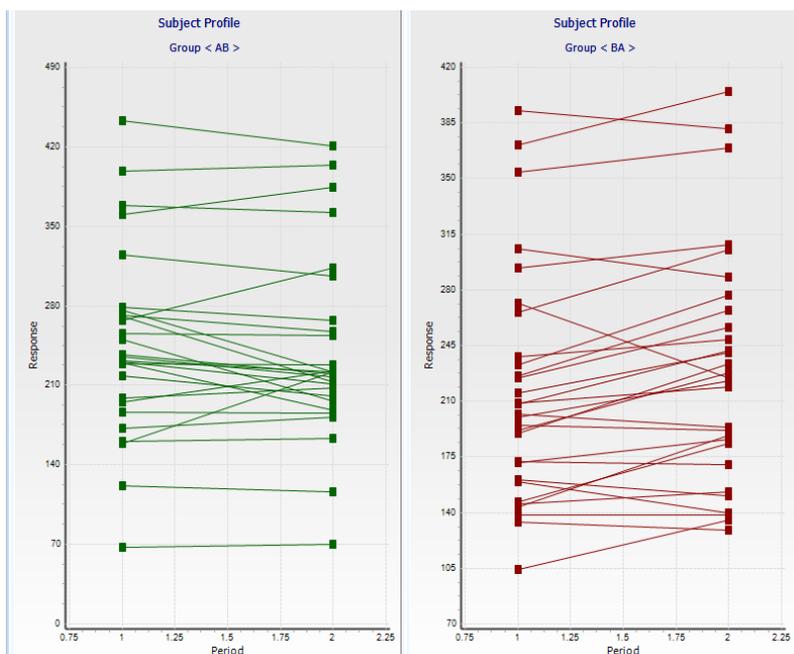

Analysis > (Crossover Plots) Subject Plots > Subject Profile

In the ensuing dialog box, select **Group_ID** as the **Group ID**, **Period_ID** as **Period ID**, **Patient_ID** as **Subject ID** and **PEFR** as **Response**. The dialog box will now

look as shown below.

Click on **OK**. The following graph is produced.

From the Subject Profile plot also the high between-patient variability is noticeable. The within patient changes are generally negative in Group < AB > and positive in Group < BA > with some exceptions. For Group < AB >, the slopes of lines are

74 Analysis-Plots

negative implying higher values for Period 1 where treatment A is applied. For Group $\langle BA \rangle$, the slopes of lines are positive showing higher values for Period 2 where A is applied. Thus the general trend implies a higher value of mean PEFr for treatment A rather than for placebo B. Most of the changes are smaller in magnitude barring some large ones.

74.5.3 Treatment-by-Periods Plot

Both the Period_2 Vs. Period_1 and Subject Profile Plots display values of Response for individual patients. To get the overall idea of the performance of both the treatments in two periods, a graph such as Treatment-by-Periods Plot is used. To draw this plot for the PEFr data:

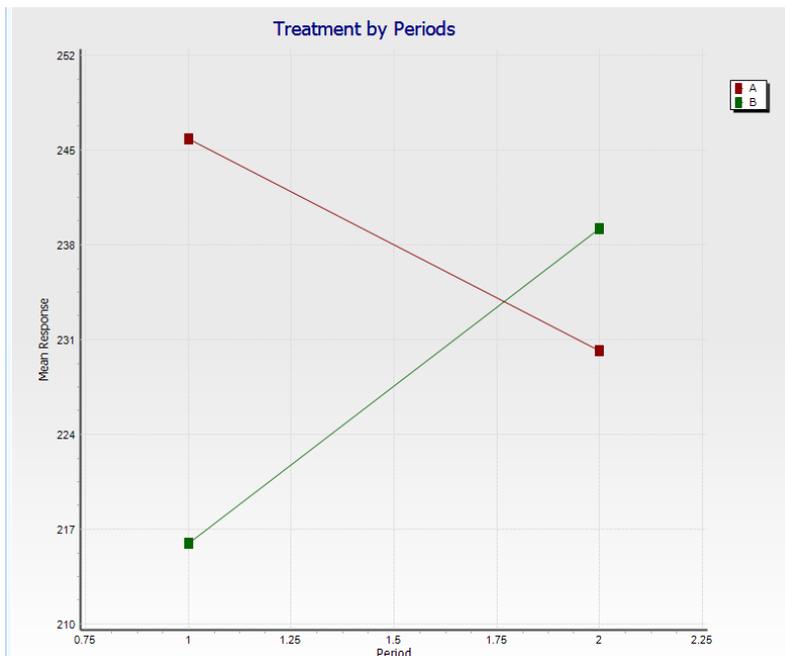

1. Choose from the menu:
Analysis > (Crossover Plots) Summary Plots > Treatment by Periods
2. In the ensuing dialog box, select **Group_ID** as the **Group ID**, **Period_ID** as **Period ID**, **Patient_ID** as **Subject ID** and **PEFR** as **Response**. In the text boxes for Treatment 1 and Treatment 2, type A and B respectively which are the treatments used in the study. The dialog box will now look as shown below.

Treatment_Period_Plot

Treatment by Periods Plot
DataSet: PEFr.cyd

| | | | | |
|---|---|-------------|--|---|
| Group ID : | <input type="text" value="Group_ID"/> | Period ID : | <input type="text" value="Period_ID"/> | Treatment Specifications Treatment 1 ((Group1,Period1) and (Group2,Period2)) <input type="text" value="A"/> Treatment 2 ((Group1,Period2) and (Group2,Period1)) <input type="text" value="B"/> |
| Subject ID : | <input type="text" value="Patient_ID"/> | Response : | <input type="text" value="PEFR"/> | |
| <input type="checkbox"/> Use Log Transform of Responses | | | | <input type="button" value="OK"/> <input type="button" value="Clear"/> |

3. Click on **OK**. The following graph is produced.

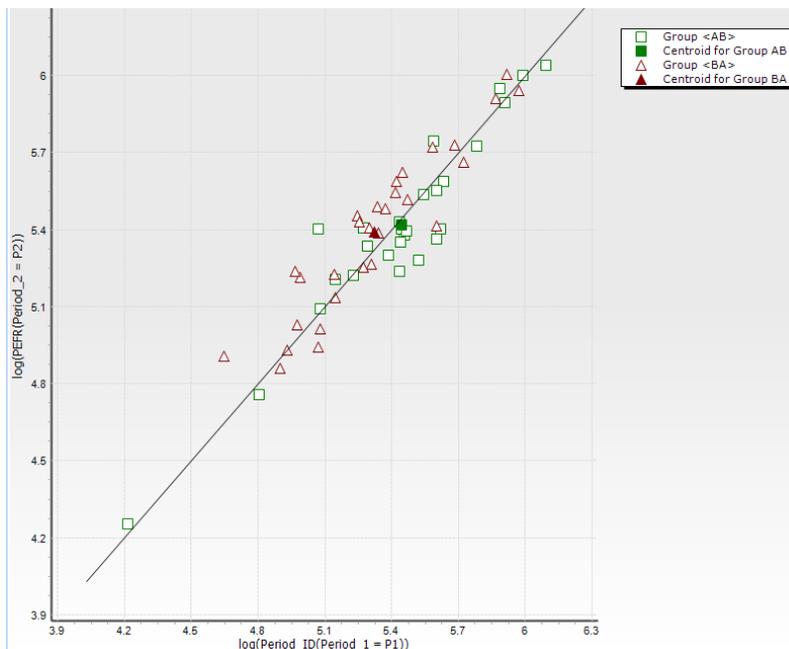

The points plotted are the means of the Response variable PEFR for Treatment and Period combination. As shown in the legend by the side of the plot, the lines join means for respective treatments for Period 1 and Period 2. If a cursor is taken to any of the points, it shows the label **Group ID** as well as the value of mean response for the corresponding treatment-by-period combination. Since no line is completely above the other, neither treatment gives higher mean response in both periods and the observed difference in means is smaller in the second period compared to the first. In Period 1, the difference is 29.847 whereas in Period 2 it is -9.041. To test whether this difference is statistically significant or not, the user is referred to the **Period Effect** test from the Crossover menu. All the above three plots could be drawn on log scale by checking the decision box for **'Use log(Response)'**. The response values are transformed to $\log(\text{Response})$ where natural logarithm of Response is plotted.

4. For instance, suppose we want to draw the Period_2 Vs. Period_1 Plot on log scale for the PEFR data, then choose from menu:
Analysis > (Crossover Plots) Subject Plots > Period 2 Vs. Period 1 Plot
5. In the ensuing dialog box, select **Group_ID** as the **Group ID**, **Period_ID** as **Period ID**, **Patient_ID** as **Subject ID** and **PEFR** as **Response**. Check

74 Analysis-Plots

the decision box for 'Use log(Response)' as well as for '**Combine Groups**'. Click on **OK**. The following graph is produced.

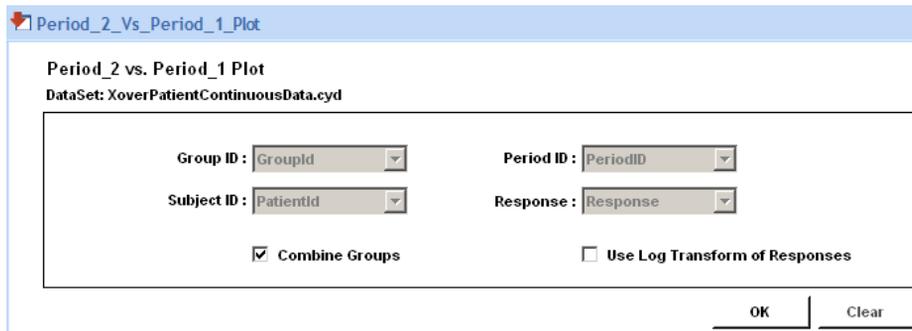

74.5.4 Crossover Plots using Crossover Patients Continuous Data

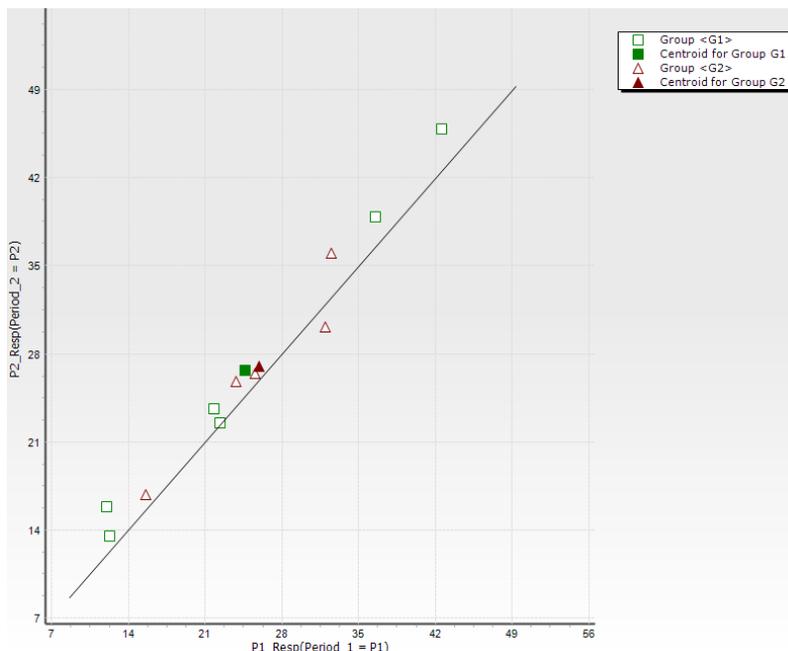

All the above graphs can be drawn on the crossover patients **continuous** data created by cross over data editor. To see this,

1. Open the data file, **XoverPatientContinuousData.cyd** available in the **Samples** directory of the Crossover installation directory.
2. Now choose the menu item:
Analysis > (Crossover Plots) Subject Plots > Period 2 Vs. Period 1 Plot

You will be presented with the following dialog box.

3. Check for **Combine Groups** as shown in the dialog box and click **OK**. The following graph is produced.

Note that when you are drawing these plots using Cross over Data editor, there is no need to select the variables etc, as they will be internally selected and the called plot will be drawn. For example, if you go in for the Subject Profile Plot on the same data,

74 Analysis-Plots

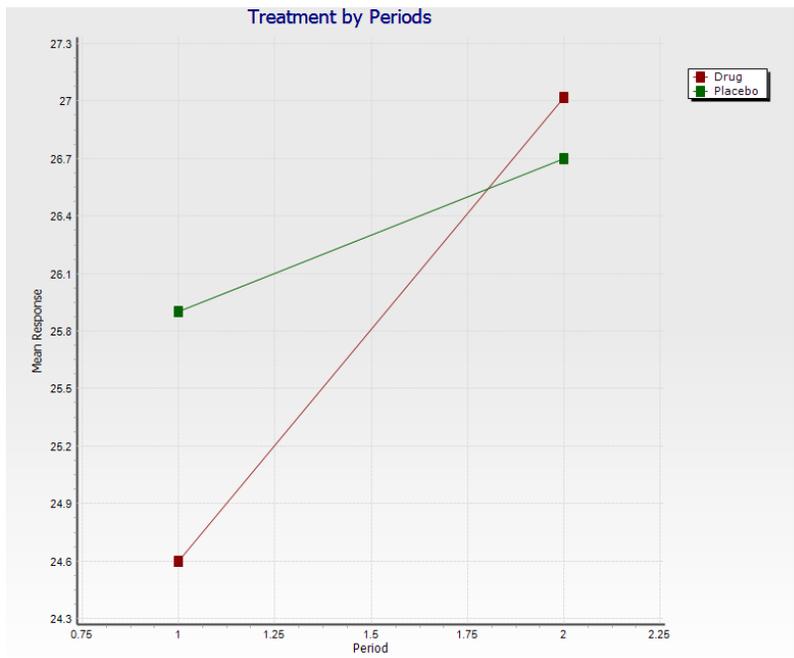

you will receive the dialog box as follows:

If you check **Use Log Transform of Responses**, the plot will be drawn on the log scale, otherwise on the original scale of the response variable. Similarly, the dialog box you get when you attempt to draw the **Treatment-by-Periods Plot** will be as follows:

| | PatientId | GroupId | P1_Resp | P2_Resp | var | var | var | var |
|----|-----------|---------|---------|---------|-----|-----|-----|-----|
| 1 | P1 | G1 | 12.3 | 13.5 | | | | |
| 2 | P3 | G1 | 12 | 15.8 | | | | |
| 3 | P5 | G1 | 36.5 | 38.9 | | | | |
| 4 | P7 | G1 | 21.8 | 23.6 | | | | |
| 5 | P9 | G1 | 22.4 | 22.5 | | | | |
| 6 | P11 | G1 | 42.6 | 45.9 | | | | |
| 7 | P2 | G2 | 15.6 | 16.8 | | | | |
| 8 | P4 | G2 | 25.6 | 26.4 | | | | |
| 9 | P6 | G2 | 23.8 | 25.8 | | | | |
| 10 | P8 | G2 | 32.5 | 36 | | | | |
| 11 | P10 | G2 | 32 | 30.1 | | | | |
| 12 | | | | | | | | |

You may specify the Treatment specifications of your choice such as **Drug** and **Placebo**, as is shown in the above dialog box. The plot will then have these

specifications in the legend as shown below:

If suppose the treatments are not specified in the text boxes provided in the dialog box, then the plot will have the default **Treatment 1** and **Treatment 2** specifications in the legend.

75 *Analysis-Normal Superiority One-Sample*

This chapter demonstrates how **East** can be used to perform inferences on data collected from a single-sample superiority study. This may consist of a random sample of observations from either a single treatment or paired observations from two treatments.

In chapter 7, the design, simulation and interim monitoring of these types of trials are discussed with reference to a Single Mean Test, a Test for the Difference of Paired Means and a Test for the Ratio of Paired Means.

East supports the analysis of all of these tests as well as the Wilcoxon Signed Rank Test. They are accessible from the **Analysis** menu and allow the validation of whether the data supports the null or alternative hypothesis of the study.

Analysis of a Single Mean Superiority Test is discussed in section 75.1, while the Two Paired Tests are discussed in section 75.2 and 75.3, respectively. Finally, the analysis of the non-parametric Wilcoxon Test is discussed in section 75.4.

75.1 *Example: Single Mean*

Consider the problem of comparing the mean of the distribution of observations from a single random sample to a specified constant. For example, when developing a new drug for treatment of a disease, there should be evidence of efficacy. In this example, the effect of a drug on children with mental retardation and ADHD is demonstrated.

For the single-sample problem, it may be desirable to compare the unknown mean response μ_t to a fixed value μ_0 . The null hypothesis $H_0: \mu_t = \mu_0$ is tested against either the two-sided alternative hypothesis $H_1: \mu_t \neq \mu_0$ or a one-sided alternative hypothesis $H_1: \mu_t < \mu_0$ or $H_1: \mu_t > \mu_0$.

Dataset: Methylphenidate.cyx

Data Description:

A trial was conducted to study the effect of Methylphenidate on cognitive functioning in children with mental retardation and ADHD. For the study details, refer to Pearson et al. (2003). For the twenty four children studied, the mean number of correct responses was observed for those receiving treatment (0.60 mg/kg of Methylphenidate) as well as those on placebo.

The first column of the dataset **D0** displays the number of correct responses after placebo, the second column **D60** shows the correct number of responses after

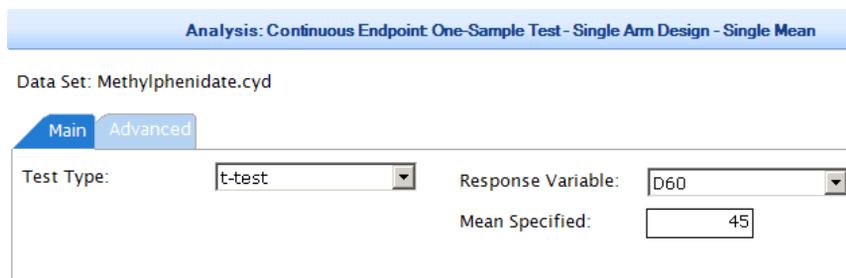

treatment (0.60 mg/kg of Methylphenidate), and the third column **diff** is the difference of the two measures.

Purpose of the Analysis:

To test whether the mean number of correct responses of children receiving treatment (0.60 mg/kg of Methylphenidate) is at least 45.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) One Sample > (Single Arm Design) Single Mean
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

4. Click **OK**. You will see the Analysis results as shown below.

Analysis: Continuous Response: Single Mean

Hypothesis

$H_0 : \mu_t = \mu_0$ Vs. $H_1 : \mu_t \neq \mu_0$ for 2-sided test

Either $H_1 : \mu_t > \mu_0$

Or $H_1 : \mu_t < \mu_0$ for 1-sided test

Input Parameters

Data File: Methylphenidate.cyd

Response Variable: D60

Test Type: t-test

Mean Specified: 45

Confidence Level: 0.95

75 Analysis-Normal Superiority One-Sample

Output

Response variable: D60
 Total no. of records: 24
 No. of records rejected: 0
 Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|-----|-----|--------|--------|---------|----|
| D60 | 29 | 77 | 42.5 | 44.708 | 12.32 | 24 |

Test of Hypothesis:

| n | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | | 95% Confidence Interval(2-Sided) | |
|----|------------------|------------|--------|----|---------|------|---------|-------------|----------------------------------|--|
| | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 24 | -0.024 | 2.515 | -0.116 | 23 | 0.454 | L.E. | 0.909 | 39.506 | 49.911 | |

For this analysis, **East** displays the p-value associated with a left-tailed test because the observed sample mean is smaller than μ_0 . The two-sided 95% confidence interval is (39.506, 49.911). The lower limit is smaller than $\mu_0 = 45$, therefore $H_0: \mu_t \leq 45$ cannot be rejected in favor of $H_1: \mu_t > 45$ at one-sided 0.025 level of significance. The computed p-values also support this conclusion.

75.2 Example: Mean of Paired Differences

The paired t-test is often used to compare the means of two normal distributions. Here each observation from a random sample in one distribution is matched with a unique observation from the other distribution. A common application of this is when treatments are compared by using subjects who are matched using demographic and baseline characteristics. Another application is when two separate observations are made from the same subject under different experimental conditions, which will be the focus of the next example. **Dataset: Methylphenidate.cydx** as described in Section 75.1

Purpose of the Analysis:

To test the efficacy of Methylphenidate on cognitive functioning in children with mental retardation and ADHD. Let μ_0 and μ_t denote the mean number of correct responses under placebo and treatment, respectively, and $\delta = \mu_t - \mu_0$. A positive value of δ suggests efficacy of the treatment. Test the null hypothesis $H_0: \delta \leq 0$ against the alternative $H_1: \delta > 0$.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) One Sample > (Paired Design) Mean of Paired

Differences

- In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

- Click **OK**. You will see the Analysis results as shown below.

Analysis: Continuous Response: Difference of Means for Paired Data

Hypothesis
 $H_0: \mu_t - \mu_c = 0$ Vs. $H_1: \mu_t - \mu_c \neq 0$ for 2-sided test
 Either $H_1: \mu_t - \mu_c < 0$
 Or $H_1: \mu_t - \mu_c > 0$ for 1-sided test

Input Parameters
 Data File: Methylphenidate.cyd
 Trial Type: Superiority
 Response Control: D0
 Response Treatment: D60
 Test Type: t-test
 Confidence Level: 0.95

Output
 Response variable: (D60-D0)
 Total no. of records: 24
 No. of records rejected: 0

Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|-----|-----|--------|--------|---------|----|
| D0 | 26 | 71 | 36 | 39.75 | 11.315 | 24 |
| D60 | 29 | 77 | 42.5 | 44.708 | 12.32 | 24 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-------|----|---------|------|---------|-------------|----------------------------------|--|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 24 | 4.958 | 0.658 | 1.539 | 3.222 | 23 | 0.002 | G.E. | 0.004 | 1.775 | 8.141 | |

The two-sided 95% confidence interval is (1.775, 8.141), which does not include 0. The one sided p-value is 0.002 which supports this conclusion. Therefore, for this

75 Analysis-Normal Superiority One-Sample

example, it is reasonable to conclude that the use of Methylphenidate significantly increases mean number of correct responses as compared to placebo.

75.3 Example: Ratio of Paired Differences

The ratio of paired differences test is used to compare the means of two log normal distributions when each observation in the random sample from one distribution is matched with a unique observation from the other distribution. As with the previous example illustrating the mean of paired differences, a common application is when two observations are made from the same subject under different experimental conditions. Another is when treatments are compared using subjects who are matched by demographic and baseline characteristics, which will be the focus of the next example.

East is used to perform a log transformation on the original data, and a ratio of paired differences test on the log-transformed data.

Dataset: `Methylphenidate.cyx` as described in Section 75.1

Purpose of the Analysis:

To test the efficacy of Methylphenidate on cognitive functioning in children with mental retardation and ADHD. Define $\rho = \frac{\mu_t}{\mu_c}$. A value of $\rho > 1$ suggests efficacy of the treatment. Test the null hypothesis $H_0: \rho = 1$ against the alternative $H_1: \rho > 1$.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) One Sample > (Paired Design) Mean of Paired Ratios
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown

below.

Analysis: Continuous Endpoint One-Sample Test - Paired Design - Mean of Paired Ratios

Data Set: Methylphenidate.cyd

Main Advanced

Trial Type: Superiority Use Ratio

Test Type: t-test Response Control: D0

Response Treatment: D60

4. Click **OK**. You will see the Analysis results as shown below.

Analysis: Continuous Response: Ratio of Means for Paired Data

Hypothesis

$H_0 : \mu_1 / \mu_2 = 1$ Vs. $H_1 : \mu_1 / \mu_2 \neq 1$ for 2-Sided test
 Either $H_1 : \mu_1 / \mu_2 < 1$
 Or $H_1 : \mu_1 / \mu_2 > 1$ for 1-Sided test

Input Parameters

Data File: Methylphenidate.cyd
 Trial Type: Superiority
 Response Control: D0
 Response Treatment: D60
 Test Type: t-test
 Confidence Level: 0.95

Response Variable: (D60/D0)
 Total Number of Records: 24
 Number of Records Rejected: 0

Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|-----|-----|--------|--------|---------|----|
| D0 | 26 | 71 | 36 | 39.75 | 11.315 | 24 |
| D60 | 29 | 77 | 42.5 | 44.708 | 12.32 | 24 |

Test of Hypothesis for: ln(D60/D0)

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided |
|----|---------------------|------------------|------------|-------|----|---------|------|---------|
| | | | | | | p-value | Tail | p-value |
| 24 | 0.118 | 0.611 | 0.039 | 2.991 | 23 | 0.003 | G.E. | 0.007 |

Parameter Estimates:

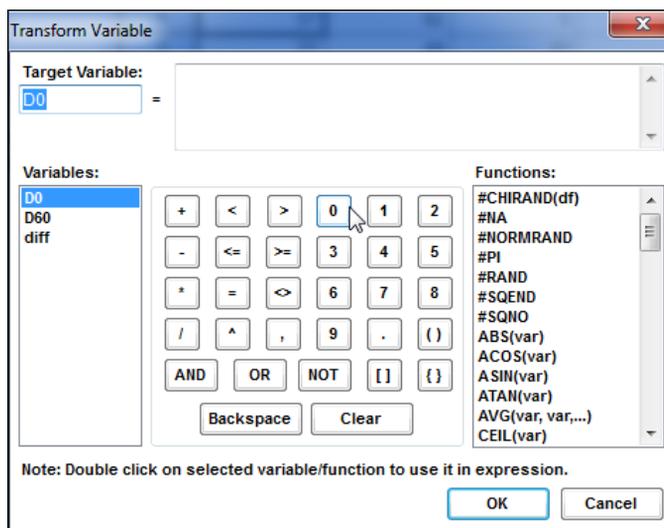

| Metric | Estimate | Std. Error | 95% Confidence Interval(2-Sided) | |
|------------|----------|------------|----------------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| ln (Ratio) | 0.118 | 0.039 | 0.036 | 0.199 |
| Ratio | 1.125 | 0.044 | 1.037 | 1.221 |

The observed value of test statistic is $t = 2.991$ and has $24 - 1 = 23$ degrees of freedom. The two-sided 95% confidence interval for $\ln(\rho)$ is (0.036, 0.199),

75 Analysis-Normal Superiority One-Sample

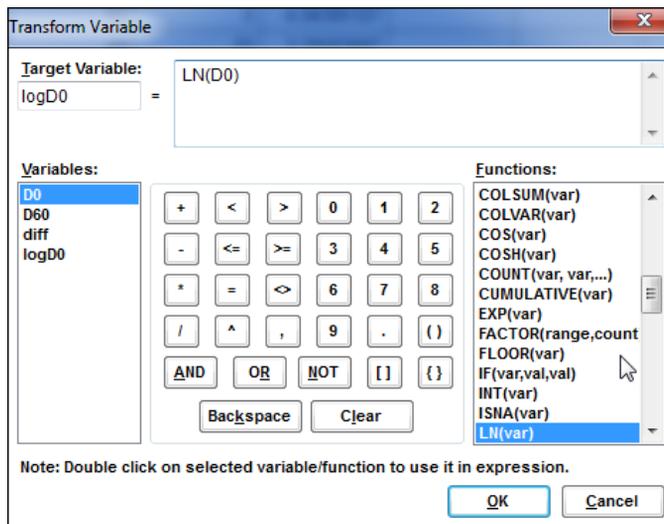

does not include 0, nor does the confidence interval for ρ (1.037, 1.221) contain 1. Therefore, $H_0: \rho = 1$ should be rejected in favor of $H_1: \rho \neq 1$, and the associated p-value of 0.007 supports this conclusion. The p-value for the one-sided test $H_0: \rho \leq 1$ versus $H_1: \rho > 1$ is 0.003. Again, for this example, it is reasonable to conclude that the use of Methylphenidate significantly increases mean number of correct responses as compared to placebo.

- Alternatively, a new log-transformed variable can be created directly in the dataset. Double click on **Methylphenidate.cyd** in the **Library** to display the data in the main window. Under the **Data Editor** tab, click the  icon in the **Variable** ribbon.

- Enter **logD0** in the **Target Variable** field. Type **LN(D0)** into the empty field on the right side of the equation, or select **D0** from the **Variables** list and **LN(var)**

from the **Functions** list:

7. Clicking **OK** will add a new column labeled `logD0` to the dataset. This contains log-transformed values of the entries in the `D0` column. In a similar manner, create a new variable `logD60` by transforming `D60` and perform a paired t-test

75 Analysis-Normal Superiority One-Sample

using logD0 and logD60.

Analysis: Continuous Response: Difference of Means for Paired Data

Hypothesis
 $H_0: \mu_t - \mu_c = 0$ Vs. $H_1: \mu_t - \mu_c \neq 0$ for 2-sided test
 Either $H_1: \mu_t - \mu_c < 0$
 Or $H_1: \mu_t - \mu_c > 0$ for 1-sided test

Input Parameters
 Data File: Methylphenidate.cyd
 Trial Type: Superiority
 Response Control: logD0
 Response Treatment: logD60
 Test Type: t-test
 Confidence Level: 0.95

Output
 Response variable: (logD60-logD0)
 Total no. of records: 24
 No. of records rejected: 0
 Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|-------|-------|--------|-------|---------|----|
| logD0 | 3.258 | 4.263 | 3.584 | 3.648 | 0.26 | 24 |
| logD60 | 3.367 | 4.344 | 3.749 | 3.766 | 0.263 | 24 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-------|----|---------|------|---------|-------------|----------------------------------|--|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 24 | 0.118 | 0.611 | 0.039 | 2.991 | 23 | 0.003 | G.E. | 0.007 | 0.036 | 0.199 | |

Notice that the value of observed test statistic and the p-values are identical with those from the test for the ratio of means for paired data. In **East**, this test is equivalent to the paired t-test for log-transformed data.

75.4 Example: Wilcoxon Signed Rank Test

The non-parametric Wilcoxon signed rank test compares the median of the difference of two paired random variables. This test is equivalent to a nonparametric version of the paired t-test, and is preferred when the distribution of data deviates from normal.

Dataset: Methylphenidate.cydx as described in Section 75.1.

Purpose of the Analysis:

To test the null hypothesis $H_0: \lambda \leq 0$ against the alternative $H_1: \lambda > 0$ where λ is the median value of the paired difference. A positive value for λ suggests efficacy of the treatment.

Analysis Steps:

1. Open the dataset from **Samples** folder.

2. Choose the menu item:
Analysis > (Continuous) One Sample > (Paired Design) Wilcoxon Signed Rank
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

Continuous Endpoint: One-Sample Test - Paired Design - Wilcoxon Signed Rank

Data Set: Methylphenidate.cyd

Main Advanced

Trial Type: Superiority Use Diff. Variable

Response Control: D0

Response Treatment: D60

75 Analysis-Normal Superiority One-Sample

4. Click **OK**. You will see the Analysis results as shown below.

Analysis: Continuous Response: Wilcoxon Signed Rank Test

Hypothesis
 $H_0: \lambda = 0$ Vs. Either $H_1: \lambda > 0$ Or $H'_1: \lambda < 0$ for 2-sided test
 $H_0: \lambda = 0$ Vs. $H_1: \lambda > 0$ and $H'_1: \lambda < 0$ for 1-sided test
 where λ is the median of (Treatment Response – Control response.)

Input Parameters

Data File: Methylphenidate.cyd
 First Response: D0
 Second Response: D60
 Confidence Level: 0.95

Output

Response Variable: (D60-D0)
 Total Number of Records: 24
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|-----|------|--------|--------|---------|----|
| 26 | 71 | 36 | 39.75 | 11.315 | | 24 |
| 29 | 77 | 42.5 | 44.708 | 12.32 | | 24 |

Summary of Test Statistic:

| Minimum | Maximum | Mean | Std. dev. | Observed Statistics | Standardized |
|---------|---------|------|-----------|---------------------|--------------|
| 0 | 300 | 150 | 34.975 | 251.5 | 2.902 |

Test of Hypothesis:

| Estimate of Median Difference | Standardized Statistic | (1 Sided) | | (2 Sided) | 95% Confidence Interval(2-Sided)* | |
|-------------------------------|------------------------|-----------|---------|-----------|-----------------------------------|-------------|
| | | Tail | p-value | p-value | Lower Limit | Upper Limit |
| 5 | 2.902 | G.E. | 0.002 | 0.004 | 1.5 | 8 |

*The Nonparametric estimates are based on Hodges-Lehmann's formulation.

The **Estimate of Median Difference** has been calculated to be 5 and the observed **Standardized Statistic** is 2.902 with an associated 2-sided p-value of 0.004 and one-sided p-value of 0.002. The two-sided 95% confidence interval for λ is (1.5, 8) and does not include 0. Therefore, $H_0: \lambda \leq 0$ should be rejected in favor of $H_1: \lambda > 0$. The non-parametric Wilcoxon signed rank test also supports the reasonable conclusion that the use of Methylphenidate significantly increases mean number of correct responses as compared to placebo.

76 Analysis-Normal Noninferiority Paired-Sample

In this chapter, we explore how we can use **EasT** to perform inference on data collected from a paired-sample noninferiority study. Two common applications of paired sample designs are:

1. Comparison of two treatments using subjects who are matched by demographic and baseline characteristics, and
2. Two observations are made from the same subject under different experimental conditions.

Designing and simulation of such kind noninferiority trials are discussed in chapter 8. Analysis based on Paired Difference of Means is presented in section 76.1 and the Ratio of Paired Means is discussed in section 76.2.

76.1 Example: Mean of Paired Differences

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of an outcome variable, X, with means μ_t and μ_c , respectively, and with a standard deviation of paired difference as σ_D^2 . Let δ_0 be the noninferiority margin. For $\delta_0 < 0$, the null hypothesis $H_0: \mu_t - \mu_c \leq \delta_0$ is tested against the one-sided alternative hypothesis $H_1: \mu_t - \mu_c > \delta_0$. For $\delta_0 > 0$, the null hypothesis $H_0: \mu_t - \mu_c \geq \delta_0$ is tested against the one-sided alternative hypothesis $H_1: \mu_t - \mu_c < \delta_0$.

Dataset: Olestra.cyd

Data Description:

The dataset **Olestra.cyd** available in **Samples** folder contains paired observations from 28 subjects on two variables X and Y. Let μ_x and μ_y denote the population means of variables X and Y, respectively and $\delta = \mu_y - \mu_x$.

Purpose of the Analysis:

To test the null hypothesis $H_0: \delta \leq \delta_0$ against the alternative hypothesis $H_1: \delta > \delta_0$. For this example, we consider a non-inferiority margin of $\delta_0 = -0.5$.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) One Sample > (Paired Design) Mean of Paired Differences

76 Analysis-Normal Noninferiority Paired-Sample

- In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

Data Set: Olestra.cyd

Main Advanced

Trial Type: Noninferiority Use Diff. Variable Frequency

Test Type: t-test Response Control: X

Response Treatment: Y

Noninferiority Margin: -0.5

- In the **Advanced** tab, enter 0.975 for **Confidence Level**.

Analysis: Continuous Endpoint One-Sample Test - Paired Design - Mean of Paired Differences

Data Set: Olestra.cyd

Main **Advanced**

By Variable 1: Confidence Level: 0.975

By Variable 2:

- Click **OK** to analyze the data. Upon completion of analysis, a new node with label **Analysis: Continuous Response: Difference of Means for Paired Data** will be added in the **Library** and the output will be displayed in the main

window.

Analysis: Continuous Response: Difference of Means for Paired Data

Hypothesis

If $\delta_0 < 0$ then, $H_0 : \mu_t - \mu_c \leq \delta_0$ Vs. $H_1 : \mu_t - \mu_c > \delta_0$
 If $\delta_0 > 0$ then, $H_0 : \mu_t - \mu_c \geq \delta_0$ Vs. $H_1 : \mu_t - \mu_c < \delta_0$

Input Parameters

Data File: Olestra.cyd
 Trial Type: Noninferiority
 Response Control: X
 Response Treatment: Y
 Test Type: t-test
 Noninferiority Margin (δ_0): -0.5
 Confidence Level: 0.975

Response Variable: (Y-X)
 Total Number of Records: 28
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|------|-------|--------|-------|---------|----|
| X | 4.13 | 12.45 | 6.75 | 7.195 | 2.063 | 28 |
| Y | 3.8 | 11.19 | 6.93 | 7.486 | 2.072 | 28 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 97.5% Confidence Interval(1-Sided) | |
|----|---------------------|------------------|------------|-------|----|---------|------|------------------------------------|-------------|
| | | | | | | p-value | Tail | Lower Limit | Upper Limit |
| 28 | 0.291 | 0.533 | 0.28 | 2.822 | 27 | 0.004 | G.E. | -0.284 | INF |

The observed value of test statistic is 2.822 and it has $28 - 1 = 27$ degrees of freedom. The lower-limit of 1- sided 97.5% confidence interval of $\delta = \mu_t - \mu_c$ is -0.284. Since this is greater than the non-inferiority margin of -0.5, we can reject $H_0 : \delta \leq \delta_0$ in favor of $H_1 : \delta > \delta_0$ at one-sided 2.5% level of significance. The p-value associated with this rejection is 0.004.

76.2 Example: Ratio of Paired Means

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of an outcome variable, X, with means μ_t and μ_c , respectively, and let σ_t^2 and σ_c^2 denote the respective variances. Let ρ_0 be the noninferiority margin. With $\rho_0 < 1$, the null hypothesis $H_0 : \mu_t/\mu_c \leq \rho_0$ is tested against the one-sided alternative hypothesis $H_1 : \mu_t/\mu_c > \rho_0$. With $\rho_0 > 1$, the null hypothesis $H_0 : \mu_t/\mu_c \geq \rho_0$ is tested against the one-sided alternative hypothesis $H_1 : \mu_t/\mu_c < \rho_0$. Let, $\rho = \mu_t/\mu_c$.

76 Analysis-Normal Noninferiority Paired-Sample

Dataset: *Olestra.cyd* as described in Section 76.1.

Purpose of the Analysis:

To test the null hypothesis $H_0: \rho \leq \rho_0$ against the alternative hypothesis $H_1: \rho > \rho_0$. For this illustrative example, we consider a non-inferiority margin (ρ_0) of 0.8.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) One Sample > (Paired Design) Mean of Paired Ratios
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

Analysis: Continuous Endpoint One-Sample Test - Paired Design - Mean of f

Data Set: Olestra.cyd

Main Advanced

Test Type: t-test Response Control: X

Response Treatment: Y

Noninferiority Margin: 0.8

4. In the **Advanced** tab, enter 0.975 for **Confidence Level**.

Analysis: Continuous Endpoint One-Sample Test - Paired Design

Data Set: Olestra.cyd

Main **Advanced**

By Variable 1: Confidence Level:

By Variable 2:

5. Click **OK** to analyze the data. Upon completion of analysis following output will be displayed in the main window.

76 Analysis-Normal Noninferiority Paired-Sample

Analysis: Continuous Response: Ratio of Means for Paired Data

Hypothesis

If $\rho_0 < 1$ then $H_0 : \mu_t / \mu_c \leq \rho_0$ Vs. $H_1 : \mu_t / \mu_c > \rho_0$

If $\rho_0 > 1$ then $H_0 : \mu_t / \mu_c \geq \rho_0$ Vs. $H_1 : \mu_t / \mu_c < \rho_0$

where ρ_0 is the non inferiority margin

Input Parameters

Data File: Olestra.cyd
 Trial Type: Noninferiority
 Response Control: X
 Response Treatment: Y
 Test Type: t-test
 Noninferiority Margin (ρ_0): 0.8
 Confidence Level: 0.975

Output

Response variable: (Y/X)
 Total no. of records: 28
 No. of records rejected: 0
 Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|------|-------|--------|-------|---------|----|
| X | 4.13 | 12.45 | 6.75 | 7.195 | 2.063 | 28 |
| Y | 3.8 | 11.19 | 6.93 | 7.486 | 2.072 | 28 |

Test of Hypothesis for:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | |
|----|---------------------|------------------|------------|-------|----|----------|------|
| | | | | | | p-value | Tail |
| 28 | 0.038 | 1.233 | 0.04 | 6.526 | 27 | 2.679E-7 | G.E. |

Parameter Estimates:

| Metric | Estimate | Std. Error | 97.5% Confidence Interval(1-Sided) | |
|-----------|----------|------------|------------------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| ln(Ratio) | 0.038 | 0.04 | -0.044 | INF |
| Ratio | 1.038 | 0.041 | 0.957 | INF |

The observed value of test statistic is 6.526 and it has $28 - 1 = 27$ degrees of freedom. The lower limit of one-sided 97.5% confidence interval for $\rho = \mu_y / \mu_x$ is 0.957. This is greater than the non-inferiority margin $\rho_0 = 0.8$. Therefore, we can reject $H_1 : \rho \leq 0.9$ in favor of $H_1 : \rho > 0.8$. The p-value associated with this rejection is very close to 0.

77 Analysis-Normal Equivalence Paired-Sample

This section demonstrates how **East** can be used to perform inference on data collected from a paired-sample equivalence study. Independent sample experimental design in some applications (e.g., bioanalytical cross-validation study) may confound statistical tests because of a possible large pooled variance that is actually due to the intersample variability, especially for incurred biological samples obtained from clinical or animal studies (Feng et. al., 2006). This problem can be overcome by applying paired sample analysis. Two common applications of paired sample designs are as follows:

- Comparison of two treatments using subjects who are matched by demographic and baseline characteristics.
- Two observations are made from the same subject under different experimental conditions.

Chapter 9 deals with design, and simulation of these types of equivalence trials. The type of endpoint for paired equivalence design could be the difference of means or ratio of means.

Analysis based on Paired Difference of Means as endpoint is presented in section 77.1 and the Ratio of Paired Means is discussed in section 77.2.

77.1 Example: Mean of Paired Differences

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of an outcome variable, X, with means μ_t and μ_c , respectively, and with a standard deviation of paired difference as σ_D^2 . Let δ_L and δ_U be the lower and upper equivalence limits respectively. We wish to test the hypothesis

$$H_0 : \mu_t - \mu_c \leq \delta_L$$

or

$$\mu_t - \mu_c \geq \delta_U$$

against

77 Analysis-Normal Equivalence Paired-Sample

$$H_1 : \delta_L < \mu_t - \mu_c < \delta_U$$

Dataset: FengData.cyx

Data Description:

Feng et al. (2006) reported the data on 12 quality control (QC) samples. Each sample were analyzed first by Lab1 and then by Lab2. The value in the columns Lab1 and Lab2 represent the measured concentration (in $\mu\text{g ML}^{-1}$) by Lab1 and Lab2.

Purpose of the Analysis:

To ensure that comparable results can be achieved between two laboratories Lab1 and Lab2, in other words to establish statistical equivalence between the two laboratories. In this example, we consider Lab1 as the standard laboratory (C) and Lab2 as the one, which needs to be, validated (T). Denote the mean concentrations from Lab1 and Lab2 by μ_c and μ_t . Considering an equivalence limit of $(-10, 10)$ we can state our hypothesis for test as

$$H_0 : \mu_t - \mu_c \leq -10$$

(or)

$$H_0 : \mu_t - \mu_c \geq 10$$

against

$$H_1 : -10 < \mu_t - \mu_c < 10$$

To reject H_0 with type I error rate not exceeding 0.025.

Analysis Steps:

1. Open the dataset from **Samples** folder. .
2. Choose the menu item:
Analysis > (Continuous) One Sample > (Paired Design) Mean of Paired Differences

3. In the ensuing dialog box (under the **Main** tab) choose the variables as shown below.

Analysis: Continuous Endpoint One-Sample Test - Paired Design - Mean

Data Set: QCSample

Main Advanced

Trial Type: Equivalence Use Diff. Variable

Test Type: t-test Response Control: Lab1

Response Treatment: Lab2

Lower Equiv. Limit: -10

Upper Equiv. Limit: 10

4. In the **Advanced** tab, enter 0.975 for **Confidence Level**.

Analysis: Continuous Endpoint One-Sample Test - Paired Design - Mean of Paired Differences

Data Set: QCSample

Main Advanced

By Variable 1: Confidence Level: 0.975

By Variable 2: Confidence Level (Equivalence): 0.95

5. Click **OK** to analyze the data. Following output will be displayed in the main window.

Analysis: Continuous Response: Difference of Means for Paired Data

Hypothesis

$H_{01} : \mu_t - \mu_c \leq \delta_L$ Or $H_{02} : \mu_t - \mu_c \geq \delta_U$

Vs.

$H_1 : \delta_L < \mu_t - \mu_c < \delta_U$

Input Parameters

Data File: FengData.cydx
 Trial Type: Equivalence
 Response Control: Lab1
 Response Treatment: Lab2
 Test Type: t-test
 Lower Equivalence Limit (δ_L): -10
 Upper Equivalence Limit (δ_U): 10
 Confidence Level (for Equivalence): 0.9

77 Analysis-Normal Equivalence Paired-Sample

Response Variable: (Lab2-Lab1)
 Total Number of Records: 12
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|------|------|--------|--------|---------|----|
| Lab1 | 83.7 | 102 | 93.5 | 94.242 | 6.136 | 12 |
| Lab2 | 81.3 | 95.2 | 91.25 | 89.883 | 4.825 | 12 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | | Std. Error | t | | DF | 1-Sided | 2-Sided | 90% Confidence Interval(2-Side | |
|----|---------------------|------------------|-----------|------------|---------|---------|----|-------------|-------------|--------------------------------|-------|
| | | Under H01 | Under H02 | | p-value | p-value | | Lower Limit | Upper Limit | | |
| 12 | -4.358 | 0.69 | -1.756 | 2.36 | 2.39 | -6.084 | 11 | 0.018 | 3.959E-5 | -8.597 | -0.12 |

The observed values of two test statistics are 2.39 and -6.084, and both of them have $12 - 1 = 11$ degrees of freedom. The 2-sided 95% confidence interval for $\delta = \mu_t - \mu_c$ is (-9.553, 0.836). This confidence interval is within the equivalence interval of (-10, 10), therefore, we can reject $H_0: \mu_t - \mu_c \leq -10$ or $\mu_t - \mu_c \geq 10$ in favor of $H_1: -10 < \mu_t - \mu_c < 10$ at 2.5% level of significance.

77.2 Example: Ratio of Paired Means

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of an outcome variable, X, with means μ_t and μ_c , and let σ_t^2 and σ_c^2 denote the respective variances. Here, the null hypothesis $H_0: \mu_t/\mu_c \leq \rho_L$ or $\mu_t/\mu_c \geq \rho_U$ is tested against the alternative hypothesis $H_1: \rho_L < \mu_t/\mu_c < \rho_U$. Let $\rho = \mu_t/\mu_c$ denotes the ratio of two means. Then the null hypothesis can be expressed as $H_0: \rho \leq \rho_L$ or $\rho \geq \rho_U$ and the alternative can be expressed as $H_1: \rho_L < \rho < \rho_U$. In practice, ρ_L and ρ_U are often chosen such that $\rho_L = 1/\rho_U$. The two one-sided tests (TOST) procedure of Schuirmann (1987) is commonly used for this analysis, and is employed in this section for a parallel-group study.

We can perform the test for difference as discussed in section 77.1 on the log-transformed data.

77.2.1 Example: Ratio of Paired Means

Dataset:FengData.cyd as described in section 77.1.

Purpose of the Analysis:

To test

$$H_0: \mu_t/\mu_c \leq 0.85 \text{ or } \mu_t/\mu_c \geq 1.15 \text{ against } H_1: 0.85 < \mu_t/\mu_c < 1.15$$

We want to reject H_0 with probability of type I error not exceeding 0.025.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) One Sample > (Paired Design) Mean of Paired Ratios
3. In the ensuing dialog box (under the **Main** tab) choose the variables as shown below.

Analysis: Continuous Endpoint One-Sample Test - Paired Design

Data Set: QCSample

Main Advanced

Trial Type: Equivalence Use Ratio

Test Type: t-test Response Control: Lab1

Response Treatment: Lab2

Lower Equiv. Limit: 0.85

Upper Equiv. Limit: 1.15

4. In the **Advanced** tab, enter 0.975 for **Confidence Level**.

Analysis: Continuous Endpoint One-Sample Test - Paired Design - Mean of Paired Ratios

Data Set: QCSample

Main Advanced

By Variable 1: Confidence Level: 0.975

By Variable 2: Confidence Level (Equivalence): 0.95

5. Click **OK** to analyze the data. Following output will be displayed in the main

77 Analysis-Normal Equivalence Paired-Sample

window.

Analysis: Continuous Response: Ratio of Means for Paired Data

Hypothesis

$H_{01} : \mu_t / \mu_c \leq \rho_L$ Or $H_{02} : \mu_t / \mu_c \geq \rho_U$

Vs.

$H_1 : \rho_L < \mu_t / \mu_c < \rho_U$

Input Parameters

Data File: FengData.cydx
 Trial Type: Equivalence
 Response Control: Lab1
 Response Treatment: Lab2
 Test Type: t-test
 Lower Equivalence Limit (ρ_L): 0.85
 Upper Equivalence Limit (ρ_U): 1.15
 Confidence Level (for Equivalence): 0.95

Response Variable: (Lab2/Lab1)

Total Number of Records: 12

Number of Records Rejected: 0

Summary of the Observed Data:

| Response | Min | Max | Median | Mean | Std.Dev | n |
|----------|------|------|--------|--------|---------|----|
| Lab1 | 83.7 | 102 | 93.5 | 94.242 | 6.136 | 12 |
| Lab2 | 81.3 | 95.2 | 91.25 | 89.883 | 4.825 | 12 |

Test of Hypothesis for: ln(Lab2/Lab1)

| n | Difference of Means | Std. Effect Size | | Std. Error | t | | DF | p-value | |
|----|---------------------|------------------|-----------|------------|-----------|-----------|----|-----------|-----------|
| | | Under H01 | Under H02 | | Under H01 | Under H02 | | Under H01 | Under H02 |
| 12 | -0.047 | 1.308 | -2.107 | 0.026 | 4.53 | -7.298 | 11 | 4.286E-4 | 7.738E-6 |

Parameter Estimates:

| Metric | Estimate | Std. Error | 95% Confidence Interval(2-Sided) | |
|-----------|----------|------------|----------------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| ln(Ratio) | -0.047 | 0.026 | -0.103 | 0.01 |
| Ratio | 0.954 | 0.024 | 0.902 | 1.01 |

The observed values of two test statistics are 4.53 and -7.298 and both of them have $12 - 1 = 11$ degrees of freedom. The 2-sided 95% confidence interval of $\rho = \mu_t / \mu_c$ is (0.902, 1.01). This confidence interval is within the equivalence interval of (0.85, 1.15), therefore, we can reject $H_0 : \mu_t / \mu_c \leq 0.85$ or $\mu_t / \mu_c \geq 1.15$ in favor of $H_1 : 0.85 < \mu_t / \mu_c < 1.15$ with 2.5% level of significance.

78 *Analysis-Normal Superiority Two-Sample*

To demonstrate the superiority of a new treatment over the control, it is often necessary to randomize subjects to the control and treatment arms, and contrast the group-dependent means of the outcome variables.

In chapter 10, designing, simulation and interim monitoring of such kind of trials are discussed in details.

In this chapter, we explore how we can use **East** to analyze data that comes from two independent samples and crossover superiority studies.

78.1 *Example: Difference of Means*

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of a normally distributed outcome variable, X , with means μ_t and μ_c , respectively, and with a common variance σ^2 .

Define the treatment difference to be $\delta = \mu_t - \mu_c$. The null hypothesis $H_0: \delta = 0$ is tested against the two-sided alternative hypothesis $H_1: \delta \neq 0$ or a one-sided alternative hypothesis $H_1: \delta < 0$ or $H_1: \delta > 0$.

Dataset: Myeloma.cyd as described in section 72.1.1

Purpose of the Analysis:

To compare the mean **haemoglobin** level between two groups indicated by the variable **status** (0-alive, 1-dead).

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Two Samples > (Parallel Design) Difference of Means

78 Analysis-Normal Superiority Two-Sample

3. In the ensuing dialog box choose the variables as shown below:

Analysis: Continuous Endpoint Two-Sample Test - Parallel Design - Difference of Means

Data Set: Myeloma.cyd

Main Advanced

Trial Type: Superiority Test Type: t-test

Variance Type: Equal

Population Id: status Response Variable: haemoglobin

Control: 0

Treatment: 1

4. Click **OK** to analyze the data. Following output will be displayed in the main window.

Analysis: Continuous Response: Difference of Means for Independent Data

$H_0: \mu_1 - \mu_0 = 0$ Vs. $H_1: \mu_1 - \mu_0 \neq 0$ for 2-Sided test
 Either $H_1: \mu_1 - \mu_0 < 0$
 Or $H_1: \mu_1 - \mu_0 > 0$ for 1-Sided test

Input Parameters

Data File: Myeloma.cyd
 Trial Type: Superiority
 Population Id: status(Treatment=0, Control=1)
 Response Variable: haemoglobin
 Variance Type: Equal
 Test Type: t-test
 Confidence Level: 0.95

Output

Response Variable: haemoglobin
 Total Number of Records: 65
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|------|--------|--------|---------|----|
| 1 | 5 | 14.6 | 10.1 | 9.91 | 2.564 | 48 |
| 0 | 4.9 | 14 | 11.6 | 11.024 | 2.425 | 17 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided | | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-------|----|---------|------|---------|-------------|----------------------------------|--|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 65 | 1.113 | 0.44 | 0.714 | 1.559 | 63 | 0.062 | G.E. | 0.124 | -0.313 | 2.54 | |

The observed value of test statistic is 1.559 and it has $48 + 17 - 2$ or 63 degrees of

freedom. The p-value for two-sided test is 0.124. This is the p-value associated with rejecting $H_0: \delta = 0$ in favor of alternative hypothesis $H_1: \delta \neq 0$. The p-value for right tailed test is 0.062. This p-value is associated with the rejection of $H_0: \delta \leq 0$ in favor of the alternative hypothesis $H_1: \delta > 0$. **East** displays the p-value associated with right tailed test on this occasion because $\hat{\delta} > 0$. The two-sided 95% confidence interval is (-0.313, 2.54). Since the 2-sided confidence interval includes 0 or the p-value for two-sided test is 0.124, we cannot reject $H_0: \delta = 0$ at 5% level of significance.

78.2 Example: Ratio of Means

The statistical analysis regarding the ratio of means of two independent log-normal distributions is often of interest in biomedical research. Ratio of means as endpoint should be preferred when underlying distribution is skewed and therefore a lognormal distribution is a better fit than normal. Sometimes goal of the experiment can be better represented using ratio of means instead of their difference.

Let μ_t and μ_c denote the means of the observations from the experimental treatment (T) and the control treatment (C), respectively, and let σ_t^2 and σ_c^2 denote the corresponding variances of the observations. It is assumed that $\sigma_t/\mu_t = \sigma_c/\mu_c$, i.e. the coefficient of variation $CV = \sigma/\mu$ is the same for T and C .

Define the treatment ratio to be $\rho = \mu_t/\mu_c$. The null hypothesis $H_0: \rho = 1$ is tested against the two-sided alternative hypothesis $H_1: \rho \neq 1$ or a one-sided alternative hypothesis $H_1: \rho < 1$ or $H_1: \rho > 1$.

Dataset: Myeloma.cyd as described in section 72.1.1.

Purpose of the Analysis:

To compare the mean **haemoglobin** level between two groups indicated by the variable **status** (0-alive, 1-dead).

Here, we are interested in testing the null hypothesis $H_0: \rho = 1$ against the alternative hypothesis $H_1: \rho > 1$.

Since we can translate the ratio hypothesis into difference hypothesis using log transformation, **East** performs the test for difference on log-transformed data as discussed in section 78.1 to draw inference on ρ .

78 Analysis-Normal Superiority Two-Sample

Analysis Steps:

1. Choose the menu item:
Analysis > (Continuous) Two Samples > (Parallel Design) Ratio of Means
2. In the ensuing dialog box (under the **Main**) select the variables as shown below:

The screenshot shows a software dialog box titled "Analysis: Continuous Endpoint Two-Sample Test - Parallel Design - Ratio of Means". The data set is "Myeloma.cyd". The "Main" tab is selected. The settings are as follows:

| | | | |
|----------------|-------------|--------------------|-------------|
| Trial Type: | Superiority | Test Type: | t-test |
| Variance Type: | Equal | Response Variable: | haemoglobin |
| Population Id: | status | Control: | 1 |
| | | Treatment: | 0 |

3. Click **OK** to analyze the data. Following output will be displayed in the main

window.

Analysis: Continuous Response: Ratio of Means for Independent Data

Hypothesis

$H_0: \mu_t/\mu_c = 1$ Vs. $H_1: \mu_t/\mu_c \neq 1$ for 2-Sided test

Either $H_1: \mu_t/\mu_c < 1$

Or $H_1: \mu_t/\mu_c > 1$ for 1-Sided test

Input Parameters

Data File: Myeloma.cyd
 Trial Type: Superiority
 Population Id: status(Treatment=0, Control=1)
 Response Variable: haemoglobin
 Variance Type: Equal
 Test Type: t-test
 Confidence Level: 0.95

Output

Response Variable: haemoglobin
 Total Number of Records: 65
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|------|--------|--------|---------|----|
| 1 | 5 | 14.6 | 10.1 | 9.91 | 2.564 | 48 |
| 0 | 4.9 | 14 | 11.6 | 11.024 | 2.425 | 17 |

Test of Hypothesis for: ln(haemoglobin)

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 2-Sided |
|----|---------------------|------------------|------------|-------|----|---------|------|---------|
| | | | | | | p-value | Tail | p-value |
| 65 | 0.114 | 0.41 | 0.078 | 1.453 | 63 | 0.076 | G.E. | 0.151 |

Parameter Estimates:

| Metric | Estimate | Std. Error | 95% Confidence Interval(2-Sided) | |
|-----------|----------|------------|----------------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| ln(Ratio) | 0.114 | 0.078 | -0.043 | 0.27 |
| Ratio | 1.121 | 0.088 | 0.958 | 1.311 |

The observed value of test statistic is 1.453 and it has $48 + 17 - 2 = 63$ degrees of freedom. The two-sided 95% confidence interval for $\ln \rho$ is (-0.043, 0.27) and for ρ is (0.958, 1.311). The former confidence interval includes 0 and the latter includes 1. Therefore, we cannot reject $H_0: \rho = 1$ in favor of $H_1: \rho \neq 1$. The p-value for comparing $H_0: \rho \leq 1$ in favor of $H_1: \rho > 1$ is 0.076. Therefore, we cannot reject

78 Analysis-Normal Superiority Two-Sample

$H_0: \rho \leq 1$ against $H_1: \rho > 1$ either at 5% level of significance.

78.3 Example: Difference of Means in Crossover design

In a 2×2 crossover design each subject is randomized to one of two sequence groups. Subjects in the sequence group 1 receive the test drug (T) formulation in the first period, have their outcome variable, X , recorded, wait out a washout period to ensure that the drug is cleared from their system, then receive the control drug formulation (C) in period 2 and finally have the measurement on X again. In sequence group 2, the order in which the T and C are assigned is reversed. The table below summarizes this type of trial design.

| Group | Period 1 | Washout | Period 2 |
|-------|----------|---------|----------|
| 1(TC) | Test | — | Control |
| 2(CT) | Control | — | Test |

The resulting data are commonly analyzed using a statistical linear model. The response y_{ijk} in period j on subject k in sequence group i , where $i = 1, 2$, $j = 1, 2$, and $k = 1, \dots, n_i$ is modeled as a linear function of an overall mean response μ , formulation effect τ_t and τ_c , period effects π_1 and π_2 , and sequence effects λ_1 and λ_2 . The fixed effects model can be displayed as:

| Group | Period 1 | Washout | Period 2 |
|-------|-----------------------------------|---------|------------------------------------|
| 1(TC) | $\mu + \tau_t + \pi_1 + \gamma_1$ | — | $\mu + \tau_c + \pi_2 + \lambda_1$ |
| 2(CT) | $\mu + \tau_c + \pi_1 + \gamma_2$ | — | $\mu + \tau_t + \pi_2 + \lambda_2$ |

For superiority trial, **East** can test following null hypotheses:

- Test1: $H_0 : \tau_t - \tau_c = 0$. for treatment effect
- Test2: $H_0 : \pi_1 - \pi_2 = 0$. for period effect
- Test1: $H_0 : \lambda_1 - \lambda_2 = 0$. For carryover effect

Dataset: CrossoverCaseData.cyd

Data Description:

Jones and Kenward (2003) presented data from a 2×2 crossover trial where the primary objective was to evaluate the efficacy and safety of an inhaled drug given to patients with chronic obstructive pulmonary disease. Eligible patients were randomized to either treatment sequence AB or BA (A: Drug; B=Placebo). There was

4 weeks of gap between two periods. The main comparison of efficacy was based on the mean morning peak expiratory flow rate (PEFR). The data of this trial are available in [CrossoverCaseData.cyd](#).

This dataset contains 112 observations and 7 variables. The columns **GroupID**, **PeriodID** and **subjectID** contain the information about group sequence, period and subject id, respectively. The column **Response** contains the measurements on the PEFR.

Purpose of the Analysis:

To test if there is significant carryover effect from period 1 to period 2.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Difference of Means
3. In the ensuing dialog box, there are two tabs in this window – **Main** and **Advanced**. In the **Main** tab, select different variables as shown below:

| | Minimum | 67.778 | 70.278 | 67.778 |
| 2 | No. of Subjects | 29 | 29 | 29 |
| | Mean | 215.992 | 230.162 | 223.077 |
| | Std. Dev. | 72.629 | 73.942 | 72.993 |
| | Median | 201.905 | 225 | 212.068 |
| | Minimum | 104.444 | 128.947 | 104.444 |
| Period Summary | No. of Subjects | 56 | 56 | |
| | Mean | 230.382 | 234.521 | |
| | Std. Dev. | 78.43 | 77.197 | |
| | Median | 225.595 | 222.005 | |
| | Minimum | 67.778 | 70.278 | |
| | Maximum | 443.25 | 420.5 | |

Treatment Summary:

| Statistic | Treatment 1 | Treatment 2 |
|-----------------|-------------|-------------|
| No. of Subjects | 56 | 56 |
| Mean | 237.72 | 227.183 |
| Std. Dev. | 78.008 | 77.315 |
| Median | 231.157 | 214.272 |
| Minimum | 67.778 | 70.278 |
| Maximum | 443.25 | 420.5 |

Inference for: (Response)

Test of Hypothesis for:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | (1-Sided) | | (2-Sided) | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-------|----|-----------|------|-----------|----------------------------------|-------------|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit |
| 56 | 38.888 | 0.254 | 41.008 | 0.948 | 54 | 0.174 | G.E. | 0.347 | -43.328 | 121.105 |

The observed value of test statistic is 0.948 and it has $27 + 24 - 2 = 54$ degrees of freedom. The p-value for two sided test is 0.347. Therefore, the carryover effect is not significant at 5% level of significance.

Let us further examine if there is a significant **Treatment effect**:

78 Analysis-Normal Superiority Two-Sample

Dataset: CrossoverCaseData.cyd as described in Section 78.3.

Purpose of the Analysis:

To test if there is significant treatment effect.

Analysis Steps:

1. Open the dataset.
2. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Difference of Means
3. In the ensuing dialog box, complete the **Main** tab as before except for **Effect Type**. Select **Treatment** as **Effect Type** as we are interested in testing the treatment effect.

Analysis: Continuous Endpoint Two-Sample Test - Crossover Design - Difference of Means

Data Set: CrossoverCaseData.cyd

Trial Type: Superiority Period ID: PeriodID Response Variable: Response

Effect Type: Treatment Subject ID: subjectID

Treatment Specifications

Treatment 1: Treatment 1 Group ID: GroupID

Treatment 2: Treatment 2

4. Click **OK** to start analysis. Upon completion of analysis, a new node with label **Analysis: Continuous Response: Difference of Means test for Crossover Data2** will be added to the **Library** and the output will be displayed in the main window. Scroll down to the end of the output. Output for statistical test of treatment effect is displayed in the last table.

Treatment Summary:

| Statistic | Treatment 1 | Treatment 2 |
|-----------------|-------------|-------------|
| No. of Subjects | 56 | 56 |
| Mean | 237.72 | 227.183 |
| Std. Dev. | 78.008 | 77.315 |
| Median | 231.157 | 214.272 |
| Minimum | 67.778 | 70.278 |
| Maximum | 443.25 | 420.5 |

Inference for: (Response)
Test of Hypothesis for:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | (1-Sided) | | (2-Sided) | | 95% Confidence Interval(2-Sided) | |
|----|---------------------|------------------|------------|-------|----|-----------|------|-----------|-------------|----------------------------------|--|
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 56 | 10.403 | 0.407 | 3.416 | 3.046 | 54 | 0.002 | G.E. | 0.004 | 3.555 | 17.25 | |

The observed value of test statistic is 3.046 and it has $27 + 24 - 2 = 54$ degrees of freedom. The p-value for two sided test is 0.004. Therefore, the treatment effect is significant at 5% level of significance.

78.4 Example: Ratio of Means in Crossover design

In this chapter, we show how we can use **East** to test for ratio of means from a superiority 2×2 crossover trial. We have already discussed 2×2 crossover design in section 78.3. However, unlike section 78.3, here we are interested in ratio of means. Let μ_t and μ_c denote the means of the observations from the experimental treatment (T) and the control treatment (C), respectively. **East** can test following null hypotheses:

- Test1: $H_0 : \mu_t / \mu_c = 1$. For treatment effect
- Test2: $H_0 : \pi_1 / \pi_2 = 1$. For period effect
- Test1: $H_0 : \lambda_1 / \lambda_2 = 1$. For carryover effect

Since we can translate the ratio hypothesis into difference hypothesis using log transformation, **East** performs the test for difference on log-transformed data as discussed in section 78.3.

Dataset: CrossoverCaseData.cyd as described in section 78.3.

Purpose of the Analysis:

To test the null hypothesis $H_0: \rho = 1$ against the alternative hypothesis $H_1: \rho \neq 1$.

Analysis Steps:

1. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Ratio of Means
2. In the ensuing dialog box, select different variables as shown below:

The screenshot shows the 'Analysis: Continuous Endpoint, Two-Sample Test - Crossover Design - Ratio of Means' dialog box. The 'Data Set' is 'CrossoverCaseData.cyd'. The 'Main' tab is selected. The settings are as follows:

- Trial Type: Superiority
- Effect Type: Carryover
- Treatment Specifications: Treatment 1, Treatment 2
- Period ID: PeriodID
- Subject ID: subjectID
- Group ID: GroupID
- Response Variable: Response

78 Analysis-Normal Superiority Two-Sample

- Click **OK** to start analysis. Upon completion of analysis, a new node with label **Analysis: Continuous Response: Ratio of Means for Crossover Data1** will be added to the **Library** and the output will be displayed in the main window. Scroll down to the end of the output. Output for statistical test of treatment effect is displayed in the last table.

| Treatment Summary: | | | | | | | | | |
|--|---------------------|------------------|----------------------------------|-------------|----|-----------|------|-----------|--|

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | (1-Sided) | | (2-Sided) | |
| | | | | | | p-value | Tail | p-value | |
| 56 | 0.046 | 0.388 | 0.016 | 2.904 | 54 | 0.003 | G.E. | 0.005 | |
| Parameter Estimates: | | | | | | | | | |
| Metric | Estimate | Std. Error | 95% Confidence Interval(2-Sided) | | | | | | |
| | | | Lower Limit | Upper Limit | | | | | |
| ln(Ratio) | 0.046 | 0.016 | 0.014 | 0.078 | | | | | |
| Ratio | 1.047 | 0.017 | 1.014 | 1.081 | | | | | |

East performs the analysis based on the log-transformed data. The observed value of test statistic based on log-transformed data is 2.904 and it has $27 + 24 - 2 = 54$ degrees of freedom. The p-value for two sided test is 0.005. Therefore, the treatment effect is significant at 5% level of significance.

Now we will perform the test for difference of means for crossover data based on log-transformed data. The **CrossoverCaseData.cyd** has a column labeled as **LnResp** which contains the log-transformed values of the entries in the *Response* column. The result for test of treatment effect based on **LnResp** as response variable (using

difference of means for crossover data) is as follows:

| Treatment Summary: | | | | | | | | | | | |
|-------------------------|---------------------|------------------|------------|-------|----|-----------|------|-----------|----------------------------------|-------------|--|
| Statistic | Treatment 1 | Treatment 2 | | | | | | | | | |
| No. of Subjects | 56 | 56 | | | | | | | | | |
| Mean | 5.416 | 5.369 | | | | | | | | | |
| Std. Dev. | 0.347 | 0.346 | | | | | | | | | |
| Median | 5.443 | 5.367 | | | | | | | | | |
| Minimum | 4.216 | 4.252 | | | | | | | | | |
| Maximum | 6.094 | 6.041 | | | | | | | | | |
| Inference for: (LnResp) | | | | | | | | | | | |
| Test of Hypothesis for: | | | | | | | | | | | |
| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | (1-Sided) | | (2-Sided) | 95% Confidence Interval(2-Sided) | | |
| | | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 56 | 0.046 | 0.388 | 0.016 | 2.904 | 54 | 0.003 | G.E. | 0.005 | 0.014 | 0.078 | |

Compare the value of observed test statistic and the p-values with those from test for ratio of crossover means. They are identical. This is because the test for ratio of crossover means in **East** is equivalent to test for difference of crossover means based on log-transformed data.

79 Analysis-Normal Noninferiority Two-Sample

In a noninferiority trial, the goal is to establish that an experimental treatment is **no worse than** the standard treatment, rather than attempting to establish that it is superior. A therapy that is demonstrated to be non-inferior to the current standard therapy for a particular indication might be an acceptable alternative if, for instance, it is easier to administer, cheaper, or less toxic.

In chapter 12, designing, simulation and interim monitoring of such kind of trials are discussed in details.

In this chapter, we explore how we can use **East** to perform analysis of data that comes from two independent samples and crossover noninferiority studies.

79.1 Example: Difference of Means

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of a normally distributed outcome variable, X , with means μ_t and μ_c , respectively, and with a common variance σ^2 .

Define the treatment difference to be $\delta = \mu_t - \mu_c$ and δ_0 be the non inferiority margin. When $\delta_0 < 0$, **East** tests the null hypothesis $H_0: \delta \leq \delta_0$ against the alternative hypothesis $H_1: \delta > \delta_0$. When $\delta_0 > 0$, the null hypothesis $H_0: \delta \geq \delta_0$ is tested against the alternative hypothesis $H_1: \delta < \delta_0$.

Let \bar{X}_t and \bar{X}_c be the mean responses of the experimental and control groups, respectively, based on n_t observations from T and n_c observations from C. Then the estimate of δ is $\hat{\delta} = \bar{X}_t - \bar{X}_c$. Test statistic can be defined as

$$Z = \frac{\hat{\delta} - \delta_0}{se(\hat{\delta})} \tag{79.1}$$

where $se(\hat{\delta})$ is the standard error of $\hat{\delta}$ based on $n_t + n_c$ observations. Z is distributed as variable that follows t distribution with $n_t + n_c - 2$ degrees of freedom or standard normal variate.

Dataset: `Werner.cyd` as described in section 73.4.2.

Purpose of the Analysis:

The purpose here is to compare the mean cholesterol levels between the birthpill users and nonusers. Let μ_t and μ_c be the mean cholesterol level in birthpill user group and

non-user group, respectively, and $\delta = \mu_t - \mu_c$. We want to test the null hypothesis $H_0: \delta \geq 25$ against the alternative hypothesis $H_1: \delta < 25$. For this analysis, we consider one-sided type I error rate of 0.025.

Analysis Steps:

1. To open the dataset from Samples folder
2. In case multiple workbooks are currently open, then this will bring up the **Keep in** dialog box. You can select either one of the existing workbooks or you can create new workbook. Suppose you want to create a new workbook labeled as “Birthpill Noninferiority”. In order to do this, select the radio button **New Workbook** and type in **Birthpill Noninferiority** in the field next to it.
3. Choose the menu item:
Analysis > (Continuous) Two Samples > (Parallel Design) Difference of Means
4. In the ensuing dialog box (under the **Main**) tab select **Noninferiority** as **Trial Type**, **Equal** as **Variance Type** and **t-test** as **Test Type**. Select **Birthpill** as **Population Id** variable. As you select variable for **Population Id** field, a new box will appear below where you have to specify the levels of the **Population Id** variable for control and treatment group. Choose **0** for **Control**. By doing this, **East** will treat the subjects with BIRTHPILL=0 as they are in the control group and remaining subjects in the treatment group. Select **Response Variable** as **CHOLESTEROL** and enter **25** for **Noninferiority Margin**. Leave the **Frequency Variable** field blank.

Hypothesis

If $\delta_0 < 0$ then, $H_0: \mu_t - \mu_c \leq \delta_0$ Vs. $H_1: \mu_t - \mu_c > \delta_0$
 If $\delta_0 > 0$ then, $H_0: \mu_t - \mu_c \geq \delta_0$ Vs. $H_1: \mu_t - \mu_c < \delta_0$

Input Parameters

Data File: Werner.cyd
 Trial Type: Noninferiority
 Population Id: BIRTHPILL(Treatment=1, Control=0)
 Response Variable: CHOLESTEROL
 Variance Type: Equal
 Test Type: t-test
 Noninferiority Margin (δ_0): 25
 Confidence Level: 0.975

Output

Response Variable: CHOLESTEROL
 Total Number of Records: 188
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|---------|---------|----|
| 0 | 155 | 335 | 230 | 232.968 | 43.492 | 94 |
| 1 | 50 | 600 | 235 | 240.585 | 58.924 | 94 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | | 97.5% Confidence Interval(1-Sided) | |
|-----|---------------------|------------------|------------|--------|-----|---------|------|------------------------------------|-------------|
| | | | | | | p-value | Tail | Lower Limit | Upper Limit |
| 188 | 7.617 | -0.336 | 7.554 | -2.301 | 186 | 0.011 | L.E. | -INF | 22.519 |

There are 94 observations in each group. The mean (standard deviation) cholesterol levels are 232.97 (43.492) and 240.59 (58.924) in birthpill non-user and user groups, respectively. Estimated treatment difference is $\hat{\delta} = 7.617$ with $se(\hat{\delta}) = 7.554$. The

effect size is -0.336 . This can be verified by plugging the value of $\hat{\delta} = 7.617$, $\delta_0 = 25$ and $\hat{\sigma} = 7.554/\sqrt{1/94 + 1/94} = 51.788$ in the following formula of effect size

$$\frac{\hat{\delta} - \delta_0}{\hat{\sigma}}$$

The observed value of test statistic is -2.301 (see eq. 79.1) and it has $94 + 94 - 2$ or 186 degrees of freedom. The p-value for one-sided test is 0.011. This is the p-value associated with rejecting $H_0: \delta \geq 25$ in favor of alternative hypothesis $H_1: \delta < 25$. The one-sided 97.5% confidence interval is $(-\infty, 22.519)$. Since the upper limit of the confidence interval is smaller than the noninferiority margin of 25, we can reject $H_0: \delta \geq 25$ at one-sided 2.5% level of significance.

79.2 Example: Ratio of Means

The statistical analysis regarding the ratio of means of two independent log-normal distributions is often of interest in biomedical research. Ratio of means as endpoint should be preferred when underlying distribution is skewed and therefore a lognormal distribution is a better fit than normal. Sometimes goal of the experiment can be better represented using ratio of means instead of their difference.

Let μ_t and μ_c denote the means of the observations from the experimental treatment (T) and the control treatment (C), respectively, and let σ_t^2 and σ_c^2 denote the corresponding variances of the observations. It is assumed that $\sigma_t/\mu_t = \sigma_c/\mu_c$, i.e. the coefficient of variation $CV = \sigma/\mu$ is the same for T and C . Finally, let $\rho = \mu_t/\mu_c$.

Let ρ_0 be the noninferiority margin. For $\rho_0 < 1$, **East** tests the null hypothesis $H_0: \rho \leq \rho_0$ against the alternative hypothesis $H_1: \rho > \rho_0$. When $\rho_0 > 1$, the null hypothesis $H_0: \rho \geq \rho_0$ is tested against the alternative hypothesis $H_1: \rho < \rho_0$.

Since we can translate the ratio hypothesis into difference hypothesis using log transformation, **East** performs the test for difference on log-transformed data as discussed in section 79.1 to draw inference on ρ .

Dataset: We will again use **Werner.cyd** dataset as described in section 73.4.2.

Purpose of the Analysis:

Let μ_t and μ_c be the mean cholesterol level in birthpill user and nonuser groups, respectively, and $\rho = \mu_t/\mu_c$. Here, we are interested in testing the null hypothesis $H_0: \rho \geq 1.10$ is tested against the alternative hypothesis $H_1: \rho < 1.10$. For this analysis, we consider one-sided type I error rate of 0.05.

79 Analysis-Normal Noninferiority Two-Sample

Analysis Steps:

1. Choose the menu item:
Analysis > (Continuous) Two Samples > (Parallel Design) Ratio of Means
2. If the dataset is not displayed in your main window, this will bring up the **Select Dataset** dialog box with the list of available workbooks and datasets available under each workbook. If the dataset is already displayed in your main window, **East** will skip this step and the dataset in the main window will be used in the analysis. In case **East** brings up the **Select Dataset** dialog box, choose **Werner.cyd** dataset under workbook **BirthpillNon inferiority** and click **OK**.
3. In the ensuing dialog box (under the **Main**) select the variables as shown below:

Analysis: Continuous Endpoint Two-Sample Test - Parallel Design

Data Set: Werner.cyd

By Variable 2:

- Click **OK** to analyze the data. Following output will be displayed in the main

79 Analysis-Normal Noninferiority Two-Sample

window.

Analysis: Continuous Response: Ratio of Means for Independent Data

Hypothesis
 If $p_0 < 1$ then $H_0 : \mu_t / \mu_c \leq p_0$ Vs. $H_1 : \mu_t / \mu_c > p_0$
 If $p_0 > 1$ then $H_0 : \mu_t / \mu_c \geq p_0$ Vs. $H_1 : \mu_t / \mu_c < p_0$
 where p_0 is the non inferiority margin

Input Parameters

Data File: Werner.cyd
 Trial Type: Noninferiority
 Population Id: BIRTHPILL(Treatment=1, Control=0)
 Response Variable: CHOLESTEROL
 Variance Type: Equal
 Test Type: t-test
 Noninferiority Margin (p_0): 1.1
 Confidence Level: 0.975

Output

Response variable: (CHOLESTEROL)
 Total no. of records: 188
 No. of records rejected: 0

Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|---------|---------|----|
| 0 | 155 | 335 | 230 | 232.968 | 43.492 | 94 |
| 1 | 50 | 600 | 235 | 240.585 | 58.924 | 94 |

Test of Hypothesis for: ln(CHOLESTEROL)

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | 1-Sided | |
|-----|---------------------|------------------|------------|------|-----|---------|------|
| | | | | | | p-value | Tail |
| 188 | 0.021 | -0.336 | 0.032 | -2.3 | 186 | 0.011 | L.E. |

Parameter Estimates:

| Metric | Estimate | Std. Error | 97.5% Confidence Interval(1-Sided) | |
|-----------|----------|------------|------------------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| ln(Ratio) | 0.021 | 0.032 | -INF | 0.085 |
| Ratio | 1.021 | 0.033 | 0 | 1.088 |

In the **Output** section, the first part provides descriptive statistics for the two groups. The second table labeled with **Test of Hypothesis for:ln(CHOLESTEROL)** provides details about the test result. Note the word “ln(CHOLESTEROL)”; this emphasize that

the analysis is performed on log-transformed data. In this table, we see the **Difference of Means** as 0.021. This is the estimated treatment difference in terms of log-transformed data on CHOLESTEROL. The estimated effect size is -0.336.

The observed value of test statistic is -2.3 and it has $94 + 94 - 2 = 186$ degrees of freedom. The one-sided 97.5% confidence interval for $\ln \rho$ is $(-\infty, 0.085)$ and for ρ is $(0, 1.088)$. The upper limit of one-sided 97.5% confidence interval for ρ is smaller than the noninferiority margin $\rho_0 = 1.10$. Therefore, we reject $H_0: \rho \geq 1.10$ in favor of $H_1: \rho < 1.10$ at one-sided 0.025 level of significance. The p-value associated with this rejection is 0.011.

79.3 Example: Difference of Means in Cross-over design

In a 2×2 crossover design each subject is randomized to one of two sequence groups. Subjects in the sequence group 1 receive the test drug (T) formulation in a first period, have their outcome variable, X recorded, wait out a washout period to ensure that the drug is cleared from their system, then receive the control drug formulation (C) in period 2 and finally have the measurement on X again. In sequence group 2, the order in which the T and C are assigned is reversed. The table below summarizes this type of trial design.

| Group | Period 1 | Washout | Period 2 |
|-------|----------|---------|----------|
| 1(TC) | Test | — | Control |
| 2(CT) | Control | — | Test |

The resulting data are commonly analyzed using a statistical linear model. The response y_{ijk} in period j on subject k in sequence group i , where $i = 1, 2$, $j = 1, 2$, and $k = 1, \dots, n_i$ is modeled as a linear function of an overall mean response μ , formulation effect τ_t and τ_c , period effects π_1 and π_2 , and sequence effects λ_1 and λ_2 . The fixed effects model can be displayed as:

| Group | Period 1 | Washout | Period 2 |
|-------|-----------------------------------|---------|------------------------------------|
| 1(TC) | $\mu + \tau_t + \pi_1 + \gamma_1$ | — | $\mu + \tau_c + \pi_2 + \lambda_1$ |
| 2(CT) | $\mu + \tau_c + \pi_1 + \gamma_2$ | — | $\mu + \tau_t + \pi_2 + \lambda_2$ |

Let $\mu_t = \mu + \tau_t$ and $\mu_c = \mu + \tau_c$. For noninferiority crossover trial, **East** tests only for treatment effect. With δ_0 as noninferiority margin, **East** tests $H_0: \mu_t - \mu_c \leq \delta_0$ when $\delta_0 < 0$ and $H_0: \mu_t - \mu_c \geq \delta_0$ when $\delta_0 > 0$.

79 Analysis-Normal Noninferiority Two-Sample

In **East** we use following test statistic to test the above null hypothesis:

$$T_L = \frac{(\bar{y}_{11} - \bar{y}_{12} - \bar{y}_{21} + \bar{y}_{22})/2 - \delta_0}{\sqrt{\frac{\hat{\sigma}^2}{2} \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$$

where, \bar{y}_{ij} is the mean of the observations from group i and period j and $\hat{\sigma}^2$ is the estimate of error variance (obtained as mean-squared error from ANOVA including period, treatment and sequence as source of variation in the model). T_τ is distributed with Student's t distribution with $(n_1 + n_2 - 2)$ degrees of freedom.

Dataset: pkfood.cyd

Data Description:

Here we will use pharmacokinetic data from 2×2 crossover trial available in **pkfood.cyd**. The dataset consists of observations from 20 subjects on AUC , C_{max} and T_{max} evaluated under two regimens A and B. For this example, we will consider regimen B as reference and regimen A as test drug and AUC as response variable.

Purpose of the Analysis:

Let μ_c and μ_t denote the mean AUC in regimen B and regimen A, respectively and $\delta = \mu_t - \mu_c$. We are interested in testing $H_0: \mu_t - \mu_c \leq \delta_0$ against $H_1: \mu_t - \mu_c > \delta_0$. Here we set the noninferiority margin, δ_0 as -5000 . For this analysis, one-sided type I error of 0.025 is considered.

Analysis Steps:

1. Choose the menu item:
Home > Open > Data to open the dataset from **Samples** folder.
2. In case multiple workbooks are currently open, then this will bring up the **Keep in** dialog box. You can select either one of the existing workbooks or you can create new workbook. Suppose you want to create a new workbook labeled as "Crossover noninferiority". In order to do this, select the radio button **New Workbook** and type in **Crossover noninferiority** in the field next to it. Click **OK**. This will open the **pkfood.cyd** dataset in the main window of under the **Data Editor**.
3. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Difference of Means

4. In the ensuing dialog box (under the **Main**) select/enter the different variables as shown below.

The screenshot shows a software dialog box titled "Analysis: Continuous Endpoint, Two-Sample Test - Crossover Design - Difference of Means". The "Data Set" is "pkfood.cyd". The "Main" tab is active. The "Trial Type" is set to "Noninferiority". The "Period ID" is "PERIOD", "Subject ID" is "SUBJECT", and "Group ID" is "SEQUENCE". The "Response Variable" is "AUC" and the "Noninferiority Margin(δ_0)" is "-5000". Under "Treatment Specifications", "Treatment 1" is "Test" and "Treatment 2" is "Reference".

5. In the **Advanced** tab, leave the fields **By Variable 1** and **By Variable 2** blank and enter 0.975 for **Confidence Level**.
6. Click **OK** to analyze the data. Following output will be displayed in the main

79 Analysis-Normal Noninferiority Two-Sample

window.

Inference for: (AUC)

Test of Hypothesis for:

| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | (1-Sided) | | 97.5% Confidence Interval(1-Sided) | |
|----|---------------------|------------------|------------|-------|----|-----------|------|------------------------------------|-------------|
| | | | | | | p-value | Tail | Lower Limit | Upper Limit |
| 20 | -1645.9 | 0.95 | 789.591 | 4.248 | 18 | 2.42E-4 | G.E. | -3304.769 | INF |

In the **Output** section, the first part provides descriptive statistics for the two groups. The second table provides the treatment summary. The third table labeled as **Test of Hypothesis for** provides results for statistical test of treatment effect. The estimated effect size is 0.95. The observed value of test statistic is 4.248 and it has $10 + 10 - 2 = 18$ degrees of freedom. The p-value for one-sided test is 0. This is the p-value associated with rejecting $H_0: \delta \leq -5000$ in favor of alternative hypothesis $H_1: \delta > -5000$. The one-sided 97.5% confidence interval is $(-3304.769, -\infty)$. Since the lower limit of the confidence interval is greater than the noninferiority margin of -5000, we can reject $H_0: \delta \leq -5000$ at one-sided 2.5% level of significance.

79.4 Example: Ratio of Means in Crossover design

In this chapter, we show how we can use **East** to test for ratio of means from a noninferiority 2×2 crossover trial. We have already discussed 2×2 crossover design in section 79.3. However, unlike section 79.3, here we are interested in ratio of means. Let μ_t and μ_c denote the means of the observations from the experimental treatment (T) and the control treatment (C), respectively. For noninferiority trial, **East** tests only for treatment effect. With ρ_0 as noninferiority margin, **East** tests $H_0: \mu_t/\mu_c \leq \rho_0$ when $\rho_0 < 1$ and $H_0: \mu_t/\mu_c \geq \rho_0$ when $\rho_0 > 1$.

Since we can translate the ratio hypothesis into difference hypothesis using log transformation, **East** performs the test for difference on log-transformed data as discussed in section 79.3.

Dataset: We will again use **pkfood.cyd** dataset as described in section 79.3.

Purpose of the Analysis:

Here, we are interested in testing the null hypothesis $H_0: \rho \leq 0.8$ is tested against the alternative hypothesis $H_1: \rho > 0.8$. For this analysis, we consider one-sided type I error of 0.025.

1. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Ratio of Means
2. If the dataset is not displayed in your main window, this will bring up the **Select Dataset** dialog box with the list of available workbooks and datasets available under each workbook. If the dataset is already displayed in your main window, **East** will skip this step and the dataset in the main window will be used in the analysis. In case **East** brings up the **Select Dataset** dialog box, choose **pkfood.cyd** dataset under workbook **Crossover noninferiority** and click **OK**.
3. In the ensuing dialog box (under the **Main**) select the variables as shown below:

Analysis: Continuous Endpoint: Two-Sample Test - Crossover Design - Ratio of Means

Treatment 2: Reference

4. In **Advanced** tab specify confidence interval as **0.975**. Click **OK** and the output will be displayed in the main window. Scroll down to the end of the output.

79 Analysis-Normal Noninferiority Two-Sample

Output for statistical test of treatment effect is displayed in the last table.

| Treatment Summary: | | | | | | | |
|-------------------------|---------------------|------------------|------------------------------------|-------------|----|-----------|------|
| Statistic | Test | Reference | | | | | |
| No. of Subjects | 20 | 20 | | | | | |
| Mean | 8455.7 | 10101.6 | | | | | |
| Std. Dev. | 3067.804 | 3590.908 | | | | | |
| Median | 8091.5 | 9604.5 | | | | | |
| Minimum | 4686 | 5648 | | | | | |
| Maximum | 16510 | 18864 | | | | | |
| Inference for: ln(AUC) | | | | | | | |
| Test of Hypothesis for: | | | | | | | |
| n | Difference of Means | Std. Effect Size | Std. Error | t | DF | (1-Sided) | |
| | | | | | | p-value | Tail |
| 20 | -0.179 | 0.126 | 0.079 | 0.561 | 18 | 0.291 | G.E. |
| Parameter Estimates: | | | | | | | |
| Metric | Estimate | Std. Error | 97.5% Confidence Interval(1-Sided) | | | | |
| | | | Lower Limit | Upper Limit | | | |
| ln(Ratio) | -0.179 | 0.079 | -0.345 | INF | | | |
| Ratio | 0.836 | 0.066 | 0.708 | INF | | | |

East performs the analysis based on the log-transformed data. The observed value of test statistic based on log-transformed data is 0.561 and it has $10 + 10 - 2 = 18$ degrees of freedom. The p-value associated with rejection $H_0: \rho \leq 0.8$ is 0.291. The one-sided 97.5% confidence interval for ρ is $(0.708, \infty)$. Since the lower limit of the confidence interval is smaller than the noninferiority margin of 0.8, we cannot reject $H_0: \rho \leq 0.8$ at one-sided 2.5% level of significance.

80 *Analysis-Normal Equivalence Two-Sample*

In many cases, the goal of a clinical trial is neither superiority nor non-inferiority, but equivalence. Chapter 13 deals with the design and simulation of these types of trials. This chapter explains how we can use **East** to perform analysis of data that comes from two independent samples and crossover equivalence studies.

80.1 *Example: Difference of Means*

Dataset: Iris.cyd

Data Description:

Iris flower dataset (Fisher, 1936) consists of 50 samples from each of three species of Iris (Iris setosa, Iris virginica and Iris versicolor). Four features were measured for each sample: the length and the width of the sepals and petals, in centimeters. In this example we will consider sepal widths from I. virginica and I. versicolor respectively. The purpose here is to compare the mean sepal widths between I. virginica and I. versicolor.

Purpose of the Analysis:

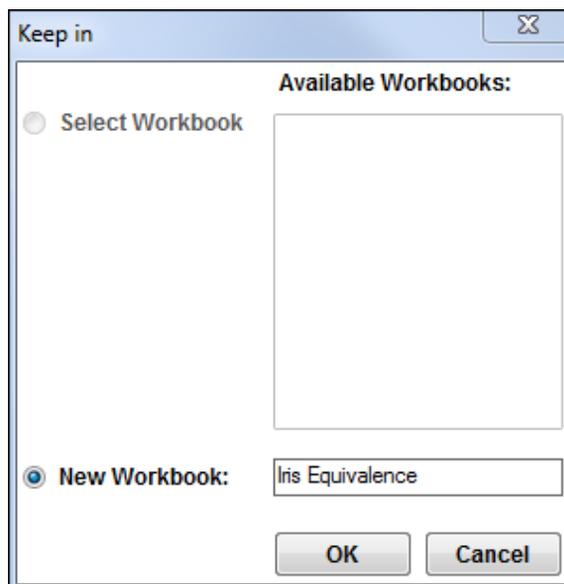

Let μ_t and μ_c be the mean sepal widths in I. virginica and I. versicolor, and $\delta = \mu_t - \mu_c$. We want to test the null hypothesis $H_0: \delta \leq -5$ or $\delta \geq 5$ against the alternative hypothesis $H_1: -5 < \delta < 5$. We want to reject H_0 with probability of type I error not exceeding 0.025.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. In case multiple workbooks are currently open, then this will bring up the **Keep in** dialog box. You can select either one of the existing workbooks or you can create new workbook. Suppose you want to create a new workbook labeled as “Iris Equivalence”. In order to do this, select the radio button **New Workbook**

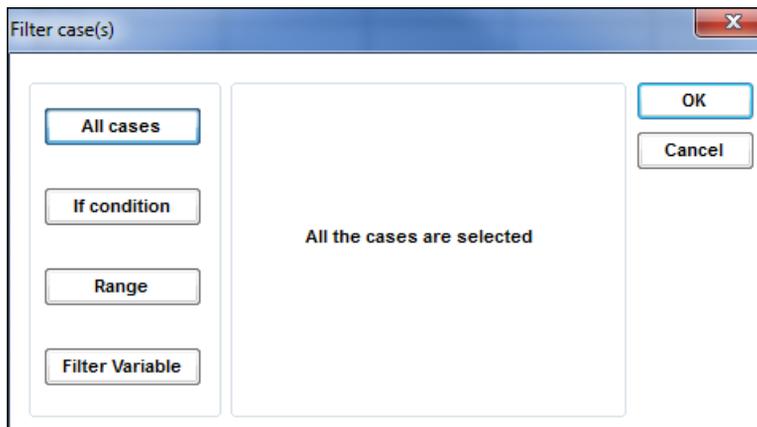

80 Analysis-Normal Equivalence Two-Sample

and type in **Iris Equivalence** in the field next to it.

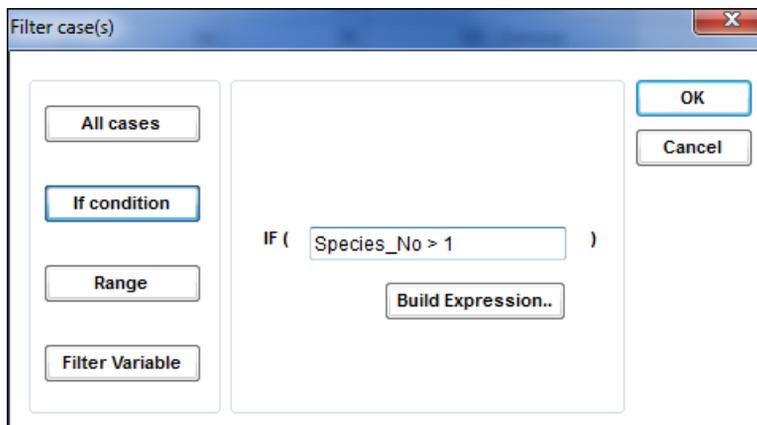

3. Click **OK**. The **Iris.cyd** dataset opens in the main window under the **Data Editor** menu. The dataset has observation from 150 subjects from the 3 species. The columns **Species_na** and **Sepal_widt** contains the information on name of species and width of sepals. We are considering **I. virginica** and **I. versicolor** only in this example. Therefore, we need to keep the data only from these two datasets and remove the remaining observations.
4. Under the **Data Editor** menu, click  icon in the **Data** ribbon. This shows

the **Filter case(s)** dialog box.

5. Click **If condition** button and enter **Species_No > 1**.

6. You can also use **Build Expression** to formulate a conditional expression for the **IF ()** field instead of directly writing the expression. Click **OK**. The observations pertaining to species **Setosa** are highlighted. Select these highlighted observations and click  icon under the **Data Editor** menu. The dataset will now have only 100 observations pertaining to *I. virginica* and *I. versicolor*.
7. Choose the menu item:
Analysis > (Continuous) Two Samples > (Parallel Design) Difference of

80 Analysis-Normal Equivalence Two-Sample

Means

- In the **Main** tab, select **Equivalence** as **Trial Type**, **Equal** as **Variance Type** and **t-test** as **Test Type**. For the **Population Id** field you have to choose a dichotomous variable. The variable selected in this field is the population identifier. Select **Species_na** as **Population Id** variable. As you select variable for **Population Id** field, a new box will appear below where you have to specify the levels of the **Population Id** variable for control and treatment group. Choose **Versicolor** for **Control**. **East** will treat the Versicolor as control and Verginica the treatment.
Select **sepal_widt** as **Response Variable** and enter -5 and 5 for **Lower Equiv. Limit** and **Upper Equiv. Limit**. The Frequency Variable allows the user to specify a variable that represents a frequency, or weighted value. For the current example, leave the **Frequency Variable** field blank.

Analysis: Continuous Endpoint Two-Sample Test - Parallel Desig

- Click **OK** to start the analysis. Upon completion of analysis, a new node with the label **Analysis: Continuous Response: Difference of Means for Independent Data** will be added in the **Library** and the output is displayed in

the main window.

Analysis: Continuous Response: Difference of Means for Independent Data

Hypothesis
 $H_{01} : \mu_1 - \mu_c \leq \delta_L$ Or $H_{02} : \mu_1 - \mu_c \geq \delta_U$
 Vs.
 $H_1 : \delta_L < \mu_1 - \mu_c < \delta_U$

Input Parameters
 Data File: Iris.cyd
 Trial Type: Equivalence
 Population Id: Species_na(Treatment=Verginica, Control=Versicolor)
 Response Variable: Sepal_widt
 Variance Type: Equal
 Test Type: t-test
 Lower Equivalence Limit (δ_L): -5
 Upper Equivalence Limit (δ_U): 5
 Confidence Level (for Equivalence): 0.95

Output
 Response variable: (Sepal_widt)
 Total no. of records: 100
 No. of records rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|-------|---------|----|
| Versicolor | 20 | 34 | 28 | 27.64 | 3.141 | 50 |
| Verginica | 22 | 38 | 30 | 29.74 | 3.225 | 50 |

Test of Hypothesis:

| n | Difference of Means | Std. Effect Size | | Std. Error | t | | DF | 95% Confidence Interval(2-Sided) | | p-value | |
|-----|---------------------|------------------|-----------|------------|-----------|-----------|----|----------------------------------|-------------|-----------|-----------|
| | | Under H01 | Under H02 | | Under H01 | Under H02 | | Lower Limit | Upper Limit | Under H01 | Under H02 |
| 100 | 2.1 | 2.23 | -0.911 | 0.637 | 11.152 | -4.555 | 98 | 0.837 | 3.363 | 1.110E-16 | 7.552E-6 |

The result of the analysis is divided in three sections. The **Hypothesis** section states the null and alternative hypothesis for 2-sided and 1-sided tests.

The **Input Parameters** section displays the name of the data file, the response variable, type of test performed, type I error set for the analysis and other parameter(s) used in the analysis. It is important to review this section to ensure correct and complete input parameters are specified.

The last section is **Output**. First part of the output section is about the descriptive statistics about the response variable. There are 50 observations in each group. Mean sepal lengths (standard deviation) are 27.64 (3.141) and 29.74 (3.225) in I. versicolor and I. verginica groups. Estimated treatment difference is $\hat{\delta} = 2.1$ with $se(\hat{\delta}) = 0.637$. There are two effect sizes - 2.23 (under H_{01}) and -0.911 (under H_{02}). These values can be verified by plugging the value of $\hat{\delta} = 2.1$, $\delta_L = -5$, $\delta_U = 5$ and $\hat{\sigma} = 0.637 / \sqrt{1/50 + 1/50} = 3.185$ in the following formula of effect size under H_{01} and H_{02} .

80 Analysis-Normal Equivalence Two-Sample

$$\frac{\hat{\delta} - \delta_L}{\hat{\sigma}} \quad \text{and} \quad \frac{\hat{\delta} - \delta_U}{\hat{\sigma}}$$

The observed value of two test statistics are 11.152 and -4.555 and both of them have $50 + 50 - 2 = 98$ degrees of freedom. The two-sided 95% confidence interval of $\delta = \mu_t - \mu_c$ is (0.837, 3.363). This confidence interval is within the equivalence interval of (-5, 5), therefore, we can reject $H_0: \mu_t - \mu_c \leq -5$ or $\mu_t - \mu_c \geq 5$ in favor of $H_1: -5 < \mu_t - \mu_c < 5$ with 5% level of significance.

80.2 Example: Log-ratio of Means

Dataset: We will again use dataset **Iris.cyd** here.

Data Description:

Description of this dataset is given in subsection 80.1.

Purpose of the Analysis:

Let μ_t and μ_c be the mean sepal widths of I. virginica and I. versicolor, and $\rho = \mu_t / \mu_c$. Here, we are interested in testing the null hypothesis

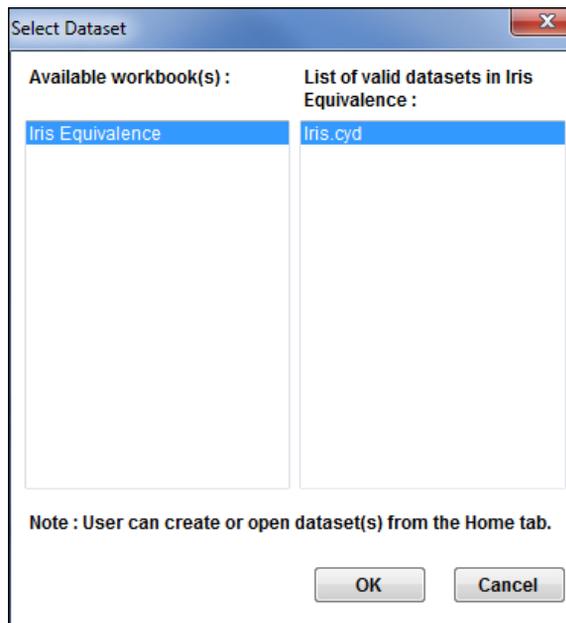

$H_0: \rho \leq 0.8$ or $\rho \geq 1.25$ is tested against the alternative hypothesis

$H_1: 0.8 < \rho < 1.25$. We want to reject H_0 with type I error not exceeding 0.025.

Analysis Steps:

1. Choose the menu item:
Analysis > (Continuous) Two Samples > (Parallel Design) Ratio of Means
2. If the dataset is not displayed in your main window, this will bring up the **Select Dataset** dialog box with the list of available workbooks and datasets available under each workbook. If the dataset is already displayed in your main window, **East** will skip this step and the dataset in the main window will be used in the analysis. In case **East** brings up the **Select Dataset** dialog box, choose **Iris.cyd**

dataset under workbook **Iris Equivalence** and click **OK**.

3. In the ensuing dialog box (under the **Main** tab) select the variables as shown below:

Data Set: Iris.cyd

| Main | | Advanced | |
|----------------|-------------|---------------------|------------|

5. Click **OK** to start the analysis. Upon completion of the analysis, following

output is displayed in the main window.

Analysis: Continuous Response: Ratio of Means for Independent Data

Hypothesis

$H_{01} : \mu_t / \mu_c \leq p_L$ Or $H_{02} : \mu_t / \mu_c \geq p_U$

Vs.

$H_1 : p_L < \mu_t / \mu_c < p_U$

Input Parameters

Data File: Iris.cyd
 Trial Type: Equivalence
 Population Id: Species_na(Treatment=Verginica, Control=Versicolor)
 Response Variable: Sepal_widt
 Variance Type: Equal
 Test Type: t-test
 Lower Equivalence Limit (p_L): 0.8
 Upper Equivalence Limit (p_U): 1.25
 Confidence Level (for Equivalence): 0.95

Output

Response variable: (Sepal_widt)
 Total no. of records: 100
 No. of records rejected: 0

Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|-------|---------|----|
| Versicolor | 20 | 34 | 28 | 27.64 | 3.141 | 50 |
| Verginica | 22 | 38 | 30 | 29.74 | 3.225 | 50 |

Test of Hypothesis for: ln(Sepal_widt)

| n | Difference of Means | Std. Effect Size | | Std. Error | t | | DF | p-value | |
|-----|---------------------|------------------|-----------|------------|-----------|-----------|----|-----------|-----------|
| | | Under H01 | Under H02 | | Under H01 | Under H02 | | Under H01 | Under H02 |
| 100 | 0.074 | 2.636 | -1.322 | 0.023 | 13.181 | -6.611 | 98 | 1.110E-16 | 1.008E-9 |

Parameter Estimates:

| Metric | Estimate | Std. Error | 95% Confidence Interval(2-Sided) | |
|-----------|----------|------------|----------------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| ln(Ratio) | 0.074 | 0.023 | 0.029 | 0.119 |
| Ratio | 1.077 | 0.024 | 1.03 | 1.126 |

First two sections display the information about the hypothesis tested and the inputs specified. In the **Output** section, the first part provides descriptive statistics for the two groups. The second table labeled with **Test of Hypothesis for:ln(Sepal_widt)** provides details about the test result. Note the word “ln(Sepal_widt)”; this emphasizes that the analysis is performed on log-transformed data. In this table, the **Difference of Means** is 0.074. This is the estimated treatment difference in terms of log-transformed data on **Sepal_widt**. In this example, the two effects sizes are 2.636 and -1.322. The observed value of two test statistics are 13.181 and -6.611 and both of them have 98 degrees of

80 Analysis-Normal Equivalence Two-Sample

freedom. The two-sided 95% confidence interval of $\rho = \mu_t/\mu_c$ is (1.03, 1.126). This confidence interval is within the equivalence interval of (0.80, 1.25), therefore, we can reject $H_0: \mu_t/\mu_c \leq 0.80$ or $\mu_t/\mu_c \geq 1.25$ in favor of $H_1: 0.80 < \mu_t/\mu_c < 1.25$ with 5% level of significance..

80.3 Example: Difference of Means in Crossover Designs

Crossover trials are widely used in clinical and medical research and in other diversified areas such as veterinary science, psychology, sports science, dairy science, and agriculture. Crossover design is often preferred over parallel design because each subject receives all the treatments and thus each subject acts as their own control. In this section, we show how **East** supports the design and simulation of such experiments with endpoint as difference of means.

Dataset: pkfood.cyd

Data Description:

Here we will use pharmacokinetic data from 2×2 crossover trial available in **pkfood.cyd**. The dataset consists of observations from 20 subjects on AUC , C_{max} and T_{max} evaluated under two regimens A and B. For this example, we will consider regimen B as reference and regimen A as test drug and AUC as response variable.

Purpose of the Analysis:

Let μ_c and μ_t denote the mean AUC in regimen B and regimen A and $\delta = \mu_t - \mu_c$. Here we set the bioequivalence limits (δ_L, δ_U) as $(-5000, 5000)$. We are interested in testing $H_0: \delta \leq -5000$ or $\delta \geq 5000$ against $H_1: -5000 < \delta < 5000$. For this analysis, probability of type I error of 0.05 is considered.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. In case multiple workbooks are currently open, then this will bring up the **Keep in** dialog box. You can select either one of the existing workbooks or you can create new workbook. Suppose you want to create a new workbook labeled as “Crossover Equivalence”. In order to do this, select the radio button **New Workbook** and type in **Crossover Equivalence** in the field next to it. Click **OK**. This will open the **pkfood.cyd** dataset in the main window of under the **Data Editor**.
3. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Difference of Means

4. In the ensuing dialog box (under the **Main** tab) select/enter the different variables as shown below.

5. In the **Advanced** tab, leave **By Variable 1** and **By Variable 2** blank and enter 0.95 for **Confidence Level**.

6. Click **OK** to analyze the data. Following output will be displayed in the main

80 Analysis-Normal Equivalence Two-Sample

window.

Analysis: Continuous Response: Difference of Means test for Crossover Data

| Maximum | 16510 | 18864 |

Inference for: (AUC)
Test of Hypothesis for:

| n | Difference of Means | Std. Effect Size | | Std. Error | t | | DF | (1-Sided) | (2-Sided) | 90% Confidence Interval(2-Side | |
|----|---------------------|------------------|-----------|------------|---------|---------|----|-------------|-------------|--------------------------------|----------|
| | | Under H01 | Under H02 | | p-value | p-value | | Lower Limit | Upper Limit | | |
| 20 | -1645.9 | 0.95 | -1.882 | 789.591 | 4.248 | -8.417 | 18 | 2.42E-4 | 5.9E-8 | -3015.101 | -276.699 |

In the **Output** section, the first part provides descriptive statistics for the two groups. The second table provides the treatment summary. The third table labeled as **Test of Hypothesis for** provides results for statistical test of treatment effect. The observed values of two test statistics are 4.248 and -8.417 and both of them have 18 degrees of freedom. The 2-sided 90% confidence interval of $\delta = \mu_t - \mu_c$ is (-3015, -277). This confidence interval is well within the equivalence interval of (-5000, 5000), therefore, we can reject $H_0: \mu_t - \mu_c \leq -5000$ or $\mu_t - \mu_c \geq 5000$ in favor of $H_1: -5000 < \mu_t - \mu_c < 5000$ with 5% level of significance.

80.4 Example: Ratio of Means in Crossover Designs

Often in crossover designs, equivalence hypothesis is tested in terms of ratio of means. This type of trial is very popular in establishing bioequivalence and bioavailability between two formulations in terms of pharmacokinetic parameters (FDA guideline on BA/BE studies for orally administered drug products, 2003). In particular, FDA considers two products bioequivalent if the 90% confidence interval of the ratio of two means lie within (0.8, 1.25). This chapter, shows how **East** is used to analyze data from such experiments with endpoint as ratio of means.

Since the ratio hypothesis is translated into difference hypothesis using log transformation, **East** performs two one sided tests (TOST) on the log-transformed data as discussed in section 80.3.

Dataset: We will again use **pkfood.cyd** dataset here.

Data Description:

Description of this dataset is given in subsection 80.3.

Purpose of the Analysis:

Here we are interested in ratio of means. Let μ_t and μ_c denote the means of the observations from the experimental treatment (T) and the control treatment (C). In equivalence trial with endpoint as ratio of means, the goal is to establish $\rho_L < \rho < \rho_U$, where ρ_L and ρ_U are specified values used to define equivalence. In practice, ρ_L and ρ_U are often chosen such that $\rho_L = 1/\rho_U$

The null hypothesis $H_0: \rho \leq \rho_L$ or $\rho \geq \rho_U$ is tested against the two-sided alternative

80 Analysis-Normal Equivalence Two-Sample

hypothesis $H_1: \rho_L < \rho < \rho_U$ at level α , using two one-sided tests. Schuirmann (1987) proposed working this problem out on the natural logarithm scale. Thus we are interested in the parameter $\delta = \ln(\rho) = \ln(\mu_t) - \ln(\mu_c)$ and the null hypothesis $H_0: \delta \leq \delta_L$ or $\delta \geq \delta_U$ is tested against the 2-sided alternative hypothesis $H_1: \delta_L < \delta < \delta_U$ at level α , using two one-sided t-tests. Here $\delta_L = \ln(\rho_L)$ and $\delta_U = \ln(\rho_U)$.

Here, we are interested in testing the null hypothesis $H_0: \rho \leq 0.8$ or $\rho \geq 1.25$ against the alternative hypothesis $H_1: 0.8 < \rho < 1.25$. For this analysis, consider type I error rate of 0.05.

Analysis Steps:

1. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Ratio of Means
2. If the dataset is not displayed in your main window, this will bring up the **Select Dataset** dialog box with the list of available workbooks and datasets available under each workbook. If the dataset is already displayed in your main window, **East** will skip this step and the dataset in the main window will be used in the analysis. In case **East** brings up the **Select Dataset** dialog box, choose **pkfood.cyd** dataset under workbook **Crossover Equivalence** and click **OK**.
3. In the ensuing dialog box (under the **Main** tab) select/enter the variables as shown below:

Analysis: Continuous Endpoint Two-Sample Test - Crossover Design - Ratio of Means

Data Set: pkfood.cyd

| 20 | -0.179 | 0.126 | -1.137 | 0.079 | 0.561 | -5.086 | 0.291 | 3.854E-5 |
| Parameter Estimates: | | | | | | | | |
| Metric | Estimate | Std. Error | 90% Confidence Interval(2-Sided) | | | | | |
| | | | Lower Limit | Upper Limit | | | | |
| ln(Ratio) | -0.179 | 0.079 | -0.316 | -0.042 | | | | |
| Ratio | 0.836 | 0.066 | 0.729 | 0.959 | | | | |

East performs the analysis based on the log-transformed data. The observed values of test statistics based on log-transformed data are 0.561 and -5.086 and they are distributed with $10 + 10 - 2 = 18$ degrees of freedom. The 2-sided 95% confidence interval of $\rho = \mu_t/\mu_c$ is (0.729, 0.959). This confidence interval is NOT within the equivalence interval of (0.80, 1.25), therefore, we can reject $H_0: \mu_t/\mu_c < 0.80$ or $\mu_t/\mu_c > 1.25$ in favor of $H_1: 0.80 \leq \mu_t/\mu_c \leq 1.25$ NOT at 5% level of significance.

81 Analysis-Nonparametric Two-Sample

The Wilcoxon-Mann-Whitney nonparametric test is commonly used for the comparison of two distributions when the observations cannot be assumed to come from normal distributions. It is used when the distributions differ only in a location parameter and is especially useful when the distributions are not symmetric.

East supports analysis using Wilcoxon-Mann-Whitney nonparametric test for parallel as well as crossover designs. The former is discussed in Section 81.1, 81.2 and 81.3 and the later in Section 81.4, 81.5 and 81.6.

81.1 Test for Superiority

81.1.1 Example

Let X_1, \dots, X_{n_t} be the n_t observations from the treatment (T) with distribution function F_t and Y_1, \dots, Y_{n_c} be the n_c observations from the control (C) with distribution function F_c . F_t and F_c are assumed to be continuous with corresponding densities f_t and f_c , respectively.

The primary objective in Wilcoxon-Mann-Whitney test is to investigate whether there is a shift of location, which indicates the presence of the treatment effect. Let θ represents the treatment effect. That is, $F_t(z) = F_c(z + \theta)$.

In a superiority trial, we test the null hypothesis $H_0: \theta = 0$ against the two-sided alternative $H_1: \theta \neq 0$ or a one-sided alternative hypothesis $H_1: \theta < 0$ or $H_1: \theta > 0$. The test statistic is the sum of the ranks for the treatment in the pooled sample minus $n_t(n_t + 1)/2$ or equivalently the number of pairs (X_i, Y_j) such that $X_i < Y_j$. Usually, the test statistic is denoted by W . Asymptotically, this is distributed with following mean and variance

$$E(W) = \frac{n_t(n_t + n_c + 1)}{2} \quad \text{var}(W) = \frac{n_t n_c (n_t + n_c + 1)}{12}$$

The standardized test statistic, Z , is obtained as

$$Z = \frac{W - E(W)}{\sqrt{\text{var}(W)}}$$

The p-value is calculated assuming Z is distributed as standard normal variate.

81.1.1 Example

Dataset : Myeloma.cyd as described in Section 72.1.1.

Purpose of the Analysis:

The purpose here is to compare the values of the variable haemoglobin level between two groups indicated by the variable status (0-alive, 1-dead). Let θ be the median difference between the two groups. We will use θ_t and θ_c to denote the median haemoglobin in the alive and dead groups, respectively. We are interested in testing the null hypothesis $H_0: \theta = 0$ with type I error not exceeding 5% level of significance, where $\theta = \theta_t - \theta_c$.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
**Analysis > (Continuous) Two Samples > (Parallel Design)
Wilcoxon-Mann-Whitney**
3. In the ensuing dialog box choose the variables as shown below:

Analysis: Continuous Endpoint Two-Sample Test - Parallel Design - Wilcoxon-Mann-Whitney

Data Set: Myeloma.cyd

Main Advanced

Trial Type: Superiority Response Variable: haemoglobin

Population Id: status

Control: 1

Treatment: 0

4. Click **OK** to start analysis. The output will be displayed in the main window

81 Analysis-Nonparametric Two-Sample

now.

Analysis: Continuous Response: Wilcoxon Mann Whitney Test for Independent Data

Hypothesis
 $H_0 : \theta_t - \theta_c = 0$ Vs. $H_1 : \theta_t - \theta_c \neq 0$ for 2-sided test
 Either $H_1 : \theta_t - \theta_c < 0$
 Or $H_1 : \theta_t - \theta_c > 0$ for 1-sided test
 where θ_t and θ_c are the medians of the Treatment Group and Control Group.

Input Parameters

Data File: Myeloma.cyd
 Trial Type: Superiority
 Population Id: status(Treatment=0, Control=1)
 Response Variable: haemoglobin
 Confidence Level: 0.95

Output

Response Variable: (haemoglobin)
 Total Number of Records: 65
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|------|------|--------|-------|---------|---|
| 5 | 14.6 | 10.1 | 9.91 | 2.564 | 48 | |
| 4.9 | 14 | 11.6 | 11.024 | 2.425 | 17 | |

Summary of Test Statistic:

| Minimum | Maximum | Mean | Std. dev. | Observed Statistics | Standardized |
|---------|---------|------|-----------|---------------------|--------------|
| 153 | 968 | 561 | 66.959 | 672 | 1.658 |

Test of Hypothesis:

| Estimate of Median Difference | Standardized Statistic | (1-Sided) | | (2-Sided) | 95% Confidence Interval(2-Sided)* | |
|-------------------------------|------------------------|-----------|---------|-----------|-----------------------------------|-------------|
| | | Tail | p-value | p-value | Lower Limit | Upper Limit |
| 1.2 | 1.658 | G.E. | 0.049 | 0.097 | -0.2 | 2.7 |

*The Nonparametric estimates are based on Hodges-Lehmann's formulation.

The last section is the **Output**. First part of the output is about the descriptive statistics about the response variable. There are 65 observations. The mean (standard deviation) hemoglobin levels are 9.91 (2.564) and 11.024 (2.425) in control and treatment groups, respectively. Estimated median difference between the two groups is 1.2. The observed test statistic is $W=672$. The value of standardized statistic is 1.658 and this is obtained according to Eq. 81.1. The 2-sided p-value for comparison of two groups is 0.097. We conclude that based on Wilcoxon Mann Whitney test, the medians in two groups are not significantly different at 5% significance level.

81.2 Test for Non-inferiority

81.2.1 Example

As before, we assume that X_1, \dots, X_{n_t} be the n_t observations from the treatment (T) with distribution function F_t and Y_1, \dots, Y_{n_c} be the n_c observations from the control (C) with distribution function F_c . F_t and F_c are assumed to be continuous with corresponding densities f_t and f_c , respectively. Let θ be the shift of location such that, $F_t(z) = F_c(z + \theta)$.

In a non-inferiority trial, we test the null hypothesis $H_0: \theta \leq \delta_0$ against the alternative hypothesis $H_1: \theta > \delta_0$ if $\delta_0 < 0$ or $H_0: \theta \geq \delta_0$ against the alternative hypothesis $H_1: \theta < \delta_0$ if $\delta_0 > 0$. **East** first subtracts δ_0 from X_1, \dots, X_{n_t} and then the value of test statistic, standardized test statistic and p-value are calculated as done in superiority trial.

81.2.1 Example

Dataset: `Werner.cyd` as described in Section 73.4.2

Purpose of the Analysis:

The purpose here is to compare the median cholesterol level in birthpill user group (T) with the non-user group (C) with non-inferiority margin (δ_0) of 25 and one-sided type I error of 0.025. Let θ_t and θ_c be the median cholesterol levels in birthpill user and non-user groups, respectively. Since $\delta_0 = 25 > 0$, we are testing $H_0: \theta \geq \delta_0$ against the alternative hypothesis $H_1: \theta < \delta_0$, where $\theta = \theta_t - \theta_c$.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
**Analysis > (Continuous) Two Samples > (Parallel Design)
 Wilcoxon-Mann-Whitney**

81 Analysis-Nonparametric Two-Sample

3. In the ensuing dialog box choose the variables as shown below:

Analysis: Continuous Endpoint Two-Sample Test - Parallel Design - Wilcoxon-Mann-Whitney

Data Set: Werner.cyd

Main Advanced

Trial Type: Noninferiority Response Variable: CHOLESTEROL

Population Id: BIRTHPILL Noninferiority Margin: 25

Control: 0

Treatment: 1

4. Now, click on **Advanced** tab and enter 0.975 for **Confidence Level**.

Analysis: Continuous Endpoint Two-Sample Test - Parallel Design - Wilcoxon-Mann-Whitney

Data Set: Werner.cyd

Main Advanced

By Variable 1: Confidence Level: 0.975

By Variable 2:

5. Click **OK** to start analysis. The output will be displayed in the main window

now.

Analysis: Continuous Response: Wilcoxon Mann Whitney Test for Independent Data

If $\delta_0 < 0$ then $H_0 : \theta_t - \theta_c \leq \delta_0$ Vs. $H_1 : \theta_t - \theta_c > \delta_0$

If $\delta_0 > 0$ then $H_0 : \theta_t - \theta_c \geq \delta_0$ Vs. $H_1 : \theta_t - \theta_c < \delta_0$

where θ_t, θ_c are the medians of the Treatment Group and Control Group.

Data File: Werner.cyd
 Trial Type: Noninferiority
 Population Id: BIRTHPILL(Treatment=1, Control=0)
 Response Variable: CHOLESTEROL
 Noninferiority Margin (δ_0): 25
 Confidence Level: 0.975

Output

Response Variable: (CHOLESTEROL)
 Total Number of Records: 188
 Number of Records Rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|---------|---------|----|
| 0 | 155 | 335 | 230 | 232.968 | 43.492 | 94 |
| 1 | 50 | 600 | 235 | 240.585 | 58.924 | 94 |

Summary of Test Statistic:

| Minimum | Maximum | Mean | Std. dev. | Observed Statistics | Standardized |
|---------|---------|------|-----------|---------------------|--------------|
| 4465.5 | 13300.5 | 8883 | 372.95 | 7781.5 | -2.953 |

Test of Hypothesis:

| Estimate of Median Difference | Standardized Statistic | (1-Sided) | | 97.5% Confidence Interval(1-Sided)* | |
|-------------------------------|------------------------|-----------|---------|-------------------------------------|-------------|
| | | Tail | p-value | Lower Limit | Upper Limit |
| 5 | -2.953 | L.E. | 0.002 | -INF | 19 |

*The Nonparametric estimates are based on Hodges-Lehmann's formulation.

The last section is the **Output**. First part of the output is about the descriptive statistics about the response variable. There are 25 observations. Estimate of $\theta = \theta_t - \theta_c$ (i.e., median difference) is 5. The observed value of the test statistic (W) and standardized test statistic (Z) are 7781.5 and -2.953, respectively. The p-value for this non-inferiority test is 0.002. Therefore, we conclude that the Birthpill user group is non-inferior to the non-user group in terms of cholesterol level with non-inferiority margin of 25.

81.3 Test for Equivalence

81.3.1 Example

As before, we assume that X_1, \dots, X_{n_t} be the n_t observations from the treatment (T) with distribution function F_t and Y_1, \dots, Y_{n_c} be the n_c observations from the control (C) with distribution function F_c . F_t and F_c are assumed to be continuous with

81 Analysis-Nonparametric Two-Sample

corresponding densities f_t and f_c , respectively. Let θ be the shift of location such that, $F_t(z) = F_c(z + \theta)$.

The null hypothesis $H_0: \theta \leq \delta_L$ or $\theta \geq \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L < \theta < \delta_U$ at level α , using the following two one-sided tests (TOST).

- Test1: $H_{0L}: \theta \leq \delta_L$ against $H_{1L}: \theta > \delta_L$ at level α
- Test2: $H_{0U}: \theta \geq \delta_U$ against $H_{1U}: \theta < \delta_U$ at level α

East subtracts δ_L and δ_U from X_1, \dots, X_{n_t} for Test1 and Test2, respectively. Then the value of test statistic, standardized test statistic and p-value are calculated separately as done in superiority trial. To declare equivalence, both H_{0L} and H_{0U} need to be rejected.

81.3.1 Example

Dataset: **Iris.cyd** as described in Section 80.1

Purpose of the Analysis:

The purpose here is to compare the median sepal widths between I. virginica and I. versicolor with equivalence limits (δ_L, δ_U) as $(-5, 5)$. Let θ_t and θ_c denote the median sepal widths in I. virginica and I. versicolor, respectively, and $\theta = \theta_t - \theta_c$.

We want to test the null hypothesis $H_0: \theta \leq -5$ or $\theta \geq 5$ against the alternative hypothesis $H_1: -5 < \theta < 5$. We want to reject H_0 with type I error rate not exceeding 0.05.

Analysis Steps:

1. Open the **Iris.cyd** from the **Samples** folder and keep only the observations pertaining to I. virginica and I. versicolor as described in subsection 80.1.
2. Choose the menu item:
**Analysis > (Continuous) Two Samples > (Parallel Design)
Wilcoxon-Mann-Whitney**

3. In the ensuing dialog box choose the variables as shown below:

Data Set: Iris.cyd

Main **Advanced**

Trial Type: Response Variable:

Population Id: Lower Equiv. Limit:

Control: Upper Equiv. Limit:

Treatment:

4. Now click on **Advanced** tab. Enter 0.975 for **Confidence Level**.

Analysis: Continuous Endpoint Two-Sample Test - Parallel Design - Wilcoxon-Mann-Whitney

Data Set: Iris.cyd

Main **Advanced**

By Variable 1: Confidence Level:

By Variable 2: Confidence Level (Equivalence):

5. Click **OK** to start analysis. The output will be displayed in the main window

81 Analysis-Nonparametric Two-Sample

now.

Analysis: Continuous Response: Wilcoxon Mann Whitney Test for Independent Data

Hypothesis
 $H_{01} : \theta_t - \theta_c \leq \delta_L$ Or $H_{02} : \theta_t - \theta_c \geq \delta_U$
 Vs. $H_1 : \delta_L < \theta_t - \theta_c < \delta_U$
 where θ_t and θ_c are the medians of the Treatment Group and Control Group.

Input Parameters

Data File: Iris.cyd
 Trial Type: Equivalence
 Population Id: Species_na(Treatment=Verginica, Control=Versicolor)
 Response Variable: Sepal_widt
 Lower Equivalence Limit (δ_L): -5
 Upper Equivalence Limit (δ_U): 5
 Confidence Level (for Equivalence): 0.95

Output

Response variable: (Sepal_widt)
 Total no. of records: 100
 No. of records rejected: 0
 Summary of the Observed Data:

| Treatment Group | Min | Max | Median | Mean | Std.Dev | n |
|-----------------|-----|-----|--------|-------|---------|----|
| Versicolor | 20 | 34 | 28 | 27.64 | 3.141 | 50 |
| Verginica | 22 | 38 | 30 | 29.74 | 3.225 | 50 |

Summary of Test Statistic:

| Statistic | Minimum | Maximum | Mean | Std. dev. | Observed Statistics | Standardized |
|-----------|---------|---------|------|-----------|---------------------|--------------|
| Under H01 | 1278 | 3772 | 2525 | 144.647 | 3656.5 | 7.822 |
| Under H02 | 1283 | 3767 | 2525 | 144.39 | 1905 | -4.294 |

Test of Hypothesis:

| Estimate of Median Difference | Standardized Statistic | | p-value | | 95% Confidence Interval(2-Sided)* | |
|-------------------------------|------------------------|-----------|-----------|-----------|-----------------------------------|-------------|
| | Under H01 | Under H02 | Under H01 | Under H02 | Lower Limit | Upper Limit |
| 2 | 7.822 | -4.294 | 0 | 8.777E-6 | 1 | 3 |

The last section is the **Output**. First part of the output is about the descriptive statistics about the response variable. There are 50 observations in each group. Median sepal lengths are 28 and 30 in I. versicolor and I. verginica groups, respectively. Estimate of $\theta = \theta_t - \theta_c$ is 2. The observed values of test statistic and standardized test statistic are 3656.5 and 7.822, respectively for the H_{0L} and 1905 and -4.294, respectively for the H_{0U} . The p-values associated with H_{0L} and H_{0U} are very close to 0. Therefore, we can reject individually both H_{0L} and H_{0U} . Thus, we reject $H_0: \theta \leq -5$ or $\theta \geq 5$ with very small p-value

81.4 Test for Superiority in Crossover Trial

81.4.1 Example

In a 2×2 crossover design each subject is randomized to one of two sequence groups. Subjects in the sequence group 1 receive the test drug (T) formulation in a first period, have their outcome variable, X recorded, wait out a washout period to ensure that the drug is cleared from their system, then receive the control drug formulation (C) in period 2 and finally have the measurement on X again. In sequence group 2, the order in which the T and C are assigned is reversed. The table below summarizes this type of trial design.

| Group | Period 1 | Washout | Period 2 |
|-------|----------|---------|----------|
| 1(TC) | Test | — | Control |
| 2(CT) | Control | — | Test |

The resulting data are commonly analyzed using a statistical linear model. The response y_{ijk} in period j on subject k in sequence group i , where $i = 1, 2$, $j = 1, 2$, and $k = 1, \dots, n_i$ is modeled as a linear function of an overall mean response μ , formulation effect τ_t and τ_c , period effects π_1 and π_2 , and sequence effects λ_1 and λ_2 . The fixed effects model can be displayed as:

| Group | Period 1 | Washout | Period 2 |
|-------|-----------------------------------|---------|------------------------------------|
| 1(TC) | $\mu + \tau_t + \pi_1 + \gamma_1$ | — | $\mu + \tau_c + \pi_2 + \lambda_1$ |
| 2(CT) | $\mu + \tau_c + \pi_1 + \gamma_2$ | — | $\mu + \tau_t + \pi_2 + \lambda_2$ |

For superiority trial, **East** can test following null hypotheses:

- Test1: $H_0 : \tau_t - \tau_c = 0$. for treatment effect
- Test2: $H_0 : \pi_1 - \pi_2 = 0$. for period effect
- Test1: $H_0 : \lambda_1 - \lambda_2 = 0$. for carryover effect

To test the above hypotheses **East** uses Hodges-Lehmann (HL) implementation of Wilcoxon Mann Whitney test. For example, for test of treatment effect, HL estimate of $\tau_t - \tau_c$ is obtained as

$$\frac{1}{2} \cdot [\text{Median}(Y_{11k_1} - Y_{12k_1}, Y_{22k_2} - Y_{21k_2} : k_1 = 1, \dots, n_1; k_2 = 1, \dots, n_2)]$$

81.4.1 Example

Dataset: CrossOverCaseData.cyd as described in Section 78.3

81 Analysis-Nonparametric Two-Sample

Purpose of the Analysis:

The purpose here is to compare the median morning peak expiratory flow rate (PEFR) between placebo and test drug. Let θ be the median difference between Drug and Placebo groups.

Analysis Steps:

1. Open the Dataset from the **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Wilcoxon-Mann-Whitney
3. In the ensuing dialog box choose the variables as shown below:

Analysis: Continuous Endpoint: Two-Sample Test - Crossover Design - Wilcoxon-Mann-Whitney

|-----------------|-------------|-------------|
| No. of Subjects | 56 | 56 |
| Mean | 237.72 | 227.183 |
| Std. Dev. | 78.008 | 77.315 |
| Median | 231.157 | 214.272 |
| Minimum | 67.778 | 70.278 |
| Maximum | 443.25 | 420.5 |

Summary of Test Statistic:

| Minimum | Maximum | Mean | Std. dev. | Observed Statistic | Standardized |
|---------|---------|-------|-----------|--------------------|--------------|
| 378 | 1161 | 769.5 | 60.986 | 835 | 1.074 |

Test of Hypothesis:

| Type | Standardized Statistic | Estimate of Median Difference | (1-Sided) | | (2-Sided) | 95% Confidence Interval(2-Sided)* | | | |
|------------|------------------------|-------------------------------|-----------|---------|-----------|-----------------------------------|-------------|---------|---------|
| | | | Tail | p-value | p-value | Lower Limit | Upper Limit | | |
| Asymptotic | 1.074 | | | 35.476 | G.E. | 0.141 | 0.283 | -34.357 | 114.804 |

*The Nonparametric estimates are based on Hodges-Lehmann's formulation.

In the **Output** section, the first part provides descriptive statistics for the two groups. The second table provides the treatment summary. The third table, labeled as **Test of Hypothesis**, provides results for statistical test of carryover effect. The observed value of statistic and standardized test statistic are 835 and 1.074, respectively. The p-value for two sided test is 0.283. Therefore, the carryover effect is not significant in this case and we can ignore this carryover effect.

Test for Treatment effect

Dataset: CrossOverCaseData.cyd as described in Section 78.3

Purpose of the Analysis:

The purpose here is to compare the median morning peak expiratory flow rate (PEFR) between placebo and test drug.

Analysis Steps:

1. Open the Dataset from the **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Wilcoxon-Mann-Whitney
3. In the ensuing dialog box choose the variables as shown below:

Click **OK** to start analysis. Upon completion of analysis, the output will be displayed in the main window. Scroll down to the end of the output. Output for statistical test of treatment effect is displayed in the last two tables.

Treatment Summary:

| Statistic | Treatment 1 | Treatment 2 |
|-----------------|-------------|-------------|
| No. of Subjects | 56 | 56 |
| Mean | 237.72 | 227.183 |
| Std. Dev. | 78.008 | 77.315 |
| Median | 231.157 | 214.272 |
| Minimum | 67.778 | 70.278 |
| Maximum | 443.25 | 420.5 |

Summary of Test Statistic:

| Minimum | Maximum | Mean | Std. dev. | Observed Statistic | Standardized |
|---------|---------|-------|-----------|--------------------|--------------|
| 378 | 1161 | 769.5 | 60.986 | 953 | 3.009 |

Test of Hypothesis:

| Type | Standardized Statistic | Estimate of Median Difference | (1-Sided) | | (2-Sided) | | 95% Confidence Interval(2-Sided)* | |
|------------|------------------------|-------------------------------|-----------|---------|-----------|-------------|-----------------------------------|--|
| | | | Tail | p-value | p-value | Lower Limit | Upper Limit | |
| Asymptotic | 3.009 | 11.494 | G.E. | 0.001 | 0.003 | 4.06 | 18.244 | |

*The Nonparametric estimates are based on Hodges-Lehmann's formulation.

The observed value of statistic and standardized test statistic are 953 and 3.009,

81 Analysis-Nonparametric Two-Sample

respectively. The p-value for two sided test is 0.003. Therefore, the treatment effect is significant in this case. In other words, the test drug significantly increases the median PEFR level over the placebo.

81.5 Test for Non-inferiority in Crossover Trial

81.5.1 Example

Let $\theta = \tau_t - \tau_c$. In a non-inferiority trial, we test the null hypothesis $H_0: \theta \leq \delta_0$ against the alternative hypothesis $H_1: \theta > \delta_0$ if $\delta_0 < 0$ or $H_0: \theta \geq \delta_0$ against the alternative hypothesis $H_1: \theta < \delta_0$ if $\delta_0 > 0$. **East** first subtracts δ_0 from all the observations pertaining to Test drug (T). Then the HL estimator is calculated as discussed in Section 81.4.

81.5.1 Example

Dataset: `pkfood.cyd` as described in Section 79.3.

Purpose of the Analysis:

Here the purpose is to compare the median AUC in regimen A with the regimen B considering the latter as reference and the former as test drug with non-inferiority margin (δ_0) of -5000 and one-sided type I error of 0.025. We will use θ_t and θ_c to denote the median AUC in regimen A and regimen B, respectively. Since $\delta_0 = -5000 < 0$, we are testing $H_0: \theta \leq \delta_0$ against the alternative hypothesis $H_1: \theta > \delta_0$, where $\theta = \theta_t - \theta_c$.

Analysis Steps:

1. Open the Dataset from the **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Two Samples > (Crossover Design) Wilcoxon-Mann-Whitney
3. In the ensuing dialog box choose the variables as shown below:

4. In the **Advanced** tab, leave the fields **By Variable 1** and **By Variable 2** blank and enter 0.975 for **Confidence Level**.
5. Click **OK** to start analysis. Upon completion of analysis, a new node with label **Analysis: Continuous Response: Difference of Means test for Crossover Data1** is added in the **Library** and the output will be displayed in the main window.

Analysis: Continuous Response: Wilcoxon Mann Whitney Test: 2X2 Crossover

Hypothesis

If $\delta_0 < 0$ then $H_0 : \theta_1 - \theta_2 \leq \delta_0$ Vs. $H_1 : \theta_1 - \theta_2 > \delta_0$
 If $\delta_0 > 0$ then $H_0 : \theta_1 - \theta_2 \geq \delta_0$ Vs. $H_1 : \theta_1 - \theta_2 < \delta_0$

where θ_1, θ_c are the medians of the Treatment Group and Control Group.

Input Parameters

Data File: pkfood.cyd
 Trial Type: Noninferiority
 Response Variable: AUC
 Group ID: SEQUENCE
 Subject ID: SUBJECT
 Period ID: PERIOD
 Test Type: t-Test
 Non Inferiority Margin (δ_0): -5000
 Confidence Level: 0.95
 Treatment Assignment:

| Group ID | Period ID | |
|----------|-----------|-----------|
| | P1 | P2 |
| G1 | Test | Reference |
| G2 | Reference | Test |

Output

Response variable: (AUC)
 Total no. of records: 40
 No. of records rejected: 0

81 Analysis-Nonparametric Two-Sample

Summary of the Observed Data:

| Group ID | Statistic | Period ID | | Group Summary |
|----------------|-----------------|-----------|----------|---------------|
| | | 1 | 2 | |
| AB | No. of Subjects | 10 | 10 | 10 |
| | Mean | 8542 | 9582.9 | 9062.45 |
| | Std. Dev. | 2978.945 | 3820.535 | 3376.8 |
| | Median | 8641 | 7859.5 | 8012 |
| | Minimum | 4686 | 5648 | 4686 |
| | Maximum | 14059 | 15765 | 15765 |
| BA | No. of Subjects | 10 | 10 | 10 |
| | Mean | 10620.3 | 8369.4 | 9494.85 |
| | Std. Dev. | 3468.083 | 3313.29 | 3497.233 |
| | Median | 9852.5 | 7607.5 | 9165.5 |
| | Minimum | 5911 | 5118 | 5118 |
| | Maximum | 18864 | 16510 | 18864 |
| Period Summary | No. of Subjects | 20 | 20 | |
| | Mean | 9581.15 | 8976.15 | |
| | Std. Dev. | 3322.27 | 3535.775 | |
| | Median | 9641.5 | 7859.5 | |
| | Minimum | 4686 | 5118 | |
| | Maximum | 18864 | 16510 | |

Treatment Summary:

| Statistic | Test | Reference |
|-----------------|----------|-----------|
| No. of Subjects | 20 | 20 |
| Mean | 8455.7 | 10101.6 |
| Std. Dev. | 3067.804 | 3590.908 |
| Median | 8091.5 | 9604.5 |
| Minimum | 4686 | 5648 |
| Maximum | 16510 | 18864 |

Summary of Test Statistic:

| Minimum | Maximum | Mean | Std. dev. | Observed Statistic | Standardized |
|---------|---------|------|-----------|--------------------|--------------|
| 55 | 155 | 105 | 13.229 | 146 | 3.099 |

Test of Hypothesis:

| Type | Standardized Statistic | Estimate of Median Difference | (1-Sided) | | 95% Confidence Interval(1-Sided)* | |
|------------|------------------------|-------------------------------|-----------|---------|-----------------------------------|-------------|
| | | | Tail | p-value | Lower Limit | Upper Limit |
| Asymptotic | 3.099 | -1427.25 | G.E. | 0.001 | -2432.5 | INF |

*The Nonparametric estimates are based on Hodges-Lehmann's formulation.

In the **Output** section, the first part provides descriptive statistics for the two groups. The second table provides the treatment summary. The table labeled as **Test of Hypothesis** provides results for statistical test of treatment effect. The estimated median difference is -1427.25. The observed value of test statistic and standardized test statistic are 146 and 3.099, respectively. The p-value for one-sided test is 0.001. This is the p-value associated with rejecting $H_0: \theta \leq -5000$ in favor of alternative hypothesis $H_1: \theta > -5000$. The one-sided 97.5% confidence interval is $(-2432, \infty)$. Since the lower limit of the confidence interval is greater than the non-inferiority margin of -5000, we can reject $H_0: \theta \leq -5000$ at one-sided 2.5% level of significance.

81.6 Test for Equivalence in Crossover Trial

Let $\theta = \tau_t - \tau_c$. The null hypothesis $H_0: \theta \leq \delta_L$ or $\theta \geq \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L < \theta < \delta_U$ at level α , using the following two one-sided tests (TOST).

- Test1: $H_{0L}: \theta \leq \delta_L$ against $H_{1L}: \theta > \delta_L$ at level α
- Test2: $H_{0U}: \theta \geq \delta_U$ against $H_{1U}: \theta < \delta_U$ at level α

East subtracts θ_L and θ_U from all the observations pertaining to Test drug (T) for Test1 and Test2, respectively. Then the HL estimator is calculated as discussed in Section 81.4. To declare equivalence, both H_{0L} and H_{0U} need to be rejected.

81.6.1 Example

Dataset: `pkfood.cyd` as described in Section 79.3.

Purpose of the Analysis:

Here the purpose is to compare the median AUC in regimen A with the regimen B considering the latter as reference and the former as test drug with bioequivalence limits (δ_L, δ_U) as (-5000, 5000) and type I error rate not exceeding 0.05. Let θ_t and θ_c be the median AUC in regimen A and regimen B, respectively, and $\theta = \theta_t - \theta_c$.

We want to test the null hypothesis $H_0: \theta \leq -5000$ or $\theta \geq 5000$ against the alternative hypothesis $H_1: -5000 < \theta < 5000$.

Analysis Steps:

1. Open the Dataset from the **Samples** folder.
2. Choose the menu item:
**Analysis > (Continuous) Two Samples > (Crossover Design)
 Wilcoxon-Mann-Whitney**

81 Analysis-Nonparametric Two-Sample

3. In the ensuing dialog box choose the variables as shown below:

4. Click **OK** to start analysis. Upon completion of analysis, a new node with label **Analysis: Continuous Response: Difference of Means test for Crossover Data1** is added in the **Library** and the output will be displayed in the main window.

Analysis: Continuous Response: Difference of Means test for Crossover Data

$$H_{01} : \mu_1 - \mu_2 \leq \delta_L \quad \text{Or} \quad H_{02} : \mu_1 - \mu_2 \geq \delta_U$$

Vs.

$$H_1 : \delta_L < \mu_1 - \mu_2 < \delta_U$$

Data File: pkfood.cyd
 Trial Type: Equivalence
 Response Variable: AUC
 Group ID: SEQUENCE
 Subject ID: SUBJECT
 Period ID: PERIOD
 Test Type: t-Test
 Lower Equivalence Limit(δ_L): -5000
 Upper Equivalence Limit(δ_U): 5000
 Confidence Level (for Equivalence): 0.9
 Treatment Assignment:

| Group ID | Period ID | |
|----------|-----------|-----------|
| | 1 | 2 |
| AB | Test | Reference |
| BA | Reference | Test |

Output

Response Variable: (AUC)
 Total Number of Records: 40
 Number of Records Rejected: 0

| | | | | |
|--|---------|-------|-------|--|
| | Maximum | 18864 | 16510 | |
|--|---------|-------|-------|--|

Treatment Summary:

| Statistic | Test | Reference |
|-----------------|----------|-----------|
| No. of Subjects | 20 | 20 |
| Mean | 8455.7 | 10101.6 |
| Std. Dev. | 3067.804 | 3590.908 |
| Median | 8091.5 | 9604.5 |
| Minimum | 4686 | 5648 |
| Maximum | 16510 | 18864 |

Summary of Test Statistic:

| Statistic | Minimum | Maximum | Mean | Std. dev. | Observed Statistic | Standardized |
|-----------|---------|---------|------|-----------|--------------------|--------------|
| Under H01 | 55 | 155 | 105 | 13.229 | 146 | 3.099 |
| Under H02 | 55 | 155 | 105 | 13.229 | 55 | -3.78 |

Test of Hypothesis:

| Type | Standardized Statistic | | Estimate of Median Difference | p-value | | 90% Confidence Interval(2-Sided)* | |
|------------|------------------------|-----------|-------------------------------|-----------|-----------|-----------------------------------|-------------|
| | Under H01 | Under H02 | | Under H01 | Under H02 | Lower Limit | Upper Limit |
| Asymptotic | 3.099 | -3.78 | -1427.25 | 9.699E-4 | 7.853E-5 | -2432.5 | -296.5 |

In the **Output** section, the first part provides descriptive statistics for the two groups. The second table provides the treatment summary. The third table labeled as **Test of Hypothesis** provides results for statistical test of treatment effect.

The estimated median difference is -1427.25. The observed values of test statistic and standardized test statistic are 146 and 3.099 respectively for the H_{01} and 55 and -3.78, respectively for the H_{02} .

82

Analysis-ANOVA

Sometimes the goal of a clinical trial is to compare more than two treatment arms. For example, in a phase II dose-finding study multiple doses of an experimental drug may be compared with placebo or some other control. The most popular method applied to this kind of data is Analysis of Variance (ANOVA). Designing of such studies with continuous endpoint is discussed in chapter 14.

In this section, we focus on how to analyze data collected from such studies using ANOVA in **East**. As an alternative to ANOVA, you can analyze these kind of data using multiple comparison procedures as well and this is discussed in chapter 84.

82.1 Example: One Way ANOVA

In a one-way Analysis of Variance (ANOVA) test, we wish to test the equality of means across R independent groups.

Let X_{ij} indicate the response from j^{th} unit of i^{th} group; $i = 1, \dots, R, j = 1, \dots, n_i$. Further assume, $X_{ij} \sim N(\mu_i, \sigma^2)$; $i = 1, \dots, R$. In one-way ANOVA, the goal is to compare the null hypothesis

$$H_0 : \mu_1 = \mu_2 = \dots = \mu_R$$

against the alternative hypothesis

$$H_1 : \text{for at least one pair } (i, i'), \mu_i \neq \mu_{i'}, \text{ where } i, i' = 1, 2, \dots, R.$$

Dataset: leucolyte.cyd.

Data Description

Kontula K et al (1980, 1982) conducted a study to compare the number of glucocorticoid receptor (GR) sites per leukocyte cell in 5 groups of patients:

1. Group 1: normal subjects
2. Group 2: patients with hairy-cell leukemia
3. Group 3: patients with chronic lymphatic leukemia
4. Group 4: patients with chronic myelocytic leukemia
5. Group 5: patients with acute leukemia

Purpose of the Analysis:

The goal is to compare the mean GR sites per leukocyte cell among the 5 groups of patients.

Let μ_i denote the mean number of GR sites per leukocyte cell in i^{th} group of subjects/patients; $i = 1, \dots, R$. To test the null hypothesis

$H_0 : \mu_1 = \mu_2 = \mu_3 = \mu_4 = \mu_5$ with 5% level of significance.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous): Many Samples > (Factorial Design) One-Way ANOVA
3. In the **Main** tab, select **Group** as **Factor** and **GR** as **Response**. Leave the check box for **Contrast** unchecked.

Analysis: Continuous Endpoint Many-Sample Test - Factorial Design - One-Way ANOVA

Data Set: leukocyte.cyd

Main Advanced

Factor: Group Contrast

Response: GR

4. In the **Advanced** tab, you can select up to 2 grouping variables. If only one grouping variable is selected, then a different analysis will be displayed for each level of the selected grouping variable. If two grouping variables are selected then **East** will display different analysis for each combination of levels of two grouping variables. In this analysis, leave the fields **By Variable 1** and **By Variable 2** blank.

Analysis: Continuous Endpoint Many-Sample Test - Factorial Design - One-Way ANOVA

Data Set: leukocyte.cyd

Main Advanced

By Variable 1:

By Variable 2:

82 Analysis-ANOVA

- Click **OK** to start the analysis. After completion of the analysis, the output is displayed in the main window.

Analysis: ANOVA: One Way

Hypothesis

$$H_0 : \mu_1 = \mu_2 = \dots = \mu_r$$

Vs.

H_1 : At least one μ_i differs , for $i=1,2,3 \dots r$ where r is the number of treatment groups

Input Parameters

Data File: leukocyte.cyd

Factor: Group

Response: GR

Output

Total no. of records: 37

No. of records rejected: 0

ANOVA Table:

| Source | DF | Sum of Squares | Mean Square | F Statistic | p-value |
|-----------|----|----------------|--------------|-------------|---------|
| Group | 4 | 353735187.391 | 88433796.848 | 4.308 | 0.007 |
| Residuals | 32 | 656834693.69 | 20526084.178 | | |
| Total | 36 | 1.011E9 | | | |

Summary Table:

| Overall Mean | Root MSE | R-Square | Adjusted R-Square | Coeff. of Variation |
|--------------|----------|----------|-------------------|---------------------|
| 7107.568 | 4530.572 | 0.35 | 0.269 | 63.743 |

The last section is the **Output**. From the **ANOVA Table**, the significance level for Group effect is 0.007. Therefore, the conclusion is to reject

$H_0 : \mu_1 = \mu_2 = \mu_3 = \mu_4 = \mu_5$ at 5% level of significance.

82.2 Example: One Way Contrast

Often one may be interested in testing significance of linear combination of group means instead of just finding the difference in group means. This can be done through the use of contrast. A contrast of the population means is a linear combination of the

μ_i 's.

