

Preface

Acknowledgements

Welcome to East, a software platform for the statistical design, simulation and monitoring of clinical trials.

The current release of East (version 6.4) was developed by a team comprising (in alphabetical order): Gordhan Bagri, Dhaval Bapat, Priyanka Bhosle, Jim Bolognese, Sudipta Basu, Jaydeep Bhattacharyya, Swechhya Bista, Apurva Bodas, Pushkar Borkar, V. P. Chandran, Soorma Das, Pratiksha Deoghare, Aniruddha Deshmukh, Namita Deshmukh, Yogesh Dhanwate, Suraj Ghadge, Pranab Ghosh, Karen Han, Aarati Hasabnis, Pravin Holkar, Munshi Imran Hossain, Abhijit Jadhav, Yogesh Jadhav, Prachi Jagtap, Paridhi Jain, Yannis Jemiai, Ashwini Joshi, Nilesh Kakade, Janhavi Kale, Aditya Kamble, Anthiyur Kannappan, Parikshit Katikar, Uday Khadilkar, Kapildev Koli, Yogita Kotkar, Hrishikesh Kulkarni, Mandar Kulkarni, Mangesh Kulkarni, Shailesh Kulthe, Charles Liu, Lingyun Liu, Shashank Maratkar, Cyrus Mehta, Pradoshkumar Mohanta, Manashree More, Tejal Motkar, Ankur Mukherjee, Nabeela Muzammil, Neelam Nakadi, Vijay Nerkar, Sandhya Paranjape, Gaurangi Patil, Vidyadhar Phadke, Anup Pillai, Shital Pokharkar, Vidyagouri Prayag, Achala Sabane, Sharad Sapre, Rohan Sathe, Pralay Senchaudhuri, Rhiannon Sheaparé, Pradnya Shinde, Priyadarshan Shinde, Sumit Singh, Sheetal Solanki, Chitra Tirodkar, Janhavi Vaidya, Shruti Verma, Pantelis Vlachos, Suchita Wageshwari, Kiran Wadje, Ritika Yadav.

Others contributors to this release include Asmita Ghatnekar, Sam Hsiao, Brent Rine, Ajay Sathe, Chinny Swamy, Nitin Patel, Yogesh Gajjar, Shilpa Desai.

Other contributors who worked on previous releases of East: Gayatri Bartake, Ujwala Bamishte, Apurva Bhingare, Bristi Bose, Chandrashekhar Budhwant, Krisnaiah Byagari, Vibhavari Deo, Rupali Desai, Namrata Deshpande, Yogesh Deshpande, Monika Ghatage, Ketan Godse, Vishal Gujar, Shashikiran Halvagal, Niranjan Kshirsagar, Kaushal Kulkarni, Nilesh Lanke, Manisha Lohokare, Jaydip Mukhopadhyay, Abdulla Mulla, Seema Nair, Atul Paranjape, Rashmi Pardeshi, Sanket Patekar, Nabarun Saha, Makarand Salvi, Abhijit Shelar, Amrut Vaze, Suryakant Walunj, Sanhita Yeolekar.

We thank all our beta testers for their input and obvious enthusiasm for the East software. They are acknowledged by name in Appendix Z.

We owe a debt of gratitude to Marvin Zelen and to Swami Sarvagatananda, special

people whose wisdom, encouragement and generosity have inspired Cytel for over two decades.

Finally, we dedicate this software package to our families and to the memory of our dearly departed Stephen Lagakos and Aneesh Patel.

Our Philosophy

We would like to share with you what drives and inspires us during the research and development stages of the East software.

Empower, do not Frustrate

We believe in making simple, easy-to-use software that empowers people.

We believe that statisticians have a strategic role to play within their organization and that by using professionally developed trial design software they will utilize their time better than if they write their own computer programs in SAS or R to create and explore complex trial designs. With the help of such software they can rapidly generate many alternative design options that accurately address the questions at hand and the goals of the project team, freeing time for strategic discussions about the choice of endpoints, population, and treatment regimens.

We believe that software should not frustrate the user's attempt to answer a question. The user experience ought to engage the statistician and inspire exploration, innovation, and the quest for the best design. To that end, we believe in the following set of principles:

- **Fewer, but Important and Useful Features** It is better to implement fewer, but important and useful features, in an elegant and simple-to-use manner, than to provide a host of options that confuse more than they clarify. As Steve Jobs put it: 'Innovation is not about saying "Yes" to everything. It's about saying "No" to all but the most crucial features.'
- **Just because we Can, doesn't mean we Should** Just because we can provide functionality in the software, doesn't mean we should.
- **Simplify, Simplify, Simplify** Find and offer simple solutions - even for the most complex trial design problems.
- **Don't Hurry, but continually Improve** Release new solutions when they are ready to use and continually improve the commercial releases with new features, bug fixes, and better documentation.
- **Provide the best Documentation and Support** Our manuals are written like textbooks, to educate, clarify, and elevate the statistical knowledge of the user.

Preface

Our support is provided by highly competent statisticians and software engineers, focusing on resolving the customer's issue, and being mindful of the speed and quality requirements. We believe that delivering *delightful customer support is essential to our company's lifeblood*.

Finally, we listen to our customers constantly and proactively through countless informal and formal interactions, software trainings, and user group meetings. This allows us to follow all the principles laid out above in the most effective manner.

Assess

It is essential to be able to assess the benefits and flaws of various design options and to work one's way through a sensitivity analysis to evaluate the robustness of design choices. East can very flexibly generate multiple fixed sample size, group sequential, and other adaptive designs at a click of a button. The wealth of design data generated in this manner requires new tools to preview, sort, and filter through in order to make informed decisions.

Share

Devising the most innovative and clever designs is of no use if the statistician is unable to communicate in a clear and convincing manner what the advantages and characteristics of the design are for the clinical trial at hand. We believe statistical design software tools should also be communication tools to share the merits of various trial design options with the project team and encourage dialog in the process.

The many graphs, tables, simulation output, and other flexible reporting capabilities of East have been carefully thought out to provide clear and concise communication of trial design options in real time with the project team.

Trust

East has been fully validated and intensely tested. In addition, the East software package has been in use and relied upon for almost 20 years. East has helped design and support countless actual studies at all the major pharmaceutical and biotech companies, academic research centers, and government institutions.

We use and rely on our software every day in our consulting activities to collaborate with our customers, helping them optimize and defend their clinical trial designs. This also helps us quickly identify things that are frustrating or unclear, and improve them fast - for our own sake and that of our customers.

What's New in East 6.4

Version 6.4 of East introduces some important new features:

1. **Multi-arm multi-stage designs** East now offers the ability to design multi-arm multi-stage studies with options for early stopping, dose selection, and sample size re-estimation. The group sequential procedures (Gao et al., 2014) have been implemented for normal endpoint whereas the p-value combination approaches (Posch et al. 2005) have been implemented for both normal and binomial endpoints. See Chapters 17, 18 and 29 for more details.
2. **Multiple endpoints designs for binomial endpoints** Gatekeeping procedures to control family-wise type-1 error when testing multiple families of binomially distributed endpoints are now available in East for fixed sample (1-look) designs. East will also use the intersection-union test when testing a single family of endpoints. See Chapter 16 and 28 for more details.
3. **Multi-arm designs for survival endpoints** Designs for pairwise comparisons of treatment arms to control have been added for survival endpoints. See Chapter 51 for more details.
4. **Enrollment and event prediction** East now includes options to predict enrollment and events based on accumulating blinded data and summary statistics. Prediction based on unblinded data was already implemented in the previous version so the current version provides both options - Unblinded as well as Blinded. See Chapter 68 for more details.
5. **Dual agent dose-escalation designs** This version of East adds methods to the Escalate module for dual-agent dose-escalation designs, including the Bayesian logistic regression model (BLRM; Neuenschwander et al., 2014), and the Product of Independent beta Probabilities dose Escalation (PIPE; Mander et al., 2015). Numerous feature enhancements have also been made to the existing single-agent dose escalation designs. See Chapter 32 for more details.
6. **Bayesian probability of success (assurance) and predictive power for survival designs**
East 6.4 will now calculate assurance (O'Hagan et al., 2005), or Bayesian probability of success, and predictive power for survival endpoints. See Chapter 48 for more details.
7. **Interim monitoring using Muller and Schafer method** East6.4 will now provide the capability of monitoring clinical trials using the adaptive approach. It can be done using the Muller and Schafer method. Currently, this feature is

Preface

available for Survival Endpoint tests only. See Chapter 56 for more details.

8. **General usability enhancements** Numerous enhancements have been made to the software to improve the user experience and workflow.

What's New in East 6.3

Version 6.3 of East introduces some important new features:

1. **Updates to Promising Zone designs: Ratio of Proportions designs; Müller and Schäfer type-1 error control method; Estimation**
East 6.3 introduces Promising Zone designs for the ratio of proportions. East 6.3 also implements the method of Müller and Schäfer (2001) to control type-1 error for adaptive unblinded sample size re-estimation designs. This is available for simulation and interim monitoring. Also estimation using Repeated Confidence Intervals (RCI) and Backward Image Confidence Intervals (BWCI) (Gao, Liu & Mehta, 2013) are available in Müller and Schäfer simulations. See Chapter 52 for more details.
2. **Multiple endpoint designs**
Parallel gatekeeping procedures to control family-wise type-1 error when testing multiple families of normally distributed endpoints are now available in East for fixed sample (1-look) designs. East will also use the intersection-union test when testing a single family of endpoints. See Chapter 16 for more details.
3. **Exact designs for binomial endpoints**
East now includes the ability to use the exact distribution when computing power and samples size for binomial endpoints. This applies for all binomial tests in the case of fixed designs. In addition, group sequential exact designs are available for the single proportion case, and the Simon's two-stage optimal and minimax designs (Simon, 1989) have been implemented that allow for early futility stopping while optimizing the expected sample size and the maximum sample size, respectively. See Chapter 33 for more details.
4. **Dose escalation designs**
East 6.3 now includes a module for the design, simulation, and monitoring of modern dose-escalation clinical trials. Model-based dose-escalation methods in this module include the Continual Reassessment Method (mCRM; Goodman et al., 1995), the Bayesian logistic regression model (BLRM; Neuenschwander et al., 2008), and the modified Toxicity Probability Interval (mTPI; Ji et al., 2010). See Chapter 32 for more details.
5. **Predictive interval plots, conditional simulations, , and enrolment/events**

prediction

East 6.3 now includes a module that offers the ability to simulate and forecast the future course of the trial based on current data. This includes conditional simulations to assess expected treatment effects and associated repeated confidence intervals at future looks (also called Predicted Interval Plots or PIP; Li et al. 2009), as well as the probability of finishing with a successful trial (conditional power). You can also plan and simulate clinical trials with greater precision using different accrual patterns and response information for different regions/sites. East allows you to make probabilistic statements about accruals, events, and study duration using Bayesian models and accumulating data. See Chapters 65, 66 and 67 for more details.

6. Sample size and information calculators

Sample size and information calculators have been added back into East to allow easy calculation of the two quantities. See Chapter 59 for more details.

7. Exporting/Importing between East and East Procs

East 6.3 designs can now be exported to work with the newly released East Procs. The output from East Procs can be imported back into East 6.3 for use in the East Interim Monitoring dashboard and to conduct conditional inference and simulations. See Chapters 69 for more details.

8. Changes to East input

Many changes have been implemented in East to enhance the user experience in providing input for their designs. These changes include the ability to specify multiple values of input parameters for survival designs (most notably the Hazard Ratio), the ability to directly convert many fixed sample designs into group sequential designs with the use of the Sample Size based design option, and the ability to convert an ANOVA design into a Multiple Comparison to Control design.

9. Changes to East output

Display of East output has been changed in many ways, including color coding of input and output, ability to collapse and expand individual tables, greater decimal display control, and more exporting options for results (e.g. ability to export graphs directly into Microsoft Power Point).

What's New in East 6.2

Version 6.2 of East introduces some important new features:

1. Promising Zone Designs using CHW and CDL type-1 error control methods

Preface

East 6.2 introduces Promising Zone Designs from East 5.4 for differences of means, proportions, and the log-rank test. The methods of Cui, Hung, and Wang (1999) and Chen, DeMets, and Lan (2003) are implemented for adaptive unblinded sample size re-estimation designs and available for simulation and interim monitoring.

2. **Multiple endpoint designs** Serial gatekeeping procedures to control family-wise type-1 error when testing multiple families of normally-distributed endpoints are now available in East for fixed sample (1-look) designs.
3. **Power and sample size calculations for count data** East now offers power analysis and sample size calculations for count data in fixed sample (1-look) designs. Specifically, East provides design capabilities for:
 - (a) Test of a single Poisson rate
 - (b) Test for a ratio of Poisson rates
 - (c) Test for a ratio of Negative Binomial rates
4. **Precision-based sample size calculations** Sample size calculations are now available based on specification of a confidence interval for most tests provided in East.

What's New in East 6.1

Version 6.1 of East introduces some important new features:

1. **Bayesian probability of success (assurance) and predictive power**

For one-sample and two-sample continuous and binomial endpoints, East 6.1 will now compute Assurance (O'Hagan et al., 2005) or Bayesian probability of success, a Bayesian version of power, which integrates power over a prior distribution of the treatment effect, giving an unconditional probability that the trial will yield a significant result. When monitoring such a design using the Interim Monitoring dashboard, East 6.1 will also compute Bayesian predictive power using the pre-specified prior distribution on the treatment effect. This computation will be displayed in addition to the fiducial version of predictive power, which uses the estimated treatment effect and standard error to define a Gaussian prior distribution.
2. **Stratification in simulation of survival endpoints**

When simulating a trial design with a time-to-event endpoint, East 6.1 accommodates data generation in a stratified manner, accounting for up to 3 stratification variables and up to 25 individual strata. The fraction of subject data generated in each stratum, and the survival response generation mechanism for each stratum, can be flexibly adjusted. In addition, stratified versions of the logrank statistic and other test statistics available for analysis of the simulated data are provided.

3. **Integration of R code into simulations**

East 6.1 simulations now include the option to use custom R code to define specific elements of the simulation runs. R code can be used to modify the way the subjects are accrued, how they are randomized, how their response data are generated, and how the test statistic is computed.

4. **Reading East 5.4 workbooks**

East 5.4 workbooks can be read into East 6.1 after conversion using the utility provided in the program menu. Go to the start menu and select:

Programs > East Architect > File Conversion > East5 to East6

5. **Floating point display of sample size**

East 6.1 now has a setting to choose whether to round sample sizes (at interim and final looks) up to the nearest integer, or whether to display them as a floating point number, as in East 5. (See

6. **Enhancement to the Events vs. Time plot**

This useful graphic for survival designs has been updated to allow the user to edit study parameters and create a new plot directly from a previous one, providing the benefit of quickly assessing the overall impact of input values on a design prior to simulation. (See

7. **Interim monitoring (IM) dashboard**

The capability to save snapshots of the interim monitoring (IM) dashboard is now supported in East 6.1. At each interim look of a trial, updated information can be saved and previous looks can be easily revisited. Alternatively, prior to employing actual data this functionality could be used to compare multiple possible scenarios, providing the user a sense of how a future trial could unfold.

8. **Enhancement to the Logrank test**

For trials with survival endpoints, East 6.1 allows the user to simultaneously create multiple designs by specifying a range of values for key parameters in the Logrank test. (See Subsection

9. **Enhancement to binomial designs**

For studies with discrete outcomes, East 6.1 allows the user to simultaneously create multiple designs by specifying a range of values for key parameters.

What's New in East 6.0 on the Architect Platform

East Architect is version 6.0 of the East package and builds upon earlier versions of the

software. The transition of East to the next generation platform that is Architect has abandoned all prior dependencies of Microsoft Excel. As a result the user interface is very different leading to a new user experience and workflow. Although you might find that there is a learning curve to getting comfortable with the software, we trust that you will find that the new platform provides for a superior user experience and improved workflow.

Preface

The Architect platform also adds data management and analysis capabilities similar to those found in Cytel Studio, StatXact, and LogXact, as well as a powerful reporting tool we call Canvas, which provides flexible and customizable reports based on design and simulation information.

Version 6.0 of East introduces some important new features in addition to the new platform environment. Here is a selection:

1. **New designs** A large number of fixed sample designs have been added for various endpoints and trial types. These were present in the SiZ software and have now been fully integrated into East.
2. **Multi-arm designs** Designs for pairwise comparisons of treatment arms to control have been added for differences of means and differences of proportions. These designs are mostly simulation-based and provide operating characteristics for fixed sample studies using multiplicity adjusting procedures such as Dunnett's, Bonferroni, Sidak, Hochberg, Fallback, and others.
3. **Creation of multiple designs or simulations at once:** East Architect provides the ability to create multiple designs or to run multiple simulation scenarios at once, by specifying lists or sequences of values for specific parameters rather than single scalars. This capability allows the user to explore a greater space of possibilities or to easily perform sensitivity analysis. Accompanying tools to preview, sort, and filter are provided to easily parse the large output generated by East.
4. **Response lag, accrual, and dropouts for continuous and discrete endpoints:** Designs created for continuous and discrete endpoints now have the option for the user to specify a response lag (between randomization and observation of the endpoint), as well as an accrual rate and dropout rate for the study population. As a result, some terminology has been introduced to distinguish between the number of subjects who need to be enrolled in the study (Sample Size) and the number of subjects whose endpoint must be observed in order to properly power the study (Completers).
5. **Flexibility in setting up boundaries** Both the efficacy and futility rules of a design need not be present at each and every look anymore. The user can specify whether a look includes either the efficacy stopping rule or the futility rule or both. Therefore, a design can be set up where at the first look only futility stopping is possible, whereas at later looks both efficacy and futility or maybe only efficacy stopping is allowed. In addition, the futility rule can now be specified on two new scales, which are the standardized treatment scale and the conditional power scale.
6. **Predictive power** Predictive power is now provided as an alternative to conditional power in the interim monitoring sheet of the software. Further

details about how this is implemented can be found in the appendix C.

7. **Comparing designs** One can compare multiple designs either graphically or in tabular format simply by selecting them and choosing a plot or table output button.
8. **Improvements in algorithms** Many improvements have been made to the way computations are performed, both to improve accuracy and speed, but also to provide more intuitive results. For example, older versions of East used an approximation to conditional power based on ignoring all future looks but the final one. This approximation has been dropped in favor of computing the exact value of conditional power. Many other changes have been made that might result in different values being computed and displayed in East Architect as compared to earlier versions of the software. For greater details about the changes made, please refer to the "Read Me" notes that accompany the software release.

What's New in East 5

After East 5 (version 5.0) was released, a few upgrades have been issued. The details are:

1. In the current release of version 5.4, the module EastSurvAdapt has been added.
2. In the previous version 5.3, the module EastAdapt was substantially revised.
3. In the earlier version 5.2, the module EastExact was released.
4. In the still earlier version 5.1, several improvements were introduced in EastSurv module.

The details of these modules can be found in the respective chapters of the user manual.

East 5 upgraded the East system in several important ways in direct response to customer feedback. Six important extensions had been developed in East 5:

1. **Designs using t-tests:**

In previous versions of East, the single look design was treated as a special case of a group sequential design. Thus the same large sample theory was used to power and size these traditional types of designs. Recognizing this solution not to be entirely satisfactory for small sample trials, in East 5, we have implemented single-look t-test designs for continuous data. (Sections 8.1.4, 8.2.4, 9.1.3, and 11.1.3)

2. **New boundaries:**

East 5 provides two new procedures for specifying group sequential boundaries.

- Generalized Haybittle-Peto boundaries allow the user to specify unequal p-values at each interim look for a group sequential plan. East will

Preface

- recalculate the final p-value in order to preserve the type I error. (Section 38.1)
 - The cells for entering the cumulative alpha values of an interpolated spending function can be automatically populated with the cumulative alpha values of any of the published spending functions available to East, and subsequently edited to suit user requirements. For example, a 4-look Lan and DeMets O'Brien-Fleming spending function can be modified so that the critical value at the first look is less conservative than usual. (Section 38.3.1)
3. **Interim monitoring and simulation for single-look designs:**
Interim monitoring and simulation sheets have been provided for all single look designs in East 5.
 4. **Improvement to Charts:**
Many improvements to existing charts in East have been implemented in this version.
 - Scaling in the Duration vs. Accrual chart has been corrected to provide a better tool for the user.
 - The use of semi-log scaling has enabled us to represent many charts on the natural scale of the treatment effect. This concerns mostly any ratio and odds ratio metrics such as the relative risk, the hazard ratio, and the odds ratio. Boundaries on the relative risk scale for example are now available in East 5.
 - Boundaries can also be visualized on the score scale.
 - Charts can be summarized in tabular form. Option is given to the user to generate tables of power vs. sample size, power vs. treatment effect, events vs. time, and so on. These tables can easily be copied and pasted into external applications like Microsoft Word and Excel (Section 4.5)
 5. **Improved usability:**
Much attention in East 5 was spent to improve the user's experience within the environment.
 - A graph sheet allows the user to compare up to 16 charts side by side. Charts for any number of plans within a workbook can be exported to the graph sheet. (Section 5.3)
 - The scratch sheet is a full-fledged Microsoft Excel sheet that can be brought up within the East application . (Section 4.4)
 - The split view option enables the user to see two sheets of the same workbook simultaneously. This can be useful if one window pane contains a scratch sheet where side calculations may be done based on numbers in

the other window pane. Another use can be to have two or plans to show up on one pane and their graphsheets containing boundaries or other charts to show up on another pane for easy comparison. (Section 4.8)

- Messages in the help menu, pop-up help, and context sensitive help have been revised and rendered more informative to the user.
- The default appearance of charts can be specified by the user through the preferences settings menu item. (Section 4.7)

6. Installation validation:

East 5 includes an installation validation procedure that will easily check that the software has been properly installed on the user's system. (Section 2.3)

Finally, there has been an important reorganization of the East manual, which now comprises seven volumes organized as follows: (1) The East System (2) Continuous Endpoints (3) Binomial and Categorical Endpoints (4) Time-to-Event Endpoints (5) Adaptive Designs (6) Special Topics (7) Appendices. Page numbers are continuous through volumes 1-7. Each volume contains a full table of contents and index to the whole manual set.

Preface to East 4

East 4 was a very large undertaking involving over 20 developers, documenters, testers and helpers over a two-year period. Our goal was to produce one single powerful design and monitoring tool with a simple, intuitive, point and click, menu driven user interface, that could cover the full range of designs commonly encountered in a clinical trial setting, for either fixed sample or group sequential designs. The resulting product, East 4, extends the East system for flexible design and interim monitoring in four major ways as listed below.

1. Broad Coverage:

Previous versions of East dealt primarily with the design of two-arm group sequential trials to detect a difference of means for normal and binomial endpoints and a hazard ratio for survival endpoints. East 4 extends these capabilities to other settings.

- Easily design and monitor up to 34 different clinical trial settings including one-, two- and K-sample tests; linear, logistic and Cox regression; longitudinal designs; non-inferiority and bioequivalence designs; cross-over and matched-pair designs; nonparametric tests for continuous and ordered categorical outcomes.
- Comparisons between treatment and control groups can be in terms of differences, ratios or odds ratios.

Preface

- Non-inferiority trials can be designed to achieve the desired power at superiority alternatives
2. **New Stopping Boundaries and Confidence Intervals:**
 - Non-binding futility boundaries. Previously futility boundaries could not be overruled without inflating the type-1 error. New non-binding futility boundaries preserve power and type-1 error and yet can be overruled if desired.
 - Asymmetric two-sided efficacy boundaries. You can allocate the type-1 error asymmetrically between the upper and lower stopping boundaries, and can spend it at different rates with different error spending functions. This will provide added flexibility for aggressive early stopping if the treatment is harmful and conservative early stopping if the treatment is beneficial.
 - Futility boundaries can be represented in terms of conditional power. This brings greater objectivity to conditional power criteria for early stopping.
 - Two sided repeated confidence intervals are now available for one-sided tests with efficacy and futility boundaries. Previously only one-sided confidence bounds were available.
 - Interactive repeated confidence intervals are provided at the design stage to aid in sample size determination and selection of stopping boundaries.
 3. **New Analytical and Simulation Tools for Survival Studies:**

EastSurv is an optional new module, fully integrated into the East system, that extends East's design capabilities to survival studies with non-uniform accrual, piecewise exponential distributions, drop outs, and fixed length of follow-up for each subject. Designs can be simulated under general settings including non-proportional hazard alternatives.
 4. **Design and Simulation of Adaptive Trials:**

EastAdapt is an optional new module, fully integrated into the East system, that permits data-dependent changes to sample size, spending functions, number and spacing of interim looks, study objectives, and endpoints using a variety of published flexible approaches.

In addition to these substantial statistical capabilities, East 4 has added numerous improvements to the user interface including clearer labeling of tables and graphs, context sensitive help, charts of power versus sample size and power versus number of events, convenient tools for calculating the test statistics to be entered into the interim monitoring worksheet for binomial endpoints, and the ability to type arithmetic expressions into dialog boxes and into design, interim monitoring and simulation worksheets.

Preface to East 3

East 3 is a major upgrade of the East-2000 software package for design and interim monitoring of group sequential clinical trials. It has evolved over a three-year period with regular input from our East-2000 customers. The main improvements that East 3 offers relative to East-2000 are greater flexibility in study design, better tracking of interim results, and more powerful simulation capabilities. Many of our East-2000 customers expressed the desire to create group sequential designs that are ultra-conservative in terms of stopping early for efficacy, but which can be quickly terminated for futility. The extremely wide selection of spending functions and stopping boundaries in East 3, combined with its interactive Excel-based spreadsheet user interface for comparing multiple designs quickly and effortlessly, make such designs possible. The interim monitoring module of East 3 has been completely revised, with a “dashboard” user interface that can track the test statistic, error spent, conditional power, post-hoc power and repeated confidence intervals on a single worksheet, over successive interim monitoring time points, for superior trial management and decision making by a data monitoring committee. Finally, we have enhanced the simulation capabilities of East 3 so that it is now possible to evaluate the operating characteristics not only of traditional group sequential designs, but also of adaptive designs that permit mid-course alterations in the sample size based on interim estimates of variance or treatment effect. A list of the substantial new features in East 3 relative to East-2000 is given below. (The items on this list beginning with ‘(*)’ are optional extras.)

New Design Features

1. Design of non-inferiority trials.
2. Design of trials with unequally spaced looks.
3. Use of Lan and DeMets (1983) error spending functions to derive stopping boundaries.
4. (*) Flexible stopping boundaries derived from the gamma spending function family (Hwang, Shih and DeCani, 1990) and the rho spending function family (Kim and DeMets, 1987).
5. Haybittle-Peto stopping boundaries (Haybittle, 1971).
6. (*) Boundaries derived from user-specified spending functions with interpolation.
7. Boundaries for early stopping for futility only.
8. Graphical and numerical representation of stopping boundaries on other scales besides the standard normal scale; e.g., boundaries expressed on the p-value scale, effect size scale, and conditional power scale.
9. Computing power for a fixed sample size.
10. Chart displaying the number of events as a function of time (for survival studies).

Preface

New Interim Monitoring Features

1. Detailed worksheet for keeping track of interim monitoring data and providing input to the data monitoring committee.
2. Simultaneous view of up to four thumbnail charts on the interim monitoring worksheet. Currently one may select any four charts from, the stopping boundary chart, the error spending chart, the conditional power chart, the post-hoc power chart, and the repeated confidence intervals chart. You can also expand each thumbnail into a full-sized chart by a mouse click.
3. Computation of repeated confidence interval (Jennison and Turnbull, 2000) at each interim look.

New Simulation Features

1. (*) Simulation of actual data generated from the underlying normal or binomial model instead of simulating the large sample distribution of the test statistic.
2. (*) Simulation on either the maximum sample size scale, or the maximum information scale.
3. (*) Simulation of the adaptive design due to Cui, Hung and Wang (1999).

New User Interface Features

1. Full integration into the Microsoft Excel spreadsheet for easy generation and display of multiple designs, interim monitoring or simulation worksheets, and production of reports.
2. Save design details and interim monitoring results in Excel worksheets for easy electronic transmission to regulatory reviewers or to end-users.
3. Create custom calculators in Excel and save them with the East study workbook.

Preface to East-2000

For completeness we repeat below the preface that we wrote for the East-2000 software when it was released in April, 2000.

Background to the East-2000 Development The precursor to East-2000 was East-DOS an MS-DOS program with design and interim monitoring capabilities for normal, binomial and survival end points. When East-DOS was released in 1991 its user interface and statistical features were adequate to the needs of its customer base. MS-DOS was still the industry standard operating system for desktop computers. Group sequential designs were not as popular then as they are now. The role of data and safety monitoring boards (DSMB's) in interim monitoring was just beginning to emerge. FDA and industry guidelines on the conduct of group sequential studies were in the early draft stage. Today the situation is very different. Since the publication of

the ICH-E9 guidance on clinical trials by the FDA and regulatory bodies in Europe and Japan, industry sponsors of phase-III clinical trials are more favorably inclined to the group sequential approach. For long-term mortality studies especially, interim monitoring by an independent DSMB is almost mandatory. As the popularity of group sequential studies has increased so has the demand for good software to design and monitor such studies. For several years now we have been flooded with requests from our old East-DOS customers to move away from the obsolete MS-DOS platform to Microsoft Windows and to expand the statistical capabilities of the software. We have responded by developing East-2000, a completely re-designed Windows package with unparalleled design, simulation and interim monitoring capabilities.

What's New in East-2000 The East-2000 software adds considerable functionality to its MS-DOS predecessor through a superior user interface and through the addition of new statistical methods.

New User Interface East-2000 is developed on the Microsoft Windows platform. It supports a highly interactive user interface with ready access to stopping boundary charts, error spending function charts, power charts and the ability to present the results as reports in Microsoft Office.

1. *Interactivity* Designing a group sequential study is much more complex than designing a fixed sample study. The patient resources needed in a group sequential setting depend not only on the desired power and significance level, but also on how you will monitor the data.

How many interim looks are you planning to take? What stopping boundary will you use at each interim look? Does the stopping boundary conform to how you'd like to spend the type-1 error at each look? Do you intend to stop early only for benefit, only for futility, or for both futility and benefit? In a survival study, how long are you prepared to follow the patients?

These design and monitoring decisions have profound implications for the maximum sample size you must commit up-front to the study, the expected sample size under the null and alternative hypotheses, and the penalty you will have to pay in terms of the nominal p-value needed for declaring significance at the final look. To take full advantage of the group sequential methodology and consider the implications of potential decisions you must have highly interactive software available, both at the study design stage and at the interim monitoring stage. East-2000 is expressly developed with this interactivity in mind. Its intuitive form-fill-in graphical user interface can be an invaluable tool for visualizing how these design and monitoring decisions will affect the operating characteristics of the study.

Preface

2. *Charts* By clicking the appropriate icon on the East toolbar you can view stopping boundary charts, study duration charts, error spending function charts, conditional and post-hoc power charts, and exit probability tables. The ease with which these charts can be turned on and off ensures that they will be well utilized both at the design and interim monitoring phases of the study.
3. *Reports* All worksheets, tables and charts produced by East-2000 can be copied and pasted into Microsoft Word, Excel and PowerPoint pages thus facilitating the creation of annotated reports describing the study design and interim monitoring schedule.

New Statistical Methods East-2000 has greatly expanded the design and interim monitoring capabilities previously available in East-DOS. In addition East-2000 provides a simulation module for investigating how the power of a sequential design is affected by different assumptions about the magnitude of the treatment difference. Some highlights from these new capabilities are listed below.

1. *Design* Whereas East-DOS only provided design capabilities for normal, binomial and survival end points East-2000 makes it possible to design more general studies as well. This is achieved through the use of an inflation factor. The inflation factor determines the amount by which the sample size of a fixed sample study should be inflated so as to preserve its type-1 error in the presence of repeated hypothesis tests. It is thus possible to use any external software package to determine the fixed sample size of the study, input this fixed sample size into the design module of East-2000 and have the sample size inflated appropriately. These general capabilities are discussed in Chapter 8.
2. *Interim Monitoring* A major new feature in the interim monitoring module of East-2000 is the computation of adjusted p-values, confidence intervals and unbiased parameter estimates at the end of the sequential study. Another important feature is the ability to monitor the study on the Fisher information scale and thereby perform sample-size re-estimation if initial assumptions about the data generating process were incorrect. Chapter 9 provides an example of sample-size re-estimation for a binomial study in which the initial estimate of the response rate of the control drug was incorrect.
3. *Simulation* East-2000 can simulate an on-going clinical trial and keep track of the frequency with which a stopping boundary is crossed at each interim monitoring time-point. These simulations can be performed under the null hypothesis, the alternative hypothesis or any intermediate hypothesis thus permitting us to evaluate how the various early stopping probabilities are affected by miss-specifications in the magnitude of the treatment effect.

Continuous Development of East East-2000 will undergo continuous development with major new releases expected on an annual basis and smaller improvements regularly posted on the Cytel web site. We will augment the software and implement new techniques based on the recommendations of the East Advisory Committee, and as the demand for them is expressed by our customers. The following items are already on the list:

- Easy links to fixed-sample design packages so as to extend the general methods in Chapter 8;
- Analytical and simulation tools to convert Fisher information into sample size and thereby facilitate the information based design and interim monitoring methods of Chapter 9, especially for sample-size re-estimation.

We will build a forum for discussing East related issues on the Cytel web site, www.cytel.com. Interesting case studies, frequently asked questions, product news and other related matters will be posted regularly on this site.

Roster of East Consultants Cytel offers consulting services to customers requiring assistance with study design, interim monitoring or representation on independent data and safety monitoring boards. Call us at 617-661-2011, or email sales@cytel.com, for further information on this service.

Volume 1 *The East System*

- 1 Introduction to Volume 1* [2](#)
- 2 Installing East 6* [3](#)
- 3 Getting Started* [7](#)
- 4 Data Editor* [55](#)

1 Introduction to Volume 1

This volume contains chapters which introduce you to East software system.

Chapter 2 explains the hardware and operating system requirements and the installation procedures. It also explains the installation validation procedure.

Chapter 3 is a tutorial for introducing you to East software quickly. You will learn the basic steps involved in getting in and out of the software, selecting various test options under any of the endpoints, designing a study, creating and comparing multiple designs, simulating and monitoring a study, invoking the graphics, saving your work in files, retrieving previously saved studies, obtaining on-line help and printing reports. It basically describes the menu structure and the menus available in East software, which is a menu driven system. Almost all features are accessed by making selections from the menus.

Chapter 4 discusses the Data Editor menu of East 6 which allows you to create and manipulate the contents of your Case Data and Crossover Data. This menu is in use while working with the **Analysis** menu as well as with some other features like PIP or Conditional Simulations.

These features are illustrated with the help of a simple worked example of a binary endpoint trial.

2 *Installing East 6*

2.1 System Requirements to run East 6

The minimum hardware/operating system/software requirements for East 6 (standalone version of the software or the East client in case of concurrent version) are listed below:

- In case of Standalone version and East clients in case of concurrent version, the following operating systems are supported:
 - Windows 7 (32-bit / 64 bit)
 - Windows 8 (32-bit / 64 bit)
 - Windows 8.1 (32-bit / 64-bit)
 - Windows 10 (32-bit / 64-bit)
 - All of above for computers with English, European and Japanese versions of Windows.
- In case of concurrent user version, the following server operating systems are supported:
 - Windows 7 (32-bit / 64 bit)
 - Windows 8 (32-bit / 64 bit)
 - Windows 8.1 (32-bit / 64-bit)
 - Windows 10 (32-bit / 64-bit)
 - All of above for computers with English, European and Japanese versions of Windows
 - Windows Server 2008 (32-bit / 64-bit)
 - Windows Server 2012
 - Citrix
 - * XenApp 6.0 on Windows 2008
 - * XenApp 6.5 on Windows 2008
 - * XenApp 7.6 on Windows 2008
 - * XenApp 7.6 on Windows 2012
- Further, East has the following hardware/software requirements:
 - CPU -1 GHz or faster x86 (32 bit) or x64 (64 bit) processor
 - Memory - Minimum 1 GB of RAM
 - Hard Drive - Minimum 5 GB of free hard disk space
 - Display - 1024 x 768 or higher resolution

2 Installing East 6

- Microsoft .Net Framework 4.0 Full (this will be installed as a part of prerequisites if your computer does not have it)
- Microsoft Visual C++ 2010 SP1 (this will be installed as a part of prerequisites if your computer does not have it) Installer 4.5
- Internet Explorer 9.0 or above
- A stable internet connection is required during installation so that prerequisites like the
- East is compatible and supported with R versions between 2.9.0 to 3.2.3. East may or may not work well with later versions of R. If R is not installed, the ability to include custom R functions to modify specific simulation steps will not be available. The R integration feature is an Add-on to East and is required only to integrate custom R functions with East. But note that this feature doesn't affect any of the core functionalities of East.

2.2 Other Requirements

Users with Windows 7 or above: East uses the font Verdana. Generally Verdana is a part of the default fonts installed by Windows. However, sometimes this font may not be available on some computers, especially if a language other than English has been selected. In such cases, the default fonts need to be restored. To restore fonts, go to Control Panel → Fonts → Font settings. Click the button “Restore default font settings”. This will restore all default fonts including Verdana. Note that this must be done before the first use of East.

Users with Windows 8.1 On some computers with Windows 8.1, problems may be observed while uninstalling East, especially if the user has upgraded from the previous version using a patch. This is because of a security update KB2962872 (MS14-037) released by Microsoft for Internet Explorer versions 6, 7, 8, 9, 10 and 11. Microsoft has fixed this issue and released another security update [KB2976627 \(MS14-051\)](#) for Internet Explorer which replaces the old problematic update. So it is recommended that users who are affected by this issue install security update [KB2976627 \(MS14-051\)](#) on their computers.

2.3 Installation

IMPORTANT: Please follow the steps below if you are installing a standalone/single user version of East. If you are installing a concurrent version, please refer to the document “Cytel License Manager Setup.pdf” for detailed installation instructions.

1. **Uninstalling Previous Versions** If any version (including a beta or demo) of East 6 is currently installed on your PC, please uninstall it completely or else the

installation of the current version will not proceed correctly. To uninstall the earlier version of East 6, go to the **Start** Menu and select:

All Programs → **Cytel Architect** → **East 6.x** → **Uninstall**
Or

All Programs → **East Architect** → **Uninstall East Architect**

depending upon the version installed on your computer.

2. **Installing Current Version** You will need to be an administrator of your computer in order to perform the following steps. If you do not have administrator privileges on your computer, please contact your system administrator / IT.

In order to install East, please follow these steps:

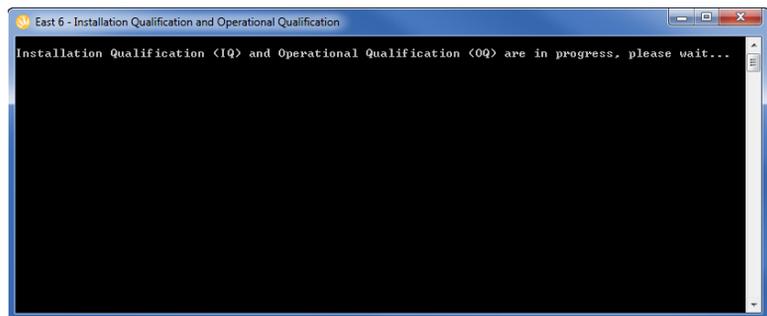

- (a) If you received an email containing a link for downloading the setup, please follow the link and download the setup. This will be a zipped folder. Unzip this folder completely.
- (b) In the setup folder, locate the program **setup.exe** and double-click on it. Follow the instructions on the subsequent windows.

2.4 Installation Qualification and Operational Qualification

To perform the installation and operational qualification of East 6, go to the **Start** Menu and select

All Programs → **Cytel Architect** → **East 6.4** → **Installation Qualification (IQ)**.

You will be presented with the following dialog box.

It will take a few minutes to complete. At the end of the process, the status of the installation qualification will appear. Press Enter (or any other key) to open the

2 Installing East 6

validation log. Similarly, one can run the Operational Qualification (OQ). If the validation is successful, the log file will contain a detailed list of all files installed by East on your computer and other details related to IQ and OQ.

If the validation fails, the validation log file will contain detailed error messages. Please contact your system administrator with the log file.

- **IQ (Installation Qualification) script:** This script verifies whether the software is completely and correctly installed on the system or not. It does this by checking whether all the software components, XML and DLL files are in place.
- **OQ (Operational Qualification) script:** This script runs some representative test cases covering all the major modules/features of East and compares the runtime results to the benchmarks (benchmarks are validated results stored internally in the OQ program). It ensures the quality and consistency of the results in the new version.
- **Manual Examples:** In addition to IQ/OQ, if more testing is to be done, refer to the user manual and reproduce the results for some representative examples/modules. The flow of examples is easy to follow. Some examples in the manual require additional files (datasets) which are available to you in the Samples folder.
- **Validation Chapter:** There is a chapter in this manual dedicated to describe how every feature was validated within Cytel. Refer to the appendix chapter [Y](#) on "Validating East Software". This covers validation strategies for all the features available in East 6.

3

Getting Started

East has evolved over the past several years with MS Excel[®] as the user interface. The East on MS Excel[®] did not integrate directly with any other **Cytel** products. Under the **Architect** platform, East is expected to coexist and integrate seamlessly with other **Cytel** products such as SiZ, and Compass. Architect is a common platform designed to support various Cytel products. It provides a user-friendly, Windows-standard graphical environment, consisting of tabs, icons, and dialog boxes, with which you can design, simulate and analyze. Throughout the user manual, this product is referred to as East 6.

One major advantage of East 6 is the facility for creating multiple designs. This is achieved by giving multiple inputs of the parameters as either comma separated, or in a range such as **(a:b:c)** with **a** as the initial value, **b** as the last value and **c** as the step size. If you give multiple values for more than one parameter, East creates all possible combinations of the input parameters. This is an immense advancement over earlier versions of East, where you had to create one design at a time. Furthermore, one could not compare different types of designs (e.g., superiority vs. noninferiority designs). Similarly, graphical comparison of designs with different numbers of looks was difficult with earlier versions of East. All such comparisons are readily available in East 6.