For the given scalars, $\{c_i : i = 1, \dots, R\}$, $C = \sum c_i \mu_i$ denotes a linear contrast of population mean if $\sum c_i = 0$. For a single contrast test of many means in a one-way ANOVA, the null hypothesis that we wish to test is:

$$H_0 : \sum c_i \mu_i = 0$$

versus a 2-sided alternative

$$H_1 : \sum c_i \mu_i \neq 0$$

Or a 1-sided alternative

$$H_1 : \sum c_i \mu_i < 0 \text{ or } H_1 : \sum c_i \mu_i > 0.$$

Dataset: *leucolyte.cyd* as described in section 82.1

Purpose of the Analysis:

Let μ_i denote the mean number of GR sites per leukocyte cell in i^{th} group of subjects/patients; $i = 1, \dots, R$.

We are interested in comparing the mean number of GR sites in normal subjects (Group 1) with the average of mean number of GR sites in all the remaining groups. That is, we are interested in comparing:

$$\mu_1 \text{ with } \frac{\mu_2 + \mu_3 + \mu_4 + \mu_5}{4}.$$

To do this comparison, test the following null hypothesis:

$$H_0 : \frac{1}{4}\mu_2 + \frac{1}{4}\mu_3 + \frac{1}{4}\mu_4 + \frac{1}{4}\mu_5 - \mu_1 = 0$$

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous): Many Samples > (Factorial Design) One-Way ANOVA

82 Analysis-ANOVA

- In the **Main** tab, select **Group** as **Factor** and **GR** as **Response**. Select the check box for **Contrast**. A table is displayed below it. Enter -1 , 0.25 , 0.25 , 0.25 and 0.25 in **Coefficient** column for the 5 categories.

Analysis: Continuous Endpoint Many-Sample Test - Factorial Design - One-Way ANOVA

Data Set: leukocyte.cyd

Main Advanced

Factor: Group

Response: GR

Contrast

| Category | Coefficient |
|----------|-------------|
| 1 | -1 |
| 2 | 0.25 |
| 3 | 0.25 |
| 4 | 0.25 |
| 5 | 0.25 |

- Click **OK** to start the analysis. After completion of the analysis, the output is

displayed in the main window.

Analysis: One-way Contrast ANOVA

Hypothesis

$H_0 : t_1 \mu_1 + t_2 \mu_2 + \dots + t_m \mu_m = 0$

Vs.

$H_1 : t_1 \mu_1 + t_2 \mu_2 + \dots + t_m \mu_m \neq 0$ where $\sum t = 0$ and m is the levels of the factor

Input Parameters

Data File: leukocyte.cyd

Factor: Group

Response: GR

Contrast:

| Levels | Coefficient |
|--------|-------------|
| 1 | -1 |
| 2 | 0.25 |
| 3 | 0.25 |
| 4 | 0.25 |
| 5 | 0.25 |

Output

Total no. of records: 37

No. of records rejected: 0

ANOVA Table:

| Source | DF | Sum of Squares | Mean Square | F Statistic | p-value |
|-----------|----|----------------|--------------|-------------|---------|
| Group | 4 | 353735187.391 | 88433796.848 | 4.308 | 0.007 |
| Residuals | 32 | 656834693.69 | 20526084.178 | | |
| Total | 36 | 1.011E9 | | | |

Table of contrast:

| Source | DF | Sum of Squares | Mean Square | F Statistic | t Statistic | 1-Sided p-value | | 2-Sided p-value |
|----------|----|----------------|---------------|-------------|-------------|-----------------|-------------|-----------------|
| | | | | | | F Statistic | t Statistic | t Statistic |
| Contrast | 1 | 107544481.594 | 107544481.594 | 5.239 | 2.289 | 0.007 | 0.014 | 0.029 |

Summary Table:

| Overall Mean | Root MSE | R-Square | Adjusted R-Square | Coeff. of Variation |
|--------------|----------|----------|-------------------|---------------------|
| 7107.568 | 4530.572 | 0.35 | 0.269 | 63.743 |

The result of the analysis is divided into three sections. Test for contrast is displayed in the third section labeled as **Output**. The 2-sided p-value for testing the $H_0 : \frac{1}{4}\mu_2 + \frac{1}{4}\mu_3 + \frac{1}{4}\mu_4 + \frac{1}{4}\mu_5 - \mu_1 = 0$ is 0.029. Therefore, we can conclude that mean number of average GR sites in normal subjects (Group 1) is significantly different than the average of mean number of average GR sites in all the remaining groups with observed significance level of 0.029.

82 Analysis-ANOVA

82.3 Example: One Way Repeated Measures (Constant Correlation) ANOVA

As with the one-way ANOVA discussed in section 82.1, the repeated measures ANOVA also tests for equality of population means. However, in a repeated measures setting, the subjects are measured repetitively over time. Therefore, the measurements observed within a same subject are correlated. This correlation between observations from the same subject needs to be accounted for in ANOVA. The constant correlation assumption refers to the equal correlation between any pair of observations from a subject. Denote this constant correlation by ρ . The **Repeated ANOVA** module in **East** allows to test the effects of subject and time as well as test for contrast in subject means.

Dataset: Body_wight.cyd

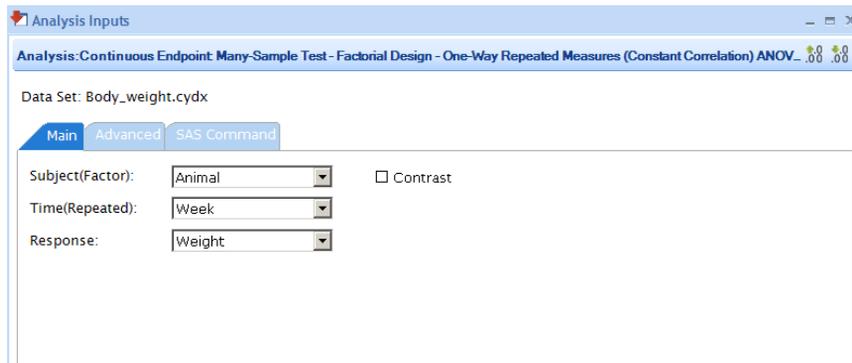

Data Description

Here consider the body weight data of guinea pigs given by Crowder and Hand (1989, p. 27). The data was obtained to investigate the effect of vitamin E diet supplement on the growth of guinea pigs. For each animal the body weight (in gram) were recorded at the end of 1, 3, 4, 5, 6, and 7 weeks. All animals were given a growth-inhibiting substance during week 1 and the vitamin E therapy was started at the beginning of week 5. Three groups of animals, numbering five in each, received respectively zero, low and high doses of vitamin E.

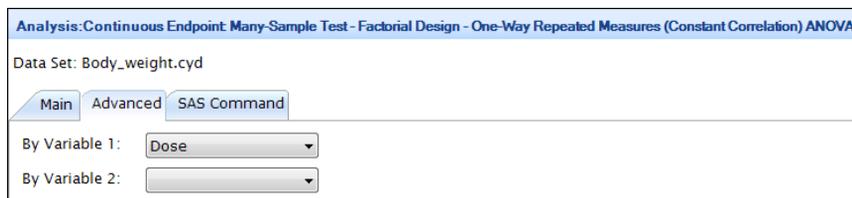

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous): Many Samples > (Factorial Design) One-Way Repeated Measures
3. In the **Main** tab, select **Animal** as **Subject(Factor)**, **Week** as **Time(Repeated)**

and **Weight** as **Response**. Leave the check box for **Contrast** unchecked.

- In the **Advanced** tab, you can select up to 2 grouping variables. If only one grouping variable is selected, then a different analysis will be displayed for each level of the selected grouping variable. If two grouping variables are selected then **East** will display different analysis for each combination of levels of two grouping variables. Select **Dose** as **By Variable 1**.

- The third tab is **SAS Command** where you can put SAS code for more sophisticated analysis. For this example, do not make any changes in this tab.
- Click **OK** to start the analysis. The output is displayed in the main window.

82 Analysis-ANOVA

ANOVA for all the three dose groups is displayed in the **Output** section.

| By: | | Dose = No | | | |
|---------------------------------|----------|----------------|-------------------|---------------------|-----------|
| Total no. of records: | | 30 | | | |
| No. of records rejected: | | 0 | | | |

| Week | 5 | 63185.867 | 12637.173 | 20.875 | 2.587E-7 |
| Residuals | 20 | 12107.467 | 605.373 | | |
| Total | 29 | 117433.867 | | | |
| Summary Table: | | | | | |
| Overall Mean | Root MSE | R-Square | Adjusted R-Square | Coeff. of Variation | |
| 572.267 | 24.604 | 0.897 | 0.851 | 4.299 | |
| By: | | Dose = High | | | |
| Total no. of records: | | 30 | | | |
| No. of records rejected: | | 0 | | | |
| ANOVA Table: | | | | | |
| Source | DF | Sum of Squares | Mean Square | F Statistic | p-value |
| Animal | 4 | 24468.867 | 6117.217 | 25.722 | 1.222E-7 |
| Week | 5 | 48129.5 | 9625.9 | 40.476 | 8.642E-10 |
| Residuals | 20 | 4756.333 | 237.817 | | |
| Total | 29 | 77354.7 | | | |
| Summary Table: | | | | | |
| Overall Mean | Root MSE | R-Square | Adjusted R-Square | Coeff. of Variation | |
| 565.9 | 15.421 | 0.939 | 0.911 | 2.725 | |

The output suggests that the effect of animal and week is highly significant in all the three dose groups.

82.4 Example: Two Way ANOVA

In a two-way ANOVA, there are two factors to consider, say A and B. Let X_{ijk} indicate the response from k^{th} replication of i^{th} level of A and j^{th} level of B; $i = 1, \dots, a, j = 1, \dots, b, k = 1, \dots, n$. Further we assume, $X_{ijk} \sim N(\mu_{ij}, \sigma^2)$; $i = 1, \dots, R$.

In two-way ANOVA, the goal is to test the following null hypotheses

- **Test for main effect of factor A.** H_0 : The group means for all the levels of factor A is same.
- **Test for main effect of factor B.** H_0 : The group means for all the levels of factor B is same.
- **Test for interaction effect of A and B.** H_0 : The effect of A remains same for all levels of B or the effect of B remains same for all levels of A.

Dataset: `Body_wight.cyd` as described in Section 82.3

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous): Many Samples > (Factorial Design) Two-Way ANOVA
3. In the **Main** tab, select **Dose** as **Factor1**, **Week** as **Factor2** and **Weight** as **Response**. Leave the **Interaction Effect** check box checked for test of interaction effect between the two factors.

Analysis: Continuous Endpoint Many-Sample Test - Factorial Design - Two-Way ANOVA

Data Set: Body_wight.cyd

4. Click **OK** to start the analysis. The output is displayed in the main window now.

Analysis: ANOVA:Two way

Hypothesis

$H_{01} : \mu_{A1} = \mu_{A2} = \dots = \mu_{Aa}$ Vs. $H_{11} : \text{At least one } \mu_{Ai} \text{ differs. For } i = 1, 2, \dots, a$, where a is the number of levels of the 1st factor 'A'.
 $H_{02} : \mu_{B1} = \mu_{B2} = \dots = \mu_{Bb}$ Vs. $H_{12} : \text{At least one } \mu_{Bj} \text{ differs. For } j = 1, 2, \dots, b$, where b is the number of levels of the 2nd factor 'B'.
 $H_{03} : \text{There is no interaction term in the model. vs } H_{13} : \text{There is an interaction term in the model.}$

Input Parameters

Data File: Body_weight.cydx
 Factor1: Dose
 Factor2: Week
 Response: Weight

Total Number of Records: 90

Number of Records Rejected: 0

ANOVA Table:

| Source | DF | Sum of Squares | Mean Square | F Statistic | p-value |
|-------------|----|----------------|-------------|-------------|----------|
| Dose | 2 | 18548.067 | 9274.033 | 4.839 | 0.011 |
| Week | 5 | 142554.5 | 28510.9 | 14.877 | 5.19E-10 |
| Interaction | 10 | 9762.733 | 976.273 | 0.509 | 0.878 |
| Residuals | 72 | 137986.8 | 1916.483 | | |
| Total | 89 | 308852.1 | | | |

Summary Table:

| Overall Mean | Root MSE | R-Square | Adjusted R-Square | Coeff. of Variation |
|--------------|----------|----------|-------------------|---------------------|
| 559.1 | 43.778 | 0.553 | 0.448 | 7.83 |

The p-values associated with main effect of Dose and Week are 0.011 and 5.19×10^{-10} . These p-values suggest significant main effect for Dose and Week. The interaction between Dose and Week is not significant (p-value = 0.878).

83

Analysis-Regression Procedures

This chapter demonstrates how to run regression analysis in **East**. **East** can perform multiple linear regression, repeated measure regression and fit linear mixed effect (LME) model on data obtained from 2×2 crossover design. The LME model on 2×2 crossover data can be fit either to test for difference of means or ratio of means. These are discussed in sections 83.1, 83.2, 83.2, 83.3 and 83.4. In addition to fitting the regression coefficients, **East** can also be used to:

- perform significance testing of regression coefficients using Wald test
- perform 1st order autocorrelation in residuals using Durbin-Watson test
- compute collinearity diagnostics
- compute different types of residuals
- compute influential statistics
- compute predicted values
- perform variable selection

83.1 Example: Multiple Linear Regression

Dataset: **Werner.cyx** as described in Section 73.4.2.

Purpose of the Analysis:

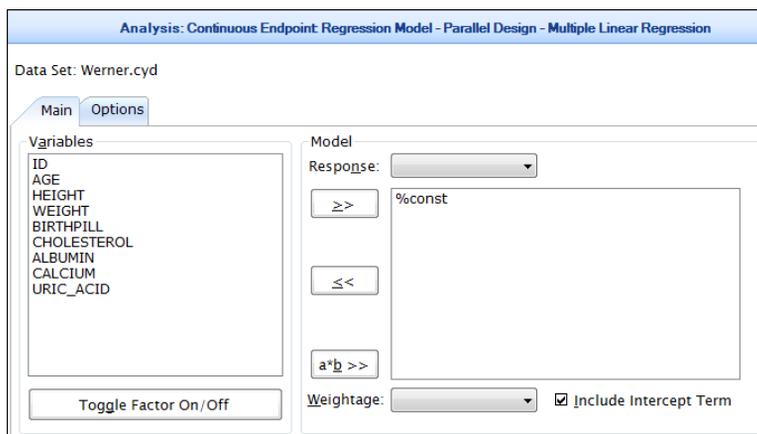

In this example, the multiple regression technique is used to find relationship of the variable Cholesterol with the other variables.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Regression > (Parallel Design) Multiple Linear Regression
This will display several input fields associated with regression analysis in the

83 Analysis-Regression Procedures

main window.

In the **Main** tab, there are two boxes – **Variables** and **Model**. In the **Variable** box, all the numeric variables in the dataset are displayed. The **Toggle Factor On/Off** button can change the status of a variable between numeric and factor variable.

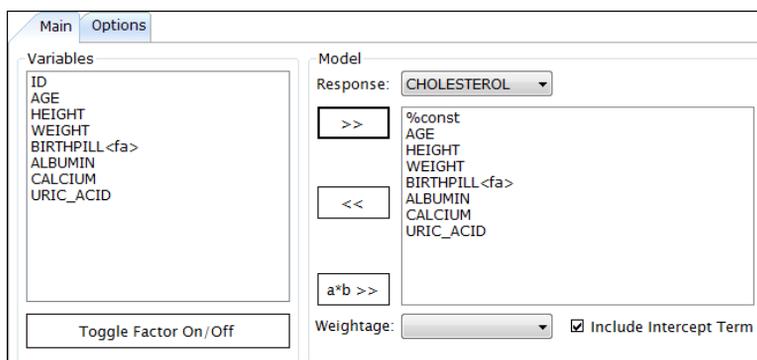

- For example, select the **BIRTHPILL** variable and click **Toggle Factor On/Off** button. This will declare the **BIRTHPILL** variable as factor variable.

The suffix **<fa>** is added to **BIRTHPILL** in the list of variables. The suffix **<fa>** indicates that the **BIRTHPILL** will be treated as factor variable in the multiple linear regression, if included as predictor. We can declare any variable in the **Variables** box as factor variable. For this example, only consider

BIRTHPILL as factor variable.

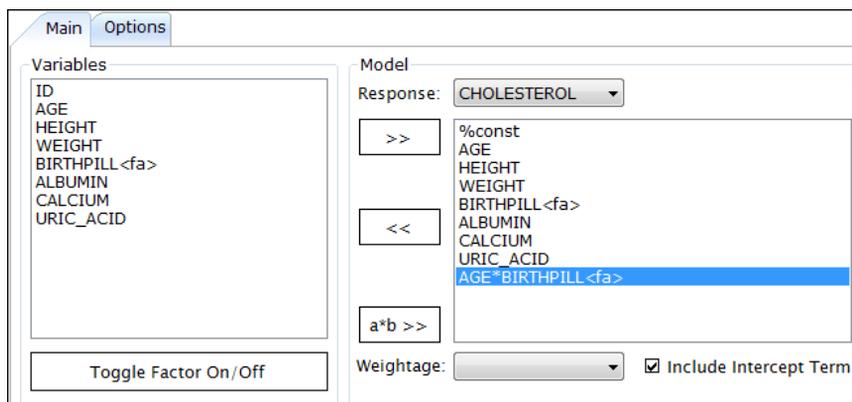

- In the box **Model**, choose **CHOLESTEROL** as **Response** variable. Below this, there is a box with only entry %const. This is where all the predictors in the model has to be included. The term %const refers to the intercept (β_0). To remove this term clear the checkbox **Include Intercept Term**. In the absence of this term, **East** will perform multiple regression analysis without any intercept. For this example, keep this term. Include all the variables except ID in this box. To include a variable in this box, select the variable from the list of variables in the **Variable** box then click button. To de-select a selected term click button.

- Now, we might believe that the effect of birth pill use on cholesterol level varies with age. In other words, there might be interaction between age and birth pill use. To include the interaction effect, select **Age** and **BIRTHPILL < fa >** in the **Variable** box using **Ctrl key**, and click button. This adds the term

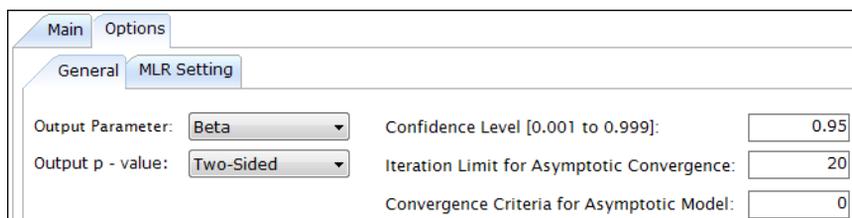

83 Analysis-Regression Procedures

AGE*BIRTHPILL<fa> in the predictor variable list.

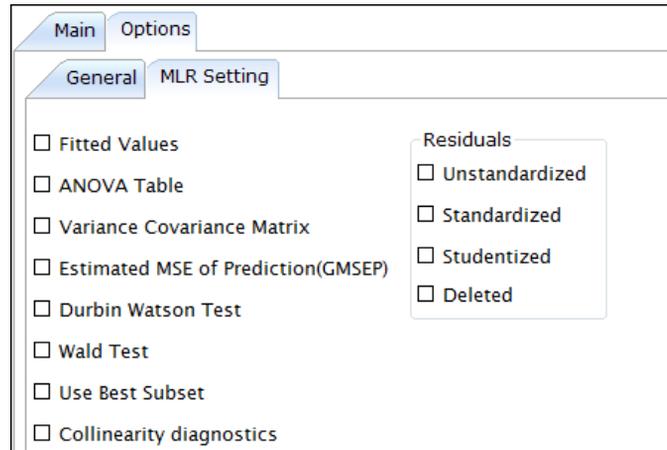

The interaction effect AGE*BIRTHPILL<fa> is an example of first order interaction. In **East**, you can also include interaction effect of higher orders. To include interaction effect, select all the variables that are interacting and click **a*b >>** button.

- Click the **Options** tab. There are two sub-tabs within this tab – **General** and **MLR Setting**.

- In the **General** sub-tab, leave the default choice of **Beta** for **Output Parameter** and **Two-Sided** for **Output p - value**.

In the **MLR Setting** sub-tab, there is a list of checkboxes in two columns.

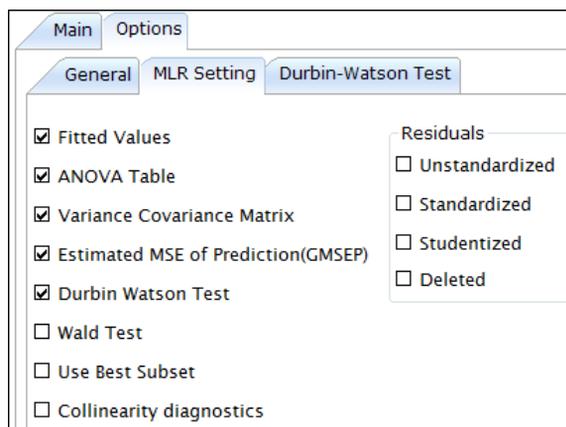

The purpose of the checkboxes is given below:

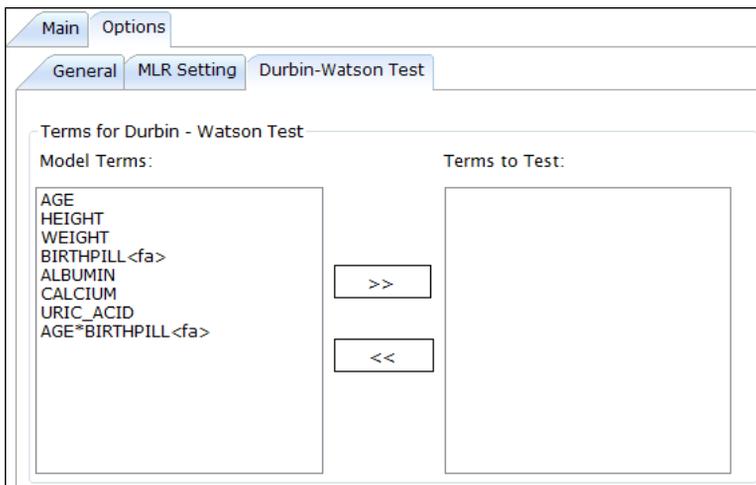

- **Fitted Values:** Calculates the fitted values.
- **ANOVA:** Includes ANOVA table in the regression output.
- **Variance Covariance Matrix:** Includes variance covariance matrix for estimated regression coefficients in the regression output.
- **Estimated MSE of Prediction (GMSEP):** Includes mean squared error (MSE) (or variance of residuals) and mean squared error of prediction (MSEP) in the regression output.
- **Durbin Watson Test:** Performs the test for first order autocorrelation among residuals and the results are displayed in the regression output.
- **Wald Test:** Performs the Wald test for significance of regression coefficients and the results are displayed in the regression output.
- **Use Best Subset:** Performs the subset selection using backward elimination, forward selection, sequential replacement, stepwise selection or exhaustive search technique.
- **Collinearity diagnostics:** Provides collinearity diagnostics such as Eigenvalues of $(X^T X)^{-1}$ and condition numbers. Before calculation of Eigenvalues, $X^T X$ is scaled to have 1's on the diagonal. The condition numbers are the square roots of the ratio of the largest Eigenvalue to each individual Eigenvalue. The largest condition number is the condition number of the scaled X matrix.
- **Unstandardized Residuals:** Calculates the residuals.

83 Analysis-Regression Procedures

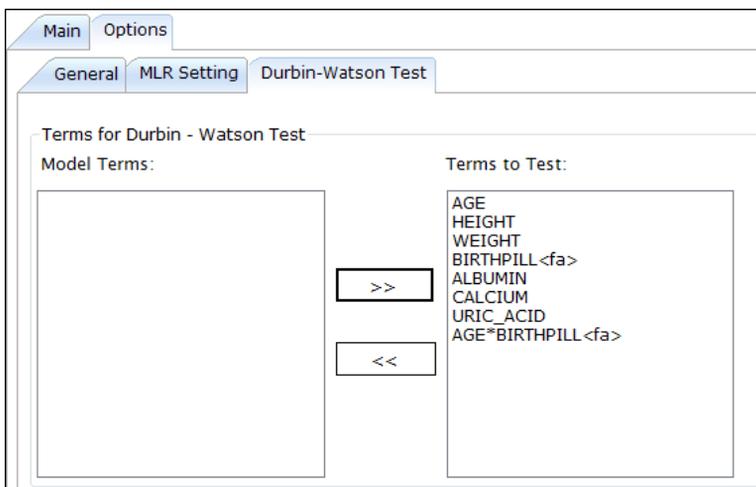

- **Standardized Residuals:** Calculates the standardized residuals.
 - **Studentized Residuals:** Calculates the studentized residuals.
 - **Deleted Residuals:** Calculates the deleted residuals deleting the corresponding observation.
8. Select the first 4 checkboxes – **Fitted Values**, **ANOVA Table**, **Variance Covariance Matrix** and **Estimated MSE of Prediction (MSEP)**. Then select the checkbox for **Durbin Watson Test**. A third sub-tab **Durbin-Watson Test** is added.

9. Click the **Durbin-Watson Test** tab.

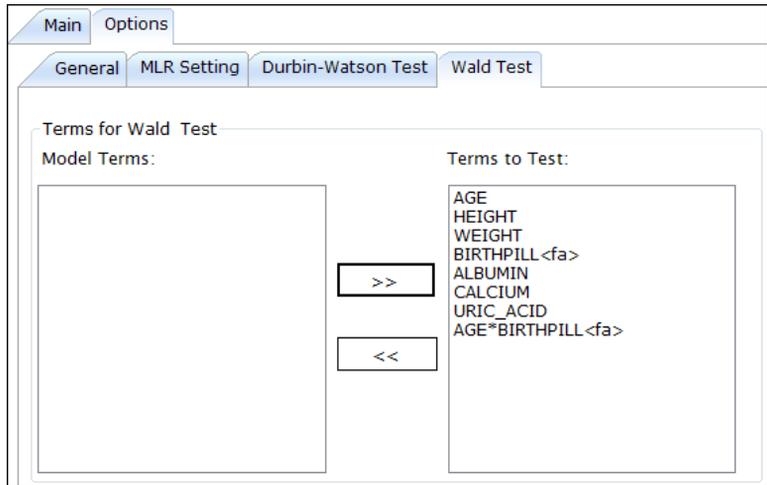

10. In this tab select or de-select the terms for the Durbin-Watson test using and buttons. Select all the variables from **Model Terms** to **Terms to test**.

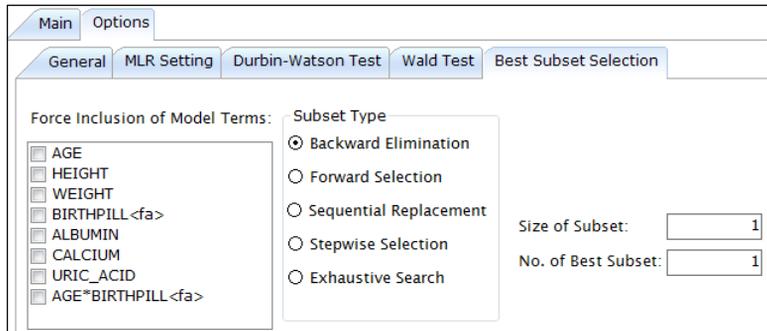

11. Come back to **MLR Setting** sub-tab. Now check the box for Wald Test. This

83 Analysis-Regression Procedures

will add a new sub-tab labeled as **Wald Test**. Click on this sub-tab and select all the variables from **Model Terms** to **Terms to test**.

12. Come back to **MLR Setting** sub-tab and select the **Use Best Subset** check box. This will add a new sub-tab labeled as **Best Subset Selection**. Click on this sub-tab.

13. The first column is a box with label **Force Inclusion of Model Terms** and it includes all the model terms. Here select the variables that needs to be retained forcefully in the model and selection method will be applied on the remaining terms. In this example, use of Birthpill is an important factor that influences cholesterol level. Therefore, select **BIRTHPILL< fa >**. **BIRTHPILL< fa >**

will skip the variable selection procedure and it will always be part of the best subset of variables.

14. In the second column choose the method of subset selection. The choices are **Backward Elimination**, **Forward Selection**, **Sequential Replacement**, **Stepwise Selection** and **Exhaustive Search**.

In *Forward Selection* procedure, the model starts with the constant term (or with the forced terms) and it keeps adding new terms in each step that gives largest reduction in sum of squares of the residuals (SSE). The method stops when inclusion of none of the additional terms results in sufficient amount of reduction in SSE. In *Backward Elimination* procedure, the model starts with all the available terms and then eliminates a variable in each step that provides minimum reduction in SSE. The method stops when the reduction in SSR due to dropping of any variable exceeds some threshold amount. The *Stepwise Selection* procedure is like *Forward Selection* except that at each step dropping of variables is also considered as in *Backward Elimination* procedure. At each step, the F value is calculated for each variable. If S indicates the set of all the variables in the subset in the current step, then for i^{th} variable, F value, F_i is calculated as follows:

$$F_i = \frac{SSR(S \cup \{i\}) - SSR(S)}{MSE(S \cup \{i\})} \quad i \notin S$$

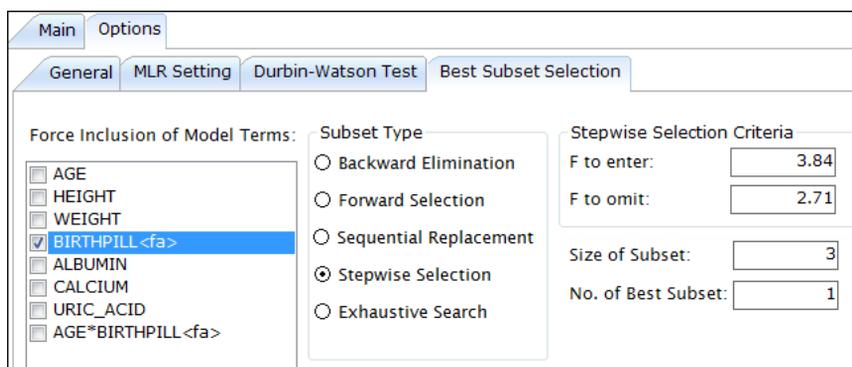

$$F_i = \frac{SSR(S) - SSR(S - \{i\})}{MSE(S)} \quad i \in S$$

For $i \notin S$, the i^{th} variable is entered in subset if $F_i > F_{in}$. For $i \in S$, the i^{th} variable will be dropped from the subset if $F_i < F_{out}$. In the *sequential replacement* procedure, for a given number of variables, variables are sequentially replaced and replacements that improve performance are retained. This approach checks whether any of the variables selected in the current model can be replaced with another variable to give a smaller residual sum of squares. In *exhaustive search* procedure, all possible subset are evaluated and the subset with largest *adjusted R^2* is chosen.

15. Select **Stepwise Selection**. A box labeled as **Stepwise Selection Criteria** appears. Keep the default values 3.84 and 2.71 for **F to enter** and **F to omit**. These two values corresponds to F_{in} and F_{out} , as explained above. There are two fields – **Size of Subset** and **No. of Best Subset**. In **Size of Subset**, enter the maximum allowed size of the subset. For example, the data contains 20

83 Analysis-Regression Procedures

independent variables, but you want to restrict the search to subsets which have a maximum of 7 variables. In this case, specify the size of subset as 7. In the field No. of Best Subset, specify the number of top models of each subset size which will be included in the output. In this example, enter 3 and 1 for these two fields. With this specification, we are looking for subset of variables of size 2 and 3 of which one of the term must be BIRTHPILL<fa>. The subset of size 1 will not be displayed as we have already specified one variable to enter forcefully in all the subset and thus the subset of 1 variable does not require any variable to come from subset selection procedure.

The screenshot shows the 'Best Subset Selection' dialog box with the following settings:

- Force Inclusion of Model Terms:**
 - AGE
 - HEIGHT
 - WEIGHT
 - BIRTHPILL<fa>
 - ALBUMIN
 - CALCIUM
 - URIC_ACID
 - AGE*BIRTHPILL<fa>
- Subset Type:**
 - Backward Elimination
 - Forward Selection
 - Sequential Replacement
 - Stepwise Selection
 - Exhaustive Search
- Stepwise Selection Criteria:**
 - F to enter: 3.84
 - F to omit: 2.71
 - Size of Subset: 3
 - No. of Best Subset: 1

16. Click the **MLR Setting** sub-tab and select the check box **Collinearity**

diagnostics. A new box labeled as **Parameters for Collinearity** appears.

The screenshot shows the 'Options' dialog box in the East 6.4 software. The 'Durbin-Watson Test' tab is selected. In the 'Parameters for Collinearity' section, the 'Multi Collinearity Criterion' is set to 0.05 and the 'No. of Collinearity Component' is set to 2. The 'Residuals' section is also visible, with checkboxes for Unstandardized, Standardized, Studentized, and Deleted.

17. In the **Parameters for Collinearity** box, specify two parameters – **Multi Collinearity Criterion** and **No. of Collinearity Component**.

The **Multi Collinearity Criterion** refers to the value that controls how small the determinant of the matrix (that is inverted to compute the coefficient estimates) is allowed to be. This value must be less than 1 and greater than 0. The latter refers to number of collinearity components we want **East** to display. This number can be between 2 and the number of terms in the model including intercept, if any. In this case choose a number of collinearity components between 2 to 10. **East** specifies default values of 0.05 for **Multi Collinearity Criterion** and 2 for **No. of Collinearity Component**. For this example, keep these two values unchanged.

18. In the **Residual** box, check all the 4 types of residuals - **Unstandardized**, **Standardized**, **Studentized** and **Deleted**. Upon checking any of these residuals,

83 Analysis-Regression Procedures

a new box appears labeled as **Influential statistics**.

Unstandardized residuals (r_i) are obtained simply by subtracting predicted value of response variable (\hat{Y}_i) from the observed value (Y_i) for each observations.

That is,

$$r_i = Y_i - \hat{Y}_i$$

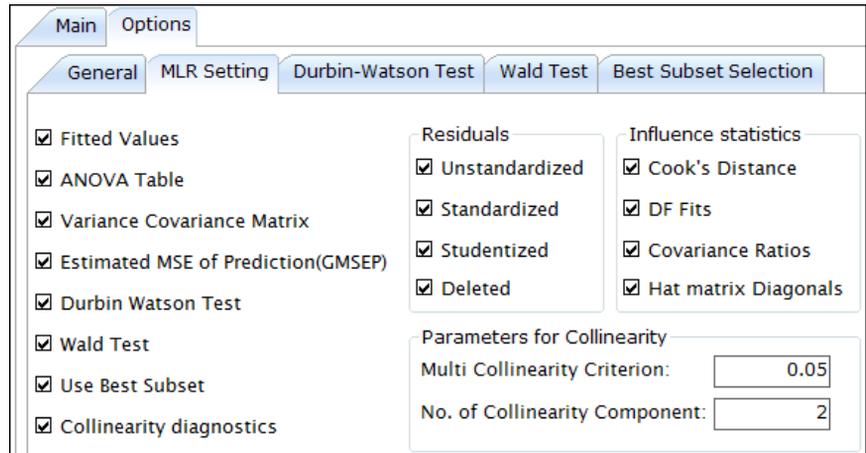

Standardized residuals are the *Unstandardized residuals* divided by the root mean square error (RMSE). Even though this is called as *standardized residuals*, this is not standardized in true sense, because the residuals does not have equal variance (even with constant variance assumption). The variance for i^{th} residual is estimated as $\sigma^2(1 - h_{ii})$, where, h_{ii} is the i^{th} diagonal element of hat matrix, H . It is more appropriate to standardize the residuals as follows:

$$\frac{r_i}{\hat{\sigma} \sqrt{(1 - h_{ii})}}$$

This is known as studentized residuals. Cook and Weisberg refer to this as external studentization. These residuals have t-distributions with $N - K$ degrees of freedom, so any residual with absolute value exceeding 3 usually requires attention. The *deleted residuals* are obtained as $Y_i - \hat{Y}_i^{-i}$, where \hat{Y}_i^{-i} indicates the predicted value of Y_i where prediction is done excluding i^{th} observation.

19. Check all the influential statistics in the **Influence statistics** box next to the

Residuals.

Cook's distance is an overall measure of the impact of i^{th} datapoint on the estimated regression coefficients. This is defined as:

$$D_i = \frac{\sum_{i=1}^N (\hat{Y}_i - \hat{Y}_i^{-i})^2}{K \hat{\sigma}}$$

D_i 's are distributed as $F(K, N - K)$. If $D_i < F(0.2, K, N - K)$ then the i^{th} case has only little apparent influence on the fitted values. On the other hand, if $D_i > F(0.5, K, N - K)$, the i^{th} observation should be considered influential. *DFFITs* are calculated for each observation. For i^{th} observation this is defined as:

$$(DFFIT)_i = \frac{\hat{Y}_i - \hat{Y}_i^{-i}}{\hat{\sigma}^{-i} \sqrt{h_{ii}}}$$

where $\hat{\sigma}^{-i}$ is the RMSE or estimate of σ obtained excluding i^{th} observation. Kutner et al. (2004) suggested to consider a case as influential if the absolute value exceeds 1 for small to medium size data and $2\sqrt{K/N}$ for large datasets. The measure *Covariance Ratios* reflects the change in the variance-covariance matrix of the estimated coefficients when the i^{th} observation is omitted. For i^{th} observation, it is obtained as ratio of determinant of covariance matrix of estimate of β excluding i^{th} observation to the determinant of covariance matrix of estimate of β including all the observations. It is suggested that $|CR_i - 1| \geq 3K/N$ warrants further investigation.

83 Analysis-Regression Procedures

Hat matrix diagonals simply refers to i^{th} diagonal element, h_{ii} , of hat matrix, H , for i^{th} observation. This measure is also known as the leverage of the i^{th} observation. The diagonal elements sum to the number of parameters being fitted. Any value greater than $2K/N$ suggests further investigation.

- Click **OK** to start the analysis. After completion of the analysis a new node with title **Analysis: Multiple Linear Regression1** is added to the **Library**. It has two sub-nodes – **MLR-Residuals1** and **MLR-Best Subset Selection1**.

Library

 - Werner.cyd
 - Analysis: Multiple Linear Regression1
 - MLR-Residuals1
 - MLR-Best Subset Selection1

Analysis: Multiple Linear Regression

Input Parameters

Data File: Werner.cyd
 Model: CHOLESTEROL~%const+AGE+HEIGHT+WEI
 Confidence Level: 0.95

Output

Total no. of records: 188
 No. of records rejected: 7
 Terms dropped due to:

| | |
|-------------------|------|
| No Variation | None |
| Multicollinearity | None |

- The output is displayed in the main window. The first part of the output is as shown below:

Total no. of records: 188
No. of records rejected: 7
Terms dropped due to:

| | |
|-------------------|------|
| No Variation | None |
| Multicollinearity | None |

Summary Statistics:

| Item | Value |
|-------------------|------------|
| Residual df | 172 |
| Multiple R-square | 0.256 |
| Std.Dev.Estimate | 39.49 |
| Residual SS | 268221.407 |

The dataset contains a total of 188 records and out of this 7 are rejected due to missing

observations. The table titled “Terms dropped due to” refers to some essential pre-processing of the data. If a particular independent variable assumes the same value throughout the data set, it is not really a ‘variable’ and has to be dropped. Its presence creates ‘singularity’ in the design matrix X . In the present data set there is no such problem and hence the entry is ‘None’. Multicollinearity is another possible characteristic of the data, which could make the problem unstable. In the present data set, no such difficulty is encountered and hence the entry ‘None’ appears.

The table “Summary Statistics” displays some relevant summary statistics on residuals. In this example, $N = 181$ and $K = 9$. Thus the residual degrees of freedom is $181 - 9 = 172$. The multiple R^2 value is 0.256. This is obtained as:

$$R^2 = \frac{SSR}{SST}$$

The estimate of σ or error variance is 39.49. The *residual sum of squares* or SSE is 268221.407.

| Parameter Estimates: | | | | | | | |
|----------------------|-------------|------------|-------------------------|-------------|-------------|---------|-------------|
| Model term | Coefficient | Std. Error | 95% Confidence Interval | | t-statistic | p-value | SS |
| | | | Lower Limit | Upper Limit | | | |
| %CONST | 70.534 | 96.183 | -119.317 | 260.385 | 0.733 | 0.464 | 9951593.818 |
| AGE | 1.271 | 0.418 | 0.445 | 2.096 | 3.037 | 0.003 | 51320.975 |
| HEIGHT | -2.425 | 1.388 | -5.164 | 0.313 | -1.748 | 0.082 | 1123.665 |
| WEIGHT | 0.061 | 0.182 | -0.298 | 0.42 | 0.335 | 0.738 | 1196.139 |
| BIRTHPILL_0 | -26.842 | 21.168 | -68.625 | 14.941 | -1.268 | 0.207 | 851.006 |
| ALBUMIN | 0.166 | 0.998 | -1.804 | 2.136 | 0.167 | 0.868 | 7263.968 |
| CALCIUM | 2.342 | 0.723 | 0.914 | 3.77 | 3.237 | 0.001 | 19442.367 |
| URIC_ACID | 0.7 | 0.281 | 0.145 | 1.255 | 2.488 | 0.014 | 9811.723 |
| AGE*BIRTHPILL_0 | 0.591 | 0.601 | -0.595 | 1.778 | 0.984 | 0.326 | 1509.933 |

The table with title **Parameter Estimates** provides the estimate of regression coefficients with its standard error. It also provides 95% confidence interval of these estimates, the observed value of t-statistic, the p-value for testing $H_0 : \beta_k = 0$ and sum of squares. It appears that the terms age, calcium and uric acid is significant at 5% level of significance and the term height is significant at 10% level of significance. Notice that the variable BIRTHPILL considered as factor variable now has a suffix “_0”. **East** creates a dummy variable for the level 0 of factor BIRTHPILL. This dummy variable takes 1 for the observations with BIRTHPILL=0; otherwise it takes value 0. Here, the

83 Analysis-Regression Procedures

level 1 for the factor BIRTHPILL is considered as the reference level.

Estimated MSE of Prediction (GMSEP):

| Item | Value |
|-----------------------------|----------|
| Mean Squared Error | 1559.427 |
| Root Mean Squared Error | 39.49 |
| Estimated MSE of Prediction | 1641.401 |

The MSE ($\hat{\sigma}^2$) and RMSE ($\hat{\sigma}$) are 1559.427 and 39.49. The MSE of prediction is

1641.401. The following table displays the estimated covariance matrix of $\hat{\beta}$:

Variance-Covariance Matrix:

| | %CONST | AGE | HEIGHT | WEIGHT | BIRTHPILL_0 | ALBUMIN | CALCIUM | URIC_ACID | AGE*BIRTHPILL_0 |
|-----------------|----------|--------|---------|--------|-------------|---------|---------|-----------|-----------------|
| %CONST | 9251.198 | -5.392 | -97.616 | 3.465 | -229.172 | -3.624 | -30.564 | 0.138 | 4.905 |
| AGE | -5.392 | 0.175 | 0.044 | -0.013 | 5.724 | -0.012 | -0.006 | -0.012 | -0.168 |
| HEIGHT | -97.616 | 0.044 | 1.925 | -0.119 | 3.479 | -0.155 | -0.077 | 0.021 | -0.058 |
| WEIGHT | 3.465 | -0.013 | -0.119 | 0.033 | -0.287 | 0.054 | -0.013 | -0.012 | 0.006 |
| BIRTHPILL_0 | -229.172 | 5.724 | 3.479 | -0.287 | 448.1 | -2.361 | -0.811 | 0.126 | -12.173 |
| ALBUMIN | -3.624 | -0.012 | -0.155 | 0.054 | -2.361 | 0.996 | -0.329 | -0.014 | 0.028 |
| CALCIUM | -30.564 | -0.006 | -0.077 | -0.013 | -0.811 | -0.329 | 0.523 | -0.026 | 0.028 |
| URIC_ACID | 0.138 | -0.012 | 0.021 | -0.012 | 0.126 | -0.014 | -0.026 | 0.079 | -0.003 |
| AGE*BIRTHPILL_0 | 4.905 | -0.168 | -0.058 | 0.006 | -12.173 | 0.028 | 0.028 | -0.003 | 0.361 |

The table below displays the collinearity diagnostics:

Collinearity Diagnostics:

| Components | 1 | 2 |
|-------------------|--------|--------|
| Eigenvalues | 0.001 | 0.001 |
| Condition numbers | 119.39 | 77.177 |
| Intercept | 0.928 | 0.022 |
| AGE | 0.013 | 0.001 |
| HEIGHT | 0.768 | 0.183 |
| WEIGHT | 0.128 | 0.014 |
| BIRTHPILL_0 | 0.014 | 0.005 |
| ALBUMIN | 0.009 | 0.136 |
| CALCIUM | 0.115 | 0.869 |
| URIC_ACID | 0 | 0.016 |
| AGE*BIRTHPILL_0 | 0.006 | 0.005 |

When there is no collinearity at all, the Eigenvalues and condition number will all equal 1. As collinearity increases, Eigenvalues will be both greater and smaller than 1 (Eigenvalues close to zero indicates a multicollinearity problem), and the condition number will increase. Belsey, Kuh, and Welsch (1980) suggest that, when this number is around 10, weak dependencies might be starting to affect the regression estimates.

83 Analysis-Regression Procedures

Montgomery et al recommend use of 100 as indicative of moderate concern while a value of 1000 is an alarm trigger (Montgomery, Peck, and Vining, 2003, page 339). For this model, the condition number of scaled X matrix is 119.39. Thus, it may be pertinent to take corrective step such as centering the data.

| ANOVA: | | | | | |
|------------|-----|------------|-----------|-------------|----------|
| Source | df | SS | MS | F-statistic | p-value |
| Regression | 8 | 92519.776 | 11564.972 | 7.416 | 1.811E-8 |
| Error | 172 | 268221.407 | 1559.427 | | |
| Total | 180 | 360741.182 | | | |

The ANOVA table shows that the total degrees of freedom are 180, 8 independent variables give rise to 8 d.f. for regression and the remaining 172 degrees of freedom are assigned to error. The very low p-value shows that the model fitted is 'significant'. Therefore, we have to reject the null hypothesis that all regression coefficients are zero.

1. Click **MLR-Residuals1** in the **Library**. It displays the predicted values,

residuals and influential observations.

| Predicted Values | Residuals | Standardised Residuals | Studentised Residuals | Deleted Residuals | Cook's Distance |
|------------------|-----------|------------------------|-----------------------|-------------------|-----------------|
| 202.995 | -44.995 | -1.139 | -1.161 | -1.163 | 0.006 |
| 251.545 | -26.545 | -0.672 | -0.716 | -0.715 | 0.008 |
| 189.831 | 20.169 | 0.511 | 0.522 | 0.521 | 0.001 |
| 204.631 | -12.631 | -0.32 | -0.328 | -0.327 | 0.001 |
| 223.673 | 22.327 | 0.565 | 0.579 | 0.578 | 0.002 |
| 210.068 | -10.068 | -0.255 | -0.26 | -0.26 | 0 |
| 209.68 | -1.68 | -0.043 | -0.044 | -0.044 | 1.503E-5 |

- Click **MLR-Best Subset Selection1** in the **Library**. This displays the output for best subset selection.

Analysis: Multiple Linear Regression

Multiple Linear Regression – Best Subset Selection:

| No. of Variables | RSS | CP | R-Squared | Adj. R-Squared | Probability | Var1 | Var2 |
|------------------|------------|-------|-----------|----------------|-------------|------|---------|
| 3 | 308891.673 | 23.08 | 0.144 | 0.134 | 0 | AGE | * |
| 4 | 284696.132 | 9.565 | 0.211 | 0.197 | 0.066 | AGE | CALCIUM |

For this example, the best subset of model with two terms includes BIRTHPILL and AGE as predictor. The best subset model of size 3 includes the predictors BIRTHPILL, AGE and CALCIUM.

83.2 Repeated Regression

Example: Repeated Regression

In a repeated measures setting, the subjects are measured repetitively over time. Therefore, the measurements observed within a same subject are correlated. In repeated regression analysis we take account of this correlation.

East performs repeated regression analysis using the MIXED procedure of SAS. East

83 Analysis-Regression Procedures

first generates equivalent SAS code and then displays the one obtained from the MIXED procedure in SAS.

Example: Repeated Regression

Dataset: Body_Weight.cyd as described in Section 82.3.

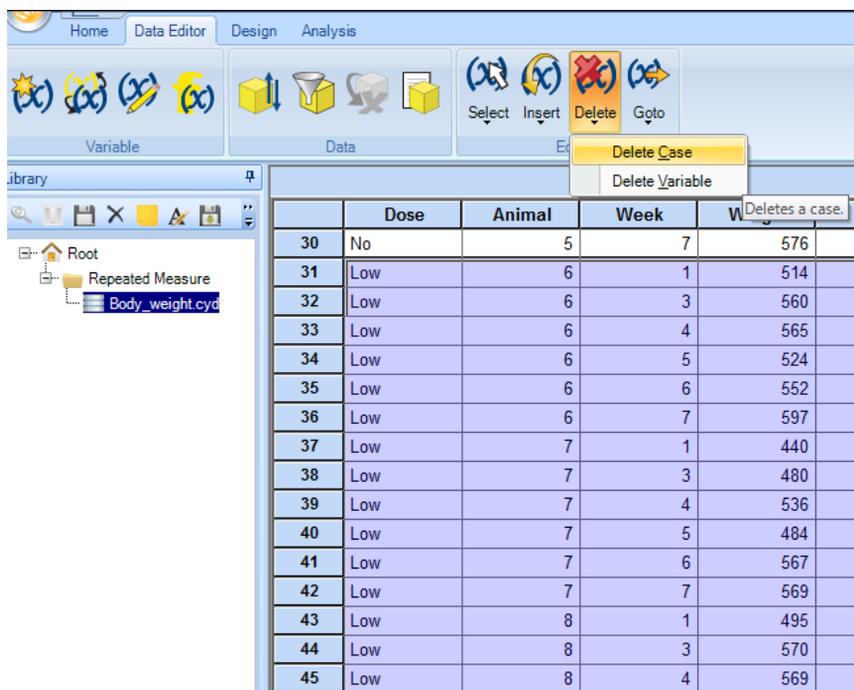

Purpose of the Analysis:

The data was obtained to investigate the effect of vitamin E diet supplement on the growth of guinea pigs. For each animal the body weight (in gram) was recorded at the end of weeks 1, 3, 4, 5, 6 and 7. All animals were given a growth-inhibiting substance during week 1 and the vitamin E therapy was started at the beginning of week 5. Three groups of animals, numbering five in each, received respectively zero, low and high doses of vitamin E. For this example, we will consider only observation from zero and high dose-groups. Here we want to fit the following model:

$$Weight_{ij} = \beta_0 + \beta_1 I(Dose_i = High) + \beta_2 j Week_{ij} + \epsilon_{ij}$$

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Delete the observations pertaining to “Low” dose (row 31 to 60). To delete the observations, select these observations, click  under the **Data Editor** menu and click **Delete Case**.

Now there are 60 observations left from “No” and “High” dose groups.

3. Choose the menu item:
Analysis > (Continuous) Regression > (Parallel Design) Repeated Measures Regression
 This will display several input fields associated with repeated regression analysis

83 Analysis-Regression Procedures

in the main window.

Analysis: Continuous Endpoint Regression Model - Parallel Design - Repeated Measures Regression

Data Set: Body_weight.cyd

Main Advanced SAS Command

Response: = Treatment: + Time(Repeated):

Subject:

Method of Estimation: REML Covariate Structure: UN DF: Contain

Covariates: Dose Animal Week Weight

Frequency Variable:

- There are three tabs in this window – **Main**, **Advanced** and **SAS Command**. In the **Main** tab, select **Weight** as **Response**, **Dose** as **Treatment**, **Animal** as **Subject** and **Week** as **Time(Repeated)**. All the remaining variables are displayed in **Covariates** field and you can select all or some of them as covariates. In the last row, there are 3 fields. First one is the **Method of Estimation** with choices of restricted maximum likelihood estimation (**REML**) and maximum likelihood estimation (**MLE**). Second one is the field **Covariance Structure** with choices of first order auto-regressive correlation (**AR(1)**), compound symmetry (**CS**), unstructured (**UN**), unstructured using correlations (**UNR**) and variance components (**VC**). Since all the animals were measured at fixed and equal times points, we can choose any reasonable covariance structure from **AR(1)**, **CS**, **UN** and **UNR**. The last one is the **DF** where you have to specify the method for computing the denominator degrees of freedom for the tests of significance of coefficients. Keep the default selections of **REML**, **UN** and **Contain** for **Method of Estimation**, **Covariance Structure** and **DF**.

Analysis: Continuous Endpoint Regression Model - Parallel Design - Repeated Measures Regression

Data Set: Body_weight.cyd

Main Advanced SAS Command

Response: Weight = Treatment: Dose + Time(Repeated): Week

Subject: Animal

Method of Estimation: REML Covariate Structure: UN DF: Contain

Covariates:

Frequency Variable:

- In the **Advanced** tab, leave the fields **By Variable 1** and **By Variable 2** blank. Enter 0.95 for **Confidence Level**.

| Analysis: Continuous Endpoint Regression Model - Parallel Design - Repeated Measures Regression | | | |
|---|----------------------|-------------------|-----------------------------------|
| Data Set: Body_weight.cyd | | | |
| Main Advanced SAS Command | | | |
| By Variable 1: | <input type="text"/> | Confidence Level: | <input type="text" value="0.95"/> |
| By Variable 2: | <input type="text"/> | Sing Res.: | <input type="text"/> |

- The third tab is **SAS Command** where you can put SAS code for more sophisticated analysis. For this example, do not make any changes in this tab.
- Click **OK** to start analysis. The output will be displayed in the main window now. ANOVA for all the three dose groups is displayed in the **Output** section.
- The output for estimated covariance structure is displayed in following

83 Analysis-Regression Procedures

screenshot.

| Covariance Parameter Estimates | | | | | |

| UN(6,5) | Animal | 2442.42 | 1176.46 | 2.08 | 0.0379 |
| UN(6,6) | Animal | 2265.32 | 1068.05 | 2.12 | 0.0170 |

9. The estimated coefficients are given in the following screenshot:

| Solution for Fixed Effects | | | | | | | | | | |
|----------------------------|------|------|----------|----------------|----|---------|---------|-------|----------|----------|
| Effect | Dose | Week | Estimate | Standard Error | DF | t Value | Pr > t | Alpha | Lower | Upper |
| Intercept | | | 572.94 | 15.3413 | 53 | 37.35 | <.0001 | 0.05 | 542.17 | 603.71 |
| Dose | High | | 49.3225 | 5.9412 | 53 | 8.30 | <.0001 | 0.05 | 37.4060 | 61.2390 |
| Dose | No | | 0 | . | . | . | . | . | . | . |
| Week | | 1 | -115.50 | 14.3769 | 53 | -8.03 | <.0001 | 0.05 | -144.34 | -86.6637 |
| Week | | 3 | -70.6000 | 10.2417 | 53 | -6.89 | <.0001 | 0.05 | -91.1423 | -50.0577 |
| Week | | 4 | -23.3000 | 10.6667 | 53 | -2.18 | 0.0334 | 0.05 | -44.6947 | -1.9053 |
| Week | | 5 | -30.9000 | 9.9436 | 53 | -3.11 | 0.0030 | 0.05 | -50.8444 | -10.9556 |
| Week | | 6 | -30.2000 | 4.9369 | 53 | -6.12 | <.0001 | 0.05 | -40.1022 | -20.2978 |
| Week | | 7 | 0 | . | . | . | . | . | . | . |

Therefore, the fitted model in this case is:

$$Weight_{ij} = 572.94 + 49.32I(Dose_i = Height) - 115.5I(Week = 1)$$

$$-70.6I(Week = 3) - 23.3I(Week = 4) - 30.9I(Week = 5) - 30.2I(Week = 6)$$

for $i = 1, \dots, 60$ with covariance structure as

$$\begin{bmatrix} 588.80 & 563.65 & 407.72 & 505.86 \\ 563.65 & 1461.05 & 1406.26 & 1574.66 \\ 407.72 & 1406.26 & 1513.03 & 1588.52 \\ 505.86 & 1574.66 & 1588.52 & 1934.95 \end{bmatrix}$$

83.3 Linear Mixed Effects Model: Difference of Means (Crossover Data)

In linear mixed effects model a linear model is fitted to explain variability in the response variable with the help of factors with levels, which have fixed effects and more than one random effect. Mixed Effects model is used for hierarchical or dependent data.

You will need to specify **Response** variable for which you want to fit the model. In this particular design, **Response** variable is often difference of means in test and control group. You will need to specify factors (variables) with fixed effects namely **Period**

83 Analysis-Regression Procedures

ID, **Group ID** and **Treatment ID**. You will also need to specify **Subject ID** which identifies the source of the response variable.

You have an option of checking the box **Run using SAS** on **Advanced** tab. By doing this **East** will invoke **Mixed** procedure of SAS. You can also choose not to use SAS. If you use SAS, you will have the option of including covariates in our model. Without SAS, your model will not include covariates. You can also invoke SAS command option from the dialogue box for this test.

East will display among other things estimates, t-statistics and ANOVA table for fixed effects. In this section, we will illustrate repeated regression analysis of 2x2 crossover data using all the three options.

Dataset: CrossoverCaseData.cyd

Analysis Using East:

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Continuous) Regression > (Crossover Design) Linear Mixed Effects Model: Difference of Means

This will display several input fields associated with linear mixed effects model analysis in the main window.

Analysis: Continuous Endpoint Regression Model - Crossover Design - Linear Mixed Effects Model: Difference of Means

Data Set: CrossoverCaseData.cyd

Main Advanced SAS Command

Response: = Period ID: + Group ID: + Treatment ID:

Subject ID (Random Effect):

3. There are three tabs in this window – **Main**, **Advanced** and **SAS Command**. In the **Main** tab, select **Response** as **Response**, **PeriodID** as **Period ID**, **GroupID** as **Group ID** and **SubjectID** as **Subject ID (Random Effect)**. Once you select a random effect, options of **Method of Estimation** with choices of restricted maximum likelihood estimation (**REML**) and maximum likelihood estimation (**MLE**) will become available. Keep the default selection of **REML**.

Analysis: Continuous Endpoint Regression Model - Crossover Design - Linear Mixed Effects Model: Difference of Means

Data Set: CrossoverCaseData.cyd

Main **Advanced** SAS Command

Response: = Period ID: + Group ID: + Treatment ID: Method of estimation: REML MLE

Subject ID (Random Effect):

- In the **Advanced** tab, leave the fields **By Variable 1** and **By Variable 2** blank. Keep the default value **0.95** for **Confidence Level** as well as all the statistics to be computed. Don't check the **Run Using SAS** checkbox.

Analysis: Continuous Endpoint Regression Model - Crossover Design - Linear Mixed Effects Model: Difference of Means

Data Set: CrossoverCaseData.cyd

run;
/* Write your code here */
ods html close;
```

The first few commands are meant for reading the data in SAS. You will also see the statement

```
/* Write your code here */
```

We will replace this part by our code.

```
DATA CrossoverCaseData ;
set CrossoverCaseData ;
proc mixed method = REML;
class GroupID PeriodID ;
model Response = GroupID PeriodID ;
repeated PeriodID ;
random subjectID;
run;
```

Please remove the following lines from the existing code.