Another new feature is the option to add assumptions for accruals and dropouts at the design stage. Previously, this was available only for survival endpoint trials, but has been extended to continuous and discrete endpoints in East 6. Information about accrual rates, response lag, and dropouts can be given whether designing or simulating a trial. This makes more realistic, end-to-end design and simulation of a trial possible. Section 3.6 discusses all the above features under the **Design** menu with the help of a case study, CAPTURE.

Simulations help to develop better insight into the operating characteristic of a design. In East 6, the simulation module has now been enhanced to allow fixed or random allocation to treatment and control, and different sample sizes. Such options were not possible with earlier versions of East. Section 3.7 briefly describes the **Simulations** in East 6.

Section 3.8 discusses capability to flexibly monitoring a group sequential trial using the **Interim Monitoring** feature of East 6.

We have also provided powerful data editors to create, view, and modify data. A wide variety of statistical tests are now a part of East 6, which enables you to conduct

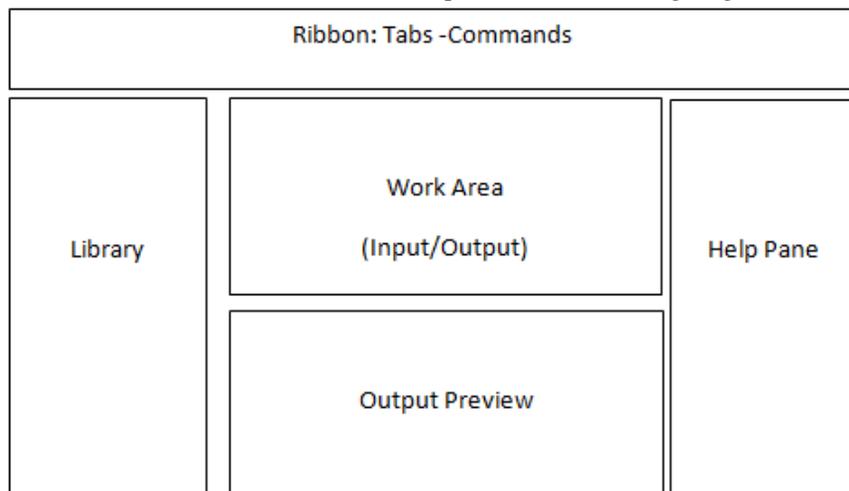

3 Getting Started

statistical analysis of interim data for continuous, discrete and time to event endpoints. Sections 3.4 and 3.5 briefly describes the **Data Editor** and **Analysis** menus in East 6. The purpose of this chapter is to familiarize you with the East 6 user interface.

3.1 Workflow in East

In this section, the architecture of East 6 is explained. The logical workflow in which the different parts of the user interface co-ordinate with each other is discussed.

The basic structure of the user interface is depicted in the following diagram.

Besides the top **Ribbon**, there are four main windows in East 6 namely, (starting from left), the **Library** pane, the **Input / Output** window, the **Output Preview** window and the **Help** pane. Note that both, the **Library** and the **Help Pane** can be auto-hidden temporarily or throughout the session, allowing the other windows to occupy larger area on the screen for display.

Initially, **Library** shows only the **Root** node. As you work with East, several nodes corresponding to designs, simulation scenarios, data sets and related analyses can be managed using this panel. Various nodes for outputs and plots are created in the **Library**, facilitating work on multiple scenarios at a time. The width of the **Library** window can be adjusted for better readability.

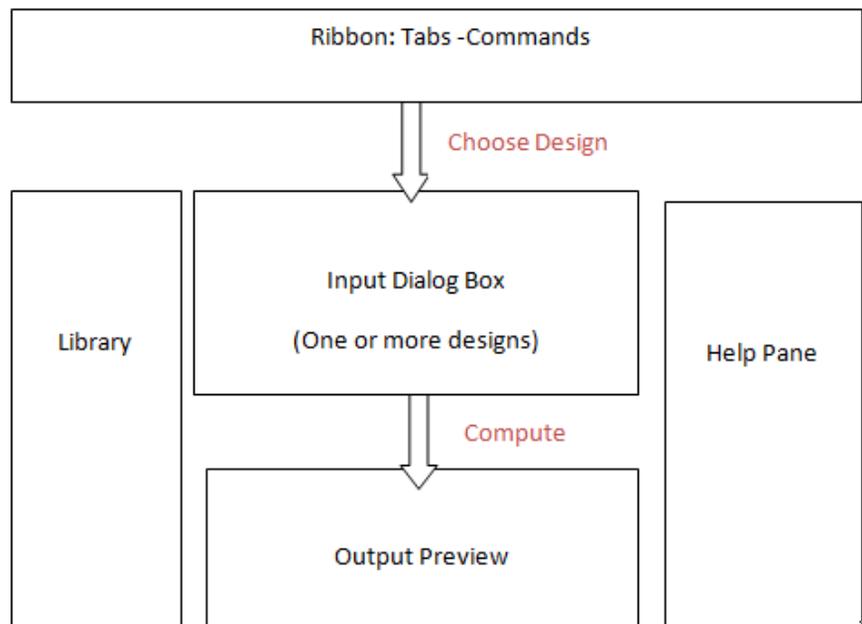

The central part of the user interface, the **Input / Output** window, is the main work area where you can-

- Enter input parameters for design computation create and compare multiple designs, view plots
- Simulate a design under different scenarios
- Perform interim analysis on a group sequential design look by look and view the results, receive decisions such as stopping or continuing during the execution of a trial
- Open a data on which you want to perform analysis, enter new data, view outputs, prepare a report etc.

This is the area where the user interacts with the product most frequently.

The **Output Preview** window compiles several outputs together in a grid like structure where each row is either a design or simulation run. This area is in use only when working with Design or Simulations.

When the **Compute** or **Simulate** button is clicked, all requested design or simulation results are computed and are listed row wise in the **Output Preview** window:

By clicking different rows of interest while simultaneously holding the **Ctrl** key, either a single or multiple designs can be displayed in the **Output Summary** in vertical

3 Getting Started

manner or side-by-side comparison can be done.

The screenshot shows two windows from a software application. The top window is titled 'Output Summary' and displays a detailed comparison of three designs: Des1, Des2, and Des3. The bottom window is titled 'Output Preview' and shows a table summarizing the parameters for each design.

| | | | | Output Summary | | |
|---|--|--|--|------------------|------------------|------------------|
| | | | | Des1 | Des2 | Des3 |
| | | | | MN-25-D1 | MN-25-D1 | MN-25-D1 |

| Des1 | Superiority | 1 | 1-Sided | 0.025 | 0.9 | 1 | 467 | | 0.3 | | | Individual Means | 0 | 0.3 | 1 | Z | Equal | LD (OF) |
| Des2 | Superiority | 3 | 1-Sided | 0.025 | 0.9 | 1 | 473 | | 0.3 | | | Individual Means | 0 | 0.3 | 1 | Z | Equal | LD (OF) |
| Des3 | Superiority | 3 | 1-Sided | 0.025 | 0.9 | 1 | 526 | | 0.3 | | | Individual Means | 0 | 0.3 | 1 | Z | Equal | LD (OF) |

Note that the active window and the **Output Preview** can be minimized, maximized, or resized. If you want to focus on the **Output Summary**, click the  icon in the top-right corner of the main window. The Output will be maximized as shown below:

The screenshot shows the 'Output Summary' window maximized, displaying the parameters for 'Des2' in detail.

| | | Des2 |
|---|--|------------------|
| Mnemonic | | MN-25-D1 |
| Test Parameters | | |
| Design Type | | Superiority |
| No. of Looks | | 3 |
| Test Type | | 2-Sided |
| Specified α | | 0.05 |
| Power | | 0.9 |
| Model Parameters | | |
| Input Method | | Individual Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | | 0.3 |
| Mean Control (μ_c) | | 0 |
| Mean Treatment (μ_t) | | 0.3 |
| Std. Deviation (σ) | | 1 |
| Test Statistic | | Z |
| Allocation Ratio (nt/nc) | | 1 |
| Boundary Parameters | | |
| Efficacy Boundary | | LD (OF) |

| Expected Under H0 | | 471.064 |
| Expected Under H1 | | 379.185 |

Any of the designs/simulations in the **Output Preview** window can be saved in the **Library**, as depicted in the following workflow diagram.

Double click any of these nodes and the detailed output of the design will be displayed. This will include all relevant input and output information. Right clicking any design node in the **Library** will allow you to perform various operations on the design such as interim monitoring and simulation.

The **Help** pane displays the context sensitive help for the control currently under the focus. This help is available for all the controls in the **Input / Output** window. This pane also displays the design specific help which discusses the purpose of the selected test, the published literature referred while developing it and the chapter/section numbers of this user manual to quickly look-up for more details. This pane can be hidden or locked by clicking the pin in its corner.

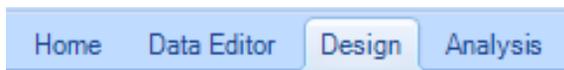

All the windows and features mentioned above are described in detail with the help of an illustration in the subsequent sections of this chapter.

3.2 A Quick Overview of User Interface

Almost all the functionalities of East 6 are invoked by selecting appropriate menu items and icons from the **Ribbon**. The interface consists of four windows as described

3 Getting Started

in the previous section and four major menu items. These menu items are:

- **Home.** This menu contains typical file-related Windows sub-menus. The **Help** sub-menu provides access to this manual.
- **Data Editor.** This menu will be available once a data set is open, providing several sub-menus used to create, manage and transform data.
- **Design.** This menu provides a sub-menu for each of the study designs which can be created using East 6. The study designs are grouped according to nature of the response. The tasks like Simulations and Interim Monitoring are available for almost all the study designs under this menu.
- **Analysis.** This menu provides a sub-menu for each of the analysis procedure that can be carried out in East 6. The tests are grouped according to the nature of the response. There are also options for basic statistics and plots.

3.3 Home Menu

3.3.1 File

3.3.2 Importing workbooks from East5.4

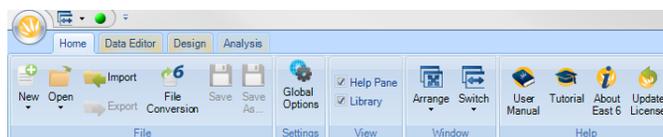

3.3.3 Settings

3.3.4 View

3.3.5 Window

3.3.6 Help

The **Home** menu contains icons that are logically grouped under *File*, *Settings*, *View*, *Window* and *Help*. These icons can be used for specific tasks.

3.3.1 File

New

Click this icon to create new case data or crossover data. A new workbook or log can also be created.

Open

Click this icon to open a saved data set, workbook, or log file.

Import

Click this icon to import external files created by other programs.

Export

Click this icon to export files in various formats.

Save

Click this icon to save the current files or workbooks.

Save As...

Click this icon to save a file or workbook with different name.

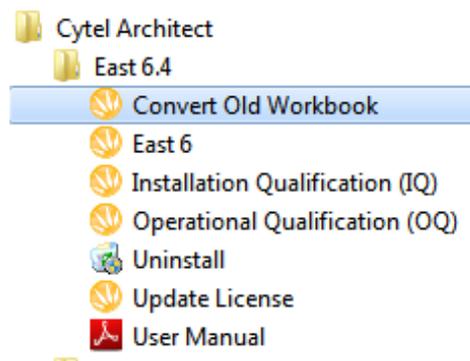

3.3.2 Importing workbooks from East5.4

East allows the conversion of workbooks previously created in East 5.4 (and above) to be imported into East 6 for further development. In order to open a workbook with the .es5 extension given by previous versions of East, it must first be converted to a file with the .cywx extension that will be recognized by East 6. This is easily accomplished

through the **Covert Old Workbook** utility. Click the  icon under **Home** menu to see the location of this utility.

From the **Start** Menu and select:

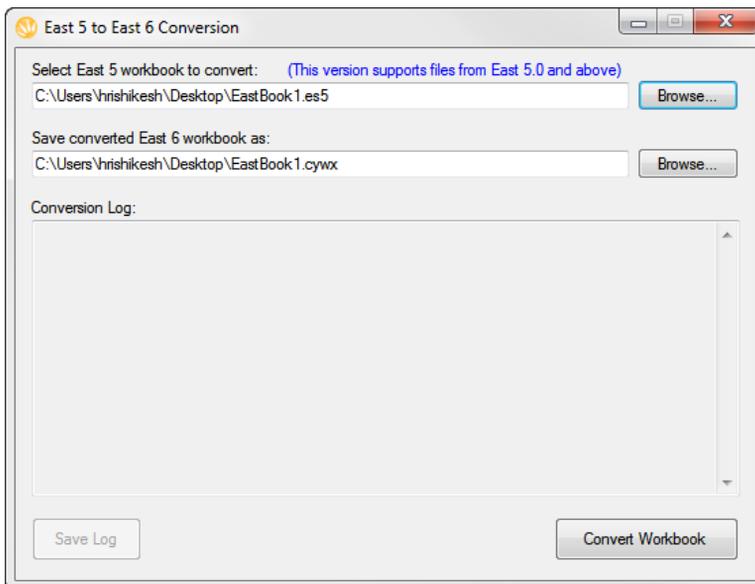

All Programs → **Cytel Architect** → **East 6.x** → **Convert Old Workbook**

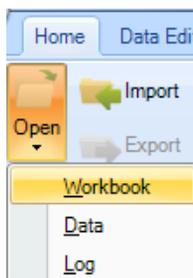

We can see the following window which accepts East5.4 workbook as input and outputs a workbook of East6. Click the **Browse** buttons to choose the East 5.4 file to

3 Getting Started

be converted and the file to be saved with **.cywx** extension of East 6 version.

To start the conversion, click **Convert Workbook**. Once complete, the file can be opened as a workbook in East 6 as shown below:

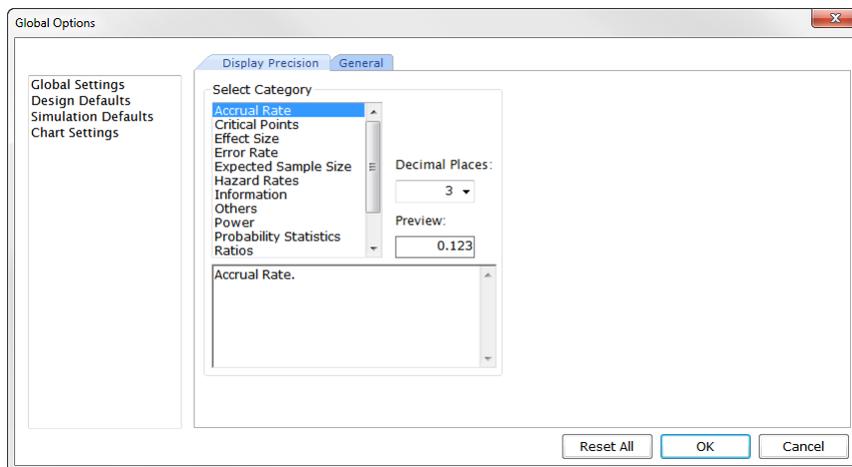

In order to convert files from East 5.3 or older versions, open the file in East 5.4, save it with a new name say with a suffix *.East5.4* and then convert this 5.4 file to 6.x as explained above. To get East 5.4 or any help regarding file conversion, contact Cytel at support@cytel.com.

3.3.3 Settings

Click the **Global Options** icon in the **Home** menu to adjust default values in East 6.

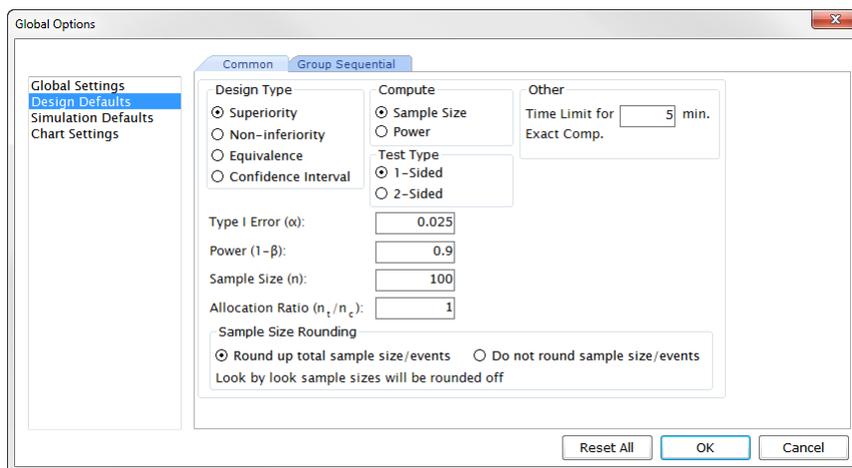

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East6.

3 Getting Started

The **Design Defaults** is where the user can change the settings for trial design:

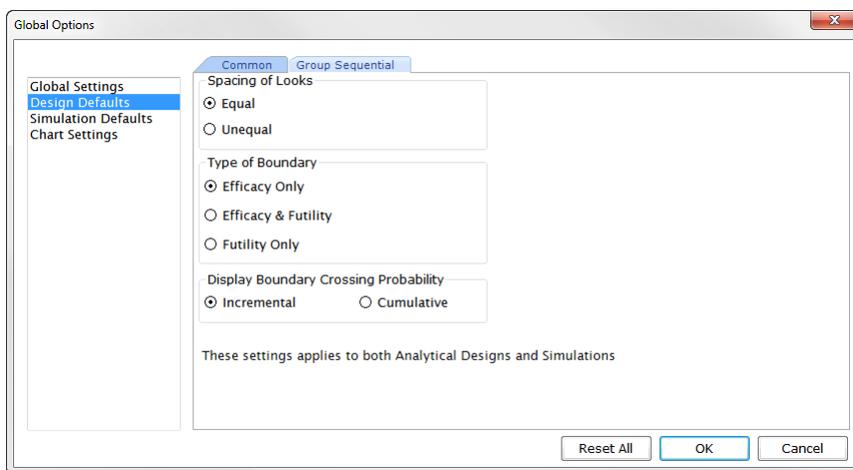

Under the **Common** tab, default values can be set for input design parameters.

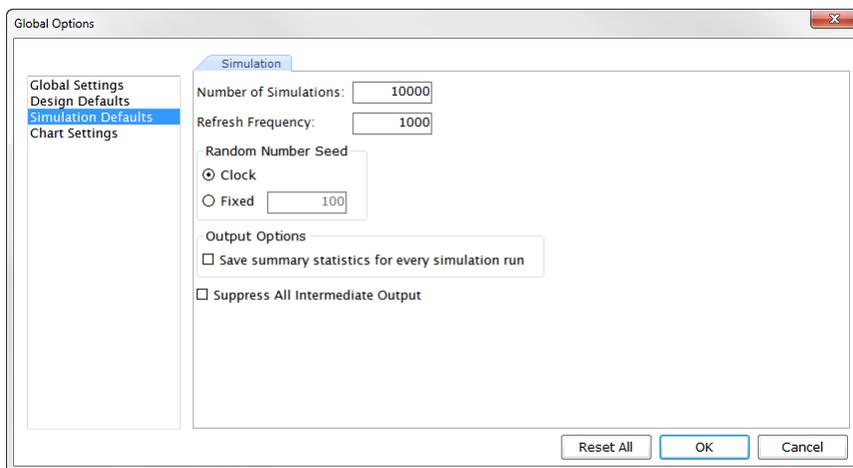

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

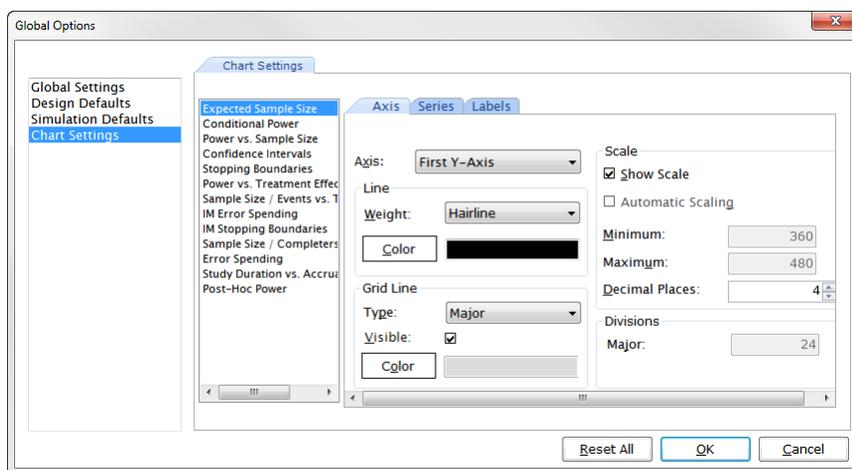

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

3 Getting Started

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

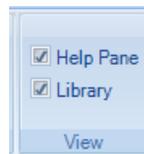

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

We suggest that you do not alter the defaults until you are quite familiar with the software.

3.3.4 View

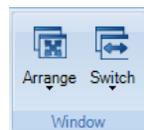

The **View** submenu consists of enabling or disabling the **Help** and **Library** panes by (un)checking the respective check boxes.

3.3.5 Window

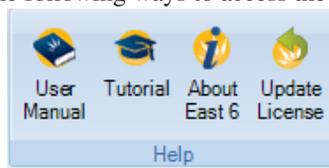

The **Window** submenu contains an **Arrange** and **Switch** option. This provides the

ability to view different standard arrangements of available windows (Design Input Output, Log, Details, charts and plots) and to switch the focus from one window to another.

3.3.6 Help

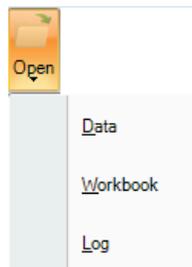

The **Help** group provides the following ways to access the East6 documentation:

- **User Manual:** Invoke the current East 6 user manual.
- **Tutorial:** Invoke the available East 6 tutorials.
- **About East 6:** Displays the current version and license information for the installed software.
- **Update License:** Use this utility to update the license file which you will be receiving from Cytel.

3.4 Data Editor Menu

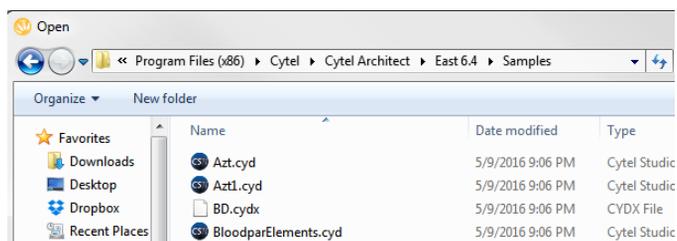

All submenus under the **Data Editor** menu are enabled once a new or existing data set is open. The **Open** command under the **Home** menu shows the list of items that can be opened:

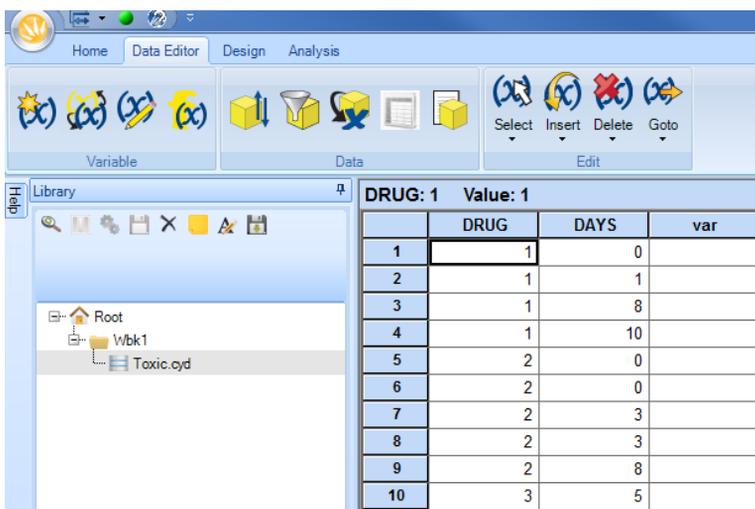

Suppose East 6 is installed in the directory **C:/Program Files (x86)/Cytel/Cytel**

3 Getting Started

Architect/East 6.4 on your machine. You can find sample datasets in the **Samples** under this directory.

Suppose, we open the file named **Toxic** from the **Samples** folder. The data is displayed in the main window under the **Data Editor** menu as shown:

Here the columns represent the variable and the rows are the different records. Placing the cursor on a cell containing data will enable all submenus under the **Data Editor** menu. The submenus are grouped into three sections, **Variable**, **Data** and **Edit**. Here we can modify and transform variables, perform operations on case data, and edit a case or variable in the data.

The icons in the **Variable** group are:

Creates a new variable at the current column position.

-  Renames the current variable.
-  Modifies the currently selected variable.
-  Transforms the currently selected variable.

Numerous algebraic, statistical functions are available which can be used to transform the variable. This feature can also be used to generate a data randomly from distributions such as Normal, Uniform, Chi-Square etc.

The following functions are available in the **Data** group:

-  Sorts case data in ascending or descending order.
-  Filter cases from the case data as per specified criteria.
-  Converts case data to crossover data.
-  Converts crossover data to case data.
-  Displays case data contents to the log window.

For the **Edit** group the following options are available:

-  Selects a case or variable.
-  Inserts a case or variable.
-  Deletes a case or variable.
-  Navigates to a specified case.

3.5 Analysis Menu

3.5.1 Basic Plots

3.5.2 Crossover Plots

The **Analysis** menu allows access to analytical tests which can be performed in East 6.

The tests available in the **Analysis** menus are grouped according to the nature of the response variable. Click an icon to select the test available in a drop down menu.

3 Getting Started

- **Basic Statistics** - This part contains tests to compute basic statistics and frequency distribution from a dataset.
- **Continuous** - This part groups analysis tests for continuous response.
- **Discrete** - This part groups all analysis tests for discrete response.
- **Events** - This group contains tests for time to event outcomes
- **Predict** - This group contains different procedures to predict the future course of the trial given the current subject level data or summary data. Refer to chapter 68 for more details.

3.5.1 Basic Plots

Bar and pie charts for categorical data.

Plots such as area, bubble, scatter plot and normality plots for continuous data.

Plots related to frequency distributions such as histogram, stem and leaf plots, cumulative plots.

3.5.2 Crossover Plots

This menu provides plots applicable to 2x2 crossover data.

Subject plots.

Summary plots.

Diagnostic plots.

All the tests under **Analysis** menu are discussed in detail under **Volume 8** of this manual.

3.6 Design Menu

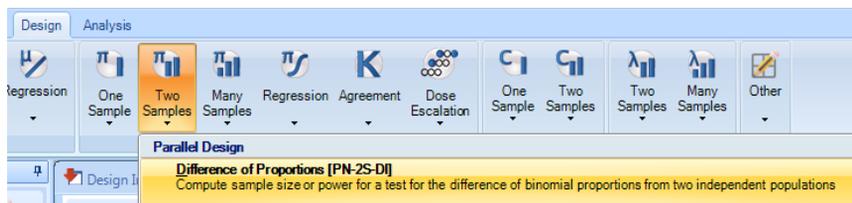

- 3.6.1 Design Input-Output Window
- 3.6.2 Creating Multiple Designs
- 3.6.3 Filter Designs
- 3.6.4 What is a Workbook?
- 3.6.5 Group Sequential Design for the CAPTURE Trial
- 3.6.6 Adding a Futility Boundary
- 3.6.7 Accrual Dropout Information
- 3.6.8 Output Details

This section discusses with the help of the CAPTURE trial the various East features mentioned so far in this chapter. This was a randomized clinical trial of placebo versus Abciximab for patients with refractory unstable angina. Results from this trial were presented at a workshop on clinical trial data monitoring committees *Randomised placebo-controlled trial of abciximab before and during coronary intervention in refractory unstable angina: the CAPTURE study, THE LANCET: Vol 349 - May 17, 1997.*

Let us design, simulate and monitor the CAPTURE trial using East6. The goal of this study is to test the null hypothesis, H_0 , that the Abciximab and placebo arms both have an event rate of 15%, versus the alternative hypothesis, H_1 , that Abciximab reduces the event rate by 5%, from 15% to 10%. It is desired to have a 2-Sided test with three looks at the data, a type-1 error, α as 0.05 and a power, $(1 - \beta)$ as 0.8.

We shall start with a fixed sample design and then extend it to group sequential design. In this process, we demonstrate the useful features of Architect one by one.

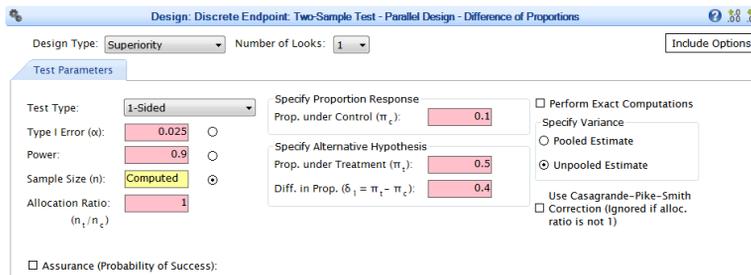

To begin, click **Design** menu, then **Two Samples** on the **Discrete** group, and then click **Difference of Proportions**.

Below the top ribbon, there are three windows: the **Input/Output**, the **Library**, and the **Help**. All these windows are explained in section 3.1 on Workflow of East. Both the **Library** and the **Help** can be hidden temporarily or throughout the session. The

3 Getting Started

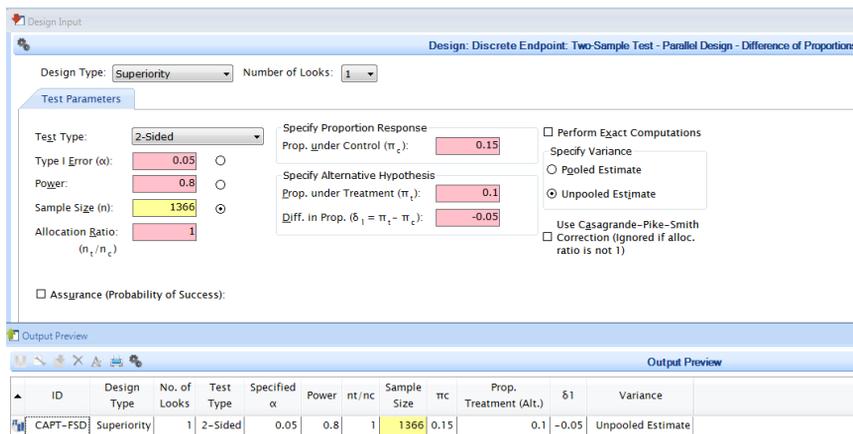

input window for **Difference of Proportions** test appears as shown below:

The design specific help can be accessed by clicking the  icon after invoking a design. This help is available for all the designs in East6.

3.6.1 Design Input-Output Window

This window is used to enter various design specific input parameters in the input fields and drop-down options available. Let us enter the following inputs for the CAPTURE Trial and create a fixed sample design. *Test Type* as 2-Sided, *Type I Error* as 0.05, *Power* as 0.8, π_c as 0.15 and π_t as 0.1. On clicking **Compute** button, a new row for this design gets added in the **Output Preview** window. Select this row and click the  icon. Rename this design as **CAPT-FSD** to indicate that it is a fixed sample design for the CAPTURE trial.

3.6.2 Creating Multiple Designs

Before finalizing on any particular study design, the statisticians might want to assess the operating characteristics of the trial under different conditions and over a range of parameter values. For example, when we are working on time-to-event trials, we want to see the effect of different values of hazard ratio on the overall power and duration of the study.

East makes it easy to rapidly generate and assess multiple options, to perform sensitivity analysis, and select the optimal plan. We can enter multiple values for one or more input parameters and East creates designs for all possible combinations. These designs can then be compared in a tabular as well as graphical manner.

Following are the three ways in which we can enter the multiple values:

- Comma-separated values: (0.8, 0.9, 0.95)
- Colon-separated range of values: (0.8 to 0.9 in steps of 0.05 can be entered as 0.8:0.9:0.05)
- Combined values: (0.7, 0.8, 0.85: 0.95: 0.01)

Multiple values can be entered only in the cells with **pink** background color.

Now suppose, we want to create designs for two values of **Type I Error**, three values of **Power** and four values of π_t : 0.1, 0.2 : 0.3 : 0.05. Without changing other parameters, let us enter these ranges for the three parameters as shown below:

On clicking **Compute** button, East will create $2 \times 3 \times 4 = 24$ designs for the CAPTURE Trial. To view all the designs in the **Output Preview** window, maximize it

3 Getting Started

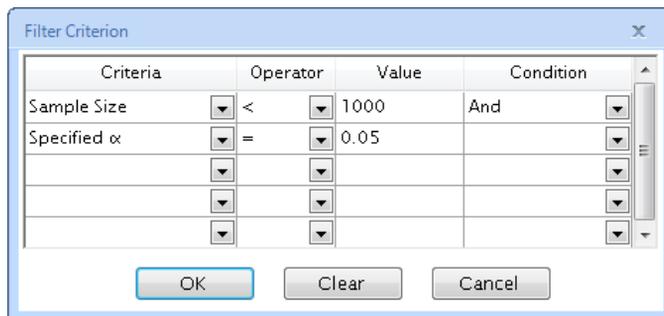

from the right-hand top.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | πc | Prop. Treatment (Alt.) | $\delta 1$ | Variance |
|-------|-------------|--------------|-----------|--------------------|-------|-------|-------------|---------|------------------------|------------|-------------------|
| Des1 | Superiority | 1 | 2-Sided | 0.025 | 0.8 | 1 | 1654 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |
| Des2 | Superiority | 1 | 2-Sided | 0.025 | 0.8 | 1 | 2187 | 0.15 | 0.2 | 0.05 | Unpooled Estimate |
| Des3 | Superiority | 1 | 2-Sided | 0.025 | 0.8 | 1 | 599 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| Des4 | Superiority | 1 | 2-Sided | 0.025 | 0.801 | 1 | 286 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |
| Des5 | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 1366 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |
| Des6 | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 1806 | 0.15 | 0.2 | 0.05 | Unpooled Estimate |
| Des7 | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 495 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| Des8 | Superiority | 1 | 2-Sided | 0.05 | 0.801 | 1 | 236 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |
| Des9 | Superiority | 1 | 2-Sided | 0.025 | 0.85 | 1 | 1870 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |
| Des10 | Superiority | 1 | 2-Sided | 0.025 | 0.85 | 1 | 2472 | 0.15 | 0.2 | 0.05 | Unpooled Estimate |
| Des11 | Superiority | 1 | 2-Sided | 0.025 | 0.85 | 1 | 677 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| Des12 | Superiority | 1 | 2-Sided | 0.025 | 0.851 | 1 | 323 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |
| Des13 | Superiority | 1 | 2-Sided | 0.05 | 0.85 | 1 | 1563 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |
| Des14 | Superiority | 1 | 2-Sided | 0.05 | 0.85 | 1 | 2066 | 0.15 | 0.2 | 0.05 | Unpooled Estimate |
| Des15 | Superiority | 1 | 2-Sided | 0.05 | 0.85 | 1 | 566 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| Des16 | Superiority | 1 | 2-Sided | 0.05 | 0.851 | 1 | 270 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |
| Des17 | Superiority | 1 | 2-Sided | 0.025 | 0.9 | 1 | 2160 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |
| Des18 | Superiority | 1 | 2-Sided | 0.025 | 0.9 | 1 | 2855 | 0.15 | 0.2 | 0.05 | Unpooled Estimate |
| Des19 | Superiority | 1 | 2-Sided | 0.025 | 0.9 | 1 | 782 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| Des20 | Superiority | 1 | 2-Sided | 0.025 | 0.901 | 1 | 373 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |
| Des21 | Superiority | 1 | 2-Sided | 0.05 | 0.9 | 1 | 1829 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |
| Des22 | Superiority | 1 | 2-Sided | 0.05 | 0.9 | 1 | 2417 | 0.15 | 0.2 | 0.05 | Unpooled Estimate |
| Des23 | Superiority | 1 | 2-Sided | 0.05 | 0.9 | 1 | 662 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| Des24 | Superiority | 1 | 2-Sided | 0.05 | 0.901 | 1 | 316 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |

3.6.3 Filter Designs

Suppose we are interested in designs with some specific input/output values, we can set up a criterion by using **Filter** functionality by clicking the  icon available on the top right corner of **Output Preview** window. For example, we want to see designs with *Sample Size* less than 1000 and *Type I Error*

equal to 0.05.

The qualified designs appear in the **Output Preview** window as shown below:

| | ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | nc | Prop. Treatment (Alt.) | δ1 | Variance |
|--|-------|-------------|--------------|-----------|-------------|-------|-------|-------------|------|------------------------|------|-------------------|
| | Des7 | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 495 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| | Des8 | Superiority | 1 | 2-Sided | 0.05 | 0.801 | 1 | 236 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |
| | Des15 | Superiority | 1 | 2-Sided | 0.05 | 0.85 | 1 | 566 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| | Des16 | Superiority | 1 | 2-Sided | 0.05 | 0.851 | 1 | 270 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |
| | Des23 | Superiority | 1 | 2-Sided | 0.05 | 0.9 | 1 | 662 | 0.15 | 0.25 | 0.1 | Unpooled Estimate |
| | Des24 | Superiority | 1 | 2-Sided | 0.05 | 0.901 | 1 | 316 | 0.15 | 0.3 | 0.15 | Unpooled Estimate |

The filter criteria can be edited or cleared by again clicking the Filter icon. On clearing the above criterion, all the 24 designs are displayed back. Before we proceed, let us first delete these recently created 24 designs, leaving behind **CAPT-FSD** and then minimize the **Output Preview** window from the right-hand top.

One or more rows in the can be deleted by selecting them and clicking the icon. Use the **Ctrl** key and mouse click to select specific rows. Use the **Shift** key and mouse click to select all the rows in the range. Use the combination **Ctrl + A** to select all the rows. The resulting **Output Preview** is shown below:

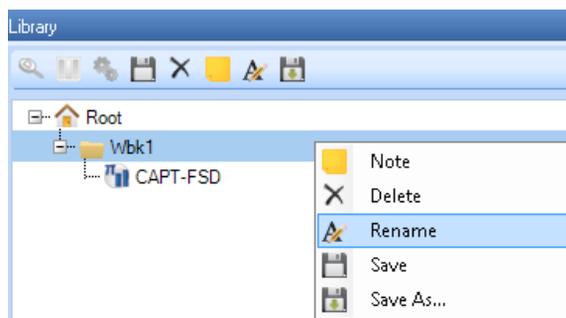

| | ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | nc | Prop. Treatment (Alt.) | δ1 | Variance |
|--|----------|-------------|--------------|-----------|-------------|-------|-------|-------------|------|------------------------|-------|-------------------|
| | CAPT-FSD | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 1366 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |

It is advisable to save this design or any work which you would like to refer in future in an East **Workbook**. The next subsection briefly discusses about use of workbooks.

3 Getting Started

3.6.4 What is a Workbook?

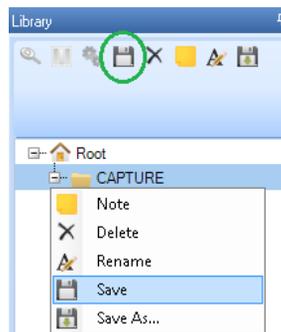

A *Workbook* is a storage construct managed by East for holding different types of generated outputs. The user designs a trial, simulates it, monitors it at several interim looks, conducts certain analyses, draws plots, etc. All of these outputs can be kept together in a workbook which can be saved and retrieved for further development when required. . Note that a single workbook can also contain outputs from more than one design. Select the design **CAPT-FSD** in the **Output Preview** window and click the  icon. When a design is saved to the library for the first time, East automatically creates a workbook named **Wbk1** which can be renamed by right-clicking the node.

Let us name it as **CAPTURE**. Now this is still a temporary storage which means if we exit out of East without saving it permanently, the workbook will not be available in future.

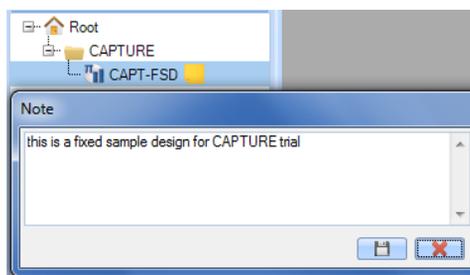

Note that Workbooks are not saved automatically on your computer; they are to be saved by either right-clicking the node in the Library and selecting Save or

clicking the  icon.

In addition, the user will be prompted to save contents of the **Library** while closing East 6.

Many a times, we wish to add some specific comments to a design or any other output window. These comments are useful for future references. One can do that by attaching a *Note* to any node by selecting it and clicking on the  icon. A small window will pop up where comments can be stored.

Once saved, a yellow icon against the design node will indicate the presence of a note. If you want to view or remove the note, right click the design node, select **Note**, and clear the contents.

The tabs available on the status bar at the bottom left of the screen can be used to navigate between the active windows of East.

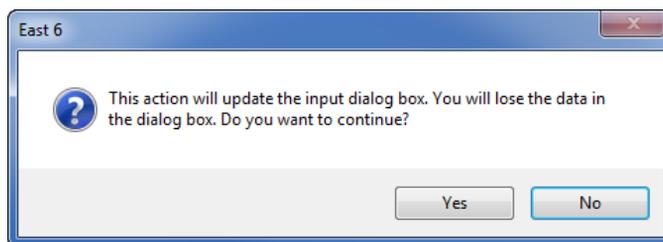

3 Getting Started

For example, if you wish to return to the design inputs, click the **Input** button which will take you the latest Input window you worked with. As we proceed further, more such tabs will appear enabling us to navigate from one screen of East to another.

3.6.5 Group Sequential Design for the CAPTURE Trial

Select the design **CAPT-FSD** and click the  icon in the **Library** to modify the design. On clicking this icon, following message will pop up. Click "Yes" to continue.

Let us extend this fixed sample design to a group sequential design by changing the *Number of Looks* from 1 to 3. It means that we are planning to take 2 interim looks and one final look at the data while monitoring the study.

Number of Looks:

An additional tab named **Boundary** is added which allows us to enter inputs related to

the boundary family, look spacing and error spending functions.

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks: Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.333 | 0.000 | 3.710 | -3.710 |
| 2 | 0.667 | 0.012 | 2.511 | -2.511 |
| 3 | 1.000 | 0.050 | 1.993 | -1.993 |

Let the boundary family be **Spending Functions** and the alpha spending function, **Lan-DeMets** with the parameter **OF**. Click on **Compute** to create the three-look design and rename it as **CAPT-GSD**.

As you go on creating multiple designs in East, the output preview area can become too busy to manage. Thus, you can also select the designs you are interested in, save them in the workbook and then rename them appropriately. The **Output Preview** window now looks as shown below:

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | mc | Prop. Treatment (Alt.) | δ_1 | Variance | Spacing of Looks | Efficacy Boundary | Expected SS (H0) | Expected SS (H1) |
|----------|-------------|--------------|-----------|--------------------|-------|-------|-------------|------|------------------------|------------|-------------------|------------------|-------------------|------------------|------------------|
| CAPT-FSD | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 1366 | 0.15 | 0.1 | -0.05 | Unpooled Estimate | | | | |
| CAPT-GSD | Superiority | 3 | 2-Sided | 0.05 | 0.8 | 1 | 1384 | 0.15 | 0.1 | -0.05 | Unpooled Estimate | Equal | LD (OF) | 1378.32 | 1182.678 |

Notice that **CAPT-GSD** requires 18 subjects more than **CAPT-FSD** to achieve 80% power. This view gives us the horizontal comparison of two designs. Save the design **CAPT-GSD** in the workbook.

One can also compare these designs in a vertical manner. Select the two designs by clicking on one of them, pressing **Ctrl** and then clicking on the other one. Next, click

3 Getting Started

the  icon.

| | CAPT-FSD | CAPT-GSD |
|--|-------------------|-------------------|
| Mnemonic | PN-2S-DI | PN-2S-DI |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 1 | 3 |
| Test Type | 2-Sided | 2-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.8 | 0.8 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Proportion under Control (π_c) | 0.15 | 0.15 |
| Proportion under Treatment (π_t) | 0.1 | 0.1 |
| Diff. in Prop. ($\pi_t - \pi_c$) | -0.05 | -0.05 |
| Variance | Unpooled Estimate | Unpooled Estimate |
| Boundary Parameters | | |
| Spacing of Looks | | Equal |
| Efficacy Boundary | | LD (OF) |
| Sample Size | | |
| Maximum | 1366 | 1384 |
| Expected Under H0 | | 1378.32 |
| Expected Under H1 | | 1182.678 |

This is the **Output Summary** window of East which compares the two designs vertically. We can easily copy this display from East to MS Excel and modify/save it further in any other format. To do that, right click anywhere in the **Output Summary** window, select **Copy All** option and paste the copied data in an Excel workbook. The table gets pasted as two formatted columns.

Let us go back to the input window of **CAPT-GSD** (select the design and click the  icon) and activate the **Boundary** tab. By default, the boundary values in the table at the bottom of this tab are displayed on **Z Scale**. We can also view these boundaries on other scales such as: *Score Scale*, *δ Scale* and *p-value Scale*.

Spacing of Looks: Equal Unequal Efficacy Boundary: Z Scale  

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.333 | 0.000 | 3.710 | -3.710 |
| 2 | 0.667 | 0.012 | 2.511 | -2.511 |
| 3 | 1.000 | 0.050 | 1.993 | -1.993 |

Let us view the efficacy boundaries for **CAPT-GSD** on a p-value scale.

Spacing of Looks: Equal Unequal Efficacy Boundary: p-value Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|-------|
| | | | Upper | Lower |
| 1 | 0.333 | 0.000 | 0.000 | 0.000 |
| 2 | 0.667 | 0.012 | 0.006 | 0.006 |
| 3 | 1.000 | 0.050 | 0.023 | 0.023 |

The final p-value required to attain statistical significance at level 0.05 is 0.0463. This is sometimes regarded as the penalty for taking two interim looks at the data.

Also observe that, although the maximum sample size for this design is 1384, the expected sample size under alternative that $\delta = -0.05$ is much less, 1183. However, there is very little saving under the null hypothesis that $\delta = 0$. The sample size in this case is 1378.

Therefore, it might be beneficial to consider replacing the lower efficacy boundary by a futility boundary. Also, sometimes we might wish to stop a trial early because the effect size observed at an interim analysis is too small to warrant continuation. This can be achieved by using β -spending function and introducing a futility boundary at the design stage.

3.6.6 Adding a Futility Boundary

Select the design **CAPT-GSD** and click  icon to edit it. Change the *Test Type* from **2-Sided** to **1-Sided** and also the *Type I Error* from 0.05 to 0.025. Go to **Boundary** tab and add the futility boundaries by using γ (-2) spending function.

Test Parameters **Boundary**

3 Getting Started

Before we create this design, we can see the error spending chart and the boundaries chart for the CAPTURE trial with efficacy as well as futility boundaries. This gives us a way to explore different boundary families and error spending functions and deciding upon the desired combination before even creating a design. Click the  icon to view the Error Spending Chart.

Click the  icon to view the Boundaries Chart.

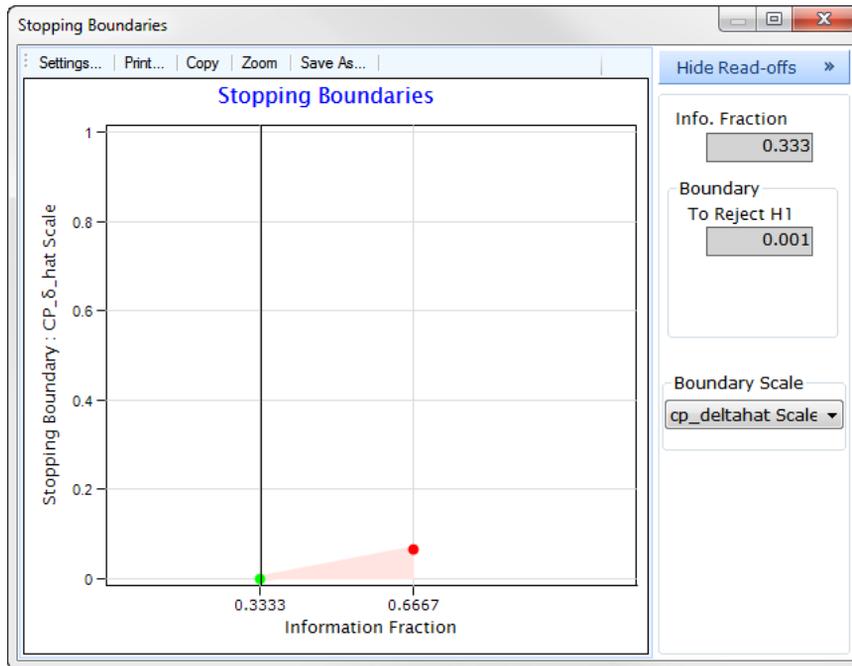

The shaded region in light pink corresponds to the critical region for futility and the one in light blue corresponds to the critical region for efficacy.

We can also view the boundaries on conditional power scale in presence of a futility boundary. Select the entry named *cp_deltahat Scale* from the dropdown **Boundary**

3 Getting Started

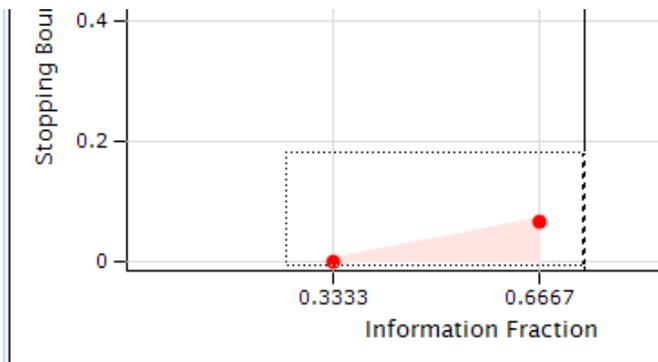

Scale. The chart is be updated and the boundaries are displayed on CP scale.

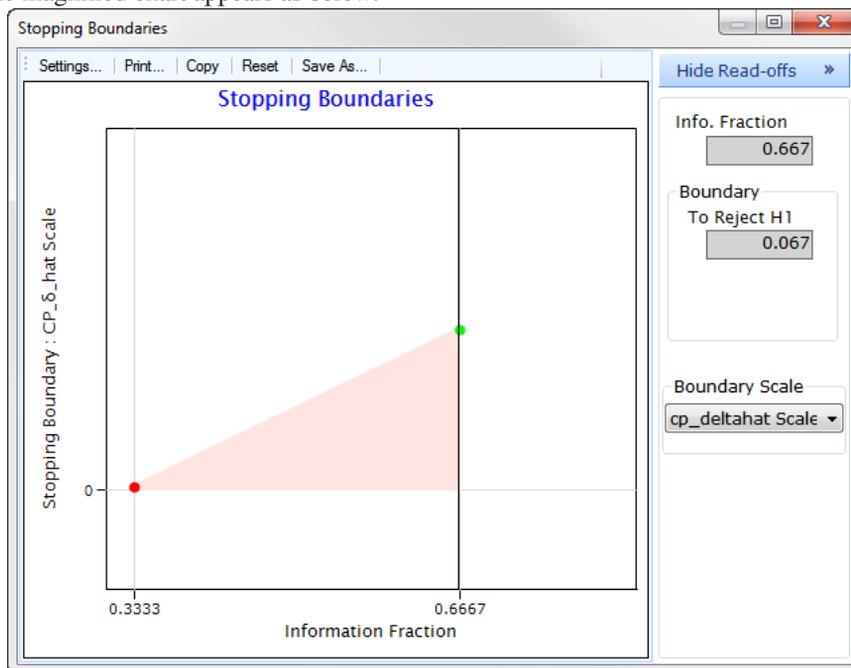

Zooming the Charts

To zoom into any area of the chart, click and drag the mouse over that area. After clicking Zoom button, click on the plot at the top left corner of the area you want to magnify, keep the mouse button pressed and drag the mouse over the desired area. This draws a rectangle around that area. Now leave the mouse button and East magnifies the

selected area. You can keep doing this to zoom in further.

The magnified chart appears as below:

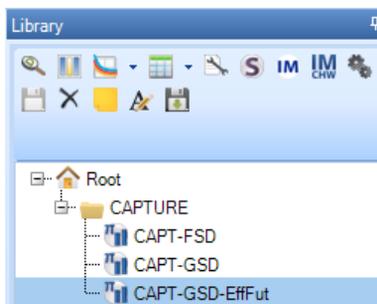

Note that after zooming, the Zoom button changes to Reset. When you click it, the plot

3 Getting Started

is reset back to the original shape.

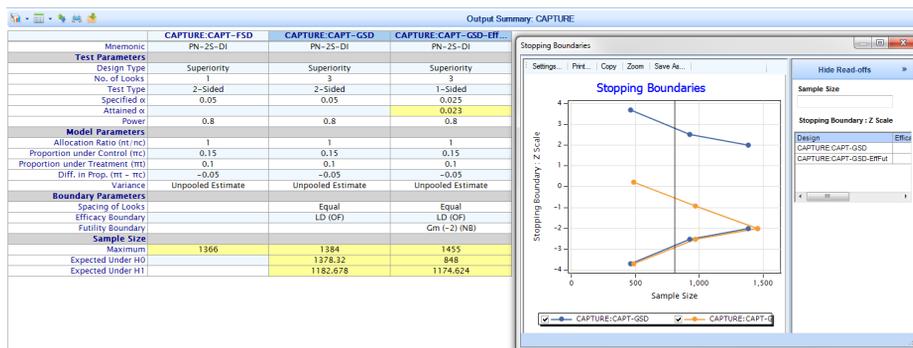

Let us compute the third design for the CAPTURE trial and rename it as **CAPT-GSD-EffFut**. Save it in the workbook.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | tTC | Prop. Treatment (Alt.) | δ | Variance | Spacing of Looks | Efficacy Boundary | Futility Boundary | Expected SS (H0) | Expected SS (H1) | Attained α |
|-----------------|-------------|--------------|-----------|--------------------|-------|-------|-------------|------|------------------------|----------|-------------------|------------------|-------------------|-------------------|------------------|------------------|-------------------|
| CAPT-FSD | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 1366 | 0.15 | 0.1 | -0.05 | Unpooled Estimate | Equal | LD (OF) | | | | |
| CAPT-GSD | Superiority | 3 | 2-Sided | 0.05 | 0.8 | 1 | 1384 | 0.15 | 0.1 | -0.05 | Unpooled Estimate | Equal | LD (OF) | 1378.32 | 1182.678 | | |
| CAPT-GSD-EffFut | Superiority | 3 | 1-Sided | 0.025 | 0.8 | 1 | 1455 | 0.15 | 0.1 | -0.05 | Unpooled Estimate | Equal | LD (OF) | Gm (-2) (NB) | 848 | 1174.624 | 0.023 |

Click the icon to compare all the three designs side-by-side as explained above.

Along with the side-by-side comparison, let us compare the two group sequential designs graphically. Press **Ctrl** and click on **CAPT-FSD**. Notice that the remaining two designs are still highlighted which means they are selected and **CAPT-FSD** is unselected. Now click the icon and select **Stopping Boundaries** to view the graphical comparison of boundaries of the two designs.

As we can see, the design **CAPT-GSD** uses an upper efficacy boundary whereas **CAPT-GSD-EffFut** uses an upper futility boundary. We can turn ON and OFF the boundaries by checking the boxes available in the legends.

Before we proceed, let us save this third design in the workbook. We can also create several workbooks in the **Library** and then compare multiple designs across the workbooks. This is an advantage of working with workbooks in East6.

3.6.7 Accrual / Dropout option for Continuous and Discrete Endpoints

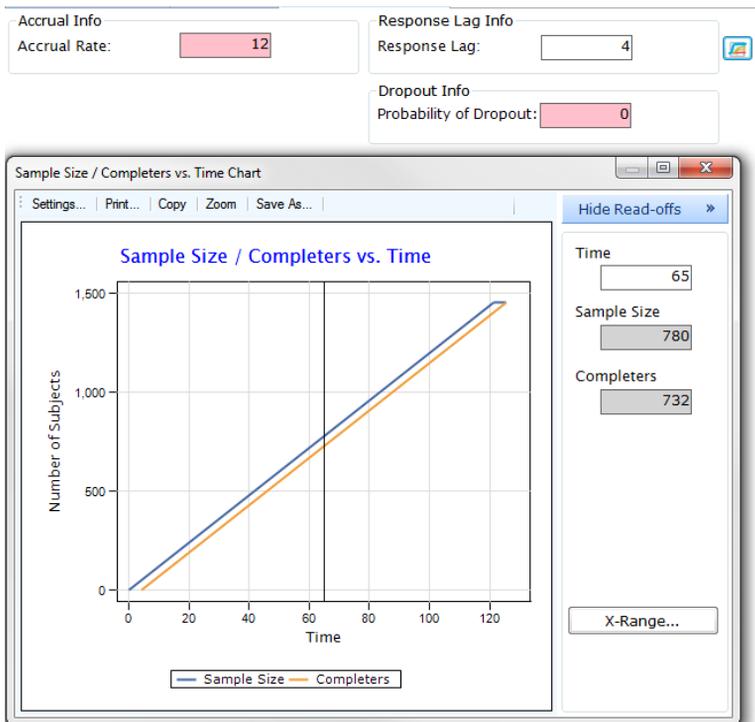

In the earlier versions of East, the option to incorporate the accrual and dropout information was available only for tests under time-to-event/survival endpoint. East 6 now provides this option for almost all the tests under Continuous and Discrete endpoints as well. Let us see the use it in CAPTURE trial. Select the design **CAPT-GSD-EffFut** from the **Library** and edit it to add the accrual-dropout information. From the **Design Parameters** tab, add the option **Accrual/Dropout Info** by clicking on **Include Options** button.

The screenshot shows the 'Accrual / Dropouts' configuration panel. It is divided into three sections: 'Accrual Info', 'Response Lag Info', and 'Dropout Info'.
- 'Accrual Info': 'Accrual Rate' is set to 8.
- 'Response Lag Info': 'Response Lag' is set to 0.
- 'Dropout Info': 'Probability of Dropout' is set to 0.

Let the accrual rate be 12 subjects/week. Suppose we expect the response to be observed after 4 weeks from the recruitment. Let us create a design by first assuming that there will not be any dropouts during the course of trial. We will then introduce some dropouts and compare the two designs. After entering the above inputs, click on

3 Getting Started

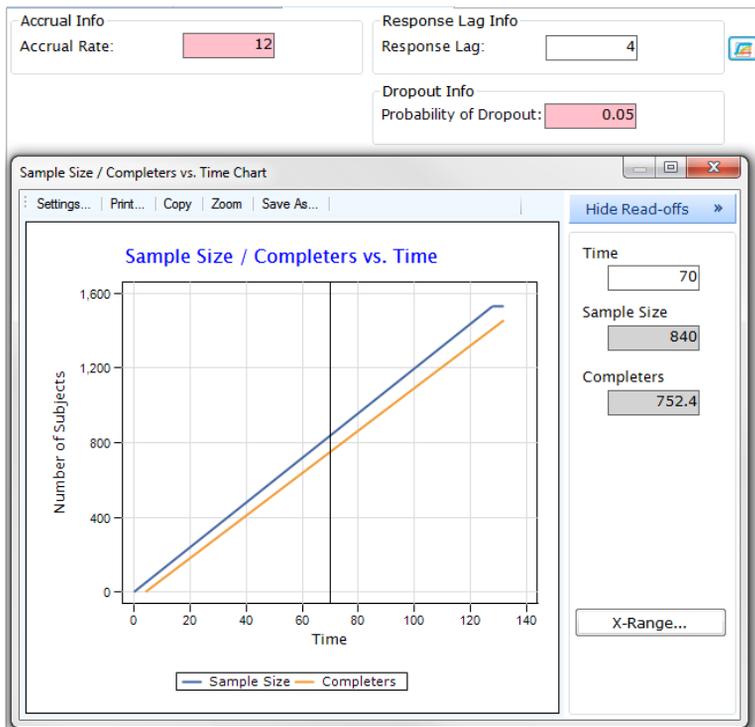

the  icon to see how the subjects will accrue and complete the study.

Close the chart, create the design by clicking the **Compute** button, save it in the workbook **CAPTURE** and rename it as **CAPT-GSD-NoDrp** to indicate that there are no dropouts in this design. Notice that in this design, the maximum sample size and maximum number of completers is same as there is no dropout.

Let us now introduce dropouts. Suppose there is a 5% chance of a subject dropping out

of the trial.

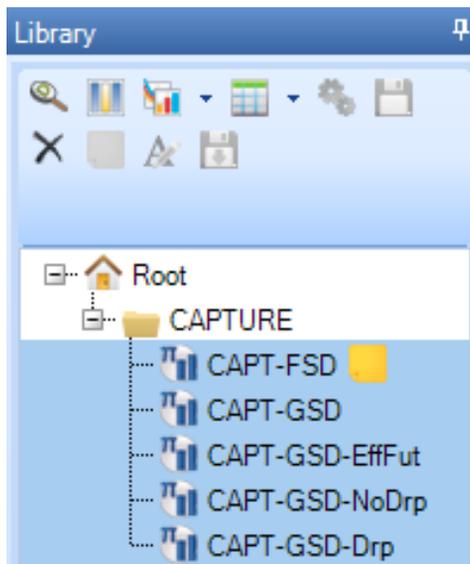

Notice that the two lines are not parallel anymore because of the presence of dropouts. Click **Compute** button to create this design. Save the design in the workbook **CAPTURE** and rename it as **CAPT-GSD-Drp**. Compare this design with **CAPT-GSD-NoDrp** by selecting the two designs and clicking on  icon

Notice the inflation in sample size for **CAPT-GSD-Drp**. This design will require additional 80 subjects to obtain data on 1455 subjects (1455 completers). Let us now compare all the five designs saved in the workbook. Select them all

3 Getting Started

together and click the  icon.

The resulting screen will look as shown below:

| | CAPTURE-CAPT-FSD | CAPTURE-CAPT-GSD | CAPTURE-CAPT-GSD-Eff... | CAPTURE-CAPT-GSD-No... | CAPTURE-CAPT-GSD-Drp |
|---|-------------------|-------------------|-------------------------|------------------------|----------------------|
| Mnemonic | PN-25-DI | PN-25-DI | PN-25-DI | PN-25-DI | PN-25-DI |

| Proportion under Treatment (trt) | 0.1 | 0.1 | 0.1 | 0.1 | 0.1 |
| Diff. in Prop. (trt - trc) | -0.05 | -0.05 | -0.05 | -0.05 | -0.05 |
| Variance | Unpooled Estimate | Unpooled Estimate | Unpooled Estimate | Unpooled Estimate | Unpooled Estimate |
| Boundary Parameters | | | | | |
| Spacing of Looks | Equal | Equal | Equal | Equal | Equal |
| Efficacy Boundary | | LD (OF) | LD (OF) | LD (OF) | LD (OF) |
| Futility Boundary | | | Gm (-2) (NB) | Gm (-2) (NB) | Gm (-2) (NB) |
| Accrual & Dropout Parameters | | | | | |
| Accrual Rate | | | | 12 | 12 |
| Response Lag | | | | 4 | 4 |
| Probability of Dropout | | | | 0 | 0.05 |
| Sample Size | | | | | |
| Maximum | 1366 | 1384 | 1455 | 1455 | 1532 |
| Expected Under H0 | | 1378.32 | 848 | 888.177 | 933.474 |
| Expected Under H1 | | 1182.678 | 1174.624 | 1199.958 | 1262.455 |
| Completers | | | | 1455 | 1455 |
| Maximum | | | | 848 | 848 |
| Expected Under H0 | | | | 1174.624 | 1174.624 |
| Expected Under H1 | | | | | |
| Study Duration | | | | | |
| Maximum | | | | 125.25 | 131.667 |

We can see additional quantities in the design **CAPT-GSD-Drp**. These correspond to

the information on total number of completers and the study duration which are computed by taking into account the non-zero response lag and possibility of dropouts. Also notice the trend in **Maximum Sample Size** across all these designs. We can see that it increases as more constraints are added to the study. But if we see values of **Expected Sample Size** under null and alternative, there is a significant potential saving.

You can also save this output summary window comparing three designs in the library by clicking the  icon

3.6.8 Output Details

In the earlier part of this chapter, we have seen the design output at two different places: **Output Preview** (horizontal view) and **Output Summary** (vertical view). The final step in the East6 design workflow is to see the detailed output in the form of an **HTML** file.

Select the design **CAPT-GSD-Drp** from the **Library** and click the  icon. Alternatively, one can also double-click on any of the nodes in the **Library** to see the

3 Getting Started

details.

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Stopping Boundaries: Look by Look

| Look # | Info. Fraction (s/s_max) | Sample Size (n) | Cumulative α Spent | Cumulative β Spent | Boundaries | |
|--------|--------------------------|-----------------|---------------------------|--------------------------|------------|------------|
| | | | | | Efficacy Z | Futility Z |
| 1 | 0.333 | 559 | 1.035E-4 | 0.03 | -3.71 | 0.216 |
| 2 | 0.667 | 1070 | 0.006 | 0.087 | -2.511 | -0.923 |
| 3 | 1 | 1532 | 0.026 | 0.2 | -1.993 | -1.993 |

The output details are broadly divided into two panels. The left panel consists of all the input parameters and the right panel consists of all the design output quantities in the tabular format. These tables will be explained in detail in subsequent chapters of this manual.

Click the Save icon to save all the work done so far. This is the end of introduction to the **Design Menu**. The next section discusses another very useful feature called **Simulations**.

3.7 Simulations in East6

A simulation is a very useful way to perform sensitivity analysis of the design assumptions. For instance - What happens to the power of the study when the δ value is not the same as specified at the design stage?

We will now simulate design **CAPT-GSD-Drp**. Select this design from the library and click the **S** icon. Alternatively, you can right-click this design in the **Library**, and select **Simulate**.

The default view of input window for simulations is as shown below:

The screenshot shows the 'Response Generation' tab of the simulation input window. It includes the following fields and a table:

- Trial Type: Superiority
- Test Type: 1-Sided
- Sample Size (n): 1532
- Specify Variance:
 - Pooled Estimate
 - Unpooled Estimate

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z | Futility Z |
|--------|----------------|---------------------|------------|------------|
| 1 | 0.333 | 0.000 | -3.710 | 0.216 |
| 2 | 0.667 | 0.006 | -2.511 | -0.923 |
| 3 | 1.000 | 0.025 | -1.993 | -1.993 |

Notice that the value of δ on the **Response Generation** tab is -0.05. This corresponds to the difference in proportions under the alternative hypothesis. You may either keep this default value for the simulation or change it if you wish to simulate the study with a different value of δ . Let us run some simulations by changing the value of δ . We will run simulations over a range of values for π_t , say, 0.1, 0.125 and 0.14. Enter the values as shown below:

The 'Specify Proportion' section shows the following values:

- Prop. under Control (π_c): 0.15
- Prop. under Treatment (π_t): .1, .125, 0.14

Before running simulations, let us have a quick look at the **Simulation Control** tab where we can change the number of simulations, save the simulation data in East format or in a csv format and some more useful things. You can manipulate the simulations with the following actions:

- Enter the number of simulations you wish to run in the "Number of Simulations" field. The default is 10000 simulations.
- Increase/ Decrease the "Refresh Frequency" field to speed up or slow down the simulations. The default is to refresh the screen after every 1000 simulations.
- Set the Random Number Seed to **Clock** or **Fixed**. The default is **Clock**.
- Select the checkbox of "Suppress All Intermediate Output" to suppress the intermediate output.

3 Getting Started

To see the intermediate results after a specific number of simulations, select the checkbox of "Pause after Refresh" and enter the refresh frequency accordingly. The checkbox of "Stop At End" is selected by default to display the summary results at the end of all the simulations a corresponding item gets created in the **Output Preview** window. One can uncheck this box and save the simulation node directly in the **Output Preview** window.

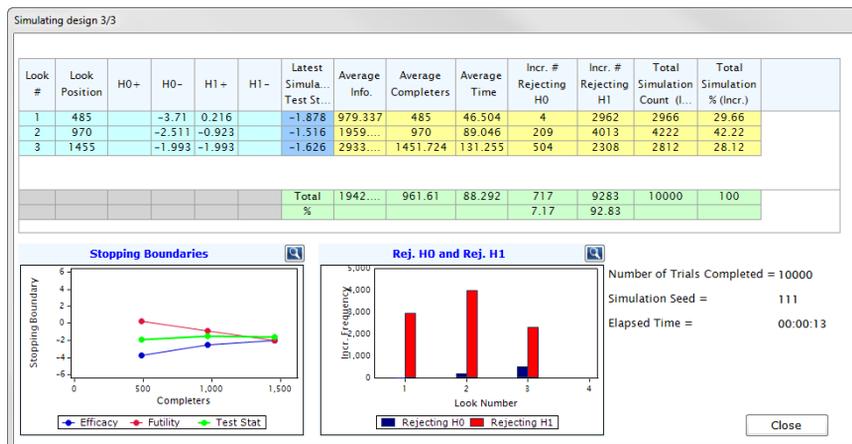

One can also save the summary statistics for each simulation run and the subject level simulated data in the form of a Case Data or a Comma Separated File. Select the checkboxes accordingly and provide the file names and paths while using the CSV option. If you are saving the data as Case Data, the corresponding data file will be associated with the simulation node. It can be accessed by saving the simulation node from **Output Preview** to the workbook in **Library**.

For now, let us keep the **Simulation Control** tab as shown below:

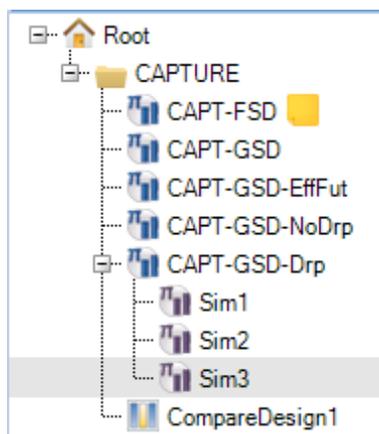

The screenshot shows the 'Simulation Controls' tab of a software interface. It contains several input fields and checkboxes. On the left side, there are fields for 'Number of Simulations' (set to 10000) and 'Refresh Frequency' (set to 1000). Below these is a 'Random Number Seed' section with radio buttons for 'Clock' and 'Fixed' (selected), with a text input field containing '111'. Further down are checkboxes for 'Suppress All Intermediate Output', 'Pause after Refresh', and 'Stop at End' (which is checked). On the right side, there is an 'Output Options' section with a dropdown menu for 'Output Type' set to 'Case Data'. Below this are two checkboxes: 'Save summary statistics for every simulation run' (unchecked) and 'Save subject level data for' (unchecked) with a text input field containing '1'. A note below states 'Note: Max. 100,000 records will be saved.'

Click the **Simulate** button on right hand side bottom to run the simulations. Three scenarios corresponding to three values of π_t are simulated one after the other and in the end, the following output window appears. This is the **Simulation Intermediate Output window** which shows the results from **last simulated scenario**. The two plots

on this window are useful to see how the study performed over 10000 simulations.

Click the **Close** button on this intermediate window which takes us to the **Output Preview** window. Save these three simulation rows in the workbook **CAPTURE**. Since we simulated the design **CAPT-GSD-Drp**, the three simulation nodes get saved as child nodes of this design. This is the hierarchy which is followed throughout the East6 software.

A full picture of the CAPTURE trial design with accrual/dropout information and its simulations can be viewed easily. Select the three simulation nodes and the parent

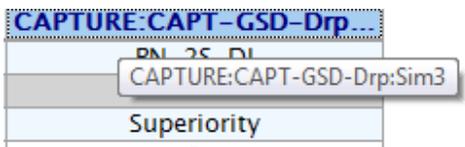

3 Getting Started

design node in the **Library** and click the  icon.

| Average Completers | | 1173.081 | 1128.516 | 961.61 |

Note the drop in simulated power as the difference between the two arms decreased. This is because, the sample size of 1532 was insufficient to detect the δ value -0.025 and -0.01. It shows the effect of mis-specifying the alternative hypothesis. It did achieve the power of 80% for the first case with δ equal to -0.05 which was actually the δ at the design stage. This is called simulating the design under *Alternative*. We can also simulate a design under *Null* by entering π_t equal to 0.15, same as π_c and verify that the type I error is preserved.

The column width in the comparison mode is fixed and the heading appears in the format *workbook_name.design_name.Sim*. If this string is longer than the fixed width then you may not be able to see the complete heading. In that case, you can hover the mouse on cell of column heading to see the complete heading.

Thus, simulations in East6 are one of the very powerful tools which help us to verify the operating characteristics of the design.

The next section introduces us to another key feature of East6 - **Interim Monitoring**. Let us see monitor the CAPTURE Trial using this feature.

3.8 Interim Monitoring

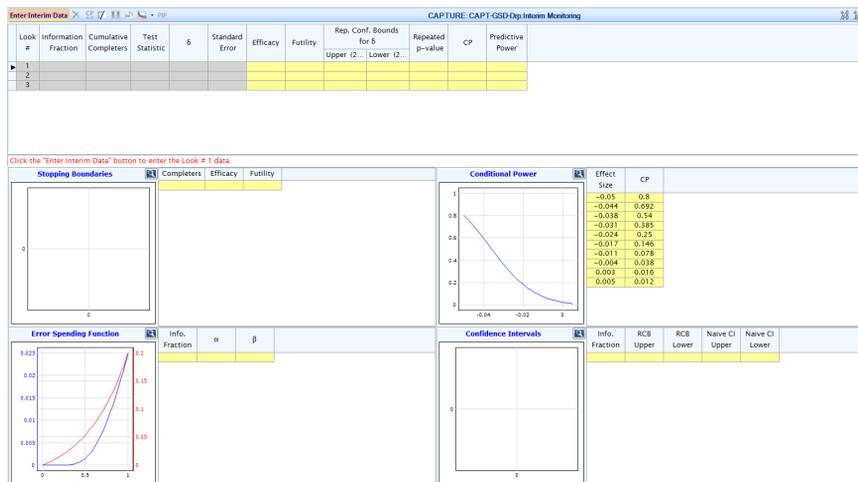

Interim monitoring is critical for the management of group sequential trials, and there are many reasons why flexibility in both design and monitoring is necessary. Administrative schedules may call for the recalculation of statistical information and unplanned analyses at arbitrary time points, while the need for simultaneously preserving both the type-1 error and power of the study must be maintained. East provides the capability to flexibly monitor a group sequential trial using the **Interim Monitoring**.

The **IM dashboard** provides a coherent visual display of many output values based on interim information. In addition to important statistical information, included are tables and graphs for stopping boundaries, conditional power, error spending and confidence intervals for each interim look. All of this information is useful in tracking the progress of a trial for decision making purposes, as well as allowing for improvements to a study design adaptively.

Consider the monitoring of **CAPT-GSD-Drp** of the CAPTURE trial. Select this design from the **Library** and click the  icon. The adaptive version of IM dashboard can be invoked by clicking the  icon. But for this example, we will use regular IM dashboard. A node named Interim Monitoring gets associated with the design in the **Library** and a

3 Getting Started

blank IM dashboard is opened up as shown below:

Suppose we have to take the first look at the data based on 485 completers.

The interim data on these subjects is to be entered in **Test Statistic Calculator** which can be opened by clicking **Enter Interim Data** button. Open this calculator and click OK with default parameters.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Read from Analysis Node

Select Workbook:

Select Analysis Node:

Input for Binomial end point

Completers and Responses

| | Control | Treatment |
|------------------------|---------|-----------|
| Cumulative Completers: | 242 | 243 |
| Cumulative Response: | 36 | 24 |

Completers (Overall): 485

Input for Binomial end point

Estimate of δ : -0.05

$\delta = (\pi_t - \pi_c)$

Standard Error of Estimate of δ : 0.03

Output

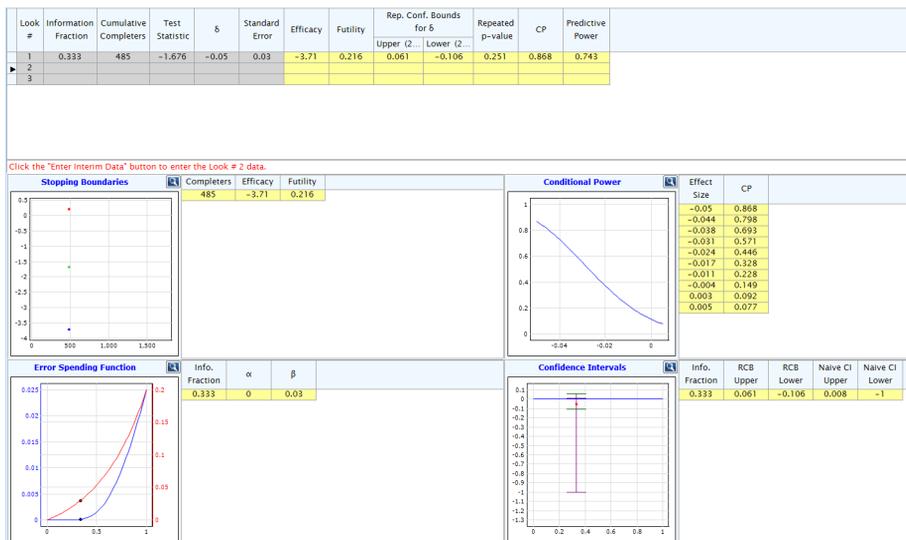

Test Statistic: -1.676

Recalc OK Cancel

If we have run any analysis procedure on the interim data then the test statistic calculator can read in the information from Analysis node. Select the appropriate workbook and the node and hit Recalc to see the interim inputs. Alternatively, for binomial endpoint trials, we can enter the interim data in terms of the number of responses on each arm and East computes the difference in proportion and its standard error. Alternatively, we can directly enter the and its standard error which can be the output of some external computation. The inputs on the test statistic calculator depend upon the type of trial you are monitoring.

3 Getting Started

The resulting screen is as shown below:

The output quantities for the first look are computed in that row and all the four charts are updated based on the look1 data.

There some more advanced features like Conditional Power calculator, Predicted Intervals Plot, Conditional Simulations available from the IM dashboard. These are explained in later sections of this manual.

Let us take the second look at 970 subjects. Open the test statistic calculator and leaving all other parameters default, change the number of responses on Treatment arm

to 30. Click the OK button. The screen will look as shown below:

| Look # | Information Fraction | Cumulative Completers | Test Statistic | δ | Standard Error | Efficacy | Futility | Rep. Conf. Bounds for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|-----------------------|----------------|----------|----------------|----------|----------|--------------------------------|--------------|------------------|-------|------------------|
| | | | | | | | | Upper (2...) | Lower (2...) | | | |
| 1 | 0.333 | 485 | -1.676 | -0.05 | 0.03 | -3.71 | 0.216 | 0.061 | -0.106 | 0.251 | 0.868 | 0.743 |
| 2 | 0.667 | 970 | -4.441 | -0.087 | 0.02 | -2.511 | -0.923 | -0.038 | -0.119 | 0 | 1 | 1 |

Boundary Crossed

Since the value of Test Statistic is \leq the critical point for efficacy, H_0 is rejected.

Although boundary has been crossed, East gives you choice either to stop the study or to continue entering further looks. Please make your decision.

stop the study and bar further looks input

allow the study to continue

Click the "Edit Interim Data" button to edit

Stopping Boundaries

| Final Inference | |
|--|--------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0 |
| Adj. Pt. Est. for δ | -0.085 |
| Adj. 95% CI for δ | |
| Upper Confidence Bound | -0.043 |
| Lower Confidence Bound | -0.124 |
| Post-Hoc Power | |

East tells us that the null hypothesis is rejected at second look, provides an option to stop the trial and conclude efficacy of the drug over the control arm. It computes the final inference in the end. At this stage, it also provides another option to continue entering data for future looks. But the final inference is computed only once.

In the last part of this chapter, we shall see how to capture a snapshot of any ongoing interim monitoring of a trial.

The **IM dashboard** can also be used as a tool at design time, where we can construct and analyze multiple possible trial scenarios before actual data is collected. The feature to save a snapshot of information at interim looks can be employed to allow a user the benefit of quickly comparing multiple scenarios under a variety of assumptions. This option increases the flexibility of both, design and interim monitoring process. At each interim look, a snapshot of the updated information in the dashboard can be saved for the current design in the workbook.

Click the  icon located at the top of **IM Dashboard** window to save the current contents of the dashboard:

A new snapshot node is added under the **Interim Monitoring** node in the library. The **Interim Monitoring** window is the input window which can't be printed whereas it

3 Getting Started

snapshot is in the HTML format which can be printed and shared.

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Snapshot of Look 2 of Interim Monitoring:

| Look # | Information Fraction | Cumulative Completers | Test Statistic | δ | Standard Error | Efficacy | Futility | Rep. Conf. Bounds for δ | | Repeated p-value | INLP | CP | Predictive Power |
|--------|----------------------|-----------------------|----------------|----------|----------------|----------|----------|--------------------------------|--------------|------------------|------|-------|------------------|
| | | | | | | | | Upper (20%) | Lower (2.5%) | | | | |
| 1 | 0.333 | 485 | -1.676 | -0.05 | 0.03 | -3.71 | 0.216 | 0.061 | -0.106 | 0.251 | 1397 | 0.968 | 0.743 |
| 2 | 0.667 | 970 | -4.441 | -0.087 | 0.02 | -2.511 | -0.923 | -0.038 | -0.119 | 1.799E-4 | NA | NA | NA |

Final Inference

| | |
|----------------------------|----------|
| Final Outputs at Look # | 2 |
| Adj. p-Value | 1.067E-4 |
| Adj. Pt. Est. for δ | -0.085 |
| Adj. 95% CI for δ | |
| Upper Confidence Bound | -0.043 |
| Lower Confidence Bound | -0.124 |
| Post-Hoc Power | NA |

To illustrate the benefit of the snapshot feature, it is often the case that actual trial data is not available at design time. Determining a reasonable estimate of nuisance parameters, such as the variance, rather than making strong assumptions of its certainty may be desired. The ability to quickly compare potential results under a variety of different estimates of the variance by easily looking at multiple interim snapshots of a study can be a powerful tool.

Other examples could include sample size re-estimation where initial design assumptions may be incorrect or using hypothetical interim data to compare relevant treatment differences.

With this, we come to an end of the chapter on getting started with East6. The subsequent chapters in this manual discuss in detail with the help of case studies all the features available in the software. The theory part of all the design and analysis procedures is explained in Appendix A of this manual.

4 Data Editor

Data Editor allows you to manipulate the contents of your data. **East** caters to Case Data and Crossover Data. Depending on the type of data, a corresponding set of menu items becomes available in the **Data Editor** menu.

4.1 Case Data

4.1.1 Data Editor

Capabilities for Case Data

4.1.2 Creating Variables

4.1.3 Variable Type Setting

4.1.4 Editing Data

4.1.5 Filter Cases

The **Data editor** window for case data is a spreadsheet-like facility for creating or editing case data files. A case data file is organized as a sequence of **records** called **cases** one below the other. Each record is subdivided into a fixed number of **fields**, called **variables**. The name assigned to that field is referred to as the **variable name**. Each such name identifies a specific variable across all the cases. Each cell holds a value of a variable for a case. The top line of the Data editor holds the **variable names**. Case data is the most common format to enter and store data. If you plan to share data with any other package you need to use case data editor.