```
<Response> = log(<Response>);
run;
proc sort data = CrossoverCaseData out =
SASortMixed;
by <By Variable 1> <By Variable 2> ... <By Variable
N> ;
run;
```

This is required as we don't want to log transform the **Response** and also don't want to sort the data on any by variable.

- Click **OK**. East will invoke SAS and the SAS output will be displayed in the main window.

83.4 Linear Mixed Effects Model: Ratio of Means (Crossover Data)

This test is very similar to the test described in previous subsection except here the **Response** variable is often the ratio of means of treatment and control group. The previous test is applied to logarithm of the response variable.

Both the options of SAS link (Run using SAS) and SAS commands are available for this test.

84 *Analysis-Multiple Comparison Procedures for Continuous Data*

It is often the case that multiple objectives are to be addressed in one single trial. These objectives are formulated into a family of hypotheses. Type I error rate is inflated when one considers the inferences together as a family. Failure to compensate for multiplicities can have adverse consequences. For example, a drug could be approved when actually it is not better than Placebo. Multiple comparison (MC) procedures provide a guard against inflation of type I error due to multiple testing. Probability of making at least one type I error is known as family wise error rate (FWER). **East** supports several parametric and p-value based MC procedures.

We have seen how to simulate data under different MC procedures with specified group means and variance in chapter 15. In this chapter we explain how to analyze data with different MC procedures available in **East**. For MC procedures in **East**, we can either provide the dataset containing the observations under each arm or the raw p-values to obtain the adjusted p-values.

84.1 Available Procedures

The probability of making at least one type I error is known as family wise error rate (FWER). All the MC procedures available in **East** strongly control FWER. Strong control of FWER refers to preserving the probability of incorrectly claiming at least one null hypothesis. To contrast strong control with weak control of FWER, the latter controls the FWER under the assumption that all hypotheses are true. **East** supports following MC procedures based on continuous endpoint.

| Category | Procedure | Reference |
|---------------|-----------------------|------------------------------------|
| Parametric | Dunnett's Single Step | Dunnett CW (1955) |
| | Dunnett's Step Down | Dunnett CW and Tamhane AC (1991) |
| | Dunnett's Step Up | Dunnett CW and Tamhane AC (1992) |

Dose-Finding Hypertension Trial

Throughout this chapter we consider the data from a dose-finding hypertension trial (Dmitreinko and Offen, 2005) to illustrate different MC procedures. The trial was conducted to compare four doses of a new antihypertensive drug to a Placebo. The primary outcome is reduction in diastolic blood pressure. Doses with significant mean reduction in mean diastolic blood pressure will be declared efficacious. The data from this trial are available in **East** through the dataset **Hypertension-trial.cyd**.

Let $\mu_0, \mu_1, \mu_2, \mu_3$ and μ_4 indicate the group means in Placebo, Dose1, Dose2, Dose3 and Dose4 treatment groups. We are interested in testing following right tailed tests:

$$H_i : \mu_i - \mu_0 \leq 0 \text{ vs } K_i : \mu_i - \mu_0 > 0 \quad i = 1, 2, 3, 4$$

and the global null hypothesis

$$H_0 : \mu_0 = \mu_1 = \mu_2 = \mu_3 = \mu_4$$

We want to control the FWER at 5% level of significance.

84.2 Example: Dunnett's single step

Dataset: Hypertension-trial.cyd

Data Description:

The trial was conducted to compare four doses of a new antihypertensive drug to a Placebo. The primary outcome is reduction in diastolic blood pressure. Doses with significant mean reduction in mean diastolic blood pressure will be declared efficacious.

The dataset has 130 observations and 2 columns. The first column **Dose** contains the information on the dose level. There are 5 dose levels including Placebo. In this column, **P** represents Placebo where as “D1” through “D4” represent 4 dose levels of the drug. The second column, **Response**, contains the reduction in diastolic blood pressure (expressed in mmHg). Each line in the data set represents a subject in the study.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

**Analysis > (Continuous) Many Samples > (Multiple Comparisons)
Pairwise Comparisons to Controls - Difference of Means**

84 Analysis-Multiple Comparison Procedures for Continuous Data

- In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

Analysis Inputs

Analysis: Continuous Endpoint Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Differences of Means

Data Set: Hypertension-trial.cyd

Main Advanced

 D2
 D3
 D4

Response Variable
 Select Response Variable: Response

Equal Variance Unequal Variance

Multiple Comparison Procedure
 Select MCP: Dunnett's single step

- Now click on **Advanced** tab. Leave the fields **By Variable 1** and **By Variable 2** blank. On the left, enter **0.95** for **Confidence Level** and select **Right-Tail** for **Rejection Region**.

Data Set: Hypertension-trial.cyd

Main Advanced

By Variable 1: [] Confidence Level: 0.95

By Variable 2: [] Rejection Region: Right-Tail

- Click **OK** to start the analysis. Once the analysis is over, the output will be

displayed in the main window now.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_1 : \mu_i - \mu_0 \leq 0$ Vs. $K_1 : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: Equal
 Multiple Comparison Procedure: Dunnett's single step
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 1.963 | -0.354 | 0.638 | 0.896 | -3.95 | INF |
| D2 | 26 | 5.254 | 1.924 | 2.364 | 0.01 | 0.033 | 1.36 | INF |
| D3 | 24 | 5.629 | 1.963 | 2.508 | 0.007 | 0.023 | 1.671 | INF |
| D4 | 26 | 7.331 | 1.924 | 3.443 | 0 | 0.001 | 3.437 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The last section is the **Output**. For each treatment group (referred as **Arm**), sample size, mean and standard error of difference of mean are given in a table. The **Ctrl** arm in this table indicates “Placebo”. Mean responses for Placebo, Dose1, Dose2, Dose3 and Dose4 are 0.704, 0.008, 5.254, 5.629 and 7.331 mmHg, respectively.

The table in the **Output** section also includes the observed value of test statistic and p-values for comparison with control group along with 95% one-sided confidence interval for the difference with Placebo. There are two types of p-values in this table. The **Naive** p-values are referred to raw or un-adjusted p-values. The p-values in the **Adjusted** column are obtained after multiplicity adjustment according to Dunnett’s single step procedure so that FWER is maintained at 5% level of significance. The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.896, 0.033, 0.023 and 0.001, respectively. Therefore, after multiplicity adjustment according to Dunnett’s single step procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

84 Analysis-Multiple Comparison Procedures for Continuous Data

Under this table, adjusted global p-value is given which is 0.001 in this case. This is the p-value to reject the following global null hypothesis:

$$H_0 : \mu_0 = \mu_1 = \mu_2 = \mu_3 = \mu_4$$

One can verify that global p-value is the minimum of all the 4 adjusted p-values given in the table above.

84.3 Example: Dunnett's step-down and step-up procedures

Dataset: *Hypertension-trial.cyd* as described in Section 84.2

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

The screenshot shows the 'Analysis Inputs' dialog box for a 'Continuous Endpoint Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Differences of Means'. The 'Data Set' is 'Hypertension-trial.cyd'. The 'Main' tab is selected. Under 'Treatment Variable and its Control Arm', 'Dose' is selected as the 'Treatment Variable' and 'P' is selected as the 'Control Arm'. Under 'Response Variable', 'Response' is selected. The 'Multiple Comparison Procedure' is set to 'Dunnett's step-down'. The 'Equal Variance' option is selected.

4. Now click on **Advanced** tab. Leave the fields **By Variable 1** and **By Variable 2** blank. On the left, enter 0.95 for **Confidence Level** and select **Right-Tail** for **Rejection Region**.

- Click **OK** to analyze the data. The output will be displayed in the main window once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_1: \mu_i - \mu_0 \leq 0$ Vs. $K_1: \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: Equal
 Multiple Comparison Procedure: Dunnett's step-down
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 1.963 | -0.354 | 0.638 | 0.638 | -3.95 | INF |
| D2 | 26 | 5.254 | 1.924 | 2.364 | 0.01 | 0.018 | 1.36 | INF |
| D3 | 24 | 5.629 | 1.963 | 2.508 | 0.007 | 0.018 | 1.671 | INF |
| D4 | 26 | 7.331 | 1.924 | 3.443 | 0 | 0.001 | 3.437 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.638, 0.018, 0.018 and 0.001, respectively. Therefore, after multiplicity adjustment according to Dunnett’s step-down procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

We can perform **Dunnett’s step-up** test by selecting **Dunnett’s step-up** from the drop-down menu in **Select MCP** in the **Main** tab of input window. However, Dunnett’s step-up test cannot be performed with **Hypertension-trial.cyd** dataset as the number of observations for all the 5 treatment are not equal. In other words, the treatment groups are not balanced in this data. Number of observations in Placebo, Dose1, Dose2, Dose3 and Dose4 groups are 25, 24, 26, 24 and 26 respectively.

Comparison of Dunnett’s single step and step-down procedures results

The table below compares the p-values for comparison with Placebo for the two

84 Analysis-Multiple Comparison Procedures for Continuous Data

different methods (Dunnett's single step and step-down) along with the raw p-values.

| Arm | Raw | Single step | Step-down |
|-----|-------|-------------|-----------|
| D1 | 0.638 | 0.896 | 0.638 |
| D2 | 0.010 | 0.033 | 0.018 |
| D3 | 0.007 | 0.023 | 0.018 |
| D4 | 0.000 | 0.001 | 0.001 |

Notice that the p-values for the step-down procedure are all smaller than the p-values for the single-step procedure except for the Dose4.

84.4 p-value based Procedures

The p-value based procedures strongly control the FWER regardless of the joint distribution of the raw p-values as long as the individual raw p-values are legitimate p-values. Assume that there are k arms including the Placebo arm. Let n_i be the number of subjects for i -th treatment arm ($i = 0, 2, \dots, k - 1$). Let $N = \sum_{i=0}^{k-1} n_i$ be the total sample size and the arm 0 refers to Placebo. Let Y_{ij} be the response from subject j in treatment arm i and y_{ij} be the observed value of Y_{ij} ($i = 0, 2, \dots, k - 1, j = 1, 2, \dots, n_i$).

Suppose that

$$Y_{ij} = \mu_i + e_{ij} \tag{84.1}$$

where $e_{ij} \sim N(0, \sigma_i^2)$.

We are interested in the following hypotheses:

- For the right tailed test: $H_i : \mu_i - \mu_0 \leq 0$ vs $K_i : \mu_i - \mu_0 > 0$
- For the left tailed test: $H_i : \mu_i - \mu_0 \geq 0$ vs $K_i : \mu_i - \mu_0 < 0$

For the global null hypothesis at least one of the H_i is rejected in favor of K_i after controlling for FWER. Here H_i and K_i refer to null and alternative hypotheses, respectively, for comparison of i -th arm with the Placebo arm.

Let \bar{y}_i be the sample mean for treatment arm i , s_i^2 be the sample variance from i -th arm and s^2 be the pooled sample variance for all arms. For the equal variance case, one

need to replace s_i^2 and s_0^2 by the pooled sample variance s^2 . For both the case, T_i is distributed as Student's t distribution. However, the degrees of freedom varies for equal variance and unequal variance case. For equal variance case the degrees of freedom would be $N - k$. For the unequal variance case, the degrees of freedom is subject to Satterthwaite correction.

Let t_i be the observed value of T_i and these observed values for $K - 1$ treatment arms can be ordered as $t_{(1)} \geq t_{(2)} \geq \dots \geq t_{(k-1)}$. For the right tailed test the marginal p-value for comparing the i -th arm with Placebo is calculated as $p_i = P(T > t_i)$ and for left tailed test $p_i = P(T < t_i)$, where T is distributed as Student's t distribution. Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the ordered p-values.

For the unequal variance case, the test statistic for comparing treatment effect of arm i with Placebo can be defined as

$$T_i = \frac{\bar{y}_i - \bar{y}_0}{\sqrt{\frac{1}{n_i} s_i^2 + \frac{1}{n_0} s_0^2}} \tag{84.2}$$

84.5 Single step MC procedures

East supports three p-value based single step MC procedures:

- Bonferroni procedure
- Sidak procedure and
- Weighted Bonferroni procedure.

For the Bonferroni procedure, H_i is rejected if $p_i < \frac{\alpha}{k-1}$ and the adjusted p-value is given as $\min(1, (k - 1)p_i)$.

For the Sidak procedure, H_i is rejected if $p_i < 1 - (1 - \alpha)^{\frac{1}{k-1}}$ and the adjusted p-value is given as $1 - (1 - p_i)^{k-1}$.

For the weighted Bonferroni procedure, H_i is rejected if $p_i < w_i \alpha$ and the adjusted p-value is given as $\min(1, \frac{p_i}{w_i})$. Here w_i denotes the proportion of α allocated to the H_i such that $\sum_{i=1}^{k-1} w_i = 1$. Note that, if $w_i = \frac{1}{k-1}$, then the Bonferroni procedure is reduced to the regular Bonferroni procedure.

Example: Bonferroni procedure

Dataset: Hypertension-trial.cyd as described in Section 84.2

84 Analysis-Multiple Comparison Procedures for Continuous Data

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

Analysis Inputs

Analysis: Continuous Endpoint Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Differences of Mean

Data Set: Hypertension-trial.cyd

Select MCP: Bonferroni

4. Click **OK** to analyze the data. The output will be displayed in the main window.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: UnEqual
 Multiple Comparison Procedure: Bonferroni
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 2.026 | -0.343 | 0.634 | 1 | -4.097 | INF |
| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.031 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.045 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 0 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 1, 0.031, 0.045 and 0.001, respectively. Therefore, after multiplicity adjustment according to Bonferroni procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

Example: Sidak procedure

Dataset: Hypertension-trial.cyd as described in Section 84.2

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

| D1 | 0.25 |
| D2 | 0.25 |
| D3 | 0.25 |
| D4 | 0.25 |

4. Upon selection of weighted Bonferroni procedure, a table will appear under the drop-down box. The table has two columns - **Arm** and **Proportion of Alpha**. In the column **Proportion of Alpha**, you have to specify the proportion of total alpha you want to spend in each test. Ideally, the values in this column should add up to 1; if not, then **East** will normalize it to add them up to 1. By default, **East** distributes the total alpha equally among all tests. Here we have 4 tests in total, therefore each of the tests have proportion of alpha as $1/4$ or 0.25 . You can specify other proportions as well. For this example, keep the equal proportion of alpha for each test.
5. Click **OK** to analyze the data. The output will be displayed in the main window

once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis

$H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: UnEqual
 Multiple Comparison Procedure: Weighted Bonferroni
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail
 Table For Proportion of Alpha:

| Arms | Proportion of Alpha |
|------|---------------------|
| D1 | 0.25 |
| D2 | 0.25 |
| D3 | 0.25 |
| D4 | 0.25 |

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 2.026 | -0.343 | 0.634 | 1 | -4.097 | INF |
| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.031 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.045 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 0 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.982, 0.031, 0.044 and 0.001, respectively. Therefore, after multiplicity adjustment according to Sidak procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

Notice that the adjusted p-values in weighted Bonferroni MC procedure and the simple Bonferroni procedures are identical. This is because the weighted Bonferroni procedure with equal proportion reduces to the simple Bonferroni procedure.

84 Analysis-Multiple Comparison Procedures for Continuous Data

84.6 Step down MC procedure

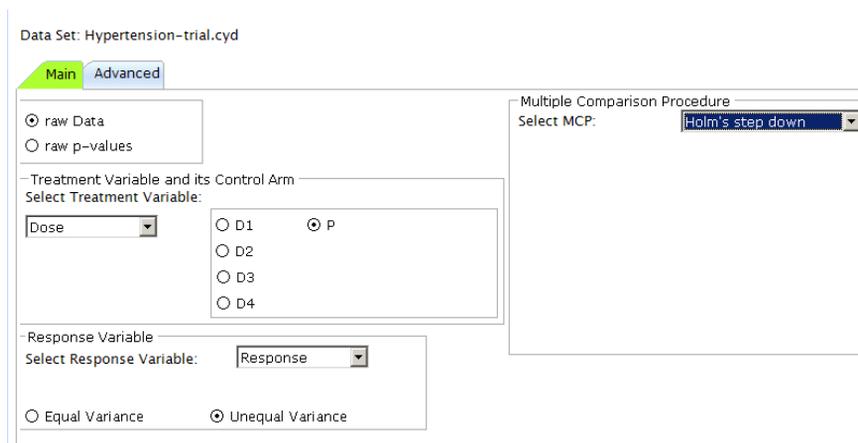

In the single step MC procedures, the decision to reject any hypothesis does not depend on the decision to reject other hypotheses. On the other hand, in the stepwise procedures decision of one hypothesis test can influence the decisions on the other tests of hypotheses. There are two types of stepwise procedures. One type of procedures proceeds in data-driven order. The other type proceeds in a fixed order set a priori. Stepwise tests in a data-driven order can proceed in step-down or step-up manner. **East** supports Holm step-down MC procedure which start with the most significant comparison and continue as long as tests are significant until the test for certain hypothesis fails. The testing procedure stops at the first time a non-significant comparison occurs and all remaining hypotheses will be retained. In i -th step, $H_{(k-i)}$ is rejected if $p_{(k-i)} \leq \frac{\alpha}{i}$ and go to the next step.

Example: Holm's step-down

Dataset: Hypertension-trial.cyd as described in Section 84.2

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

4. Click **OK** to analyze the data. The output will be displayed in the main window

once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis

$H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: UnEqual
 Multiple Comparison Procedure: Holm's step down
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 2.026 | -0.343 | 0.634 | 0.634 | -4.097 | INF |
| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.023 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.023 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 0 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.634, 0.023, 0.023 and 0.001, respectively. Therefore, after multiplicity adjustment according to Holm's step-down procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

84.7 Data-driven step-up MC procedures

Step-up tests start with the least significant comparison and continue as long as tests are not significant until the first time when a significant comparison occurs and all remaining hypotheses will be rejected. East supports two such MC procedures - Hochberg step-up and Hommel step-up procedures. In the Hochberg step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-i)} > \frac{\alpha}{i}$. In the Hommel step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-j)} > \frac{i-j+1}{i} \alpha$ for $j = 1, \dots, i$. Fixed sequence test and fallback test are the types of tests which proceed in a prespecified order.

84 Analysis-Multiple Comparison Procedures for Continuous Data

Example: Hochberg's step-up procedure

Dataset: Hypertension-trial.cyd as described in Section 84.2

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

The screenshot shows the 'Multiple Comparison Procedure' dialog box for the dataset 'Hypertension-trial.cyd'. The 'Main' tab is selected. The 'raw Data' radio button is chosen. Under 'Treatment Variable and its Control Arm', 'Dose' is selected in the dropdown, and the 'P' radio button is selected. Under 'Response Variable', 'Response' is selected in the dropdown. The 'Unequal Variance' radio button is selected. On the right side, 'Hochberg's step up' is selected in the 'Select MCP:' dropdown.

4. Click **OK** to analyze the data. The output will be displayed in the main window

once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_1: \mu_i - \mu_0 \leq 0$ Vs. $K_i: \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: Unequal
 Multiple Comparison Procedure: Hochberg's step Up
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |

| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.022 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.022 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 0 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.634, 0.022, 0.022 and 0.001, respectively. Therefore, after multiplicity adjustment according to Hochberg's step-up procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

Example: Hommel's step-up procedure

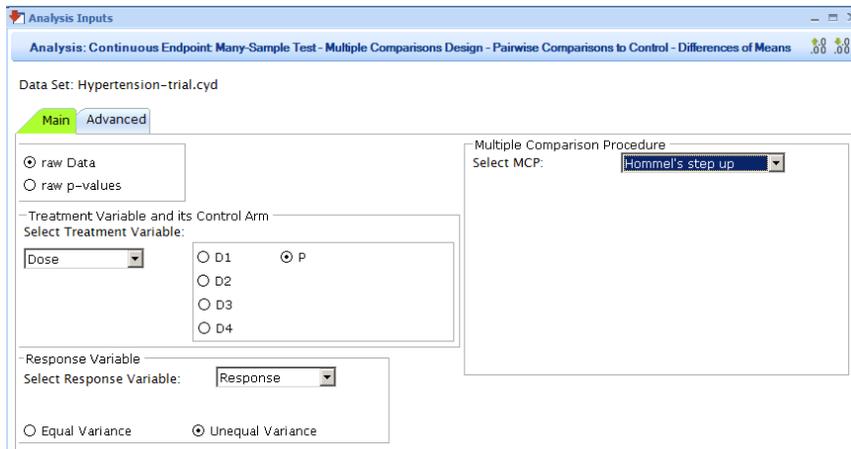

Dataset: Hypertension-trial.cyd as described in Section 84.2

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown

84 Analysis-Multiple Comparison Procedures for Continuous Data

below.

4. Click **OK** to analyze the data. The output will be displayed in the main window

once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

$H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: UnEqual
 Multiple Comparison Procedure: Hommel's step up
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|----------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 2.026 | -0.343 | 0.634 | 0.634 | -4.097 | INF |
| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.017 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.022 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 3.196E-4 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total Number of Records: 130
 Number of Records Rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.634, 0.017, 0.022 and 0.001, respectively. Therefore, after multiplicity adjustment according to Hommel's step-up procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

84.8 Fixed-sequence stepwise MC procedures

In data-driven stepwise procedures, we don't have any control on the order of the hypotheses to be tested. However, sometimes based on our preference or prior knowledge we might want to fix the order of tests a priori. Fixed sequence test and fallback test are the types of tests which proceed in a pre-specified order. East supports both these procedures.

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is pre-specified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the associated raw marginal p-values. In the fixed sequence testing procedure, for $i = 1, \dots, k - 1$, in i -th step, if $p_i < \alpha$, reject H_i and go to the next step; otherwise

84 Analysis-Multiple Comparison Procedures for Continuous Data

retain H_i, \dots, H_{k-1} and stop.

Fixed sequence testing strategy is optimal when early tests in the sequence have largest treatment effect and performs poorly when early hypotheses have small treatment effect or are nearly true (Westfall and Krishen (2001)). The drawback of fixed sequence test is that once a hypothesis is not rejected no further testing is permitted. This will lead to lower power to reject hypotheses tested later in the sequence.

Fallback test alleviates the above undesirable feature for fixed sequence test. Let w_i be the proportion of α for testing H_i such that $\sum_{i=1}^{k-1} w_i = 1$. In the fixed sequence testing procedure, in i -th step ($i = 1, \dots, k-1$), test H_i at $\alpha_i = \alpha_{i-1} + \alpha w_i$ if H_{i-1} is rejected and at $\alpha_i = \alpha w_i$ if H_{i-1} is retained. If $p_i < \alpha_i$, reject H_i ; otherwise retain it. Unlike the fixed sequence testing approach, the fallback procedure can continue testing even if a non-significant outcome is encountered by utilizing the fallback strategy. If a hypothesis in the sequence is retained, the next hypothesis in the sequence is tested at the level that would have been used by the weighted Bonferroni procedure. With $w_1 = 1$ and $w_2 = \dots = w_{k-1} = 0$, the fallback procedure simplifies to fixed sequence procedure.

Example: Fixed sequence testing procedure

Dataset: Hypertension-trial.cyd as described in Section 84.2

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

**Analysis > (Continuous) Many Samples > (Multiple Comparisons)
Pairwise Comparisons to Controls - Difference of Means**

3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below. Upon selection of **Fixed Sequence** procedure, a table will appear under the drop-down box. The table has two columns - **Arm** and **Test Sequence**. In the column **Test Sequence**, you have to specify the order in which the hypotheses will be tested. Specify 1 for the arm that will be compared first with Placebo, 2 for the arm that will be compared next and so on. By default **East** specifies 1 to the first arm, 2 to the second arm and so on. This default order implies that Dose1 will be compared first with Placebo, then Dose2 will be compared followed by comparison of Dose3 vs. Placebo and finally Dose 4 will be compared with Placebo. However, if we believe that efficacy of drug increases with dose, then the dose groups should be compared in descending order of dose. Therefore, specify 4, 3, 2 and 1 in column **Test Sequence** for D1,

D2, D3 and D4, respectively. This order implies that Dose4 will be compared first with Placebo, then Dose3 will be compared followed by comparison of Dose2 vs. Placebo and finally Dose 1 will be compared with Placebo.

| D4 | 26 | 7.331 | 1.814 | 3.654 | 0 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The input section of the output displays the tests sequence along with the other input values we have provided. The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs. Placebo and Dose4 vs. Placebo are 0.634, 0.022, 0.022 and 0.001, respectively. Therefore, after multiplicity adjustment according to fallback procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

84.9 Example: Raw p-values as input

Suppose we don't have the dataset containing all the observations, rather we have the raw p-values and we want to adjust these using Bonferroni procedure. Here we will consider the 4 raw p-values returned by **East** using **Hypertension-trial.cyd** in all the above output. These p-values are 0.634, 0.008, 0.011 and 0.000. We will use these raw

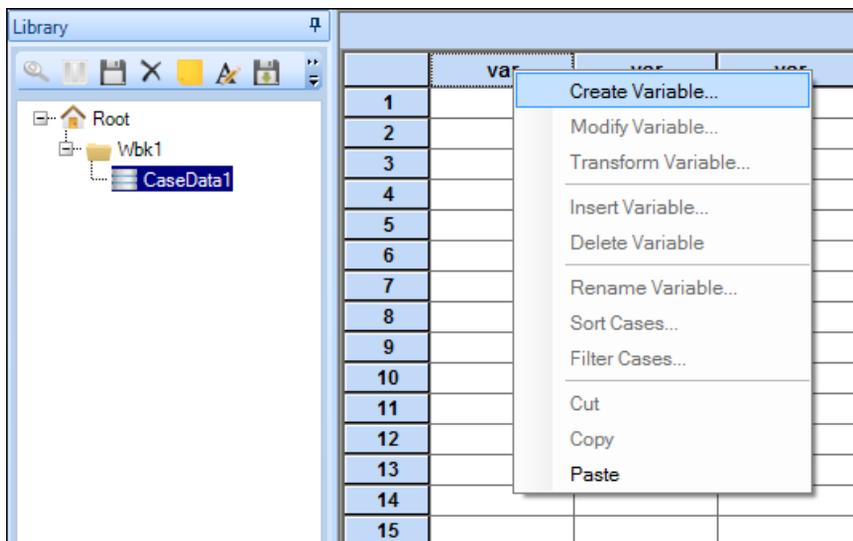

p-values to obtain adjusted p-values. In order to do this, first, we need to create a dataset containing these p-values.

Dataset: New Dataset to be created.

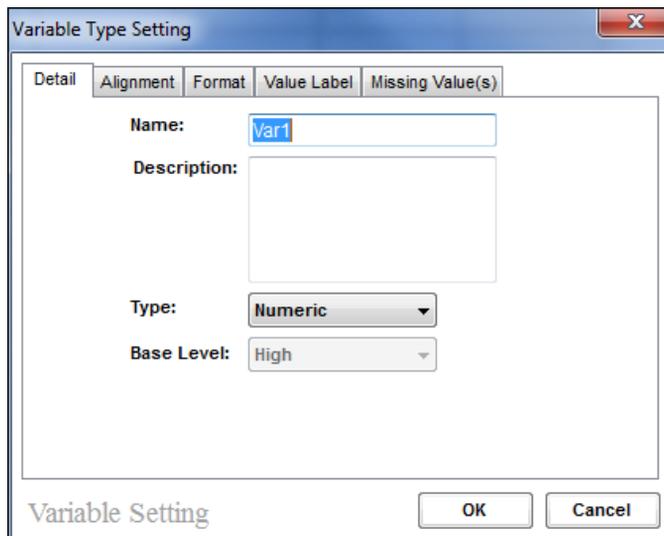

84 Analysis-Multiple Comparison Procedures for Continuous Data

Analysis Steps:

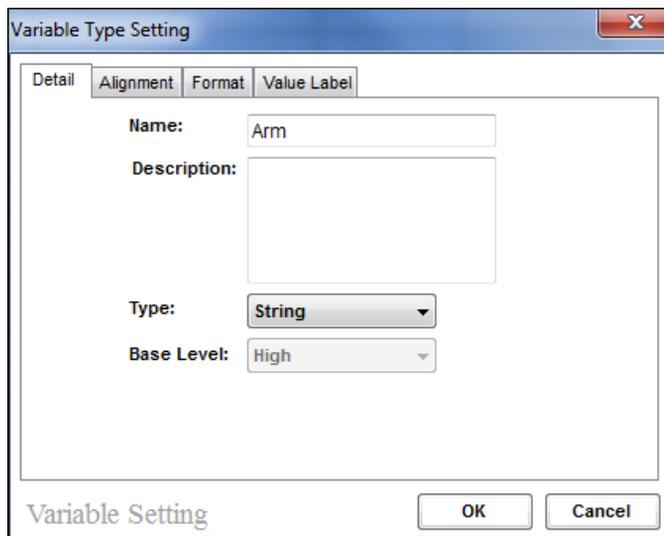

1. Choose textbf New > Case Data. This will open a black dataset in the main window. Now right click on the column header and click **Create Variable** as shown below.

2. This will bring up the following **Variable Type Setting** dialog box.

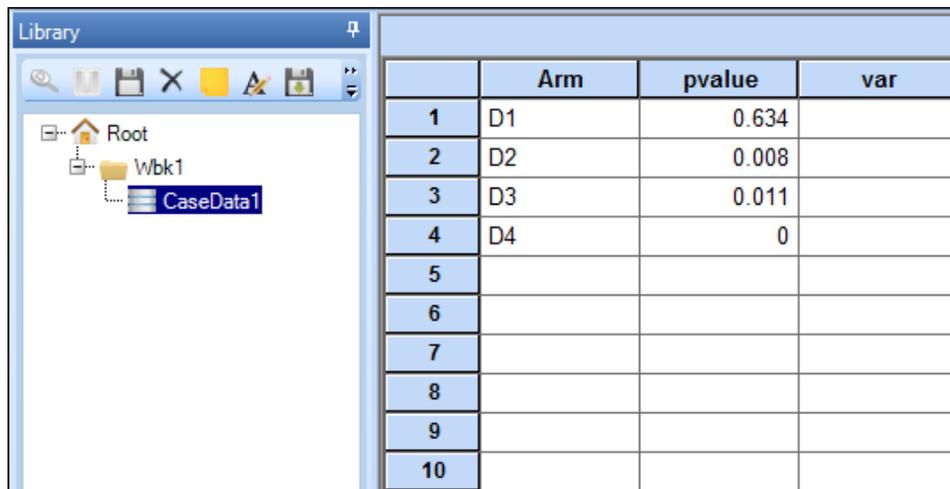

3. Type in **Arm** for **Name** and choose the type of variable as **String**.

84 Analysis-Multiple Comparison Procedures for Continuous Data

- Click **OK** and this will add a column with name **Arm** in the dataset. Similarly, create a numeric column with label **pvalue**. Now, enter the values in the table as follows:

| | Arm | pvalue | var |
|----|-----|--------|-----|
| 1 | D1 | 0.634 | |
| 2 | D2 | 0.008 | |
| 3 | D3 | 0.011 | |
| 4 | D4 | 0 | |
| 5 | | | |
| 6 | | | |
| 7 | | | |
| 8 | | | |
| 9 | | | |
| 10 | | | |

5. East assigns a default name **CaseData1** to this dataset.
6. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
7. This will display several input fields associated with multiple comparison test in the main window. In the **Main tab**, select the radio-button corresponding to **raw p-values**. In the ensuing two boxes, select **Arm** as **Treatment variable** and select **pvalue** for **Select raw p-values**. Choose **Bonferroni** from the drop-down list in **Select MCP**.

Analysis: Continuous Endpoint: Many-Sample Test - Multi-Arm Design - Pairwise Comparisons to Control - Differences of Means

Data Set: CaseData1

The screenshot displays the software's configuration window for a multiple comparison test. It features two tabs: 'Main' and 'Advanced'. Under the 'Main' tab, there are two radio buttons: 'raw Data' (unselected) and 'raw p-values' (selected). Below these, there are two sections for variable selection. The first section, 'Treatment Variable', has a dropdown menu set to 'Arm' and a list of options: D1, D2, D3, and D4. The second section, 'Raw p-value Variable', has a dropdown menu set to 'pvalue'. To the right of these sections is a separate box titled 'Multiple Comparisons Procedures' containing a dropdown menu labeled 'Select MCP:' which is set to 'Bonferroni'.

84 Analysis-Multiple Comparison Procedures for Continuous Data

8. Click **OK**. The output will be displayed in the main window.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: CaseData1
 Treatment Variable: Arm
 Raw p-values variable: pvalue
 Multiple Comparison Procedure: Bonferroni
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | p-value | |
|-----|---------|----------|
| | Raw | Adjusted |
| D1 | 0.634 | 1 |
| D2 | 0.008 | 0.032 |
| D3 | 0.011 | 0.044 |
| D4 | 0 | 0 |

Adjusted Global p-value: 0
 Total no. of records: 4
 No. of records rejected: 0
 Total Number of Arms (k): 4

The adjusted p-values for D1, D2, D3 and D4 are 1, 0.032, 0.044 and 0.000, respectively. Note that these adjusted p-values are very close to what we have obtained with Bonferroni procedure using the dataset [Hypertension-trial.cyd](#). Ideally, both set of p-values should exactly match. The difference in p-values is only due to rounding error.

85 *Analysis-Multiple Endpoints for Continuous Data*

In Chapter 16, we have seen how to evaluate different gatekeeping procedures through intensive simulations. In this chapter, we will illustrate how to analyze a trial with gatekeeping multiple comparison procedures. Consider the Alzheimer's disease example reported in Reisberg et al. 2003. This study is designed to investigate memantine, an N-methyl-D-aspartate (NMDA) antagonist, for the treatment of Alzheimer's disease in which patients with moderate-to-severe Alzheimer's disease were randomly assigned to receive placebo or 20 mg of memantine daily for 28 weeks. The two primary efficacy variables were: (1) the Clinician's Interview-Based Impression of Change Plus Caregiver Input (CIBIC-Plus) global score at 28 weeks, (2) the change from base line to week 28 in the Alzheimer's Disease Cooperative Study Activities of Daily Living Inventory modified for severe dementia (ADCS-ADLsev). The CIBIC-Plus measures overall global change relative to base line and is scored on a seven-point scale ranging from 1 (markedly improved) to 7 (markedly worse). The secondary efficacy endpoints included the Severe Impairment Battery and other measures of cognition, function, and behavior. Suppose that the trial is declared successful only if the treatment effect is demonstrated on both endpoints. If the trial is successful, it is of interest to assess the two secondary endpoints: (1) Severe Impairment Battery (SIB), (2) Mini-Mental State Examination (MMSE). The data set is saved in the installation folder of EAST as Alzheimer.csv. To analyze this data set, we need to import the data into EAST by clicking on the Import icon as seen in the following screen.

Select the Alzheimer.csv file and click OK to see the data set displayed in EAST. The

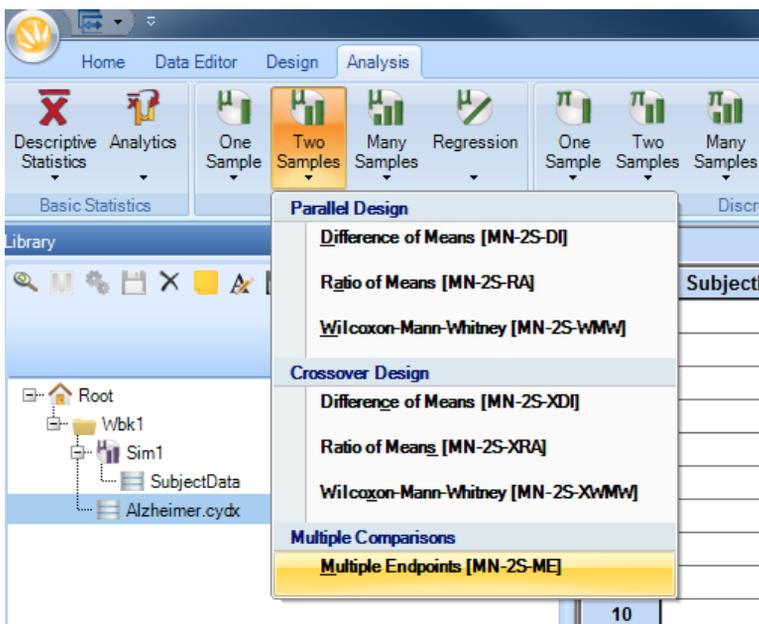

85 Analysis-Multiple Endpoints for Continuous Data

following screen shows a snapshot of the data set.

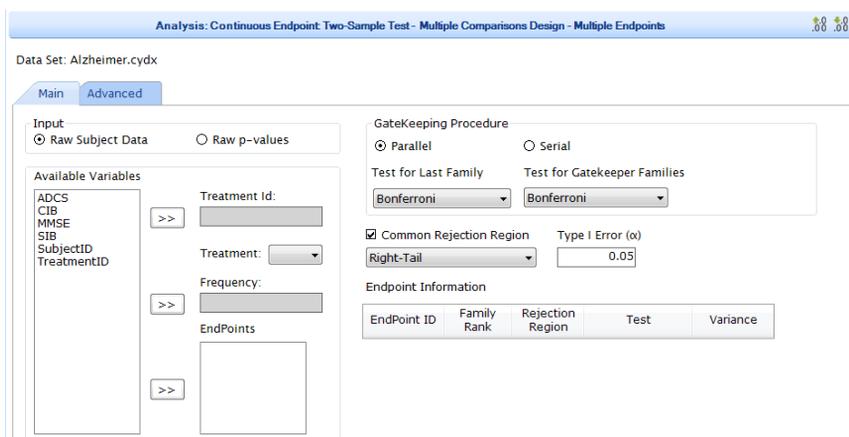

| SubjectID | TreatmentID | CIB | ADCS | SIB | MMSE |
|-----------|-------------|------------|-------------|-------------|--------------|
| 1 | 0 | 5.66492653 | 4.36394922 | -6.32570582 | -3.32797968 |
| 2 | 0 | 3.95074349 | -3.3850377 | 7.06432058 | -0.483275732 |
| 3 | 0 | 4.36113329 | -7.09915667 | -12.5260734 | -2.08573408 |
| 4 | 0 | 3.19733356 | -12.2679343 | -27.2717159 | -4.24276931 |
| 5 | 0 | 3.59878247 | -6.02594982 | -27.1493254 | -3.27394314 |
| 6 | 0 | 4.60578509 | -10.071646 | -20.9660857 | -3.32429613 |
| 7 | 0 | 5.86933156 | 0.525622886 | -8.14458525 | 2.68263096 |
| 8 | 0 | 4.73326277 | -5.41094781 | -6.79993922 | -1.27626971 |
| 9 | 0 | 4.74888428 | -9.43789172 | -33.5473889 | -0.853782244 |
| 10 | 0 | 3.48522851 | -5.75471209 | -7.64045638 | -5.57948689 |
| 11 | 0 | 3.2053906 | -14.8363446 | -17.7253033 | -5.44609824 |
| 12 | 0 | 6.75611159 | 4.52154357 | 23.8728393 | 1.47453882 |
| 13 | 0 | 3.929523 | -2.8980647 | -19.0296683 | -2.55714285 |
| 14 | 0 | 5.37510233 | -8.38883153 | -15.1115339 | 3.31528606 |
| 15 | 0 | 3.95012484 | -9.23173693 | -1.39008734 | 4.34674624 |
| 16 | 0 | 5.84104094 | 3.18117957 | -11.1542966 | 6.16735651 |
| 17 | 0 | 5.27755294 | -4.42540448 | -25.2515189 | -4.67474173 |

Now click on the Analysis menu on the top of EAST window, select Two Samples and

then select Multiple Comparisons-Multiple Endpoints from the dropdown list.

The main input dialog window pops up as seen in the following screen.

85 Analysis-Multiple Endpoints for Continuous Data

the Alzheimer’s disease example, the data is raw subject level data so we select the left radio button. The left bottom panel of the screen displays all the variables contained in the data set. We need to specify which variable contains the information on treatment group ID for each subject and further specify which one is active treatment group. The next input is to identify all the endpoints to be analyzed. For this example, CIBIC-Plus and ADCS-ADLsev constitute the primary family of endpoints. SIB and MMSE constitutes the secondary family of endpoints. Suppose we need to analyze the data using serial gatekeeping procedure and using Bonferroni to adjust the multiplicity for the two endpoints from the secondary family. After filling in all inputs, the screen looks as follows

Analysis: Continuous Endpoint Two-Sample Test - Multiple Comparisons Design - Multiple Endpoints

| SIB | Diff of Means | Equal | 100 | -9.519 | -8.983 | 0.536 | 2.265 | 0.236 | -3.96 | 5.031 |

Inference of Gatekeeping Procedures:

| Family Rank | EndPoint ID | Rejection Region | Test Statistic | Degrees of Freedom(DF) | p-Value | | Status |
|-------------------|-------------|------------------|----------------|------------------------|---------|----------|------------------|
| | | | | | Raw | Adjusted | |
| 1 | ADCS | Right-Tail | 1.445 | 98 | 0.076 | 0.076 | Unable to Reject |
| | CIB | Left-Tail | -1.832 | 98 | 0.035 | 0.076 | Unable to Reject |
| Not Passed | | | | | | | |
| 2 | MMSE | Right-Tail | -0.16 | 98 | 0.563 | 1 | Not Tested |
| | SIB | Right-Tail | 0.236 | 98 | 0.407 | 0.814 | Not Tested |

*Using Bonferroni test for the last family in the Serial gatekeeping procedure, the treatment arm is not significantly different from the control arm on the co-primary endpoints. As a result, the other non-primary endpoints are not tested.

The first table shows the summary statistics for each endpoint including mean for each treatment group, estimate of treatment effect, standard error of the effect estimate, test statistic and marginal two-sided confidence interval. The second table shows the inference summary including raw p-values, multiplicity adjusted p-values with the gatekeeping procedure and significance status. It also shows whether the primary family is passed as the serial gatekeeper for the secondary family of endpoints.

86 Analysis-Binomial Superiority One-Sample

This chapter demonstrates how **East** can be used to perform inferences on data collected from a single-sample superiority study when the observations on a binary variable have an unknown probability of success. You need to either test a null hypothesis about the probability, or compute an exact confidence interval for the probability of success. The section also discusses the analysis of paired data on a binary random variable.

Chapter 22 deals with the design, simulation and interim monitoring of these types of trials with reference to a single sample test for proportion.

East supports both the asymptotic and exact analysis of these tests. These are accessible from the **Analysis** menu and allow the validation of whether the data supports the null or alternative hypothesis of the study. Analysis of a single mean superiority test is discussed in section 86.1, while McNemar's test for paired observations is discussed in section 86.2.

86.1 Example: Single Proportion

Dataset: Pilot.cyx

Data Description

In a pilot study of a new drug, 20 patients were treated. The column **Response** displays the successes and failures after administering the drug. There were 4 responders (successes) and 16 non-responders (failures).

Purpose of the Analysis:

Consider the null hypothesis: $H_0: \pi = \pi_0$ to be tested against a two-sided alternative hypothesis $H_1: \pi \neq \pi_0$ or a one-sided alternative hypothesis $H_1: \pi < \pi_0$ or $H_1: \pi > \pi_0$.

In this analysis, the hypothesis is tested asymptotically as well as using Exact Inference. We will obtain a 95% confidence interval for the underlying success rate and test the null hypothesis that $\pi = 0.05$. We would also like to compute the power of the test for the alternative hypothesis that $\pi = 0.30$.

Analysis Steps: Asymptotic Test

1. Open the dataset from **Samples** folder.

2. Choose the menu item
Analysis > (Discrete) One Sample > (Single Arm Design) Single Proportion
3. In the ensuing dialog box (under the **Main** tab) choose the variables as shown below. To run the **Asymptotic** test, do not check the **Perform Exact Computation** checkbox.

Analysis: Discrete Endpoint One-Sample Test - Single Arm Design - Single Proportion

Data Set: Pilot.cyx

Main Advanced

Response Variable: Proportion Specified under H0:

Response Value:

Perform Exact Computations

86 Analysis-Binomial Superiority One-Sample

- Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Single Proportion

$H_0 : \pi = \pi_0$ Vs. $H_1 : \pi \neq \pi_0$ for 2-Sided test
 Either $H_1 : \pi > \pi_0$
 Or $H_1 : \pi < \pi_0$ for 1-Sided test

Input Parameters

Data File: Pilot.cydx
 Response Variable: Response(1)
 Exact p-values for testing π : 0.05
 Confidence Level: 0.95

Output

Response Variable: (Response)
 Total Number of Records: 20
 Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|---|-------|
| 1 | 16 | 4 | 20 |
| Total | 16 | 4 | 20 |

Test of Hypothesis:

| Type | Proportion | Std. Error | Std. Error (H0) | Test Statistic | (1-Sided) | | (2-Sided) | 95% Confidence Interval(2-Sided) | |
|------------|------------|------------|-----------------|----------------|-----------|------|-----------|----------------------------------|-------------|
| | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit |
| Asymptotic | 0.2 | 0.089 | 0.049 | 3.078 | 0.001 | G.E. | 0.002 | 0.025 | 0.375 |

Note that the test statistic is 3.078 with a 1-sided p-value of 0.001. Since the hypothesized proportion under the null hypothesis is 0.05 which is less than the observed proportion of responders in the data, namely 0.2, the tail type considered for one sided alternative hypothesis is G.E. meaning greater than or equal to. The null hypothesis that $\pi = 0.05$ is rejected at the 5% significance level.

Analysis Steps: Exact Test

- Click the **Analysis Inputs/Outputs** tab on the status bar below.
- Under the **Main** tab, select variables as shown below. Make sure to check the

Perform Exact Computation checkbox.

Analysis: Discrete Endpoint One-Sample Test - Single Arm Design - Single Proportion

Data Set: Pilot.cyx

Main **Advanced**

Response Variable: Proportion Specified under H0:

Response Value:

Perform Exact Computations

- Under the **Advanced** tab leave the fields **By Variable 1** and **By Variable 2** blank. Select the **Compute Power** checkbox, enter the value 0.05 for **Alpha** and 0.3 for **Probability under H1**. Keep the default value 0.95 for **Confidence Level**.

Analysis: Discrete Endpoint One-Sample Test - Single Arm Design - Single Proportion

Data Set: Pilot.cyx

Main **Advanced**

Compute Power

Alpha: Probability under H₁:

By Variable 1:

By Variable 2:

Confidence Level:

86 Analysis-Binomial Superiority One-Sample

4. Click **OK** to start the analysis. The result is displayed in the main window.

Analysis: Binomial Response: Single Proportion

$H_0 : \pi = \pi_0$ Vs. $H_1 : \pi \neq \pi_0$ for 2-Sided test
 Either $H_1 : \pi > \pi_0$
 Or $H_1 : \pi < \pi_0$ for 1-Sided test

Input Parameters

Data File: Pilot.cyx
 Response Variable: Response(1)
 Exact p-values for testing π : 0.05
 Confidence Level: 0.95

Output

Response Variable: (Response)
 Total Number of Records: 20
 Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|---|-------|
| 1 | 16 | 4 | 20 |
| Total | 16 | 4 | 20 |

Test of Hypothesis:

| Type | Statistic | p-value | | | | |
|-------|-----------|---------|---------|-----------|------|---------|
| | | Tail | 1-Sided | 2*1 Sided | Tail | 2-Sided |
| Exact | 4 | G.E. | 0.016 | 0.032 | G.E. | 0.032 |

Confidence Interval:

| Type | 95% Confidence Interval | | |
|---------------------|-------------------------|-------------|-------------|
| | MLE of π | Lower Limit | Upper Limit |
| Clopper-Pearson | 0.2 | 0.057 | 0.437 |
| Blyth-Still-Casella | 0.2 | 0.071 | 0.411 |

Exact Conditional Power:

| | |
|--------------------------------|-------|
| Null Hypothesis (H0) | 0.05 |
| Alternative Hypothesis (H1) | 0.3 |
| Desired Significance Level | 0.05 |
| Cut-off value for rejecting H0 | 4 |
| Power | 0.893 |

The exact 95% confidence interval using the Clopper-Pearson method is (0.057, 0.437). Notice that the Blyth-Still-Casella confidence interval is (0.071, 0.411), which is thus about 10% narrower than the Clopper-Pearson confidence interval. The exact 1-sided p-value is 0.016, and so the null hypothesis that $\pi = 0.05$ is rejected at the 5% significance level. The power of the test for the Type-I error $\alpha = .05$, where testing $H_0 : \pi = 0.05$ against $H_1 : \pi = 0.30$ at $\alpha = 0.05$, is 0.893.

86.2 Example: McNemar's Test for Matched Pairs . Dataset: Vote.cyx

Data Description

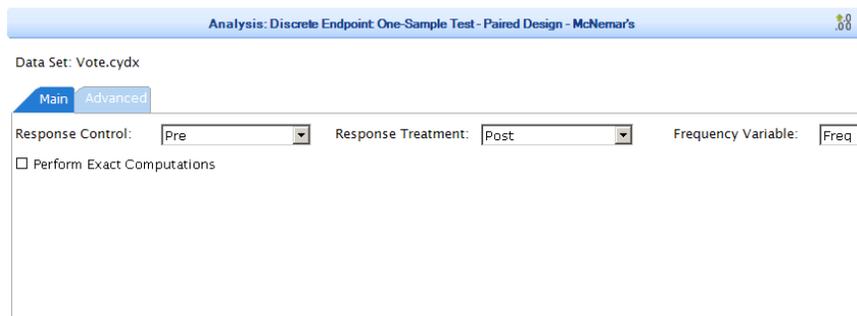

This data are taken from Siegel and Castellan (1988, page 77). It shows changes in preference for Presidential candidates before and after a television debate.

Table 86.1: Preference for Presidential Candidates

| Preference Before TV Debate | Preference After TV Debate | |
|-----------------------------|----------------------------|--------|
| | Carter | Reagan |
| Carter | 28 | 13 |
| Reagan | 7 | 27 |

Analysis Steps: Asymptotic Test

1. Open the dataset from **Samples** folder.
2. Choose the menu item **Analysis > (Discrete) One Sample > (Paired Design) McNemar's**
3. In the ensuing dialog box (under the **Main** tab) choose the variables as shown below. To run the **Asymptotic** test, do not check the **Perform Exact Computation** checkbox.

4. Under the **Advanced** tab, leave the fields **By Variable 1** and **By Variable 2** blank, keep the **Confidence Level** as 0.95.

86 Analysis-Binomial Superiority One-Sample

5. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: McNemar's test for Matched Pairs

Hypothesis

$H_0 : \pi_t - \pi_c = 0$ Vs. $H_1 : \pi_t - \pi_c \neq 0$ for 2-sided Test

Either $H_1 : \pi_t - \pi_c < 0$

Or $H_1 : \pi_t - \pi_c > 0$ for 1-sided Test

Input Parameters

Data File: Vote.cydx
 Response Control: Pre
 Response Treatment: Post
 Frequency Variable: Freq
 Confidence Level: 0.95

Output

Total no. of records: 4

No. of records rejected: 0

Table of observed frequencies:

| | Carter | Reagan | Total |
|--------|--------|--------|-------|
| Carter | 28 | 7 | 35 |
| Reagan | 13 | 27 | 40 |
| Total | 41 | 34 | 75 |

Summary of the Observed Data:

| Response Variable | n | Responses | Proportion |
|-------------------|----|-----------|------------|
| Pre | 75 | 41 | 0.547 |
| Post | 75 | 35 | 0.467 |

Test of Hypothesis:

| n | Diff. of Proportions | Std. Error | Test Statistic | (1-Sided) | | (2-Sided) | | 95% Confidence Interval(2-Sided) | |
|----|----------------------|------------|----------------|-----------|------|-----------|-------------|----------------------------------|--|
| | | | | p-value | Tail | p-value | Lower Limit | Upper Limit | |
| 75 | -0.08 | 0.06 | -1.342 | 0.09 | L.E. | 0.18 | -0.197 | 0.037 | |

The negative sign of the test statistic indicates that of the 20 discordant pairs, more switched preference from Carter to Reagan (13) than those switched preference from Reagan to Carter (7). The 2-sided p-value is 0.18 indicating not a significant change in preference for Presidential candidates before and after the television debate. The 95% confidence interval for difference of proportions based on the data is $(-0.197, 0.037)$. The fact that this interval includes 0 indicate that we are unable to reject the null hypothesis of no difference on the basis of the data.

Analysis Steps: Exact Test

| | | | | | p-value | Tail | p-value |
| Exact | 75 | -0.08 | 0.06 | -1.342 | 0.132 | L.E. | 0.263 |

The exact p-value is 0.263 indicating not a significant change in preference for Presidential candidates before and after the television debate.

87 *Analysis-Binomial Superiority Two-Sample*

In clinical trials involving binomial endpoint data, the interest lies in investigating if the subjects on treatment arm possess significantly different proportion of some characteristic, such as proportion of patients developing tumor, showing some side effect, requiring special attention etc as against the same on the control arm.

Chapter 23 deals with designing of such clinical trials considering difference of proportions, ratio of proportions or odds ratio of proportions of the two populations.

This chapter explores how **East** is used to analyze data from two independent binomial samples generated while conducting a superiority trial. Assume that the data are sampled independently from two binomial populations with response probabilities π_t and π_c for treatment and control. This comparison is based on difference of response probabilities, ratio of proportions or odds ratio of the two populations.

87.1 *Example: Difference of Proportions-Asymptotic*

Dataset: Clntrt.cydx

Data Description:

The following 2×2 table is obtained from a clinical trial of two treatments with a binary end-point:

| Outcome | Drug A | Drug B |
|-------------|--------|--------|
| Response | 5 | 9 |
| No Response | 5 | 1 |

The Drug B is the treatment whereas Drug A is control.

Purpose of the Analysis:

The following 2×2 table is obtained from a clinical trial of two treatments with a binary end-point:

| Outcome | Drug A | Drug B |
|-------------|--------|--------|
| Response | 5 | 9 |
| No Response | 5 | 1 |

87 Analysis-Binomial Superiority Two-Sample

To test the hypothesis $H_0 : \delta = 0$ against a 1-sided alternative hypothesis $H_1 : \delta > 0$. For this analysis, consider 1-sided type I error of 0.05.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item **Analysis > (Discrete) Two Samples > (Parallel Design) Difference of Proportions**
3. In the ensuing dialog box (under the **Main**) tab select **Superiority** as the **Trial Type**. Choose other variables as shown below. Do not check **Perform Exact Computation** checkbox.

Analysis: Binomial Response: Difference of Proportions

Hypothesis

$H_0 : \pi_t - \pi_c = 0$ Vs. $H_1 : \pi_t - \pi_c \neq 0$ for 2-Sided test

Either $H_1 : \pi_t - \pi_c < 0$

Or $H_1 : \pi_t - \pi_c > 0$ for 1-Sided test

Input Parameters

Data File: Clntrt.cydx
 Trial Type: Superiority
 Population Variable: Drug(Treatment=B, Control=A)
 Response Variable: Outcome(1)
 Frequency Variable: Freq
 Confidence Level: 0.95

Output

Response Variable: (Outcome)

Total Number of Records: 4

Number of Records Rejected: 0

Table of Observed Frequencies:

| | A | B | Total |
|-------|----|----|-------|
| 1 | 5 | 9 | 14 |
| 0 | 5 | 1 | 6 |
| Total | 10 | 10 | 20 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| A | 10 | 5 | 0.5 |
| B | 10 | 9 | 0.9 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | Test Statistic | 1-Sided | | 2-Sided | 95% Confidence Interval | |
|------------|----|---------------------------|------------|----------------|---------|---------|---------|-------------------------|-------------|
| | | | | | Tail | p-value | p-value | Lower Limit | Upper Limit |
| Asymptotic | 20 | 0.4 | 0.205 | 1.952 | G.E. | 0.025 | 0.051 | -0.002 | 0.699 |

The observed value of test statistic is 1.952. The p-value for 2-sided test is 0.051. The p-values for 2-sided test and for the right tailed test are 0.051 and 0.025 respectively. This p-value is associated with the rejection of $H_0: \delta = 0$ in favor of the alternative hypothesis $H_1: \delta > 0$. East displays the p-value associated with right tailed test on this occasion because $\hat{\delta} > 0$. The 2-sided 95% confidence interval is (-0.002, 0.699).

87 Analysis-Binomial Superiority Two-Sample

The p-value as well as the confidence interval indicates the rejection of null hypothesis and superiority of the drug over Control.

87.2 Example: Difference of Proportions-Exact

Dataset: `Clntrt.cydx` as described in Section 87.1

Purpose of the Analysis:

The following 2×2 table is obtained from a clinical trial of two treatments with a binary end-point:

| Outcome | Drug A | Drug B |
|-------------|--------|--------|
| Response | 5 | 9 |
| No Response | 5 | 1 |

The drug B is the treatment where as drug A is control. To test the hypothesis $H_0 : \delta = 0$ against a 1-sided alternative hypothesis $H_1 : \delta > 0$. For this analysis, consider 1-sided type I error of 0.05.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item
Analysis > (Discrete) Two Samples > (Parallel Design) Difference of Proportions
3. In the ensuing dialog box (under the **Main**) tab select **Superiority** as the **Trial Type**. Choose other variables as shown below. Check **Perform Exact**

Computation checkbox.

Hypothesis

$H_0 : \pi_t - \pi_c = 0$ Vs. $H_1 : \pi_t - \pi_c \neq 0$ for 2-Sided test
 Either $H_1 : \pi_t - \pi_c < 0$
 Or $H_1 : \pi_t - \pi_c > 0$ for 1-Sided test

Input Parameters

Data File: Clntrt.cydx
 Trial Type: Superiority
 Test Type: Wald
 Population Variable: Drug(Treatment=B, Control=A)
 Response Variable: Outcome(1)
 Frequency Variable: Freq
 Confidence Level: 0.95

Output

Response Variable: (Outcome)
 Total Number of Records: 4
 Number of Records Rejected: 0

87 Analysis-Binomial Superiority Two-Sample

Table of Observed Frequencies:

| | A | B | Total |
|-------|----|----|-------|
| 1 | 5 | 9 | 14 |
| 0 | 5 | 1 | 6 |
| Total | 10 | 10 | 20 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| A | 10 | 5 | 0.5 |
| B | 10 | 9 | 0.9 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | Test Statistic | 1-Sided | | 2-Sided | 95% Confidence Interval | |
|-------|----|---------------------------|------------|----------------|---------|---------|---------|-------------------------|-------------|
| | | | | | Tail | p-value | p-value | Lower Limit | Upper Limit |
| Exact | 20 | 0.4 | 0.205 | 1.952 | G.E. | 0.031 | 0.062 | -0.02 | 0.741 |

The one-sided p-value as well as the confidence interval indicates the rejection of null hypothesis and superiority of the Treatment over Control.

87.3 Example: Ratio of Proportions-Asymptotic

Dataset: Clntrt.cyx as described in Section 87.1.

Purpose of the Analysis:

In the **Ratio of Proportions** test, let π_t and π_c denote the proportions of the successes from the experimental treatment (T) and the control treatment (C), respectively.

To test the null hypothesis $H_0: \pi_t/\pi_c = 1$ against the 2-sided alternative hypothesis $H_1: \pi_t/\pi_c \neq 1$ or a 1-sided alternative hypothesis $H_1: \pi_t/\pi_c < 1$ or $H_1: \pi_t/\pi_c > 1$.

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item
Analysis > (Discrete) Two Samples > (Parallel Design) Ratio of Proportions
3. In the ensuing dialog box (under the **Main**) tab select **Superiority** as the **Trial Type**. Choose other variables as shown below. Do not check **Perform Exact**

Computation checkbox.

| 0 | 5 | 1 | 6 |
| Total | 10 | 10 | 20 |

87 Analysis-Binomial Superiority Two-Sample

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| A | 10 | 5 | 0.5 |
| B | 10 | 9 | 0.9 |

Test of Hypothesis:

| Type | n | Ratio of Proportions | Std. Error | Test Statistic | (1-Sided) | | (2-Sided) | 95% Confidence Interval | |
|------------|----|----------------------|------------|----------------|-----------|------|-----------|-------------------------|-------------|
| | | | | | p-value | Tail | p-value | Lower Limit | Upper Limit |
| Asymptotic | 20 | 1.8 | 0.205 | 1.952 | 0.025 | G E | 0.051 | 0.997 | 3.873 |

The observed value of test statistic is 1.952 with a 1-sided p-value equal to 0.025. The 2-sided 95% confidence interval for π_t/π_c is (0.997, 3.873). The null hypothesis is rejected establishing the superiority of the Treatment over Control.

87.4 Example: Ratio of Proportions-Exact

Dataset: Clntrt.cydx as described in Section 87.1.

Purpose of the Analysis:

In the **Ratio of Proportions** test, let π_t and π_c denote the proportions of the successes from the experimental treatment (T) and the control treatment (C), respectively.

To test the null hypothesis $H_0: \pi_t/\pi_c = 1$ against the 2-sided alternative hypothesis $H_1: \pi_t/\pi_c \neq 1$ or a 1-sided alternative hypothesis $H_1: \pi_t/\pi_c < 1$ or $H_1: \pi_t/\pi_c > 1$.

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item
Analysis > (Discrete) Two Samples > (Parallel Design) Ratio of Proportions
3. In the ensuing dialog box (under the **Main**) tab select **Superiority** as the **Trial Type**. Choose other variables as shown below. Check **Perform Exact**

Computation checkbox.

| Exact | 20 | 1.8 | 0.205 | 1.952 | 0.031 | G.E. | 0.062 | 0.97 | 4.805 |

The one-sided p-value indicates the rejection of null hypothesis and establishes the superiority of drug B over A.

87.5 Example: Odds Ratio of Proportions

Dataset: Clntrt.cydx as described in Section 87.1.

Purpose of the Analysis:

Let π_t and π_c denote proportion of responses under treatment and control arm respectively. The odds ratio of proportions denoted by Ψ is defined as

$$\Psi = \frac{\pi_t (1 - \pi_c)}{\pi_c (1 - \pi_t)}$$

The null hypothesis $H_0 : \Psi = 1$ is to be tested against the 2-sided alternative hypothesis $H_1 : \Psi \neq 1$ or against 1-sided alternative hypotheses $H_1 : \Psi < 1$ or $H_1 : \Psi > 1$.

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item
Analysis > (Discrete) Two Samples > (Parallel Design) Odds Ratio of Proportions
3. In the ensuing dialog box (under the **Main**) tab select **Superiority** as the **Trial**

Type. Choose other variables as shown below.

displayed in the main window.

Analysis: Binomial Response: Odds Ratio of Proportions

Hypothesis

$H_0 : \pi_t (1 - \pi_c) / \pi_c (1 - \pi_t) = 1$ Vs. $H_1 : \pi_t (1 - \pi_c) / \pi_c (1 - \pi_t) \neq 1$ for 2-sided test

Either $H_1 : \pi_t (1 - \pi_c) / \pi_c (1 - \pi_t) < 1$

Or $H_1 : \pi_t (1 - \pi_c) / \pi_c (1 - \pi_t) > 1$ for 1-sided test

Input Parameters

Data File: C:\ntrt.cyx
 Trial Type: Superiority
 Population Variable: Drug(Treatment=B, Control=A)
 Response Variable: Outcome(1)
 Frequency Variable: Freq
 Confidence Level: 0.95

Output

Response Variable: (Outcome)

Total no. of records: 4

No. of records rejected: 0

Table of observed frequencies:

| | A | B | Total |
|-------|----|----|-------|
| 1 | 5 | 9 | 14 |
| 0 | 5 | 1 | 6 |
| Total | 10 | 10 | 20 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| A | 10 | 5 | 0.5 |
| B | 10 | 9 | 0.9 |

Test of Hypothesis:

| n | Odds Ratio | M-H Estimate | 2-Sided p-value | | 95% Confidence Interval(2-Sided) | |
|----|------------|--------------|-----------------|--------------|----------------------------------|-------------|
| | | | RBG variance | M-H variance | Lower Limit | Upper Limit |
| 20 | 9 | 9 | 0.074 | 0.057 | 0.809 | 100.139 |

The output gives estimate of odds ratio and 2-sided p-value using RBG variance and M-H variance. The two sided p values indicate failing to reject the null hypothesis.

87.6 Example: Common Odds Ratio of Proportions for stratifies 2X2 tables

Dataset: BD.cydx

Data Description

The data below for six age groups, relating alcohol to oesophageal cancer, are taken from Breslow and Day (1980).

| Age Group | Alcohol Exposure | | No Exposure | |
|-----------|------------------|---------|-------------|---------|
| | Case | Control | Case | Control |
| 25-34 | 1 | 9 | 0 | 106 |
| 35-44 | 4 | 26 | 5 | 164 |
| 45-54 | 25 | 29 | 21 | 138 |
| 55-64 | 42 | 27 | 34 | 139 |
| 65-74 | 19 | 18 | 36 | 88 |
| 75+ | 5 | 0 | 8 | 31 |

Purpose of the Analysis:

The Homogeneity test is executed on these data to determine if the Odds-Ratios across the six age groups are constant.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item
Analysis > (Discrete) Two Samples > (Parallel Design) Common Odds Ratio for Stratifies 2X2 Tables
3. In the ensuing dialog box (under the **Main**) tab choose the variables as shown

87 Analysis-Binomial Superiority Two-Sample

below.

The screenshot shows the SAS software interface for a binomial superiority two-sample test. The title bar reads "Analysis: Discrete Endpoint Two-Sample Test - Parallel Design - Common Odds Ratio for Stratified". Below the title bar, the data set is identified as "BD.cydx". There are two tabs, "Main" and "Advanced", with "Advanced" selected. The "Row:" dropdown is set to "Row", the "Column:" dropdown is set to "Col", and the "Stratum:" dropdown is set to "Stratum". The "Frequency Variable:" field is set to "Freq".

Analysis: Discrete Endpoint Two-Sample Test - Parallel Design - Common Odds Ratio for Stratified

Stratum: Stratum

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Common Odds Ratio For Stratified 2X2 table

Hypothesis

Define $\Psi_i = \pi_{1i} (1 - \pi_{ci}) / \pi_{ci} (1 - \pi_{1i})$ $H_0 : \Psi_i = \Psi$ for all $i = 1, \dots, s$ where s is the number of strata Vs. (i) $H_1 : \Psi_i \neq \Psi$ for 2-sid

Input Parameters

Data File: BD.cydx
 Row Variable: Row
 Column Variable: Col
 Stratum Variable: Stratum
 Frequency Variable: Freq
 Confidence Level: 0.95

Output

Total no. of records: 22
 No. of records rejected: 0
 Summary of the Observed Data:

| Strata | n | $\pi_{.0}$ | $\pi_{.1}$ | Odds Ratio |
|--------|-----|------------|------------|------------|
| 1 | 116 | 0.1 | 0 | 0 |
| 2 | 199 | 0.133 | 0.03 | 0.198 |
| 3 | 213 | 0.463 | 0.132 | 0.177 |
| 4 | 242 | 0.609 | 0.197 | 0.157 |
| 5 | 161 | 0.514 | 0.29 | 0.388 |
| 6 | 44 | 1 | 0.205 | 0 |

Breslow and Day Statistic: 9
 (with Tarone's correction): 9
 Test of Hypothesis:

| Type | | p-value | | 99% CI for exact P-Value | | | |
|------------|--|-----------|----|--------------------------|---------|-------------|-------------|
| | | Statistic | DF | Tail | 2-Sided | Lower Limit | Upper Limit |
| Asymptotic | Breslow and Day | 9.323 | 5 | G.E. | 0.097 | 0.085 | 0.086 |
| | Breslow and Day with Tarone's Correction | 9.299 | 5 | G.E. | 0.098 | | |

Warning Message: Since the asymptotic p value is not contained in the 99% CI, the Asymptotic

Estimation and Testing of Common Odds Ratio:

Mantel-Haenszel Inference:

| Type | 2-Sided P-Value | | | 95% CI with RBG Variance | |
|------------|-----------------|--------------|--------------|--------------------------|-------------|
| | Point Estimate | RBG variance | M-H variance | Lower Limit | Upper Limit |
| Asymptotic | 5.158 | 0 | 4.799E-10 | 3.562 | 7.468 |

The output gives observed odds ratios across strata, Breslow and Day statistic with and without Tarone's correction and 2-sided p-value using RBG variance and M-H variance. Note that the two sided p values for both Breslow and Day (1980) statistic and with Tarone's correction are greater than 0.05 thereby accepting the null

87 Analysis-Binomial Superiority Two-Sample

hypothesis of common odds ratio across the strata. However, you see a warning in the output.

East computes 95% confidence intervals for the exact p value and checks if the asymptotic p value lies in the interval. In case, it doesn't, **East** gives the warning message that the asymptotic inference would be unreliable.

Having accepted the hypothesis of common odds ratio across all strata, the Mantel-Haenszel inference tests the hypothesis that this common odds ratio is equal to 1. Both the p values using RBG variance and MH variance are very close to zero indicating rejection of the null hypothesis that the common odds ratio is equal to 1.

87.7 Example: Fisher's Exact Test

Dataset: `Clntrt.cydx` as described in Section 87.1.

Purpose of the Analysis:

As in the **Difference of Proportions** test, suppose π_t and π_c denote the proportions of the successes from the experimental treatment (T) and the control treatment (C). To test the null hypothesis:

$$H_0: \pi_t = \pi_c, \quad (87.1)$$

against 1-sided alternatives of the form,

$$H_1: \pi_t > \pi_c, \quad (87.2)$$

or

$$H'_1: \pi_t < \pi_c, \quad (87.3)$$

and against 2-sided alternatives of the form

$$H_2: \pi_t \neq \pi_c. \quad (87.4)$$

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item
Analysis > (Discrete) Two Samples > (Parallel Design) Fisher's Exact

3. In the ensuing dialog box (under the **Main**) tab choose the variables as shown below.

Analysis: Discrete Endpoint Two-Sample Test - Parallel Design

Data Set: Clntrt.cydx

Main Advanced

Row: Drug Column: Outcome Frequency Variable: Freq

Control: 0
Treatment: 1

87 Analysis-Binomial Superiority Two-Sample

- Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Fisher's Exact Test

Hypothesis
 $H_0 : \pi_t = \pi_c$ Vs. $H_1 : \pi_t \neq \pi_c$ for 2-Sided test
 Either $H_1 : \pi_t > \pi_c$ Or $H_1 : \pi_t < \pi_c$ for 1-Sided test

Input Parameters
 Data File: C:\ntrt.cyx
 Column Variable: Outcome
 Row Variable: Drug
 Frequency Variable: Freq

Output
 Total no. of records: 4
 No. of records rejected: 0
 Observed Frequency Table:

| | 0 | 1 | Total |
|-------|---|----|-------|
| A | 5 | 5 | 10 |
| B | 1 | 9 | 10 |
| Total | 6 | 14 | 20 |

Summary of Test Statistic:
 Y: Observed value in Row 1 and column 1

| Y | Minimum | Maximum | Mean | Std.Deviation | Observed |
|---|---------|---------|------|---------------|----------|
| 5 | 0 | 6 | 3 | 1.051 | 3.58 |

Hypergeometric Prob. of Table: 0.065
 Test of Hypothesis:

| Type | Statistic | DF | (1-Sided) | | (2-Sided) |
|------------|-----------|----|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| Asymptotic | 3.58 | 1 | G.E. | 0.029 | 0.058 |
| Exact | 3.58 | | G.E. | | 0.141 |
| Exact | 5 | | G.E. | 0.07 | |

The above output provides Fisher statistic, and the 2-sided asymptotic p-value as the tail area to the right of the observed Fisher statistic from a chi-square distribution with 1 df as shown in the equation. It is 0.058. The asymptotic 1-sided p-value is defined to be half the corresponding 2-sided p-value, or 0.0292. The bottom portion of the screen provides exact 1 and 2-sided p-values. The exact 2-sided p-value, 0.141 with $D(Y)$ as the Fisher statistic. This is considerably larger than the asymptotic p-value,

highlighting the unreliability of asymptotic inference for small datasets. The output screen shows that the 1-sided p-value is obtained as the tail area to the left of 5 from the distribution of y_{11} . The magnitude of the p-value is 0.07.

The one sided exact p value can be obtained from the exact distribution of y_{11} , the entry in row 1 and column 1 of the 2×2 table.

88 *Analysis-Binomial Noninferiority Two-Sample*

In a binomial noninferiority trial the goal is to establish that the response rate of an experimental treatment is no worse than that of an active control, rather than attempting to establish that it is superior. A therapy that is demonstrated to be noninferior to the current standard therapy for a particular indication might be an acceptable alternative if, for instance, it is easier to administer, cheaper, or less toxic.

Such noninferiority trials are designed by specifying a noninferiority margin. The amount by which the response rate on the experimental arm is worse than the response rate on the control arm must fall within this margin in order for the claim of noninferiority to be sustained. Chapter 18 deals with the designing of such clinical trials considering difference of proportions, ratio of proportions or odds ratio of proportions of the two populations.

This chapter demonstrates how **East** is used to analyze the data from two independent binomial samples generated while conducting a noninferiority trial. We shall assume that the data is sampled independently from two binomial populations with response probabilities π_t and π_c for treatment and control. This comparison is based on difference of proportions, ratio of proportions or odds ratio of the two populations. For difference and ratio of proportions, we follow two formulations, namely Wald's (1940) and Farrington and Manning's (1990) score.

88.1 *Example: Noninferiority -Diff. of Proportions - Asymptotic*

Dataset: Nephrodash.cyd.

Data Description

The data is for childhood nephroblastoma. Details of the data are as given below:

| Response | Chemo (New) | Radio (Standard) | Total |
|-----------------|------------------------|-----------------------------|--------------|
| Rupture-free | 83 | 80 | 163 |
| Ruptured tumor | 5 | 7 | 12 |
| Total | 88 | 87 | 175 |

The dataset has three variables **Resp**, **PopID** and **Freq**. A value of 1 in **Resp** represents response and 0 as non-response. In **PopID**, 0 is control and 1 is treatment.

Purpose of the Analysis:

The standard treatment for this disease is nephrectomy followed by post-operative radiotherapy. Whereas the experimental treatment is pre-operative chemotherapy to reduce the tumor mass, followed by nephrectomy.

First perform superiority test to see if the experimental treatment is superior to the standard therapy. For this analysis, consider 1-sided type I error of 0.05.

This will be followed by a noninferiority test with a noninferiority margin of 0.1

Analysis Steps: For Superiority Test

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Two Samples > (Parallel Design) Difference of Proportions
3. In the **Main** tab, select variables as shown below. Do not check **Perform Exact Computation** checkbox.

Analysis: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Data Set: Nephrodash.cyx

Main Advanced

Trial Type: Superiority Response Variable: Resp Frequency Variable: Freq

Population Id: PopID Response Value: 1

Control: 0

Treatment: 1

88 Analysis-Binomial Noninferiority Two-Sample

- Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Difference of Proportions

Hypothesis

$H_0: \pi_t - \pi_c = 0$ Vs. $H_1: \pi_t - \pi_c \neq 0$ for 2-Sided test

Either $H_1: \pi_t - \pi_c < 0$

Or $H_1: \pi_t - \pi_c > 0$ for 1-Sided test

Input Parameters

Data File: Nephrodash.cyx
 Trial Type: Superiority
 Population Variable: PopD(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: Freq
 Confidence Level: 0.95

Output

Response Variable: (Resp)

Total Number of Records: 4

Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 80 | 83 | 163 |
| 0 | 7 | 5 | 12 |
| Total | 87 | 88 | 175 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 87 | 80 | 0.92 |
| 1 | 88 | 83 | 0.943 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | Test Statistic | 1-Sided | | 2-Sided | | 95% Confidence Interval | |
|------------|-----|---------------------------|------------|----------------|---------|---------|---------|-------------|-------------------------|--|
| | | | | | Tail | p-value | p-value | Lower Limit | Upper Limit | |
| Asymptotic | 175 | 0.024 | 0.038 | 0.619 | G E | 0.268 | 0.536 | -0.057 | 0.108 | |

Note that the p-value for one-sided test is 0.268. Clearly there is no evidence that the chemotherapy arm is superior to radiotherapy. However, the goal of this study was different. The investigators only wished to establish the noninferiority of chemotherapy relative to radiotherapy at a noninferiority margin of 10%. In other words, the chemotherapy arm is considered to be non-inferior to the radiotherapy arm if the probability of being rupture free following the surgery is at most 10% lower for the chemotherapy arm than for the radiotherapy arm.

Analysis Steps: For Noninferiority Test

- Click **Analysis Inputs** tab on the status bar below. This will open recent inputs you gave for superiority in the main window. In the **Main** tab, change the trial

type to **Noninferiority**. Input the value of Noninferiority margin as 0.1. Click **Wald** in **Test Type**. Here also, do not check **Perform Exact Computation** checkbox.

|-----------------|----|-----------|------------|
| 0 | 87 | 80 | 0.92 |
| 1 | 88 | 83 | 0.943 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | Test Statistic | 1-Sided | | 95% Confidence Interval | |
|------------|-----|---------------------------|------------|----------------|---------|---------|-------------------------|-------------|
| | | | | | Tail | p-value | Lower Limit | Upper Limit |
| Asymptotic | 175 | 0.024 | 0.038 | -1.999 | L.E. | 0.023 | -1 | 0.086 |

Note the 1-sided p-value is now 0.023. This p-value is associated with the rejection of $H_0: \delta \leq 0$ in favor of the alternative hypothesis $H_1: \delta > 0$. East displays the p-value associated with right tailed test on this occasion because $\hat{\delta} > 0$. The 2-sided 95% confidence interval is (-1, 0.086). The p-value as well as the confidence interval indicate the rejection of null hypothesis and Noninferiority of chemotherapy over radiotherapy.

In the **Main** tab, if you select **Score** in Test Type, the following output is displayed:

Analysis: Binomial Response: Difference of Proportions

Hypothesis

If $\delta_0 > 0$ then $H_0: \pi_t - \pi_c \geq \delta_0$ Vs. $H_1: \pi_t - \pi_c < \delta_0$

If $\delta_0 < 0$ then $H_0: \pi_t - \pi_c \leq \delta_0$ Vs. $H_1: \pi_t - \pi_c > \delta_0$

Input Parameters

Data File: Nephrodash.cydx
 Trial Type: Noninferiority
 Test Type: Score
 Population Variable: PopID(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: Freq
 Noninferiority Margin(δ_0): 0.1
 Confidence Level: 0.95

Output

Response Variable: (Resp)
 Total Number of Records: 4
 Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 80 | 83 | 163 |
| 0 | 7 | 5 | 12 |
| Total | 87 | 88 | 175 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 87 | 80 | 0.92 |
| 1 | 88 | 83 | 0.943 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | Test Statistic | 1-Sided | | 95% Confidence Interval | |
|------------|-----|---------------------------|------------|----------------|---------|---------|-------------------------|-------------|
| | | | | | Tail | p-value | Lower Limit | Upper Limit |
| Asymptotic | 175 | 0.024 | 0.042 | -1.801 | L.E. | 0.036 | -Infinity | 0.093 |

In this case, the 1-sided p-value is 0.036 establishing Noninferiority.

88.2 Example: Diff. of Proportions - Exact

Dataset: Nephrodash.cyd as described in Section 88.1.

Purpose of the Analysis:

The standard treatment for this disease is nephrectomy followed by post-operative radiotherapy. Whereas the experimental treatment is pre-operative chemotherapy to reduce the tumor mass, followed by nephrectomy.

First perform superiority test to see if the experimental treatment is superior to the standard therapy. For this analysis, consider 1-sided type I error of 0.05.

This will be followed by a noninferiority test type with a noninferiority margin of 0.1

Analysis Steps: For Superiority Test

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Two Samples > (Parallel Design) Difference of Proportions
3. In the **Main** tab, select variables as shown below. Check **Perform Exact**

88 Analysis-Binomial Noninferiority Two-Sample

Computation checkbox.

Analysis: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Data Set: Nephrodash.cydx

Main Advanced

Trial Type: Superiority Response Variable: Resp Frequency Variable: Freq

Population ID: PopID Response Value: 1

Control: 0 Treatment: 1

Perform Exact Computation

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Difference of Proportions

Hypothesis

$H_0: \pi_t - \pi_c = 0$ Vs. $H_1: \pi_t - \pi_c \neq 0$ for 2-Sided test

Either $H_1: \pi_t - \pi_c < 0$

Or $H_1: \pi_t - \pi_c > 0$ for 1-Sided test

Input Parameters

Data File: Nephrodash.cydx
 Trial Type: Superiority
 Test Type: Wald
 Population Variable: PopID(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: Freq
 Confidence Level: 0.95

Output

Response Variable: (Resp)
 Total Number of Records: 4
 Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 80 | 83 | 163 |
| 0 | 7 | 5 | 12 |
| Total | 87 | 88 | 175 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 87 | 80 | 0.92 |
| 1 | 88 | 83 | 0.943 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | Test Statistic | 1-Sided | | 2-Sided | 95% Confidence Interval | |
|-------|-----|---------------------------|------------|----------------|---------|---------|---------|-------------------------|-------------|
| | | | | | Tail | p-value | p-value | Lower Limit | Upper Limit |
| Exact | 175 | 0.024 | 0.038 | 0.619 | G.E. | 0.289 | 0.579 | -0.057 | 0.108 |

Note that the p-value for one-sided test is 0.289. Clearly there is no evidence that the chemotherapy arm is superior to radiotherapy. However, the goal of this study was different. The investigators only wished to establish the noninferiority of chemotherapy relative to radiotherapy at a noninferiority margin of 10%. In other words, the chemotherapy arm is considered to be non-inferior to the radiotherapy arm if the probability of being rupture free following the surgery is at most 10% lower for the chemotherapy arm than for the radiotherapy arm.

88 Analysis-Binomial Noninferiority Two-Sample

Analysis Steps: For Noninferiority Test

1. Click **Analysis Inputs** tab on the status bar below. This will open recent inputs you gave for superiority in the main window. In the **Main** tab, change the trial type to **Noninferiority**. Input the value of Noninferiority margin as 0.1. Click **Score** in **Test Type**. Check **Perform Exact Computation** checkbox.
2. Click **OK** to display following output in the main window.

Analysis: Binomial Response: Difference of Proportions

Hypothesis

If $\delta_0 > 0$ then $H_0 : \pi_t - \pi_c \geq \delta_0$ Vs. $H_1 : \pi_t - \pi_c < \delta_0$

If $\delta_0 < 0$ then $H_0 : \pi_t - \pi_c \leq \delta_0$ Vs. $H_1 : \pi_t - \pi_c > \delta_0$

Input Parameters

Data File: Nephrodash.cydx
 Trial Type: Noninferiority
 Test Type: Score
 Population Variable: PopID(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: Freq
 Noninferiority Margin(δ_0): 0.1
 Confidence Level: 0.95

Output

Response Variable: (Resp)
 Total Number of Records: 4
 Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 80 | 83 | 163 |
| 0 | 7 | 5 | 12 |
| Total | 87 | 88 | 175 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 87 | 80 | 0.92 |
| 1 | 88 | 83 | 0.943 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | Test Statistic | 1-Sided | | 95% Confidence Interval | |
|-------|-----|---------------------------|------------|----------------|---------|---------|-------------------------|-------------|
| | | | | | Tail | p-value | Lower Limit | Upper Limit |
| Exact | 175 | 0.024 | 0.042 | -1.801 | L.E. | 0.037 | -Infinity | 0.093 |

In exact computations, the p-value is 0.037 indicating the significance. This concludes that Chemotherapy is noninferior to Radiotherapy.

88.3 Ratio of Proportions

*Example: Ratio of
Proportions -
Asymptotic*

*Example: Ratio of
Proportions - Exact*

As before, let π_t and π_c denote the proportions of the successes from the experimental treatment (T) and the control treatment (C), respectively. To test the null hypothesis, we transform the original data using log and perform difference of proportions test.

*Example: Ratio of Proportions - Asymptotic
Dataset: Vaccine.cydx.*

Data Description

Chan (1998) discusses a vaccine efficacy study of a recombinant DNA Influenza A vaccine against wild-type H1N1 virus challenge. The study compares the infection rates in the vaccinated and placebo groups. There were 15 individuals in each group. The following data was obtained.

| Disease Status | Treatment Group | | Total |
|----------------|-----------------|---------|-------|
| | Placebo | Vaccine | |
| Infected | 12 (80%) | 7 (47%) | 19 |
| Not Infected | 3 (20%) | 8 (53%) | 11 |
| Total | 15 | 15 | 30 |

Purpose of the Analysis:

Let π_t be the infection rate in the vaccinated group and π_c be the infection rate in the placebo group. Define $\rho = \pi_t/\pi_c$, and define $\lambda = 1 - \rho$. The parameter λ is known as the vaccine efficacy. Assume that $\pi_t \leq \pi_c$. Therefore the new vaccine has 100% efficacy if $\pi_t = 0$ and no efficacy if $\pi_t = \pi_c$. From a public health standpoint, the benefits from vaccination must exceed a given threshold in order to justify the risk of vaccinating healthy subjects. Therefore, in designing vaccine trials, one typically chooses a non-zero efficacy lower bound. Suppose we choose $\lambda_0 = 0.1$ as the non-zero efficacy lower bound. This implies that if $\lambda \leq 0.1$, the virus does not offer sufficient benefit relative to placebo to justify using it on a large scale for the prevention of infection. Thus we wish to test the null hypothesis of insufficient vaccine efficacy (i.e., inferiority) $\lambda \leq 0.1$ against the 1-sided alternative hypothesis of sufficient vaccine efficacy (i.e., noninferiority), $\lambda > 0.1$.

Equivalently, we wish to test the null hypothesis of inferiority,

$$H_0 : \rho \geq 0.9, \quad (88.1)$$

88 Analysis-Binomial Noninferiority Two-Sample

against the alternative hypothesis of noninferiority.

$$H_1 : \rho < 0.9. \tag{88.2}$$

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Two Samples > (Parallel Design) Ratio of Proportions
3. In the Main tab, select **Noninferiority** as **Trial Type**. Select all other variables as shown below. Do not check **Perform Exact Computation** checkbox.

Analysis: Discrete Endpoint: Two-Sample Test - Parallel Design - Ratio of Proportions

Data Set: Vaccine.cydx

Main Advanced

Trial Type: Noninferiority Response Variable: Resp Frequency Variable: freq

Population Id: Popn Response Value: 1

Control: 0

Treatment: 1

Test Type

Noninferiority Margin: 0.9

Wald Score(Farrington Manning)

Perform Exact Computation

4. In the **Advanced** tab, leave the **By Variable 1** and **By Variable 2** blank and keep default value of 0.95 in **Confidence level**.

5. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Ratio of Proportions

Hypothesis

If $\rho_0 > 1$ then $H_0: \pi_t / \pi_c \geq \rho_0$ Vs. $H_1: \pi_t / \pi_c < \rho_0$

If $\rho_0 < 1$ then $H_0: \pi_t / \pi_c \leq \rho_0$ Vs. $H_1: \pi_t / \pi_c > \rho_0$

Input Parameters

Data File: Vaccine.cyx
 Trial Type: Noninferiority
 Test Type: Wald
 Population Variable: Popn(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: freq
 Noninferiority Margin (ρ_0): 0.9
 Confidence Level: 0.95

Output

Response Variable: (Resp)

Total Number of Records: 4

Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 12 | 7 | 19 |
| 0 | 3 | 8 | 11 |
| Total | 15 | 15 | 30 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 15 | 12 | 0.8 |
| 1 | 15 | 7 | 0.467 |

Test of Hypothesis:

| Type | n | Ratio of Proportions | Std. Error | Test Statistic | (1-Sided) | | 95% Confidence Interval | |
|------------|----|----------------------|------------|----------------|-----------|------|-------------------------|-------------|
| | | | | | p-value | Tail | Lower Limit | Upper Limit |
| Asymptotic | 30 | 0.583 | 0.305 | -1.423 | 0.923 | G.E. | 0.353 | Infinity |

The observed value of test statistic is -1.423 with a 1-sided p-value equal to 0.923. The 1-sided 95% confidence interval for π_t / π_c is (0.353, *Infinity*). The p-value indicates that the null hypothesis of insufficient vaccine efficacy cannot be rejected. The corresponding 95% lower confidence bound for ρ is 0.353, which confirms that we cannot rule out the possibility that $\rho \leq 0.9$.

88 Analysis-Binomial Noninferiority Two-Sample

If you select **Score (Farrington Manning)** in Test Type, the following output is displayed:

Analysis: Binomial Response: Ratio of Proportions

Hypothesis

If $\rho_0 > 1$ then $H_0: \pi_t / \pi_c \geq \rho_0$ Vs. $H_1: \pi_t / \pi_c < \rho_0$

If $\rho_0 < 1$ then $H_0: \pi_t / \pi_c \leq \rho_0$ Vs. $H_1: \pi_t / \pi_c > \rho_0$

Input Parameters

Data File: Vaccine.cydx
 Trial Type: Noninferiority
 Test Type: Score(Farrington Manning)
 Population Variable: Popn(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: freq
 Noninferiority Margin (ρ_0): 0.9
 Confidence Level: 0.95

Output

Response Variable: (Resp)

Total Number of Records: 4

Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 12 | 7 | 19 |
| 0 | 3 | 8 | 11 |
| Total | 15 | 15 | 30 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 15 | 12 | 0.8 |
| 1 | 15 | 7 | 0.467 |

Test of Hypothesis:

| Type | n | Ratio of Proportions | Std. Error | Test Statistic | (1-Sided) | | 95% Confidence Interval | |
|------------|----|----------------------|------------|----------------|-----------|------|-------------------------|-------------|
| | | | | | p-value | Tail | Lower Limit | Upper Limit |
| Asymptotic | 30 | 0.583 | 0.159 | -1.525 | 0.936 | G.E. | 0.257 | Infinity |

Since the p-value is 0.936, the noninferiority can not be established.

Example: Ratio of Proportions - Exact

Dataset: Vaccine.cydx as described in Section 88.3.

Purpose of the Analysis:

To test the null hypothesis of inferiority,

$$H_0 : \rho \geq 0.9, \tag{88.3}$$

against the alternative hypothesis of noninferiority.

$$H_1 : \rho < 0.9. \tag{88.4}$$

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Two Samples > (Parallel Design) Ratio of Proportions
3. In the Main tab, select **Noninferiority** as **Trial Type**. Also make sure to check **Perform Exact Computation** checkbox.

Analysis: Discrete Endpoint: Two-Sample Test - Parallel Design - Ratio of Proportions .00 .00

Data Set: Vaccine.cyx

88 Analysis-Binomial Noninferiority Two-Sample

5. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Ratio of Proportions

Hypothesis

If $\rho_0 > 1$ then $H_0 : \pi_t / \pi_c \geq \rho_0$ Vs. $H_1 : \pi_t / \pi_c < \rho_0$

If $\rho_0 < 1$ then $H_0 : \pi_t / \pi_c \leq \rho_0$ Vs. $H_1 : \pi_t / \pi_c > \rho_0$

Input Parameters

Data File: Vaccine.cyx
 Trial Type: Noninferiority
 Test Type: Score(Farrington Manning)
 Population Variable: Popn(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: freq
 Noninferiority Margin (ρ_0): 0.9
 Confidence Level: 0.95

Output

Response Variable: (Resp)

Total Number of Records: 4

Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 12 | 7 | 19 |
| 0 | 3 | 8 | 11 |
| Total | 15 | 15 | 30 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 15 | 12 | 0.8 |
| 1 | 15 | 7 | 0.467 |

Test of Hypothesis:

| Type | n | Ratio of Proportions | Std. Error | Test Statistic | (1-Sided) | | 95% Confidence Interval | |
|-------|----|----------------------|------------|----------------|-----------|------|-------------------------|-------------|
| | | | | | p-value | Tail | Lower Limit | Upper Limit |
| Exact | 30 | 0.583 | 0.166 | -1.525 | 0.086 | L.E. | -Infinity | 0.967 |

The p-value is 0.086 suggesting non-significance, however the value is drastically reduced from the corresponding asymptotic p-value.

88.4 Example: Odds Ratio of Proportion

Dataset: Vaccine.cydx as described in Section 88.3.

Purpose of the Analysis:

Use the same data to demonstrate the testing of Noninferiority of Odds Ratio in case of two independent binomial samples. **Analysis Steps**

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Two Samples > (Parallel Design) Odds Ratio of Proportions
3. In the Main tab, select **Noninferiority** as **Trial Type**. Select all other variables as shown below.

Analysis: Discrete Endpoint Two-Sample Test - Parallel Design - Odds Ratio of Proportions

Data Set: Vaccine.cydx

Main | Advanced

Trial Type: Noninferiority | Response Variable: Resp | Frequency Variable: freq

Population Id: Popn | Response Value: 1

Control: 0 | Treatment: 1

Test Type

Noninferiority Margin: 1.3

Wald Score

4. In the **Advanced** tab, leave the **By Variable 1** and **By Variable 2** blank and keep default value of 0.95 in **Confidence level**.

88 Analysis-Binomial Noninferiority Two-Sample

5. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Odds Ratio of Proportions

Hypothesis

If $\Psi_0 > 0$ $H_0 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) \geq \Psi_0$ Vs. $H_1 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) < \Psi_0$
 If $\Psi_0 < 0$ $H_0 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) \leq \Psi_0$ Vs. $H_1 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) > \Psi_0$

Input Parameters

Data File: Vaccine.cydx
 Trial Type: Noninferiority
 Test Type: Wald
 Population Variable: Popn(Treatment=1, Control=0)
 Response Variable: Resp(1)
 Frequency Variable: freq
 Noninferiority Margin (Ψ_0): 1.3
 Confidence Level: 0.95

Output

Response Variable: (Resp)
 Total Number of Records: 4
 Number of Records Rejected: 0

Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 12 | 7 | 19 |
| 0 | 3 | 8 | 11 |
| Total | 15 | 15 | 30 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 15 | 12 | 0.8 |
| 1 | 15 | 7 | 0.467 |

Test of Hypothesis:

| n | Odds Ratio | Std. Error | Test Statistic | (1-Sided) | | 95% Confidence Interval(1-Sided) | |
|----|------------|------------|----------------|-----------|------|----------------------------------|-------------|
| | | | | p-value | Tail | Lower Limit | Upper Limit |
| 30 | 0.219 | 0.827 | -2.154 | 0.016 | L.E. | 0 | 0.853 |

The output gives Test Statistic value as -2.154 with a 1-sided p-value equal to 0.016. As a result, the vaccination can be considered noninferior to the control.

If you select **Score** as Test Type, the following output is displayed:

Analysis: Binomial Response: Odds Ratio of Proportions

Hypothesis

If $\Psi_0 > 0$ $H_0 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) \geq \Psi_0$ Vs. $H_1 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) < \Psi_0$
 If $\Psi_0 < 0$ $H_0 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) \leq \Psi_0$ Vs. $H_1 : \pi_t(1 - \pi_c) / \pi_c(1 - \pi_t) > \Psi_0$

Input Parameters

| | | | | p-value | Tail | Lower Limit | Upper Limit |
| 30 | 0.219 | 1.229 | 1.527 | 0.937 | L.E. | 0 | 16.387 |

89 Analysis-Binomial Equivalence Two-Samples

89.1 Equivalence: Difference of Proportions

This test arises when the difference is in establishing the bioequivalence of a new compound with an established compound. It is the 2-sided version of the noninferiority test for difference of proportions. Thus if π_c and π_t are the response rates of control and treatment, respectively, then the goal is to test the null hypothesis of inequivalence, $|\pi_t - \pi_c| \geq \delta_0$, against 2-sided alternative hypothesis of equivalence, $|\pi_t - \pi_c| < \delta_0$, for a pre-specified equivalence margin $\delta_0 > 0$.

We test the above null hypothesis by performing two separate one-sided non-inferiority hypothesis tests of the form

$$H_{01}: \pi_c - \pi_t \geq \delta_0 \text{ versus } H_{11}: \pi_c - \pi_t < \delta_0 \quad (89.1)$$

and

$$H_{02}: \pi_t - \pi_c \geq \delta_0 \text{ versus } H_{12}: \pi_t - \pi_c < \delta_0 . \quad (89.2)$$

Each hypothesis test is carried out separately. Hypothesis test H_{01} is performed under the assumption that $\pi_c - \pi_t$ is at its threshold null value $\pi_c - \pi_t = \delta_0$. Similarly hypothesis test H_{02} is tested under the assumption that $\pi_t - \pi_c$ is at its threshold null value $\pi_t - \pi_c = \delta_0$. We reject the null hypothesis of inequivalence and accept the alternative hypothesis of equivalence only if **both** H_{01} and H_{02} are rejected.

89.2 Example: Equivalence: Dataset: Nephrodash.cyd as described in Section 88.1. Difference of Proportions- Asymptotic

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Two Samples > (Parallel Design) Difference of Proportions
3. In the **Main** tab, select variables as shown below. Do not check **Exact**

Computation checkbox.

|-------|----|----|-------|
| 1 | 80 | 83 | 163 |
| 0 | 7 | 5 | 12 |
| Total | 87 | 88 | 175 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 87 | 80 | 0.92 |
| 1 | 88 | 83 | 0.943 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | | Test Statistic | | 1-Sided p-value | | | | 95% Confidence Inter | |
|------------|-----|---------------------------|------------|-------|----------------|--------|-----------------|------------|------|------------|----------------------|----------|
| | | | SE 01 | SE 02 | t 01 | t 02 | Tail | Under H 01 | Tail | Under H 02 | Lower Limit | Upper Li |
| Asymptotic | 175 | 0.024 | 0.044 | 0.042 | -2.801 | -1.801 | L.E. | 0.003 | L.E. | 0.036 | -0.057 | 0.10 |

The output gives Test Statistic values as -2.801 and -1.801 with 1-sided p-values equal to 0.003 and 0.036 , respectively.

The null hypothesis of inequivalence can be rejected only if both the noninferiority null hypotheses are rejected. Each noninferiority hypothesis is typically tested at the 2.5% level of significance since each test is 1-sided. In the present example a statistically significant p-value ($p = 0.003$) is obtained for the H_{01} non-inferiority tests and a non-significant p-value ($p = 0.036$) is obtained for the H_{02} non-inferiority test. Therefore we cannot reject the null hypothesis of inequivalence.

89.3 Example: Equivalence: Difference of Proportions-Exact

Dataset: **Nephrodash.cyd** as described in Section 88.1.

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Two Samples > (Parallel Design) Difference of Proportions
3. In the **Main** tab, select variables as shown below. Make sure to check **Exact**

Computation checkbox.

Analysis: Discrete Endpoint Two-Sample Test - Parallel Design - Difference of Proportions

Data Set: Nephrodash.cydx

Main Advanced

|---|-------------------------|--------------------------|
| Trial Type: Equivalence | Response Variable: Resp | Frequency Variable: Freq |
| Population Id: PopID | Response Value: 1 | |
| Control: 0 | Test Type | |
| Treatment: 1 | Equivalence Margin: 0.1 | |
| <input checked="" type="checkbox"/> Perform Exact Computation | | |

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Difference of Proportions

$$H_{01} : \pi_c - \pi_t \geq \delta_0 \text{ Vs. } H_{11} : \pi_c - \pi_t < \delta_0$$

$$H_{02} : \pi_t - \pi_c \geq \delta_0 \text{ Vs. } H_{12} : \pi_t - \pi_c < \delta_0$$

Input Parameters

Data File: Nephrodash.cydx
Trial Type: Equivalence
Population Variable: PopID(Treatment=1, Control=0)
Response Variable: Resp(1)
Frequency Variable: Freq
Equivalence Margin: 0.1
Confidence Level: 0.95

89 Analysis-Binomial Equivalence Two-Samples

Output

Response Variable: (Resp)
 Total Number of Records: 4
 Number of Records Rejected: 0
 Table of Observed Frequencies:

| | 0 | 1 | Total |
|-------|----|----|-------|
| 1 | 80 | 83 | 163 |
| 0 | 7 | 5 | 12 |
| Total | 87 | 88 | 175 |

Summary of the Observed Data:

| Treatment Group | n | Responses | Proportion |
|-----------------|----|-----------|------------|
| 0 | 87 | 80 | 0.92 |
| 1 | 88 | 83 | 0.943 |

Test of Hypothesis:

| Type | n | Difference of Proportions | Std. Error | | Test Statistic | | 1-Sided p-value | | | | 95% Confidence Interval | |
|-------|-----|---------------------------|------------|-------|----------------|--------|-----------------|------------|------|------------|-------------------------|-------------|
| | | | SE_01 | SE_02 | t_01 | t_02 | Tail | Under H_01 | Tail | Under H_02 | Lower Limit | Upper Limit |
| Exact | 175 | 0.024 | 0.044 | 0.042 | -2.801 | -1.801 | L.E. | 0.002 | L.E. | 0.037 | -0.057 | 0.108 |

In this example, a statistically significant p-value ($p = 0.002$) is obtained for the H01 non-inferiority tests and a non-significant p-value ($p = 0.037$) is obtained for the H02 non-inferiority test. Therefore we can not reject the null hypothesis of inequivalence.

90

Analysis-Discrete: Many Proportions

In clinical trials involving categorical endpoints, there are several situations where either the data are coming from many binomial populations or the responses are from multinomial distribution. In case of multiple binomial populations, the interest lies in testing whether the success probability differs across several binomial populations, in particular does it increase or decrease with reference to an index variable. For data coming from multinomial distributions, one is interested in testing if the cell probabilities are according to some theoretical law. **East** can be used to analyze both these types of data. In this chapter we will demonstrate how the tests on many proportions can be executed in **East**.

90.1 Example: Chi-square Test of Specified Proportions

Dataset: Smallt.cyx

Data Description

The dataset has four variables **Category**, **Freq**, **Prob** and **ExpFreq**. The **Category** variable has four categories. **Freq** is the observed frequency for these four categories, and the variable **prob** represents expected probabilities for these categories. Table 90.1 shows the observed counts and the multinomial probabilities under the null hypothesis for a multinomial distribution with four categories.

Table 90.1: Frequency Counts from a Multinomial with 4 Categories

| | Multinomial Categories | | | | Row |
|--------------------|------------------------|-----|-----|-----|-------|
| | 1 | 2 | 3 | 4 | Total |
| Cell Counts | 7 | 1 | 1 | 1 | 10 |
| Cell Probabilities | 0.3 | 0.3 | 0.3 | 0.1 | 1 |

Purpose of the Analysis:

To test whether the observed cell counts are according to the specified Cell probabilities.

Analysis Steps: Based on expected probabilities

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Many Samples > (Single Arm Design) Chi-Square for

90 Analysis-Discrete: Many Proportions

Specified Proportions in C categories

This will display several input fields associated with the Chi-square Test in the main window.

3. In the **Main** tab, select **Category** in **Category** and **Freq** in the **Observed Frequency** variable. Since the data consist of expected probabilities, select the **Probability** option and select variable **prob** in **Probability**.

Analysis: Discrete Endpoint Many-Sample Test - Single Arm Design - Chi-Square for Specified Proportions in C Categories

Data Set: Smallt.cydx

Main Advanced

Category: Category

Observed Frequency: Freq

Expected Count Probability

Probability: prob

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Categorical Response: Chi Square Test for Specified Proportions in C Categories

Hypothesis
 $H_0 : (O_1, O_2, \dots, O_C) \sim MN(\pi_1, \pi_2, \dots, \pi_C, N)$
 Vs
 $H_1 : H_0$ is not true for 2-sided test

Input Parameters
 Data File: Smallt.cyx
 Distinct Category: Category
 Observed Frequency: Freq
 Probability: prob
 Confidence Level: 0.95

Output
 Total Number of Records: 4
 Number of Records Rejected: 0
 Table of Observed Frequencies:

| | 1 | 2 | 3 | 4 | Total |
|-------|---|---|---|---|-------|
| 1 | 7 | 1 | 1 | 1 | 10 |
| Total | 7 | 1 | 1 | 1 | 10 |

Estimation of Multinomial Probability:

| Category | Count | Prob (P) | 95% Confidence Interval | |
|----------|-------|----------|-------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| 1 | 7 | 0.7 | 0.329 | 0.917 |
| 2 | 1 | 0.1 | 0.012 | 0.495 |
| 3 | 1 | 0.1 | 0.012 | 0.495 |
| 4 | 1 | 0.1 | 0.012 | 0.495 |

Test of hypothesis for Goodness of Fit:

| Type | p-value | | | |
|------------|-----------|----|------|---------|
| | Statistic | DF | Tail | 2-Sided |
| Asymptotic | 8 | 3 | G.E. | 0.046 |

Note that the output contains estimation of multinomial probabilities as well as the confidence intervals for these based on the observed data. The observed value of chi-square test statistic with degrees of freedom 3 is 8. The 2-sided p-value is 0.046. This p-value is associated with the rejection of $H_0 : \pi_i = \pi_{0i}, i = 1, 2, 3, \dots, C$ in favor of the alternative hypothesis of not following the multinomial distribution with specified proportions.

Analysis Steps: Based on expected frequencies

The test can also be run if the data contains expected frequencies rather than expected probabilities for the categories.

1. Click **Analysis Input/output** tab on the **Status bar** below.
2. In the main tab, select the **Expected Count** option instead of **Probability** and choose **ExpFreq** in **Expected Frequency**.

90 Analysis-Discrete: Many Proportions

3. Click **OK** and the following output is displayed.

Analysis: Categorical Response: Chi Square Test for Specified Proportions in C Categories

Hypothesis
 $H_0: (O_1, O_2, \dots, O_C) \sim MN(\pi_1, \pi_2, \dots, \pi_C, N)$
Vs
 $H_1: H_0$ is not true for 2-sided test

Input Parameters
Data File: Smallt.cydx
Distinct Category: Category
Observed Frequency: Freq
Expected Frequency: Expfreq
Confidence Level: 0.95

Output
Total Number of Records: 4
Number of Records Rejected: 0
Table of Observed Frequencies:

| | 1 | 2 | 3 | 4 | Total |
|-------|---|---|---|---|-------|
| 1 | 7 | 1 | 1 | 1 | 10 |
| Total | 7 | 1 | 1 | 1 | 10 |

Estimation of Multinomial Probability:

| Category | Count | Prob (Pi) | 95% Confidence Interval | |
|----------|-------|-----------|-------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| 1 | 7 | 0.7 | 0.329 | 0.917 |
| 2 | 1 | 0.1 | 0.012 | 0.495 |
| 3 | 1 | 0.1 | 0.012 | 0.495 |
| 4 | 1 | 0.1 | 0.012 | 0.495 |

Test of hypothesis for Goodness of Fit:

| Type | p-value | | | |
|------------|-----------|----|------|---------|
| | Statistic | DF | Tail | 2-Sided |
| Asymptotic | 8 | 3 | G.E. | 0.046 |

As before, the output shows estimates of multinomial probabilities and the asymptotic inference. Since the expected counts in the data were consistent with the probabilities, the inference is the same.

90.2 Example: Two group Chi-square test

Dataset: vari.cydx as described in Section 74.4.1.

Purpose of the Analysis:

To test if the two groups specified in row and column are independent of each other.

Analysis Steps

1. Open the dataset from **Samples** folder.

2. Choose the menu item:

Analysis > (Discrete) Many Samples > (Single Arm Design) Two Group Chi-Square for Proportions in C categories

This will display several input fields associated with the Chi-square Test in the main window.

3. In the **Main** tab, select **Group** in **Row (Group)**, **Category** in **Column(Categories)**, and **Freq** in the **Frequency Variable**.

Analysis: Discrete Endpoint Many-Sample Test - Parallel Design - Chi-Square for Proportions in C Categories

Data Set: Vari.cyx

Main Advanced

Row (Group): Column (Categories): Frequency Variable:

90 Analysis-Discrete: Many Proportions

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Categorical Response: Chi-square Test for Comparing Proportions in C Categories

Hypothesis
 $H_0: \pi_{1j} = \pi_{2j}$ for all $j = 1, 2, 3, \dots, C$
Vs
 H_1 : at least one π_{ij} differs for $i = 1, 2$ and $j = 1, 2, 3, \dots, C$

Input Parameters

Data File: Vari.cyx
Row Variable: Group
Column Variable: Category
Frequency Variable: Freq
Confidence Level: 0.95

Output

Total Number of Records: 6
Number of Records Rejected: 0

Table of Observed Frequencies:

| | 1 | 2 | 3 | 4 | Total |
|-------|----|---|---|---|-------|
| 1 | 21 | 0 | 2 | 0 | 23 |
| 2 | 15 | 3 | 1 | 2 | 21 |
| Total | 36 | 3 | 3 | 2 | 44 |

Pearson Chi-Square Statistic: 6.255
Chi-Square Statistic with Yates CC: NA
Likelihood Ratio Statistic: 8.185

Test of hypothesis for Chi-Square Test

| Type | p-value | | | | 99% CI for exact p-value | |
|------------|-----------|----|------|---------|--------------------------|-------------|
| | Statistic | DF | Tail | 2-Sided | Lower Limit | Upper Limit |
| Asymptotic | 6.255 | 3 | G.E. | 0.1 | 0.061 | 0.074 |

Warning Message: Since the asymptotic p value is not contained in the 99% CI, the Asymptotic Outcomes may be considered unreliable.

Test of hypothesis for Likelihood Ratio Test:

| Type | p-value | | | | 99% CI for exact p-value | |
|------------|-----------|----|------|---------|--------------------------|-------------|
| | Statistic | DF | Tail | 2-Sided | Lower Limit | Upper Limit |
| Asymptotic | 8.185 | 3 | G.E. | 0.042 | 0.073 | 0.087 |

Warning Message: Since the asymptotic p value is not contained in the 99% CI, the Asymptotic Outcomes may be considered unreliable.

Measure of Association:

| Coefficient | Estimate | ASE_MLE | 95% Confidence Interval | |
|------------------|----------|---------|-------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| Phi | 0.377 | 0.095 | 0.249 | 0.505 |
| Pearson's CC | 0.353 | 0.071 | 0.214 | 0.491 |
| Sakoda's CC | 0.499 | 0.1 | 0.303 | 0.695 |
| Tschuprow's CC | 0.286 | 0.038 | 0.212 | 0.361 |
| Cramer's V | 0.377 | 0.086 | 0.208 | 0.546 |
| Uncertainty(C R) | 0.139 | 0.044 | 0.052 | 0.225 |

Note that the output contains inference using chi-square test, likelihood ratio test and several measures of association such as Phi, Pearson's contingency coefficient, Sakoda's as well as Tshuprov coefficient, Cramer's V, and Uncertainty coefficient etc. It also displays a warning in case the asymptotic p-value does not belong to the 99% CI for exact p-value. The observed value of chi-square test statistic with degrees of freedom 3 is 6.255. The 2-sided p-value is 0.1. Accordingly, there is not enough evidence for rejecting the null hypothesis. Therefore, we cannot conclude that Interferon is more effective than placebo in preventing adverse effects.

90.3 Example: Wilcoxon Rank Sum Test for Ordered Categories Data

The Wilcoxon-Rank-Sum test (Lehmann, 1975) is one of the most popular nonparametric tests for detecting a shift in location between two populations. It can accommodate either continuous or ordinal categorical data. It has an asymptotic relative efficiency of 95.5%, relative to the *t* test when the underlying distributions are normal. The Wilcoxon rank sum test is used for comparing two populations that generate either continuous or ordinal categorical responses. The Wilcoxon rank sum statistic is defined by equation R.234.

Dataset: `vari.cydx` as described in Section 74.4.1.

Purpose of the Analysis:

To test that two populations, each generating an ordered categorical response, have the same underlying multinomial distribution for the response variable.

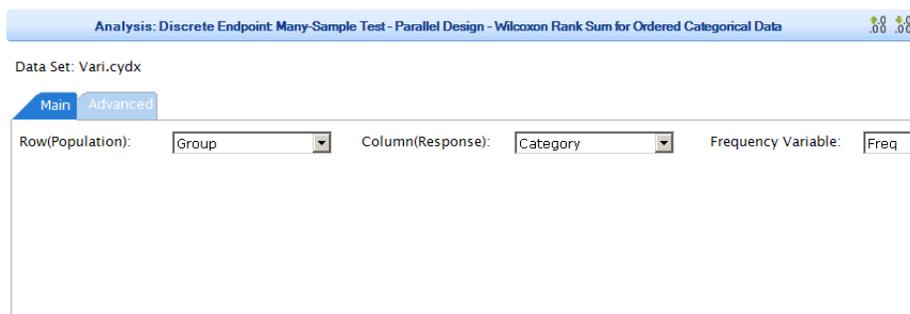

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Many Samples > (Single Arm Design) Wilcoxon Rank Sum for Ordered Categorical Data

This will display several input fields associated with the Chi-square Test in the main window.

3. In the **Main** tab, select **Group** in **Row(Population)**, **Category** in **Column(Response)**, and **Freq** in the variable **Frequency Variable**.

90 Analysis-Discrete: Many Proportions

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Wilcoxon Rank Sum Test

Hypothesis
 For $j = 1, 2, \dots, c$ and $k = 1, 2, \dots, s$ define $\pi_k = (\pi_{1k}, \pi_{2k}, \dots, \pi_{ck})$; $\pi'_k = (\pi'_{1k}, \pi'_{2k}, \dots, \pi'_{ck})$; and $V_{jk} = \sum_i \pi_{ik}$, and $V'_{jk} = \sum_i \pi'_{ik}$, where $i=1,2,\dots,j$.

$H_0: \pi_k = \pi'_k$ for all $k = 1, 2, \dots, s$ Vs either $H_1: V_{jk} \geq V'_{jk}$ Or $H_1: V_{jk} \leq V'_{jk}$ for 2-Sided test and
 $H_1: V_{jk} \geq V'_{jk}$ or $H_1: V_{jk} \leq V'_{jk}$ for 1-sided test with strict inequality for at least one j, k .

Input Parameters
 Data File: Vari.cydx
 Population: Group
 Response Variable: Category
 Frequency Variable: Freq
 Confidence Level: 0.95

Output
 Total Number of Records: 6
 Number of Records Rejected: 0
 Summary of Test Statistic:

| Response | Min | Max | Mean | Std.Dev | Observed | Standardized |
|----------|-------|-------|-------|---------|----------|--------------|
| Category | 425.5 | 601.5 | 517.5 | 28.606 | 470.5 | -1.643 |

Mann-Whitney Statistic: 194
 Test of Hypothesis:

| Type | p-value | | | |
|------------|-----------|------|---------|-----------|
| | Statistic | Tail | 1-Sided | 2*1-Sided |
| Asymptotic | -1.643 | L.E. | 0.05 | 0.1 |

Parameter Estimates:

| Type | CMLE | Std.Dev | 95% Confidence Interval | | 2-Sided p-value |
|------------|--------|---------|-------------------------|-------------|-----------------|
| | | | Lower Limit | Upper Limit | |
| Asymptotic | -0.062 | 0.039 | -0.139 | 0.016 | 0.118 |

Estimation of Odds Ratio:

| Column Value | Score | OR | Asymptotic 95% CI Limits | |
|--------------|-------|-----------|--------------------------|-----------|
| | | | Lower | Upper |
| 1 | 18.5 | Base Line | Base Line | Base Line |
| 2 | 38 | 0.3 | 0.066 | 1.357 |
| 3 | 41 | 0.25 | 0.044 | 1.422 |
| 4 | 43.5 | 0.214 | 0.031 | 1.479 |

Note that the output contains asymptotic inference for Wilcoxon Rank Sum Statistic as well as estimation of odds ratios for the categories with the corresponding confidence intervals

90.4 Example: Trend in R ordered proportions

Dataset: Korn_case_data.cydx

Data Description

Data from a prospective study of maternal drinking and congenital sex organ malformations (Graubard and Korn, 1987).

| | Maternal Alcohol Consumption (drinks/day) | | | | |
|--------------|---|-------|-------|-------|-----|
| Malformation | 0 | < 1 | 1 – 2 | 3 – 5 | ≥ 6 |
| Absent | 17066 | 14464 | 788 | 126 | 37 |
| Present | 48 | 38 | 5 | 1 | 1 |

Purpose of the Analysis:

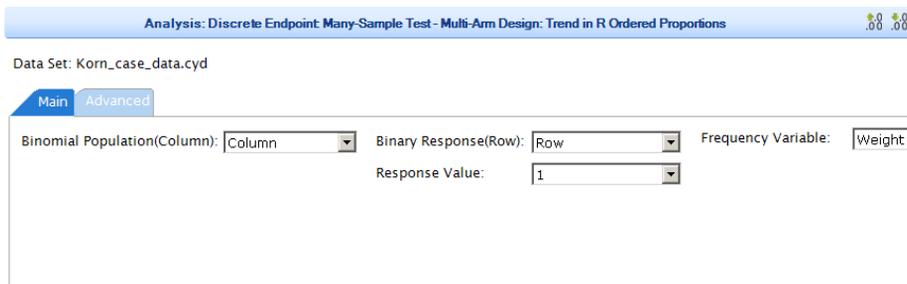

To test if a series of observed proportions all have the same underlying binomial response rate, where the alternative is that these rates are unequal, but ordered in some natural way. In other words, there is a trend in the binomial response rates.

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Many Samples > (Multi-Arm Design) Trend in R Ordered Proportions

This will display several input fields associated with the Trend in R Ordered Proportions in the main window.

3. In the **Main** tab, select **Column** in **Binomial Population(Column)**, **Row** in **Binary Response(Row)** with **Response Value** of 1. Select **Weight** as the **Frequency Variable**.

90 Analysis-Discrete: Many Proportions

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binomial Response: Cochran-Armitage Trend Test

Hypothesis

$H_0: \pi_1 = \pi_2 \dots \pi_R$

Vs.

(i) Either $H_1: \pi_1 < \pi_2 < \dots \pi_R$ Or $\pi_1 > \pi_2 > \dots \pi_R$ for 2-sided test

Input Parameters

Data File: Korn_case_data.cyd

Population Variable: Column

Response Variable: Row(1)

Frequency Variable: Weight

Confidence Level: 0.95

Output

Total Number of Records: 10

Number of Records Rejected: 0

Table of Observed Frequencies:

| | 1 | 2 | 3 | 4 | 5 | Total |
|-------|-------|-------|-----|-----|----|-------|
| 1 | 17066 | 14464 | 788 | 126 | 37 | 32481 |
| 2 | 48 | 38 | 5 | 1 | 1 | 93 |
| Total | 17114 | 14502 | 793 | 127 | 38 | 32574 |

Summary of the Observed Data:

| Population | 1 | 2 | 3 | 4 | 5 | Total |
|----------------|-------|-------|-------|-------|-------|-------|
| Response Value | 17066 | 14464 | 788 | 126 | 37 | 32481 |
| Proportion | 0.997 | 0.997 | 0.994 | 0.992 | 0.974 | 0.997 |

Summary of Test Statistic:

| Row | Minimum | Maximum | Mean | Std. dev. | Observed Statistics | Standardized |
|-----|---------|---------|-----------|-----------|---------------------|--------------|
| 1 | 16304 | 16621 | 16573.546 | 5.582 | 16566 | -1.352 |

Test of Hypothesis:

| Statistic | p-value | | | | | 99% CI for exact P-Value | |
|-----------|---------|---------|-----------|------|---------|--------------------------|-------------|
| | Tail | 1-Sided | 2*1-Sided | Tail | 2 Sided | Lower Limit | Upper Limit |
| -1.352 | L.E. | 0.088 | 0.176 | G.E. | 0.176 | 0.171 | 0.191 |

Parameter Estimates:

| CMLE | Std.Dev | 95% Confidence Interval | | p-value |
|--------|---------|-------------------------|-------------|---------|
| | | Lower Limit | Upper Limit | 2-Sided |
| -0.228 | 0.168 | -0.558 | 0.102 | 0.176 |

Estimation of Odds Ratio:

| Column Value | Score | OR | 95% Confidence Interval | |
|--------------|-------|-----------|-------------------------|-----------|
| | | | Lower | Upper |
| 1 | 0 | Base Line | Base Line | Base Line |
| 2 | 1 | 0.796 | 0.572 | 1.108 |
| 3 | 2 | 0.634 | 0.328 | 1.227 |
| 4 | 3 | 0.505 | 0.188 | 1.358 |
| 5 | 4 | 0.402 | 0.107 | 1.504 |

Note that the output contains asymptotic inference for Cochran-Armitage Trend Test as well as estimation of odds ratios for the categories with the corresponding confidence intervals. The 2-sided p-value namely, 0.176 indicates that we are unable to reject the null hypothesis of no trend in the proportions across the categories.

90 Analysis-Discrete: Many Proportions

90.5 Example: Chi-Square Test for $R \times 2$ Proportions

Dataset: Fda1.cyx

Data Description

We are grateful to Dr. Mirza W. Ali of the Food and Drug Administration (FDA) for providing this data set. Animals were treated with four dose levels of a carcinogen and then observed (at necropsy) for the presence or absence of a tumor type. The data were stratified by survival time (in weeks) into the four time intervals 0–50, 51–80, 81–104, and terminal sacrifice. Since there were, no tumors found in the first time interval, this stratum may be excluded from data entry. The data for the remaining three strata are given below. We will use the stratum variable as a By variable.

| Stratum 1: 51–80 weeks of survival | | | | | |
|------------------------------------|--------------------|--------|---------|----------|-------|
| Disease Status | Dose of Carcinogen | | | | Total |
| | None | 1 unit | 5 units | 50 units | |
| Tumor Present | 0 | 0 | 0 | 1 | 1 |
| Tumor Absent | 7 | 10 | 6 | 8 | 31 |

| Stratum 2: 81–104 weeks of survival | | | | | |
|-------------------------------------|--------------------|--------|---------|----------|-------|
| Disease Status | Dose of Carcinogen | | | | Total |
| | None | 1 unit | 5 units | 50 units | |
| Tumor Present | 0 | 1 | 0 | 1 | 2 |
| Tumor Absent | 11 | 9 | 13 | 14 | 47 |

| Stratum 3: Sacrificed at end of 104 weeks | | | | | |
|---|--------------------|--------|---------|----------|-------|
| Disease Status | Dose of Carcinogen | | | | Total |
| | None | 1 unit | 5 units | 50 units | |
| Tumor Present | 1 | 1 | 1 | 2 | 5 |
| Tumor Absent | 29 | 26 | 28 | 20 | 103 |

Purpose of the Analysis:

To test if the data come from binomial distributions having same probability of response.

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Many Samples > (Multi-Arm Design) Chi-square

Test for Rx2 Proportions

This will display several input fields associated with the Chi-square Test for Rx2 Proportions in the main window.

90 *Analysis-Discrete: Many Proportions*

proportions and Likelihood ratio test as well as the concordance coefficients for each of the value of stratum. All the 2-sided p-values are greater than 0.05 showing no evidence to reject the null hypothesis. This is true for all strata.

90.6 *Example: Chi-square Test for Prop in RxC Tables*

Dataset: Oral.cyx

Data Description

data is obtained on the location of oral lesions, in house to house surveys in three geographic regions of rural India. These data are displayed here in the form of 9×3 contingency table (Table 90.2) in which the counts are the number of patients with oral lesions at that site, in that geographic region.

Table 90.2: Oral Lesions Data Set

| Site of Lesion | Kerala | Gujarat | Andhra |
|----------------|--------|---------|--------|
| Labial Mucosa | 0 | 1 | 0 |
| Buccal Mucosa | 8 | 1 | 8 |
| Commissure | 0 | 1 | 0 |
| Gingiva | 0 | 1 | 0 |
| Hard Palate | 0 | 1 | 0 |
| Soft Palate | 0 | 1 | 0 |
| Tongue | 0 | 1 | 0 |
| Floor of Mouth | 1 | 0 | 1 |
| Alveolar Ridge | 1 | 0 | 1 |

Purpose of the Analysis:

To test if the distribution of the site of the oral lesion is significantly different in the three geographic regions.

Analysis Steps

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Discrete) Many Samples > (Multi-Arm Design) Chi-square for Proportions in RxC Tables

This will display several input fields associated with the Chi-square test for RxC proportions in the main window.

90 Analysis-Discrete: Many Proportions

3. In the **Main** tab select all variables as shown below.

The screenshot shows the SAS software interface for an analysis. At the top, a blue header bar contains the text "Analysis: Discrete Endpoint: Many-Sample Test - Multi-Arm Design: Chi-Square for Proportions in RxC Tables" and two small icons. Below this, the text "Data Set: Oral.cyx" is displayed. The interface has two tabs: "Main" (selected) and "Advanced". Under the "Main" tab, there are three input fields: "Row (Group):" with a dropdown menu set to "Row", "Column (Categories):" with a dropdown menu set to "Column", and "Frequency Variable:" with a text box containing "Weight".

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Categorical Response: Chi-square Test for Comparing Proportions

| Cramer's V | 0.64 | 0.088 | 0.468 | 0.812 |
| Uncertainty(C R) | 0.397 | 0.099 | 0.203 | 0.592 |

Note that the output contains asymptotic inference for Chi-square test for RxC proportions and Likelihood ratio test as well as the concordance coefficients for each of the value of stratum. The 2-sided p-value is 0.14 and 0.106 for chi-square and likelihood ratio tests, we are unable to reject H_0 . Note that in addition to the inference a warning is displayed as 'Warning: Since the asymptotic p-value is not contained in the 99% CI for exact p-value, the asymptotic outcomes may be considered unreliable.'

The sparseness of data is causing this problem. We recommend you to refer to the **StatXact** software for further details.

91 *Analysis-Binary Regression Analysis*

In this chapter we focus on how to run binary regression analysis in **East**. **East** provides logistic, probit, and complementary log-log regression models for data with a binary response variable. Along with regular maximum likelihood inference for logistic model, **East** provides Firth bias-correction for asymptotic estimates for unstratified logistic regression. Profile likelihood based confidence intervals for estimates are available for unstratified data.

Section 91.1 describes the Logistic Regression model for binary data and how **East** can be used to analyze data. Section 91.3 describes the Firth Procedure. Section 91.4 describes Profile Likelihood Based Confidence Intervals. Section 91.5 describes the Probit Model for Binary Data and Section 91.6 discusses the complementary Log-log Model which is also for binary data.

91.1 *Logistic Regression* *Example: Logistic Regression*

Consider a set of independent binary random variables, Y_1, Y_2, \dots, Y_n . Corresponding to each random variable, Y_j , there is a $(p \times 1)$ vector $\mathbf{x}_j = (x_{1j}, x_{2j}, \dots, x_{pj})'$ of explanatory variables (or covariates). Let π_j be the probability that $Y_j = 1$. Logistic regression models the dependency of π_j on \mathbf{x}_j through the relationship

$$\log \left(\frac{\pi_j}{1 - \pi_j} \right) = \gamma + \mathbf{x}_j' \beta, \quad (91.1)$$

where γ and $\beta \equiv (\beta_1, \beta_2, \dots, \beta_p)'$ are unknown parameters. We usually refer to γ as the constant term.

In this section, we demonstrate how **East** can be used to perform binary logistic regression analysis. Additionally, the asymptotic bias corrected estimates (Firth (1993)) and confidence intervals of the estimates using profile likelihood method (Venzon and Moolgavkar (1988)) based on the normal score function and the penalized score function are also available using **East**.

In addition to fitting the regression coefficients, **East** can also be used to:

- Perform significance testing of regression coefficients using Wald test
- Perform 1st order autocorrelation in residuals using Durbin-Watson test
- Compute collinearity diagnostics
- Compute different types of residuals
- Compute Influential statistics
- Compute predicted values
- Perform variable selection

91 Analysis-Binary Regression Analysis

Example: Logistic Regression

Dataset: LogisticData.cyx

Data Description

This data has been provided by Dr. S. Lai, University of Miami for a hospital based prospective study of perinatal infection and human immunodeficiency virus (HIV-1). Hutto, Parks, Lai, et al. (1991) investigated the possibility that the CD4 and CD8 blood serum levels measured in infants at 6 months of age might be good predictors of eventual HIV infection. In the dataset, CD4 and CD8 assume the values 0, 1, 2. However, these are not the actual blood serum levels. Rather they are coded surrogates for them.

The data on HIV infection rates and blood serum levels are tabulated below:

| Proportion Developing HIV | Serum Levels at 6 Months | |
|---------------------------|--------------------------|-----|
| | CD4 | CD8 |
| 4/7 (57%) | 0 | 0 |
| 1/1 (100%) | 0 | 2 |
| 2/7 (29%) | 1 | 0 |
| 4/12 (33%) | 1 | 1 |
| 2/2 (100%) | 1 | 2 |
| 0/2 (0%) | 2 | 0 |
| 0/13 (0%) | 2 | 1 |
| 1/3 (33%) | 2 | 2 |

Purpose of the Analysis:

We want to fit a Logistic model using the model terms, **CD4** and **CD8**. To specify the Logistic model **HIV = CD4+CD8** to the data.

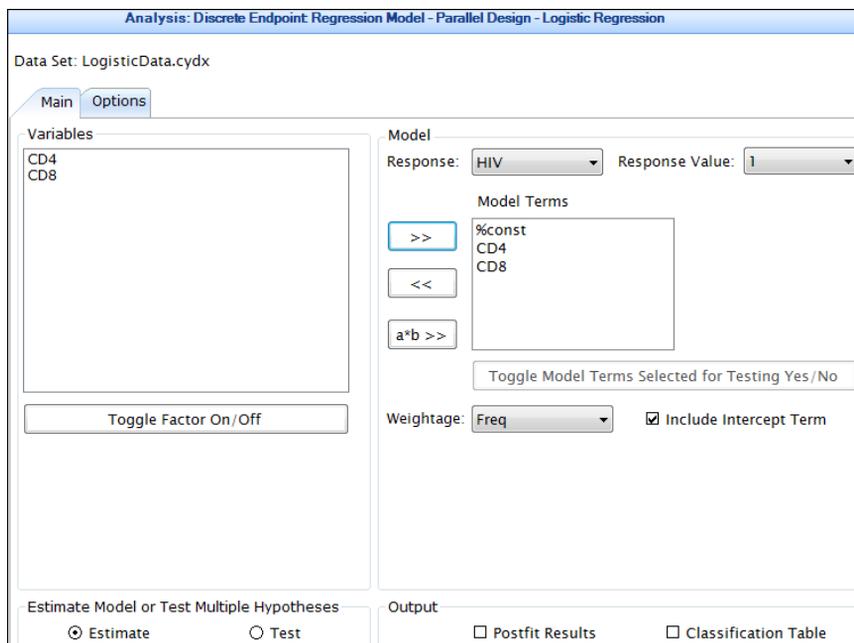

Analysis Steps: Regression based on Logistic Estimate

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Regression > (Parallel Design) Logistic Regression

3. In the **Main** tab, select **HIV** as the **Response** variable with **Response Value 1**, and **Freq** as the **Weightage** variable. Also notice that **% Const** is shown as a

model term. This is because **East**, by default always fits a model which includes the constant term unless you clear the “**Include Intercept Term**” check box. To specify an appropriate model, we would define HIV response rate as a function of CD4 and CD8, both covariates being regarded as ordinal. In the **Variables** box, select **CD4** and **CD8** and click button to include these terms under the **Model Terms**. Leave the default option as **Estimate**.

4. Click **OK** to estimate the regression coefficients. The maximum likelihood estimates, p-values, and confidence intervals for the regression parameters are

91 Analysis-Binary Regression Analysis

computed and displayed in the main window.

Analysis: Binary Regression: Logistic Model

Input Parameters

Data File: LogisticData.cydx
 Model: HIV(Response = 1)=%const+CD4+CD8
 Link Type: LOGIT
 Weight Variable: Freq
 Analysis Type: Estimate:Asymptotic
 Confidence Level: 0.95

Output

Terms in the Model : 3
 # Term(s) Dropped: 0
 Total Number of Records: 47
 Number of Records Rejected: 0
 # Groups: 8
 Summary Statistics:

| Statistics | Value | DF | p-value |
|------------------|--------|----|----------|
| Deviance | 4.471 | 5 | 0.484 |
| Likelihood Ratio | 23.652 | 3 | 2.952E-5 |

Parameter Estimates:

| Model Terms | Point Estimate | | | Confidence Interval and p-value for Beta | | |
|-------------|----------------|--------|----------|--|--------|-------------------|
| | Type | Beta | SE(Beta) | 95% CI | | 2*1-Sided p-value |
| | | | | Lower | Upper | |
| %const | MLE | 0.513 | 0.681 | -0.821 | 1.848 | 0.451 |
| CD4 | MLE | -2.542 | 0.839 | -4.187 | -0.897 | 0.002 |
| CD8 | MLE | 1.659 | 0.821 | 0.049 | 3.268 | 0.043 |

The third section is **Summary Statistics**. This section displays the deviance and its degrees of freedom, and the likelihood ratio statistic and degrees of freedom for testing the null hypothesis that the response probability of each observation is 0.5, i.e., all the model parameters, **including the constant term**, are simultaneously 0. The likelihood ratio statistic may be used to test for overall significance of the model. For the present example, the output displays a value of 4.471 on 5 df for the deviance, and a value of

23.652 on 3 df for the likelihood ratio statistic, with a p-value < 0.05 , thereby rejecting the null hypothesis that all the parameters of the model are 0.

The last section **Parameter Estimates**, displays the **Model Term**, **Point Estimate**, and the **Confidence Interval and p-value for Beta**. The **Model Terms** show there are two covariates, **CD4**, **CD8** in the model. The next three columns (under **Point Estimates**) show **MLE as Type**, estimates and standard error of Beta's. For **CD4**, the estimate of Beta is -2.542 . For **CD8**, the estimate of Beta is 1.659 . The next four columns show the inference type, confidence interval of Beta, and the p-value (2*1-sided) for testing Beta = 0. Here the p-value for **CD4** is 0.002.

Analysis Steps: Logistic Estimate in Odds Ratio

Here we would switch from displaying the regression parameters on the log scale (the default) to displaying them on the odds ratio scale.

1. In the **Options** tab, select **Odds Ratio/ Risk Ratio** in the **Output Parameter**.
2. Click **OK** to re-run the estimation, the parameter estimates are all transformed

91 Analysis-Binary Regression Analysis

by exponentiation into odds ratios.

Analysis: Binary Regression: Logistic Model

Input Parameters

Data File: LogisticData.cydx
 Model: HIV(Response = 1)=%const+CD4+CD8
 Link Type: LOGIT
 Weight Variable: Freq
 Analysis Type: Estimate:Asymptotic
 Confidence Level:0.95

Output

Terms in the Model : 3
 # Term(s) Dropped: 0
 Total Number of Records: 47
 Number of Records Rejected: 0
 # Groups: 8
 Summary Statistics:

| Statistics | Value | DF | p-value |
|------------------|--------|----|----------|
| Deviance | 4.471 | 5 | 0.484 |
| Likelihood Ratio | 23.652 | 3 | 2.952E-5 |

Parameter Estimates:

| Model Terms | Point Estimate | | | Confidence Interval and p-value for Odds Ratio | | |
|-------------|----------------|-------|----------|--|--------|-------------------|
| | Type | Beta | SE(Beta) | 95% CI | | 2*1-Sided p-value |
| | | | | Lower | Upper | |
| %const | MLE | 1.671 | NA | 0.44 | 6.346 | 0.451 |
| CD4 | MLE | 0.079 | NA | 0.015 | 0.408 | 0.002 |
| CD8 | MLE | 5.252 | NA | 1.05 | 26.257 | 0.043 |

- Now return to the default display by choosing **Beta** as the **Output parameter** in the **Options** tab.

Analysis Steps: Regression based on Factor Variables

In the LogisticData.cydx data set, CD4 and CD8 assume the values 0, 1, 2. However, these are not the actual blood serum levels. Rather they are coded surrogates for them. Thus suppose you are unwilling to treat CD4 and CD8 as ordinal variables, but would

like to treat them as factors. This requires that CD4 and CD8 each be split up into two dummy variables. The **Toggle Factor** option in the **Logistic Regression** dialog box accomplishes this splitting.

1. To accomplish this, press the Shift key on the keyboard, select **CD4** and **CD8** and then click on the **Toggle Factor On/Off** button. Notice that the **Model Terms** section of the window shows < fa > next to both CD4 and CD8. This means that CD4 has been split into two dummy variables, CD4_0 and CD4_1. The CD4_0 variable assumes the value 1 when CD4 is 0, and assumes the value 0 otherwise. The CD4_1 variable assumes the value 1 when CD4 is 1 and 0 otherwise. CD8 has been similarly split.
2. Click **OK** to obtain the unconditional maximum likelihood estimates of the regression coefficients for the model **HIV=CD4+CD8** with CD4 and CD8 declared as factor variables.

91 Analysis-Binary Regression Analysis

Analysis: Binary Regression: Logistic Model

Input Parameters

Data File: LogisticData.cdx
 Model: HIV(Response = 1)=%const+CD4_0+CD4_1+CD8_0+CD8_1
 Link Type: LOGIT
 Weight Variable: Freq
 Analysis Type: Estimate:Asymptotic
 Confidence Level: 0.95

Output

Terms in the Model : 5
 # Term(s) Dropped: 0
 Total Number of Records: 47
 Number of Records Rejected: 0
 # Groups: 8
 Summary Statistics:

| Statistics | Value | DF | p-value |
|------------------|-------|----|---------|
| Deviance | ? | ? | ? |
| Likelihood Ratio | ? | ? | ? |

Parameter Estimates:

| Model Terms | Point Estimate | | | Confidence Interval and p-value for Beta | | |
|-------------|----------------|------|----------|--|-------|-------------------|
| | Type | Beta | SE(Beta) | 95% CI | | 2*1-Sided p-value |
| | | | | Lower | Upper | |
| %const | MLE | ? | ? | ? | ? | ? |
| CD4_0 | MLE | ? | ? | ? | ? | ? |
| CD4_1 | MLE | ? | ? | ? | ? | ? |
| CD8_0 | MLE | ? | ? | ? | ? | ? |
| CD8_1 | MLE | ? | ? | ? | ? | ? |

Because the maximum likelihood estimates do not exist for this small data set, convergence is not possible in this case. The **Output** window only contains question marks for all the model terms.

This is not a problem in **East** alone. You will face the same difficulty with any other logistic regression software: **SAS**, **BMDP**, **GLIM** or **Egret**. The question is "Is there any other way to assess the significance of CD4 and CD8 when they are factor variables?" Interested users are referred to the **LogXact** software by **Cytel Inc**.

Analysis Steps: Test Multiple Hypothesis Regression

Suppose you are interested in a simultaneous test that the parameters corresponding to both **CD4** and **CD8** in the previously specified model are equal to 0.

1. Click the **Input Parameters** tab from the status bar below. Select variables **CD4** and **CD8** and click **Toggle Factor On/Off** button.
2. In the bottom left corner of the Input dialog, click the **Test** option. Select **CD4** and **CD8** in the **Model Terms** box and click the **Toggle Model Terms Selected for Testing Yes/No** button.

The screenshot shows the 'Analysis: Discrete Endpoint Regression Model - Parallel Design - Logistic Regression' dialog box. The 'Data Set' is 'LogisticData.cydx'. The 'Variables' list on the left contains 'CD4' and 'CD8'. The 'Model' section shows 'Response: HIV' and 'Response Value: 1'. The 'Model Terms' list contains '%const', 'CD4', and 'CD8'. The 'Test' list contains '%const(No)', 'CD4(Yes)', and 'CD8(Yes)'. A 'Toggle Model Terms Selected for Testing Yes/No' button is present. The 'Weightage' is set to 'Freq' and 'Include Intercept Term' is checked. At the bottom, the 'Estimate Model or Test Multiple Hypotheses' section has 'Test' selected, and the 'Output' section has 'Postfit Results' and 'Classification Table' options.

91 Analysis-Binary Regression Analysis

3. Click **OK** to start the analysis. **East** displays the following Output.

Analysis: Binary Regression: Logistic Model

Input Parameters

Data File: LogisticData.cydx

| Wald | 9.195 | 2 | 0.01 |

The title **Hypothesis Testing Tests** $\langle CD4 = CD8 = 0 \rangle$ appears near the bottom of the Test results output. Below that, you can see the results of three tests: Scores, Likelihood ratio and Wald of the null hypothesis that the regression parameters corresponding to **CD4** and **CD8** are both 0. Since two parameters are being tested, this is a 2 degree of freedom test. All three tests are two-sided. Notice that the p-values based for all the tests are very small indicating that we reject the null hypothesis that the parameters corresponding to both **CD4** and **CD8** are equal to 0.

91.2 Receiver Operating Characteristic (ROC) Curve

Example: ROC curve
ROC Curve vs Classification Table
Example: Classification Table

As part of post-fit diagnostics, you can obtain the computed results that are required for producing an ROC curve. Before we discuss ROC curve in detail a few of the technical terms like **sensitivity** and **specificity** need to be explained.

Terms Explained Consider the example of a medical test carried out on a person to determine whether the person is suffering from HIV disease. Based on the test result, can we compute the probability that the person has the disease. The following table shows the possible alternatives that can occur.

| | Event (Disease Present) | Non-Event (Disease Absent) |
|---------------|-----------------------------------|---------------------------------------|
| Test Positive | Correct Event Prediction (a) | Incorrect Non-Event Prediction (b) |
| Test Negative | Incorrect Event Prediction (c) | Correct Non-Event Prediction (d) |

Suppose a, b, c and d denote the number of persons for whom the test results were as shown in the above table. Then we can define **Sensitivity** and **Specificity** of the test as given below.

The **Sensitivity** of a test is defined as the proportion of Correct Event predictions in the population having the event.

$$\text{Sensitivity} = \frac{a}{a+c}$$

The **Specificity** of a test is defined as the proportion of Correct Non-Event predictions in the population having the non-event.

$$\text{Specificity} = \frac{d}{b+d}$$

In other words, Sensitivity is a measure of **True Positive** and Specificity is a measure of **True Negative** of the test. The measure **False Positive** is given by **1-Specificity** or **1- True Negative** of the test.

91 Analysis-Binary Regression Analysis

When is a test positive?

Deciding on whether a test is positive or not may involve obtaining the value of a single prognostic variable and checking whether the value is more than or less than a pre-defined cut point. Or the test may involve several prognostic variables. A statistical model like **Binary Logistic Regression** may be used in such a situation, to estimate the probability of the disease. If the estimated probability is more than a pre-defined cut point, the test may be taken to be positive for the presence of the disease. For each such cut point of the probability, the sensitivity and specificity will vary. An ROC curve is a graphical representation of the tradeoff between **False Positive** and **True Positive** for various values of the cut point probability.

Example:ROC curve

Dataset: `LogisticData.cyx` as described in Section 91.1.

Purpose of the Analysis:

To fit logistic regression model and produce an ROC curve.

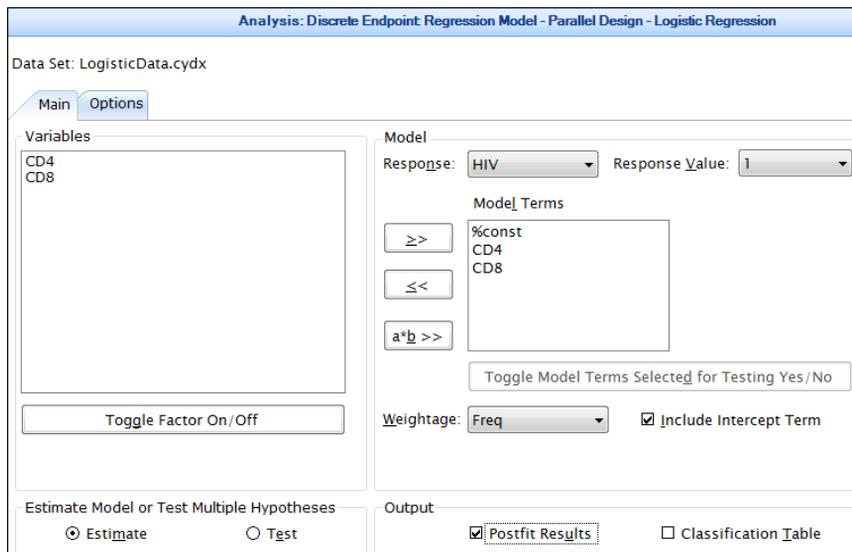

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Regression > (Parallel Design) Logistic Regression

3. This will display several input fields associated with Logistic Regression in the main window. In the **Main** tab, select **HIV** as the **Response** variable with **Response Value 1**, and **Freq** as the **Weightage** variable. Select **Model Terms** to specify an appropriate model. To begin with, model the HIV response rate as a function of CD4 and CD8, both covariates being regarded as ordinal. In the **Variables** box, select **CD4** and **CD8** as the **Model Terms**. The variables **CD4** and **CD8** will appear in the **Model Terms** box. Leave the default option as

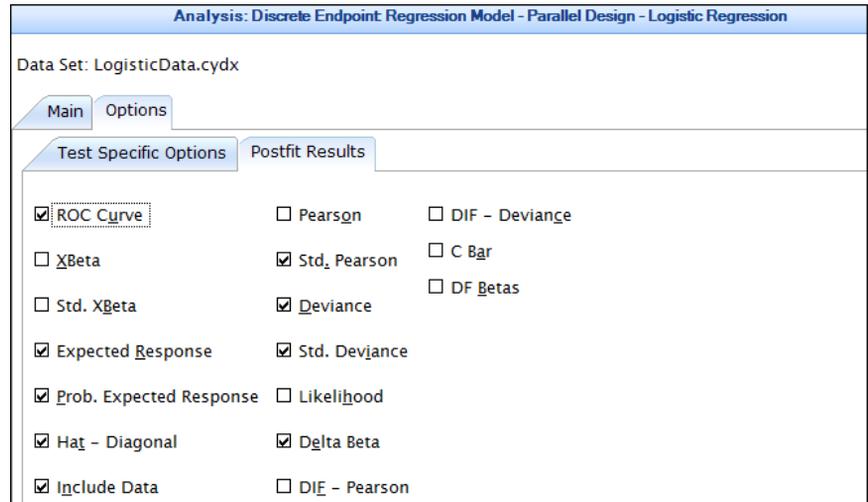

Estimate. In the Output dialog, select the **Postfit Results** checkbox.

4. In the Options tab, click the **Postfit Results** tab. Select the **ROC Curve**

91 Analysis-Binary Regression Analysis

checkbox.

5. Click **OK** to start the analysis. The following output is displayed in the main

window.

Analysis: Binary Regression: Logistic Model**Input Parameters**

Data File: LogisticData.cydx
Model: HIV(Response = 1)=%const+CD4+CD8
Link Type: LOGIT
Weight Variable: Freq
Analysis Type: Estimate:Asymptotic
Confidence Level: 0.95

Output

Terms in the Model : 3
Term(s) Dropped: 0
Total Number of Records: 47
Number of Records Rejected: 0
Groups: 8

Summary Statistics:

| Statistics | Value | DF | p-value |
|------------------|--------|----|----------|
| Deviance | 4.471 | 5 | 0.484 |
| Likelihood Ratio | 23.652 | 3 | 2.952E-5 |

Parameter Estimates:

| Model Terms | Point Estimate | | | Confidence Interval and p-value for Beta | | |
|-------------|----------------|--------|----------|--|--------|-------------------|
| | Type | Beta | SE(Beta) | 95% CI | | 2*1-Sided p-value |
| | | | | Lower | Upper | |
| %const | MLE | 0.513 | 0.681 | -0.821 | 1.848 | 0.451 |
| CD4 | MLE | -2.542 | 0.839 | -4.187 | -0.897 | 0.002 |
| CD8 | MLE | 1.659 | 0.821 | 0.049 | 3.268 | 0.043 |

91 Analysis-Binary Regression Analysis

Hosmer-Lemeshow Test:

| Statistics | Value | DF | p-value |
|-----------------|-------|----|---------|
| Hosmer-Lemeshow | 3.396 | 3 | 0.335 |

| Hosmer-Lemeshow Percentile of Risk | Response | | Non-Response | | Total |
|------------------------------------|----------|----------|--------------|----------|-------|
| | Observed | Expected | Observed | Expected | |
| 1 | 0 | 0.691 | 15 | 14.309 | 15 |
| 2 | 2 | 0.814 | 5 | 6.186 | 7 |
| 3 | 5 | 5.57 | 10 | 9.43 | 15 |
| 4 | 4 | 4.379 | 3 | 2.621 | 7 |
| 5 | 3 | 2.547 | 0 | 0.453 | 3 |
| Total | 14 | 14 | 33 | 33 | |

6. The postfit output in the output sheet titled "Regression Diagnostics1" is as follows:

Analysis: Binary Regression: Logistic Model

Regression Diagnostics

| Sequence | GrpSize | ObsvResp | ExptResp | ProbResp | Hat_Diag | StdPearson | Deviance | Std_Deviance |
|----------|---------|----------|----------|----------|----------|------------|----------|--------------|
| 1 | 2 | 0 | 0.021 | 0.01 | 0.044 | -0.147 | -0.203 | -0.208 |
| 2 | 13 | 0 | 0.671 | 0.052 | 0.483 | -1.17 | -1.174 | -1.632 |
| 3 | 7 | 2 | 0.814 | 0.116 | 0.441 | 1.872 | 1.212 | 1.621 |
| 4 | 3 | 1 | 0.667 | 0.222 | 0.36 | 0.579 | 0.441 | 0.551 |
| 5 | 12 | 4 | 4.903 | 0.409 | 0.488 | -0.741 | -0.537 | -0.75 |
| 6 | 7 | 4 | 4.379 | 0.626 | 0.76 | -0.604 | -0.293 | -0.599 |
| 7 | 2 | 2 | 1.568 | 0.784 | 0.363 | 0.93 | 0.987 | 1.236 |
| 8 | 1 | 1 | 0.979 | 0.979 | 0.059 | 0.152 | 0.207 | 0.214 |

7. Notice the column titled **ProbResp** containing the Estimated Response probabilities computed from the fitted model. These probability values are used as the cut points for carrying out the computations that are in the **ROC-Curve**

worksheet, which is shown below.

Analysis: Binary Regression: Logistic Model

ROC-Curve

| Corr_events | Corr_noevents | Incorr_events | Incorr_noevents | Sensitivity | 1-Specificity |
|-------------|---------------|---------------|-----------------|-------------|---------------|
| 14 | 0 | 33 | 0 | 1 | 1 |
| 14 | 2 | 31 | 0 | 1 | 0.939 |
| 14 | 15 | 18 | 0 | 1 | 0.545 |
| 12 | 20 | 13 | 2 | 0.857 | 0.394 |
| 11 | 22 | 11 | 3 | 0.786 | 0.333 |
| 7 | 30 | 3 | 7 | 0.5 | 0.091 |
| 3 | 33 | 0 | 11 | 0.214 | 0 |
| 1 | 33 | 0 | 13 | 0.071 | 0 |

Examine how the computations for ROC-Curve are carried out. First take the cut point probability as 0.01, the first value in the column **ProbResp** from **Regression Diagnostics** results. The rule in using this cut point is that for any individual in the data set, compute the expected probability for response and if this probability is ≥ 0.01 , allot that individual as **Response** or **Event**. These expected or predicted probabilities are already computed and are shown in the column titled **ProbResp**. We can tabulate the prediction results for this rule as shown below.

Cut Point: $z = 0.01$

Rule: An individual is 'Response' or 'Event' if $\text{ProbResp} \geq z$.

Since for all the groups, $\text{ProbResp} \geq 0.01$, all the individuals in all the groups are predicted as 'Response'.

91 Analysis-Binary Regression Analysis

| GrpSize | Observed | | Model ProbResp | Predicted | |
|---------|----------|----------|----------------|-----------|----------|
| | Resp | Non-Resp | | Resp | Non-Resp |
| 2 | 0 | 2 | 0.010251 | 2 | 0 |
| 13 | 0 | 13 | 0.051587 | 13 | 0 |
| 7 | 2 | 5 | 0.11625 | 7 | 0 |
| 3 | 1 | 2 | 0.222194 | 3 | 0 |
| 12 | 4 | 8 | 0.408579 | 12 | 0 |
| 7 | 4 | 3 | 0.625565 | 7 | 0 |
| 2 | 2 | 0 | 0.783934 | 2 | 0 |
| 1 | 1 | 0 | 0.97876 | 1 | 0 |

By comparing the Predicted figures and Observed figures, we can tabulate 'Predicted Correct' numbers as shown below.

| Grp Size | Observed | | Model ProbResp | Predicted | | Predicted Correct | |
|----------|----------|----------|----------------|-----------|----------|-------------------|----------|
| | Resp | Non-Resp | | Resp | Non-Resp | Resp | Non-Resp |
| 2 | 0 | 2 | 0.010251 | 2 | 0 | 0 | 0 |
| 13 | 0 | 13 | 0.051587 | 13 | 0 | 0 | 0 |
| 7 | 2 | 5 | 0.11625 | 7 | 0 | 2 | 0 |
| 3 | 1 | 2 | 0.222194 | 3 | 0 | 1 | 0 |
| 12 | 4 | 8 | 0.408579 | 12 | 0 | 4 | 0 |
| 7 | 4 | 3 | 0.625565 | 7 | 0 | 4 | 0 |
| 2 | 2 | 0 | 0.783934 | 2 | 0 | 2 | 0 |
| 1 | 1 | 0 | 0.97876 | 1 | 0 | 1 | 0 |

By subtracting 'Predicted Correct' numbers from 'Predicted' numbers, 'predicted Incorrect' numbers can be obtained as shown below.

| Grp Size | Observed | | Model ProbResp | Predicted | | Predicted Correct | | Predicted Incorrect | |
|----------|----------|----------|----------------|-----------|----------|-------------------|----------|---------------------|----------|
| | Resp | Non-Resp | | Resp | Non-Resp | Resp | Non-Resp | Resp | Non-Resp |
| 2 | 0 | 2 | 0.010251 | 2 | 0 | 0 | 0 | 2 | 0 |
| 13 | 0 | 13 | 0.051587 | 13 | 0 | 0 | 0 | 13 | 0 |
| 7 | 2 | 5 | 0.11625 | 7 | 0 | 2 | 0 | 5 | 0 |
| 3 | 1 | 2 | 0.222194 | 3 | 0 | 1 | 0 | 2 | 0 |
| 12 | 4 | 8 | 0.408579 | 12 | 0 | 4 | 0 | 8 | 0 |
| 7 | 4 | 3 | 0.625565 | 7 | 0 | 4 | 0 | 3 | 0 |
| 2 | 2 | 0 | 0.783934 | 2 | 0 | 2 | 0 | 0 | 0 |
| 1 | 1 | 0 | 0.97876 | 1 | 0 | 1 | 0 | 0 | 0 |
| Total | | | | | | 14 | 0 | 33 | 0 |

The figures in the last line ‘Total’, 14, 0, 33 and 0 are what you saw in the first row of ROC table.

| | Event (Disease Present) | Non-Event (Disease Absent) |
|---------------|-------------------------------------|--|
| Test Positive | Correct Event Prediction (a=14) | Incorrect Non-Event Prediction (b=33) |
| Test Negative | Incorrect Event Prediction (c=0) | Correct Non-Event Prediction (d=0) |

$$\text{Sensitivity} = \frac{a}{a+c} = \frac{14}{14+0} = 1$$

$$\text{Specificity} = \frac{d}{b+d} = \frac{0}{33+0} = 0$$

Hence,

$$1 - \text{Specificity} = 1 - 0 = 1$$

The above values of Sensitivity and (1-Specificity), 1 and 1 are what you see in the first row of ROC table.

If you carry out similar computations for the fifth group with the cut point of $z = 0.408579$ you will get the following results.

91 Analysis-Binary Regression Analysis

| Grp Size | Observed | | Model ProbResp | Predicted | | Predicted Correct | | Predicted Incorrect | |
|----------|----------|----------|----------------|-----------|----------|-------------------|----------|---------------------|----------|
| | Resp | Non-Resp | | Resp | Non-Resp | Resp | Non-Resp | Resp | Non-Resp |
| 2 | 0 | 2 | 0.010251 | 0 | 2 | 0 | 2 | 0 | 0 |
| 13 | 0 | 13 | 0.051587 | 0 | 13 | 0 | 13 | 0 | 0 |
| 7 | 2 | 5 | 0.11625 | 0 | 7 | 0 | 5 | 0 | 2 |
| 3 | 1 | 2 | 0.222194 | 0 | 3 | 0 | 2 | 0 | 1 |
| 12 | 4 | 8 | 0.408579 | 12 | 0 | 4 | 0 | 8 | 0 |
| 7 | 4 | 3 | 0.625565 | 7 | 0 | 4 | 0 | 3 | 0 |
| 2 | 2 | 0 | 0.783934 | 2 | 0 | 2 | 0 | 0 | 0 |
| 1 | 1 | 0 | 0.97876 | 1 | 0 | 1 | 0 | 0 | 0 |
| Total | | | | | | 11 | 22 | 11 | 3 |

The figures in the last line 'Total', 11, 22, 11, and 3 are what you see in the fifth row of the ROC table.

| | Event (Disease Present) | Non-Event (Disease Absent) |
|---------------|-------------------------------------|--|
| Test Positive | Correct Event Prediction (a=11) | Incorrect Non-Event Prediction (b=11) |
| Test Negative | Incorrect Event Prediction (c=3) | Correct Non-Event Prediction (d=22) |

$$\text{Sensitivity} = \frac{a}{a+c} = \frac{11}{11+3} = 0.785714$$

$$\text{Specificity} = \frac{d}{b+d} = \frac{22}{22+11} = 0.666667$$

Hence,

$$1 - \text{Specificity} = 1 - 0.666667 = 0.333333$$

The above values of Sensitivity and (1-Specificity), 0.785714 and 0.333333, respectively, are what you see in the fifth row of the ROC table.

You have just seen the computations required to obtain the results shown in the ROC table, for 2 cut points. In a similar way, you can check the computations for the remaining 6 cut points.

ROC Curve vs Classification Table

Similar to ROC Curve computations, **East** also provides Classification Table estimates. Though in both the types of analysis, we get information on Sensitivity and Specificity estimates, they differ in the following way:

1. The classification error estimates computed in ROC Curve for any observation is biased because the model used was fitted with data that included that observation. In Classification Table, this bias is eliminated by again estimating the model parameters after leaving out each observation one at a time and then classifying the observation based on new estimates. These new estimates are actually produced as one-step approximations from the computations carried out for the complete data and no separate models are fitted. The formulas used are listed in Appendix W.
2. Classification Table uses Bayes' theorem and computes posterior probabilities in classification, using prior probabilities and probabilities of events.

Example: Classification Table

You can obtain classification table information using the **Classification table** option.

Dataset: **LogisticData.cyx** as described in Section 91.1.

Purpose of the Analysis:

To fit logistic regression and obtain classification table.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

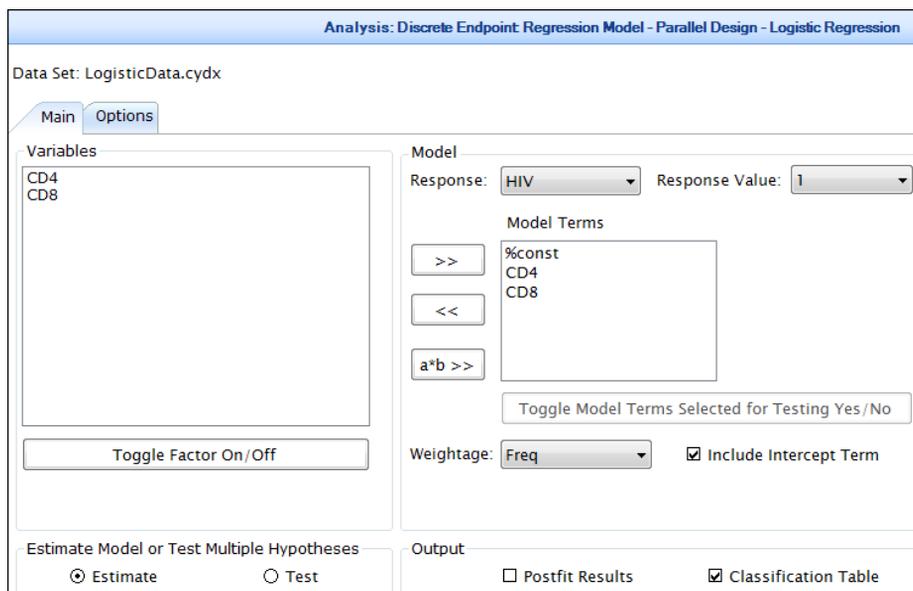

Analysis > (Discrete) Regression > (Parallel Design) Logistic Regression

This will display several input fields associated with Logistic Regression in the main window.

3. In the **Main** tab, select the variables as shown below. Make sure to select the

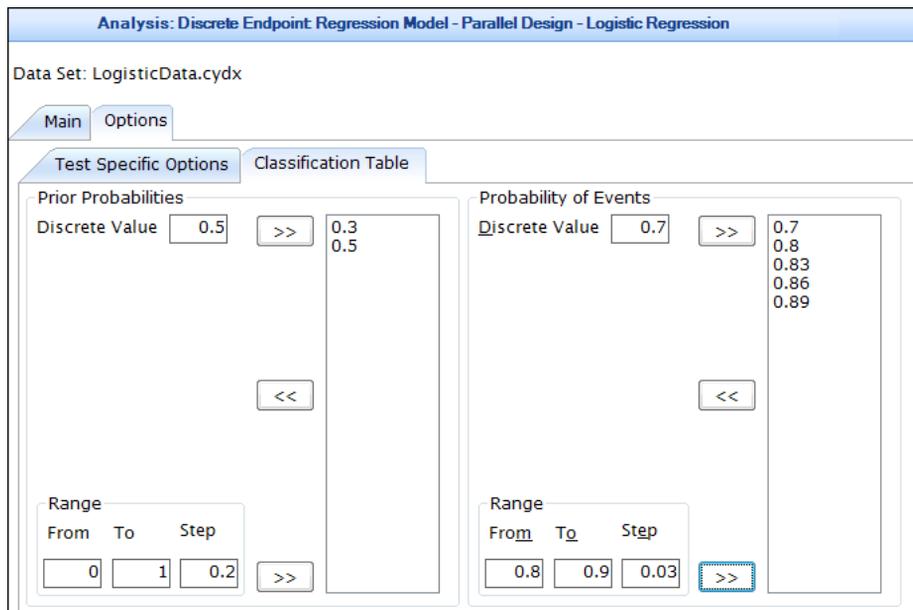

91 Analysis-Binary Regression Analysis

Classification Table checkbox in the Output dialog

- In the **Options** tab, click the **Classification Table** tab. In the ensuing dialog box, specify the set of values for **Prior Probabilities** and **Probability of Events**. You can specify these values as discrete values, by entering each value in the box against 'Discrete value' and then clicking to post it on the right side box. If your set of values is a range of equidistant values, then you can specify the starting value (From), the ending value (To) and the step value (Step) and then click . **East** will compute the individual values in the range and display them on the right side box. You are allowed to specify some values as discrete and some as a range. For this example, in the **Prior Probabilities** section, enter 0.3 and 0.5 in the **Discrete Value** and click . In the **Probability of Events** section, enter 0.7 and click . In the Range, enter 0.8 in the **From** value, 0.9 in the **To** value and 0.03 in the **Step** value. Click button next to the **Range**

ensuing box.

For each combination of the values of ‘prior probability’ and ‘probability of event’, East would produce classification results.

- Click **OK** to start the analysis. The output will be displayed in the main window. In the library along with the **Analysis: Binary Regression: Logistic Model1** node there is another node named the **Classification Table1**. Click the node **Classification Table1** to see the classification table.

Analysis: Binary Regression: Logistic Model

Classification Table

| Seq Number | Prob_event | Cut_off_Prob | Correct_Events | Correct_NoEvents | Incorrect_Events | Incorrect_NoEvents | Percent_Correct |
|------------|------------|--------------|----------------|------------------|------------------|--------------------|-----------------|

| 10 | 0.89 | 0.5 | 7 | 30 | 3 | 7 | 0.545 |

91 Analysis-Binary Regression Analysis

91.3 Firth Procedure

Example: Firth Procedure

Since the MLE is only asymptotically unbiased, various methods have been proposed to reduce the bias. One such approach is due to Firth (1993), which reduces the bias in the MLE by introducing a small bias into the score function. The general idea is to remove the $O(n^{-1})$ term in the expression for the bias of the MLE. This is accomplished by calculating the posterior mode based on Jeffrey's prior. One advantage of the Firth estimator is that it exists when there is complete separation or quasi-complete separation.

Example: Firth Procedure

Dataset: esr.cyx

Data Description

The Firth estimator performs well under separation and near separation and we will illustrate the improvement over the MLE by using a well-known dataset that was originally given by Collett and Jermain (1985) and is also found in Collett (2002).

The response variable was erythrocyte sedimentation rate (ESR), which is used as an indicator of infections and certain types of diseases. The lower the ESR value the better, and as so often it happens in medical applications, the continuous response variable was dichotomized with less than 20 assigned a value of zero and at least 20 assigned a value of one. The two predictor variables are Fibrinogen and γ -globulin.

The data were obtained in a study performed by the Institute of Medical Research, Kuala Lumpur, Malaysia.

Purpose of the Analysis:

To determine if a patient's ESR value is a valuable diagnostic. This is accomplished by trying to determine if there is a relationship between ESR and the two predictors, since the latter are commonly elevated in the presence of inflammatory diseases

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Regression > (Parallel Design) Logistic Regression

3. In the **Main** tab, select **esr** as the **Response** variable with **Response value** as 1. Select **fibrinogn** and **gam_glob** as the **Model Terms**.

4. In the **Options** tab the default asymptotic method is Maximum Likelihood Estimate.
5. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binary Regression: Logistic Model

Input Parameters

Data File: esr.cydx

Analysis: Binary Regression: Logistic Model

Input Parameters

Data File: esr.cydx
 Model: esr(Response = 1)=%const+fibrinogn+gam_glob
 Link Type: LOGIT
 Analysis Type: Estimate:Asymptotic
 Confidence Level: 0.95

Output

Terms in the Model : 3
 # Term(s) Dropped: 0
 Total Number of Records: 32
 Number of Records Rejected: 0
 # Groups: 32

Summary Statistics:

| Statistics | Value | DF | p-value |
|------------------|--------|----|----------|
| Deviance | 23.285 | 29 | 0.763 |
| Likelihood Ratio | 21.076 | 3 | 1.015E-4 |

Parameter Estimates:

| Model Terms | Point Estimate Type | Beta | SE(Beta) | Confidence Interval and p-value for Beta | | |
|-------------|--|---------|----------|--|--------|-------------------|
| | | | | 95% CI | | 2*1-Sided p-value |
| | | | | Lower | Upper | |
| %const | Penalized MLE for bias Correction (Firth's Method) | -10.289 | 4.931 | -19.953 | -0.624 | 0.037 |
| fibrinogn | Penalized MLE for bias Correction (Firth's Method) | 1.471 | 0.815 | -0.127 | 3.069 | 0.071 |
| gam_glob | Penalized MLE for bias Correction (Firth's Method) | 0.127 | 0.109 | -0.086 | 0.34 | 0.243 |

We can see that MLE and Firth estimates differ. However, the Confidence Intervals for Penalized MLE's are shorter than those for MLE's.

91.4 Profile Likelihood Based Confidence Intervals

Example

Classical Wald's confidence intervals are based on the asymptotic normality of the maximum likelihood estimate of a parameter. However, in case of small samples, the properties of the estimator can be very different. A symmetric shape of the likelihood function allows use of Wald's intervals, while an asymmetric shape may result into inaccurate confidence intervals. A more robust construction of confidence intervals is derived from the asymptotic χ^2 distribution of the generalized likelihood ratio test. We have seen in Section 91.3 that Firth's estimator is recommended whenever there is a problem of separation, and is a better alternative to Exact when the latter is not computationally feasible. The problem of separation also leads to inflated standard error which results into an infinite or large Wald's confidence intervals. In such situations, the confidence intervals based on profile likelihood method are a way out. Heinze and Schemper (2002) show that the confidence intervals based on profile likelihood are often preferable to Wald's confidence intervals. Heinze (2006) demonstrated that the confidence intervals based on penalized likelihood equation show excellent behavior in terms of the coverage probability and the higher power.

Example

Dataset: `esr.cydx` as described in Section 91.3.

Purpose of the Analysis:

This example includes the confidence intervals based on profile likelihood method for MLE and PMLE estimates.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Regression > (Parallel Design) Logistic Regression

3. In the **Main** tab, select `esr` as the **Response** variable. Choose a value of 1 as the

91 Analysis-Binary Regression Analysis

Response value. Select **fibrinogn** and **gam_glob** as the **Model Terms**.

|-----------|--------|-----------|----------|
| %const | 24.315 | -2.318 | -0.464 |
| fibrinogn | -2.318 | 0.665 | 0.009 |
| gam_glob | -0.464 | 0.009 | 0.012 |

Note that for every estimate now there are two confidence intervals. The later one is based on Profile likelihood. You can as well have the profile based Confidence Intervals when the Penalized MLE option is chosen.

91 Analysis-Binary Regression Analysis

91.5 Probit Regression

91.5.0 Example

The probit model is a generalized linear model that uses the inverse cumulative distribution function (cdf) from the standard normal distribution as a link function. Let y_i be a binary response for subject i , $i = 1, \dots, n$, such that $y_i = 1$ if subject i experiences a "success" and $y_i = 0$ otherwise. Further, let π_i and \mathbf{x}_i be the probability of a response and a vector of covariates for subject i , $i = 1, \dots, n$, respectively. A probit model for y_i is

$$\Phi^{-1}(\pi_i) = \beta_0 + \beta'_b \mathbf{x}_i,$$

where Φ is the standard normal cdf. Here, as in the case of logistic regression, the link function Φ^{-1} maps the (0,1) scale for π_i onto the scale of the entire real line for the linear predictor $\beta_0 + \beta'_b \mathbf{x}_i$. Also similar to the logistic case, the probit link is symmetric around 0.5 in the sense that $\Phi^{-1}(\pi) = -\Phi^{-1}(1 - \pi)$. Thus, the response curve for the probability of a response π is symmetric around 0.5.

Example: Probit Regression

Dataset: Devtox.cydx.

Data Description

This data set contains 1,512 observations of which you can only see the first few. Use the horizontal and vertical scroll bars or the and keys to examine the data set. There are 8 variables, **ID**, **Dose**, **Death**, **Weight**, **Malf**, **Sex**, **Impl** and **LittSz**, and 1,512 cases (1,512 implantations in 112 litters). The explanation of each variable represents and their codes are described below:

| Variable | Description | Code |
|----------|--|------------------|
| Dose | dose administered in g/kg body weight | 0, 0.5, 1 or 2 |
| Death | fetal death | 1=Yes, 0=No |
| Weight | fetal weight in grams | |
| Malf | fetal malformation | 1=Yes, 0=No |
| Sex | gender of the rat | 1=Male, 2=Female |
| Impl | number of implantations in the litter | |
| LittSz | number of live offspring in the litter | |

Purpose of the Analysis:

We will analyze a single binary outcome, **death**, in a developmental toxicity study of a substance conducted in rats, through a probit model. We want to fit a probit model using the model terms, **Dose**, **Impl** and their interaction **Dose*Impl**. To specify the probit model:

$$\text{Death} = \text{Dose} + \text{Impl} + \text{Dose} * \text{Impl}$$

to the data.

Analysis Steps: Probit Regression - Estimate Model

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Regression > (Parallel Design) Probit Regression

3. In the **Main** tab, select **Death** as the **Response** variable with Response value as
 1. Select **Dose** and **Impl** as the **Model Terms**. Add an interaction term **Dose*Impl**: click on **Dose** in the **Variables** section, Press the Ctrl key on the

91 Analysis-Binary Regression Analysis

keyboard, click on **Impl** in the **Variables** section, and click the **a*b** > button.

The screenshot shows a software interface for a binary regression analysis. The data set is 'Devtox.cyx'. The 'Variables' list on the left includes Id, Dose, Weight, Malf, Sex, Impl, and LittSz. The 'Model' section on the right has 'Response' set to 'Death' and 'Response Value' set to '1'. The 'Model Terms' list includes %const, Dose, Impl, and Dose*Impl. The 'a*b >>' button is highlighted. At the bottom, there are options for 'Estimate Model or Test Multiple Hypotheses' (with 'Estimate' selected) and 'Output' (with 'Postfit Results' and 'Classification Table' options).