4.1.1 Data Editor Capabilities for Case Data

The Data Editor is used to create a new Case Data file or to edit one that was previously saved. You can:

- Create new variables
- Change names and attributes of existing variables
- Alter the column width
- Alter the row height
- Type in new case data records
- Edit existing case data records
- Insert new variables into the data set
- Remove variables from the data set
- Select or reject subsets of the data
- Transform variables
- List data in the log window
- Calculate summary measures from the variables

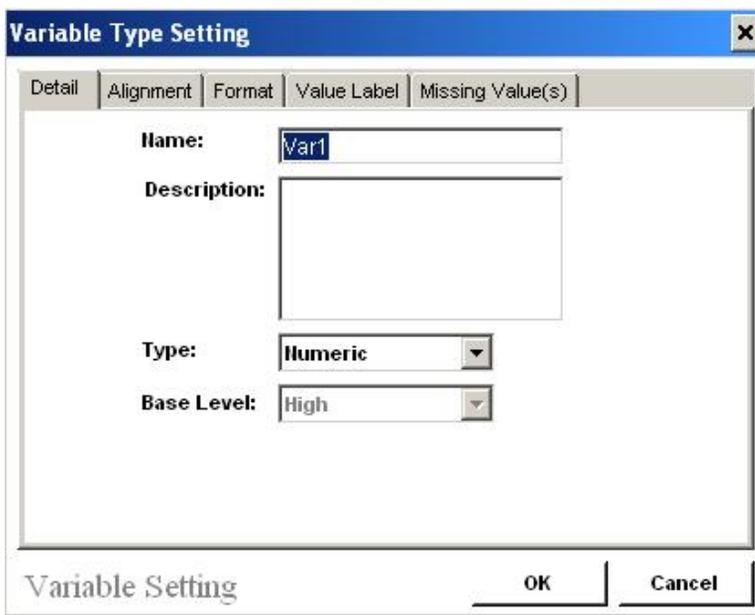

4.1.2 Creating Variables

To create a new Case Data set, invoke the menu **Home**. Click on the icon . Select **Case Data**. When you create a new case data set, all the columns are labeled **var**, indicating that new variables may be created in any of the columns. To create a new variable simply start entering data in a blank column. The column is given a default name Var1, Var2, etc. Alternatively, select any unused column, right click and select **Create Variable** from the menu that appears. The data editor will create all the variables with default names up to the column you are working on. To create a new

4 Data Editor

variable in the first unused column and to select its attributes, choose menu **Data Editor**. Click on the icon .

You will be presented with the dialog box shown below, in which you can select the variable name, variable type, alignment, format, value labels and missing values.

4.1.3 Variable Type Setting

You can change the default variable name and its type in this dialog box and click on the **OK** button. **East** will automatically add this new variable to the case data file. New variables are added immediately adjacent to the last existing variable in the case data set.

The **Variable Type Setting** dialog box contains five tabs: **Detail**, **Alignment**, **Format**, **Value Label**, and **Missing Value(s)**.

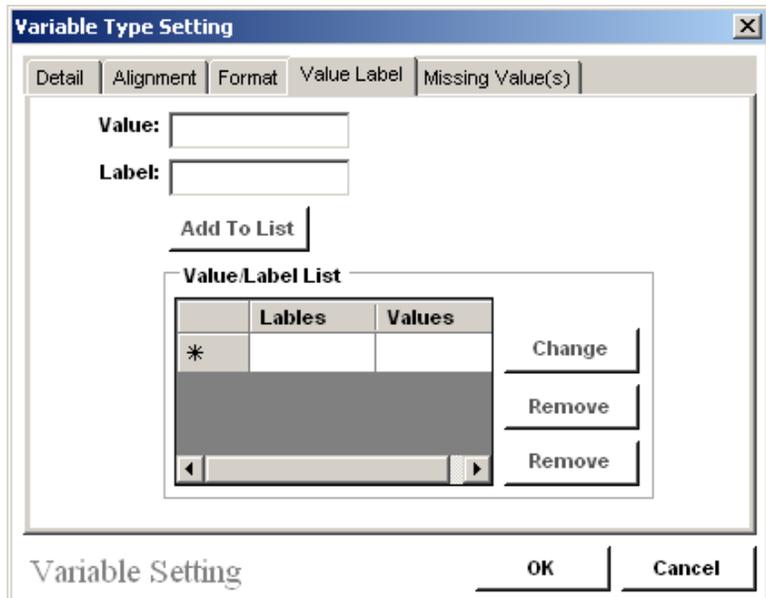

Detail

The **Detail** tab allows you to change the default variable name, add a description of the variable and select the type (**Numeric**, **String**, **Date**, **Binary**, **Categorical** or **Integer**). Note that depending on the **type** of the variable, different tabs and options become available in

the **Variable Type Settings**. For example the tab **Category Details** and option **Base Level** become available only if you select Variable **Type** as **Categorical**.

Value Label

The **Value label** tab is displayed below. Here, you can add labels for particular data values, change a selected label, or remove a selected label, or remove all value labels for the current variable.

Missing Value(s)

The **Missing Value (s)** tab is used for specifying which values are to be treated as missing. You have three choices: **Not Defined**, which means that no values will be treated as missing values; **Discrete value (s)**, which allows you to add particular values to the list of missing values; or **Range**, which lets you specify an entire range of numbers as missing values.

4.1.4 Editing Data

Besides changing the actual cell entries of a case data set you can:

- Add new Cases and Variables
- Insert or delete Cases and Variables

4 Data Editor

- Sort Cases

4.1.5 Filter Cases

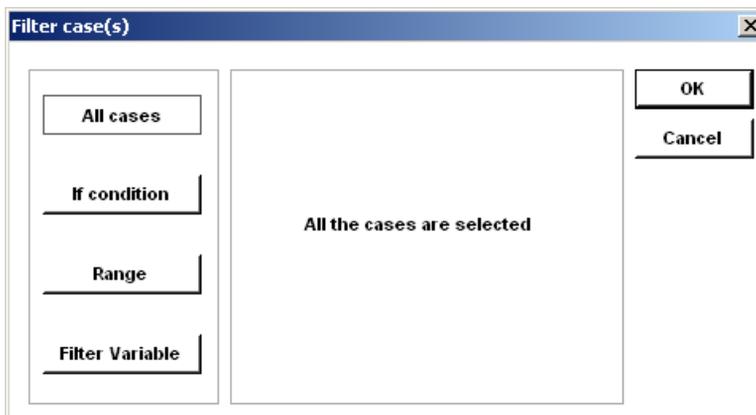

We illustrate the ability of **East** to filter cases with the help of the following example:

Step 1: Open the Data set

Open the data set **leukemia.cyd** by clicking on menu **Home**. Click on the icon  **Open**. Select **Data**. The data is stored in the **Samples** folder of the installation directory of **East**.

Step 2: Invoke the Filter Cases menu

Invoke the menu item **Data Editor**. Click on the icon  **Filter cases**. **East** will present you with a dialog box that allows you to use subsets of data in the Case Data editor. The dialog box will allow you to select **All cases**, those satisfying an **If condition**, falling in a **Range**, or using a **Filter Variable** as shown below.

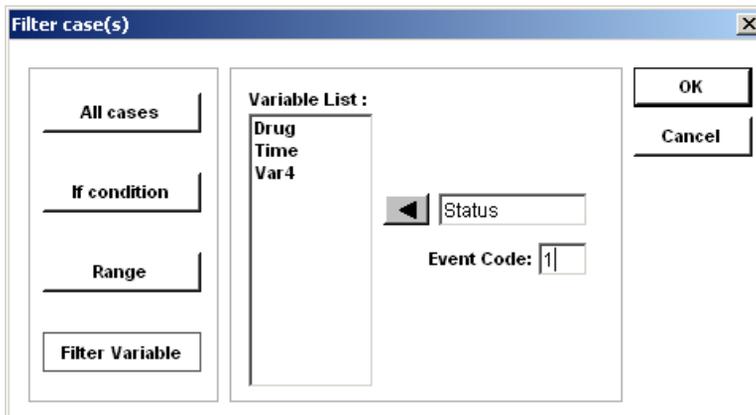

Step 3: Filter Variable option

Select the **Filter Variable** option. Select **Status** from the variable list and click on the black triangle, which will remove the variable **Status** from the variable list and add it to the empty box on the other side.

Suppose we want to filter the cases for which the **Status** variable has value 1. Insert

1 in the empty box next to **Event code**.

Step 4: Output

Click on **OK**. As shown in the following screenshot, **East** will grey out all the cases that have **Status** variable value 1. Now any analysis carried out on the data set uses only the filtered cases. In this way you, can carry out subgroup analyses if the

4 Data Editor

subgroups are identified by the values of a variable in the data set.

| Drug: 1 Value: Placebo | | | |
|------------------------|---------|------|--------|
| | Drug | Time | Status |
| 1 | Placebo | 1 | 1 |
| 2 | 6-MP | 10 | 1 |
| 3 | Placebo | 22 | 1 |
| 4 | 6-MP | 7 | 1 |
| 5 | Placebo | 3 | 1 |
| 6 | 6-MP | 32 | 0 |
| 7 | Placebo | 12 | 1 |
| 8 | 6-MP | 23 | 1 |
| 9 | Placebo | 8 | 1 |
| 10 | 6-MP | 22 | 1 |
| 11 | Placebo | 17 | 1 |
| 12 | 6-MP | 6 | 1 |
| 13 | Placebo | 2 | 1 |
| 14 | 6-MP | 16 | 1 |
| 15 | Placebo | 11 | 1 |
| 16 | 6-MP | 34 | 0 |
| 17 | Placebo | 8 | 1 |
| 18 | 6-MP | 32 | 0 |
| 19 | Placebo | 12 | 1 |
| 20 | 6-MP | 25 | 0 |
| 21 | Placebo | 2 | 1 |
| 22 | 6-MP | 11 | 0 |
| 23 | Placebo | 5 | 1 |
| 24 | 6-MP | 20 | 0 |
| 25 | Placebo | 4 | 1 |
| 26 | 6-MP | 19 | 0 |
| 27 | Placebo | 15 | 1 |
| 28 | 6-MP | 6 | 1 |
| 29 | Placebo | 8 | 1 |
| 30 | 6-MP | 17 | 0 |
| 31 | Placebo | 23 | 1 |
| 32 | 6-MP | 35 | 0 |
| 33 | Placebo | 5 | 1 |

4.2 Crossover Data

4.2.1 Data Editor

Capabilities for Crossover Data

4.2.2 Creating a New

Crossover Data Set

The **Data Editor** allows you to enter data for a 2×2 crossover trial with one record for each patient. You can use this crossover data editor to input individual patients' responses in 2×2 crossover trials. The response could be continuous (such as systolic blood pressure) or binary (such as the development of a tumor after injecting a carcinogenic agent). Only the continuous response type is currently supported in **East**.

4.2.1 Data Editor Capabilities for Crossover Data

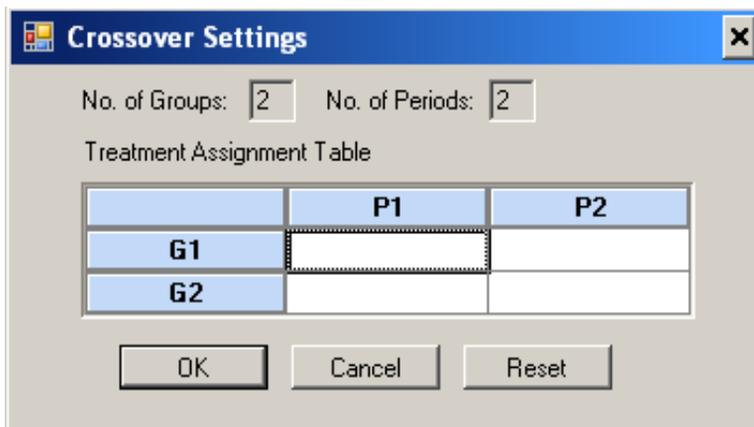

The Data Editor is used to create a new 2×2 Crossover Data file or to edit one that was previously saved. You can:

- Create and edit data with continuous response of individual patients.
- Edit period labels.
- Assign treatments to different groups and periods.
- Convert to case data.
- Convert case data into crossover data.
- List data to the log

4.2.2 Creating a New Crossover Data Set

To create a new crossover data set, invoke the menu **Home**. Click on icon  and from the drop down menu choose **Crossover data**.

You will be presented with a dialog box as shown below:

In the above dialog box, you see a 2×2 grid called **Treatment Assignment Table**. This grid is provided to assign the treatments to different groups and periods.

4 Data Editor

In this version of the software, you can analyze data for 2×2 crossover trials. Hence the number of groups and number of periods are always two. The rows specify the two groups labeled as **G1** and **G2**. The columns represent two periods of the crossover data labeled "P1" and "P2". If you'd like to change these labels, click inside the table cells. Type the treatment names associated with the corresponding group and period. Having entered the treatments, the crossover data editor settings dialog box will look as follows:

The screenshot shows a dialog box titled "Crossover Settings". At the top, there are two input fields: "No. of Groups:" with the value "2" and "No. of Periods:" with the value "2". Below these is a section titled "Treatment Assignment Table" containing a table with the following structure:

| | P1 | P2 |
|----|----|----|
| G1 | A | B |
| G2 | B | A |

At the bottom of the dialog box are three buttons: "OK", "Cancel", and "Reset".

Rules for editing these fields The row names **G1** and **G2** can be changed using a string consisting of a maximum of 8 characters from the set A-Z, 0-9, '.', '_' (underscore), starting with either a letter or a digit; blank spaces are not accepted as part of a name. The column names **P1** and **P2** can be changed the same way. Also note that the Group names as well as the Period names must be distinct. The letters are *not* case sensitive. Once you have assigned all the treatments, click on the button [OK](#).

This will open up the Patients' crossover data editor.

No. of Groups:

No. of Periods:

Treatment Assignment Table

| | | |
|----|----|----|
| | P1 | P2 |
| G1 | A | B |
| G2 | B | A |

| | Patient_Id | Group_Id | P1_Resp | P2_Resp | var |
|---|---|----------|---------|---------|-----|
| 1 | <input style="width: 100%;" type="text"/> | | | | |
| 2 | | | | | |
| 3 | | | | | |

This editor resembles the case data editor. Like the case data editor, this is a spreadsheet into which you can enter data directly. There are four pre-defined fields in this editor. The **PatientId** column must contain the Patients' identification number. The **GroupId** column will contain the group identification to which the patient belongs. The entry in this column should be one of the labels that you have entered as row names in the 2 × 2 grid earlier. The inputs in the next two columns are numeric and contain the responses of the patient in two periods respectively. The title of the next two columns is created by concatenating the word "Resp" to the period identifications that you have entered previously. For example, here in the setting dialog we have entered P1 and P2 as period identifiers and these two response columns are labeled as P1_Resp and P2_Resp. However, if the period values are starting with digits such as 1 and 2, then the period ids are prefixed by the letter P, and the heading of the next two columns would be P1_Resp and P2_Resp.

The variable names **PatientId**, **GroupId**, are fixed and cannot be edited in the data editor. If you use **Transform Variable** on **Group Id** and the result is either "G1" or "G2," then the value is displayed; otherwise, the value is shown as missing. You can also add covariates such as age and sex. All variable settings of the case data editor are applicable to these covariates. The button allows you to edit the **GroupId**, **PeriodId** or the treatment labels that you have edited earlier. If you make any changes, these changes will automatically be made in the data editor.

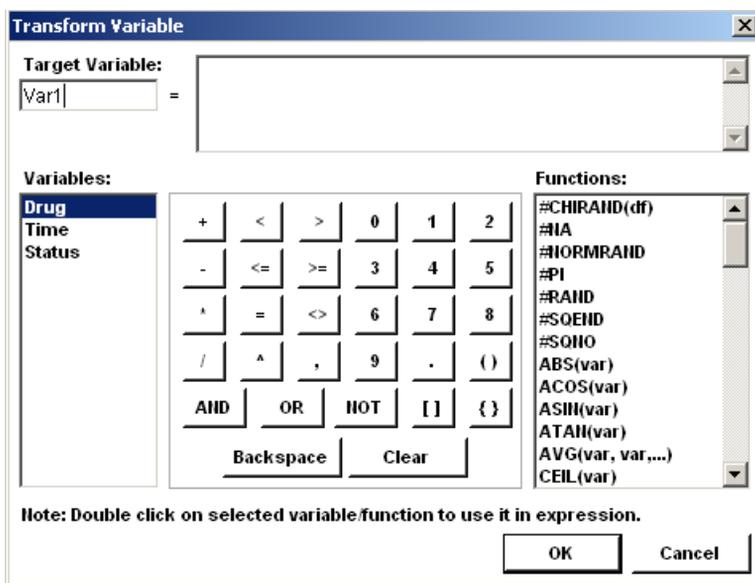

4.3 Data Transformation

You can transform an existing variable with the data transformation facility available in the **Data Editor** of **East** .

4 Data Editor

To transform any variable:

1. Select the menu **Data Editor**. Click on the icon . You will be presented with the expression builder dialog box screen. Here you can transform the values of the current variable using a combination of statistical, arithmetic, and logical operations.

The current variable name is the target variable on the left hand side of an equation with the form:

VAR =

Where, **VAR** is the variable name of the current variable. In order to create a new variable, type the variable name in the **target variable** field.

2. Complete the right hand side of the equation with any combination of allowable functions. To select a function, double-click on it. If the function that you select needs any extra parameters (typically variable names), this will be indicated by a **?** for each required parameter. Replace the **?** character with the desired parameter.
3. Select the **OK** button to fill in values for the current variable computed according to the expression that you have constructed.

The statistical, arithmetical, and logical functions that are available in the **Transform Variable** dialog box are given below:

4.4 Mathematical and Statistical Functions

The following is a list of mathematical and statistical functions available in **East** used for variable transformation.

ABS(X) Returns the absolute value of X.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

ACOS(X) Returns the arccosine of X.

Argument Range: $-1 \leq X \leq 1$.

ASIN(X) Returns the arcsine of X.

Argument Range: $-1 \leq X \leq 1$.

ATAN(X) Returns the arctangent of X.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

AVG(X_1, X_2, \dots) Returns the mean of (X_1, X_2, \dots).

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

CEIL(X) Returns the ceiling, or smallest integer greater than or equal to X.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

CHIDIST(X,df) Returns the probability in the tail area to the left of X from the chi-squared distribution with $df > 0$ degrees of freedom.

Argument Range: $0 \leq X \leq 1 \times 10^{25}$.

CHIINV(X,df) Returns the Xth percentile value of the chi-squared distribution with $d > 0$ degrees of freedom, i.e., returns z such that $\Pr(Z \leq z) = X$.

Argument Range: $0.0001 \leq X \leq 0.9999$.

COS(X) Returns the cosine of X, where X is expressed in radians.

Argument Range: $-2.14 \times 10^9 \leq X \leq 2.14 \times 10^9$.

COSH(X) Returns the hyperbolic cosine of X.

Argument Range: $-87 \leq X \leq 87$.

CUMULATIVE(X) Given a column of X values this function returns a new column in which the entry in row j is the sum of entries in the first j rows of the original column.

EXP(X) Returns the exponential function evaluated at X.

Argument Range: $-87 \leq X \leq 87$.

FLOOR(X) Returns the floor, or largest integer less than or equal to X.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

INT(X) Returns the integer part of X.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

ISNA(X) Returns a value of 1 if X is a missing value 0 otherwise.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$. This function is useful. For example, set missing observations to average values.

X1 = IF (ISNA (X)=1, COLMEAN (X), X)

Another extremely useful task performed by the ISNA() function is to eliminate records from the data set in which there are missing values.

4 Data Editor

REJECTIF (ISNA (X) =1)

SELECTIF (ISNA (V1) +ISNA (V2) +ISNA (V3) =0)

LOG(X) Returns the logarithm of X to base 10.

Argument Range: $1 \times 10^{-25} \leq X \leq 1 \times 10^{25}$.

LN(X) Returns the logarithm of X to base e .

Argument Range: $1 \times 10^{-25} \leq X \leq 1 \times 10^{25}$.

MAX(X₁, X₂, ...) Returns the maximum value of (X₁, X₂, ...).

MIN(X₁, X₂, ...) Returns the minimum value of (X₁, X₂, ...).

MOD(X,Y) Returns the remainder of X divided by Y. The sign of this remainder is the same as that of X.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

NORMDIST(X) Returns the probability in the tail area to the left of X from the standardized normal distribution.

Argument Range: $-10 \leq X \leq 10$.

NORMINV(X) Returns the Xth percentile value of the standard normal distribution, i.e., returns z such that $\Pr(Z \leq z) = X$.

Argument Range: $0.001 \leq X \leq 0.999$.

ROUND(X,d) Returns a floating point number obtained by rounding X to d decimal digits. If d=0, X is rounded to the nearest integer.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$.

SIN(X) Returns the sine of X, where X is expressed in radians.

Argument Range: $-2.14 \times 10^9 \leq X \leq 2.14 \times 10^9$.

SINH(X) Returns the hyperbolic sine of X.

Argument Range: $-87 \leq X \leq 87$.

SQRT(X) Returns the square root of X.

Argument Range: $0 \leq X \leq 1 \times 10^{25}$.

TAN(X) Returns the tangent of X, where X is expressed in radians.

Argument Range: $-1 \times 10^{25} \leq X \leq 1 \times 10^{25}$; $X \neq (2n + 1)\frac{\pi}{2}$, n an integer.

TANH(X) Returns the hyperbolic tangent of X.

Argument Range: $-87 \leq X \leq 87$.

4.4.1 The IF Function

This function tests arithmetic or logical condition and returns one value if true, another value if false. The syntax is

IF (CONDITION, X, Y)

The function returns the value **X** if **CONDITION** is "true" and **Y** if **CONDITION** is "false". For example consider the following equation:

HIVPOS = IF (CD4>1, 1, -1)

The above equation defines a variable **HIVPOS** that assumes the value 1, if the variable **CD4** exceeds 1 and assumes the value -1 otherwise. Usually **CONDITION** is made up of two arithmetic expressions separated by a "comparison operator", e.g., **CD4>CD8**, **CD4+CD8=15*BLOOD**, etc. The following comparison operators are allowed:

=, >, <, >=, <=, <>

More generally, **CONDITION** can be constructed by combining two or more individual conditions with **AND**, **OR**, or **NOT** operators. For example consider the following expression

HIVPOS = IF ((CD4>1) !AND! (CD8>1), 1, -1)

The above expression means that **HIVPOS** will take on the value 1 if **both CD4>1** and **CD8>1**, and -1 otherwise. On the other hand consider the following expression:

HIVANY = IF ((CD4>1) !OR! (CD8>1), 1, -1)

The above expression means that **HIVANY** will take on the value 1 if **either CD4>1** or **CD8>1** and -1 otherwise.

4.4.2 The *SELECTIF* Function

This function provides a powerful way of selecting only those records that satisfy a specific arithmetic or logical condition. All other records are deleted from the current data set. The syntax is:

SELECTIF (CONDITION)

This function selects only those records for which **CONDITION** is "true" and excludes all other records from the current dataset. For example consider the following equation:

HIVPOS = SELECTIF (CD4>1)

The above condition retains records for which **CD4** exceeds 1. The same rules governing **CONDITION** for the **IF** function are applicable here as well.

Note that the column location of the cursor when **Transform Variable** was selected plays no role in the execution of this function.

4.4.3 The *RECODE* Function

This function recodes different ranges of a variable. It is extremely useful for creating a new variable consisting of discrete categories at pre-specified cut-points of the original variable. The syntax for **RECODE** has two forms — one for recoding a

4 Data Editor

categorical variable and one for recoding a continuous variable. In both cases, the variable being recoded must assume numerical values.

Recoding a Categorical Variable syntax is:

$$\mathbf{RECODE}(X, S_1 = c_1, S_2 = c_2, \dots, S_n = c_n, [\mathbf{else}]),$$

where X is the categorical variable (or arithmetic expression) being recoded, S_j represents a set of numbers in X , all being recoded to c_j , and the optional argument **[else]** is a default number to which all the numbers belonging to X , but excluded from the sets S_1, S_2, \dots, S_n , are recoded. If **[else]** is not specified as an argument of **RECODE**, then all the numbers excluded from the sets S_1, S_2, \dots, S_n are unchanged.

Notice that the argument $S_j = c_j$ in the **RECODE** function consists of a set of numbers S_j being recoded to a single number c_j . The usual mathematical convention is adopted of specifying a set of numbers within braces. Thus if set S_j consisted of m distinct numbers $s_{1j}, s_{2j}, \dots, s_{mj}$, it would be represented in the **RECODE** argument list as $\{s_{1j}, s_{2j}, \dots, s_{mj}\}$. For example

$$\mathbf{Y} = \mathbf{RECODE}(\mathbf{X}, \{1, 2, 3\}=1, \{7, 9\}=2, \{10\}=3)$$

will recode the categorical variable X into another categorical variable Y that assumes the value 1 for $X \in \{1, 2, 3\}$, 2 for $X \in \{7, 9\}$, and 3 for $X = 10$.

Other values of X , if any, remain unchanged. If you want those other values of X to be recoded to, e.g., -1, simply augment the argument list by including -1 at the end of the recode statement:

$$\mathbf{Y} = \mathbf{RECODE}(\mathbf{X}, \{1, 2, 3\}=1, \{7, 9\}=2, \{10\}=3, -1) .$$

Recoding a Continuous Variable syntax is:

$$\mathbf{RECODE}(X, I_1 = c_1, I_2 = c_2, \dots, I_n = c_n, [\mathbf{else}])$$

where X is the continuous variable (or arithmetic expression) being recoded, I_j represents an interval of numbers all being recoded to c_j , and the optional argument **[else]** is a default number to which all the numbers belonging to X , but excluded from the intervals I_1, I_2, \dots, I_n , are recoded. If **[else]** is not specified as an argument of **RECODE**, then all the numbers excluded from the intervals I_1, I_2, \dots, I_n are unchanged. Notice that the arguments of **RECODE** are intervals being recoded to individual numbers. The usual mathematical convention for specifying an interval I_j as open, semi-open, and closed is adopted.

Thus:

- An interval I_j of the form (u, v) is open and includes all numbers between u and v , but not the end points.

- An interval I_j of the form $[u, v]$ is closed and includes all numbers between u and v inclusive of the end points.
- An interval of the form $(u, v]$ is open on the left but closed on the right. It excludes u , includes v , and includes all the numbers in between.
- An interval of the form $[u, v)$ is closed on the left but open on the right. It includes u , excludes v , and includes all the numbers in between.

For example

```
Y = RECODE (X, (2.5, 5.7]=1, (5.7, 10.4]=2)
```

will recode the continuous variable X so that all numbers $2.5 < X \leq 5.7$ are replaced by 1, all numbers $5.7 < X \leq 10.4$ are replaced by 2, and all other values of X are unchanged. If you want all other values of X to also be recoded to say -1, append the -1 as the last argument of the equation:

```
Y = RECODE (X, (2.5, 5.7]=1, (5.7, 10.4]=2, -1) .
```

4.4.4 Column Functions

Column functions operate on an entire column of numbers and return a scalar quantity. The returned value is often used in arithmetic expressions. The following column functions are available. All of them are prefixed by the letters **COL**. The argument **var** of all these column functions must be a variable in the worksheet; arithmetic expressions are not permitted. This may require you to create an intermediate column of computed expressions before using a column function. Also note that missing values are ignored in computing these column functions.

COLMEAN(X) Returns the sample mean of X .

COLVAR(X) Returns the sample variance of X .

COLSTD(X) Returns the sample standard deviation of X .

COLSUM(X) Returns the sum of all the numbers in X .

COLMAX(X) Returns the maximum value of X .

COLMIN(X) Returns the minimum value of X .

COLRANGE(X) Returns the value of **COLMAX(X) - COLMIN(X)**.

COLCOUNT(X) Returns the number of elements in X .

You can use the values returned by these column functions in arithmetic expressions and as arguments of other functions. To do this, it is not necessary to know the actual value returned by the column function. However, if you want to know the value returned by any column function, you must define a new variable in the worksheet and fill its entire column with the value of the column function.

4.4.5 Random Numbers

4 Data Editor

You can fill an entire column of a worksheet with random numbers and constants. Suppose the cursor is in a cell of a variable named **RANDNUM**.

The expression

$$\mathbf{RANDNUM} = \mathbf{\#RAND}$$

will result in the variable **RANDNUM** being filled with a column of uniform random numbers in the range (0, 1).

Three random number functions or generators are available to you with the editors:

#RAND Generates uniform random numbers in the range (0, 1).

#NORMRAND Generates random numbers from the standard Normal Distribution.

#CHIRAND(X) Generates random numbers from the chi-squared distribution with X degrees of freedom.

You may of course use these three random number generators to generate random numbers from other distributions. For example, the equation

$$\mathbf{Y} = \mathbf{3+2*\#NORMRAND}$$

will generate random numbers from the normal distribution with mean 3 and standard deviation 2, in variable **Y**. Again, the equation

$$\mathbf{Z} = \mathbf{\#CHIRAND(5)}$$

will generate random numbers from the chi-squared distribution with 5 degrees of freedom.

4.4.6 Special functions

The following special functions are available for use in arithmetic expressions:

#PI This is the value of π .

#NA This is the missing value code. It can be used to detect if a value is missing, or to force a value to be treated as missing.

#SQNO This is the value of the current sequence number (**SQNO**) in the current data set.

#SQEND This is the largest value of the sequence number (**SQNO**) in the current data set.

5 *Introduction to Volume 2*

This volume describes the procedures for continuous endpoints (normal) applicable to one-sample, two-samples, many-samples and regression situations. All the three type of designs - superiority, non-inferiority and equivalence are discussed in detail.

Chapter 6 introduces you to East on the Architect platform, using an example clinical trial to test difference of means.

Chapter 7, 8 and 9 detail the design and interim monitoring in one-sample situation where it may be required to compare a new treatment to a well-established control, using a single sample. These chapters respectively cover superiority, non-inferiority and equivalence type of trials.

Chapter 10 details the design and interim monitoring in superiority two-sample situation where the superiority of a new treatment over the control treatment is tested comparing the group-dependent means of the outcome variables.

Chapter 11 details the design in the Wilcoxon-Mann-Whitney nonparametric test which is a commonly used test for the comparison of two distributions when the observations cannot be assumed to come from normal distributions. It is used when the distributions differ only in a location parameter and is especially useful when the distributions are not symmetric. For Wilcoxon-Mann-Whitney test, East supports single look superiority designs only.

Chapter 12 provides an account of the design and interim monitoring in non-inferiority two-sample situation where the goal is to establish that an experimental treatment is no worse than the standard treatment, rather than attempting to establish that it is superior. Non-inferiority trials are designed by specifying a non-inferiority margin. The amount by which the mean response on the experimental arm is worse than the mean response on the control arm must fall within this margin in order for the claim of non-inferiority to be sustained.

Chapter 13 narrates the details of the design and interim monitoring in equivalence two-sample situation where the goal is neither establishing superiority nor non-inferiority, but equivalence. When the goal is to show that two treatments are similar, it is necessary to develop procedures with the goal of establishing equivalence in mind. In Section 13.1, the problem of establishing the equivalence with respect to the difference of the means of two normal distributions using a parallel-group design is presented. The corresponding problem of establishing the equivalence with respect to

5 Introduction to Volume 2

the log ratio of means is presented in Section 13.2. For the crossover design, the problem of establishing the equivalence with respect to the difference of the means is presented in Section 13.3 and with respect to the log ratio of means in Section 13.4.

Chapter 16 details the clinical trials that are often designed to assess benefits of a new treatment compared to a control treatment with respect to multiple clinical endpoints which are divided into hierarchically ordered families. It discusses two methods - Section 16.2 discusses Serial Gatekeeping whereas section 16.3 discusses Parallel Gatekeeping.

Chapter 14 details the various tests available for comparing more than two continuous means in East. Sections 14.1, 14.2 and 14.3 discuss One Way ANOVA, One Way Repeated Measures ANOVA and Two Way ANOVA respectively.

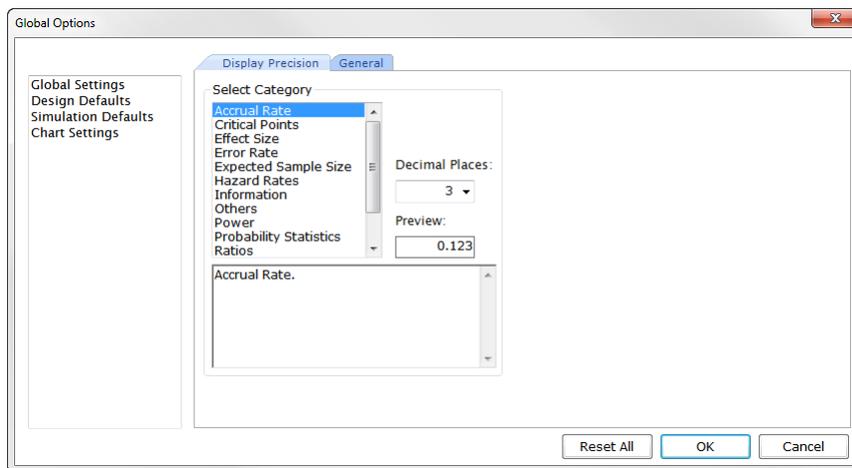

Chapter 15 details the Multiple Comparison Procedures (MCP) for continuous data. It is often the case that multiple objectives are to be addressed in one single trial. These objectives are formulated into a family of hypotheses. Multiple comparison (MC) procedures provides a guard against inflation of type I error while testing these multiple hypotheses. East supports several parametric and p-value based MC procedures. This chapter explains how to design a study using a chosen MC procedure that strongly maintains FWER.

Chapter 19 elaborates on the design and interim monitoring in superiority regression situation where linear regression models are used to examine the relationship between a response variable and one or more explanatory variables. This chapter discusses the design and interim monitoring of three types of linear regression models. Section 19.1 examines the problem of testing a single slope in a simple linear regression model involving one continuous covariate. Section 19.2 examines the problem of testing the equality of two slopes in a linear regression model with only one observation per subject. Finally Section 19.3 examines the problem of testing the equality of two slopes in a linear regression repeated measures model, applied to a longitudinal setting.

5.1 Settings

Click the **Global Options** icon in the **Home** menu to adjust default values in East 6.

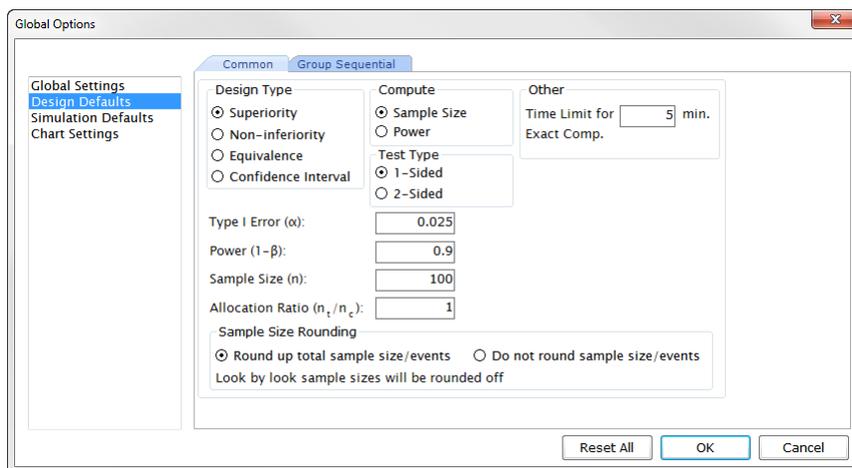

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

5 Introduction to Volume 2

The **Design Defaults** is where the user can change the settings for trial design:

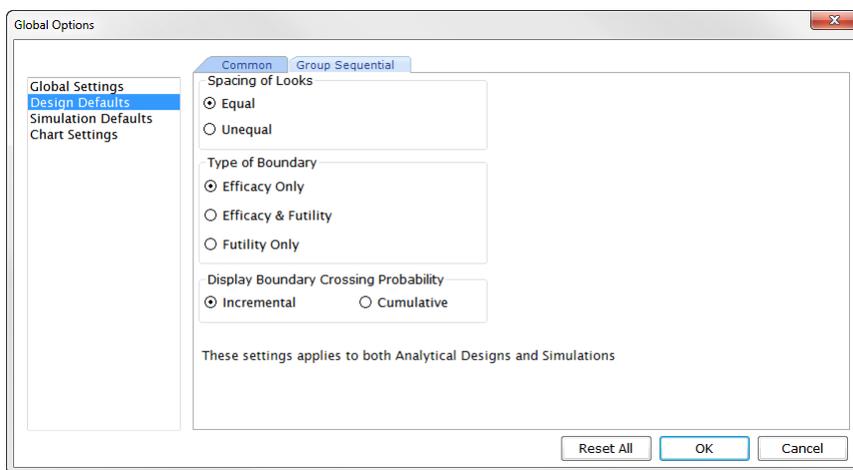

Under the **Common** tab, default values can be set for input design parameters.

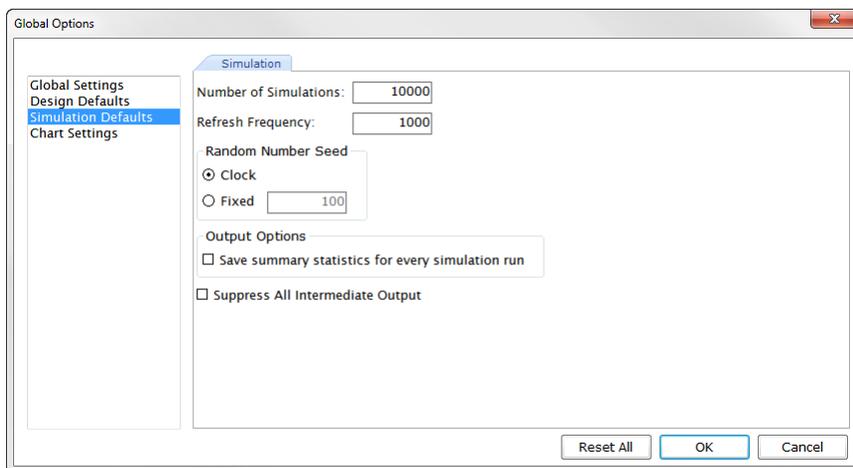

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

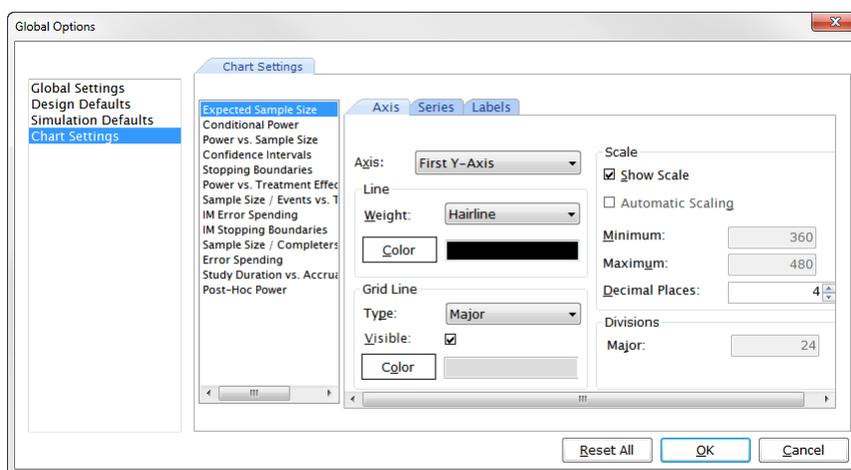

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

5 Introduction to Volume 2

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

We suggest that you do not alter the defaults until you are quite familiar with the software.

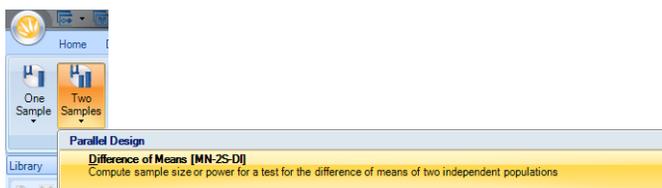

6 Tutorial: Normal Endpoint

This tutorial introduces you to East on the Architect platform, using an example clinical trial to test difference of means.

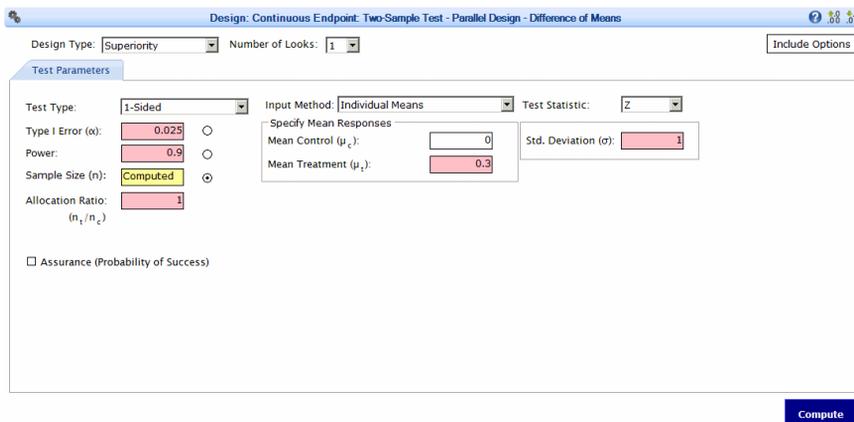

6.1 Fixed Sample Design

When you open East, by default, the Design tab in the ribbon will be active.

The items on this tab are grouped under the following categories of endpoints: Continuous, Discrete, Count, Survival, and General. Click **Continuous: Two Samples**, and then **Parallel Design: Difference of Means**.

The following input window will appear.

By default, the radio button for **Sample Size (n)** is selected, indicating that it is the variable to be computed. The default values shown for **Type I Error** and **Power** are 0.025 and 0.9. Keep the same for this design. Since the default inputs provide all of the necessary input information, you are ready to compute sample size by clicking the **Compute** button. The calculated result will appear in the **Output Preview** pane, as

6 Tutorial: Normal Endpoint

shown below.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | Input Method | δ | μ_c | Mean Treatment (Alt.) | σ | Test Statistic |
|------|-------------|--------------|-----------|--------------------|-------|-------|-------------|------------------|----------|---------|-----------------------|----------|----------------|
| Des1 | Superiority | 1 | 1-Sided | 0.025 | 0.9 | 1 | 467 | Individual Means | 0.3 | 0 | 0.3 | 1 | Z |

This single row of output contains relevant details of inputs and the computed result of total sample size (and total completers) of 467. Select this row, and click  to display a summary of the design details in the upper pane (known as **Output Summary**).

| Des 1 | |
|---|------------------|
| Mnemonic | MN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.9 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Input Method | Individual Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 0.3 |
| Mean Control (μ_c) | 0 |
| Mean Treatment (μ_t) | 0.3 |
| Std. Deviation (σ) | 1 |
| Test Statistic | Z |
| Sample Size | |
| Maximum | 467 |

The discussion so far gives you a quick feel of the software for computing sample size for a single look design. We will describe further features in an example for a group sequential design in the next section.