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Binary Regression: Probit Model

Input Parameters

Data File: Devtox.cydx
 Model: Death(Response = 1)=%const+Dose+Impl+Dose*Impl
 Link Type: Probit
 Analysis Type: Estimate:Asymptotic
 Confidence Level: 0.95

Output

Terms in the Model : 4
 # Term(s) Dropped: 0
 Total Number of Records: 1512
 Number of Records Rejected: 0
 # Groups: 34

Summary Statistics:

| Statistics | Value | DF | p-value |
|------------------|----------|----|----------|
| Deviance | 890.746 | 30 | 2.979E-9 |
| Likelihood Ratio | 1205.331 | 4 | 0 |

Parameter Estimates:

| Model Terms | Point Estimate | | | Confidence Interval and p-value for Beta | | |
|-------------|----------------|--------|----------|--|--------|-------------------|
| | Type | Beta | SE(Beta) | 95% CI | | 2*1-Sided p-value |
| | | | | Lower | Upper | |
| %const | MLE | -2.762 | 0.684 | -4.102 | -1.422 | 5.36E-5 |
| Dose | MLE | 1.08 | 0.442 | 0.214 | 1.946 | 0.014 |
| Impl | MLE | 0.07 | 0.048 | -0.023 | 0.163 | 0.141 |
| Dose*Impl | MLE | -0.044 | 0.031 | -0.104 | 0.016 | 0.151 |

The third section is **Summary Statistics**. This section displays the deviance and its degrees of freedom, and the likelihood ratio statistic and degrees of freedom for testing the null hypothesis that the response probability of each observation is 0.5, i.e., all the model parameters, **including the constant term**, are simultaneously 0. The likelihood ratio statistic may be used to test for overall significance of the model. For the present example, the output displays a value of 890.7457 on 30 df for the deviance, and a value of 1205.3314 on 4 df for the likelihood ratio statistic, thereby rejecting the null

91 Analysis-Binary Regression Analysis

hypothesis that all the parameters of the model are 0.

The last section, **Parameter Estimates**, displays the **Model Term**, **Point Estimate** and the **Confidence Interval and p-value for Beta**. The **Model Terms** show there are three covariates, **Dose**, **Impl** and **Dose*Impl**, in the model. The next three columns (the **Point Estimates**) show **MLE** as **Type**, estimates and standard error of Beta's. For **Dose**, the estimate of Beta is 1.08. For **Impl**, the estimate of Beta is 0.07. For **Dose*Impl**, the estimate of Beta is -0.044. The next four columns show the inference type, confidence interval of Beta, and the p-value (2*1-sided) for testing Beta = 0. Here the p-value for **Dose** is 0.014.

Analysis Steps: Probit Regression - Test Multiple Hypothesis Model

Suppose you are interested in a simultaneous test that the parameters corresponding to both **Impl** and **Dose*Impl** in the previously specified model are equal to 0.

1. Invoke the **Analysis Input** tab from the status bar below. In the Input dialog, click the **Test** option. Use the Toggle **Selected for Estimation or Testing** button in the **Model Terms** box to select **Impl** and **Dose*Impl** for testing and deselect **Dose**.

Hypothesis Testing:

Test: <Impl=Dose*Impl=0>

| Type of Test | Statistics | DF | p-value |
|------------------|------------|----|---------|
| Score | 2.241 | 2 | 0.326 |
| Likelihood Ratio | 2.235 | 2 | 0.327 |
| Wald | 2.238 | 2 | 0.327 |

91 Analysis-Binary Regression Analysis

The title **Hypothesis Testing Tests** $\langle Impl = Dose * Impl = 0 \rangle$ appears near the bottom of the Test results worksheet. Below that, you can see the results of three asymptotic tests (based on the Scores, likelihood ratio, and Wald statistics, respectively) of the null hypothesis that the regression parameters corresponding to **Impl** and **Dose*Impl** are both 0. Since two parameters are being tested, this is a 2 degree of freedom test. All three tests are two-sided. Notice that the test statistics and p-values based on the Score test (2.241 and 0.326) are very similar to those based on the Likelihood Ratio and Wald tests. The p-values are quite large, indicating that we cannot reject the null hypothesis that the parameters corresponding to both **Impl** and **Dose*Impl** are equal to 0.

Since we are only interested in a positive trend, it is appropriate to perform 1-sided tests.

1. In the **Options** tab change the **Output p- value** to **One-sided**.
2. Click **OK** to estimate the model once more. The output is displayed in the main window.

Analysis: Binary Regression: Probit Model

Input Parameters

Data File: Devtox.cyx
Model: Death(Response = 1)=%const+Dose+Impl+Dose*Impl
Link Type: Probit
Analysis Type: Test:Asymptotic
Confidence Level: 0.95

Output

Terms in the Model : 4
Term(s) Dropped: 0
Total Number of Records: 1512
Number of Records Rejected: 0
Groups: 34
Summary Statistics:

| Statistics | Value | DF | p-value |
|------------------|----------|----|----------|
| Deviance | 890.746 | 30 | 2.979E-9 |
| Likelihood Ratio | 1205.331 | 4 | 0 |

Parameter Estimates:

| Model Terms | Point Estimate | | | Confidence Interval and p-value for Beta | | |
|-------------|----------------|--------|----------|--|--------|-----------------|
| | Type | Beta | SE(Beta) | 95% CI | | 1-Sided p-value |
| | | | | Lower | Upper | |
| %const | MLE | -2.762 | 0.684 | -INF | -1.638 | 2.68E-5 |
| Dose | MLE | 1.08 | 0.442 | 0.354 | INF | 0.007 |
| Impl | MLE | 0.07 | 0.048 | -0.008 | INF | 0.071 |
| Dose*Impl | MLE | -0.044 | 0.031 | -INF | 0.006 | 0.075 |

Hypothesis Testing:

Test: <Impl=Dose*Impl=0>

| Type of Test | Statistics | DF | p-value |
|------------------|------------|----|---------|
| Score | 2.241 | 2 | 0.326 |
| Likelihood Ratio | 2.235 | 2 | 0.327 |
| Wald | 2.238 | 2 | 0.327 |

Note that since we specified **One-sided** p-values, **East** reports 1-sided p-values as well as corresponding 1-sided confidence bounds. Since the remaining analyses will all be 2-sided, re-set the option for **output p-value** to **Two-sided** in the **Options** tab.

Post-Fit Analysis Now that we have fit a model to the data, let us obtain regression diagnostics to evaluate the fit. To do so, invoke **Analysis Inputs** from the lower status bar. Select the **Postfit Results** check box. Click **OK** to run the analysis. In the Library, there will be two more nodes named **Regression Diagnostics1** and **ROC Curve-1**

91 Analysis-Binary Regression Analysis

which essentially forms the post-fit analysis. The main output is as follows:

Analysis: Binary Regression: Probit Model

91.6 Complementary Log Log Model

The complementary log-log model also falls within the generalized linear model framework. The model uses the complementary log-log function to link the probability

91 Analysis-Binary Regression Analysis

of response to a linear combination of the covariates. Using the notation from the previous section, the complementary log-log model is

$$\log[-\log(1 - \pi_i)] = \beta_0 + \beta'_b \mathbf{x}_i.$$

The model gets its name from the fact that the log-log function is applied to $(1 - \pi)$, or the complement of the probability of a success. Thus, the model applies a log-log link to the probability that $Y_i = 0$. Unlike the logistic and probit models, the complementary log-log model implies that the probability of a response is asymmetric around 0.5. That is, the model specifies that this probability approaches 0 relatively slowly but approaches 1 relatively quickly. See Agresti (2002; Section 6.6.4) for graphical comparison of these rates in relation to the logit and probit models. As a result, the model will fit data that exhibit asymmetric rates of change in the probability of success better than the corresponding logistic and probit models, and is preferable in such cases.

Example: Complementary Log Log Model

Dataset: Seropos.cydx

Data Description

Consider the Serological Malaria data that have been discussed by Draper, Voller, and Carpenter (1972), and by Collett (1991). A serologic survey was carried out in 1971 in two areas of Amazonas, Brazil. An indirect fluorescent antibody test was used to detect the presence of antibodies to a malarial parasite in the villagers. The data reproduced in Table below refers to the proportion of individuals in each of seven age groups who were found to be seropositive.

Table: Seropositivity rates for villagers in Amozonas, Brazil in 1971

| Age group | Mid-point of age range in years | Proportion seropositive |
|-------------|---------------------------------|-------------------------|
| 0-11 months | 0.5 | 3/10 (30.00%) |
| 1-2 years | 1.5 | 1/10 (10.00%) |
| 2-4 years | 3.0 | 5/29 (17.24%) |
| 5-9 years | 7.0 | 39/69 (56.52%) |
| 10-14 years | 12.0 | 31/51 (60.78%) |
| 15-19 years | 17.0 | 8/15 (53.33%) |
| ≥ 20 years | 30.0 | 91/108 (84.26%) |

Analysis Steps: Clog Log Regression - Estimate Model

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Regression > (Parallel Design) Clog Log Regression

3. In the **Main** tab, select **AgeGroup** as the variable to be included as the **Model Terms**. Select **Seropositive** as the **Response** variable. Enter 1 as **Response Value**. Select **Frequency** as the **Weightage** variable. Click the **Estimate** option.
4. Click **OK** to start the analysis. The output displayed in the main window.

91 Analysis-Binary Regression Analysis

The third section is **Summary Statistics**. This section displays the deviance and its degrees of freedom, and the likelihood ratio statistic and degrees of freedom for testing the null hypothesis that the response probability of each observation is 0.5, i.e., all the model parameters, **including the constant term**, are simultaneously 0. The likelihood ratio statistic has a chi-squared distribution under the null hypothesis and can be used to test for overall significance of the model. For the present example, the output displays a value of 338.362 on 5 df for the deviance, and a value of 52.927 on 2 df for the likelihood ratio statistic, thereby rejecting the null hypothesis that all the parameters of the model are 0.

The last section, **Parameter Estimates**, displays the **Model Term, Point Estimate** and the **Confidence Interval and p-value for Beta**. The **Model Term** shows one covariate **AgeGroup** in the model. The next three columns the **Point Estimate**) show **MLE as Type**, estimates and standard error of **Betas**. For **AgeGroup**, the estimate of **Beta** is 0.0511.

The next four columns shows the inference type, confidence interval of **Beta** and the p-value(2*1-sided) for testing **Beta** equal to 0. Here the p-value for **AgeGroup** is < 0.0001.

A node **Analysis: Binary Regression: Complementary Log Log Model** is created in the Library.

Analysis Steps: Clog Log Regression - Test Multiple Hypotheses

Suppose you wish to test the null hypothesis that the parameter corresponding to **AgeGroup** in the model is equal to 0.

1. Click the **Analysis Input** tab from the status bar below. In the Input dialog, select the **Test** option. Use the **Toggle Model term Selected for Testing** button

in the **Model Terms** box to select **AgeGroup** for testing.

Hypothesis Testing:

Test: <AgeGroup=0>

| Type of Test | Statistics | DF | p-value |
|------------------|------------|----|-----------|
| Score | 53.902 | 1 | 5.999E-10 |
| Likelihood Ratio | 52.294 | 1 | 4.62E-10 |
| Wald | 50.242 | 1 | 6.389E-10 |

The title **Hypothesis testing Tests** $\langle \text{AgeGroup} = 0 \rangle$ appears near the bottom of the **Test** worksheet. Below that, you can see the results of three tests: Score, likelihood ratio, and Wald respectively of the null hypothesis that the regression parameter corresponding to **AgeGroup** is 0. Since a single parameter is being tested, this is a 1 degree of freedom test. All three tests are 2-sided. See Agresti (2002). Notice that all three p-values are very small (< 0.0001) indicating that we reject the null hypothesis that the parameter corresponding to **AgeGroup** is 0.

Estimation Results The estimation output currently displays the point estimates, confidence intervals, and two-sided p-values for the parameters corresponding to **AgeGroup**. These statistics were computed by the maximum likelihood method (See Agresti). Let us look at the individual items computed as estimation output. Specifically, look at the output corresponding to **AgeGroup** in the **Estimate** worksheet. The MLE for the β coefficient, its standard error, its confidence interval, and the p-value are all displayed.

Post-Fit Analysis Now that we have fit a model to the data, let us obtain regression diagnostics to evaluate the fit. Click the **Input Parameters** tab from the status bar below. Select the **Postfit Results** check box. Click **OK** to start the analysis. The output is displayed in the main window. In the Library along with the node **Analysis: Binary Regression:Complementary Log Log Model2**, there is two more nodes named **Regression Diagnostics1** and **ROC Curve-1** which essentially form the post-fit

91 Analysis-Binary Regression Analysis

analysis. The main output is as follows:

92 *Analysis- Multiple Comparison Procedures for Binary Data*

It is often the case that multiple objectives are to be addressed in one single trial. These objectives are formulated into a family of hypotheses. Type I error rate is inflated when one considers the inferences together as a family. Failure to compensate for multiplicities can have adverse consequences. For example, a drug could be approved when actually it is not better than Placebo.

Probability of making at least one type I error is known as family wise error rate (FWER). Multiple comparison (MC) procedures provide a guard against inflation of type I error due to multiple testing. All the MC procedures available in **East** strongly control FWER. Strong control of FWER refers to preserving the probability of incorrectly claiming at least one null hypothesis. To contrast strong control with weak control of FWER, the latter controls the FWER under the assumption that all hypotheses are true.

East supports several p-value based MC procedures for binary data. We have seen how to simulate data under different MC procedures with specified response rates and types of variance such as pooled or unpooled in chapter 27. In this chapter we explain how to analyze binary data with different MC procedures available in **East**. For MC procedures in **East**, we can either provide the dataset containing observations under each arm or the raw p-values to obtain the adjusted p-values.

92.1 Available Procedures **East** supports following MC procedures based on binary endpoint.

| PROCEDURE | REFERENCE |
|---------------------|----------------------------------|
| Bonferroni | Bonferroni CE. (1935) |
| Sidak | Sidak Z. (1967) |
| Weighted Bonferroni | Benjamini Y, Hochberg Y. (1997) |
| Holm’s Step Down | Holm S. (1979) |
| Hochberg’s Step Up | Hochberg Y. (1988) |
| Hommel’s Step Up | Hommel G. (1988) |
| Fixed Sequence | Westfall PH, Krishen A. (2001) |
| Fallback | Wiens B. (2003) |

East supports three p-value based single step MC procedures - Bonferroni procedure, Sidak procedure and Weighted Bonferroni procedure. Whereas, Hocheberg Procedure and Holm procedure are available as Data-driven step-up MC procedures.

Fixed-sequence stepwise procedure and fallback procedure are also part of **East** multiple comparison procedures for binary end points.

92.2 Single step MC procedures

Example: Bonferroni procedure

Example: Sidak Procedure

Example: Weighted Bonferroni Procedure

East supports three p-value based single step MC procedures. These are:

- Bonferroni procedure
- Sidak procedure and
- Weighted Bonferroni procedure

For the Bonferroni procedure, H_i is rejected if $p_i < \frac{\alpha}{k-1}$ and the adjusted p-value is given as $\min(1, (k-1)p_i)$.

For the Sidak procedure, H_i is rejected if $p_i < 1 - (1 - \alpha)^{\frac{1}{k-1}}$ and the adjusted p-value is given as $1 - (1 - p_i)^{k-1}$.

For the weighted Bonferroni procedure, H_i is rejected if $p_i < w_i\alpha$ and the adjusted p-value is given as $\min(1, \frac{p_i}{w_i})$. Here w_i denotes the proportion of α allocated to the H_i such that $\sum_{i=1}^{k-1} w_i = 1$. Note that, if $w_i = \frac{1}{k-1}$, then the Bonferroni procedure is reduced to the regular Bonferroni procedure.

Example: Bonferroni procedure

Dataset: HIV-study.cyx

Data Description

Throughout this chapter we will use the data from a dose finding HIV Study. It was a randomized, double-blind, parallel-group, placebo-controlled, multi-center trial to assess the efficacy and safety of 125mg(L), 250 mg(M), and 500 mg(H) orally twice daily of a new drug for a treatment of HIV associated diarrhea. The primary efficacy endpoint is clinical response, defined as two or less watery bowel movements per week, during at least two of the four weeks of the 4-week efficacy assessment period. The efficacy is evaluated by comparing the proportion of responders in the placebo group to the proportion of responders in the three treatment groups at a 1-sided alpha of 0.025.

The data set consists of two variables. The first variable, **Trt_group**, takes four values as "P", "L", "M", and "H". The "P" value represents the placebo group, "L" the low dose (125 mg) group, "M" the middle dose (250 mg) group, and "H" the high dose (500 mg) group. The second variable, **response**, is a binary indicator of whether or not each subject was a responder (1 represents a responder, 0 represents a non-responder).

92 *Analysis- Multiple Comparison Procedures for Binary Data*

Purpose of the Analysis:

To analyze the data of the dose finding HIV trial using Bonferroni procedure.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Many Samples > (Multiple Comparisons) Pairwise Comparison to Control - Differences of Proportions

3. In the **Main** tab, select the **raw data** option. In the ensuing box with label **Treatment Variable and its Control Arm**, select **Trt_group** and select the **P** option next to it. Select **response** as the **Select Response Variable** with a **Response Value** of **1**. Under the dropdown box for selecting the response variable there are two options, pooled variance and un-pooled variance. For this example, select the **Pooled Variance** option. If **Pooled Variance** is selected, the software will use the pooled variance estimate in calculating the standard error of the test statistics. If **Un-pooled Variance** is selected, the software will use the un-pooled variance estimate in calculating the standard error of the test statistics. The technical details on variance estimates are provided in the technical appendix **H**. Select **Bonferroni** from the **Select MCP** drop-down list.

 Confidence Level: 0.95
 Test Type: z-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Proportion | Std. Err. of Diff. of Proportions | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Proportions(One sided) | |
|------|-------------|------------|-----------------------------------|----------------|----------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 125 | 0.344 | NA | NA | NA | NA | NA | NA |
| H | 125 | 0.544 | 0.063 | 3.182 | 7.306E-4 | 0.002 | 0.097 | 1 |
| L | 125 | 0.392 | 0.061 | 0.787 | 0.216 | 0.647 | -0.052 | 1 |
| M | 125 | 0.44 | 0.062 | 1.555 | 0.06 | 0.18 | -0.006 | 1 |

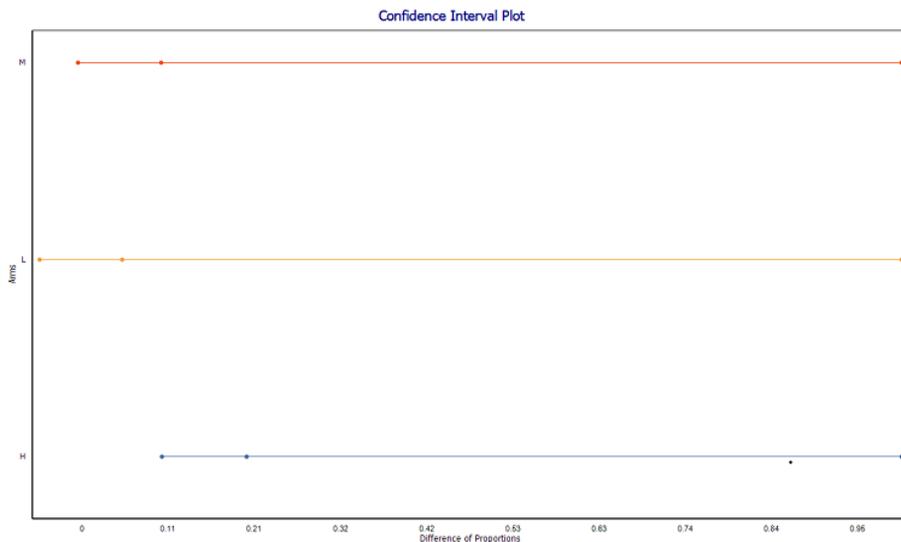

Adjusted Global p-value: 0.002
 Total Number of Records: 500
 Number of Records Rejected: 0
 Total Number of Arms (k): 4

The **Output** section gives us a table with our results. The sample size of each group and the sample mean of our response variable (response) are given. The Std. Err. of Diff. of Means column gives us the standard error of the difference of means (not the standard error of the mean) for comparing that specific treatment to placebo. The next column gives us the test statistic. The two columns after that give us the naive and adjusted (using Bonferroni's procedure) p-values. The technical appendix **H** contains the technical details on Bonferroni's procedure. You can refer to it to see how the

p-values are calculated. From these results we can see that after adjusting for multiplicity there is a significant difference, at the $\alpha = 0.05$ level, in the proportion of clinical response between placebo and the high dose (adjusted p-value = 0.002). We did not find any evidence of a difference between placebo and the low dose (adjusted p-value = 0.647), and placebo group and the middle dose (adjusted p-value = 0.180). Also, the naive p-values are all less than or equal to the adjusted p-values, as expected.

The final two columns of the table give us the lower and upper bounds for the 95% one sided confidence intervals. The last section shows us the adjusted global p-value, total number of records, number of records rejected, and total number of arms.

In **Library**, there would also be another node labeled **Confidence Interval Plot1**. Double click this node to display a Confidence Interval plot.

Example: Sidak Procedure

Dataset: HIV-study.cyx as described in Section 92.2.

92 Analysis- Multiple Comparison Procedures for Binary Data

Purpose of the Analysis:

To analyze the data of the dose finding HIV trial using Sidak procedure.

Analysis Steps:

1. Click **Analysis Inputs** tab on the status bar below. This will display several input fields associated with multiple comparison test in the main window.
2. In the **Main** tab, select **Sidak** in the **Select MCP** drop-down. Leave all other parameters as selected for the Bonferroni procedure above.

 Total Number of Arms (k): 4

The interpretation of the above output is similar to what was described for the output of Bonferroni procedure in section 92.2.

In addition to the above output, East also creates a confidence interval plot. A node labeled Analysis: Multiple Pairwise Comparisons with Control: Difference of Proportions2 is displayed in the Library. Under this node there is another node

92 Analysis- Multiple Comparison Procedures for Binary Data

labeled as **Confidence Interval Plot2**. To open the plot, double click this node.

Example: Weighted Bonferroni Procedure

Dataset: HIV-study.cyx as described in Section 92.2.

Purpose of the Analysis:

To analyze the data of the dose finding HIV trial using Weighted Bonferroni procedure.

Analysis Steps:

1. Click **Analysis Inputs** tab on the status bar below. This will display several input fields associated with multiple comparison test in the main window.
2. In the **Main** tab, select **Weighted Bonferroni** in the **Select MCP** drop-down. After selecting Weighted Bonferroni a table is displayed below the dropdown box. The table is to specify the proportion of alpha allocated to each comparison. By default **East** distributes the proportion of alpha equally among the treatment groups. For this example, enter **0.2** for group **L**, **0.3** for group **M**, and **0.5** for group **H**. Ideally, the sum of these values must add up to one. If the sum of these values do not add up to 1, **East** will automatically scale them to add up to 1.

Leave all other parameters as selected for the Bonferroni procedure above.

Under this node there is another node labeled as **Confidence Interval Plot3**. To open

the plot, double click the **Confidence Interval Plot** node.

92.3 Data-driven step-down MC procedure

92.3.0 Holm's Procedure

In the single step MC procedures, the decision to reject any hypothesis does not depend on the decision to reject other hypotheses. On the other hand, in the stepwise procedures decision of one hypothesis test can influence the decisions on the other tests of hypotheses. There are two types of stepwise procedures. One type of procedures proceed in data-driven order. The other type proceeds in a fixed order set a priori. Stepwise tests in a data-driven order can proceed in step-down or step-up manner.

East supports Holm step-down MC procedure which starts with the most significant comparison and continue as long as tests are significant until the test for certain hypothesis fails. The testing procedure stops at the first time a non-significant comparison occurs and all remaining hypotheses will be retained. In i -th step, $H_{(k-i)}$ is rejected if $p_{(k-i)} \leq \frac{\alpha}{i}$ and go to the next step.

Example: *Holm's Step Down Procedure*

Dataset: **HIV-study.cyx** as described in Section 92.2.

Purpose of the Analysis:

To analyze the data of the dose finding HIV trial using Holm's Step Down Procedure.

92 Analysis- Multiple Comparison Procedures for Binary Data

Analysis Steps:

1. Click **Analysis Inputs** tab on the status bar below. This will display several input fields associated with multiple comparison test in the main window.
2. In the **Main** tab, select **Holm's step down** in the **Select MCP** drop-down. Leave all other parameters as selected for the Bonferroni procedure above.

The interpretation of the above output is similar to what was described for the output of Bonferroni procedure in section 92.2.

In addition to the above output, East also creates a confidence interval plot. A node labeled **Analysis: Multiple Pairwise Comparisons with Control: Difference of Proportions4** is displayed in the Library. Under this node there is another node labeled as **Confidence Interval Plot4**.

92 Analysis- Multiple Comparison Procedures for Binary Data

To open the plot, double click the **Confidence Interval Plot4** node.

92.4 Data-driven step-up MC procedures

92.4.0 Hochberg's Procedure

92.4.0 Hommel's Step up

Step-up tests start with the least significant comparison and continue as long as tests are not significant until the first time when a significant comparison occurs and all remaining hypotheses will be rejected.

East supports two such MC procedures - Hochberg step-up and Hommel step-up procedures.

In the Hochberg step-up procedure, in i^{th} step $H_{(k-i)}$ is retained if $p_{(k-i)} > \frac{\alpha}{i}$.

In the Hommel step-up procedure, in i^{th} step $H_{(k-i)}$ is retained if $p_{(k-j)} > \frac{i-j+1}{i}\alpha$ for $j = 1, \dots, i$. Fixed sequence test and fallback test are the types of tests, which proceed, in a prespecified order.

Example: Hochberg's Step Up Procedure

Dataset: HIV-study.cydx as described in Section 92.2.

Purpose of the Analysis:

To analyze the data of the dose finding HIV trial using Hochberg's Step Up Procedure.

Analysis Steps:

1. Click **Analysis Inputs** tab on the status bar below. This will display several input fields associated with multiple comparison test in the main window.
2. In the **Main** tab, select **Hochberg's step up** in the **Select MCP** drop-down. Leave all other parameters as selected for the Bonferroni procedure above.

The screenshot shows a software window titled "Analysis: Discrete Endpoint Many-Sample Test - Multi-Arm Design - Pairwise Comparisons to Control - Differences of Proportions". The "Data Set" is "HIV-study.cyd". The "Main" tab is selected, and the "Advanced" tab is also visible. The "raw Data" option is selected. Under "Treatment Variable and its Control Arm", "Trt_group" is selected in the dropdown, and radio buttons for H, L, M, and P are shown, with P being selected. Under "Response Variable", "response" is selected in the dropdown, and "1" is selected in the "Select Value" dropdown. The "Pooled Variance" option is selected. The "Frequency" dropdown is empty. On the right, the "Multiple Comparison Procedure" section shows "Hochberg's step up" selected in the "Select MCP" dropdown.

3. Click **OK** to start the analysis. The output, as shown below, is displayed in the **Output Preview Area**.

92 Analysis- Multiple Comparison Procedures for Binary Data

Analysis: Multiple Pairwise Comparisons with Control: Difference of Proportions

Hypothesis

$H_1 : \pi_i - \pi_0 \leq 0$ Vs. $K_i : \pi_i - \pi_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: HIV-study.cyd
 Treatment Variable: Trt_group
 Response Variable: response(1)
 Control Arm: P
 Variance Type: Pooled
 Multiple Comparison Procedure: Hochberg's step up
 Confidence Level: 0.95
 Test Type: z-test
 Rejection Region: Right-Tail

Output

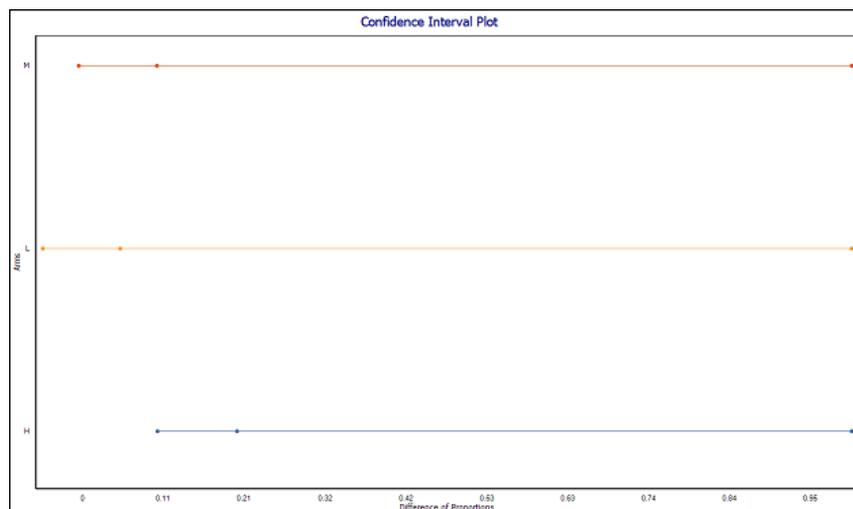

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Proportion | Std. Err. of Diff. of Proportions | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Proportions(One sided) | | |

The interpretation of the above output is similar to what was described for the output of Bonferroni procedure in section 92.2. In addition to the above output, **East** also creates a confidence interval plot. A node labeled **Analysis: Multiple Pairwise Comparisons with Control: Difference of Proportions6** is displayed in the Library. Under this node there is another node labeled as **Confidence Interval Plot6**. To open the plot, double click the **Confidence Interval Plot6** node.

92.5 Fixed-seq stepwise MC procedures

In data-driven stepwise procedures, we don't have any control on the order of the hypotheses to be tested. However, sometimes based on our preference or prior knowledge we might want to fix the order of tests a priori. Fixed sequence test and fallback test are the types of tests which proceed in a pre-specified order. **East** supports both of these procedures.

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is pre-specified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the associated raw marginal p-values. In the fixed sequence testing procedure, for $i = 1, \dots, k - 1$, in i -th step, if $p_i < \alpha$, reject H_i and go to the next step; otherwise retain H_i, \dots, H_{k-1} and stop.

Fixed sequence testing strategy is optimal when early tests in the sequence have largest treatment effect and performs poorly when early hypotheses have small treatment effect or are nearly true (Westfall and Krishen 2001). The drawback of fixed sequence

92 Analysis- Multiple Comparison Procedures for Binary Data

test is that once a hypothesis is not rejected no further testing is permitted. This will lead to lower power to reject hypotheses tested later in the sequence.

Fallback test alleviates the above undesirable feature for fixed sequence test. Let w_i be the proportion of α for testing H_i such that $\sum_{i=1}^{k-1} w_i = 1$. In the fixed sequence testing procedure, in i -th step ($i = 1, \dots, k-1$), test H_i at $\alpha_i = \alpha_{i-1} + \alpha w_i$ if H_{i-1} is rejected and at $\alpha_i = \alpha w_i$ if H_{i-1} is retained. If $p_i < \alpha_i$, reject H_i ; otherwise retain it. Unlike the fixed sequence testing approach, the fallback procedure can continue testing even if a non-significant outcome is encountered by utilizing the fallback strategy. If a hypothesis in the sequence is retained, the next hypothesis in the sequence is tested at the level that would have been used by the weighted Bonferroni procedure. With $w_1 = 1$ and $w_2 = \dots = w_{k-1} = 0$, the fallback procedure simplifies to fixed sequence procedure.

Example: Fixed Sequence Procedure

Dataset: `HIV-study.cyx` as described in Section 92.2.

Purpose of the Analysis:

To analyze the data of the dose finding HIV trial using Fixed Sequence Procedure.

Analysis Steps:

1. Click **Analysis Inputs** tab on the status bar below. This will display several input fields associated with multiple comparison test in the main window.
2. In the **Main** tab, select **Fixed sequence** in the **Select MCP** drop-down. After selecting Fixed sequence a table will appear below the dropdown box. The table has two columns - **Arm** and **Test Sequence**. In the column **Test Sequence**, you have to specify the order in which the hypotheses will be tested. Specify 1 for the arm that will be compared first with Placebo, 2 for the arm that will be compared next and so on. By default **East** specifies 1 to the first arm, 2 to the second arm and so on. This default order implies that Dose1 will be compared first with Placebo, then Dose2 will be compared followed by comparison of Dose3 vs. Placebo. However, if we believe that efficacy of drug increases with dose, then the dose groups should be compared in descending order of dose. For this example, assign the high dose a sequential priority of 1, the middle dose as 2, and the low dose as 3. Leave all other parameters as selected for the

Bonferroni procedure above.

the plot, double click the **Confidence Interval Plot** node.

93

Analysis-Comparison of Multiple Comparison Procedures for Continuous Data- Analysis

In this chapter, we will use the hypertension trial example to illustrate the different multiple testing procedures. There are two scenarios. One scenario has increasing dose-response profile and the other one has decreasing dose-response profile. The data sets are available in the Samples subfolder in the **East** installation directory with file names Hypertension-trial.cyd and Hypertension-trial 2.cyd. The trial was conducted to compare the effects of four doses of the new drug. The doses are labeled as D1, D2, D3, and D4 from the lowest dose D1 to the highest dose D4. Table 93.1 and 93.2 display the mean treatment effects of each dose group against placebo group, standard errors, t statistics, raw p -values and 97.5% lower confidence limits for the two scenarios.

Table 93.1: Summary Statistics for scenario 1

| Dose | Mean Effect | Standard Error | t statistics | p -value | 97.5% Lower Confidence Limit |
|------|-------------|----------------|----------------|------------|------------------------------|
| D1 | -0.6957 | 1.9634 | -0.3543 | 0.638138 | -4.5831 |
| D2 | 4.5498 | 1.9245 | 2.3642 | 0.009838 | 0.7395 |
| D3 | 4.9252 | 1.9634 | 2.5085 | 0.00673 | 1.0378 |
| D4 | 6.6268 | 1.9245 | 3.4434 | 0.000396 | 2.8164 |

Table 93.2: Summary Statistics for scenario 2

| Dose | Mean Effect | Standard Error | t statistics | p -value | 97.5% Lower Confidence Limit |
|------|-------------|----------------|----------------|------------|------------------------------|
| D1 | 8.3574 | 1.9817 | 4.2173 | 0.000024 | 4.4354 |
| D2 | 4.979 | 1.9817 | 2.5125 | 0.006631 | 1.057 |
| D3 | 4.5469 | 1.9817 | 2.2944 | 0.011717 | 0.6249 |
| D4 | 0.9544 | 1.9817 | 0.4816 | 0.315461 | -2.9676 |

Table 93.3 displays the adjusted p -values for all the multiplicity adjustment methods. The numbers highlighted in red are significant at 0.025 level.

Single step Dunnett test finds two significant doses in both scenario 1 and 2. Using Bonferroni test, only Dose 4 is superior to placebo in Scenario 1 and only Dose 1 is superior to placebo in Scenario 2. Also, note that the adjusted p -values by single step Dunnett test are all smaller than those by Bonferroni test. This is because single step

93 Analysis-Comparison of Multiple Comparison Procedures for Continuous Data- Analysis

Table 93.3: Adjusted p values for scenario 1

| MCP procedure | D1 | D2 | D3 | D4 |
|---------------------------------------|----------|----------|----------|----------|
| Single step Dunnett | 0.895822 | 0.032812 | 0.022962 | 0.001488 |
| Step down Dunnett | 0.638138 | 0.018357 | 0.018067 | 0.001488 |
| Bonferroni | 1 | 0.039351 | 0.02692 | 0.001584 |

Dunnett test is a parametric test, which takes into account the joint distribution of the test statistics.

Dunnett step down test finds three significant doses in both scenario 1 and 2. It is a closed test based on single step Dunnett procedure and is uniformly more powerful than single step Dunnett test. This can be seen from the fact that all adjusted p-values by Dunnett step down test are smaller than those by single step Dunnett test. The relationship between Dunnett step down test and Holm test is similar to that between single step Dunnett and Bonferroni test. Dunnett step down test is a parametric procedure of Holm test and is uniformly more powerful than Holm test which is confirmed by the smaller p -values adjusted by step down Dunnett test than those adjusted by Holm test.

Sidak test gives similar adjusted p-values to those provided by Bonferroni test. These two test have very similar performance.

Holm test rejects three doses in both scenarios and all the adjusted p-values by Holm test are smaller than or equal to those by Bonferroni test. This is because Holm test is a closed test based on Bonferroni procedure and consequently it is uniformly more powerful than Bonferroni test.

Hochberg and Hommel procedures also reject the same three hypotheses in both scenarios. However, their adjusted p -values for all the doses are smaller than or equal to those by Holm procedure. This is the well-known fact that Hochberg and Hommel procedures are uniformly more powerful than Holm test. Hommel procedure is

Table 93.4: Adjusted p values for scenario 2

| MCP procedure | D1 | D2 | D3 | D4 |
|---------------------------------------|----------|----------|----------|----------|
| Single step Dunnett | 0.000092 | 0.022646 | 0.038631 | 0.60987 |
| Step down Dunnett | 0.000092 | 0.017788 | 0.02176 | 0.315461 |
| Bonferroni | 0.000094 | 0.026523 | 0.046866 | 1 |
| Sidak | 0.000094 | 0.026261 | 0.046049 | 0.78042 |
| Holm | 0.000094 | 0.019893 | 0.023433 | 0.315461 |
| Hochberg | 0.000094 | 0.019893 | 0.023433 | 0.315461 |
| Hommel | 0.000094 | 0.017575 | 0.023433 | 0.315461 |
| Fixed sequence (D1,D2,D3,D4) | 0.000024 | 0.006631 | 0.011717 | 0.315461 |
| Fallback (D1,D2,D3,D4, equal weights) | 0.000094 | 0.013262 | 0.015622 | 0.315461 |

uniformly more powerful than Hochberg procedure. Their performances are similar which can be seen from the similar adjusted p -values with Hommel adjusted p -values being slightly smaller than the Hochberg ones. Note that Hochberg and Hommel tests control the FWER when the joint distribution of the test statistics have a certain type of positive dependence so called multivariate totally positive of order two (Sarkar and Chang 1997, Sarkar 1998). For negatively correlated test statistics, Hochberg and Hommel procedures might not control the FWER.

Fixed sequence test fails to reject all the doses in Scenario 1 where all the adjusted p values are more than 0.5. However, this test rejects dose 1, 2 and 3 in Scenario 2. Further note that the fixed sequence test performs uniformly better than all other procedures since the adjusted p -values are smaller than all those by other procedures. This illustrates an important feature of the fixed sequence test. This test performs best when the testing order is in line with the magnitudes of the underlying true treatment effects. In other words, if the hypotheses being tested earlier in the sequence have larger treatment effects, the fixed sequence procedure is more powerful. On the other hand, if the treatment effects are not monotone with respect to the testing order, this test performs poorly.

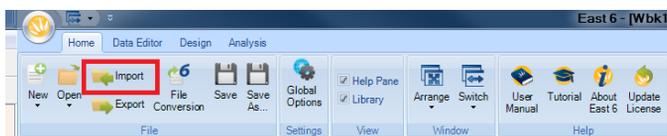

Fallback procedure rejects dose 4 in Scenario 1 like Bonferroni and Sidak procedures. However, it rejects three doses in Scenario 2, dose 1, 2, and 3. The adjusted p -values generated by fallback test are smaller than those produced by Holm, Hochberg and Hommel tests. This implies that fallback test with equal weights performs better than Holm, Hochberg and Hommel tests when the testing order is in line with the magnitudes of the treatment effects. Also, note that fallback test is more robust than

93 *Analysis-Comparison of Multiple Comparison Procedures for Continuous Data- Analysis*

fixed sequence test, especially when the testing order is not consistent with the order of the true treatment effects as in Scenario 1 where fallback finds one significance whereas fixed sequence does not find any significant results.

94 *Analysis-Multiple Endpoints for Binary Data*

In Chapter 28, we have seen how to evaluate different gatekeeping procedures for correlated binary outcome through intensive simulations. In this chapter, we will illustrate how to analyze a trial with binary outcome with gatekeeping multiple comparison procedures. Consider the same example used in Chapter 27: a randomized, placebo-controlled, double blind, parallel treatment clinical trial designed to compare two treatments for migraine. In this study, Telcagepant (300mg), an antagonist of the CGRP receptor associated with migraine, and zolmitriptan (5mg) the standard treatment against migraine, are compared against a placebo. The five co-primary endpoints include pain freedom, pain relief, absence of photophobia (sensitivity to light), absence of phonophobia (sensitivity to sound), and absence of nausea two hours post treatment. Three co-secondary endpoints included more sustained measurements of pain freedom, pain relief, and total migraine freedom for up to a 24 hour period. For illustration purpose, we consider three primary endpoints, pain freedom (PF), absence of phonophobia (phono) and absence of photophobia (photo) at two hours post treatment. Only one endpoint from the secondary family, sustained pain freedom (SPF), will be included in the example. The data set is saved in the installation folder of EAST as Migraine.csv. To analyze this data set, we need to import the data into EAST by clicking on the Import icon as seen in the following screen.

Select the Migraine.csv file and click OK to see the data set displayed in EAST. The

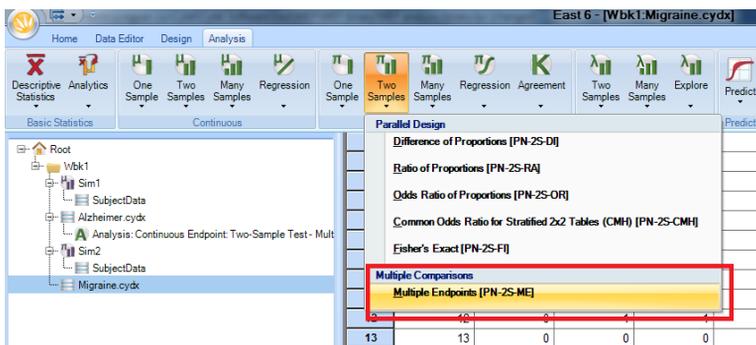

94 Analysis-Multiple Endpoints for Binary Data

following screen shows a snapshot of the data set.

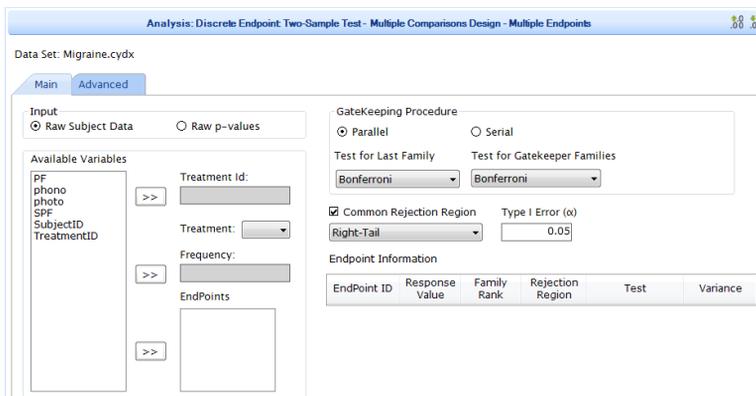

| SubjectID | TreatmentID | PF | phono | photo | SPF |
|-----------|-------------|----|-------|-------|-----|
| 1 | 0 | 0 | 1 | 1 | 0 |
| 2 | 0 | 0 | 1 | 0 | 0 |
| 3 | 0 | 0 | 0 | 1 | 0 |
| 4 | 0 | 0 | 1 | 0 | 0 |
| 5 | 0 | 0 | 0 | 0 | 0 |
| 6 | 0 | 0 | 0 | 1 | 0 |
| 7 | 0 | 1 | 1 | 1 | 0 |
| 8 | 0 | 0 | 1 | 1 | 0 |
| 9 | 0 | 0 | 0 | 0 | 0 |
| 10 | 0 | 0 | 1 | 1 | 1 |
| 11 | 0 | 0 | 0 | 0 | 0 |
| 12 | 0 | 0 | 0 | 0 | 0 |
| 13 | 0 | 0 | 1 | 0 | 0 |
| 14 | 0 | 0 | 0 | 0 | 0 |
| 15 | 0 | 0 | 0 | 1 | 0 |
| 16 | 0 | 0 | 0 | 0 | 0 |
| 17 | 0 | 1 | 1 | 1 | 1 |
| 18 | 0 | 1 | 1 | 1 | 0 |
| 19 | 0 | 0 | 0 | 0 | 0 |
| 20 | 0 | 0 | 0 | 1 | 0 |
| 21 | 0 | 0 | 0 | 0 | 0 |

Now click on the Analysis menu on the top of EAST window, select Two Samples for discrete outcome and then select Multiple Comparisons-Multiple Endpoints from the

dropdown list.

The main input dialog window pops up as seen in the following screen.

EAST can analyze two types of data: (1) raw subject level data, (2) raw p-values. For the migraine example, the data is raw subject level data so we select the left radio button. The left bottom panel of the screen displays all the variables contained in the data set. We need to specify which variable contains the information on treatment group ID for each subject and further specify which one is active treatment group. The next input is to identify all the endpoints to be analyzed. For this example, PF, phono and photo constitute the primary family of endpoints. SPF constitutes the secondary family. Suppose we need to analyze the data using serial gatekeeping procedure. After

94 Analysis-Multiple Endpoints for Binary Data

filling in all inputs, the screen looks as follows

The screenshot shows the 'Advanced' tab of the software interface. The 'Data Set' is 'Migraine.cyx'. The 'Input' section has 'Raw Subject Data' selected. The 'Available Variables' list contains 'SubjectID'. The 'Treatment ID' is 'TreatmentID', 'Treatment' is '1', and 'Frequency' is empty. The 'EndPoints' list contains 'PF', 'phono', 'photo', and 'SPF'. The 'GateKeeping Procedure' is 'Serial'. The 'Test for Last Family' is 'Bonferroni'. The 'Common Rejection Region' is checked and set to 'Right-Tail' with a 'Type I Error (α)' of 0.05. The 'Endpoint Information' table is as follows:

| Endpoint ID | Response Value | Family Rank | Rejection Region | Test | Variance |
|-------------|----------------|-------------|------------------|---------------|----------|
| PF | 1 | 1 | Right-Tail | Diff of Props | Pooled |
| phono | 1 | 1 | Right-Tail | Diff of Props | Pooled |
| photo | 1 | 1 | Right-Tail | Diff of Props | Pooled |
| SPF | 1 | 2 | Right-Tail | Diff of Props | Pooled |

Now click on OK button on the right bottom of the screen to run the analysis. The

following screen displays the detailed output of this analysis.

Analysis: Discrete Endpoint: Two-Sample Test - Multiple Comparisons Design - Multiple Endpoint

Data File: Migraine.cydx
 Data Input Method: Raw Data
 Treatment Variable: TreatmentID
 Total Number of Endpoints: 4
 Type I Error (α): 0.05
 Gatekeeping Procedure: Serial
 Test for Last Family: Bonferroni

Output

Total Number of Records: 100
 Number of Records Rejected: 0
 Summary of each Endpoint:

| EndPoint ID | Test | Variance Type | Sample Size | Control Proportion | Treatment Proportion | Est. of Delta | Std. Err. of Est. of Delta | Test Statistic | 95% Confidence Interval of Delta (Two-Sided) | |
|-------------|---------------|---------------|-------------|--------------------|----------------------|---------------|----------------------------|----------------|--|-------------|
| | | | | | | | | | Lower Limit | Upper Limit |
| PF | Diff of Props | Pooled | 100 | 0.12 | 0.26 | 0.14 | 0.078 | 1.784 | -0.014 | 0.294 |
| phono | Diff of Props | Pooled | 100 | 0.4 | 0.66 | 0.26 | 0.1 | 2.605 | 0.064 | 0.456 |
| photo | Diff of Props | Pooled | 100 | 0.32 | 0.48 | 0.16 | 0.098 | 1.633 | -0.032 | 0.352 |
| SPF | Diff of Props | Pooled | 100 | 0.04 | 0.24 | 0.2 | 0.069 | 2.882 | 0.064 | 0.336 |

Inference of Gatekeeping Procedures:

| Family Rank | EndPoint ID | Rejection Region | Test Statistic | p-Value | | Status |
|-------------|-------------|------------------|----------------|---------|----------|------------------|
| | | | | Raw | Adjusted | |
| 1 | PF | Right-Tail | 1.784 | 0.037 | 0.051 | Unable to Reject |
| | phono | Right-Tail | 2.605 | 0.005 | 0.051 | Unable to Reject |
| | photo | Right-Tail | 1.633 | 0.051 | 0.051 | Unable to Reject |
| Not Passed | | | | | | |
| 2 | SPF | Right-Tail | 2.882 | 0.002 | 0.051 | Not Tested |

*Using Bonferroni test for the last family in the Serial gatekeeping procedure, the treatment arm is not significantly different from the control arm on the co-primary endpoints. As a result, the other non-primary endpoints are not tested.

The first table shows the summary statistics for each endpoint including mean for each treatment group, estimate of treatment effect, standard error of the effect estimate, test statistic and marginal two-sided confidence interval. The second table shows the inference summary including raw p-values, multiplicity adjusted p-values with the gatekeeping procedure and significance status. It also shows whether the primary family is passed as the serial gatekeeper for the secondary family of endpoints.

95 *Analysis-Agreement*

This chapter discusses Cohen’s Kappa and the Weighted Kappa measures. These two measures are used to assess the level of agreement between two observers classifying a sample of objects on the same categorical scale. The joint ratings of the observers are displayed on a square $r \times r$ contingency table.

95.1 Available Measures

A reference for each measure of agreement is provided in the table shown below:

| Measure Of Agreement | References |
|----------------------|------------------|
| Cohen’s Kappa | Agresti (2002) |
| Weighted Kappa | Liebetrau (1983) |

Note the following special features of these procedures.

- For every possible option, in addition to the option specific output, you also get the maximum likelihood point estimate of the measure of agreement (MLE), its asymptotic standard error (ASE_MLE), a confidence interval for the measure of agreement, and asymptotic 1 and 2-sided p-values for testing the null hypothesis that Kappa (or weighted Kappa) equals zero.
- Negative values of Kappa are possible, reflecting agreement weaker than might be expected by chance, but are rare in practice.

95.2 When to Use Each Measure

The two measures in this chapter capture the extent to which two sets of observers classifying the same set of objects agree.

- **Cohen’s Kappa:** Use Cohen’s Kappa when the classification of each object by the two observers is on a nominal scale.
- **Weighted Kappa:** Use the Weighted Kappa when the classification of each object by the two observers is on an ordered scale.

95.3 Example: Cohen’s Kappa

Dataset: Radio_Case_data.cyx

Data Description

It is hypothetical data concerning two radiologists who rated 85 patients with respect to liver lesions. The ratings were designated on an ordinal scale as "Normal", "Benign", "Suspected", and "Cancer". The following table provides the data:

| Rater1/Rater2 | Normal | Benign | Suspected | Cancer |
|---------------|--------|--------|-----------|--------|
| Normal | 21 | 12 | 0 | 0 |
| Benign | 4 | 17 | 1 | 0 |
| Suspected | 3 | 9 | 15 | 2 |
| Cancer | 0 | 0 | 0 | 1 |

Purpose of the Analysis:

To calculate Cohen’s Kappa estimates based on the selected dataset.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Discrete) Agreement > (Parallel Design) Cohen’s Kappa

This will display several input fields associated with Cohen’s Kappa test in the main window.

3. In the **Main** tab, select the variables as shown below:

Analysis: Discrete Endpoint Agreement Test - Paired Design - Cohen's Kappa

Data Set: Radio_Case_data.cyd

Main
Advanced

Variable 1(Rater 1): Column
 Weighted Kappa
Frequency Variable: Weight

Variable 2(Rater 2): Row

95 Analysis-Agreement

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Categorical Response: Cohen's Kappa

Hypothesis

H_0 : Agreement between two raters is purely from Random variation Vs. (i) H_1 ; Agreement between two raters is not purely from Random variation, for 2-Sided test
 Either (ii) H_1 ; Agreement between two raters is greater than that is expected from Random variation only
 Or (iii) H_1 ; Agreement between two raters is less than that is expected from Random variation only for 1-Sided test

Input Parameters

Data File: Radio_Case_data.cyd
 Rater1: Column
 Rater2: Row
 Frequency Variable: Weight
 Coefficient : Weighted Kappa
 Confidence Level: 0.95

Output

Total Number of Records: 10
 Number of Records Rejected: 0

Table of Observed Frequencies:

| | 1 | 2 | 3 | 4 | Total |
|-------|----|----|----|---|-------|
| 1 | 21 | 4 | 3 | 0 | 28 |
| 2 | 12 | 17 | 9 | 0 | 38 |
| 3 | 0 | 1 | 15 | 0 | 16 |
| 4 | 0 | 0 | 2 | 1 | 3 |
| Total | 33 | 22 | 29 | 1 | 85 |

Summary of Test Statistic:

| Coefficient | Estimate | ASE(MLE) | 95% Confidence Interval | |
|----------------|----------|----------|-------------------------|-------------|
| | | | Lower Limit | Upper Limit |
| Weighted Kappa | 0.671 | 0.068 | 0.538 | 0.805 |

Test of Hypothesis:

| Type | Statistic | p-value | | | | |
|--------------------|-----------|---------|-----------|-----------|------|-----------|
| | | Tail | 1 Sided | 2*1-Sided | Tail | 2 Sided |
| Asymptotic | Observed | G.E. | 2.454E-10 | 4.907E-10 | G.E. | 4.907E-10 |
| 99% CI Lower Limit | | | 0 | | | 0 |
| 99% CI Upper Limit | | | 4.604E-4 | | | 4.604E-4 |

East displays estimate of Kappa to be 0.671 which indicates moderate agreement between two radiologist. The asymptotic 1-sided as well as 2-sided p-value is very low. The hypothesis of no agreement is rejected at 5% two sided level of significance.

96 *Analysis-Survival Data*

96.1 *Superiority*

In this section, we explore how we can use **East** to compare two survival curves. **East** provides the option of using Log Rank Test for this purpose.

Here, our endpoint of interest is time-to-event. Some situations in medical research could be: study of a new-anticancer agent on patient survival; study of an anti-depressant drug on shortening the interval between diagnosis of depression and response to treatment and so on. More formally, we are interested in comparing the hazard rate parameters λ_t and λ_c between the treatment and control populations. Define $\delta = \ln(\lambda_t/\lambda_c)$. The null hypothesis $H_0 : \delta = 0$ is tested against a 2-sided alternative $H_1 : \delta \neq 0$ or against a one-sided alternative $H_1 : \delta < 0$ or $H_1 : \delta > 0$.

where

$$\lambda_t(u) = \frac{f_t(u)}{1 - F_t(u)}$$

and

$$\lambda_c(u) = \frac{f_c(u)}{1 - F_c(u)}$$

associated with the survival distributions F_t and F_c , respectively. Then the Logrank test is especially effective for detecting the proportional hazards alternative hypothesis.

Under the null hypothesis, $\log \delta = 0$. If $\log \delta$ is positive, population F_c prolongs survival relative to population F_t , while if $\log \delta$ is negative, population F_t prolongs survival relative to population F_c .

96.2 *Example: Survival Superiority Two Samples:Logrank*

Dataset: Cancer.cyx

Data Description

This data is from a small lung cancer clinical trial involving a new and control drug. The dataset has three variables **Drug**, **Response** and **Censored**.

The variable **Drug** acts as an identifier of the population to which the observation belongs. The value **1** corresponds to the control group and value **2** corresponds to the treatment group.

The **Response** variable provides survival time (in days).

96 Analysis-Survival Data

The variable **Censored** gives information about which observation is censored. The value **0** corresponds to censoring and the value **1** corresponds to non-censoring.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Events) Two Samples > (Parallel Design) Logrank

This will display several input fields associated with Logrank Test in the main window.

3. In the **Main** tab, select **Superiority** as **Trial Type** and **Drug** as **Population Id.** Enter **1** as **Control** and **2** as **Treatment**. Select **Response** as **Response** variable and **Censored** as **Censor** variable with **Censor Value** as 0 and **Complete** as 1. This data does not have a frequency variable, so leave it blank.

4. In the **Advanced** tab leave the fields **By Variable 1** and **By Variable 2** blank. Keep the default value **0.95** for **Confidence Level**.

5. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Time to Event Response: Logrank Test

Let $\delta = \ln(\lambda_1 / \lambda_0)$
 $H_0 : \delta = 0$ Vs. $H_1 : \delta \neq 0$ for 2-Sided test
 Either $H_1 : \delta > 0$ Or $H_1 : \delta < 0$ for 1-Sided test

Data File: Cancer.cyd
 Trial Type: Superiority
 Population ID: Drug(Treatment=2, Control=1)
 Response Variable: Response
 Censor: Censored(Censor Value=0, Complete=1)
 Confidence Level: 0.95

Output

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | |
|--------------|-----------------|--------|--------|----------|--------|
| | | Count | % | Count | % |
| 1 | 5 | 2 | 40 | 3 | 60 |
| 2 | 9 | 9 | 100 | 0 | 0 |
| Total | 14 | 11 | 78.571 | 3 | 21.429 |

Parameter Estimates:

| Hazard Ratio (HR) | 95% Confidence Interval(2-Sided) | |
|-------------------|----------------------------------|-------------|
| | Lower Limit | Upper Limit |
| 11.168 | 1.252 | 99.626 |

Test of Hypothesis:

| Log Rank Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|----------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| 4.076 | 1.439 | 2.833 | G.E. | 0.002 | 0.005 |

Estimated Hazard Rates:

| | |
|-------------------------------|----------|
| Control (λ_0) | 6.207E-4 |
| Treatment (λ_0 * HR) | 0.007 |

East calculates 2-sided as well as 1-sided p-values. 2-sided p-value for this test is 0.005 and 1-sided p-value is 0.002. At 5% significance level, the null hypothesis is rejected.

96.3 Example :Survival Superiority Two Samples: Wilcoxon-Gehan

Dataset: Cancer.cydx

Data Description

96 Analysis-Survival Data

This data is from a small lung cancer clinical trial involving a new and control drug. The dataset has three variables **Drug**, **Response** and **Censored**.

The variable **Drug** acts as an identifier of the population to which the observation belongs. The value **1** corresponds to the control group and value **2** corresponds to the treatment group.

The **Response** variable provides survival time (in days).

The variable **Censored** gives information about which observation is censored. The value **0** corresponds to censoring and the value **1** corresponds to non-censoring.

Analysis Steps:

96.4 Example:Survival Superiority Two Samples: Harrington-Fleming

Dataset: Cancer.cyx

Data Description

This data is from a small lung cancer clinical trial involving a new and control drug. The dataset has three variables **Drug**, **Response** and **Censored**.

The variable **Drug** acts as an identifier of the population to which the observation belongs. The value **1** corresponds to the control group and value **2** corresponds to the treatment group.

The **Response** variable provides survival time (in days).

The variable **Censored** gives information about which observation is censored. The value **0** corresponds to censoring and the value **1** corresponds to non-censoring.

Analysis Steps:

1. Open the dataset from **Samples** folder.

- Choose the menu item:

**Analysis > (Events) Two Samples > (Parallel Design)
 Harrington-Fleming-Sup**

This will display several input fields associated with Harrington-Fleming Test in the main window.

- In the **Main** tab, select **Superiority** as **Trial Type** and **Drug** as **Population Id**. Enter **1** as **Control** and **2** as **Treatment**. Select **Response** as **Response** variable and **Censored** as **Censor** variable with **Censor Value** as **0** and **Complete** as **1**. This data does not have a frequency variable, so leave it blank. Choose **Test Statistic** as **Harrington-Fleming**. Leave the default values of p and q as 1 each.

96 Analysis-Survival Data

Analysis: Time to Event Response: Logrank Test

Let $\delta = \ln(\lambda_1 / \lambda_0)$

$H_0 : \delta = 0$ Vs. $H_1 : \delta \neq 0$ for 2-Sided test

Either $H_1 : \delta > 0$ Or $H_1 : \delta < 0$ for 1-Sided test

Data File: Cancer.cyd
Trial Type: Superiority
Population ID: Drug(Treatment=2, Control=1)
Response Variable: Response
Censor: Censored (Censor Value=0, Complete=1)
Type of Test Statistic: Harrington-Fleming
Weight Parameter p: 1
Weight Parameter q: 1
Confidence Level: 0.95

Output

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | | Average Follow-up Time |
|--------------|-----------------|--------|----------|----------|---------|------------------------|
| | | Count | % | Count | % | |
| 1 | 5 | 2 | 40.000% | 3 | 60.000% | 644.4 |
| 2 | 9 | 9 | 100.000% | 0 | 0.000% | 178 |
| Total | 14 | 11 | 78.571% | 3 | 21.429% | 344.571 |

Test of Hypothesis:

| Harrington Fleming Score | Std. Error | Standardized Test Statistic | (1-Sided) | | (2-Sided) |
|--------------------------|------------|-----------------------------|-----------|---------|-----------|
| | | | Tail | p-value | p-value |
| 0.612 | 0.271 | 2.262 | G.E. | 0.012 | 0.024 |

Parameter Estimates from Cox Model:

| Hazard Ratio (HR) | ln(Hazard Ratio) (δ) | Std. Error of Estimate of δ | Wald Statistic | 95% Confidence Interval(2-Sided) | |
|-------------------|-------------------------------|------------------------------------|----------------|----------------------------------|-------------|
| | | | | Lower Limit | Upper Limit |
| 11.168 | 2.413 | 1.08 | 2.235 | 1.346 | 92.679 |

Estimated Hazard Rates:

| | |
|--------------------------------|----------|
| Control (λ_c) | 6.207E-4 |
| Treatment ($\lambda_c * HR$) | 0.007 |

East calculates 2-sided as well as 1-sided p-values. 2-sided p-value for this test is 0.024 and 1-sided p-value is 0.012. At 5% significance level, the null hypothesis is rejected.

96.5 Example: Survival Noninferiority two Samples:Logrank

Dataset: Cancer.cyx as described in section 96.2.

Purpose of the Analysis:

This section will illustrate through a worked example how to analyze data generated from a two-sample noninferiority study with a time-to-event trial endpoint. The noninferiority margin is generally determined by performing a meta-analysis on past clinical trials of the active control versus placebo. Regulatory agencies then require the sponsor of the clinical trial to demonstrate that a fixed percentage of the active control effect (usually 50%) is retained by the new treatment. In a noninferiority trial the goal is to establish that an experimental treatment is **no worse than** the standard treatment, rather than attempting to establish that it is superior. The between-treatment difference

96 Analysis-Survival Data

is expressed in terms of the hazard ratio,

$$\rho = \frac{\lambda_t}{\lambda_c},$$

or equivalently, in terms of the log hazard ratio

$$\delta = \ln(\rho) = \ln\left(\frac{\lambda_t}{\lambda_c}\right).$$

Where ρ_0 is the noninferiority margin for the hazard ratio, whereas, $\delta_0 = \ln(\rho_0)$ is the noninferiority margin for log hazard ratio.

We perform the comparison of the two treatments by testing

$$H_0: \delta \geq \delta_0$$

against the one-sided alternative

$$H_1: \delta < \delta_0,$$

when $\delta_0 (\geq 0)$

Or

$$H_0: \delta \leq \delta_0$$

against the one-sided alternative

$$H_1: \delta > \delta_0,$$

when $\delta_0 (\leq 0)$.

Analysis Steps:

1. Click **Analysis Inputs** tab on the status bar below. This will display several input fields associated with Logrank Test in the main window.
2. In the **Main** tab, select **Noninferiority** as **Trial Type**. Enter noninferiority margin as $\ln(0.511692)$ which is -0.67 . Select **Drug** in the **Population Id** field with 1 as **Control** and 2 as **Treatment**. Select **Response** as **Response** variable. Select **Censored** as **Censor** variable with **Censor value** as 0. This data does not have a frequency variable, so leave the **Frequency Variable** blank. Choose the Test Statistic **LogRank**

3. In the **Advanced** tab, leave the fields **By Variable 1** and **By Variable 2** blank. Enter 0.975 as the value of **Confidence Level**.

96 Analysis-Survival Data

4. Click **OK** to start the analysis. The output is displayed in the main window.

Analysis: Time to Event Response: Logrank Test

Let $\delta = \ln(\lambda_1 / \lambda_c)$
 If $\delta_0 < 0$ then $H_0 : \delta \leq \delta_0$ Vs. $H_1 : \delta > \delta_0$
 If $\delta_0 > 0$ then $H_0 : \delta \geq \delta_0$ Vs. $H_1 : \delta < \delta_0$

Data File: Cancer.cyd
 Trial Type: Noninferiority
 Population ID: Drug(Treatment=2, Control=1)
 Response Variable: Response
 Censor: Censored(Censor Value=0, Complete=1)
 Confidence Level: 0.975
 Noninferiority Margin: -0.67

Output

Summary of Observed Data:

| Treatment ID | No. of Subjects | Events | | Censored | |
|--------------|-----------------|--------|--------|----------|--------|
| | | Count | % | Count | % |
| 1 | 5 | 2 | 40 | 3 | 60 |
| 2 | 9 | 9 | 100 | 0 | 0 |

96.8 Example: Survival Multi-arm-Kaplan Meier Estimator

Dataset: Cancer.cydx as described in section 96.2.

Purpose of the Analysis:

The Kaplan-Meier estimator also known as the product limit estimator is an estimator for estimating the survival function from lifetime data. In medical research, it is often used to measure the fraction of patients living for a certain amount of time after treatment.

A plot of the Kaplan-Meier estimate of the survival function is a series of horizontal steps of declining magnitude which, when a large enough sample is taken, approaches the true survival function for that population. The value of the survival function between successive distinct sampled observations is assumed to be constant.

An important advantage of the Kaplan-Meier estimator is that the method can take into account some types of censored data, particularly right-censoring, which occurs if a patient withdraws from a study, that is, lost from the sample before the final outcome is observed.

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Events) Explore > (Multi-Arm Design) Kaplan Meier

This will display several input fields associated with Kaplan Meier Test in the main window.

3. In the **Main** tab, select **Drug** as **Population ID**, **Response** as **Response** variable. Select **Censored** as **Censor** variable with **Censor value** as 0. Leave the **Frequency Variable** field blank.

| 2 | 563 | 1 | 1 | 0 | 0 | NA |

A node **Analysis: Time to Event Response:Kaplan-Meier1** is created in the Library. Also a sub-node **Kaplan-Meier Plot1** is created in the Library. Click the **Kaplan-Meier Plot1** node to open the plot.

Note that in this plot, the estimated survivals are plotted for both the drugs on the same time axis, so that comparison of survivals is possible. The Kaplan-Meier Plot indicates that the patients on Drug arm have better survival as compared with those on the control arm.

97 *Analysis-Multiple Comparison Procedures for Survival Data*

It is often the case that multiple objectives are to be addressed in one single trial. These objectives are formulated into a family of hypotheses. Type I error rate is inflated when one considers the inferences together as a family. Failure to compensate for multiplicities can have adverse consequences. For example, a drug could be approved when actually it is not better than placebo. Multiple comparison (MC) procedures provide a guard against inflation of type I error due to multiple testing. Probability of making at least one type I error is known as family wise error rate (FWER). **East** supports several parametric and p-value based MC procedures.

We have seen how to simulate survival data under different MC procedures in chapter 51. This chapter explains how to analyze survival data with different MC procedures available in **East**.

97.1 Available Procedures

The probability of making at least one type I error is known as family wise error rate (FWER). All the MC procedures available in **East** strongly control FWER. Strong control of FWER refers to preserving the probability of incorrectly claiming at least one null hypothesis. To contrast strong control with weak control of FWER, the latter controls the FWER under the assumption that all hypotheses are true.

The following MC procedures are available for survival endpoints in East.

| Category | Procedure | Reference |
|---------------|-------------------------------|------------------------------------|
| P-value Based | Bonferroni | Bonferroni CE (1935, 1936) |
| | Sidak | Sidak Z (1967) |
| | Weighted Bonferroni | Benjamini Y and Hochberg Y (1997) |
| | Holm’s Step Down | Holm S (1979) |
| | Hochberg’s Step Up | Hochberg Y (1988) |
| | Hommel’s Step Up | Hommel G (1988) |
| | Fixed Sequence | Westfall PH, Krishen A (2001) |
| Fallback | Wiens B, Dimitrienko A (2005) | |

East provides three types of test statistics for the analysis of survival data incorporating MC procedures, which include the Logrank, Wilcoxon-Gehan, and the Harrington-Fleming. For illustration purposes, the examples below will only utilize the Logrank test statistic for data analysis.

STAMPEDE Trial

Throughout this chapter we consider the data derived from the design of the STAMPEDE trial discussed in chapter 51 to illustrate the analysis of survival data under different MC procedures. The STAMPEDE study is an ongoing, open-label, 5-stage, 6-arm randomized controlled trial using multi-arm, multi-stage (MAMS) methodology for men with prostate cancer. Started in 2005, it was the first trial of this design to use multiple arms and stages synchronously. The study population consists of men with high-risk localized or metastatic prostate cancer, who are being treated for the first time with long-term androgen deprivation therapy (ADT) or androgen suppression. The study started with 5 treatment groups:

- Standard of care (SOC) = ADT
- SOC + zoledronic acid (IV)
- SOC + docetaxel (IV)
- SOC + celecoxib, an orally administered cox-2 inhibitor
- SOC + zoledronic acid + docetaxel
- SOC + zoledronic acid + celecoxib

We want to control the FWER at 5% level of significance.

Dataset: The data to be used for the examples below arise from the STAMPEDE design described in chapter 51. The resulting **SubjectData** was generated during a

97.2 Single step MC procedures

East supports three p-value based single step MC procedures:

- Bonferroni procedure
- Sidak procedure and
- Weighted Bonferroni procedure.

For the Bonferroni procedure, H_i is rejected if $p_i < \frac{\alpha}{k-1}$ and the adjusted p-value is given as $\min(1, (k-1)p_i)$.

For the Sidak procedure, H_i is rejected if $p_i < 1 - (1 - \alpha)^{\frac{1}{k-1}}$ and the adjusted p-value is given as $1 - (1 - p_i)^{k-1}$.

For the weighted Bonferroni procedure, H_i is rejected if $p_i < w_i\alpha$ and the adjusted p-value is given as $\min(1, \frac{p_i}{w_i})$. Here w_i denotes the proportion of α allocated to the H_i such that $\sum_{i=1}^{k-1} w_i = 1$. Note that, if $w_i = \frac{1}{k-1}$, then the Bonferroni procedure is reduced to the regular Bonferroni procedure.

Example: Bonferroni procedure

Select the **SubjectData** node under the appropriate **Simulation** node in the **Library**. Next, under the **Analysis** tab in the **Events** group, select **Many Samples - Pairwise Comparisons to Control - Logrank**. The following screen is displayed:

The screenshot displays the configuration window for a survival analysis test. The title bar reads "Analysis: Survival Endpoint: Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Logrank Test". The "Data Set" is "SubjectData". The "Advanced" tab is selected. Under "Input", "Raw Subject Data" is chosen. The "Test Statistic" is set to "Logrank". Under "Multiple Comparison Procedure", "Select MCP:" is set to "Bonferroni". Other fields include "Treatment Variable:", "Control Arm:", "Response Variable:", and "Censor:", all of which are currently empty.

97 Analysis-Multiple Comparison Procedures for Survival Data

Select the following values for the **Main** tab:

Adjusted Global p-value: 1
 Total Number of Records: 3400
 Number of Records Rejected: 0
 Total Number of Arms (k): 6

The adjusted p-values for comparison of Dose1, Dose 2 ... up to Dose 5 vs. Placebo are all essentially 1. Therefore, after multiplicity adjustment according to Sidak procedure for this design, we can conclude that no additional treatment in addition to the standard of care at the tested dose levels is significantly different from the current standard treatment (ADT only).

Example: Weighted Bonferroni procedure Dataset:

97 Analysis-Multiple Comparison Procedures for Survival Data

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

Analysis: Continuous Endpoint Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Differences... .00 .00

Data Set: Hypertension-trial.cyd

Multiple Comparison Procedure

Select MCP:

No. of Treatment Arms:

Table of Treatment specific parameters:

| Arm | Proportion of... |
|-----|------------------|
| D1 | 0.25 |
| D2 | 0.25 |
| D3 | 0.25 |
| D4 | 0.25 |

4. Upon selection of weighted Bonferroni procedure, a table will appear under the drop-down box. The table has two columns - **Arm** and **Proportion of Alpha**. In the column **Proportion of Alpha**, you have to specify the proportion of total alpha you want to spend in each test. Ideally, the values in this column should add up to 1; if not, then **East** will normalize it to add them up to 1. By default, **East** distributes the total alpha equally among all tests. Here we have 4 tests in total, therefore each of the tests have proportion of alpha as $1/4$ or 0.25 . You can specify other proportions as well. For this example, keep the equal proportion of alpha for each test.
5. Click **OK** to analyze the data. The output will be displayed in the main window

once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis

$H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: UnEqual
 Multiple Comparison Procedure: Weighted Bonferroni
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail
 Table For Proportion of Alpha:

| Arms | Proportion of Alpha |
|------|---------------------|
| D1 | 0.25 |
| D2 | 0.25 |
| D3 | 0.25 |
| D4 | 0.25 |

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 2.026 | -0.343 | 0.634 | 1 | -4.097 | INF |
| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.031 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.045 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 0 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.982, 0.031, 0.044 and 0.001, respectively. Therefore, after multiplicity adjustment according to Sidak procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

Notice that the adjusted p-values in weighted Bonferroni MC procedure and the simple Bonferroni procedures are identical. This is because the weighted Bonferroni procedure with equal proportion reduces to the simple Bonferroni procedure.

97 Analysis-Multiple Comparison Procedures for Survival Data

97.3 Step down MC procedure

In the single step MC procedures, the decision to reject any hypothesis does not depend on the decision to reject other hypotheses. On the other hand, in the stepwise procedures decision of one hypothesis test can influence the decisions on the other tests of hypotheses. There are two types of stepwise procedures. One type of procedures proceeds in data-driven order. The other type proceeds in a fixed order set a priori. Stepwise tests in a data-driven order can proceed in step-down or step-up manner. **East** supports Holm step-down MC procedure which start with the most significant comparison and continue as long as tests are significant until the test for certain hypothesis fails. The testing procedure stops at the first time a non-significant comparison occurs and all remaining hypotheses will be retained. In i -th step, $H_{(k-i)}$ is rejected if $p_{(k-i)} \leq \frac{\alpha}{i}$ and go to the next step.

Example: Holm's step-down

Dataset:

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

4. Click **OK** to analyze the data. The output will be displayed in the main window

once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: UnEqual
 Multiple Comparison Procedure: Holm's step down
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|
| | | | | | Naive | Adjusted | Lower Limit | Upper Limit |
| Ctrl | 25 | 0.704 | NA | NA | NA | NA | NA | NA |
| D1 | 24 | 0.008 | 2.026 | -0.343 | 0.634 | 0.634 | -4.097 | INF |
| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.023 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.023 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 0 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total no. of records: 130
 No. of records rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.634, 0.023, 0.023 and 0.001, respectively. Therefore, after multiplicity adjustment according to Holm's step-down procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

97.4 Data-driven step-up MC procedures

newline Step-up tests start with the least significant comparison and continue as long as tests are not significant until the first time when a significant comparison occurs and all remaining hypotheses will be rejected. East supports two such MC procedures - Hochberg step-up and Hommel step-up procedures. In the Hochberg step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-i)} > \frac{\alpha}{i}$. In the Hommel step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-j)} > \frac{i-j+1}{i} \alpha$ for $j = 1, \dots, i$. Fixed sequence test and fallback test are the types of tests which proceed in a prespecified order.

97 Analysis-Multiple Comparison Procedures for Survival Data

Example: Hochberg's step-up procedure newline **Dataset:**

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below.

The screenshot shows the 'Multiple Comparison Procedure' dialog box with the 'Main' tab selected. The 'Data Set' is 'Hypertension-trial.cyd'. Under 'raw Data', the 'raw Data' radio button is selected. The 'Treatment Variable and its Control Arm' section has 'Dose' selected in the dropdown and 'P' selected with a radio button. The 'Response Variable' section has 'Response' selected in the dropdown. At the bottom, the 'Unequal Variance' radio button is selected. On the right, the 'Multiple Comparison Procedure' section has 'Hochberg's step up' selected in the dropdown.

4. Click **OK** to analyze the data. The output will be displayed in the main window

once the analysis is over.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_1 : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: Hypertension-trial.cyd
 Treatment Variable: Dose
 Response Variable: Response
 Control Arm: P
 Variance Type: UnEqual
 Multiple Comparison Procedure: Hochberg's step Up
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | Sample Size | Mean | Std. Err. of Diff. of Means | Test Statistic | p-value | | 95% Confidence Interval of Diff. of Means(One sided) | |
|------|-------------|-------|-----------------------------|----------------|---------|----------|--|-------------|

| D2 | 26 | 5.254 | 1.815 | 2.507 | 0.008 | 0.017 | 1.506 | INF |
| D3 | 24 | 5.629 | 2.081 | 2.367 | 0.011 | 0.022 | 1.43 | INF |
| D4 | 26 | 7.331 | 1.814 | 3.654 | 3.196E-4 | 0.001 | 3.585 | INF |

Adjusted Global p-value: 0.001
 Total Number of Records: 130
 Number of Records Rejected: 5
 Total Number of Arms (k): 5

The adjusted p-values for comparison of Dose1 vs. Placebo, Dose2 vs. Placebo, Dose3 vs Placebo and Dose4 vs. Placebo are 0.634, 0.017, 0.022 and 0.001, respectively. Therefore, after multiplicity adjustment according to Hommel's step-up procedure, we can conclude that Dose2, Dose3 and Dose4 are significantly different from Placebo, but Dose1 is not significantly different from Placebo at 5% level of significance.

97.5 Fixed-sequence stepwise MC procedures

In data-driven stepwise procedures, we don't have any control on the order of the hypotheses to be tested. However, sometimes based on our preference or prior knowledge we might want to fix the order of tests a priori. Fixed sequence test and fallback test are the types of tests which proceed in a pre-specified order. East supports both these procedures.

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is pre-specified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the associated raw marginal p-values. In the fixed sequence testing procedure, for $i = 1, \dots, k - 1$, in i -th step, if $p_i < \alpha$, reject H_i and go to the next step; otherwise

97 Analysis-Multiple Comparison Procedures for Survival Data

retain H_i, \dots, H_{k-1} and stop.

Fixed sequence testing strategy is optimal when early tests in the sequence have largest treatment effect and performs poorly when early hypotheses have small treatment effect or are nearly true (Westfall and Krishen (2001)). The drawback of fixed sequence test is that once a hypothesis is not rejected no further testing is permitted. This will lead to lower power to reject hypotheses tested later in the sequence.

Fallback test alleviates the above undesirable feature for fixed sequence test. Let w_i be the proportion of α for testing H_i such that $\sum_{i=1}^{k-1} w_i = 1$. In the fixed sequence testing procedure, in i -th step ($i = 1, \dots, k - 1$), test H_i at $\alpha_i = \alpha_{i-1} + \alpha w_i$ if H_{i-1} is rejected and at $\alpha_i = \alpha w_i$ if H_{i-1} is retained. If $p_i < \alpha_i$, reject H_i ; otherwise retain it. Unlike the fixed sequence testing approach, the fallback procedure can continue testing even if a non-significant outcome is encountered by utilizing the fallback strategy. If a hypothesis in the sequence is retained, the next hypothesis in the sequence is tested at the level that would have been used by the weighted Bonferroni procedure. With $w_1 = 1$ and $w_2 = \dots = w_{k-1} = 0$, the fallback procedure simplifies to fixed sequence procedure.

Example: Fixed sequence testing procedure Dataset:

Analysis Steps:

1. Open the dataset from **Samples** folder.
2. Choose the menu item:

Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means

3. In the ensuing dialog box, under the **Main** tab choose the variables as shown below. Upon selection of **Fixed Sequence** procedure, a table will appear under the drop-down box. The table has two columns - **Arm** and **Test Sequence**. In the column **Test Sequence**, you have to specify the order in which the hypotheses will be tested. Specify 1 for the arm that will be compared first with Placebo, 2 for the arm that will be compared next and so on. By default **East** specifies 1 to the first arm, 2 to the second arm and so on. This default order implies that Dose1 will be compared first with Placebo, then Dose2 will be compared followed by comparison of Dose3 vs. Placebo and finally Dose 4 will be compared with Placebo. However, if we believe that efficacy of drug increases with dose, then the dose groups should be compared in descending order of dose. Therefore, specify 4, 3, 2 and 1 in column **Test Sequence** for D1,

D2, D3 and D4, respectively. This order implies that Dose4 will be compared first with Placebo, then Dose3 will be compared followed by comparison of Dose2 vs. Placebo and finally Dose 1 will be compared with Placebo.

97.6 Example: Raw p-values as input

Suppose we don't have the dataset containing all the observations, rather we have the raw p-values and we want to adjust these using Bonferroni procedure. Here we will consider the 4 raw p-values returned by East using the example STAMPEDE data in all the above output. These p-values are 0.634, 0.008, 0.011 and 0.000. We will use

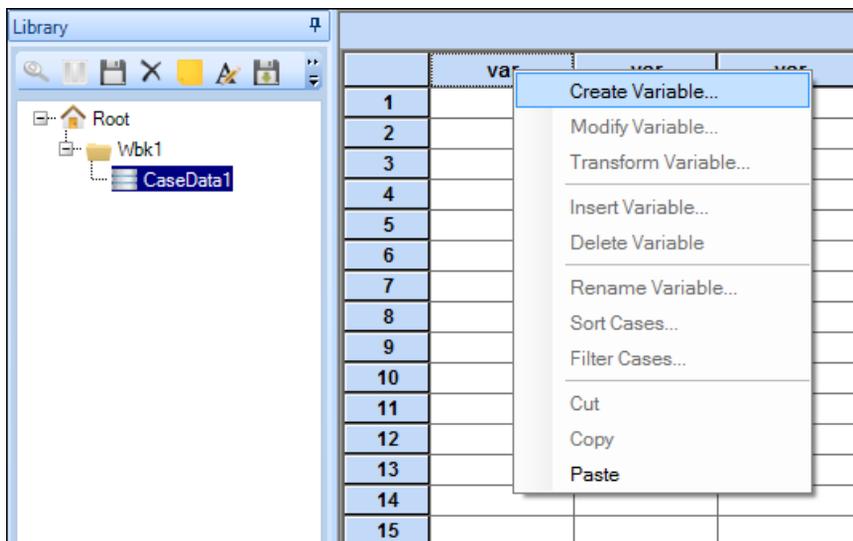

these raw p-values to obtain adjusted p-values. In order to do this, first, we need to create a dataset containing these p-values.

Dataset: New Dataset to be created.

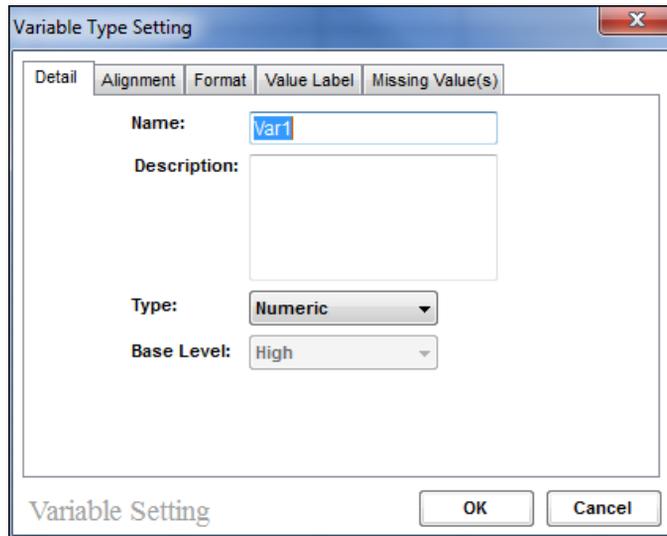

97 Analysis-Multiple Comparison Procedures for Survival Data

Analysis Steps:

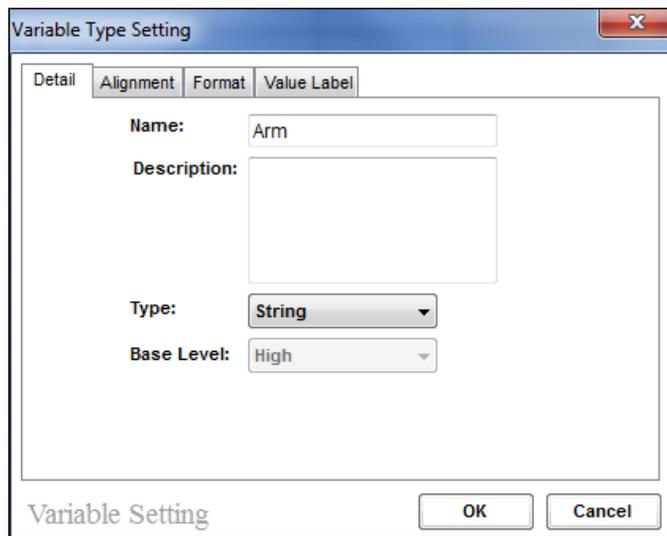

1. In the **Home** tab, choose textbf New > Case Data.
This will open an empty dataset in the main window. Now right click on the column header and click **Create Variable** as shown below.

2. This will bring up the following **Variable Type Setting** dialog box.

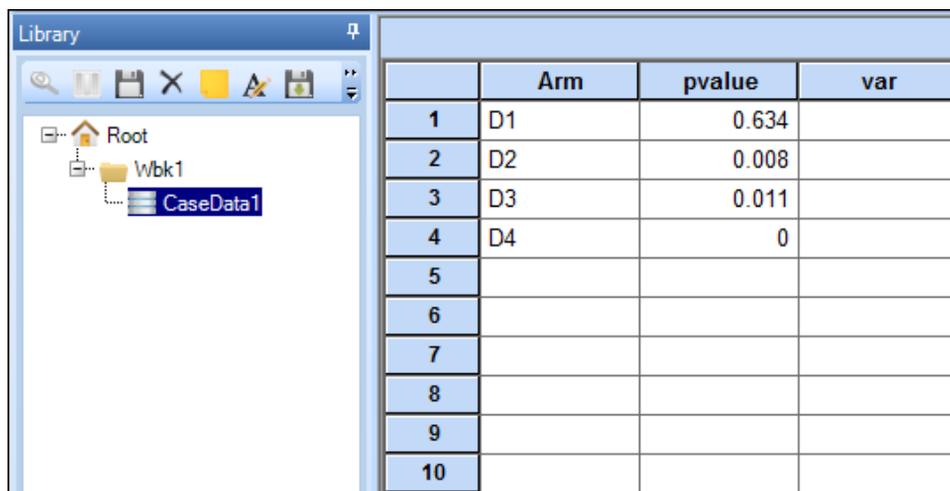

3. Type in **Arm** for **Name** and choose the type of variable as **String**.

97 Analysis-Multiple Comparison Procedures for Survival Data

4. Click **OK** and this will add a column with name **Arm** in the dataset. Similarly, create a numeric column with label **pvalue**. Now, enter the values in the table as follows:

| | Arm | pvalue | var |
|----|-----|--------|-----|
| 1 | D1 | 0.634 | |
| 2 | D2 | 0.008 | |
| 3 | D3 | 0.011 | |
| 4 | D4 | 0 | |
| 5 | | | |
| 6 | | | |
| 7 | | | |
| 8 | | | |
| 9 | | | |
| 10 | | | |

5. East assigns a default name **CaseData1** to this dataset.
6. Choose the menu item:
Analysis > (Continuous) Many Samples > (Multiple Comparisons) Pairwise Comparisons to Controls - Difference of Means
7. This will display several input fields associated with multiple comparison test in the main window. In the **Main tab**, select the radio-button corresponding to **raw p-values**. In the ensuing two boxes, select **Arm** as **Treatment variable** and select **pvalue** for **Select raw p-values**. Choose **Bonferroni** from the drop-down list in **Select MCP**.

Analysis: Continuous Endpoint: Many-Sample Test - Multi-Arm Design - Pairwise Comparisons to Control - Differences of Means

Data Set: CaseData1

The screenshot displays the software's configuration window for a multiple comparison test. It features two tabs: 'Main' and 'Advanced'. Under the 'Main' tab, there are two radio buttons: 'raw Data' (unselected) and 'raw p-values' (selected). Below these are two input sections. The first, 'Treatment Variable', has a dropdown menu set to 'Arm' and a list of options: D1, D2, D3, and D4. The second, 'Raw p-value Variable', has a dropdown menu set to 'pvalue'. To the right, the 'Multiple Comparisons Procedures' section contains a dropdown menu labeled 'Select MCP:' which is set to 'Bonferroni'.

97 Analysis-Multiple Comparison Procedures for Survival Data

8. Click **OK**. The output will be displayed in the main window.

Analysis: Multiple Pairwise Comparisons with Control: Difference of Means

Hypothesis
 $H_i : \mu_i - \mu_0 \leq 0$ Vs. $K_i : \mu_i - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

Input Parameters

Data File: CaseData1
 Treatment Variable: Arm
 Raw p-values variable: pvalue
 Multiple Comparison Procedure: Bonferroni
 Confidence Level: 0.95
 Test Type: t-test
 Rejection Region: Right-Tail

Output

Inference for each Treatment Level versus Control:

| Arm | p-value | |
|-----|---------|----------|
| | Raw | Adjusted |
| D1 | 0.634 | 1 |
| D2 | 0.008 | 0.032 |
| D3 | 0.011 | 0.044 |
| D4 | 0 | 0 |

Adjusted Global p-value: 0
 Total no. of records: 4
 No. of records rejected: 0
 Total Number of Arms (k): 4

The adjusted p-values for D1, D2, D3 and D4 are 1, 0.032, 0.044 and 0.000, respectively. Note that these adjusted p-values are very close to what we have obtained with Bonferroni procedure using the dataset [Hypertension-trial.cyd](#). Ideally, both set of p-values should exactly match. The difference in p-values is only due to rounding error.

A *Introduction to Volume 10*

This volume contains all the Appendices for East 6 manual.

Appendix **B** provides the technical details of the design phase.

Appendix **C** deals with the technical explanation of interim monitoring phase.

Appendix **D** deals with the formulas used for the expected number of events in one treatment arm in various situations. The situations we consider vary from simple ones where the hazard rate is constant, the accrual rate is constant, there are no dropouts and each patient is followed until the end of the study, to complex ones where the survival curve is modeled as a piecewise exponential function with K pieces of variable hazard rates, variable accrual rates, constant non-zero dropout rates and where patients are followed for a fixed duration.

Appendix **E** gives the details of the powerful simulation tools available in East for trials with time-to-event endpoints. The simulations may be used to actually design for non-standard problems where power and sample size calculations are analytically intractable. For instance, East allows the user to simulate trials in which the hazard rates for each treatment arm are non-proportional. By trial and error, running simulations under various parameter choices, the user may find an appropriate design for this kind of trial.

Appendix **F** discusses the technical aspects involved in using spending functions boundaries and Wang-Tsiatis or Pampallona-Tsiatis family boundaries in design and monitoring of trials.

Appendix **G** explains the efficiency achieved by employing the Recursive Integration Algorithm in the computations for the various procedures in East.

Appendix **H** lays out the theory behind multiple comparison procedures like Step-up and Step-down Dunnett's test and other p-value based procedures like Bonferroni, Sidak and some more.

Appendix **I** lays out the theory behind multiple endpoint procedures like Serial Gatekeeping and Parallel Gatekeeping.

Appendix **S** lays out the theory behind East's power and sample size computations in the case of the exact fixed sample test and the exact group sequential test of a proportion π being equal to a constant π_0 .

A Introduction to Volume 10

Appendix **T** lays out the theory behind East's power and sample size computations in the case of the exact McNemar's test for the difference of proportions arising from paired binomial populations.

Appendix **U** lays out the theory behind the two-stage optimal design for phase 2 clinical trials developed by Simon (1989).

Appendix **V** lays out the theory behind exact power and sample size computations for comparing two independent binomials.

Appendix **N** lays out the theory behind the dose escalation procedures like 3+3, CRM, mTPI and BLRM introduced in East 6.3

Appendix **M** lays out the theory behind the subject enrollment and event prediction introduced in East 6.3.

Appendix **Q** lays out the theory behind the designs in **East** and formulas used for calculations. For each test we provide its null hypothesis, test statistic, distribution of the test statistic under null hypothesis.

Appendix **R** lays out the theory and formulas used in **East** for analyzing data under the **Analysis** menu.

Appendix **W** lists down the formulas used in computing classification errors.

Appendix **O** discusses the R Integration feature in simulation module which provides the user the opportunity to perform various tasks using R. In this appendix, we list all tasks for which R functions can be used. We will provide syntax and suggested format for various functions.

Appendix **X** provides a glossary of terms and quantities used in East6.

Appendix **Y** describes the extensive validating procedures carried out on all the features incorporated in East 6 and some earlier versions of East.

Appendix **Z** lists down all the beta testers of East who have given their valuable inputs while developing this software.

B Group Sequential Design in East 6

East provides the software support for a repeated significance testing strategy whereby the accumulating data in a phase-III randomized clinical trial are monitored, and the trial is terminated with early rejection of either the null or the alternative hypothesis if a given test statistic crosses a given stopping boundary. This strategy is executed in two phases – the design phase and the interim monitoring phase. Appendix B provides the technical details of the design phase. Appendix C deals with the interim monitoring phase. A thorough coverage of group-sequential methods for clinical trials is offered at an expository level in the textbook by Jennison and Turnbull (2000). This textbook is an excellent complement to the methods discussed in these appendix chapters and implemented in the East software.

At the design phase the user specifies the statistical process generating the data, the null and alternative hypotheses being tested, the desired type-I error, the power of the sequential testing procedure, the shape parameters for the spending functions or stopping boundaries, the planned number of interim looks, and the timing of the interim looks. East uses these input parameters to generate the appropriate stopping boundaries and to compute the maximum statistical information that would be needed to achieve the desired operating characteristics of the sequential testing procedure. Depending on the end point of the clinical trial, the maximum statistical information might be expressed in terms of the patient accrual, the number of events such as failures or deaths, or an abstract dimensionless quantity termed Fisher information.

We lay the ground work for designing group sequential studies in Section B.1 where we define the test statistic to be monitored and specify its distributional properties. This distribution theory is presented first in terms of a general framework which is then applied to studies with normal, binomial, time to failure and general end points. In Section B.2 we derive the stopping boundaries for various group sequential designs. In Section B.3 we introduce the notion of an inflation factor and show how it can be applied in the General and Information Based designs available in East. In Section B.4 we compute the expected sample size and expected study duration for these group sequential designs.

Although the methodology in this appendix has been developed with reference to two-arm clinical trials, it applies with obvious modifications to the one-sample setting as well. For multi-arm trials in which two or more treatment arms are compared to a common control arm, the two-arm approach can still be applied if supplemented by multiple testing procedures such as Bonferroni or Hochberg. More general situations are handled as special cases of the regression problem discussed in Section B.1.4. In effect one unified approach is adopted for all the group sequential procedures in East.

B Group Sequential Design in East 6

However, since the various cases considered utilize different test statistics for interim monitoring we have provided the formula for each test statistic in Appendix Q.

B.1 Distribution Theory

B.1.1 Normal Data

B.1.2 Binomial Data

B.1.3 Time to Event Data

B.1.4 General Regression Models

Consider a two arm randomized clinical trial comparing an experimental treatment with a control treatment. Let the treatment difference of primary interest be denoted by a single scalar parameter δ . The choice of parameter δ will depend on the model generating the patient response. For normal response, δ might represent the difference of means. For binomial response, δ might represent a difference of proportions, a ratio of proportions, an odds ratio, or a log odds ratio. For time-to-event response, δ might represent a difference of medians, a difference of survival rates at a given time-point, a hazard ratio, or a log hazard ratio. More generally, δ might be the coefficient of the treatment effect in a regression model. Suppose we intend to monitor the accumulating data sequentially up to a maximum of K times thereby gathering, in succession, I_1, I_2, \dots, I_K units of statistical information about δ . In a parametric model I is called the Fisher information. In a semiparametric model, it is called the semiparametric information bound. Since I_K represents the maximum information we could obtain, we will also denote it by I_{\max} . It is convenient to define the information fraction $t_j = I_j/I_{\max}$. For trials with normal or binomial response, I_j is proportional to n_j , the total sample size attained by the j th monitoring time-point, and $t_j = n_j/n_{\max}$. For trials with time-to-event response, I_j is approximately proportional to d_j , the total number of events observed by the j th monitoring time-point. In that case $t_j = d_j/d_{\max}$. One may regard the information fraction $t \in [0, 1]$ as the internal time of the clinical trial.

We assume that at each interim monitoring time-point, t_j , we can obtain an efficient estimate, $\hat{\delta}(t_j)$ for δ , a consistent estimate, $\text{var}[\hat{\delta}(t_j)]$ for the variance of $\hat{\delta}(t_j)$, and the sample size (or number of events) is large enough that

$$I_j^{-1} \approx \text{var}[\hat{\delta}(t_j)].$$

Formally an estimate is efficient if it achieves the Cramer-Rao lower bound for parametric models and the information bound as defined by Bickel et. al. (1993) for semiparametric models. In particular maximum likelihood estimates are efficient. Most estimates produced by standard statistical packages like SAS or S-plus for parametric or semiparametric models are efficient. Scharfstein, Tsiatis and Robins (1997) have shown that, under the above conditions, the joint distribution of the Wald statistics

$$Z(t_j) = \frac{\hat{\delta}(t_j) - \delta_0}{\sqrt{\text{var}[\hat{\delta}(t_j)]}} \tag{B.1}$$

for testing

$$H_0: \delta = \delta_0, \tag{B.2}$$

computed sequentially at information fractions t_1, t_2, \dots, t_K , is asymptotically multivariate normal with

$$E[Z(t_j)] = \eta\sqrt{t_j}, \tag{B.3}$$

$$\text{var}[Z(t_j)] = 1, \tag{B.4}$$

and for any $t_{j_1} < t_{j_2}$,

$$\text{covar}[Z(t_{j_1}), Z(t_{j_2})] = \sqrt{\frac{I_{j_1}}{I_{j_2}}}, \tag{B.5}$$

where

$$\eta = (\delta - \delta_0)\sqrt{I_{\max}} \tag{B.6}$$

is known as the drift parameter. Usually, $\delta_0 = 0$ for superiority trials and $\delta_0 > 0$ for non-inferiority trials.

An alternative way to express this result is in terms of a process of independent increments. Define

$$W(t_j) = \sqrt{t_j}Z(t_j). \tag{B.7}$$

Then the joint distribution of $\{W(t_1), W(t_2), \dots, W(t_K)\}$ is asymptotically multivariate normal with

$$E[W(t_j)] = \eta t_j, \tag{B.8}$$

$$\text{var}[W(t_j)] = t_j \tag{B.9}$$

and

$$\text{covar}[W(t_{j_1}), W(t_{j_2})] = t_{j_1}. \tag{B.10}$$

From this it follows that, for any $t_{j_2} > t_{j_1}$, the random variables $W(t_{j_1})$ and $W(t_{j_2}) - W(t_{j_1})$ are independent. A parallel result has been obtained by Jennison and Turnbull (1997). This important result has three implications.

1. Most clinical trials, including trials with normal, binomial and survival endpoints, utilize test statistics of the form (B.1). Therefore, by the above theorem, the distributional structure of these test statistics after applying the transformation (B.7), is asymptotically the same as that of the $W(t_j)$'s. Thus one may construct group sequential stopping boundaries for the $W(t_j)$ stochastic process, having the property that under $H_0: \eta = 0$ the probability of crossing a boundary is limited to α , the desired type-1 error. These same

B Group Sequential Design in East 6

boundaries will then be applicable to the test statistics developed to monitor trials with normal, binomial or survival endpoints, or even more general endpoints like those available through the information based design module of East. Thereby we can construct a common set of boundaries that are applicable to any type of trial provided the test statistics used for monitoring the trial have the same asymptotic distributional structure as the $W(t_j)$ stochastic process. The details of boundary construction are provided in Section B.2.

2. Having generated the appropriate boundaries one may compute boundary crossing probabilities for the stochastic process $W(t_j)$ under alternative hypotheses of the form $H_1: \eta = \eta_1$. One can thereby search for the value of η_1 at which the boundary crossing probability equals the desired power, $1 - \beta$. By substituting this value of η into equation (B.6) one can estimate I_{\max} , the maximum information needed to attain the desired power $1 - \beta$, at any pre-specified clinically meaningful treatment difference $\delta = \delta_1$. The details of these computations are provided in Section B.2.
3. Because of the independent increments structure of the $W(t_j)$'s it is possible to perform the actual computations that lead to these group sequential stopping boundaries and their crossing probabilities very efficiently by the recursive integration techniques of Armitage, McPherson and Rowe (1969).

The distribution theory developed above is applicable to data generated from any arbitrary probability model in which a single scalar parameter δ characterizes the relationship under investigation. In the remainder of Section B.1 we demonstrate that many different statistical models for generating the data provide us with a test statistic whose distributional structure is asymptotically the same as that of the $W(t_j)$ stochastic process. We first consider two-arm randomized clinical trials with normal, binomial and survival endpoints. We then show how the approach may be generalized to any data generating process in which inference is required for a single scalar parameter estimated by an efficient estimator.

B.1.1 Normal Data

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of a normally distributed outcome variable, X , with means μ_t and μ_c , respectively, and with a common variance σ^2 . We intend to monitor the data up to K times after accruing $n_1, n_2, \dots, n_K \equiv n_{\max}$ patients. The information fraction at the j th look is given by $t_j = n_j/n_{\max}$. Let r denote the fraction randomized to treatment T.

Efficacy Trials

Define the treatment difference to be

$$\delta = \mu_t - \mu_c .$$

The null hypothesis of interest is

$$H_0 : \delta = 0 .$$

We wish to construct a K -look group sequential level- α test of H_0 having $1 - \beta$ power at the alternative hypothesis

$$H_1 : \delta = \delta_1 .$$

Let $\bar{X}_t(t_j)$ and $\bar{X}_c(t_j)$ be the mean responses of the experimental and control groups, respectively, at time t_j . Then

$$\hat{\delta}(t_j) = \bar{X}_t(t_j) - \bar{X}_c(t_j) \tag{B.11}$$

and

$$\text{var}[\hat{\delta}(t_j)] = \frac{\sigma^2}{n_j(r)(1-r)} . \tag{B.12}$$

Therefore, by the Scharfstein, Tsiatis and Robins (1997), Jennison and Turnbull (1997) theorem the stochastic process

$$W(t_j) = \sqrt{t_j} \frac{\bar{X}_t(t_j) - \bar{X}_c(t_j)}{\sqrt{\frac{\sigma^2}{n_j(r)(1-r)}}}, \quad j = 1, 2, \dots, K, \tag{B.13}$$

is $N(\eta t_j, t_j)$ with independent increments, where $\eta = 0$ under H_0 and $\eta = \delta_1 \sqrt{I_{\max}}$ under H_1 . We refer to η as the drift parameter.

Non-Inferiority Trials

Define the treatment difference to be

$$\delta = \mu_t - \mu_c .$$

Let δ_0 be the non-inferiority margin. The null hypothesis of interest is

$$H_0 : \delta = \delta_0 .$$

We wish to construct a K -look group sequential level- α test of H_0 having $1 - \beta$ power at the alternative hypothesis

$$H_1 : \delta = \delta_1 .$$

B Group Sequential Design in East 6

Then, by the Scharfstein, Tsiatis and Robins (1997), Jennison and Turnbull (1997) theorem, the stochastic process

$$W(t_j) = \sqrt{t_j} \frac{\bar{X}_t(t_j) - \bar{X}_c(t_j) - \delta_0}{\sqrt{\frac{\sigma^2}{n_j(r)(1-r)}}, \quad j = 1, 2, \dots, K, \quad (\text{B.14})$$

is $N(\eta t_j, t_j)$ with independent increments, where $\eta = 0$ under H_0 and $\eta = (\delta_1 - \delta_0)\sqrt{I_{\max}}$ under H_1 . We refer to η as the drift parameter.

Note that equation (B.12) implies that

$$I_{\max} = \left[\frac{\sigma^2}{n_{\max}(r)(1-r)} \right]^{-1}, \quad (\text{B.15})$$

for both the efficacy and non-inferiority trials. We shall show in Section B.2 how to estimate the value of I_{\max} needed in order to achieve a desired amount of power. Equation (B.15) is required for converting maximum information, an abstract dimensionless quantity, into maximum sample size, a physical resource that one usually has to specify at the planning stages of the clinical trial. The equation shows that in order to make the translation from I_{\max} to n_{\max} one must know the value of σ^2 , a nuisance parameter.

Test Statistics Used for the Interim Monitoring

The test statistics (B.13) and (B.14) both contain σ^2 , a nuisance parameter whose value is typically unknown. Thus we cannot track the path traced by these statistics in the course of a clinical trial, and cannot know for sure if they have crossed a stopping boundary. In practice therefore we replace σ^2 by its estimate $s^2(t_j)$, at each interim monitoring time-point t_j , when monitoring a clinical trial with normal endpoints. The modified statistics also have the same large sample behavior and independent increment structure as the $W(t_j)$'s. Therefore the operating characteristics of hypothesis tests and confidence intervals derived by tracking the modified statistics will resemble those that would have been obtained by tracking the original statistics.

B.1.2 Binomial Data

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of a binary response variable, X , with response probabilities π_t and π_c for the experimental and control arms, respectively. We intend to monitor the data up to K times after accruing $n_1, n_2, \dots, n_K \equiv n_{\max}$ patients. The information fraction at the j th look is given by $t_j = n_j/n_{\max}$. Let r denote the fraction randomized to treatment T.

Efficacy Trials

Define the treatment difference to be

$$\delta = \pi_t - \pi_c$$

The null hypothesis of interest is

$$H_0 : \delta = 0 .$$

We wish to construct a K -look group sequential level- α test of H_0 having $1 - \beta$ power at the alternative hypothesis

$$H_1 : \delta = \delta_1 .$$

Let $\hat{\pi}_t(t_j)$ and $\hat{\pi}_c(t_j)$ be the maximum likelihood estimates of π_t and π_c , respectively, at time t_j . Then

$$\hat{\delta}(t_j) = \hat{\pi}_t(t_j) - \hat{\pi}_c(t_j) \tag{B.16}$$

and

$$\text{var}[\hat{\delta}(t_j)] = \frac{\pi_t(1 - \pi_t)}{rn_j} + \frac{\pi_c(1 - \pi_c)}{(1 - r)n_j} . \tag{B.17}$$

Therefore, by the Scharfstein, Tsiatis and Robins, Jennison and Turnbull (1997) theorem, the stochastic process

$$W_0(t_j) = \sqrt{t_j} \frac{\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j)}{\sqrt{\frac{\pi_c(1 - \pi_c)}{n_j(r)(1 - r)}}} \tag{B.18}$$

is $N(0, t_j)$ with independent increments, under H_0 . Under H_1 , the stochastic process

$$W_1(t_j) = \sqrt{t_j} \frac{\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j)}{\sqrt{\frac{(\pi_c + \delta_1)(1 - \pi_c - \delta_1)}{rn_j} + \frac{\pi_c(1 - \pi_c)}{(1 - r)n_j}}} \tag{B.19}$$

is $N(\eta t_j, t_j)$ with independent increments, where $\eta = \delta_1 \sqrt{I_{\max}}$ is known as the drift parameter.

Note that equation (B.17) and H_1 together imply that

$$I_{\max} = \left[\frac{(\pi_c + \delta_1)(1 - \pi_c - \delta_1)}{rn_{\max}} + \frac{\pi_c(1 - \pi_c)}{(1 - r)n_{\max}} \right]^{-1} . \tag{B.20}$$

We shall show in Section B.2 how to estimate the value of I_{\max} needed in order to achieve a desired amount of power. Equation (B.20) is required for converting maximum information, an abstract dimensionless quantity, into maximum sample size,

B Group Sequential Design in East 6

a physical resource that one usually has to specify at the planning stages of the clinical trial. The equation shows that in order to make the translation from I_{\max} to n_{\max} one must know the value of π_c , a nuisance parameter.

Non-Inferiority Trials

Define the treatment difference to be

$$\delta = \pi_t - \pi_c .$$

Let the non-inferiority margin be δ_0 . The null hypothesis of interest is

$$H_0 : \delta = \delta_0 .$$

We wish to construct a K -look group sequential level- α test of H_0 having $1 - \beta$ power at the alternative hypothesis

$$H_1 : \delta = \delta_1 .$$

Then, by the Scharfstein, Tsiatis and Robins (1997), Jennison and Turnbull (1997) theorem, the stochastic process

$$W_0(t_j) = \sqrt{t_j} \frac{\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j) - \delta_0}{\sqrt{\frac{(\pi_c - \delta_0)(1 - \pi_c + \delta_0)}{rn_j} + \frac{\pi_c(1 - \pi_c)}{(1 - r)n_j}}} \tag{B.21}$$

is $N(0, t_j)$ with independent increments under H_0 . Under H_1 , the stochastic process

$$W_1(t_j) = \sqrt{t_j} \frac{\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j) - \delta_0}{\sqrt{\frac{(\pi_c - \delta_1)(1 - \pi_c + \delta_1)}{rn_j} + \frac{\pi_c(1 - \pi_c)}{(1 - r)n_j}}} \tag{B.22}$$

is $N(\eta t_j, t_j)$ with independent increments, where $\eta = (\delta_1 - \delta_0)\sqrt{I_{\max}}$ is known as the drift parameter.

Note that equation (B.17) and H_1 together imply that

$$I_{\max} = \left[\frac{(\pi_c - \delta_1)(1 - \pi_c + \delta_1)}{rn_{\max}} + \frac{\pi_c(1 - \pi_c)}{(1 - r)n_{\max}} \right]^{-1} . \tag{B.23}$$

We shall show in Section B.2 how to estimate the value of I_{\max} needed in order to achieve a desired amount of power. Equation (B.23) is required for converting maximum information, an abstract dimensionless quantity, into maximum sample size, a physical resource that one usually has to specify at the planning stages of the clinical trial. The equation shows that in order to make the translation from I_{\max} to n_{\max} one must know the value of π_c , a nuisance parameter.

Test Statistics Used for the Interim Monitoring

The test statistics (B.18), (B.19), (B.21) and (B.22) all contain π_c , an unknown nuisance parameter. Therefore, in practice, modified test statistics, whose values can be computed from the interim data, are used to track the progress of the trial and determine if a stopping boundary has been crossed.

1. For superiority trials East provides two options in the choice of test statistic to be used during interim monitoring. The default assumption is that the test statistic

$$\tilde{W}_s(t_j) = \sqrt{t_j} \frac{\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j)}{\sqrt{\frac{\hat{\pi}_t(t_j)(1-\hat{\pi}_t(t_j))}{n_{tj}} + \frac{\hat{\pi}_c(t_j)(1-\hat{\pi}_c(t_j))}{n_{cj}}}}, \quad (\text{B.24})$$

will be used for the interim monitoring, where n_{tj} and n_{cj} are the sample sizes on the treatment and control arms, respectively, at monitoring time-point t_j .

Asymptotically, $\tilde{W}_s(t_j)$ behaves like (B.18) under H_0 and behaves like (B.19) under H_1 . Thus in either case $\tilde{W}_s(t_j)$ has the same asymptotic behavior as the $N(\eta t_j, t_j)$ stochastic process with independent increments. Therefore the operating characteristics of hypothesis tests and confidence intervals derived by tracking $\tilde{W}_s(t_j)$ will resemble those that would have been obtained by tracking the (B.18) under H_0 and tracking (B.19) under H_1 .

An alternative choice for the test statistic to be used during the interim monitoring phase is

$$\tilde{W}_{0s}(t_j) = \sqrt{t_j} \frac{\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j)}{\sqrt{\frac{\hat{\pi}(t_j)(1-\hat{\pi}(t_j))}{n_j(r)(1-r)}}}, \quad (\text{B.25})$$

where $\hat{\pi}(t_j)$, the **pooled** estimate of the binomial response probability at time t_j , is given by

$$\hat{\pi}(t_j) = \frac{n_{tj}\hat{\pi}_t(t_j) + n_{cj}\hat{\pi}_c(t_j)}{n_j}. \quad (\text{B.26})$$

The denominator of (B.25) is an estimate of the standard error of $\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j)$ under the null hypothesis H_0 : $\delta = 0$. Therefore $\tilde{W}_{0s}(t_j)$ behaves asymptotically like (B.18) under H_0 . However, unlike $\tilde{W}_s(t_j)$, it does not behave like (B.19) under H_1 . For this reason, as we shall show in Section B.2.5, the maximum information I_{\max} , required to attain any given power $1 - \beta$, differs by whether the unpooled statistic $\tilde{W}_s(t_j)$ or the pooled statistic $\tilde{W}_{0s}(t_j)$ is used for interim monitoring.

2. For non-inferiority trials we use the test statistic

$$\tilde{W}_{ni}(t_j) = \sqrt{t_j} \frac{\hat{\pi}_t(t_j) - \hat{\pi}_c(t_j) - \delta_0}{\sqrt{\frac{\hat{\pi}_t(t_j)(1-\hat{\pi}_t(t_j))}{n_{tj}} + \frac{\hat{\pi}_c(t_j)(1-\hat{\pi}_c(t_j))}{n_{cj}}}}, \quad (\text{B.27})$$

B Group Sequential Design in East 6

where n_{tj} and n_{cj} are the sample sizes on the treatment and control arms, respectively, at monitoring time-point t_j . Asymptotically, $\tilde{W}_{ni}(t_j)$ behaves like (B.21) under H_0 and behaves like (B.22) under H_1 . Thus in either case $\tilde{W}_{ni}(t_j)$ has the same asymptotic behavior as the $N(\eta t_j, t_j)$ stochastic process with independent increments. Therefore the operating characteristics of hypothesis tests and confidence intervals derived by tracking $\tilde{W}_{ni}(t_j)$ will resemble those that would have been obtained by tracking the (B.21) under H_0 and tracking (B.22) under H_1 .

B.1.3 Time to Event Data

Consider a randomized clinical trial comparing two treatments, T and C, on the basis of time to event data. Let the fraction of patients randomized to treatment T be r . We intend to monitor the data up to K times at calendar times l_1, l_2, \dots, l_K . At calendar time l_j let there be q_j distinct failures, with corresponding failure times denoted by $\tau_1(l_j), \tau_2(l_j), \dots, \tau_{q_j}(l_j)$ (on the patient follow-up time-scale, not the calendar time-scale). At the i th of these q_j failure times let $d_t(\tau_i(l_j))$ be the number of failures on treatment T, $n_t(\tau_i(l_j))$ be the number of subjects on treatment T at risk of failure, $d_c(\tau_i(l_j))$ be the number of failures on treatment C, and $n_c(\tau_i(l_j))$ be the number of subjects on treatment C at risk of failure. The data at calendar time l_j may thus be represented as $q_j \times 2$ contingency tables, where the i th table is of the form

| Status | Treatment T | Treatment C | Total |
|------------|---------------------------------------|---------------------------------------|-----------------------------------|
| Failed | $d_t(\tau_i(l_j))$ | $d_c(\tau_i(l_j))$ | $d(\tau_i(l_j))$ |
| Not Failed | $n_t(\tau_i(l_j)) - d_t(\tau_i(l_j))$ | $n_c(\tau_i(l_j)) - d_c(\tau_i(l_j))$ | $n(\tau_i(l_j)) - d(\tau_i(l_j))$ |
| Total | $n_t(\tau_i(l_j))$ | $n_c(\tau_i(l_j))$ | $n(\tau_i(l_j))$ |

Efficacy Trials

The logrank score statistic $S(l_j)$, at calendar time l_j , is obtained by summing the observed minus the expected values in cell (1, 1) of the above collection of $q_j \times 2$ tables:

$$S(l_j) = - \sum_{i=1}^{q_j} \left\{ d_t(\tau_i(l_j)) - \frac{n_t(\tau_i(l_j)) \times d(\tau_i(l_j))}{n(\tau_i(l_j))} \right\}. \quad (\text{B.28})$$

If treatments T and C have the same underlying distribution, it is well known (see for example, Mantel, 1966) that the marginal distribution of $S(l_j)$ is asymptotically normal with a mean of zero and with variance equal to the sum of hypergeometric

variances across all the tables:

$$\text{var}[S(l_j)] = \sum_{i=1}^{q_j} \frac{n_t(\tau_i(l_j)) \times n_c(\tau_i(l_j)) \times d(\tau_i(l_j)) \times [n(\tau_i(l_j)) - d(\tau_i(l_j))]}{[n(\tau_i(l_j))]^2 [n(\tau_i(l_j)) - 1]} . \tag{B.29}$$

The above variance cannot be used for designing a time-to-event trial, however, since it depends on quantities that cannot be estimated a priori. However, the asymptotic distribution of $S(l_j)$ under proportional hazard alternatives was reduced to a simpler form suitable for designing time-to-event trials by Schoenfeld (1981). Specifically, let $\lambda_t(\tau)$ and $\lambda_c(\tau)$ be the hazard functions for treatment T and treatment C, respectively. Assume that the ratio of hazard functions is constant for all values of τ and define the treatment difference as

$$\delta = \ln \frac{\lambda_t(\tau)}{\lambda_c(\tau)} .$$

Let the total number of failures observed by calendar time l_j be

$$D(l_j) = \sum_{i=1}^{q_j} d(\tau_i(l_j)) ,$$

and let r denote the proportion randomized to treatment T. Then, for $j = 1, 2, \dots, K$, $S(l_j)$ is asymptotically normal with

$$E[S(l_j)] = \delta D(l_j) r (1 - r) , \tag{B.30}$$

$$\text{var}[S(l_j)] = D(l_j) r (1 - r) . \tag{B.31}$$

Tsiatis (1981) proved that the sequentially computed logrank score statistics $S(l_1), S(l_2), \dots, S(l_K)$ have independent increments. That is, and for any $j_2 > j_1$, $S(l_{j_1})$ and $S(l_{j_2}) - S(l_{j_1})$ are independent. The independent increments property and the asymptotic normality of $S(l_j)$ makes it possible to design group sequential trials by the same methods as are used to design group sequential trials with normal endpoints, as we now show.

We wish to test the null hypothesis

$$H_0: \delta = 0$$

versus the alternative hypothesis

$$H_1: \delta = \delta_1 .$$

B Group Sequential Design in East 6

In performing this hypothesis test it is useful to transform the stochastic process $S(l_j)$, $j = 1, 2, \dots, K$, from a process defined on the calendar time l_j , to a process defined on the information fraction

$$t_j = \frac{D(l_j)}{D(l_K)} \equiv \frac{D(l_j)}{D_{\max}} .$$

Thus we define

$$W(t_j) = \frac{S(l_j)}{\sqrt{r(1-r)D_{\max}}} . \tag{B.32}$$

Now, since the variance of $S(l_j)$ is also the Fisher information for δ at the monitoring time l_j (Jennison and Turnbull, 2000, page 78), it follows that the Fisher information at the final monitoring time l_K is given by

$$I_{\max} = \text{var}[S(l_K)] = r(1-r)D_{\max} . \tag{B.33}$$

Therefore $W(t_j) \sim N(\eta t_j, t_j)$ with independent increments, where $\eta = 0$ under H_0 and $\eta = \delta_1 \sqrt{I_{\max}}$ under H_1 . We refer to η as the drift parameter. We shall show in Section B.2 how to estimate the value of I_{\max} needed in order to achieve a desired amount of power. Equation (B.33) establishes the relationship between maximum information, an abstract dimensionless quantity, and the maximum number of events, a physical resource that one usually has to specify at the planning stages of the clinical trial. Notice that D_{\max} plays the same role in a time-to-event trial that N_{\max} plays in a normal endpoint trial.

As an alternative to computing $W(t_j)$ by equation (B.32) one may compute

$$Z(t_j) = \frac{\hat{\delta}(t_j)}{\sqrt{\text{var}(\hat{\delta}(t_j))}} \tag{B.34}$$

where $\hat{\delta}(t_j)$ and its standard error are obtained by fitting a Cox proportional hazards model to the data. Then $\sqrt{t_j}Z(t_j)$ has the same asymptotic distribution as $W(t_j)$.

Non-Inferiority Trials

For non-inferiority trials we again define the treatment difference as

$$\delta = \ln \frac{\lambda_t(\tau)}{\lambda_c(\tau)} . \tag{B.35}$$

Now, however, we are interested in testing the null hypothesis

$$H_0: \delta = \delta_0 ,$$

against the alternative hypothesis

$$H_1: \delta = \delta_1 .$$

where δ_0 is the non-inferiority margin. Accordingly we derive the logrank statistic $S(l_j)$ from the score equations evaluated at $\delta = \delta_0$ (see, for example, Collett, 1994, page 105) so that

$$S(l_j) = \sum_{i=1}^{q_j} \left\{ d_t(\tau_i(l_j)) - \frac{d(\tau_i(l_j)) \times n_t(\tau_i(l_j)) \exp(-\delta)}{n_t(\tau_i(l_j)) \exp(-\delta) + n_c(\tau_i(l_j))} \right\} \quad (\text{B.36})$$

and the variance of this statistic is

$$\text{var}[S(l_j)] = \sum_{i=1}^{q_j} \left\{ \frac{d(\tau_i(l_j)) \times n_t(\tau_i(l_j)) \exp(-\delta) \times n_c(\tau_i(l_j))}{(n_t(\tau_i(l_j)) \exp(-\delta) + n_c(\tau_i(l_j)))^2} \right\} . \quad (\text{B.37})$$

By extending Schoenfeld's (1981) results to this setting we can show that $S(l_j)$ is asymptotically normal with

$$E(S(l_j)) = (\delta - \delta_0)D(l_j)r(1 - r) , \quad (\text{B.38})$$

$$\text{var}[S(l_j)] = D(l_j)r(1 - r) . \quad (\text{B.39})$$

Also it can be shown by application of Martingale results derived from counting processes (L.J.Wei, 2005; personal communication) that the sequentially computed non-central logrank score statistics $S(l_1), S(l_2), \dots, S(l_K)$ have independent increments. Define

$$W(t_j) = \frac{S(l_j)}{\sqrt{\text{var}[S(l_K)]}} . \quad (\text{B.40})$$

Then, asymptotically, $W(t_j) \sim N(\eta t_j, t_j)$ with independent increments, where $\eta = 0$ under H_0 , $\eta = (\delta_1 - \delta_0)\sqrt{I_{\max}}$ under H_1 , and

$$I_{\max} = \text{var}[S(l_K)] = r(1 - r)D_{\max} . \quad (\text{B.41})$$

We refer to η as the drift parameter. We shall show in Section B.2 how to estimate the value of I_{\max} needed in order to achieve a desired amount of power. Equation (B.41) is required for converting maximum information, an abstract dimensionless quantity, into the maximum number of events, a physical resource that one usually has to specify at the planning stages of the clinical trial.

B Group Sequential Design in East 6

As an alternative to computing $W(t_j)$ by equation (B.40) one may compute

$$Z(t_j) = \frac{\hat{\delta}(t_j) - \delta_0}{\sqrt{\text{var}(\hat{\delta}(t_j))}} \tag{B.42}$$

where $\hat{\delta}(t_j)$ and its standard error are obtained by fitting a Cox proportional hazards model to the data. Then $\sqrt{t_j}Z(t_j)$ has the same asymptotic distribution as $W(t_j)$.

B.1.4 General Regression Models

Consider any general regression model including, for example, the linear regression model, the Cox proportional hazards model, the logistic regression model, and the random effects model for longitudinal data. Let δ be the single scalar coefficient of this model that characterizes the treatment effect of interest. (The case where δ is a vector is not considered in this development.) Let $\tau_1, \tau_2, \dots, \tau_K$ denote K monitoring time-points of calendar time. Let $\hat{\delta}(\tau_j)$ be an efficient estimator of δ , $\text{se}(\hat{\delta}(\tau_j))$ be its standard error and

$$Z(\tau_j) = \frac{\hat{\delta}(\tau_j) - \delta_0}{\text{se}(\hat{\delta}(\tau_j))}$$

be the Wald test statistic, based on all the data available at time τ_j . Let $I(\tau_j)$ be the statistical (or Fisher) information about δ available at time τ_j . The quantity $I(\tau_j)$ is estimated by $[\text{se}(\hat{\delta}(\tau_j))]^{-2}$. At any time τ_j we define the information fraction

$$t_j = \frac{I(\tau_j)}{I(\tau_K)} \approx \frac{[\text{se}(\hat{\delta}(\tau_j))]^{-2}}{[\text{se}(\hat{\delta}(\tau_K))]^{-2}}$$

and compute the test statistic

$$W(t_j) = \sqrt{t_j}Z(\tau_j) .$$

Then, using results derived by Scharfstein, Tsiatis and Robins (1997), Jennison and Turnbull (1997), we can show that

$$W(t_j) \sim N(\eta t_j, t_j) , \tag{B.43}$$

where

$$\eta = (\delta - \delta_0)\sqrt{I(\tau_K)} , \tag{B.44}$$

and for any $t_{j'} > t_j$,

$$\text{covar}\{W(t_j), W(t_{j'})\} = t_j . \tag{B.45}$$

This general result encompasses all situations in which group sequential inference is desired for a single scalar parameter δ and where an efficient estimator for δ exists. East provides the option to design and monitor studies within this general framework through its information based approach discussed in Chapter 59.

B.2 Stopping Boundaries and Maximum Information

B.2.1 Haybittle-Peto Boundaries

B.2.2 W-T Power Boundaries

B.2.3 P-T Power Boundaries

B.2.4 Spending Function Boundary

B.2.5 Special Considerations

Suppose we plan to monitor the study a maximum of K times at information fractions t_1, t_2, \dots, t_K . Let the desired type-1 error be α . In this section we show how to compute the following quantities:

1. One- and two-sided boundaries for early stopping to reject the null hypothesis $H_0: \delta = \delta_0$;
2. One- and two-sided boundaries for early stopping to reject either the null hypothesis $H_0: \delta = \delta_0$ or the alternative hypothesis $H_1: \delta = \delta_1$;
3. One- and two-sided boundaries for early stopping to reject only the alternative hypothesis $H_1: \delta = \delta_1$ (also known as futility boundaries);
4. I_{\max} , the maximum information needed to achieve a power of $1 - \beta$ at the alternative hypothesis $H_1: \delta = \delta_1$.

All computations will be performed for the process of independent increments $W(t_j) \sim N(\eta t_j, t_j)$. We have seen in Section B.1 that a very large class of group sequential tests, including all those available in East, are represented by this stochastic process. Hypotheses about δ , the primary parameter of interest, can be converted into corresponding hypotheses about η by the relationship (B.6). Once stopping boundaries have been obtained for the $W(t_j)$ statistic they can readily be transformed into corresponding stopping boundaries for the Wald statistic $Z(t_j)$ because of the relationship $W(t_j) = \sqrt{t_j} Z(t_j)$ implied by equation (B.1). Boundaries in East are represented primarily in terms of the Wald statistic.

Three classes of stopping boundaries are available in East: p-value boundaries – also known as Haybittle-Peto boundaries; power boundaries – also known as Wang-Tsiatis or Pampallona-Tsiatis boundaries; spending function boundaries. Each class is discussed separately below.

B.2.1 P-Value or Haybittle-Peto Boundaries

P-value or Haybittle-Peto boundaries are available for early rejection of the null hypothesis. As first proposed by Haybittle (1971), these boundaries are derived by pre-specifying a small p-value, p_1 say, as the stopping criterion for the first $K - 1$ interim analyses and then computing a final p-value, p_2 say, for declaring statistical significance at the last look in such a way that the overall type-1 error is α . Let z_p denote the upper p th quantile of the standard normal distribution; i.e., $1 - \Phi(z_p) = p$. The trial stops at the first interim look that the p-value is less than or equal to p_1 . If this event does not occur, the trial proceeds to the K th look and statistical significance is declared if the final p-value is less than or equal to p_2 . For one-sided tests, the value of

B Group Sequential Design in East 6

p_2 needed to preserve the type-1 error is obtained by solving the equation

$$1 - P_0(W(t_1) < \sqrt{t_1}z_{p_1}, \dots, W(t_{K-1}) < \sqrt{t_{K-1}}z_{p_1}, W(t_K) < z_{p_2}) = \alpha, \quad (\text{B.46})$$

where $P_0(\cdot)$ denotes probability under the assumption that $\eta = 0$. The solution is obtained by numerical search using the recursive integration method of Armitage, McPherson and Rowe (1969) (the AMR algorithm) discussed in Appendix G. Once the value of p_2 has been determined, the maximum information is obtained by invoking the AMR algorithm repeatedly and searching for the value of η at which

$$P_\eta(W(t_1) < \sqrt{t_1}z_{p_1}, \dots, W(t_{K-1}) < \sqrt{t_{K-1}}z_{p_1}, W(t_K) < z_{p_2}) = \beta. \quad (\text{B.47})$$

Denote the solution by η_1 . Then, by (B.6) the desired maximum information I_{\max} is

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

To obtain Haybittle-Peto stopping boundaries for two-sided tests, replace $W(t_j)$ by $|W(t_j)|$ throughout equations (B.46) and (B.47).

In East 6, we have generalized the Haybittle-Peto stopping boundaries to accommodate unequal p-values at each look. Consider a K -look design where we pre-specify small p-values p_1, \dots, p_{K-1} as stopping criteria for each of the first $K - 1$ interim looks at the data. We would now like to compute a final p-value p_K for declaring statistical significance in such a way as to preserve the overall type-1 error α . This is achieved by solving the equation

$$1 - P_0(W(t_1) < \sqrt{t_1}z_{p_1}, \dots, W(t_{K-1}) < \sqrt{t_{K-1}}z_{p_{K-1}}, W(t_K) < z_{p_K}) = \alpha, \quad (\text{B.48})$$

Where $P_0(\cdot)$ denotes probability under the assumption that $\eta = 0$. The solution is obtained by numerical search using the recursive integration method of Armitage,

McPherson and Rowe (1969) (the AMR algorithm) discussed in Appendix G. Once the value of p_K has been determined, the maximum information is obtained by invoking the AMR algorithm repeatedly and searching for the value of η at which

$$P_\eta(W(t_1) < \sqrt{t_1}z_{p_1}, \dots, W(t_{K-1}) < \sqrt{t_{K-1}}z_{p_{K-1}}, W(t_K) < z_{p_K}) = \beta. \quad (\text{B.49})$$

Denote the solution by η_1 . Then, by (B.6) the desired maximum information I_{\max} is

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

B.2.2 Wang-Tsiatis Power Boundaries

The power boundaries of Wang and Tsiatis (1987) are available for early rejection of the null hypothesis. These boundaries are of the form

$$c(t_j) = C(\Delta, \alpha, K)t_j^\Delta \quad (\text{B.50})$$

for $j = 1, 2, \dots, K$, where Δ is a shape parameter that characterizes the boundary shape and $C(\Delta, \alpha, K)$ is a positive constant indexed by Δ, α and K . The choice $\Delta = 0$ yields the O'Brien-Fleming (1979) stopping boundaries while $\Delta = 0.5$ yields the Pocock stopping boundaries. More generally Wang and Tsiatis (1987) explore this family to find the value of Δ that minimizes the expected sample size for various design specifications. For one-sided tests, the trial stops at the first interim look that $W(t_j) \geq c(t_j)$. Therefore, in order to preserve the type-1 error the boundaries must satisfy

$$1 - P_0\left\{ \bigcap_{j=1}^K W(t_j) < c(t_j) \right\} = \alpha. \quad (\text{B.51})$$

Since, by equation (B.50), the boundary values $c(t_1), c(t_2), \dots, c(t_K)$ are completely specified by $C(\Delta, \alpha, K)$, this constant can be evaluated by numerical search for any

B Group Sequential Design in East 6

choice of Δ , α and K using the AMR algorithm. Once the boundaries have been determined the maximum information is obtained by again invoking the AMR algorithm, this time to find the value of η that satisfies the type-2 error equation

$$P_{\eta}\left\{\bigcap_{j=1}^K W(t_j) < c(t_j)\right\} = \beta. \tag{B.52}$$

Denote the solution by η_1 . Then, by (B.6) the desired maximum information I_{\max} is

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0}\right]^2.$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

To obtain Wang-Tsiatis stopping boundaries for two-sided tests, replace $W(t_j)$ by $|W(t_j)|$ throughout equations (B.51) and (B.52).

B.2.3 Pampallona-Tsiatis Power Boundaries

The power boundaries of Pampallona and Tsiatis (1994) are available for early rejection of either H_0 or H_1 . It is convenient to discuss the one-sided and two-sided tests separately for these boundaries.

One-Sided Tests

There are two stopping boundaries for these designs; an “upper” stopping boundary for early rejection of H_0 and a “lower” stopping boundary for early rejection of H_1 . We reject H_0 in favor of H_1 the first time we encounter an information fraction t_j such that

$$W(t_j) \geq C_1(\Delta_1, \alpha, \beta, K)t_j^{\Delta_1} \text{ (upper boundary) ,}$$

and reject H_1 in favor of H_0 the first time we encounter an information fraction t_j such that

$$W(t_j) < \eta t_j - C_2(\Delta_2, \alpha, \beta, K)t_j^{\Delta_2} \text{ (lower boundary) ,}$$

where $C_1(\Delta_1, \alpha, \beta, K)$ and $C_2(\Delta_2, \alpha, \beta, K)$ are positive and indexed by shape parameters, Δ_1 and Δ_2 , that might take different values. We impose the additional constraint

$$C_1(\Delta_1, \alpha, \beta, K) = \eta - C_2(\Delta_2, \alpha, \beta, K)$$

so as to force the boundaries to meet at the last look, thereby ensuring that a decision to reject either of the two hypotheses will indeed be made. The upper and lower stopping boundaries thus form a triangular continuation region.

We wish these stopping boundaries to have the property that at the null hypothesis, $\delta = 0$, we will cross the upper stopping boundary with probability α , but at the specific alternative hypothesis of interest, say $\delta = \delta_1$, we will cross the upper stopping boundary with probability $1 - \beta$ and the lower stopping boundary with probability β . The coefficients $C_1(\Delta_1, \alpha, \beta, K)$ and $C_2(\Delta_2, \alpha, \beta, K)$ are found using a two-dimensional search to simultaneously solve the two equations corresponding to the desired type-1 and type-2 errors of the test:

$$P_0(W(t_1) \geq u_1) + P_0(l_1 < W(t_1) < u_1, W(t_2) \geq u_2) + \dots \\ \dots + P_0(l_1 < W(t_1) < u_1, \dots, l_{K-1} < W(t_{K-1}) < u_{K-1}, W(t_K) \geq u_K) = \alpha$$

and

$$P_\eta(W(t_1) \leq l_1) + P_\eta(l_1 < W(t_1) < u_1, W(t_2) \leq l_2) + \dots \\ \dots + P_\eta(l_1 < W(t_1) < u_1, \dots, l_{K-1} < W(t_{K-1}) < u_{K-1}, W(t_K) \leq l_K) = \beta$$

where

$$u_j = C_1(\Delta_1, \alpha, \beta, K)t_j^{\Delta_1}$$

and

$$l_j = \eta t_j - C_2(\Delta_2, \alpha, \beta, K)t_j^{\Delta_2}$$

for $j = 1, 2, \dots, K$. The parameter η is determined simultaneously along with $C_1(\Delta_1, \alpha, \beta, K)$ and $C_2(\Delta_2, \alpha, \beta, K)$ through the relationship

$$\eta = C_1(\Delta_1, \alpha, \beta, K) + C_2(\Delta_2, \alpha, \beta, K) . \tag{B.53}$$

Denote the solution by η_1 . Then, by (B.6) the desired maximum information I_{\max} is

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

Two-Sided Tests

The two-sided test is based on a pair of outer boundaries for early rejection of H_0 plus an inner wedge for early rejection of H_1 . These tests reject H_0 in favor of H_1^+ : $\delta > 0$ if

$$W(t_j) \geq C_1(\Delta_1, \alpha, \beta, K)t_j^{\Delta_1} \quad (\text{top outer boundary}) ,$$

reject H_0 in favor of H_1^- : $\delta < 0$ if

$$W(t_j) \leq -C_1(\Delta_1, \alpha, \beta, K)t_j^{\Delta_1} \quad (\text{bottom outer boundary}) ,$$

B Group Sequential Design in East 6

and reject $H_1: \delta \neq 0$ if

$$C_2(\Delta_2, \alpha, \beta, K)t_j^{\Delta_2} - \eta t_j \leq W(t_j) \leq \eta t_j - C_2(\Delta_2, \alpha, \beta, K)t_j^{\Delta_2} \quad \text{.(inner wedge)}$$

The boundaries for these tests jointly form two symmetric triangular continuation regions with outer regions for stopping to reject H_0 and an inner wedge for stopping to reject H_1 . The boundaries are required to have the property that, under $H_0: \delta = 0$, the overall probability of crossing either of the two outer boundaries is α , while for the specific alternative of interest, $\delta = \delta_1$ say, the overall probability of crossing either outer boundaries is $1 - \beta$ and the probability of entering the inner wedge is β . Again we will impose the constraint

$$C_1(\Delta_1, \alpha, \beta, K) = \eta - C_2(\Delta_2, \alpha, \beta, K)$$

so that in the end a decision to reject one of the two hypotheses is reached. Notice that the inner wedge is undefined at information fractions t_j such that

$$C_2(\Delta_2, \alpha, \beta, K)t_j^{\Delta_2} - \eta t_j > \eta t_j - C_2(\Delta_2, \alpha, \beta, K)t_j^{\Delta_2} .$$

Therefore it will not be possible to stop the trial with rejection of H_1 at the j th information fraction unless the trial has progressed sufficiently far so that

$$t_j \geq \left[\frac{C_2(\Delta_2, \alpha, \beta, K)}{\eta} \right]^{\frac{1}{1-\Delta_2}} . \tag{B.54}$$

With this in mind we will find it convenient to set $t_j = -\infty$ whenever t_j fails to satisfy the condition (B.54).

Computing Maximum Information The above computations show that the Wang-Tsiatis and Pampallona-Tsiatis boundaries are generated simultaneously with the drift parameter η needed to achieve $1 - \beta$ power. Denote the solution by η_1 . Then, by (B.6) the desired maximum information I_{\max} is

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

B.2.4 Spending Function Boundaries

The most general way to generate stopping boundaries is through α and β spending

functions where α and β are, respectively, the type-1 and type-2 errors pre-specified for the trial. An α spending function is any monotone function defined on the unit interval with $\alpha(0) = 0$ and $\alpha(1) = \alpha$. Similarly a β spending function is any monotone function defined on the unit interval with $\beta(0) = 0$ and $\beta(1) = \beta$. The idea of using an α spending function to derive stopping boundaries for early rejection of H_0 was first introduced by Lan and DeMets (1983). Subsequently Pampallona, Tsiatis and Kim (1995) (2001) developed the notion of a β spending function to derive stopping boundaries for early rejection of H_1 . One may either use the α - and β - spending functions singly, or combine both α - and β -spending in a single trial, with one-sided or two-sided, symmetric or asymmetric boundaries.

Below we list and briefly describe all the α - and β -spending functions available in East. We give all the functional forms in terms of $\alpha(t)$ but it is understood that these functional forms also apply to $\beta(t)$.

LD (OF) Lan-DeMets spending function with O'Brien-Fleming flavor. Published by Lan and DeMets (Biometrika, 1983). Functional form:

$$\alpha(t) = \begin{cases} 2 - 2\Phi\left(\frac{z_{\alpha/2}}{\sqrt{t}}\right) & \text{for one-sided tests} \\ 4 - 4\Phi\left(\frac{z_{\alpha/4}}{\sqrt{t}}\right) & \text{for two-sided tests} \end{cases}$$

This function generates stopping boundaries that closely resemble the O'Brien-Fleming (1979) stopping boundaries.

LD (PK) Lan-DeMets spending function with Pocock flavor. Published by Lan and DeMets (Biometrika, 1983). Functional form:

$$\alpha(t) = \alpha \ln\{1 + (e - 1)t\} .$$

This function generates stopping boundaries that closely resemble the Pocock (1977) stopping boundaries.

Gm (γ) Gamma spending function. Published by Hwang, Shih and DeCani (Statistics in Medicine, 1990). Functional Form:

$$\alpha(t) = \begin{cases} \alpha \frac{(1 - e^{-\gamma t})}{(1 - e^{-\gamma})}, & \text{if } \gamma \neq 0 \\ \alpha t & \text{if } \gamma = 0 . \end{cases}$$

Negative values of γ yield convex spending functions that increase in conservatism as γ decreases, while positive values of γ yield concave spending functions that increase in aggressiveness as γ increases. The choice $\gamma = 0$ spends the error linearly. The choice $\gamma = -4$ produces stopping boundaries that resemble the O'Brien-Fleming boundaries. The choice $\gamma = 1$ produces stopping boundaries that resemble the Pocock boundaries.

B Group Sequential Design in East 6

Rho (ρ) Rho spending function. First published by Kim and DeMets (Biometrika, 1987) and generalized by Jennison and Turnbull (2000). Functional form:

$$\alpha(t) = at^\rho, \rho > 0.$$

When $\rho = 1$, the corresponding stopping boundaries resemble the Pocock stopping boundaries. When $\rho = 3$, the boundaries resemble the O'Brien-Fleming boundaries. Larger values of ρ yield increasingly conservative boundaries.

Power Documented in the East 3 User Manual, Appendix B and C (Cytel Software Corporation, 2000). Obtained by inverting 10-look Wang-Tsiatis (1987) stopping boundaries at ten equally spaced intervals and fitting a smooth curve through the ten points.

In the following paragraphs, we provide the technical details for generating a stopping boundary from a spending function. We assume throughout that the study is designed for a total of K looks at the information fractions t_1, t_2, \dots, t_K . A one sided test is assumed for simplicity. The extension to two-sided tests follows readily by replacing $W(t_j)$ throughout by $|W(t_j)|$.

Boundaries and Maximum Information for Early Rejection of H_0 Only

The boundaries are computed recursively, with $c(t_j)$ being based on the values of $c(t_l)$, $l = 1, 2, \dots, j - 1$. For the first look, at information fraction t_1 , find the upper boundary $c(t_1)$ such that

$$P_0(W(t_1) \geq c(t_1)) = \alpha(t_1) . \tag{B.55}$$

For subsequent looks $j = 2, 3, \dots, K$, having already computed the upper boundaries $c(t_1), c(t_2), \dots, c(t_{j-1})$, find the upper boundary $c(t_j)$ such that

$$\alpha(t_{j-1}) + P_0(W(t_1) < c(t_1), \dots, W(t_{j-1}) < c(t_{j-1}), W(t_j) \geq c(t_j)) = \alpha(t_j) . \tag{B.56}$$

These computations are performed by the AMR algorithm. Once the boundaries have been determined the maximum information is obtained by again invoking the AMR algorithm, this time to find the value of η that satisfies the type-2 error equation

$$P_\eta\left\{\bigcap_{j=1}^K W(t_j) < c(t_j)\right\} = \beta . \tag{B.57}$$

Denote the solution by η_1 . Then, by (B.6) the desired maximum information I_{\max} is

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0}\right]^2$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

To obtain spending function boundaries for symmetric two-sided tests, replace $W(t_j)$ by $|W(t_j)|$ throughout equations (B.56) and (B.57).

Two-Sided Asymmetric Boundaries for Early Rejection of H_0 Only

Suppose one wishes to split the total type-1 error, α , of a two-sided test into two components α_l and α_u , with $\alpha_l + \alpha_u = \alpha$ in such a way that the probability, under the null hypothesis, of crossing the upper (lower) boundary is α_u (α_l). Denote the critical values of the two-sided boundary at interim monitoring time t_j by $(a(t_j), b(t_j))$, $j = 1, 2, \dots, K$. These boundary values are obtained by inverting corresponding spending function values $(\alpha_l(t_j), \alpha_u(t_j))$, $j = 1, 2, \dots, K$, as follows. For the first look, at information fraction t_1 , find the lower boundary $a(t_1)$ such that

$$P_0(W(t_1) \leq a(t_1)) = \alpha_l(t_1) , \tag{B.58}$$

B Group Sequential Design in East 6

and the upper boundary $b(t_1)$ such that

$$P_0(W(t_1) \geq b(t_1)) = \alpha_u(t_1) . \tag{B.59}$$

For subsequent looks $j = 2, 3, \dots, K$, having already computed the boundaries $\{(a(t_1), b(t_1)), (a(t_2), b(t_2)), \dots, (a(t_{j-1}), b(t_{j-1}))\}$ compute $(a(t_j), b(t_j))$ such that $\alpha_l(t_{j-1}) + P_0(a(t_1) < W(t_1) < b(t_1), \dots, a(t_{j-1}) < W(t_{j-1}) < b(t_{j-1}), W(t_j) \leq a(t_j)) = \alpha_l(t_j)$ (B.60)

and

$$\alpha_u(t_{j-1}) + P_0(a(t_1) < W(t_1) < b(t_1), \dots, a(t_{j-1}) < W(t_{j-1}) < b(t_{j-1}), W(t_j) \geq b(t_j)) = \alpha_u(t_j) . \tag{B.61}$$

We wish to point out that spending functions used to obtain the upper and lower boundaries in the above procedure can belong to different families if desired.

Boundaries and Maximum Information for Early Rejection of either H_0 or H_1

There are two stopping boundaries for these designs; an “upper” stopping boundary for early rejection of H_0 and a “lower” stopping boundary for early rejection of H_1 . We reject H_0 in favor of H_1 the first time we encounter an information fraction t_j such that a boundary is crossed and it is an upper boundary. We reject H_1 in favor of H_0 the first time we encounter an information fraction t_j such that a boundary is crossed and it is a lower boundary. We impose the constraint that the upper and lower boundaries must meet at t_K , thereby ensuring that a decision to reject either of the two hypotheses will indeed be made. The upper and lower stopping boundaries thus form a triangular continuation region.

We wish these stopping boundaries to have the property that at the null hypothesis, $\delta = 0$, we will cross the upper stopping boundary with probability α , but at the specific alternative hypothesis of interest, say $\delta = \delta_1$, we will cross the upper stopping boundary with probability $1 - \beta$ and the lower stopping boundary with probability β . The upper boundaries, u_j and the lower boundaries l_j , $j = 1, 2, \dots, K$, are found using a two-dimensional search to simultaneously solve two equations corresponding to the desired type-1 and type-2 errors of the test. The drift parameter η is determined simultaneously along with the boundaries. The procedure is specified below:

1. Set the drift parameter η to some arbitrary initial value $\eta = \eta_1$.
2. At the first look, at information fraction t_1 , search for the upper boundary u_1 such that

$$P_0(W(t_1) \geq u_1) = \alpha(t_1) , \tag{B.62}$$

and for the lower boundary l_1 such that

$$P_\eta(W(t_1) \leq l_1) = \beta(t_1) . \tag{B.63}$$

3. For subsequent looks $j = 2, 3, \dots, K - 1$, having already computed the pairs of boundaries up to and including (l_{j-1}, u_{j-1}) , find the upper boundary u_j such that

$$\begin{aligned} & P_0(W(t_1) \geq u_1) + P_0(l_1 < W(t_1) < u_1, W(t_2) \geq u_2) + \dots \\ & \dots + P_0(l_1 < W(t_1) < u_1, \dots, l_{j-1} < W(t_{j-1}) < u_{j-1}, W(t_j) \geq u_j) = \alpha(t_j) \end{aligned} \quad (\text{B.64})$$

and find the lower boundary l_j such that

$$\begin{aligned} & P_\eta(W(t_1) \leq l_1) + P_\eta(l_1 < W(t_1) < u_1, W(t_2) \leq l_2) + \dots \\ & \dots + P_\eta(l_1 < W(t_1) < u_1, \dots, l_{j-1} < W(t_{j-1}) < u_{j-1}, W(t_j) \leq l_j) = \beta(t_j). \end{aligned} \quad (\text{B.65})$$

4. At the K th and final look the upper boundary u_K satisfies

$$\begin{aligned} & P_0(W(t_1) \geq u_1) + P_0(l_1 < W(t_1) < u_1, W(t_2) \geq u_2) + \dots \\ & \dots + P_0(l_1 < W(t_1) < u_1, \dots, l_{K-1} < W(t_{K-1}) < u_{K-1}, W(t_K) \geq u_K) = \alpha. \end{aligned} \quad (\text{B.66})$$

Since we want to reach a decision at the last look (either in favor of the null or the alternative) we have to set the lower boundary l_K equal to the upper boundary u_K . Thus set $l_K = u_K$ and find the value of β^* by calculating

$$\begin{aligned} & \beta^* = P_\eta(W(t_1) \leq l_1) + P_\eta(l_1 < W(t_1) < u_1, W(t_2) \leq l_2) + \dots \\ & \dots + P_\eta(l_1 < W(t_1) < u_1, \dots, l_{K-1} < W(t_{K-1}) < u_{K-1}, W(t_K) \leq l_K). \end{aligned} \quad (\text{B.67})$$

- (a) If $\beta^* = \beta$, then the set of boundaries just computed satisfy the required operating characteristics at the alternative $\eta = \eta_1$.
- (b) If $\beta^* > \beta$ select a new value $\eta_{\text{new}} < \eta_1$. Set $\eta_1 = \eta_{\text{new}}$ and repeat the steps from Step 2 onward.
- (c) If $\beta^* < \beta$ select a new value $\eta_{\text{new}} > \eta_1$. Set $\eta_1 = \eta_{\text{new}}$ and repeat the steps from Step 2 onward

The above iterative procedure ends with simultaneous computation of the final stopping boundaries and the final drift parameter η_1 . Then, by (B.6) the desired maximum information I_{max} is

$$I_{\text{max}} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

Two-sided boundaries for early rejection of H_0 or H_1 are obtained by replacing $W(t_j)$ with $|W(t_j)|$. The boundary for early rejection of H_0 in the one-sided case is now

B Group Sequential Design in East 6

replaced by two boundaries for early rejection of H_0 , symmetrically placed on either side of the X-axis. Similarly the boundary for early rejection of H_1 is now replaced by two boundaries for early rejection of H_1 , symmetrically placed on either side of the X-axis, and constructed so as to meet their corresponding H_0 -rejection boundaries at the final look. This results in two triangular continuation regions and an inner wedge.

Making the H_0 - H_1 Boundaries Non-Binding

In the discussion that follows we will refer to the boundary for early rejection of H_0 as the “efficacy” boundary and the boundary for early rejection of H_1 as the “futility” boundary. Equations (B.62) through (B.67) were used to generate the efficacy and futility boundaries simultaneously. One practical drawback of this simultaneous computation is that the futility boundary cannot be overruled. In other words, if the test statistic crosses the futility boundary the trial **must** be terminated, or else the type-1 error might be inflated. This is so because the interaction between the two boundaries during their construction causes the efficacy boundary to be shifted relative to the position it would have occupied if there were no futility boundary. It could happen, for example, that the presence of the futility boundary “pulls down” the efficacy boundary, making it easier to cross under the null hypothesis, if the futility boundary can be arbitrarily overruled. If the efficacy boundary is disturbed in this manner, the only way to prevent the possibility of inflating the type-1 error is to make the futility boundary strictly binding. This is usually not acceptable to the sponsor of a clinical trial or to the data monitoring committee assigned to the trial. This is the primary motivation for constructing non-binding futility boundaries.

We now show how to simultaneously compute the efficacy and futility boundaries in such a way that the early rejection criteria of the efficacy boundary remain the same as the corresponding criteria in a H_0 -only design. In that case there is no danger of inflating the type-1 error even if the futility boundary is overruled. The only cost of this added flexibility is an increase in the maximum information. For ease of exposition we will only describe the one-sided H_0 - H_1 case

1. Generate the one-sided level- α efficacy boundary as specified by equations (B.55) and (B.56). Denote this boundary by $\{u_1, u_2, \dots, u_K\}$.
2. For this boundary find the value of η that will satisfy the type-2 error equation (B.57).
3. Keeping this value of η and the previously obtained efficacy boundary values $\{u_1, u_2, \dots, u_K\}$ fixed, compute the futility boundary $\{l_1, l_2, \dots, l_K\}$ as follows:

$$P_\eta(W(t_1 \leq l_1) = \beta(t_1)) \quad (\text{B.68})$$

and for $j = 2, 3, \dots, K - 1$,

$$P_\eta(W(t_1) \leq l_1) + P_\eta(l_1 < W(t_1) < u_1, W(t_2) \leq l_2) + \dots \\ \dots + P_\eta(l_1 < W(t_1) < u_1, \dots, l_{j-1} < W(t_{j-1}) < u_{j-1}, W(t_j) \leq l_j) = \beta(t_j). \quad (\text{B.69})$$

Since the efficacy and futility boundaries are required to meet at look K simply set $l_K = u_K$.

4. Compute the power of a K -look design utilizing these boundaries with drift parameter η by evaluating

$$P_\eta(W(t_1) \geq u_1) + P_\eta(l_1 < W(t_1) < u_1, W(t_2) \geq u_2) + \dots \\ \dots + P_\eta(l_1 < W(t_1) < u_1, \dots, l_{K-1} < W(t_{K-1}) < u_{K-1}, W(t_K) \geq u_K) \quad (\text{B.70})$$

Denote this power by $1 - \beta_{i-1}^*$.

5. Repeat Step 4 with progressively increasing values of η until $1 - \beta^*$ is equal to the desired power $1 - \beta$. At that point denote final the drift parameter by η_1 . Then, by (B.6) the desired maximum information I_{\max} is

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2.$$

We can convert maximum information into maximum sample size or maximum events, depending on the model being used, by selecting the appropriate translation equation from (B.15) for normal endpoints, (B.20) or (B.23) for binomial endpoints, and (B.33) or (B.41) for time to event endpoints.

The above iterative procedure produces efficacy and futility boundaries having the property that the probability of crossing the efficacy boundary under the alternative hypothesis $\delta = \delta_1$ is $1 - \beta$. Thus the desired power is obtained. Next, since the efficacy boundary was computed at Step 1 in the absence of a futility boundary, and was never altered in any subsequent step, the probability of crossing it under the null hypothesis is at most α . This probability is exactly equal to α if the futility boundary is always overruled and can only decrease if the futility boundary is respected at one or more looks. Thus, in either case the type-1 error cannot exceed α . This shows that boundaries constructed as described above produce the desired power and preserve the type-1 error with the added flexibility that the futility boundary can be overruled.

Boundaries and Maximum Information for Early Rejection of H_1 Only

Boundaries for early rejection of H_1 only are also known as futility boundaries. They are obtained by only spending the β error at the interim looks according to a β -spending function. The α error is spent in its entirety at the last look. These boundaries and the associated maximum information can therefore be obtained by setting $\alpha(t_j) = 0$ for $j = 1, 2, \dots, K - 1$ in equations (B.62), (B.64) and (B.66). Equations (B.63), (B.65), (B.66) and (B.67) are unchanged. The computations then proceed as before.

B Group Sequential Design in East 6

B.2.5 Special Considerations for Binomial Designs

Maximum information and maximum sample size computations for binomial designs are complicated by the dependence of the variance of a binomial random variable on its mean. Therefore, even if we keep all other design parameters the same, the required maximum sample size for a binomial trial may differ, depending on how we intend to estimate the variance of the treatment difference at the interim monitoring stage. Although this special consideration applies both to superiority trials as well as to non-inferiority trials, the present discussion will be restricted to superiority trials only, where East provides two options at the design stage.

The issue is, how will the observed treatment difference

$$\hat{\delta}(t_j) = \hat{\pi}_t(t_j) - \hat{\pi}_c(t_j)$$

be standardized at the interim monitoring stage of the trial? The standardization method one intends to use at the interim monitoring stage must be reflected in the computation of sample size at the design stage. In East we offer two options.

Unpooled Estimate the variance without pooling the data from the two treatment arms. Thus

$$\text{var}[\hat{\delta}(t_j)] = \frac{\hat{\pi}_t(t_j)(1 - \hat{\pi}_t(t_j))}{n_{tj}} + \frac{\hat{\pi}_c(t_j)(1 - \hat{\pi}_c(t_j))}{n_{cj}}, \quad (\text{B.71})$$

which implies that the statistic $\tilde{W}_s(t_j)$ given by equation (B.24) will be used to monitor the data. We have already seen in Section B.1.2 that this statistic is asymptotically $N(0, t_j)$ under the null hypothesis, asymptotically $N(\eta t_j, t_j)$ under the alternative hypothesis, and has independent increments. Therefore all the computations discussed in Section B.2 for obtaining stopping boundaries, estimating the maximum information I_{\max} , and converting maximum information into maximum sample size N_{\max} , remain valid without any modifications. In the East software, the unpooled estimate of variance is the default for the design of binomial endpoint trials.

Pooled Estimate the variance after pooling the data from the two treatments. Thus

$$\text{var}[\hat{\delta}(t_j)] = \frac{\hat{\pi}(t_j)(1 - \hat{\pi}(t_j))}{n_j(r)(1 - r)} \quad (\text{B.72})$$

where $\hat{\pi}(t_j)$, the **pooled** estimate of the binomial response probability at time t_j , is given by equation (B.26). This implies that the statistic $\tilde{W}_{0s}(t_j)$ given by equation (B.25) will be used to monitor the data. As already stated in Section B.1.2, $\tilde{W}_{0s}(t_j)$ is $N(0, t_j)$ with independent increments under

$H_0: \delta = 0$. However, since the variance term (B.72) is based on a pooled estimate of response, the distribution of $\tilde{W}_{0s}(t_j)$ is no longer $N(\eta t_j, t_j)$ under the alternative hypothesis. Therefore if we intend to use the pooled estimate of variance at the interim monitoring stage, the computation of I_{\max} and N_{\max} must be modified for H_0 -only boundaries, and the computation of stopping boundaries, I_{\max} and N_{\max} must be altered for H_0 - H_1 boundaries. These modifications are described below.

First consider the case of H_0 -only boundaries. For expository purposes we will only consider boundaries derived from α -spending functions for one-sided tests. The same approach also works for the Haybittle-Peto and Wang-Tsiatis boundaries, and for two-sided tests. Since $\tilde{W}_{0s}(t_j) \sim N(0, t_j)$ with independent increments, the boundaries $\{c(t_1), c(t_2), \dots, c(t_K)\}$ generated by equation (B.56) will preserve the type-1 error without any modification. These boundaries cannot, however, be directly utilized by equation (B.57) because $\tilde{W}_{0s}(t_j)$ is not $N(\eta t_j, t_j)$ under the alternative hypothesis. It is easy to show, however, that asymptotically

$$P_{\eta} \left\{ \bigcap_{j=1}^K \tilde{W}_{0s}(t_j) < c(t_j) \right\} \approx P_{\eta} \left\{ \bigcap_{j=1}^K \tilde{W}_s(t_j) < hc(t_j) \right\} \tag{B.73}$$

where

$$h = \sqrt{\frac{\bar{\pi}(1 - \bar{\pi})(r^{-1} + (1 - r)^{-1})}{\pi_e(1 - \pi_e)r^{-1} + \pi_c(1 - \pi_c)(1 - r)^{-1}}} \tag{B.74}$$

and

$$\bar{\pi} = r\pi_e + (1 - r)\pi_c. \tag{B.75}$$

Since $\tilde{W}_s(t_j)$ is asymptotically distributed as $N(\eta t_j, t_j)$ with independent increments, we can estimate the maximum information, I_{\max} , by finding the value of η that satisfies the following modification of equation B.57:

$$P_{\eta} \left\{ \bigcap_{j=1}^K W(t_j) < hc(t_j) \right\} = \beta. \tag{B.76}$$

For H_0 - H_1 boundaries the modification is slightly more complex since in this case the stopping boundaries are not computed independently of I_{\max} . The procedure is identical to the four-step procedure outlined on page 2294 with the following modification: for any equation involving $\beta(t_j)$ on the right hand side, replace (l_j, u_j) by (hl_j, hu_j) .

B Group Sequential Design in East 6

The test statistic $W_{0s}(t_j)$ based on the pooled variance can be transformed into

$$X_{0s}^2(t_j) = \left[\frac{W_{0s}(t_j)}{\sqrt{(t_j)}} \right]^2 \tag{B.77}$$

which reduces to the familiar Pearson chi-square statistic.

The option to base the design on the pooled estimate of variance is being offered because the chi-square test is a popular method for comparing two binomial populations. For a fixed sample study ($K = 1$) and the sample size obtained by the pooled approach specializes to the following formula given by Lachin (1981):

$$N = \left[\frac{z_\alpha \sqrt{\bar{\pi}(1 - \bar{\pi})(r^{-1} + (1 - r)^{-1})} + z_\beta \sqrt{\pi_e(1 - \pi_e)r^{-1} + \pi_c(1 - \pi_c)(1 - r)^{-1}}}{\delta_1} \right]^2 \tag{B.78}$$

In contrast the sample size for a fixed sample design based on the unpooled estimate of variance is

$$N = [\pi_e(1 - \pi_e)r^{-1} + \pi_c(1 - \pi_c)(1 - r)^{-1}] \times \left[\frac{z_\alpha + z_\beta}{\delta_1} \right]^2 . \tag{B.79}$$

We shall show in the next section that when $K > 1$ the above sample sizes are multiplied by an appropriate inflation factor that takes into account the number of looks, K , as well as the type of stopping boundary. For balanced designs ($r \approx 0.5$) the maximum sample sizes for the pooled and unpooled methods are very similar. If, however, the design is severely unbalanced, there can be substantial differences in the maximum sample sizes required to attain the desired power. It follows from equations (B.73) and (B.74) that if $h < 1$, the pooled variance will produce a more powerful test than the unpooled variance, whereas if $h > 1$, the unpooled variance will produce a more powerful test than the pooled variance. We have illustrated these points with examples in Chapter 23.

B.3 The Inflation Factor

B.3.1 General Designs

B.3.2 Information Based Designs

B.3.3 G versus I Designs

It should be clear from the manner in which the drift parameter was computed in the previous section that its value depends on K, α, β and the stopping boundary or spending function selected for the design. Therefore, in this section we will recognize explicitly that drift parameter is a function of these items by denoting it as $\eta(\alpha, \beta, K, \text{boundaries})$.

The relationship

$$I_{\max} = \left[\frac{\eta_1(\alpha, \beta, K, \text{boundaries})}{\delta_1 - \delta_0} \right]^2$$

implied by equation (B.6) is equivalent to

$$I_{\max} = \left[\frac{z_{\alpha} + z_{\beta}}{\delta_1 - \delta_0} \right]^2 \times \left[\frac{\eta_1(\alpha, \beta, K, \text{boundaries})}{z_{\alpha} + z_{\beta}} \right]^2. \tag{B.80}$$

Observe that the first term in equation (B.80) is the information needed to achieve $1 - \beta$ power at an effect size of δ_1 for a single-look, one-sided, level- α study of the null hypothesis $\delta = \delta_0$. We denote this term by

$$I_1 = \left[\frac{z_{\alpha} + z_{\beta}}{\delta_1 - \delta_0} \right]^2. \tag{B.81}$$

The second term is a multiplier for inflating the information required by the single-look study so that it will preserve the desired power of $1 - \beta$ if $K > 1$ looks are taken. We refer to the second term as the inflation factor and denote it by

$$\text{IF}(\alpha, \beta, K, \text{boundaries}) = \left[\frac{\eta_1(\alpha, \beta, K, \text{boundaries})}{z_{\alpha} + z_{\beta}} \right]^2 \tag{B.82}$$

If we denote I_{\max} by I_K for a K -look group sequential study, we have the relationship

$$I_K = I_1 \times \text{IF}(\alpha, \beta, K, \text{boundaries}). \tag{B.83}$$

In Table B.1 we have tabulated the inflation factors for some common choices of α, β, K and the shape parameter, Δ for the Wang-Tsiatis boundaries.

Table B.1: Inflation Factors for Pocock ($\Delta = 0.5$) and O’Brien-Fleming ($\Delta = 0$) Stopping Boundaries

| $\alpha = 0.05$ (two-sided) | | | | | $\alpha = 0.01$ (two-sided) | | | | |
|-----------------------------|-------------------|-----------------------|------|------|-----------------------------|-------------------|-----------------------|------|------|

B.3.1 Role of Inflation Factors in General Designs

The inflation factor is a convenient device for converting fixed sample studies into

B Group Sequential Design in East 6

corresponding group sequential studies. This is the basis of the General design module. In this module East accepts the sample size (or information) required for a single-look study with a given power and type-1 error. East then uses the appropriate inflation factor to convert the single-look study into a K -look group sequential study. This is useful when we are required to design a group sequential study to evaluate some end point that is not currently available directly in East. (For example, the end point might be the comparison of two Poisson rates, or it might be a covariate in a logistic regression model). The first step is to obtain the sample-size or statistical information that would be required if this were a fixed-sample study. This can be done with the help of any convenient non-sequential design package. The sample size so obtained is then inflated by the appropriate inflation factor based on the desired number of looks, significance level, power and stopping boundary desired for the group sequential trial. See Chapter 60 for examples where East designs and monitors general studies of this type.

B.3.2 Role of Inflation Factor in Information Based Designs

Suppose one wishes to test $H_0: \delta = \delta_0$ versus $H_1: \delta = \delta_1$ where δ is a scalar parameter of interest in some mathematical model of the data generating process. In the Information Based Design module of East one specifies $\delta_1 - \delta_0$. East then computes the required fixed sample information through equation (B.81) and inflates it appropriately for a K look group sequential study through equation (B.82). The information is expressed in the dimensionless units of $[\text{se}(\hat{\delta}(\tau))]^{-2}$. The study is then monitored on this information scale.

Designing a study so that the information will be in the dimensionless units of $[\text{se}(\hat{\delta}(\tau))]^{-2}$ has both advantages and disadvantages. The disadvantage is that, prior to activating the study, one needs to interpret the desired information in terms of a physical resource like sample size or number of failures. The formula for making this conversion depends on the mathematical model of the data generating process. Sometimes a closed-form formula exists, but for more complex models one must resort to simulation. (See, for example, Scharfstein, Tsiatis and Robins, 1997, or Scharfstein and Tsiatis 1998.) Additionally, the conversion usually depends on initial estimates of nuisance parameters like the baseline response rate or the other covariates in the mathematical model of the data generating process. If we estimate the values of these nuisance parameters incorrectly, the sample size (or other physical resource) too will be incorrect and the study will not have the operating characteristics it was intended to have. For this reason it is often preferable to design the study and implement the interim monitoring on the dimensionless information scale where we do not require any knowledge about the nuisance parameters. Provided we continue to monitor the data until either full information I_K is achieved (in terms of the desired $[\text{se}(\hat{\delta}(\tau))]^{-2}$),

or else a stopping boundary is crossed, we are assured of preserving the operating characteristics of the design. We might of course wish to update the conversion of the desired statistical information into a physical resource like sample size at each interim monitoring time point, as revised estimates of the nuisance parameters become available. Illustrative examples in which the value of I_K remains constant on the dimensionless information scale but changes on the sample size scale, as more accurate estimates of nuisance parameters are obtained, are given in Chapter 59.

B.3.3 Selecting the General versus the Information Based Option

The General (**G**) and the Information Based (**I**) modules in East both rely on the same general distribution theory developed by Scharfstein, Tsiatis and Robins (1997) and by Jennison and Turnbull (1997). In both cases an inflation factor is applied to a corresponding fixed sample design as discussed at the beginning of this section. The question then arises as to which module to adopt for a given problem. Here are some guidelines.

1. If software to design the corresponding single-look study is available, the **G** module is easier to use than **I** module since the information is measured in terms of a physical resource like sample size or number of events.
2. If software to design the corresponding single-look study is not available, the **I** module can still be used since it only requires one to input the size of the treatment effect δ_1 under the alternative hypothesis. The **I** module, however, specifies the maximum required information in terms of a dimensionless quantity representing the inverse square of the standard error of the parameter being tested. It is usually necessary to translate this dimensionless information into a physical resource, either through simulation or analytically.
3. The **I** module is preferable to the **G** module in situations where the model for generating the data contains unknown nuisance parameters like the variance, the baseline response, or the coefficients of covariates in a regression model. To use the **G** module one would have to make assumptions about these unknown nuisance parameters. But the **I** module only requires you to specify the magnitude of the treatment effect you are interested in detecting.
4. The **I** module facilitates sample-size re-estimation since the maximum information is specified in dimensionless units that remain constant while the translation of maximum information into the corresponding sample size can be made more accurate at each interim look as increasingly accurate estimates of nuisance parameters become available.

B Group Sequential Design in East 6

B.4 Computation of Expected Information

- B.4.1 Exit Probabilities
- B.4.2 Expected Sample Size
- B.4.3 Expected Events

In Section B.1 we defined the maximum information, $I_{\max} \equiv I_K$, to be committed up-front for a K look group sequential clinical trial, and in Section B.2 we showed how to compute this quantity for various stopping boundaries. In practice of course a group sequential study might be terminated earlier than the K th look because of the sequential monitoring. Thus the actual information is a random variable. In this section we show how to compute the probability of crossing the stopping boundaries at each interim look. We then derive from these exit probabilities, the expected value of the information that will be obtained in a group sequential clinical trial. For normal and binomial end points, information will be represented by sample size. For time to failure end points, information will be represented by the number of failures.

B.4.1 Boundary Crossing Probability at Each Look

Let u_1, u_2, \dots, u_K be the upper stopping boundaries for a one-sided group sequential test with possible early rejection of H_0 . The probability of boundary crossing for the first time at look j is

$$P_{bc,j} = P_{\eta}[W(t_1) < u_1, W(t_2) < u_2, \dots, W(t_j) > u_j]$$

East computes and displays this boundary crossing probabilities under both H_0, H_1 and $H_{1/2}$ (half way between the null and alternative hypotheses) for all $j = 1, 2, \dots, K$.

Similarly for one-sided tests allowing for early to reject either H_0 or H_1 , East computes and displays

$$P_{bc,j} = P_{\eta}[l_1 < W(t_1) < u_1, \dots, l_{j-1} < W(t_{j-1}) < u_{j-1}, W(t_j) > u_j] + P_{\eta}[l_1 < W(t_1) < u_1, \dots, l_{j-1} < W(t_{j-1}) < u_{j-1}, W(t_j) < l_j]$$

under H_0, H_1 and $H_{1/2}$.

Similar displays are also available for the two-sided tests. For two-sided tests we simply replace $W(t_j)$ with $|W(t_j)|$ in the above boundary crossing probability equations.

B.4.2 Expected Sample Sizes for Normal and Binomial Studies

In general, for a study with K interim analyses performed at information fractions t_1, t_2, \dots, t_K , the expected stopping time, E_t , can be computed under various hypotheses on the basis of the boundary crossing probabilities as follows:

$$E_t = \sum_{j=1}^{K-1} t_j \times P_{bc,j} + 1 - \sum_{j=1}^{K-1} P_{bc,j} .$$

The expected sample size is then computed as

$$E_N = N_{\max} E_t, \quad (\text{B.84})$$

where N_{\max} is the projected maximum sample size, evaluated as discussed at the end of each subsection of Section B.2. The expected value E_N is referred to as ASN or average sample number in some of the East charts.

B.4.3 Expected Number of Events for Survival Studies

We have shown in each subsection of Section B.2 that the value of I_{\max} needed to detect $\delta = \delta_1$ with $1 - \beta$ power is given by

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2. \quad (\text{B.85})$$

Furthermore, equations (B.33) and (B.41) show that I_{\max} is directly proportional to D_{\max} , the maximum number of events. It follows that

$$D_{\max} = \frac{1}{(r)(1-r)} \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2, \quad (\text{B.86})$$

where δ_0 and δ_1 are specified by the null and alternative hypotheses, r is the proportion randomized to treatment T under the alternative hypothesis, and η_1 is computed along with the stopping boundaries as discussed in Section B.2. The expected number of events is thus

$$E_D = D_{\max} E_t, \quad (\text{B.87})$$

B.5 Sample Size and Expected Study Duration for Survival Studies

Equation (B.86) shows that the power of a time-to-event trial is determined by the maximum number of events, D_{\max} , rather than the maximum sample size, N_{\max} . However, the total time one must wait for the D_{\max} events to arrive can be controlled through sample size. The larger the sample size, the faster the required number of events are expected to arrive. A typical time-to-event trial is characterized by an accrual phase during which new subjects are enrolled, and a follow-up phase during which there is no further enrollment but subjects continue to be followed until the required number of events have been observed. A longer accrual phase implies a shorter follow-up phase, and usually also implies a shorter total study duration. Kim and Tsatis (1990) analyzed this trade off for the simplest possible case in which subjects enroll at a constant rate a for a fixed period S_a , there are no drop-outs, the survival distributions for the two treatment arms are exponential, and all subjects who have not yet experienced the event are followed until the trial is terminated. For this

B Group Sequential Design in East 6

special case they calculated that the expected number of events at calendar time l given a constant hazard rate of λ is

$$E(l|a, S_a, \lambda) = \begin{cases} a[l - \frac{1-e^{-\lambda l}}{\lambda}] & \text{if } l \leq S_a \\ a[S_a - \frac{e^{-\lambda l}}{\lambda}(e^{\lambda S_a} - 1)] & \text{if } l > S_a \end{cases} \quad (\text{B.88})$$

In Appendix D we have generalized (B.88) to handle variable enrollment rates, drop-outs, and piece-wise exponential survival, for both the **variable follow-up setting**, where the each subject still on-study is followed until the trial ends, and the **fixed follow-up setting**, where each subject still on-study is followed for a fixed amount of time, m . The generalized expression is denoted here by

$$E(l|\mathbf{a}, S_{\mathbf{a}}, \boldsymbol{\lambda}, \gamma, m) = \text{expected number of events at calendar time } l \text{ given}$$

- \mathbf{a} : a vector of enrollment rates for different intervals in the enrollment phase;
- $S_{\mathbf{a}}$: a vector of enrollment durations corresponding to the components of \mathbf{a} ;
- $\boldsymbol{\lambda}$: a vector of hazard rates for piece-wise exponential survival;
- γ : a drop-out rate for subjects lost to follow-up;
- m : a fixed follow-up time for each subject ($m = \infty$ denotes variable follow-up).

Thus, if the fraction randomized to the treatment arm is r , the expected number of events from both arms together at calendar time l is

$$E_{(1)}(l|\mathbf{a}, S_{\mathbf{a}}, \boldsymbol{\lambda}, \gamma, m) = rE(l|\mathbf{a}, S_{\mathbf{a}}, \boldsymbol{\lambda}_T, \gamma_T, m) + (1 - r)E(l|\mathbf{a}, S_{\mathbf{a}}, \boldsymbol{\lambda}_C, \gamma_C, m), \quad (\text{B.89})$$

where $\boldsymbol{\lambda} = (\boldsymbol{\lambda}_E, \boldsymbol{\lambda}_C)$ and $\boldsymbol{\gamma} = (\gamma_E, \gamma_C)$. A chart displaying $E(l|\mathbf{a}, S_{\mathbf{a}}, \boldsymbol{\lambda}_C, \gamma, m)$, $E(l|\mathbf{a}, S_{\mathbf{a}}, \boldsymbol{\lambda}_T, \gamma, m)$ and $E_{(1)}(l|\mathbf{a}, S_{\mathbf{a}}, \boldsymbol{\lambda}, \gamma, m)$ versus calendar time l can be displayed by clicking on the  icon in the **Plots** menu of East's Library.

B.5.1 Estimating Maximum Expected Study Duration

In a K -look group sequential trial we are committed to keeping the trial open until D_{\max} events are observed, unless a stopping boundary is crossed earlier. Although the actual calendar time at which these D_{\max} events will occur is a random variable it is nevertheless useful, for design purposes, to compute the calendar time, l_{\max} say, at which we would expect to observe D_{\max} events under various assumptions about accrual, drop-outs and survival distributions. Therefore we solve for l_{\max} from the

equation

$$E_{(1)}(l_{\max}|a, S_a, \lambda, \gamma, m) = D_{\max} . \tag{B.90}$$

The solution to l_{\max} in the above equation is obtained by iteration and represents the maximum length of time that we would expect the study to remain open if no early stopping boundary was crossed.

B.5.2 Trading-Off Maximum Study Duration Against Sample Size

We now establish a trade-off between the maximum expected study duration l_{\max} and sample size. In order to present the essential features of this trade-off, we will only discuss the special case where enrollment is constant at a rate a per unit time and the duration of the enrollment phase is S_a . In Appendix D we show that East does indeed handle the more general case in which there are Q distinct enrollment rates $\mathbf{a} = (a_1, a_2, \dots, a_Q)$ with corresponding enrollment durations denoted by $\mathbf{S}_a = (S_{a_1}, S_{a_2}, \dots, S_{a_Q})$. However a detailed discussion of the general case in the present section would be a distraction. It involves more complex notation and would needlessly prolong the discussion without providing any additional insight about the trade-off involved.

Case (i): Variable Follow-Up Design ($m = \infty$)

In this design subjects are enrolled for S_a units of time. All subjects are followed until the trial ends, unless they drop out or achieve the endpoint before trial termination. Thus the first subject enrolled could potentially be followed for l_{\max} units of time while the last subject enrolled could potentially be followed for $l_{\max} - S_a$ units of time.

We may express the maximum expected study duration in the form

$$l_{\max} = S_a + S_f \tag{B.91}$$

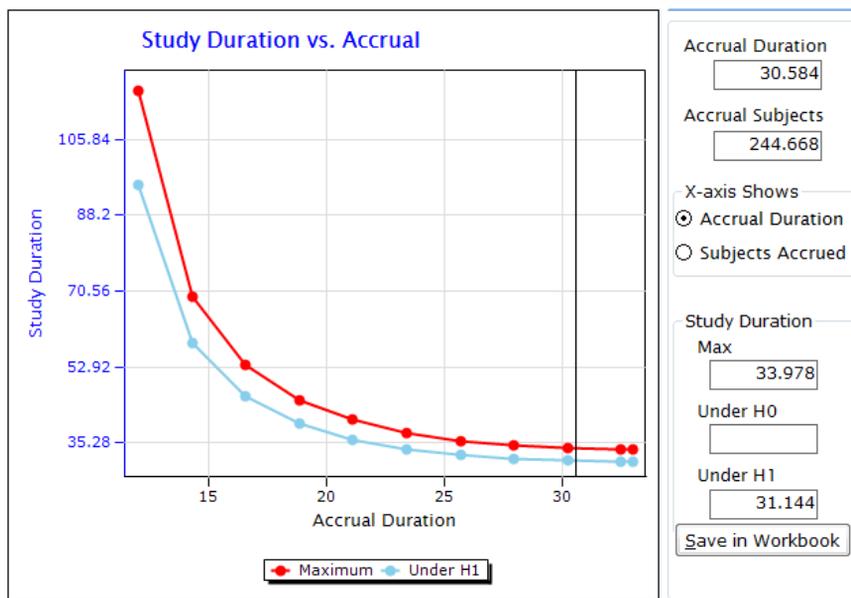

where S_f is the duration of the follow-up phase of the trial. Then, for a fixed value of S_a , East determines the value of S_f such that

$$E_{(1)}(S_a + S_f|a, S_a, \lambda, \gamma, \infty) = D_{\max} . \tag{B.92}$$

(Observe that the symbol $m = \infty$ has been used in the above expression for $E_{(1)}(\cdot|a, S_a, \lambda, \gamma, m)$, thereby indicating that this is a variable follow-up design.) By entering different enrollment durations, S_a , into equation (B.92) one obtains corresponding follow-up durations, S_f , and hence also obtains corresponding maximum study durations, $l_{\max} = S_a + S_f$. Graphs of l_{\max} versus study duration, S_a ,

B Group Sequential Design in East 6

and l_{\max} versus sample size, aS_a , are obtained by clicking on the  icon in the **Plots** menu of East's Library. A typical pair of graphs is shown below:

The red line on the graph displays the maximum expected study duration, l_{\max} , versus enrollment duration S_a . The calculation of l_{\max} is done under the alternative hypothesis and does not take into consideration a possible shortening of the study duration caused by the early stopping. The blue graph on the graph displays the expected study duration under the alternative hypothesis that accounts for the possibility of early stopping. Similar graphs can be obtained for l_{\max} (or its expectation under H_1) versus the sample size aS_a . All these relationships are monotone decreasing, highlighting that the greater the duration of the enrollment phase, or number of patients enrolled, the shorter the follow up phase and hence the shorter the total expected study duration.

We can establish a range of acceptable enrollment durations, $(S_{a,\min}, S_{a,\max})$, as well as a range of corresponding acceptable sample sizes $(aS_{a,\min}, aS_{a,\max})$ within which it is reasonable to make a selection. To determine $S_{a,\max}$ we argue that it is not necessary to prolong the enrollment phase beyond the time required to obtain D_{\max} events. Thus we search iteratively for the value of l at which

$$E_{(1)}(l|a, S_a = l, \lambda, \gamma, \infty) = D_{\max} \tag{B.93}$$

$S_{a,max}$, is the value of l that solves equation (B.93).

To determine $S_{a,min}$ we start with the smallest possible enrollment duration $S_a^* = D_{max}/a$ and see if it is feasible. To determine feasibility we progressively increase the follow-up time, starting with $S_f = 0$, and compute $E_1(S_a^* + S_f|a, S_a^*, \lambda, \gamma, \infty)$. If it should turn out that no matter how large we make S_f we always have

$$E_{(1)}(S_a^* + S_f|a, S_a^*, \lambda, \gamma, \infty) < D_{max} ,$$

then the current value of S_a^* is not feasible. In that case we increase the enrollment duration by a small amount ϵ . After setting $S_a^* \leftarrow S_a^* + \epsilon$, we once again test for feasibility by computing $E_1(S_a^* + S_f|a, S_a^*, \lambda, \gamma, \infty)$ with progressively increasing values of S_f . We iterate in this manner until we finally obtain the smallest possible S_a^* , denoted by $S_{a,min}$, such that there exists a value of S_f at which

$$E_1(S_a^* + S_f|a, S_a^*, \lambda, \gamma, \infty) = D_{max} \tag{B.94}$$

The solution, $S_{a,min}$, is the smallest that we can make the enrollment period and still hope to obtain D_{max} events. If there are no drop-outs, $S_{a,min} = \frac{D_{max}}{a}$, but in the presence of drop-outs, $S_{a,min} > \frac{D_{max}}{a}$.

East displays the enrollment duration range ($S_{a,min}, S_{a,max}$) (as well as corresponding sample size range ($aS_{a,min}, aS_{a,max}$)), and selects the mid-point of this range as the default. The user can change this default value and thereby trade-off sample size against total study duration.

Case (ii): Designs with Fixed Follow-Up m

In many trials the clinical endpoint is of interest only if it is obtained within a fixed time period m . For example, in trials involving acute coronary syndrome, the primary question is whether the clinical endpoint (e.g., death, MI or refractory ischemia) has occurred within $m = 30$ days of entry into the study. In such trials each subject is only followed for a maximum of m units of time, after which the subject goes off-study. Therefore the maximum study duration is actually fixed at m units after the

B Group Sequential Design in East 6

last subject has been enrolled; i.e., at time $S_a + m$. The design question is to determine the value of S_a that will ensure that

$$E_{(1)}(S_a + m | a, S_a, \lambda, \gamma, m) = D_{\max} . \tag{B.95}$$

Here m is fixed and we iterate on S_a until equation (B.95) is satisfied. Denote this solution by $S_{a,\min}$. In this case if we enroll $aS_{a,\min}$ subjects and follow each subject for a maximum of m units of time we expect to obtain the desired D_{\max} events at time

$$l_{\max} = S_{a,\min} + m .$$

If we enroll for longer than $S_{a,\min}$ units of time then the desired D_{\max} events are expected to arrive before $S_{a,\min} + m$. In particular if the duration of enrollment extends up to $S_{a,\max}$ units of time, where

$$E_{(1)}(S_{a,\max} | a, S_{a,\max}, \lambda, \gamma, m) = D_{\max} , \tag{B.96}$$

then the desired D_{\max} events will have arrived by the end of the enrollment phase itself. Therefore East specifies that $(S_{a,\min}, S_{a,\max})$ is an acceptable range within which to select the enrollment duration and $(aS_{a,\min}, aS_{a,\max})$ is an acceptable range within which to select the corresponding sample size. Unlike the variable follow-up case where the mid-point of the range is selected as the default, East selects $S_{a,\min}$ ($aS_{a,\min}$) as default choice for the enrollment duration (sample size). With this choice, the trial is expected to be fully powered precisely when the last subject enrolled has been followed for m units of time.

B.5.3 Choice of Variance for Survival Studies

The maximum amount of Fisher information needed to achieve the desired power is shown in Section B.2 to be

$$I_{\max} = \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2 .$$

Equation (B.33) relates the required Fisher information, I_{\max} , to the required number of events, D_{\max} by noting that

$$I_{\max} \approx \text{var}[S(l_K)] = r(1 - r)D_{\max} . \tag{B.97}$$

In the above expression the $\text{var}[S(l_K)]$ has been evaluated under the null hypothesis, leading to the result

$$D_{\max} = \frac{1}{(r)(1-r)} \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2, \tag{B.98}$$

An alternative approach would be to estimate of the variance of $S(l_K)$ under the alternative hypothesis. In that case

$$I_{\max} \approx \text{var}[S(l_K)] = (p_K)(1-p_K)D_{\max} \tag{B.99}$$

where p_K is the proportion of of the D_{\max} events that occur in the experimental group. This leads to the result

$$D_{\max} = \frac{1}{(p_K)(1-p_K)} \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2, \tag{B.100}$$

Since under local alternatives p_K converges to r the above two expressions for $\text{var}[S(l_K)]$, and hence for D_{\max} , are asymptotically equivalent. In small samples, however, the two ways of computing D_{\max} can lead to different results, especially if the randomization fraction is not equal to 0.5. East provides the user with the option to use either the null variance or the alternative variance for evaluating D_{\max} on the **Design Parameters** tab.

Variance of Log Hazard Ratio

Null
 Alternative

The evaluation of p_K for use in equation (B.100) is an iterative process. For any given a and S_a , we proceed through the following steps:

1. Initialize $p_K = r$
2. Compute

$$D_{\max} = \frac{1}{(p_K)(1-p_K)} \left[\frac{\eta_1}{\delta_1 - \delta_0} \right]^2$$

3. Find the value of l_K such that

$$E_{(1)}(l_K | a, S_a, \lambda, \gamma, m) = D_{\max}$$

B Group Sequential Design in East 6

4. With this value of l_K compute $E(l_K|a, S_a, \lambda_T, \gamma_T, m)$, $E(l_K|a, S_a, \lambda_C, \gamma_C, m)$ and

$$D_{\max}(\text{new}) = E(l_K|a, S_a, \lambda_T, \gamma_T, m) + E(l_K|a, S_a, \lambda_C, \gamma_C, m)$$

5. Compute

$$p_K = \frac{E(l_K|a, S_a, \lambda_T, \gamma_T, m)}{D_{\max}(\text{new})}$$

6. Return to step 2

We iterate steps 2 through 5 until the value of D_{\max} stabilizes.

Note: This refinement for computing D_{\max} is only available for superiority trials. For non-inferiority trials $p(l_K) = r$ under the alternative hypothesis, and equation (B.98) may be used with no modification.

C

Interim Monitoring in East 6

The primary characteristic of the interim monitoring phase in East is flexibility. At the design phase East obtains the stopping boundaries and the maximum statistical information by assuming that the study will be monitored a total of K times, after pre-specified increments of information. Provided the study adheres strictly to its planned schedule of interim monitoring, it is assured of maintaining the desired type-I error and power. It is, however, administratively inconvenient to fix in advance the number and timing of the interim looks. For instance, it might be necessary to set the dates of the interim monitoring looks so as to accommodate the schedule of a data and safety monitoring board (DSMB). Typically, the DSMB would plan to meet after equal increments of calendar time, which would not necessarily coincide with the information fractions specified at the design stage. Again, it might be necessary to alter K , the planned number of looks at the data, either for safety reasons, because the accrual assumptions were not met, or for some other administrative reason. These alterations to the original plan could change the operating characteristics of the study unless suitable adjustments were made in the interim monitoring phase. East makes the necessary adjustments by implementing the error spending function methodology first proposed by Lan and DeMets (1983) for studies that stop early to reject H_0 , and subsequently generalized by Pampallona, Tsiatis and Kim (1995), (2000), to studies that stop early to reject either H_0 or H_1 . This appendix chapter covers all the key components of the interim monitoring module in East. The following topics are discussed:

- Flexibility to alter the number and timing of the interim monitoring time-points through the error spending function methodology while preserving the type-1 and type-2 errors (Section C.1).
- Measuring the impact that deviations from the number and timing of the interim monitoring time-points specified at the design phase have on the post-hoc power of the study (Section C.2).
- Conditional power calculations aimed at assisting in the decision to stop early due to futility (Section C.3).
- Repeated confidence intervals that provide the desired coverage for the primary parameter of interest despite the multiple looks (Section C.5).
- Inference at the end of a group sequential trial (Section C.6).
- Sequential monitoring from any general data generating process, not necessarily the normal, binomial or time to failure models that are supported directly by East (Section C.7).
- The ability to monitor on a dimensionless information scale and thereby facilitate sample size recalculation (Section C.8).

C Interim Monitoring in East 6

C.1 Flexible Interim Monitoring

C.1.1 Monitoring with Alpha Functions

C.1.2 Monitoring with Alpha and Beta Functions

The boundary and maximum information computations at the design phase were performed under the assumption that the number and spacing of the interim looks are known in advance. In practice this assumption is unrealistic. A major goal of a practical interim monitoring strategy is to give the user flexibility to monitor the data at arbitrary time points at the interim monitoring stage, possibly perform one or more unplanned analyses, possibly drop one or more planned analyses, and still preserve the type-1 error of the study design. This flexibility is achieved through the spending function approach as originally introduced by Lan and DeMets (1983). If the boundaries at the design stage were themselves derived from spending functions (as discussed in Section B.2.4), one simply uses the same spending functions to re-compute the boundaries at any arbitrary interim monitoring time point. If, however the boundaries constructed at the design stage belong to the Wang-Tsiatis family (Section B.2.2) or the Pampallona-Tsiatis family (Section B.2.3) they are re-computed by inverting special ten-look error spending functions that capture the spirit of these boundaries. (The construction of these ten-look error spending functions is described in detail in Appendix F.)

C.1.1 Monitoring with α -Spending Functions

Suppose the clinical trial was designed for early stopping to reject H_0 . Let $\alpha(t)$ denote its α -spending function. Suppose that the study was originally planned for up to K looks at the accumulating data, at the interim monitoring fractions t_1, t_2, \dots, t_K . Stopping boundaries c_1, c_2, \dots, c_K have already been generated on this basis using the methods discussed in Section B.2.4. If the study is monitored strictly according to plan these same stopping boundaries may be used to make early stopping decisions. If, however, one deviates from the plan, the original stopping boundaries are no longer valid and new boundaries have to be computed on the fly at each interim monitoring time point to reflect the amount of type-1 error that has actually been spent.

Suppose, for example, that the first time we monitor the data, the information fraction is $t'_1 \neq t_1$. We then re-compute the first boundary value c'_1 such that, under the null hypothesis of no treatment difference (H_0),

$$P_0(W(t'_1) \geq c'_1) = \alpha(t'_1).$$

If we do not stop the study at the first interim test, then the data are monitored a second time. Suppose the second monitoring takes place at information fraction $t'_2 \neq t_2$. At this stage, we are allowed to use up a total of $\alpha(t'_2)$ of the significance level. Since we already used $\alpha(t'_1)$ at the first look, we then compute the next boundary value c'_2 so that

$$\alpha(t'_1) + P_0(W(t'_1) < c'_1, W(t'_2) \geq c'_2) = \alpha(t'_2).$$

This guarantees that the probability of stopping and rejecting at the first or second monitoring, under H_0 , will be $\alpha(t'_j)$. In general we compute the boundary c'_j at

information fraction $t'_j \leq 1$ by solving equation

$$\alpha(t'_{j-1}) + P_0(W(t'_1) < c'_1, \dots, W(t'_{j-1}) < c'_{j-1}, W(t'_j) \geq c'_j) = \alpha(t'_j). \quad (C.1)$$

If it should happen that I_j , the information accrued by look j , exceeds I_{\max} , the maximum information stipulated at the design stage, so that $t'_j = I_j/I_{\max} > 1$, East will set $\alpha(t'_j) = \alpha$ and force the j th look to be the last one. Thus, since $\alpha(t'_j) \leq \alpha$ for any j and any information fraction t'_j , this procedure guarantees that the probability under H_0 of ever crossing the upper boundary can never exceed α . Therefore this flexible interim monitoring procedure always preserves the overall type-1 error.

We should note that the α -spending procedure does not guarantee that the type-2 error will be preserved. However, Lan and DeMets (1983) have shown that these procedures, even with few monitoring times, will yield statistical properties similar to those expected with continual monitoring. The operating characteristics and early stopping properties of sequential tests would not be very different whether you monitored the data 5 times, 10 times, or continually. For this reason, once the spending function is specified, we are free to either monitor the accumulating data continually, monitor after equal increments of calendar time, monitor after equal information fractions, or monitor sporadically, without any significant change in the type-2 error. The post-hoc power chart displayed by East (see Section C.2) shows that as long as a study reaches its accrual goals its power is affected minimally even if the interim monitoring schedule differs from what was planned at the design stage.

C.1.2 Monitoring with α - and β -Spending Functions

The spending function approach of Lan and DeMets (1983) was developed in the context of designs that do not allow for early stopping with rejection of the alternative hypothesis. Rejection of the alternative hypothesis could only occur at the last look. Thus, in the initial approach of Lan and DeMets (1983), whereas the type-1 error was spent in accordance with a spending function $\alpha(t)$, the type-2 error had probability exactly equal to zero at all looks except the last, where it had the desired probability, β . However, when sequential designs are constructed in terms of an upper boundary for early rejection of the null hypothesis and a lower boundary for early rejection of the alternative hypothesis, then the total probability of the type-2 error, β , can also be distributed over successive looks. The rate at which the error probability is to be spent can be described by an appropriate strictly increasing function of the information time. Let $\beta(t)$ denote this function such that $\beta(0) = 0$ and $\beta(1) = \beta$. The design of trials that spend α and β simultaneously and stop early to reject either H_0 or H_1 has already been described in Section B.2.4. Suppose we have designed such a trial for up to K monitoring time points at the information fractions t_1, t_2, \dots, t_K . For the one-sided test, let l_j and u_j be the values of the lower and upper boundaries, respectively, at the j^{th} look, $j = 1, 2, \dots, K$.

C Interim Monitoring in East 6

Now suppose we are about to monitor the trial and no longer wish to adhere to either the number or timing of the interim looks specified at the design stage. Pampallona, Tsiatis and Kim (1995) have suggested the following adaptation of the Lan and DeMets (1983) procedure for flexible interim monitoring while simultaneously preserving both the type-1 error and type-2 errors of the study. Suppose that we monitor the data for the first time at information fraction $t'_1 \neq t_1$. Then we would compute the first pair of boundary values, (l'_1, u'_1) , so as to satisfy

$$P_0(W(t'_1) \geq u'_1) = \alpha(t'_1)$$

and

$$P_\eta(W(t'_1) \leq l'_1) = \beta(t'_1)$$

where η , the drift parameter, has been computed at the design stage along with the upper and lower stopping boundaries as described in Section B.2.4. Similarly the boundary values, (l'_j, u'_j) , at subsequent looks, $j \geq 2$, will have to satisfy

$$\alpha(t'_{j-1}) + P_0(l'_1 < W(t'_1) < u'_1, \dots, l'_{j-1} < W(t'_{j-1}) < u'_{j-1}, W(t'_j) \geq u'_j) = \alpha(t'_j) \quad (\text{C.2})$$

and

$$\beta(t'_{j-1}) + P_\eta(l'_1 < W(t'_1) < u'_1, \dots, l'_{j-1} < W(t'_{j-1}) < u'_{j-1}, W(t'_j) \leq l'_j) = \beta(t'_j). \quad (\text{C.3})$$

If it should happen at some look, j^* say, that $I_{j^*} > I_{\max}$, so that $t'_{j^*} = I_{j^*}/I_{\max} > 1$, East will set $\alpha(t'_{j^*}) = \alpha$ and force the j^* th look to be the last one. The upper boundary, u_{j^*} , will then be computed as the solution to

$$\alpha(t'_{j-1}) + P_0(l'_1 < W(t'_1) < u'_1, \dots, l'_{j-1} < W(t'_{j-1}) < u'_{j-1}, W(t'_{j^*}) \geq u'_{j^*}) = \alpha. \quad (\text{C.4})$$

Since we require the stopping boundaries to meet at the last look, it will not be necessary to compute l_{j^*} , the lower boundary at the last look. Instead we will simply set $l_{j^*} = u_{j^*}$. In that case the probability of crossing the lower boundary at the last look or earlier is evaluated by computing

$$\beta^* = \beta(t'_{j-1}) + P_\eta(l'_1 < W(t'_1) < u'_1, \dots, l'_{j^*-1} < W(t'_{j^*-1}) < u'_{j^*-1}, W(t'_{j^*}) \leq u'_{j^*}). \quad (\text{C.5})$$

Since the right hand sides of equations (C.2) and (C.4) can never exceed α this procedure guarantees that the probability under H_0 of ever crossing the upper

boundary can never exceed α . Therefore this flexible interim monitoring procedure always preserves the overall type-1 error. In its present form, however, this procedure is not guaranteed to preserve the type-2 error because β^* , evaluated by equation (C.5), could in principle exceed β . In order to ensure that the type-2 error is always preserved we need to position the last look in such a way that $\beta^* \leq \beta$. The optimal positioning of the last look, to be discussed in Section C.2.3, will ensure this.

C.2 Post-Hoc Power and Preservation of Error

C.2.1 Last-Look Boundary

C.2.2 Computation

C.2.3 Optimal Last Look

C.2.4 Post-Hoc Power Chart

In Section C.1 we developed the error spending function methodology for preserving the type-1 error, despite deviations from the number and timing of the interim looks specified at the design phase of the study. While the type-1 error is indeed preserved by this methodology, it is possible for the alterations in the interim monitoring schedule to affect the type-2 error (hence the power) of the study. Thus it is helpful to compute the post-hoc power at the end of the study, taking into account the actual number and timing of the interim looks. For instance, we would not be too concerned about the impact of the alterations in the interim monitoring schedule if the study was designed for 90% power and the post-hoc power turned out to be 89.5%. This section shows how such post-hoc calculations can be performed. As a by-product we generate a power chart in which, under the assumption that the next look will be the last one, the relationship of post-hoc power to the final statistical information is plotted. The optimal placement of the last look (on the statistical information scale) so as to achieve the power specified at the design phase, is thus obtained. This provides us with a strategy for preserving power by altering the information horizon. Although all the calculations in this section are derived for one-sided tests, they can be readily extended to the two-sided setting by replacing $W(t_j)$ with $|W(t_j)|$.

Note that the post-hoc power calculations in this section differ from the conditional power calculations in Section C.3. Post-hoc power calculations utilize the placement on the information scale of the interim looks already taken, while conditional power calculations utilize, in addition, the current value of the test statistic. Also, the post-hoc power chart is plotted as a function of statistical information whereas the conditional power chart is plotted as a function of the standardized treatment difference.

C.2.1 Boundary Derivation if the Next Look is the Last

Suppose a study has been active for a while, accruing information without the test statistic crossing the stopping boundary at any of the interim monitoring time-points. Eventually, however, the decision must be taken to make the next analysis the last one regardless of the value of the test statistic. As a practical matter it is very unlikely that this last analysis can be performed at the precise time-point that the planned maximum information is attained. In some cases the actual information will exceed the planned maximum and in other cases it will fall short. Some studies may even need to be

C Interim Monitoring in East 6

closed prematurely for administrative reasons, like poor accrual or withdrawal of the drugs under investigation. In all such cases the information fraction $t_L \neq 1$, where L indexes the last analysis. This situation brings up two issues:

1. The boundary for the last look should be computed by spending the balance of the type-I error probability, namely $\alpha - \alpha(t_{L-1})$, in order for the group sequential test to have the desired size α .
2. The power of the adopted sequential procedure usually won't equal the desired, $1 - \beta$, due to the probable departure of the sequence of analyses actually performed from the analyses assumed at the design stage.

For designs allowing for early stopping only to reject the null hypothesis we compute u_L , the boundary for the L -th look, by satisfying the following equation (here given for one-sided tests):

$$\alpha(t_{L-1}) + P_0(W(t_1) < u_1, W(t_2) < u_2, \dots, W(t_{L-1}) < u_{L-1}, W(t_L) \geq u_L) = \alpha. \quad (\text{C.6})$$

For designs allowing for early stopping in favor of either the null or the alternative the last-look upper stopping boundary, u_L , (which must equal the last-look lower stopping boundary, l_L) is obtained by satisfying the following equation (here given for one-sided tests):

$$\alpha(t_{L-1}) + P_0(l_1 < W(t_1) < u_1), \dots, l_{L-1} < W(t_{L-1}) < u_{L-1}, W(t_L) \geq u_L) = \alpha. \quad (\text{C.7})$$

In either case, however, the achieved overall power of the procedure probably won't be what was specified at design time because of deviations from the planned number and timing of the interim analyses. Therefore East computes "post-hoc power" to quantify the power actually achieved by the adopted analysis strategy. This is discussed next.

C.2.2 Calculating Post-Hoc Power

As stated previously, it is highly unlikely that the actual number and timings of the interim analyses will match the K equally spaced analyses assumed at the design stage, and this discrepancy affects the power of the sequential testing procedure. It might be of interest to know what the real power of the study was, based on the actual interim monitoring time-points rather than the assumed ones, even though we can only perform this power calculation post-hoc. If the post-hoc power is reasonably close to the planned power despite deviations in the interim monitoring schedule, one can feel satisfied that the study preserved its original operating characteristics.

If the study is designed for a one-sided test with early stopping to only reject H_0 , East

computes the post-hoc power (PHP) from the following equation.

$$\text{PHP} = 1 - P_{\eta}[W(t_1) < u_1, W(t_2) < u_2, \dots, W(t_{L-1}) < u_{L-1}, W(t_L) < u_L] \quad (\text{C.8})$$

where u_L is the boundary used at the last look to satisfy the type-I error probability, as specified by equation (C.6). Similarly, in the case of a one-sided test allowing for early stopping to reject either H_0 or H_1 , the post-hoc power becomes

$$\text{PHP} = 1 - \left[P_{\eta}[W(t_1) < l_1] + P_{\eta}[l_1 < W(t_1) < u_1, W(t_2) < l_2] + \dots \right] \quad (\text{C.9})$$

where $u_L = l_L$ is the boundary used at the last look to satisfy the type-I error probability, as computed by equation (C.7).

C.2.3 Optimal Placement of Last Look

Suppose that, in the course of the interim monitoring, it was decided to make the next look the last one, regardless of the current interim monitoring time-point. Where should that last look be positioned? To answer this question consider that we designed the sequential test for a type-I error of α and a power of $1 - \beta$. The discussion in Section C.2.1, ensures that the overall type-I error will indeed be α no matter where we position the last look. The deviations from the planned schedule of interim monitoring imply, however, that if we take the last look at the time point specified in the original design, the power of test may no longer be $1 - \beta$.

Pampallona, Tsiatis and Kim (1995) have proposed the following strategy in order to match as closely as possible the desired power, $1 - \beta$. Suppose we have completed look j at information fraction $t_j < 1$ and have not yet crossed a stopping boundary. Let the next look be the last one and suppose that it will be taken at information fraction t_{L^*} , selected in such a way that the power of the test will be $1 - \beta$. For a one-sided test allowing for early stopping to either reject H_0 or H_1 , we jointly solve the following equations for $u_L^* = l_L^*$ and $t_L^* > t_j$, the latter being referred to as the optimal last look position:

$$\alpha(t_j) + P_0[l_1 < W(t_1) < u_1, \dots, l_j < W(t_j) < u_j, W(t_L^*) \geq u_L^*] = \alpha$$

$$\beta(t_j) + P_{\eta}[l_1 < W(t_1) < u_1, \dots, l_j < W(t_j) < u_j, W(t_L^*) \leq u_L^*] = \beta.$$

For a one-sided test allowing for early stopping to only reject H_0 the entire type-2 error can only be spent at the last look. In that case we jointly solve the following

C Interim Monitoring in East 6

equations for $u_L^* = l_L^*$ and $t_L^* > t_j$:

$$\alpha(t_j) + P_0[W(t_1) < u_1, W(t_2) < u_2, \dots, W(t_j) < u_j, W(t_L^*) \geq u_L^*] = \alpha$$

$$P_\eta[W(t_L^*) < u_L^*] = \beta$$

These equations provide the information fraction, t_L^* , and the boundary value, u_L^* , for the next analysis, assuming it to be the last, such that the type-I error and the power are **both** preserved under the adopted schedule of analyses.

Let t_L be the actual information fraction at which the next and last analysis occurs. Then, the position of t_L^* is optimal in the sense that $t_L < t_L^*$ would entail a loss of power, while $t_L > t_L^*$ would make the study unnecessarily overpowered, while only $t_L = t_L^*$ would match the desired power exactly. East computes t_L^* before and after every interim analysis, converts it into units of relevance to the current application (for example, total number of patients or total number of events) and displays this quantity in the box labeled “Ideal Next Look Position”. In the course of the study, this information can guide the investigator to position the next look optimally.

It should be noted that t_1^* corresponds to the information fraction required for a study without interim monitoring (fixed sample size study) relative to the group sequential study under consideration. That is, given that no analyses have yet been performed, the optimum position of the last (and in this case also the first) look, would be the one corresponding to the fixed sample size. East displays this value when the Interim Monitoring module is entered for the first time. If the actual first analysis is performed at $t_1 < t_1^*$ and the stopping boundary has not been crossed then clearly $t_2^* > t_1^*$ and the process continues. In this context it should be pointed out that since the error spending functions are defined only for $t_j \leq 1$, any analysis performed at $t_j > 1$ must necessarily be the last. East is capable of detecting this situation, and will accordingly compute the boundaries, spend the balance of the type I error, and display the post-hoc power.

C.2.4 Post-Hoc Power Chart

We have seen in Section C.2.3 that East is able to adjust the maximum information through the optimal last look methodology so as to satisfy the desired power and significance level of the design, despite departures from the chosen number of equally spaced analyses specified at the design stage. It may however be of interest to know what loss or gain in power would derive from the last analysis being performed at a

time point different from the suggested optimal last look position. The post-hoc power chart answers this question by providing a graph of the post-hoc power (on the Y-axis) versus the total information accumulated by the last look (on the X-axis). The point on the X-axis that matches the optimal last look position will correspond to full power on the Y-axis. Information is expressed in the post-hoc power chart in terms of units of relevance to the outcome being considered (e.g., patient accrual for normally distributed data or events for time to failure data). Towards the end of the study the post-hoc power chart tends to flatten out so that relatively small increases in power occur for relatively large increases in information. The post-hoc power chart is updated after each look and allows the user to decide whether the adjustment to the maximum information suggested by East is worth accepting, should the next look be the last. The chart is not displayed after a stopping boundary is crossed.

C.3 Conditional Power at Ideal Next Look Position (East 5.4)

The concept of conditional power at ideal next look position is borrowed from the setting of fixed sample size studies. It was first proposed in this setting by Lan and Wittes (1988). If the test statistic is computed when only part of the required total information has been collected, then the conditional power quantifies the probability of rejecting the null hypothesis should the total information be eventually available, conditional on the current information. Such a probability, when computed over a range of alternatives, can be of guidance in deciding whether to continue the study given the available evidence. In East this idea is extended to group sequential studies.

Let us initially consider a one-sided group sequential test of size α , designed for early rejection of H_0 . Suppose at the j th analysis the information fraction is t_j and the test statistic, $W(t)$, has value $w(t_j)$. In the notation of Section C.2.3 let t_L^* be the optimal placement of the next look, assuming it to be the last one, with corresponding boundary value u_L^* . In East we define the conditional power at ideal next look position, CP at INLP, as the following probability :

$$\text{CP at INLP} = P_\eta[W(t_L^*) \geq u_L^* \mid w(t_j)] \quad (\text{C.10})$$

Recall from Section B.1 that the statistic $W(t_j)$ is defined as a sum of independent increments. This implies that the decomposition

$$W(t_L^*) = W(t_j) + [W(t_L^*) - W(t_j)]$$

has the following three properties:

1. The random variables $W(t_j)$ and $W(t_L^*) - W(t_j)$ are normal and independent.
2. The means of these random variables are $E[W(t_j)] = \eta t_j$ and $E[W(t_L^*) - W(t_j)] = \eta(t_L^* - t_j)$.

C Interim Monitoring in East 6

3. The variances of these random variables are $\text{Var}[W(t_j)] = t_j$ and $\text{Var}[W(t_L^*) - W(t_j)] = (t_L^* - t_j)$.

Once we have reached the information fraction t_j we know that the random variable $W(t_j)$ has assumed the value $w(t_j)$. Therefore

$$\begin{aligned} \text{CP at INLP} &= P_\eta[W(t_L^*) - w(t_j) \geq u_L^* - w(t_j)] \\ &= P_\eta \left[\frac{W(t_L^*) - w(t_j) - \eta(t_L^* - t_j)}{\sqrt{t_L^* - t_j}} \geq \frac{u_L^* - w(t_j) - \eta(t_L^* - t_j)}{\sqrt{t_L^* - t_j}} \right] \\ &= 1 - \Phi \left(\frac{u_L^* - w(t_j) - \eta(t_L^* - t_j)}{\sqrt{t_L^* - t_j}} \right). \end{aligned} \tag{C.11}$$

where $\Phi(x)$ is the cumulative distribution function for a standard normal random variable.

For two-sided tests the conditional power is expressed as follows:

$$\begin{aligned} \text{CP at INLP} &= P_\eta[|W(t_L^*)| \geq u_L^* \mid w(t_j)] \\ &= 1 - \Phi \left(\frac{u_L^* - w(t_j) - \eta(t_L^* - t_j)}{\sqrt{t_L^* - t_j}} \right) \\ &\quad + \Phi \left(\frac{-u_L^* + w(t_j) - \eta(t_L^* - t_j)}{\sqrt{t_L^* - t_j}} \right). \end{aligned} \tag{C.12}$$

Analogous expressions can be derived for designs with boundaries for early rejection of either H_0 or H_1 .

In East the conditional power is presented as a graph plotted against a wide range of alternatives for δ , including the one specified at the design stage. Now equations (C.11) and (C.12) express conditional power as a function of the drift parameter η rather than as a function of δ . At the design stage, the relationship between η and δ is captured by the equation

$$\eta = (\delta - \delta_0) \sqrt{I_{\max}} \tag{C.13}$$

introduced in Section B.1 of Appendix B.

Finally, it should be noted that, given the described approach, the conditional power curve computed before the very first look is the usual power curve. In particular, at that stage the optimal placement of the next and last look corresponds to a fixed sample size study so that under the alternative specified at design the conditional power is actually equivalent to the a priori unconditional power.

C.4 Conditional and predictive power (East 6)

The concept of conditional power is borrowed from the setting of fixed sample size studies. It was first proposed in this setting by Lan and Wittes (1988). If the test statistic is computed when only part of the required total information has been collected, then the conditional power quantifies the probability of rejecting the null hypothesis should the total information be eventually available, conditional on the current information. Such a probability, when computed over a range of alternatives, can be of guidance in deciding whether to continue the study given the available evidence. In East this idea is extended to group sequential studies.

Suppose at the j th analysis the information fraction is t_j and the test statistic, $W(t)$, has value $w(t_j)$. We define the conditional power at look j as the probability of attaining statistical significance in the direction of the alternative hypothesis at any future look, given $w(t_j)$. Thus, if we are testing the null hypothesis that $\delta = \delta_0$ against the alternative that $\delta > \delta_0$, the conditional power is defined as

$$CP_{\eta}(w(t_j)) = Pr_{\eta}(\cup_{k=j+1}^K W(t_k) > u_k | w(t_j))$$

Here $\eta = (\delta - \delta_0) \sqrt{I_{max}}$ is the trend parameter under the alternative hypothesis. If the alternative hypothesis is that $\delta < \delta_0$, then the conditional power is defined as

$$CP_{\eta}(w(t_j)) = Pr_{\eta}(\cup_{k=j+1}^K W(t_k) < l_k | w(t_j))$$

Analogous expressions can be written for designs with boundaries for early rejection of either H_0 or H_1 and designs for early rejections of the two sided tests. The corresponding probabilities are obtained by the recursive integration.

The reference values of the conditional power are often based on the design or estimated value of the trend parameter η

$$\left[\begin{array}{l} \eta_d = (\delta_d - \delta_0) \sqrt{I_{max}} \\ \hat{\eta}_j = \frac{w(t_j)}{t_j} \end{array} \right]$$

The predictive power $PP(w(t_j))$ provides a weighted average of the conditional power values for a range of values of η

$$PP(w(t_j)) = \int CP_{\eta}(w(t_j)) f(\eta) d\eta$$

C Interim Monitoring in East 6

We follow suggestion of Lan, Hu and Proschan (2009) and use the weighting function

$$f(\eta) = \phi\left(\mu = \hat{\eta}_j, \sigma^2 = \frac{1}{t_j}\right)$$

where ϕ denotes the probability density function of standard normal distribution.

C.5 Repeated Confidence Intervals

C.5.1 RCI's Derived from Boundaries that Reject H_0

C.5.2 RCI's for Boundaries that Reject either H_0 or H_1

C.5.3 East Inputs

In this section we discuss the computation of repeated confidence intervals (RCI's), each interval being computed as part of an interim analysis. These RCI's were first proposed by Jennison and Turnbull (1989) and are discussed in detail in Chapter 9 of their text book (Jennison and Turnbull, 2000). The naive confidence interval one would ordinarily compute from the data gathered at the end of a clinical trial is inappropriate if the confidence interval is computed repeatedly in a group sequential setting. In this setting the naive confidence interval will fail to provide the desired coverage for the parameter of interest due to the problem of multiplicity. In contrast the RCI's provide simultaneous coverage for the parameter of interest at any desired confidence level despite the multiple looks at the data.

C.5.1 RCI's Derived from Boundaries that Reject H_0

For ease of exposition let us consider RCI's for two-sided group sequential trials of efficacy endpoints. The extension to one-sided efficacy or non-inferiority trials is straightforward. Let the primary parameter of interest be δ and suppose we perform K interim analyses at the information fractions t_1, t_2, \dots, t_K . At information fraction t_j we compute the Wald statistic

$$Z(t_j) = \frac{\hat{\delta}(t_j)}{\text{se}(\hat{\delta}(t_j))}. \tag{C.14}$$

Recognizing that in large samples $[\text{se}(\hat{\delta}(t_j))]^{-2} \approx I_j$, where I_j is the information about δ at time t_j , we may also write the Wald statistic as

$$Z(t_j) = \hat{\delta}(t_j)\sqrt{I_j}. \tag{C.15}$$

By the Scharfstein, Tsiatis and Robins (1997) theorem introduced in Section B.1 of Appendix B, $Z(t_j) \sim N(\delta\sqrt{I_j}, 1)$ and $\text{cov}[Z(t_{j_1}), Z(t_{j_2})] = \sqrt{I_{j_1}/I_{j_2}}$.

Let b_1, b_2, \dots, b_K be any two-sided level- α stopping boundaries for the Wald statistic for testing the null hypothesis that $\delta = 0$. That is,

$$P_0\left\{\bigcap_{j=1}^K |Z(t_j)| < b_j\right\} = 1 - \alpha.$$

Now observe that $(Z(t_j) - \delta\sqrt{I_j}) \sim N(0, 1)$ and has the same covariance structure as $Z(t_j)$. Therefore

$$P_\delta\left\{\bigcap_{j=1}^K |Z(t_j) - \delta\sqrt{I_j}| < b_j\right\} = 1 - \alpha \quad (\text{C.16})$$

for any value of δ .

Let H_1, H_2, \dots, H_K denote K two-sided RCI's that maintain simultaneous coverage for δ at level $1 - \alpha$. Therefore we require these confidence intervals to satisfy the probability condition

$$P_\delta\left\{\bigcap_{j=1}^K \delta \in H_j\right\} = 1 - \alpha. \quad (\text{C.17})$$

We can show that the sequence of intervals

$$H_j = \hat{\delta}(t_j) \pm \text{se}(\hat{\delta}(t_j))b_j \text{ for } j = 1, 2, \dots, K, \quad (\text{C.18})$$

satisfy the simultaneous coverage requirement (C.17). To prove this assertion observe that

$$\begin{aligned} P_\delta\left\{\bigcap_{j=1}^K \delta \in H_j\right\} &= P_\delta\left\{\bigcap_{j=1}^K \hat{\delta}(t_j) - \text{se}(\hat{\delta}(t_j))b_j < \delta < \hat{\delta}(t_j) + \text{se}(\hat{\delta}(t_j))b_j\right\} \\ &= P_\delta\left\{\bigcap_{j=1}^K \hat{\delta}(t_j)\sqrt{I_j} - b_j < \delta\sqrt{I_j} < \hat{\delta}(t_j)\sqrt{I_j} + b_j\right\} \\ &= P_\delta\left\{\bigcap_{j=1}^K |\hat{\delta}(t_j) - \delta|\sqrt{I_j} < b_j\right\} \\ &= P_\delta\left\{|Z(t_j) - \delta\sqrt{I_j}| < b_j\right\} \\ &= 1 - \alpha \text{ (by equation (C.16))}. \end{aligned}$$

C.5.2 RCI's for Boundaries that Reject either H_0 or H_1

Consider a K -look, level- α one sided group sequential test of the null hypothesis $H_0: \delta = 0$ having $1 - \beta$ power to detect the alternative hypothesis $H_1: \delta = \delta_1 > 0$. Suppose the interim monitoring takes place at the information fractions t_1, t_2, \dots, t_K .

C Interim Monitoring in East 6

Let $(l_j, u_j), j = 1, 2, \dots, K$ be the futility and efficacy boundaries, respectively, for this test. These boundaries have been derived in Section B.2.4 of Appendix B. Since these boundaries preserve the type-1 error we must have

$$P_0\left\{\bigcap_{j=1}^K Z(t_j) < u_j\right\} = 1 - \alpha . \tag{C.19}$$

Therefore, following the argument made in the previous section,

$$P_\delta\left\{\bigcap_{j=1}^K Z(t_j) - \delta\sqrt{I_j} < u_j\right\} = 1 - \alpha . \tag{C.20}$$

Now the event $Z(t_j) - \delta\sqrt{I_j} < u_j$ if and only if $\delta > \hat{\delta}(t_j) - u_j\text{se}(\hat{\delta}(t_j))$. Thus sequence $\{\hat{\delta}(t_j) - u_j\text{se}(\hat{\delta}(t_j)): j = 1, 2, \dots, K\}$ simultaneously excludes δ from below with probability $1 - \alpha$. It follows that the probability that one or more of these lower confidence bounds fails to cover δ from below is at most α .

Next consider the behaviour of the Wald statistics under $H_1: \delta = \delta_1$. Since the lower stopping boundaries were constructed from a β spending function we must have

$$P_{\delta_1}\left\{\bigcap_{j=1}^K Z(t_j) > l_j\right\} = 1 - \beta . \tag{C.21}$$

Therefore by centralizing the Wald statistic we get

$$P_\delta\{Z(t_j) - \delta\sqrt{I_j} + \delta_1\sqrt{I_j} > l_j\} = 1 - \beta . \tag{C.22}$$

From this we can easily show that the sequence $\{\hat{\delta}(t_j) - \delta_1 - l_j\text{se}(\hat{\delta}(t_j)): j = 1, 2, \dots, K\}$ simultaneously excludes δ from above with probability $1 - \beta$. It follows that the probability that one or more of these upper confidence bounds fails to cover δ from above is at most β . Thus the sequence of intervals

$$\{[\hat{\delta}(t_j) - u_j\text{se}(\hat{\delta}(t_j)), \hat{\delta}(t_j) + \delta_1 - l_j\text{se}(\hat{\delta}(t_j))]: j = 1, 2, \dots, K\} \tag{C.23}$$

simultaneously contains the true value of δ with probability $1 - \alpha - \beta$.

C.5.3 Inputs to East for RCI Computation

Equation (C.18) shows that in order to compute the RCI's East needs to know both the numerator ($\hat{\delta}(t_j)$) and denominator ($\text{se}(\hat{\delta}(t_j))$) of the Wald statistic (C.14). East provides a **Test Statistic Calculator** for entering these two components separately into the appropriate cell of the interim monitoring worksheet. For example, in the case of interim monitoring of a normal design study, if you click the button

Enter Interim Data

on the IM dashboard, the following dialog box appears into which you may enter the observed values for $\hat{\delta}(t_j)$ and $(se(\hat{\delta}(t_j)))$.

The dialog box titled "Test Statistic Calculator" contains the following fields and controls:

- Editing Look #1
 - Set Current Look as Last
- Cumulative Sample Size: 158
- Input for Normal end point: 0.3
- Estimate of δ : $\delta = (\mu_t - \mu_c)$: 0.159
- Standard Error of Estimate of δ : 0.159
- Output
 - Test Statistic: 1.885
- Buttons: Recalc, OK, Cancel

Sometimes, however, the separate components of the Wald statistic may not be known. Then the user has no choice but to directly enter the observed value of the Wald statistic $Z(t_j)$ into the Interim Monitoring worksheet. In such cases, East suppresses the output of repeated confidence intervals, conditional power estimates and the final adjusted inference estimates from the interim monitoring worksheet.

C Interim Monitoring in East 6

C.6 Inference Following Group Sequential Testing

C.6.1 Stage-Wise Ordering

C.6.2 Adjusted P-values

C.6.3 Adjusted Confidence Interval

C.6.4 Point Estimation

C.6.5 Acceptance Boundaries

C.6.6 Drift Parameter and Effect Size

In this section we discuss the computation of p-values and confidence intervals for the parameter of interest at the end of a group sequential clinical trial. The naive approach of computing these quantities in the usual way, ignoring the fact that a sequential monitoring procedure was used to possibly stop early, will fail to preserve the desired type-I error of the significance test or the desired coverage of the confidence interval. Rather, one must first order the sample space to reflect the sequential nature of the test procedure, and then obtain p-values and confidence intervals on the basis of this ordering. Jennison and Turnbull (2000, Chapter 8) discuss four ways to order the sample space of a group sequential experiment and thereby perform an adjusted inference in which the type-I error and the coverage are both preserved. These four ways are, stage-wise ordering, MLE ordering, likelihood ratio ordering, and score test ordering. In East we adopt stage-wise ordering of the sample space. This ordering was first proposed by Armitage (1957) and later used by Fairbanks and Madsen (1982), Tsiatis, Rosner and Mehta (1984), and Kim and DeMets (1987). Of all the four orderings this is the one most favored by Jennison and Turnbull (2000) because it does not require knowledge about the interim monitoring time-points that would have been adopted in the future, had the study not stopped early. The other three orderings of the sample space do require this knowledge and are therefore limited in their practical applicability. In addition, stage-wise ordering ensures consistency between the p-value and the confidence interval. That is, a $100 \times (1 - \alpha)\%$ confidence interval will exclude the parameter value under the null hypothesis if and only if the corresponding p-value does not exceed α . Finally, the p-value based on stage-wise ordering is less than the significance level, α , if and only if H_0 is rejected.

C.6.1 Stage-Wise Ordering of the Sample Space

Suppose that the sequentially computed random variable $W(t) \sim N(\eta t, t)$ crosses a stopping boundary for the first time at the j th look in a group sequential clinical trial where the current information fraction is t_j and the current value of the test statistic is $w^*(t_j)$. Let the information fractions at the earlier looks be $\{t_1, t_2, \dots, t_{j-1}\}$ with corresponding lower and upper stopping boundaries given by (l_i, u_i) , $i = 1, 2, \dots, j - 1$. Define the i th continuation region as $C_i = (l_i, u_i)$. The l_i 's might each be $-\infty$, in which case we have a one-sided sequential test with early stopping to reject H_0 . On the other hand, if $l_i = -u_i$ for all i , we have a two-sided sequential test with early stopping to reject H_0 . More generally the (l_i, u_i) pairs could represent the lower and upper stopping boundaries, respectively, of the Pampallona and Tsiatis (1994) family for a one-sided sequential test with early stopping to reject either H_0 or H_1 . The most complex case, inner-wedge stopping boundaries to reject either H_0 or H_1 with a two-sided test, is not covered in this section but is discussed in Section C.6.5.

The sample space of a sequential experiment which was terminated at the j th interim look with an observed value of $w^*(t_j)$ for the test statistic, consists of the union over all $i = 1, 2, \dots, j$ of all possible trajectories that terminate at the i th look. These trajectories are of the form

$$(t_1, w(t_1)) \rightarrow (t_2, w(t_2)) \rightarrow \dots \rightarrow (t_i, w(t_i))$$

where $w(t_i) \notin \mathcal{C}_i$ but $w(t_g) \in \mathcal{C}_g$, for all $g = 1, 2, \dots, i - 1$. The idea behind stage-wise ordering of this sample space is to associate earlier stopping with larger values of η . Accordingly, in stage-wise ordering, the ordered pair $(t_a, w(t_a))$ is more extreme than the ordered pair $(t_b, w(t_b))$ whenever any one of the following four conditions holds:

- (i) $w(t_a) \geq u_a$ and $w(t_b) \leq l_b$ for $t_a, t_b = 1, 2, \dots, j - 1$,
- (ii) $w(t_a) > w(t_b)$ if $t_a = t_b$ for $t_a, t_b = 1, 2, \dots, j$,
- (iii) $t_a < t_b$ if $w(t_a) \geq u_a$ and $w(t_b) \geq u_b$ for $t_a, t_b = 1, 2, \dots, j - 1$,
- (iv) $t_a > t_b$ if $w(t_a) \leq l_a$ and $w(t_b) \leq l_b$ for $t_a, t_b = 1, 2, \dots, j - 1$.

Figure C.1 is a visual display of the stage-wise ordering of the sample space for a study with three interim looks. For additional discussion of stage-wise ordering refer to Jennison and Turnbull (2000, page 179).

C.6.2 Adjusted P-values

A p-value is defined as the probability, under the null hypothesis, of obtaining an outcome at least as extreme as the one actually observed. The set of points which are at least as extreme as the observed point, $(t_j, w^*(t_j))$, can be identified by applying the stage-wise ordering scheme to each sample point in accordance with the rules set forth in Section C.6.1. Denote this set by \mathcal{E}^* . Then the p-value, adjusted for the sequential testing, is the probability under the null hypothesis of obtaining the event \mathcal{E}^* . That is,

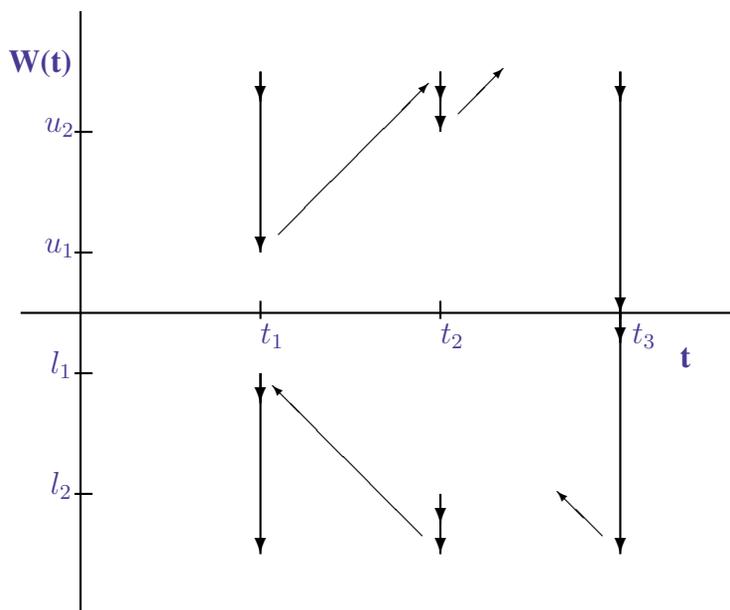

$$p^* = P_0\{\mathcal{E}^*\}. \tag{C.24}$$

C.6.3 Adjusted Confidence Interval

The method applied in East for deriving a confidence interval for η follows the approach proposed by Tsiatis, Rosner and Mehta (1984) and later extended by Kim and DeMets (1987). The basic idea is to search for the upper and lower confidence bounds of η such that the p-value under the alternative hypothesis just becomes statistically significant. Suppose the study was terminated at the observed point $(t_j, w^*(t_j))$ and let \mathcal{E}^* be the set of points at least as extreme as $(t_j, w^*(t_j))$ in accordance with the stage-wise ordering scheme developed in Section C.6.1. Then the

C Interim Monitoring in East 6

Figure C.1: Example of the ordering of the sample space $\{(t_i, W(t_i)); i = 1, 2, 3\}$. (Arrows point from more extreme to less extreme points, where extreme refers to evidence of larger values of the effect size, η .)

$100 \times (1 - 2\nu)$ confidence interval for η is (η^L, η^U) where

$$\eta^U = \sup \{ \eta : P_\eta \{ \mathcal{E}^* \} \leq 1 - \nu \} , \quad (\text{C.25})$$

$$\eta^L = \inf \{ \eta : P_\eta \{ \mathcal{E}^* \} \geq \nu \} . \quad (\text{C.26})$$

C.6.4 Point Estimation

Kim (1989) has proposed the following median unbiased estimator (MUE) for the parameter η . The MUE, denoted by $\tilde{\eta}$ is the value of η that satisfies

$$P_{\tilde{\eta}} \{ \mathcal{E}^* \} = 0.5 . \quad (\text{C.27})$$

C.6.5 Boundaries to Accept H_0

The adjusted p-values, confidence intervals and point estimations discussed in

Sections C.6.2, C.6.3 and C.6.4, respectively, can be extended to the one-sided and two-sided $H_0 - -H_1$ stopping boundaries. We must be careful, however, to exclude from the set \mathcal{E}^* all points that lie within the region where the null hypothesis is accepted. This approach will produce adjusted p-values and confidence intervals with the correct properties so long as the study is not terminated by the test statistic entering the acceptance region. In the latter case, since the null hypothesis is accepted, East will not report a p-value or confidence interval.

C.6.6 Drift Parameter and Effect Size

In Sections C.6.3 and C.6.4 we showed how East computes adjusted confidence intervals and median unbiased point estimates, respectively, for the drift parameter η . These estimates must be transformed into corresponding estimates of the effect size δ in order to be meaningful to the end user. The relationship between η and δ was shown in Section B.1 of Appendix B to be

$$\eta = (\delta - \delta_0) \sqrt{I_{\max}}. \quad (\text{C.28})$$

Thus if we know the value of I_{\max} we can solve the above equation for δ in terms of η . For example,

$$\begin{aligned} \delta^U &= \delta_0 + \frac{\eta^U}{\sqrt{I_{\max}}} \\ \delta^L &= \delta_0 + \frac{\eta^L}{\sqrt{I_{\max}}}. \end{aligned}$$

For each specific application (e.g. normal, binomial or time to failure data) we have derived, in Section B.1 of Appendix B, an expression for I_{\max} in terms of n_{\max} and other parameters specified at the design stage. These relationships are used to transform the confidence interval for η into a corresponding confidence interval for δ . However, these relationships usually contain nuisance parameters that must be estimated from the current data. For example, we would use equation (B.15) to compute I_{\max} for the normal case and would therefore need to estimate σ^2 from the data. We would use equation (B.20) to compute I_{\max} for binomial superiority trials and equation (B.23) to compute I_{\max} for binomial non-inferiority trials. In either case we would need to estimate π_c , the control response rate, from the current data.

In East we use the following unified method to evaluate the maximum information, I_{\max} . Suppose we have just completed the j th interim analysis. Let I_j denote the current information and $t_j = I_j/I_{\max}$ denote the current information fraction. Then we can re-write I_{\max} as

$$I_{\max} = t_j^{-1} I_j = [\sqrt{t_j} \text{se}(\hat{\delta}_j)]^{-2}. \quad (\text{C.29})$$

C Interim Monitoring in East 6

Thus as long as we provide East with the current standard error estimate, $se(\hat{\delta}_j)$, East can estimate I_{\max} from equation (C.29). The value of $se(\hat{\delta}_j)$ is passed to East through the test statistic calculator. If this calculator is by-passed in favor of entering the current value of the test statistic directly into the interim monitoring worksheet, East will not produce adjusted p-values, point estimates or confidence intervals upon study termination.

C.7 Monitoring Data from any General Distribution

The interim monitoring of studies that are designed with the General Design module in East is no different than the procedure used for studies designed by the Normal, Binomial or Survival Design modules. The user supplies East with the maximum information, I_1 needed for a single look study that is designed to investigate some parameter of interest, say δ . Usually I_1 will be translated into a sample size N_1 before it is input to the General Design worksheet of East. Sometimes I_1 will be expressed in terms of the number of events needed for a single look study. The Poisson example in Chapter 60 is one such case. It is also permissible to retain I_1 in terms of Fisher information for a single look study, and to approximate it by $[se(\hat{\delta}(\tau))]^{-2}$. This case is, however, better handled by the **I** module, discussed in Section C.8. Once the value of I_1 is provided to East, it is inflated to I_K by the appropriate K -look inflation factor, as discussed in Section B.3 of Appendix B. Thereafter the inflated information is utilized to determine the information fraction at each interim look in the interim monitoring phase of the study and the entire machinery of flexible monitoring with error spending functions is made available to the study. The study stops when the Wald statistic, given by equation (B.1) crosses a stopping boundary.

This approach is very useful in all those situations that are not currently covered by a specialized module within East. For instance, from any commercial sample size package one might obtain the fixed sample size requirements for the comparison of survival of two groups by means of a stratified log-rank test (expressed in terms of a fixed number of events) or for the comparison of two groups in terms of repeated measures (expressed in terms of a fixed number of subjects). East can then compute the corresponding information needed for group-sequential monitoring.

C.8 Information Based Monitoring

Suppose that the observations are generated from some probability model and a single parameter, δ , from this model characterizes the relationship under investigation while the remainder of the model is characterized by nuisance parameters. Interest focuses on developing a sequential procedure, with possible early stopping, for testing the null hypothesis $H_0 : \delta = \delta_0$ against the alternative $H_1 : \delta = \delta_1$. Suppose the study has been designed for a total of K interim looks. Then the maximum information,

$I_K \equiv I_{\max}$, to be committed up-front is given by equation (B.83) as

$$I_K = \left[\frac{z_\alpha + z_\beta}{\delta_1 - \delta_0} \right]^2 \times \text{IF}(\alpha, \beta, K, \text{boundaries}). \quad (\text{C.30})$$

This information is approximated by $[\text{se}(\hat{\delta}(\tau_K))]^{-2}$, where τ_K is the calendar time at the last look. The information at any intermediate look, taken at calendar time τ_j , is likewise approximated by $[\text{se}(\hat{\delta}(\tau_j))]^{-2}$. Suppose that the interim monitoring takes place at calendar times $\tau_1, \tau_2, \dots, \tau_K$. Then the sequential monitoring procedure at calendar time τ_j requires us to compute the information fraction

$$t_j = \frac{[\text{se}(\hat{\delta}(\tau_j))]^{-2}}{[\text{se}(\hat{\delta}(\tau_K))]^{-2}},$$

read off the values $\alpha(t_j)$ and $\beta(t_j)$ from the appropriate error spending functions, and re-compute the stopping boundaries based on these values, in the manner described in Section C.1 of this appendix. The study is terminated if the Wald statistic

$$Z(t_j) = \frac{\hat{\delta}(t_j) - \delta_0}{\sqrt{\text{var}[\hat{\delta}(\tau_j)]}}$$

crosses a stopping boundary.

The big advantage of monitoring on the above information scale is that the total information, I_K , required in order for the study to achieve the desired $1 - \beta$ power, only depends on $\delta_1 - \delta_0$, the specific parameters of interest under H_0 and H_1 . No nuisance parameters are involved in the computation of maximum information. In contrast, if we were to monitor the study on the scale of a physical resource like sample size or number of events, the maximum information would depend on one or more nuisance parameters. If those nuisance parameters were guessed incorrectly, the study would not have the power it was intended to have at the design phase. This will become much clearer as you work through the example of sample size re-estimation provided in Chapter 59.

D Computing the Expected Number of Events

D.1 General expressions

We consider a single arm of a survival study and derive an expression for the expected number of events $d(l)$ to be observed at the calendar time l . A delay between the calendar time when a subject experiences an event or drops out of a study and the calendar time when this information becomes available to an investigator is assumed to be negligible. Our equations may be viewed as a slight generalization of the expressions presented in Kim and Tsiatis (1990).

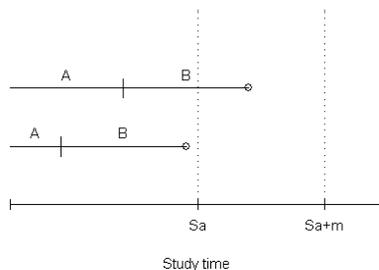

Figure D.1: Geometry of a problem

We are interested in a following general setting:

- A subject is followed no longer than a maximum period of time m . An observation of the event of interest or the subject's drop out from the study terminates a follow-up process.
- An accrual rate $a(u)$, $0 \leq u \leq S_a$ is not uniform.
- The event hazard rate $\lambda(t)$ and the drop-out hazard rate $\gamma(t)$ depend on the subject's follow-up time $t = l - u$.

An important special case arises when a limitation on the maximum follow-up time is removed. It corresponds to $m = \infty$. The accrual rate is often considered known at the time of the design of a study. It may also be calculated based on the known total number of subjects in the study and the known proportion of subjects recruited during the interval $(u, u + du)$.

Figure D.1 illustrates a geometry of the problem. The horizontal axis denotes a calendar time. An accrual period ends at S_a . The follow-up of a subject accrued at $l = S_a$ is completed no later than $l = S_a + m$. Each of the two horizontal lines connects the beginning of an accrual period with a calendar time l which may be positioned within (the lower line) or after (the upper line) an accrual period. At a calendar time l the subjects with the accrual time $0 \leq u \leq l - m$ (group A) are no longer followed because their follow-up windows are closed. Subjects who were accrued later (group B) are continued to be observed unless their follow-up was terminated by the event of interest or a drop out. The value of interest $d(l)$ may be presented as a sum of contributions

$$d(l) = d_A(l) + d_B(l) \tag{D.1}$$

from these groups. We note that in the absence of the restriction on a follow-up time ($m = \infty$) the group A does not exist and the corresponding contribution in (D.1) disappears.

Let us denote by v a time from randomization to an event of interest and by w a time from randomization to the time of subject's drop-out from the study. We assume that random variables v and w are independent and express their probability density functions $f(v)$ and $g(w)$ through the event $\lambda(t)$ and drop-out $\gamma(t)$ hazard functions

$$f(v) = \lambda(v)e^{-\Lambda(v)}, \quad \Lambda(v) = \int_0^v \lambda(t)dt$$

$$g(w) = \gamma(w)e^{-H(w)}, \quad H(w) = \int_0^w \gamma(t)dt,$$

Let us denote by $\Psi(t) = P(v \leq t, w > v)$ a probability that event occurred before the follow-up t and was not censored. We note that

$$\Psi(t) = \int_0^t \left(\int_v^\infty g(w)dw \right) f(v)dv = \int_0^t \kappa(t')dt'$$

with

$$\kappa(t) = \lambda(t) e^{-[\Lambda(t)+H(t)]}$$

D Computing the Expected Number of Events

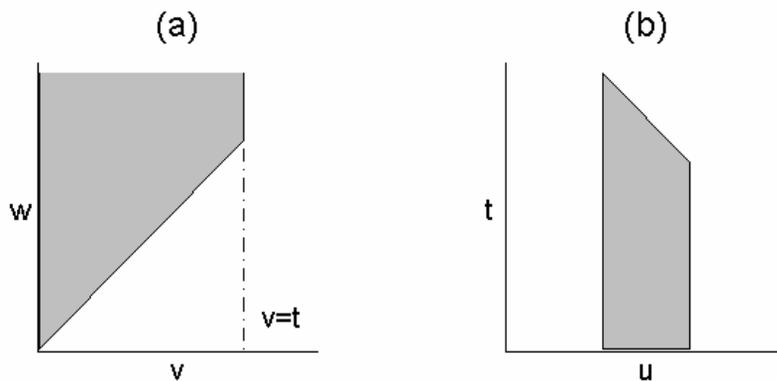

Figure D.2: Geometry of integration

Figure D.2 (a) illustrates a geometry of the integration. A shaded area marks the area of integration in the (v, u) plane.

In a calculation of $d(l)$ we make a distinction between the following cases

Table 1 Special cases.

| Case | l and l^* | $d_A(l)$ | $d_B(l)$ |
|------|--|-------------------------------|------------------------------------|
| 1 | $0 \leq l \leq S_a$ $l^* < 0$ | 0 | $\int_0^l a(u)\Psi(l-u)du$ |
| 2 | $0 \leq l \leq S_a$ $0 \leq l^* \leq S_a - m$ | $\Psi(m) \int_0^{l^*} a(u)du$ | $\int_{l^*}^l a(u)\Psi(l-u)du$ |
| 3 | $S_a < l \leq S_a + m$ $l^* < 0$ | 0 | $\int_0^{S_a} a(u)\Psi(l-u)du$ |
| 4 | $S_a < l \leq S_a + m$ $0 \leq l^* \leq S_a$ | $\Psi(m) \int_0^{l^*} a(u)du$ | $\int_{l^*}^{S_a} a(u)\Psi(l-u)du$ |
| 5 | $S_a + m < l$ $S_a < l^*$ | $\Psi(m) \int_0^{S_a} a(u)du$ | 0 |

We approximate $a(u)$ by a piece-wise constant function splitting an accrual interval

into $i = 1, \dots, n_a$ subintervals with the boundaries $[u_{i-1}, u_i)$ and denoting a constant accrual rate within an interval i by a_i . If the calendar time l^* is located within the interval i^* then

$$\int_0^{l^*} a(u)du = \sum_{i=1}^{i^*-1} a_i (u_i - u_{i-1}) + a_{i^*} (l^* - u_{i^*-1})$$

If $l^* = S_a = u_{n_a}$ then we get

$$\int_0^{S_a} a(u)du = \sum_{i=1}^{n_a} a_i (u_i - u_{i-1})$$

An integral $\int_{u_1}^{u_2} a(u)\Psi(l-u)du$ where u_1 belongs to an interval i_1 and u_2 belongs to an interval i_2 may be written as

$$\begin{aligned} \int_{u_1}^{u_2} a(u)\Psi(l-u)du = & a_{i_1} \varphi(u_1, u_{i_1}, l) + \sum_{i=i_1+1}^{i_2-1} a_i \varphi(u_{i-1}, u_i, l) + \\ & + a_{i_2} \varphi(u_{i_2-1}, u_2, l) \end{aligned}$$

with

$$\varphi(u_{min}, u_{max}, l) = \int_{u_{min}}^{u_{max}} \Psi(l-u)du = \int_{u_{min}}^{u_{max}} du \int_0^{l-u} \kappa(t)dt$$

and $l \geq u_{max}$. An integration region of the two-dimensional integral is shown as a shaded area on Figure D.2 (b). A more convenient expression for $\varphi(u_{min}, u_{max}, l)$ is obtained by changing the order of integration

$$\begin{aligned} \varphi(u_{min}, u_{max}, l) &= \int_0^{l-u_{max}} dt \int_{u_{min}}^{u_{max}} \kappa(t)du + \int_{l-u_{max}}^{l-u_{min}} dt \int_{u_{min}}^{l-t} \kappa(t)du \\ &= (u_{max} - u_{min}) \int_0^{l-u_{max}} \kappa(t)dt \\ &+ \int_{l-u_{max}}^{l-u_{min}} (l - u_{min} - t)\kappa(t)dt \end{aligned} \tag{D.2}$$

The integrals can be calculated numerically for an arbitrary hazard functions $\lambda(t)$ and $\gamma(t)$. In a special case of piece-wise constant hazard functions a calculation of the integrals $\int_a^b \kappa(t)dt$ and $\int_a^b \kappa(t)tdt$ in equation (D.2) is simplified. An integral over the interval (a, b) is presented as a sum of the integrals over the intervals $[t_{j-1}, t_j)$, $j = 1, \dots, J$ where both hazard and drop out rates λ_j and γ_j are constant. These integrals are calculated analytically

$$\int_a^b \kappa(t)dt = \sum_{j=1}^J I_{0j} \tag{D.3}$$

D Computing the Expected Number of Events

where

$$\begin{aligned} I_{0j} &= \int_{t_{j-1}}^{t_j} \kappa(t) dt = \lambda_j e^{-[\Lambda(t_{j-1})+H(t_{j-1})]} \int_{t_{j-1}}^{t_j} e^{-\lambda_{s,j}(t-t_{j-1})} dt \\ &= c_j \left[1 - e^{-\lambda_{s,j}(t_j-t_{j-1})} \right] \end{aligned}$$

with $\lambda_{s,j} = \lambda_j + \gamma_j$ and

$$c_j = \frac{\lambda_j}{\lambda_{s,j}} e^{-[\Lambda(t_{j-1})+H(t_{j-1})]} \tag{D.4}$$

Similarly

$$\int_a^b \kappa(t) t dt = \sum_{j=1}^J I_{1j} \tag{D.5}$$

where

$$\begin{aligned} I_{1j} &= \int_{t_{j-1}}^{t_j} \kappa(t) t dt = \lambda_j e^{-[\Lambda(t_{j-1})+H(t_{j-1})]} \int_{t_{j-1}}^{t_j} e^{\lambda_{s,j}(t-t_{j-1})} t dt \\ &= c_j \left[\left(t_{j-1} + \frac{1}{\lambda_{s,j}} \right) - e^{-\lambda_{s,j}(t_j-t_{j-1})} \left(t_j + \frac{1}{\lambda_{s,j}} \right) \right] \end{aligned} \tag{D.6}$$

In the following sections we present simplified versions of these general expressions that correspond to the more restrictive settings.

D.2 Fixed hazard rate, uniform accrual

- D.2.1 General setting
- D.2.2 No drop out and no fixed follow-up
- D.2.3 Drop out and no fixed follow-up.
- D.2.4 No drop out and fixed follow-up.

D.2.1 General setting

Consider a situation where the event hazard rate is constant ($\lambda(t) = \lambda$), the accrual rate is uniform ($a(t) = a$), and there are the drop outs hazard rate is constant ($\gamma(t) = \gamma$). A subject is followed up to a maximum of $m < \infty$ units of time if an event of interest or drop out does not occur first. The following derivation gives the formula for the expected number of events at calendar time l for all of the cases listed in Table 1.

$0 \leq l \leq S_a, l^* < 0$:

$$d(l) = a \varphi(0, l, l) = a \left[\int_0^l (l-t) \kappa(t) dt \right] = a \left[l \int_0^l \kappa(t) dt - \int_0^l \kappa(t) t dt \right]$$

An application of expressions (D.4) and (D.6) leads to the following results

$$\int_0^l \kappa(t)dt = \frac{\lambda}{\lambda + \gamma} \left[1 - e^{-(\lambda + \gamma)l} \right]$$

$$\int_0^l \kappa(t)t dt = \frac{\lambda}{\lambda + \gamma} \left[\frac{1}{\lambda + \gamma} - e^{-(\lambda + \gamma)l} \left(l + \frac{1}{\lambda + \gamma} \right) \right]$$

Therefore

$$d(l) = \frac{a\lambda}{\lambda + \gamma} \left[\left(l - \frac{1}{\lambda + \gamma} \right) + \frac{e^{-(\lambda + \gamma)l}}{\lambda + \gamma} \right] \tag{D.7}$$

$0 \leq l \leq S_a, 0 \leq l^* \leq S_a - m:$

$$d_A(l) = a(l - m) \int_0^m \kappa(t)dt = \frac{a\lambda(l - m)}{\lambda + \gamma} \left(1 - e^{-(\lambda + \gamma)m} \right)$$

$$\begin{aligned} d_B(l) &= a \varphi(l^*, l, l) = a \int_0^{l-l^*} (l - l^* - t) \kappa(t) dt = \\ &= a \left[m \int_0^m \kappa(t) dt - \int_0^m \kappa(t)t dt \right] \end{aligned}$$

An application of equations (D.4) – (D.6) leads to the following expressions

$$\int_0^m \kappa(t)dt = \frac{\lambda}{\lambda + \gamma} \left(1 - e^{-(\lambda + \gamma)m} \right)$$

$$\int_0^m \kappa(t)t dt = \frac{\lambda}{\lambda + \gamma} \left[\frac{1}{\lambda + \gamma} - e^{-(\lambda + \gamma)m} \left(m + \frac{1}{\lambda + \gamma} \right) \right]$$

Therefore

$$d_B(l) = \frac{a\lambda}{\lambda + \gamma} \left[\left(m - \frac{1}{\lambda + \gamma} \right) + \frac{e^{-(\lambda + \gamma)m}}{\lambda + \gamma} \right]$$

The resulting expression is

$$d(l) = \frac{a\lambda}{\lambda + \gamma} \left[\left(l - \frac{1}{\lambda + \gamma} \right) - e^{-(\lambda + \gamma)m} \left(l - m - \frac{1}{\lambda + \gamma} \right) \right] \tag{D.8}$$

D Computing the Expected Number of Events

$$S_a < l \leq S_a + m, l^* < 0 :$$

$$\begin{aligned} d(l) &= a \varphi(0, S_a, l) = a \left[S_a \int_0^{l-S_a} \kappa(t) dt + \int_{l-S_a}^l (l-t) \kappa(t) dt \right] \\ &= a \left[S_a \int_0^{l-S_a} \kappa(t) dt + l \int_{l-S_a}^l \kappa(t) dt - \int_{l-S_a}^l \kappa(t) t dt \right] \end{aligned}$$

An application of equations (D.4) – (D.6) leads to the following expressions

$$\int_0^{l-S_a} \kappa(t) dt = \frac{\lambda}{\lambda + \gamma} \left(1 - e^{-(\lambda+\gamma)(l-S_a)} \right)$$

$$\int_{l-S_a}^l \kappa(t) dt = \frac{\lambda}{\lambda + \gamma} e^{-(\lambda+\gamma)(l-S_a)} \left(1 - e^{-(\lambda+\gamma)S_a} \right)$$

$$\begin{aligned} \int_{l-S_a}^l \kappa(t) t dt &= \frac{\lambda}{\lambda + \gamma} e^{-(\lambda+\gamma)(l-S_a)} \\ &\quad \left[\left(l - S_a + \frac{1}{\lambda + \gamma} \right) - e^{-(\lambda+\gamma)S_a} \left(l + \frac{1}{\lambda + \gamma} \right) \right] \end{aligned}$$

and the resulting expression for $d(l)$ has the following form

$$d(l) = \frac{a\lambda}{\lambda + \gamma} \left[S_a - \frac{e^{-(\lambda+\gamma)l}}{\lambda + \gamma} \left(e^{(\lambda+\gamma)S_a} - 1 \right) \right] \quad (D.9)$$

$$S_a < l \leq S_a + m, 0 \leq l^* \leq S_a :$$

$$d_A(l) = \Psi(m) \int_0^{l^*} a(u) du = \left[\frac{\lambda}{\lambda + \gamma} \left(1 - e^{-(\lambda+\gamma)m} \right) \right] a(l - m)$$

$$\begin{aligned} d_B(l) &= a \varphi(l^*, S_a, l) = a \left[(S_a - l^*) \int_0^{l-S_a} \kappa(t) dt + \int_{l-S_a}^{l-l^*} (l-l^*-t) \kappa(t) dt \right] \\ &= a \left[(S_a - l^*) \int_0^{l-S_a} \kappa(t) dt + m \int_{l-S_a}^m \kappa(t) dt - \int_{l-S_a}^m \kappa(t) t dt \right] \end{aligned}$$

An application of equations (D.4) – (D.6) leads to the following expressions

$$\int_0^{l-S_a} \kappa(t)dt = \frac{\lambda}{\lambda + \gamma} \left(1 - e^{-(\lambda+\gamma)(l-S_a)}\right)$$

$$\int_{l-S_a}^m \kappa(t)dt = \frac{\lambda}{\lambda + \gamma} e^{-(\lambda+\gamma)(l-S_a)} \left(1 - e^{-(\lambda+\gamma)(m+S_a-l)}\right)$$

$$\int_{l-S_a}^m \kappa(t)tdt = \frac{\lambda}{\lambda + \gamma} e^{-(\lambda+\gamma)(l-S_a)} \left[\left(l - S_a + \frac{1}{\lambda + \gamma}\right) - e^{-(\lambda+\gamma)(m+S_a-l)} \left(m + \frac{1}{\lambda + \gamma}\right) \right]$$

Therefore

$$d_B(l) = \frac{a\lambda}{\lambda + \gamma} \left[(S_a + m - l) - \frac{e^{-(\lambda+\gamma)l}}{\lambda + \gamma} \left(e^{(\lambda+\gamma)S_a} - e^{(\lambda+\gamma)(l-m)} \right) \right]$$

and

$$d(l) = \frac{a\lambda}{\lambda + \gamma} \left[S_a - (l - m)e^{-(\lambda+\gamma)m} - \frac{e^{-(\lambda+\gamma)l}}{\lambda + \gamma} \left(e^{(\lambda+\gamma)S_a} - e^{(\lambda+\gamma)(l-m)} \right) \right] \tag{D.10}$$

$S_a + m < l, S_a < l^*$:

Events that occur at the calendar time l exceeding $S_a + m$ are not observed because the maximum follow-up time m is limited. The expression for $d(l)$ has the following form

$$d(l) = a S_a \Psi(m) = \frac{a S_a \lambda}{\lambda + \gamma} \left(1 - e^{-(\lambda+\gamma)m}\right) \tag{D.11}$$

D.2.2 No drop out and no fixed follow-up

In this situation the event hazard rate is constant ($\lambda(t) = \lambda$), the accrual rate is uniform ($a(u) = a$), there are no drop outs ($\gamma(t) = 0$), and subjects are followed up until the end of study ($m = \infty$). In the unlimited follow-up time setting $l^* = l - m$ is always negative and only the cases 1 and 3 from the Table 1 are to be considered. The

D Computing the Expected Number of Events

following expressions for $d(l)$ are obtained from equations (D.7, D.9) by a substitution of $\gamma = 0$.

$$0 < l \leq S_a, l^* < 0:$$

$$d(l) = a \left[\left(l - \frac{1}{\lambda} \right) + \frac{e^{-\lambda l}}{\lambda} \right]$$

$$S_a < l, l^* < 0:$$

$$d(l) = a \left[S_a - \frac{e^{-\lambda l}}{\lambda} (e^{\lambda S_a} - 1) \right]$$

D.2.3 Drop out and no fixed follow-up.

In this situation we consider the event hazard rate is constant ($\lambda(t) = \lambda$), the accrual rate is uniform ($a = a$), the drop out hazard rate $\gamma(t) = \gamma$ is non-zero, and subjects are followed up until the end of study ($m = \infty$). Once again, the cases 1 and 3 from Table 1 are to be considered and the expressions (D.7, D.9) are directly applicable.

$$0 < l \leq S_a, l^* < 0:$$

$$d(l) = \frac{a\lambda}{\lambda + \gamma} \left[\left(l - \frac{1}{\lambda + \gamma} \right) + \frac{e^{-(\lambda + \gamma)l}}{\lambda + \gamma} \right]$$

$$S_a < l, l^* < 0:$$

$$d(l) = \frac{a\lambda}{\lambda + \gamma} \left[S_a - \frac{e^{-(\lambda + \gamma)l}}{\lambda + \gamma} (e^{(\lambda + \gamma)S_a} - 1) \right]$$

D.2.4 No drop out and fixed follow-up.

Now consider a situation where the event hazard rate is constant ($\lambda(t) = \lambda$), the accrual rate is uniform ($a(t) = a$), and there are no drop outs ($\gamma(t) = 0$). However, each subject is now followed up to a maximum of $m < \infty$ units of time if an event of

interest or drop out does not occur first. The following expressions are obtained from equations (D.7–D.11) by a substitution of $\gamma = 0$.

$0 \leq l \leq S_a, l^* < 0$:

$$d(l) = a \left[\left(l - \frac{1}{\lambda} \right) + \frac{e^{-\lambda l}}{\lambda} \right]$$

$0 \leq l \leq S_a, 0 \leq l^* \leq S_a - m$:

$$d(l) = a \left[\left(l - \frac{1}{\lambda} \right) - e^{-\lambda m} \left(l - m - \frac{1}{\lambda} \right) \right]$$

$S_a < l \leq S_a + m, l^* < 0$:

$$d(l) = a \left[S_a - \frac{e^{-\lambda l}}{\lambda} (e^{\lambda S_a} - 1) \right]$$

$S_a < l \leq S_a + m, 0 \leq l^* \leq S_a$:

$$d(l) = a \left[S_a - (l - m)e^{-\lambda m} - \frac{e^{-\lambda l}}{\lambda} (e^{\lambda S_a} - e^{\lambda(l-m)}) \right]$$

$S_a + m < l, S_a < l^*$:

$$d(l) = a S_a (1 - e^{-\lambda m})$$

D.3 Piecewise constant hazard and drop out rates, no follow-up limit

Consider a setting where an accrual is uniform ($a(u) = a$) and hazard and drop-out rates are piece-wise constant so that $\lambda(t) = \lambda_k$ and $\gamma(t) = \gamma_k$ for $[\tau_{k-1} \leq t < \tau_k)$. We also assume that there is no follow-up limit ($m = \infty$). For the unlimited follow-up time m the value $l^* = l - m$ is always negative and therefore only the cases 1 and 3 from the Table 1 are to be considered.

$0 < l \leq S_a, l^* < 0$:

$$d(l) = a \varphi(0, l, l) = \int_0^l (l - t)\kappa(t)dt = l \int_0^l \kappa(t)tdt - \int_0^l \kappa(t)tdt$$

We denote by k^* the number of the interval $[\tau_{k^*-1}, \tau_{k^*})$ which contains l . The integrals $\int_0^l \kappa(t)tdt$ and $\int_0^l \kappa(t)tdt$ are calculated using the expressions (D.3) – (D.6) with $a = 0, b = l, J = k^*, t_j = \tau_j$ for $j = 0, \dots, J - 1$ and $t_J = l$.

D Computing the Expected Number of Events

$S_a < l, l^* < 0$:

$$\begin{aligned} d(l) &= a \varphi(0, S_a, l) = S_a \int_0^{l-S_a} \kappa(t) dt + \int_{l-S_a}^l (l-t) \kappa(t) dt \\ &= S_a \int_0^{l-S_a} \kappa(t) dt + l \int_{l-S_a}^l \kappa(t) dt - \int_{l-S_a}^l \kappa(t) t dt \end{aligned}$$

We denote by k^* the number of the interval $[\tau_{k^*-1}, \tau_{k^*})$ which contains S_a and by k' the number of the interval $\tau_{k'-1}, \tau_{k'}$ which contains $l - S_a$. The calculation of the integrals $\int_0^{S_a} \kappa(t) dt$, $\int_{l-S_a}^l \kappa(t) dt$ and $\int_{l-S_a}^l \kappa(t) t dt$ is based on the expressions (D.3) – (D.6). In the calculation of an integral over the interval $(0, S_a)$ we use $a = 0, b = S_a, J = k^*, t_j = \tau_j$ for $j = 0, \dots, J-1$ and $t_J = S_a$. The corresponding values used in the calculation of the integrals over the interval $(l - S_a, l)$ are $a = l - S_a, b = l, J = k^* - k' + 1, t_0 = l - S_a, t_j = \tau_{k'-1+j}, j = 1, \dots, J-1$ and $t_J = l$.

D.4 Non-uniform accrual, constant hazard and drop out rates

If the setting where an accrual $a(u)$ is not uniform but hazard and drop-out rates are constant the following simplified expressions for the integrals in the expression D.2 are available

$$\int_0^{l-u_{max}} \kappa(t) dt = \frac{\lambda}{\lambda_s} \left[1 - e^{-\lambda_s(l-u_{max})} \right]$$

$$\int_{l-u_{max}}^{l-u_{min}} \kappa(t) dt = \frac{\lambda}{\lambda_s} e^{-\lambda_s(l-u_{max})} \left[1 - e^{-\lambda_s(u_{max}-u_{min})} \right]$$

$$\begin{aligned} \int_{l-u_{max}}^{l-u_{min}} \kappa(t) t dt &= \frac{\lambda}{\lambda_s} e^{-\lambda_s(l-u_{max})} \\ &\left[l - u_{max} + \frac{1}{\lambda_s} - e^{-\lambda_s(u_{max}-u_{min})} \left(l - u_{min} + \frac{1}{\lambda_s} \right) \right] \end{aligned}$$

and $\lambda_s = \lambda + \gamma$.

E Generating Survival Simulations in EastSurv

East provides the user with powerful simulation tools for trials with time-to-event endpoints. In addition to easily verifying the operating characteristics of the many different design scenarios mentioned in Appendix B, the simulations may be used to actually design for non-standard problems where power and sample size calculations are analytically intractable. For instance, East allows the user to simulate trials in which the hazard rates for each treatment arm are non-proportional. By trial and error, running simulations under various parameter choices, the user may find an appropriate design for this kind of trial. East actually provides two simulation methods: a) Basic simulation and b) Enhanced simulation.

The Basic simulation method uses asymptotic theory when generating the data and is discussed in the main East manual. In East 3.1, the enhanced simulation also used asymptotic theory to generate the data, but allowed the user to change some of the design parameter values in order to simulate under various scenarios. EastSurv's enhanced simulation tool no longer generates the data using asymptotic theory. The purpose of this appendix in fact is to outline how the data are generated in the new enhanced survival simulations.

When initiating an enhanced survival simulation session, East uses as input all the parameters selected during the design stage. By clicking on the "Show Survival Parameters" button, a survival sheet is opened that allows the user to change these parameter values. In fact, the flexibility offered to the user in this screen is such that the piecewise exponential hazard curves in each treatment arm can be individually specified. This permits the user to specify late separating hazard curves or even crossing hazard curves. In addition, the user must also decide how each simulated trial will terminate by choosing whether to a) fix the number of events in the trial or b) fix the study duration. Once this is done, clicking either the "Run" button or "Single Step" button starts the simulations. East then proceeds as follows.

In each simulation:

1. For each accrual period
 - (a) East computes the number of subjects to be accrued in the control group and the treatment group.
 - (b) For each subject i
 - i. A random accrual time $t_{acc,i}$ of subject i is generated as a random value from the uniform distribution bounded by the starting and ending times of the current accrual period

E Generating Survival Simulations in EastSurv

- ii. A random survival time $t_{surv,i}$ is generated as a random value from the survival time distribution characterized by a piecewise hazard rate
- iii. A random dropout time $t_{drop,i}$ is generated as a random value from the exponential distribution characterized by the dropout rate.
- iv. An indicator of censoring C_i is computed as

$$\begin{cases} C_i = 0 & \text{if } t_{surv,i} \geq t_{drop,i} \text{ and } t_{surv,i} \geq t_{fix} \\ C_i = 1 & \text{otherwise} \end{cases}$$

where t_{fix} is the user-specified fixed maximum follow-up time of a subject.

2. Now for each look j
 - (a) If the timing of the look j is characterized by the time S_j since the initiation of the study then the value of S_j is predefined.
 - (b) If the timing of the look j is driven by the number of events so that the look j occurs immediately after observing N_j events then S_j is calculated based on the study times $t_{study,i} = t_{acc,i} + t_{surv,i}$ of the uncensored observations (with $C_i = 0$).
 - (c) At the time S_j the subset of observations of interest is limited to the observations from accrued subjects ($t_{acc,i} \leq S_j$). For the look-based analysis the observations with $t_{study,i} > S_j$ are treated as censored.
 - (d) The calculated values of S_j or N_j are stored for the subsequent calculation of average values across the simulations.
 - (e) East computes the test statistic and checks if a stopping boundary has been crossed.
 - i. If yes, or if the last look has been reached without crossing a stopping boundary, it proceeds to the next simulation.
 - ii. Otherwise, it proceeds to the next look.

F Spending Functions Derived from Power Boundaries

East provides several families of published spending functions, each with a well defined functional form. These spending functions are all documented in Section B.2.4 of Appendix B. The general approach is to select one of these published spending functions for generating the stopping boundaries at the design stage and to select the same spending function to re-compute the stopping boundaries at the interim monitoring stage. This gives us the flexibility to change the number and spacing of the interim looks during the interim monitoring stage.

However, the Wang-Tsiatis (1987) and Pampallona-Tsiatis (1994) power boundaries are not derived from spending functions. If these boundaries is used for the study design they should also be used for interim monitoring. This could be problematic if the number and spacing of the interim looks changes from what was specified at the design stage. For this reason we construct special “ten-look” spending functions that correspond to the members of the Wang-Tsiatis or Pampallona-Tsiatis family. The next section shows how this is accomplished.

F.1 Inverting Ten-Look Power Boundaries

For each Wang-Tsiatis power boundary of the form

$$C(\Delta, \alpha, K)t_j^\Delta, \quad j = 1, 2, \dots, K,$$

we compute the type-1 errors, as they accumulate at each of the equally spaced looks, t_1, t_2, \dots, t_K , according to the selected values of Δ and α , but with a preset value for the maximum number of looks, $K = 10$. For example, suppose we wish to generate a spending function that corresponds to a one-sided Wang-Tsiatis power boundary for a specific value of α and Δ . The first step is to compute the actual boundary values at the ten equally spaced looks t_1, t_2, \dots, t_{10} , where $t_j = j/10$, using the procedure described in Section B.2.2 of Appendix B. Denote these ten boundary values by c_1, c_2, \dots, c_{10} . Next, compute the cumulative errors $\alpha(t_j)$, $j = 1, 2, \dots, 10$, where

$$\alpha(t_1) = P_0[W(t_1) \geq c_1],$$

and for $j = 2, 3, \dots, 10$,

$$\alpha(t_j) = \alpha(t_{j-1}) + P_0[W(t_1) < c_1, \dots, W(t_{j-1}) < c_{j-1}, W(t_j) \geq c_j].$$

These computations are clearly unaffected by the type of end point since the test statistic can be expressed in the general framework of Section B.1. Linear interpolation between these cumulative errors is then applied for setting up approximate spending functions for the type-1 and type-2 error probabilities to be used at the interim monitoring stage. This approach will make the resulting re-computed boundaries at the

F Spending Functions Derived from Power Boundaries

interim monitoring stage enjoy approximately the same properties as the corresponding original boundaries obtained at the design stage while still providing flexibility to deviate from the pre-specified number and timing of the interim looks. However, as a consequence of fixing $K = 10$ for deriving the spending function in the interim monitoring module, even though we might have used a different value of K in the design module, there can be slight differences in the boundary values computed at the design stage and the boundary values computed at the interim monitoring stage. In practice this difference is negligible, as we show below in Section F.2..

F.2 Comparison of Design Boundaries and Interim Monitoring Boundaries

At the design stage East computes the Wang and Tsatis (1987) or Pampallona and Tsatis (1990) power boundaries directly, as documented in Appendix B, Sections B.2.2 and B.2.3. These boundaries depend on K , the number of equally spaced interim looks. At the interim monitoring stage, however, East re-computes the stopping boundaries by inverting a ten-look error spending function, as documented above Section F.1. This implies that, even if the interim monitoring actually takes place as designed at K equally spaced looks, the design boundaries won't match the interim monitoring boundaries, unless $K = 10$. This is not of much practical importance since, as a consequence of the flexible spending function methodology, interim monitoring will rarely occur at precisely the same time-points as was specified in the design. Table F.1 and Table F.2, display the O'Brien-Fleming power boundaries obtained at the design stage, for $K = 5$ and $K = 3$, respectively, and the corresponding boundaries obtained by inverting a ten-look error spending function, for a two-sided test at $\alpha = 0.05$. We observe that the difference between the design and interim monitoring boundaries is very small.

Table F.1: Design and Interim Monitoring Boundaries for Five Equally Spaced Looks

| Look No. | Information Fraction | Design Boundary | Monitoring Boundary |
|----------|----------------------|-----------------|---------------------|
| 1 | 0.2 | ± 4.562 | ± 4.692 |
| 2 | 0.4 | ± 3.226 | ± 3.285 |
| 3 | 0.6 | ± 2.634 | ± 2.656 |
| 4 | 0.8 | ± 2.281 | ± 2.285 |
| 5 | 1.0 | ± 2.040 | ± 2.035 |

Table F.2: Design and Interim Monitoring Boundaries for Three Equally Spaced Looks

| Look No. | Information Fraction | Design Boundary | Monitoring Boundary |
|----------|----------------------|-----------------|---------------------|
| 1 | 0.333 | ±3.471 | ±3.518 |
| 2 | 0.667 | ±2.454 | ±2.487 |
| 3 | 1.000 | ±2.004 | ±1.998 |

F.3 Comparison of Ten-Look and Lan and DeMets Spending Functions

We stated in Section B.2.2 of Appendix B that the power boundaries proposed by Wang and Tsiatis (1987) generate, as a special case, the boundaries of O'Brien and Fleming (1979) if the shape parameter takes on the value $\Delta = 0$. We also stated in Section B.2.4 of Appendix B that the **LD (OF)** spending function (Lan-DeMets spending function with O'Brien-Fleming flavor) of the form

$$\alpha(t) = 4 - 4\Phi\left(\frac{z_{\alpha/4}}{\sqrt{t}}\right) \quad (\text{F.1})$$

generates two-sided boundaries similar to those proposed by O'Brien and Fleming. It is therefore of interest to see how the spending function derived from the ten-look design compares with $\alpha(t)$. The figure below shows that the two spending functions

F Spending Functions Derived from Power Boundaries

have very similar behaviors.

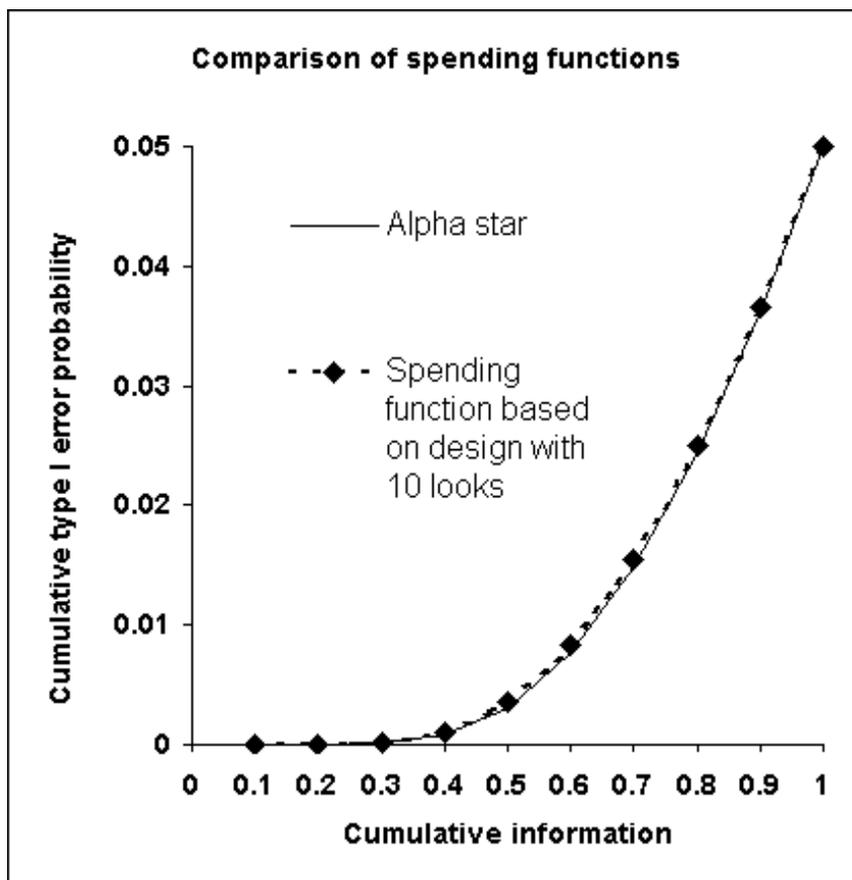

Table F.3 displays the amount of type-I error actually spent, at each of five equally spaced looks by the two error spending functions given an overall type-I error of $\alpha = 0.05$. Corresponding stopping boundaries are also displayed. We note that the differences are very minor. The last column of Table F.3 displays the actual O'Brien and Fleming power boundaries based on shape parameter $\Delta = 0$, and number of looks $K = 5$, using the computations discussed in Appendix B, Section B.2.2. These boundaries too are very similar to the boundaries derived from the two error spending functions.

Table F.3: Comparing 10-Look and Lan-DeMets Spending Functions

| Look No. | Fraction (t) | Error Spent | | Stopping Boundaries | | |
|----------|----------------|-------------|-------------|---------------------|-------------|-------------|
| | | 10-Look | $\alpha(t)$ | 10-Look | $\alpha(t)$ | 5-look |
| 1 | 0.2 | 0.000003 | 0.000001 | ± 4.692 | ± 4.877 | ± 4.562 |
| 2 | 0.4 | 0.001020 | 0.000789 | ± 3.285 | ± 3.357 | ± 3.226 |
| 3 | 0.6 | 0.008262 | 0.007617 | ± 2.656 | ± 2.680 | ± 2.634 |
| 4 | 0.8 | 0.025008 | 0.024424 | ± 2.285 | ± 2.290 | ± 2.281 |
| 5 | 1 | 0.05 0000 | 0.050000 | ± 2.035 | ± 2.031 | ± 2.040 |

G *The Recursive Integration Algorithm*

Substantial savings in computational effort can be achieved in the computations of the group sequential boundaries. We will give details of this savings using one-sided tests of hypothesis with boundary only for the rejection of H_0 . But the same applies to other situations.

At the time of the j^{th} interim monitoring, the group sequential boundary is determined by

$$\Pr_0(W(t_1) < b_1, \dots, W(t_{j-1}) < b_{j-1}, W(t_j) \geq b_j) = \alpha^*(t_j) - \alpha^*(t_{j-1}). \quad (G.1)$$

The probability above is evaluated by the recursive integration formula by Armitage, McPherson and Rowe (1969); the density function for $W(t)$ in the discrete sequential procedure is given by

$$f_1(w; \eta) = t_1^{-1/2} \phi[t_1^{-1/2}(w - \eta t_1)],$$

and, by recursion

$$f_j(w; \eta) = \int_{-\infty}^{b_{j-1}} f_{j-1}(v; \eta) \Delta t_j^{-1/2} \phi[\Delta t_j^{-1/2}(w - v - \eta \Delta t_j)] dv \quad (G.2)$$

where $\Delta t_j = t_j - t_{j-1}$, for $j = 1, \dots, K$, with $t_0 = 0$, and ϕ is the standard normal density function. Equation (G.2) follows from the fact that, as discussed in Section B.1 of Appendix B, the distribution of $W(t_j)$ is $N(\eta t_j, t_j)$ with an independent increments structure..

To find the boundary for the j^{th} interim monitoring, we simply need to find the value of b_j such that

$$\int_{b_j}^{\infty} f_j(w; \eta) dw = \alpha^*(t_j) - \alpha^*(t_{j-1}).$$

Therefore, at each time of interim monitoring, instead of repeating the recursive numerical integration, we need to evaluate the numerical integration only once by storing internally previous boundary values b_1, \dots, b_{j-1} and the coordinates of the density function $f_{j-1}(w; \eta)$ for $-\infty < w < b_{j-1}$.

H Theory - Multiple Comparison Procedures

H.1 Parametric Procedures

H.1.1 Introduction

H.1.2 Single Step Dunnett Test

H.1.3 Step Down Dunnett Test

H.1.1 Introduction

Assume that there are k arms including the placebo arm. Let n_0 be the number of subjects for placebo arm and n_i the number of subjects for i^{th} treatment arm ($i = 1, 2, \dots, k - 1$). Let $N = \sum_{i=0}^{k-1} n_i$ be the total sample size. Let Y_{ij} be the response from subject j in treatment arm i and y_{ij} be the observed value of Y_{ij} ($i = 0, 1, \dots, k - 1, j = 1, 2, \dots, n_i$). Suppose that

$$Y_{ij} = \mu_i + e_{ij} \tag{H.1}$$

where $e_{ij} \sim N(0, \sigma^2)$. Let \bar{y}_i ($i = 0, 1, \dots, k - 1$) be the sample mean for treatment arm i and s^2 be the pooled sample variance for all arms. Let $T_i = \frac{\bar{y}_i - \bar{y}_0}{s \sqrt{\frac{1}{n_i} + \frac{1}{n_0}}}$ be the

test statistic for comparing treatment effect of arm i with placebo. Let $T_{(1)} \geq T_{(2)} \geq \dots \geq T_{(k-1)}$ be the ordered statistics of T_i . Let t_i ($i = 1, \dots, k - 1$) be the observed values of T_i and $t_{(1)} \geq t_{(2)} \geq \dots \geq t_{(k-1)}$ be the observed values of $T_{(1)} \geq T_{(2)} \geq \dots \geq T_{(k-1)}$. We are interested in the following hypotheses

- For the right tailed test: $H_i : \mu_i - \mu_0 \leq 0$ vs $K_i : \mu_i - \mu_0 > 0$
- For the left tailed test: $H_i : \mu_i - \mu_0 \geq 0$ vs $K_i : \mu_i - \mu_0 < 0$
- For the global null hypothesis: $H_0 : \mu_0 = \mu_1 = \mu_2 = \dots = \mu_{k-1}$ vs $H_{01} : \text{At least one } \mu_i > \mu_0$ for right tailed test ($\mu_i < \mu_0$ for left tailed test)

H.1.2 Single Step Dunnett Test in One-Way ANOVA Design

Let $F(x)$ denote the distribution function of $T_{(1)}$ under the global null hypothesis H_0 , i.e.

$$F(x) = \Pr(T_{(1)} \leq x) = \int_0^\infty \int_{-\infty}^\infty J d\Phi(z) d\psi_\nu(u) \tag{H.2}$$

where $J = \prod_{i=1}^{k-1} \Phi\left[\frac{\gamma_i z + x u}{\sqrt{1 - \gamma_i^2}}\right]$ and $\Phi(\cdot)$ be the cumulative distribution function of standard normal variable such that

$$\frac{d\Phi(z)}{dz} = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2}\right) \tag{H.3}$$

is the standard normal density function and

$$\frac{d\psi_\nu(u)}{du} = \frac{\nu^{\frac{\nu}{2}}}{\Gamma\left(\frac{\nu}{2}\right) 2^{\frac{\nu}{2}-1}} u^{\nu-1} \exp\left(-\frac{\nu u^2}{2}\right) \tag{H.4}$$

H Theory - Multiple Comparison Procedures

is the density of $\sqrt{\frac{V}{\nu}}$, where V is a Chi-squared random variable with ν degrees of freedom and $\nu = N - k$. The parameter γ_i is

$$\gamma_i = \sqrt{\frac{n_i}{n_0 + n_i}} \quad (\text{H.5})$$

- Test statistics:

$$T_i = \frac{\bar{y}_i - \bar{y}_0}{s\sqrt{\frac{1}{n_i} + \frac{1}{n_0}}} \quad (i = 1, 2, \dots, k - 1) \quad (\text{H.6})$$

where

$$s^2 = \frac{1}{N - k} \sum_{i=0}^{k-1} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_i)^2 \quad (\text{H.7})$$

is the pooled sample variance.

- The critical values for single step Dunnett, denoted by c_α , satisfied the following equation
 - For the right tailed test

$$\int_0^\infty \int_{-\infty}^\infty \prod_{i=1}^{k-1} \Phi \left[\frac{\gamma_i z + c_\alpha u}{\sqrt{1 - \gamma_i^2}} \right] d\Phi(z) d\psi_\nu(u) = 1 - \alpha \quad (\text{H.8})$$

- For the left tailed test

$$\int_0^\infty \int_{-\infty}^\infty J d\Phi(z) d\psi_\nu(u) = 1 - \alpha \quad (\text{H.9})$$

where $J = \prod_{i=1}^{k-1} \left(1 - \Phi \left[\frac{\gamma_i z + c_\alpha u}{\sqrt{1 - \gamma_i^2}} \right] \right)$.

- Decisions:
 - For the right tailed test, reject H_i if $t_i > c_\alpha$
 - For the left tailed test, reject H_i if $t_i < c_\alpha$
- Adjusted p -values for individual hypothesis H_i : $\tilde{p}_i = 1 - F(t_i)$ where
 - For the right tailed tests:

$$F(t_i) = \int_0^\infty \int_{-\infty}^\infty \prod_{i=1}^{k-1} \Phi \left[\frac{\gamma_i z + t_i u}{\sqrt{1 - \gamma_i^2}} \right] d\Phi(z) d\psi_\nu(u) \quad (\text{H.10})$$

– For the left tailed tests:

$$F(t_i) = \int_0^\infty \int_{-\infty}^\infty Jd\Phi(z) d\psi_\nu(u) \tag{H.11}$$

where $J = \prod_{i=1}^{k-1} \left(1 - \Phi \left[\frac{\gamma_i z + t_i u}{\sqrt{1 - \gamma_i^2}} \right] \right)$.

■ Adjusted p - value for testing the global null hypothesis H_0 :

– For the right tailed tests $\tilde{p} = 1 - F(t_{(1)})$ where $t_{(1)} = \max \{t_i : i = 1, \dots, k - 1\}$ and

$$F(t_{(1)}) = \int_0^\infty \int_{-\infty}^\infty Jd\Phi(z) d\psi_\nu(u) \tag{H.12}$$

where $J = \prod_{i=1}^{k-1} \Phi \left[\frac{\gamma_i z + t_{(1)} u}{\sqrt{1 - \gamma_i^2}} \right]$.

– For the left tailed tests $\tilde{p} = 1 - F(t_{(k-1)})$ where $t_{(k-1)} = \min \{t_i : i = 1, \dots, k - 1\}$ and

$$F(t_{(k-1)}) = \int_0^\infty \int_{-\infty}^\infty Jd\Phi(z) d\psi_\nu(u) \tag{H.13}$$

where $J = \prod_{i=1}^{k-1} \left(1 - \Phi \left[\frac{\gamma_i z + t_{(k-1)} u}{\sqrt{1 - \gamma_i^2}} \right] \right)$.

H.1.3 Step Down Dunnett Test in One-Way ANOVA

Let $H_{(i)}$ be the associated null hypothesis with $t_{(i)}$ ($i = 1, \dots, k - 1$). Let $n_{(i)}$ be the number of subjects for the treatment arm associated with $H_{(i)}$. Let R_{k-1} be the correlation matrix of the unordered statistics associated with $H_{(1)}, H_{(2)}, \dots, H_{(k-1)}$ which has the element at i th row and j th column $\rho_{ij} = \gamma_i \gamma_j$ where $\gamma_i = \sqrt{\frac{n_{(i)}}{n_{(i)} + n_0}}$ and $\gamma_j = \sqrt{\frac{n_{(j)}}{n_{(j)} + n_0}}$. Let $\nu = N - k$. Let c_i ($i = 1, 2, \dots, k - 1$) be the critical values for step-down Dunnett procedure. Let $\Phi(\cdot)$ be the cumulative distribution function of standard normal variable such that

$$\frac{d\Phi(z)}{dz} = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{z^2}{2}\right) \tag{H.14}$$

is the standard normal density function and

$$\frac{d\psi_\nu(u)}{du} = \frac{\nu^{\frac{\nu}{2}}}{\Gamma\left(\frac{\nu}{2}\right) 2^{\frac{\nu}{2}-1}} u^{\nu-1} \exp\left(-\frac{\nu u^2}{2}\right) \tag{H.15}$$

H Theory - Multiple Comparison Procedures

is the density of $U = \sqrt{\frac{V}{\nu}}$, where V is a Chi-squared random variable with ν degrees of freedom and $\nu = N - k$.

- Test statistics:

$$T_i = \frac{\bar{y}_i - \bar{y}_0}{s \sqrt{\frac{1}{n_i} + \frac{1}{n_0}}} \quad (\text{H.16})$$

where

$$s^2 = \frac{1}{N - k} \sum_{i=0}^{k-1} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_i)^2 \quad (\text{H.17})$$

is the pooled sample variance for all arms.

- Critical values c_i satisfy the following equations

- For the right tailed tests

$$G_i(c_i) = \int_0^\infty \int_{-\infty}^\infty J d\Phi(z) d\psi_\nu(u) = 1 - \alpha \quad (\text{H.18})$$

where $J = \prod_{j=i}^{k-1} \Phi \left[\frac{\gamma_j z + c_i u}{\sqrt{1 - \gamma_j^2}} \right]$.

- For the left tailed tests

$$G_i(c_i) = \int_0^\infty \int_{-\infty}^\infty J d\Phi(z) d\psi_\nu(u) = 1 - \alpha \quad (\text{H.19})$$

where $J = \prod_{j=1}^i \left(1 - \Phi \left[\frac{\gamma_j z + c_i u}{\sqrt{1 - \gamma_j^2}} \right] \right)$.

- Decisions: The step down Dunnett procedure can be carried out as follows:

- For the right tailed tests

- * Step 1: If $t_{(1)} > c_1$, reject $H_{(1)}$ and go to the next step; otherwise retain all hypotheses and stop.
- * Step $i = 2, \dots, k - 2$: If $t_{(i)} > c_i$, reject H_i and go to the next step; otherwise retain $H_{(i)}, H_{(i+1)}, \dots, H_{(k-1)}$ and stop.
- * Step $k - 1$: If $t_{(k-1)} > c_{k-1}$, reject $H_{(k-1)}$ and stop; otherwise retain $H_{(k-1)}$ and stop.

- For the left tailed tests

- * Step 1: If $t_{(k-1)} < c_1$, reject $H_{(k-1)}$ and go to the next step; otherwise retain all hypotheses and stop.

- * Step $i = 2, \dots, k - 2$: If $t_{(k-i)} < c_i$, reject H_{k-i} and go to the next step; otherwise retain $H_{(1)}, H_{(2)}, \dots, H_{(k-i)}$ and stop.
- * Step $k - 1$: If $t_{(1)} < c_{k-1}$, reject $H_{(1)}$ and stop; otherwise retain $H_{(1)}$ and stop.

■ Adjusted p-values for individual hypothesis:

- For the right tailed test

$$\tilde{p}_{(i)} = \begin{cases} p_i & \text{if } i = 1 \\ \max \{ \tilde{p}_{(i-1)}, p_i \} & \text{if } i = 2, \dots, k - 1 \end{cases} \quad (\text{H.20})$$

where

$$p_i = 1 - F(t_{(i)}) \quad (\text{H.21})$$

$$G_i(t_{(i)}) = \int_0^\infty \int_{-\infty}^\infty \prod_{j=i}^{k-1} \Phi \left[\frac{\gamma_j z + t_{(i)} u}{\sqrt{1 - \gamma_j^2}} \right] d\Phi(z) d\psi_\nu(u) \quad (\text{H.22})$$

- For the left tailed test

$$\tilde{p}_{(i)} = \begin{cases} p_i & \text{if } i = k - 1 \\ \max \{ \tilde{p}_{(i+1)}, p_i \} & \text{if } i = k - 2, \dots, 1 \end{cases} \quad (\text{H.23})$$

where

$$p_i = 1 - F(t_{(i)}) \quad (\text{H.24})$$

$$G_i(t_{(i)}) = \int_0^\infty \int_{-\infty}^\infty \prod_{j=1}^i \left(1 - \Phi \left[\frac{\gamma_j z + t_{(i)} u}{\sqrt{1 - \gamma_j^2}} \right] \right) d\Phi(z) d\psi_\nu(u) \quad (\text{H.25})$$

■ Adjusted p-value for the global null hypothesis

- For the right tailed test $\tilde{p} = \tilde{p}_{(1)} = p_1$
- For the left tailed test $\tilde{p} = \tilde{p}_{(k-1)} = p_{k-1}$

H.2.1 Hypotheses, test statistics and marginal p-values for continuous response

- Individual hypotheses:

- For the right tailed tests

$$H_i : \mu_i \leq \mu_0 \text{ vs } K_i : \mu_i > \mu_0 \quad (i = 1, \dots, k - 1) \quad (\text{H.26})$$

- For the left tailed tests

$$H_i : \mu_i \leq \mu_0 \text{ vs } K_i : \mu_i > \mu_0 \quad (i = 1, \dots, k - 1) \quad (\text{H.27})$$

where k is the total number of arms.

- Global null hypothesis:

$$H_0 : \mu_0 = \mu_1 = \dots = \mu_{k-1} \quad (\text{H.28})$$

against the alternative hypothesis H_{01} : at least one $\mu_i > \mu_0$ for right tailed test or $\mu_i < \mu_0$ for left tailed test.

- Test statistics: The calculation for test statistics is slightly different depending on whether the checkbox for **Common Standard Deviation** is checked or not.
 - If **Common Standard Deviation** for design is checked (or **Equal Variance** for analysis is selected),

$$T_i = \frac{\bar{y}_i - \bar{y}_0}{s \sqrt{\frac{1}{n_i} + \frac{1}{n_0}}} \quad (i = 1, 2, \dots, k - 1) \quad (\text{H.29})$$

where

$$s^2 = \frac{1}{N - k} \sum_{i=0}^{k-1} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_i)^2 \quad (\text{H.30})$$

is the variance estimate pooled for all arms, y_{ij} is the response for j^{th} subject in i^{th} arm, \bar{y}_i is the sample mean for the i^{th} arm, N is the total sample size and n_i ($i = 0, 1, \dots, k - 1$) is the number of subjects in arm i

- If **Common Standard Deviation** for design is not checked (**Unequal Variance** for analysis is selected),

$$T_i = \frac{\bar{y}_i - \bar{y}_0}{\sqrt{\frac{1}{n_i} s_i^2 + \frac{1}{n_0} s_0^2}} \quad (i = 1, 2, \dots, k - 1) \quad (\text{H.31})$$

where

$$s_0^2 = \frac{1}{n_0 - 1} \sum_{j=1}^{n_0} (y_{0j} - \bar{y}_0)^2 \quad (\text{H.32})$$

is the variance estimate for the control arm and

$$s_i^2 = \frac{1}{n_i - 1} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_i)^2 \quad (\text{H.33})$$

is the variance estimate for the i^{th} arm.

- Marginal p-values:

- For the right tailed test

$$p_i = P(T_i > t_i) = 1 - P(T_i < t_i) = \Phi(-t_i) \quad (\text{H.34})$$

- For the left tailed test

$$p_i = P(T_i < t_i) = \Phi(t_i) \quad (\text{H.35})$$

where T_i follows t distribution with degree of freedom ν and $\Phi(\cdot)$ is the cumulative distribution function of the t distribution with degree of freedom ν and the value of ν depends on whether the checkbox for **Common Standard Deviation** for design is checked (or the radio button for **Equal Variance** or **Unequal Variance** for analysis is selected)

- If **Common Standard Deviation** for design is checked (or **Equal Variance** for analysis is selected)

$$\nu = N - k \quad (\text{H.36})$$

H Theory - Multiple Comparison Procedures

- If **Common Standard Deviation** for design is not checked (or **Unequal Variance** for analysis is selected)

$$\nu = \left(\frac{s_i^2}{n_i} + \frac{s_0^2}{n_0} \right)^2 / \left[\frac{(s_i^2/n_i)^2}{n_i - 1} + \frac{(s_0^2/n_0)^2}{n_0 - 1} \right] \quad (\text{H.37})$$

H.2.2 Hypotheses, test statistics and marginal p-values for binary response

- Individual hypotheses:

- For the right tailed test

$$H_i : \pi_i - \pi_0 = 0 \text{ vs } K_i : \pi_i - \pi_0 > 0 \quad (i = 1, 2, \dots, k - 1) \quad (\text{H.38})$$

- For the left tailed test

$$H_i : \pi_i - \pi_0 = 0 \text{ vs } K_i : \pi_i - \pi_0 < 0 \quad (i = 1, 2, \dots, k - 1) \quad (\text{H.39})$$

where k is the total number of arms.

- Global null hypothesis

$$H_0 : \pi_0 = \pi_1 = \dots = \pi_{k-1} \quad (\text{H.40})$$

against the alternative H_{01} : at least one $\pi_i > \pi_0$ for right tailed test ($\pi_i < \pi_0$ for left tailed test).

- Test statistics: The calculation for test statistics is slightly different depending on whether **Pooled Variance** or **Unpooled Variance** is selected.

- If **Pooled Variance** is selected,

$$T_i = \frac{\hat{\pi}_i - \hat{\pi}_0}{\sqrt{\tilde{\pi}_i (1 - \tilde{\pi}_i) \left(\frac{1}{n_0} + \frac{1}{n_i} \right)}} \quad (i = 1, 2, \dots, k - 1) \quad (\text{H.41})$$

where $\hat{\pi}_i$ is the sample proportion for the i^{th} arm, $\hat{\pi}_0$ is the sample proportion for the control arm, $\tilde{\pi}_i = \frac{n_i \hat{\pi}_i + n_0 \hat{\pi}_0}{n_i + n_0}$ is the pooled sample proportion, N is the total sample size and n_i ($i = 0, 1, \dots, k - 1$) is the number of subjects in arm i

- If **Unpooled Variance** is selected,

$$T_i = \frac{\hat{\pi}_i - \hat{\pi}_0}{\sqrt{\frac{1}{n_i} \hat{\pi}_i (1 - \hat{\pi}_i) + \frac{1}{n_0} \hat{\pi}_0 (1 - \hat{\pi}_0)}} \quad (i = 1, 2, \dots, k - 1) \quad (\text{H.42})$$

where $\hat{\pi}_i$ is the sample proportion for the i^{th} arm $\hat{\pi}_0$ is the sample proportion for the control arm.

- Marginal p-values:

- For the right tailed test

$$p_i = P(T_i > t_i) = 1 - P(T_i < t_i) = \Phi(-t_i) \quad (\text{H.43})$$

- For the left tailed test

$$p_i = P(T_i < t_i) = \Phi(t_i) \quad (\text{H.44})$$

where T_i follows standard normal distribution and $\Phi(\cdot)$ is the cumulative distribution function

H.2.3 Bonferroni Procedure

Suppose p_1, p_2, \dots, p_{k-1} are the marginal p -values associated with H_i ($i = 1, 2, \dots, k - 1$). Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the ordered p -values. Suppose α is the significance level.

- The Bonferroni procedure will reject H_i , if $p_i < \frac{\alpha}{k-1}$, $i = 1, 2, \dots, k - 1$.
- The adjusted p -value for the individual hypothesis H_i is given by

$$\tilde{p}_i = \min(1, (k - 1) p_i), \quad i = 1, 2, \dots, k - 1 \quad (\text{H.45})$$

- The adjusted p -value for the global null hypothesis is given by

$$\begin{aligned} \tilde{p} &= \min\{\tilde{p}_i : i = 1, 2, \dots, k - 1\} \\ &= \min(1, mp_{(1)}) \end{aligned} \quad (\text{H.46})$$

H.2.4 Sidak Procedure

Let p_1, p_2, \dots, p_{k-1} be the marginal p -values associated with H_i ($i = 1, 2, \dots, k - 1$). Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the ordered p -values. Let α be the significance level.

H Theory - Multiple Comparison Procedures

- The Sidak procedure will reject H_i if $p_i < 1 - (1 - \alpha)^{\frac{1}{k-1}}$, $i = 1, 2, \dots, k - 1$.
- The adjusted p -value for the individual hypothesis H_i is given by

$$\tilde{p}_i = 1 - (1 - p_i)^{k-1}, \quad i = 1, 2, \dots, k - 1 \quad (\text{H.47})$$

- The adjusted p -value for the global null hypothesis is given by

$$\begin{aligned} \tilde{p} &= \min \{ \tilde{p}_i : i = 1, 2, \dots, k - 1 \} \\ &= 1 - (1 - p_{(1)})^{k-1} \end{aligned} \quad (\text{H.48})$$

H.2.5 Weighted Bonferroni Procedure

Let p_1, p_2, \dots, p_{k-1} be the marginal p -values associated with H_i ($i = 1, 2, \dots, k - 1$). Let α be the significance level. Let α be the overall type I error rate. Let w_1, w_2, \dots, w_{k-1} be the proportions indicating the allocations of α to each hypothesis such that $\sum_{i=1}^{k-1} w_i = 1$. Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the order p -values.

- The weighted Bonferroni procedure will reject H_i if $p_i < w_i \alpha$, $i = 1, 2, \dots, k - 1$.
- The adjusted p -value for the individual hypothesis H_i is given by

$$\tilde{p}_i = \min \left(1, \frac{p_i}{w_i} \right), \quad i = 1, 2, \dots, k - 1 \quad (\text{H.49})$$

- The adjusted p -value for the global null hypothesis is given by

$$\tilde{p} = \min \{ \tilde{p}_i : i = 1, 2, \dots, k - 1 \} \quad (\text{H.50})$$

Note that, if $w_1 = w_2 = \dots = w_{k-1} = \frac{1}{k-1}$, the weighted Bonferroni procedure is reduced to the regular Bonferroni procedure.

H.2.6 Holm Step-Down Procedure

Let p_1, p_2, \dots, p_{k-1} be the marginal p -values. Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the order p -values and $H_{(i)}$ ($i = 1, 2, \dots, k - 1$) be the associated hypotheses. Let α be the significance level. Holm (1979) step-down procedure is carried out as follows:

- Step 1: If $p_{(1)} \leq \frac{\alpha}{k-1}$, reject $H_{(1)}$ and go to the next step. Otherwise retain all hypotheses and stop

- Step $i = 2, \dots, k - 2$: If $p_{(i)} \leq \frac{\alpha}{k-i}$, reject $H_{(i)}$ and go to the next step. Otherwise retain $H_{(i)}, \dots, H_{(k-1)}$ and stop
- Step $k - 1$. If $p_{(k-1)} \leq \alpha$, reject $H_{(k-1)}$ and stop. Otherwise retain $H_{(k-1)}$ and stop.

The adjusted p -value for the individual hypothesis $H_{(i)}$ ($i = 1, 2, \dots, k - 1$) is given by

$$\tilde{p}_{(i)} = \begin{cases} \min(1, (k - 1) p_{(i)}) & \text{if } i = 1, \\ \max(\tilde{p}_{(i-1)}, (k - i) p_{(i)}, 1) & \text{if } i = 2, \dots, k - 1. \end{cases} \quad (\text{H.51})$$

The adjusted p -value for the global hypothesis H_0 is

$$\tilde{p}_{(1)} = \min(1, (k - 1) p_{(1)}) \quad (\text{H.52})$$

H.2.7 Hochberg Step-Up Procedure

Let p_1, p_2, \dots, p_{k-1} be the marginal p -values. Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the order p -values and $H_{(i)}$ ($i = 1, 2, \dots, k - 1$) be the associated hypotheses. Let α be the significance level. Hochberg (1988) step-up procedure is carried out as follows:

- Step 1: If $p_{(k-1)} > \alpha$, retain $H_{(k-1)}$ and go to the next step. Otherwise reject all hypotheses and stop
- Step $i = 2, \dots, k - 2$: if $p_{(k-i)} > \frac{\alpha}{i}$, retain $H_{(k-i)}$ and go to the next step. Otherwise reject all remaining hypotheses and stop.
- Step $k - 1$: If $p_{(1)} > \frac{\alpha}{k-1}$, retain $H_{(1)}$ and stop. Otherwise reject $H_{(1)}$ and stop.

The adjusted p -values for individual hypothesis is given by

$$\tilde{p}_{(i)} = \begin{cases} p_{(i)} & \text{if } i = k - 1 \\ \min(\tilde{p}_{(i+1)}, (k - i) p_{(i)}) & \text{if } i = k - 2, k - 3, \dots, 1 \end{cases} \quad (\text{H.53})$$

The adjusted p -value for the global null hypothesis is

$$\tilde{p} = \min \{ \tilde{p}_{(i)} : i = 1, 2, \dots, k - 1 \} \quad (\text{H.54})$$

$$= \min \{ p_{(k-1)}, 2p_{(k-2)}, \dots, ip_{(k-i)}, \dots, (k - 1) p_{(1)} \}$$

Compared with Simes adjusted p -value, Hochberg adjusted p -value tends to be larger for testing the global hypothesis.

H Theory - Multiple Comparison Procedures

H.2.8 Fixed Sequence Testing Procedure

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is prespecified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the associated raw marginal p values. Let α be the significance level. The fixed sequence testing procedure can be carried out as follows:

- Step 1: If $p_1 < \alpha$, reject H_1 and go the next step. Otherwise retain all hypotheses and stop.
- Step $i = 2, 3, \dots, k - 2$: If $p_i < \alpha$, reject H_i and go the the next step. Otherwise retain $H_i, H_{i+1}, \dots, H_{k-1}$.
- Step $k - 1$: If $p_{k-1} < \alpha$, reject H_{k-1} and stop. Otherwise retain H_{k-1} and stop.

The adjusted p - values for individual hypothesis H_i ($i = 1, \dots, k$) is given by

$$\tilde{p}_i = \max \{p_1, p_2, \dots, p_i\} \tag{H.55}$$

The adjusted p - value for the global null hypothesis is given by

$$\tilde{p} = p_1 \tag{H.56}$$

H.2.9 Hommel Step-Up Procedure

Let p_1, p_2, \dots, p_{k-1} be the marginal p -values. Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the ordered p -values and $H_{(i)}$ ($i = 1, 2, \dots, k - 1$) be the associated hypotheses. Let α be the significance level. The Hommel procedure is carried out as follows:

- Step 1: If $p_{(k-1)} > \alpha$, retain $H_{(k-1)}$ and go to the next step. Otherwise reject all hypotheses and stop.
- Step $i = 2, \dots, k - 2$: If $p_{(k-j)} > \frac{i-j+1}{i} \alpha$ for $j = 1, \dots, i$, retain $H_{(k-i)}$ and go to the next step. Otherwise reject all remaining hypotheses with $p_{(k-1)} < \frac{\alpha}{i-1}$ and stop.
- Step $k - 1$: If $p_{(k-j)} > \frac{k-j}{k-1} \alpha$ for $j = 1, \dots, k - 1$, retain $H_{(1)}$; otherwise reject $H_{(1)}$ if $p_{(1)} < \frac{\alpha}{k-2}$.

Another way of describing Hommel procedure is as follows:

Let $J \subseteq \{1, 2, \dots, k - 1\}$ be defined as $J = \{i \mid i \text{ belongs to } \{1, 2, \dots, k - 1\} \text{ such that } p_{(k-j)} > \frac{i-j+1}{i} \alpha \text{ for all } j = 1, 2, \dots, i\}$. If J is nonempty, reject H_{k-1} whenever $p_{k-1} \leq \frac{\alpha}{v'}$ with $v' = \max_{i \in J} \{i\}$. If J is empty, reject all H_i ($i = 1, \dots, k - 1$).

The adjusted p -values for Hommel procedure can be calculated as

$$\tilde{p}_i = \max \{p_I : i \in I\} \tag{H.57}$$

where p_I denotes the p -value for testing the intersection hypothesis H_I using Simes (1986) test.

H.2.10 Fallback Procedures

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is prespecified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the marginal p values. Let α be the overall type I error rate. Let w_1, w_2, \dots, w_{k-1} be the proportions indicating the allocations of α to each hypothesis such that $\sum_{i=1}^{k-1} w_i = 1$. The amount of type I error assigned to hypothesis H_i ($i = 1, 2, \dots, k - 1$) is $w_i\alpha$. The fallback procedures can be carried out as follows:

- Step 1: Test H_1 at $\alpha_1 = w_1\alpha$. If $p_1 \leq \alpha_1$, reject H_1 and go to the next step; otherwise retain it and go to the next step
- Step $i = 2, \dots, k - 2$: Test H_i at $\alpha_i = \alpha_{i-1} + w_i\alpha$ if H_{i-1} is rejected and at $\alpha_i = w_i\alpha$ if H_{i-1} is retained. If $p_i \leq \alpha_i$, reject H_i ; otherwise retain it and go to the next step.
- Step $k - 1$: Test H_{k-1} at $\alpha_{k-1} = \alpha_{k-2} + w_{k-1}\alpha$ if H_{k-2} is rejected and at $\alpha_{k-1} = w_{k-1}\alpha$ if H_{k-2} is retained. If $p_{k-1} \leq \alpha_{k-1}$, reject H_{k-1} ; otherwise retain it.

The adjusted p -values for the fallback procedure can be computed as

$$\tilde{p}_i = \max_{J:i \in J} \{p_J\} \tag{H.58}$$

where p_J denotes the p -value for testing the intersection hypothesis H_J using weighted Bonferroni test. The algorithm is described in Appendix A in the paper by Wiens and Dmitrienko (2005). The fallback procedure is equivalent to the closed test using Weighted Bonferroni for the intersection hypotheses. The following algorithm described in Appendix A in the paper by Wiens and Dmitrienko (2005) is used to assign weights to each elementary hypothesis of a particular intersection hypothesis. Let $I = \{1, 2, \dots, k - 1\}$ be the index set. Assume that H_1, H_2, \dots, H_{k-1} is already ordered so that H_1 is tested first followed by H_2 and so on as described in the fall back procedure above. Let w_1, w_2, \dots, w_{k-1} be the associated weights initially assigned to H_1, H_2, \dots, H_{k-1} respectively such that $\sum_{i=1}^{k-1} w_i \leq 1$. For any intersection hypothesis H_J , let $\mathbf{v} = (v_1(H_J), v_2(H_J), \dots, v_{k-1}(H_J))$ be the decision vector to test H_J . This decision vector represents a weighted Bonferroni test for H_J in the following sense. We will compare p_1 with $v_1(H_J)\alpha$, p_2 with $v_2(H_J)\alpha, \dots, p_{k-1}$ with $v_{k-1}(H_J)\alpha$. The following algorithm shows how to determine the decision vector for a particular intersection hypothesis H_J .

H Theory - Multiple Comparison Procedures

- Step 1: $v_1(H_J) = w_1$ if H_J contains H_1 and 0 otherwise
- Step 2: $v_2(H_J) = w_1 + w_2 - v_1(H_J)$ if H_J contains H_2 and 0 otherwise.
-
- Step i : $v_i(H_J) = w_1 + w_2 + \dots + w_i - v_1(H_J) - v_2(H_J) - \dots - v_{i-1}(H_J)$ if H_J contains H_i and 0 otherwise.
-
- Step $k - 1$:
 $v_{k-1}(H_J) = w_1 + \dots + w_{k-1} - v_1(H_J) - v_2(H_J) - \dots - v_{k-2}(H_J)$ if H_J contains H_{k-1} and 0 otherwise.

Once we obtain the decision vector \mathbf{v} according to the above algorithm, we can compute the weighted Bonferroni adjusted p -values as follows for a particular intersection hypothesis H_J as follows

$$p_J = \min_{i=1, \dots, k-1} \{p_i/v_i(H_J)\} \tag{H.59}$$

Consequently, the adjusted p -value for fallback procedure is

$$\tilde{p}_i = \max_{J:i \in J} \{p_J\} \tag{H.60}$$

For example, suppose we have three hypotheses of interest H_1, H_2, H_3 and w_1, w_2, w_3 are the associated weights. The fallback procedure is carried out as follows:

- Step 1: Test H_1 at $\alpha_1 = w_1\alpha$. If $p_1 \leq \alpha_1$, reject H_1 and go to the next step; otherwise retain it and go to the next step
- Step 2: Test H_2 at $\alpha_2 = \alpha_1 + w_2\alpha$ if H_1 is rejected and at $\alpha_2 = w_2\alpha$ if H_1 is retained. If $p_2 \leq \alpha_2$, reject H_2 ; otherwise retain it and go to the next step.
- Step 3: Test H_3 at $\alpha_3 = \alpha_2 + w_3\alpha$ if H_2 is rejected and at $\alpha_3 = w_3\alpha$ if H_2 is retained. If $p_3 \leq \alpha_3$, reject H_3 ; otherwise retain it.

To calculate the adjusted p -values, we first need to obtain the decision vectors for all the intersection hypotheses. In this example, we have 7 intersection hypotheses including the three single hypotheses. The decision vectors are given in the following table

Hence the adjusted p -value for H_1 is $\max \{p_{\{123\}}, p_{\{12\}}, p_{\{13\}}, p_{\{1\}}\}$. Similarly the adjusted p -value for H_2 is $\max \{p_{\{123\}}, p_{\{12\}}, p_{\{23\}}, p_{\{2\}}\}$ and that for H_3 is

$$\max \{p_{\{123\}}, p_{\{13\}}, p_{\{23\}}, p_{\{3\}}\}.$$

| Intersection | Decision Vectors | Bonferrni p -values |
|---------------|--------------------|---|
| $H_{\{123\}}$ | (w_1, w_2, w_3) | $p_{\{123\}} = \min \left\{ \frac{p_1}{w_1}, \frac{p_2}{w_2}, \frac{p_3}{w_3} \right\}$ |
| $H_{\{12\}}$ | (w_1, w_2) | $p_{\{12\}} = \min \left\{ \frac{p_1}{w_1}, \frac{p_2}{w_2} \right\}$ |
| $H_{\{13\}}$ | $(w_1, w_2 + w_3)$ | $p_{\{13\}} = \min \left\{ \frac{p_1}{w_1}, \frac{p_3}{w_2 + w_3} \right\}$ |
| $H_{\{23\}}$ | $(w_1 + w_2, w_3)$ | $p_{\{23\}} = \min \left\{ \frac{p_2}{w_2 + w_3}, \frac{p_3}{w_3} \right\}$ |
| $H_{\{1\}}$ | w_1 | $p_{\{1\}} = \frac{p_1}{w_1}$ |
| $H_{\{2\}}$ | $w_1 + w_2$ | $p_{\{2\}} = \frac{p_2}{w_1 + w_2}$ |
| $H_{\{3\}}$ | $w_1 + w_2 + w_3$ | $p_{\{3\}} = \frac{p_3}{w_1 + w_2 + w_3}$ |

H.3 Generate Means/Proportions through DR Curves

- Four Parameter Logistic

$$E(Y | D) = \beta + \frac{\delta}{1 + \exp\left(\frac{\theta - D}{\tau}\right)} \tag{H.61}$$

where $\tau > 0, -\infty < \beta, \delta, \theta < \infty$

- Linear

$$E(Y | D) = a + bD \tag{H.62}$$

where E_0 is the intercept and b represents the slope.

- Quadratic

$$E(Y | D) = E_0 + B_1 * D + B_2 * D^2 \tag{H.63}$$

where E_0 represents the mean response for placebo, B_1 represents the linear coefficient and B_2 represents the quadratic coefficient.

- E_{max}

$$E(Y | D) = E_0 + \frac{E_{max}}{1 + \exp\{S [\ln(ED_{50}) - \ln(D)]\}} \tag{H.64}$$

where E_0 represents the y -intercept, E_{max} is the difference between the mean response at a very large dose and placebo, $ED_{50} > 0$ is the value of the dose that gives a response of $E_0 + \frac{1}{2}E_{max}$ and $S > 0$ is a slope factor (Hill parameter) that controls the rate at which response increases as a function of dose at ED_{50} .

I Theory - Multiple Endpoint Procedures

I.1 Serial Gatekeeping

Assume that we are interested in testing K endpoints which are grouped into m families F_1, F_2, \dots, F_m . A family is called a serial gatekeeper if all hypotheses must be rejected within that family in order to proceed to test the hypotheses in the next family. In other words, if $F_i (i = 1, 2, \dots, m - 1)$ is a serial gatekeeper, then hypotheses in the next family F_{i+1} are tested only if all the hypotheses in F_i are rejected. Serial gatekeeping over m families is implemented in the following m steps. Note that in the following serial gatekeeping testing procedure any α -level FWER-controlling multiple testing procedure can be used for testing the preceding $m-1$ families. But since we need to reject all hypotheses in one family in order to proceed to test the next family, the most powerful test is the intersection-union (IU) test. The IU test is a min test which is tailored to test a composite null hypothesis. For example, the IU test would reject $\cup_{j=1}^{n_i} H_{in_i}$ if all the hypotheses H_{in_i} in F_i are rejected at their α -level tests, i.e. $\max_{j=1, \dots, n_i} p_{ij} \leq \alpha$.

Serial gatekeeping procedure based on intersection-union test

- Step 1: Test all the hypotheses in F_1 at their nominal α levels using the intersection-union test; i.e., reject all H_{1j} if $\max_{j=1, \dots, n_1} p_{1j} \leq \alpha$, $j = 1, 2, \dots, n_1$. If all the n_1 hypotheses are rejected, go to Step 2, otherwise stop. The term intersection-union test arises because, as shown by Berger (1982), this procedure offers level- α protection against rejecting the null hypothesis $H_1 = \cup_{j=1}^{n_1} H_{1j}$ in favor of the alternative hypothesis $\bar{H}_1 = \cap_{j=1}^{n_1} \bar{H}_{1j}$.
 - Step 2: Test all the hypotheses in F_2 at their nominal α levels using the intersection-union test. If all the hypotheses are rejected, go to step 3, otherwise stop.
- ⋮
- Step $m-1$: Test all the hypotheses in F_{m-1} at their nominal α levels using the intersection-union test. If all the hypotheses are rejected, go to step m , otherwise stop.
 - Step m : Test all the hypotheses in F_m using any multiple testing procedure that guarantees strong control of type-1 error within the family F_m .

To obtain adjusted p-values, let p_i^* denote the largest p-value in F_i , for

$i = 1, 2, \dots, m - 1$. Then

$$\tilde{p}_{ij} = \begin{cases} \max(p_1^*, p_2^*, \dots, p_i^*) & \text{if } i = 1, 2, \dots, m - 1 \\ \max(p'_{ij}, p_1^*, p_2^*, \dots, p_{i-1}^*) & \text{if } i = m \end{cases}$$

where p'_{mj} is the adjusted p-value for H_{mj} based on the multiple testing procedure that has been adopted for family F_m . In terms of adjusted p-values, the serial gatekeeping condition implies that hypotheses in family F_{i+1} will only be tested if

$$\max_{j=1, \dots, n_i} \tilde{p}_{ij} \leq \alpha$$

1.2 Parallel Gatekeeping

Assume that we are interested in testing K endpoints which are grouped into m families F_1, F_2, \dots, F_m . F_i is termed a parallel gatekeeper if at least one hypothesis within it must be rejected in order to proceed to family F_{i+1} ($i = 1, 2, \dots, m - 1$). We consider the general multistage parallel gatekeeping procedure proposed by Dmitrienko, Tamhane and Wiens 2008. Control of the FWER relies on using a so-called “separable” multiple testing procedure. In order to define separable tests we require the concept of an error rate function. Consider the problem of testing a single family of n null hypotheses H_1, H_2, \dots, H_n . Let $I \subseteq N$ be the index set of true null hypotheses. The error rate function $e(I)$ of a multiple testing procedure is the maximum probability of making at least one type-1 error.

$$e(I) = \sup P \left(\bigcup_{i \in I} \{\text{Reject } H_i\} \mid H_I \right)$$

where $H_I = \cap_{i \in I} H_i$ and the supremum is computed over the the entire parameter space of the hypotheses in $N \setminus I$. In other words, $e(I)$ is error that the multiple testing procedure will produce under the worst configuration of alternative hypotheses for a specific set of $I \subseteq N$ null hypotheses. An explicit expression for $e(I)$ is not generally available, but an upper bound can be used instead. A multiple testing procedure is separable if its error rate is strictly less than α unless all hypotheses are true. That is, $e(I) < \alpha$ for all. Suppose $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(n)}$ are the ordered p-values for corresponding null hypotheses $H_{(1)}, H_{(2)}, \dots, H_{(n)}$. Then the following three multiple testing procedures are separable.

I Theory - Multiple Endpoint Procedures

Bonferroni Test: Bonferroni Test: The upper bound of the error rate function for Bonferroni test is given by

$$e(I) = \frac{|I|}{n} \alpha$$

where $|I|$ is the cardinality of set I .

Note that Bonferroni procedure is separable. But regular Holm or Hochberg is not separable. To see this, consider a family of two hypotheses where one hypothesis is true and the other hypothesis is infinitely false. The type I error of regular Holm applied to such a family of hypotheses would be α . Similar argument applies to regular Hochberg procedure. Hence regular Holm or Hochberg can't be directly used in parallel gatekeeping procedure. However we can modify them by taking the convex combination of their own critical values and the critical values of Bonferroni test. The modified procedures are separable which we call truncated Holm and truncated Hochberg described as follows.

Truncated Holm: For any prespecified truncation fraction γ , the truncated Holm test performs as follows

- Step 1: If $p_{(1)} \leq \frac{\alpha}{n}$, then reject $H_{(1)}$ and go to the next step, otherwise retain all hypotheses.
- Step 2: If $p_{(2)} \leq \left(\frac{\gamma}{n-1} + \frac{1-\gamma}{n} \right) \alpha$, then reject $H_{(2)}$ and go to the next step, otherwise retain $H_{(2)}, H_{(3)}, \dots, H_{(n)}$ and stop.
- ⋮
- Step i : If $p_{(i)} \leq \left(\frac{\gamma}{n-i+1} + \frac{1-\gamma}{n} \right) \alpha$, then reject $H_{(i)}$ and go to the next step, otherwise retain $H_{(i)}, H_{(i+1)}, \dots, H_{(n)}$ and stop.
- ⋮
- Step n : If $p_{(n)} \leq \left(\gamma + \frac{1-\gamma}{n} \right) \alpha$, then reject $H_{(n)}$, otherwise retain $H_{(n)}$.

The upper bound of the error rate function for truncated Holm is given by

$$e(I) = \begin{cases} \left(\gamma + \frac{(1-\gamma)|I|}{n}\right) \alpha & \text{if } |I| > 0 \\ 0 & \text{if } |I| = 0 \end{cases}$$

Truncated Hochberg: For any prespecified truncation fraction γ , the truncated Hochberg test performs as follows:

- Step 1: If $p_{(n)} \leq \left(\gamma + \frac{1-\gamma}{n}\right) \alpha$, then rejects all hypotheses and stop, otherwise retain $H_{(n)}$ and go to the next step to test $H_{(n-1)}$.
- Step 2: If $p_{(n-1)} \leq \left(\frac{\gamma}{2} + \frac{1-\gamma}{n}\right) \alpha$, then rejects $H_{(1)}, H_{(2)}, \dots, H_{(n-1)}$ and stop, otherwise retain $H_{(n-1)}$ and go to the next step to test $H_{(n-2)}$.
- ⋮
- Step i : If $p_{(i)} \leq \left(\frac{\gamma}{n-i+1} + \frac{1-\gamma}{n}\right) \alpha$, then reject $H_{(1)}, H_{(2)}, \dots, H_{(i)}$ and stop, otherwise retain $H_{(i)}$ and go to the next step to test $H_{(i-1)}$.
- ⋮
- Step n : If $p_{(1)} \leq \frac{\alpha}{n}$, then reject $H_{(1)}$ and stop, otherwise retain $H_{(1)}$ and stop.

The upper bound of truncated Hochberg test is given by

$$e(I) = \begin{cases} 1 - P \left\{ p_{(i)}(I) > \left[\frac{\gamma}{|I|-i+1} + \frac{1-\gamma}{n} \right] \alpha \text{ for all } i \in I \right\} & \text{if } |I| > 0 \\ 0 & \text{if } |I| = 0 \end{cases}$$

In general, the upper bound on $e(I)$ for truncated Holm can also be used for truncated Hochberg. Using the above expression, we can obtain more stringent upper bound than the one for truncated Holm. Consequently, more type I error will be carried over to the next family. Observe that the above expression for the error rate function requires knowledge of the joint distribution of the p-values. If the p-values are for comparisons of multiple treatments versus a common control, then the correlations among them are known and the error rate function can be evaluated. If, however, the p-values are for comparisons of a single treatment versus a control with respect to multiple endpoints, we typically will not know the correlations amongst these endpoints. In that case we can obtain a conservative upper bound for the error rate function by assuming

I Theory - Multiple Endpoint Procedures

independence of p-values and using the following result due to Sen (1999): Let $U_{(1)} < \dots < U_{(k)}$ denote the order statistics of $k > 1$ i.i.d. observations from a uniform (0,1) distribution. For any $0 < a_1 < \dots < a_k < 1$,

$$P(a_1, a_2, \dots, a_k) = P(U_{(i)} > a_i \text{ for all } i = 1, \dots, k) = k!H_k(1)$$

where $H_i(u) = \int_{a_i}^u H_{i-1}(v)dv$, $i = 1, \dots, k$ and $H_0(u) = I(u \geq a_1)$ and $I(\cdot)$ is an indicator function.

Consider $m \geq 2$ families, $F_i = \{H_{i1}, \dots, H_{in_i}\}$ ($1 \leq i \leq m$) of null hypotheses. Let $N_i = \{1, 2, \dots, n_i\}$ and $A_i \subseteq N_i$ be the index set corresponding to the accepted hypotheses in F_i . Parallel gatekeeping is implemented in the following m steps.

Step 1 : Let $\alpha_1 = \alpha$ and test all hypotheses in F_1 at level α_1 using any separable multiple testing procedure (Bonferroni, Truncated Holm, Truncated Hochberg) with a suitable upper bound on the error rate function $e_1(I)$. If $A_1 = N_1$, i.e., no hypotheses in F_1 are rejected, then stop testing and retain all hypotheses in F_2, \dots, F_m ; otherwise go to the next step.

Step 2: Let $\alpha_2 = \alpha_1 - e_1(A_1)$ and test all hypotheses in F_2 at level α_2 using any of the separable multiple test procedures with a suitable upper bound on the error rate function $e_2(I)$. If $A_2 = N_2$, i.e. no hypotheses in F_2 are rejected, then stop testing and retain all hypotheses in F_3, \dots, F_m ; otherwise go to the next step.

⋮

Step i: Let $\alpha_i = \alpha_{i-1} - e_{i-1}(A_{i-1})$ and test all hypotheses in F_i at level α_i using any of the separable multiple test procedures with a suitable upper bound on the error rate function $e_i(I)$. If $A_i = N_i$, i.e. no hypotheses in F_i are rejected, then stop testing and retain all hypotheses in F_{i+1}, \dots, F_m ; otherwise go to the next step.

⋮

Step m: Let $\alpha_m = \alpha_{m-1} - e_{m-1}(A_{m-1})$ and test all hypotheses in F_m at level α_m using any of multiple test procedures which don't have to be separable.

Adjusted P Values:

The adjusted p-values associated with the gatekeeping procedure can be computed by looping through a discrete grid of significance levels. Let $\alpha = \frac{k}{K}$ ($0 < k < K$) for some sufficiently large value of K . The adjusted p-value, \tilde{p}_{ij} for hypotheses H_{ij} is the smallest α (corresponding to the smallest k) for which H_{ij} is rejected.

J Theory-Multi-arm Multi-stage Group Sequential Design

J.1 Notations

Let $\delta_i = \mu_i - \mu_0$ be the mean difference for group i versus control group. Suppose that there are K_1 analysis times including final one. Assume unequal sample size allocation. We use the first subscript index to denote doses and the second subscript to denote interim analysis time. Let $n_{i1} < \dots < n_{iK_1}$ ($i = 0, 1, 2, \dots, D$) be the cumulative sample size for group i at each interim where 0 denotes control arm. Let $n_{i(j)}$ be the incremental sample size from look $j - 1$ to look j . Let σ_i^2 ($i = 0, 1, 2, \dots, D$) be the variance for responses in the i th group. Let $\bar{X}_{i(j)}$ ($i = 0, 1, 2, \dots, D; j = 1, 2, \dots, K_1$) be the sample mean based on the incremental data from look $j - 1$ to j for the i th group. Let $\hat{\delta}_{i(j)} = \bar{X}_{i(j)} - \bar{X}_{0(j)}$ ($i = 1, 2, \dots, D$) be the observed mean difference from control group for group i . Let $\xi_{i(j)} = [\text{var}(\bar{X}_{i(j)})]^{-1} = \frac{n_{i(j)}}{\sigma_i^2}$ be the incremental information from look $j - 1$ to look j for the i th group. Let $\xi_{ij} = \sum_{h=1}^j \xi_{i(h)}$. Let $I_{i(j)} = [\text{var}(\bar{X}_{i(j)} - \bar{X}_{0(j)})]^{-1} = [\xi_{i(j)}^{-1} + \xi_{0(j)}^{-1}]^{-1}$. Let $Z_{i(j)} = \hat{\delta}_{i(j)} \sqrt{I_{i(j)}}$ be the Z statistic for the comparison of group i versus control based on incremental data. Let $W_{i(j)} = \hat{\delta}_{i(j)} I_{i(j)} = Z_{i(j)} \sqrt{I_{i(j)}}$ be the score statistic based on incremental data. Let $W_{ij} = \sum_{h=1}^j W_{i(h)} = \sum_{h=1}^j Z_{i(h)} \sqrt{I_{i(h)}} = \sum_{h=1}^j \hat{\delta}_{i(h)} I_{i(h)}$. Assume that we will monitor the trial based on the processes $W_{1j}, W_{2j}, \dots, W_{Dj}$. Let $I_{ij} = \sum_{h=1}^j I_{i(h)}$ be the cumulative information up to look j for W_{ij} .