6.2 Group Sequential Design for a Normal Superiority Trial

6.2.1 Study Background

Drug X is a newly developed lipase inhibitor for obesity management that acts by inhibiting the absorption of dietary fats. The performance of this drug needs to be compared with an already marketed drug Y for the same condition. In a randomized,

double-blind, trial comparing the efficacy and safety of 1 year of treatment with X to Y (each at 120 mg for three times a day), obese adults are to be randomized to receive either X or Y combined with dietary intervention for a period of one year. The endpoint is weight loss (in pounds). You are to design a trial having 90% power to detect a mean difference of 9 lbs between X and Y, assuming 15 lbs and 6 lbs weight loss in each treatment arm, respectively, and a common standard deviation of 32 lbs. The design is required to be a 2-sided test at the 5% significance level.

From the design menu choose **Continuous: Two Samples**, and then **Parallel Design: Difference of Means**. Select **2-Sided** for **Test Type**, and enter **0.05** for **Type I Error**. Specify the **Mean Control** be **6**, the **Mean Treatment** to be **15**, and the common **Std. Deviation** to be **32**. Next, change the **Number of Looks** to be **5**. You will see a new tab, **Boundary**, added to the input dialog box.

Click the **Boundary** tab, and you will see the following screen. On this tab, you can choose whether to specify stopping boundaries for efficacy, or futility, or both. For this trial, choose efficacy boundaries only, and leave all other default values. We will implement the Lan-Demets (O’Brien-Fleming) spending function, with equally spaced

6 Tutorial: Normal Endpoint

looks.

Design Type: Superiority Number of Looks: 5

Test Parameters **Boundary**

Efficacy
 Boundary Family: Spending Functions
 Spending Function: Lan-DeMets
 Parameter: OF
 Type I Error (α): 0.05

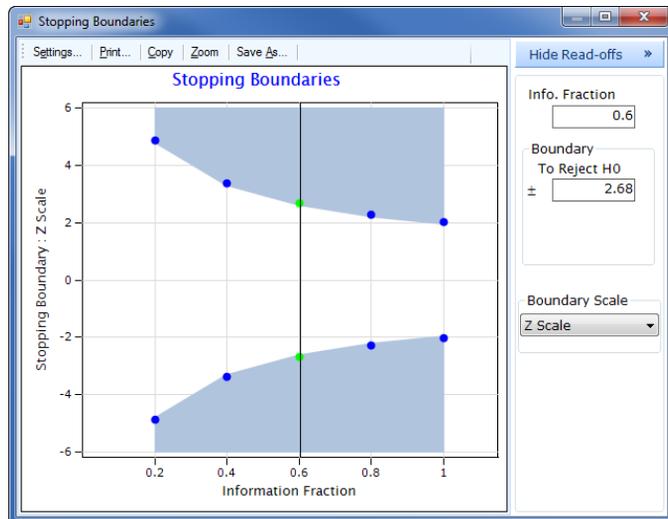

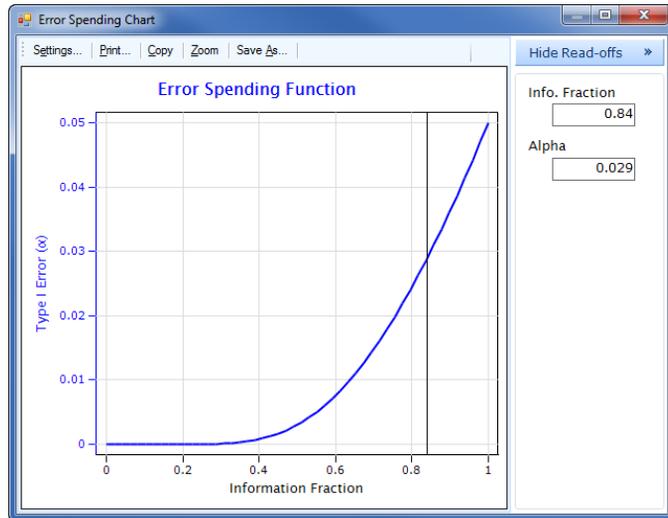

Futility
 Boundary Family: None

Spacing of Looks: Equal Unequal Efficacy Boundary: Z Scale  

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.200 | 0.000 | 4.877 | -4.877 |
| 2 | 0.400 | 0.001 | 3.357 | -3.357 |
| 3 | 0.600 | 0.008 | 2.680 | -2.680 |
| 4 | 0.800 | 0.024 | 2.290 | -2.290 |
| 5 | 1.000 | 0.050 | 2.031 | -2.031 |

On the **Boundary** tab near the Efficacy drop-down box, click on the icons  or

 , to generate the following charts.

Click **Compute**. East will show the results in the **Output Preview**.

The maximum combined sample size required under this design is 544. The expected

6 Tutorial: Normal Endpoint

sample sizes under H0 and H1 are 540 and 403, respectively. Click  in the **Output Preview** toolbar to save this design to Wbk1 in the **Library**. Double-click on Des1 to generate the following output.

Design: Continuous Endpoint: Two-Sample Test - Parallel Design - Difference of Means

| 4 | 0.8 | 435 | 0.024 | 2.29 | -2.29 | 0.008 | 0.008 | 0.301 | 7.455E-8 |
| 5 | 1 | 544 | 0.05 | 2.031 | -2.031 | 0.013 | 0.013 | 0.154 | 4.003E-8 |

Once you have finished examining the output, close this window, and re-start East before continuing.

6.2.2 Creating multiple designs easily

In East, it is easy to create multiple designs by inputting multiple parameter values. In the trial described above, suppose we want to generate designs for all combinations of the following parameter values: **Power** = 0.8, 0.9, and **Difference in Means** = 8.5, 9, 9.5, 10. The number of such combinations is $2 \times 4 = 8$.

East can create all 8 designs by a single specification in the input dialog box. Enter the following values as shown below. Remember that the common **Std. Deviation** is 32. From the **Input Method**, select the **Difference of Means** option. The values of **Power** have been entered as a list of comma-separated values, while **Difference in**

Means has been entered as a colon-separated range of values: 8.5 to 10 in steps of 0.5.

Now click compute. East computes all 8 designs, and displays them in the **Output Preview** as shown below. Click to maximize the **Output Preview**.

Select the first 3 rows using the Ctrl key, and click to display a summary of the design details in the upper pane, known as the **Output Summary**.

| | Des1 | Des2 | Des3 |
|--|---------------------|---------------------|---------------------|
| Mnemonic | MN-25-DI | MN-25-DI | MN-25-DI |

| Expected Under H ₀ | 453.004 | 404.326 | 363.595 |
| Expected Under H ₁ | 366.549 | 327.093 | 294.023 |

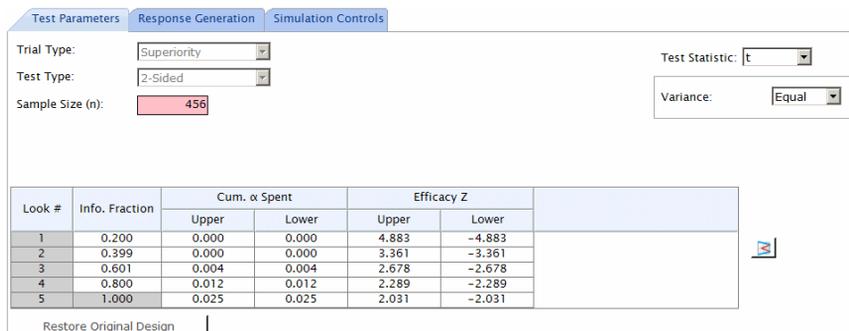

Select Des1 in the **Output Preview**, and click toolbar to save this design in the **Library**. We will use this design for simulation and interim monitoring, as described below. Now that you have saved Des1, delete all designs from the **Output Preview** before continuing, by selecting all designs with the Shift key, and clicking in the toolbar.

6.2.3 Simulation

Right-click Des1 in the **Library**, and select **Simulate**. Alternatively, you can select

6 Tutorial: Normal Endpoint

Des1 and click the  icon.

The screenshot shows the 'Simulation Controls' tab of a software interface. The parameters are set as follows:

- Trial Type: Superiority
- Test Type: 2-Sided
- Sample Size (n): 456
- Test Statistic: Z
- Variance: Equal

Below the parameters is a table with the following data:

| Look # | Info. Fraction | Cum. α Spent | | Efficacy Z | |
|--------|----------------|---------------------|-------|------------|--------|
| | | Upper | Lower | Upper | Lower |
| 1 | 0.200 | 0.000 | 0.000 | 4.883 | -4.883 |
| 2 | 0.399 | 0.000 | 0.000 | 3.361 | -3.361 |
| 3 | 0.601 | 0.004 | 0.004 | 2.678 | -2.678 |
| 4 | 0.800 | 0.012 | 0.012 | 2.289 | -2.289 |
| 5 | 1.000 | 0.025 | 0.025 | 2.031 | -2.031 |

At the bottom of the interface, there is a 'Restore Original Design' button.

We will carry out a simulation of Des1 to check whether it preserves the specified power. Click **Simulate**. East will execute by default 10000 simulations with the specified inputs. Close the intermediate window after examining the results. A row labeled as Sim1 will be added in the **Output Preview**.

Click the  icon to save this simulation to the **Library**. A simulation sub-node will be added under Des1 node. Double clicking on the Sim1 node, will display the

detailed simulation output in the work area.

Simulation Seed and Elapsed Time

Starting Seed: 725323
 Total Number of Simulations: 10000
 Elapsed Time: 00.01.05

In 80.23% of the simulated trials, the null hypothesis was rejected. This value is very close to the specified power of 80%. Note that your results may differ from the results displayed over here as the simulations would be run with different seed. The next section will explore interim monitoring with this design.

6 Tutorial: Normal Endpoint

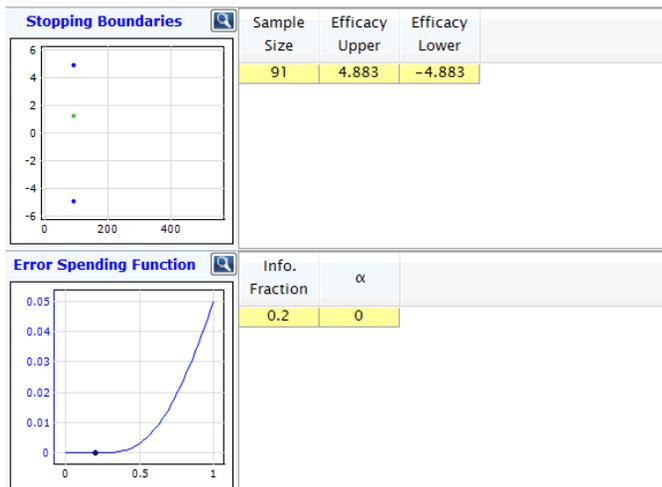

6.2.4 Interim Monitoring

Right-click Des1 in the **Library** and select **Interim Monitoring**. Click the **Enter Interim Data** to open the **Test Statistic Calculator**. Suppose that after 91 subjects, at the first look, you have observed a mean difference of 8.5, with a standard error of 6.709.

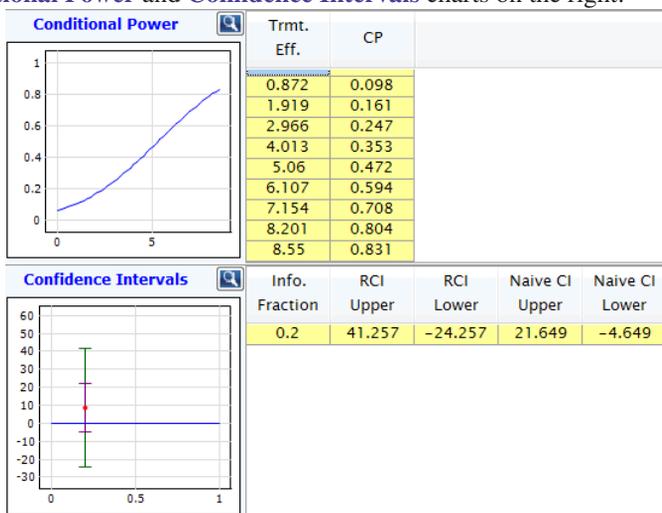

Click **OK** to update the IM Dashboard.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|--------|----------------------|---------|------------------|-------|------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.2 | 91 | 1.267 | 8.5 | 6.709 | 4.883 | -4.883 | 41.257 | -24.257 | 0.932 | 0.828 | 0.673 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |
| 4 | | | | | | | | | | | | |
| 5 | | | | | | | | | | | | |

The **Stopping Boundaries** and **Error Spending Function** charts on the left:

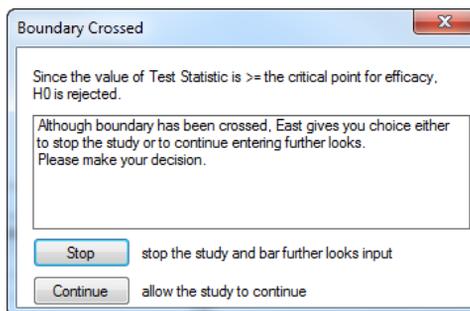

The Conditional Power and Confidence Intervals charts on the right:

Suppose that after 182 subjects, at the second look, you have observed a mean difference of 16, with a standard error of 4.744. Click **Recalc**, and then **OK** to update the IM Dashboard. In this case, a boundary has been crossed, and the following

6 Tutorial: Normal Endpoint

window appears.

Click **Stop** to complete the trial. The IM Dashboard will be updated accordingly, and a table for **Final Inference** will be displayed as shown below.

| Final Inference | |
|--|--------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0.001 |
| Adj. Pt. Est. for δ | 16 |
| Adj. 95% CI for δ | |
| Upper Confidence Bound | 25.298 |
| Lower Confidence Bound | 6.702 |
| Post-Hoc Power | |

7 Normal Superiority One-Sample

To compare a new process or treatment to a well-established control, a single-sample study may suffice for preliminary information prior to a full-scale investigation. This single sample may either consist of a random sample of observations from a single treatment when the mean is to be compared to a specified constant or a random sample of paired differences or ratio between two treatments. The former is presented in Section (7.1) and the latter is discussed in Section (7.2) and Section (7.3).

7.1 Single Mean

7.1.1 Trial Design

7.1.2 Simulation

7.1.3 Interim Monitoring

7.1.4 Trial Design Using a t-Test (Single Look)

The problem of comparing the mean of the distribution of observations from a single random sample to a specified constant is considered. For example, when developing a new drug for treatment of a disease, there should be evidence of efficacy. For this single-sample problem, it is desired to compare the unknown mean μ to a fixed value μ_0 . The null hypothesis $H_0: \mu = \mu_0$ is tested against the two-sided alternative hypothesis $H_1: \mu \neq \mu_0$ or a one-sided alternative hypothesis $H_1: \mu < \mu_0$ or $H_1: \mu > \mu_0$. The power of the test is computed at a specified value of $\mu = \mu_1$ and standard deviation σ .

Let $\hat{\mu}_j$ denote the estimate of μ based on n_j observations, up to and including the j -th look, $j = 1, \dots, K$, with a maximum of K looks. The test statistic at the j -th look is based on the value specified by the null hypothesis, namely

$$Z_j = n_j^{1/2}(\hat{\mu}_j - \mu_0)/\hat{\sigma}_j, \tag{7.1}$$

where $\hat{\sigma}_j^2$ is the sample variance based on n_j observations.

7.1.1 Trial Design

Consider the situation where treatment for a certain infectious disorder is expected to result in a decrease in the length of hospital stay. Suppose that hospital records were reviewed and it was determined that, based on this historical data, the average hospital stay is approximately 7 days. It is hoped that the new treatment can decrease this to less than 6 days. It is assumed that the standard deviation is $\sigma = 2.5$ days. The null hypothesis $H_0: \mu = 7 (= \mu_0)$ is tested against the alternative hypothesis $H_1: \mu < 7$.

First, click **Continuous: One Sample** on the **Design** tab and then click **Single Arm Design: Single Mean**.

This will launch a new input window.

Single-Look Design

7 Normal Superiority One-Sample

We want to determine the sample size required to have power of 90% when $\mu = 6 (= \mu_1)$, using a test with a one-sided type-1 error rate of 0.05. Choose **Test Type** as **1-Sided**. Specify **Mean Response under Null (μ_0)** as 7, **Mean Response under Alt. (μ_1)** as 6 and **Std. Deviation (σ)** as 2.5. The upper pane should appear as below:

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview**. The computed sample size is 54 subjects.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | Sample Size | σ | μ_0 | μ_1 | Test Statistic |
|------|-------------|--------------|-----------|--------------------|-------|-------------|----------|---------|---------|----------------|
| Des1 | Superiority | 1 | 1-Sided | 0.05 | 0.902 | 54 | 2.5 | 7 | 6 | Z |

This design has default name Des 1. Select this design by clicking anywhere along the row and click  in the **Output Preview** toolbar. Some of the design details will

be displayed in the upper pane, labeled as **Output Summary**.

| Output Summary | |
|--------------------------------------|--------------|
| | Des 1 |
| Mnemonic | MN-1S-SM |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |
| Specified α | 0.05 |
| Power | 0.902 |
| Model Parameters | |
| Std. Deviation (σ) | 2.5 |
| Mean Response under Null (μ_0) | 7 |
| Mean Response under Alt. (μ_1) | 6 |
| Test Statistic | Z |
| Sample Size | |
| Maximum | 54 |

In the **Output Preview** toolbar select Des 1, click  to save this design to Wbk1 in the **Library**.

Five-Look Design

To allow the opportunity to stop early and proceed with a full-scale plan, five equally-spaced analyses are planned, using the Lan-DeMets (O'Brien-Fleming) stopping boundary. Create a new design by right-clicking Des 1 in the **Library**, and selecting **Edit Design**. In the Input, change the **Number of Looks** from 1 to 5, to generate a study with four interim looks and a final analysis. A new tab for **Boundary Info** should appear. Click this tab to reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. By default, there is an efficacy boundary (to reject H_0) selected, but no futility boundary (to reject H_1). The **Boundary Family** specified is of the **Spending Functions** type. The default **Spending Function** is the **Lan-DeMets** (Lan & DeMets, 1983), with **Parameter** as **OF** (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O'Brien and Fleming (1979). For a detailed description of the different spending functions and stopping boundaries available in East refer to Chapter 62. The cumulative alpha spent and the boundary values are displayed below.

7 Normal Superiority One-Sample

Design Type: **Superiority** Number of Looks: **5** Include Options

Design Parameters **Boundary Info**

Efficacy
 Boundary Family: **Spending Functions**
 Spending Function: **Lan-DeMets**
 Parameter: **OF**
 Type I Error (α): 0.05

Futility
 Boundary Family: **None**

Spacing of Looks: Equal Unequal Efficacy Boundary: **Z Scale**

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|---------------------|-------------------|
| 1 | 0.200 | 0.000 | -4.229 |
| 2 | 0.400 | 0.002 | -2.888 |
| 3 | 0.600 | 0.011 | -2.298 |

| Power | 0.902 | 0.903 |
| Model Parameters | | |
| Std. Deviation (σ) | 2.5 | 2.5 |
| Mean Response under Null (μ_0) | 7 | 7 |
| Mean Response under Alt. (μ_1) | 6 | 6 |
| Test Statistic | Z | Z |
| Boundary Parameters | | |
| Spacing of Looks | | Equal |
| Efficacy Boundary | | LD (OF) |
| Sample Size | | |
| Maximum | 54 | 56 |
| Expected Under H0 | | 55.531 |
| Expected Under H1 | | 39.897 |

Des 2 results in a maximum of 56 subjects in order to attain 90% power, with an expected sample size of 40 under the alternative hypothesis. In order to see the stopping probabilities, double-click Des 2 in the **Library**.

☺ **Stopping Boundaries: Look by Look**

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|------------|---|----------|
| | | | | | Under H0 | Under H1 |
| | | | | Efficacy Z | Efficacy | Efficacy |
| 1 | 0.196 | 11 | 9.767E-6 | -4.27 | 9.767E-6 | 0.002 |
| 2 | 0.393 | 22 | 0.002 | -2.918 | 0.002 | 0.147 |
| 3 | 0.607 | 34 | 0.012 | -2.279 | 0.01 | 0.376 |
| 4 | 0.804 | 45 | 0.029 | -1.958 | 0.017 | 0.25 |
| 5 | 1 | 56 | 0.05 | -1.741 | 0.021 | 0.128 |

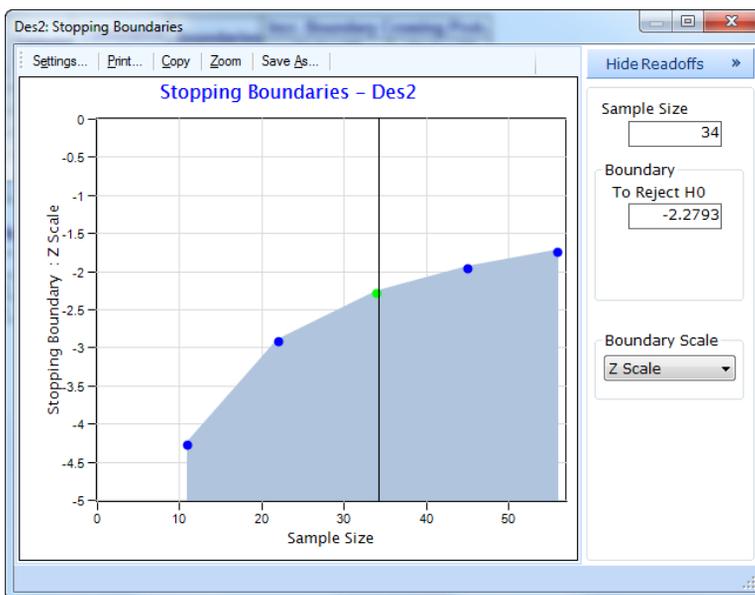

The clear advantage of this sequential design resides in the relatively high cumulative probability of stopping by the third look if the alternative is true, with a sample size of 34 patients, which is well below the requirements for a fixed sample study (54 patients). Close the Output window before continuing.

Examining stopping boundaries and spending functions

You can plot the boundary values of Des 2 by clicking  on the **Library** toolbar,

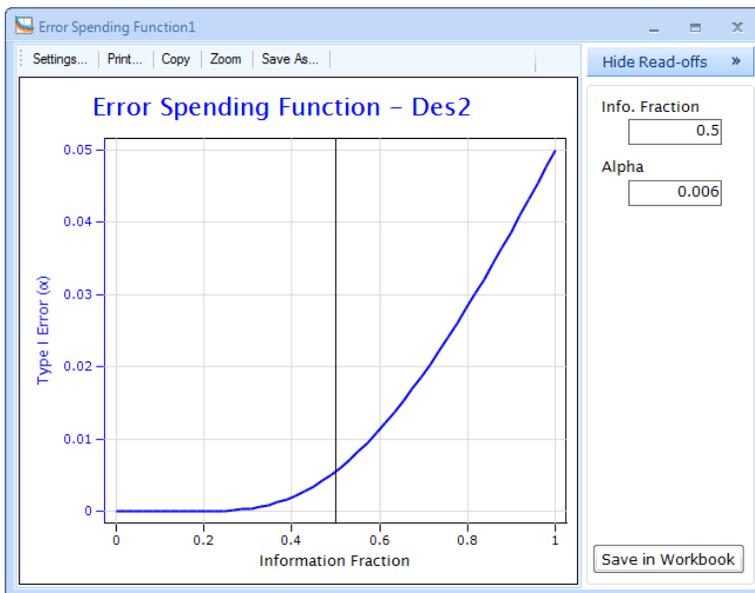

7 Normal Superiority One-Sample

and then clicking **Stopping Boundaries**. The following chart will appear:

You can choose different boundary scales from the drop down box located in the right hand side. The available boundary scales are Z scale, Score Scale, μ/σ Scale and p -value scale. To plot the error spending function for Des 2, select Des 2 in the **Library**, click  in the toolbar, and then click **Error Spending**. The following

chart will appear:

The above spending function is according to Lan and DeMets (1983) with O’Brien-Fleming flavor and for one-sided tests has the following functional form:

$$\alpha(t) = 2 - 2\Phi\left(\frac{Z_{\alpha/2}}{\sqrt{t}}\right)$$

Observe that very little of the total type-1 error is spent early on, but more is spent rapidly as the information fraction increases, and reaches 0.05 at an information fraction of 1. Feel free to try other plots by clicking  in the Library toolbar. Close all charts before continuing.

7.1.2 Simulation

Suppose we want to see the advantages of performing the interim analyses, as it relates to the chance of stopping prior to the final analysis. This examination can be conducted using simulation. Select Des 2 in the **Library**, and click  in the toolbar. Alternatively, right-click on Des 2 and select **Simulate**. A new Simulation window will appear. For example, suppose you wish to determine how quickly this trial could be

7 Normal Superiority One-Sample

terminated if the treatment difference was much greater than expected. For example, under the alternative hypothesis, $\mu = 4.5$. Click on the **Response Generation Info** tab, and specify: **Mean Response**(μ) = 4.5 and **Std. Deviation** (σ) = 2.5.

Test Parameters
Response Generation
Simulation Controls

Specify Mean Response

Mean Response (μ):

Std. Deviation (σ):

Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1.

Select Sim 1 in the **Output Preview** and click . Now double-click on Sim 1 in the **Library**. The simulation output details will be displayed in the upper pane.

⊖ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Count | % |
| | | Lower | Efficacy | | |
| 1 | 11 | -4.27 | Efficacy | 2606 | 26.060% |
| 2 | 22 | -2.918 | Efficacy | 6886 | 68.860% |
| 3 | 34 | -2.279 | Efficacy | 504 | 5.040% |
| 4 | 45 | -1.958 | Efficacy | 4 | 0.040% |
| 5 | 56 | -1.741 | Efficacy | 0 | 0.000% |
| Total | | | Efficacy | 10000 | |
| % | | | Efficacy | 100.000% | |

Observe that 100% simulated trials rejected the null hypothesis, and about 26% of these simulations were able to reject the null at the first look after enrolling only 11 subjects. Your numbers might differ slightly due to a different starting seed.

7.1.3 Interim Monitoring

Suppose that the trial has commenced and Des 2 was implemented. Right-click Des 2 in the **Library**, and select **Interim Monitoring**.

Although we specified that there will be five equally spaced interim looks, the Lan-DeMets methodology implemented in East allows you to alter the number and spacing of these looks. Accordingly, suppose that an interim look was taken after enrolling 20 subjects and the sample mean, based on these 20 subjects, was 5.1 with a standard error of 0.592. Since $\mu_0 = 7$, based on equation (7.1) the value of the test statistic at the first look would be $Z_1 = (5.1 - 7)/0.592$ or -3.209.

Click **Enter Interim Data** on the toolbar. In the **Test Statistic Calculator**, enter the following values, and click **Recalc** and then **OK**.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Cumulative Sample Size: 20

Input for Normal end point

Estimate of μ : 5.1

Standard Error of Estimate of μ : 0.592

Output

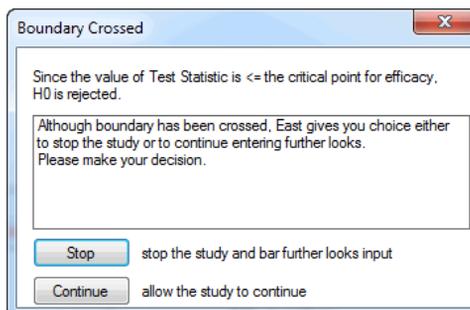

Estimate of $\mu - \mu_0$: -1.9

Test Statistic: -3.209

Recalc OK Cancel

Since the stopping boundary is crossed, the following dialog box appears.

7 Normal Superiority One-Sample

Click **Stop** to take you back to the interim monitoring dashboard. For final inference, East will display the following summary information on the dashboard.

| Final Inference | |
|---|-------|
| Final Outputs at Look # | 1 |
| Adj. p-value | 0.001 |
| Adj. Pt. Est. for μ | 5.1 |
| Adj. 90% CI for μ | |
| Upper Confidence Bound | 6.074 |
| Lower Confidence Bound | 4.126 |
| Post-Hoc Power | |

7.1.4 Trial Design Using a t-Test (Single Look)

The sample size obtained to correctly power Des 1 in Section (7.1.1) relied on using a Wald-type statistic for the hypothesis test, given by equation (7.1). Due to the assumption of normal distribution for the test statistic, we have ignored the fact that the variance σ is estimated from the sample. For large sample sizes this approximation is acceptable. However, in small samples with unknown standard deviation the test statistic

$$Z = n^{1/2}(\hat{\mu} - \mu_0)/\hat{\sigma}, \quad (7.2)$$

is distributed with student's t distribution with $(n - 1)$ degrees of freedom. Here, $\hat{\sigma}^2$ denotes the sample variance based on n observations.

Consider the example in Section 7.1.1 where we would like to test the null hypothesis that the average hospital stay is 7 days, $H_0: \mu = 7 (= \mu_0)$, against the alternative hypothesis that is less than 7 days, $H_1: \mu < 7$. We will now design the same trial in a different manner, using the t distribution for the test statistic.

Right-click Des 1 in the **Library**, and select **Edit Design**. In the input window, change

the **Test Stat.** from **z** to **t**. The entries for the other fields need not be changed.

Click **Compute**. East will add an additional row to the **Output Preview** labeled as Des 3. The required sample size is 55. Select the rows corresponding to Des 1 and Des 3 and click . This will display Des 1 and Des 3 in the **Output Summary**.

| | Des 1 | Des 3 |
|--------------------------------------|-------------|-------------|
| Mnemonic | MN-1S-SM | MN-1S-SM |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 1 | 1 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.902 | 0.9 |
| Model Parameters | | |
| Std. Deviation (σ) | 2.5 | 2.5 |
| Mean Response under Null (μ_0) | 7 | 7 |
| Mean Response under Alt. (μ_1) | 6 | 6 |
| Test Statistic | Z | t |
| Sample Size | | |
| Maximum | 54 | 55 |

Des 3, which uses the t distribution, requires that we commit a combined total of 55 patients to the study, just one more compared to Des 1, which uses the normal distribution. The extra patient is needed to compensate for the extra variability due to estimation of the $\text{var}[\hat{\delta}]$.

7.2 Mean of Paired Differences

7.2.1 Trial Design

7.2.2 Simulation

7.2.3 Interim Monitoring

7.2.4 Trial Design Using a t-Test (Single Look)

The paired t-test is used to compare the means of two normal distributions when each observation in the random sample from one distribution is matched with a unique observation from the other distribution. Let μ_c and μ_t denote the two means to be compared and let σ^2 denote the variance of the differences.

The null hypothesis $H_0: \mu_c = \mu_t$ is tested against the two-sided alternative hypothesis $H_1: \mu_c \neq \mu_t$ or a one-sided alternative hypothesis $H_1: \mu_c < \mu_t$ or $H_1: \mu_c > \mu_t$. Let $\delta = \mu_t - \mu_c$. The null hypothesis can be expressed as $H_0: \delta = 0$ and the alternative can be expressed as $H_1: \delta \neq 0$, $H_1: \delta > 0$, or $H_1: \delta < 0$. The power of the test is computed at specified values of μ_c, μ_t , and σ .

Let $\hat{\mu}_{cj}$ and $\hat{\mu}_{tj}$ denote the estimates of μ_c and μ_t based on n_j observations, up to and including j -th look, $j = 1, \dots, K$ where a maximum of K looks are to be made. The estimate of the difference at the j -th look is

$$\hat{\delta}_j = \hat{\mu}_{tj} - \hat{\mu}_{cj}$$

7 Normal Superiority One-Sample

and the test statistic at the j -th look is

$$Z_j = n_j^{1/2} \hat{\delta}_j / \hat{\sigma}_j, \tag{7.3}$$

where $\hat{\sigma}_j^2$ is the sample variance of n_j paired differences.

7.2.1 Trial Design

Consider the situation where subjects are treated once with placebo after pain is experimentally induced, and later treated with a new analgesic after pain is induced a second time. Pain is reported by the subjects using a 10 cm visual analog scale (0=“no pain”, . . . , 10=“extreme pain”). After treatment with placebo, the average is expected to be 6 cm. After treatment with the analgesic, the average is expected to be 4 cm. It is assumed that the common standard deviation is $\sigma = 5$ cm. The null hypothesis $H_0: \delta = 0$ is tested against the alternative hypothesis $H_1: \delta < 0$.

Start East afresh. First, **Continuous: One Sample** on the **Design** tab, and then click **Paired Design: Mean of Paired Differences**

This will launch a new input window.

Single-Look Design

We want to determine the sample size required to have power of 90% when $\mu_c = 6$ and $\mu_t = 4$, using a test with a one-sided type-1 error rate of 0.05. Select **Test Type** as **1-Sided, Individual Means** for **Input Method**, and specify the **Mean Control** (μ_c) as 6 and **Mean Treatment** (μ_t) as 4. Enter **Std. Dev. of Paired Difference** (σ_D) as 5. The upper pane should appear as below:

Design: Continuous Endpoint: One-Sample Test - Paired Design - Mean of Paired Differences

In the **Output Preview** toolbar select Des 1, click  to save this design to Wbk1 in the **Library**.

Three-Look Design

For the above study, suppose we wish to take up to two equally spaced interim looks and one final look as we accrue data, using the Lan-DeMets (O'Brien-Fleming) stopping boundary. Create a new design by right-clicking Des 1 in the **Library**, and **Edit Design**. In the Input, change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis.

Click **Compute**. The maximum and expected sample sizes are highlighted in yellow in the **Output Preview**. Save this design in the current workbook by selecting the corresponding row in **Output Preview** and clicking  on the **Output Preview** toolbar. To compare Des 1 and Des 2, select both rows in **Output Preview** using the

7 Normal Superiority One-Sample

Ctrl key and click  . Both designs will be displayed in the **Output Summary** pane.

| | Des 1 | Des 2 |

| Expected Under H1 | | 42.646 |

Des 2 results in a maximum of 55 subjects in order to attain 90% power, with an expected sample size of 43 under the alternative hypothesis. In the **Output Preview** toolbar select Des 2, click  to save this design to Wbk1 in the **Library**. In order to see the stopping probabilities, double-click Des 2 in the **Library**.

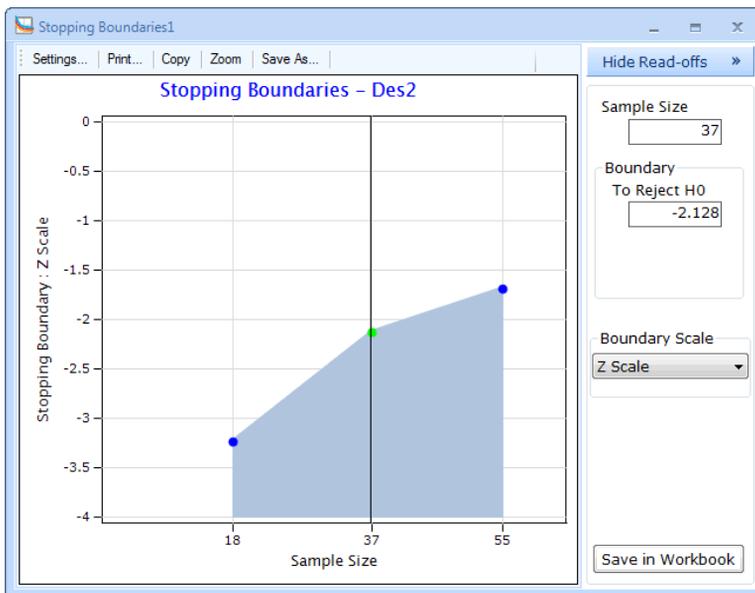

Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|------------|---|----------|
| | | | | | Under H0 | Under H1 |
| | | | | Efficacy Z | Efficacy | Efficacy |
| 1 | 0.327 | 18 | 6.124E-4 | -3.233 | 6.124E-4 | 0.062 |
| 2 | 0.673 | 37 | 0.017 | -2.128 | 0.016 | 0.558 |
| 3 | 1 | 55 | 0.05 | -1.696 | 0.033 | 0.282 |

The clear advantage of this sequential design resides in the high cumulative probability of stopping by the third look if the alternative is true, with a sample size of 37 patients, which is well below the requirements for a fixed sample study (54 patients). Close the Output window before continuing.

Select Des 2 and click  on the Library toolbar. You can select one of many

plots, including one for **Stopping Boundaries**:

Close this chart before continuing.

7.2.2 Simulation

Select Des 2 in the **Library**, and click  in the toolbar. Click on the **Response Generation Info** tab, and make sure **Mean Treatment**(μ_t) = 4, **Mean Control**(μ_c) = 6 and **Std. Deviation** (σ) = 5. Click **Simulate**. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1.

Select Sim 1 in the **Output Preview** and click  . Now double-click on Sim 1 in

7 Normal Superiority One-Sample

the **Library**. The simulation output details will be displayed.

Simulation: Continuous Endpoint: One-Sample Test - Paired Design - Mean of Paired Differences

| 2 | 37 |
| 3 | 55 |
| Average | 41.981 |

Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Count | % |
| | | Lower | Efficacy | | |
| 1 | 18 | -3.233 | 950 | 950 | 9.500% |
| 2 | 37 | -2.128 | 5280 | 5280 | 52.800% |
| 3 | 55 | -1.696 | 2719 | 3770 | 37.700% |
| Total | | | 8949 | 10000 | |
| % | | | 89.490% | | |

Overall, close to 90% of simulations have rejected H_0 . The numbers on your screen might differ slightly due to a different seed.

7.2.3 Interim Monitoring

For an ongoing study we evaluate the test statistic at an interim stage to see whether we have enough evidence to reject H_0 . Right-click Des 2 in the Library, and select **Interim Monitoring**.

Although the design specified that there be three equally spaced interim looks, the Lan-DeMets methodology implemented in East allows you to alter the number and spacing of these looks. Suppose that an interim look was taken after enrolling 18 subjects and the sample mean, based on these subjects, was -2.2 with a standard error of 1.4. Then based on equation (7.3), the value of the test statistic at first look would be $Z_1 = (-2.2)/1.4$ or -1.571.

Click **Enter Interim Data** on the toolbar. In the **Test Statistic Calculator**, enter the

following values, and click **Recalc** and then **OK**.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Cumulative Sample Size:

Input for Normal end point:

Estimate of δ :
 δ = mean of paired difference

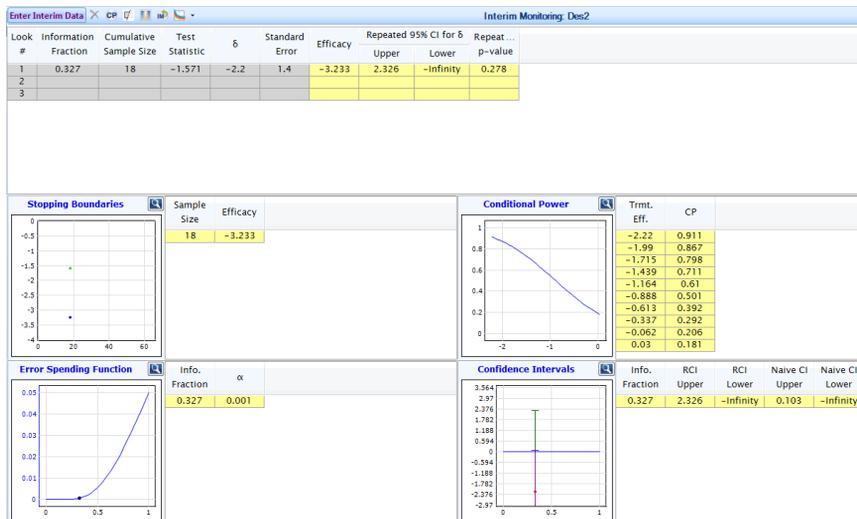

Standard Error of Estimate of δ :

Output:

Test Statistic:

Recalc OK Cancel

The dashboard will be updated accordingly.

As the observed value -1.571 has not crossed the critical boundary value of -3.233, the trial continues. Now, 18 additional subjects are enrolled, and a second interim analysis with 36 subjects is conducted. Suppose that the observed difference is -2.3 with

7 Normal Superiority One-Sample

standard error as 0.8. Select the Look 2 row and click **Enter Interim Data**. Enter these values, and click **Recalc**, and then **OK**.

Test Statistic Calculator

Editing look #2

Set Current Look as Last

Cumulative Sample Size:

Input for Normal end point

Estimate of δ :

δ = mean of paired difference

Standard Error of Estimate of δ :

Output

Test Statistic:

Recalc OK Cancel

Since the stopping boundary is crossed, the following dialog box appears. Click on **Stop**.

Boundary Crossed

Since the value of Test Statistic is \leq the critical point for efficacy, H_0 is rejected.

Although boundary has been crossed, East gives you choice either to stop the study or to continue entering further looks. Please make your decision.

Stop stop the study and bar further looks input

Continue allow the study to continue

For final inference, East will display the following summary information on the dashboard.

| Final Inference | |
|--|--------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0.002 |
| Adj. Pt. Est. for δ | -2.287 |
| Adj. 90% CI for δ | |
| Upper Confidence Bound | -0.959 |
| Lower Confidence Bound | -3.607 |
| Post-Hoc Power | |

7.2.4 Trial Design Using a t-Test (Single Look)

The sample size obtained to correctly power the trial in Section (7.2.1) relied on using a Wald-type statistic for the hypothesis test, given by equation (7.3). However, we neglected the fact that the variance σ is estimated by assuming that the test statistic follows a standard normal distribution. For large sample sizes, asymptotic theory supports this approximation. In a single-look design, this test statistic is calculated as

$$Z = n^{1/2} \hat{\delta} / \hat{\sigma}, \quad (7.4)$$

where $\hat{\sigma}^2$ is the sample variance based on n observed paired differences. In the following calculations we take into consideration that Z follows a Student's t-distribution with $(n - 1)$ degrees of freedom.

Consider the example in Section 7.2.1 where we would like to test the null hypothesis that the analgesic does not reduce pain, $H_0: \delta = 0$, against the alternative hypothesis that the new analgesic works to reduce pain, $H_1: \delta < 0$. We will design this same trial using the t distribution for the test statistic.

Right-click Des 1 from the **Library**, and select **Edit Design**. Change the **Test Stat.** from **Z** to **t**. The entries for the other fields need not be changed, and click **Compute**. East will add an additional row to the **Output Preview** labeled as Des 3. Select the rows corresponding to Des 1 and Des 3. This will display Des 1 and Des 3 in the

7 Normal Superiority One-Sample

Output Summary.

| | Des1 | Des3 |

| Diff. of Means ($\mu_t - \mu_c$) | -2 | -2 |
| Std. Deviation (σ_D) | 5 | 5 |
| Sample Size | | |
| Maximum | 54 | 55 |

Using the t distribution, we need one extra subject to compensate for the extra variability due to estimation of the $\text{var}[\hat{\delta}]$.

7.3 Ratio of Paired Means

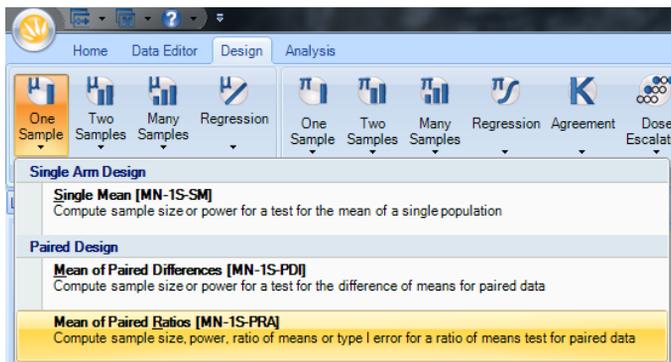

The test for ratio of paired difference is used to compare the means of two log normal distributions when each observation in the random sample from one distribution is matched with a unique observation from the other distribution. Let μ_c and μ_t denote the two means to be compared and let σ_c^2 and σ_t^2 be the respective variances.

The null hypothesis $H_0: \mu_c/\mu_t = 1$ is tested against the two-sided alternative hypothesis $H_1: \mu_c/\mu_t \neq 1$ or a one-sided alternative hypothesis $H_1: \mu_c/\mu_t < 1$ or $H_1: \mu_c/\mu_t > 1$. Let $\rho = \mu_t/\mu_c$. Then the null hypothesis can be expressed as $H_0: \rho = 1$ and the alternative can be expressed as $H_1: \rho \neq 1$, $H_1: \rho > 1$, or $H_1: \rho < 1$. The power of the test is computed at specified values of μ_c , μ_t , and σ . We assume that $\sigma_t/\mu_t = \sigma_c/\mu_c$ i.e., the coefficient of variation (CV) is the same under both control and treatment.

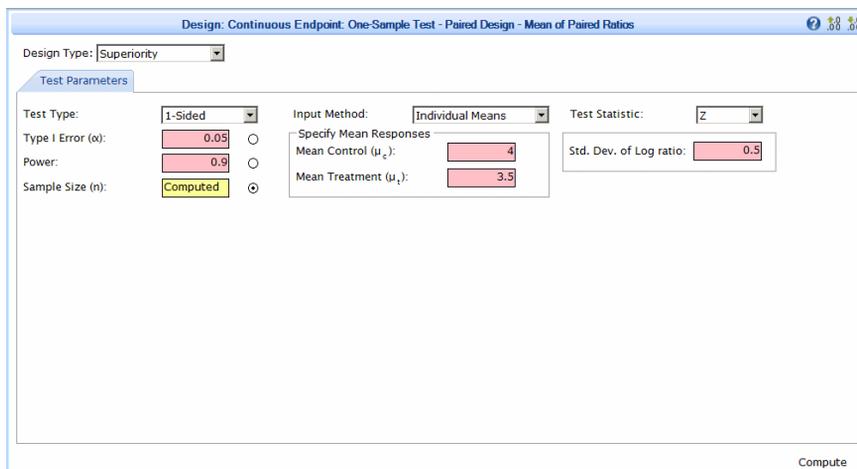

7.3.1 Trial Design

Start East afresh. Click **Continuous: One Sample** on the **Design** tab, and then click

Paired Design: Mean of Paired Ratios as shown below.

This will launch a new window. The upper pane of this window displays several fields with default values. Select **Test Type** as **1-Sided**, and **Individual Means** for **Input Method**. Specify the **Mean Control** (μ_c) as 4 and **Mean Treatment** (μ_t) as 3.5. Enter **Std. Dev. of Log ratio** as 0.5. The upper pane should appear as below:

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview**. The computed sample size is 121 subjects (or pairs of observations).

This design has default name Des 1. In the **Output Preview** toolbar select Des 1, click

7 Normal Superiority One-Sample

to save this design to Wbk1 in the **Library**.

7.3.2 Trial Design Using a t-test

Right-click Des 1 in the **Library** and select **Edit Design**. In the input window, change the **Test Stat.** from **Z** to **t**.

Click **Compute**. East will add an additional row to the **Output Preview** labeled as Des 2. Select the rows corresponding to Des 1 and Des 2 using the Ctrl key and click

. This will display Des 1 and Des 2 in the **Output Summary**.

| | Des 1 | Des 2 |

| Sample Size | | |
| Maximum | 121 | 122 |

Des 2 uses the t distribution and requires that we commit a combined total of 122 patients to the study, one more compared to Des 1, which uses a normal distribution.

8 Normal Noninferiority Paired-Sample

Two common applications of the paired sample design include: (1) comparison of two treatments where patients are matched on demographic and baseline characteristics, and (2) two observations made from the same patient under different experimental conditions. The type of endpoint for paired noninferiority design could be difference of means or ratio of means. The former is presented in Section 8.1 and the latter is discussed in Section 8.2. For paired sample noninferiority trials, East can be used only when no interim look is planned.

8.1 Mean of Paired Differences

8.1.1 Trial Design

8.1.2 Trial Design Using a t-Test (Single Look)

8.1.3 Simulation

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of outcome variable, X, with means μ_t and μ_c , respectively, and with a standard deviation of paired difference as σ_D^2 . Here, the null hypothesis $H_0: \mu_t - \mu_c \leq \delta_0$ is tested against the one-sided alternative hypothesis $H_1: \mu_t - \mu_c > \delta_0$. Here δ_0 denotes the noninferiority margin and $\delta_0 < 0$. Let $\delta = \mu_t - \mu_c$. Then the null hypothesis can be expressed as $H_0: \delta \leq \delta_0$ and the alternative can be expressed as $H_1: \delta > \delta_0$.

Here we assume that the each paired observation on X from T and C are distributed according to a bivariate normal distribution with means as (μ_t, μ_c) , variances as (σ_t^2, σ_c^2) and correlation coefficient as ρ . Let us have N such paired observations from T and C and $\hat{\mu}_c$ and $\hat{\mu}_t$ denote the estimates of μ_c and μ_t based on these N pairs. Therefore, the estimate of the difference is $\hat{\delta} = \hat{\mu}_t - \hat{\mu}_c$. Denoting the standard error of $\hat{\delta}$ by $se(\hat{\delta})$, the test statistic can be defined as

$$Z = \frac{\hat{\delta} - \delta_0}{se(\hat{\delta})} \tag{8.1}$$

The test statistic Z is distributed as a t distribution with $(N - 1)$ degrees of freedom. For large samples, the t-distribution can be approximated by the standard normal distribution. The power of the test is computed at specified values of μ_c, μ_t , and σ_D . East allows you to analyze using both normal and t distribution.

The advantage of the paired sample noninferiority design compared to the two independent sample noninferiority design lies in the smaller $se(\hat{\delta})$ in former case. The paired sample design is more powerful than the two independent sample design: to achieve the same level of power, the paired sample design requires fewer subjects.

8.1.1 Trial Design

Iezzi et. al. (2011) investigated the possibility of reducing radiation dose exposure

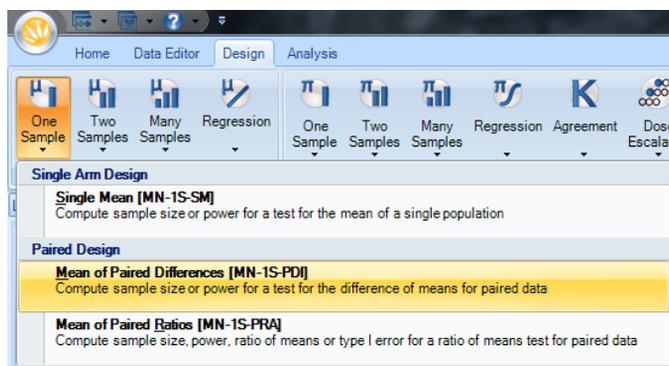

8 Normal Noninferiority Paired-Sample

while maintaining the image quality in a prospective, single center, intra-individual study. In this study, patients underwent two consecutive multidetector computed tomography angiography (MDCTA) scans 6 months apart, one with a standard acquisition protocol (C) and another using a low dose protocol (T). Image quality was rated as an ordinal number using a rating scale ranging from 1 to 5. Let μ_c and μ_t denote the average rating of image quality for standard acquisition and low dose protocol, respectively, and $\delta = \mu_t - \mu_c$ be the difference between two means. Based on the 30 samples included in the study, μ_c and μ_t were estimated as 3.67 and 3.12, respectively. The noninferiority margin for image quality considered was -1 . Accordingly, we will design the study to test

$$H_0 : \delta \leq -1 \quad \text{against} \quad H_1 : \delta > -1$$

The standard deviation of paired difference was estimated as 0.683. We want to design a study with 90% power at $\mu_c = 3.67$ and $\mu_t = 3.12$ and that maintains overall one-sided type I error of 0.025.

First, click **Continuous: One Sample** on the **Design** tab and then click **Paired Design: Mean of Paired Differences** as shown below.

This will launch a new window. Select **Noninferiority** for **Design Type**, and **Individual Means** for **Input Method**. Specify the **Mean Control** (μ_c) as 3.67, **Mean Treatment** (μ_t) as 3.12, and the **Std. Dev. of Paired Difference** (σ_D) as 0.683. Finally, enter -1 for the **Noninferiority Margin** (δ_0). Leave all other entries with their

default values. The upper pane should appear as below:

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (25 subjects) is highlighted.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | Sample Size | Test Statistic | Input Method | μ_c | Mean Treatment (Alt.) | δ_1 | δ_0 | σ_D |
|------|----------------|--------------|-----------|--------------------|-------|-------------|----------------|------------------|---------|-----------------------|------------|------------|------------|
| Des1 | Noninferiority | 1 | 1-Sided | 0.025 | 0.909 | 25 | Z | Individual Means | 3.67 | 3.12 | -0.55 | -1 | 0.683 |

This design has default name Des 1. You can select this design by clicking anywhere along the row in the **Output Preview**. Select this design and click  in the **Output Preview** toolbar. Some of the design details will be displayed in the upper

8 Normal Noninferiority Paired-Sample

pane, labeled as **Output Summary**.

| Des 1 | |
|--------------------------------------|------------------|
| Mnemonic | MN-1S-PDI |
| Test Parameters | |
| Design Type | Noninferiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.909 |
| Model Parameters | |
| Test Statistic | Z |
| Input Method | Individual Means |
| Mean Control (μ_c) | 3.67 |
| Mean Treatment (μ_t) | 3.12 |
| Diff. of Means ($\mu_t - \mu_c$) | -0.55 |
| Noninferiority Margin (δ_0) | -1 |
| Std. Deviation (σ_D) | 0.683 |
| Sample Size | |
| Maximum | 25 |

A total of 25 subjects must be enrolled in order to achieve the desired 90% power under the alternative hypothesis. In the **Output Preview** select Des 1 and click  in the toolbar to save this design to Wbk1 in the **Library**.

The noninferiority margin of -1 considered above is the minimal margin. Since the observed difference is only little less than -0.5 we would like to calculate sample size for a range of noninferiority margins, say, -0.6 , -0.7 , -0.8 , -0.9 and -1 . This can be done easily in East. First select Des 1 in the **Library**, and click  on the **Library** toolbar. In the Input, change the **Noninferiority Margin** (δ_0) $-0.6 : -1 : -0.1$.

Specify Null Hypothesis

Noninferiority Margin (δ_0):

Click **Compute** to generate sample sizes for different noninferiority margins. This will add 5 new rows to the **Output Preview**. There will be a single row for each of the

noninferiority margins.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | Sample Size | Test Statistic | Input Method | μ | Mean Treatment (Alt.) | δ_1 | δ_0 | σ_D |
|------|----------------|--------------|-----------|--------------------|-------|-------------|----------------|------------------|-------|-----------------------|------------|------------|------------|
| Des1 | Noninferiority | 1 | 1-Sided | 0.025 | 0.909 | 25 | Z | Individual Means | 3.67 | 3.12 | -0.55 | -1 | 0.683 |
| Des2 | Noninferiority | 1 | 1-Sided | 0.025 | 0.9 | 1961 | Z | Individual Means | 3.67 | 3.12 | -0.55 | -0.6 | 0.683 |
| Des3 | Noninferiority | 1 | 1-Sided | 0.025 | 0.9 | 218 | Z | Individual Means | 3.67 | 3.12 | -0.55 | -0.7 | 0.683 |
| Des4 | Noninferiority | 1 | 1-Sided | 0.025 | 0.902 | 79 | Z | Individual Means | 3.67 | 3.12 | -0.55 | -0.8 | 0.683 |
| Des5 | Noninferiority | 1 | 1-Sided | 0.025 | 0.907 | 41 | Z | Individual Means | 3.67 | 3.12 | -0.55 | -0.9 | 0.683 |
| Des6 | Noninferiority | 1 | 1-Sided | 0.025 | 0.909 | 25 | Z | Individual Means | 3.67 | 3.12 | -0.55 | -1 | 0.683 |

The computed sample sizes are 1961, 218, 79, 41 and 25 with noninferiority margins -0.60 , -0.7 , -0.8 , -0.9 and -1 , respectively. To compare all 5 designs, select last 5 rows in **Output Preview**, and click . The 5 designs will be displayed in the **Output Summary** pane.

Suppose we have decided to go with Des 3 to test the noninferiority hypothesis with noninferiority margin of -0.7 . This requires a total sample size of 218 to achieve 90% power. Select Des 3 in the **Output Preview** and click in the toolbar to save this design to Wbk1 in the **Library**. Before we proceed we would like to delete all designs from the **Output Preview**. Select all rows and then either click in the toolbar, or click **Delete** after right click. To delete the designs from the workbook in **Library** select the corresponding designs individually (one at a time) and then click **Delete** after right click. You can try deleting Des 1 from the **Library**.

Plotting

With Des 3 selected in the **Library**, click on the **Library** toolbar, and then

8 Normal Noninferiority Paired-Sample

click **Power vs Sample Size**. The resulting power curve for this design will appear.

You can move the vertical bar along the X axis. To find out power at any sample size, move the vertical bar to that sample size and the numerical value of sample size and power will be displayed on the right of the plot. You can export this chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...**. Close this chart before continuing. In a similar fashion one can see power vs delta plot by clicking  and then **Power vs Treatment Effect**.

You can obtain the tables associated with these plot by clicking , and then clicking the appropriate table. Close the plots before continuing.

8.1.2 Trial Design Using a t-Test (Single Look)

The sample size obtained to correctly power Des 3 relied on using a Wald-type statistic for the hypothesis test. Due to the assumption of a normal distribution for the test statistic, we have ignored the fact that the variance σ is estimated from the sample. For large sample sizes, this approximation is acceptable. However, in small samples with unknown standard deviation, the test statistic

$$Z = (\hat{\delta} - \delta_0) / se(\hat{\sigma})$$

is distributed as Student's t distribution with $(n - 1)$ degrees of freedom where n is the

number of paired observations.

Select Des 3 from the **Library**, and click . This will take you to the input window. Now change the **Test Statistic** from **z** to **t**. The entries for the other fields need not be changed.

Click **Compute**. East will add an additional row to the **Output Preview**. The required sample size is 220. This design uses the t distribution and it requires us to commit a combined total of 220 patients to the study, two more compared to Des 3 which uses the normal distribution. The extra couple of patients are needed to compensate for the extra variability due to estimation of the var[$\hat{\delta}$].

8.1.3 Simulation

Select Des 3 in the **Library**, and click  in the toolbar. Alternatively, right-click on Des 3 and select **Simulate**. A new Simulation window will appear. Click on the **Response Generation Info** tab, and specify: **Mean control** = 3.67, **Mean Treatment** = 3.12, and **Std. Deviation of Paired Difference** (σ_D) = 0.683.

| Simulation Parameters | Response Generation Info | Simulation Control Info |
|-----------------------------|-----------------------------------|---|
| Specify Mean Responses | | |
| Mean Control (μ_c): | <input type="text" value="3.67"/> | Std. Dev. of Paired Difference (σ_D): <input type="text" value="0.683"/> |
| Mean Treatment (μ_t): | <input type="text" value="3.12"/> | |

Leave all default values, and click **Simulate**. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1.

Select Sim 1 in the **Output Preview** and click . Double-click Sim 1 in the **Library**, and the simulation output details will be displayed in the right pane under the

8 Normal Noninferiority Paired-Sample

Simulation tab.

Simulation: Continuous Endpoint: One-Sample Test - Paired Design - Mean of Paired Differences

| Simulation Parameters | |
|--------------------------------|----------------|
| Simulation ID | Sim1 |
| Design Type | Noninferiority |
| Number of Looks | 1 |
| Test Type | 1-Sided |
| Sample Size (n) | 218 |
| Noninf. Margin (δ_c) | -0.7 |
| Test Statistic | t |

| | | Efficacy | Stopping For | Count | % |
| 1 | 218 | 1.96 | Efficacy | 10000 | 100.000% |
| Total | | | 233 | 10000 | |
| % | | | 2.330% | | |

The upper efficacy stopping boundary was crossed close to the specified type I error of 2.5%. The exact result of the simulations may differ slightly, depending on the seed.

8.2 Ratio of Paired Means

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of outcome variable, X, with means μ_t and μ_c , respectively, and let σ_t^2 and σ_c^2 denote the respective variances. The null hypothesis $H_0: \mu_t/\mu_c \leq \rho_0$ is tested against the one-sided alternative hypothesis $H_1: \mu_t/\mu_c > \rho_0$. Here, ρ_0 denotes the noninferiority margin and $\rho_0 < 1$. Let $\rho = \mu_t/\mu_c$. Then the null hypothesis can be expressed as $H_0: \rho \leq \rho_0$ and the alternative can be expressed as $H_1: \rho > \rho_0$.

Let us have N such paired observations from T and C and (X_{it}, X_{ic}) denotes the i th pair of observations ($i = 1, \dots, N$). Then $\log X_{it} - \log X_{ic} = \log (X_{it}/X_{ic})$ denotes the logarithm of ratio of means for i th subject. We assume that the paired log-transformed observations on X from T and C, $(\log X_{it}, \log X_{ic})$ are bivariate normally distributed with common parameters. In other words, (X_{it}, X_{ic}) is distributed as bivariate log-normal distribution.

Denote $\log X_{it}$ by y_{it} , $\log X_{ic}$ by y_{ic} , and the corresponding difference by $\delta_{yi} = y_{it} - y_{ic}$. Assume that $\hat{\delta}_y$ denotes the sample mean for these paired differences with estimated standard error $se(\hat{\delta}_y)$. The test statistic can be defined as

$$Z = \frac{\hat{\delta}_y - \log \rho_0}{se(\hat{\delta}_y)}, \tag{8.2}$$

8 Normal Noninferiority Paired-Sample

The test statistic Z is distributed as a t distribution with $(N - 1)$ degrees of freedom. For large samples, the t-distribution can be approximated by the standard normal distribution. East allows you to analyze using both normal and t distribution. The power of the test is computed at specified values of μ_c , μ_t , and σ .

8.2.1 Trial Design

We will use the same example cited in the previous section, but will transform the difference hypothesis into the ratio hypothesis. Let μ_c and μ_t denote the average rating of image quality for standard acquisition and low dose protocol, estimated as 3.67 and 3.12, respectively. Let $\rho = \mu_t/\mu_c$ be the ratio between two means. Considering a noninferiority margin of -0.7 for the test of difference, we can rewrite the hypothesis mentioned in previous section as

$$H_0 : \rho \leq 0.81 \quad \text{against} \quad H_1 : \rho > 0.81$$

We are considering a noninferiority margin of $0.81 (= \rho_0)$. For illustration we will assume the standard deviation of log ratio as 0.20. As before, we want to design a study with 90% power at $\mu_c = 3.67$ and $\mu_t = 3.12$, and maintains overall one-sided type I error of 0.025.

Start East afresh. Click **Continuous: One Sample** on the **Design** tab and then click **Paired Design: Mean of Paired Ratios**.

This will launch a new window. The upper pane of this window displays several fields with default values. Select **Noninferiority** for **Design Type**, and **Individual Means** for **Input Method**. Specify the **Mean Control** (μ_c) as 3.67, **Mean Treatment** (μ_t) as 3.12, and **Noninferiority margin** (ρ_0) as 0.81. Enter 0.20 for **Std. Dev. of Log Ratio**, and 0.025 for **Type I Error** (α). The upper pane now should appear as below:

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (180 subjects) is highlighted in yellow.

| ▲ | ID | Design Type | Test Type | Specified α | Power | Input Method | Sample Size | Test Statistic | μ c | Mean Treatment (Alt.) | ρ 0 | Std Dev Log Ratio |
|---|------|----------------|-----------|--------------------|-------|------------------|-------------|----------------|---------|-----------------------|----------|-------------------|
| ■ | Des1 | Noninferiority | 1-Sided | 0.025 | 0.9 | Individual Means | 180 | Z | 3.67 | 3.12 | 0.81 | 0.2 |

This design has default name Des 1. You can select this design by clicking anywhere along the row in the **Output Preview**. Select this design and click  in the **Output Preview** toolbar. Some of the design details will be displayed in the upper pane, labeled as **Output Summary**.

| Des 1 | |
|-----------------------------------|------------------|
| Mnemonic | MN-15-PRA |
| Test Parameters | |
| Design Type | Noninferiority |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.9 |
| Model Parameters | |
| Mean Control (μ c) | 3.67 |
| Mean Treatment (μ t) | 3.12 |
| Noninferiority Margin (ρ 0) | 0.81 |
| Std.Dev. of Log Ratio | 0.2 |
| Input Method | Individual Means |
| Test Statistic | Z |
| Sample Size | |
| Maximum | 180 |

A total of 180 subjects must be enrolled in order to achieve the desired 90% power under the alternative hypothesis. In the **Output Preview** select Des 1 and click  in the toolbar to save this design to Wbk1 in the **Library**.

Suppose you think enrolling 180 subjects is too much for your organization and you can go up to only 130 subjects. You want to evaluate the power of your study at sample size 130 but with the design parameters remain unaltered. In order to compute power with 130 subjects, first select the Des 1 in the **Library**, and click  on the **Library** toolbar. In the Input dialog box, first select the radiobutton for **Power**, and

8 Normal Noninferiority Paired-Sample

then enter 130 for **Sample Size**.

Design Type: Noninferiority

Design Parameters

Test Type: 1-Sided

Type I Error (α): 0.025

Power: Computed

Sample Size (n): 130

Now click **Compute**. This will add another row labeled as Des 2 in **Output Preview** with computed power highlighted in yellow. The design attains a power of 78.7%.

Now select both the rows in **Output Preview** by pressing the Ctrl key, and click  in the **Output Preview** toolbar to see a summary of both designs in the **Output Summary**.

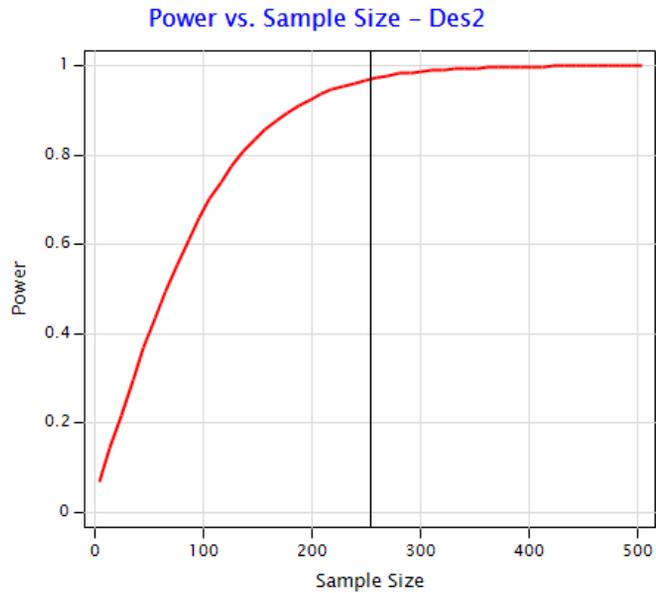

| | Des 1 | Des 2 |
|---------------------------------|------------------|------------------|
| Mnemonic | MN-1S-PRA | MN-1S-PRA |

| Test Statistic | Z | Z |
| Sample Size | | |
| Maximum | 180 | 130 |

In the **Output Preview** select Des 2 and click  in the toolbar to save this design to Wbk1 in the **Library**.

Plotting

With Des 2 selected in the **Library**, click  on the **Library** toolbar, and then click **Power vs Sample Size**. The resulting power curve for this design will appear.

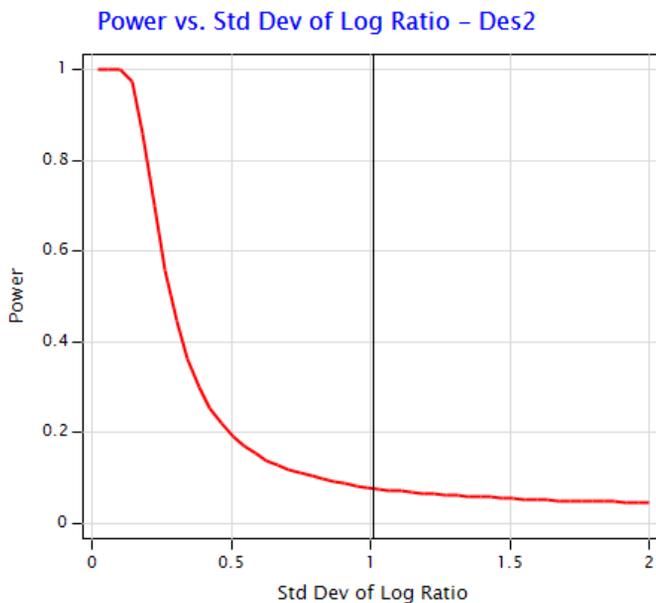

You can move the vertical bar along the X axis.

Suppose you would like to explore the relationship between power and standard deviation. In order to visualize this relationship, select Des 2 in the **Library**, click  on the **Library** toolbar, and then click **General (User Defined Plot)**. Select **Std Dev**

8 Normal Noninferiority Paired-Sample

of **Log Ratio** for **X-Axis**. This will display the power vs. standard deviation plot.

Close the plot window before you continue.

8.2.2 Simulation

Select Des 2 in the **Library**, and click  in the toolbar. Alternatively, right-click on Des 2 and select **Simulate**. A new Simulation window will appear. Click on the **Response Generation Info** tab, and specify: **Mean control** = 3.67, **Mean Treatment** = 3.12, and **Std Dev of Log Ratio** = 0.2.

| Simulation Parameters | Response Generation Info | Simulation Control Info |
|----------------------------|-----------------------------------|---|
| Mean Control(μ_c): | <input type="text" value="3.67"/> | Std Dev. of Log Ratio: <input type="text" value="0.2"/> |
| Mean Treatment(μ_t): | <input type="text" value="3.12"/> | |

Click **Simulate**. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1.

Select Sim 1 in the **Output Preview** and click  . Now double-click on Sim 1 in the **Library**. The simulation output details will be displayed.

Normal Equivalence Paired-Sample

Two common applications of the paired sample designs include: (1) comparison of two treatments where patients are matched on demographic and baseline characteristics, and (2) two observations made from the same patient under different experimental conditions. The type of endpoint for paired equivalence design may be a difference of means or ratio of means. The former is presented in Section 9.1 and the latter is discussed in Section 9.2.

9.1 Mean of Paired Differences

9.1.1 Trial Design

9.1.2 Simulation

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of a outcome variable, X, with means μ_t and μ_c , respectively, and with a standard deviation of paired difference as σ_D^2 . Here, the null hypothesis $H_0: \mu_t - \mu_c < \delta_L$ or $\mu_t - \mu_c > \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L \leq \mu_t - \mu_c \leq \delta_U$. Here, δ_L and δ_U denote the equivalence limits. The two one-sided tests (TOST) procedure of Schuirmann (1987) is commonly used for this analysis.

Let $\delta = \mu_t - \mu_c$ denotes the true difference in the means. The null hypothesis $H_0: \delta \leq \delta_L$ or $\delta \geq \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L < \delta < \delta_U$ at level α , using TOST procedure. Here, we perform the following two tests together:

- Test1: $H_{0L}: \delta \leq \delta_L$ against $H_{1L}: \delta > \delta_L$ at level α
- Test2: $H_{0U}: \delta \geq \delta_U$ against $H_{1U}: \delta < \delta_U$ at level α

H_0 is rejected in favor of H_1 at level α if and only if both H_{0L} and H_{0U} are rejected. Note that this is the same as rejecting H_0 in favor of H_1 at level α if the $(1 - 2\alpha)$ 100% confidence interval for δ is completely contained within the interval (δ_L, δ_U) .

Here we assume that the each paired observation on X from T and C are bivariate normally distributed with parameters $\mu_t, \mu_c, \sigma_t^2, \sigma_c^2$ and ρ . Let us have N such paired observations from T and C, and let $\hat{\mu}_c$ and $\hat{\mu}_t$ denote the estimates of μ_c and μ_t based on these N pairs. The estimate of the difference is $\hat{\delta} = \hat{\mu}_t - \hat{\mu}_c$. Denoting the standard error of $\hat{\delta}$ by $se(\hat{\delta})$, test statistics for Test1 and Test2 are defined as:

$$T_L = \frac{(\hat{\delta} - \delta_L)}{se(\hat{\delta})} \quad \text{and} \quad T_U = \frac{(\hat{\delta} - \delta_U)}{se(\hat{\delta})}$$

T_L and T_U are assumed to follow Student's t-distribution with $(N - 1)$ degrees of freedom under H_{0L} and H_{0U} , respectively. H_{0L} is rejected if $T_L \geq t_{1-\alpha, (N-1)}$, and H_{0U} is rejected if $T_U \leq t_{\alpha, (N-1)}$.

The null hypothesis H_0 is rejected in favor of H_1 if $T_L \geq t_{1-\alpha, (N-1)}$ and $T_U \leq t_{\alpha, (N-1)}$, or in terms of confidence intervals: Reject H_0 in favor of H_1 at level α if

$$\delta_L + t_{1-\alpha, (N-1)} se(\hat{\delta}) < \hat{\delta} < \delta_U + t_{\alpha, (N-1)} se(\hat{\delta}) \quad (9.1)$$

We see that decision rule (9.1) is the same as rejecting H_0 in favor of H_1 if the $(1 - 2\alpha)$ 100% confidence interval for δ is entirely contained within interval (δ_L, δ_U) .

The power or sample size of such a trial design is determined for a specified value of δ , say δ_1 , for a single-look study only. The choice $\delta_1 = 0$, i.e. $\mu_t = \mu_c$, is common. For a specified value of δ_1 , the power is given by

$$\Pr(\text{Reject } H_0) = 1 - \tau_\nu(t_{\alpha, \nu} | \Omega_1) + \tau_\nu(-t_{\alpha, \nu} | \Omega_2) \quad (9.2)$$

where $\nu = N - 1$ and Ω_1 and Ω_2 are non-centrality parameters given by $\Omega_1 = (\delta_1 - \delta_L) / se(\hat{\delta})$ and $\Omega_2 = (\delta_1 - \delta_U) / se(\hat{\delta})$, respectively. $t_{\alpha, \nu}$ denotes the upper $\alpha \times 100\%$ percentile from a Student's t distribution with ν degrees of freedom. $\tau_\nu(x | \Omega)$ denotes the distribution function of a non-central t distribution with ν degrees of freedom and non-centrality parameter Ω , evaluated at x .

Since the sample size N is not known ahead of time, we cannot characterize the bivariate t -distribution. Thus, solving for sample size must be performed iteratively by equating the formula (9.2) to the power $1 - \beta$.

The advantage of the paired sample equivalence design compared to the two sample equivalence design lies in the smaller $se(\hat{\delta})$ in former case. The paired sample equivalence design is more powerful than the two sample equivalence design: to achieve the same level of power, the paired sample equivalence design requires fewer subjects.

9.1.1 Trial Design

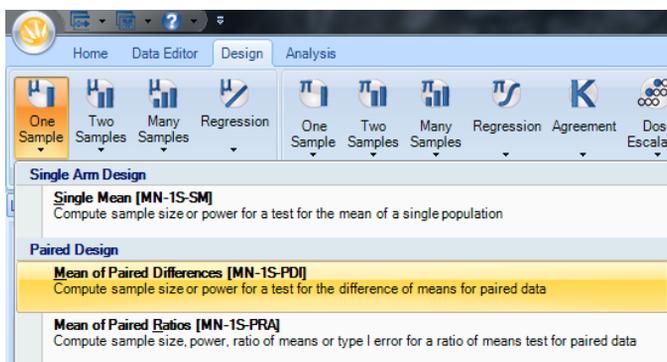

To ensure that comparable results can be achieved between two laboratories or methods, it is important to conduct cross-validation or comparability studies to establish statistical equivalence between the two laboratories or methods. Often, to establish equivalence between two laboratories, a paired sample design is employed. Feng et al. (2006) reported the data on 12 quality control (QC) samples. Each sample was analyzed first by Lab1 and then by Lab2. In this example we will consider Lab1 as the standard laboratory (C) and Lab2 is the one to be validated (T). Denote the mean concentrations from Lab1 and Lab2 by μ_c and μ_t , respectively. Considering an equivalence limit of $(-10, 10)$ we can state our hypotheses as:

$$H_0: \mu_t - \mu_c < -10 \text{ or } \mu_t - \mu_c > 10 \text{ against } H_1: -10 \leq \mu_t - \mu_c \leq 10$$

9 Normal Equivalence Paired-Sample

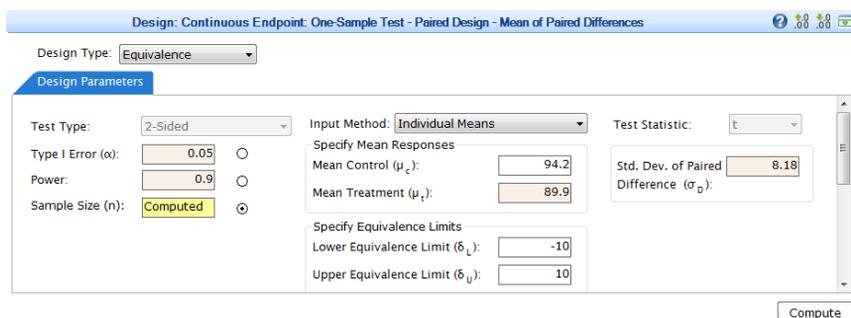

Based on the reported data μ_c and μ_t are estimated as 94.2 pg mL^{-1} and 89.9 pg mL^{-1} , respectively. The standard deviation of paired difference was estimated as 8.18. We want to design a study with 90% power at $\mu_c = 94.2$ and $\mu_t = 89.9$. We want to reject H_0 with type I error not exceeding 0.025.

First, click **Continuous: One Sample** on the **Design** tab, and then click **Paired Design: Mean of Paired Differences** as shown below.

This will launch a new window.

Since we are interested in testing an equivalence hypothesis select **Equivalence** for **Trial Type**, with an **Type I Error** of 0.025, and **Power** of 0.9. Select **Individual Means** for **Input Method**. Enter -10 for **Lower Equivalence Limit** (δ_L) and 10 for **Upper Equivalence Limit** (δ_U). Specify the **Mean Control** (μ_c) as 94.2, **Mean Treatment** (μ_t) as 89.9, and **Std. Dev. of Paired Difference** (σ_D) as 8.18. The upper pane should appear as below:

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (20 samples) is highlighted in yellow.

| ▲ | ID | Design Type | Test Type | Specified α | Power | Sample Size | Test Statistic | Input Method | μ_c | Mean Treatment (Alt.) | δ_L | δ_U | δ_U | σ_D |
|---|------|-------------|-----------|--------------------|-------|-------------|----------------|------------------|---------|-----------------------|------------|------------|------------|------------|
| ■ | Des1 | Equivalence | 2-Sided | 0.05 | 0.913 | 20 | t | Individual Means | 94.2 | 89.9 | -4.3 | -10 | 10 | 8.18 |

This design has default name Des 1 and you can select this design by clicking anywhere along the row in the **Output Preview** and then clicking  in the **Output Preview** toolbar. Some of the design details will be displayed in the upper pane, labeled as **Output Summary**.

| Output Summary | |
|--|------------------|
| | Des 1 |
| Mnemonic | MN-15-PDI |
| Test Parameters | |
| Design Type | Equivalence |
| No. of Looks | 1 |
| Test Type | 2-Sided |
| Specified α | 0.05 |
| Power | 0.913 |
| Model Parameters | |
| Test Statistic | t |
| Input Method | Individual Means |
| Mean Control (μ_c) | 94.2 |
| Mean Treatment (μ_t) | 89.9 |
| Diff. of Means ($\mu_t - \mu_c$) | -4.3 |
| Equivalence Lower Limit (δ_L) | -10 |
| Equivalence Upper Limit (δ_U) | 10 |
| Std. Deviation (σ_D) | 8.18 |
| Sample Size | |
| Maximum | 20 |

A total of 20 samples is required to achieve the desired 90% power under the alternative hypothesis. In the **Output Preview** select Des 1 and click  in the toolbar to save this design to Wbk1 in the **Library**.

The equivalence limits of $(-10, 10)$ might be too narrow and therefore a wider equivalence interval $(-12.5, 12.5)$ could be considered. Select Des 1 in the **Library**, and click  on the **Library** toolbar. In the **Design Parameters** tab, change the entry for **Lower Equivalence Limit (δ_L)** and **Upper Equivalence Limit (δ_U)** to -12.5 and 12.5 , respectively, and click **Compute**.

This will add a new row in the **Output Preview** labeled as Des 2. In the **Output**

9 Normal Equivalence Paired-Sample

Preview select Des 2 and click  in the toolbar to save this design to Wbk1 in the **Library**. To compare the two designs, select both rows in **Output Preview** using the Ctrl key and click  in the **Output Preview** toolbar. This will display the two designs side by side in the **Output Summary** pane.

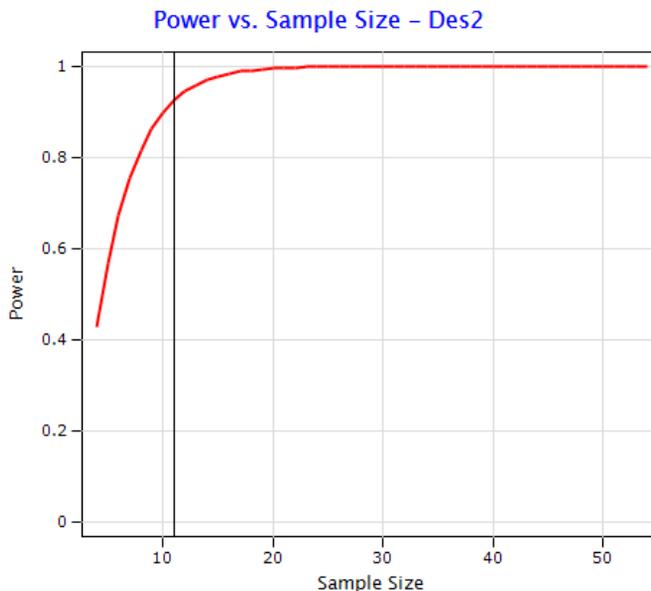

| | Des 1 | Des 2 |
|--|------------------|------------------|
| Mnemonic | MN-1S-PDI | MN-1S-PDI |
| Test Parameters | | |
| Design Type | Equivalence | Equivalence |
| No. of Looks | 1 | 1 |
| Test Type | 2-Sided | 2-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.913 | 0.926 |
| Model Parameters | | |
| Test Statistic | t | t |
| Input Method | Individual Means | Individual Means |
| Mean Control (μ_C) | 94.2 | 94.2 |
| Mean Treatment (μ_T) | 89.9 | 89.9 |
| Diff. of Means ($\mu_T - \mu_C$) | -4.3 | -4.3 |
| Equivalence Lower Limit (δ_L) | -10 | -12.5 |
| Equivalence Upper Limit (δ_U) | 10 | 12.5 |
| Std. Deviation (σ_D) | 8.18 | 8.18 |
| Sample Size | | |
| Maximum | 20 | 11 |

As we widen the equivalence limit from $(-10, 10)$ to $(-12.5, 12.5)$, the required sample size is reduced from 20 to 11.

Plotting

We would like to explore how power is related to the required sample size. Select Des 2 in the **Library**, click  on the **Library** toolbar, and then click **Power vs**

Sample Size. The resulting power curve for this design will appear.