Now let N be the total sample size for the whole study. Let $\lambda_i = \frac{n_{i(1)}}{n_{0(1)}} = \frac{n_{i(2)}}{n_{0(2)}} = \dots = \frac{n_{i(K_1)}}{n_{0(K_1)}}$ ($i = 0, 1, 2, \dots, D$) be the sample size allocation ratio of dose i to control group. Note that as long as the allocation ratio for a particular dose to control remains the same across all interim looks, the W_{ij} is the same as $Z_{ij} \sqrt{I_{ij}}$. Let $\frac{n_{0K_1}}{N} = \lambda_0$ be the fraction of total sample size for control arm to total sample size of the whole study. Let $t_{(j)} = \frac{n_{0(j)}}{n_{0K_1}} = \frac{n_{1(j)}}{n_{1K_1}} = \dots = \frac{n_{D(j)}}{n_{DK_1}}$ and let $t_j = \frac{n_{0j}}{n_{0K_1}} = \frac{n_{1j}}{n_{1K_1}} = \dots = \frac{n_{Dj}}{n_{DK_1}}$ be the cumulative sample size fraction up to look j for control arm. Note that $t_{(j)} = \frac{I_{i(j)}}{I_{iK_1}}$, ($i = 0, 1, \dots, D$) and $t_j = \frac{I_{ij}}{I_{iK_1}}$, ($i = 0, 1, \dots, D$). Then we have

$$\xi_{i(j)} = \frac{n_{i(j)}}{\sigma_i^2}$$

$$I_{i(j)} = \left[\frac{\sigma_i^2}{n_{i(h)}} + \frac{\sigma_0^2}{n_{0(h)}} \right]^{-1} = \left[\frac{\sigma_i^2}{\lambda_i} + \sigma_0^2 \right]^{-1} n_{0(j)}$$

$$I_{ij} = \sum_{h=1}^j I_{i(j)} = \left[\frac{\sigma_i^2}{\lambda_i} + \sigma_0^2 \right]^{-1} \sum_{h=1}^j n_{0(h)} = \left[\frac{\sigma_i^2}{\lambda_i} + \sigma_0^2 \right]^{-1} n_{0j}$$

$$E(W_{i(j)}) = \delta_i I_{i(j)}$$

$$Var(W_{i(j)}) = I_{i(j)}$$

$$Cov(W_{k(j)}, W_{l(j)}) = \xi_{0(j)}^{-1} I_{k(j)} I_{l(j)} = \left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2 \right) \right]^{-1} \sigma_0^2 * n_{0(j)}$$

For the cumulative process W_{ij} , we have

$$E(W_{ij}) = E\left(\sum_{h=1}^j W_{i(h)}\right) = \delta_i I_{ij}$$

$$Var(W_{ij}) = Var\left(\sum_{h=1}^j W_{i(h)}\right) = I_{ij}$$

$$Cov(W_{kj}, W_{lj}) = \sum_{h=1}^j Cov(W_{k(h)}, W_{l(h)}) = \left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2 \right) \right]^{-1} \sigma_0^2 * n_{0j}$$

Next we derive the conditional distribution of $\vec{W}_{j_2} = (W_{1j_2}, W_{2j_2}, \dots, W_{Dj_2})$ given $\vec{W}_{j_1} = \vec{x}_{j_1} = (x_{1j_1}, x_{2j_1}, \dots, x_{Dj_1})$ for $j_1 < j_2$. For each process W_{ij_2} , $W_{ij_2} = W_{ij_1} + \sum_{h=j_1+1}^{j_2} W_{i(h)}$. Hence conditional on $W_{ij_1} = x_{ij_1}$, W_{ij_2} has a normal distribution with mean $x_{ij_1} + \delta_i (I_{ij_2} - I_{ij_1})$ and variance $I_{ij_2} - I_{ij_1}$. And conditional on \vec{W}_{j_1} , the covariance between W_{kj_2} and W_{lj_2} is given by

$$Cov(W_{kj_2}, W_{lj_2} | \vec{W}_{j_1}) = Cov\left(\sum_{h=j_1+1}^{j_2} W_{k(h)}, \sum_{h=j_1+1}^{j_2} W_{l(h)}\right)$$

J Theory-Multi-arm Multi-stage Group Sequential Design

$$\begin{aligned}
 &= \sum_{h=j_1+1}^{j_2} Cov(W_{k(h)}, W_{l(h)}) \\
 &= \left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2 \right) \right]^{-1} \sigma_0^2 * \sum_{h=j_1+1}^{j_2} n_{0(h)} \\
 &= \left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2 \right) \right]^{-1} \sigma_0^2 * (n_{0j_2} - n_{0j_1})
 \end{aligned}$$

Then the transition density of the process \vec{W} from look j_1 to look j_2 is given by

$$\begin{aligned}
 p_{\vec{\delta}, \Sigma_{j_2|j_1}} \left(\left(\vec{I}_{j_1}, \vec{x}_{j_1} \right), \left(\vec{I}_{j_2}, \vec{x}_{j_2} \right) \right) &= (2\pi)^{-D/2} | \Sigma_{j_2|j_1} |^{-\frac{1}{2}} \\
 \exp \left\{ - \frac{ \left(\vec{x}_{j_2} - \left[\vec{x}_{j_1} + (A_{j_2} - A_{j_1}) \vec{\delta} \right] \right)^T \left[\Sigma_{j_2|j_1} \right]^{-1} \left(\vec{x}_{j_2} - \left[\vec{x}_{j_1} + (A_{j_2} - A_{j_1}) \vec{\delta} \right] \right) }{2} \right\} & \tag{J.1}
 \end{aligned}$$

where $x_{j_2} = (x_{1j_2}, \dots, x_{Dj_2})^T$, $x_{j_1} = (x_{1j_1}, \dots, x_{Dj_1})^T$, $\vec{\delta} = (\delta_1, \dots, \delta_D)^T$, $\vec{I}_{j_1} = (I_{1j_1}, I_{2j_1}, \dots, I_{Dj_1})^T$, and the matrix $\Sigma_{j_2|j_1} = (\zeta_{kl})_{D \times D}$ and A_j has the following form

$$\zeta_{kl} = \begin{cases} I_{kj_2} - I_{kj_1} = \left[\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right]^{-1} (n_{0j_2} - n_{0j_1}) & \text{if } k = l \\ \left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2 \right) \right]^{-1} \sigma_0^2 * (n_{0j_2} - n_{0j_1}) & \text{if } k \neq l \end{cases}$$

$$A_j = \begin{pmatrix} I_{1j}^{(1)} & 0 & 0 & 0 \\ 0 & I_{2j}^{(1)} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & I_{Dj}^{(1)} \end{pmatrix}$$

J.2 Design

J.2.1 Look 1

J.2.2 Look 2

J.2.3 Look 3

Assume that a group sequential design with K_1 looks including the final look is planned initially. Let $e_j^{(1)}$ ($j = 1, 2, \dots, K_1$) be the level α exit boundaries for the initial design using $W_{ij}^{(1)}$ to test H_0 . The boundaries $e_j^{(1)}$ satisfy

$$P\left(\bigcup_{j=1}^{K_1} \left\{ \max_i \left\{ W_{ij}^{(1)} \right\} > e_j^{(1)} \right\} \mid \vec{\delta} = 0\right) = \alpha$$

Let α_j ($j = 1, \dots, K_1$) be the cumulative type I error by look j such that

$$P\left(\bigcup_{h=1}^j \left\{ \max_i \left\{ W_{ih}^{(1)} \right\} > e_h^{(1)} \right\} \mid \vec{\delta} = 0\right) = \alpha_j$$

Let $T = \max_{i=1, \dots, D} \{I_{iK_1}\} = n_{0K_1} * \max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}$. Now let $U_{ij} = \frac{W_{ij}}{\sqrt{T}}$. Then the process U_{ij} is a Brownian process with mean $\eta_i \tilde{t}_{ij}$ and variance \tilde{t}_{ij} where

$$\eta_i = \delta_i \sqrt{T}$$

$$\tilde{t}_{ij} = \frac{\left[\frac{\sigma_i^2}{\lambda_i} + \sigma_0^2 \right]^{-1}}{\max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}} t_j$$

Next we derive the conditional distribution for the process U . Note that

$U_{ij_2} = U_{ij_1} + \frac{1}{\sqrt{T}} \sum_{h=j_1+1}^{j_2} W_{i(h)}$. Hence, conditional on $U_{ij_1} = y_{ij_1}$, U_{ij_2} is normal with mean $y_{ij_1} + \frac{1}{\sqrt{T}} \sum_{h=j_1+1}^{j_2} E(W_{i(h)}) = y_{ij_1} + \eta_i (\tilde{t}_{ij_2} - \tilde{t}_{ij_1})$ and variance $\tilde{t}_{ij_2} - \tilde{t}_{ij_1}$ where and $\vec{\eta} = (\eta_1, \eta_2, \dots, \eta_D)^T$ and $\eta_i = \delta_i \sqrt{T}$. Conditional on \vec{U}_{j_1} , the covariance between U_{kj_2} and U_{lj_2} is given by

$$\begin{aligned} Cov\left(U_{kj_2}, U_{lj_2} \mid \vec{U}_{j_1}\right) &= Cov\left(U_{kj_1} + \frac{1}{\sqrt{T}} \sum_{h=j_1+1}^{j_2} W_{k(h)}, U_{lj_1} + \frac{1}{\sqrt{T}} \sum_{h=j_1+1}^{j_2} W_{l(h)}\right) \\ &= \frac{\left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2 \right) \right]^{-1}}{\max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}} \sigma_0^2 * (t_{j_2} - t_{j_1}) \end{aligned}$$

J Theory-Multi-arm Multi-stage Group Sequential Design

Hence the transition density of the process U is given by

$$p_{\vec{\eta}, \tilde{\Sigma}_{j_2|j_1}}((t_{j_1}, \vec{y}_{j_1}), (t_{j_2}, \vec{y}_{j_2})) = (2\pi)^{-D/2} |\tilde{\Sigma}_{j_2|j_1}|^{-\frac{1}{2}} \exp \left\{ -\frac{(\vec{y}_{j_2} - [\vec{y}_{j_1} + (A_{j_2} - A_{j_1})\vec{\eta}])^T [\tilde{\Sigma}_{j_2|j_1}]^{-1} (\vec{y}_{j_2} - [\vec{y}_{j_1} + (A_{j_2} - A_{j_1})\vec{\eta}])}{2} \right\}$$

where $\vec{\eta} = (\eta_1, \eta_2, \dots, \eta_D)^T$ and $\eta_i = \delta_i \sqrt{T}$, $\vec{y}_{j_2} = (y_{1j_2}, y_{2j_2}, \dots, y_{Dj_2})^T$ and the covariance matrix $\tilde{\Sigma}_{j_2|j_1} = (\zeta_{kl})_{D \times D}$ has the form

$$\zeta_{kl} = \begin{cases} \tilde{t}_{kj_2} - \tilde{t}_{kj_1} = \frac{\left[\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2\right]^{-1}}{\max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2\right]^{-1} \right\}} (t_{j_2} - t_{j_1}) & \text{if } k = l \\ = \frac{\left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2\right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2\right)\right]^{-1}}{\max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2\right]^{-1} \right\}} \sigma_0^2 * (t_{j_2} - t_{j_1}) & \text{if } k \neq l \end{cases}$$

and the matrix A_{j_2} has the form

$$A_{j_2} = \begin{pmatrix} \tilde{t}_{1j_2} & 0 & 0 & 0 \\ 0 & \tilde{t}_{2j_2} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \tilde{t}_{Dj_2} \end{pmatrix}$$

Note that

$$P \left(\bigcup_{h=1}^j \left\{ \max_i \{W_{ih}^{(1)}\} > e_h^{(1)} \right\} \mid \vec{\delta} = 0 \right) = \alpha_j$$

is equivalent to

$$P \left(\bigcup_{h=1}^j \left\{ \max_i \{U_{ih}\} > \frac{e_h^{(1)}}{\sqrt{T}} \right\} \mid \vec{\delta} = 0 \right) = \alpha_j$$

For Boundary computation, we will work on the process U . Let $b_j = \frac{e_j^{(1)}}{\sqrt{T}}$ be the boundary based on the process U . We can find b_j recursively and the computation for boundary b_j is independent of sample size.

J.2.1 Look 1

The boundaries b_j ($j = 1, \dots, K_1$) satisfy the following equation

$$P\left(\bigcap_{h=1}^{j-1} \left\{ \max_i \{U_{ih}\} \leq b_j \right\} \cap \left\{ \max_i \{U_{ij}\} > b_j \right\} \mid \vec{\delta} = 0\right) = \alpha_j - \alpha_{j-1}$$

More specifically, b_1 satisfies the following equation

$$P\left(\max_i \{U_{i1}\} > b_1 \mid \vec{\delta} = 0\right) = \alpha_1$$

The left hand side of the above equation under any values of $\vec{\delta}$ is

$$1 - \int_{-\infty}^{b_1} \dots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}}\left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)}\right)\right) d\vec{y}_1^{(1)} \quad (J.2)$$

i.e.

$$\int_{-\infty}^{b_1} \dots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}}\left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)}\right)\right) d\vec{y}_1^{(1)} = 1 - \alpha_1$$

where $\vec{y}_1^{(1)} = \left(y_{11}^{(1)}, \dots, y_{D1}^{(1)}\right)^T$, $\vec{\eta} = (\eta_1, \dots, \eta_D)^T$ and $p_{\vec{\eta}, \tilde{\Sigma}_{1|0}}\left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)}\right)\right)$ is the joint density function of U_{11}, \dots, U_{D1} given by

$$p_{\vec{\eta}, \tilde{\Sigma}_{1|0}}\left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)}\right)\right) = (2\pi)^{-\frac{D}{2}} \left| \tilde{\Sigma}_{1|0} \right|^{-\frac{1}{2}}$$

$$\exp\left\{-\frac{\left(\vec{y}_1^{(1)} - A_1 \vec{\eta}\right)^T \left(\tilde{\Sigma}_{1|0}\right)^{-1} \left(\vec{y}_1^{(1)} - A_1 \vec{\eta}\right)}{2}\right\}$$

and

$$A_1 = \begin{pmatrix} \tilde{t}_{11}^{(1)} & 0 & 0 & 0 \\ 0 & \tilde{t}_{21}^{(1)} & 0 & 0 \\ 0 & 0 & \ddots & 0 \\ 0 & 0 & 0 & \tilde{t}_{D1}^{(1)} \end{pmatrix}$$

J Theory-Multi-arm Multi-stage Group Sequential Design

J.2.2 Look 2

The boundary b_2 satisfies the following equation

$$P \left(\left\{ \max_i \{U_{i1}\} \leq b_1 \right\} \cap \left\{ \max_i \{U_{i2}\} > b_2 \right\} \mid \vec{\delta} = 0 \right) = \alpha_2 - \alpha_1$$

The left hand side of the above equation under any $\vec{\delta}$ is

$$\int_{-\infty}^{b_1} \cdots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right)$$

$$\left[1 - \int_{-\infty}^{b_2} \cdots \int_{-\infty}^{b_2} p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left(\left(t_1^{(1)}, \vec{y}_1^{(1)} \right), \left(t_2^{(1)}, \vec{y}_2^{(1)} \right) \right) d\vec{y}_2^{(1)} \right] d\vec{y}_1^{(1)} \quad (J.3)$$

i.e.

$$\int_{-\infty}^{b_1} \cdots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right)$$

$$\left[\int_{-\infty}^{b_2} \cdots \int_{-\infty}^{b_2} p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left(\left(t_1^{(1)}, \vec{y}_1^{(1)} \right), \left(t_2^{(1)}, \vec{y}_2^{(1)} \right) \right) d\vec{y}_2^{(1)} \right] d\vec{y}_1^{(1)}$$

$$= 1 - \alpha_2$$

where $\vec{y}_2^{(1)} = \left(y_{12}^{(1)}, \dots, y_{D2}^{(1)} \right)^T$ and

$$p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right) = (2\pi)^{-\frac{D}{2}} \left| \tilde{\Sigma}_{1|0} \right|^{-\frac{1}{2}}$$

$$\exp \left\{ - \frac{\left(\vec{y}_1^{(1)} - A_1 \vec{\eta} \right)^T \tilde{\Sigma}_{1|0}^{-1} \left(\vec{y}_1^{(1)} - A_1 \vec{\eta} \right)}{2} \right\}$$

$$p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left(\left(t_1^{(1)}, \vec{y}_1^{(1)} \right), \left(t_2^{(1)}, \vec{y}_2^{(1)} \right) \right) = (2\pi)^{-\frac{D}{2}} \left| \tilde{\Sigma}_{2|1} \right|^{-\frac{1}{2}}$$

$$\exp \left\{ - \frac{\left(\vec{y}_2^{(1)} - \left[\vec{y}_1^{(1)} + (A_2 - A_1) \vec{\eta} \right] \right)^T \tilde{\Sigma}_{2|1}^{-1} \left(\vec{y}_2^{(1)} - \left[\vec{y}_1^{(1)} + (A_2 - A_1) \vec{\eta} \right] \right)}{2} \right\}$$

J.2.3 Look 3

Now let's consider the calculation of the boundary b_3 which satisfies the following

$$P \left(\left\{ \max_i \{U_{i1}\} \leq b_1 \right\} \cap \left\{ \max_i \{U_{i2}\} \leq b_2 \right\} \cap \left\{ \max_i \{U_{i3}\} > b_3 \right\} \mid \vec{\delta} = 0 \right) = \alpha_3 - \alpha_2$$

The left hand side of the above equation under any $\vec{\delta}$ is the following integration

$$\int_{-\infty}^{b_1} \cdots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right) \int_{-\infty}^{b_2} \cdots \int_{-\infty}^{b_2} p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left(\left(t_1^{(1)}, \vec{y}_1^{(1)} \right), \left(t_2^{(1)}, \vec{y}_2^{(1)} \right) \right) \left\{ 1 - \int_{-\infty}^{b_3} \cdots \int_{-\infty}^{b_3} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left(\left(t_2^{(1)}, \vec{y}_2^{(1)} \right), \left(t_3^{(1)}, \vec{y}_3^{(1)} \right) \right) d\vec{y}_3^{(1)} \right\} d\vec{y}_2^{(1)} d\vec{y}_1^{(1)} \quad (J.4)$$

i.e.

$$\int_{-\infty}^{b_1} \cdots \int_{-\infty}^{b_1} \int_{-\infty}^{b_2} \cdots \int_{-\infty}^{b_2} \int_{-\infty}^{b_3} \cdots \int_{-\infty}^{b_3} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right) p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left(\left(t_1^{(1)}, \vec{y}_1^{(1)} \right), \left(t_2^{(1)}, \vec{y}_2^{(1)} \right) \right) p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left(\left(t_2^{(1)}, \vec{y}_2^{(1)} \right), \left(t_3^{(1)}, \vec{y}_3^{(1)} \right) \right) d\vec{y}_3^{(1)} d\vec{y}_2^{(1)} d\vec{y}_1^{(1)} = 1 - \alpha_3$$

J Theory-Multi-arm Multi-stage Group Sequential Design

where $p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), (t_1^{(1)}, \vec{y}_1^{(1)}) \right)$ and $p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left((t_1^{(1)}, \vec{y}_1^{(1)}), (t_2^{(1)}, \vec{y}_2^{(1)}) \right)$ are defined as before. $p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((t_2^{(1)}, \vec{y}_2^{(1)}), (t_3^{(1)}, \vec{y}_3^{(1)}) \right) d\vec{y}_3^{(1)}$ is given as

$$p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((t_2^{(1)}, \vec{y}_2^{(1)}), (t_3^{(1)}, \vec{y}_3^{(1)}) \right) d\vec{y}_3^{(1)} = (2\pi)^{-\frac{D}{2}} |\tilde{\Sigma}_{3|2}|^{-\frac{1}{2}} \exp \left\{ -\frac{\left(\vec{y}_3^{(1)} - \left[\vec{y}_2^{(1)} + (A_3 - A_2)\vec{\eta} \right] \right)^T \tilde{\Sigma}_{3|2}^{-1} \left(\vec{y}_3^{(1)} - \left[\vec{y}_2^{(1)} + (A_3 - A_2)\vec{\eta} \right] \right)}{2} \right\}$$

J.3 Conditional Power and Conditional Type I Error

J.3.1 look $l + 1$

J.3.2 Look $l + 2$

Assume that the trial didn't cross the boundaries at look $1, \dots, l$. At look l , we observed $\vec{x}_l^{(1)}$. The conditional rejection probability under any $\vec{\delta}$ is given by

$$P \left(\bigcup_{j=l+1}^{K_1} \left\{ \max_i \{W_{ij}\} > e_j^{(1)} \right\} \mid \vec{x}_l^{(1)} \right)$$

where $\vec{x}_l^{(1)} = (x_{1l}^{(1)}, x_{2l}^{(1)}, \dots, x_{Dl}^{(1)})$. Then the above probability is reduced to

$$P \left(\left\{ \max_i \{W_{i,l+1}\} > e_{l+1}^{(1)} \right\} \mid \vec{x}_l^{(1)} \right)$$

$$+ P \left(\left\{ \max_i \{W_{i,l+1}\} \leq e_{l+1}^{(1)} \right\} \cap \left\{ \max_i \{W_{i,l+2}\} > e_{l+2}^{(1)} \right\} \mid \vec{x}_l^{(1)} \right) + \dots \quad (J.5)$$

For computational purpose, we will work on the U process which is defined as follows. Let $T = \max_{i=1, \dots, D} \{I_{iK_1}\} = n_{0K_1} * \max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}$. Now let $U_{ij} = \frac{W_{ij}}{\sqrt{T}}$. Then the process U_{ij} is a Brownian process with mean $\eta_i \tilde{t}_{ij}$ and variance \tilde{t}_{ij} where

$$\eta_i = \delta_i \sqrt{T}$$

$$\tilde{t}_{ij} = \frac{\left[\frac{\sigma_i^2}{\lambda_i} + \sigma_0^2 \right]^{-1}}{\max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}} t_j$$

Let b_j be the initial boundaries based on the process U . Then the conditional power can be calculated as follows.

$$P \left(\left\{ \max_i \{U_{i,l+1}\} > b_{l+1} \right\} \mid \vec{y}_l^{(1)} \right)$$

$$+ P \left(\left\{ \max_i \{U_{i,l+1}\} \leq b_{l+1} \right\} \cap \left\{ \max_i \{U_{i,l+2}\} > b_{l+2} \right\} \mid \vec{y}_l^{(1)} \right) + \dots$$

where $\vec{y}_l^{(1)} = \frac{1}{\sqrt{T}} (x_{1l}, x_{2l}, \dots, x_{Dl})^T$.

J.3.1 look $l + 1$

Note that the first probability is as follows

$$P \left(\left\{ \max_i \{U_{i,l+1}\} > b_{l+1} \right\} \mid \vec{y}_l^{(1)} \right)$$

$$= 1 - \int_{-\infty}^{b_{l+1}} \dots \int_{-\infty}^{b_{l+1}} p_{\vec{\eta}, \tilde{\Sigma}_{l+1|l}} \left((t_l^{(1)}, \vec{y}_l^{(1)}), (t_{l+1}^{(1)}, \vec{y}_{l+1}^{(1)}) \right) d\vec{y}_{l+1}^{(1)}$$

where the transition density from J.1 is given by

$$p_{\vec{\eta}, \tilde{\Sigma}_{l+1|l}} \left((t_l^{(1)}, \vec{y}_{j_1}^{(1)}), (t_{l+1}^{(1)}, \vec{y}_{j_2}^{(1)}) \right) = (2\pi)^{-D/2} |\tilde{\Sigma}_{l+1|l}|^{-\frac{1}{2}} \exp \left\{ - \frac{\left(\vec{y}_{l+1}^{(1)} - \left[\vec{y}_l^{(1)} + (A_{j_2} - A_{j_1}) \vec{\eta} \right] \right)^T \left[\tilde{\Sigma}_{l+1|l} \right]^{-1} \left(\vec{y}_{l+1}^{(1)} - \left[\vec{y}_l^{(1)} + (A_{j_2} - A_{j_1}) \vec{\eta} \right] \right)}{2} \right\}$$

where the matrix $\tilde{\Sigma}$ and A are defined as in section 2.

Hence under $\vec{\delta} = 0$, the probability

$$P \left(\left\{ \max_i \{U_{i,l+1}\} > b_{l+1} \right\} \mid \vec{y}_l^{(1)} \right)$$

J Theory-Multi-arm Multi-stage Group Sequential Design

$$= 1 - \int_{-\infty}^{b_{l+1}} \cdots \int_{-\infty}^{b_{l+1}} p_{\tilde{\Sigma}_{l+1|l}} \left((t_l^{(1)}, \vec{y}_l^{(1)}), (t_{l+1}^{(1)}, \vec{y}_{l+1}^{(1)}) \right) d\vec{y}_{l+1}^{(1)}$$

where the transition density is given by

$$p_{\tilde{\Sigma}_{l+1|l}} \left((t_l^{(1)}, \vec{y}_{j_1}^{(1)}), (t_{l+1}^{(1)}, \vec{y}_{j_2}^{(1)}) \right) = (2\pi)^{-D/2} |\tilde{\Sigma}_{l+1|l}|^{-\frac{1}{2}} \exp \left\{ -\frac{(\vec{y}_{l+1}^{(1)} - \vec{y}_l^{(1)})^T [\tilde{\Sigma}_{l+1|l}]^{-1} (\vec{y}_{l+1}^{(1)} - \vec{y}_l^{(1)})}{2} \right\}$$

J.3.2 Look $l + 2$

The second term in J.5 under any $\vec{\delta}$ is

$$P \left(\left\{ \max_i \{W_{i,l+1}\} \leq e_{l+1}^{(1)} \right\} \cap \left\{ \max_i \{W_{i,l+2}\} > e_{l+2}^{(1)} \right\} \mid \vec{x}_l^{(1)} \right)$$

which can be expressed in term of the process U

$$\begin{aligned} & P \left(\left\{ \max_i \{U_{i,l+1}\} \leq b_{l+1} \right\} \cap \left\{ \max_i \{U_{i,l+2}\} > b_{l+2} \right\} \mid \vec{y}_l^{(1)} \right) \\ &= \int_{-\infty}^{b_{l+1}} \cdots \int_{-\infty}^{b_{l+1}} p_{\vec{\eta}, \tilde{\Sigma}_{l+1|l}} \left((t_l^{(1)}, \vec{y}_l^{(1)}), (t_{l+1}^{(1)}, \vec{y}_{l+1}^{(1)}) \right) \\ & \left[1 - \int_{-\infty}^{b_{l+2}} \cdots \int_{-\infty}^{b_{l+2}} p_{\vec{\eta}, \tilde{\Sigma}_{l+2|l+1}} \left((t_{l+1}^{(1)}, \vec{y}_{l+1}^{(1)}), (t_{l+2}^{(1)}, \vec{y}_{l+2}^{(1)}) \right) d\vec{y}_{l+2}^{(1)} \right] d\vec{y}_{l+1}^{(1)} \end{aligned}$$

where

$$p_{\vec{\eta}, \tilde{\Sigma}_{l+1|l}} \left((t_l^{(1)}, \vec{y}_l^{(1)}), (t_{l+1}^{(1)}, \vec{y}_{l+1}^{(1)}) \right) = (2\pi)^{-\frac{D}{2}} |\tilde{\Sigma}_{l+1|l}|^{-\frac{1}{2}} \exp \left\{ -\frac{(\vec{y}_{l+1}^{(1)} - [\vec{y}_l^{(1)} + (A_{l+1} - A_l) \vec{\eta}])^T \tilde{\Sigma}_{l+1|l}^{-1} (\vec{y}_{l+1}^{(1)} - [\vec{y}_l^{(1)} + (A_{l+1} - A_l) \vec{\eta}])}{2} \right\}$$

$$p_{\vec{\eta}, \tilde{\Sigma}_{l+2|l+1}} \left((t_{l+1}^{(1)}, \vec{y}_{l+1}^{(1)}), (t_{l+2}^{(1)}, \vec{y}_{l+2}^{(1)}) \right) = (2\pi)^{-\frac{D}{2}} |\tilde{\Sigma}_{l+2|l+1}|^{-\frac{1}{2}}$$

$$\exp \left\{ - \frac{\left(\vec{y}_{l+2}^{(1)} - \left[\vec{y}_{l+1}^{(1)} + (A_{l+2} - A_{l+1}) \vec{\eta} \right] \right)^T \tilde{\Sigma}_{l+2|l+1}^{-1} \left(\vec{y}_{l+2}^{(1)} - \left[\vec{y}_{l+1}^{(1)} + (A_{l+2} - A_{l+1}) \vec{\eta} \right] \right)}{2} \right\}$$

Under $\vec{\delta} = 0$, we will obtain the conditional type I error by replacing $\vec{\eta}$ by 0.

J.4 Compute power and sample size

J.4.1 Compute power for user-specified sample size

J.4.1 Compute power for user-specified sample size

To compute power for user-specified sample size, we first need to compute boundaries b_j ($j = 1, \dots, K_1$) using the method in Section 2. Once the boundaries have been computed, we can compute power for user-specified sample size. The power is given by

$$\begin{aligned} & P \left(\bigcup_{j=1}^{K_1} \left\{ \max_i \left\{ W_{ij}^{(1)} \right\} > e_j^{(1)} \right\} \mid \vec{\delta} \right) \\ &= P \left(\max_i \left\{ W_{i1}^{(1)} \right\} > e_1^{(1)} \mid \vec{\delta} \right) \\ &+ P \left(\left\{ \max_i \left\{ W_{i1}^{(1)} \right\} \leq b_1^{(1)} \right\} \cap \left\{ \max_i \left\{ W_{i2}^{(1)} \right\} > b_2^{(1)} \right\} \mid \vec{\delta} \right) + \dots \end{aligned}$$

Let N be the total sample size for the study. Assume we want to power the study at some $\vec{\delta} = (\delta_1, \delta_2, \dots, \delta_D)$. To compute the power for a sample size of N , we work with the process U which is defined as $U_{ij} = \frac{W_{ij}^{(1)}}{\sqrt{T}}$ and

$$T = \max_{h=1, \dots, D} \{ I_{hK_1} \} = n_{0K_1} * \max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}$$

From Section 2, we have

$$P \left(\max_i \left\{ W_{i1}^{(1)} \right\} > e_1^{(1)} \mid \vec{\delta} \right) = P \left(\max_i \left\{ U_{i1} \right\} > b_1 \mid \vec{\delta} \right)$$

$$1 - \int_{-\infty}^{b_1} \dots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_1|0} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right) d\vec{y}_1^{(1)}$$

J Theory-Multi-arm Multi-stage Group Sequential Design

where

$$\begin{aligned}
 & p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right) = (2\pi)^{-\frac{D}{2}} |\tilde{\Sigma}_{1|0}|^{-\frac{1}{2}} \\
 & \exp \left\{ -\frac{\left(\vec{y}_1^{(1)} - A_1 \vec{\eta} \right)^T \left(\tilde{\Sigma}_{1|0} \right)^{-1} \left(\vec{y}_1^{(1)} - A_1 \vec{\eta} \right)}{2} \right\} \\
 & P \left(\left\{ \max_i \{ W_{i1}^{(1)} \} \leq e_1^{(1)} \right\} \cap \left\{ \max_i \{ W_{i2}^{(1)} \} > e_2^{(1)} \right\} \mid \vec{\delta} \right) \\
 & = P \left(\left\{ \max_i \{ U_{i1} \} \leq b_1 \right\} \cap \left\{ \max_i \{ U_{i2} \} > b_2 \right\} \mid \vec{\delta} \right) \\
 & = \int_{-\infty}^{b_1} \cdots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right) \\
 & \left[1 - \int_{-\infty}^{b_2} \cdots \int_{-\infty}^{b_2} p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left(\left(t_1^{(1)}, \vec{y}_1^{(1)} \right), \left(t_2^{(1)}, \vec{y}_2^{(1)} \right) \right) d\vec{y}_2^{(1)} \right] d\vec{y}_1^{(1)}
 \end{aligned}$$

where $\vec{y}_2^{(1)} = \left(y_{12}^{(1)}, \dots, y_{D2}^{(1)} \right)^T$ and

$$\begin{aligned}
 & p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), \left(t_1^{(1)}, \vec{y}_1^{(1)} \right) \right) = (2\pi)^{-\frac{D}{2}} |\tilde{\Sigma}_{1|0}|^{-\frac{1}{2}} \\
 & \exp \left\{ -\frac{\left(\vec{y}_1^{(1)} - A_1 \vec{\eta} \right)^T \tilde{\Sigma}_{1|0}^{-1} \left(\vec{y}_1^{(1)} - A_1 \vec{\eta} \right)}{2} \right\} \\
 & p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left(\left(t_1^{(1)}, \vec{y}_1^{(1)} \right), \left(t_2^{(1)}, \vec{y}_2^{(1)} \right) \right) = (2\pi)^{-\frac{D}{2}} |\tilde{\Sigma}_{2|1}|^{-\frac{1}{2}} \\
 & \exp \left\{ -\frac{\left(\vec{y}_2^{(1)} - \left[\vec{y}_1^{(1)} + (A_2 - A_1) \vec{\eta} \right] \right)^T \tilde{\Sigma}_{2|1}^{-1} \left(\vec{y}_2^{(1)} - \left[\vec{y}_1^{(1)} + (A_2 - A_1) \vec{\eta} \right] \right)}{2} \right\}
 \end{aligned}$$

Similarly,

$$\begin{aligned}
 & P \left(\bigcap_{j=1}^2 \left\{ \max_i \{W_{i,j}^{(1)}\} \leq e_j^{(1)} \right\} \cap \left\{ \max_i \{W_{i,3}^{(1)}\} > e_3^{(1)} \right\} \mid \vec{\delta} \right) \\
 &= P \left(\bigcap_{j=1}^2 \left\{ \max_i \{U_{i,j}\} \leq b_j \right\} \cap \left\{ \max_i \{U_{i,3}\} > b_3 \right\} \mid \vec{\delta} \right) \\
 &= \int_{-\infty}^{b_1} \cdots \int_{-\infty}^{b_1} p_{\vec{\eta}, \tilde{\Sigma}_{1|0}} \left((0, 0), (t_1^{(1)}, \vec{y}_1^{(1)}) \right) \\
 &\quad \int_{-\infty}^{b_2} \cdots \int_{-\infty}^{b_2} p_{\vec{\eta}, \tilde{\Sigma}_{2|1}} \left((t_1^{(1)}, \vec{y}_1^{(1)}), (t_2^{(1)}, \vec{y}_2^{(1)}) \right) \\
 &\quad \left\{ 1 - \int_{-\infty}^{b_3} \cdots \int_{-\infty}^{b_3} p_{\vec{\eta}, \tilde{\Sigma}_{3|2}} \left((t_2^{(1)}, \vec{y}_2^{(1)}), (t_3^{(1)}, \vec{y}_3^{(1)}) \right) d\vec{y}_3^{(1)} \right\} d\vec{y}_2^{(1)} d\vec{y}_1^{(1)}
 \end{aligned}$$

To compute sample size needed to achieve a target power specified by users, we will need to use bisection search algorithm to find the required sample size for a target power.

J.5 Simulation

Let $n_{i,j}^{(1)}$ be the cumulative sample size up to look j for each group for the primary trial. Let L_1 be the look number at which dose selection occurs. For $\alpha_1 < \alpha_2 < \dots < \alpha_{K_1} = \alpha$ be the cumulative α spent by each interim look, let $e_j^{(1)}$ ($j = 1, 2, \dots, K_1$) be the exiting boundaries for the process $W_{i,j}^{(1)}$ ($i = 1, \dots, D; j = 1, \dots, K_1$) such that

$$P \left(\bigcup_{h=1}^j \left\{ \max_i \{W_{i,h}^{(1)}\} > e_h^{(1)} \right\} \mid \vec{\delta} = 0 \right) = \alpha_j$$

We first generate the incremental data for each dose group and control group at each look. Then we calculate $W_{i,j}^{(1)}$ ($i = 1, \dots, D; j = 1, \dots, L_1$). If there exists such a $j \leq L_1$ such that $\max_i \{W_{i,j}^{(1)}\} > e_j^{(1)}$, then stop the trial. If the trial doesn't cross the boundaries until look L_1 and suppose we observed $W_{i,L_1}^{(1)} = x_{i,L_1}^{(1)}$ ($i = 1, \dots, D$), we

J Theory-Multi-arm Multi-stage Group Sequential Design

will drop those doses with $x_{iL_1}^{(1)} < \gamma$. Let $S \subseteq F \equiv \{1, 2, \dots, D\}$ be the index set of the doses selected and denote the cardinality of S by D^* . Let α' be the conditional type I error at look L_1 based on the initial design.

Suppose K_2 additional looks will be planned after dose selection. Let $n_{ij}^{(2)}$ ($1 \leq j \leq K_2$) be the cumulative sample size by look j after dose selection. Suppose that the remaining sample size for the dropped doses are reallocated to other dose groups according to the same allocation ratios. Then n_{ij} Suppose user specifies how to spend this conditional type I error α' with $\alpha'_1 < \alpha'_2 \dots < \alpha'_{K_2} = \alpha'$. Next we need to compute the new boundaries after dose selection. Let $e_1^{(2)}, e_2^{(2)}, \dots, e_{K_2}^{(2)}$ be the exiting boundaries after dose selection. Then $e_1^{(2)}, e_2^{(2)}, \dots, e_{K_2}^{(2)}$ satisfy the following equation

$$P \left(\bigcup_{j=1}^{K_2} \left\{ \max_{i \in S} \{W_{ij}^{(2)}\} > e_j^{(2)} \right\} \mid x_{iL_1}^{(1)} (i \in S); \vec{\delta} = 0 \right) = \alpha' \quad (J.6)$$

Suppose sample size adaptation is planned at look L_2 with $0 \leq L_2 < K_2$. If $L_2 = 0$, then dose selection and sample size adaptation will be performed at the same look. We will generate the incremental statistics at each look j ($0 < j \leq L_2$) (Note that if $L_2 = 0$, skip this step). If there exists a j such that the boundary $e_j^{(2)}$ is crossed, then the trial stops. If the trial didn't cross any of the boundaries up to look L_2 , we will perform sample size adaptation. We will increase the total sample size by a flat rate, say 50%, for each of the selected doses and control group if

$\nu_{low} < \max_{i \in S} \{W_{iL_2}^{(2)}\} < \nu_{up}$, otherwise keep the total sample size for each selected dose and control group as planned.

Suppose K_3 additional looks will be performed after sample size adaptation. Let $n_{ij}^{(3)}$ ($1 \leq j \leq K_3$) be the cumulative sample size by look j after sample size adaptation. If the sample size is adapted, we will need to recalculate the boundaries such that the conditional type I error at look L_2 , denoted by α'' is preserved. Suppose we observed $W_{iL_2}^{(2)} = x_{iL_2}^{(2)}$ at look L_2 . Suppose user specifies how to spend this conditional type I error α'' with $\alpha''_1 < \alpha''_2 \dots < \alpha''_{K_3} = \alpha''$. Next we need to compute the new boundaries after sample size adaptation. Let $e_1^{(3)}, e_2^{(3)}, \dots, e_{K_3}^{(3)}$ be the exiting

boundaries after adaptations. We need to find $e_1^{(3)}, \dots, e_{K_3}^{(3)}$ such that

$$P \left(\bigcup_{j=1}^{K_3} \left\{ \max_{i \in S} \{W_{ij}^{(3)}\} > e_j^{(3)} \right\} \mid x_{iL_2}^{(2)}; \vec{\delta} = 0 \right) = \alpha'' \quad (J.7)$$

The new boundary $e_1^{(2)}, e_2^{(2)}, \dots, e_{K_2}^{(2)}$ after dose selection and the new boundary $e_1^{(3)}, e_2^{(3)}, \dots, e_{K_2}^{(3)}$ after sample size adaptation can be calculated by recursively solving the equation J.6 and J.7. The technical details for new boundary calculation is described in Section 5.1 and 5.2.

J.5.1 Compute boundaries after dose selection at look L_1

To compute the boundaries $e_1^{(2)}, e_2^{(2)}, \dots, e_{K_2}^{(2)}$, we first need to compute the conditional type I error α' . The conditional type I error for the primary trial at look L_1 is the following probability.

$$P \left(\bigcup_{j=L_1+1}^{K_1} \max_{i \in F} \{W_{ij}^{(1)}\} > e_j^{(1)} \mid x_{iL_1}^{(1)}; \vec{\delta} = 0 \right) \quad (J.8)$$

To compute J.8, we need to work with the process $U^{(1)}$ which is defined as $U_{ij}^{(1)} = \frac{W_{ij}^{(1)}}{\sqrt{T^{(1)}}}$ and $T^{(1)} = \max_{i \in F} \{I_{iK_1}^{(1)}\} = n_{0K_1}^{(1)} * \max_h \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}$. Let $b_j^{(1)}$ be the boundaries based on the process $U^{(1)}$. Then the equation J.8 is equivalent to

$$P \left(\bigcup_{j=L_1+1}^{K_1} \max_{i \in F} \{U_{ij}^{(1)}\} > b_j^{(1)} \mid U_{iL_1}^{(1)} = y_{iL_1}^{(1)}; \vec{\delta} = 0 \right) = \alpha'$$

where $y_{iL_1}^{(1)} = \frac{x_{iL_1}^{(1)}}{\sqrt{T^{(1)}}}$. The above probability can be obtained by recursively computing the following probability for all $K_1 \geq j > L_1$ and then adding up these probabilities for all j with $K_1 \geq j > L_1$

$$P \left(\bigcap_{h=L_1+1}^{j-1} \left\{ \max_{i \in F} \{U_{ih}^{(1)}\} \leq b_h^{(1)} \right\} \cap \left\{ \max_{i \in F} \{U_{ij}^{(1)}\} > b_j^{(1)} \right\} \mid y_{iL_1}^{(1)}; \vec{\delta} = 0 \right)$$

J Theory-Multi-arm Multi-stage Group Sequential Design

Once we obtain α' , we can calculate the new boundary $e_1^{(2)}, e_2^{(2)}, \dots, e_{K_2}^{(2)}$ which satisfy the following equation.

$$P \left(\bigcup_{j=1}^{K_2} \max_{i \in S} \{W_{ij}^{(2)}\} > e_j^{(2)} \mid x_{iL_1}^{(1)} (i \in S) \right) = \alpha' \tag{J.9}$$

To compute the probability sitting to the left hand side of the equation J.9, we define the process $U^{(2)}$ as $U_{ij}^{(2)} = \frac{W_{ij}^{(2)}}{\sqrt{T^{(2)}}}$ and

$T^{(2)} = \max_{i \in F} \{I_{iK_2}^{(2)}\} = n_{0K_2}^{(2)} * \max_{h \in F} \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}$. If there is no sample size reallocation after dropping doses, then $n_{0K_2}^{(2)} = n_{0K_1}^{(1)}$. If there is sample size reallocation after dropping doses and assume that we keep the same allocation ratios for the selected doses to control arm, then the sample size allocated to control arm after look L_1 is $\frac{N - n_{0L_1}^{(1)}(1 + \sum_{i \in F} \lambda_i)}{1 + \sum_{i \in S} \lambda_i}$ and $n_{0K_2}^{(2)} = \frac{N - n_{0L_1}^{(1)}(1 + \sum_{i \in F} \lambda_i)}{1 + \sum_{i \in S} \lambda_i} + n_{0L_1}^{(1)}$ and $n_{iK_2}^{(2)} = \lambda_i n_{0K_2}^{(2)}$. Let $U_{i0}^{(2)} = y_{i0}^{(2)} = \frac{x_{iL_1}^{(1)}}{\sqrt{T^{(2)}}}$ where we use subscript 0 to indicate the starting state for the secondary trial. We first compute the boundaries $b_1^{(2)}, b_2^{(2)}, \dots, b_{K_2}^{(2)}$ where $b_j^{(2)} = \frac{e_j^{(2)}}{\sqrt{T^{(2)}}}$ such that

$$P \left(\bigcup_{j=1}^{K_2} \max_{i \in S} \{U_{ij}^{(2)}\} > b_j^{(2)} \mid U_{i0}^{(2)} = y_{i0}^{(2)} (i \in S) \right) = \alpha' \tag{J.10}$$

Note that $U_{ij}^{(2)} = y_{i0}^{(2)} + \frac{1}{\sqrt{T^{(2)}}} \sum_{h=1}^j W_{i(h)}^{(2)}$. Hence $U_{ij}^{(2)}$ is normal distributed with mean $y_{i0}^{(2)} + \frac{\delta_i \sum_{h=1}^j I_{i(h)}^{(2)}}{\sqrt{T^{(2)}}} = y_{i0}^{(2)} + \eta_i^{(2)} \frac{\sum_{h=1}^j I_{i(h)}^{(2)}}{T^{(2)}}$ and variance $\frac{\sum_{h=1}^j I_{i(h)}^{(2)}}{T^{(2)}}$ where

$$\eta_i^{(2)} = \delta_i \sqrt{T^{(2)}}$$

$$I_{i(j)}^{(2)} = \left[\frac{\sigma_i^2}{\lambda_i} + \sigma_0^2 \right]^{-1} n_{0(j)}^{(2)} \text{ where } j = 1, \dots, K_2$$

The covariance between $U_{kj}^{(2)}$ and $U_{lj}^{(2)}$ is

$$\begin{aligned} Cov\left(U_{kj}^{(2)}, U_{lj}^{(2)} \mid y_{i0}^{(2)}\right) &= \frac{1}{T^{(2)}} Cov\left(\sum_{h=1}^j W_{k(h)}^{(2)}, \sum_{h=1}^j W_{l(h)}^{(2)}\right) \\ &= \frac{\left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2\right)\left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2\right)\right]^{-1} \sigma_0^2 * (n_{0j}^{(2)} - n_{00}^{(2)})}{\max_{h \in F} \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2\right]^{-1} \right\} n_{0K_2}^{(2)}} \end{aligned}$$

where $n_{00}^{(2)} = n_{0L_1}^{(1)}$. We can find $b_j^{(2)}$ recursively by solving the following equation

$$P\left(\bigcap_{h=1}^{j-1} \left\{ \max_{i \in S} \{U_{ih}^{(2)}\} \leq b_h^{(2)} \right\} \cap \left\{ \max_{i \in S} \{U_{ij}^{(2)}\} > b_h^{(2)} \right\} \mid y_{i0}^{(2)} (i \in S)\right) = \alpha'_j$$

Once we obtain $b_j^{(2)}$, we can compute $e_j^{(2)}$ as $e_j^{(2)} = b_j^{(2)} \sqrt{T^{(2)}}$.

J.5.2 Compute boundaries after sample size adaptation at look L_2

To compute the boundaries $e_1^{(3)}, e_2^{(3)}, \dots, e_{K_2}^{(3)}$, we first need to compute the conditional type I error α'' at look L_2 of the secondary trial. The conditional type I error for the secondary trial at look L_2 is the following probability.

$$P\left(\bigcup_{j=L_2+1}^{K_2} \max_{i \in S} \{W_{ij}^{(2)}\} > e_j^{(2)} \mid x_{iL_2}^{(2)} (i \in S); \vec{\delta} = 0\right) \tag{J.11}$$

To compute J.11, we need to work with the process $U_{ij}^{(2)} = \frac{W_{ij}^{(2)}}{\sqrt{T^{(2)}}}$ and

$T^{(2)} = \max_{i \in F} \{I_{iK_2}^{(2)}\} = n_{0K_2}^{(2)} * \max_{h \in F} \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2\right]^{-1} \right\}$. By this step, the

boundaries $b_1^{(2)}, b_2^{(2)}, \dots, b_{K_2}^{(2)}$ have been computed. Then J.11 is equivalent to

$$P\left(\bigcup_{j=L_2+1}^{K_2} \max_{i \in F} \{U_{ij}^{(2)}\} > b_j^{(2)} \mid y_{iL_2}^{(2)}; \vec{\delta} = 0\right)$$

where $y_{iL_2}^{(2)} = \frac{x_{iL_1}^{(2)}}{\sqrt{T^{(2)}}}$. The above probability can be obtained by recursively computing the following probability for all $K_1 \geq j > L_1$ and then adding up these probabilities

J Theory-Multi-arm Multi-stage Group Sequential Design

for all j with $K_2 \geq j > L_2$

$$P \left(\bigcap_{h=L_2+1}^{j-1} \left\{ \max_{i \in F} \{U_{ih}^{(2)}\} \leq b_h^{(2)} \right\} \cap \left\{ \max_{i \in F} \{U_{ij}^{(2)}\} > b_j^{(2)} \right\} \mid y_{iL_2}^{(2)}; \vec{\delta} = 0 \right)$$

Once we obtain α'' , we can calculate the new boundary $e_1^{(3)}, e_2^{(3)}, \dots, e_{K_3}^{(3)}$ which satisfy the following equation.

$$P \left(\bigcup_{j=1}^{K_3} \max_{i \in S} \{W_{ij}^{(3)}\} > e_j^{(3)} \mid x_{i,L_2}^{(2)} (i \in S) \right) = \alpha'' \quad (J.12)$$

To compute the probability sitting to the left hand side of the equation J.12, we define the process $U^{(3)}$ as $U_{ij}^{(3)} = \frac{W_{ij}^{(3)}}{\sqrt{T^{(3)}}}$ and

$$T^{(3)} = \max_{i \in F} \{I_{iK_2}^{(3)}\} = n_{0K_2}^{(3)} * \max_{h \in F} \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\}. \text{ Let } U_{i0}^{(3)} = y_{i0}^{(3)} = \frac{x_{iL_2}^{(2)}}{\sqrt{T^{(3)}}}.$$

We first compute the boundaries $b_1^{(3)}, b_2^{(3)}, \dots, b_{K_3}^{(3)}$ where $b_j^{(3)} = \frac{e_j^{(3)}}{\sqrt{T^{(3)}}}$ such that

$$P \left(\bigcup_{j=1}^{K_3} \max_{i \in S} \{U_{ij}^{(3)}\} > b_j^{(3)} \mid y_{i0}^{(3)} (i \in S) \right) = \alpha''$$

Note that $U_{ij}^{(3)} = y_{i0}^{(3)} + \frac{1}{\sqrt{T^{(3)}}} \sum_{h=1}^j W_{i(h)}^{(3)}$. Hence $U_{ij}^{(3)}$ is normally distributed with mean $y_{i0}^{(3)} + \frac{\delta_i \sum_{h=1}^j I_{i(h)}^{(3)}}{\sqrt{T^{(3)}}} = y_{i0}^{(3)} + \eta_i^{(3)} \frac{\sum_{h=1}^j I_{i(h)}^{(3)}}{T^{(3)}}$ and variance $\frac{\sum_{h=1}^j I_{i(h)}^{(3)}}{T^{(3)}}$ where

$$\eta_i^{(3)} = \delta_i \sqrt{T^{(3)}}$$

$$I_{i(j)}^{(3)} = \left[\frac{\sigma_i^2}{\lambda_i} + \sigma_0^2 \right]^{-1} n_{0(j)}^{(3)}$$

The covariance between $U_{kj}^{(3)}$ and $U_{lj}^{(3)}$ is

$$\begin{aligned} Cov \left(U_{kj}^{(3)}, U_{lj}^{(3)} \mid y_{i0}^{(3)} \right) &= \frac{1}{T^{(3)}} Cov \left(\sum_{h=1}^j W_{k(h)}^{(3)}, \sum_{h=1}^j W_{l(h)}^{(3)} \right) \\ &= \frac{\left[\left(\frac{\sigma_k^2}{\lambda_k} + \sigma_0^2 \right) \left(\frac{\sigma_l^2}{\lambda_l} + \sigma_0^2 \right) \right]^{-1} \sigma_0^2 * \left(n_{0j}^{(3)} - n_{00}^{(3)} \right)}{\max_{h \in F} \left\{ \left[\frac{\sigma_h^2}{\lambda_h} + \sigma_0^2 \right]^{-1} \right\} n_{0K_3}^{(3)}} \end{aligned}$$

where $n_{00}^{(3)} = n_{0L_2}^{(2)}$. We can find $b_j^{(3)}$ recursively by solving the following equation

$$P \left(\bigcap_{h=1}^{j-1} \left\{ \max_{i \in S} \{U_{ih}^{(3)}\} \leq b_h^{(3)} \right\} \cap \left\{ \max_{i \in S} \{U_{ij}^{(3)}\} > b_h^{(3)} \right\} \mid y_{i0}^{(3)} (i \in S) \right) = \alpha_j''$$

Once we obtain $b_j^{(3)}$, we can compute $e_j^{(3)}$ as $e_j^{(3)} = b_j^{(3)} \sqrt{T^{(3)}}$.

K ***Theory - MultiArm Two Stage Designs*** ***Combining p-values***

K.1 Introduction

This appendix describes theory behind two stage multi arm designs which combine p-values. These designs are available for difference of means test and difference of proportions test. We also provide details of various computations used in East for these designs.

K.2 Treatment Effect Scales

K.2.1 Estimated Mean

K.2.2 Estimated Delta

K.2.3 Estimated

Standardized Effect Size

K.2.4 Test Statistic

K.2.5 Conditional Power

K.2.6 Isotonic Mean

K.2.7 Isotonic Delta

K.2.8 Isotonic Standardized Effect Size

K.2.9 Estimated Proportion

K.2.10 Isotonic Proportion

East provides various treatment effect scales for selecting treatments for stage 2 for difference of means as well as difference of proportions tests. This section describes these treatment effect scales. Treatment effect scale is used along with treatment selection rule for selecting treatments for stage 2.

For any treatment effect scale, if a tie or ties are observed then they are broken using following conventions.

1. If responses are generated using dose response curve then the treatment with the lowest dose among tied treatments is selected.
2. If responses are not generated using dose response curve then treatment is selected at random among tied treatments.

For isotonic computations 'Pooled Adjacent Violators Algorithm' (PAVA) proposed by Ayers et. al. (1955) is used.

K.2.1 Estimated Mean

This treatment effect scale is available only for difference of mean test. The estimated mean response for each treatment is used in this treatment effect scale.

K.2.2 Estimated Delta

This treatment effect scale is available for difference of mean as well as difference of proportions test.

For difference of mean test, the estimated δ which is the difference between estimated mean for a particular treatment and estimated mean for control is used in this treatment effect scale.

For difference of proportions test, the estimated δ which is the difference between estimated proportion for a particular treatment and estimated proportion for control is used in this treatment effect scale.

K.2.3 Estimated Standardized Effect Size

This treatment effect scale is available only for difference of means test. It is available only if variance option is equal for t statistic and common standard deviation option is selected for Z statistic.

The estimated δ for each treatment is difference between estimated mean for a particular treatment and estimated mean for control. If test statistic option is Z then common standard deviation provided by user is used in the computations. If test statistic is t then estimated pooled standard deviation across all data is used in the computations.

K.2.4 Test Statistic

This treatment effect scale is available for difference of mean as well as difference of proportions test.

For difference of means test, test statistic (Z or t) considering variance option (equal or unequal) is used for this treatment effect scale.

For difference of proportions test, test statistic Z considering pooled or un-pooled option is used for this treatment effect scale.

K.2.5 Conditional Power

This treatment effect scale is available for difference of mean as well as difference of proportions test.

The computation of conditional power is done under the assumption that only control and specified treatment are carried forward to stage 2. The details of computation of conditional power for each specific treatment as given below.

$w^{(1)}$: Weight for stage 1

$Z^{(1)}$: Incremental statistic for stage 1

RB : Cumulative efficacy boundary on Z scale for stage 2 for right tailed test

LB : Cumulative efficacy boundary on Z scale for stage 2 for left tailed test

p : Raw p value for stage 1

q : Raw p value for stage 2

SN : Standard Normal random variable

$n_t^{(2)}$: Sample size corresponding to the specified treatment in stage 2.

$n_c^{(2)}$: Sample size corresponding to the control in Stage 2.

λ : Allocation ratio for specified treatment as specified in initial allocation.

K Theory - MultiArm Two Stage Designs Combining p-values

$n_t^{(2)}$ and $n_c^{(2)}$ are computed using stage 2 sample size as planned initially and allocation ratio under the assumption that only specified treatment and control are carried to stage 2.

Right Tailed Test

$$CP = P(SN > RC - B) \tag{K.1}$$

Where

$$RC = \frac{RB - w^{(1)}\Phi^{(-1)}(1 - p)}{w^{(2)}} \tag{K.2}$$

Left Tailed Test

$$CP = P(SN < LC - B) \tag{K.3}$$

Where

$$LC = \frac{LB - w^{(1)}\Phi^{(-1)}(p)}{w^{(2)}} \tag{K.4}$$

For Difference of Means Test

$$B = \frac{\hat{\delta}}{D} \tag{K.5}$$

Where,

$$\hat{\delta} = \bar{d}_t^{(1)} - \bar{d}_c^{(1)}$$

If Variance option is equal then

$$D = \sigma \sqrt{\frac{1}{n_t^{(2)}} + \frac{1}{n_c^{(2)}}} \tag{K.6}$$

If Test statistic option is t then

σ : Estimate of Pooled standard deviation for stage 1

If Test statistic option is Z then

σ : Design common standard deviation

If Variance option is un-equal then

$$D = \sqrt{\frac{\sigma_t^2}{n_t^{(2)}} + \frac{\sigma_c^2}{n_c^{(2)}}} \tag{K.7}$$

If test statistic option is t then

σ_t^2 : Estimate of variance for specified treatment based on stage 1

σ_c^2 : Estimate of variance for control based on stage 1

If test statistic option is Z then

σ_t^2 : Design variance for specified treatment

σ_c^2 : Design variance for control

For Difference of Proportions Test

$$B = \frac{\hat{\delta}}{D} \quad (\text{K.8})$$

Where

$$\hat{\delta} = \hat{\pi}_t - \hat{\pi}_c \quad (\text{K.9})$$

Where

$\hat{\pi}_t$: Estimate of Proportion for treatment based on stage 1

$\hat{\pi}_c$: Estimate of Proportion for control based on stage 1

When variance is Un-Pooled

$$D = \sqrt{\frac{\hat{\pi}_t(1 - \hat{\pi}_t)}{n_t^{(2)}} + \frac{\hat{\pi}_c(1 - \hat{\pi}_c)}{n_c^{(2)}}} \quad (\text{K.10})$$

When variance is Pooled

$$D = \sqrt{\bar{\pi}(1 - \bar{\pi}) \left(\frac{1}{n_t^{(2)}} + \frac{1}{n_c^{(2)}} \right)} \quad (\text{K.11})$$

Where $\bar{\pi}$: Estimate of pooled proportion based on stage 1

K.2.6 Isotonic Mean

This treatment effect scale is available only for difference of mean test. Isotonic means are computed after applying PAVA algorithm to estimated means of all treatments and control.

K.2.7 Isotonic Delta

This treatment effect scale is available for difference of mean as well as for difference of proportions test.

First Isotonic means are computed by applying PAVA algorithm to estimated means of all treatments and control. Using these computed isotonic means, the value of isotonic δ for each treatment is computed.

K Theory - MultiArm Two Stage Designs Combining p-values

K.2.8 Isotonic Standardized Effect Size

This treatment effect scale is available for difference of mean test only. It is available only if variance option is equal for t statistic and common standard deviation option is selected for Z statistic.

Isotonic $\frac{\delta}{\sigma}$ values are computed by first computing isotonic δ values for all treatments. If test statistic option is Z then value of σ used is the value of common standard deviation and if test statistic is t then estimated pooled standard deviation across all data is used in the computations.

K.2.9 Estimated Proportion

This treatment effect scale is available only for difference of proportions test. The estimated proportion for each treatment is used in this treatment effect scale.

K.2.10 Isotonic Proportion

This treatment effect scale is available only for difference of proportions test. Isotonic proportions are computed after applying PAVA algorithm to estimated proportions of all treatments and control.

K.3 Combination Method

East uses "Inverse Normal" combination function to combine p values (or adjusted p values) from two stages.

Default values of weights for two stages are computed as follows.

$$w^{(1)} = \sqrt{\frac{n^{(1)}}{n}} \quad (\text{K.12})$$

$$w^{(2)} = \sqrt{\frac{n^{(2)}}{n}} \quad (\text{K.13})$$

Where $n^{(1)}$ and $n^{(2)}$ are the total sample sizes corresponding to stage 1 and stage 2 respectively and n is the total sample size.

East allows the user to change the weights as long as the weights satisfy the following condition

$$w^{(1)} * w^{(1)} + w^{(2)} * w^{(2)} = 1 \quad (\text{K.14})$$

East uses "Inverse Normal" combination function to combine p values (or adjusted p values) from two stages.

Let $p^{(1)}$ and $p^{(2)}$ be p-values (or adjusted p-values) from stage 1 and stage 2 respectively. The combined p value is given by the formula

$$p = 1 - \Phi \left(w^{(1)} \Phi^{-1} \left(1 - p^{(1)} \right) + w^{(2)} \Phi^{-1} \left(1 - p^{(2)} \right) \right) \quad (\text{K.15})$$

K.4 Closed Testing

No elementary hypothesis can be rejected unless all intersection hypotheses which contain that elementary hypothesis are rejected is the closed testing principle of Marcus et. al. (1976). This principle is applied in analysis after both stages.

For multiplicity adjustment, East provides Bonferroni, Sidak, Simes and Dunnett methods. Dunnett method is available only for difference of means test. For details of these methods please see appendix of multiple comparison procedures.

After stage 1, multiplicity adjusted p-values are computed for each intersection hypothesis and then closed testing is used to perform hypothesis test of each individual hypothesis.

After stage 2, multiplicity adjusted p values from both stages are combined for each intersection hypothesis using combination method and then closed testing is used to perform hypothesis test of each individual hypothesis.

K.5 Stopping Boundaries

East allows stopping after stage 1 using efficacy or futility boundaries. Trial is terminated after stage 1 if any of the treatment arms crosses efficacy boundary. Trial is terminated for futility after stage 1 if all treatment arms cross futility boundary.

At the end of stage 2, for efficacy futility design, if no arm has crossed efficacy boundary then trial is declared futile.

For efficacy as well as futility stopping, adjusted p value obtained using combination and closed testing procedures is used.

For futility stopping, user can specify futility boundary in terms of δ for difference of proportions test and in terms of $\frac{\delta}{\sigma}$ for difference of means test.

K Theory - MultiArm Two Stage Designs Combining p-values

K.6 Sample Size Re-estimation

Sample size re-estimation allows the user to increase sample size after stage 1. User can specify a target conditional power which will be used to compute re-estimated sample size. User may also directly specify re-estimated sample size. Sample size reduction is not allowed.

Promising zone approach used in adaptive simulations in East is also used here. If a trial lands in the promising zone then only sample size is re-estimated and used. If a trial lands in unfavorable to favorable zones then sample size is not re-estimated.

The conditional power calculation will be based on the assumption that only the control treatment and the best treatment (according to the treatment effect scale) are carried to the second stage. $Z^{(1)}$: Incremental statistic for stage 1 corresponding to best treatment.

$n_c^{(2)}$: Sample size corresponding to control in stage 2.

$n_t^{(2)}$: Sample size corresponding to the best treatment in Stage 2.

p : Raw p-value for the best treatment at stage 1.

$\lambda_b^{(2)}$: Allocation ratio for the best treatment as specified in treatment selection tab

RBA: Adjusted Cumulative efficacy boundary on Z scale for stage 2 for right tailed test. Adjusted using $\frac{\alpha}{k}$ where α is the design type I error and k is the number of active treatments in stage 1.

LBA: Adjusted Cumulative efficacy boundary on Z scale for stage 2 for left tailed test. Adjusted using $\frac{\alpha}{k}$ where α is the design type I error and k is the number of active treatments in stage 1.

tCP: Target conditional power *SN*: Standard Normal random variable

For right tailed test, the formula for conditional power is given by

$$CP = P(SN > RC - B) = tCP \quad (K.16)$$

Where

$$RC = \frac{RBA - w^{(1)}\Phi^{(-1)}(1 - p)}{w^{(2)}} \quad (K.17)$$

For Left tailed test, the formula for conditional power is given by

$$CP = P(SN < LC - B) = tCP \quad (K.18)$$

Where

$$LC = \frac{LBA - w^{(1)}\Phi^{(-1)}(p)}{w^{(2)}} \quad (K.19)$$

For Difference of Means Test

$$B = \frac{\hat{\delta}}{D} \tag{K.20}$$

Where,

$$\hat{\delta} = \bar{d}_t^{(1)} - \bar{d}_c^{(1)}$$

If Variance option is equal then

$$D = \sigma \sqrt{\frac{1}{n_t^{(2)}} + \frac{1}{n_c^{(2)}}} \tag{K.21}$$

Let us define

$$D_1 = \sigma \sqrt{\frac{1}{\lambda_b^{(2)}} + 1} \tag{K.22}$$

If Test statistic option is t then

σ : Estimate of Pooled standard deviation for stage 1

If Test statistic option is Z then

σ : Design common standard deviation

If Variance option is un-equal then

$$D = \sqrt{\frac{\sigma_t^2}{n_t^{(2)}} + \frac{\sigma_c^2}{n_c^{(2)}}} \tag{K.23}$$

Let us define

$$D_1 = \sqrt{\frac{\sigma_t^2}{\lambda_b^{(2)}} + \sigma_c^2} \tag{K.24}$$

If test statistic option is t then

σ_t^2 : Estimate of variance for specified treatment based on stage 1

σ_c^2 : Estimate of variance for control based on stage 1

If test statistic option is Z then

σ_t^2 : Design variance for specified treatment

σ_c^2 : Design variance for control

K Theory - MultiArm Two Stage Designs Combining p-values

For Difference of Proportions Test

$$B = \frac{\hat{\delta}}{D} \tag{K.25}$$

Where

$$\hat{\delta} = \hat{\pi}_t - \hat{\pi}_c \tag{K.26}$$

Where

$\hat{\pi}_t$: Estimate of Proportion for treatment based on stage 1

$\hat{\pi}_c$: Estimate of Proportion for control based on stage 1

When variance is Un-Pooled

$$D = \sqrt{\frac{\hat{\pi}_t(1 - \hat{\pi}_t)}{n_t^{(2)}} + \frac{\hat{\pi}_c(1 - \hat{\pi}_c)}{n_c^{(2)}}} \tag{K.27}$$

Let us define

$$D_1 = \sqrt{\frac{\hat{\pi}_t(1 - \hat{\pi}_t)}{\lambda_b^{(2)}} + \hat{\pi}_c(1 - \hat{\pi}_c)} \tag{K.28}$$

When variance is Pooled

$$D = \sqrt{\bar{\pi}(1 - \bar{\pi}) \left(\frac{1}{n_t^{(2)}} + \frac{1}{n_c^{(2)}} \right)} \tag{K.29}$$

Let us define

$$D = \sqrt{\bar{\pi}(1 - \bar{\pi}) \left(\frac{1}{\lambda_b^{(2)}} + 1 \right)} \tag{K.30}$$

Where $\bar{\pi}$: Estimate of pooled proportion based on stage 1

Finally the formulae for sample size on control arm on stage 2 are as follows. For Right Tailed Test

$$n_c^{(2)} = (RC - \Phi^{-1}(1 - tCP))^2 * \frac{D_1^2}{\hat{\delta}^2} \tag{K.31}$$

For Left Tailed Test

$$n_c^{(2)} = (LC - \Phi^{-1}(tCP))^2 * \frac{D_1^2}{\hat{\delta}^2} \tag{K.32}$$

Once the re-estimated control sample size $n_c^{(2)}$ is computed then we will consider the allocation ratio specified in the treatment selection tab (for second stage) and compute the sample size for a specific treatment which is carried forward to stage two.

Sample size re-estimation is not performed if estimated delta value after stage 1 is in opposite direction of the rejection type of the test.

L Technical Details - Predicted Interval Plots

Predicted interval plots (PIP) are useful tool in accessing magnitude of future treatment effect and its associated uncertainty given current data. Predicted interval plots are available in regular interim monitoring as well as Muller and Schafer interim monitoring. In this appendix, we describe technical details related to PIP. We have divided the appendix in following four sections.

1. Inputs for PIP
2. Estimation of Parameters from Data
3. Simulating the future for PIP
4. Computing and Displaying PIP

L.1 Inputs for PIP

Below we describe details about inputs required for PIP.

1. **PIP for Look** - This corresponds to the various choices about the future that you want generated in PIP. There are three choices.
 - (a) **PIP at Final Look** - This option corresponds to the final look in Design. With this option, it is assumed that there is only one specified look in the future and future will be generated so that completers or events corresponding to the final look as per design are achieved.
 - (b) **PIP at Any Future Look** - All looks specified in design which have not yet happened in Interim Monitoring Sheet are considered in this option. In the future looks, early stopping is also considered with this option.
 - (c) **PIP at User specified Look** - With this option, it is assumed that there is only one specified look in the future but here user can alter completers or events which correspond to this future look. This option is not available in PIP for Muller and Schafer interim monitoring.
2. **Population ID** - The variable corresponding to the Population ID must be binary which contains only two distinct values. In user interface, you can specify which value corresponds to the control arm and which value corresponds to the treatment arm.
3. **Arrival Time** - The variable corresponding to Arrival Time is required only for Survival end point tests. This variable must be numeric (values strictly greater than zero) representing time of entry into the trial for each subject.
4. **Status Indicator** - The variable corresponding to Status Indicator is mandatory for Survival end point trials. It is required for normal or binomial end point trials if data contains delayed responses. In this variable, value of 1 represents that response has been observed for that subject. Value of -1 represents that the subject has dropped out before giving response. Value 0 represents that the subject is still in the trial but has not responded.

5. **Response Variable** - The variable which corresponds to the Response Variable must be numeric for Normal End Point test. It must be binary which contains only two distinct values for discrete end point test. In user interface, you can specify which value corresponds to the control arm and which value corresponds to the treatment Arm. For Survival End Point tests, this variable must be continuous representing time spent in the trial until event (for subject whose Status Indicator is 1) or until drop out (for subject whose Status Indicator is -1) or total follow up time (for pending subject whose Status Indicator is 0).

L.2 Estimation of Parameters from Data

Estimation of Parameter from current Data is optional. By default design values of parameters are copied whenever possible. Of course after estimating parameters from current data, you can edit their values as you desire. Before estimating parameters from data, invalid observations are ignored from the data. Sample size is calculated as total number of subjects accrued in the trial, based on the current data. Number of completers or events (if they are different than Sample size because of response lag or drop out probability) are computed as subjects whose response is observed. Sample Size and Number of Completers are not editable for regular PIP. Sample size is editable for MS PIP. You should verify that number of completers or events computed from the data match with the number used in Interim Monitoring Sheet. In case of Normal or Binomial end point, if data does not contain delayed responses then all subjects in the data are assumed to be responders and their responses are used for parameter estimation. If the data contains delayed responses then response for subjects who have Status Indicator value equal to 1 are used for parameter estimation. In case of Survival end point, Data Base Lock Time (DBLT) is computed from that data which is the maximum observed calendar time in the data. For subjects whose Status Indicator is 0 i.e. for pending subjects, the Response value must be the difference between DBLT and arrival time for that subject. If this condition is not met for any subject then Response value will be correctly updated for such a subject and used in parameter estimation. Here are the formulae for estimation of various parameters.

1. Difference of Means Test

Let

n_c : Number of responders on control arm.

n_t : Number of responders on treatment arm.

$x_{i,c}$: Response value of i^{th} subject on control arm.

$x_{i,t}$: Response value of i^{th} subject on treatment arm.

Estimate of Mean Control is given by

$$\mu_c = \frac{\sum_{i=1}^{n_c} x_{i,c}}{n_c} \quad (\text{L.1})$$

L Technical Details - Predicted Interval Plots

Estimate of Mean Treatment is given by

$$\mu_t = \frac{\sum_{i=1}^{n_t} x_{i,t}}{n_t} \quad (\text{L.2})$$

Estimate of Difference of Means is given by

$$\delta = \mu_t - \mu_c \quad (\text{L.3})$$

Estimate of Probability of Dropout is given by

$$PD = \frac{\text{No. of DropOuts}}{\text{Sample Size}} \quad (\text{L.4})$$

Estimate of Std. Deviation is given by pooled standard deviation computed from the data.

2. Difference of Proportions and Ratio of Proportions Test

Let

x_c : Number of responses on control arm

y_t : Number of responses on treatment arm

n_c : Number of subjects on control arm

n_t : Number of subjects on treatment arm

Estimate of Proportion under control is given by

$$\pi_c = \frac{(x_c + 0.5)}{(n_c + 1)} \quad (\text{L.5})$$

Estimate of Proportion under treatment is given by

$$\pi_t = \frac{(x_t + 0.5)}{(n_t + 1)} \quad (\text{L.6})$$

Estimate of Difference of Proportions is given by

$$\delta = \pi_t - \pi_c \quad (\text{L.7})$$

Estimate of Probability of Dropout is given by

$$PD = \frac{\text{No. of DropOuts}}{\text{Sample Size}} \quad (\text{L.8})$$

3. Survival (GADAR and GADSD) Tests Let E_c : Number of Events on Control Arm. E_t : Number of Events on Treatment Arm. D_c : Number of Drop outs on Control Arm. D_t : Number of Drop outs on Treatment Arm . FT_c : Total follow up time of all patients on Control Arm. FT_t : Total follow up time of all patients on Treatment Arm.

Estimate of Hazard Rate for Control is given by

$$\lambda_c = \frac{E_c}{FT_c} \quad (\text{L.9})$$

Estimate of Hazard Ratio (HR) is computed from the Cox proportional hazard model.

Estimate of Hazard Rate for Treatment is given by

$$\lambda_t = \lambda_c * HR \quad (\text{L.10})$$

Estimate of Drop out Hazard Rate for Control is given by

$$\gamma_c = \frac{D_c}{FT_c} \quad (\text{L.11})$$

Estimate of Drop out Hazard Rate for Treatment is given by

$$\gamma_t = \frac{D_t}{FT_t} \quad (\text{L.12})$$

L.3 Simulating the future for PIP

For simulating the future for PIP, parameters estimated from data (editable) are used. Other values of parameters required for simulation (like allocation ratio for example) are used from the corresponding design.

For Normal and Binary end point, response value is generated for pending subjects but treatment indicator for them is preserved from current data. Treatment indicator and response values both are generated for future subjects.

For Survival end point also for pending subjects Treatment Indicator is preserved as is in the current data. For generating survival and dropout times for pending subjects, memory less property of exponential distribution is used. Generation of arrival times for future subjects starts after Data Base Lock Time. Generation of survival and drop out times for future subjects is similar to enhanced simulation.

L Technical Details - Predicted Interval Plots

L.4 Computing and Displaying PIP

The current data is fixed in all simulations but generated future data varies across simulations. For each simulation, the cumulative estimate of Delta (HR for survival end point) and associated standard error is computed. For PIP in non-adaptive IM as well as PIP in MS IM, futility boundary if present in design is ignored in all simulation computations. For regular PIP, two sided confidence interval is always computed even for one sided trial design. Boundary computation at a particular future look or any future look is similar to the boundary computation performed in Interim Monitoring sheet. Repeated confidence interval (RCI) is computed for each simulation with computations similar to that of Interim Monitoring sheet.

For MS PIP, one sided RCI is always computed using shift method.

For Efficacy Two Sided and for Efficacy Futility Two Sided designs with type I error α , the confidence coefficient that is used in regular PIP is $100 \times (1 - \alpha) \%$

For Efficacy One Sided and for Efficacy Futility one sided designs with type I error α , the confidence coefficient that is used in regular PIP is $100 \times (1 - 2 \times \alpha) \%$

For Efficacy One Sided and for Efficacy Futility one sided designs with type I error α , the confidence coefficient that is used in MS PIP is $100 \times (1 - \alpha) \%$

For Any Future Look, RCI is computed at stopping look or last look. For Final Look, RCI is computed at final look as per design. RCI's computed for all simulations are sorted on estimated value of Delta (or HR for survival end point) and are displayed on X -axis. On Y-axis estimated values of Delta are plotted. Current (Interim Monitoring) value of confidence interval is displayed by a black horizontal line in the PIP. Color coding is applied which helps in deciding the density of the observed estimated values of Delta (or HR). Read-offs on PIP is a simple matter of computation of counting the number of repeated confidence intervals which satisfy particular condition.

M Enrollment/Events Prediction - Theory

The terms 'Enrollment' and 'Accruals' are used interchangeably in this Appendix chapter. The Predict module in East 6.4 simulates subject enrollment and events in a clinical trial. These simulations are also part of Enrollment/Events simulation at design stage (Chapter 66 and Enrollment/Events simulation at Interim Monitoring stage (Chapter 67). The underlying theory of generating accruals and/or events is same for both the situations. In this Appendix we present the theory and algorithms based on which the arrival times, time to event data (survival data) and drop out times are simulated. Generation of these quantities make the realizations of accruals, events and drop outs possible which are further used in deriving estimates of average accrual duration, average follow up time, average study duration etc which are of much use to the investigator.

13.1 Enrollments Generation

In East 6.4, the subjects are enrolled assuming a Poisson process for the arrivals. In case the arrivals are across a number of sites, the option of Uniform arrivals is also provided. The arrivals are assumed to occur independently of each other. **Exponential Distribution** : In the Poisson process, the inter-arrival times follow an exponential distribution which has a density function as follows:

$$f(x) = \lambda e^{-\lambda x}, x \in [0, \infty)$$

The 'Poisson' option in the Predict module of East generates subject enrollments by randomly sampling successive inter-arrival times from an exponential distribution with parameter λ . The inter-arrival times obtained describe the time difference (in terms of days, months or years depending on the chosen unit of analysis) between the arrivals of consecutive subjects. In East 6.4 the accruals are assumed to occur in a specified period with fixed accrual rate λ . **Input** The primary input for East Predict simulation is the enrollment plan. It specifies for a set of regions/sites the activation periods (the duration over which the site is to be initialized), the accrual rates per site and the maximum number of subjects that may be enrolled in that region/site. The tables below display examples of enrollment plans by region and by site.

| Region ID | Number of Sites | Site Initiation Period | | Accrual Rate/Site | Enrollment Cap |
|-----------|-----------------|------------------------|-----|-------------------|----------------|
| | | Start | End | | |
| Region 1 | 5 | 0 | 0 | 3 | 1000 |
| Region 2 | 5 | 0 | 2 | 4 | 1000 |
| Region 3 | 10 | 2 | 5 | 2 | 1000 |

13 Enrollment/Events Prediction - Theory

| Site ID | Site Initiation Period | | Accrual Rate/Site | Enrollment Cap |
|---------|------------------------|-----|-------------------|----------------|
| | Start | End | End | |
| | | | Start | |
| Site 1 | 0 | 1 | 5 | 1200 |
| Site 2 | 0 | 1 | 5 | 1200 |
| Site 3 | 1 | 2 | 8 | 1200 |

13.2 Enrollment Simulation Algorithm

Suppose the number of accruals to be simulated in every simulation run is N . Let g : # distinct regions in the study

s : Total # Sites in the study s_i : # Sites in Region $i, i = 1, 2, \dots, g$. The algorithm will involve following steps: For every simulation,

13.2.1 Generation of Site Initiation Times

For a multi-center trial, the arrivals could be from different sites which may be grouped into a number of regions. At the beginning of the trial, some of the sites may be unopened which would get opened later. In order to simulate this scenario, East provides the option of specifying an Enrollment Plan (Chapter 67, Enrollments/Events prediction at Design Stage) which stores the information about Site Start time and Site End time for every site. The input can be either region wise or site wise. A region is comprised of many sites. If the input is region wise, then the variables **Site Initiation Period Start, Site Initiation Period End, Accrual Rate per Site** and **Enrollment Cap** are applicable region wise. For all the sites belonging to a region, the same values of the above mentioned variables apply. The site initiation can be anytime between Site Initiation Period Start and Site Initiation Period End. For the unopened sites, the Site Initiation Times are generated as Uniform random numbers between (Start Time, End Time) Generate a Site Initiation Time from Uniform (SIPStart, SIPEnd) as follows: - Generate a random value from Uniform (0,1), say u - Then, $X = \text{SIPStart} + (\text{SIPEnd} - \text{SIPStart}) * u$ X is the generated Site Initiation time random value from Uniform(SIPStart, SIPEnd) At the end of this step we will have the Site Initiation times (SI Times) for all the sites.

13.2.2 Generation of Enrollments

Sort the Sites data in order of the **Region IDs** and then in order of their **SI times**. The

enrolments will start at each site as per the individual site accrual rate. Suppose ‘a’ is the site accrual rate. (i) Poisson Process: Inter-arrival Times Exponential R : random number between (0,1) $R = F(x) = Exp(-ax) \ x = -\ln(R)/a \ c_{ij} = SITime + x \ c_{ij} =$ arrival time for the next subject at the j -th site in the i -th region. (ii) Uniform Process R : random number between (0,1)

$$R = F(x) = (x - Min)/(Max - Min)$$

$$x = Minimum + (Max-Min)R$$

Minimum = SITime Maximum = SITime+ $\frac{1}{a} \ c_{ij} = SITime + x \ c_{ij} =$ arrival time for the next subject at the j -th site in the i -th region.

13.2.3 Generation of Time on Study

There is no generation of response for normal and binomial end point studies in Predict module. Only for survival studies, the ‘Time to event’ data are generated. The generation of Time on Study follows the procedure described below: **Input: Hazard rates specified. Notation** : c_{ij} : survival time to be generated for i -th subject $(\tau_i, \tau_{i+1}]$: i -th interval in which survival information is specified, k : number of hazard pieces τ_i : starting time of i -th hazard piece with $\tau_0 = 0$. λ_i : hazard rate in i -th hazard piece For the l -th subject, generate its survival time as follows. Compute the survival time for this subject using the formula given below.

$$S_l = \tau_{i-1} - \frac{1}{\lambda_{i-1}} \ln \left(1 - v_l \left(1 - e^{-\lambda_{i-1}(\tau_i - \tau_{i-1})} \right) \right)$$

Where u_i and v_l are random numbers between (0,1) .

13.2.4 Generation of Dropout Times

The drop out time generation is on similar lines as that of time on study.

N Dose Escalation - Theory

N.1 The 3 + 3 Design

The 3 + 3 design method for finding the Maximum Tolerated Dose (MTD) in Phase I clinical trials is described in detail in this section. The 3 + 3 is a rule based design method which starts by allocating the lowest dose level to the first cohort and adaptively escalates/de-escalates to the next dose level based on observed number of dose limiting toxicities (DLTs), until either the MTD is obtained or the trial is stopped for excessive toxicity. It requires no modeling of the dose-toxicity curve beyond the classical assumption for cytotoxic drugs that toxicity increases with dose.

There are three different versions of the 3 + 3: $3 + 3^L$, $3 + 3^L$ (modified), and $3 + 3^H$. The $3 + 3^L$ algorithm proceeds as follows:

1. At each dose level, treat 3 patients beginning with dose level 1. Escalate to the next dose level or de-escalate to the previous dose according to the following rules:
 - (a) If 0 of 3 patients have a dose limiting toxicity (DLT), increase dose to next level.
 - (b) If 2 or more patients has a DLT, decrease dose to previous level¹
 - (c) If 1 of 3 patients has a DLT, treat 3 more patients at current dose level.
 - i. If 1 of 6 has DLT, increase to next dose level.
 - ii. If 2 or more of 6 have DLT, decrease to previous level.
 - (d) If a dose has de-escalated to previous level:
 - i. If only 3 had been treated at the previous level, enroll 3 more patients.
 - ii. If 6 have already been treated at the previous level, stop study and declare it the MTD.
2. The maximum tolerated dose (MTD) is defined as the largest dose for which 1 or fewer DLTs occurred.
3. Escalation never occurs to a dose at which 2 or more DLTs have already occurred.

If we have observed 1 DLT out of 6 patients at the current dose: $3 + 3^H$ and $3 + 3^L$ will recommend escalation, $3 + 3^L$ (modified) will declare the current dose as MTD.

If we have observed 2 DLTs out of 6 patients at the current dose: $3 + 3^H$ will declare the current dose as MTD, $3 + 3^L$ and $3 + 3^L$ (modified) will recommend de-escalation

¹ if de-escalation occurs at the first dose level, then the study is discontinued

N.2 The Continual Reassessment Method

N.2.1 Model

N.2.2 Dose Escalation rules

The Continual Reassessment Method(CRM) for finding the Maximum Tolerated Dose (MTD) in Phase I clinical trials is described in detail in this section. The CRM, introduced originally by O’Quigley et al. (1990), assumes a-priori a monotonically increasing single-parameter dose-toxicity curve (DTC) and a desired toxicity rate p_T . The estimated DTC is updated after each patient’s toxicity outcome is observed, so that each patient’s dose level is based on information about how previous patients tolerated the treatment.

N.2.1 Model

Y_j is the binary toxicity outcome observed in the j th patient recruited to the trial, with $Y_j = 1$ denoting a DLT.

d_1, \dots, d_k are the doses

p_1, \dots, p_k are the true unknown probabilities of toxicities for dose levels d_1, \dots, d_k

θ is the unknown parameter specifying the DTC

$\psi(d_i, \theta)$ is the functional form of the DTC, with $Prob(Y_i = 1) = \psi(d_i, \theta)$. There are three different forms of the DTC considered in East:

1. The Power Model

$$\psi(d_i, \theta) = d_i^\theta, \text{ for } \theta > 0$$

2. The Hyperbolic Tangent Model

$$\psi(d_i, \theta) = \left(\frac{\tanh d_i + 1}{2} \right)^\theta, \text{ for } \theta > 0, \text{ and}$$

3. The single-parameter Logistic Model

$$\psi(d_i, \theta) = \frac{e^{c+\theta d_i}}{1 + e^{c+\theta d_i}} \text{ for } \theta > 0, \text{ and } c \text{ fixed}$$

A Bayesian approach is implemented by placing a prior distribution, $\pi(\theta)$ on the model parameter. The adaptive nature of the CRM arises from choosing the dose for the next patient based on the posterior distribution from the currently recruited patients which is

$$\pi(\theta|y_1, \dots, y_n) \propto L(\theta; y_1, \dots, y_r)\pi(\theta),$$

where $L(\theta; y_1, \dots, y_r) = \prod_{j=1}^r \psi(d_i, \theta)^{y_j} (1 - \psi(d_i, \theta))^{1-y_j}$ and r is the number of subjects for which responses are observed.

Prior distributions

N Dose Escalation - Theory

The choice of a prior distribution for the parameter θ depends on the choice of a DTC. In particular

Power and Hyperbolic Tangent Models: θ is a-priori distributed as a Gamma random variable,

$$\pi(\theta) = \frac{\theta^{\alpha-1} \exp(-\theta\beta)\beta^\alpha}{\Gamma(\alpha)}, \text{ for } \theta > 0, \alpha, \beta > 0$$

Single-parameter Logistic Model: θ is a-priori distributed as a log-normal random variable,

$$\pi(\theta) = \frac{\exp\left(-\frac{(\ln\theta-\mu)^2}{2\sigma^2}\right)}{\theta\sigma\sqrt{2\pi}}, \text{ for } \theta > 0, \mu \in \mathcal{R}, \sigma > 0$$

N.2.2 Dose Escalation rules

The dose to be assigned to the next patient, or cohort of patients is the one that has posterior probability of being closest to the target toxicity probability p_T and simultaneously below an upper limit of the toxicity probability denoted by p_{UL} . In particular, the next cohort of patients is assigned to dose $d_i = \operatorname{argmin}_i(\hat{p}_{ir} - p_T)$ where \hat{p}_{ir} is the posterior probability of toxicity after r subject responses.

By default East uses in its dose escalation rules, the modification in the original CRM proposed by Goodman et al. based on which any given dose escalation cannot increase by more than one level, although dose de-escalations can be large. In addition a dose escalation is not allowed if the previous subject experienced a DLT. Both restrictions can be lifted by selecting the corresponding “Dose Skipping Options” in the “Design Parameters” tab.

N.3 The Modified Toxicity Probability Interval Design

N.3.1 Dosing Intervals

N.3.2 Dose Escalation Rules

N.3.3 Computation of the MTD

This section describes the modified Toxicity Probability Intervals (mTPI) proposed by Yuan Ji et al.(2010). The mTPI is a model-based design and it consists of 3 components:

1. Three dosing intervals,
2. a beta/binomial Bayesian model, and
3. a dose-assignment rule based on Unit Probability Mass (UPM).

Following the notation of Section N.2, we let p_1, \dots, p_k denote the toxicity probabilities for doses d_1, \dots, d_k where k is the total number of candidate doses in the trial. The observed data include n_i , the number of patients treated at dose i , and x_i , the

number of patients experiencing a toxicity. The likelihood function for data $\{(x_i, n_i), i = 1, \dots, k\}$ is a product of binomial densities. The estimates of these toxicity probabilities p_i are sequentially updated and are used to decide if some of the doses studied would be close to the true MTD. This is achieved through Bayes' Theorem. Each p_i is a-priori distributed as a Beta-random variable $Beta(\alpha, \beta)$ and a-posteriori is $Beta(\alpha + x_i, \beta + n_i - x_i)$.

N.3.1 Dosing Intervals

The mTPI design employs a simple beta-binomial hierarchic model. Decision rules are based on calculating the unit probability mass (UPM) of three intervals corresponding to underdosing, proper dosing, and overdosing in terms of toxicity. More specifically, the underdosing interval is defined as $(0, p_T - \epsilon_1)$, the overdosing interval as $(p_T + \epsilon_2, 1)$ and the proper dosing interval as $(p_T - \epsilon_1, p_T + \epsilon_2)$ where ϵ_i are small fractions, such as 0.05, to account for the uncertainty around the true target toxicity. These three dosing intervals are associated with three different dose-escalation decisions. The underdosing interval corresponds to a dose escalation (E), overdosing corresponds to a dose de-escalation (D), and proper dosing corresponds to staying at the current dose (S).

N.3.2 Dose Escalation Rules

Given an interval and a probability distribution, the UPM of that interval is defined as the probability of the interval divided by the length of the interval. The mTPI design calculates the UPMs for the three dosing intervals, and the one with the largest UPM implies the corresponding dose-finding decision. That decision provides the dose level to be used for future patients. In particular, the algorithm proceeds as follows:

1. Compute the posterior probability of excessive toxicity at the current tried dose, i.e., $Prob(p_i > p_T | x_i)$ which is a function of the cumulative Beta distribution $Beta(\alpha + x_i, \beta + n_i - x_i)$. Using a threshold for early stopping for safety, ξ , the current and all higher doses are excluded from the trial due to excessive toxicity if $Prob(p_i > p_T | x_i) > \xi$
2. If $Prob(p_i > p_T | x_i) < \xi$ we compute the UPM for each of the three toxicity probability intervals described in section N.3.1 as follows:

(a)

$$UPM(D)_{d_i} = \frac{Prob(p_i > (p_T + \epsilon_2) | x_i)}{1 - (p_T + \epsilon_2)}$$

(b)

$$UPM(S)_{d_i} = \frac{Prob((p_T - \epsilon_1) \leq p_i \leq (p_T + \epsilon_2) | x_i)}{\epsilon_2 - \epsilon_1}$$

N Dose Escalation - Theory

(c)

$$UPM(E)_{d_i} = \frac{Prob(p_i < (p_T - \epsilon_1)|x_i)}{p_T - \epsilon_1}$$

3. Select one of the following actions: E, S or D corresponding to the highest UPM of each toxicity interval provided that the resulting dose level was not excluded in Step 1.
4. If the selected action is 'E' and the current tried dose is the highest dose, then stop the trial. Similarly,
5. if the selected action is 'D' and the current tried dose is the lowest dose, then stop the trial.

N.3.3 Computation of the MTD

Once all the N toxicity responses are observed, we compute the MTD by using all the observed data. To compute the MTD, follow the steps as given below:

1. Using the accumulated information about x_i and n_i for $i = 1, \dots, k$ compute the posterior mean and variance for all the dose levels.
2. Compute isotonic regression estimates of the posterior mean by using the PAVA method with the inverse of the posterior variances of p_i as the weights to obtain isotonically transformed posterior means denoted by say, p_i^* .
3. Among all the tried doses i for which $Prob(p_i > p_T|x_i) < \xi$, select the estimated MTD as the dose with the smallest difference $p_T - p_i^*$.
4. In case of a tie (i.e. two or more doses have the smallest difference),
 - (a) If all the tied doses have the probability of toxicity above the target, select the lower dose as the MTD.
 - (b) Else select the higher dose level as MTD.

N.4 The Bayesian Logistic Regression Model

N.4.1 Prior distribution specification

N.4.2 Dosing Intervals and Selection

N.4.3 Posterior Calculations

This section describes the Bayesian Logistic Regression model as proposed by Neuenschwander et. al. (2009). We follow the notation of Section N.2 and consider a bivariate DTC of the form

$$\psi(d_i, \alpha, \beta) = \frac{e^{\ln \alpha + \beta d_i^*}}{1 + e^{\ln \alpha + \beta d_i^*}} \text{ for } \alpha, \beta > 0, \text{ and } d_i^* = \ln(d_i/d_R), \quad (\text{N.1})$$

where d_R is a reference dose, determined in a way so that $\ln \alpha$ becomes the log-odds of toxicity when $d_i = d_R$.

N.4.1 Prior distribution specification

The vector $\theta = (\ln \alpha, \ln \beta)'$ follows a-priori a bivariate normal distribution with mean vector μ_θ and variance-covariance matrix Σ . Determining the prior distribution parameters can be done in two ways; directly or indirectly.

Direct Prior Elicitation

Using the direct prior elicitation approach involves incorporating information about α and β directly. The parametrization of Equation (N.1) allows for the interpretation of the parameters as follows:

1. $\ln \alpha$ is the log-odds of a toxicity when $d_i = d_R$. As such, the normal distribution of $\ln \alpha$ would represent prior information for this dose. As stated in Neuenschwander et al (2008), if one sets the reference dose d_R to the a-priori anticipated MTD, the mean of $\ln \alpha$ would follow from the target probability p_T and an additional quantile would be needed to obtain the prior standard deviation.
2. For two doses d_i and d_j , the parameter β is the log-odds ratio of a DTL, i.e.,

$$\beta = \frac{\text{logit}(\psi(d_j)) - \text{logit}(\psi(d_i))}{\ln(d_j/d_i)}.$$

As an example, the parameters of the normal distribution of $\ln \beta$ can be obtained by specifying two quantiles for the change in the odds of a DLT if the dose is doubled.

Indirect Prior Elicitation

The indirect prior elicitation approach results in an uninformative prior specification for $\theta = (\ln \alpha, \ln \beta)'$. The following steps are used for this prior distribution specification:

1. Using preclinical data, one can calculate the starting dose and predicted MTD for the study. Median DLT rates are assigned for this two doses, e.g., 0.05 and 0.33 respectively.
2. The remaining doses are assumed to be linear in log-odds in one the $\ln(d/d_R)$ scale and lead to estimated median DLT rates for doses of interest.
3. At each dose level, a minimally informative Beta prior for the probability of a DLT is set and the 2.5% and 97.5% quantiles for each distribution are calculated.
4. The parameters of the bivariate normal distribution of θ are tuned so that the difference between the 2.5% and 97.5% quantiles of this distribution and the targeted values from the Beta distributions is minimized.

N Dose Escalation - Theory

N.4.2 Dosing Intervals and Selection

The probability of a DLT is classified into four categories: underdosing ($c_0 = 0, c_1$], targeted toxicity, (c_1, c_2], excessive toxicity (c_2, c_3] and unacceptable toxicity ($c_3, c_4 = 1$].

Dose selection proceeds with one of the two following methods:

Bayes Risk Minimization

A formal loss function is introduced, quantifying the penalty of ending up in each of the four aforementioned intervals:

$$L((\alpha, \beta), d^*) = \begin{cases} l_1 & \text{if } \text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_0, c_1]) \\ l_2 & \text{if } \text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_1, c_2]) \\ l_3 & \text{if } \text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_2, c_3]) \\ l_4 & \text{if } \text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_3, c_4]) \end{cases}$$

leading to an estimated Bayes risk of $\sum_{i=1}^4 l_i \{ \text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_{i-1}, c_i]) \}$. The dose minimizing the Bayes risk is selected as the next dose.

Escalation With Overdose Control (EWOC) Babb et al.(1998) proposed to select the dose for each patient as the one that maximizes the probability of targeted toxicity, i.e., $\text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_1, c_2])$ subject to the constraint that the probability of overdosing (i.e., excessive and unacceptable toxicity) does not exceed a predefined threshold α_T , say 0.25, called “the feasibility bound”. That is, choose the dose level subject to the constraint $\text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_2, c_4]) \leq \alpha_T$.

N.4.3 Posterior Calculations

The dose selection process described in Section N.4.2 depends in the calculation of the posterior probability

$$\text{Prob}((\alpha, \beta | \text{data}, d^*) \in (c_{i-1}, c_i]), \tag{N.2}$$

for $i = 1, 2, 3, 4$ which is calculated with respect to

$$\pi(\theta | \mathbf{y}, d_i^*) \propto \frac{e^{\sum_{j=1}^r (\ln \alpha + \beta d_i^*) y_j}}{\prod_{j=1}^r \{1 + e^{(\ln \alpha + \beta d_i^*)}\}} \times \pi(\theta) \tag{N.3}$$

As this bivariate posterior distribution is not a standard known distribution we calculate (N.2) by employing two different sampling-based methods.

Metropolis-Hastings The Metropolis-Hastings algorithm for obtaining samples from (N.3) proceeds as follows:

1. Given a starting value of $\theta = \theta^{(0)}$, generate a candidate value $\theta^* = \theta^{(0)} + \sigma\epsilon$, where $\epsilon \sim N_2(\mathbf{0}, \mathbf{I}_2)$.

2. Calculate

$$\rho = \min \left\{ \frac{\pi(\theta^* | \mathbf{y}, d_i^*)}{\pi(\theta^{(0)} | \mathbf{y}, d_i^*)}, 1 \right\}$$

3. Draw randomly $v \sim Unif(0, 1)$
4. If $v \leq \rho$ then set $\theta^{(1)} = \theta^*$, otherwise retain $\theta^{(1)} = \theta^{(0)}$
5. Repeat steps 1-4 until convergence

Direct sampling The second sampling method from the posterior distribution in (N.3) is a block sampling method. It involves discretizing $\ln \alpha$ and $\ln \beta$ values along with their probability of occurrence. The likelihood of each support point $(\ln \alpha, \ln \beta)$ is computed in this discrete prior. A block of values for $(\ln \alpha, \ln \beta)$ is sampled by first sampling a value $\ln \alpha$ from its discrete marginal distribution and then a value of $\ln \beta$ from the discrete conditional distribution of $\ln \beta | \ln \alpha$ using the inverse cumulative distribution method.

N.5 Bayesian Logistic Regression Model for Combination of Two Agents

This section describes the BLRM design for a combination of two active agents.

Prior Distribution

The vector $\theta = \begin{pmatrix} \log \alpha \\ \log \beta \end{pmatrix}$ of model parameters for each active agent a priori follows a bivariate normal distribution as follows:

$$\theta = \begin{pmatrix} \log \alpha \\ \log \beta \end{pmatrix} \sim BVN \left[\begin{pmatrix} \mu_\alpha \\ \mu_\beta \end{pmatrix}, \begin{bmatrix} \sigma_\alpha^2 & \sigma_{\alpha\beta} \\ \sigma_{\alpha\beta} & \sigma_\beta^2 \end{bmatrix} \right]$$

$$\sigma_{\alpha\beta} = \rho\sigma_\alpha\sigma_\beta$$

Where μ_α refers to prior mean of $\log \alpha$, μ_β refers to prior mean of $\log \beta$, σ_α refers to prior SD for $\log \alpha$, σ_β refers to prior SD for $\log \beta$ and ρ refers to correlation between $\log \alpha$ and $\log \beta$. The interaction parameter (η) a priori follows a normal distribution as follows:

$$\eta \sim N(\mu_\eta, \sigma_\eta^2)$$

N Dose Escalation - Theory

where μ_η denotes the prior mean of η and σ_η denotes the prior SD of η .

Model Definition

The proposed model has the following properties:

- (a) It has three components which stands for
 - Single-agent 1 toxicity, represented by parameters α_1, β_1
 - Single-agent 2 toxicity, represented by parameters α_2, β_2
 - Interaction, represented by parameter η .
- (b) If one of the doses is 0, $d_2 = 0$, say, the model should simplify to the single-agent model with parameters α_1, β_1 .

Single-agent probabilities of DLT:

Probability of DLT, given Agent1: π_{d_1}

Probability of DLT, given Agent2: π_{d_2} .

π_{d_1} and π_{d_2} are vectors of Probability of DLT at each dose of Agent 1 and Agent 2 respectively. In the special case of no interaction the single-agent parameters fully determine the risk of a DLT. For dose combination (d_1, d_2) a patient's probability to have no DLT is $(1 - \pi_{d_1})(1 - \pi_{d_2})$. Hence, Probability of DLT under no interaction is

$$\pi_{d_1, d_2}^0 = 1 - (1 - \pi_{d_1})(1 - \pi_{d_2}) = \pi_{d_1} + \pi_{d_2} - \pi_{d_1} \pi_{d_2}$$

On the odds scale this is equivalent to

$$odds_{d_1, d_2}^0 = odds_{d_1} + odds_{d_2} + odds_{d_1} odds_{d_2}$$

Interaction parameter (η) has the interpretation of an odds-multiplier, as follows:

$$odds_{d_1, d_2} = odds_{d_1, d_2}^0 \times g(\eta, d_1, d_2)$$

The odds-multiplier g should fulfill the constraints $g(\eta, 0, d_2) = g(\eta, d_1, 0) = 1$, since if one of the doses is 0, it should result in the single-agent odds. Hence, $g(\eta, d_1, d_2)$ is defined as $g(\eta, d_1, d_2) = \exp(\eta, d_1, d_2)$.

We will use same interaction for all dose combination and hence we can simply use $\exp(\eta)$. Typically $\eta > 0$, but not necessarily

$\eta = 0$: No interaction, the drug combination produces a toxic effect whose magnitude is **equal** to that obtained if the drugs act independently in the body.

$\eta < 0$: Protective, the drug combination produces a toxic effect whose magnitude is **less** than that obtained if the drugs act independently in the body.

$\eta > 0$: Synergistic, the drug combination produces a toxic effect whose magnitude is **greater** than that obtained if the drugs act independently in the body.

Likelihood

$$L(\theta_1, \theta_2, \eta | d_1, d_2, y) = \prod_{p=1}^S \left[(\pi_{d_{1p}, d_{2p}})^{y_p} \times (1 - \pi_{d_{1p}, d_{2p}})^{1-y_p} \right]$$

S = Observed sample size

d_{1p} = Dose of Agent1 assigned to patient p

d_{2p} = Dose of Agent2 assigned to patient p

$\pi_{d_{1p}, d_{2p}}$ = Probability of DLT with interaction (η) for patient p

y_p = Binary response (0 or 1) of patient p .

Prior Distribution for Two Parameter Logistic Model

$$\text{Prior distribution } \pi(\theta_i) \propto \frac{1}{\sigma_{\alpha_i} \sigma_{\beta_i} \sqrt{1 - \rho_i^2}} e^{\frac{-z_i}{2(1 - \rho_i^2)}}$$

$$Z = \frac{(\log \alpha_i - \mu_{\alpha_i})^2}{\sigma_{\alpha_i}^2} + \frac{(\log \beta_i - \mu_{\beta_i})^2}{\sigma_{\beta_i}^2} - \frac{2\rho_i(\log \alpha_i - \mu_{\alpha_i})(\log \beta_i - \mu_{\beta_i})}{\sigma_{\alpha_i} \sigma_{\beta_i}}$$

$i = 1$ for Agent 1 and $i = 2$ for Agent 2.

Prior distribution for interaction parameter η .

$$\text{Prior distribution } \pi(\eta) \propto \frac{1}{\sigma_{\eta}} e^{-Z} \text{ where } Z = \frac{(\eta - \mu_{\eta})^2}{2\sigma_{\eta}^2}.$$

Posterior Distribution

$$\pi(\theta_1, \theta_2, \eta | y) \propto L(\theta_1, \theta_2, \eta | d_1, d_2, y) \times \pi(\theta_1) \times \pi(\theta_2) \times \pi(\eta).$$

N Dose Escalation - Theory

Posterior Sampling Method : Metropolis Hastings

Step 1 : Initialize $\theta_1 = (\log \alpha_1^0, \log \beta_1^0), \theta_2 = (\log \alpha_2^0, \log \eta_2^0), \eta = \eta^0$ and $Sim = 1$.

Step 2 : Generate a new candidate for Agent1, $\theta_1^* = \theta_1 + RW\sigma_1 * \epsilon_1$ where $\epsilon_1 \sim BVN(0, 1)$.

Step 3 : Calculate ratio $R_1 = \min \left(\frac{\pi(\theta_1^*, \theta_2, \eta | y)}{\pi(\theta_1, \theta_2, \eta | y)}, 1 \right)$.

Step 4 : Draw a random number $v_1 \sim U(0, 1)$ and if $v_1 < R_1$ then accept the new candidate θ_1^* and set $\theta_1 = \theta_1^*$.

Step 5 : Generate a new candidate for Agent2, $\theta_2^* = \theta_2 + RW\sigma_2 * \epsilon_2$ where $\epsilon_2 \sim BVN(0, 1)$.

Step 6 : Calculate ratio $R_2 = \min \left(\frac{\pi(\theta_1, \theta_2^*, \eta | y)}{\pi(\theta_1, \theta_2, \eta | y)}, 1 \right)$.

Step 7 : Draw a random number $v_2 \sim U(0, 1)$ and if $v_2 < R_2$ then accept the new candidate θ_2^* and set $\theta_2 = \theta_2^*$.

Step 8 : Generate a new candidate for interaction, $\eta^* = \eta + RW\sigma_\eta * \epsilon_3$ where $\epsilon_3 \leftarrow BVN(0, 1)$.

Step 9 : Calculate ratio $R_3 = \min \left(\frac{\pi(\theta_1, \theta_2, \eta^* | y)}{\pi(\theta_1, \theta_2, \eta | y)}, 1 \right)$.

Step 10 : Draw a random number $v_3 \leftarrow U(0, 1)$ and if $v_3 < R_3$ then accept the new candidate η^* and set $\eta = \eta^*$.

Step 11 : Store the value in parameter θ_1, θ_2 and η for simulation Sim .

Step 12 : Go to next simulation, $Sim = Sim + 1$. If $Sim > Sim_{MH} + Burnin_{MH}$ then Stop else Go to Step 2.

Dose Finding Method

1. Compute posterior samples using the Metropolis Hastings method.
2. Compute posterior probability of DLT for every dose pair using steady state samples and Model definition for Combination of Two Agents.
3. Compute probability of being in each toxicity interval for every dose pair as follows,
 - (a) Count number of steady state simulations for which posterior probability of DLT lies within each interval
 - (b) Divide the count for each interval by number of steady state simulations.
4. Exclude the dose pairs which doesn't satisfy the following EWOC principle, Probability of being in overdosing interval $< EWOC$ threshold.
5. If all dose pairs are excluded then stop the trial due to overdosing else go to next step
6. If user has selected any stopping rule(s) to determine MTD early in the trial then check the rules as follows,
 - (a) Consider only the dose pairs which are not excluded due to overdosing
 - (b) Select the dose pair which has maximum probability in the target interval and minimum probability in the overdosing interval. In case the ties still exist, then select the largest of dose pairs based on the dose indices. (See the Note below for this change)
 - (c) Min SS Rule: Check whether the total number of subjects observed in the trial is \geq user specified threshold
 - (d) Allocation Rule: Check whether the total number of subjects observed on the selected dose pair is \geq user specified threshold
 - (e) Target Rule: Check whether the probability of being in targeted toxicity interval for the selected dose pair is \geq user specified threshold.
7. Stop the trial if MTD is determined in the Step6 else go to next step
8. Compute the next dose pair to be assigned to the next group of subjects as follows,
 - (a) Consider only the dose pairs which are not excluded due to overdosing
 - (b) Filter the dose pairs which satisfies the selected Dose Skipping Option and the requirement of whether to increase dose of both agents at the same time
 - (c) Select the highest dose pair which has maximum probability of being in targeted toxicity interval as the next dose.
9. Compute MTD for the final analysis as follows,
 - (a) Consider only the tried dose pairs which are not excluded due to overdosing

N Dose Escalation - Theory

- (b) Select the highest dose pair which has maximum probability of being in targeted toxicity interval as MTD.

N.6 The Product of Independent Beta Probabilities Escalation Design

The Product of Independent Beta Probabilities Escalation design is a Bayesian dose finding method for a combination therapy with two active agents. This method allows for the specification of prior risk of toxicity for all dose combinations and uses posterior probabilities from all proposed dose combinations for dose escalation. The aim is to design a dual agent dose escalation trial targeting a MTD contour such that the risk of toxicity for all dose combinations on this contour is the pre-specified target toxicity level p_T .

Prior and Posterior Distributions

Let $d_i A$ denote the i -th dose level of drug A and $d_j B$ denote the j -th dose level of drug B where doses increase with i and j and $i = 1, \dots, I$ and $j = 1, \dots, J$. We assume that the probabilities of toxicity at every dose combination follow an independent Beta distribution i.e. $\pi_{ij} | a_{ij}, b_{ij} \rightarrow \text{Beta}(a_{ij}, b_{ij}) \forall i, j$. Prior distribution can be specified in two formats:

1. Prior median of P(DLT) π_{ij} and prior sample size SS_{ij} for each dose combination d_{ij} .
2. Prior parameters a_{ij} and b_{ij} of the Beta distribution for each dose combination d_{ij} .

If the prior is specified in format (a), it is internally converted into the format (b) by the software. Suppose $Y^{(m)} = \{r_{ij}^{(m)}, n_{ij}^{(m)}, i = 1, \dots, I, j = 1, \dots, J\}$: Data up to the end of m^{th} cohort. Such that we have observed $r_{ij}^{(m)}$ DLTs from $n_{ij}^{(m)}$ patients for the dose combination d_{ij} . Then because of conjugacy and prior independence of the π_{ij} , the posterior distribution of π_{ij} is also a Beta distribution given by

$$(\pi_{ij} | Y^{(m)} a_{ij}, b_{ij}) \leftarrow \text{Beta}(a_{ij} + r_{ij}^{(m)}, b_{ij} + n_{ij}^{(m)} - r_{ij}^{(m)}) \forall i, j.$$

We assume that the toxicity risk increases with increasing dose, i.e.

$$\begin{aligned} \pi_{ij} &< \pi_{(i+1)j}, I = 1, \dots, I-1, \forall j \text{ and} \\ \pi_{ij} &< \pi_{i(j+1)}, j = 1, \dots, J-1, \forall i, j = 1, \dots, J-1. \end{aligned}$$

Maximum Tolerated Contour

The Maximum Tolerated Contour is formed by the dose combinations that have a posterior mean of DLT rate equal to the targeted toxicity risk. The PIPE design method targets the MTC corresponding to the pre-specified target probability of toxicity (p_T) to recommend the dose level for the next cohorts. Let us denote this MTC as MTC_θ . It is estimated by the line partitioning the dose combination space into toxicity risks above θ or less than θ . MTC_θ must be such that it does not contradict the assumption of monotonicity.

Dose Escalation Rules

For dose escalation, the PIPE method begins by identifying the set of admissible dose combination based on one of the following three criteria: adjacent to MTC_θ , closest to MTC_θ , and those lying in the interval of fixed pre-specified length around the targeted toxicity probability p_T . “Adjacent” doses are the dose levels that lie adjacent to the current estimated MTC_θ . The “closest” doses are defined as those adjacent doses below/above the contour that cannot move up (for below) or down (for above) by one dose level without crossing the contour. Hence “closest” doses must be a subset of adjacent doses. The “Interval” criteria picks up the dose levels having probability of DLT within the interval $(p_T - \epsilon, p_T + \epsilon)$ where ϵ is the pre-specified margin.

Dose Skipping Rules

Dose skipping during escalation can be achieved by using one of the following criteria: Neighborhood constraint, non- neighborhood constraint. Under the neighborhood constraint, the admissible doses for the next cohort further reduces to a set of doses that are a maximum of one dose level higher or lower than the current experimented dose, both for agents A and B. Hence any dose combination can be chosen up to one dose level above or below current drug A and drug B levels including the current dose combination. Under the non-neighborhood constraint, all the previous doses administered are considered, and to allow dose skipping, the constraint allows any dose that is a single-dose level higher in both agents A and B than any previously administered dose combination. The option related to diagonal dose escalation allows escalating levels of both agents at the same time.

Dose Selection

The dose combination for the next cohort is selected from the admissible dose set. This can be done in two possible ways. One is to select the next dose to be the admissible dose with the smallest current sample size. Here sample size is defined as the sum of the prior sample size and the sample size observed in the trial.

N Dose Escalation - Theory

That is, we select a dose d_{ij} where $(i, j) = \arg \min_{\xi \in \Omega^{(m)}} S_{\xi}^{(m)}$ where

$S_{ij}^{(m)} = n_{ij}^{(m)} + a_{ij} + b_{ij}$. The other possible dose selection method is based on a weighted randomization, where the selection of the admissible doses is weighted by the inverse of their sample size.

$P(\text{cohort } m \text{ is allocated } d_{ij} | (i, j) \in \Omega^{(m)}) = \frac{S_{ij}^{-1(m)}}{\sum_{\xi \in \Omega^{(m)}} S_{\xi}^{-1(m)}}$ and the dose combination with the highest probability is chosen.

At the end of the trial, the MTD is selected as the dose closest to the estimated MTC_{θ} from below.

O *R Functions*

O.1 Introduction

For [East6](#), in simulation module we will provide the user the opportunity to perform various tasks using R. In this chapter, we list all tasks for which R functions can be used. We will provide syntax and suggested format for various functions. We have divided functions in various categories.

1. Function for initialization
2. Functions for data generation
3. Functions for test statistic and perform test computations
4. Functions for performing basic simulations
5. Functions for re-estimating sample size in adaptive simulations
6. Function for selecting treatment in multi-arm combining p-values design

O.2 Initialization Function

This function will be optional. If provided, this function will be executed before executing any of the other user defined functions. User can use this function for various reasons. Below we list some of these.

1. Setting seed for R environment
2. Setting working directory for R
3. Initializing global variables.

For more details of uses of this function please see section [O.12](#).

The following table provides details about Initialization function.

O R Functions

Table O.1: Initialization Function

| Suggested Name of the function | <i>Init()</i> | | | | |
|---------------------------------------|--|----------|-------------|------|--|
| Description | Performs Initialization for all simulations | | | | |
| Syntax | <i>Init(Seed)</i> | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>Seed</td> <td>Seed to be set at the beginning of all simulations</td> </tr> </tbody> </table> | Argument | Description | Seed | Seed to be set at the beginning of all simulations |
| Argument | Description | | | | |
| Seed | Seed to be set at the beginning of all simulations | | | | |
| Return Value Type | Integer (Optional). This function may return Error Code (optional) | | | | |
| Suggested format | <pre>Init ← function(Seed) { Error = 0 set.seed(Seed) # User may use other options in set.seed like setting the random # number generator. User may also initialize global variables or # set up the working directory etc. # Do the error handling. Modify Error appropriately return (as.integer(Error)) }</pre> | | | | |

0.3 Data Generation Functions

0.3.1 Generating Arrival Times

0.3.2 Generating Censor indicator

0.3.3 Generating Dropout Times

0.3.4 Randomizing Subjects to Treatments

0.3.5 Randomizing Subjects to Groups

0.3.6 Randomizing Subjects to Populations

Following points are applicable to all functions used for Data Generation described in this document.

1. This document provides suggested name for each function.
2. Argument names and Argument Type for each function are compulsory but the order of the arguments is not. Input argument names are case sensitive.
3. User can have additional input arguments in the function but he must make sure that appropriate values will be available for those additional arguments during function call. For details please see section [0.13](#).
4. Function will return a list. The Identifier Names (Case Insensitive) and Type (we strongly advice that user should type cast the output elements) mentioned for outputs in a list for a particular function are compulsory while their order in the list is not. User can have additional outputs in the list. If user wants to print the arrays (Same size as number of subjects) in the Simulation CSV file then he has to provide identifier for those arrays. These identifiers will be the columns names in output. Any repeated identifiers (column names) will be ignored.
5. We suggest that the return List contain an identifier "ErrorCode". If specified, it has to be of Type Integer. Its values are classified as follows.

0: No Error

Positive integer: Non Fatal Error - Particular Simulation will be aborted but Next Simulation will be performed.

Negative Integer: Fatal Error - No further simulation will be attempted.

We suggest that user should classify error in these categories depending on the context.

O R Functions

0.3.1 Generating Arrival Times

Table O.2: Function for Generating Arrival Times

| Suggested Name of the function | <i>GenArrTimes()</i> | | | | | | | | | | | | |
|---------------------------------------|--|---------|--|---------------------|-------------|--------|--------------------|-------------------------------------|---------------------------|----------|---|----------|--|
| Description | Generates arrival times for a specified number of subjects. Start time and accrual rate (one per period) for each period is provided. | | | | | | | | | | | | |
| Syntax | <i>GenArrTimes(NumSub, NumPrd, PrdStart, AccrRate)</i> | | | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Compulsory Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>NumPrd</td> <td>Number of Accrual Periods</td> </tr> <tr> <td>PrdStart</td> <td>Array of start times of specified periods</td> </tr> <tr> <td>AccrRate</td> <td>Array of accrual rates (one rate per period)</td> </tr> </tbody> </table> | | | Compulsory Argument | Description | NumSub | Number of Subjects | NumPrd | Number of Accrual Periods | PrdStart | Array of start times of specified periods | AccrRate | Array of accrual rates (one rate per period) |
| Compulsory Argument | Description | | | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | | | |
| NumPrd | Number of Accrual Periods | | | | | | | | | | | | |
| PrdStart | Array of start times of specified periods | | | | | | | | | | | | |
| AccrRate | Array of accrual rates (one rate per period) | | | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>ArrivalTime</td> <td>An array of generated arrival times</td> <td>Double.</td> </tr> </tbody> </table> | | | Identifier | Description | Type | ArrivalTime | An array of generated arrival times | Double. | | | | |
| Identifier | Description | Type | | | | | | | | | | | |
| ArrivalTime | An array of generated arrival times | Double. | | | | | | | | | | | |
| Suggested format | <pre>GenArrTimes ← function(NumSub, NumPrd, PrdStart, AccrRate) { Error = 0 # Write the actual code here. # Store the generated accrual times in an array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(ArrivalTime = as.double(retval), ErrorCode = as.integer(Error))) }</pre> | | | | | | | | | | | | |

0.3.2 Generating Censor indicator

Table O.3: Generating Censor Indicator (Normal and Binary)

| Suggested Name of the function | <i>GenCensorInd()</i> | | | | | | | | |
|---------------------------------------|---|---------|--|---------------------|-------------|--------|--------------------|--|-------------------------|
| Description | Generates Censor Indicator (Subject has dropped out (0) or not (1)) for a specified number of subjects. | | | | | | | | |
| Syntax | <i>GenCensorInd (NumSub, ProbDrop)</i> | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Compulsory Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>ProbDrop</td> <td>Probability of Drop out</td> </tr> </tbody> </table> | | | Compulsory Argument | Description | NumSub | Number of Subjects | ProbDrop | Probability of Drop out |
| Compulsory Argument | Description | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | |
| ProbDrop | Probability of Drop out | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>CensorInd</td> <td>An array of censor indicator values 0 (Drop out) and 1(No Drop out)</td> <td>Integer</td> </tr> </tbody> </table> | | | Identifier | Description | Type | CensorInd | An array of censor indicator values 0 (Drop out) and 1(No Drop out) | Integer |
| Identifier | Description | Type | | | | | | | |
| CensorInd | An array of censor indicator values 0 (Drop out) and 1(No Drop out) | Integer | | | | | | | |
| Suggested format | <pre> GenCensorInd ← function(function(NumSub, ProbDrop) { Error = 0 # Write the actual code here. # Store the generated censor indicator values in an # array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(CensorInd = as.integer(retval), ErrorCode = as.integer(Error))) } </pre> | | | | | | | | |

O R Functions

0.3.3 Generating Dropout Times

Table O.4: Generating Dropout Times (Survival)

| Suggested Name of the function | <i>GenDropTimes()</i> | | | | | | | | | | | | | |
|--|---|--|----------|-------------|--------|--------------------|--------|---|-------------|--|------------|--|--------|---------------------------|
| Description | Generates dropout times for a specified number of subjects for survival end point. | | | | | | | | | | | | | |
| Syntax for one arm test | <i>GenDropTimes (NumSub, DropMethod, NumPrd, PrdTime, DropParam)</i> | | | | | | | | | | | | | |
| Syntax for more than one arm test | <i>GenDropTimes (NumSub, NumArm, TreatmentID, DropMethod, NumPrd, PrdTime, DropParam)</i> | | | | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>NumArm</td> <td>Number of Arms in the trial (including placebo/control)</td> </tr> <tr> <td>TreatmentID</td> <td>Array specifying indexes of arms to which subjects are allocated (one arm index per subject) Index for placebo / control is 0. For other arms, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 arms (1 placebo + 3 treatment arms), arm indexes will be 0, 1, 2 and 3.</td> </tr> <tr> <td>DropMethod</td> <td>Input method for specifying dropout parameters. 1 - Hazard rates 2 - Probability of Dropouts</td> </tr> <tr> <td>NumPrd</td> <td>Number of dropout periods</td> </tr> </tbody> </table> | | Argument | Description | NumSub | Number of Subjects | NumArm | Number of Arms in the trial (including placebo/control) | TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject) Index for placebo / control is 0. For other arms, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 arms (1 placebo + 3 treatment arms), arm indexes will be 0, 1, 2 and 3. | DropMethod | Input method for specifying dropout parameters. 1 - Hazard rates 2 - Probability of Dropouts | NumPrd | Number of dropout periods |
| Argument | Description | | | | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | | | | |
| NumArm | Number of Arms in the trial (including placebo/control) | | | | | | | | | | | | | |
| TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject) Index for placebo / control is 0. For other arms, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 arms (1 placebo + 3 treatment arms), arm indexes will be 0, 1, 2 and 3. | | | | | | | | | | | | | |
| DropMethod | Input method for specifying dropout parameters. 1 - Hazard rates 2 - Probability of Dropouts | | | | | | | | | | | | | |
| NumPrd | Number of dropout periods | | | | | | | | | | | | | |

Table O.5: Generating Dropout Times (Survival) (Continued)

| Arguments | Argument | Description | | | | | | | |
|--------------------------|---|--|--|------------|-------------|------|-------------|-------------------------------------|--------|
| | PrdTime | <p>Array of times used to specify dropout parameters.</p> <p>If DropMethod is 1, then this array specifies the starting times of dropout periods.</p> <p>If DropMethod is 2, then this array specifies the times at which the probabilities of dropout are specified.</p> | | | | | | | |
| | DropParam | <p>2-D array of parameters uses to generate dropout times.</p> <p>Number of rows = Number of Dropout Periods</p> <p>Number of Columns = Number of Arms including Control/Placebo</p> <p>If DropMethod is 1, the DropParam array specifies arm by arm hazard rates (one rate per arm per piece). Thus DropParam [i, j] specifies hazard rate in ith piece for jth arm.</p> <p>If DropMethod is 2, the DropParams array specifies arm by arm probabilities of dropout (one value of probability of dropout per arm per piece). Thus DropParams [i, j] specifies probability of dropout in ith piece for jth arm.</p> | | | | | | | |
| Return Value Type | <p>R List</p> <p>The must identifiers in this list are</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="width: 25%;">Identifier</th> <th style="width: 50%;">Description</th> <th style="width: 25%;">Type</th> </tr> </thead> <tbody> <tr> <td>DropOutTime</td> <td>An array of generated dropout times</td> <td>Double</td> </tr> </tbody> </table> | | | Identifier | Description | Type | DropOutTime | An array of generated dropout times | Double |
| Identifier | Description | Type | | | | | | | |
| DropOutTime | An array of generated dropout times | Double | | | | | | | |

Table O.6: Generating Dropout Times (Survival) (Continued)

| | |
|-------------------------|--|
| Suggested format | <pre>GenDropTimes ← function(NumSub, NumArm, TreatmentID, DropMethod, NumPrd, PrdTime, DropParam) { Error = 0 If(DropMethod == 1) { # Write the actual code for method 1 here. # Store the generated dropouts times in an array called retval. } If(DropMethod == 2) { # Write the actual code for method 2 here. # Store the generated dropout times in an array called retval. } # Use appropriate error handling and modify the # Error in each of the methods appropriately. return(list(DropOutTime = as.double(retval), ErrorCode = as.integer(Error)) } Please note that ErrorCode is optional for this function.</pre> |
|-------------------------|--|

0.3.4 Randomizing Subjects to Treatments

Table O.7: Treatment Randomization

| Suggested Name of the function | <i>GenTreatID()</i> | | | | | | | | | | |
|---------------------------------------|--|---------|--|------------|-------------|--------|---------------------------------|--|-----------------------------------|------------|--|
| Description | Randomizes subjects to specified arms. The function should produce 0-based indexes of arms to which the subjects are allocated. The treatment arms have consecutive positive arm indices starting with 1. | | | | | | | | | | |
| Syntax | <i>randomize(NumSub, NumArm, AllocRatio)</i> | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects to randomize</td> </tr> <tr> <td>NumArm</td> <td>Total Number of arms in the trial</td> </tr> <tr> <td>AllocRatio</td> <td>Array of size (NumArm-1) specifying expected allocation ratios for the treatment arms (Allocation ratios are relative to placebo.)</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects to randomize | NumArm | Total Number of arms in the trial | AllocRatio | Array of size (NumArm-1) specifying expected allocation ratios for the treatment arms (Allocation ratios are relative to placebo.) |
| Argument | Description | | | | | | | | | | |
| NumSub | Number of Subjects to randomize | | | | | | | | | | |
| NumArm | Total Number of arms in the trial | | | | | | | | | | |
| AllocRatio | Array of size (NumArm-1) specifying expected allocation ratios for the treatment arms (Allocation ratios are relative to placebo.) | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>TreatmentID</td> <td>An array of generated allocation indices for all subjects. Placebo = 0</td> <td>Integer</td> </tr> </tbody> </table> | | | Identifier | Description | Type | TreatmentID | An array of generated allocation indices for all subjects. Placebo = 0 | Integer | | |
| Identifier | Description | Type | | | | | | | | | |
| TreatmentID | An array of generated allocation indices for all subjects. Placebo = 0 | Integer | | | | | | | | | |
| Suggested format | <pre> GenTreatID ← function(NumSub, NumArm, AllocRatio) { Error = 0 # Write the actual code here. Store the generated treatment indices # in an array called retval. Use error handling and modify the error appropriately. return(list(TreatmentID = as.integer(retval), ErrorCode = as.integer(Error))) } </pre> | | | | | | | | | | |

O R Functions

0.3.5 Randomizing Subjects to Groups

Table O.8: Group Randomization

| Suggested Name of the function | <i>GenGroupID()</i> | | | | | | | | | | |
|---------------------------------------|---|---------|--|------------|-------------|--------|---------------------------------|--|--------------------------------|------------|--|
| Description | Randomizes subjects to specified groups. The function should produce 0-based indexes of groups to which the subjects are allocated. The groups have consecutive positive group indices starting with 1. The first group will have index 0. | | | | | | | | | | |
| Syntax | <i>GenGroupID (NumSub, NumGrp, AllocRatio)</i> | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects to randomize</td> </tr> <tr> <td>NumGrp</td> <td>Number of Groups in the trial.</td> </tr> <tr> <td>AllocRatio</td> <td>Array of size (NumGrp-1) specifying expected allocation ratios for the Groups (Allocation ratios are relative to first Group.)</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects to randomize | NumGrp | Number of Groups in the trial. | AllocRatio | Array of size (NumGrp-1) specifying expected allocation ratios for the Groups (Allocation ratios are relative to first Group.) |
| Argument | Description | | | | | | | | | | |
| NumSub | Number of Subjects to randomize | | | | | | | | | | |
| NumGrp | Number of Groups in the trial. | | | | | | | | | | |
| AllocRatio | Array of size (NumGrp-1) specifying expected allocation ratios for the Groups (Allocation ratios are relative to first Group.) | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>GroupID</td> <td>An array of generated allocation indices for all subjects.</td> <td>Integer</td> </tr> </tbody> </table> | | | Identifier | Description | Type | GroupID | An array of generated allocation indices for all subjects. | Integer | | |
| Identifier | Description | Type | | | | | | | | | |
| GroupID | An array of generated allocation indices for all subjects. | Integer | | | | | | | | | |
| Suggested format | <pre>GenGroupID ← function(NumSub, NumGrp, AllocRatio) { Error = 0 # Write the actual code here. Store the generated group indices # in an array called retval. Use appropriate error handling # and modify the Error appropriately. return(list(GroupID = as.integer(retval), ErrorCode = as.integer(Error))) }</pre> | | | | | | | | | | |

0.3.6 Randomizing Subjects to Populations

Table O.9: Population Randomization

| Suggested Name of the function | <i>GenPopulationID()</i> | | | | | | | | | | |
|---------------------------------------|---|---------|--|------------|-------------|--------|---------------------------------|---|-------------------------------------|-----------|--|
| Description | Randomizes subjects to specified populations. Used only for Trend in R ordered proportions test. The function should produce 0-based indices of populations to which the subjects are allocated. The populations have consecutive positive population indices starting with 1. The first population will have index 0. | | | | | | | | | | |
| Syntax | <i>GenPopulationID (NumSub, NumPop, AllocFrac)</i> | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects to randomize</td> </tr> <tr> <td>NumPop</td> <td>Number of populations in the trial.</td> </tr> <tr> <td>AllocFrac</td> <td>Array of size (NumPop) specifying expected allocation fractions for the populations.</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects to randomize | NumPop | Number of populations in the trial. | AllocFrac | Array of size (NumPop) specifying expected allocation fractions for the populations. |
| Argument | Description | | | | | | | | | | |
| NumSub | Number of Subjects to randomize | | | | | | | | | | |
| NumPop | Number of populations in the trial. | | | | | | | | | | |
| AllocFrac | Array of size (NumPop) specifying expected allocation fractions for the populations. | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>PopulationID</td> <td>An array of generated populations indices for all subjects.</td> <td>Integer</td> </tr> </tbody> </table> | | | Identifier | Description | Type | PopulationID | An array of generated populations indices for all subjects. | Integer | | |
| Identifier | Description | Type | | | | | | | | | |
| PopulationID | An array of generated populations indices for all subjects. | Integer | | | | | | | | | |
| Suggested format | <pre>GenPopulationID ← function(NumSub, NumPop, AllocFrac) { Error = 0 # Write the actual code here. Store the generated population # indices in an array called retval. Use appropriate error handling # and modify the Error appropriately. return(list(PopulationID = as.integer(retval), ErrorCode = as.integer(Error))) }</pre> | | | | | | | | | | |

O *R Functions*

O.4 *Generating Continuous Response*

O.4.1 Response for Single Mean Test

O.4.2 Response for Mean of Paired Differences Test

O.4.3 Response for Difference of Means Test

O.4.4 Response for Mean of Paired Ratio Test

O.4.5 Generating Response for Ratio of Means Test

O.4.6 Generating Binary Response Values

O.4.7 Generating Categorical Response Values

O.4.8 Generating Survival Times

In this section we describe various functions for generating continuous response for various tests in East as well as SiZ.

O.4.1 *Response for Single Mean Test*

Table O.10: Generating response for Single Mean Test

| Suggested Name of the function | <i>GenRespSingleMean()</i> | | | | | | | | | | |
|---|---|--------|--|------------|-------------|--------|--------------------|---|--|--------|---|
| Description for a specified number of subjects. | Generates response values for Single Mean Test | | | | | | | | | | |
| Syntax | <i>GenRespSingleMean (NumSub, Mean, StdDev)</i> | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>Mean</td> <td>Array (Size 1) specifying mean response value.</td> </tr> <tr> <td>StdDev</td> <td>Array (Size 1) specifying standard deviation.</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects | Mean | Array (Size 1) specifying mean response value. | StdDev | Array (Size 1) specifying standard deviation. |
| Argument | Description | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | |
| Mean | Array (Size 1) specifying mean response value. | | | | | | | | | | |
| StdDev | Array (Size 1) specifying standard deviation. | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>Response</td> <td>An array of generated response for all subjects</td> <td>Double</td> </tr> </tbody> </table> | | | Identifier | Description | Type | Response | An array of generated response for all subjects | Double | | |
| Identifier | Description | Type | | | | | | | | | |
| Response | An array of generated response for all subjects | Double | | | | | | | | | |
| Suggested format | <pre>GenRespSingleMean ← function(NumSub, Mean, StdDev) { Error = 0 # Write the actual code here. # Store the generated response values in an # array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(Response = as.double(retval), Error- Code = as.integer(Error))) } Please note that ErrorCode is optional for this function.</pre> | | | | | | | | | | |

0.4.2 Response for Mean of Paired Differences Test

O R Functions

Table O.11: Generating response for Mean of Paired Differences test

| Suggested Name of the function | <i>GenRespPairedDiff()</i> | | | | | | | | | | | | | | | | | |
|---------------------------------------|--|--------|--|------------|-------------|--------|--------------------|---|---|--------|--|--|-------|--|--------|-------|--|--------|
| Description | Generates response values for Mean of Paired Differences Test for a specified number of subjects. | | | | | | | | | | | | | | | | | |
| Syntax | <i>GenRespPairedDiff (NumSub, Mean, SigmaD)</i> | | | | | | | | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>Mean</td> <td>Array (Size 2) specifying mean response value for Control (First element) and Treatment (second element) Arm.</td> </tr> <tr> <td>SigmaD</td> <td>Array (Size 1) specifying Standard Deviation of Paired Difference.</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects | Mean | Array (Size 2) specifying mean response value for Control (First element) and Treatment (second element) Arm. | SigmaD | Array (Size 1) specifying Standard Deviation of Paired Difference. | | | | | | | |
| Argument | Description | | | | | | | | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | | | | | | | | |
| Mean | Array (Size 2) specifying mean response value for Control (First element) and Treatment (second element) Arm. | | | | | | | | | | | | | | | | | |
| SigmaD | Array (Size 1) specifying Standard Deviation of Paired Difference. | | | | | | | | | | | | | | | | | |
| Return Value Type | <p>R List</p> <p>The must identifiers in this list are</p> <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>DiffResp</td> <td>An array of Difference of generated response values on Treatment and Control arm.</td> <td>Double</td> </tr> <tr> <td colspan="3" style="text-align: center;">OR</td> </tr> <tr> <td>RespC</td> <td>An array of generated Control response values for all subjects</td> <td>Double</td> </tr> <tr> <td>RespT</td> <td>An array of generated Treatment response values for all subjects</td> <td>Double</td> </tr> </tbody> </table> <p>Note - If "DiffResp" is found in output list then "RespC" and "RespT" will be optional identifiers otherwise they will be mandatory identifiers</p> | | | Identifier | Description | Type | DiffResp | An array of Difference of generated response values on Treatment and Control arm. | Double | OR | | | RespC | An array of generated Control response values for all subjects | Double | RespT | An array of generated Treatment response values for all subjects | Double |
| Identifier | Description | Type | | | | | | | | | | | | | | | | |
| DiffResp | An array of Difference of generated response values on Treatment and Control arm. | Double | | | | | | | | | | | | | | | | |
| OR | | | | | | | | | | | | | | | | | | |
| RespC | An array of generated Control response values for all subjects | Double | | | | | | | | | | | | | | | | |
| RespT | An array of generated Treatment response values for all subjects | Double | | | | | | | | | | | | | | | | |

0.4.3 Response for Difference of Means Test

The following table provides details of the functions for generating response for difference of means test.

Table O.12: Generating response for Mean of Paired Differences test (Contd.)

| | |
|--------------------------------|--|
| <p>Suggested format</p> | <p>Format1 GenRespPairedDiff ← function(NumSub, Mean, SigmaD) { Error = 0 # Write the actual code here. # Store the generated difference of response values in an # array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(DiffResp = as.double(retval), ErrorCode = as.integer(Error))) } Format2 GenRespPairedDiff ← function(NumSub, Mean, SigmaD) { Error = 0 # Write the actual code here. # Store the generated Responses on control arm values in an # array called retval1. # Store the generated Responses on treatment arm values in an # array called retval2. # Use appropriate error handling and modify the # Error appropriately. return(list(RespC = as.double(retval1), RespT = as.double(retval2), ErrorCode = as.integer(Error))) }</p> |
|--------------------------------|--|

O R Functions

Table O.13: Generating Response for Difference of Mean Test

| Suggested Name of the function | <i>GenRespDiffofMeans()</i> | | | | | | | | | | | | |
|---------------------------------------|---|--------|--|------------|-------------|--------|--------------------|---------------------------------------|---|------|--|--------|--|
| Description | Generates response values for Difference of Means test for a specified number of subjects. | | | | | | | | | | | | |
| Syntax | <i>GenRespDiffofMeans (NumSub, TreatmentID, Mean, StdDev)</i> | | | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>TreatmentID</td> <td>Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0.</td> </tr> <tr> <td>Mean</td> <td>Array (size 2) specifying mean response values for control (first element) and treatment (second element) arms</td> </tr> <tr> <td>StdDev</td> <td>Array (of size 2) specifying standard deviations for control (first element) and treatment (second element) arm.</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects | TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0. | Mean | Array (size 2) specifying mean response values for control (first element) and treatment (second element) arms | StdDev | Array (of size 2) specifying standard deviations for control (first element) and treatment (second element) arm. |
| Argument | Description | | | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | | | |
| TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0. | | | | | | | | | | | | |
| Mean | Array (size 2) specifying mean response values for control (first element) and treatment (second element) arms | | | | | | | | | | | | |
| StdDev | Array (of size 2) specifying standard deviations for control (first element) and treatment (second element) arm. | | | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>Response</td> <td>An array of response for all subjects</td> <td>Double</td> </tr> </tbody> </table> | | | Identifier | Description | Type | Response | An array of response for all subjects | Double | | | | |
| Identifier | Description | Type | | | | | | | | | | | |
| Response | An array of response for all subjects | Double | | | | | | | | | | | |
| Suggested format | <pre>GenRespDiffofMeans ← function (NumSub, TreatmentID, Mean, StdDev) { Error = 0 # Write the actual code here. Store the generated continuous # response values in an array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(Response = as.double(retval), ErrorCode = as.integer(Error))) } Please note that ErrorCode is optional for this function.</pre> | | | | | | | | | | | | |

0.4.4 Response for Mean of Paired Ratio Test

Table O.14: Generating Response for Mean of Paired Ratio Test

| Suggested Name of the function | <i>GenRespPairedRatio()</i> | | | | | | | | | | | | | | | | | |
|---------------------------------------|---|--------|--|------------|-------------|--------|--------------------|--|---|----------------|--|--|-------|--|--------|-------|--|--------|
| Description | Generates response values for Mean of Paired Ratios Test for a specified number of subjects. | | | | | | | | | | | | | | | | | |
| Syntax | <i>GenRespPairedRatio(NumSub, Mean, StdDevLogRatio)</i> | | | | | | | | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>Mean</td> <td>Array (Size 2) specifying mean response values (i.e. means of corresponding Log Normal distribution) for Control (first element) and Treatment (second element)Arm.</td> </tr> <tr> <td>StdDevLogRatio</td> <td>Array (Size 1) specifying Standard Deviation of Log of Ratio of Response of Treatment and Control.</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects | Mean | Array (Size 2) specifying mean response values (i.e. means of corresponding Log Normal distribution) for Control (first element) and Treatment (second element)Arm. | StdDevLogRatio | Array (Size 1) specifying Standard Deviation of Log of Ratio of Response of Treatment and Control. | | | | | | | |
| Argument | Description | | | | | | | | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | | | | | | | | |
| Mean | Array (Size 2) specifying mean response values (i.e. means of corresponding Log Normal distribution) for Control (first element) and Treatment (second element)Arm. | | | | | | | | | | | | | | | | | |
| StdDevLogRatio | Array (Size 1) specifying Standard Deviation of Log of Ratio of Response of Treatment and Control. | | | | | | | | | | | | | | | | | |
| Return Value Type | <p>R List The must identifiers in this list are</p> <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>RatioResp</td> <td>An array of Ratio of generated response values on treatment and control arm.</td> <td>Double</td> </tr> <tr> <td colspan="3" style="text-align: center;">OR</td> </tr> <tr> <td>RespC</td> <td>An array of generated control response values for all subjects</td> <td>Double</td> </tr> <tr> <td>RespT</td> <td>An array of generated treatment response values for all subjects</td> <td>Double</td> </tr> </tbody> </table> <p>Note - If "RatioResp" is found in output list then "RespC" and "RespT" will be optional identifiers otherwise they will be mandatory identifiers</p> | | | Identifier | Description | Type | RatioResp | An array of Ratio of generated response values on treatment and control arm. | Double | OR | | | RespC | An array of generated control response values for all subjects | Double | RespT | An array of generated treatment response values for all subjects | Double |
| Identifier | Description | Type | | | | | | | | | | | | | | | | |
| RatioResp | An array of Ratio of generated response values on treatment and control arm. | Double | | | | | | | | | | | | | | | | |
| OR | | | | | | | | | | | | | | | | | | |
| RespC | An array of generated control response values for all subjects | Double | | | | | | | | | | | | | | | | |
| RespT | An array of generated treatment response values for all subjects | Double | | | | | | | | | | | | | | | | |

O R Functions

| | |
|--------------------------------|--|
| <p>Suggested format</p> | <p>Format1 GenRespPairedRatio ← function(NumSub, Mean, StdDevLogRatio) { Error = 0 # Write the actual code here. # Store the generated ratio of response values in an # array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(RatioResp = as.double(retval), ErrorCode = as.integer(Error))) } Format2 GenRespPairedRatio ← function(NumSub, Mean, StdDevLogRatio) { Error = 0 # Write the actual code here. # Store the generated Responses on control arm values in an # array called retval1. # Store the generated Responses on treatment arm values in an # array called retval2. # Use appropriate error handling and modify the # Error appropriately. return(list(RespC = as.double(retval1), RespT = as.double(retval2), ErrorCode = as.integer(Error))) }</p> |
|--------------------------------|--|

0.4.5 Generating Response for Ratio of Means Test

Table O.15: Generating response for Ratio of Means Test

| Suggested Name of the function | <i>GenRespRatioofMeans()</i> | | | | | | | | | | | | |
|---------------------------------------|--|--------|--|------------|-------------|--------|--------------------|---|--|------|---|----|--|
| Description | Generates response values for Ratio of Means test for a specified number of subjects. | | | | | | | | | | | | |
| Syntax | <i>GenRespRatioofMeans (NumSub, TreatmentID, Mean, CV)</i> | | | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>NumSub</td> <td>Number of Subjects</td> </tr> <tr> <td>TreatmentID</td> <td>Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0.</td> </tr> <tr> <td>Mean</td> <td>Array (size 2) specifying mean response values (i.e. means of corresponding Log Normal distribution) for control (first element) and treatment (second element) arms.</td> </tr> <tr> <td>CV</td> <td>Array (size 2) specifying Coefficient of Variation for control (first element) and treatment (second element) arm.</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects | TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0. | Mean | Array (size 2) specifying mean response values (i.e. means of corresponding Log Normal distribution) for control (first element) and treatment (second element) arms. | CV | Array (size 2) specifying Coefficient of Variation for control (first element) and treatment (second element) arm. |
| Argument | Description | | | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | | | |
| TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0. | | | | | | | | | | | | |
| Mean | Array (size 2) specifying mean response values (i.e. means of corresponding Log Normal distribution) for control (first element) and treatment (second element) arms. | | | | | | | | | | | | |
| CV | Array (size 2) specifying Coefficient of Variation for control (first element) and treatment (second element) arm. | | | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>Response</td> <td>An array of generated response (from Log Normal Distribution)</td> <td>Double</td> </tr> </tbody> </table> | | | Identifier | Description | Type | Response | An array of generated response (from Log Normal Distribution) | Double | | | | |
| Identifier | Description | Type | | | | | | | | | | | |
| Response | An array of generated response (from Log Normal Distribution) | Double | | | | | | | | | | | |

O R Functions

Table O.16: Generating response for Ratio of Means Test (Contd)

| | |
|-------------------------|---|
| Suggested format | <pre> GenRespRatioofMeans ← function(NumSub,TreatmentID, Mean, CV) { Error = 0 # Write the actual code here. Store the generated response # values in an array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(Response = as.double(retval), ErrorCode = as.integer(Error))) } Please note that ErrorCode is optional for this function. </pre> |
|-------------------------|---|

0.4.6 Generating Binary Response Values

The following table provides details of generating binary response values.

Table O.17: Generating Binary Response Values

| | |
|---|--|
| Suggested Name of the function | <i>GenBinResp()</i> |
| Description | Generates Binary response (Two categories 0 (Non-Responder) and 1 (Responder) values for a specified number of subjects. |
| Syntax for one arm test | <i>GenBinResp (NumSub, PropResp)</i> |
| Syntax for more than one arm test | <i>GenBinResp (NumSub, NumArm, TreatmentID, PropResp)</i> |
| Syntax only for Trend in R Ordered Proportions | <i>GenTrendResp (NumSub, NumPop, PopulationID, PropResp)</i> |

Table O.18: Generating Binary Response Values (Contd)

| <p>Arguments</p> | <table border="1"> <thead> <tr> <th data-bbox="539 355 689 389">Argument</th> <th data-bbox="689 355 1189 389">Description</th> </tr> </thead> <tbody> <tr> <td data-bbox="539 389 689 423">NumSub</td> <td data-bbox="689 389 1189 423">Number of Subjects</td> </tr> <tr> <td data-bbox="539 423 689 491">NumArm</td> <td data-bbox="689 423 1189 491">Number of arms in the trial (including placebo / control)</td> </tr> <tr> <td data-bbox="539 491 689 722">TreatmentID</td> <td data-bbox="689 491 1189 722">Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0. For other arms, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 arms (1 placebo + 3 treatment arms), arm indexes will be 0, 1, 2 and 3.</td> </tr> <tr> <td data-bbox="539 722 689 953">PopulationID</td> <td data-bbox="689 722 1189 953">Array specifying indexes of populations to which subjects are allocated (one population index per subject). Index for first population is 0. For other populations, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 populations, their indices will be 0, 1, 2 and 3.</td> </tr> <tr> <td data-bbox="539 953 689 1021">PropResp</td> <td data-bbox="689 953 1189 1021">An array specifying expected proportions of responders on each arm/Population.</td> </tr> </tbody> </table> | | | Argument | Description | NumSub | Number of Subjects | NumArm | Number of arms in the trial (including placebo / control) | TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0. For other arms, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 arms (1 placebo + 3 treatment arms), arm indexes will be 0, 1, 2 and 3. | PopulationID | Array specifying indexes of populations to which subjects are allocated (one population index per subject). Index for first population is 0. For other populations, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 populations, their indices will be 0, 1, 2 and 3. | PropResp | An array specifying expected proportions of responders on each arm/Population. |
|---------------------------------|--|--------|--|------------|-------------|--------|--------------------|--|---|-------------|---|--------------|---|----------|--|
| Argument | Description | | | | | | | | | | | | | | |
| NumSub | Number of Subjects | | | | | | | | | | | | | | |
| NumArm | Number of arms in the trial (including placebo / control) | | | | | | | | | | | | | | |
| TreatmentID | Array specifying indexes of arms to which subjects are allocated (one arm index per subject). Index for placebo / control is 0. For other arms, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 arms (1 placebo + 3 treatment arms), arm indexes will be 0, 1, 2 and 3. | | | | | | | | | | | | | | |
| PopulationID | Array specifying indexes of populations to which subjects are allocated (one population index per subject). Index for first population is 0. For other populations, indexes are consecutive positive numbers starting with 1. Thus if the trial has 4 populations, their indices will be 0, 1, 2 and 3. | | | | | | | | | | | | | | |
| PropResp | An array specifying expected proportions of responders on each arm/Population. | | | | | | | | | | | | | | |
| <p>Return Value Type</p> | <p>R List - The must identifiers in this list are</p> <table border="1"> <thead> <tr> <th data-bbox="539 1072 689 1106">Identifier</th> <th data-bbox="689 1072 1096 1106">Description</th> <th data-bbox="1096 1072 1189 1106">Type</th> </tr> </thead> <tbody> <tr> <td data-bbox="539 1106 689 1175">Response</td> <td data-bbox="689 1106 1096 1175">An array of generated Binary response for all subjects</td> <td data-bbox="1096 1106 1189 1175">Double</td> </tr> </tbody> </table> | | | Identifier | Description | Type | Response | An array of generated Binary response for all subjects | Double | | | | | | |
| Identifier | Description | Type | | | | | | | | | | | | | |
| Response | An array of generated Binary response for all subjects | Double | | | | | | | | | | | | | |
| <p>Suggested format</p> | <pre> GenBinResp ← function(NumSub, NumArm, TreatmentID, PropResp) {Error = 0 # Write the actual code here. Store the generated binary response # values in an array called retval. # Use appropriate error handling and modify the # Error appropriately. return(list(Response = as.double(retval), ErrorCode = as.integer(Error))) } </pre> | | | | | | | | | | | | | | |

O R Functions

0.4.7 Generating Categorical Response Values

Table O.19: Generating Categorical Response Values

| Suggested Name of the function | <i>GenCatResp()</i> | | | | | | | | | | | |
|--|--|--|----------|-------------|--------|--------------------|--------|--------------------------------|---------|---|--------------------|--|
| Description | Generates Categorical response values (0 to (Number of categories-1)) for a specified number of subjects. Binary response is a special case of this when number of categories is 2. | | | | | | | | | | | |
| Syntax for one group test | <i>GenCatResp(NumSub, NumCat, PropResp)</i> | | | | | | | | | | | |
| Syntax for more than one group test | <i>GenCatResp (NumSub, NumGrp, GroupID, NumCat, PropResp)</i> | | | | | | | | | | | |

O R Functions

O.5 Enhanced Simulations

O.5.1 Input Arguments for One Look Test

O.5.2 Input Arguments for Multi Look Test

O.5.3 Output from R function

User will provide an R function for computing test statistic as well as for performing test for the current look in current simulation. Name of this R function is not mandatory.

O.5.1 Input Arguments for One Look Test

This section describes input arguments for R function for one look test for computing test statistic or perform test for One Look as well as Multi Look tests.

For One Look Test, R function will have following two mandatory named arguments

1. **SimData** - R Data frame which consists of data generated in current simulation (Case Data). This data frame will have headers indicating the names of the columns. These names will be same as those used in Data Generation. User should access the variables using headers for ex. `SimData$ArrivalTime` and not order. Optional outputs from Data Generation will also be available.
2. **DesignParam** - R List which consists of Design and Simulation Parameters which user may need to compute test statistic and perform test. User should access the variables using names for eg. `DesignParam$SideType` and not order. For details of this list please see below.

Table O.23: Input Table for One Look Test

| Argument Name | Description | Applicability | Codes |
|---------------|--|--|---|
| Alpha | Type I Error | Multi Look Enabled One Sided and Two Sided Symmetric Tests | |
| LowerAlpha | Lower Type I Error | Multi Look Enabled Two Sided Asymmetric Tests | |
| UpperAlpha | Upper Type I Error | Multi Look Enabled Two Sided Asymmetric | |
| TrialType | Type of the Trial | All Tests | 0 - Superiority 1 - Non-Inferiority 2 - Equivalence |
| TestType | Type of Test | All Tests | 0 - One Side 1 - Two Sided 2 - Two Sided Asymmetric |
| TailType | Nature of Critical Region | One Sided Tests | 0 - Left Tailed 1 - Right Tailed |
| AllocInfo | Array of the ratios of the treatment group sample sizes to control group sample size | Multi Arms Tests | |
| | Population Fractions | Trend Test | |

O R Functions

Table O.24: Input Table for One Look Test (Contd)

| Argument Name | Description | Applicability | Codes |
|--------------------|------------------------------|--------------------------------------|--|
| CriticalPoint | Critical value | Single Look One Sided Tests | |
| UpperCriticalPoint | Upper Critical value | Single Look Two Sided Tests | |
| LowerCriticalPoint | Lower Critical value | Single Look Two Sided Tests | |
| SampleSize | Sample Size | All | |
| MaxCompleters | Maximum Number of Completers | All Non Survival Tests | |
| RespLag | Response Lag | All non survival tests | |
| LookFixOption | Time/Events Based Flag | All Survival Tests | 0 - Event Based 1 - Time Based |
| MaxEvents | Maximum Events | All Survival Event Based Tests | |
| MaxStudyDur | Maximum Study Duration | All Survival Time Based Tests | |
| FollowUpType | Follow Up Type | All Survival Tests | 0 - Until End of the Study 1 - For Fixed Period |
| FollowUpDur | Follow Up Duration | All Survival Tests | |
| TestStatType | Test Statistic Type | All Normal Tests | 3 - Z test 4 - t Test |
| | | All Survival Tests | 0 - Log Rank 1 - Wilcoxon Gehan 2 - Harrington Fleming |
| | | Ratio of Proportions Non-Inferiority | 5 - Wald 6 - Score |

Table O.25: Input Table for One Look Test (Contd)

| Argument Name | Description | Applicability | Codes |
|----------------|--|--|---|
| HFParam | Harrington Fleming Parameter | Survival Tests | |
| VarType | Variance Type | t Test Diff of Prop Ratio of Prop Single Prop Ratio of Proportions Score | 4 - Equal 5 - UnEqual 0 - Pooled 1 - UnPooled 2 - Null 3 - Empirical |
| SigmaD | Standard Deviation of Paired Difference | Mean of Paired Difference Z test | |
| SigmaLogRatio | Standard Deviation of Log Ratio | Mean of Paired Ratios Z test | |
| CoeffVar | Coefficient of Variation | Ratio of Means Z test | |
| Sigma | Standard Deviation | All other Normal Z tests | |
| TrtEffNull | Treatment Effect under Null on natural scale | All Single Arms Test and Non-Inferiority Trials in Two Arms Tests | |
| UpperEquiLimit | Upper Equivalence Limit on Natural Scale | All Continuous Tests with Equivalence Trial Type | |
| LowerEquiLimit | Lower Equivalence Limit on Natural Scale | All Continuous Tests with Equivalence Trial Type | |
| EquiMargin | Equivalence Margin | Difference of Proportions Test with Equivalence Trial Type | |
| MuC | Mean for the Control Arm | Multi Look Enabled Normal Two Arms Tests | |

FM - 305 Odds Ratio - 306 Survival Given study Durn. - 401 Survival Given Accrual Rates - 410 Ratio of Means test= 103 Mean of Paired Ratios= 106 Diff of Prop Equivalence = 309 Trend in R ordered Proportions = 310 Chisquare test for specified proportions in C categories = 201 Two Group Chi square for Proportions in C Categories = 202 Chi Square for Proportions in RxC tables= 203 Chi Square for Proportions in Rx2 tables = 314 |

Table O.27: Input Table for One Look Test (Contd)

| Argument Name | Description | Applicability | Codes |
|---------------|--|---|-------|
| Scores | Array of Scores | Trend in R proportions Test | |
| NumPop | Number of Populations | Trend in R proportions Test | |
| NumGrp | Number of Groups | Chi Square Tests | |
| NumCat | Number of Categories | Chi Square Tests | |
| CatPropNull | Array of category wise Proportions under Null Hypothesis | Chi-Square for Specified Proportions in C Categories Test | |

0.5.2 Input Arguments for Multi Look Test

For Multi Look Test, R function will have following three mandatory named arguments

1. SimData - Same as for One Look Test
2. DesignParam - Same as for One Look Test
3. LookInfo - R List which consists of Design and Simulation

Parameters related to multi looks which user may need to compute test statistic and perform test. User should access the variables using names for ex. LookInfo\$SideType and not order. For details of this list please see below.

O R Functions

Table O.28: Input Table for Multi Look Tests

| Argument Name | Description | Applicability | Codes |
|---------------|---------------------------------------|--------------------------------|--|
| NumLooks | Number of Looks | All Tests | |
| CurrLookIndex | Current Look Index (1- Based) | All Tests | |
| InfoFrac | Array of Information Fraction | All Tests | |
| CumAlpha | Array of cumulative alpha spent | One Sided Tests | |
| CumAlphaUpper | Array of Upper cumulative alpha spent | Two Sided Tests | |
| CumAlphaLower | Array of Lower cumulative alpha spent | Two Sided Tests | |
| CumCompleters | Array of Cumulative Completers | All Non Survival-Tests | |
| CumEvents | Array of Cumulative Events | All Survival Event Based tests | |
| LookTime | Array of Look Times on Calendar Scale | All Survival Time Based tests | |
| RejType | Rejection Type | All Tests | 1 Sided Efficacy Upper = 0 1 Sided Futility Upper = 1 1 Sided Efficacy Lower = 2 1 Sided Futility Lower = 3 1 Sided Efficacy Upper Futility Lower = 4 1 Sided Efficacy Lower Futility Upper = 5 2 Sided Efficacy Only = 6 2 Sided Futility Only = 7 2 Sided Efficacy Futility = 8 Equivalence = 9 |

Table O.29: Input Table for Multi Look Tests (Contd)

| Argument Name | Description | Applicability | Codes |
|---------------|--|--|---|
| EffBdryScale | Efficacy Boundary Scale | All Tests | 0 - Z Scale 1 - p value scale |
| EffBdry | Array of Efficacy Boundaries | One Sided Tests | |
| EffBdryUpper | Array of Upper Efficacy Boundary | Two Sided Tests | |
| EffBdryLower | Array of Lower Efficacy Boundary | Two Sided Tests | |
| FutBdryScale | Futility Boundary Scale | All Tests | 0 - Z scale 1 - p Value scale 2 - Delta Scale 3 - CP Scale |
| CPDeltaOption | Option of using Design or Estimated Delta for CP Computation | Tests with Futility Boundary on CP Scale | 0 - Design Delta Option 1 - Estimated Delta Option |
| FutBdry | Array of Futility Boundaries | One Sided Tests | |
| FutBdryUpper | Array of Upper Futility Boundary | Two Sided Tests | |
| FutBdryLower | Array of Lower Futility Boundary | Two Sided Tests | |
| BindingType | Binding Type | All Tests | 0 - Non Binding 1 - Binding |

O R Functions

0.5.3 Output from R function

R function will return a list. The Identifier Names (Case Insensitive) and Type (we suggest user type casts the output) mentioned for outputs are compulsory while their order in the list is not. User can have additional outputs (scalars) in the list.

If user wants to print scalars in the Simulation CSV file then he has to provide identifier for those scalars. These identifiers will be the columns names in output. Any repeated identifiers (column names) will be ignored.

User can either return identifier 'Decision' in which case other identifiers will become optional. If 'Decision' is not returned then other identifiers will become mandatory.

We suggest that the return List contain an identifier "ErrorCode". If specified, it has to be of Type Integer. Its values are classified as follows.

1. **0:** No Error
2. **Positive Integer:** Non Fatal Error - Particular Simulation will be terminated but Next Simulation will be performed.
3. **Negative Integer:** Fatal Error - No further simulation will be attempted

We suggest that user should classify error in these categories depending on the context.

Table O.30: Output from R function (Decision Only)

| Identifier | Description | Type | Applicability |
|------------|---|---------|---------------|
| Decision | Decision Code 0 - No Boundary Crossed 1 - Lower Efficacy Boundary Crossed 2 - Upper Efficacy Boundary Crossed 3 - Futility Boundary Crossed 4 - Equivalence Boundary Crossed | Integer | All Tests |

Table O.31: Output from R function (without 'Decision')

| Identifier | Description | Type | Applicability |
|-------------------------------|---|---------|--|
| TestStat | Value of appropriate Test Statistic. Regardless of the Efficacy or Futility Boundary Scale (ex. Delta or p Value or CP Scale) R function should return Test Statistic on Wald (Z) Scale | Double | All Tests except Equivalence Trial Type |
| TestStatLeft TestStatRight | Left and Right Test Statistic on Wald Scale Corresponding to Two Hypotheses | Double | All test with Equivalence Trial Type |
| Delta | Estimate of Delta | Double | Futility Boundary Scale is Delta or CP |
| CtrlCompleters | Number of Completers on Control Arm | Integer | Endpoint is Binomial and FutBdryScale is CP and Delta option is estimated. |
| TrmtCompleters | Number of Completers on Treatment Arm | Integer | Endpoint is Binomial and FutBdryScale is CP and delta options is estimated |
| CtrlPi | Proportion on Control Arm | Double | Endpoint is Binomial and FutBdryScale is CP and delta options is estimated |

O R Functions

O.6 Suggested Formats

O.6.1 Test Stat for One Look

O.6.2 Performing Test for One Look Tests

O.6.3 Computing Test Statistic for Multi Look Tests

O.6.4 Performing Test for Multi Look Tests

O.6.1 Test Stat for One Look

Suggested format for computing test statistic for one look tests is `ComputeTestStat` ← `function(SimData, DesignParam)`

```
{  
Error = 0  
# Write the actual code here.  
# Store the computed test statistic value in retval.  
# Use appropriate error handling and modify the Error appropriately.  
return(list(TestStat = as.double(retval), ErrorCode = as.integer(Error)))  
}
```

Please note that `ErrorCode` is optional for this function. You can also return quantities of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

O.6.2 Performing Test for One Look Tests

Suggested format for performing test for one look tests is `PerformDecision` ← `function(SimData, DesignParam)`

```
{  
Error = 0  
# Write the actual code here.  
# compute the test statistic value and store the decision in retval.  
# Use appropriate error handling and modify the Error appropriately.  
return(list(Decision = as.integer(retval), ErrorCode = as.integer(Error)))  
}
```

Please note that `ErrorCode` is optional for this function. You can also return quantities of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

O.6.3 Computing Test Statistic for Multi Look Tests

`ComputeTestStat` ← `function(SimData, DesignParam, LookInfo)`

```
{  
Error = 0  
# Write the actual code here.  
# Store the computed test statistic value in retval.  
# Use appropriate error handling and modify the Error appropriately.  
return(list(TestStat = as.double(retval), ErrorCode = as.integer(Error)))  
}
```

Please note that `ErrorCode` is optional for this function. You can also return quantities

of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

0.6.4 Performing Test for Multi Look Tests

```
PerformDecision ← function(SimData, DesignParam, LookInfo)
{
Error = 0
# Write the actual code here.
# Compute the test statistic value and store the decision
# value (appropriate code) in retval.
# Use appropriate error handling and modify the Error appropriately.
return(list(Decision = as.integer(retval), ErrorCode = as.integer(Error)))
}
```

Please note that ErrorCode is optional for this function. You can also return quantities of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

0.7 Basic Simulation

0.7.1 Input Arguments for One Look Test

0.7.2 Input Arguments for Multi Look Tests

User can perform basic simulation in East6.1 using R function. This option will be available if user performs simulation for Difference of Means Z Test and generates data using Difference of Means option. In this case R function will directly generate test statistic.

0.7.1 Input Arguments for One Look Test

For One Look Test, R function for basic simulation will have only one mandatory named argument

DesignParam - R List which consists of Design and Simulation Parameters which user may need to compute test statistic and perform test. User should access the variables using names for e.g. DesignParam\$SideType and not order.

0.7.2 Input Arguments for Multi Look Tests

For Multi Look Test, R function will have following two mandatory named arguments

1. **DesignParam** - Same as for One Look Test
2. **LookInfo** - R List which consists of Design and Simulation Parameters related to multi looks which user may need to compute test statistic and perform test. User should access the variables using names for ex. LookInfo\$SideType and not order.

O R Functions

O.8 Output from R function

R function for basic simulation will return a list. The Identifier Names (Case Insensitive) and Type (we suggest user type casts the output) mentioned for outputs are compulsory while their order in the list is not. User can have additional outputs (scalars) in the list. If user wants to print scalars in the Simulation CSV file then user has to provide identifier for those scalars. These identifiers will be the columns names in output. Any repeated identifiers (column names) will be ignored.

The must identifier(s) in this list are

| Identifier | Description | Type |
|------------|---|---------|
| Decision | Decision Code 0 - No Boundary Crossed 1 - Lower Efficacy Boundary Crossed 2 - Upper Efficacy Boundary Crossed 3 - Futility Boundary Crossed 4 - Equivalence Boundary Crossed | Integer |
| | OR | |
| TestStat | Test Statistic Value | Double |

We suggest that the return List contain an identifier "ErrorCode". If specified, it has to be of Type Integer. Its values are classified as follows

1. **0:** No Error
2. **Positive Integer:** Non Fatal Error - Particular Simulation will be aborted but Next Simulation will be performed.
3. **Negative Integer:** Fatal Error - No further simulation will be attempted

We suggest that user should classify error in these categories depending on the context.

O.9 Suggested Formats**O.9.1 Test Stat for One Look****O.9.2 Performing Test for One Look Tests****O.9.3 Test Statistic for Multi Look Tests****O.9.4 Performing Test for Multi Look Tests****O.9.1 Test Stat for One Look**

Suggested format for computing test statistic for one look tests is

```
ComputeBasicTestStat ← function(DesignParam)
```

```
{
```

```
Error = 0
```

```
# Write the actual code here.
```

```
# Store the computed test statistic value in retval.
```

```
# Use appropriate error handling and modify the Error appropriately.
```

```
return(list(TestStat = as.double(retval), ErrorCode = as.integer(Error)))
```

```
}
```

Please note that ErrorCode is optional for this function. You can also return quantities of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

O.9.2 Performing Test for One Look Tests

Suggested format for performing test for one look tests is PerformDecision ←

```
function(DesignParam)
```

```
{
```

```
Error = 0
```

```
# Write the actual code here.
```

```
# compute the test statistic value and store the decision in retval.
```

```
# Use appropriate error handling and modify the Error appropriately.
```

```
return(list(Decision = as.integer(retval), ErrorCode = as.integer(Error)))
```

```
}
```

Please note that ErrorCode is optional for this function. You can also return quantities of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

O.9.3 Test Statistic for Multi Look Tests

```
ComputeBasicTestStat ← function(DesignParam, LookInfo)
```

```
{
```

```
Error = 0
```

```
# Write the actual code here.
```

```
# Store the computed test statistic value in retval.
```

```
# Use appropriate error handling and modify the Error appropriately.
```

```
return(list(TestStat = as.double(retval), ErrorCode = as.integer(Error)))
```

```
}
```

Please note that ErrorCode is optional for this function. You can also return quantities

O R Functions

of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

0.9.4 Performing Test for Multi Look Tests

```
PerformDecision ← function(DesignParam, LookInfo)
{
Error = 0
# Write the actual code here.
# Compute the test statistic value and store the decision
# value (appropriate code) in retval.
# Use appropriate error handling and modify the Error appropriately.
return(list(Decision = as.integer(retval), ErrorCode = as.integer(Error)))
}
```

Please note that ErrorCode is optional for this function. You can also return quantities of interest (scalar) (like estimates) in the output list. Provide identifiers for such outputs and they will be displayed in Output of East6.1

O.10 Treatment Selection Function

Treatment Selection can be performed in combining p-values difference of means and difference of proportions designs using R. This section provides details on this functionality.

This function will be called once in each simulation after first look if trial is not terminated.

The use of error codes in this R function is similar to that explained in other R functions.

This function has following inputs

1. **SimData** - R Data frame which consists of data generated in current simulation (Case Data). This data frame will have headers indicating the names of the columns. These names will be same as those used in Data Generation. User should access the variables using headers for ex. `SimData$TreatmentID` and not order.
2. **DesignParam** - R List which consists of Design parameters which user may need to perform treatment selection. User should access the variables using names for ex. `DesignParam$SideType` and not order. For details of this list please see appropriate table in this section
3. **LookInfo** - R List which consists of Design Parameters related to two looks which user may need to perform treatment selection. User should access the variables using names for ex. `LookInfo$NumLooks` and not order. For details of this list please see appropriate table in this section

O R Functions

Table O.32: Function for treatment selection

| Suggested Name of the function | <i>TreatmentSelection()</i> | | | | | | | | | |
|--|--|---------------------|-------------|---------|----------------|-----------------------------------|----------------------|------------|-------------------------------|---------|
| Description | Performs treatment selection for combining p-values designs. This function is called once in each simulation after first look. | | | | | | | | | |
| Syntax | <i>TreatmentSelection(SimData, DesignParam, LookInfo)</i> | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Compulsory Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>SimData</td> <td>Simulated Data</td> </tr> <tr> <td>DesignParam</td> <td>Parameters of design</td> </tr> <tr> <td>LookInfo</td> <td>Look-wise information</td> </tr> </tbody> </table> | Compulsory Argument | Description | SimData | Simulated Data | DesignParam | Parameters of design | LookInfo | Look-wise information | |
| Compulsory Argument | Description | | | | | | | | | |
| SimData | Simulated Data | | | | | | | | | |
| DesignParam | Parameters of design | | | | | | | | | |
| LookInfo | Look-wise information | | | | | | | | | |
| Return Value Type | <p>R List</p> <p>The must identifiers in this list are</p> <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>TreatmentID</td> <td>An array of treatment identifiers</td> <td>Integer.</td> </tr> <tr> <td>AllocRatio</td> <td>An array of allocation ratios</td> <td>Double.</td> </tr> </tbody> </table> | Identifier | Description | Type | TreatmentID | An array of treatment identifiers | Integer. | AllocRatio | An array of allocation ratios | Double. |
| Identifier | Description | Type | | | | | | | | |
| TreatmentID | An array of treatment identifiers | Integer. | | | | | | | | |
| AllocRatio | An array of allocation ratios | Double. | | | | | | | | |
| Suggested format and additional information | <pre>TreatmentSelection ← function(SimData, DesignParam, Look- Info) { Error = 0 # Write the actual code here. # TreatmentID must contain values 1, 2, ... (No.ofTreatment - 1) # Allocation ratios are with respect to control # East expects TreatmentIDs sorted according to preference of treatment selection # Use appropriate error handling and modify the # Error appropriately. return(list(TreatmentID = as.integer(retval1), AllocRatio = as.double(retval2), ErrorCode = as.integer(Error))) }</pre> | | | | | | | | | |

Table O.33: DesignParam for Treatment Selection

| Argument Name | Description | Codes |
|----------------|---|---|
| Alpha | Type I Error | |
| Trial Type | Type of the trial | 0 - Superiority 1 - Non-inferiority 2 - Equivalence |
| Taile Type | Nature of critical region | 0 - Left tailed 1 - Right Tailed |
| SampleSize | Total Sample Size | |
| TestStatType | Test Statistic Type | 3 - Z-stat 4 - t-Stat |
| VarType | Variance Type | 4 - equal 5 - Un-equal 0 - Pooled 1 - Un-pooled |
| MultAdjMethod | Multiplicity adjustment method | 0 - Bonferonni 1 - Sidak 2 - Simes 3 - Dunnett |
| PValCombMethod | P-Value Combination Method | 0 - Inverse Normal |
| Sigma | Common Standard deviation or standard deviation array | |
| w1 | Weight for stage 1 | |
| w2 | Weight for stage 2 | |
| TestID | Test ID | 418 - DOM 419 - DOP |
| NumTreatments | Number of treatments including control | |

O R Functions

Table O.34: LookInfo for Treatment Selection

| Argument Name | Description | Codes |
|---------------|--------------------------------|---|
| NumLooks | Number of Looks | |
| CurrLookIndex | Current Look Index (1-based) | |
| InfoFrac | Array of Information fractions | |
| EffBdry | Array of Efficacy Boundaries | |
| FutBdryScale | Futility Boundary Scale | 1 - p-value scale 2 - Delta/Sigma Scale (DOM) or Delta Scale (DOP) |

***0.11 Functions
for Adaptive
Simulations***

This section describes details of various R functions for adaptive simulations.

R function can be used for performing sample size re-estimation. R function can be used along with CHW or CDL simulation but not with Muller and Schafer simulation.

R function assumes that Promising Zone scale is 'Conditional Power'. For Survival endpoint, R function can be used to re-estimate events. Whereas for Normal and Binary endpoints, R function can be used to re-estimate completers.

Even with R function, East will not allow reduction of planned events or completers and will not allow exceeding maximum feasible number of events or completers.

R function can also be used for computing cumulative Wald statistic in adaptive survival simulations.

O R Functions

Table O.35: Function for Re-estimating events

| Suggested Name of the function | <i>PerformSSR()</i> | | | | | | | | | | |
|--|--|---------------------|-------------|--------|--|---------------------|---|-------|---|-----------|-------------------------|
| Description | Performs re-estimation of events at adapt look in survival simulation. | | | | | | | | | | |
| Syntax | <i>PerformSSR(OrigCP, CPmin, CPmax, DesEvents)</i> | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Compulsory Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>OrigCP</td> <td>CP computed with design number of events</td> </tr> <tr> <td>CPmin</td> <td>Minimum CP threshold for promising zone</td> </tr> <tr> <td>CPmax</td> <td>Minimum CP threshold for promising zone</td> </tr> <tr> <td>DesEvents</td> <td>Design Number of Events</td> </tr> </tbody> </table> | Compulsory Argument | Description | OrigCP | CP computed with design number of events | CPmin | Minimum CP threshold for promising zone | CPmax | Minimum CP threshold for promising zone | DesEvents | Design Number of Events |
| Compulsory Argument | Description | | | | | | | | | | |
| OrigCP | CP computed with design number of events | | | | | | | | | | |
| CPmin | Minimum CP threshold for promising zone | | | | | | | | | | |
| CPmax | Minimum CP threshold for promising zone | | | | | | | | | | |
| DesEvents | Design Number of Events | | | | | | | | | | |
| Return Value Type | <p>R List</p> <p>The must identifiers in this list are</p> <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>ReEstEvents</td> <td>Re-estimated events</td> <td>Integer.</td> </tr> </tbody> </table> | Identifier | Description | Type | ReEstEvents | Re-estimated events | Integer. | | | | |
| Identifier | Description | Type | | | | | | | | | |
| ReEstEvents | Re-estimated events | Integer. | | | | | | | | | |
| Suggested format and additional information | <pre>PerformSSR ← function(OrigCP, CPmin, CPmax, DesEvents) { Error = 0 # Write the actual code here. # Use appropriate error handling and modify the # Error appropriately. return(list(ReEstEvents = as.integer(retval), ErrorCode = as.integer(Error))) }</pre> | | | | | | | | | | |

Table O.36: Function for Re-estimating Completers

| Suggested Name of the function | <i>PerformSSR()</i> | | | | | | | | | | |
|--|--|---------------------|-------------|--------|--|-------------------------|---|-------|---|---------------|-----------------------------|
| Description | Performs re-estimation of completers at adapt look in Normal and Binary adaptive simulations. | | | | | | | | | | |
| Syntax | <i>PerformSSR(OrigCP, CPmin, CPmax, DesCompleters)</i> | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Compulsory Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>OrigCP</td> <td>CP computed with design number of completers</td> </tr> <tr> <td>CPmin</td> <td>Minimum CP threshold for promising zone</td> </tr> <tr> <td>CPmax</td> <td>Minimum CP threshold for promising zone</td> </tr> <tr> <td>DesCompleters</td> <td>Design Number of Completers</td> </tr> </tbody> </table> | Compulsory Argument | Description | OrigCP | CP computed with design number of completers | CPmin | Minimum CP threshold for promising zone | CPmax | Minimum CP threshold for promising zone | DesCompleters | Design Number of Completers |
| Compulsory Argument | Description | | | | | | | | | | |
| OrigCP | CP computed with design number of completers | | | | | | | | | | |
| CPmin | Minimum CP threshold for promising zone | | | | | | | | | | |
| CPmax | Minimum CP threshold for promising zone | | | | | | | | | | |
| DesCompleters | Design Number of Completers | | | | | | | | | | |
| Return Value Type | R List The must identifiers in this list are <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>ReEstCompleters</td> <td>Re-estimated completers</td> <td>Integer.</td> </tr> </tbody> </table> | Identifier | Description | Type | ReEstCompleters | Re-estimated completers | Integer. | | | | |
| Identifier | Description | Type | | | | | | | | | |
| ReEstCompleters | Re-estimated completers | Integer. | | | | | | | | | |
| Suggested format and additional information | <pre>PerformSSR ← function(OrigCP, CPmin, CPmax, DesCompleters) { Error = 0 # Write the actual code here. # Use appropriate error handling and modify the # Error appropriately. return(list(ReEstCompleters = as.integer(retval1), ErrorCode = as.integer(Error))) }</pre> | | | | | | | | | | |

O R Functions

Table O.37: Computing cumulative Wald Statistic in Survival adaptive Simulations

| Suggested Name of the function | <i>CumWaldAdapt()</i> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|---------------------------------------|--|---------------------|-------------|---------|------------------|---------------------------|-------------------|-----------|-----------------------|------------|---------------------|-------------|------|----------|-------------------------|---------|---------------|-------------------------------------|----------|---------------|---|---------|---------------|---|---------|-------------|--------------------------------|--------|-----------------|-------------------------------|--------|
| Description | Computes cumulative Wald statistics at each look in CHW or CDL survival simulations. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Syntax | <i>CumWaldAdapt(SimData, DesignParam, LookInfo, AdaptParam)</i> | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Arguments | <table border="1"> <thead> <tr> <th>Compulsory Argument</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>SimData</td> <td>Simulated Data</td> </tr> <tr> <td>DesignParam</td> <td>Design Parameters</td> </tr> <tr> <td>LookInfo</td> <td>Look-wise Information</td> </tr> <tr> <td>AdaptParam</td> <td>Adaptive Parameters</td> </tr> </tbody> </table> | Compulsory Argument | Description | SimData | Simulated Data | DesignParam | Design Parameters | LookInfo | Look-wise Information | AdaptParam | Adaptive Parameters | | | | | | | | | | | | | | | | | | | | |
| Compulsory Argument | Description | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| SimData | Simulated Data | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| DesignParam | Design Parameters | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| LookInfo | Look-wise Information | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| AdaptParam | Adaptive Parameters | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Return Value Type | <p>R List</p> <p>The must identifiers in this list are</p> <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>CumWaldStatistic</td> <td>Cumulative Wald Statistic</td> <td>Double.</td> </tr> <tr> <td>CumEvents</td> <td>Cumulative Events</td> <td>Integer.</td> </tr> </tbody> </table> <p>Optional identifiers in this list are</p> <table border="1"> <thead> <tr> <th>Identifier</th> <th>Description</th> <th>Type</th> </tr> </thead> <tbody> <tr> <td>LookTime</td> <td>Look Time for each Look</td> <td>Double.</td> </tr> <tr> <td>CumSampleSize</td> <td>Cumulative sample size at each Look</td> <td>Integer.</td> </tr> <tr> <td>CumEventsCtrl</td> <td>Cumulative Events on Control Arm at each Look</td> <td>Integer</td> </tr> <tr> <td>CumEventsTrmt</td> <td>Cumulative Events on Treatment Arm at each Look</td> <td>Integer</td> </tr> <tr> <td>AvgFollowUp</td> <td>Average Follow up at each Look</td> <td>Double</td> </tr> <tr> <td>AccrualDuration</td> <td>Accrual Duration at each Look</td> <td>Double</td> </tr> </tbody> </table> | Identifier | Description | Type | CumWaldStatistic | Cumulative Wald Statistic | Double. | CumEvents | Cumulative Events | Integer. | Identifier | Description | Type | LookTime | Look Time for each Look | Double. | CumSampleSize | Cumulative sample size at each Look | Integer. | CumEventsCtrl | Cumulative Events on Control Arm at each Look | Integer | CumEventsTrmt | Cumulative Events on Treatment Arm at each Look | Integer | AvgFollowUp | Average Follow up at each Look | Double | AccrualDuration | Accrual Duration at each Look | Double |
| Identifier | Description | Type | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| CumWaldStatistic | Cumulative Wald Statistic | Double. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| CumEvents | Cumulative Events | Integer. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Identifier | Description | Type | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| LookTime | Look Time for each Look | Double. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| CumSampleSize | Cumulative sample size at each Look | Integer. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| CumEventsCtrl | Cumulative Events on Control Arm at each Look | Integer | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| CumEventsTrmt | Cumulative Events on Treatment Arm at each Look | Integer | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| AvgFollowUp | Average Follow up at each Look | Double | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| AccrualDuration | Accrual Duration at each Look | Double | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

O R Functions

O.12 Use of Initialization Function

O.12.1 Setting Seed

O.12.2 Setting Working Directory

O.12.3 Initialize Global Variable

This appendix provides more information on **Init(Seed)** function. This function will be optional. If provided, this function will be executed before executing any of the other user defined functions. User can use this function for various reasons. Below we list some of these.

O.12.1 Setting Seed

If user wants repeatability of the results for a run of simulations, he can set the seed using **set.seed** command inside this function. He can also choose the Random Number Generator as well as the method for Normal method generation. The default random number generator is "Mersenne-Twister" in R.

Example 1

Default random number generator will be used.

```
Init(Seed)
{
Error = 0
set.seed(seed = Seed)
return(as.integer(Error))
}
```

Example2

Wichmann Hill random number generator will be used.

```
Init(Seed)
{
Error = 0
set.seed(seed = Seed, kind = "Wichmann-Hill")
return(as.integer(Error))
}
```

O.12.2 Setting Working Directory

User can set the working directory. User may want to source the files he intends to use.

Example 1

```
Init(Seed)
{ Error = 0
setwd("E:\\Work\\East6.1")
source('ConstantsFile.R')
return(as.integer(Error))
}
```

0.12.3 Initialize Global Variable

User can initialize the global variables which may be used by his other R functions

Example 1

```

Init(Seed)
{ Error = 0
Tolerance ;;- 1e-6
NoIntervals ;;- 3
return(as.integer(Error))
}

```

0.13 Additional Arguments

Suppose for a user defined function f, the mandatory named arguments are **Arg1** and **Arg2**.

This function will be called as follows **f(Arg1 = Val1, Arg2 = Val2)** where Val1 and Val2 will be appropriately passed. Now user can have additional arguments for this function f, for example suppose he has additional arguments Arg3 and Arg4. The syntax for this function is `f ← function(Arg1, Arg3, Arg2, Arg4)`

```

{
Body of the function
}

```

Note that in the call to this function; only appropriate values will be passed to mandatory named arguments hence it is important that user initializes the other arguments.

Some of the ways to do this are

Initialize in the Definition

```

f ← function(Arg1, Arg3 = 2, Arg2, Arg4 = 5)
{
Body of the function
}

```

Initialize using Global Variables initialized in Init function.