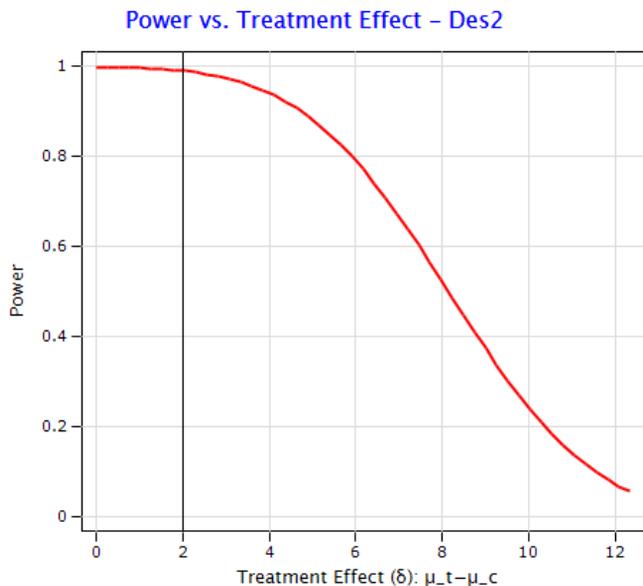

You can move the vertical bar along the X axis. To find out power at any sample size simply move the vertical bar to that sample size and the numerical value of sample size and power will be displayed on the right of the plot. You can export this chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...** Close this chart before continuing.

In a similar fashion one can see power vs delta plot by clicking  and then

9 Normal Equivalence Paired-Sample

Power vs Treatment Effect.

To produce tables associated with these plots, first click  in the toolbar and then select the appropriate table.

9.1.2 Simulation

Now we wish to simulate from Des 2 to verify whether the study truly maintains the power and type I error. Select Des 2 in the **Library**, and click  in the toolbar. Alternatively, right-click on Des 2 and select **Simulate**. Click on the **Response Generation Info** tab, and specify: **Mean control** = 94.2, **Mean Treatment** = 89.9, and **Std. Dev. of Paired Difference** (σ_D) = 8.18.

| Simulation Parameters | Response Generation Info | Simulation Control Info |
|-----------------------------|--|-----------------------------------|
| Specify Mean Responses | | |
| Mean Control (μ_c): | <input type="text" value="94.2"/> | |
| Mean Treatment (μ_t): | <input type="text" value="89.9"/> | |
| | Std. Dev. of Paired Difference (σ_D): | <input type="text" value="8.18"/> |

Click **Simulate**. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1.

Select Sim 1 in the **Output Preview** and click  icon. Now double-click on Sim 1 in the **Library**. The simulation output details will be displayed.

Simulation: Continuous Endpoint: One-Sample Test - Paired Design - Mean of Paired Differences

| Simulation Parameters | |

| Total | | | | 9275 | 0 | 10000 | |
| % | | | | 92.750% | 0.000% | | |

Notice that the simulated power is close to the attained power of 92.6% for Des 2. The exact result of the simulations may differ slightly, depending on the seed.

Now we wish to simulate from a point that belongs to H_0 to check whether the chosen design maintains type I error of 5% or not. For this we consider, $\mu_c = 94.2$ and $\mu_t = 81.7$. Since in this case $\delta = 81.7 - 94.2 = -12.5$, this $(\mu_t, \mu_c) = (81.7, 94.2)$ point belongs to H_0 . Right-click on Sim 1 in the **Library** and select **Edit Simulation**. Go to the **Response Generation Info** tab in the upper pane and specify: **Mean control** = 94.2, **Mean Treatment** = 81.7, and **Std. Dev. of Paired Difference** (σ_D) = 8.18.

| Total | | | | 508 | 0 | 10000 | |
| % | | | | 5.080% | 0.000% | | |

Notice that the simulated power here is close to the pre-set type I error of 5%. The exact result of the simulations may differ slightly, depending on the seed.

9.2 Ratio of Paired Means

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of a outcome variable, X, with means μ_t and μ_c , respectively, and let σ_t^2 and σ_c^2 denote the respective variances. Here, the null hypothesis $H_0: \mu_t/\mu_c \leq \rho_L$ or $\mu_t/\mu_c \geq \rho_U$ is tested against the alternative hypothesis $H_1: \rho_L < \mu_t/\mu_c < \rho_U$. Let $\rho = \mu_t/\mu_c$ denotes the ratio of two means. Then the null hypothesis can be expressed as $H_0: \rho \leq \rho_L$ or $\rho \geq \rho_U$ and the alternative can be expressed as $H_1: \rho_L < \rho < \rho_U$. In practice, ρ_L and ρ_U are often chosen such that $\rho_L = 1/\rho_U$. The two one-sided tests (TOST) procedure of Schuirmann (1987) is commonly used for this analysis, and is employed in this section for a parallel-group study.

Let us have N such paired observation from T and C and (X_{it}, X_{ic}) denotes the i th pair of observations ($i = 1, \dots, N$). Then $\log X_{it} - \log X_{ic} = \log (X_{it}/X_{ic})$ denotes the logarithm of ratio of means for the i th subject. Here we assume that the each paired log-transformed observations on X from T and C, $(\log X_{it}, \log X_{ic})$ are bivariate normally distributed with common parameters. In other words, (X_{it}, X_{ic}) is distributed as a bivariate log-normal distribution.

Since we have translated the ratio hypothesis into a difference hypothesis using the log transformation, we can perform the test for difference as discussed in section 9.1. Note that we need the standard deviation of log of ratios. Sometimes, we are provided with information on coefficient of variation (CV) of ratios instead, and the standard

deviation of log ratios can be obtained using: $sd = \sqrt{\ln(1 + CV^2)}$.

This is a test for the comparison of geometric means of ratio, as we are taking the mean of the logarithms of ratios.

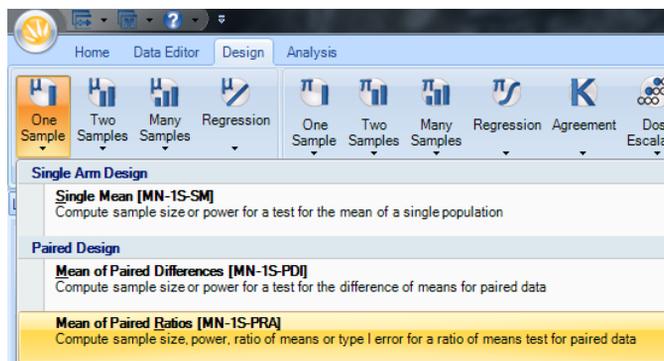

9.2.1 Trial Design

Here we will use the same example reported by Feng et al (2006). Denote the mean concentrations from Lab1 and Lab2 by μ_c and μ_t , and $\rho = \mu_t/\mu_c$ is the ratio between two means. Considering an equivalence limit of (0.85, 1.15) we can state our hypotheses as

$$H_0: \mu_t/\mu_c < 0.85 \text{ or } \mu_t/\mu_c > 1.15 \text{ against } H_1: 0.85 \leq \mu_t/\mu_c \leq 1.15$$

Based on the reported data, μ_c and μ_t are estimated as 94.2 pg mL⁻¹ and 89.9 pg mL⁻¹, respectively. Assume that the standard deviation of log ratio can be estimated is 0.086. As before, we want to design a study with 90% power at $\mu_c = 94.2$ and $\mu_t = 89.9$. We want to reject H_0 with type I error not exceeding 0.025.

Start East afresh. First, click **Continuous: One Sample** on the **Design** tab and then click **Paired Design: Mean of Paired Ratios** as shown below.

This will launch a new window.

Select **Equivalence** for **Trial Type**, and enter 0.025 for **Type I Error**, and 0.9 for **Power**. Then select **Individual Means** for **Input Method**, and enter the **Mean Control** (μ_c) as 94.2, **Mean Treatment** (μ_t) as 89.9, and **Std. Dev. of Log Ratio** as 0.086. Enter 0.85 for **Lower Equiv. Limit** (ρ_L) and 1.15 for **Upper Equiv. Limit**

9 Normal Equivalence Paired-Sample

(ρ_U). The upper pane should appear as below:

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (8 samples) is highlighted in yellow.

| ID | Design Type | Test Type | Specified α | Power | Input Method | Sample Size | Test Statistic | μ_C | Mean Treatment (Alt.) | ρ_L | ρ_U | Std Dev Log Ratio |
|------|-------------|-----------|--------------------|-------|------------------|-------------|----------------|---------|-----------------------|----------|----------|-------------------|
| Des1 | Equivalence | 2-Sided | 0.025 | 0.901 | Individual Means | 8 | t | 94.2 | 89.9 | 0.85 | 1.15 | 0.086 |

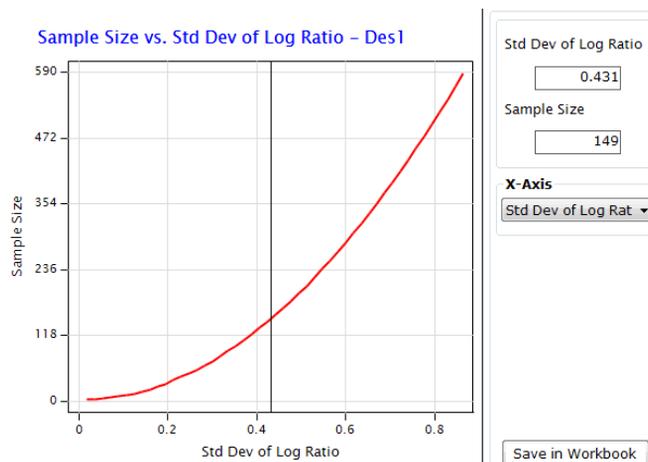

This design has default name Des 1. Select this design and click  in the **Output Preview** toolbar. Some of the design details will be displayed in the upper pane, labeled as **Output Summary**.

| Des1 | |
|--------------------------------------|------------------|
| Mnemonic | MN-1S-PRA |
| Test Parameters | |
| Design Type | Equivalence |
| Test Type | 2-Sided |
| Specified α | 0.025 |
| Power | 0.901 |
| Model Parameters | |
| Mean Control (μ_C) | 94.2 |
| Mean Treatment (μ_T) | 89.9 |
| Equivalence Lower Limit (ρ_L) | 0.85 |
| Equivalence Upper Limit (ρ_U) | 1.15 |
| Std.Dev. of Log Ratio | 0.086 |
| Input Method | Individual Means |
| Test Statistic | t |
| Sample Size | |
| Maximum | 8 |

In the **Output Preview** select Des 1 and click  in the toolbar to save this design to Wbk1 in the **Library**.

Plotting

Suppose you want to see how the standard deviation influences the sample size. In order to visualize this relationship, select Des 1 in the **Library**, click  on the **Library** toolbar, and then click **General (User Defined Plot)**. Select **Std Dev of Log Ratio** for **X-Axis** in right of the plot. This will display the sample size vs. standard deviation plot.

Close this plot before continuing.

9.2.2 Simulation

Now we want to check by simulation whether the sample size of 8 provides at least 90% power. Select Des 1 in the **Library**, and click  in the toolbar. Click on the **Response Generation Info** tab, and specify: **Mean control** = 94.2, **Mean Treatment** = 89.9, and **Std Dev. of Log Ratio**= 0.086.

| Simulation Parameters | Response Generation Info | Simulation Control Info |
|----------------------------|--------------------------|------------------------------|
| Mean Control(μ_c): | 94.2 | Std Dev. of Log Ratio: 0.086 |
| Mean Treatment(μ_t): | 89.9 | |

9 Normal Equivalence Paired-Sample

Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1. Notice that the simulated power is very close to the design power.

| ▲ | ID | Design Type | Test Type | Specified α | Power | Input Method | Sample Size | Test Statistic | μ c | Mean Treatment (Alt.) | ρ L | ρ U | Std Dev Log Ratio |
|---|-------|-------------|-----------|--------------------|-------|------------------|-------------|----------------|---------|-----------------------|----------|----------|-------------------|
| # | Des 1 | Equivalence | 2-Sided | 0.025 | 0.901 | Individual Means | 8 | t | 94.2 | 89.9 | 0.85 | 1.15 | 0.086 |
| # | Sim 1 | Equivalence | 2-Sided | | 0.902 | | | t | 94.2 | 89.9 | 0.85 | 1.15 | 0.086 |

10 Normal Superiority Two-Sample

To demonstrate the superiority of a new treatment over the control, it is often necessary to randomize subjects to the control and treatment arms, and contrast the group-dependent means of the outcome variables. In this chapter, we show how East supports the design and interim monitoring of such experiments.

10.1 Difference of Means

10.1.1 Trial Design (Weight

Control Trial of Orlistat)

10.1.2 IM of the Orlistat trial

10.1.3 t-Test Design

Consider a randomized clinical trial comparing an experimental treatment, T, to a control treatment, C, on the basis of a normally distributed outcome variable, X , with means μ_t and μ_c , respectively, and with a common variance σ^2 . We intend to monitor the data up to K times after accruing $n_1, n_2, \dots, n_K \equiv n_{\max}$ patients. The information fraction at the j th look is given by $t_j = n_j/n_{\max}$. Let r denote the fraction randomized to treatment T.

Define the treatment difference to be

$$\delta = \mu_t - \mu_c .$$

The null hypothesis of interest is

$$H_0 : \delta = 0 .$$

We wish to construct a K -look group sequential level α test of H_0 having $1 - \beta$ power at the alternative hypothesis

$$H_1 : \delta = \delta_1 .$$

Let $\bar{X}_t(t_j)$ and $\bar{X}_c(t_j)$ be the mean responses of the experimental and control groups, respectively, at time t_j . Then

$$\hat{\delta}(t_j) = \bar{X}_t(t_j) - \bar{X}_c(t_j) \tag{10.1}$$

and

$$\text{var}[\hat{\delta}(t_j)] = \frac{\sigma^2}{n_j r(1-r)} . \tag{10.2}$$

Therefore, by the Scharfstein, Tsiatis and Robins (1997), Jennison and Turnbull (1997) theorem the stochastic process

$$W(t_j) = \sqrt{t_j} \frac{\bar{X}_t(t_j) - \bar{X}_c(t_j)}{\sqrt{\frac{\sigma^2}{n_j r(1-r)}}}, \quad j = 1, 2, \dots, K, \tag{10.3}$$

is $N(\eta t_j, t_j)$ with independent increments, where $\eta = 0$ under H_0 and $\eta = \delta_1 \sqrt{I_{\max}}$ under H_1 . We refer to η as the drift parameter.

10 Normal Superiority Two-Sample

10.1.1 Trial Design (Weight Control Trial of Orlistat)

Eighteen U.S. research centers participated in this trial, where obese adults were randomized to receive either Orlistat or placebo, combined with a dietary intervention for a period of two years (Davidson et al, 1999). Orlistat is an inhibitor of fat absorption, and the trial was intended to study its effectiveness in promoting weight loss and reduce cardiovascular risk factors. The study began in October 1992. More than one outcome measure was of interest, but we shall consider only body weight changes between baseline and the end of the first year intervention. We shall consider a group sequential design even though the original study was not intended as such. The published report does not give details concerning the treatment effect of interest or the desired significance level and power of the test. It does say, however, that 75% of subjects had been randomized to the Orlistat arm, probably to maximize the number of subjects receiving the active treatment.

Single-Look Design Suppose that the expected mean body weight change after one year of treatment was 9 kg in the Orlistat arm and 6 kg in the control arm. Assume also that the common standard deviation of the observations (weight change) was 8 kg. The standardized difference of interest would therefore be $(9 - 6)/8 = 0.375$. We shall consider a one sided test with 5% significance level and 90% power, and an allocation ratio (treatment:control) of 3:1; that is, 75% of the patients are randomized to the Treatment (Orlistat) arm.

First, click **Continuous: Two Samples** on the **Design** tab, and then click **Parallel Design: Difference of Means**.

In the upper pane of this window is the Input dialog box, which displays default input values. The effect size can be specified in one of three ways, selected from **Input Method**: (1) individual means and common standard deviation, (2) difference of means and common standard deviation, or (3) standardized difference of means. We will use the **Individual Means** method. Enter the appropriate design parameters so that the dialog box appears as shown. Remember to set the **Allocation Ratio** to 3.

Then click **Compute**.

The design is shown as a row in the **Output Preview**, located in the lower pane of this window. The computed sample size is 325 subjects.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | Input Method | δ | μ_c | Mean Treatment (Alt.) | σ | Test Statistic |
|------|-------------|--------------|-----------|--------------------|-------|-------|-------------|------------------|----------|---------|-----------------------|----------|----------------|
| Des1 | Superiority | 1 | 1-Sided | 0.05 | 0.9 | 3 | 325 | Individual Means | 3 | 6 | 9 | 8 | Z |

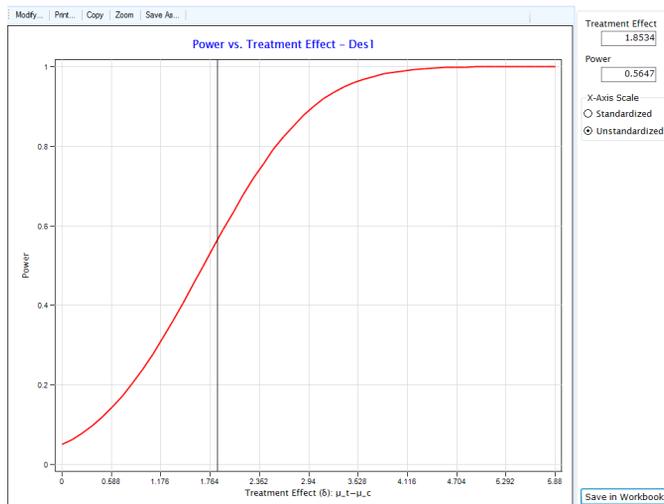

You can select this design by clicking anywhere along the row in the **Output Preview**.

On the **Output Preview** toolbar, click  to display a summary of the design details in the upper pane. Then, in the **Output Preview** toolbar, click  to save this design to Wbk1 in the **Library**. If you hover the cursor over Des1 in the **Library**, a tooltip will appear that summarizes the input parameters of the design.

With Des1 selected in the **Library**, click  on the **Library** toolbar, and then click **Power vs Treatment Effect (δ)**. The resulting power curve for this design is shown. You can save this chart to the **Library** by clicking **Save in Workbook**. You can also export the chart in one of several image formats (e.g., Bitmap or JPEG) by

10 Normal Superiority Two-Sample

clicking **Save As...** For now, you may close the chart before continuing.

Three-Look Design Create a new design by selecting Des1 in the **Library**, and clicking  on the **Library** toolbar, or by right-clicking and selecting **Edit Design**. In the Input, change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab for **Boundary Info** should appear. Click this tab to reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. By default, there is an efficacy boundary (to reject H_0) selected, but no futility boundary (to reject H_1). The **Boundary Family** specified is of the **Spending Functions** type. The default **Spending Function** is the **Lan-DeMets** (Lan & DeMets, 1983), with **Parameter OF** (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O'Brien and Fleming (1979).

The cumulative alpha spent, and the boundary values, are displayed in the table below.

Design Type: Superiority Number of Looks: 3

Design Parameters **Boundary Info**

| Efficacy Boundary | | LD (OF) |
| Spacing of Looks | | Equal |
| Sample Size | | |
| Maximum | 325 | 331 |
| Expected Under H ₀ | | 329.115 |
| Expected Under H ₁ | | 256.591 |

The price to be paid for multiple looks is the commitment of a higher maximum sample size (331 patients) compared to that of a single-look design (325 patients). However, if the alternative hypothesis *H*₁ holds, the study has a chance of stopping at one of the two interim analyses and saving patient accrual: on average, Des2 will stop

10 Normal Superiority Two-Sample

with 257 patients if the alternative is true. The expected sample size under the null is 329, less than the maximum since there is a small probability of stopping before the last look and, wrongly, rejecting the null.

With Des2 selected in the **Output Preview**, click  to save Des2 to the **Library**. In order to see the stopping probabilities, as well as other characteristics, double-click Des2 in the **Library**. The clear advantage of this sequential design resides in the high probability of stopping by the second look, if the alternative is true, with a sample size of 221 patients, which is well below the requirements for a fixed sample study (325 patients). Even under the null, however, there is a small chance for the test statistic to cross the boundary for its early rejection (type-1 error probability) at the first or second look. Close the Details window before continuing.

Examining stopping boundaries and spending functions

Plot the boundary values of Des2 by clicking  on the **Library** toolbar, and then

selecting **Stopping Boundaries**. The following chart will appear:

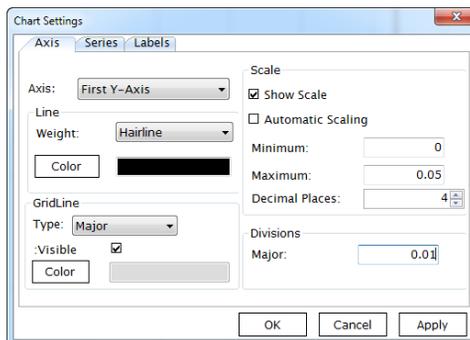

The three solid dots correspond to the actual boundary values to be used at the three planned analyses. Although the three looks are assumed to be equally spaced at design time, this assumption need not hold at analysis time. Values of the test-statistic (z-test) greater than the upper boundary values would warrant early stopping in favor of H_1 , that Orlistat is better than placebo. The horizontal axis expresses the total number of patients at each of the three analysis time-points. The study is designed so that the last analysis time point coincides with the maximum sample size required for the chosen design, namely 331 patients. By moving the vertical line cursor from left to right, one can observe the actual values of the stopping boundaries at each interim analysis time-point. The boundaries are rather conservative: for example, you would need the standardized test statistic to exceed 2.139 in order to stop the trial at the second look.

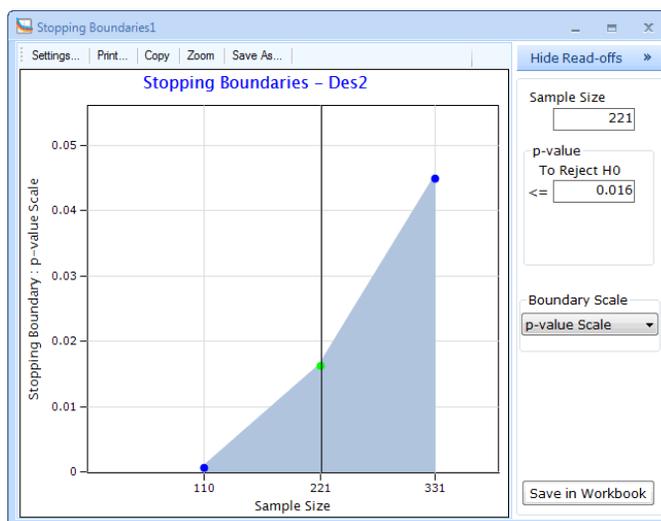

It is sometimes convenient to display the stopping boundaries on the p-value scale. Under **Boundary Scale**, select the **p-value Scale**. The chart now displays the cumulative number of patients on the X-axis and the nominal p-value (1-sided) that we would need in order to stop the trial at that interim look. To change the scale of this chart, click **Settings...** and in the **Chart Settings** dialog box, change the **Maximum** to

10 Normal Superiority Two-Sample

0.05, and the **Divisions: Major** to 0.01, and click **OK**.

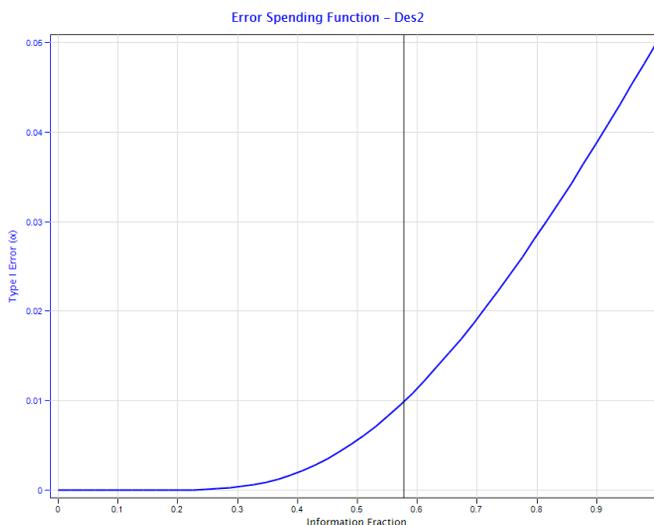

The following chart will be displayed.

For example, at the second look, after 221 subjects have been observed, we require a p-value smaller than 0.016 in order to stop the study. Notice that the p-value at the 3rd and final look needs to be smaller than 0.045, rather than the usual 0.05 that one would require for a single-look study. This is the penalty we pay for the privilege of taking three looks at the data instead of one. You may like to display the boundaries in the delta scale. In this scale, the boundaries are expressed in units of the effect size, or the difference in means. We need to observe a difference in average weight loss of 2.658

kg or more, in order to cross the boundary at the second look.

Close these charts, and click  and then **Error Spending**. The following chart will appear.

This spending function was proposed by Lan and DeMets (1983), and for one-sided tests has the following functional form:

$$\alpha(t) = 2 - 2\Phi\left(\frac{Z_{\alpha/2}}{\sqrt{t}}\right). \tag{10.4}$$

Observe that very little of the total type-1 error is spent early on, but more is spent rapidly as the information fraction increases, and reaches 0.05 at an information fraction of 1. A recursive method for generating stopping boundaries from spending functions is described in the Appendix G. Close this chart before continuing.

Lan and DeMets (1983) also provided a function for spending the type-1 error more aggressively. This spending function is denoted by **PK**, signifying that it is the Lan-DeMets spending function for generating stopping boundaries that closely resemble the classical Pocock (1977) stopping boundaries. It has the functional form:

$$\alpha(t) = \alpha \ln[1 + (e - 1)t] \tag{10.5}$$

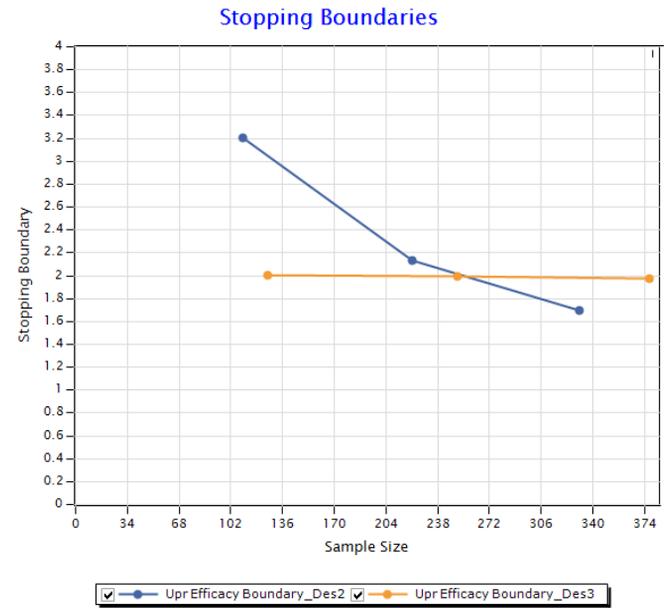

10 Normal Superiority Two-Sample

Select Des2 in the **Library**, and click  on the **Library** toolbar. On the **Boundary Info** tab, change the **Parameter** from **OF** to **PK**, and click **Compute**. With Des3 selected in the **Output Preview**, click . In the **Library**, select both Des2 and Des3, by holding the Ctrl key, and then click . The upper pane will display the details of the two designs side-by-side:

| | Des 2 | Des 3 |
|---|------------------|------------------|
| Mnemonic | MN-2S-DI | MN-2S-DI |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 3 | 3 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.9 | 0.9 |
| Model Parameters | | |
| Input Method | Individual Means | Individual Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 3 | 3 |
| Mean Control (μ_c) | 6 | 6 |
| Mean Treatment (μ_t) | 9 | 9 |
| Std. Deviation (σ) | 8 | 8 |
| Test Statistic | Z | Z |
| Allocation Ratio (nt/nc) | 3 | 3 |
| Boundary Parameters | | |
| Efficacy Boundary | LD (OF) | LD (PK) |
| Spacing of Looks | Equal | Equal |
| Sample Size | | |
| Maximum | 331 | 377 |
| Expected Under H0 | 329.115 | 369.359 |
| Expected Under H1 | 256.591 | 229.499 |

In the **Output Summary** toolbar, click  to compare the two designs according to **Stopping Boundaries**. Notice that the stopping boundaries for Des3 (PK) are relatively flat; almost the same critical point is used at all looks to declare significance.

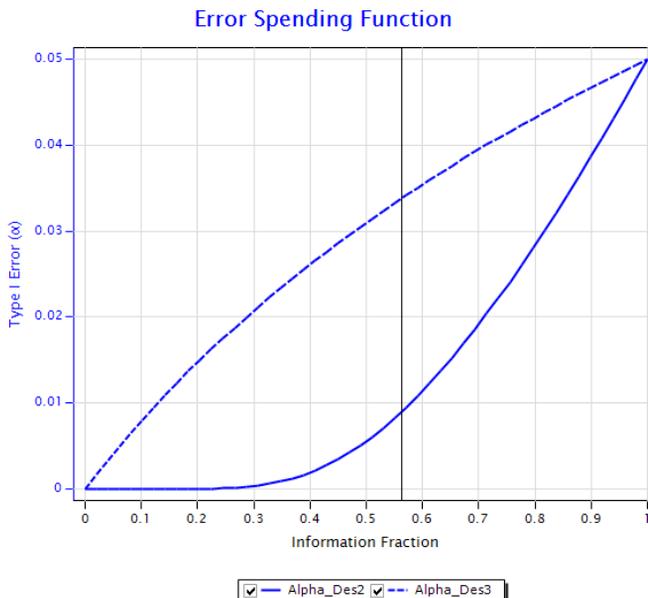

Close the chart before continuing.

Click  and select **Error Spending**. Des3 (PK) spends the type-1 error

10 Normal Superiority Two-Sample

probability at a much faster rate than Des2 (OF). Close the chart before continuing.

Wang and Tsiatis Power Boundaries

The stopping boundaries generated by the Lan-Demets **OF** and **PK** functions closely resemble closely the classical O’Brien-Fleming and Pocock stopping boundaries, respectively. These classical boundaries are a special case of a family of power boundaries proposed by Wang and Tsiatis (1987). For a two-sided level- ψ test, using K equally spaced looks, the power boundaries for the standardized test statistic Z_j at the j -th look are of the form

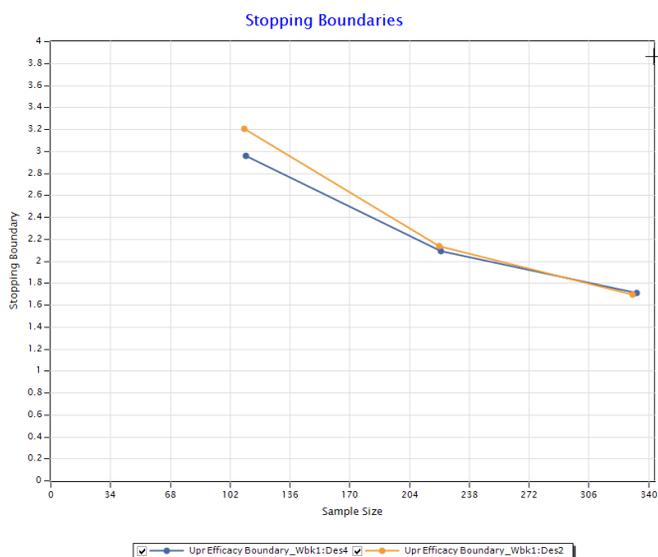

$$Z_j \geq \frac{C(\Delta, \alpha, K)}{(j/K)^{0.5-\Delta}} \tag{10.6}$$

The normalizing constant $C(\Delta, \alpha, K)$ is evaluated by recursive integration so as to ensure that the K -look group sequential test has type-1 error equal to α (see Appendix G for details), and Δ is a parameter characterizing the shape of the stopping boundary. For example, if $\Delta = 0.5$, the boundaries are constant at each of the K looks. These are the classical Pocock stopping boundaries (Pocock, 1977). If $\Delta = 0$, the width of the boundaries is inversely proportional to the square root of the information fraction j/K at the j -th look. These are the classical O’Brien-Fleming stopping boundaries (O’Brien and Fleming, 1979). Other choices produce boundaries of different shapes. Notice from equation (10.6) that power boundaries have a specific

functional form, and can be evaluated directly, or tabulated, once the normalizing constant $C(\Delta, \alpha, K)$ has been worked out for various combinations of α and K . In contrast, spending function boundaries are evaluated indirectly by inverting a pre-specified spending function as shown in Appendix F.

Right-click Des3 in the **Library** and select **Edit Design**. On the **Boundary Info** tab, change the **Boundary Family** from **Spending Functions** to **Wang-Tsiatis**. Leave the default value of Δ as 0, and click **Compute**. With Des4 selected in the **Output Preview**, click  .

In the **Library**, select both Des2 and Des4 by holding the Ctrl key. Click  and select **Stopping Boundaries**. As expected from our discussion above, the boundary values for Des2 (Lan-Demets, OF) and for Des4 (Wang-Tsiatis, $\Delta = 0$) are very similar. Close the chart before continuing.

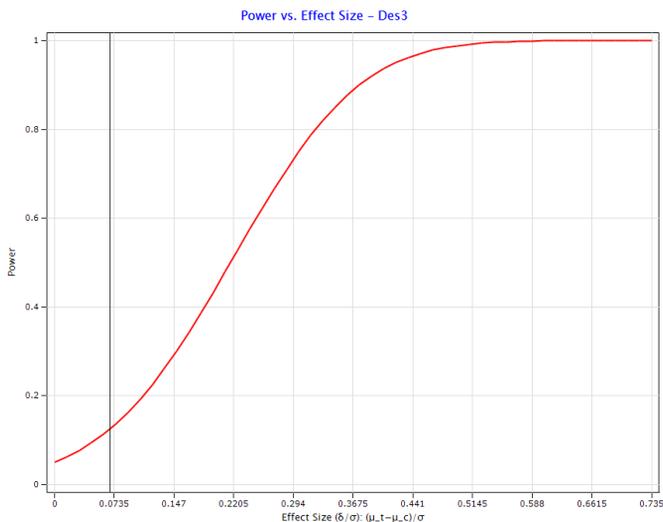

More charts

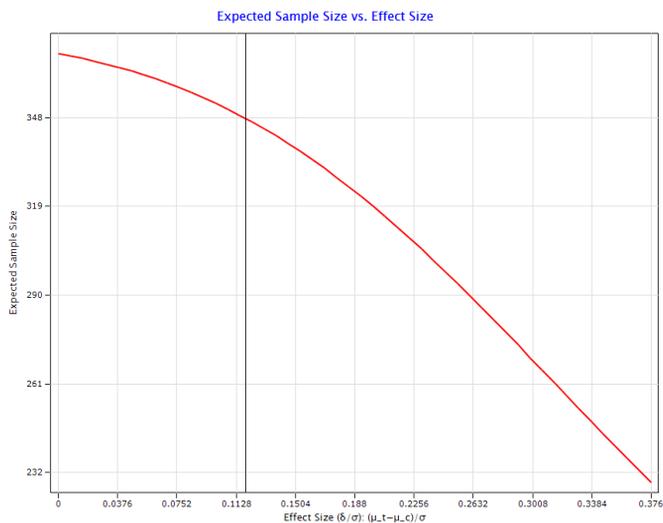

Select Des3 in the **Library**, click  , and then click **Power vs. Treatment effect** (δ). Click the radiobutton for **Standardized** under **X-Axis Scale**. By scrolling from left to right with the vertical line cursor, one can observe the power for various

10 Normal Superiority Two-Sample

values of the effect size.

Close this chart, and with Des3 selected, click  again. Then click **Expected Sample Size**. Click the radio button for **Standardized** under **X-Axis Scale**. The following chart appears:

By scrolling from left to right with the vertical line cursor we can observe how the expected number of events decreases as the effect size increases. Close this chart before continuing.

Unequally spaced analysis time points

In the above designs, we have assumed that analyses were equally spaced. This assumption can be relaxed if you know *when* interim analyses are likely to be performed (e.g., for administrative reasons). In either case, departures from this assumption are allowed during the actual interim monitoring of the study, but sample size requirements will be more accurate if allowance is made for this knowledge.

With Des3 selected in the **Library**, right-click **Edit Design**. Under **Spacing of Looks** in the **Boundary Info** tab, click the **Unequal** radio button.

The column titled **Info. Fraction** can be edited to modify the relative spacing of the analyses. The information fraction refers to the proportion of the maximum (yet unknown) sample size. By default, this table displays equal spacing, but suppose that the two interim analyses will be performed with 0.25 and 0.5 of the maximum sample size. Click **Recalc** to recompute the cumulative alpha spent and the efficacy boundary values.

Spacing of Looks Equal Unequal

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|---------------------|-------------------|
| 1 | 0.25 | 0.018 | 2.100 |
| 2 | 0.5 | 0.031 | 2.077 |
| 3 | 1 | 0.050 | 1.913 |

After entering these new information fraction values, click **Compute**. Select Des5 in the **Output Preview** and click  to save it in the **Library** for now.

Arbitrary amounts of error probability to be spent at each analysis

Another feature of East is the possibility to specify arbitrary amounts of cumulative error probability to be used at each look. This option can be combined with the option of unequal spacing of the analyses. With Des5 selected in the **Library**, click  on the **Library** toolbar. Under the **Boundary Info** tab, select **Interpolated** for the **Spending Function**. In the column titled **Cum. α Spent**, enter 0.005 for the first look

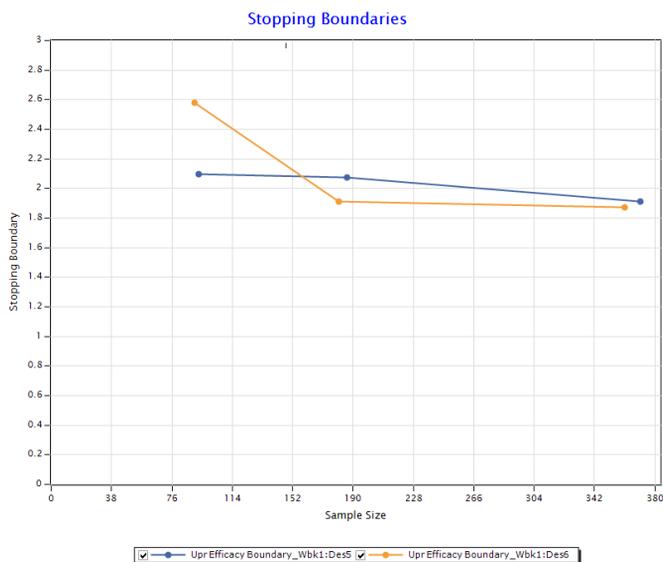

10 Normal Superiority Two-Sample

and 0.03 for the second look, click **Recalc**, and then **Compute**.

Spacing of Looks Equal Unequal

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|---------------------|-------------------|
| 1 | 0.250 | 0.005 | 2.576 |
| 2 | 0.500 | 0.03 | 1.913 |
| 3 | 1.000 | 0.05 | 1.874 |

Select Des6 in the **Output Preview** and click . From the **Library**, select Des5 and Des6 by holding the Ctrl key. Click , and select **Stopping Boundaries**. The following chart will be displayed.

The advantage of Des6 over Des5 is the more conservative boundary (less type-1 error probability spent) at the first look. Close these charts before continuing.

Computing power for a given sample size

East can compute the achieved power, given the other design parameters such as sample size. Select Des6 in the **Library** and right-click **Edit Design**. On the **Design Parameters** tab, click the radio button for **Power**. You will notice that the field for power will contain the word “Computed”. You may now enter a value for the sample

size: Enter 250, and click **Compute**. As expected, the achieved power is less than 0.9, namely 0.781.

Test Type: 1-Sided
 Type I Error (α): 0.05
 Power: 0.781
 Sample Size (n): 250
 Allocation Ratio: 3
 (n_1/n_2)

To delete this design, click Des7 in the **Output Preview**, and click  in the toolbar. East will display a warning to make sure that you want to delete the selected row. Click **Yes** to continue.

Spending function boundaries for early stopping in favor of H_0 or H_1

So far we have considered only efficacy boundaries, which allow for early stopping in favor of the alternative. It may be of interest, in addition, to consider futility boundaries, which allow for early stopping when there is *lack* of evidence against the null hypothesis. Select Des2 in the **Library** and click . On the **Boundary Info** tab, you can select from one of several types of futility boundaries, such as from a spending function, or by conditional power. Note that some of these options are available for one-sided tests only.

Futility
 Boundary Family: Spending Functions
 Spending Function: Spending Functions
 Parameter: p-value
 Conditional Power
 δ/σ

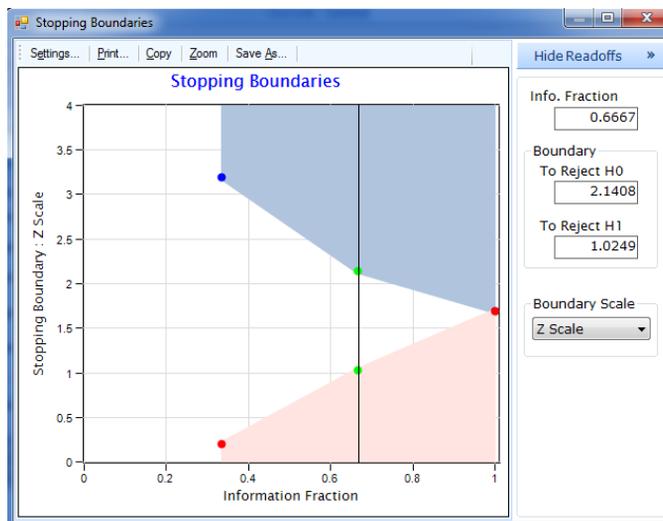

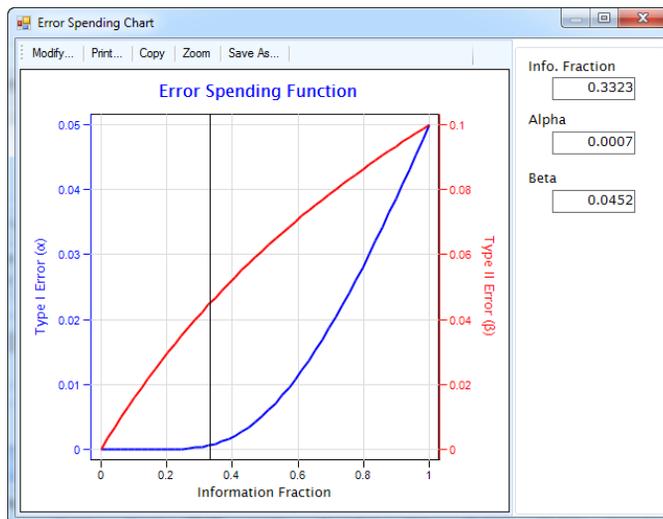

Select **Spending Functions** under **Boundary Family**. Select **PK** for the **Parameter**, and leave all other default settings. See the updated values of the stopping boundaries populated in the table below.