```

f ← function(Arg1, Arg3 = Tolerance, Arg2, Arg4 = NoIntervals)
{
Body of the function
}

```

P *East 5.x to East 6.4 Import Utility*

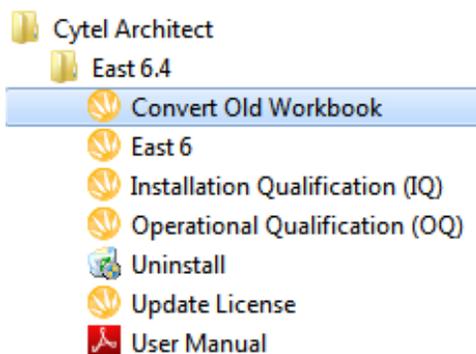

P.1 Import capabilities

This document serves the purpose of providing a step-by-step procedure as well as describing the scope of the **East 5.x to East 6.4 Import** Utility provided by Cytel to the East 6.4 Users. The Utility has been developed with a view to facilitate importing and converting the workbooks created in the earlier versions of East, namely the Microsoft Excel based **East 5.x** to the new architect based version of East namely, **East 6.4**. With the help of this Utility provided in the **All Program menu**, the East 6.4 user can now import the older workbooks and continue working on the imported designs for further development. For example, monitoring the design at subsequent interim looks or simulating the design is possible within the East 6.4 environment.

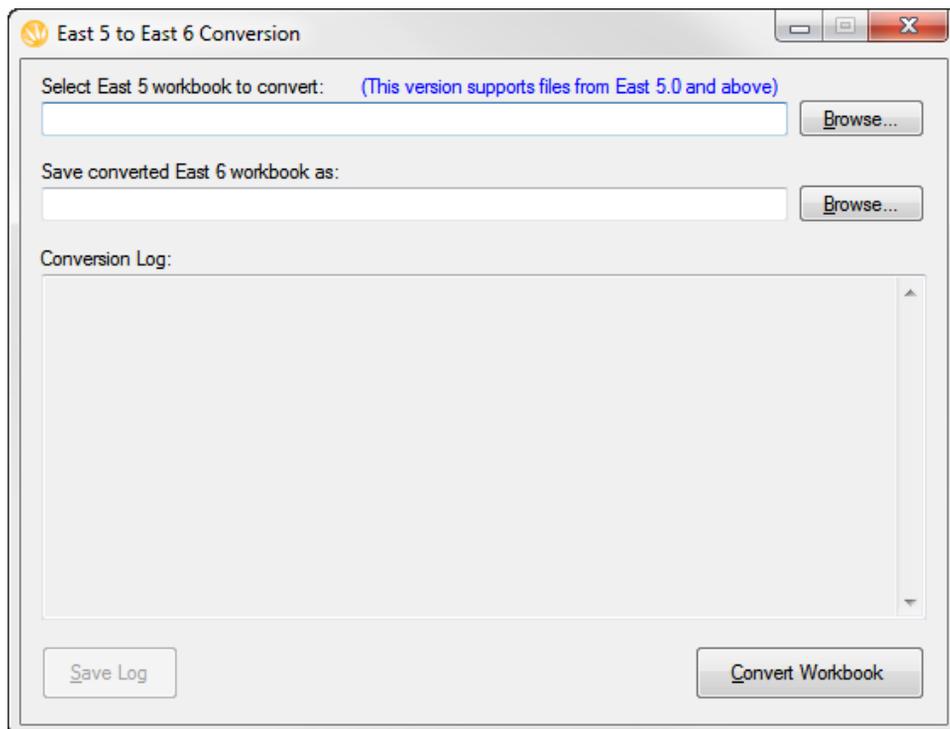

In order to open a workbook with the **.es5** extension given by East 5.x version, it must first be converted to a file with the **.cywx** extension that will be recognized by **East 6.4**.

From the **Start** Menu select:

All Programs → **Cytel Architect** → **East 6.4** → **Convert Old Workbook**

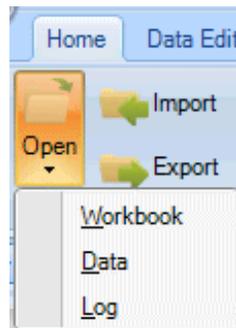

We can see the following window which accepts **East5.x** workbook as input and outputs a workbook of **East 6**. Click the **Browse** buttons to choose the **East 5.x** file to be converted and the file to be saved with **.cywx** extension of **East 6** version. To start the conversion click **Convert Workbook**:

The default location for the converted **East 6** workbook will be the same as that of the old workbook. You may select a different location of your choice for saving the same. While the conversion is in process, you will see a detailed log being displayed about the progress of the workbook creation. After completion of the conversion, you can save the log at the location of your choice.

Once complete, the file can be opened as a workbook in **East 6.4** as usual as shown below:

P East 5.x to East 6.4 Import Utility

When user imports an **East 5.x** workbook into **East 6.4**, East 6.4 will retain the input parameters and re-compute all output and make it available in the **6.4 (.cywx)** format. Since there have been major computational improvements from earlier versions of **East** to this version, some results may not match with those computed in **East 5.x**. In some rare situations, **East 6.4** will give a message that the input parameters are too extreme and it won't be able to import the workbooks. In general, user should be able to import any workbook created in **East 5.x** using any supported version of Excel into **East 6.4**. The list includes workbooks containing single look designs, group sequential designs, interim monitoring sheets, simulations etc. All supported locales will work including English (US/UK), French, Spanish, Japanese etc. However, there are some exceptions to the **Convert Old Workbook** functionality. These are described below:

1. **East 6.4** will not support importing of the following:
Direct monitoring, Basic simulations, Enhanced simulations with information scale, Adaptive worksheets for two-sided tests, expected sample size under H1/2, graph sheets and scratch sheets, interim monitoring sheets for single look designs.
2. Adaptive worksheets (like CHW simulations) for the odds ratio (OR) test from **East 5.0** will not be imported into **East 6.4** as **East 6.4** does not have adaptive features for this test yet. If user tries to import, **East 6.4** will display the following message: "CHW simulations are not available for this test in this version of **East**."
3. **East 5.x** allowed user to input floating point sample size / events value while

computing power of a design. If it is a group sequential design, **East 6.4** uses the option "Do not round sample size/events" to deal with the specified floating point value.

However, in case of some designs which are necessarily fixed look designs only, such as ratio of means, crossover designs, difference of means designs using t statistic etc, the option of using floating point input is not amenable by East 6.4. For such designs, East 6.4 will round down the sample size to the nearest integer for computing the power.

4. **East 6.4** won't import group sequential designs from **East 5.x** for the following tests:

- Linear Regression, Single Slope
- Linear Regression for Comparing Two Slopes
- Repeated Measures for Comparing Two Slopes

If user tries to import, East will display the following message:

"Group sequential option is not available for this test in this version of East."

East 6.4 supports only fixed sample (single look) designs for these tests.

5. **East 6.4** will not import **East 5.x** designs of the following type as these are not available in **East 6.4**:

- Logistic regression
- Cox proportional hazards regression

If user tries to import, East will display the following message:

"Unable to convert workbook as this test is not implemented in this version."

6. **East 6.4** will not import **East 5.x** designs with spending functions of type "Power Family" as these spending functions are not available in **East 6.4**. If user tries to import, East will display the following message:
"Power family spending function is not supported in this version."

7. Definition of treatment effect and effect size has been changed from **East 5.x** to **East 6.4** in the following cases:

In these cases, corresponding changes will be observed in the workbook after importing.

8. Muller and Schafer adaptive simulations performed with SWACI method in **East 5.x** workbooks will be run with BWCI method of estimation instead of SWACI

P East 5.x to East 6.4 Import Utility

Table P.1: Treatment effect in non-inferiority trials

| Test | East 5.x | East 6.4 |
|---|--|--|
| Difference of Means for Independent Data | $\delta = \mu_c - \mu_t$ | $\delta = \mu_t - \mu_c$ |
| Difference of Proportion for Independent Data | $\delta = \pi_c - \pi_t$ | $\delta = \pi_t - \pi_c$ |
| Odds Ratio of Proportion for Independent Data | $\psi = \frac{\pi_c(1 - \pi_t)}{\pi_t(1 - \pi_c)}$ | $\psi = \frac{\pi_t(1 - \pi_c)}{\pi_c(1 - \pi_t)}$ |

Table P.2: Longrank Test

| Test | East 5.x | East 6.4 |
|-----------------------------|---|--|
| Effect Size in Logrank Test | $\delta = -\ln\left(\frac{\lambda_t}{\lambda_c}\right)$ | $\delta = \ln\left(\frac{\lambda_t}{\lambda_c}\right)$ |

while importing to **East 6.4**. This is because **East 6.4** has replaced the SWACI method with the BWCI method as the latter is more advanced.

- East 6.4** will not import exact paired difference design from **East 5.x** as this design is not yet available in **East 6.4**. The **East 5.x** design is for the exact unconditional test for matched pairs whereas the design in **East 6.4** is for the exact McNemar's test which is a conditional test. If user tries to import the **East 5.x** design, **East 6.4** will display the following message:

"The exact unconditional test for matched pairs is not available in the current version of East. This workbook cannot be imported."

- While importing survival designs from **East 5.x**, **East 6.4** will convert input method to hazard rates if the **East 5.x** design was created with any other **input**

method.

11. In case of Logrank test with accrual rates and accrual duration, **East** first computes a range for the target accrual and when user specifies the committed accrual, East computes the study duration and other outputs. Because of computational improvements from **East 5.x** to **East 6.4**, the target accrual range in **East 6.4** could be a little different for the same design compared to **East 5.x**. If user has an **East 5.x** workbook where the committed accrual is equal or very close to the minimum, this workbook may not be imported in **East 6.4** as specified committed accrual may be less than the minimum accrual computed by **East 6.4**.
12. **East 6.4** will not import an **East 5.x** workbook if its file name contains the single quote (') character.

For technical support, please call us on 617-661-2011 or send a fax on 617-661-4405, or send email to support@cytel.com. Visit our website www.cytel.com for more information.

Q

Technical Reference and Formulas: Single Look Designs

Q.1 Introduction

In this Appendix, we provide theory used in the computation of single look designs in **East** and formulas used for computing sample size N (total number of subjects on the treatment arm in case of single arm studies, total number of pairs of subjects included in the study in paired designs and total number of subjects on the treatment and control arms both in case of two sample studies).

We begin with introducing common notations. The general method of computing sample size is solving the power equation for 'N' given other parameters such as δ , α , σ^2 . In a few cases, the procedure resorts to a closed form formula for the sample size. In rest of the cases, such a closed form expression for sample size is not possible. As a result, it requires use of an iterative method for computing the sample size for given power, starting with a sensible initial solution for N . In this Appendix, we describe the closed form solution wherever possible and in other cases state the initial solution for N along with the power equation used to derive the solution for N .

Q.2 Common Notation

Below we give notation which will be used throughout this chapter.

Common Notation

μ : Unknown mean of a single population

μ_0 : Mean response under Null hypothesis

S : Sample standard deviation

\bar{X} : Sample Mean

D : Difference variable of treatment and control when the response is continuous

\bar{D} : Sample Mean of D

σ_D : Population standard deviation of D

S_D : Sample standard deviation of D

λ : Median of the difference variable

μ_t : Unknown mean of treatment group

μ_c : Unknown mean of control group

σ : Population standard deviation

δ : Effect size, for example, difference of means, difference of proportions, log hazard ratio etc

SE : Standard Error

δ_0 : Non-inferiority margin for difference

ρ_0 : Non-inferiority margin for ratio

δ_L : Lower equivalence limit for difference

δ_U : Upper equivalence limit for difference

ρ_L : Lower equivalence limit for ratio

ρ_U : Upper equivalence limit for ratio
 $\phi(x)$: density function of standard normal variable, evaluated at x
 $\Phi(x)$: Distribution function of standard normal variable, evaluated at x
 Z_α : Upper α percent point of standard normal distribution
 $\tau_\nu(x)$: Distribution function of a student's t distribution, with ν degrees of freedom evaluated at x
 $\tau_\nu(x|\Omega)$: Distribution function of a non-central t distribution with ν degrees of freedom and non-centrality parameter Ω , evaluated at x
 $t_{\alpha,\nu}$: Upper α percent point of a student's t-distribution with ν degrees of freedom

**Q.3 Sample Size :
Continuous**

Q.3.1 Single:Sup:Normal

Q.3.2 Single:Sup:t

Q.3.3 Paired:Diff:Sup:
Normal

Q.3.9 Paired:Ratios:Sup:t

Q.3.10 Paired:Ratios:
Noninf:Normal

Q.3.11 Paired:Ratios:
Noninf:t

Q.3.12 Paired:Ratios:
Equiv:t

**Q.3.1 Single Arm Design : Single Mean : Superiority: Test Statistic
Distribution: Normal**

$$\sigma = \mu - \mu_0$$

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$N = \frac{\sigma^2}{\delta^2} (Z_\alpha + Z_\beta)^2$$

$$Power = 1 - \Phi \left(Z_\alpha - \frac{|\delta| \sqrt{N}}{\sigma} \right)$$

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2}{\delta^2} (Z_{\alpha/2} + Z_\beta)^2$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{\delta \sqrt{N}}{\sigma} \right)$$

Q Technical Reference and Formulas: Single Look Designs

$$+ \Phi \left(-Z_{\alpha/2} - \frac{\delta\sqrt{N}}{\sigma} \right)$$

- Two sided asymmetric (both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2}{\delta^2} (Z_{\alpha/2} + Z_{\beta})^2$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\begin{aligned} \text{Power} &= 1 - \Phi \left(Z_{\alpha_u} - \frac{\delta\sqrt{N}}{\sigma} \right) \\ &+ \Phi \left(-Z_{\alpha_l} - \frac{\delta\sqrt{N}}{\sigma} \right) \end{aligned}$$

Q.3.2 Single Arm Design : Single Mean : Superiority: Test Statistic Distribution: t

$$\delta = \mu - \mu_0$$

- One sided (both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2}{\delta^2} (Z_{\alpha} + Z_{\beta})^2 + \frac{Z_{\alpha}^2}{2}$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\text{Power} = 1 - \tau_{N-1} \left(t_{\alpha, N-1} \left| \frac{|\delta| \sqrt{N}}{\sigma} \right. \right)$$

- Two sided symmetric (both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2}{\delta^2} (Z_{\alpha} + Z_{\beta})^2 + \frac{Z_{\alpha}^2}{2}$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\begin{aligned} Power &= 1 - \tau_{N-1} \left(t_{\frac{\alpha}{2}, N-1} \left| \frac{\delta\sqrt{N}}{\sigma} \right. \right) \\ &+ \tau_{N-1} \left(-t_{\frac{\alpha}{2}, N-1} \left| \frac{\delta\sqrt{N}}{\sigma} \right. \right) \end{aligned}$$

Q.3.3 Paired Design: Superiority: Test Statistic Distribution: Normal: Mean of paired differences

$$\delta = \mu_t - \mu_c$$

- One sided (both $\delta > 0$ and $\delta < 0$)

$$N = \frac{\sigma_D^2}{\delta^2} (Z_\alpha + Z_\beta)^2$$

$$Power = 1 - \Phi \left(Z_\alpha - \frac{|\delta|\sqrt{N}}{\sigma_D} \right)$$

- Two sided symmetric (both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma_D^2}{\delta^2} (Z_{\alpha/2} + Z_\beta)^2$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\begin{aligned} Power &= 1 - \Phi \left(Z_{\frac{\alpha}{2}} - \frac{\delta\sqrt{N}}{\sigma_D} \right) \\ &+ \Phi \left(-Z_{\frac{\alpha}{2}} - \frac{\delta\sqrt{N}}{\sigma_D} \right) \end{aligned}$$

Q Technical Reference and Formulas: Single Look Designs

- Two sided asymmetric (both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma_D^2}{\delta^2} (Z_{\alpha/2} + Z_{\beta})^2$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\begin{aligned} \text{Power} &= 1 - \Phi \left(Z_{\alpha_{\mu}} - \frac{\delta\sqrt{N}}{\sigma_D} \right) \\ &+ \Phi \left(-Z_{\alpha_l} - \frac{\delta\sqrt{N}}{\sigma_D} \right) \end{aligned}$$

Q.3.4 Paired Design: Superiority: Test Statistic Distribution: t

$$\delta = \mu_t - \mu_c$$

- One sided (both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2}{\delta^2} (Z_{\alpha} + Z_{\beta})^2 + \frac{Z_{\alpha}^2}{2}$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\text{Power} = 1 - \tau_{N-1} \left(t_{\alpha, N-1} \left| \frac{|\delta|\sqrt{N}}{\sigma_D} \right. \right)$$

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2}{\delta^2} (Z_{\alpha} + Z_{\beta})^2 + \frac{Z_{\alpha}^2}{2}$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\text{Power} = 1 - \tau_{N-1} \left(t_{\frac{\alpha}{2}, N-1} \left| \frac{\delta\sqrt{N}}{\sigma} \right. \right)$$

$$+ \tau_{N-1} \left(-t_{\frac{\alpha}{2}, N-1} \left| \frac{\delta \sqrt{N}}{\sigma} \right. \right)$$

Q.3.5 Paired Design : Non-inferiority: Test Statistic Distribution: Normal

$$\delta = \mu_t - \mu_c$$

- One sided (for both $\delta > \delta_0$ and $\delta < \delta_0$)

$$N = \frac{\sigma_D^2 (Z_\alpha + Z_\beta)^2}{(\delta - \delta_0)^2}$$

$$Power = 1 - \Phi \left(Z_\alpha - \frac{|\delta - \delta_0| \sqrt{N}}{\sigma_D} \right)$$

- Two sided symmetric (for both $\delta > \delta_0$ and $\delta < \delta_0$)
Start with the initial solution as

$$N = \frac{\sigma_D^2 (Z_{\alpha/2} + Z_\beta)^2}{(\delta - \delta_0)^2}$$

and solve using an iterative procedure the following equation, so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{(\delta - \delta_0) \sqrt{N}}{\sigma_D} \right) + \Phi \left(-Z_{\alpha/2} - \frac{(\delta - \delta_0) \sqrt{N}}{\sigma_D} \right)$$

- Two sided asymmetric (for both $\delta > \delta_0$ and $\delta < \delta_0$)
Start with the initial solution as

$$N = \frac{\sigma_D^2 (Z_{\alpha/2} + Z_\beta)^2}{(\delta - \delta_0)^2}$$

and solve using an iterative procedure the following equation, so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha_u} - \frac{(\delta - \delta_0) \sqrt{N}}{\sigma_D} \right) + \Phi \left(-Z_{\alpha_l} - \frac{(\delta - \delta_0) \sqrt{N}}{\sigma_D} \right)$$

Q Technical Reference and Formulas: Single Look Designs

Q.3.6 Paired Design : Non-inferiority: Test Statistic Distribution: t

$$\delta = \mu_t - \mu_c$$

- One sided (for both $\delta > 0$ and $\delta < 0$) Start with the initial solution as

$$N = \frac{\sigma^2}{(\delta - \delta_0)^2} (Z_\alpha + Z_\beta)^2 + \frac{Z_\alpha^2}{2}$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \tau_{N-1} \left(t_{\alpha, N-1} \left| \frac{|\delta - \delta_0| \sqrt{N}}{\sigma_D} \right. \right)$$

Q.3.7 Paired Design : Equivalence: Test Statistic Distribution: t

$$\delta = \mu_t - \mu_c$$

- Solve using an iterative procedure the following equation, so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \tau_{N-1} \left(t_{\alpha, N-1} \left| \frac{(\delta - \delta_L) \sqrt{N}}{\sigma_D} \right. \right) + \tau_{N-1} \left(-t_{\alpha, N-1} \left| \frac{(\delta - \delta_U) \sqrt{N}}{\sigma_D} \right. \right)$$

Q.3.8 Paired Design: Superiority: Test Statistic Distribution: Normal: Mean of Paired Ratios

$$\delta = \ln \left(\frac{\mu_t}{\mu_c} \right)$$

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$N = \frac{\sigma_D^2}{\delta^2} (Z_\alpha + Z_\beta)^2$$

$$Power = 1 - \Phi \left(Z_{\alpha} - \frac{|\delta| \sqrt{N}}{\sigma_D} \right)$$

Where σ_D = standard deviation of log ratios

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma_D^2}{\delta^2} (Z_{\alpha/2} + Z_{\beta})^2$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{\delta \sqrt{N}}{\sigma_D} \right) + \Phi \left(-Z_{\alpha/2} - \frac{\delta \sqrt{N}}{\sigma_D} \right)$$

Where σ_D = standard deviation of log ratios

σ = Common standard deviation

σ_m^2 = Variance of means

r = Number of groups.

Solve for n using an iterative procedure the following equation, so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = P_{\lambda}(F > F_{1,(r-1)(n-r),\alpha})$$

with non-centrality parameter

$$\lambda = \frac{n \sigma_m^2}{\sigma^2}$$

Q.6.2 One Way ANOVA : Single One Way Contrast: t

σ = Common standard deviation

σ_{mc}^2 = Variance of means

r = Number of groups

- One sided

Solve for n using an iterative procedure the following equation, so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = P_{\lambda_1}(t > t_{n-r,\alpha})$$

with non-centrality parameter

$$\lambda_1 = \sqrt{n} \frac{\sigma_{mc}}{\sigma}$$

- Two Sided

Solve for n using an iterative procedure the following equation, so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = P_{\lambda}(F > F_{1,(n-r),\alpha})$$

with non-centrality parameter

$$\lambda = \frac{n \sigma_{mc}^2}{\sigma^2}$$

Q.6.3 One Way Repeated Measures: ANOVA: Superiority: Constant Correlation

M=number of levels

μ_i = mean at level I

σ = standard deviation at each level

ρ = between level correlation

$\sigma_m^2 = \frac{\sum (\mu_i - \bar{\mu})^2}{M}$ = variance of means

Effective size = $\Delta = \frac{\sigma_m^2}{\sigma^2(1-\rho)}$

Power = $P_\lambda(F > F_{(M-1), (M-1)(n-1), \alpha})$ with noncentrality parameter $\lambda = nM\Delta$

Q.6.4 One Way Repeated Measures Contrast

M=number of levels

μ_i = mean at level i

σ = standard deviation at each level

ρ = between level correlation

Contrast $C = \sum C_i \mu_i$ such that $\sum C_i = 0$

$D = \sqrt{\sum C_i^2}$

Effective size = $\Delta = \frac{|C|}{\sigma D \sqrt{1-\rho}}$

Power = $P_\lambda(F > F_{1, (M-1)(n-1), \alpha})$ with noncentrality parameter $\lambda = n \Delta^2$

Q.6.5 Two Way ANOVA

r = number of factor A levels,

Q Technical Reference and Formulas: Single Look Designs

s = number of factor B levels,

μ = overall mean

σ = common s.d. in each of the groups

μ_i = mean across factor A levels for factor A level i

μ_j = mean across factor B levels for factor B level j

μ_{ij} = mean for factor A level i and factor B level j

V_A = Variance of the marginal means for factor A

$$V_A = \frac{\sum_i (\mu_i - \mu)^2}{r}$$

V_B = Variance of the marginal means for factor B

$$V_B = \frac{\sum_j (\mu_j - \mu)^2}{r}$$

V_{AB} = Variance of cell means for factor A and B

$$V_{AB} = \frac{\sum_i \sum_j (\mu_{ij} - \mu_i - \mu_j + \mu)^2}{rs}$$

$Power_A = P(F > F_{(r-1),rs,(n-1),\alpha})$ with non-centrality parameter $\lambda = nrs \frac{V_A}{\sigma^2}$

$Power_B = P(F > F_{(s-1),rs,(n-1),\alpha})$ with non-centrality parameter $\lambda = nrs \frac{V_B}{\sigma^2}$

$Power_{AB} = P(F > F_{(r-1)(s-1),rs,(n-1),\alpha})$ with non-centrality parameter

$$\lambda = nrs \frac{V_{AB}}{\sigma^2}$$

Q.6.6 Linear regression single slope

Use $\delta = \theta - \theta_0$ and $\sigma = \frac{s.d.of\ residual}{s.d.of X} = \frac{\sigma_\epsilon}{\sigma_x}$ throughout the computation of power, sample size .

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$N = \frac{\sigma^2}{\delta^2} (Z_\alpha + Z_\beta)^2$$

$$Power = 1 - \Phi \left(Z_\alpha - \frac{\delta \sqrt{N}}{\sigma} \right)$$

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2}{\delta^2} (Z_{\alpha/2} + Z_{\beta})^2$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{\delta\sqrt{N}}{\sigma} \right) + \Phi \left(-Z_{\alpha/2} - \frac{\delta\sqrt{N}}{\sigma} \right)$$

Q.6.7 Linear Regression : Difference of slopes

Use $\delta = \theta_t - \theta_c$, $TF = \frac{N_t}{N}$, $\sigma = \sigma_e \sqrt{\frac{(1-TF)*\sigma_{xc}^2 + (1-TF)*\sigma_{xt}^2}{\sigma_{xc}^2 \sigma_{xt}^2}}$

where

σ_{xc} = Std dev of X under control

σ_{xt} = Std dev of X under treatment

σ_e = Std dev of residuals

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$N = \frac{\sigma^2 (Z_{\alpha} + Z_{\beta})^2}{\delta^2 * TF * (1 - TF)}$$

$$Power = 1 - \Phi \left(Z_{\alpha} - \frac{|\delta| \sqrt{N * TF * (1 - TF)}}{\sigma} \right)$$

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$) Start with the initial solution as

$$N = \frac{\sigma^2 (Z_{\alpha/2} + Z_{\beta})^2}{\delta^2 * TF * (1 - TF)}$$

and solve using an iterative procedure following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{\delta\sqrt{N * TF * (1 - TF)}}{\sigma} \right) + \Phi \left(-Z_{\alpha/2} - \frac{\delta\sqrt{N * TF * (1 - TF)}}{\sigma} \right)$$

Q Technical Reference and Formulas: Single Look Designs

Q.6.8 Repeated measures: Difference of slopes

Use $\delta = \theta_t - \theta_c$, $TF = \frac{N_t}{N}$, $\sigma = \sqrt{\sigma_b^2 + \frac{12(M-1)\sigma_w^2}{M(M-1)S^2}}$ throughout the computation of power, sample size, alpha and delta.

Where

M = Number of measurements

S = Duration of follow up

σ_w = Within subject std. dev

σ_b = Between subject std. dev

σ_e = Std dev of residuals

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$N = \frac{\sigma^2(Z_\alpha + Z_\beta)^2}{\delta^2 * TF * (1 - TF)}$$

$$Power = 1 - \Phi \left(Z_\alpha - \frac{|\delta| \sqrt{N * TF * (1 - TF)}}{\sigma} \right)$$

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{\sigma^2(Z_{\alpha/2} + Z_\beta)^2}{\delta^2 * TF * (1 - TF)}$$

and solve using an iterative procedure using the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{\delta \sqrt{N * TF * (1 - TF)}}{\sigma} \right) + \Phi \left(-Z_{\alpha/2} - \frac{\delta \sqrt{N * TF * (1 - TF)}}{\sigma} \right)$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{|\delta|}{\sqrt{\hat{\pi}(1-\hat{\pi})\left(\frac{1}{n_t} + \frac{1}{n_c}\right)}} \right)$$

$$+ \Phi \left(-Z_{\alpha/2} - \frac{|\delta|}{\sqrt{\hat{\pi}(1-\hat{\pi})\left(\frac{1}{n_t} + \frac{1}{n_c}\right)}} \right)$$

- Two sided asymmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{(Z_{\alpha/2} + Z_{\beta})^2 \hat{\pi}(1-\hat{\pi})}{\delta^2 TF(1-TF)}$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\begin{aligned} Power = 1 - \Phi \left(Z_{\alpha_u} - \frac{|\delta|}{\sqrt{\hat{\pi}(1-\hat{\pi})\left(\frac{1}{n_t} + \frac{1}{n_c}\right)}} \right) \\ + \Phi \left(-Z_{\alpha_l} - \frac{|\delta|}{\sqrt{\hat{\pi}(1-\hat{\pi})\left(\frac{1}{n_t} + \frac{1}{n_c}\right)}} \right) \end{aligned}$$

Casagrande-Pike-Smith Correction

The Casagrande-Pike-Smith correction is applicable to Difference of Proportions - Superiority and Noninferiority. The correction is applicable in the case of equal allocation ratio only.

For the Alternative hypothesis $H_1 : \pi_t > \pi_c$ the corrected formula for sample size is

$$n_t = n_c = \frac{A \left[1 + \sqrt{1 + \frac{4(\pi_t - \pi_c)}{A}} \right]^2}{4(\pi_t - \pi_c)^2}$$

where

$$A = \left[Z_{1-\alpha} \sqrt{2\bar{\pi}(1-\bar{\pi})} + Z_{\beta} \sqrt{\pi_t(1-\pi_t) + \pi_c(1-\pi_c)} \right]^2$$

where

$$\bar{\pi} = \frac{\pi_t + \pi_c}{2}$$

Q.8.3 Two Independent Samples : Difference of Proportions: Noninferiority: Test Statistic Distribution: Normal

$$\delta = \mu_t - \mu_c$$

Q Technical Reference and Formulas: Single Look Designs

$$Z = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{\hat{\pi}_t(1-\hat{\pi}_t)}{n_t} + \frac{\hat{\pi}_c(1-\hat{\pi}_c)}{n_c}}}$$

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$Power = 1 - \Phi \left(Z_\alpha - \frac{|\delta - \delta_0|}{\sqrt{\frac{\hat{\pi}_t(1-\hat{\pi}_t)}{n_t} + \frac{\hat{\pi}_c(1-\hat{\pi}_c)}{n_c}}} \right)$$

$$N = \frac{(Z_\alpha + Z_\beta)^2 [(1 - TF) * \hat{\pi}_t(1 - \hat{\pi}_t) + TF * \hat{\pi}_c(1 - \hat{\pi}_c)]}{(\delta - \delta_0)^2 (1 - TF)}$$

Q.8.4 Two Independent Samples : Difference of Proportions: Equivalence: Test Statistic Distribution: Z

Effect Size: $\delta = \pi_t - \pi_c$,

δ_1 = Expected effect size,

δ_0 = Equivalence Margin,

$r = \frac{n_t}{N}$

$H_0 : |\pi_t - \pi_c| = \delta_0$ against $H_1 : |\pi_t - \pi_c| < \delta_0 > 0$

- Compute Sample Size

$$N = \frac{(Z_\alpha + Z_\beta)^2}{(\delta_0 - \delta_1)^2} \left(\frac{\pi_c(1 + \pi_c)}{1 - r} + \frac{(\pi_c - \delta_1)(1 - (\pi_c + \delta_1))}{r} \right)$$

Q.8.5 Two Independent Samples : Ratio of Proportions: Superiority: Test Statistic Distribution: Normal :Variance: Unpooled

$$\delta = \mu_t - \mu_c, TF = \frac{N_t}{N}$$

$$Z = \frac{\ln(\hat{\pi}_t) - \ln(\hat{\pi}_c)}{\sqrt{\frac{(1-\hat{\pi}_t)}{n_t \hat{\pi}_t} + \frac{(1-\hat{\pi}_c)}{n_c \hat{\pi}_c}}}$$

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$Power = 1 - \Phi \left(Z_{\alpha} - \frac{|\delta|}{\sqrt{\frac{(1-\hat{\pi}_t)}{n_t \hat{\pi}_t} + \frac{(1-\hat{\pi}_c)}{n_c \hat{\pi}_c}}} \right)$$

$$N = \frac{(Z_{\alpha} + Z_{\beta})^2}{\delta^2} \left[\frac{1 - \hat{\pi}_t}{TF \hat{\pi}_t} + \frac{1 - \hat{\pi}_c}{(1 - TF) \hat{\pi}_c} \right]$$

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{(Z_{\alpha/2} + Z_{\beta})^2}{\delta^2} \left[\frac{1 - \hat{\pi}_t}{TF \hat{\pi}_t} + \frac{1 - \hat{\pi}_c}{(1 - TF) \hat{\pi}_c} \right]$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\frac{\alpha}{2}} - \frac{|\delta|}{\sqrt{\frac{(1-\hat{\pi}_t)}{n_t \hat{\pi}_t} + \frac{(1-\hat{\pi}_c)}{n_c \hat{\pi}_c}}} \right) +$$

$$\Phi \left(-Z_{\frac{\alpha}{2}} - \frac{|\delta|}{\sqrt{\frac{(1-\hat{\pi}_t)}{n_t \hat{\pi}_t} + \frac{(1-\hat{\pi}_c)}{n_c \hat{\pi}_c}}} \right)$$

- Two sided asymmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{(Z_{\alpha/2} + Z_{\beta})^2}{\delta^2} \left[\frac{1 - \hat{\pi}_t}{TF \hat{\pi}_t} + \frac{1 - \hat{\pi}_c}{(1 - TF) \hat{\pi}_c} \right]$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha_u} - \frac{|\delta|}{\sqrt{\frac{(1-\hat{\pi}_t)}{n_t \hat{\pi}_t} + \frac{(1-\hat{\pi}_c)}{n_c \hat{\pi}_c}}} \right) + \Phi \left(-Z_{\alpha_l} - \frac{|\delta|}{\sqrt{\frac{(1-\hat{\pi}_t)}{n_t \hat{\pi}_t} + \frac{(1-\hat{\pi}_c)}{n_c \hat{\pi}_c}}} \right)$$

Q.8.11 Two Independent Samples : Common Odds Ratio for Stratified 2 × 2 tables: Superiority: Test Statistic Distribution: Normal

G = Total number of strata

$$\delta = G^{-1} \sum_{g=1}^G \left\{ \ln \left(\frac{\hat{\pi}_{tg}}{1 - \hat{\pi}_{tg}} \right) \right\} - \ln \left(\frac{\hat{\pi}_{tg}}{1 - \hat{\pi}_{tg}} \right)$$

Q Technical Reference and Formulas: Single Look Designs

$$Z = \frac{G^{-1} \sum_{g=1}^G \left\{ \ln\left(\frac{\hat{\pi}_{tg}}{1-\hat{\pi}_{tg}}\right) - \ln\left(\frac{\hat{\pi}_{cg}}{1-\hat{\pi}_{cg}}\right) \right\}}{\sqrt{G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1-\hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1-\hat{\pi}_{cg})} \right\}}}$$

where $\hat{\pi}_{tg}$ and $\hat{\pi}_{cg}$ are the sample proportions based on n_{tg} and n_{cg} observations seen in the treatment and control arms respectively of the g^{th} stratum.

- One sided (for both $\delta > 0$ and $\delta < 0$)

$$Power = 1 - \Phi \left(Z_{\alpha} - \frac{|\delta|}{\sqrt{G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1-\hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1-\hat{\pi}_{cg})} \right\}}} \right)$$

$$N = \frac{(Z_{\alpha} + Z_{\beta})^2}{\delta^2 \left(G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1-\hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1-\hat{\pi}_{cg})} \right\} \right)}$$

- Two sided symmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution

$$N = \frac{(Z_{\alpha/2} + Z_{\beta})^2}{\delta^2 \left(G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1-\hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1-\hat{\pi}_{cg})} \right\} \right)}$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$Power = 1 - \Phi \left(Z_{\alpha/2} - \frac{|\delta|}{\sqrt{G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1-\hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1-\hat{\pi}_{cg})} \right\}}} \right)$$

$$+ \Phi \left(-Z_{\alpha/2} - \frac{|\delta|}{\sqrt{G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1-\hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1-\hat{\pi}_{cg})} \right\}}} \right)$$

- Two sided asymmetric (for both $\delta > 0$ and $\delta < 0$)
Start with the initial solution as

$$N = \frac{(Z_{\alpha/2} + Z_{\beta})^2}{\delta^2 \left(G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1 - \hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1 - \hat{\pi}_{cg})} \right\} \right)}$$

and solve using an iterative procedure the following equation so that the computed power matches with the desired power with 1.e-6 precision.

$$\text{Power} = 1 - \Phi \left(Z_{\alpha_u} - \frac{|\delta|}{\sqrt{G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1 - \hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1 - \hat{\pi}_{cg})} \right\}}} \right) + \Phi \left(-Z_{\alpha_l} - \frac{|\delta|}{\sqrt{G^{-1} \sum_{g=1}^G \left\{ \frac{1}{n_{tg} \hat{\pi}_{tg} (1 - \hat{\pi}_{tg})} + \frac{1}{n_{cg} \hat{\pi}_{cg} (1 - \hat{\pi}_{cg})} \right\}}} \right)$$

Q.9 Sample Size
:Discrete : Many Samples

- Q.9.1 Single Arm: Chi-square
- Q.9.2 Two Group Chi-square
- Q.9.3 Wilcoxon Rank Sum
- Q.9.4 Multi-arm: Trend Test
- Q.9.5 Multi-arm: Chi-square for Rx2
- Q.9.6 Multi-arm: Chi-square: Rx C

Q.9.1 Many Samples: Single Arm: Chi-square for specified proportions in C categories

C= number of categories
Proportions under Ho : $\{p_{0i}; i = 1, 2, 3, \dots, c\}$
Proportions under H1 : $\{p_{1i}; i = 1, 2, 3, \dots, c\}$
Effect size

$$\Delta^2 = \sum_{i=1}^c \frac{(p_{0i} - p_{1i})^2}{p_{0i}}$$

Test statistic

$$\chi^2_{c-1} = N \Delta^2$$

- Compute power
Find $\chi^2_{c-1, \alpha}$ such that $P(\chi^2_{c-1} > \chi^2_{c-1, \alpha}) = \alpha$ from central Chisquare with c-1

Q Technical Reference and Formulas: Single Look Designs

degrees of freedom.

$Power = P_{\lambda}(\chi^2 > \chi_{c-1,\alpha}^2)$ where $Power = P_{\lambda}(\chi^2 > \chi_{c-1,\alpha}^2)$ is a non-central chi square variable with c-1 degree of freedom and non-centrality parameter λ .

$$\lambda = N \Delta^2$$

- Compute sample size
 N is determined using iterative method so that the power is maintained. If user has given allocation $\{r_i; i = 1, 2, 3, \dots, c\}$ N is divided into $\{N_i; i = 1, 2, 3, \dots, c\}$. These N_i s are rounded up to nearest integers and added up to get actual N.

Q.9.2 Many Samples: Parallel Design: Two group Chi-square for proportions in C categories

n_t = sample size on treatment arm

n_c = sample size on control arm

Proportions for treatment : $\{\pi_{tj}; j = 1, 2, 3, \dots, c\}$

Proportions for control : $\{\pi_{cj}; j = 1, 2, 3, \dots, c\}$

Effect size:

$$\Delta^2 = Q_1(1 - Q_1) \sum_{i=1}^c \frac{(\pi_{tj} - \pi_{cj})^2}{(\pi_{cj}(1 - Q_1) + \pi_{tj} Q_1)}$$

Where $Q_1 = \frac{n_t}{N} = \frac{n_t}{n_t + n_c}$

Noncentrality parameter λ

$$\lambda = N \Delta^2$$

- Compute Power
 Find $\chi_{c-1,\alpha}^2$ such that $P(\chi_{c-1}^2 > \chi_{c-1,\alpha}^2) = \alpha$ from central Chisquare with c-1 degrees of freedom.

$$Power = P_{\lambda}(\chi^2 > \chi_{c-1,\alpha}^2)$$

where χ^2 is a non-central chi square variable with c-1 degree of freedom and non-centrality parameter .

- Compute Sample Size
 For given power, N is determined using iterative method.

Q.9.3 Many Samples: Parallel Design: Wilcoxon Rank Sum for ordered categorical data

$\{\pi_{tj}; j = 1, 2, , \dots, c\}$ proportions for category j for treatment, $j=1,2,\dots,J$

$\{\pi_{cj}; j = 1, 2, , \dots, c\}$ proportions for category j for control, $j=1,2,\dots,J$

$$\gamma_{ci} = \sum_{j=1}^i \pi_{cj}$$

$$\gamma_{ti} = \sum_{j=1}^i \pi_{tj}$$

Effect Size

$$\psi = \ln(\gamma_{ci}) - \ln(1 - \gamma_{ci}) - (\ln(\gamma_{ti}) - \ln(1 - \gamma_{ti}))$$

$H_0 : \psi = 0$ Vs $H_1 : \psi \neq 0$ or $H_1 : \psi > 0$

m_i = multinomial samples $i=c, t$

x_{ij} = number of these m_i = observations that fall into the j th ordered category.

$$x_{cj} + x_{tj} = n_j; m_c + m_t = N$$

$$X_t = (x_{t1}, x_{t2}, \dots, x_{tC})$$

$$X_c = (x_{c1}, x_{c2}, \dots, x_{cC})n = (n_1, n_2, \dots, n_C);$$

Test Statistic:

- Wilcoxon Rank Sum

$$T = \sum_1^C w_j x_j$$

Asymptotic approximation for the exact conditional power is given by:

$$\beta(n) = 1 - \Phi \left(\frac{t_\alpha(n) - E(T|n, H_1)}{\sqrt{\text{var}(T|n, H_1)}} \right)$$

Where

$$t_\alpha(n) = E(T|n, H_0) - Z_\alpha \sqrt{\text{var}(T|n, H_0)}$$

For more details, the user is referred to Rabee et al (2003)

Q.9.4 Many Samples: Multi-arm: Trend in R ordered proportions

Case 1: User based Probabilities $r_i = i^{th}$ Population Fraction

$w_i = i^{th}$ Population Score

$\pi_i = i^{th}$ Proportion response

$$\bar{w} = \sum r_i w_i$$

Q Technical Reference and Formulas: Single Look Designs

$$\delta = \sum \pi_i r_i (w_i - \bar{w})$$

$$N_i = N * r_i$$

N_i = Population size for the i^{th} group

$$\pi = \sum r_i \pi_i$$

$$N = \sum N_i$$

$$\text{Var(Pooled)} = N\pi(1 - \pi) \sum r_i (w_i - \bar{w})^2$$

$$\text{Var(Unpooled)} = N \sum \pi_i(1 - \pi_i)r_i (w_i - \bar{w})^2$$

- One sided

$$\text{Power} = 1 - \Phi \left[\left(Z_\alpha - \frac{N * \delta}{\sqrt{\text{var(Pooled)}}} \right) \sqrt{\frac{\text{var(Pooled)}}{\text{var(UnPooled)}}} \right]$$

- Two sided

$$\text{Power} = 1 - \Phi \left[\left(Z_{\alpha/2} - \frac{N * \delta}{\sqrt{\text{var(Pooled)}}} \right) \sqrt{\frac{\text{var(Pooled)}}{\text{var(UnPooled)}}} \right] + \Phi \left[\left(-Z_{\alpha/2} - \frac{N * \delta}{\sqrt{\text{var(Pooled)}}} \right) \sqrt{\frac{\text{var(Pooled)}}{\text{var(UnPooled)}}} \right]$$

Case 2: Model based probabilities

In this case, our first aim is to compute the vector of proportion responses i.e., π_i and then apply the methods described above.

We have

$$\text{log of common odds ratio (K)} = \frac{\pi_i(1 - \pi_{i-1}) / (\pi_{i-1}(1 - \pi_i))}{W_i - W_{i-1}}$$

$$\frac{\pi_i}{(1 - \pi_i)} = \frac{\pi_{i-1}}{(1 - \pi_{i-1})} e^{K(W_i - W_{i-1})}$$

$$\pi_i = \frac{\frac{\pi_{i-1}}{(1 - \pi_{i-1})} e^{K(W_i - W_{i-1})}}{1 + \frac{\pi_{i-1}}{(1 - \pi_{i-1})} e^{K(W_i - W_{i-1})}}$$

Determine all π_i 's and then apply the steps mentioned in Case 1 to compute Power. Sample size computation is by iterating on the power function.

Q.9.5 Many Samples: Multi-arm: Chi-square for Rx2 proportions

R= number of groups
 n_t = sample size for the i^{th} arm

$$r_i = \frac{n_i}{n_1}$$

$$\pi_0 = \frac{\sum r_i \pi_i}{\sum r_i}$$

$$V = \frac{\sum r_i (\pi_i - \pi_0)^2}{\sum r_i}$$

Effect size:

$$\Delta^2 = \frac{V}{\pi_0(1 - \pi_0)}$$

Where $Q_1 = \frac{n_t}{N} = \frac{n_t}{n_t + n_c}$ Noncentrality parameter λ

$$\lambda = N \Delta^2$$

- Compute Power Find $x_{R-1,\alpha}^2$ such that $P(\chi_{R-1}^2 > \chi_{R-1,\alpha}^2) = \alpha$ from central Chisquare with c-1 degrees of freedom.

$$Power = P_{\lambda}(\chi^2 > \chi_{R-1,\alpha}^2)$$

where χ^2 is a non-central chi square variable with R-1 d.f. and non-centrality parameter λ .

- Compute Sample Size For given power, N is determined using iterative method.

Q.9.6 Many Samples: Multi-arm: Chi-square for proportions in RxC tables

R= number of groups (arms)
 C= number of categories
 n_i = sample size for the i^{th} arm
 $r_i = \frac{n_i}{n_1}$

π_{ij} = proportion of subjects belonging to the i^{th} group and j^{th} category. $i=1,2,\dots, R$, $j=1,2,\dots,C$

π_j = proportion in the j^{th} category.

Effect size:

$$\Delta^2 = \frac{\sum_{i=1}^R r_i \sum_{j=1}^C \frac{(\pi_{ij} - \pi_j)^2}{\pi_j}}{\sum r_i}$$

Q Technical Reference and Formulas: Single Look Designs

Noncentrality parameter: $\lambda = N\Delta^2$

- Compute Power
Find $\chi^2_{R-1,\alpha}$ such that $P(\chi^2_{(R-1)(C-1)} > \chi^2_{(R-1)(C-1),\alpha}) = \alpha$ from central Chisquare with $(R - 1)(C - 1)$ degrees of freedom.

$$Power = P_\lambda(\chi^2 > \chi^2_{(R-1)(C-1),\alpha})$$

where χ^2 is a non-central chi square variable with $(R - 1)(C - 1)$ degrees of freedom and non-centrality parameter λ .

- Compute Sample Size
For given power, N is determined using iterative method.

Q.10 Sample Size :Discrete : Regression

Q.10.1 Logistic Regression: Odds Ratio

Q.10.1 Logistic Regression: Odds Ratio

One Covariate

P_0 = Proportion successes of events at the mean value of the covariate, μ

P_1 = Proportion successes of events at the mean value of the covariate, $\mu + \sigma$

$$\theta = \text{Odds ratio} = \frac{P_1(1-P_0)}{P_0(1-P_1)}$$

- One sided
 - Compute Power

$$Power = \Phi \left[e^{\left(\frac{\eta^2}{4}\right)} \left(\sqrt{\frac{NP_0\eta^2}{[1 + 2P_0\delta]}} - Z_\alpha \right) \right]$$

where

$$\delta = \frac{1 + (1 + \eta^2)e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(-\frac{\eta^2}{4}\right)}}$$

$$\eta = \ln(\theta) \text{ and } Z_\alpha = \Phi^{-1}(1 - \alpha)$$

- Compute Sample Size

$$N = \frac{[Z_\alpha + Z_\beta e^{\left(-\frac{\eta^2}{4}\right)}]^2}{P_0\eta^2} [1 + 2P_0\delta]$$

where

$$\delta = \frac{1 + (1 + \eta^2) e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(\frac{-\eta^2}{4}\right)}}$$

$$\eta = \ln(\theta)$$

- Two Sided
 - Compute Power

$$Power = \Phi \left[e^{\left(\frac{\eta^2}{4}\right)} \left(\sqrt{\frac{NP_0\eta^2}{[1 + 2P_0\delta]}} - Z_{\alpha/2} \right) \right]$$

where

$$\delta = \frac{1 + (1 + \eta^2) e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(\frac{-\eta^2}{4}\right)}}$$

$$\eta = \ln(\theta) \text{ and } Z_{\alpha} = \Phi^{-1}(1 - \alpha).$$

- Compute Sample Size

$$N = \frac{\left[Z_{\alpha/2} + Z_{\beta} e^{\left(\frac{-\eta^2}{4}\right)} \right]^2}{P_0\eta^2} [1 + 2P_0\delta]$$

where

$$\delta = \frac{1 + (1 + \eta^2) e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(\frac{-\eta^2}{4}\right)}}$$

$$\eta = \ln(OR) = \ln(\theta)$$

More Than One Covariate

P_0 = Proportion successes of events at the mean value of the covariate, μ

P_1 = Proportion successes of events at the mean value of the covariate, $\mu + \sigma$

θ = odds ratio = $\frac{P_1(1-P_0)}{P_0(1-P_1)}$, ρ^2 = the square of multiple correlation coefficient (ρ) (between X_1 and other remaining covariate.)

- One sided
 - Compute Power

$$Power = \Phi \left[e^{\left(\frac{\eta^2}{4}\right)} \left(\sqrt{\frac{NP_0\eta^2(1 - \rho^2)}{[1 + 2P_0\delta]}} - Z_{\alpha} \right) \right]$$

Q Technical Reference and Formulas: Single Look Designs

where

$$\delta = \frac{1 + (1 + \eta^2)e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(-\frac{\eta^2}{4}\right)}}$$

$$\eta = \ln(\theta) \text{ and } Z_\alpha = \Phi^{-1}(1 - \alpha)$$

– Compute Sample Size

$$N = \frac{N_1}{(1 - \rho^2)}$$

where

$$N_1 = \frac{\left[Z_\alpha + Z_\beta e^{\left(-\frac{\eta^2}{4}\right)} \right]^2}{P_0 \eta^2} [1 + 2P_0 \delta]$$

and

$$\delta = \frac{1 + (1 + \eta^2)e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(-\frac{\eta^2}{4}\right)}}$$

$$\eta = \ln(\theta)$$

■ Two Sided

– Compute Power

$$Power = \Phi \left[e^{\left(\frac{\eta^2}{4}\right)} \left(\sqrt{\frac{NP_0 \eta^2 (1 - \rho^2)}{[1 + 2P_0 \delta]}} - Z_{\alpha/2} \right) \right]$$

where

$$\delta = \frac{1 + (1 + \eta^2)e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(-\frac{\eta^2}{4}\right)}}$$

$$\eta = \ln(\theta)$$

– Compute Sample Size

$$N = \frac{N_1}{(1 - \rho^2)}$$

where

$$N_1 = \frac{\left[Z_{\alpha/2} + Z_\beta e^{\left(-\frac{\eta^2}{4}\right)} \right]^2}{P_0 \eta^2} [1 + 2P_0 \delta]$$

and

$$\delta = \frac{1 + (1 + \eta^2)e^{\left(\frac{5\eta^2}{4}\right)}}{1 + e^{\left(-\frac{\eta^2}{4}\right)}}$$

Q.11 Sample Size : Agreement

Q.11.1 Cohen's Kappa: Two Binary Ratings

Q.11.2 Cohen's Kappa: Two Categorical Ratings

Q.11.1 Cohen's Kappa: Two Binary Ratings

π_{ij} = Proportion of population given rating i by Rater 1 and j by Rater 2.

K_0 = Kappa under Null,

K_1 = Kappa under Alternative

- One Sided

$$Power = \Phi \left(\frac{\sqrt{N_1}(|K_1 - K_0|) - Z_\alpha \sqrt{Q_0}}{\sqrt{Q_1}} \right)$$

where

$$Q_1 = \sum_i \pi_{ii} [(1 - \pi_c) - (\pi_{i.} + \pi_{.i})(1 + \pi_0)]^2$$

- Compute Sample Size

$$N = \left[\frac{Z_\alpha \sqrt{Q_0} + Z_\beta \sqrt{Q_1}}{K_1 - K_0} \right]^2$$

- Two Sided

$$Power = \Phi \left(\frac{\sqrt{N_1}(|K_1 - K_0|) - Z_{\alpha/2} \sqrt{Q_0}}{\sqrt{Q_1}} \right)$$

Where

$$Q_1 = \sum_i \pi_{ii} [(1 - \pi_c) - (\pi_{i.} + \pi_{.i})(1 + \pi_0)]^2$$

- Compute Sample Size

$$N = \left[\frac{Z_\alpha \sqrt{Q_0} + Z_\beta \sqrt{Q_1}}{K_1 - K_0} \right]^2$$

Q.11.2 Agreement: Cohen's Kappa: Two Categorical Ratings

C = Number of ratings

π_0 = Proportion of agreement

Q Technical Reference and Formulas: Single Look Designs

- π_e = Expected proportion of agreement
- π_{ij} = Proportion of population given rating i by Rater 1 and j by Rater 2.
- K_0 = Kappa under Null
- K_1 = Kappa under Alternative

- Compute Power

$$Power = \Phi \left(\frac{\sqrt{N}(K_1 - K_0) - Z_{1-\alpha} \max \tau(\hat{k}|k = 0.4)}{\max \tau(\hat{k}|k = 0.6)} \right)$$

where

$$\tau(\hat{k}) = \frac{\sqrt{Q_1 + Q_2 - 2Q_3 - Q_4}}{(1 - \pi_e)^2}$$

$$Q_1 = \pi_0 (1 - \pi_e)^2$$

$$Q_2 = (1 - \pi_0)^2 \sum_i \sum_j \pi_{ij} (\pi_{i.} + \pi_{.j})^2$$

$$Q_3 = 2(1 - \pi_0)(1 - \pi_e) \sum_i \pi_{ij} (\pi_{i.} + \pi_{.j})$$

$$Q_4 = (\pi_0 \pi_e - 2\pi_e + \pi_0)^2$$

- Compute Sample Size

$$N \geq \left(\frac{Z_{1-\alpha} \max \tau(\hat{k}|k = k_0) + Z_{1-\beta} \max \tau(\hat{k}|k = k_1)}{k_1 - k_0} \right)^2$$

Ref : Flack, V.F., et. Al. (1988).

**Q.12 Sample Size :
Count Data**

Q.12.1 One Sample: Single Poisson rate

Q.12.2 Two Samples: Ratio of Poisson Rates

Q.12.3 Ratio of Negative Binomial Rates

Q.12.1 One Sample: Single Poisson rate

X : No. of events (outcomes) observed during an interval of specified length.

D = Exposure Duration (This could be time, length, volume, area etc)

$X \sim \text{Poisson}(\lambda D)$

λ = Poisson rate (mean number of occurrences of X during a unit length interval)

λ_0 = Hypothesized value of λ

λ_1 = Value of λ at which Power is to be computed.

n = sample size = Number of times observations on X taken over the Exposure duration D

$G(.,k)$ denote the CDF of chi square distribution with k d.f.

- One sided test (right tailed)

$$H_0 : \lambda = \lambda_0 \text{ Vs } H_1 : \lambda = \lambda_0$$

- Compute Power

1. Find 'k' such that

$$G(2nD \lambda_0; 2k) \leq \alpha \tag{Q.1}$$

2. Compute

$$\text{Power} = 1 - F(k - 1, nD \lambda_1) = G(2nD \lambda_1; 2k) \tag{Q.2}$$

where k is obtained from equation Q.1.

- Compute sample size

Solve equation (Q.1) and equation (Q.2) simultaneously for n and k .

- One sided test (left tailed)

$$H_0 : \lambda = \lambda_0 \text{ VS } H_1 : \lambda < \lambda_0$$

- Compute Power

1. Find 'k' such that

$$G(2nD \lambda_0; 2(k + 1)) \geq 1 - \alpha \tag{Q.3}$$

2. Compute

$$\text{Power} = 1 - G(2nD \lambda_1; 2(k + 1)) \tag{Q.4}$$

where k is obtained from equation

Q Technical Reference and Formulas: Single Look Designs

- Compute sample size Solve equation (Q.3) and equation (Q.4) simultaneously for n and k.

- Two sided test

$$H_0 : \lambda = \lambda_0 \text{ Vs } H_1 : \lambda \neq \lambda_0$$

For carrying out a two sided design,(compute power and sample size and duration) compute

$$\alpha' = \frac{\alpha}{2}$$

Execute the algorithm for one sided (right or left depending upon the sign of the difference $\lambda_1 - \lambda_0$) with α' as the value of level of significance, α .

Q.12.2 Two Samples: Ratio of Poisson Rates

- λ_c : Poisson rate for control arm
 λ_t : Poisson rate for treatment arm
 D_t : Duration of study for the treatment arm
 D_c : Duration of study for the control arm
 X_t : No of events (outcomes) observed on Treatment arm in time D_t
 $X_t \sim \text{Poisson}(\lambda_t D_t)$
 X_c : No of events (outcomes) observed on Control arm in time D_c
 $X_c \sim \text{Poisson}(\lambda_c D_c)$
 n_t : Number of observations on Treatment arm
 n_c : Number of observations on Control arm
 $r = \frac{n_t}{n_c}$ allocation ratio
 $d = \frac{D_c n_c}{D_t n_t}$
 $\rho_0 =$ Hypothecated value of the ratio, $\frac{\lambda_t}{\lambda_c}$
 $\rho_1 =$ value of the ratio at which the power is to be computed

- One sided test (right tailed)
 $H_0 : \frac{\lambda_t}{\lambda_c} > \rho_0 \geq 1 \text{ Vs } H_1 : \frac{\lambda_t}{\lambda_c} = \rho_0$
 $H_1 : \frac{\lambda_t}{\lambda_c} = \rho_1$
 where $\rho_1 > \rho_0$
 Test Statistic

$$W_3 = \frac{\ln\left(\frac{X_t}{X_c}\right) - \ln\left(\frac{\rho_0}{d}\right)}{\sqrt{\frac{1}{X_t} + \frac{1}{X_c}}}$$

In case X_t or $X_c = 0$, the value is set to 0.5 for that variable.

- Compute Power

$$Power = 1 - \Phi\left(Z_{1-\alpha} - \frac{\mu}{\sigma}\right) \tag{Q.5}$$

where $\mu = \ln\left(\frac{\rho_1}{\rho_0}\right)$ and $\sigma^2 = \frac{d + \rho_1}{D_c n_c \lambda_c \rho_1}$

- Compute Sample Size
Solve equation (Q.5) for n_c by using the following algorithm.

1. Compute

$$\sigma^2 = \left[\frac{\ln\left(\frac{\rho_1}{\rho_0}\right)}{Z_{1-\alpha} - \Phi^{-1}(1 - power)} \right]^2$$

2. Compute

$$n_c = \frac{d + \rho_1}{D_c \sigma^2 \lambda_c \rho_1}$$

3. Compute

$$n_t = r * n_c$$

$$n = n_t + n_c$$

- One sided test (left tailed)

$$H_0 : \frac{\lambda_t}{\lambda_c} = \rho_0 \geq 1 \text{ Vs } H_1 : \frac{\lambda_t}{\lambda_c} < \rho_0$$

$$H_1 : \frac{\lambda_t}{\lambda_c} = \rho_1$$

Where $\rho_1 < \rho_0$

$$Power = \Phi\left(Z_\alpha - \frac{\mu}{\sigma}\right) \tag{Q.6}$$

Where $\mu = \ln\left(\frac{\rho_1}{\rho_0}\right)$ and $\sigma^2 = \frac{d + \rho_1}{D_c n_c \lambda_c \rho_1}$ In case X_t or $X_c = 0$, the value is set to 0.5 for that variable.

- Compute Sample Size
Solve equation (Q.6) for n_c by using the following algorithm.

1. Compute

$$\sigma^2 = \left[\frac{\ln\left(\frac{\rho_1}{\rho_0}\right)}{Z_\alpha - \Phi^{-1}(1 - power)} \right]^2$$

2. Compute

$$n_c = \frac{d + \rho_1}{D_c \sigma^2 \lambda_c \rho_1}$$

Q Technical Reference and Formulas: Single Look Designs

3. Compute

$$n_t = r * n_c$$

$$n = n_t + n_c$$

■ Two Sided Test

$$H_0 : \frac{\lambda_t}{\lambda_c} = \rho_0 \geq 1 \text{ Vs } H_1 : \frac{\lambda_t}{\lambda_c} \neq \rho_0$$

Depending upon the ratio of rates > 1 or < 1 , use the power computation formula for $\rho_1 > \rho_0$ or $\rho_1 < \rho_0$ as the case may be with α replaced by $\frac{\alpha}{2}$.

Q.12.3 Two Samples: Ratio of Negative Binomial Rates

$$X_c \sim NB(\lambda_c, \Upsilon_c)$$

$$X_t \sim NB(\lambda_t = \theta\lambda_c, \Upsilon_t) \quad \theta = \frac{\lambda_t}{\lambda_c} \quad u = \text{Fixed follow up } k = \text{Allocation Ratio} \\ = n_t/n_c$$

■ One sided test (Left tailed)

$$H_0 : \theta = 1 \text{ Vs } H_1 : \theta < 1$$

– Compute power

$$\text{Power} = \Phi(E_\theta - z_\alpha)$$

$$\text{Where } E_\theta = \text{Test statistic} = -\sqrt{n_c} \frac{\ln(\hat{\theta})}{\sqrt{\frac{1+\gamma_c \lambda_c u}{\lambda_c \mu} + \frac{1+\gamma_t \lambda_c \theta u}{k \lambda_c \theta u}}}$$

$$A = \frac{1}{[\ln(\hat{\theta})]^2} \left[\sqrt{\frac{1 + \gamma_c \lambda_c u}{\lambda_c \mu} + \frac{1 + \gamma_t \lambda_c \theta u}{k \lambda_c \theta u}} \right]$$

– Compute Sample Size

$$n = A(z_\alpha + z_\beta)^2(1 + k)$$

■ One sided test (Right tailed)

$$H_0 : \theta = 1 \text{ Vs } H_1 : \theta > 1$$

– Compute Power

$$\text{Power} = \Phi(E_\theta - (-1 * z_\alpha))$$

- Compute Sample Size

$$n = A((-1 * z_{\alpha}) + z_{\beta})^2(1 + k)$$

- Two sided test
 $H_0 : \theta = 1$ Vs. $H_1 : \theta \neq 1$

- Compute Power

$$Power = 1 - \Phi(E_{\theta} - (-1 * z_{\alpha/2})) + \Phi(E_{\theta} - z_{\alpha/2})$$

- Compute Sample Size

$$n = A(z_{\alpha/2} + z_{\beta})^2(1 + k)$$

Q.13 Sample Size :Time to Event Data

Q.13.1 Two Samples: Superiority: Logrank

Effect Size: $\delta = \ln\left(\frac{\lambda_t}{\lambda_c}\right)$ where λ_t and λ_c are hazard rates for treatment and control arms respectively. In Time to event studies, maximum number of events are determined for given power.

$H_0: \delta = 0$ Vs $H_1: \delta = \delta_1$

Test Statistic (Log Rank) Suppose at the end of study, in all q failures are observed with failure times $\tau_1, \tau_2, \dots, \tau_i, \dots, \tau_q$. Accordingly, there will be q 2x2 tables of the following type.

The i^{th} table is shown below:

Where the subscripts t and c indicate values observed under treatment and control.

$$S = \sum_{i=1}^q \left\{ d_t(\tau_i) - \frac{n_t(\tau_i) d_t(\tau_i)}{n(\tau_i)} \right\}$$

Q Technical Reference and Formulas: Single Look Designs

| Status | Treatment T | Treatment C | Total |
|------------|-----------------------------|-----------------------------|-------------------------|
| Failed | $d_t(\tau_i)$ | $d_c(\tau_i)$ | $d(\tau_i)$ |
| Not Failed | $n_t(\tau_i) - d_t(\tau_i)$ | $n_c(\tau_i) - d_c(\tau_i)$ | $n(\tau_i) - d(\tau_i)$ |
| Total | $n_t(\tau_i)$ | $n_c(\tau_i)$ | $n(\tau_i)$ |

$$S \sim AN(\text{Mean} = \delta D_{\max} r(1 - r), \text{Variance} = r(1 - r) D_{\max})$$

Where r= proportion randomized to treatment T .

- One sided test (Variance under Null)

$$D_{\max} = \frac{(Z_{\alpha} + Z_{\beta})^2}{\delta_1^2 r(1 - r)}$$

- One sided test (Variance under Alternative)

$$D_{\max} = \frac{(Z_{\alpha} + Z_{\beta})^2}{\delta_1^2 p(1 - p)}$$

where p=proportion of D_{\max} estimated to be on the experimental arm under the alternative hypothesis. East uses an iterative procedure to estimate p.

- Two sided test (Variance under Null)

$$D_{\max} = \frac{(Z_{\alpha/2} + Z_{\beta})^2}{\delta_1^2 r(1 - r)}$$

- Two sided test (Variance under Alternative)

$$D_{\max} = \frac{(Z_{\alpha/2} + Z_{\beta})^2}{\delta_1^2 p(1 - p)}$$

where p=proportion of D_{\max} estimated to be on the experimental arm under the alternative hypothesis. East uses an iterative procedure to estimate p.

Q.13.2 Two Samples: Noninferiority: Logrank

Effect Size: $\delta = \ln\left(\frac{\lambda_t}{\lambda_c}\right)$ where λ_t and λ_c are hazard rates for treatment and control arms respectively. In Time to event studies, maximum number of events are determined for given power.

H0: $\delta > \delta_0$ Vs H1: $\delta < \delta_0$

Test Statistic (Log Rank)

Suppose at the end of study, in all q failures are observed with failure times $\tau_1, \tau_2, \dots, \tau_i, \dots, \tau_q$. Accordingly, there will be q 2x2 tables of the following type. The i^{th} table is shown below:

| Status | Treatment T | Treatment C | Total |
|------------|-----------------------------|-----------------------------|-------------------------|
| Failed | $d_t(\tau_i)$ | $d_c(\tau_i)$ | $d(\tau_i)$ |
| Not Failed | $n_t(\tau_i) - d_t(\tau_i)$ | $n_c(\tau_i) - d_c(\tau_i)$ | $n(\tau_i) - d(\tau_i)$ |
| Total | $n_t(\tau_i)$ | $n_c(\tau_i)$ | $n(\tau_i)$ |

Where the subscripts t and c indicate values observed under treatment and control.

$$S = \sum_{i=1}^q \left\{ d_t(\tau_i) - \frac{n_t(\tau_i) d(\tau_i)}{n(\tau_i)} \right\} - \delta_0$$

$$S \sim AN(\text{Mean} = \delta D_{\max} r(1-r) - \delta_0, \text{Variance} = r(1-r) D_{\max})$$

Where r= proportion randomized to treatment T

δ_0 = Noninferiority margin.

- One sided test (Variance under Null and Alternative both)

$$D_{\max} = \frac{(Z_\alpha + Z_\beta)^2}{(\delta_1 - \delta_0)^2 r(1-r)}$$

R Technical Reference and Formulas: Analysis

In this Appendix, we provide the theory used in **East 6.4** for analyzing data under the **Analysis** menu.

Note: The test statistics formulas provided in this Appendix can be used in interim analysis of data while monitoring a group sequential study or for analyzing data arising out of a single sample study. For common notations and references the user is referred to the Technical Reference and Formulas:Single Look Designs or the respective chapters of the tests.

R.1 Basic Statistics- Descriptive Statistics

R.1.1 Central Tendency

R.1.2 Dispersion

R.1.3 Distribution

R.1.4 Summary

R.1.1 Central Tendency

Mean If $X_i, i = 1, 2, \dots, n$ are n observations, then the mean \bar{X} is defined as

$$\bar{X} = \frac{1}{n} \sum_{i=1}^n X_i \tag{R.1}$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then the mean \bar{X} is defined as

$$\bar{X} = \frac{1}{\sum_{i=1}^n f_i} \sum_{i=1}^n X_i f_i \tag{R.2}$$

Median: Median is the value of the middle most observation, when the observations are arranged in ascending or descending order. If the number of observations is even, then the median is defined as the mean of the middle most two observations.

Mode: Mode is the value of X_i with the maximum frequency f_i . If there are more than one X_i with maximum frequency, then the smallest of all such X_i 's will be used as the value of mode.

Geometric Mean: If $X_i, i = 1, 2, \dots, n$ are n observations, then the geometric mean GM is defined as

$$GM = \left[\prod_{i=1}^n X_i \right]^{\frac{1}{n}} \tag{R.3}$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then the geometric mean GM is defined as

$$GM = \left[\prod_{i=1}^n X_i^{f_i} \right]^{\frac{1}{\sum f_i}} \quad (R.4)$$

Harmonic Mean If $X_i, i = 1, 2, \dots, n$ are n observations, then the harmonic mean HM is defined as

$$HM = \frac{n}{\sum_{i=1}^n \frac{1}{X_i}} \quad (R.5)$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then the harmonic mean HM is defined as

$$HM = \frac{\sum_{i=1}^n f_i}{\sum_{i=1}^n \frac{f_i}{X_i}} \quad (R.6)$$

R.1.2 Dispersion

Standard Deviation If $X_i, i = 1, 2, \dots, n$ are n observations, then the standard deviation is defined as

$$s = \left[\frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2 \right]^{0.5} \quad (R.7)$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then the standard deviation is defined as

$$s = \left[\frac{1}{\sum_{i=1}^n f_i - 1} \sum_{i=1}^n (X_i - \bar{X})^2 f_i \right]^{0.5} \quad (R.8)$$

Standard Error of Mean If $X_i, i = 1, 2, \dots, n$ are n observations and s is the standard deviation, then the standard error of mean is defined as

$$SE = \frac{s}{\sqrt{n}} \quad (R.9)$$

R Technical Reference and Formulas: Analysis

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then the standard error of mean is defined as

$$SE = \frac{s}{\sqrt{\sum_{i=1}^n f_i}} \quad (R.10)$$

Variance Variance is defined as the square of the standard deviation and is denoted as s^2 .

Coefficient of variation If \bar{x} and s are the mean and standard deviation respectively, then Coefficient of Variation is defined as follows:

$$CV = \frac{\bar{X}}{s} \quad (R.11)$$

Minimum is the minimum value of $X_i, i = 1, 2, \dots, n$.

Maximum is the maximum value of $X_i, i = 1, 2, \dots, n$.

Range is calculated as the difference: Maximum-Minimum.

R.1.3 Distribution

Skewness If $X_i, i = 1, 2, \dots, n$ are n observations, then a measure of skewness is defined as

$$skewness = \frac{\frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^3}{\left(\frac{(n-1)}{n} s^2\right)^{(3/2)}} \quad (R.12)$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then a measure of skewness is defined as

$$skewness = \frac{\frac{1}{\sum_{i=1}^n f_i} \sum_{i=1}^n (X_i - \bar{X})^3 f_i}{\left(\frac{(n-1)}{n} s^2\right)^{(3/2)}} \quad (R.13)$$

For normal distribution, skewness is zero and for any symmetric data, the value of skewness should be zero or close to zero. A negative value of skewness indicates that the data are skewed to the left or the left tail is heavier than the right tail. A positive value of skewness can be interpreted in a similar way.

Kurtosis If $X_i, i = 1, 2, \dots, n$ are n observations, then a measure of kurtosis is defined as

$$Kurtosis = \frac{\frac{1}{n} \sum_{i=1}^n (X_i - \bar{X})^4}{\left(\frac{(n-1)}{n} s^2\right)^2} - 3 \quad (R.14)$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then a measure of kurtosis is defined as

$$Kurtosis = \frac{\frac{1}{\sum_{i=1}^n f_i} \sum_{i=1}^n (X_i - \bar{X})^4 f_i}{\left(\frac{(n-1)}{n} s^2\right)^2} - 3 \quad (\text{R.15})$$

The standard normal distribution has a kurtosis of 3. A kurtosis value > 3 indicates a relatively **peaked** distribution and a value < 3 indicates relatively **flat** distribution of the data.

R.1.4 Summary

Sum If $X_i, i = 1, 2, \dots, n$ are n observations, then sum is defined as

$$Sum = \sum_{i=1}^n X_i \quad (\text{R.16})$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then sum is defined as

$$Sum = \sum_{i=1}^n X_i f_i \quad (\text{R.17})$$

Count If $X_i, i = 1, 2, \dots, n$ are n observations, then Count is defined as

$$Count = n \quad (\text{R.18})$$

Further if f_i is the frequency or weight for $X_i, i = 1, 2, \dots, n$, then Count is defined as

$$Count = \sum_{i=1}^n f_i \quad (\text{R.19})$$

R.2.4 Spearman's Rank-Order Correlation

R.2.5 Multiple Linear Regression

R.2.6 Collinearity Diagnostics

R.2.7 Multivariate Analysis of Variance

R.2.1 Independent t-test

Equal variance

If x_1, x_2, \dots, x_{n_x} is a random sample from a normal population with mean μ_x and standard deviation σ_x and y_1, y_2, \dots, y_{n_y} is a random sample from a normal population with mean μ_y and standard deviation σ_y , we want to test null hypothesis:

$$H_0: \mu_x = \mu_y \text{ under the assumption } \sigma_x = \sigma_y$$

The test statistic is:

$$t = \frac{\bar{x} - \bar{y}}{s \sqrt{\frac{1}{n_x} + \frac{1}{n_y}}} \tag{R.20}$$

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i, \quad \text{and} \quad \bar{y} = \frac{1}{n} \sum_{i=1}^n y_i \tag{R.21}$$

and s is the pooled standard deviation.

$$s = \sqrt{\frac{(n_x - 1)s_x^2 + (n_y - 1)s_y^2}{n_x + n_y - 2}} \tag{R.22}$$

The above statistic is distributed as t with $(n_x + n_y - 2)$ degrees of freedom.

Unequal variance

If x_1, x_2, \dots, x_{n_x} is a random sample from a normal population with mean μ_x and standard deviation σ_x and y_1, y_2, \dots, y_{n_y} is a random sample from a normal population with mean μ_y and standard deviation σ_y , we want to test null hypothesis:

$$H_0: \mu_x = \mu_y \text{ under the assumption } \sigma_x \neq \sigma_y$$

The testing procedure uses the approximation described by Scheffe (1970) as follows:.

$$t = \frac{\hat{\delta}}{\sqrt{\frac{S_y^2}{n_y} + \frac{S_x^2}{n_x}}} \sim t_\nu \tag{R.23}$$

where ν is the degrees of freedom given by

$$\nu = \frac{\left(\frac{S_y^2}{n_y} + \frac{S_x^2}{n_x}\right)^2}{\frac{\left(\frac{S_y^2}{n_y}\right)^2}{n_y - 1} + \frac{\left(\frac{S_x^2}{n_x}\right)^2}{n_x - 1}} \tag{R.24}$$

R.2.2 Paired t-test

If $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ are n paired observations, we would like to test the hypothesis that the differences $d_1 = x_1 - y_1, d_2 = x_2 - y_2, \dots, d_n = x_n - y_n$ come from a normal distribution with mean 0. If μ is the population mean of the differences, then we want to test null hypothesis:

$$H_0: \mu = 0.$$

The test statistic is

$$t = \frac{\bar{d}}{s/\sqrt{n}} \tag{R.25}$$

where

$$\bar{d} = \frac{1}{n} \sum_{i=1}^n d_i \tag{R.26}$$

$$s = \sqrt{\frac{1}{n-1} \sum_{i=1}^n (d_i - \bar{d})^2} \tag{R.27}$$

This statistic is distributed as t with degrees of freedom (n-1).

R.2.3 Analysis of Variance

One-way Analysis of Variance: Suppose n subjects have been allocated randomly to r treatments and measurements have been made on a variate x for all the subjects, with the resulting data being denoted as follows:

Treatment 1: $x_{11}, x_{12}, \dots, x_{1n_1}$

Treatment 2: $x_{21}, x_{22}, \dots, x_{2n_2}$

⋮

Treatment r: $x_{r1}, x_{r2}, \dots, x_{rn_r}$

We assume that the data of the r treatment groups come from r normally distributed populations with the same variance σ^2 and with means $\mu_1, \mu_2, \dots, \mu_r$. We want to test the hypothesis that these means are equal:

$$H_0 : \mu_1 = \mu_2 = \dots = \mu_r \tag{R.28}$$

The sum of squares is

$$S = \sum_{i=1}^r \sum_{k=1}^{n_i} (x_{ik} - \bar{x})^2, \tag{R.29}$$

R Technical Reference and Formulas: Analysis

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^r \sum_{k=1}^{n_i} x_{ik} = \frac{1}{n} \sum_{i=1}^r n_i \bar{x}_i, \tag{R.30}$$

$$\bar{x}_i = \frac{1}{n_i} (x_{i1} + x_{i2} + \dots + x_{in_i}) \tag{R.31}$$

and

$$n = \sum_{i=1}^r n_i. \tag{R.32}$$

We decompose the “sum of squares” S into two parts S_1 and S_2 ,

$$S = S_1 + S_2 \tag{R.33}$$

where

$$S_1 = \sum_{i=1}^r n_i (\bar{x}_i - \bar{x})^2 \tag{R.34}$$

$$S_2 = \sum_{i=1}^r \sum_{k=1}^{n_i} (x_{ik} - \bar{x}_i)^2. \tag{R.35}$$

S_1 refers to the variation between the treatments and S_2 the variation within treatments. The ratio,

$$F = \frac{S_1/(r-1)}{S_2/(n-r)} \tag{R.36}$$

follows F distribution with (r-1, n-r) degrees of freedom. All these computations can be displayed in the usual ANOVA table as shown below:

ANOVA Table Two-way Analysis of Variance: In a two-way experimental design,

| Source of Variation | Sum of Squares | Degrees of Freedom | Mean Square | F | P-Value |
|---------------------|----------------|--------------------|-------------------|-----------|---------|
| Between groups | S_1 | r-1 | $M_1 = S_1/(r-1)$ | M_1/M_2 | |
| Residuals | S_2 | n-r | $M_2 = S_2/(n-r)$ | | |
| Total | S | n-1 | | | |

there are two factors: A and B, with A having levels A_1, A_2, \dots, A_a and B having levels B_1, B_2, \dots, B_b . Suppose there are c observations for each combination of the factor levels A_i and B_j , then the data from such a study can be represented as:

$(x_{ijk}, i = 1, \dots, a, j = 1, \dots, b, k = 1, \dots, c)$ where the subscript i refers to level A_i of factor A, j refers to level B_j of factor B and k refers to k^{th} observation for the

combination of A_i and B_j . We assume that the number of replications for each combination of i and j is equal to c .

We assume that $n = abc$ observations x_{ijk} correspond to n random variables which are independent and are distributed normally with the same variance σ^2 . We want to test the hypotheses that:

- the means of A at all the a levels are same
- the means of B at all the b levels are same

For carrying out these tests, we proceed as follows: We decompose the total "sum of squares"

$$S = \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c (x_{ijk} - \bar{x})^2 \tag{R.37}$$

into three parts S_1 , S_2 , and S_3 ,

$$S = S_1 + S_2 + S_3 \tag{R.38}$$

where

$$S_1 = bc \sum_{i=1}^a (x_{i..} - \bar{x})^2 \tag{R.39}$$

refers to the sum of squares due to the variation between the levels of A,

$$S_2 = ac \sum_{j=1}^b (x_{.j.} - \bar{x})^2 \tag{R.40}$$

refers to the sum of squares due to the variation between the levels of B, and

$$S_3 = \sum_{i=1}^a \sum_{j=1}^b \sum_{k=1}^c (x_{ijk} - \bar{x}_{i..} - \bar{x}_{.j.} - \bar{x})^2 \tag{R.41}$$

refers to the sum of squares due to the residual variation. Under the null hypothesis, the quantities $\frac{1}{(a-1)}S_1$, $\frac{1}{(b-1)}S_2$ and $\frac{1}{(n-a-b+1)}S_3$ have χ^2 distribution with $(a - 1)$, $(b - 1)$ and $(abc - a - b + 1)$ degrees of freedom respectively. From this it follows that the quantity

$$f_1 = \frac{S_1/(a-1)}{S_3/(abc-a-b+1)} \tag{R.42}$$

R Technical Reference and Formulas: Analysis

follows F-distribution with $(a - 1, n - a - b + 1)$ degrees of freedom and the quantity

$$f_2 = \frac{S_2/(b - 1)}{S_3/(abc - a - b + 1)} \tag{R.43}$$

follows F-distribution with $(b - 1, n - a - b + 1)$ degrees of freedom. All these computations are displayed in the usual ANOVA table as shown below:

ANOVA Table

| Source of Variation | Sum of Squares | Degrees of Freedom | Mean Square | F | P-Value |
|---------------------|----------------|--------------------|-------------------------|-----------|---------|
| Factor A | S_1 | a-1 | $M_1 = S_1/(a-1)$ | M_1/M_3 | |
| Factor B | S_2 | b-1 | $M_2 = S_1/(b-1)$ | M_2/M_3 | |
| Residuals | S_3 | abc-a-b+1 | $M_3 = S_3/(abc-a-b+1)$ | | |
| Total | S | n-1 | | | |

R.2.4 Correlations

Pearson's Product-Moment Correlation Coefficient

Let $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ be the n paired observations of two continuous random variables x and y . The Pearson product-moment correlation coefficient is a measure of association for these two variables. The formula for the Pearson product-moment correlation coefficient is

$$r_{xy} = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2}} \tag{R.44}$$

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i, \quad \text{and} \quad \bar{y} = \frac{1}{n} \sum_{i=1}^n y_i \tag{R.45}$$

If f_i is the frequency or weight for the i^{th} paired observation (x_i, y_i) , then the formula for Pearson product-moment correlation coefficient can be written as:

$$r_{xy} = \frac{\sum_{i=1}^n (x_i - \bar{x})(y_i - \bar{y}) f_i}{\sqrt{\sum_{i=1}^n (x_i - \bar{x})^2 f_i} \sqrt{\sum_{i=1}^n (y_i - \bar{y})^2 f_i}} \tag{R.46}$$

where

$$\bar{x} = \frac{1}{\sum_{i=1}^n f_i} \sum_{i=1}^n x_i f_i, \quad \text{and} \quad \bar{y} = \frac{1}{\sum_{i=1}^n f_i} \sum_{i=1}^n y_i f_i. \quad (\text{R.47})$$

Spearman’s Rank-Order Correlation Coefficient

If we are reluctant to make the assumption of bivariate normality, we may use Spearman’s rank-order correlation coefficient instead of Pearson’s product-moment correlation coefficient. The only difference between the two measures of association is that Pearson’s measure uses the raw data whereas Spearman’s uses ranks derived from the raw data. Spearman’s rank-order correlation coefficient can be computed by substituting the ranks of x_i and ranks of y_i in the formulas for Pearson product-moment correlation coefficient. If ties are present in the raw data, the average ranks are used.

Kendall’s Tau

Kendall’s Tau is an alternative to Pearson’s product-moment correlation coefficient and Spearman’s rank-order correlation coefficient for ordinal data. The main distinction between this measure and Pearson’s or Spearman’s measures is that we can compute Kendall’s Tau without specifying numerical values. The actual values are needed only to order the variables, hence, different values that preserve the order will output same values of Kendall’s taus. All that is needed is an implicit ordering of the data. Kendall’s Tau is a nonparametric measure of association. It is based on the number of concordances and discordances in paired observations. When paired observations vary together, it denotes concordance and when they vary differently, it indicates discordance. The formula for Kendall’s Tau can be written as,

$$\tau = \frac{\sum_{i < j} \text{sgn}(x_i - x_j) \text{sgn}(y_i - y_j)}{\sqrt{(t_1 - t_2)(t_1 - t_3)}} \quad (\text{R.48})$$

with

$$\begin{aligned} t_1 &= n(n - 1)/2 \\ t_2 &= \sum_k u_k(u_k - 1)/2 \\ t_3 &= \sum_l v_l(v_l - 1)/2 \end{aligned}$$

where u_k is the number of tied x values in the k^{th} group of tied x values, v_l is the number of tied y values in the l^{th} group of tied y values.

R Technical Reference and Formulas: Analysis

R.2.5 Multiple Linear Regression

The regression procedures are performed using a variance-covariance updating procedure described in Maindonald, J. H. (1984). The least squared solution is facilitated by using Cholesky decomposition.

Model

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_1 + \dots + \beta_k X_k + \varepsilon$$

where Y is the dependent variable (response) and X_1, \dots, X_k are the independent variables (predictors) and ε is a random error with a normal distribution having mean=0 and variance= σ^2 . The multiple linear regression algorithm computes the estimates $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k$, of the regression coefficients $\beta_0, \beta_1, \dots, \beta_k$, so as to minimize the sum of squares of residuals.

R.2.6 Collinearity Diagnostics

You can obtain **Collinearity Diagnostics** along the lines of Belsey, Kuh, and Welsh (1980), as a part of regression output. Under **Collinearity Diagnostics** the columns represent the variance components (related to principal components in multivariate analysis) and the rows represent the **variance proportion decomposition** explained by each variable in the model. The eigenvalues are those associated with the **singular value decomposition** of the covariance matrix of the coefficients (in fact the eigenvalues are the squares of the singular values) and the **condition numbers** are the ratios of the square root of the largest eigenvalue to all the rest. Since two or more variables are required to establish a dependency, it follows that two or more regression coefficient variances will be adversely affected by high variance decomposition proportions associated with a particular eigenvalue. It can be shown that only one high variance proportion in a given column cannot be indicative of a multicollinearity problem since the variance decomposition matrix of an orthogonal matrix (the ideal case indicating total independence) consists of only 0's and 1's. Thus, the broad rule for assessing collinearity is that there is an eigenvalue associated with a high condition index (> 30 , say) and with very high variance decomposition proportion (> 0.5 , say) for two or more regression coefficient variances. Interpretations are less obvious when there are competing dependencies (two or more near dependencies with the same condition index values) or two or more near dependencies with one condition index greatly dominating the others.

The general principle suggested by Belsley, Kuh and Welsh is that near dependencies or collinearity, problems exist if the condition index exceeds some threshold, variously quoted as 10, 15 or 30. It is suggested that a condition index greater than 30 indicates moderate to severe collinearity.

Parameters for Collinearity Diagnostics

The parameters you need to provide for these diagnostics are described below:

Number of collinearity components: Enter the number of collinearity components. This number can be between 2 and the number of degrees of freedom for the model. When the model is fitted without an intercept, the model degrees of freedom is equal to the number of predictors in the model. When the model is fitted with an intercept, the model degrees of freedom is equal to the number of predictors in the model plus one.

Multicollinearity Criterion: The default value is 0.05. It controls how small the determinant of the matrix inverted to compute the coefficient estimates, is allowed to be. If a finer tolerance is required, decrease this value, this achieves a coarser tolerance can be achieved. This value must be between 0 and 1.

Residuals

You can obtain the results of various types of residuals which are described in this section.

Unstandardized Residuals: These are computed by the formula *Unstandardized residual = Actual response - Predicted response*.

Standardized Residuals: These consist of residuals divided by their standard deviation. They have the drawback that they do not have a common standard deviation.

Studentized Residuals: These are computed by dividing the unstandardized residuals by quantities related to the diagonal elements of the hat matrix, using a common scale estimate computed without the i^{th} case in the model. (Cook and Weisberg refer to this as **external studentization**). These residuals have t - distributions with (n-k-1) degrees of freedom, so any residual with absolute value exceeding 3, usually requires attention. (n is the number of cases).

Deleted (predicted) Residuals: The deleted residual for the i^{th} observation is obtained by fitting the model with the i^{th} observation omitted, using the model to predict the i^{th} observation and then computing the difference from the actual i^{th} observation. The sum of squares of these deleted residuals is referred to as the

Predicted Residual Error Sum of Squares (PRESS) statistic and is often used to select from competing regression models. The expression for PRESS is based on the studentized residuals (see Cook and Weisberg (1982)).

Influence Statistics

Cook's Distance: Cook's Distance is an overall measure of the impact of the i^{th} datapoint on the estimated regression coefficient. In linear regression, Cook's distance has, approximately, an F distribution with k and (n-k) degrees of freedom. A guide to the influence of the i^{th} observation is given as follows: (see Bowerman, O'Connell, and Dickey (1986)).

- If D_i is less than $F(.8, k, n-k)$ (the upper 20th percentile of the F-distribution having k and n-k degrees of freedom), then the i^{th} observation should not be considered influential.

R Technical Reference and Formulas: Analysis

- If D_i is greater than $F(.5, k, n - k)$ (the 50th percentile of the F-distribution having k and $n - k$ degrees of freedom), then the i^{th} observation should be considered influential.
- If $F(.8, k, n - k) \leq D_i \leq F(.5, k, n - k)$ then the nearer D_i is to $F(.5, k, n - k)$ the greater the extent of the influence of the i^{th} observation.

DFFIT's (change in the regression fit): These reflect coefficient changes as well as forecasting effects when an observation is deleted and are similar to Cook's distance.

Covariance Ratios: This measure reflects the change in the covariance matrix of the estimated coefficients when the i^{th} observation is omitted. The suggestion is that $|covarianceratio - 1| \geq 3p/n$ warrants further investigation.

Diagonal of the hat matrix: This measure is also known as the leverage of the i^{th} observation. The diagonal elements sum to the number of parameters being fitted. Any value greater than $2 * p/n$ suggests further investigation.

R.2.7 Multivariate Analysis of Variance

One-way MANOVA

Suppose, n individuals have been subjected randomly to r treatments and measurements have been made on p variates with resulting data represented as follows:

Treatment 1: $X_{11}, X_{12}, \dots, X_{1n_1}$

Treatment 2: $X_{21}, X_{22}, \dots, X_{2n_2}$

⋮

Treatment r : $X_{r1}, X_{r2}, \dots, X_{rn_r}$.

where $n_1 + n_2 + \dots + n_r = n$ (we assume that there are at least two observations in each group). We note that each X_{ij} is a p -dimensional column vector. Assume that each vector observation $\sim N(\mu, \Sigma)$. We want to test the hypothesis that these mean vectors are equal i.e.:

$$H_0 : \mu_1 = \mu_2 \dots = \mu_r$$

We draw an analogy with univariate one way ANOVA. There we calculated various sums of squares, namely 'between groups sum of squares', 'residuals sum of squares', and 'total sum of squares. Here too, we will compute similar entities. In the multivariate situation, instead of one value, we will have a $p \times p$ matrix of values. The values along the diagonal and the off diagonal elements will be sums of cross products (SSP). The formulas are given in the table below.

Manova Table For Comparing Mean Vectors Of Populations

| Source of Variation | Matrix Sum of Squares and Cross Product | Degrees of Freedom |
|---------------------|---|--------------------|
| Treatment | $B = \sum_{i=1}^r n_i (X_i - \bar{X})(X_i - \bar{X})'$ | $r - 1$ |
| Residual | $W = \sum_{i=1}^r \sum_{j=1}^{n_i} (X_{ij} - \bar{X}_i)(X_{ij} - \bar{X}_i)'$ | $\sum n_i - r$ |
| Total | $B + W = \sum_{i=1}^r \sum_{j=1}^{n_i} (X_{ij} - \bar{X})(X_{ij} - \bar{X})'$ | $\sum n_i - 1$ |

where $\bar{X}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} X_{ij}$ and $\bar{X} = \frac{1}{n} \sum_{i=1}^r \sum_{j=1}^{n_i} X_{ij}$. The test is based on Wilk's Λ which is given by

$$\text{Wilk's } \Lambda = \frac{|W|}{|B + W|}$$

Small values of Wilk's Λ suggest rejection of the null hypothesis. A general result regarding approximate distribution of Λ is that $-\ln \Lambda$ follows a chi-square distribution with $p(r - 1)$ d.f. For a detailed table regarding distribution of Wilk's λ , (see Johnson and Wichern, 1998).

Test for Parallel Profiles

Here the hypothesis to be tested is weaker than the earlier hypothesis that asserted equality of mean vectors. Instead, now we ask if differences in successive co-ordinate wise means are the same in all populations. In other words our hypothesis is: H_0 : The difference $\mu_{ij} - \mu_{i,j-1}$ is the same for all groups $i = 1, 2, \dots, r$, and for all components $j = 2, 3, \dots, p$. This hypothesis in matrix form can be expressed as

$$H_0 : C\mu_1 = C\mu_2 = \dots = C\mu_r$$

Where

$$C_{(p-1) \times p} = \begin{pmatrix} -1 & 1 & 0 & 0 & \dots & 0 & 0 \\ 0 & -1 & 1 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & -1 & 1 \end{pmatrix}$$

Clearly a test for this hypothesis is the same test as above after transforming the variables from $X_{p \times 1}$ to $Y_{(p-1) \times 1}$ where $Y = CX$.

R.3.4 Wilcoxon Signed Rank Test

Notation

R_i : Rank of $|D_i|$ when absolute values are arranged in ascending order.

I : is the indicator function.

R Technical Reference and Formulas: Analysis

- **Hypothesis:** $H_0 : \lambda = 0$
- **Test Statistic:**

$$W^+ = \sum_{i=1}^n R_i \mathbf{I}(D_i > 0) \sim AN(\mu_W, \sigma_W^2) \quad (\text{R.49})$$

where,

$$\mu_W = \frac{n(n+1)}{4}. \quad (\text{R.50})$$

and

$$\sigma_W^2 = \frac{n(n+1)(2n+1)}{24}. \quad (\text{R.51})$$

R.3.5 Linear Regression

Normal Superiority Trials: Linear Regression - Comparing Slope to Predefined Value

- Hypothesis : $H_0 : \theta_t = \theta_c$
- Model:
Given a response Y_l and a covariate $X_l \sim N(\mu_x, \sigma_x^2)$ for subject $l = 1, \dots, n_j$, consider the linear model:

$$Y_l = \gamma + \theta X_l + \varepsilon_l,$$

where all ε_l 's are independent and identically distributed (i.i.d.) as $N(0, \sigma_\varepsilon^2)$.

- Test statistic

$$Z = \frac{\hat{\theta} - \hat{\theta}_0}{\sqrt{\frac{\hat{\sigma}_\varepsilon^2}{n\hat{\sigma}_x^2}}},$$

where $\hat{\theta}$ is the estimated regression slope parameter, $\hat{\sigma}_x^2$ is the sample variance of the covariate X in the sample, and $\hat{\sigma}_\varepsilon^2$ is the sample error variance, all based on the n observations.

- References:
 1. Dupont, WD and Plummer, WD, Jr. (1998).
 2. Jennison, C and Turnbull, BW (2000).

Normal Superiority Trials: Linear Regression - Comparing Two Slopes

- Hypothesis : $H_0 : \theta_t = \theta_c$

- Model:
Given a response Y_{il} and a covariate $X_{il} \sim N(\mu_{xi}, \sigma_{xi}^2)$ for subject $l = 1, \dots, n_j$ submitted to treatment $i = c, t$, consider the linear model:

$$Y_{il} = \gamma + \theta_i X_{il} + \varepsilon_{il}.$$

where all ε'_{il} s are i.i.d. $N(0, \sigma_\varepsilon^2)$

- Test statistic:

$$Z = \frac{\hat{\theta}_t - \hat{\theta}_c}{\sqrt{\hat{\sigma}_\varepsilon^2 \left(\frac{1}{n_t \hat{\sigma}_{xt}^2} + \frac{1}{n_c \hat{\sigma}_{xc}^2} \right)}}$$

where $\hat{\theta}_t$ and $\hat{\theta}_c$ are the estimated regression slope parameters and $\hat{\sigma}_{xt}^2$ and $\hat{\sigma}_{xc}^2$ are the sample variances of the covariate X in the treatment and control arm, respectively, based on the n_t and the n_c observations, while $\hat{\sigma}_\varepsilon^2$ is the sample error variance.

- References:
 1. Dupont, WD and Plummer, WD, Jr (1998).
 2. Jennison, C and Turnbull, BW (2000).

Normal Superiority Trials: Repeated Measures Regression - Comparing Two Slopes

- Hypothesis : $H_0 : \theta_t = \theta_c$
where θ_t and θ_c are regression fixed slope parameters for two distinct population regressions using independent random samples of subject-specific repeated measures.
- Model:
Given a final response Y_{iml} and a prior series of repeated measurements on the response variable at times $v_m, m = 1, \dots, M$ for subject $l = 1, \dots, n$ submitted to treatment $i = c, t$, consider the linear mixed effects model:

$$Y_{iml} = \gamma_i + \theta_i v_m + a_l + b_l v_m + \varepsilon_{ml},$$

where the random effect $(a_l, b_l)'$ is multivariate normal with mean $(0, 0)'$ and variance-covariance matrix:

$$G = \begin{bmatrix} \sigma_a^2 & \sigma_{ab} \\ \sigma_{ab} & \sigma_b^2 \end{bmatrix},$$

and all ε_{ml} are i.i.d. $N(0, \sigma_w^2)$.

R Technical Reference and Formulas: Analysis

- Test statistic:

$$Z = \frac{\hat{\theta}_t - \hat{\theta}_c}{\sqrt{\left(\hat{\sigma}_b^2 + \frac{12(M-1)\hat{\sigma}_w^2}{M(M+1)S^2}\right) \left(\frac{1}{n_t} + \frac{1}{n_c}\right)}}$$

where $\hat{\theta}_t$ and $\hat{\theta}_c$ are the estimated regression fixed slope parameters based on n_t and n_c observations in the treatment and control arm, respectively, $\hat{\sigma}_b^2$ and $\hat{\sigma}_w^2$ are the between and within sample variances, respectively, M is the total number of measurements on each subject, and S is the follow-up time for each subject.

R.4 Discrete

R.4.1 Test for Proportion in One Sample Binomial

R.4.2 McNemar's Test for Paired Binomial

R.4.1 Test for Proportion in One Sample Binomial

- Hypothesis : $H_0 : \pi = \pi_0$
to be tested against a two-sided alternative hypothesis $H_1 : \pi \neq \pi_0$ or a one-sided alternative hypothesis $H_1 : \pi < \pi_0$ or $H_1' : \pi > \pi_0$. In this analysis, the hypothesis is tested asymptotically as well as using Exact Inference.

- Asymptotic Inference**

Test Statistic: Using the variance estimated under the null hypothesis:

$$Z = \frac{\hat{\pi} - \pi_0}{\sqrt{\frac{\pi_0(1-\pi_0)}{n}}}$$

where $\hat{\pi}$ is the sample proportion based on the n observations. **East** computes 1-sided and 2-sided asymptotic p-values using standard normal distribution of the test statistic Z . Also, confidence interval for the population proportion is derived for the specified value of confidence level.

- Exact Inference**

Suppose the data consist of t successes, and $n - t$ failures, in n independent Bernoulli trials. Let π be the true underlying success rate. Then the outcome $T = t$ has the Binomial probability

$$\Pr(T = t|\pi) = \binom{n}{t} \pi^t (1 - \pi)^{n-t} . \tag{R.52}$$

East computes the maximum likelihood estimate of π as

$$\hat{\pi} = t/n .$$

Next, **East** computes a $100 \times (1 - \gamma)\%$ exact confidence interval for π using the method of Clopper and Pearson (1934). This method computes the interval in the form $(\pi_*(t), \pi^*(t))$, where $\pi_*(t)$ is such that:

$$\pi_*(t) = 0, \text{ if } t = 0 \quad (\text{R.53})$$

$$\Pr(T \geq t | \pi_*(t)) = \frac{\gamma}{2}, \text{ if } 0 < t \leq n \quad (\text{R.54})$$

and $\pi^*(t)$ is such that:

$$\Pr(T \leq t | \pi^*(t)) = \frac{\gamma}{2}, \text{ if } 0 \leq t < n \quad (\text{R.55})$$

$$\pi^*(t) = 1, \text{ if } t = n . \quad (\text{R.56})$$

A unique and very useful option available in **East** is Casella's procedure for computing confidence intervals (Casella, 1986). This procedure guarantees *uniformly shorter* exact confidence intervals than the commonly used Clopper-Pearson confidence intervals described above. In other words, for any value of n and any observed value of t , we will obtain shorter confidence intervals for π . The Casella procedure generalizes the technique of Blyth and Still (1983); in **East** we refer to these intervals as Blyth-Still-Casella intervals. To test the null hypothesis:

$$H_0: \pi = \pi_0 , \quad (\text{R.57})$$

East computes the following 1 and 2-sided p-values:

$$p_1 = \min\{\Pr(T \leq t | \pi_0), \Pr(T \geq t | \pi_0)\} , \quad (\text{R.58})$$

$$p_2 = 2 * p_1 . \quad (\text{R.59})$$

East also computes the power against the alternative hypothesis:

$$H_1: \pi = \pi_1 (\pi_1 > \pi_0) . \quad (\text{R.60})$$

Let α be the probability of a Type I error and t_0 be the smallest integer such that:

$$\Pr(T \geq t_0 | \pi_0) \leq \alpha . \quad (\text{R.61})$$

R Technical Reference and Formulas: Analysis

Then, the exact (one-sided) power is given by:

$$1 - \beta = \Pr(T \geq t_0 | \pi_1) . \tag{R.62}$$

If $\pi_1 < \pi_0$,

$$1 - \beta = \Pr(T \leq t_0 | \pi_1) , \tag{R.63}$$

where t_0 is the largest integer for which

$$\Pr(T \leq t_0 | \pi_0) \leq \alpha . \tag{R.64}$$

R.4.2 McNemar's Test for Paired Binomial

Suppose that two binomial responses are observed on each of N pairs. Let y_{11} be the count of the number of individuals whose first and second responses are both positive. Let y_{22} be the count of the number of individuals whose first and second responses are both negative. Let y_{12} be the count of the number of individuals whose first response is positive and whose second response is negative. Finally let y_{21} be the count of the number of individuals whose first response is negative and whose second response is positive. Then McNemar's test is defined on a single 2×2 table of the form

$$\mathbf{y} = \begin{matrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{matrix} .$$

Let $(\pi_{11}, \pi_{12}, \pi_{21}, \pi_{22})$, denote the four cell probabilities for this table. The null hypothesis of interest is:

$$H_0: \pi_{12} = \pi_{21} .$$

verus

$$H_1: \pi_{12} \neq \pi_{21} .$$

McNemar's statistic only depends on the values of the off-diagonal elements of the 2×2 table. The Test Statistic is:

$$MC(\mathbf{y}) = y_{12} - y_{21} . \tag{R.65}$$

Let y represent any generic 2×2 contingency table and suppose that \mathbf{x} is the 2×2 table actually observed. The exact permutation distribution of the test statistic (R.65) is obtained by conditioning on the observed sum of off-diagonal terms, or "discordant pairs",

$$N_d = y_{12} + y_{21} \tag{R.66}$$

We define the reference set by

$$\Gamma = \{ \mathbf{y}: \mathbf{y} \text{ is } 2 \times 2; y_{12} + y_{21} = N_d \} . \tag{R.67}$$

Given

$$\mu = \frac{\pi_1}{\pi_1 + \pi_2}, \tag{R.68}$$

We see that evaluation of H_0 versus H_1 is equivalent to testing

$$H'_0 : \mu = 0.5 \tag{R.69}$$

versus

$$H'_1 : \mu \neq 0.5. \tag{R.70}$$

The conditional probability $P(\mathbf{y})$ of observing any $\mathbf{y} \in \Gamma$ is binomial with parameters (μ, N_d) . Thus

$$P(\mathbf{y}) = \binom{N_d}{y_{12}} \mu^{y_{12}} (1 - \mu)^{N_d - y_{12}}, \tag{R.71}$$

which reduces under (R.69) to

$$P(\mathbf{y}) = \frac{(0.5)^{N_d} N_d!}{y_{12}! y_{21}!}. \tag{R.72}$$

Hence, under the null hypothesis the probability that McNemar's statistic equals or exceeds its observed value $MC(\mathbf{x})$ is readily evaluated as

$$\Pr(MC(\mathbf{Y}) \geq MC(\mathbf{x})) = \sum_{MC(\mathbf{Y}) \geq MC(\mathbf{x})} \mathbf{P}(\mathbf{Y}), \tag{R.73}$$

the sum being taken over all $\mathbf{y} \in \Gamma$. The probability that McNemar's statistic is less than or equal to $MC(\mathbf{x})$ is similarly obtained. The exact one-sided p-value is then defined as

$$p_1 = \min\{\Pr(MC(\mathbf{Y}) \leq MC(\mathbf{x})), \Pr(MC(\mathbf{Y}) \geq MC(\mathbf{x}))\} \tag{R.74}$$

We can show that the exact distribution of the test statistic $MC(\mathbf{Y})$ is symmetric about 0. Therefore the exact two-sided p-value is defined as double the exact one-sided p-value:

$$p_2 = 2p_1. \tag{R.75}$$

In large samples, the standardized test statistic (which we report in the output for both exact and asymptotic options)

$$MC^*(\mathbf{y}) = \frac{y_{12} - y_{21}}{\sqrt{N_d}} \tag{R.76}$$

R Technical Reference and Formulas: Analysis

is asymptotically normally distributed with zero mean and unit variance. The 1-sided asymptotic p-value is defined as:

$$\tilde{p}_1 = \min\{\Phi(MC^*(\mathbf{x})), (1 - \Phi(MC^*(\mathbf{x})))\} \tag{R.77}$$

where $\Phi(z)$ is the left tail of the standard normal distribution at z , and x is the observed 2×2 contingency table. The 2-sided asymptotic p-value is double the 1-sided asymptotic p-value. The confidence interval is obtained for the difference of proportions based on the asymptotic distribution.

R.5.1 Exact Unconditional Test of Superiority : Difference of Proportions

This section presents the statistical theory underlying Exact unconditional inference for data sampled from two independent binomial populations. Although the problems we will discuss are commonly encountered, the underlying theory is not easily accessible elsewhere. Consider a randomized clinical trial comparing an experimental treatment T, to a control treatment C, on the basis of a binomially distributed outcome variable, X , with probability of success π_t and π_c respectively. Consider the data presented in the 2×2 contingency table coming from control and treatment arm, \mathbf{x} , displayed in Table R.1:

Table R.1: The Observed 2x2 Contingency Table, \mathbf{x} .

| Response | Population C | Population T | Row_Total |
|-----------|--------------|--------------|-----------|
| Success | x_{1c} | x_{1t} | m_1 |
| Failure | x_{2c} | x_{2t} | m_2 |
| Col.Total | n_c | n_t | N |

The two columns of Table R.1 arise from two independent binomial populations. In the first column for control arm, there are x_{1c} successes and x_{2c} failures in n_c independent Bernoulli trials, each with probability π_c of success. Second column corresponds to data on the treatment arm. The sum of successes from the two arms is $m_1 = x_{1c} + x_{1t}$. The sample sizes n_c and n_t are number of observations on control and treatment arm. Define the difference in proportions between treatment group and control group to be $\delta = \pi_t - \pi_c$. The null hypothesis of interest is $H_0 : \delta = 0$ which is tested against a 2-sided alternative hypothesis $H_1 : \delta \neq 0$ or a 1-sided alternative hypothesis $H_1 : \delta > 0$ or $H'_1 : \delta < 0$ as the case maybe. Let $\hat{\pi}_t$ and $\hat{\pi}_c$ be the sample

proportions based on n_t and n_c observations in the treatment and control arm respectively. Then the estimate of δ is $\hat{\delta} = \hat{\pi}_t - \hat{\pi}_c$.

Asymptotic Inference

Test statistic is defined as:

$$Z = \frac{\hat{\pi}_t - \hat{\pi}_c}{\sqrt{\left(\frac{x_{1c} + x_{1t}}{N}\right) \left(\frac{x_{2c} + x_{2t}}{N}\right) \left(\frac{1}{n_t} + \frac{1}{n_c}\right)}} \tag{R.78}$$

Z is distributed as variable that follows $N(0, 1)$ distribution under the null hypothesis.

Exact Unconditional Inference

Suppose that H_0 is true and let the common probability of success for the two binomial populations be $\pi_c = \pi_t = \pi$. Then the probability of observing the data in Table R.1 is a product of two binomial probabilities, denoted by

$$f_0(\mathbf{x}) = \binom{n_c}{x_{1c}} \binom{n_t}{x_{1t}} \pi^{x_{1c} + x_{1t}} (1 - \pi)^{x_{2c} + x_{2t}} \tag{R.79}$$

The p-value is defined to be the probability, under H_0 , of obtaining a 2×2 table at least as extreme as the observed table, \mathbf{x} . Before we can compute this p-value, however, we need to answer two questions:

1. What criterion should we use to establish that a 2×2 contingency table is at least as extreme as \mathbf{x} ?
2. What is the exact null probability of each of these extreme 2×2 contingency tables?

To answer these questions we must introduce some more notation. Let \mathbf{Y} denote any generic 2×2 table that can arise if we take two independent samples, one of size n_c from binomial population C and the other of size n_t from binomial population T. Such a generic 2×2 table is displayed below in Table R.3

Table R.2: Any Generic 2x2 Contingency Table, \mathbf{Y}

| Response | Control | Treatment | Row_Total |
|-----------|----------|-----------|-------------------|
| Success | y_{1c} | y_{1t} | $y_{1c} + y_{1t}$ |
| Failure | y_{2c} | y_{2t} | $y_{2c} + y_{2t}$ |
| Col_Total | n_c | n_t | N |

R Technical Reference and Formulas: Analysis

The probability of observing this table is $f_0(\mathbf{Y})$ which, as shown by equation (R.79), contains an unknown (nuisance) parameter, π . So long as the probability of observing any generic 2×2 table depends on π , exact inference is not possible, since the p-value is based on summing up the probabilities of many such tables, each depending on an unknown parameter. The key to exact inference is getting rid of π , the nuisance parameter. The unconditional approach is to eliminate π by taking a supremum over its entire range so as to provide for the worst-case. (Barnard, 1945, was the first to propose this idea.) The unconditional probability of observing \mathbf{x} under H_0 is $f_0(\mathbf{x})$, specified by equation (R.79). In order to compute an exact p-value we need to specify a reference set of 2×2 contingency tables and sum the probabilities of tables that are at least as extreme as \mathbf{x} in it. Unconditional inference uses reference set of 2×2 contingency tables in which only the column sums, or the binomial sample sizes, are fixed. The row sums are treated as random variables. Denote this reference set by

$$\Omega = \{ \mathbf{Y}: y_{1j} + y_{2j} = n_j, j = c, t \}, \tag{R.80}$$

and order each table $\mathbf{Y} \in \Omega$ according to the test statistic

$$D(\mathbf{Y}) = \frac{\hat{\pi}_t - \hat{\pi}_c}{\sqrt{\left(\frac{y_{1c} + y_{1t}}{N}\right)\left(\frac{y_{2c} + y_{2t}}{N}\right)\left(\frac{1}{n_c} + \frac{1}{n_t}\right)}}, \tag{R.81}$$

where $\hat{\pi}_j = y_{1j}/n_j, j = c, t$. If $y_{11} = y_{12} = 0$, or $y_{21} = y_{22} = 0$, set $D(\mathbf{Y}) = 0$. The denominator of (R.81) is the standard error of the observed difference of binomial proportions under the null hypothesis. Therefore the statistic $D(\mathbf{Y})$ has a mean of 0 and variance of 1 under H_0 . A large positive value for the observed statistic $D(\mathbf{x})$ furnishes evidence against H_1 while a large negative value furnishes evidence against H_1' . The exact p-value is the sum of probabilities of all tables $\mathbf{Y} \in \Omega$ that are more extreme than the observed table \mathbf{x} with respect to the test statistic (R.81). The trouble is that each such extreme table has a probability $f_0(\mathbf{Y})$ which, by equation (R.79) depends on the unknown nuisance parameter, π . We compute the p-value in two stages. At the first stage we express the p-value as a function of π . Then, at the second stage, we obtain the supremum of this function over all values of $\pi \in (0, 1)$. We use this supremum as the p-value. Since the p-value based on the actual value of π can never exceed the supremum over all possible values of π , this procedure guarantees that the type-1 error will always be preserved. In effect we compute a conservative p-value that will preserve the desired type-1 error rate no matter what the true value of π might be, since it is designed to cater for the worst case. Specifically, the exact one-sided p-value given π is computed as

$$p_1(\pi) = \min \left\{ \sum_{D(\mathbf{Y}) \leq D(\mathbf{x})} f_0(\mathbf{Y}), \sum_{D(\mathbf{Y}) \geq D(\mathbf{x})} f_0(\mathbf{Y}) \right\}. \tag{R.82}$$

The exact two-sided p-value given π is computed as

$$p_2(\pi) = \sum_{|D(\mathbf{Y})| \geq |D(\mathbf{x})|} f_0(\mathbf{Y}) . \tag{R.83}$$

Finally we obtain one and two-sided p-values that are independent of π by taking a supremum over all possible values of π and arguing that even in the worst possible case, the true p-value could never exceed the supremum. Thus

$$p_1 = \sup\{p_1(\pi): 0 \leq \pi \leq 1\} \tag{R.84}$$

and

$$p_2 = \sup\{p_2(\pi): 0 \leq \pi \leq 1\} . \tag{R.85}$$

R.5.2 Exact Test of Noninferiority: Difference of Proportions

An important biomedical application arises in so-called “active control” clinical trials. In these studies the goal is to demonstrate the noninferiority rather than the superiority of the new treatment relative to the active control. Define the difference in proportions

$$\delta = \pi_t - \pi_c . \tag{R.86}$$

In a noninferiority clinical trial the objective is not to demonstrate that the experimental treatment is superior to the control but rather to demonstrate that the experimental treatment is not significantly inferior. Accordingly a noninferiority margin, $\delta_0 > 0$, is specified a priori and we test the null hypothesis of inferiority.

$$H_0: \delta \geq \delta_0 \tag{R.87}$$

versus the one sided alternative hypothesis of noninferiority

$$H_1: \delta < \delta_0 . \tag{R.88}$$

The test is carried out under the assumption that δ is at its threshold null value $\delta = \delta_0$.

When $\delta_0 < 0$, **East** tests the null hypothesis $H_0: \delta \leq \delta_0$ against the alternative hypothesis $H_1: \delta > \delta_0$. When $\delta_0 > 0$, the null hypothesis $H_0: \delta \geq \delta_0$ is tested against the alternative hypothesis $H_1: \delta < \delta_0$. Let $\hat{\pi}_t$ and $\hat{\pi}_c$ be the sample proportions based on n_t and n_c observations in the treatment and control arm. Then the estimate of δ is $\hat{\delta} = \hat{\pi}_t - \hat{\pi}_c$. Test statistics for Wald test and Score Test are defined as follows:

R Technical Reference and Formulas: Analysis

Noninferiority (WALD)

$$Z = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{\hat{\pi}_c(1 - \hat{\pi}_c)}{n_c} + \frac{\hat{\pi}_t(1 - \hat{\pi}_t)}{n_t}}} \sim N(0, 1) \quad (\text{R.89})$$

Noninferiority (Score)

$$Z = \frac{\tilde{\pi}_t - \tilde{\pi}_c - \delta_0}{\sqrt{\frac{\tilde{\pi}_c(1 - \tilde{\pi}_c)}{n_c} + \frac{\tilde{\pi}_t(1 - \tilde{\pi}_t)}{n_t}}} \sim N(0, 1) \quad (\text{R.90})$$

where $\tilde{\pi}_t$ and $\tilde{\pi}_c$ are the restricted mle's of π_t and π_c as suggested by Mittinen and Nurminen(1985) whereas the test statistic has been recommended by Farrington and Manning(1990).

Z is distributed as variable that follows $N(0, 1)$ distribution under the null hypothesis.

Exact Inference

Let $\mathbf{Y} \in \Omega$ denote any generic 2×2 table of the form of Table R.3 that might be observed if we generated n_c independent bernoulli trials each with probability π_c and n_t independent bernoulli trials each with probability π_t . The probability of observing any $\mathbf{Y} \in \Omega$ under H_0 is

$$f_{\pi_c, \delta_0}(\mathbf{y}) = \binom{n_c}{y_{1c}} \binom{n_t}{y_{1t}} \pi_c^{y_{1c}} (1 - \pi_c)^{y_{2c}} (\pi_c + \delta_0)^{y_{1t}} (1 - \pi_c - \delta_0)^{y_{2t}} \quad (\text{R.91})$$

The test statistic (see Chan, 1998) is defined as

$$D(\mathbf{Y}) = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{(\hat{\pi}_c)(1 - \hat{\pi}_c)}{n_c} + \frac{(\hat{\pi}_t)(1 - \hat{\pi}_t)}{n_t}}} \quad (\text{R.92})$$

where

$$\hat{\pi}_j = \frac{y_{1j}}{n_j}, \quad (\text{R.93})$$

for $j = c, t$, and $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the maximum likelihood estimates of π_c and π_t , respectively, restricted under the null hypothesis so as to satisfy the requirement $\tilde{\pi}_t - \tilde{\pi}_c = \delta_0$. Mittinen and Nurminen (1985) have shown that one may obtain these restricted maximum likelihood estimates by solving the third degree likelihood equation

$$\sum_{k=1}^3 L_k \tilde{\pi}_c^k = 0 \quad (\text{R.94})$$

for $\tilde{\pi}_c$ and setting $\tilde{\pi}_t = \tilde{\pi}_c + \delta_0$, where

$$L_3 = N ,$$

$$L_2 = (n_t + 2n_c)\delta_0 - N - y_{1c} - y_{1t} ,$$

$$L_1 = (n_c\delta - N - 2y_{1c})\delta_0 + y_{1c} + y_{1t} ,$$

$$L_0 = y_{1c}\delta_0(1 - \delta_0) .$$

The test statistic (R.92) is known as the score statistic. Under H_0 this test statistic has mean 0 and variance 1. Let the data in Table R.1, denoted by \mathbf{x} , be the 2×2 table actually observed. Then the observed value of the test statistic is $D(\mathbf{x})$, and the left tail of the distribution of $D(\mathbf{Y})$ at its observed value under H_0 is

$$P_{\pi_c, \delta_0}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \leq \mathbf{D}(\mathbf{x})} \mathbf{f}_{\pi_c, \delta_0}(\mathbf{Y}) \quad (\text{R.95})$$

If we knew the value of π_c , then $P_{\pi_c, \delta_0}(D(\mathbf{x}))$ would be the exact p-value for testing H_0 versus H_1 . Since π_c is unknown, however, we take the supremum of (R.95) over all values of π_c in its range, just as we did for Barnard's test in Section R.5.1. This produces a conservative p-value that is guaranteed to ensure that the true type-1 error of the test will never exceed its nominal significance level. Since $\delta_0 > 0$ the range of possible values for π_c is

$$I(\delta_0) = \{\pi_c : 0 < \pi_c < 1 - \delta_0\} . \quad (\text{R.96})$$

Thereupon the unconditional exact one-sided p-value is

$$p_1 \equiv P_{\delta_0}(D(\mathbf{x})) = \sup\{\mathbf{P}_{\pi_c, \delta_0}(\mathbf{D}(\mathbf{x})) : \pi_c \in I(\delta_0)\} . \quad (\text{R.97})$$

Note that in practice the supremum in equation (R.97) is taken over a restricted range for π rather than over the entire range $I(\delta_0)$. This restriction, proposed by Berger and Boos (1994), adds stability and reduces the conservatism of the procedure. The p-values are suitably adjusted so that the restricted search for the supremum does not compromise the type-1 error. Finally, it is worth noting that when $\delta_0 = 0$ the above p-value specializes to the left tail p-value obtained by Barnard's test.

Additional Remarks

1. The score statistic $D(\mathbf{Y})$ specified by equation (R.92) is always defined except for the special case where $y_{1c} = y_{1t} = 0$ and $\delta_0 = 0$ or where $y_{2c} = y_{2t} = 0$ and $\delta_0 = 0$. For these special cases the one- and two-sided p-values are both set to 1. These special cases never arise when performing a noninferiority test with $\delta_0 > 0$.

R Technical Reference and Formulas: Analysis

2. The one-sided asymptotic p-value corresponding to p_1 is obtained by assuming that the test statistic $D(\mathbf{Y})$ converges in distribution to the standard normal.

Thus

$$\tilde{p}_1 = 1 - \Phi(D(\mathbf{x})) . \tag{R.98}$$

3. An alternative equivalent way to perform a level- α test of non-inferiority is to compute an exact $100 \times (1 - \alpha)$ lower confidence bound for δ , say δ_L , using the method described in Section R.5.4. If $\delta_L < \delta_0$ we reject the null hypothesis of inferiority.

R.5.3 Exact Test of Equivalence: Difference of Proportions

Suppose π_c is the response rate of Control and π_t is the response rate of Treatment. Define the absolute difference in proportions

$$\delta = |\pi_t - \pi_c| . \tag{R.99}$$

Suppose that for a pre-specified equivalence margin $\delta_0 > 0$ we wish to test the null hypothesis of inequivalence

$$H_0: \delta \geq \delta_0 \tag{R.100}$$

against the alternative hypothesis of equivalence

$$H_1: \delta < \delta_0 . \tag{R.101}$$

We test the above null hypothesis by performing two separate one-sided non-inferiority hypothesis tests of the form

$$H_{01}: \pi_c - \pi_t \geq \delta_0 \text{ versus } H_{11}: \pi_c - \pi_t < \delta_0 \tag{R.102}$$

and

$$H_{02}: \pi_t - \pi_c \geq \delta_0 \text{ versus } H_{12}: \pi_t - \pi_c < \delta_0 . \tag{R.103}$$

Each hypothesis test is carried out separately using the method described in Section R.5.2. Hypothesis test H_{01} is performed under the assumption that $\pi_c - \pi_t$ is at its threshold null value $\pi_c - \pi_t = \delta_0$. Similarly hypothesis test H_{02} is tested under the assumption that $\pi_t - \pi_c$ is at its threshold null value $\pi_t - \pi_c = \delta_0$. We reject the null hypothesis of inequivalence and accept the alternative hypothesis of equivalence only if **both** H_{01} and H_{02} are rejected. The probability of observing any $\mathbf{Y} \in \Omega$ under H_{01} is

$$f_{\pi_c, \delta_0}^{01}(\mathbf{Y}) = \binom{n_c}{y_{1c}} \binom{n_t}{y_{1t}} \pi_c^{y_{1c}} (1 - \pi_c)^{y_{2c}} (\pi_c - \delta_0)^{y_{1t}} (1 - \pi_c + \delta_0)^{y_{2t}} , \tag{R.104}$$

and the statistic used to test H_{01} is

$$D^{01}(\mathbf{Y}) = \frac{\hat{\pi}_c - \hat{\pi}_t - \delta_0}{\sqrt{\frac{(\hat{\pi}_c)(1-\hat{\pi}_c)}{n_c} + \frac{(\hat{\pi}_t)(1-\hat{\pi}_t)}{n_t}}}, \quad (\text{R.105})$$

where the $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are restricted maximum likelihood estimates of π_c and π_t , respectively, under the restriction that $\tilde{\pi}_c - \tilde{\pi}_t = \delta_0$. We compute

$$P_{\tilde{\pi}_c, \delta_0}^{01}(D(\mathbf{x})) = \sum_{\mathbf{D}^{01}(\mathbf{Y}) \leq \mathbf{D}^{01}(\mathbf{x})} \mathbf{f}_{\tilde{\pi}_c, \delta_0}^{01}(\mathbf{Y}), \quad (\text{R.106})$$

and then take the supremum over all $\pi_c \in I^{01}(\delta_0)$ where

$$I^{(01)}(\delta_0) = \{\pi_c : \delta_0 < \pi_c < 1\}. \quad (\text{R.107})$$

The exact unconditional one-sided p-value for testing H_{01} is thus

$$p_{01} \equiv P_{\delta_0}^{01}(D(\mathbf{x})) = \sup\{\mathbf{P}_{\tilde{\pi}_c, \delta_0}^{01}(\mathbf{D}(\mathbf{x})) : \pi_c \in I^{01}(\delta_0)\}. \quad (\text{R.108})$$

The probability of observing any $\mathbf{Y} \in \Omega$ under H_{02} is

$$f_{\pi_c, \delta_0}^{02}(\mathbf{Y}) = \binom{n_c}{y_{1c}} \binom{n_t}{y_{1t}} \pi_c^{y_{1c}} (1 - \pi_c)^{y_{2c}} (\pi_c + \delta_0)^{y_{1t}} (1 - \pi_c - \delta_0)^{y_{2t}}, \quad (\text{R.109})$$

and the statistic used to test H_{02} is

$$D^{02}(\mathbf{Y}) = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{(\hat{\pi}_c)(1-\hat{\pi}_c)}{n_c} + \frac{(\hat{\pi}_t)(1-\hat{\pi}_t)}{n_t}}}, \quad (\text{R.110})$$

where the $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are maximum likelihood estimates of π_c and π_t , respectively, under the restriction that $\tilde{\pi}_t - \tilde{\pi}_c = \delta_0$. We compute

$$P_{\tilde{\pi}_c, \delta_0}^{02}(D(\mathbf{x})) = \sum_{\mathbf{D}^{02}(\mathbf{Y}) \leq \mathbf{D}^{02}(\mathbf{x})} \mathbf{f}_{\tilde{\pi}_c, \delta_0}^{02}(\mathbf{Y}), \quad (\text{R.111})$$

and then take the supremum over all $\pi_c \in I^{02}(\delta_0)$ where

$$I^{(02)}(\delta_0) = \{\pi_c : 0 < \pi_c < 1 - \delta_0\}. \quad (\text{R.112})$$

The exact unconditional one-sided p-value for testing H_{02} is thus

$$p_{02} \equiv P_{\delta_0}^{02}(D(\mathbf{x})) = \sup\{\mathbf{P}_{\tilde{\pi}_c, \delta_0}^{02}(\mathbf{D}(\mathbf{x})) : \pi_c \in I^{02}(\delta_0)\}. \quad (\text{R.113})$$

Additional Remarks

R Technical Reference and Formulas: Analysis

1. The test statistics $D^{01}(\mathbf{Y})$ and $D^{02}(\mathbf{Y})$, specified by equations (R.105) and (R.110), respectively, are always defined except for the special cases where $y_{11} = y_{12} = 0$ and $\delta_0 = 0$ or where $y_{21} = y_{22} = 0$ and $\delta_0 = 0$. For these special case the one- and two-sided p-values are both set to 1. These special cases never arise when performing an equivalence test with $\delta_0 > 0$.

2. The one-sided asymptotic p-value corresponding to p_{01} is obtained by assuming that the test statistic $D^{01}(\mathbf{Y})$ converges in distribution to the standard normal. Thus,

$$\tilde{p}_{01} = 1 - \Phi(D^{01}(\mathbf{x})) . \tag{R.114}$$

3. The one-sided asymptotic p-value corresponding to p_{02} is obtained by assuming that the test statistic $D^{02}(\mathbf{Y})$ converges in distribution to the standard normal. Thus

$$\tilde{p}_{02} = 1 - \Phi(D^{02}(\mathbf{x})) . \tag{R.115}$$

4. An alternative equivalent way to perform a level- α test of equivalence is to compute an exact $100 \times (1 - 2\alpha)$ confidence interval for δ , say (δ_L, δ_U) , using the method described in Section R.5.4. If δ_0 is excluded from this interval, we reject the null hypothesis of equivalence.

R.5.4 Unconditional Exact Confidence Intervals for the Difference of Proportions

Suppose π_c is the binomial response rate of Control and π_t is the binomial response rate of Treatment. We wish to compute an exact $100(1 - \alpha)\%$ confidence interval for

$$\delta = \pi_t - \pi_c .$$

We use a test based procedure. That is, we invert hypothesis tests of the form $\delta = \delta_0$, where, in general, $\delta_0 \neq 0$. If we are dealing with the superiority, δ_0 will be zero.

In case of noninferiority δ_0 is nonzero. Accordingly, this section is applicable to superiority, noninferiority and equivalence. There is one further complication, however, since the p-values which we compute under these alternative hypotheses depend on a nuisance parameter. We handle this problem the same way we handled it for Barnard's unconditional exact hypothesis test; i.e., by taking a supremum over all possible values of the nuisance parameter.

Interval Estimation

Suppose we take n_c independent Bernoulli samples from control and n_t independent Bernoulli samples from treatment. Let $\mathbf{Y} \in \Omega$ (see Table R.3 denote any generic 2×2 table that might be observed, and let \mathbf{x} (see Table R.1), be the 2×2 table that was actually observed. Define

$$\hat{\pi}_j = \frac{y_{1j}}{n_j}$$

for $j = c, t$. In **East**, we provide a test based exact confidence interval using the standardized statistic

$$D(\mathbf{Y}) = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{(\tilde{\pi}_c)(1-\tilde{\pi}_c)}{n_c} + \frac{(\tilde{\pi}_t)(1-\tilde{\pi}_t)}{n_t}}} \quad (\text{R.116})$$

where $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the maximum likelihood estimates of π_c and π_t computed, under the restriction that $\tilde{\pi}_t - \tilde{\pi}_c = \delta_0$. This statistic is known as the score statistic. The use of (R.116) as the test statistic has been proposed by Farrington and Manning(1990) for asymptotic confidence intervals and by Chan and Zhang (1999) for exact confidence intervals. We note that the score statistic specified by equation (R.116) is always defined except for the special cases where $y_{1c} = y_{1t} = 0$ and $\delta_0 = 0$, or $y_{2c} = y_{2t} = 0$ and $\delta = 0$. These special cases never arise when computing a confidence interval.

Test Based Exact Confidence Intervals: Inverting Two One-Sided Tests

Let (δ_*, δ^*) be the desired $100(1 - \alpha)\%$ exact confidence interval, evaluated at $D(\mathbf{x})$, the observed value of the test statistic. This exact confidence interval may be constructed by inverting two one-sided hypothesis tests, each at the $\alpha/2$ significance level, under appropriate alternative hypotheses about δ . The probability of observing any $\mathbf{Y} \in \Omega$, for any given value of δ , is

$$f_{\pi_c, \delta}(\mathbf{Y}) = \binom{n_c}{y_{1c}} \binom{n_t}{y_{1t}} \pi_c^{y_{1c}} (1 - \pi_c)^{y_{2c}} (\pi_c + \delta)^{y_{1t}} (1 - \pi_c - \delta)^{y_{2t}} . \quad (\text{R.117})$$

Define

$$P_{\pi_c, \delta}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \leq \mathbf{D}(\mathbf{x})} \mathbf{f}_{\pi_c, \delta}(\mathbf{Y}) \quad (\text{R.118})$$

and

$$Q_{\pi_c, \delta}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \geq \mathbf{D}(\mathbf{x})} \mathbf{f}_{\pi_c, \delta}(\mathbf{Y}) . \quad (\text{R.119})$$

We must eliminate the nuisance parameter π_c from equations (R.118) and (R.119) by taking the supremum over its range. It is easy to see that the permissible range for π_c given δ is the interval

$$I(\delta) = \{\pi_c: \max(0, -\delta) \leq \pi_c \leq \min(1, 1 - \delta)\} . \quad (\text{R.120})$$

R Technical Reference and Formulas: Analysis

Thus we define

$$P_\delta(D(\mathbf{x})) = \sup\{\mathbf{P}_{\pi_c, \delta}(\mathbf{D}(\mathbf{x})): \pi_c \in \mathbf{I}(\delta)\} \quad (\text{R.121})$$

and

$$Q_\delta(D(\mathbf{x})) = \sup\{\mathbf{Q}_{\pi_c, \delta}(\mathbf{D}(\mathbf{x})): \pi_c \in \mathbf{I}(\delta)\} . \quad (\text{R.122})$$

Starting with $\delta = -1$, the desired lower confidence bound is obtained by increasing the value of δ until we find a value, denoted by δ_* , such that the equality

$$Q_{\delta_*}(D(\mathbf{x})) = \alpha/2 \quad (\text{R.123})$$

is satisfied but for any $\delta < \delta_*$, $Q_\delta(D(\mathbf{x})) < \alpha/2$. The upper confidence bound, δ^* is obtained in an analogous fashion. Starting with $\delta = 1$, the desired upper confidence bound is obtained by decreasing the value of δ until we find a value, denoted by δ^* , such that the equality

$$P_{\delta^*}(D(\mathbf{x})) = \alpha/2 \quad (\text{R.124})$$

is satisfied but for any $\delta > \delta^*$, $P_\delta(D(\mathbf{x})) < \alpha/2$.

East reports (δ_*, δ^*) as the $100 \times (1 - \alpha)\%$ confidence interval for the parameter δ . Suppose δ_0 is the true (unknown) value of δ . The long run relative frequency with which, in repeated trials, this interval excludes δ_0 is $\Pr(\delta_0 \leq \delta_*) + \Pr(\delta_0 \geq \delta^*)$. We shall show at the end of this Section that neither term in the above sum can exceed $\alpha/2$. Therefore the probability of the confidence interval excluding δ_0 cannot exceed α . However, due to the discreteness of the distribution of $D(\mathbf{Y})$, and the conservatism induced by taking a supremum over all $\pi_c \in \mathbf{I}(\delta)$, the above exclusion probability is usually less than α instead of equaling α . Thus, (δ_*, δ^*) may be regarded as a conservative confidence interval. In addition to the exact confidence interval, **East** also reports an exact one-sided p-value, defined as the smaller of the two tail areas,

$$p_1 = \min(P_0(D(\mathbf{x})), \mathbf{Q}_0(\mathbf{D}(\mathbf{x}))) , \quad (\text{R.125})$$

and the two sided exact p-value is twice the one-sided:

$$p_2 = 2p_1 . \quad (\text{R.126})$$

The two-sided p-value is weakly consistent with the corresponding exact confidence interval for δ . That is, if $0 \notin [\delta_*, \delta^*]$ then $p_t < \alpha$. The stronger consistency requirement, that $p_t < \alpha$ if and only if $0 \notin [\delta_*, \delta^*]$ cannot be established unless $P_\delta(D(\mathbf{x}))$ and $Q_\delta(D(\mathbf{x}))$ are monotone functions of δ for any given $D(\mathbf{x})$. This need not be the case, however.

The above procedure can be slightly modified in practice. The suprema in equations (R.121) and (R.122) can be taken over a restricted range for π rather than

over the entire range $I(\delta)$. This restriction, proposed by Berger and Boos (1994), adds stability and reduces the conservatism of the procedure. The right hand sides of equations (R.123) and (R.124) are suitably adjusted so that the restricted search for the supremum does not compromise the coverage properties of the resulting confidence interval.

Proof of Coverage: We shall now prove that the probability that the above confidence interval excludes the true parameter δ_0 cannot exceed α . For simplicity, denote the random variable $D(\mathbf{Y})$ by D , and its observed value $D(\mathbf{x})$ by d . In order to make explicit the dependence of the confidence interval on d , denote the lower confidence bound by $\delta_*(d)$ and the upper confidence bound by $\delta^*(d)$. Thus the lower confidence bound satisfies the relationship

$$Q_{\delta_*(d)}(D(\mathbf{x})) = \alpha/2, \tag{R.127}$$

and furthermore, by the way we conduct the search for $\delta_*(d)$,

$$Q_\delta(D(\mathbf{x})) < \alpha/2, \text{ if } \delta < \delta_*(d). \tag{R.128}$$

Define $H(\delta_0)$ to be the *smallest* value of D satisfying the inequality

$$Q_{\delta_0}(H(\delta_0)) \leq \alpha/2. \tag{R.129}$$

Observe, from the definition of $H(\delta_0)$ in (R.129), that if $d < H(\delta_0)$ we must have $Q_{\delta_0}(d) > \alpha/2$. But we know from (R.128) that there is no value of $\delta \leq \delta_*(d)$ for which $Q_\delta(d) > \alpha/2$. Therefore if $d < H(\delta_0)$, it must be the case that $\delta_0 > \delta_*(d)$. It follows that

$$\Pr\{\delta_0 > \delta_*(d)\} \geq \Pr\{D < H(\delta_0) | \delta_0, \pi_1\}. \tag{R.130}$$

We use a weak inequality instead of a strict equality in (R.130) because it is also possible in some situations to have $\delta_0 > \delta_*(d)$ when $d \geq H(\delta_0)$. Taking the complementary probability on both sides of (R.130) we have

$$\Pr\{\delta_0 \leq \delta_*(d)\} \leq \Pr\{D \geq H(\delta_0) | \delta_0, \pi_c\}. \tag{R.131}$$

Taking the supremum over all $\pi_c \in I(\delta_0)$ on the right hand side of (R.131) we have

$$\Pr\{\delta_* \geq \delta_0\} \leq Q_{\delta_0}(H(\delta_0)) \leq \alpha/2. \tag{R.132}$$

By an analogous argument we can establish that

$$\Pr\{\delta^* \leq \delta_0\} \leq \alpha/2. \tag{R.133}$$

Therefore the probability that the interval (δ_*, δ^*) excludes the parameter δ_0 cannot exceed α .

R Technical Reference and Formulas: Analysis

Asymptotic Confidence Interval

East computes asymptotic p-values and test based asymptotic confidence intervals for δ , under the assumption that the test statistic is asymptotically normally distributed. The asymptotic $100 \times (1 - \alpha)\%$ confidence interval $(\tilde{\delta}_*, \tilde{\delta}^*)$ is obtained by inverting the corresponding one-sided hypothesis tests. Thus $\tilde{\delta}_*$ satisfies the equality

$$1 - \Phi \left\{ \frac{x_{1t}/n_t - x_{1c}/n_c - \delta_*}{\sqrt{\frac{(\tilde{\pi}_c)(1-\tilde{\pi}_c)}{n_c} + \frac{(\tilde{\pi}_t)(1-\tilde{\pi}_t)}{n_t}}} \right\} = \alpha/2, \quad (\text{R.134})$$

where $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the maximum likelihood estimates of π_c and π_t , respectively, under the null hypothesis that $\pi_t - \pi_c = \delta_*$. Similarly $\tilde{\delta}^*$ satisfies the equality

$$\Phi \left\{ \frac{x_{1t}/n_t - x_{1c}/n_c - \delta^*}{\sqrt{\frac{(\tilde{\pi}_c)(1-\tilde{\pi}_c)}{n_c} + \frac{(\tilde{\pi}_t)(1-\tilde{\pi}_t)}{n_t}}} \right\} = \alpha/2, \quad (\text{R.135})$$

where $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the maximum likelihood estimates of π_c and π_t , respectively, under the null hypothesis that $\pi_t - \pi_c = \delta^*$.

R.5.5 Unconditional Exact Confidence Intervals for the Ratio of Proportions

In the **Ratio of Proportions** test, let π_t and π_c denote the proportions of the successes from the experimental treatment (T) and the control treatment (C), respectively. To test the null hypothesis $H_0: \pi_t/\pi_c = 1$ against the 2-sided alternative hypothesis

$H_1: \pi_t/\pi_c \neq 1$ or a 1-sided alternative hypothesis $H_1: \pi_t/\pi_c < 1$ or $H_1': \pi_t/\pi_c > 1$.

Test Statistic Using the pooled estimate of variance:

$$Z = \frac{\ln(\hat{\pi}_t) - \ln(\hat{\pi}_c)}{\sqrt{\frac{(1-\hat{\pi})}{\hat{\pi}} \left(\frac{1}{n_t} + \frac{1}{n_c} \right)}},$$

where

$$\hat{\pi} = \frac{n_t \hat{\pi}_t + n_c \hat{\pi}_c}{n_t + n_c},$$

where $\hat{\pi}_t$ and $\hat{\pi}_c$ are the sample proportions based on n_t and n_c observations in the treatment and control arm, respectively. Asymptotically, Z is distributed as variable that follows $N(0, 1)$ distribution under the null hypothesis.

We wish to compute an exact $100(1 - \alpha)\%$ confidence interval for

$$\rho = \frac{\pi_t}{\pi_c}. \quad (\text{R.136})$$

The procedure parallels that described in Section R.5.4 for the difference of proportions, δ . We invert hypothesis tests of the form $\rho = \rho_0$, where, in general, $\rho_0 \neq 1$. There is one further complication, however, since the p-values which we compute under these alternative hypotheses depend on a nuisance parameter. We handle this problem the same way we handled it for Barnard's unconditional exact hypothesis test; by taking a supremum over all possible values of the nuisance parameter. Suppose we take n_c independent Bernoulli samples from control and n_t independent Bernoulli samples from treatment. Let $\mathbf{Y} \in \Omega$ (see Table R.3, page 2596) denote any generic 2×2 table that might be observed, and let \mathbf{x} (see Table R.1, page 2568), be the 2×2 table that was actually observed. Define

$$\hat{\pi}_j = \frac{y_{1j}}{n_j} \tag{R.137}$$

for $j = c, t$. In **East** we provide a test based exact confidence interval using the standardized statistic.

$$D(\mathbf{Y}) = \frac{\hat{\pi}_t - \rho_0 \hat{\pi}_c}{\sqrt{\frac{(\hat{\pi}_t)(1-\hat{\pi}_t)}{n_t} + \frac{\rho_0^2(\hat{\pi}_c)(1-\hat{\pi}_c)}{n_c}}} \tag{R.138}$$

where $\hat{\pi}_c$ and $\hat{\pi}_t$ are the restricted maximum likelihood estimates of π_c and π_t computed, under the restriction that $\hat{\pi}_t/\hat{\pi}_c = \rho_0$. The restricted MLE's are suggested by Miettinen and Nurminen (1985). The use of (R.164) as the test statistic has been proposed by Farrington and Manning (1990) for asymptotic confidence intervals and by Chan and Zhang (1999) for exact confidence intervals.

Test Based Exact Confidence Intervals: Inverting Two One-Sided Tests

Let (ρ_*, ρ^*) be the desired $100(1 - \alpha)\%$ exact confidence interval, evaluated at $D(\mathbf{x})$, the observed value of the test statistic. This exact confidence interval may be constructed by inverting two one-sided hypothesis tests, each at the $\alpha/2$ significance level, under appropriate alternative hypotheses about ρ . The computations are very similar to the p-value computations performed in the next Section. The probability of observing any $\mathbf{Y} \in \Omega$ for any given value of ρ is

$$f_{\pi_c, \rho}(\mathbf{Y}) = \binom{n_c}{y_{1c}} \binom{n_t}{y_{1t}} \pi_c^{y_{1c}} (1 - \pi_c)^{y_{2c}} (\rho \pi_c)^{y_{1t}} (1 - \rho \pi_c)^{y_{2t}} . \tag{R.139}$$

Define

$$P_{\pi_c, \rho}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \leq \mathbf{D}(\mathbf{x})} f_{\rho \pi_c}(\mathbf{Y}) \tag{R.140}$$

and

$$Q_{\pi_c, \rho}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \geq \mathbf{D}(\mathbf{x})} f_{\rho \pi_c}(\mathbf{Y}) . \tag{R.141}$$

R Technical Reference and Formulas: Analysis

We must eliminate the nuisance parameter π_c from equations (R.166) and (R.167) by taking the supremum over its range. It is easy to see that the permissible range for π_c given ρ is the interval

$$I(\rho) = \{\pi_c: 0 \leq \pi_c \leq \min(1/\rho, 1)\} . \quad (\text{R.142})$$

Thus we define

$$P_\rho(D(\mathbf{x})) = \sup\{\mathbf{P}_{\pi_c, \rho}(\mathbf{D}(\mathbf{x})): \pi_c \in I(\rho)\} \quad (\text{R.143})$$

and

$$Q_{\rho}(D(\mathbf{x})) = \sup\{\mathbf{Q}_{\pi_c, \rho}(\mathbf{D}(\mathbf{x})): \pi_c \in I(\rho)\} . \quad (\text{R.144})$$

Starting with $\rho = 0$, the desired lower confidence bound is obtained by increasing the value of ρ until we find a value, denoted by ρ_* , such that the equality

$$Q_{\rho_*}(D(\mathbf{x})) = \alpha/2 \quad (\text{R.145})$$

is satisfied but for any $\rho < \rho_*$, $Q_\rho(D(\mathbf{x})) < \alpha/2$. The upper confidence bound, ρ^* is obtained in an analogous fashion. Starting with $\rho = \infty$ (i.e., a very large positive number), the desired upper confidence bound is obtained by decreasing the value of ρ until we find a value, denoted by ρ^* , such that the equality

$$P_{\rho^*}(D(\mathbf{x})) = \alpha/2 \quad (\text{R.146})$$

is satisfied but for any $\rho > \rho^*$, $P_\rho(D(\mathbf{x})) < \alpha/2$. **East** reports (ρ_*, ρ^*) as the $100 \times (1 - \alpha)\%$ confidence interval for the parameter ρ . Suppose ρ_0 is the true (unknown) value of ρ . The long run relative frequency with which, in repeated trials, this interval excludes ρ_0 is $\Pr(\rho_0 \leq \rho_*) + \Pr(\rho_0 \geq \rho^*)$. Using arguments similar to those given on page 2579 for the binomial difference, δ_0 , we can show that neither term in the above sum can exceed $\alpha/2$. Therefore the probability of the confidence interval excluding ρ_0 cannot exceed α . However, due to the discreteness of the distribution of $D(\mathbf{Y})$, and the conservatism induced by taking a supremum over all $\pi_c \in I(\rho)$, the above exclusion probability is usually less than α instead of equaling α . Thus, (ρ_*, ρ^*) may be regarded as a conservative confidence interval. In addition to the exact confidence interval, **East** also reports an exact one-sided p-value, defined as the smaller of the two tail areas,

$$p_c = \min(P_0(D(\mathbf{x})), \mathbf{Q}_0(\mathbf{D}(\mathbf{x}))) , \quad (\text{R.147})$$

and the two sided exact p-value is twice the one-sided:

$$p_t = 2p_c . \quad (\text{R.148})$$

The two-sided p-value is weakly consistent with the corresponding exact confidence interval for ρ . That is, if $1 \notin [\rho_*, \rho^*]$ then $p_t < \alpha$. The stronger consistency

requirement, that $p_t < \alpha$ if and only if $1 \notin [\rho_*, \rho^*]$ cannot be established unless $P_\rho(D(\mathbf{x}))$ and $Q_\rho(D(\mathbf{x}))$ are monotone functions of ρ for any given $D(\mathbf{x})$. This need not be the case, however.

R.5.6 Exact Test of Noninferiority: Ratio of Proportions

Suppose π_c is the response rate of an experimental treatment and π_t is the response rate of an active control treatment. Define the ratio of binomial proportions

$$\rho = \frac{\pi_t}{\pi_c} . \tag{R.149}$$

In a non-inferiority clinical trial the objective is not to demonstrate that the experimental treatment is superior to the control but rather to demonstrate that the experimental treatment is not significantly inferior. Accordingly a non-inferiority margin, ρ_0 , is specified a priori and we test the null hypothesis of inferiority $H_0 : \rho \leq \rho_0$ against $H_1 : \rho > \rho_0$ if $\rho_0 < 1$ Or $H_0 : \rho \geq \rho_0$ against $H_1 : \rho < \rho_0$ if $\rho_0 > 1$

- Test statistic: (Wald)

$$Z = \frac{\ln(\hat{\pi}_t) - \ln(\hat{\pi}_c) - \ln(\rho_0)}{\sqrt{\frac{(1-\hat{\pi}_t)}{n_t \hat{\pi}_t} + \frac{(1-\hat{\pi}_c)}{n_c \hat{\pi}_c}}},$$

where $\hat{\pi}_t$ and $\hat{\pi}_c$ are the sample proportions based on n_t and n_c observations in the treatment and control arm, respectively. $\delta_0 = \ln(\rho_0)$ is the noninferiority margin. Under Ho, Z follows asymptotic Normal distribution with mean 0 and variance 1. Only asymptotic inference is available with Wald test.

- Test statistic:(Farrington Manning)

$$Z = \frac{\hat{\pi}_t - \rho_0 \hat{\pi}_c}{\sqrt{\frac{\hat{\pi}_t(1-\hat{\pi}_t)}{n_t} + \frac{\rho_0^2 \hat{\pi}_c(1-\hat{\pi}_c)}{n_c}}},$$

where $\hat{\pi}_t$ and $\hat{\pi}_c$ are the sample proportions based on n_t and n_c observations in the treatment and control arm, respectively and $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the restricted maximum likelihood estimates of π_c and π_t , respectively.

The test is carried out under the assumption that ρ is at its threshold null value $\rho = \rho_0$.

Exact Inference

Let $\mathbf{Y} \in \Omega$ denote any generic 2×2 table of the form of Table R.3 that might be observed if we generated n_c independent bernoulli trials each with probability π_c and

R Technical Reference and Formulas: Analysis

n_t independent bernoulli trials each with probability π_t . The probability of observing any $\mathbf{Y} \in \Omega$ under H_0 is

$$f_{\pi_c, \rho_0}(\mathbf{Y}) = \binom{n_c}{y_{1c}} \binom{n_t}{y_{1t}} \pi_c^{y_{1c}} (1 - \pi_c)^{y_{2c}} (\rho_0 \pi_c)^{y_{1t}} (1 - \rho_0 \pi_c)^{y_{2t}} . \quad (\text{R.150})$$

The test statistic (see Farrington and Manning(1990) is defined as

$$D(\mathbf{Y}) = \frac{\hat{\pi}_t - \rho_0 \hat{\pi}_c}{\sqrt{\frac{(\hat{\pi}_t)(1-\hat{\pi}_t)}{n_t} + \frac{\rho_0^2(\hat{\pi}_c)(1-\hat{\pi}_c)}{n_c}}} \quad (\text{R.151})$$

where

$$\hat{\pi}_j = \frac{y_{1j}}{n_j} , \quad (\text{R.152})$$

for $j = c, t$, and $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the maximum likelihood estimates of π_c and π_t , respectively, restricted under the null hypothesis to satisfy the requirement that $\tilde{\pi}_t/\tilde{\pi}_c = \rho_0$. Miettinen and Nurminen (1985) have shown that one may obtain these restricted maximum likelihood estimates by solving a quadratic likelihood equation. Thus

$$\tilde{\pi}_1 = \frac{-B - \sqrt{B^2 - 4AC}}{2A} , \quad (\text{R.153})$$

and

$$\tilde{\pi}_t = \rho_0 \tilde{\pi}_c , \quad (\text{R.154})$$

where

$$A = \rho_0 N , \quad (\text{R.155})$$

$$B = -(\rho_0 n_t + y_{1t} + n_c + \rho_0 y_{1c}) , \quad (\text{R.156})$$

$$C = y_{1c} + y_{1t} . \quad (\text{R.157})$$

The test statistic (R.151) is known as the score statistic. Under H_0 this test statistic has mean 0 and variance 1. Let the data in Table R.1, denoted by \mathbf{x} , be the 2×2 table actually observed. Then the observed value of the test statistic is $D(\mathbf{x})$, and the left tail of the distribution of $D(\mathbf{Y})$ at its observed value under H_0 is

$$P_{\pi_c, \rho_0}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \leq \mathbf{D}(\mathbf{x})} \mathbf{f}_{\pi_c, \rho_0}(\mathbf{Y}) . \quad (\text{R.158})$$

If we knew the value of π_c , then $P_{\pi_c, \rho_0}(D(\mathbf{x}))$ would be the exact p-value for testing H_0 versus H_1 . Since π_c is unknown, however, we take the supremum of (R.158) over

all values of π_c in its range, just as we did for Barnard’s test in Section R.5.1. This produces a conservative p-value that is guaranteed to ensure that the true type-1 error of the test will never exceed its nominal significance level. Since $\rho_0 > 1$ the range of possible values for π_c is

$$I(\rho_0) = \{\pi_c : 0 < \pi_c < \min(1, 1/\rho_0)\}. \tag{R.159}$$

Thereupon the unconditional exact one-sided p-value is

$$p_1 \equiv P_{\rho_0}(D(\mathbf{x})) = \sup\{\mathbf{P}_{\pi_c, \rho_0}(D(\mathbf{x})) : \pi_c \in I(\rho_0)\}. \tag{R.160}$$

Note that in practice the supremum in equation (R.160) is taken over a restricted range for π rather than over the entire range $I(\rho_0)$. This restriction, proposed by Berger and Boos (1994), adds stability and reduces the conservatism of the procedure. The p-values are suitably adjusted so that the restricted search for the supremum does not compromise the type-1 error. Finally, it is worth noting that when $\rho_0 = 1$ the above p-value specializes to the left tail p-value obtained by Barnard’s test.

Additional Remarks

1. The score statistic $D(\mathbf{Y})$ specified by equation (R.151) is undefined when $y_{1c} = y_{1t} = 0$ and $\rho_0 = 1$, or when $y_{2c} = y_{2t} = 0$ and $\rho_0 = 1$. For these special cases the one- and two-sided p-values are both set to 1. These special cases never arise when performing a non-inferiority test with $\rho_0 \neq 1$.
2. The one-sided asymptotic p-value corresponding to p_1 is obtained by assuming that the test statistic $D(\mathbf{Y})$ converges in distribution to the standard normal.

Thus,

$$\tilde{p}_1 = 1 - \Phi(D(\mathbf{x})). \tag{R.161}$$

3. An alternative equivalent way to perform a level- α test of non-inferiority is to compute an exact $100 \times (1 - \alpha)$ lower confidence bound for ρ , say (ρ_L, ∞) , using the method described in Section R.5.4. If $\rho_L < \rho_0$ we reject the null hypothesis of inferiority.

R.5.7 Unconditional Exact Confidence Interval for the Ratio of Proportions

Suppose π_c is the binomial response rate of Control and π_t is the binomial response rate of treatment. We wish to compute an exact $100(1 - \alpha)\%$ confidence interval for

$$\rho = \frac{\pi_t}{\pi_c}. \tag{R.162}$$

The procedure parallels that described in Section R.5.4 for the difference of proportions, δ . We use a test based procedure. That is, we invert hypothesis tests of the

R Technical Reference and Formulas: Analysis

form $\rho = \rho_0$, where, in general, $\rho_0 \neq 1$. There is one further complication, however, since the p-values which we compute under these alternative hypotheses depend on a nuisance parameter. We handle this problem the same way we handled it for Barnard's unconditional exact hypothesis test and for the various exact tests of non-inferiority; by taking a supremum over all possible values of the nuisance parameter. **Choice of Test Statistic for Test Based Interval Estimation**

Suppose we take n_c independent Bernoulli samples from Control and n_t independent Bernoulli samples from Treatment. Let $\mathbf{Y} \in \Omega$ (see Table R.3 denote any generic 2×2 table that might be observed, and let \mathbf{x} (see Table R.1, page 2568), be the 2×2 table that was actually observed. Define

$$\hat{\pi}_j = \frac{y_{1j}}{n_j} \tag{R.163}$$

for $j = c, t$. In **East** we provide a test based exact confidence interval using the standardized statistic.

$$D(\mathbf{Y}) = \frac{\hat{\pi}_t - \rho_0 \hat{\pi}_c}{\sqrt{\frac{(\hat{\pi}_t)(1-\hat{\pi}_t)}{n_t} + \frac{\rho_0^2(\hat{\pi}_c)(1-\hat{\pi}_c)}{n_c}}} \tag{R.164}$$

where $\hat{\pi}_c$ and $\hat{\pi}_t$ are the maximum likelihood estimates of π_c and π_t computed, under the restriction that $\hat{\pi}_t/\hat{\pi}_c = \rho_0$. The use of (R.164) as the test statistic has been proposed by Farrington and Manning (1990) for asymptotic confidence intervals and by Chan and Zhang (1999) for exact confidence intervals.

Test Based Exact Confidence Intervals: Inverting Two One-Sided Tests

Let (ρ_*, ρ^*) be the desired $100(1 - \alpha)\%$ exact confidence interval, evaluated at $D(\mathbf{x})$, the observed value of the test statistic. This exact confidence interval may be constructed by inverting two one-sided hypothesis tests, each at the $\alpha/2$ significance level, under appropriate alternative hypotheses about ρ . The probability of observing any $\mathbf{Y} \in \Omega$ for any given value of ρ is

$$f_{\pi_c, \rho}(\mathbf{Y}) = \binom{n_c}{y_{1c}} \binom{n_t}{y_{1t}} \pi_c^{y_{1c}} (1 - \pi_c)^{y_{2c}} (\rho \pi_c)^{y_{1t}} (1 - \rho \pi_c)^{y_{2t}} . \tag{R.165}$$

Define

$$P_{\pi_c, \rho}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \leq \mathbf{D}(\mathbf{x})} f_{\rho \pi_c}(\mathbf{Y}) \tag{R.166}$$

and

$$Q_{\pi_c, \rho}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \geq \mathbf{D}(\mathbf{x})} f_{\rho \pi_c}(\mathbf{Y}) . \tag{R.167}$$

We must eliminate the nuisance parameter π_c from equations (R.166) and (R.167) by taking the supremum over its range. It is easy to see that the permissible range for π_c given ρ is the interval

$$I(\rho) = \{\pi_c: 0 \leq \pi_c \leq \min(1/\rho, 1)\}. \quad (\text{R.168})$$

Thus we define

$$P_\rho(D(\mathbf{x})) = \sup\{\mathbf{P}_{\pi_c, \rho}(\mathbf{D}(\mathbf{x})): \pi_c \in I(\rho)\} \quad (\text{R.169})$$

and

$$Q_\rho(D(\mathbf{x})) = \sup\{\mathbf{Q}_{\pi_c, \rho}(\mathbf{D}(\mathbf{x})): \pi_c \in I(\rho)\}. \quad (\text{R.170})$$

Starting with $\rho = 0$, the desired lower confidence bound is obtained by increasing the value of ρ until we find a value, denoted by ρ_* , such that the equality

$$Q_{\rho_*}(D(\mathbf{x})) = \alpha/2 \quad (\text{R.171})$$

is satisfied but for any $\rho < \rho_*$, $Q_\rho(D(\mathbf{x})) < \alpha/2$. The upper confidence bound, ρ^* is obtained in an analogous fashion. Starting with $\rho = \infty$ (i.e., a very large positive number), the desired upper confidence bound is obtained by decreasing the value of ρ until we find a value, denoted by ρ^* , such that the equality

$$P_{\rho^*}(D(\mathbf{x})) = \alpha/2 \quad (\text{R.172})$$

is satisfied but for any $\rho > \rho^*$, $P_\rho(D(\mathbf{x})) < \alpha/2$.

East reports (ρ_*, ρ^*) as the $100 \times (1 - \alpha)\%$ confidence interval for the parameter ρ . Suppose ρ_0 is the true (unknown) value of ρ . The long run relative frequency with which, in repeated trials, this interval excludes ρ_0 is $\Pr(\rho_0 \leq \rho_*) + \Pr(\rho_0 \geq \rho^*)$. Using arguments similar to those given on page 2579 for the binomial difference, δ_0 , we can show that neither term in the above sum can exceed $\alpha/2$. Therefore the probability of the confidence interval excluding ρ_0 cannot exceed α . However, due to the discreteness of the distribution of $D(\mathbf{Y})$, and the conservatism induced by taking a supremum over all $\pi_c \in I(\rho)$, the above exclusion probability is usually less than α instead of equaling α . Thus, (ρ_*, ρ^*) may be regarded as a conservative confidence interval.

In addition to the exact confidence interval, East also reports an exact one-sided p-value, defined as the smaller of the two tail areas,

$$p_1 = \min(P_0(D(\mathbf{x})), \mathbf{Q}_0(\mathbf{D}(\mathbf{x}))), \quad (\text{R.173})$$

R Technical Reference and Formulas: Analysis

and the two sided exact p-value is twice the one-sided:

$$p_2 = 2p_1 . \tag{R.174}$$

The two-sided p-value is weakly consistent with the corresponding exact confidence interval for ρ . That is, if $1 \notin [\rho_*, \rho^*]$ then $p_2 < \alpha$. The stronger consistency requirement, that $p_2 < \alpha$ if and only if $1 \notin [\rho_*, \rho^*]$ cannot be established unless $P_\rho(D(\mathbf{x}))$ and $Q_\rho(D(\mathbf{x}))$ are monotone functions of ρ for any given $D(\mathbf{x})$. This need not be the case, however.

We shall see in Section R.5.8 that the above procedure can be slightly modified in practice. The suprema in equations (R.169) and (R.170) can be taken over a restricted range for π rather than over the entire range $I(\rho)$. This restriction, proposed by Berger and Boos (1994), adds stability and reduces the conservatism of the procedure. The right hand sides of equations (R.171) and (R.172) are suitably adjusted so that the restricted search for the supremum does not compromise the coverage properties of the resulting confidence interval.

Asymptotic Results

East provides asymptotic confidence interval and p-values for ρ . They are due to Farrington and Manning (1990). The standardized test statistic (R.164) is adopted and assumed to have a standard normal distribution. Under the null hypothesis that $\rho = 1$ the standardized test statistic is identical to the statistic used for Barnard's test. Therefore the asymptotic one-sided p-value is the same as the asymptotic one-sided p-value for Barnard's test. The asymptotic two-sided p-value is double the asymptotic one-sided p-value.

The asymptotic $100 \times (1 - \alpha)\%$ confidence interval $(\tilde{\rho}_*, \tilde{\rho}^*)$ is obtained by inverting the corresponding one-sided hypothesis tests. Thus $\tilde{\rho}_*$ satisfies the equality

$$1 - \Phi \left\{ \frac{(x_{1t}/n_t) - \rho_*(x_{1c}/n_c)}{\sqrt{\frac{\rho_*^2(\tilde{\pi}_c)(1-\tilde{\pi}_c)}{n_c} + \frac{(\tilde{\pi}_t)(1-\tilde{\pi}_t)}{n_t}}} \right\} = \alpha/2 , \tag{R.175}$$

where $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the maximum likelihood estimates of π_c and π_t , respectively, under the restriction that $\tilde{\pi}_t/\tilde{\pi}_c = \rho_*$. Similarly $\tilde{\rho}^*$ satisfies the equality

$$\Phi \left\{ \frac{(x_{1t}/n_t) - \rho^*(x_{1c}/n_c)}{\sqrt{\frac{\rho_*^2(\tilde{\pi}_c)(1-\tilde{\pi}_c)}{n_c} + \frac{(\tilde{\pi}_t)(1-\tilde{\pi}_t)}{n_t}}} \right\} = \alpha/2 , \tag{R.176}$$

where $\tilde{\pi}_c$ and $\tilde{\pi}_t$ are the maximum likelihood estimates of π_c and π_t , respectively, under the restriction that $\tilde{\pi}_t/\tilde{\pi}_c = \delta^*$.

R.5.8 Searching for Nuisance Parameters in a Restricted Range: Berger-Boos Correction

A source of conservatism, present in all the unconditional procedures covered in this chapter, is the fact that we must cater for the worst possible value of the nuisance parameter, π_c , by taking a supremum over its range. If this source of conservatism could be reduced in some way, it would result in shorter confidence intervals. A modification based on a proposal by Berger and Boos (1994) achieves this end. It should be noted that Berger and Boos (1994) actually proposed their method only for hypothesis tests. To our knowledge the extension to confidence intervals is new. To avoid unnecessary repetition, we will discuss the Berger-Boos modification only as it applies to Section (R.5.4), for computing an unconditional exact confidence interval for the difference of two binomial parameters based on inverting two one-sided hypothesis tests. It will be clear from this discussion that the same type of Berger-Boos correction also applies to all the other settings in this chapter, such as exact unconditional tests of superiority, non-inferiority or equivalence, and exact confidence intervals for ratios of binomials.

Let x be the observed 2×2 table. The main idea is that the information available in x about π_c and π_t can be used to reduce the conservatism of the exact confidence interval for δ . As a first step, we compute an exact $100(1 - \gamma/2)\%$ confidence interval, $A_1(x) = [l_1(x), u_1(x)]$, for π_c , and, independently, an exact $100(1 - \gamma/2)\%$ confidence interval, $A_2(x) = [l_2(x), u_2(x)]$, for π_t . Let \mathcal{E} denote the event $(\pi_c, \pi_t) \in A_1(x) \times A_2(x)$. If \mathcal{E} is true that restricts the range of δ and the associated range of π_c . It is easy to show that if \mathcal{E} is true, the range of possible values for δ must be restricted to the interval $[\delta_{\min}, \delta_{\max}]$, where

$$\delta_{\min} = l_2(x) - u_1(x), \tag{R.177}$$

and

$$\delta_{\max} = u_2(x) - l_1(x). \tag{R.178}$$

For any δ in this interval, π_c must lie in the restricted interval

$$I_x(\delta) = \{\pi_c: \max(l_1(x), l_2(x) - \delta) \leq \pi_c \leq \min(u_1(x), u_2(x) - \delta)\}. \tag{R.179}$$

Clearly $I_x(\delta) \subseteq I(\delta)$.

Define the right tail probability

$$Q_{\pi_c, \delta}(D(\mathbf{x})) = \sum_{\mathbf{D}(\mathbf{Y}) \geq \mathbf{D}(\mathbf{x})} \mathbf{f}_{\pi_c, \delta}(\mathbf{Y}) \tag{R.180}$$

R Technical Reference and Formulas: Analysis

and its supremum

$$Q_{\delta|\mathcal{E}}(D(\mathbf{x})) = \sup\{Q_{\pi_c, \delta}(D(\mathbf{x})): \pi_c \in I_x(\delta)\} . \quad (\text{R.181})$$

Notice the difference between $Q_{\delta}(D(x))$ given by equation (R.122) and $Q_{\delta|\mathcal{E}}(D(x))$ given by above equation. The first expression eliminates π_c by searching over the unrestricted range $I(\delta)$ while the second expression eliminates π_c by searching over the restricted range $I_x(\delta)$. The restricted search reduces conservatism since we must have

$$Q_{\delta|\mathcal{E}}(D(x)) \leq Q_{\delta}(D(x)) . \quad (\text{R.182})$$

In a similar manner we define the left tail probability

$$P_{\pi_c, \delta}(D(x)) = \sum_{D(y) \leq D(x)} f_{\pi_c, \delta}(y) \quad (\text{R.183})$$

and its supremum

$$P_{\delta|\mathcal{E}}(D(x)) = \sup\{P_{\pi_c, \delta}(D(x)): \pi_c \in I_x(\delta)\} . \quad (\text{R.184})$$

We next compute upper and lower confidence bounds for δ as described in Section R.5.4. Equations (R.123) and (R.124) must be modified, however, to compensate for the fact that we are now searching over a subset of the original parameter space. This adjustment is made by decreasing the right hand side of each equation by $\gamma/2$. Thus the lower confidence bound is the value of δ_* that satisfies the condition

$$Q_{\delta_*|\mathcal{E}}(D(x)) = \alpha/2 - \gamma/2 , \quad (\text{R.185})$$

such that for any δ satisfying $\delta_{\min} \leq \delta < \delta_*$, $Q_{\delta|\mathcal{E}}(D(x)) < \alpha/2 - \gamma/2$. If no value of δ_* can be found in the interval $[\delta_{\min}, \delta_{\max}]$ such that equation (R.185) is satisfied, we set $\delta_* = \delta_{\min}$. The upper confidence bound is the value of δ^* that satisfies the condition

$$P_{\delta^*|\mathcal{E}}(D(x)) = \alpha/2 - \gamma/2 , \quad (\text{R.186})$$

such that for any δ satisfying $\delta_{\max} \geq \delta > \delta^*$, $P_{\delta|\mathcal{E}}(D(x)) < \alpha/2 - \gamma/2$. If no value of δ^* can be found in the interval $[\delta_{\min}, \delta_{\max}]$ such that equation (R.186) is satisfied, we set $\delta^* = \delta_{\max}$. Thus, no matter what the data, we will always have

$$(\delta_*, \delta^*) \subseteq (\delta_{\min}, \delta_{\max}) . \quad (\text{R.187})$$

Suppose that δ_0 is the true (unknown) value of δ . With the above adjustment to the right hand sides of equations (R.185) and (R.186) one can show that

$$\Pr\{\delta_0 \notin (\delta_*, \delta^*)\} \leq \alpha , \quad (\text{R.188})$$

the desired exclusion probability. To see this observe that

$$\begin{aligned} \Pr\{\delta_0 \notin (\delta_*, \delta^*)\} &= \Pr\{[\delta \notin (\delta_*, \delta^*)] \cap \mathcal{E}\} + \Pr\{[\delta_0 \notin (\delta_*, \delta^*)] \cap \mathcal{E}^c\} \\ &\leq \Pr\{\delta_0 \notin (\delta_*, \delta^*)\} + \Pr(\mathcal{E}^c) \end{aligned} \tag{R.189}$$

$$\begin{aligned} &= \Pr(\delta_* \geq \delta_0) + \Pr(\delta^* \leq \delta_0) + \Pr(\mathcal{E}^c) \\ &\leq \Pr(\delta_* \geq \delta_0) + \Pr(\delta^* \leq \delta_0) + \gamma. \end{aligned} \tag{R.190}$$

Inequality (R.189) uses the fact that a probability cannot exceed 1. Since, for $i = 1, 2$, the interval $A_i(x)$ excludes the parameter π_c with probability $\gamma/2$, it follows by the Bonferroni inequality that $\Pr(\mathcal{E}^c) \leq \gamma$. Inequality (R.190) follows. We show next that neither $\Pr(\delta_* \geq \delta_0)$ nor $\Pr(\delta^* \leq \delta_0)$ can exceed $\alpha/2 - \gamma/2$. Define $H_{\mathcal{E}}(\delta_0)$ to be the smallest value of the random variable $D(\mathbf{Y})$ satisfying the inequality

$$Q_{\delta_0|\mathcal{E}}(H_{\mathcal{E}}(\delta_0)) \leq \alpha/2 - \gamma/2. \tag{R.191}$$

This definition implies that if $D(x) < H_{\mathcal{E}}(\delta_0)$, then $Q_{\delta_0|\mathcal{E}}(D(x)) > \alpha/2 - \gamma/2$. But we know from (R.185) that there is no value of $\delta \leq \delta_*$ for which $Q_{\delta}(D(x)) > \alpha/2 - \gamma/2$. It follows that $\delta_0 > \delta_*$ whenever $D(x) < H_{\mathcal{E}}(\delta_0)$. Therefore the random event $\{D(y) < H_{\mathcal{E}}(\delta_0)\}$ is a proper subset of the random event $\{\delta_0 > \delta_*\}$ and hence

$$\Pr(\delta_0 > \delta_*) \geq \Pr\{D(y) < H_{\mathcal{E}}(\delta_0)\}. \tag{R.192}$$

Taking complimentary probabilities on both sides of equation (R.192) we have

$$\Pr(\delta_* \geq \delta_0) \leq \Pr\{D(y) \geq H_{\mathcal{E}}(\delta_0)\} = Q_{\pi_c, \delta_0}(H_{\mathcal{E}}(\delta_0)). \tag{R.193}$$

Next, taking the supremum over all possible values of $\pi_c \in I_x(\delta_0)$, we have

$$Q_{\pi_c, \delta_0}(H_{\mathcal{E}}(\delta_0)) \leq \sup\{Q_{\pi_c, \delta_0}(H_{\mathcal{E}}(\delta_0)): \pi_c \in I_x(\delta_0)\} = Q_{\delta_0|\mathcal{E}}(H_{\mathcal{E}}(\delta_0)) \leq \alpha/2 - \gamma/2. \tag{R.194}$$

This establishes that

$$\Pr(\delta_* \geq \delta_0) \leq \alpha/2 - \gamma/2. \tag{R.195}$$

By a similar argument, $\Pr(\delta^* \leq \delta_0) \leq \alpha/2 - \gamma/2$. Therefore

$$\Pr\{\delta_0 \notin (\delta_*, \delta^*)\} \leq 2(\alpha/2 - \gamma/2) + \gamma = \alpha \tag{R.196}$$

The above modifications generally give shorter confidence intervals than the unmodified approach wherein we search the entire sample space of the nuisance parameters. One ambiguity about the procedure, however, is the choice of γ . The

R Technical Reference and Formulas: Analysis

smaller we make γ the more the modified method resembles the original method. The choice $\gamma = 0$ corresponds to making no modification to the original approach. At the other extreme the larger we make γ , the more we restrict the region in which we search for the supremum, and the more we must compensate for this restriction on the right hand sides of equations (R.185), (R.186). These equations show that we cannot increase γ beyond $\alpha/2$.

The Implementation in East

In **East** we have set the default value to $\gamma = 0.99e - 7$. This value is very small relative to α , which is usually 0.05. Therefore it does not usually affect the right hand sides of equations (R.185) and (R.186) by much. On the other hand it can provide greater stability, narrower confidence intervals, and faster execution times, in unbalanced settings, by cutting off regions near the extremes, 0 and 1, of the parameter space. We have observed, empirically, that the functions P_{δ, π_c} and Q_{δ, π_c} can have multiple high peaks at values of π_c near 0 or 1. By cutting off these regions from the parameter space we are able to reduce conservatism and add stability to the computation of the supremum.

R.5.9 Noninferiority:Odds Ratio of Proportions

The odds ratio of proportions denoted by Ψ is defined as $\Psi = \frac{\pi_t(1 - \pi_c)}{\pi_c(1 - \pi_t)}$. In Noninferiority trial, we are interested in testing $H_0 : \Psi \geq \Psi_0$ against $H_0 : \Psi < \Psi_0$ if $\Psi_0 > 1$

Or, $H_0 : \Psi \leq \Psi_0$ against $H_0 : \Psi > \Psi_0$ if $\Psi_0 < 1$

The test statistics for the two tests are :

Noninferiority (Wald)

$$Z = \frac{\ln \hat{\Psi} - \ln \Psi_0}{\sqrt{\frac{\hat{\pi}_t}{n_t(1 - \hat{\pi}_t)} + \frac{\hat{\pi}_c}{n_c(1 - \hat{\pi}_c)}}} \sim N(0, 1) \tag{R.197}$$

Noninferiority (Score)

$$Z = \frac{n_c(\hat{\pi}_c - \tilde{\pi}_c)}{SE} \sim N(0, 1) \tag{R.198}$$

where

$$SE = \left[\frac{1}{n_t \pi_t (1 - \pi_t)} + \frac{1}{n_c \pi_c (1 - \pi_c)} \right]^{-1} \tag{R.199}$$

R.5.10 Common Odds Ratio for Stratified 2x2 Tables

Breslow-Day Test for Homogeneity of Odds-Ratios

$$H_0: \Psi_i = \Psi, i = 1, 2, \dots s .$$

Breslow and Day (1980) statistic:

$$\chi_{BD}^2 = \sum_{i=1}^s \frac{[X_i - A_i(\hat{\Psi})]^2}{var(X_i | \hat{\Psi})} , \tag{R.200}$$

where $A_i(\hat{\Psi})$ is the positive root of the quadratic equation

$$\frac{A_i(N_i - m_i - n_i + A_i)}{(m_i - A_i)(n_i - A_i)} = \hat{\Psi} , \tag{R.201}$$

formed by expressing the i^{th} table as

$$\begin{matrix} m_i - A_i & A_i \\ N_i - m_i - n_i + A_i & n_i - A_i , \end{matrix}$$

and equating its empirical Odds-Ratio to the Mantel-Haenszel common Odds-Ratio

$$\hat{\Psi} = \frac{\sum_{i=1}^s x_i(N_i - m_i - n_i + x_i)/N_i}{\sum_{i=1}^s (n_i - x_i)(m_i - x_i)/N_i} . \tag{R.202}$$

The variance of X_i is estimated by:

$$var(X_i | \hat{\Psi}) = \left[\frac{1}{A_i(\hat{\Psi})} + \frac{1}{m_i - A_i(\hat{\Psi})} + \frac{1}{n_i - A_i(\hat{\Psi})} + \frac{1}{N_i - m_i - n_i + A_i(\hat{\Psi})} \right]^{-1} \tag{R.203}$$

Tarone correction for Breslow-Day test

$$\chi_{BDT}^2 = \sum_{i=1}^s \frac{[X_i - A_i(\hat{\Psi})]^2}{var(X_i | \hat{\Psi})} - \frac{\left[\sum_{i=1}^s X_i - \sum_{i=1}^s A_i(\hat{\Psi}) \right]^2}{\sum_{i=1}^s var(X_i | \hat{\Psi})} , \tag{R.204}$$

R Technical Reference and Formulas: Analysis

where A_i , and $var(X_i | \hat{\Psi})$ are defined as above. In large samples, both χ_{BD}^2 and χ_{BDT}^2 are chi-squared distributed with $s - 1$ degrees of freedom, and the 2-sided p-values for testing H_0 is:

$$p_{BD} = \Pr(\chi_{BD}^2 \geq \chi_{0,BD}^2) \tag{R.205}$$

$$p_{BDT} = \Pr(\chi_{BDT}^2 \geq \chi_{0,BDT}^2), \tag{R.206}$$

where $\chi_{0,BD}^2$ and $\chi_{0,BDT}^2$ are the observed values of χ_{BD}^2 and χ_{BDT}^2 .

Mantel-Haenszel Inference for the Common Odds-Ratio

$$H_0: \Psi = 1.$$

Mantel-Haenszel (1959) test

$$\chi_{MH}^2 = \left[\sum_{i=1}^s \frac{x_i y'_i - x'_i y_i}{N_i} \right]^2 / \sum_{i=1}^s \frac{m_i m'_i n_i (N_i - n_i)}{(N_i - 1) N_i^2} \tag{R.207}$$

is chi-squared distributed with one degree of freedom.

$$p_{MH} = \Pr(\chi_{MH}^2 \geq \chi_0^2) \tag{R.208}$$

where χ_0^2 is the observed value of χ_{MH}^2 . The RBG variance is

$$var(\log \hat{\Psi}) = \sum_{i=1}^s \left(\frac{a_i c_i}{2c_+^2} + \frac{a_i d_i + b_i c_i}{2c_+ d_+} + \frac{b_i d_i}{2d_+^2} \right) \tag{R.209}$$

where

$$\begin{aligned} a_i &= \frac{x_i + y'_i}{N_i}, \\ b_i &= \frac{x'_i + y_i}{N_i}, \\ c_i &= \frac{x_i y'_i}{N_i}, \\ d_i &= \frac{x'_i y_i}{N_i}, \\ c_+ &= \sum_{i=1}^s c_i, \\ d_+ &= \sum_{i=1}^s d_i. \end{aligned}$$

A $100(1 - \alpha)\%$ confidence interval for $\log \Psi$

$$CI_{RBG} = \log \hat{\Psi} \pm z_{\alpha/2} [\text{var}(\log \hat{\Psi})]^{1/2}. \quad (\text{R.210})$$

The 2-sided p-value for testing

$$H_0: \Psi = 1,$$

based on the RBG variance is

$$p_{RBG} = 2[1 - \Phi(\frac{|\log \hat{\Psi}|}{\sqrt{\text{var}(\log \hat{\Psi})}})]. \quad (\text{R.211})$$

R.5.11 Fisher's Exact Test

As in the **Difference of Proportions** test, suppose π_t and π_c denote the proportions of the successes from the experimental treatment (T) and the control treatment (C). To test the null hypothesis:

$$H_0: \pi_t = \pi_c, \quad (\text{R.212})$$

against 1-sided alternatives of the form,

$$H_1: \pi_t > \pi_c, \quad (\text{R.213})$$

or

$$H_1': \pi_t < \pi_c, \quad (\text{R.214})$$

and against 2-sided alternatives of the form

$$H_2: \pi_t \neq \pi_c. \quad (\text{R.215})$$

Suppose that H_0 is true and let the common probability of success for the two binomial populations be $\pi_t = \pi_c = \pi$. Then the probability of observing the data in Table R.1 is a product of two binomial probabilities, denoted by

$$f_0(\mathbf{x}) = \binom{n_c}{x_{1c}} \binom{n_t}{x_{1t}} \pi^{x_{1c} + x_{1t}} (1 - \pi)^{x_{2c} + x_{2t}}. \quad (\text{R.216})$$

The p-value is defined to be the probability, under H_0 , of obtaining a 2×2 table at least as extreme as the observed table, \mathbf{x} . Let \mathbf{Y} denote any generic 2×2 table that can arise if we take two independent samples, one of size n_c from binomial population c and the other of size n_t from binomial population t. Such a generic 2×2 table is

R Technical Reference and Formulas: Analysis

Table R.3: Any Generic 2x2 Contingency Table, \mathbf{y}

| Response | Control | Treatment | Row_Total |
|-----------|----------|-----------|-------------------|
| Success | y_{1c} | y_{1t} | $y_{1c} + y_{1t}$ |
| Failure | y_{2c} | y_{2t} | $y_{2c} + y_{2t}$ |
| Col.Total | n_c | n_t | N |

displayed below in Table R.3: The probability of observing this table is $f_0(\mathbf{Y})$ which, as shown by equation (R.216), contains an unknown (nuisance) parameter, π . As long as the probability of observing any generic 2×2 table depends on π , exact inference is not possible. Since the p-value is based on summing up the probabilities of many such tables, each depending on an unknown parameter. The key to exact inference is getting rid of π , the nuisance parameter.

In Fisher's Exact Test, conditional approach is used. The sufficient statistic for π is $y_{11} + y_{12}$, the sum of successes from the two populations. The observed value of the sufficient statistic is m_1 . Thus, by the sufficiency principle, if the condition on $y_{11} + y_{12} = m_1$, the probability of any generic 2×2 table, \mathbf{Y} , no longer depends on the nuisance parameter π . To see this let

$$\Gamma = \left\{ \mathbf{Y} : \sum_{j=1}^2 y_{ij} = \mathbf{m}_i, \sum_{i=1}^2 y_{ij} = \mathbf{n}_j \right\} \tag{R.217}$$

denote a reference set of 2×2 contingency tables with fixed row and column margins. Since we are dealing with the case of two independent binomial samples, each of size $n_i, i = 1, 2$, (considering $n_1 = n_c$ and $n_2 = n_t$), conditioning on $y_{11} + y_{12} = m_1$ is equivalent to conditioning on $\mathbf{Y} \in \Gamma$. Let $h(\mathbf{Y})$ denote the probability of observing any $\mathbf{Y} \in \Gamma$ under the null hypothesis (R.212). Then

$$h(\mathbf{Y}) = \frac{f_0(\mathbf{Y})}{\sum_{\mathbf{Y} \in \Gamma} f_0(\mathbf{Y})} \tag{R.218}$$

which simplifies to

$$h(\mathbf{Y}) = \frac{\binom{n_1}{y_{11}} \binom{n_2}{y_{12}}}{\binom{N}{m_1}}, \tag{R.219}$$

a hypergeometric probability free of π . Exact inference is thus possible only if we confine our attention to 2×2 tables in Γ . Next turn to the question of how to

determine if a 2×2 contingency table, \mathbf{Y} , is at least as extreme as the observed table, \mathbf{x} . Let $D : \Gamma \rightarrow \mathcal{R}$ be a function assigning a real number, $D(\mathbf{Y})$, to each $\mathbf{Y} \in \Gamma$ in such a way that \mathbf{Y} is judged to be at least as extreme as \mathbf{x} provided $D(\mathbf{Y}) \geq D(\mathbf{x})$. We refer to $D(\mathbf{Y})$ as a discrepancy measure. Fisher's test statistic is given by:

$$D(\mathbf{Y}) = -2 \log(\gamma \mathbf{h}(\mathbf{Y})) . \tag{R.220}$$

where

$$\gamma = (2\pi N^{-3} m_1 m_2 n_1 n_2)^{-\frac{1}{2}} \tag{R.221}$$

The exact 2-sided p-value is defined as:

$$p_2 = \Pr(D(\mathbf{Y}) \geq D(\mathbf{x})) = \sum_{D(\mathbf{Y}) \geq D(\mathbf{x})} \mathbf{h}(\mathbf{Y}) , \tag{R.222}$$

the sum being taken over all $\mathbf{Y} \in \Gamma$ such that $D(\mathbf{Y}) \geq D(\mathbf{x})$. In large samples the distribution of $D(\mathbf{Y})$ conditional on $\mathbf{Y} \in \Gamma$ converges to the chi-square distribution with 1 degree of freedom. (Kendall and Stuart (1979)). The asymptotic 2-sided p-value is given by:

$$\tilde{p}_2 = \Pr(\chi_1^2 \geq D(\mathbf{x})) , \tag{R.223}$$

where χ_1^2 is a random variable distributed as chi-square with 1 df. You can also define the 1-sided exact p-value. It is based on the test statistic:

$$D(\mathbf{Y}) = y_{11} . \tag{R.224}$$

Since we have confined our attention only to 2×2 contingency tables in Γ , the value of y_{11} suffices to specify the entire 2×2 table \mathbf{Y} , and the exact probability of y_{11} is $h(\mathbf{Y})$. Moreover it is easy to see that y_{11} ranges from a minimum of

$$t_{\min} = \max(0, n_1 - m_2) , \tag{R.225}$$

to a maximum of

$$t_{\max} = \min(m_1, n_1) . \tag{R.226}$$

The exact 1-sided p-value for the Fisher tests is then defined as either the right or left tail area of the exact distribution of y_{11} at the observed value, x_{11} , based on the location of x_{11} relative to $n_1 m_1 / N$, the mean of y_{11} . That is,

$$p_1 = \begin{cases} \sum_{y_{11}=t_{\min}}^{x_{11}} h(\mathbf{Y}) & \text{if } x_{11} > n_1 m_1 / N \\ \sum_{y_{11}=x_{11}}^{t_{\max}} h(\mathbf{Y}) & \text{if } x_{11} \leq n_1 m_1 / N \end{cases} \tag{R.227}$$

A small 1-sided p-value furnishes evidence against the 1-sided alternative (R.213) if it is computed as the right tail of the exact distribution of y_{11} , and against the 1-sided alternative (R.214), if it is computed as the left tail of the exact distribution of y_{11} .

R.6 Many Proportions

- R.6.1 Contingency Coefficients
- R.6.2 Wilcoxon Rank Sum Test for Ordered Categories Data
- R.6.3 Trend in R ordered proportions
- R.6.4 Chi-square for R Unordered Binomial Properties
- R.6.5 Chi-square for R Unordered multinomial Properties

R.6.1 Contingency Coefficients

The **Contingency Coefficients** are derived from Pearson's chi-square statistic. The Phi contingency coefficient is given by,

$$\phi = \sqrt{\frac{\chi^2(\mathbf{x})}{N}} . \tag{R.228}$$

Pearson's contingency coefficient is given by:

$$CC = \sqrt{\frac{\chi^2(\mathbf{x})}{\chi^2(\mathbf{x}) + N}} . \tag{R.229}$$

The Sakoda contingency coefficient is given by

$$CC_1 = \sqrt{\frac{q\chi^2(\mathbf{x})}{(q-1)(\chi^2(\mathbf{x}) + N)}} . \tag{R.230}$$

The Tschuprov contingency coefficient ranges between 0 and 1, with 0 signifying no association and 1 signifying perfect association. It is given by,

$$CC_2 = \left(\frac{\chi^2(\mathbf{x})}{N\sqrt{(r-1)(c-1)}} \right)^{1/2} . \tag{R.231}$$

Finally, Cramer's V coefficient ranges between 0 and 1, with 0 signifying no association and 1 signifying perfect association. It is given by,

$$V = \sqrt{\frac{\chi^2(\mathbf{x})}{N(q-1)}} . \tag{R.232}$$

The $100 \times (1 - \alpha)\%$ confidence interval for any measure of association

$$CI = M(\mathbf{x}) \pm z_{\alpha/2} \times ASE.MLE , \tag{R.233}$$

where z_{β} is the value of the $(1 - \beta)$ percentile point of the standard normal distribution.

R.6.2 Wilcoxon Rank Sum Test for Ordered Categories Data

Each response must fall into one of c ordinal categories according to a multinomial distribution.

$$\gamma_{jk} = \sum_{i=1}^j \pi_{ik} ,$$

$$\gamma'_{jk} = \sum_{i=1}^j \pi'_{ik} ,$$

for $j = 1, 2, \dots, c$, and $k = 1, 2, \dots, s$. Then the Wilcoxon test is especially suited to detecting departures from the null of the form

$$H_1: \gamma_{jk} \geq \gamma'_{jk} ,$$

or

$$H'_1: \gamma'_{jk} \geq \gamma_{jk} ,$$

for all $j \in \{1, 2, \dots, c\}$, $k \in \{1, 2, \dots, s\}$, with strict inequality at at-least 6.3 one j, k . The 2-sided alternative hypothesis is that either H_1 or H'_1 is true; the alternative hypothesis does not specify which of the two possibilities is true, however. The Wilcoxon Rank Sum Test Statistic is of the form,

$$T = \sum_{k=1}^s \sum_{j=1}^c w_j X_{jk} , \tag{R.234}$$

where w_j are Wilcoxon-Mann-Whitney scores which are the ranks (mid-ranks in the case of tied observations) of the underlying responses.

$$w_j = n_1 + \dots + n_{j-1} + (n_j + 1)/2 \tag{R.235}$$

The mean of T , under the null hypothesis of no row and column interaction is given by

$$E(T) = \left(\frac{m}{N}\right) \sum_{j=1}^c w_j n_j \tag{R.236}$$

And the variance is

$$\sigma^2(T) = \left[\frac{mm'}{N(N-1)}\right] \sum_{j=1}^c \left[w_j - \frac{E(T)}{m}\right]^2 n_j \tag{R.237}$$

Under H_0 , T follows asymptotic Normal distribution with mean $E(T)$ and variance $\sigma^2(T)$

R Technical Reference and Formulas: Analysis

R.6.3 Trend in R ordered proportions

To determine whether a trend exists in the unknown proportions of response π_g for $g = 1, \dots, K$ ordered binomially distributed populations using independent random samples. Test statistic:

$$T = \sum_{j=1}^c w_j Y_j, \quad (\text{R.238})$$

where

$$w_j = j - 1. \quad (\text{R.239})$$

The mean of the test statistic is

$$E(T) = \left(\frac{m}{N}\right) \sum_{j=1}^c w_j n_j. \quad (\text{R.240})$$

and the variance of the test statistic is

$$\sigma^2(T) = \left[\frac{m(N-m)}{N(N-1)}\right] \sum_{j=1}^c \left[w_j - \frac{E(T)}{m}\right]^2 n_j. \quad (\text{R.241})$$

Under H_0 , $Z = \frac{T-E(T)}{\sqrt{Var(T)}}$ follows $N(0, 1)$ distribution.

R.6.4 Chi-square for R Unordered Binomial Properties

Hypothesis $H_0 : \pi_{1j} = \pi_{2j} \dots = \pi_{Rj}$ for all $j = 1, 2$

Vs H_1 : at least one π_{ij} differs for $i = 1, 2, \dots, R$ and $j = 1, 2$.

Let the $R \times 2$ contingency Table R.4: displayed in Table R.4 be the one actually observed.

Test Statistic

$$\chi_{R-1}^2 = \sum_{i=1}^R \sum_{j=1}^2 \frac{(x_{ij} - m_i n_j / N)^2}{m_i n_j / N}$$

$$\chi^2_{R-1} = \sum_{i=1}^R \sum_{j=1}^2 \frac{(x_{ij} - m_i n_j / N)^2}{m_i n_j} / N$$

R.7 Agreement

R.7.1 Cohen's Kappa

R.7.1 Cohen's Kappa

Hypothesis

R Technical Reference and Formulas: Analysis

H_0 : Agreement between two refers is purely from random variation

Vs

H_1 : Agreement between two refers is not purely from random variation (for two sided test)

Either

H_1 : Agreement between two refers is greater than that is expected from radom variation only.

Or

H_1 : Agreement between two refers is less than that is expected from random variation only.

(For 1-sided test)

Test Statistic

For Kappa

$$K = \frac{n \sum_{i=1}^r x_{ii} - \sum_{i=1}^r m_i n_i}{n^2 - \sum_{i=1}^r m_i n_i} \sim N(0, 1).$$

For Weighted Kappa

$$K_w = \frac{\sum_{i=1}^r \sum_{j=1}^r w_{ij} x_{ij} - \sum_{i=1}^r \sum_{j=1}^r w_{ij} m_i n_j}{n^2 - \sum_{i=1}^r \sum_{j=1}^r w_{ij} m_i n_j} \sim N(0, 1)$$

R.8 Survival : Two Samples

Let

$t_i, I = 1, 2, 3, \dots, M$ be the distinct time points of event on any Arm

$d_{i,t}$ = Number of events on treatment arm at time t_i

$n_{i,t}$ = Number of subjects at risk on treatment arm just before time t_i

$d_{i,c}$ = Number of events on control arm at time t_i

$n_{i,c}$ = Number of subjects at risk on control arm just before time t_i

$$d_i = d_{i,t} + d_{i,c}$$

$$n_i = n_{i,t} + n_{i,c}$$

Assumption : Censored observations are considered in the risk set if they are tied with time point at which event of treatment is observed.

For Superiority

$$Num_i = d_{i,t} - n_{i,t} \frac{d_i}{n_i}$$

$$Den_i = \frac{n_{i,t}n_{i,c}(n_i - d_i)d_i}{n_i^2(n_i - 1)}$$

For Non-inferiority

δ_0 = Non-Inferiority margin

$$n_i^* = n_{i,t} + n_{i,c}^* e^{-\delta_0}$$

$$Num_i = d_{i,t} - n_{i,t} \frac{d_i}{(n_i^*)}$$

$$Den_i = \frac{n_{i,t}n_{i,c}d_i e^{-\delta_0}}{n_i^* n_i^*}$$

Weighted Test Statistic is defined as (for both superiority and non-inferiority)

$$Num = \sum_{i=1}^M W_i Num_i \tag{R.242}$$

$$Den = \sum_{i=1}^M W_i^2 Den_i \tag{R.243}$$

$$TS = \frac{Num}{\sqrt{Den}}$$

where weights are defined as follows.

R.8.1 Logrank Test

$W_i = 1$ For all i .

R Technical Reference and Formulas: Analysis

R.8.2 Wilcoxon-Gehan

$$W_i = n_i$$

R.8.3 Harrington-Fleming

$$W_i = (\hat{S}_{i-1})^p (1 - \hat{S}_{i-1})^q$$

Where

$$W_i = \begin{cases} 1 & \text{if } q = 0 \\ 0 & \text{if } q > 0 \end{cases}$$

For $i > 1$

$$W_i = (\hat{S}_{i-1})^p (1 - \hat{S}_{i-1})^q$$

With

$$\hat{S}_t = \prod_{t_j \leq t} \left(\frac{n_j - d_j}{n_j} \right)$$

Test Statistic for Stratified Simulations

Let

S = Number of Strata

Num_j = Numerator for j^{th} stratum using (R.242)

Den_j = Denominator for j^{th} stratum using (R.243)

Test Statistic is given by

$$TS = \frac{\sum_{j=1}^S Num_j}{\sqrt{\sum_{j=1}^S Den_j}} \quad (R.244)$$

S Theory - Design - Binomial One-Sample Exact Test

This appendix lays out the theory behind East’s power and sample size computations in the case of the exact fixed sample test and the exact group sequential test of a proportion π being equal to a constant π_0 .

Both Schultz et al. (1973) and Fleming (1982) have proposed multi-stage procedures for rejecting the null hypothesis under strict assumptions about the type 1 and type 2 errors. The methods used in East and described below are based on Jennison and Turnbull (2000).

Section (S.1) explains how to calculate the power and the sample size of the exact fixed sample test. Section (S.2) continues by considering the power and sample size of the group sequential test. It also explains how the boundaries of this test are computed.

S.1 Power and Sample Size for the Exact Fixed Sample Test

S.1.1 Power

S.1.2 Sample Size

Consider a clinical trial of fixed sample size N . The goal is to test - based on the observed number of successes $S = s$ - whether the binary probability π of response is equal to some a priori hypothesized value π_0 .

The null hypothesis of interest is

$$H_0 : \pi = \pi_0$$

East computes the power of the exact test of H_0 against one of the following one-sided alternatives

$$H_1 : \pi = \pi_1 \quad \pi_1 > \pi_0$$

or

$$H_1 : \pi = \pi_1 \quad \pi_1 < \pi_0$$

In what follows, we will assume that interest resides in detecting the former alternative where $\pi_1 > \pi_0$.

The exact test is based on the binomial probability distribution of the response variable S . Recall that for a binomial distribution $Bin(N, \pi)$ the probability that $S = s$ is given by

$$\Pr(S = s|\pi) = \binom{N}{s} \pi^s (1 - \pi)^{(N-s)}$$

and that the tail end probability is the cumulative sum of probabilities

$$\Pr(S \geq s|\pi) = \sum_{i=s}^N \binom{N}{i} \pi^i (1 - \pi)^{(N-i)}.$$

S Theory - Design - Binomial One-Sample Exact Test

Suppose data from the trial provide an observed number of responses $S = s$. Then a test of the null hypothesis H_0 consists in calculating the probability under the null distribution $Bin(N, \pi_0)$ of observing s or more responses among N subjects, and then comparing this probability to the type 1 error rate α . If

$$\Pr(S \geq s | \pi_0) \leq \alpha$$

then the null hypothesis that $\pi = \pi_0$ can be rejected in favor of the alternative hypothesis that $\pi = \pi_1$.

S.1.1 Power of the Exact Fixed Sample Test

Since the power and type 1 error of a design are intimately related and because in an exact test the desired false positive rate is often not attainable, we first consider calculation of the design's type 1 error before moving on to the design's power.

Suppose a type 1 error probability of α has been specified for the study design. Due to the discreteness of the binomial distribution, this false positive rate α will more likely than not be unattainable. Instead the design will attain a type 1 error of $\alpha^* \leq \alpha$.

Under the null hypothesis H_0 , the number of responses S follows a $Bin(N, \pi_0)$. Define s_0 to be the smallest integer, such that

$$\Pr(S \geq s_0 | \pi_0) \leq \alpha$$

Then the attained significance level α^* is given by

$$\alpha^* = \Pr(S \geq s_0 | \pi_0)$$

Upon knowing the critical value s_0 that gives us type 1 error α^* under the null hypothesis distribution $Bin(N, \pi_0)$, we can calculate the exact power of the design by considering the probability distribution under the alternative hypothesis $Bin(N, \pi_1)$.

The exact power of the procedure is given by

$$(1 - \beta) = \Pr(S \geq s_0 | \pi_1)$$

S.1.2 Sample Size Calculation for the Exact Fixed Sample Design

Calculation of a sample size N for a pre-specified type 1 error α and power $(1 - \beta)$ is

complicated by the fact that neither α nor β are attainable given the discreteness of the binomial distribution.

It is well known that a plot of the power versus sample size of a design displays a saw-tooth behavior, but this zig-zag is mostly due to the concurrently varying type 1 error of the design. Due to this behavior though, multiple sample sizes may be provided in answer to the design problem. Really, however, the optimal sample size will depend on the priorities given to type 1 and 2 errors by the investigator.

The sample size N is calculated such that both attained type 1 and 2 errors α^* and β^* are controlled. A search of the parameter space of N must be performed to find those values satisfying both of the following equations

$$\alpha^* = \Pr(S \geq s_0 | N, \pi_0) \leq \alpha$$

and

$$\beta^* = \Pr(S \leq s_0 | N, \pi_1) \leq \beta$$

while either (1) primarily maximizing the attained type 1 error while maintaining it below α , (2) primarily maximizing the attained type 2 error while maintaining it below β , or (3) optimizing to get α^* and β^* as close to α and β , respectively as possible.

The most practical choice of sample size, however, may be that sample size above which power is guaranteed to be at least $(1 - \beta)$.

S.2 Power and Sample Size for the Exact Group Sequential Test

Instead of a fixed sample test of the null hypothesis, let us now consider a group sequential test. This procedure tests the null hypothesis not just once at the end of the trial, but a total of K times after each group of n_k $k = 1, \dots, K$ subjects' data have been observed. In what follows, we still consider a 1-sided test of the null hypothesis with the alternative hypothesis specified in the direction of $\pi_1 > \pi_0$.

Suppose an error-spending function has been pre-specified to control the type 1 error of the group sequential test. Let $\{\alpha_1, \dots, \alpha_K\}$ be the fractions of the type 1 error at each stage, such that they sum up to α . The efficacy boundary corresponding to this error-spending function is given by the set of critical values $\{c_1, \dots, c_K\}$.

Before considering the construction of the boundary itself and the calculation of the test's power, the probability distribution of the number of responses at stage k must be established.

S Theory - Design - Binomial One-Sample Exact Test

Define $C_k(s; \pi, N_k)$ to be the probability of observing s responses at stage k where $1 \leq k \leq K$. Here N_k refers to the cumulative sample size up to and including stage k so that $n_k = N_k - N_{k-1}$ is the sample size for stage k only. Then for the first stage, the probability distribution of response is binomial with

$$C_1(s; \pi, N_1) = \binom{N_1}{s} \pi^s (1 - \pi)^{(N_1 - s)}.$$

Thereafter, the probability of s responses at stage $k > 1$ depends on how many of those responses have been observed up to but excluding stage k . This distribution is given by

$$C_k(s; \pi, N_k) = \sum_{i=a_k(s)}^{b_k(s)} C_{k-1}(i; \pi, N_{k-1}) * B_k((s - i); \pi, n_k)$$

where

$$B_k(s; \pi, n_k) = \binom{N_k}{s} \pi^s (1 - \pi)^{(N_k - s)}$$

and

$$a_k(s) = \max(0, (s - n_k))$$

$$b_k(s) = \min(s, (c_{(k-1)} - 1))$$

S.2.1 Computing Boundaries for the Exact Group Sequential Test

Given an a priori specified α -spending function, the type 1 error fractions used at each stage are provided as $\alpha_1, \dots, \alpha_K$. However, due to the discreteness of the binomial distribution, those values are not achievable at each step. It is reasonable however to carry-over the unspent type 1 error at any stage to the subsequent stage. This informs the following calculations and adjustments to the boundary.

At the first interim look $k = 1$, operating under the null hypothesis, the boundary value is calculated simply by finding the smallest integer c_1 such that

$$\sum_{i=c_1}^{N_1} C_1(i; \pi_0, N_1) \leq \alpha_1$$

However, the actual tail end probability defined by the cut-off value c_1 is

$$\alpha_1^* = \sum_{i=c_1}^{N_1} C_1(i; \pi_0, N_1)$$

The unused type 1 error $\theta_1 = \alpha_1 - \alpha_1^*$ can be carried over to be spent at stage 2.

More generally, define $\theta_0 = 0$ then at stage k , the available type 1 error is $\alpha_k + \theta_{k-1}$ where

$$\begin{aligned}\theta_{k-1} &= (\alpha_{k-1} + \theta_{k-2}) - \alpha_{k-1}^* \\ &= \sum_{i=1}^{k-1} (\alpha_i - \alpha_i^*)\end{aligned}$$

The boundary value is then calculated by finding the smallest integer c_k for which

$$\sum_{i=c_k}^{N_k} C_k(i; \pi_0, N_k) \leq \alpha_k + \theta_{k-1}$$

Repeating this process until the ultimate look K enables the full construction of the efficacy boundary. Note that at the last look, the cumulative and thus overall attained type 1 error of the design will be $\alpha^* i \leq \alpha$ where

$$\begin{aligned}\alpha^* &= \sum_{i=1}^K \alpha_i^* \\ &= \alpha - \theta_K.\end{aligned}$$

S.2.2 Power of the Exact Group Sequential Test

Just as in the case of the exact fixed sample test, the power and type 1 error of the group sequential test are intimately tied. The previous section provided calculation of the boundary c_1, \dots, c_K under the assumption that the null hypothesis was true. These defined an attained overall type 1 error $\alpha^* \leq \alpha$ of the group sequential design.

Considering the crossing probability of that same boundary under the alternative hypothesis provides the power of the group sequential test. That is

$$(1 - \beta) = \sum_{k=1}^K \sum_{i=c_k}^{N_k} C_k(i; \pi_1, N_k)$$

S Theory - Design - Binomial One-Sample Exact Test

S.2.3 Sample Size Calculation for the Exact Group Sequential Design

As in the case of the exact fixed sample design, calculation of the maximum sample size $N_{\max} = N_K$ for a pre-specified type 1 error α and power $(1 - \beta)$ is complicated by the fact that neither α nor β are attainable given the discreteness of the binomial distribution.

As a result, the choice of N_{\max} is not unique. Rather the decision of which sample size to choose for a particular trial will depend on the priorities given to type 1 and 2 errors by the investigator.

The sample size N_{\max} is calculated such that both attained type 1 and 2 errors α^* and β^* are controlled. A search of the parameter space of $N_{\max} = N_K$ must be performed to find those values satisfying both of the following equations

$$\alpha^* = \sum_{k=1}^K \sum_{i=c_k}^{N_k} C_k(i; \pi_0, N_k) \leq \alpha$$

and

$$\beta^* = \sum_{k=1}^K \sum_{i=0}^{(c_k-1)} C_k(i; \pi_1, N_k) \leq \beta$$

while either (1) primarily maximizing the attained type 1 error while maintaining it below α , (2) primarily maximizing the attained type 2 error while maintaining it below β , or (3) optimizing to get α^* and β^* as close to α and β , respectively as possible.

The most practical choice of sample size, however, may be that sample size above which power is guaranteed to be at least $(1 - \beta)$.

T Theory - Design - Binomial Paired-Sample Exact Test

This appendix presents the theory behind the computations of power and sample size for the conditional exact McNemar's test for the difference of proportions arising from paired binomial populations. East implements the methodology and numerical algorithms for the conditional version of McNemar's test, published by Duffy (1984) and Agresti (2002). Methods and algorithms for the unconditional test, used in previous versions of East, have been published by Suissa and Shuster (1991).

Exact conditional methods are considerably faster to execute than the exact unconditional methods. In the paired binomial case, the conditional approach simplifies to a single binomial model, allowing the computation of exact p-values and confidence intervals for arbitrarily large data sets with little difficulty. This is not the case for unconditional methods, where fairly long computing times are to be expected for larger sample sizes. In addition, the theory of exact unconditional inference is more complex and historically has not possessed as extensive a bibliography as the theory of exact conditional inference. Section (T.1) presents how to calculate the power and the sample size for the exact fixed sample conditional McNemar's test.

T.1 Power and Sample Size for the Exact Conditional Fixed Sample Test: McNemar's Test

Consider a trial in which the investigator's interest is in testing for a difference in success rates between paired binary responses. Such a test is typically used in a repeated measures setting, for example when each subject's response is recorded both before and after treatment. The test then determines if the pre and post treatment response rates are equivalent. Another example would be a study involving matched pairs, such as siblings, where each member of the pair is measured for an outcome of interest and tests for the same probability of response. Here, the inference is complicated by the fact that the observations are correlated, even though there is independence across the different pairs being studied.

Suppose that two binomial responses are observed on either N individuals (pre and post event), or N matched pairs. Let y_{11} be the count of the number of individuals whose first and second responses are both positive, or in the case of matched pairs where both responses are positive. In a similar manner let y_{22} be the count where both first and second responses are negative. Let y_{12} be the count of pairs where the first response is positive and second response is negative and let y_{21} be the count where the first response is negative and second response is positive. McNemar's test is based on

T Theory - Design - Binomial Paired-Sample Exact Test

the 2×2 table of the form

$$y = \begin{matrix} y_{11} & y_{12} \\ y_{21} & y_{22} \end{matrix} \quad (\text{T.1})$$

Again, interest is in the equality of binary response rates from two populations, where the data consist of paired, dependent responses. The tests described here determine if the initial response rate is statistically equivalent to the final response rate.

Let $(\pi_{11}, \pi_{12}, \pi_{21}, \pi_{22})$, denote the four cell probabilities for table (T.1). Let π_1 be the probability that the first response is positive and π_2 be the probability that the second response is positive.

Marginal probabilities can be expressed as

$$\pi_1 = \pi_{11} + \pi_{12}, \text{ and } \pi_2 = \pi_{21} + \pi_{22}. \quad (\text{T.2})$$

Therefore the null hypothesis can be expressed as

$$H_0: \pi_1 = \pi_2, \quad (\text{T.3})$$

versus the alternative

$$H_1: \pi_1 \neq \pi_2, \quad (\text{T.4})$$

Using (T.2), $\pi_1 = \pi_2$ implies that $\pi_{12} = \pi_{21}$. The inference becomes focused on the probabilities of discordant pairs, and subsequent test statistics are all functions of the difference $y_{21} - y_{12}$.

East calculates the power for the exact conditional test of the null hypothesis:

$$H_0: \pi_{12} = \pi_{21}.$$

against the specific alternative

$$H_1: \pi_{21} - \pi_{12} = \Delta.$$

In both cases, the user inputs the probability of a discordant pair, which is $\Psi = \pi_{12} + \pi_{21}$, and the difference of interest, Δ . From this information, East determines the original cell probabilities

$$\pi_{12} = \frac{\Psi - \Delta}{2}, \quad \pi_{21} = \Psi - \pi_{12}.$$

Exact Conditional Test - Power

The unconditional power for the exact conditional test uses the fact that, conditional on the number of discordant pairs $N_d = y_{12} + y_{21}$, Y_{12} has a binomial distribution with number of trials N_d and success probability $\pi_{12}/(\pi_{12} + \pi_{21})$. Thus, one can use the power calculation for a single binomial proportion to obtain the exact conditional power for McNemar's test. Let y_α be the cut-off value for rejecting the null hypothesis with a level- α one-sided exact McNemar test conditional on N_d . Thus, y_α is the smallest integer such that, under the null hypothesis,

$$\Pr(Y_{12} \geq y_\alpha | N_d, H_0) \leq \alpha, \quad (\text{T.5})$$

where

$$\Pr(Y_{12} = y | N_d, H_0) = \frac{(0.5)^{N_d} N_d!}{y_{12}!(N_d - y_{12})!}. \quad (\text{T.6})$$

The conditional power of the one-sided exact conditional McNemar test is thus

$$\Pr(Y_{12} \geq y_\alpha | N_d, H_1) = \sum_{y \geq y_\alpha} \binom{N_d}{y} \left(\frac{\pi_{12}}{\pi_{12} + \pi_{21}} \right)^y \left(\frac{\pi_{21}}{\pi_{12} + \pi_{21}} \right)^{N_d - y}. \quad (\text{T.7})$$

Exact Conditional Test - Sample Size

The exact conditional sample size for fixed parameter and power values are obtained by evaluating the exact conditional power functions over a range of sample sizes until the resulting N is found that obtains the desired power. Since neither α nor β are guaranteed to be attainable due to discreteness of the binomial distribution, the solution to this parameter space search N is not unique. The choice of sample size for a particular trial should depend on the priorities given to type 1 and 2 errors by the investigator. Possible prioritization may involve:

- Primarily maximizing the attained type 1 error while maintaining it below α
- Primarily maximizing the attained type 2 error while maintaining it below β
- Optimizing to get α^* and β^* as close to α and β as possible.

The most practical choice of sample size, however, may be that sample size above which power is guaranteed to be at least $(1 - \beta)$.

U Theory - Design - Simon's Two-Stage Design

In this appendix, we describe the theory behind the two-stage optimal design for phase 2 clinical trials developed by Simon (1989). This design is optimal in the sense that it minimizes the maximum expected sample size under the null hypothesis. It was developed for oncology trials to ensure that patients do not receive a treatment that is clearly inferior to other available options. East also supports Simon's minimax approach as well as an admissible two-stage design, which is a graphical method used to search for an alternative with more favorable features (Jung, et al. 2004).

Simon's Optimal design

Of primary interest is testing the null hypothesis $H_0 : \pi \leq \pi_0$ that the true response probability is less than some uninteresting level π_0 . If the null hypothesis is indeed true, then the probability of a false positive should be controlled at level α . This means that the decision to carry the drug into later phases of clinical development should be less than α .

Suppose an alternative hypothesis $H_1 : \pi \geq \pi_1$ is also specified, which claims that the true response probability is at least some desirable target level π_1 . If this hypothesis is true, then the probability of a false negative should be controlled to be less than a pre-specified value β .

Finally, in addition to these two constraints, the design should be optimal in the sense that it minimizes the number of patients treated with a drug of low activity.

Define n_1 and n_2 to be the number of patients studied in the first and second stage of the trial, respectively. The expected sample size n can be computed as

$$E[n] = n_1 + (1 - PET)n_2$$

where

$$PET = \sum_{i=0}^{s_1} Bin(i; \pi, n_1)$$

Here, PET represents the probability of early termination after the first stage, a decision based on the number of responses observed for the n_1 patients in that stage of the trial. Terminating the experiment at the end of the first stage for futility is based on the herein implicit rule that the treatment is dropped if s_1 or fewer responses are observed.

At the end of the second stage, the treatment is considered ineffective if a total of s responses are observed in all $n = n_1 + n_2$ patients of the trial. Thus, the probability of

concluding the treatment is ineffective is given by

$$\sum_{i=0}^{s_1} \text{Bin}(i; \pi, n_1) + \sum_{j=(s_1+1)}^{\min[n_1, s]} \text{Bin}(j; \pi, n_1) \sum_{k=0}^{(s-j)} \text{Bin}(k; \pi, n_2).$$

To optimally design the trial given parameters π_0 , π_1 , α , and β , this probability statement must be evaluated under the null hypothesis that $\pi = \pi_0$ over all values of n_1 and n_2 as well as s_1 and s .

Note that early termination of the trial for efficacy is not permitted in this design. If it were, it would be possible to further reduce the expected sample size of the trial. However, the ethical imperative of this type of trials is to terminate early for futility.

East optimizes the two-stage design using exact binomial probabilities. For each value of total sample size n and each value of stage 1 sample size n_1 in the range $(1, n - 1)$, integer values s_1 and s are found that satisfy the type 1 and type 2 error constraints and minimize the expected sample size when $\pi = \pi_0$. The search occurs over the range $s_1 \in (0, n_1)$. For each value of s_1 the maximum value of s satisfying the type 2 error constraint is determined. Next the set of parameters (n, n_1, s_1, s) is examined to see whether it satisfies the type 1 error constraint. If it does, then the expected sample size of the corresponding design is compared to the minimum expected sample size previously achieved by the search algorithm. The search continues over the entire range of s_1 . This is repeated for values in the range of n_1 while keeping n fixed.

The search over the range of n begins from the lower value of

$$\bar{\pi}(1 - \bar{\pi}) \left[\frac{z_{1-\alpha} + z_{1-\beta}}{\pi_1 - \pi_0} \right]$$

where $\bar{\pi} = (\pi_0 + \pi_1)/2$. A check must be performed below this starting point to ensure that this is indeed the smallest maximum sample size n for which there is a nontrivial $(n_1, n_2 > 0)$ two-stage design satisfying the type 1 and type 2 error constraints. The enumeration procedure then searches upwards from this minimum value of n until it is clear that the optimum had been determined.

The minimum expected sample size for fixed n is not a unimodal function of n because of the discreteness of the underlying binomial distributions. Nevertheless, eventually as n increases the value of the local minima increase and it becomes clear that a global minimum has been found.

U Theory - Design - Simon's Two-Stage Design

Simon's Minimax and Admissible designs

In addition to the optimal design, East offers Simon's minimax approach, which minimizes the total sample size while satisfying both type-I and type-II constraints. The admissible two-stage design (Jung, et al. 2004), employs a graphical method geared to search for an alternative with more favorable features. This approach provides a compromised solution between the minimax and the optimal designs, that also satisfy type-I and type-II constraints. Resulting designs yield the same total sample sizes, as well as having the minimum expected sample size under the Null.

V Theory-Design - Binomial Two-Sample Exact Tests

This appendix deals with exact power and sample size computations for comparing two independent binomials. Exact power and sample size calculations are considered for the two-sided Fisher's test, the unconditional one-sided tests of superiority, non-inferiority test, and two one-sided tests of equivalence.

Exact tests on categorical data are usually computed conditionally, by fixing the margins of the contingency table at their observed values. Corresponding power computations are, however, more useful if they are performed unconditionally, before these table margins have been observed. Only then can they aid in determining if the sample size proposed for the study is adequate. This appendix shows how to obtain exact unconditional power as a weighted sum of exact conditional powers, and applies the results to exact conditional tests on 2×2 contingency tables. It also covers the exact power and sample size computations for exact unconditional tests of non-inferiority and equivalence of two binomial populations.

The methods used by East to compute power and sample size of these two-sample exact tests are based on Fleiss (1981) for Fisher's exact test and the conditional exact superiority test, Suissa and Shuster (1985) for the unconditional exact superiority test, Chan (1988) for the unconditional exact non-inferiority test, and finally Dunnett and Gent (1977) for the exact equivalence test. In the equivalence testing of two binomials, power of

In all that follows, consider sampling from two independent binomial populations. Suppose x_c responses out of n_c subjects are observed in the control group. The mean response rate in this group is denoted π_c . Similarly define x_t , n_t , and π_t for the treatment group. The observed data may be represented in a 2×2 contingency table \mathbf{x} of the form

| | | |
|-------------|-------------|---------|
| x_c | x_t | m |
| $n_c - x_c$ | $n_t - x_t$ | $N - m$ |
| n_c | n_t | N |

Section (V.1) explains computation of the power of Fisher's exact test. In section (V.2) power of Barnard's unconditional test of superiority is described. Section (V.3) continues with the power of the unconditional test of non-inferiority. Power for the unconditional test of equivalence between two binomial proportions is considered in section (V.4). Finally, section (V.5) briefly describes the computation of sample size for all these tests.

V Theory-Design - Binomial Two-Sample Exact Tests

V.1 Fisher's Exact Test

V.1.1 Power

Fisher's exact test is concerned with testing the null hypothesis

$$H_0 : \pi_c = \pi_t \equiv \pi \quad (\text{V.1})$$

versus the two-sided alternative hypothesis

$$H_1 : \pi_c \neq \pi_t \quad (\text{V.2})$$

at fixed sample sizes n_c and n_t .

As is well known, the exact probability of \mathbf{x} under H_0 , conditional on $x_c + x_t = m$, is given by

$$\Pr(\mathbf{x}|\mathbf{m}, H_0) = \frac{\binom{n_c}{x_c} \binom{n_t}{x_t}}{\binom{N}{m}}. \quad (\text{V.3})$$

Notice that (V.3) does not depend on the common null response probability π . Thus this probability need not be specified for purposes of calculating power. The two response probabilities π_c and π_t are, however, needed to evaluate the probability of \mathbf{x} under H_1 .

Fisher's exact test is based on the exact distribution of the test statistic

$$T = -\log \left[\frac{\binom{n_c}{x_c} \binom{n_t}{x_t}}{\binom{N}{m}} \right]. \quad (\text{V.4})$$

V.1.1 Exact Unconditional Power for Fisher's Exact Test

Consider first the exact power of level- α tests based on the statistic T . Let

$$\Gamma_m = \{\mathbf{x} : \mathbf{x}_c + \mathbf{x}_t = \mathbf{m}\} \quad (\text{V.5})$$

and define the critical region

$$\Gamma_m(t) = \{\mathbf{x} \in \Gamma_m : T \geq t\}. \quad (\text{V.6})$$

The exact null distribution of T may then be obtained by evaluating

$$\Pr(T \geq t|m, H_0) = \sum_{\mathbf{x} \in \Gamma_m(t)} \left[\frac{\binom{n_c}{x_c} \binom{n_t}{x_t}}{\binom{N}{m}} \right], \quad (\text{V.7})$$

for each possible value of t .

Let α be the maximum allowable type-1 error and $t_\alpha(m)$ be the smallest possible cut-off such that

$$\Pr(T \geq t_\alpha(m) | m, H_0) \leq \alpha. \tag{V.8}$$

The **conditional** power of Fisher’s exact test is defined as

$$\Pr(T \geq t_\alpha(m) | m, H_1) = \sum_{\mathbf{x} \in \Gamma_m(t_\alpha(m))} \left[\frac{Q_c Q_t}{\sum_{\mathbf{x} \in \Gamma_m} Q_c Q_t} \right]. \tag{V.9}$$

where

$$Q_c = \binom{n_c}{x_c} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \tag{V.10}$$

$$Q_t = \binom{n_t}{x_t} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \tag{V.11}$$

Denote this two-sided conditional power by $(1 - \beta(m))$. Then the two-sided **unconditional** power of Fisher’s exact test is defined as

$$(1 - \beta) = \sum_{m=0}^N (1 - \beta(m)) P(m) \tag{V.12}$$

where

$$P(m) = \Pr(x_c + x_t = m | H_1), \tag{V.13}$$

is a convolution of two binomials under H_1 . It is relatively straightforward to compute equation (V.12) as only 2×2 tables are involved.

V.2 Power of Unconditional Test of Superiority

V.2.1 Diff.of Proportions

V.2.2 Ratio of Proportions

V.2.1 Superiority Test: Difference of Proportions

Superiority for Difference of Proportions – Case 1 Suppose it is desired to test $H_0 : \pi_t - \pi_c \leq 0$ against the one-sided alternative $H_1 : \pi_t - \pi_c > 0$. Let π_t and π_c

V Theory-Design - Binomial Two-Sample Exact Tests

denote the binomial probabilities for the treatment and control arms, respectively. Let x_t and x_c be the observed numbers of responses for the treatment and control arms, respectively. Let $\delta = \pi_t - \pi_c$. It is of interest to test the null hypothesis $H_0 : \delta \leq 0$ against one-sided alternative $H_1 : \delta > 0$. Let $\hat{\pi}_i$ denote the estimate of π_i based on n_i observations from treatment i . The test statistic can be defined by

$$T(x_t, x_c) = \frac{\hat{\pi}_t - \hat{\pi}_c}{\sqrt{\tilde{\pi} (1 - \tilde{\pi}) \left(\frac{1}{n_c} + \frac{1}{n_t} \right)}} \quad (\text{V.14})$$

where $\hat{\pi}_t, \hat{\pi}_c$ and $\tilde{\pi}$ are given by

$$\hat{\pi}_c = \frac{x_c}{n_c}, \hat{\pi}_t = \frac{x_t}{n_t}, \tilde{\pi} = \frac{x_t + x_c}{n_t + n_c} \quad (\text{V.15})$$

Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the sample space for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.16})$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$b_{\pi_c} = \sup \{b : P_{\pi_c}(T(x_t, x_c) < b \mid H_0) \leq \alpha\} \quad (\text{V.17})$$

This probability $P_{\pi_c}(T(x_t, x_c) < b \mid H_0)$ is calculated based on the exact distribution of $T(x_t, x_c)$ under the null hypothesis $\pi_c = \pi_t$. This implies that, for a given π_c , b_{π_c} is defined such that

$$\sup \left\{ b : P_{\pi_c}(T(x_t, x_c) < b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\pi_c, \pi_c}(x_t, x_c) \leq \alpha \right\} \quad (\text{V.18})$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) < b \\ 0 & \text{otherwise} \end{cases} \quad (\text{V.19})$$

Note that there is a one-to-one correspondence between the critical value b_{π_c} and the control rate π_c . Let $b^* = \inf \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and suppose that this infimum takes place at π_c^* .

The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) < b^*$. Since b^* is the infimum of the critical values over the possible range of π_c , this test guarantees the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the underlying control rate equals π_c^* which is given by

$$P_{\pi_c^*} (T(x_t, x_c) < b^* | H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c^*, \pi_c^*}(x_t, x_c) \quad (\text{V.20})$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level α . Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

Next we will show how the unconditional power of this exact test is calculated. The unconditional power is the probability of rejecting the null hypothesis under the alternative hypothesis. Suppose that one is interested in the power of this test under $\delta = \delta_1 (< 0)$ and π_c . Under the alternative $\pi_t = \pi_c + \delta_1$. Then the unconditional power is given by

$$P_{\pi_c} (T(x_t, x_c) < b^* | H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) \quad (\text{V.21})$$

where

$$f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\pi_c + \delta_1)^{x_t} (1 - \pi_c - \delta_1)^{n_t - x_t} (\pi_c)^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.22})$$

Superiority for Difference of Proportions – Case 2 Suppose it is desired to test $H_0 : \pi_t - \pi_c \geq 0$ against the one-sided alternative $H_1 : \pi_t - \pi_c < 0$. Let π_t and π_c denote the binomial probabilities for the treatment and control arms, respectively. Let x_t and x_c be the observed numbers of responses for the treatment and control arms, respectively. Let $\delta = \pi_t - \pi_c$. It is of interest to test the null hypothesis $H_0 : \delta \geq 0$

V Theory-Design - Binomial Two-Sample Exact Tests

against one-sided alternative $H_1 : \delta < 0$. Let $\hat{\pi}_i$ denote the estimate of π_i based on n_i observations from treatment i . The test statistic can be defined by

$$T(x_t, x_c) = \frac{\hat{\pi}_t - \hat{\pi}_c}{\sqrt{\tilde{\pi}(1 - \tilde{\pi})\left(\frac{1}{n_c} + \frac{1}{n_t}\right)}} \quad (\text{V.23})$$

where $\hat{\pi}_t, \hat{\pi}_c$ and $\tilde{\pi}$ are given by

$$\hat{\pi}_c = \frac{x_c}{n_c}, \hat{\pi}_t = \frac{x_t}{n_t}, \tilde{\pi} = \frac{x_c + x_t}{n_t + n_c} \quad (\text{V.24})$$

Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the sample space for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.25})$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$b_{\pi_c} = \inf \{b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) \leq \alpha\} \quad (\text{V.26})$$

This probability $P_{\pi_c}(T(x_t, x_c) > b \mid H_0)$ is calculated based on the exact distribution of $T(x_t, x_c)$ under the null hypothesis $\pi_c = \pi_t$. This implies that, for a given π_c , b_{π_c} is defined such that

$$\inf \left\{ b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\pi_c, \pi_c}(x_t, x_c) \leq \alpha \right\} \quad (\text{V.27})$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) > b \\ 0 & \text{otherwise} \end{cases} \quad (\text{V.28})$$

Note that there is a one-to-one correspondence between the critical value b_{π_c} and the control rate π_c . Let $b^* = \sup \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and suppose that this supremum takes place at π_c^* .

The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) > b^*$. Since b^* is the supremum of the critical values over the possible range of π_c , this test guarantees the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the underlying control rate equals π_c^* which is given by

$$P_{\pi_c^*}(T(x_t, x_c) > b^* | H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c^*, \pi_c^*}(x_t, x_c) \quad (\text{V.29})$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level α . Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

Next we will show how the unconditional power of this exact test is calculated. The unconditional power is the probability of rejecting the null hypothesis under the alternative hypothesis. Suppose that one is interested in the power of this test under $\delta = \delta_1 (> 0)$ and π_c . Under the alternative $\pi_t = \pi_c + \delta_1$. Then the unconditional power is given by

$$P_{\pi_c}(T(x_t, x_c) > b^* | H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) \quad (\text{V.30})$$

where

$$f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\pi_c + \delta_1)^{x_t} (1 - \pi_c - \delta_1)^{n_t - x_t} (\pi_c)^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.31})$$

V.2.2 Superiority Test: Ratio of Proportions

Superiority for Ratio of Proportions – Case 1 Suppose that it is desired to test $H_0 : \frac{\pi_t}{\pi_c} \leq 1$ against $H_1 : \frac{\pi_t}{\pi_c} > 1$. Let π_t and π_c denote the binomial probabilities for the treatment and control arms, respectively, and let $\rho = \frac{\pi_t}{\pi_c}$. Let x_t and x_c be the observed number of responses for the treatment and control arms, respectively. It is of

V Theory-Design - Binomial Two-Sample Exact Tests

interest to test the null hypothesis $H_0 : \rho \leq 1$ against the one-sided alternative $H_1 : \rho > 1$. Let $\delta = \ln(\pi_t) - \ln(\pi_c)$. Then it is equivalent to test $H_0 : \delta \leq 0$ against $H_1 : \delta > 0$. Let $\hat{\pi}_i$ denote the estimate of π_i based on n_i observations from treatment i . The test statistic is defined by

$$T = \frac{\ln(\hat{\pi}_t) - \ln(\hat{\pi}_c)}{\sqrt{\frac{1-\tilde{\pi}}{\tilde{\pi}} \left(\frac{1}{n_t} + \frac{1}{n_c}\right)}} \quad (\text{V.32})$$

where $\hat{\pi}_t, \hat{\pi}_c$ and $\tilde{\pi}$ are given by

$$\hat{\pi}_t = \frac{x_t}{n_t}, \hat{\pi}_c = \frac{x_c}{n_c}, \tilde{\pi} = \frac{x_t + x_c}{n_t + n_c} \quad (\text{V.33})$$

Note that $\frac{1-\tilde{\pi}}{\tilde{\pi}} \left(\frac{1}{n_t} + \frac{1}{n_c}\right)$ is the maximum likelihood estimate of the variance of $\ln(\hat{\pi}_t) - \ln(\hat{\pi}_c)$ restricted under the null hypothesis. Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the sample space for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.34})$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$b_{\pi_c} = \inf \{b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) \leq \alpha\} \quad (\text{V.35})$$

This probability $P_{\pi_c}(T(x_t, x_c) > b \mid H_0)$ is calculated based on the exact distribution of $T(x_t, x_c)$. This implies that, for a given π_c, c_{π_c} is such that

$$\inf \left\{ b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\pi_c, \pi_c}(x_t, x_c) \leq \alpha \right\} \quad (\text{V.36})$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) > b \\ 0 & \text{otherwise} \end{cases} \quad (\text{V.37})$$

Note that there is a one-to-one correspondence between the critical value b_{π_c} and the control rate π_c . Let $b^* = \sup \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and this supremum takes place at π_c^* . The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) > b^*$. Since b^* is the supremum of the critical values over the possible range of π_c , this test will guarantee the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the control rate equals π_c^* which is given by

$$P_{\pi_c^*}(T(x_t, x_c) > b^* | H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c^*, \pi_c^*}(x_t, x_c) \quad (V.38)$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level. Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

Next we will show how the unconditional power of this exact test is calculated. The unconditional power is the probability of rejecting the null hypothesis under the alternative hypothesis. Suppose that one is interested in the power of this test at $\rho = \rho_1 > 1$ and π_c . Under the alternative $\pi_t = \rho_1 \pi_c$, then the unconditional power is given by

$$P_{\pi_c}(T(x_t, x_c) > b^* | H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\rho_1 \pi_c, \pi_c}(x_t, x_c) \quad (V.39)$$

where

$$f_{\rho_1 \pi_c, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\rho_1 \pi_c)^{x_t} (1 - \rho_1 \pi_c)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (V.40)$$

Superiority for Ratio for Proportions – Case 2 Suppose that it is desired to test $H_0 : \frac{\pi_t}{\pi_c} \geq 1$ against the one-sided alternative $H_1 : \frac{\pi_t}{\pi_c} < 1$. In this case, we use the same test statistic as in Case 1

$$T = \frac{\ln(\hat{\pi}_t) - \ln(\hat{\pi}_c)}{\sqrt{\frac{1 - \hat{\pi}}{\hat{\pi}} \left(\frac{1}{n_t} + \frac{1}{n_c} \right)}} \quad (V.41)$$

V Theory-Design - Binomial Two-Sample Exact Tests

where $\hat{\pi}_t, \hat{\pi}_c, \tilde{\pi}$ are defined in the same way as the above.

Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the set of all possible data values that could possibly be observed for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.42})$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$b_{\pi_c} = \sup \{b : P_{\pi_c}(T(x_t, x_c) < b \mid H_0) \leq \alpha\} \quad (\text{V.43})$$

This probability $P_{\pi_c}(T(x_t, x_c) < b \mid H_0)$ is calculated based on the exact distribution of $T(x_t, x_c)$. This implies that, for a given π_c , b_{π_c} is such that

$$\sup \left\{ b : P_{\pi_c}(T(x_t, x_c) < b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\pi_c, \pi_c}(x_t, x_c) \leq \alpha \right\} \quad (\text{V.44})$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) < b \\ 0 & \text{otherwise} \end{cases} \quad (\text{V.45})$$

Note that there is a one-to-one correspondence between the critical value b_{π_c} and the control rate π_c . Let $b^* = \inf \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and this infimum takes place at π_c^* . The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) < b^*$. Since b^* is the infimum of the critical values over the possible range of π_c , this test will guarantee the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the control rate equals π_c^* which is given by

$$P_{\pi_c^*}(T(x_t, x_c) < b^* \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c^*, \pi_c^*}(x_t, x_c) \quad (\text{V.46})$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level. Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

The unconditional power is the probability of rejecting the null hypothesis under the alternative hypothesis. Suppose that one is interested in the power of this test at $\rho = \rho_1 < 1$ and π_c . Under the alternative $\rho = \rho_1, \pi_t = \rho_1 \pi_c$, then the unconditional power is given by

$$P_{\pi_c}(T(x_t, x_c) < b^* | H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\rho_1 \pi_c, \pi_c}(x_t, x_c) \quad (V.47)$$

where

$$f_{\rho_1 \pi_c, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\rho_1 \pi_c)^{x_t} (1 - \rho_1 \pi_c)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (V.48)$$

V.3 Power of the Unconditional Test of Non-Inferiority

V.3.1 Diff.of Proportions

V.3.2 Ratio of Proportions

V.3.1 Non-inferiority Test: Difference of Proportions

Non-inferiority for Difference of Proportions – Case 1 Suppose it is desired to test $H_0 : \pi_t - \pi_c \leq \delta_0 (\delta_0 < 0)$ against the one-sided alternative $H_1 : \pi_t - \pi_c > \delta_0$. Let π_t and π_c denote the binomial probabilities for the treatment and control arms, respectively. Let x_t and x_c be the observed numbers of responses for the treatment and control arms, respectively. Let $\delta = \pi_t - \pi_c$. It is of interest to test the null hypothesis $H_0 : \delta \leq \delta_0$ against one-sided alternative $H_1 : \delta > \delta_0$. Let $\hat{\pi}_i$ denote the estimate of π_i based on n_i observations from treatment i . The test statistic can be defined by

$$T(x_t, x_c) = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{\tilde{\pi}_c(1-\tilde{\pi}_c)}{n_c} + \frac{+\tilde{\pi}_t(1-\tilde{\pi}_t)}{n_t}}} \quad (V.49)$$

where $\hat{\pi}_t$ and $\hat{\pi}_c$ are given by

$$\hat{\pi}_c = \frac{x_c}{n_c}, \hat{\pi}_t = \frac{x_t}{n_t} \quad (V.50)$$

and $\tilde{\pi}_t$ and $\tilde{\pi}_c$ are the maximum likelihood estimates of π_t and π_c , respectively, restricted under the null hypothesis such that $\tilde{\pi}_t - \tilde{\pi}_c = \delta_0$. Miettinen and Nurminen

V Theory-Design - Binomial Two-Sample Exact Tests

(1985) have shown that one may obtain these restricted maximum likelihood estimates by solving the third degree likelihood equation

$$\sum_{k=0}^3 L_k \tilde{\pi}_c^k = 0 \tag{V.51}$$

for $\tilde{\pi}_c$ and setting $\tilde{\pi}_t = \tilde{\pi}_c + \delta_0$, where

$$\begin{aligned} L_3 &= N = n_c + n_t \\ L_2 &= (n_t + 2n_c) \delta_0 - N - x_c - x_t \\ L_1 &= (n_c \delta_0 - N - 2x_c) \delta_0 + x_c + x_t \\ L_0 &= x_c \delta_0 (1 - \delta_0) \end{aligned} \tag{V.52}$$

Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the sample space for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \tag{V.53}$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$b_{\pi_c} = \sup \{b : P_{\pi_c}(T(x_t, x_c) < b \mid H_0) \leq \alpha\} \tag{V.54}$$

This probability $P_{\pi_c}(T(x_t, x_c) < b \mid H_0)$ is calculated based on the exact distribution of $T(x_t, x_c)$ under the null hypothesis $\pi_t - \pi_c = \delta_0$. This implies that, for a given π_c , b_{π_c} is defined such that

$$\sup \left\{ b : P_{\pi_c}(T(x_t, x_c) < b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\pi_c - \delta_0, \pi_c}(x_t, x_c) \leq \alpha \right\} \tag{V.55}$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) < b \\ 0 & \text{otherwise} \end{cases} \tag{V.56}$$

Note that there is a one-to-one correspondence between the critical value b_{π_c} and the control rate π_c . Let $b^* = \inf \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and suppose that this infimum takes place at π_c^* .

The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) < b^*$. Since b^* is the infimum of the critical values over the possible range of π_c , this test guarantees the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the null hypothesis is true and the underlying control rate equals π_c^* which is given by

$$P_{\pi_c^*} (T(x_t, x_c) < b^* | H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c^* - \delta_0, \pi_c^*}(x_t, x_c) \quad (V.57)$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level α . Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

Next we will show how the unconditional power of this exact test is calculated. The unconditional power is the probability of rejecting the null hypothesis under the alternative hypothesis. Suppose that one is interested in the power of this test under $\delta = \delta_1 (< \delta_0)$ and π_c . Under the alternative we have $\pi_c = \pi_t + \delta_1$. Then the unconditional power is given by

$$P_{\pi_c} (T(x_t, x_c) > b^* | H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) \quad (V.58)$$

where

$$f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\pi_c + \delta_1)^{x_t} (1 - \pi_c - \delta_1)^{n_t - x_t} (\pi_c)^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (V.59)$$

Non-inferiority for Difference of Proportions – Case 2 Suppose it is desired to test $H_0 : \pi_t - \pi_c \geq \delta_0 (> 0)$ against the one-sided alternative $H_1 : \pi_t - \pi_c < \delta_0$. Let π_t and π_c denote the binomial probabilities for the treatment and control arms, respectively. Let x_t and x_c be the observed numbers of responses for the treatment and

V Theory-Design - Binomial Two-Sample Exact Tests

control arms, respectively. Let $\delta = \pi_t - \pi_c$. It is of interest to test the null hypothesis $H_0 : \delta \geq \delta_0$ against one-sided alternative $H_1 : \delta < \delta_0$. Let $\hat{\pi}_i$ denote the estimate of π_i based on n_i observations from treatment i . The test statistic can be defined by

$$T(x_t, x_c) = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{\tilde{\pi}_c(1-\tilde{\pi}_c)}{n_c} + \frac{\tilde{\pi}_t(1-\tilde{\pi}_t)}{n_t}}} \quad (\text{V.60})$$

where $\hat{\pi}_t, \hat{\pi}_c, \tilde{\pi}_t$ and $\tilde{\pi}_c$ are defined in the same way as in Case 1.

Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the sample space for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.61})$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$b_{\pi_c} = \inf \{b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) \leq \alpha\} \quad (\text{V.62})$$

This probability $P_{\pi_c}(T(x_t, x_c) > b \mid H_0)$ is calculated based on the exact distribution of $T(x_t, x_c)$ under the null hypothesis $\pi_t - \pi_c = \delta_0$. This implies that, for a given π_c , b_{π_c} is defined such that

$$\inf \left\{ b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\pi_c - \delta_0, \pi_c}(x_t, x_c) \leq \alpha \right\} \quad (\text{V.63})$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) > b \\ 0 & \text{otherwise} \end{cases} \quad (\text{V.64})$$

Note that there is a one-to-one correspondence between the critical value b_{π_c} and the control rate π_c . Let $b^* = \sup \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and suppose that this supremum takes place at π_c^* .

The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) > b^*$. Since b^* is the supremum of the critical values over the possible range of π_c , this test guarantees the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the null hypothesis is true and the underlying control rate equals π_c^* which is given by

$$P_{\pi_c^*}(T(x_t, x_c) > b^* | H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c^* - \delta_0, \pi_c^*}(x_t, x_c) \quad (\text{V.65})$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level α . Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

Next we will show how the unconditional power of this exact test is calculated. The unconditional power is the probability of rejecting the null hypothesis under the alternative hypothesis. Suppose that one is interested in the power of this test under $\delta = \delta_1 (> \delta_0)$ and π_c . Under the alternative we have $\pi_c = \pi_t + \delta_1$. Then the unconditional power is given by

$$P_{\pi_c}(T(x_t, x_c) > b^* | H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) \quad (\text{V.66})$$

where

$$f_{\pi_c + \delta_1, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\pi_c + \delta_1)^{x_t} (1 - \pi_c - \delta_1)^{n_t - x_t} (\pi_c)^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.67})$$

V.3.2 Non-inferiority Test: Ratio of Proportions

Non-inferiority for Ratio of Proportions – Case 1 Suppose it is desired to test $H_0 : \frac{\pi_t}{\pi_c} \leq \rho_0 (< 1)$ against the one-side alternative $H_1 : \frac{\pi_t}{\pi_c} > \rho_0$. An alternative approach to establishing non-inferiority of an experimental treatment to the control treatment with respect to the ratio of probabilities was proposed by Farrington and Manning (1990). Let π_t and π_c denote the binomial probabilities for the treatment and control arms, respectively. Let x_t and x_c be the observed numbers of responses for the treatment and control arms, respectively. Let $\rho = \frac{\pi_t}{\pi_c}$. Suppose that, for some $\rho_0 < 1$,

V Theory-Design - Binomial Two-Sample Exact Tests

one is interested in testing the null hypothesis $H_0 : \rho \leq \rho_0$ against one-sided alternative $H_1 : \rho > \rho_0$. Let $\hat{\pi}_i$ denote the estimate of π_i based on n_i observations from treatment i . The test statistic can be defined by

$$T(x_t, x_c) = \frac{\hat{\pi}_t - \rho_0 \hat{\pi}_c}{\sqrt{\frac{\hat{\pi}_t(1-\hat{\pi}_t)}{n_t} + \frac{\rho_0^2 \hat{\pi}_c(1-\hat{\pi}_c)}{n_c}} \quad (\text{V.68})$$

where $\hat{\pi}_t$ and $\hat{\pi}_c$ are given by

$$\hat{\pi}_t = \frac{x_t}{n_t}, \hat{\pi}_c = \frac{x_c}{n_c} \quad (\text{V.69})$$

and $\tilde{\pi}_t$ and $\tilde{\pi}_c$ are the maximum likelihood estimates of π_t and π_c , respectively, restricted under the null hypothesis such that $\frac{\tilde{\pi}_t}{\tilde{\pi}_c} = \rho_0$. Miettinen and Nurminen (1985) have shown that one may obtain these restricted maximum likelihood estimates by solving a quadratic likelihood equation. Thus

$$\tilde{\pi}_c = \frac{-B - \sqrt{B^2 - 4AC}}{2A} \quad (\text{V.70})$$

and

$$\tilde{\pi}_t = \rho_0 \tilde{\pi}_c \quad (\text{V.71})$$

where

$$\begin{aligned} A &= \rho_0(n_t + n_c) \\ B &= -(\rho_0 n_c + x_c + n_t + \rho_0 x_t) \\ C &= x_c + x_t \end{aligned} \quad (\text{V.72})$$

Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the sample space for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.73})$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$b_{\pi_c} = \inf \{b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) \leq \alpha\} \quad (\text{V.74})$$

This probability $P_{\pi_c}(T(x_t, x_c) > b \mid H_0)$ is calculated based on the exact distribution of $T(x_t, x_c)$ under the null hypothesis $\pi_t = \rho_0\pi_c$. This implies that, for a given π_c, b_{π_c} is such that

$$\inf \left\{ b : P_{\pi_c}(T(x_t, x_c) > b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\rho_0\pi_c, \pi_c}(x_t, x_c) \leq \alpha \right\} \quad (\text{V.75})$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) > b \\ 0 & \text{otherwise} \end{cases} \quad (\text{V.76})$$

Note that there is a one-to-one correspondence between the critical value b_{π_c} and the control rate π_c . Let $b^* = \sup \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and suppose that this supremum takes place at π_c^* . The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) > b^*$. Since b^* is the supremum of the critical values over the possible range of π_c , this test guarantees the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the underlying control rate equals π_c^* which is given by

$$P_{\pi_c^*}(T(x_t, x_c) > b^* \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\rho_0\pi_c^*, \pi_c^*}(x_t, x_c) \quad (\text{V.77})$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level α . Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

Next we will show how the unconditional power of this exact test is calculated. The unconditional power is the probability of rejecting the null hypothesis under the alternative hypothesis. Suppose that one is interested in the power of this test when $\rho = \rho_1 (> \rho_0)$ and the response rate for the control arm is π_c . Under the alternative $\rho = \rho_1$, we have $\pi_t = \rho_1\pi_c$. Then the unconditional power is given by

$$P_{\pi_c}(T(x_t, x_c) > b^* \mid H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\rho_1\pi_c, \pi_c}(x_t, x_c) \quad (\text{V.78})$$

where

$$f_{\rho_1\pi_c, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\rho_1\pi_c)^{x_t} (1 - \rho_1\pi_c)^{n_t - x_t} (\pi_c)^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.79})$$

V Theory-Design - Binomial Two-Sample Exact Tests

Non-inferiority for Ratio of Proportions – Case 2 Suppose it is desired to test $H_0 : \frac{\pi_t}{\pi_c} \geq \rho_0 (> 1)$ against the one-sided alternative $H_1 : \frac{\pi_t}{\pi_c} < \rho_0$. In this case, the same test statistic can be used

$$T(x_t, x_c) = \frac{\hat{\pi}_t - \rho_0 \hat{\pi}_c}{\sqrt{\frac{\tilde{\pi}_t(1-\tilde{\pi}_t)}{n_t} + \frac{\rho_0^2 \tilde{\pi}_c(1-\tilde{\pi}_c)}{n_c}}} \quad (\text{V.80})$$

where $\hat{\pi}_t, \hat{\pi}_c, \tilde{\pi}_t$ and $\tilde{\pi}_c$ are defined in the same way as in Case 1.

Let $\mathcal{X} = \{(x_t, x_c) : 0 \leq x_t \leq n_t, 0 \leq x_c \leq n_c\}$ denote the sample space for the 2×2 table. Let $f_{\pi_t, \pi_c}(x_t, x_c)$ denote the probability of observing the data $(x_t, x_c) \in \mathcal{X}$ when the response rates for the treatment and control arms are π_t and π_c , respectively, which is given by

$$f_{\pi_t, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.81})$$

For a given π_c and nominal significance level α , let b_{π_c} be defined by

$$\sup \left\{ b : P_{\pi_c} (T(x_t, x_c) < b \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_b(x_t, x_c) f_{\rho_0 \pi_c, \pi_c}(x_t, x_c) \leq \alpha \right\} \quad (\text{V.82})$$

where the indicator function is defined by

$$I_b(x_t, x_c) = \begin{cases} 1 & \text{if } T(x_t, x_c) < b \\ 0 & \text{otherwise} \end{cases} \quad (\text{V.83})$$

Let $b^* = \inf \{b_{\pi_c} : \pi_c \in (0, 1)\}$ and suppose that this infimum takes place at π_c^* . The decision rule of the exact test is to reject H_0 if $T(x_t, x_c) < b^*$. Since b^* is the infimum of the critical values over the possible range of π_c , this test will guarantee the type I error control regardless of the underlying true response rate for the control arm.

The attained significance level of this test is the exact probability of rejecting the null hypothesis when the underlying control rate equals π_c^* which is given by

$$P_{\pi_c^*} (T(x_t, x_c) < b^* \mid H_0) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\rho_0 \pi_c^*, \pi_c^*}(x_t, x_c) \quad (\text{V.84})$$

Note that the attained significance level is the maximum type I error one can actually commit using this test given the desired significance level α . Due to the discreteness of the distributions, the attained significance level is always bounded above by α .

The unconditional power under the specific alternative $\rho = \rho_1$ and π_c is given by

$$P_{\pi_c}(T(x_t, x_c) < b^* | H_1) = \sum_{(x_t, x_c) \in \mathcal{X}} I_{b^*}(x_t, x_c) f_{\rho_1 \pi_c, \pi_c}(x_t, x_c) \quad (\text{V.85})$$

where

$$f_{\rho_1 \pi_c, \pi_c}(x_t, x_c) = \binom{n_t}{x_t} \binom{n_c}{x_c} (\rho_1 \pi_c)^{x_t} (1 - \rho_1 \pi_c)^{n_t - x_t} (\pi_c)^{x_c} (1 - \pi_c)^{n_c - x_c} \quad (\text{V.86})$$

V.4 Power of the Unconditional Test of Equivalence

V.4.1 Power

Equivalence testing usually arises in the context of a clinical trial comparing two treatments in which the goal is to assess whether the two treatments are equally efficacious rather than attempting to assess whether one treatment is more efficacious than the other. This implies an inversion of the conventional formulation of null and alternative hypotheses. The statistical formulation proposed by Dunnett and Gent (1977) is used to describe this procedure. First define the true underlying treatment difference

$$\delta = |\pi_t - \pi_c| \quad (\text{V.87})$$

and specify an equivalence margin, $\delta_0 > 0$, such that if $\delta < \delta_0$ the two treatments are considered equivalent while if $\delta \geq \delta_0$, they are not. Interest resides in testing the null hypothesis

$$H_0: \delta = \delta_0 \quad (\text{V.88})$$

against the alternative hypothesis

$$H_1: \delta < \delta_0 . \quad (\text{V.89})$$

The null hypothesis (V.88) really consists of the two possibilities

$$H_{01}: \pi_c - \pi_t = \delta_0 \quad (\text{V.90})$$

and

$$H_{02}: \pi_t - \pi_c = \delta_0. \quad (\text{V.91})$$

V Theory-Design - Binomial Two-Sample Exact Tests

In order to cater to both possibilities two one-sided level- α tests are performed using the test statistics

$$T_1 = \frac{\hat{\pi}_c - \hat{\pi}_t - \delta_0}{\sqrt{\frac{(\hat{\pi}_c)(1-\hat{\pi}_c)}{n_c} + \frac{(\hat{\pi}_t)(1-\hat{\pi}_t)}{n_t}}} \quad (\text{V.92})$$

and

$$T_2 = \frac{\hat{\pi}_t - \hat{\pi}_c - \delta_0}{\sqrt{\frac{(\hat{\pi}_c)(1-\hat{\pi}_c)}{n_c} + \frac{(\hat{\pi}_t)(1-\hat{\pi}_t)}{n_t}}} . \quad (\text{V.93})$$

Clearly $T_1 \sim N(0, 1)$ conditional on H_{01} and $T_2 \sim N(0, 1)$ conditional on H_{02} . In order to reject the null hypothesis (V.88) and declare equivalence, both H_{01} and H_{02} must be rejected. The rejection region is thus the joint event $\{(T_1 \leq z_\alpha) \cap (T_2 \leq z_\alpha)\}$. It can be shown that under the null hypothesis (V.88), regardless of whether H_{01} or H_{02} holds,

$$\Pr\{(T_1 \leq z_\alpha) \cap (T_2 \leq z_\alpha)\} \leq \alpha \quad (\text{V.94})$$

thereby preserving the type-1 error.

V.4.1 Exact Unconditional Power for Equivalence Tests

Suppose it is desired to obtain the exact power of the two one-sided equivalence test at specific values of π_c and π_t with $|\pi_c - \pi_t| = \delta_1$ where $0 \leq \delta_1 \leq \delta_0$. The exact unconditional power is then readily evaluated as the probability, $\Pr\{(T_1 \leq z_\alpha) \cap (T_2 \leq z_\alpha) | \pi_c, \pi_t\}$, of falling in the rejection region under the alternative hypothesis. Denote this probability by $(1 - \beta)$. Then

$$(1 - \beta) = \sum_{x_c=0}^{n_c} \sum_{x_t=0}^{n_t} I_\alpha(x_c, x_t) \binom{n_c}{x_c} \pi_c^{x_c} (1 - \pi_c)^{n_c - x_c} \binom{n_t}{x_t} \pi_t^{x_t} (1 - \pi_t)^{n_t - x_t} , \quad (\text{V.95})$$

where the indicator function, $I_\alpha(x_c, x_t)$, assumes the value 1 if $(T_c \leq z_\alpha) \cap (T_t \leq z_\alpha) \leq \alpha$ and assumes the value 0 otherwise.

V.5 Sample Size Computations

For all tests discussed in this section, the sample size for a fixed unconditional power value is obtained by evaluating the null and alternative power functions over a range of sample sizes until an N is found that gives the desired power.

Since neither α nor β are guaranteed to be attainable due to discreteness of the binomial distribution, the solution to this parameter space search N is not unique. The choice of sample size for a particular trial should depend on the priorities given to type 1 and 2 errors by the investigator. Possible prioritization may involve (1) primarily

maximizing the attained type 1 error while maintaining it below α , (2) primarily maximizing the attained type 2 error while maintaining it below β , or (3) optimizing to get α^* and β^* as close to α and β , respectively as possible.

The most practical choice of sample size, however, may be that sample size above which power is guaranteed to be at least $(1 - \beta)$.

W *Classification Table*

Under usual notation, the formulas used in computing classification errors are listed below.

$$h_i^1 = \text{Hat Diagonal element assuming } y = 1, G_i = 1;$$

$$h_i^0 = \text{Hat Diagonal element assuming } y = 0, G_i = 1;$$

$$V_i = \mathbf{Cov} \times \mathbf{X}_i'$$

$$\beta_i^0 = \beta - \frac{(1 - \hat{\pi}_i)}{1 - h_i^1} \times V_i$$

$$\hat{\pi}_i^1 = \mathbf{X}_i \beta_i^1$$

$$\beta_i^0 = \beta - \frac{(-\hat{\pi}_i)}{1 - h_i^0} \times V_i$$

$$\hat{\pi}_i^0 = \mathbf{X}_i \beta_i^0$$

$$P(A|\bar{B}) = \frac{1}{n_2} \sum_{i \in C_2} I(\hat{\pi}_i^0 > z)$$

| Name | Formula | Comment |
|-----------------------------|---|---|
| Prob_event | P_e | |
| Cut-off prob | z | |
| Correct events (CE) | $\sum_{i \in C_1} I(\hat{\pi}_i^1 \geq z)$ | |
| Correct noevents(CN) | $\sum_{i \in C_2} I(\hat{\pi}_i^0 \leq z)$ | |
| Incorrect events (IE) | $\sum_{i \in C_2} I(\hat{\pi}_i^0 > z)$ | |
| Incorrect noevents (IN) | $\sum_{i \in C_1} I(\hat{\pi}_i^1 < z)$ | |
| Percent correct | $\frac{(CE+CN)}{(n_1+n_2)}$ | |
| Sensitivty | $\frac{(CE)}{(n_1)}$ | |
| Specifcty | $\frac{(CN)}{(n_2)}$ | |
| False_pos | $\left(\frac{IE}{n_2}\right) \times \frac{1-P_e}{v1}$ | $v1 = \frac{IE}{n_2} + P_e \times \left(\frac{CE}{n_1} - \frac{IE}{n_2}\right)$ |
| False_neg | $\left(1 - \frac{CE}{n_1}\right) \times \frac{P_e}{1-v1}$ | |

X

Glossary

Accrual rate

The number of subjects entering the study per unit of time.

Adaptive study design

In an adaptive design estimated treatment differences at interim analyses can be used to make mid-course data-dependent alterations to the trial design – changes in sample size, error spending function, and number and spacing of interim looks – while preserving the type-1 error.

Alpha spending function

The spending function to be used for allocating the type-1 cumulative error probability as a function of the information fraction.

Alpha spent

The cumulative amount of type-1 error probability spent up to and including a given look.

ASN (Average Sample Number) chart

This plot provides a graphical rendition of how the ASN (Average Sample Number, the expected sample size) varies as a function of a range of possible values for the effect size or non-inferiority margin (e.g. standardized difference, difference in proportions, etc.).

Assigned fraction (treatment)

The proportion, r , of subjects assigned (randomized) to the treatment (experimental) arm over the total number of subjects in the trial.

Beta spending function

The spending function to be used for allocating the type-2 cumulative error probability as a function of the information fraction.

Beta spent

The cumulative amount of type-2 error probability spent up to and including a given look.

X Glossary

Binding boundaries

Binding boundaries require the termination of the trial if the test statistic crosses the futility boundary; otherwise the type-1 error might be inflated. Contrariwise, non-binding boundaries produce the desired power and preserve the type-1 error so that the crossing of the futility boundary may be overruled.

Bioequivalence

A test formulation of a drug (t) and the control (or reference) formulation of the same drug (c) are considered to be bioequivalent if the rate and extent of absorption are similar. The goal is to establish that the difference or log-ratio of the means of the observations from the test formulation and the control is within a specified equivalence margin.

Boundaries

Boundaries are the generalization to group sequential methods of the critical values of a test, the values beyond which the standardized test statistic supplies enough evidence to reject H_0 or H_1 . Boundary families allow the user to specify how conservatively or aggressively tests are performed at each analysis point, while preserving the type-1 error, the probability of accepting H_1 when H_0 is in fact true. Available boundary families are p-value, Haybittle-Peto Power, Wang-Tsiatis Spending Functions, Published Spending Function, and Interpolated.

Boundary chart

This plot provides a graphical rendition of the stopping boundaries ("Nominal critical point") corresponding to each look, the latter being indexed by the cumulative information (e.g. sample size, number of events, etc. depending on the endpoint). For the meaning of the various "Boundary Scales" please refer to other sections of the manual.

Boundary family

The boundaries at the design stage can be derived with reference to one of several approaches, depending also on whether early stopping is allowed in favor of the null only, of the alternative only, or of both. The Haybittle-Peto boundaries (p-value family) are specified in terms of a constant p-value for all interim analyses; East will compute the p-value to be used at the final analysis in order to satisfy the desired significance level of the procedure or the user can specify it and then East computes

the achieved significance level of the procedure. The Wang and Tsiatis (early stopping for H_0 only) and the Pampallona and Tsiatis (early stopping for H_0 or H_1) families are direct application of the respective power boundary families, indexed by a boundary shape parameter, Delta, in the range -0.5 to 0.5: small values of Delta yield boundaries with a small probability of early stopping and a correspondingly low average sample size, vice versa for large values of Delta. Spending Function Boundaries (published) are defined by published error spending functions (e.g. Lan-DeMets, Rho family, Gamma family). Spending Functions Interpolated are defined by the user by specifying cumulative error probabilities at various looks. When interim looks are different from the design, linear interpolation is used for computing cumulative end probabilities spent.

Boundary scale

See Boundary chart.

Boundary shape parameter

The Wang-Tsiatis and the Pampallona-Tsiatis power boundaries are indexed by a shape parameter varying between -0.5 and 0.5. Smaller values of the shape parameter correspond to boundaries with reduced probability of early stopping but also to a smaller maximum sample size, vice-versa for larger values of the shape parameter. For designs allowing for early stopping in favor of either H_0 or H_1 East allows for different shape parameters to govern the boundary for early rejection of H_1 (denoted in the East worksheets as "Boundary shape parameter to reject H_1 ") and the boundary for early rejection of H_0 (denoted in the East worksheets as "Boundary shape parameter to reject H_0 ").

Coefficient of variation

The coefficient of variation is a summary measure of variability. It is calculated by taking the ratio of the standard deviation to the mean

Committed accrual (duration or subjects)

The committed number of subjects that can be accrued into the study (or equivalently, since the accrual rate is constant, the maximum accrual duration). In time to event studies, the power of the study is not determined by the number of subjects enrolled but by the number of events observed. Thus, there exists a range of accrual (bounded by the quantities

X Glossary

Min and Max), combined with a range of study durations, that would all produce the desired power. The lower bound of the range (Minimum committed number of subjects to accrue) corresponds to an initial estimate of the number of events to be observed for the study to have the desired power: with such a low accrual, the study will however be very long since all subjects accrued will have to fail before the final analysis can be performed. On the other hand, there is no need for the study to accrue more than the upper bound of the range (Maximum committed number of subjects to accrual), that is to keep the study open to accrual beyond the point in time when the required number of events has been observed. The user can input values for the accrual within the suggested range remembering that the larger the accrual the shorter the total study duration.

Conditional power

The conditional power is the probability of rejecting the null at one of the future looks given the data accumulated so far. This quantity can contribute, together with any other relevant information, to the decision to terminate or continue the study with a possible increase of the study's sample size.

Conditional power at ideal next look position (CP at INLP)

The conditional power at ideal next look position is the probability of rejecting the null at the next and final look given the data accumulated so far and if the next and final look was performed at the recommended "Ideal next look position". This quantity can contribute, together with any other relevant information, to the decision to terminate or continue the study.

Conditional power chart

This plot provides a graphical rendition of how the conditional power of the study at the current look varies as a function of the effect size (e.g. standardized difference, difference in proportions, etc.).

Confidence interval adjusted

The method suggested by Kim and DeMets (1987) is applied to derive the adjusted confidence interval at the end of the study allowing for repeated significance testing. This method was generalized by Brannath, Mehta and Posch (2008) for the parameter estimation in the adaptive trial.

Crossover ANOVA sqrt(MSE)

In a crossover design trial, the square root of the Mean Squared Error (MSE) from an ANOVA analysis is an estimate of the standard deviation of the error.

Chen-DeMets-Lan (CDL) method

The method for making sample size modifications to an ongoing trial and then performing the interim monitoring and final analysis with the classical Wald statistic. The method is further extended to a more general setting by Gao, Ware and Mehta (2008).

Cui, Hung, and Wang (CHW) method

The CHW method is a procedure for adaptive sample size modification of an on-going two-arm, K -look group sequential clinical trial. It is based on the examination of data at any interim look $L < K$, making a sample size modification if required, and continuing with the interim monitoring, using a modified test statistic that combines the standardized treatment effects before and after the modification as a weighted sum, with appropriate weights so as to preserve the type-1 error.

Cumulative accrual

The cumulative number of subjects accrued up to a given look.

Cumulative events

The cumulative number of events observed up to a given look.

Design proportion

When designing a study to compare binomial proportions, the expected value of the difference between the two groups being compared is expressed in terms of the expected proportion of success in the Treatment and in the Control groups respectively. In non-inferiority studies this difference represents the non-inferiority margin (the treatment arm should not be worse than the control arm by more than the non-inferiority margin). A setting of particular importance for binomial studies is the Casagrande, Pike, and Smith (1978) correction factor for the normal approximation to the binomial. It may be enabled and disabled by checking the appropriate checkbox located in Settings-Binomial. By default this correction is disabled.

X Glossary

Duration-accrual chart

For time to event endpoint. For a range of values of the committed accrual duration (or committed number of subjects) this chart shows the corresponding total study duration, that is the expected time by which the number of events needed to satisfy power considerations will be observed.

Effect size

The Information based module is not sensitive to the actual measurement scale in which the parameter of interest is expressed but only to its magnitude, the Effect Size: its value can express a difference in means or in proportions or even the coefficient from a complex regression model.

Equivalence

An equivalence trial aims to determine if two treatments have similar consequence. It aims to reject the null hypothesis that the difference between the two treatments falls outside the pre-specified lower and upper equivalence boundaries in favor of the alternative hypothesis that the difference between the two treatments falls within these boundaries.

Equivalence limits

In an equivalence trial for the difference of two normal means, the goal is to establish that the treatment mean and control mean are within an equivalence range. This range is delimited by the lower and upper equivalence limits δ_l and δ_u , which need not be equidistant from the value specified for the difference of means under the alternative hypothesis δ_1 .

Equivalence margin (δ_0)

In an equivalence trial, the goal is to establish that the treatment and control parameters are within a specified value δ_0 . This δ_0 value is the equivalence margin and is often defined as a proportion, such as 25% of the control mean for the comparison of the mean normal distributions.

Error spending chart

This plot provides a graphical rendition of the error probability spending functions as functions of the cumulative information fraction.

Events/Accruals vs. Time chart

For time to event endpoints, this chart shows how accrual increases (at a constant rate) until the end of the accrual period and how events will

accumulate on each treatment arm (depending on the corresponding failure rate) as the study progresses in chronological time (horizontal axis).

Expected values under H_0 , H_1 and $H_{1/2}$

The probability to stop the trial at any of the planned looks can be computed under the null (H_0), the alternative (H_1) or the mid-alternative ($H_{1/2}$). These probabilities can be used to compute several expected quantities at study termination. The expected accrual, for instance, can be computed as the sum, over all looks, of the probability of stopping at the given look times the accumulated accrual (sample size) at that look.

Fixed sample study information

In the design worksheet of the General module, one of the needed input parameters is the information (e.g. number of subjects) required for the fixed-sample-study. This quantity can be obtained from any sample size software and on that basis East generates a group sequential study with the same size and power to detect the same alternative. See also Inflation Factor.

Group sequential designs

Group sequential designs allow the investigator to take early interim looks at the data for evidence of efficacy, harm, and/or futility with the aim of possibly stopping the trial early. The planned number of looks describes the number of time points, including the closing date of the study, at which the investigator plans to analyze the thus far collected data. The value 1 corresponds to a classic fixed-sample-size design with a single look at the end of the study when all data have been collected. The planned number of looks K can vary from 1 to 10. The number eventually performed may differ from K .

Hypothesis to be rejected

Early stopping can be allowed for in favor of H_1 only (early stopping with rejection of H_0) or in favor of either H_0 (futility) or H_1 or in favor of H_0 only (futility only).

Ideal next look position

After each look East revises the maximum information (e.g. sample size, number of failures etc. depending on the endpoint) to be achieved for the study to satisfy the desired type-1 and type-2 error probabilities allowing

X Glossary

for the actually adopted schedule of analyses (which may be different from the tentative number and relative spacing assumed at design). This quantity can contribute, together with any other relevant information, to decide when to perform a further analysis of the accumulating data.

Inflation factor

More information (e.g. number of subjects) is required for a group sequential study than for the corresponding fixed-sample study with the same operating characteristics. This is the penalty associated with repeated significance testing. The inflation factor is the proportionality constant (ratio) relating the information requirements of group sequential trial to its corresponding fixed- sample study. This ratio is independent of the test, the endpoint of interest or the actual magnitude of the effect size of interest. East uses this result in the General module to set up a group sequential study on the basis of the information requirements of a fixed-sample study. See also Fixed Sample Study Information.

Information calculator

The calculator applies to parallel two-arm randomized designs with normal or binomial endpoints. During interim monitoring of an information based study the accumulated information up to the current look can be computed on the basis of the current values of the sample size and of the observed sample mean and standard deviation (if the underlying endpoint follows a normal distribution) or number of responses (if the underlying endpoint follows a binomial distribution) in the control and treatment arm respectively. It computes the achieved statistical information, the value of the current test statistic and a new estimate of the maximum sample size required. This latter quantity may differ from the value obtained at design (using the Sample Size Calculator) if the statistical information actually accumulates at a higher or lower pace than anticipated (i.e. if for normal data the actual standard deviation of the observation is different from the value used at design and for binomial data if the observed success rate in the control group is different from the value used at design).

Information fraction

This is defined as the ratio of the information at the current time-point to the maximum information committed to the study. For a large number of studies, including studies with normal and binomial end points the information fraction is simply the ratio of the current sample size to the

maximum sample size committed to the study. For time to event end points it is the ratio of the current number of events (such as failures) to the total number of events committed to the study. For studies in which the monitoring will be performed on the Fisher information scale, the information is estimated as the square inverse of the estimate of the standard error of the parameter under investigation. Thus the information fraction is the ratio of the current inverse square estimate to the maximum inverse square estimate needed to achieve the goals of the study. Information fraction is also referred to sometimes as Process time.

Last look logic

When the trial has to come to an end for administrative reasons (i.e. not because one of the boundaries has been crossed or because the maximum information has been reached) the boundary for this last look should be determined by spending the remaining alpha so as to respect the desired size of the testing procedure. In interim monitoring, this is what happens when the **Tools-Last Look** menu item is selected in East before performing the next look.

Look number

The counter identifying successive analyses of the data.

Maximum accrual

The accrual to be reached if no early stopping occurred (i.e. if the study went on until the last look). This quantity satisfies the desired significance level and power of the design.

Maximum accrual duration

In studies with time to event endpoint, the time required to achieve the necessary maximum accrual.

Maximum events

See Maximum study duration.

Maximum information

The information to be achieved if the study does not stop at any interim analysis. This quantity computed at design is revised during interim monitoring to allow for the actual schedule of looks, since their number

X Glossary

and relative spacing may be different than assumed at design (see Ideal next look position).

Maximum study duration

In studies with time to event endpoint, the study duration and the corresponding number of events of the study to satisfy the desired operating characteristics of the study if no early stopping occurs.

Median survival

When designing a study to compare the distributions of the times to event, the expected relative advantage of the treatments being compared is expressed, by default, in terms of the expected median survival in the treatment and in the control groups respectively. Alternatively, the Design Wizard allows the specification of the relative survival experience in terms of expected percent survival at a specific time or in terms of hazard rates.

Median unbiased estimator (MUE), Adjusted

The method suggested by Kim (1989) is applied to derive the median unbiased estimator of the effect size at the end of the study allowing for repeated significance testing.

Mid-alternative

Studies where early stopping may occur either in favor of the null or of the alternative hypothesis, may extend until relatively large stopping times, if the alternative has been overestimated. In such cases, the test statistic will tend to fluctuate within the continuation region. East computes the expected quantities (e.g. sample size or accrual) at termination not only under the null and the alternative but also under an intermediate hypothesis. Due to the non-linearity of the transformation linking the scale in which the effect size of interest to the user is expressed and the internal standardized scale used by East, the mid-alternative does not correspond to half of the alternative. The expected quantities computed by East under the mid-alternative, however, express the worst case scenarios.

Muller and Schafer method

In adaptive trials, the Muller and Schafer method aims to preserve the conditional type-1 error computed at the time of the adaptation. It is permissible to make any desired data dependent change to an ongoing group sequential trial, possibly more than once, by the simple process of

preserving the conditional type-1 error of the remainder of the trial after each change.

Nominal critical point

A synonym for the boundary value against which the test statistic has to be compared. The nominal critical point is expressed in the same scale as a standard normal deviate in order to facilitate the comparison against the test statistic computed at each look. This explains the use of the adjective "Nominal". See also Test Statistic and Nominal Significance Level.

Nominal significance level

The probability of values more extreme than the Nominal Critical Point according to a standard normal distribution. See also Nominal Critical Point.

Non-binding boundaries

Non-binding boundaries produce the desired power and preserve the type-1 error so that the crossing of the futility boundary may be overruled. Contrariwise, binding boundaries require the termination of the trial if the test statistic crosses the futility boundary; otherwise the type-1 error might be inflated.

Non-inferiority margin

In non-inferiority designs for difference, the non-inferiority margin (δ_0) is the magnitude of the difference between the treatment and the control arm that should not be exceeded for the treatment arm to be considered non-inferior to the control arm. In non-inferiority designs for ratio, the non-inferiority margin (ρ_0) is the ratio between the treatment proportion response and the control proportion response that should not be exceeded for the treatment arm to be considered non-inferior to the control arm. In non-inferiority designs for odds ratio, the non-inferiority margin (Ψ_0) is the odds ratio between the treatment proportion response and the control proportion response that should not be exceeded for the treatment arm to be considered non-inferior to the control arm.

Non-inferiority trial

A non-inferiority trial aims to determine if the outcome of an experimental treatment is no worse than the outcome of the standard treatment. It aims to reject the null hypothesis that the experimental treatment exceeds a

X Glossary

pre-specified non-inferiority margin. The amount by which the mean response on the experimental arm is worse than the mean response on the control arm must fall within this non-inferiority margin for the claim of non-inferiority to be sustained.

Nuisance parameters

Nuisance parameters affect the results of mathematical and statistical models but there may be insufficient information about their magnitudes. In clinical trials inaccurate initial estimates of these parameters will lead to incorrect estimates of the sample size or other resources and the study will not have the correct operating characteristics. Adaptive trials may estimate nuisance parameters based on early results and, then given these more accurate estimates, the conclusions of the trial may be more accurate than those from traditional trials based on poorly estimated nuisance parameters.

Number of looks (K)

For design purposes, K represents the tentative number of analyses to be performed during the interim monitoring phase up to and including the last look. The number of analyses eventually performed during interim monitoring of the trial can be different from K .

Pampallona-Tsiatis boundaries

These power boundaries are characterized by two shape parameters: Δ_1 for the boundaries that facilitate early stopping for efficacy by rejecting H_0 ; and Δ_2 for the boundaries that facilitate early stopping for futility by rejecting H_1 .

Percent survival at Time t

This option in East specifies the survival curves for the control and treatment arms using their percentages surviving at Time t . Given this information East will calculate medians, hazard rates, and hazard ratios.

Post-hoc power

The post-hoc power is an a-posteriori characteristic of the actually adopted sequence of analyses: it is the probability of rejecting the null hypothesis using a testing strategy that corresponds to the analyses performed during the trial, up to and including the final one.

Post-hoc power chart

The post-hoc power is an a-posteriori characteristic of the actually adopted sequence of analyses: when computed after each interim analysis, it is the probability of rejecting the null hypothesis using a testing strategy that corresponds to the analyses performed up to and including the current look plus a hypothetical final analysis. This plot provides a graphical rendition of how the post-hoc power varies as a function of the cumulative information (e.g. sample size, number of failures etc., depending on the endpoint) at this hypothetical last look. Two special cases are worth noting: before the first analysis the post-hoc power curve corresponds to a power curve for a fixed sample study as a function of information rather than of the parameter of interest; after the actual last analysis the post-hoc power reduces to a single number (displayed in the "Post-Hoc Power" output box of the Interim Monitoring worksheet).

Power (1-beta)

The power of the study (or one minus beta, where beta is the type-2 error probability) is the probability of terminating the study with the rejection of the null hypothesis (H_0) when the alternative hypothesis (H_1) is indeed true. Usual choices of power are 0.9 and 0.8 (corresponding to 10% and 20% type-2 error probability, respectively, also known as Beta). Beta is the type-2 error, the probability of not rejecting H_0 when it is in fact false. An underpowered trial is extremely undesirable because it places human subjects at risk with a low probability of reaching a positive scientific conclusion and diverts resources that could be better utilized elsewhere.

Power chart

This plot provides a graphical rendition of how the power of the study varies as a function of the effect size or non-inferiority margin (e.g. standardized difference, difference in proportions, etc.).

p-value, adjusted

The method suggested by Fairbanks and Madsen (1982) is applied to derive the overall adjusted p- value at the end of the study allowing for repeated significance testing.

Repeated confidence interval

The sequence of repeated confidence intervals provided after each look has simultaneous coverage probability of $(1 - \alpha)100\%$. Each interval

X Glossary

provides a statistical summary of the information about the parameter of interest allowing for repeated looks at the accumulating data. This quantity can contribute, together with any other relevant information, to the decision to terminate or continue the study. The coverage probability of the procedure is maintained regardless of how the decision to terminate the study is taken.

Repeated P-value

At the k_{th} analysis, a two-sided repeated P-value for the null hypothesis $H_0 : \delta = \delta_0$ is defined as $p_k = \max(\alpha : \delta_0 \in I_k(\alpha))$, where $I_k(\alpha)$ is the current $(1 - \alpha)$ -level Repeated Confidence Interval (RCI). In other words, P_k is that value of α for which the k_{th} $(1 - \alpha)$ -level RCI contains the null value, δ_0 , as one of its endpoints. The repeated P-value provides protection against the effect due to multiple-looks.

Repeated significance test

The idea of a "repeated significance test" at a constant nominal significance level to analyze accumulating data at a number of times over the course of a study was developed by Pocock. Subject entry is divided into K equally sized groups containing m subjects on each treatment, and the data are analyzed after each new group of observations has been observed.

Sample size calculator

The calculator applies to parallel two-arm randomized designs with normal or binomial endpoints. For such studies it translates information into a sample size when supplied with the value of the nuisance parameter, namely the known and common standard deviation of the observations (if the underlying endpoint follows a normal distribution) or the success rate in the control group (if the underlying endpoint follows a binomial distribution).

Significance level (alpha)

Alpha (or type-1 error probability), is the probability of terminating the study with the rejection of the null hypothesis (H_0) when it is actually true. Usual choices of alpha are 0.05 and 0.10 (corresponding to 5% and 10% type-1 error probability, respectively).

Spacing of looks

Two options are available in East to specify the relative spacing of looks. If "Equal Spacing" is selected, East assumes, at design, that analyses are performed after equal increments of physical resources (e.g. subjects for normal or binomial endpoint, failures for survival) or of statistical information. If "Unequal Spacing" is selected, the user specifies the timing of the analyses in terms of fractions (in the range 0 to 1) of cumulative information. The actual spacing of analyses adopted during the trial can be different from the one tentatively chosen for design purposes.

Spending function

See alpha spending function or beta spending function or the next entry.

Spending Functions, Published (Pub)

These are single-parameter boundary families, the ρ (rho) or γ (gamma). $\rho = 1$ produces boundaries that resemble the Pocock; $\rho = 3$ produces boundaries that resemble the more conservative O'Brien-Fleming. When γ is negative its convex spending functions increase in conservatism as γ decreases; when γ is positive its concave spending functions increase in aggressiveness as γ increases. When $\gamma = 0$ the type-1 error is spent linearly. When $\gamma = 1$ the stopping boundaries resemble the Pocock.

Standardized difference

When designing a study to compare means of normally distributed observation the expected value of the difference between the means of the two groups being compared divided by the (common and assumed known) standard deviation of the observations is of relevance. This quantity is referred to as the standardized difference. In non-inferiority studies this difference represents the non-inferiority margin (the treatment arm should not be worse than the control arm by more than the non-inferiority margin). It can also be expressed as a function of its individual components (the two means and the common standard deviation), or of the difference in means and the standard deviation.

Stopping probabilities

The probability that the test statistic will cross a stopping boundary at a given look. These probabilities are different depending on which hypothesis is assumed to hold (for instance under the null, the alternative or an intermediate hypothesis).

Study duration

X Glossary

In studies with time to event endpoint, the study duration up to and including a given look (actual chronological time of the analysis relative to study start) computed under various hypotheses.

Superiority trial

A superiority trial aims to determine if the outcome of an experimental treatment is better than the outcome of the standard treatment. It aims to reject the null hypothesis that there is no difference between these two outcomes.

Test statistic

In any of the Interim Monitoring worksheets and in the Direct Monitoring worksheet the user is requested to input the value of the test statistic observed at the current analysis. This corresponds to the usual deviate, following a standard normal distribution under the null, as provided by statistical analysis packages. See also Nominal Critical Point.

Test statistic calculator

When at any of the interim analyses the value of the effect size of interest (delta) is known as well as its estimated standard error, the calculator computes the corresponding value of the Wald test statistic. The supplied values of delta and its estimated standard are then used to compute the repeated confidence interval at the given look instead of the design values.

Test type

The type of the test can be either one- or two-sided. A one-sided test assumes that under the alternative hypothesis the parameter of interest lies in a single direction away from the null hypothesis H_0 . A two-sided test assumes that under the alternative hypothesis the parameter of interest lies in either direction away from the null hypothesis H_0 , and the test searches in both directions for departures of the test statistic from H_0 .

Time of looks

The time at which the analyses are performed, in terms of the cumulative fraction of the maximum information (in the range 0 to 1). In particular, for Normal and Binomial endpoints the maximum information is given by the maximum accrual. For Survival type of data, it is given by the maximum number of events.

Traditional study designs

Preference for an experimental treatment can be demonstrated in terms of its improved efficacy with respect to control (a superiority trial), its equivalence to the control treatment (an equivalence trial), or its being not much worse than the control treatment (a non-inferiority trial). In an equivalence trial the goal is to establish equivalence between two treatments rather than the superiority in efficacy of one over the other. In a non-inferiority trial, the experimental treatment should be demonstrated not to be inferior by more than a tolerable non-inferiority margin.

Type of trial

Preference for an experimental treatment can be demonstrated in terms of its improved efficacy with respect to control (“Superiority” trial), its equivalence to the control treatment (“Equivalence” trial), or its being not much worse than the control treatment (“Non-inferiority” trial). In an equivalence trial, the goal is to establish equivalence between two treatments rather than the superiority in efficacy of one over the other. In a non-inferiority trial, the experimental treatment should be demonstrated not to be inferior by more than a tolerable non-inferiority margin.

Type-1 error

The type-1 error probability is the probability of selecting the alternative hypothesis H_1 when the null hypothesis H_0 is in fact true. The significance level α (alpha) quantifies the strength of the evidence against the null hypothesis $H_0 : \mu = \mu_0$. An $\alpha = .05$ implies that the test of significance would erroneously reject the null hypothesis when in fact it was true only five times in 100 tests (1 time in 20). Commonly used significance levels are: .05, .01 (1 time in 100), .025 (25 times in 1000) or .1 (1 time in 10).

Type-2 error

The type-2 error probability (β) (beta) is the probability of erroneously accepting the null hypothesis H_0 when H_1 is in fact true. Commonly used values of (β) are .10 and .20. The power of the test is defined as $1 - (\beta)$. It is the probability of correctly rejecting H_0 (the null hypothesis) when H_1 (the alternative hypothesis) is in fact true.

Wang-Tsiatis boundaries

The Wang-Tsiatis boundaries permit early stopping to reject H_0 . They are

X Glossary

used to stop a trial early for efficacy only (1-sided boundaries), safety only (1-sided boundaries), or to stop early either for efficacy or safety (two-sided boundaries).

Y.1.1 East 6.4 Validation

This section describes the extensive validating procedures carried out on all the features incorporated in East 6.4. East 6.4 will be referred to as East in this subsection. A summary table displaying the methods used for each statistical procedure is given below. Each row of the table corresponds to a statistical procedure and the columns C1-C8 correspond to the following methods:

- **C1 column: Validation using East5.4** - Most of the features which are implemented in East can be validated using the earlier version of East, version 5. Results from such features are compared and validated against East 5 and their consistency is ensured.
- **C2 column: Validation using in-house R codes** - We have developed and are using independent R scripts to validate results from East. These R codes, in some cases, can be used to validate the intermediate output quantities whereas in some cases to validate the complete feature.
- **C3 column: Validation using published R packages** - Some features in East are partially or completely available in published R packages. The results from such features are compared and validated against the results from these R packages.
- **C4 column: Validation using SAS** - Some features in East are partially or completely available in SAS. The results from such features are compared and validated against the results from these SAS procedures.
- **C5 column: Validation using SiZ 2.0** - Most of the features in East which related to Single look design come from SiZ 2.0 version. Results from such features are compared and validated against SiZ 2.0 and their consistency is ensured. SiZ 2.0 is fully validated released software. It has been thoroughly validated against external software like nQuery, PASS, SAS and R as well as with in-house validation programs in R/SAS.
- **C6 column: Using East for Internal Validation and Consistency** - All the features in East are validated by applying some internal consistency checks. These checks are generally carried out using different features within East.
- **C7 column: Validation using StatXact10** - Most of the features in East which related to Single look design come from StatXact 11 version. Results from such features are compared and validated against StatXact11.
- **C8 column: Validation using commercial software packages** - Features that are available in other commercial packages like nQuery, PASS and SAS have

Y.1.3 East 6.2 Validation

This section describes the extensive validating procedures carried out on all the features incorporated in East 6.2. East 6.3 will be referred to as East in this subsection. A summary table displaying the methods used for each statistical procedure is given below. Each row of the table corresponds to a statistical procedure and the columns C1-C5 correspond to the following methods:

- **C1 column: Validation using East5.4** - Most of the features which are implemented in East can be validated using the earlier version of East, version 5. Results from such features are compared and validated against East 5 and their consistency is ensured.
- **C2 column: Validation using in-house R codes** - We have developed and are using independent R scripts to validate results from East. These R codes, in some cases, can be used to validate the intermediate output quantities whereas in some cases to validate the complete feature.
- **C3 column: Validation using published R packages** - Some features in East are partially or completely available in published R packages. The results from such features are compared and validated against the results from these R packages.
- **C4 column: Using East for Internal Validation and Consistency** - All the features in East are validated by applying some internal consistency checks. These checks are generally carried out using different features within East.
- **C5 column: Validation using commercial software packages** - Features that are available in other commercial packages like nQuery, PASS and SAS have been validated against East.

In the table below, the symbol "1" indicates that the method in that column was used for validation of the feature in corresponding row. The symbol "-" indicates that the method in that column was not applicable for that feature.

Y.1.4 East Architect and East 6.1 Validation

This section describes the extensive validating procedures carried out on all the features incorporated in East Architect as well as East 6.1. East Architect and East 6.1 will be referred to as East in this subsection. A summary table displaying the methods used for each statistical procedure is given below. Each row of the table corresponds to a statistical procedure and the columns **C1–C6** correspond to the following methods:

- **C1 column: Validation using East5.4** - Most of the features which are implemented in East can be validated using the earlier version of East, version 5. Results from such features are compared and validated against East 5 and their consistency is ensured.
- **C2 column: Validation using in-house R codes** - We have developed and are using independent R scripts to validate results from East. These R codes, in some cases, can be used to validate the intermediate output quantities whereas in some cases to validate the complete feature.
- **C3 column: Validation using published R packages** - Some features in East are partially or completely available in some of published R packages. The results from such features are compared and validated against the results from these R packages.
- **C4 column: Validation using SAS** - Some features in East are partially or completely available in SAS. The results from such features are compared and validated against the results from these SAS procedures.
- **C5 column: Validation using SiZ 2.0** - Most of the features in East which related to Single look design come from SiZ 2.0 version. Results from such features are compared and validated against SiZ 2.0 and their consistency is ensured. SiZ 2.0 is fully validated released software. It has been thoroughly validated against external software like nQuery, PASS, SAS and R as well as with in-house validation programs in R/SAS.
- **C6 column: Using East for Internal Validation and Consistency** - All the features in East are validated by applying some internal consistency checks. These checks are generally carried out using different features within East.

In the table below, the symbol "1" indicates that the method in that column was used for validation of the feature in corresponding row. The symbol "-" indicates that the method in that column was not applicable for that feature.

Y On validating the East Software

Y.1.5 East 5.4 Validation

This section describes the extensive validating procedures carried out on adaptive features incorporated in East5.4. A summary table displaying the methods used for each statistical procedure is given below. Each row of the table corresponds to a statistical procedure and the columns **C1–C4** correspond to the following methods:

- **C1 column: Using East for Internal Validation and Consistency**- In case of adaptive simulations, the final outcome is the 'Re-estimated Sample Size' and the 'Achieved Conditional Power for that sample size. To validate these two numbers we can use intermediate parameters like 'Estimate of Delta', Standard Error of that estimate, the sample size at the adapt look in East designs. The output from CHW IM like repeated p-value is also verified using the Design level features in East.
- **C2 column: Use of R code** - We have developed and are using independent R scripts to validate results from adaptive features like CHW, CDL Simulations and CHW IM. In case of simulations this code works to compute the re-estimated sample size and the power achieved. In case of CHW IM, the R code computes Weighted statistics, the RCI's, and the repeated p-values.
- **C3 column: Use of Excel Based Tools** - We have developed in-house Excel based tools to validate the results obtained from adaptive features. These tools also require information on the adapt look parameters like 'Delta Estimate', 'Standard Error' of that estimate. The outcomes validated are the re-estimated sample size and the conditional power achieved.
- **C4 column: Use of Excel Based Tools** - Using Excel based tool (Developed and recommended By Dr. Cyrus Mehta) to verify the alpha and Power preservation from adaptive simulations. We can run the simulations under the Null/Alternative hypothesis and verify whether the Type-I Error/Design Power is indeed preserved or not. On running 100000 or more simulations, accuracy is achieved. To verify whether the simulated rejection probability is actually close to the Design Alpha or Power, we use the excel based tool which gives us the confidence of preservation of probabilities. This tool in general can be used to verify whether the observed number in (0,1) is close to the actual number or not.

In the table below, the symbol "1" indicates that the method in that column was used for validation of the feature in corresponding row. The symbol "-" indicates that the method in that column was not applicable for that feature.

All the features in the table below are validated for the two tests under **Survival Endpoint: Superiority Trial Two sample Given Accrual Duration and Accrual Rates and Superiority Trial Two sample Given Accrual Duration and Study**

Duration

| N | East 5.4 Feature | C1 | C2 | C3 | C4 |
|---|------------------|----|----|----|----|
| 1 | CHW Simulations | 1 | 1 | 1 | 1 |
| 2 | CDL Simulations | 1 | 1 | 1 | 1 |
| 3 | CHW IM | 1 | 1 | – | 1 |
| 4 | CP Calculator | 1 | 1 | 1 | 1 |

Y On validating the East Software

Y.1.6 East 5.3 Validation

This section describes the extensive validating procedures carried out on adaptive features incorporated in East5.3. A summary table displaying the methods used for each statistical procedure is given below. Each row of the table corresponds to a statistical procedure and the columns **C1–C5** correspond to the following methods:

- **C1 column: Using East for Internal Validation and Consistency** - In case of adaptive simulations, the final outcome consists of 'Re-estimated Sample Size' and the 'Achieved Conditional Power' for that sample size. To validate these two numbers, we use intermediate parameters like 'Estimate of Delta', 'Standard Error' of that estimate and the sample size at the adapt look. Output quantities like weighted test statistic and repeated p value from CHW IM sheet are also verified using internal validation.
- **C2 column: Use of R code** - We have developed independent R scripts to validate results from adaptive features like CHW and CDL Simulations as well as CHW IM sheet. In case of afore mentioned Simulations this code works to compute the re-estimated sample size and the power achieved. In case of CHW IM, it computes Weighted statistics, Repeated Confidence Intervals, and repeated p-values. We have utilized R-packages like 'lbound', 'Adapt'.
- **C3 column: Use of Excel Based Tools** - We have developed in-house Excel based tools to validate the results obtained from adaptive simulations. These tools also require information on the adapt look parameters like 'Delta Estimate', 'Standard Error' of that estimate. The outcomes validated are the re-estimated sample size and the conditional power achieved.
- **C4 column: Use of ADDPLAN** - We have compared results from CHW IM sheet and CP calculator with ADDPLAN.
- **C5 column: Confidence Interval for Probabilities using Excel** - We have used in-house Excel based tool recommended by Dr. Cyrus Mehta to verify the Alpha and Power Preservation from adaptive simulations. This tool provides confidence interval for simulated probability.

In the table below, the symbol "1" indicates that the method in that column was used for validation of the feature in corresponding row. The symbol "-" indicates that the method in that column was not applicable for that feature.

All the features in the table below are validated for **Normal Endpoint: Superiority Trial Two sample Difference of Means** and **Binomial Endpoint: Superiority Trial Two sample Difference of Proportions**.

| Serial No. | East 5.3 Feature | C1 | C2 | C3 | C4 | C5 |
|------------|--------------------------------|----|----|----|----|----|

| 9 | CP Calculator | 1 | – | – | 1 | – |

Y On validating the East Software

Y.1.7 East 5 and East 4 Validation

This manual discusses more than one hundred illustrative trial designs with simulation and interim monitoring. We used these designs to validate the internal and external consistencies of East. A summary table displaying the methods used for each statistical procedure is given below. Each row of the table corresponds to a statistical procedure and the columns **C1–C4** correspond to the following comparisons:

- **C1 column:** Comparisons of the sample sizes for single look designs obtained from East 5 with the analogous estimates from the nQuery(2005) and Egret Siz (1997) software. For the repeated measures design that is not supported by these software packages, we compared the estimates obtained from East 5 with the results reported by Fitzmaurice, Laird and Ware (2004).
- **C2 column:** Comparisons of the design values of significance level and power with the values obtained by simulation in a single look setting.
- **C3 column:** Comparisons of the design values of the probabilities of crossing the stopping boundaries, significance level and power with the values obtained in the simulation in a multiple-look setting.
- **C4 column:** Comparisons of the design boundary values with the boundary value estimates generated in the internal monitoring (IM) module.

In the table, the symbol “1” indicates that the comparison was made for the test and the symbol “-” denotes that a comparable test in other software was not available or the comparison was not applicable (e.g. a check of the boundary crossing probabilities for the East procedures that only support a single look design).

| N | Test Type | Setting | Test Name | C1 | C2 | C3 | C4 |

Y.1.8 East 3 Validation

The statistical results computed by East 3 have been subjected to rigorous and extensive quality-assurance testing for purposes of validation. A database consisting of a large number of studies has been compiled at Cytel Software Corporation. These studies have been gathered from published articles, from East-2000 software and from East-2000 beta testers. Several additional studies have been constructed by us since the release of East-2000. We have also constructed studies using the University of Wisconsin software package. We have thereby tested the software across a broad range of possible input values. The results were checked by five different methods.

1. **Checks against East-2000 and East-DOS.** The results in East 3 have been checked against East-2000, which in turn was tested against East-DOS. The East-2000 and East-DOS software were collectively tested extensively over a period of ten years both in-house and by end-users at commercial sites, academic sites and the FDA.
2. **Checks against Published Tables.** East 3 implements the family of power boundaries proposed by Wang and Tsiatis (1987) and further extended by Pampallona and Tsiatis (1994). Both papers contain extensive tabulations of the constants defining the boundaries and of expected sample numbers for numerous combinations of the various design parameters. East 3 also uses the spending function approach for generating stopping boundaries at the design stage. Tables of boundaries and inflation factors derived from published spending functions are available and have been published by Jennison and Turnbull (2000). We have verified that the numbers in these tables match corresponding numbers generated by East 3.
3. **Checks against Simulation.** The East 3 simulation module provides a further way to check some properties of the designs proposed by East 3 up to Monte Carlo accuracy. For any given set of boundaries, the several different quantities have been checked against the theoretical operating characteristics of any chosen design, such as type-I and type-II error probabilities, stopping probabilities and average sample number. Specifically we have verified the following through simulation:
 - (a) We have simulated studies with varying values for the effect size, ranging all the way from the null hypothesis up to the alternative hypothesis. In every case we have verified that the theoretical power obtained from the design module of East 3 matches with the power obtained by simulation.
 - (b) We have compared the exit probabilities, look by look, between the simulation results and the theoretical results obtained from the design details module of East 3. The exit probabilities match, up to Monte Carlo accuracy.

Y On validating the East Software

- (c) We have compared the average sample size obtained by simulation with the corresponding average sample size displayed on the design worksheet for H_0 , H_1 and $H_{1/2}$. The results match.
4. **Logical Checks.** Several logical checks have been implemented where the behavior of East 3 can either be predicted with certainty or where a high level of consistency is expected among varying but related situations. Some examples are given below:
- (a) East 3 has been extensively tested against published tables and commercial software for fixed-sample size designs. The fixed sample designs in East 3 are special cases of the group sequential designs for which East 3 was primarily developed.
 - (b) We have designed many studies with a variety of spending functions and with both equal and unequal spacings for the interim looks. We have then invoked the interim monitoring module in East 3 and implemented the monitoring schedule exactly as prescribed in the design stage. We have thereby verified through two independent computation procedures that the error spent, and stopping boundaries produced at the interim monitoring stage are identical to the corresponding values at the design stage.
 - (c) We have documented (in Appendix C) that the stopping boundaries used at the interim monitoring stage of a Wang-Tsiatis or Pampallona-Tsiatis design are derived from inverting ten-look, equally spaced stopping boundaries, generated at the design stage. The design and interim monitoring output have therefore been compared for 10-look designs that were actually monitored with 10 equally spaced looks. The results from these two independent methods of obtaining the output match.
 - (d) In the interim monitoring module, before the first look is performed, the conditional power chart corresponds to the usual power curve for fixed sample designs. This serves to validate that the power specified in the design module matches the initial estimate of conditional power.
 - (e) In the interim monitoring module, the suggested optimal look position before any data have been entered into the worksheet must correspond to the sample size requirements of a fixed sample design. We have verified that this theoretical requirement is satisfied.
 - (f) The General module can set up and allow monitoring of a group sequential design on the basis of the sample size requirement of the corresponding fixed sample design. Therefore, for any arbitrary group sequential design set up and monitored in either of the Normal, Binomial or Survival modules it is possible to replicate virtually all the output with the General module given the sample size requirement of its fixed sample counterpart.

- (g) A number of actual clinical applications published in the literature were replicated in East 3. The East 3 results were consistent with the published results. Many of these applications were used as case studies in the earlier East-2000 software.
- (h) The exit probabilities under either H_0 , H_1 or $H_{1/2}$ are displayed in the design details worksheet. We have verified that the sum of these exit probabilities, for any of the above hypotheses, is 1.
- (i) We have verified that the expected sample sizes under H_0 , H_1 or $H_{1/2}$, as displayed on the design worksheet, match with the corresponding expected samples sizes computed directly from the exit probabilities and cumulative accruals, displayed as design details in East 3.
- (j) We have verified that the cumulative alpha spent matches with the cumulative exit probabilities under H_0 from the design details portion of East 3.
- (k) We have verified that for studies with H_0 -only boundaries, the cumulative alpha spent at any intermediate look matches the cumulative exit probability under H_0 , up to that intermediate look.
- (l) We have verified that for 1-sided studies with H_1 -only boundaries, the cumulative beta spent at any intermediate look matches the cumulative exit probability under H_1 , up to that intermediate look.
- (m) We have verified that there is internal consistency between the final adjusted confidence intervals, computed by the Tsiatis, Rosner and Mehta (1989) stage-wise method, and the final adjusted p-value. That is, the final adjusted confidence interval excludes the parameter of interest if and only if the final stopping boundary is crossed, and the final adjusted p-value is less than alpha.
- (n) We have verified that there is internal consistency between the repeated confidence intervals of Jennison and Turnbull (1998) and the value of the final test statistic. That is, one extreme of the repeated confidence interval will coincide with zero for superiority trials (or with the non-inferiority margin for non-inferiority trials) if and only if the observed test statistic falls on a boundary value.
- (o) We have verified that there is internal consistency between the final adjusted p-value and the final cumulative alpha that was spent when the test statistic coincides with the stopping boundary. These two values are computed independently but logically they have to be equal.
- (p) We have verified that the maximum information obtained from the information based design module of East 3 corresponds to the maximum

Y On validating the East Software

sample size obtained from the normal or binomial design modules, for studies in which the effect size, power, type-1 error, stopping boundaries and spacing of looks is kept the same.

5. **Checks against Public Domain Software.** Public domain Fortran routines developed at the University of Wisconsin (see Reboussin et. al., 2002) can be freely downloaded from <http://www.landemets.com>. East 3 replicated the results produced by this software for adjusted p-values, confidence intervals and unbiased estimators following sequential monitoring. The stopping boundaries are evaluated differently in the two procedures and result in small differences. A detailed explanation for these differences is provided in Appendix F.

Y.2 Fixed-Sample Designs (FSD)

Y.2.1 Details

The statistical results computed by FSD have been subjected to rigorous and extensive quality-assurance testing for purposes of validation. A summary table displaying the methods used for each statistical procedure is given below. Each row of the table corresponds to a statistical procedure and the columns **C1-C6** correspond to comparison of **FSD** result with results using other software as indicated below.

- **C1 Column:** Comparison with nQuery 7.0.
- **C2 Column:** Comparison with SAS 9.1.
- **C3 Column:** Comparison with independent developed R programs and SAS macros.
- **C4 Column:** Comparison with PASS 2008.
- **C5 Column:** Comparison with StatXact8.
- **C6 Column:** Comparison with East 5.2.

In the following tables,

”1” indicates that the comparison was made for the test and results from **FSD** were comparable to the respective software.

”2” indicates that the comparison was made but the results did not match for reasons indicated at the bottom of the table.

”-” denotes that a comparable test in other software was not available or the comparison was not applicable.

Note

(*)The results for McNemar's Test for Matched Pairs from FSD do not match with those from nQuery as FSD uses Normal approximation while nQuery uses the Chi-square test.

(**) The formulation of the Odds Ratio of Proportions: Superiority Test is different in FSD and nQuery which results in the mismatch between their results.

(***) There is a difference in the results from FSD and nQuery for the Cohen's Kappa Test due to the difference in the techniques followed.

Module: Simulation

Results of Simulations in FSD are validated by checking the internal consistency. For example, the estimated probability of rejection from Simulations was compared with the analytical result obtained from FSD design procedure.

Module: Data Explorer

The Data Explorer tests' outputs have been compared with the corresponding Cytel Studio 8 results.

Y.2.2 FSD MC Procedures

The Multiple Comparison procedures implemented in FSD MCP have been validated extensively. Various methods were employed for the statistical validation of these

Y On validating the East Software

procedures. The following summary table states the methods used for validating each of the Multiple Comparison Procedures. Each row of the table corresponds to a procedure and the columns C1-C4 correspond to the validation method used as described below:

- **C1 Column:** Comparison with SAS 9.1
- **C2 Column:** Comparison with R 2.12.1 (Packages used: 'multxpert', 'mutoss')
- **C3 Column:** Comparison with PASS 2005
- **C4 Column:** Comparison with independently developed (in-house) R/SAS macros

In the following tables, '1' indicates that the comparison was made for the test and results from FSD MCP were comparable to the respective software; '2' indicates that the comparison was made but the results either matched partially or did not match for reasons indicated at the bottom of the table; '-' denotes that a comparable test in other software was not available or the comparison was not applicable.

Table Y.1: Module: Design

| Sr.# | MCP | C1 | C2 | C3 | C4 |
|------|---------------------------|----|----|----|----|
| 1 | Dunnett's single step (*) | 2 | - | 2 | 1 |
| 2 | Dunnett's step down | - | - | - | 1 |
| 3 | Dunnett's step up | - | - | - | 1 |
| 4 | Bonferroni | - | - | - | 1 |
| 5 | Sidak | - | - | - | 1 |
| 6 | Weighted Bonferroni | - | - | - | 1 |
| 7 | Holm's step down | - | - | - | 1 |
| 8 | Hochberg's step up | - | - | - | 1 |
| 9 | Hommel's step up | - | - | - | 1 |
| 10 | Fixed sequence | - | - | - | 1 |
| 11 | Fallback | - | - | - | 1 |

Note: (*) The critical value for Dunnett's single step was available with SAS and hence validated with it. This procedure was also compared with PASS. However PASS provides for 2-sided test and FSD MCP has 1-sided test. Hence the results were comparable in case of scenarios where the treatment means were either all greater than or all less than the control mean. Note that these tests are simulation based and hence cannot be matched exactly with PASS.

Table Y.2: Module: Analysis

| Sr.# | MCP | C1 | C2 | C3 | C4 |
|------|----------------------------|----|----|----|----|
| 1 | Dunnett's single step (**) | 2 | 1 | - | 1 |
| 2 | Dunnett's step down | - | 1 | - | 1 |
| 3 | Dunnett's step up | - | 1 | - | 1 |
| 4 | Bonferroni | 1 | 1 | - | - |
| 5 | Sidak | 1 | 1 | - | - |
| 6 | Weighted Bonferroni | - | 1 | - | - |
| 7 | Holm's step down | 1 | 1 | - | - |
| 8 | Hochberg's step up | 1 | 1 | - | - |
| 9 | Hommel's step up | 1 | 1 | - | - |
| 10 | Fixed sequence | - | 1 | - | - |
| 11 | Fallback | - | 1 | - | - |

(**) The critical value and Simultaneous CI was available with SAS and hence validated with it.