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Cum. β Spent | Futility Boundary |
|--------|----------------|-------------------------------------|-------------------------------------|---------------------|-------------------|--------------------|-------------------|
| 1 | 0.333 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.0007 | 3.2001 | 0.0453 | 0.1974 |
| 2 | 0.667 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.0164 | 2.1408 | 0.0763 | 1.0249 |
| 3 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.0500 | 1.6948 | 0.1000 | 1.6948 |

On the **Boundary Info** tab, you may also like to click the  or  icons to

10 Normal Superiority Two-Sample

view plots of the error spending functions, or stopping boundaries, respectively.

Click **Compute**, and with Des7 selected in the **Output Preview**, click . To view the design details, double-click Des7 in the **Library**. Because not all the type-2 error is spent at the final look, this trial has a chance of ending early if the null

hypothesis is true. This is demonstrated by the low expected sample size under the null (209 patients), compared to those of the other designs considered so far. Close the Output window before continuing.

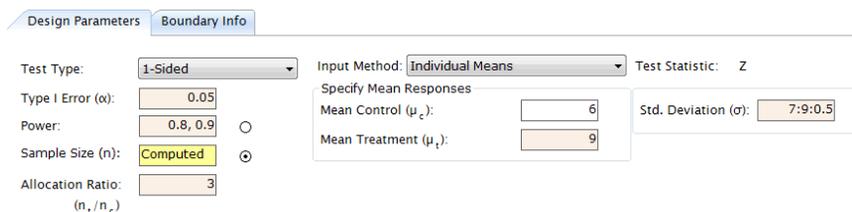

Before continuing to the next section, we will save the current workbook, and open a new workbook. Select Wbk1 in the **Library** and right-click, then click **Save**.

Next, click the  button, click **New**, and then **Workbook**. A new workbook, Wbk2, should appear in the **Library**. Delete all designs from the **Output Preview** before continuing.

Creating multiple designs

To create more than one design from the Input, one simply enters multiple values in any of the highlighted input fields. Multiple values can be entered in two ways. First, one can enter a comma-separated list (e.g., “0.8, 0.9”). Second, one can use colon notation (e.g., “7:9:0.5”) to specify a range of values, where “a:b:c” is read as from ‘a’ to ‘b’ in step size ‘c’.

Suppose that we wished to explore multiple variations of Des7. With Des7 selected in the **Library**, right-click and select **Edit Design**. In the **Design Parameters** tab of the Input, enter multiple values for the **Power(1-β)** (0.8, 0.9) and **Std.Deviation(σ)** (7 : 9 : 0.5) and click **Compute**:

The screenshot shows the 'Design Parameters' dialog box with the following settings:

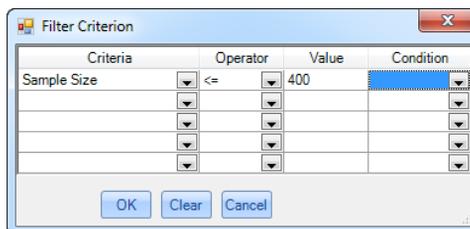

- Test Type: 1-Sided
- Type I Error (α): 0.05
- Power: 0.8, 0.9
- Sample Size (n): Computed
- Allocation Ratio: 3
- Input Method: Individual Means
- Mean Control (μ_c): 6
- Mean Treatment (μ_t): 9
- Std. Deviation (σ): 7:9:0.5
- Test Statistic: Z

We have specified 10 designs here, from the combination of 2 distinct values of the power and 5 distinct values of the standard deviation. To view all 10 designs on the screen, click  to maximize the **Output Preview**. The designs within the **Output Preview** can be sorted in ascending or descending order, according to one of the column variables. For example, if you click once on the column titled **Sample Size**, the designs will be sorted (from top to bottom) in ascending order of the total sample size.

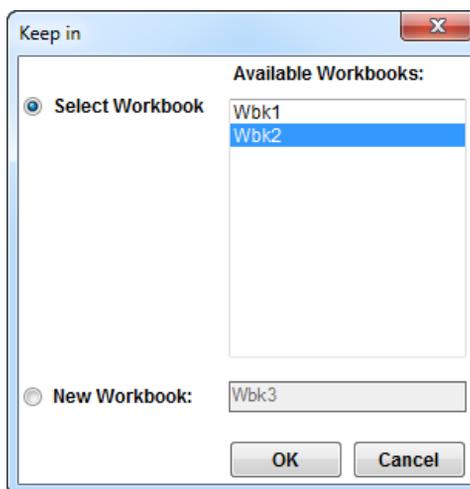

In addition, you may wish to filter and select designs that meet certain criteria. Click

10 Normal Superiority Two-Sample

 on the **Output Preview** toolbar, and in the filter criterion box, select only those designs for which the maximum sample size is less than or equal to 400, as follows:

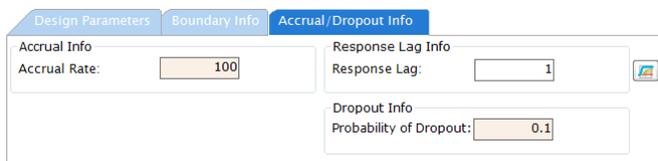

From the remaining designs, select Des8 in the **Output Preview**, and click . You will be asked to nominate the workbook in which this design should be saved. Select Wbk2 and click **OK**.

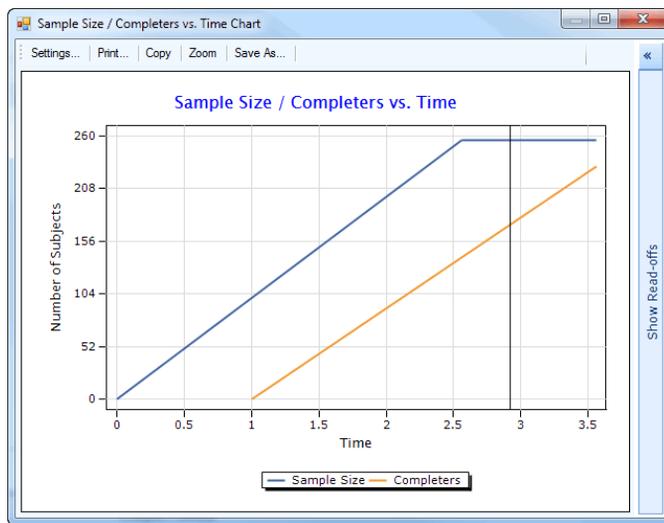

Accrual and dropout information

More realistic assumptions regarding the patient accrual process – namely, accrual rate, response lag, and probability of dropout – can be incorporated into the design stage. First, the accrual of patients may be estimated to occur at some known rate. Second, because the primary outcome measure is change in body weight from baseline to end of first year, the response lag is known to be 1 year. Finally, due to the long-term nature of the study, it is estimated that a small proportion of patients is likely to drop out over the course of the study.

With Des8 selected in the **Library**, click . Click **Include Options** in the top right hand corner of the Input, and then click **Accrual/Dropout Info**. A new tab should appear to the right of **Design Parameters** and **Boundary Info**. Click on this **Accrual/Dropout Info** tab, and enter the following information as shown below: The accrual rate is 100 patients per year, the response lag is 1 year, and the probability that a patients drops out before completing the study is 0.1.

A plot of the predicted accruals and completers over time can be generated by clicking .

Click **Compute** to generate the design. Select Des18 in the **Output Preview**, and click . Select Wbk2 and click **OK**. Double-click Des18 in the **Library**. The output details reveal that in order to ensure that data can be observed for 153 completers by the second look, one needs to have accrued 255 subjects. Close this Output window

10 Normal Superiority Two-Sample

before continuing.

Completers, Sample Size, Dropouts, Pipeline and Analysis Times: Look by Look

| Look # | Info. Fraction (s/s_max) | Sample Size (n) | Completers (s) | Dropouts (d) | Pipeline (n-s-d) | Analysis Time |
|--------|--------------------------|-----------------|----------------|--------------|------------------|---------------|
| 1 | 0.335 | 186 | 77 | 9 | 100 | 1.86 |
| 2 | 0.665 | 255 | 153 | 17 | 85 | 2.7 |
| 3 | 1 | 255 | 230 | 25 | 0 | 3.55 |

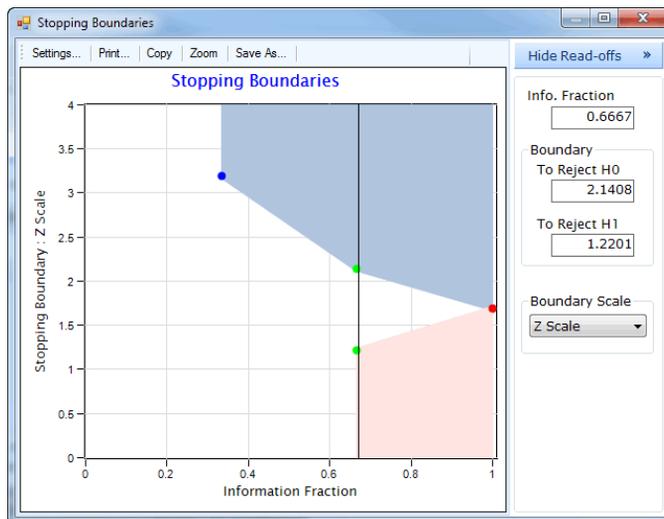

Select individual looks

With Des8 selected in Wbk2, click . In the look details table of the **Boundary Info** tab, notice that there are ticked checkboxes under the columns **Stop for Efficacy** and **Stop for Futility**. East gives you the flexibility to remove one of the stopping boundaries at certain looks. For example, untick the checkbox in the first look under the **Stop for Futility** column, and click **Recalc**.

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Cum. β Spent | Futility Boundary |
|--------|----------------|-------------------------------------|-------------------------------------|---------------------|-------------------|--------------------|-------------------|
| 1 | 0.333 | <input checked="" type="checkbox"/> | <input type="checkbox"/> | 0.0007 | 3.2001 | | NA |
| 2 | 0.667 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.0164 | 2.1408 | 0.1527 | 1.2201 |
| 3 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.0500 | 1.6948 | 0.2000 | 1.6948 |

Click  to view the new boundaries. Notice that the futility boundary does not

begin until the second look.

Simulation of the Orlistat trial

Suppose you now wish to simulate Des4 in Wbk1. Select Des4 in the **Library**, and click the **S** from the **Library** toolbar. Alternatively, right-click on Des4 and select **Simulate**. A new Simulation worksheet will appear. Click on the **Response Generation Info** tab, and input the following values: **Mean control** = 6; **Mean Treatment** = 6; **(Common) Std. Deviation** = 8. In other words, we are simulating from a population in which there is no true difference between the control and treatment means. This simulation will allow us to check the type-1 error rate when using Des4.

| Simulation Parameters | Response Generation Info | Simulation Control Info |
|---------------------------------------|---|-------------------------|
| Generate Data Using: Individual Means | <input checked="" type="checkbox"/> Common Standard Deviation | |
| Mean Control (μ_c): 6 | SD Control (σ_c): 8 | |
| Mean Treatment (μ_t): 6 | SD Treatment (σ_t): 8 | |

Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled Sim1.

10 Normal Superiority Two-Sample

With Sim1 selected in the **Output Preview**, click  , then double-click Sim1 in the **Library**. The simulation output details will be displayed in the upper pane. In the **Overall Simulation Result** table, notice that the percentage of times the upper efficacy stopping boundary was crossed is largely consistent with a type-1 error of 5%. The exact values of your simulations may differ, depending on your seed.

☯ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | | Efficacy | Count |
| | | Upper | | | |
| 1 | 111 | 2.961 | 18 | 18 | 0.180% |
| 2 | 222 | 2.094 | 180 | 180 | 1.800% |
| 3 | 333 | 1.71 | 306 | 9802 | 98.020% |
| Total | | | 504 | 10000 | |
| % | | | 5.040% | | |

Right-click Sim1 in the **Library** and click **Edit Simulation**. In the **Response Generation Info** tab, enter 9 for **Mean Treatment**. Leave all other values, and click **Simulate**. With Sim2 selected in the **Output Preview**, click  , then double-click Sim2 in the **Library**. Notice that the percentage of times the efficacy stopping boundary was crossed is largely consistent with 90% power for the original design. Feel free to experiment further with other simulation options before continuing.

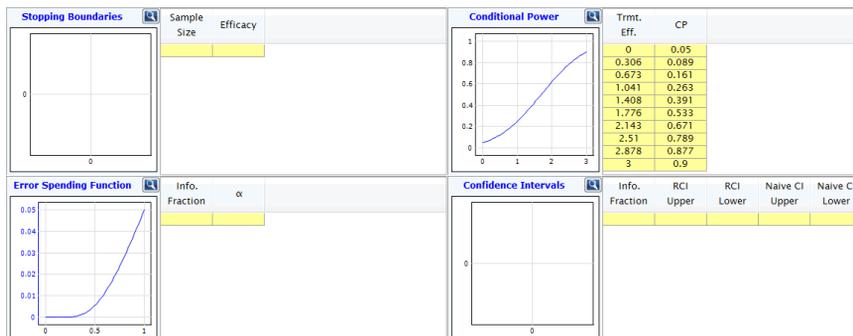

10.1.2 Interim monitoring of the Orlistat trial

Suppose we decided to adopt Des2. Select Des2 in the **Library**, and click **IM** on the **Library** toolbar. Alternatively, right-click on Des2 and select **Interim Monitoring**. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | Repeated 95% CI for δ | | Repeated p-value |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|------------------------------|-------|------------------|
| | | | | | | | Upper | Lower | |
| | | | | | | | | | |
| 1 | | | | | | | | | |
| 2 | | | | | | | | | |
| 3 | | | | | | | | | |

The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the

clinical trial and are useful tools for decision making by a data monitoring committee.

Making Entries in the Interim Monitoring Dashboard

Although the study has been designed assuming three equally spaced analyses, departures from this strategy are permissible using the spending function methodology of Lan and DeMets (1983) and its extension to boundaries for early stopping in favor of H_0 proposed by Pampallona, Tsiatis and Kim (2001). At each interim analysis time point, East will determine the amount of type-1 error probability and type-2 error probability that it is permitted to spend based on the chosen spending functions specified in the design. East will then re-compute the corresponding stopping boundaries. This strategy ensures that the overall type-1 error will not exceed the nominal significance level α . We shall also see how East proceeds so as to control the type-2 error probability.

Open the **Test Statistic Calculator** by clicking on the **Enter Interim Data** button. Assume that we take the first look after 110 patients (**Sample Size (Overall)**), with an **Estimate of δ** as 3, and **Standard Error of Estimate of δ** as 1.762. Click **OK** to

10 Normal Superiority Two-Sample

continue.

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Input for Normal end point

Estimate of δ :
 $\delta = (\mu_t - \mu_c)$

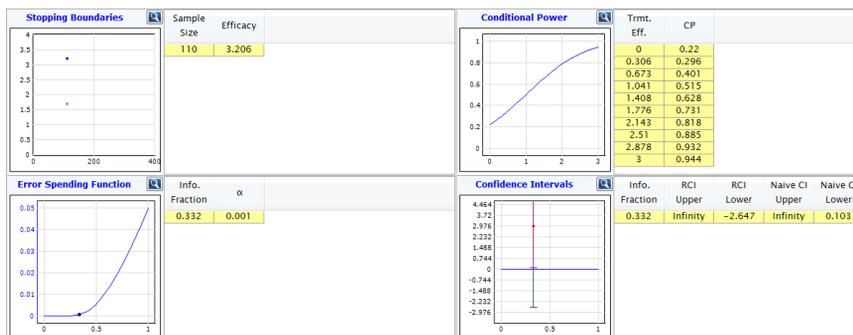

Standard Error of Estimate of δ :

Output

Test Statistic:

Recalc OK Cancel

East will update the charts and tables in the dashboard accordingly. For example the Stopping Boundaries Chart displays recomputed stopping boundaries and the path traced out by the test statistic. The Error Spending Function Chart displays the cumulative error spent at each interim look. The Conditional Power (CP) Chart shows the probability of crossing the upper stopping boundary, given the most recent information. Finally, the RCI (Repeated Confidence Interval) Chart displays repeated confidence intervals (Jennison & Turnbull, 2000).

Repeat the input procedure from above with the second look after 221 patients (Sample Size (Overall), Estimate of δ as 2, and Standard Error of Estimate of δ as 1. Click **Recalc** and **OK** to continue.

For the final look, make sure to tick the box **Set Current Look as Last**. Input the following estimates: 331 patients (**Sample Size (Overall)**), with an **Estimate of δ** as 3, and **Standard Error of Estimate of δ** as 1. Click **Recalc** and **OK** to continue.

The upper boundary has been crossed. The dashboard will be updated, and the **Final Inference** table shows the final outputs. For example, the adjusted p-value is 0.017, consistent with the rejection of the null.

| Final Inference | |
|--|-------|
| Final Outputs at Look # | 3 |
| Adj. p-value | 0.017 |
| Adj. Pt. Est. for δ | 2.505 |
| Adj. 90% CI for δ | |
| Upper Confidence Bound | 4.314 |
| Lower Confidence Bound | 0.582 |
| Post-Hoc Power | 0.9 |

10.1.3 Trial Design Using a t-Test (Single Look)

In Section 10.1.1 the sample size obtained to correctly power the trial relied on asymptotic approximation for the distribution of a Wald-type statistic. In the single look setting this statistic is

$$Z = \frac{\hat{\delta}}{\sqrt{\text{var}[\hat{\delta}]}} \quad (10.7)$$

with

$$\text{var}[\hat{\delta}] = \frac{\hat{\sigma}^2}{nr(1-r)}. \quad (10.8)$$

In a small single-look trial a more accurate representation of the distribution of Z is obtained by using Student's t-distribution with $(n-1)$ degrees of freedom.

Consider the Orlistat trial described in Section 10.1.1 where we would like to test the null hypothesis that treatment does not lead to weight loss, $H_0: \delta = 0$, against the alternative hypothesis that the treatment does result in a loss of weight, $H_1: \delta > 0$. We will now design this same trial in a different manner, using the t-distribution for the test statistic. Start East afresh. Click **Continuous: Two Samples** on the **Design** tab, and then click **Parallel Design: Difference of Means**. Enter the following design parameters so that the dialog box appears as shown. Remember to select a **1-Sided** for **Trial Type**, and enter an **Allocation Ratio** of 3. These values are the same as those

10 Normal Superiority Two-Sample

from Des1, except that under **Dist. of Test Stat.**, select **t**. Then click **Compute**.

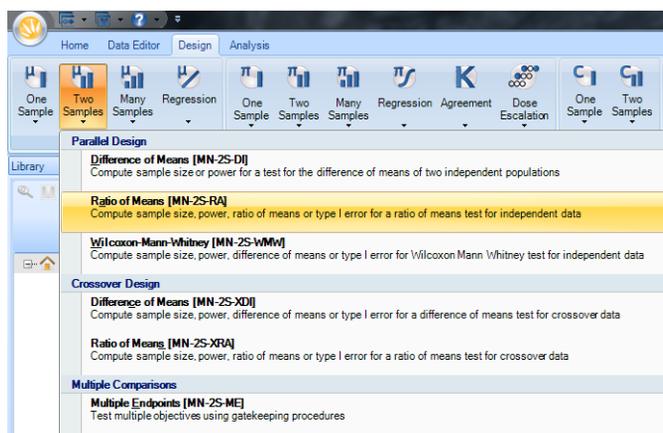

The screenshot shows the Minitab Design tool interface for a "Design: Continuous Endpoint: Two-Sample Test - Parallel Design - Difference of Means". The "Design Parameters" tab is active. The "Design Type" is set to "Superiority" and "Number of Looks" is 1. The "Test Type" is "1-Sided". The "Type I Error (α)" is 0.05, "Power" is 0.9, and "Sample Size (n)" is 327. The "Allocation Ratio" is 3. The "Input Method" is "Individual Means", with "Mean Control (μ_c)" at 6 and "Mean Treatment (μ_t)" at 9. The "Test Statistic" is "t", "Variance" is "Equal", and "Std. Deviation (σ)" is 8. A "Compute" button is visible at the bottom right.

We observe that the required sample size for this study is 327 patients. Contrast this to the 325 patients obtained using the normal distribution in Section 10.1.1.

10.2 Ratio of Means for Independent Data (Superiority)

Let σ_t and σ_c denote the standard deviations of the treatment and control group responses respectively. It is assumed that the coefficient of variation (CV), defined as the ratio of the standard deviation to the mean, is the same for both groups: $\frac{\sigma_t}{\mu_t} = \frac{\sigma_c}{\mu_c}$. Finally let $\rho = \frac{\mu_t}{\mu_c}$. For a Superiority trial, the null hypothesis $H_0 : \rho = \rho_0$ is tested against the two-sided alternative hypothesis $H_1 : \rho \neq \rho_0$ or a one-sided alternative hypothesis $H_1 : \rho < \rho_0$ or $H_1 : \rho > \rho_0$.

First, click **Continuous: Two Samples** on the **Design** tab, and then click **Parallel Design: Ratio of Means**.

Suppose that we wish to determine the sample size required for a one sided test to achieve a type-1 error of .05, and power of 90%, to detect a ratio of means of 1.25. We also need to specify the $CV = 0.25$. Enter the appropriate design parameters so that the input dialog box appears as below, and click **Compute**.

10 Normal Superiority Two-Sample

Design: Continuous Endpoint: Two-Sample Test - Parallel Design - Ratio of Means

Design Type: Superiority Include Options

Design Parameters

| | | | | | | | |
|------------------------------------|---------|--------------------------------|----------------|--|------|--------------|------|
| Test Type: | 1-Sided | Input Method: | Ratio of Means | Test Statistic: | Z | | |
| Type I Error (α): | 0.05 | Specify Alternative Hypothesis | | Ratio of Means ($\rho = \mu_1 / \mu_2$): | 1.25 | Coeff. Var.: | 0.25 |
| Power: | 0.9 | | | | | | |
| Sample Size (n): | 42 | | | | | | |
| Allocation Ratio: (n_1/n_2) | 1 | | | | | | |

Compute

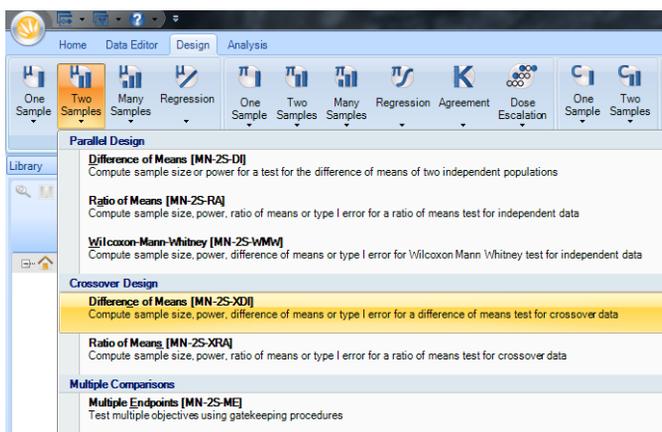

The computed sample size (42 subjects) is highlighted in yellow.

10.3 Difference of Means for Crossover Data (Superiority)

In a crossover trial, each experimental subject receives two or more different treatments. The order in which each subject receives the treatments depends on the particular design chosen for the trial. The simplest design is a 2×2 crossover trial, where each subject receives two treatments, say A and B. Half of the subjects receive A first and then, after a suitably chosen period of time, crossover to B. The other half receive B first and then crossover to A.

The null and alternative hypotheses are the same as for a two sample test for difference of means for independent data. However, a key advantage of the crossover design is that each subject serves as his/her own control. The test statistic also needs to account for not only treatment effects, but period and carryover effects.

We will demonstrate this design for a Superiority trial. First, click **Continuous: Two Samples** on the **Design** tab, and then click **Crossover Design: Difference of Means**.

Suppose that we wish to determine the sample size required to achieve a type-1 error of .05, and power of 90%, to detect a difference of means of 75 with standard deviation of the difference of 150. Enter the appropriate design parameters so that the input

10 Normal Superiority Two-Sample

dialog box appears as below, and click **Compute**.

Design: Continuous Endpoint: Two-Sample Test - Crossover Design - Difference of Means

Design Type: Superiority

Design Parameters

Test Type: 2-Sided

Type I Error (α): 0.05

Power: 0.9

Sample Size (n): 45

Allocation Ratio: 1
(n_{α} / n_{α})

Input Method: Difference of Means

Specify Alternative Hypothesis
Difference of Means (δ_1): 75

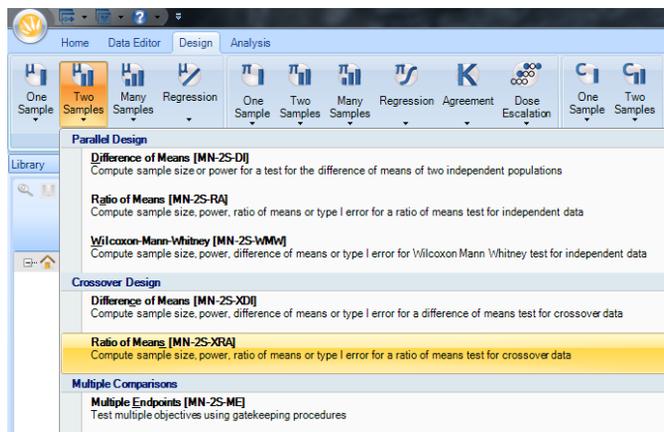

Std. Dev. of Diff.: 150

Compute

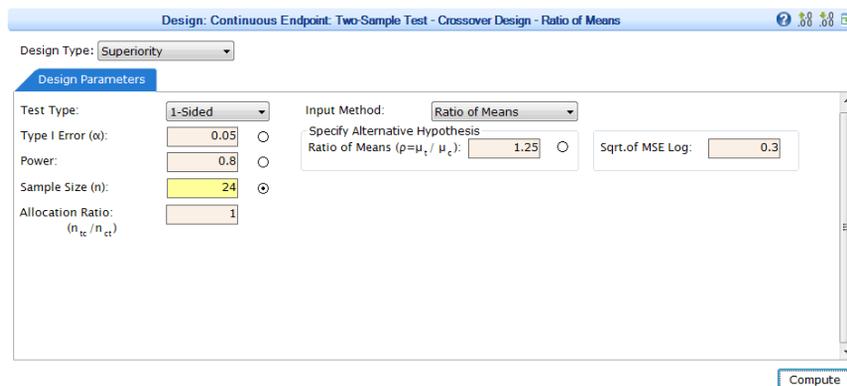

The computed sample size (45 subjects) is highlighted in yellow.

10.4 Ratio of Means for Crossover Data (Superiority)

We will demonstrate this design for a Superiority trial. The null hypothesis $H_0 : \rho = \rho_0$ is tested against the two-sided alternative hypothesis $H_1 : \rho \neq \rho_0$ or a one-sided alternative hypothesis $H_1 : \rho < \rho_0$ or $H_1 : \rho > \rho_0$. First, click **Continuous: Two Samples** on the **Design** tab, and then click **Crossover Design: Ratio of Means**.

Suppose that we wish to determine the sample size required for a one sided test to achieve a type-1 error of .05, and power of 80%, to detect a ratio of means of 1.25 with square root of MSE of 0.3. Enter the appropriate design parameters so that the input dialog box appears as below, and click **Compute**.

The computed sample size (24 subjects) is highlighted in yellow.

10 Normal Superiority Two-Sample

10.5 Assurance (Probability of Success)

Assurance, or probability of success, is a Bayesian version of power, which corresponds to the (unconditional) probability that the trial will yield a statistically significant result. Specifically, it is the prior expectation of the power, averaged over a prior distribution for the unknown treatment effect (see O’Hagan et al., 2005). For a given design, East allows you to specify a prior distribution, for which the assurance or probability of success will be computed.

Select Des2 in the **Library**, and click  on the **Library** toolbar. Alternatively, recompute this design with the following inputs: A 3-look design with Lan-Demets(OF) efficacy only boundary, Superiority Trial, 1-sided, 0.05 type-1 error, 90% power, allocation ratio = 3, mean control = 6, mean treatment = 9, and standard deviation = 8.

Select the **Assurance** checkbox in the Input window.

Suppose that we wish to specify a Normal prior distribution for the treatment effect δ , with a mean of 3, and standard deviation of 2. Thus, rather than assuming $\delta = 3$ with certainty, we use this prior distribution to reflect the uncertainty about the true treatment effect.

In the **Distribution** list, click **Normal**, and in the **Input Method** list, click **E(δ) and SD(δ)**.

Type 3 in the **E(δ)** box, and type 2 in the **SD(δ)** box, and then click **Compute**.

The computed probability of success (0.72) is shown below. Note that for this prior, assurance is less than the specified power (0.9); incorporating the uncertainty about δ has yielded a less optimistic estimate of power.

Assurance (Probability of Success): 0.72

Prior Distribution for: δ Distribution: Normal

Input Method: E(δ) and SD(δ)

User Specified

E(δ): 3

SD(δ): 2

In the Output Preview, right-click the row corresponding to this design, and rename the design ID as **Bayes1**, and save it to the **Library**.

Return to the input window. Type 0.001 in the **SD(δ)** box, and click **Compute**. Such a prior approximates the non-Bayesian power calculation, where one specifies a fixed treatment effect.

As shown below, such a prior yields a probability of success that is similar to the specified power.

Assurance (Probability of Success): 0.9

Prior Distribution for: δ Distribution: Normal

Input Method: E(δ) and SD(δ)

User Specified

E(δ): 3

SD(δ): 0.001

East also allows you to specify an arbitrary prior distribution through a CSV file. In the **Distribution** list, click **User Specified**, and then click **Browse...** to select the CSV file where you have constructed a prior.

10 Normal Superiority Two-Sample

Assurance (Probability of Success) Computed
 Prior Distribution for: δ Distribution: User Specified
 Browse...

The CSV file should contain two columns, where the first column lists the grid points for the parameter of interest (in this case, δ), and the second column lists the prior probability assigned to each grid point. For example, we consider a 5-point prior with probability = 0.2 at each point. The prior probabilities can be entered as weights that do not sum to one, in which case East will re-normalize for you.

| | A | B |
|---|---|-----|
| 1 | 1 | 0.2 |
| 2 | 2 | 0.2 |
| 3 | 3 | 0.2 |
| 4 | 4 | 0.2 |
| 5 | 5 | 0.2 |

Once the CSV filename and path has been specified, click **Compute** to calculate the assurance, which will be displayed in the box below:

Assurance (Probability of Success): 0.751
 Distribution: User Specified

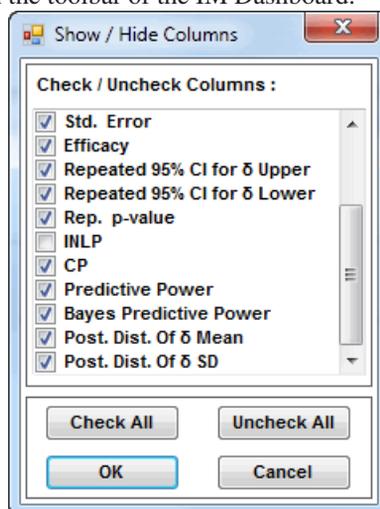

As stated in O’Hagan et al. (2005, p.190): “Assurance is a key input to decision-making during drug development and provides a reality check on other methods of trial design.” Indeed, it is not uncommon for assurance to be much lower than the specified power. The interested reader is encouraged to refer to O’Hagan et al. for further applications and discussions on this important concept.

10.6 Predictive Power and Bayesian Predictive Power

Similar Bayesian ideas can be applied to conditional power for interim monitoring. Rather than calculating conditional power for a single assumed value of the treatment effect, δ , such as at $\hat{\delta}$, we may account for the uncertainty about δ by taking a weighted average of conditional powers, weighted by the posterior distribution for δ . For normal

endpoints, East assumes a posterior distribution for δ that results from a *diffuse* prior distribution, which produces an average power called the **predictive power** (Lan, Hu, & Proschan, 2009). In addition, if the user specified a normal prior distribution at the design stage to calculate assurance, then East will also calculate the average power, called **Bayesian predictive power**, for the corresponding posterior. We will demonstrate these calculations for the design renamed as Bayes1 earlier.

In the **Library**, right-click Bayes1 and click **Interim Monitoring**, then click (Show/Hide Columns) in the toolbar of the IM Dashboard.

In the Show/Hide Columns window, make sure to show the columns for: CP (Conditional Power), Predictive Power, Bayes Predictive Power, Posterior Distribution of δ Mean, and Posterior Distribution of δ SD, and click **OK**. The following columns will be displayed in the main grid of the IM Dashboard.

| CP | Predictive Power | Bayes Predictive Power | Post. Dist. Of δ | |
|----|------------------|------------------------|-------------------------|----|
| | | | Mean | SD |
| | | | | |
| | | | | |

Assume that we observed interim data after 110 patients, with an estimate of $\delta = 1$, and a standard error of the estimate = 0.7. Enter these values in the **Test Statistic Calculator** by clicking **Enter Interim Data**, and click **OK**.

10 Normal Superiority Two-Sample

The IM Dashboard will be updated. In particular, notice the differing values for CP and the Bayesian measures of power.

| CP | Predictive Power | Bayes Predictive Power | Post. Dist. Of δ | |
|------|------------------|------------------------|-------------------------|-------|
| | | | Mean | SD |
| 0.84 | 0.719 | 0.487 | 1.218 | 0.661 |
| | | | | |
| | | | | |

11 Nonparametric Superiority Two Sample

The Wilcoxon-Mann-Whitney nonparametric test is a commonly used test for the comparison of two distributions when the observations cannot be assumed to come from normal distributions. It is used when the distributions differ only in a location parameter and is especially useful when the distributions are not symmetric. For Wilcoxon-Mann-Whitney test, East supports single look superiority designs only.

11.1 Wilcoxon-Mann-Whitney Test

Let X_1, \dots, X_{n_t} be the n_t observations from the treatment (T) with distribution function F_t and Y_1, \dots, Y_{n_c} be the n_c observations from the control (C) with distribution function F_c . F_t and F_c are assumed to be continuous with corresponding densities f_t and f_c , respectively. The primary objective in Wilcoxon-Mann-Whitney test is to investigate whether there is a shift of location, which indicates the presence of the treatment effect. Let θ represents the treatment effect. Then we test the null hypothesis $H_0: \theta = 0$ against the two-sided alternative $H_1: \theta \neq 0$ or a one-sided alternative hypothesis $H_1: \theta < 0$ or $H_1: \theta > 0$. Let U denote the number of pairs (X_i, Y_j) such that $X_i < Y_j$, so $U = \sum_{i=1}^{n_t} \sum_{j=1}^{n_c} I(X_i, Y_j)$ where $I(a, b) = 1$ if $a < b$ and $I(a, b) = 0$ if $a \geq b$. Then $U/n_c n_t$ is a consistent estimator of

$$p = P(X < Y) = \int_{-\infty}^{\infty} F_t(y) f_c(y) dy = \int_0^1 F_t[F_c^{-1}(u)] du. \quad (11.1)$$

The power is approximated using the asymptotic normality of U and depends on the value of p , and thus depends on F_c and F_t . In order to find the power for a given sample size or to find the sample size for a given power, we must specify p . However, this is often a difficult task. If we are willing to specify F_c and F_t , then p can be computed. East computes p assuming that F_c and F_t are normal distributions with means μ_c and μ_t and a common standard deviation σ , by specifying the values of the difference in the means and the standard deviation. With this assumption, equation (11.1) results in

$$p = \Phi\left(\frac{\mu_t - \mu_c}{\sqrt{2}\sigma}\right) \quad (11.2)$$

Using the results of Noether (1987), with $n_t = rN$, the total sample size for an α level two-sided test to have power $1 - \beta$ for a specified value of p is approximated by

$$N = \frac{(z_{\alpha/2} + z_{\beta})^2}{12r(1-r)(p - .5)^2}.$$

11 Nonparametric Superiority Two Sample

11.2 Example: Designing a single look superiority study

Based on a pilot study of an anti-seizure medication, we want to design a 12-month placebo-controlled study of a treatment for epilepsy in children. The primary efficacy variable is the percent change from baseline in the number of seizures in a 28-day period. The mean percent decrease was 2 for the control and 8 for the new treatment, with an estimated standard deviation of 25. We plan to design the study to test the null hypothesis $H_0:\theta = 0$ against $H_1:\theta \neq 0$. We want to design a study that would have 90% power at $\mu_c = 2$ and $\mu_t = 8$ under H_1 and maintains type I error at 5%.

11.2.1 Designing the study

Click **Continuous: Two Samples** on the **Design** tab and then click **Parallel Design: Wilcoxon-Mann-Whitney**.

Mean Treatment (μ_t):

The required sample size for this design is shown as a row in the **Output Preview**, located in the lower pane of this window. The computed total sample size (772 subjects) is highlighted in yellow.

| Output Preview | | | | | | | | | | | |
|---|------|-----|------------|-----------|------------------|-----------|-----------|-------------|---------|--------------|--|
| Design | α | 1-β | Maximum SS | Side Type | Allocation Ratio | Ctrl Mean | Trtm Mean | Probability | Std Dev | Actual Power | |
|  Design1 | 0.05 | 0.9 | 772 | 2-Sided | 1 | 2 | 8 | 0.567 | 25 | 0.9 | |

This design has default name Des 1 and results in a total sample size of 772 subjects in order to achieve 90% power. The probability displayed in the row is 0.567, which indicates the approximate probability $P[X < Y]$ assuming $X \sim N(8, 25^2)$ and $Y \sim N(2, 25^2)$. This is in accordance with the equation 11.2.

Select this design by clicking anywhere along the row in the **Output Preview** and click  in the **Output Preview** toolbar. Some of the design details will be

11 Nonparametric Superiority Two Sample

displayed in the upper pane, labeled as **Output Summary**.

Summary

The study will require a total of 772 subjects to detect a difference in response distributions between the treatment and control samples, with desired power 90.02%. This test is based on a 2-Sided non-parametric Wilcoxon Mann Whitney test for continuous response data with significance level 0.05. The treatment group mean is 8 and the control group mean is 2. The test assumes the common standard deviation of 25 for treatment and control groups. The probability that an observation in the control group is less than an observation in the treatment group under the alternative hypothesis is 0.567. The allocation ratio is 1 and therefore, of the 772 subjects, 386 are allocated to the control arm and 386 are allocated to the treatment arm.

According to this summary, the study needs a total of 772 subjects. Of these 772 subjects, 386 will be allocated to the treatment group and remaining 386 will be allocated to the control group.

Since the sample size is inversely proportional to $(p - .5)^2$, it is sensitive to mis-specification of p (see equation (11.1)). The results of the pilot study included several subjects who worsened over the baseline and thus the difference in the means might not be an appropriate approach to determining p . To obtain a more appropriate value of p , we have several alternative approaches. We can further examine the results

of the pilot study after exclusion of some of the extreme values, which will decrease the standard deviation and provide a difference in the means, which may be a more reasonable measure of the difference between the distributions. The difference in the medians may be a more reasonable measure of the difference between the distributions, especially when used with a decreased standard deviation.

The median percent decrease was 10 for the control and 18 for the new treatment, with an estimated standard deviation of 25. Create a new design by selecting Des 1 in the **Library**, and clicking  on the **Library** toolbar. In the Input, change the **Mean Control** (μ_c) and **Mean Treatment** (μ_t) to 10 and 18, respectively.

12 Normal Non-inferiority Two-Sample

In a noninferiority trial, the goal is to establish that an experimental treatment is *no worse than* the standard treatment, rather than attempting to establish that it is superior. A therapy that is demonstrated to be non-inferior to the current standard therapy for a particular indication might be an acceptable alternative if, for instance, it is easier to administer, cheaper, or less toxic. Non-inferiority trials are designed by specifying a non-inferiority margin. The amount by which the mean response on the experimental arm is worse than the mean response on the control arm must fall within this margin in order for the claim of non-inferiority to be sustained. In this chapter, we show how East supports the design and interim monitoring of such experiments, with a normal endpoint.

12.1 Difference of Means

12.1.1 Trial design

12.1.2 Three-Look Design

12.1.3 Simulation

12.1.4 Interim Monitoring

12.1.5 Trial Design Using a t-Test (Single Look)

12.1.1 Trial design

Consider the design of an antihypertension study comparing an ACE inhibitor to a new AII inhibitor. Let μ_c be the mean value of a decrease in systolic blood pressure level (in mmHg) for patients in the ACE inhibitor (control) group and μ_t be the mean value of a decrease in blood pressure level for patients in the AII inhibitor (treatment) group. Let $\delta = \mu_t - \mu_c$ be the treatment difference. We want to demonstrate that the AII inhibitor is non-inferior to the ACE inhibitor. For this example, we will consider a non-inferiority margin equal to one-third of the mean response in control group. From historical data, $\mu_c = 9$ mmHg and therefore the non-inferiority margin is 3 mmHg. Accordingly we will design the study to test the null hypothesis of inferiority $H_0 : \delta \geq -3$, against the one sided non-inferiority alternative $H_1 : \delta < -3$. The test is to be conducted at a significance level (α) of 0.025 and is required to have 90% power at $\delta = 0$. We assume that σ^2 , the variance of the patient response, is the same for both groups and is equal to 100.

Start East afresh. Click **Continuous: Two Samples** on the **Design** tab and then click **Parallel Design: Difference of Means**.

Single-look design

In the input window, select **Noninferiority** for **Design Type**. The effect size can be specified in one of three ways by selecting different options for **Input Method**: (1) individual means and common standard deviation, (2) difference of means and common standard deviation, or (3) standardized difference of means. We will use the **Individual Means** method. Select **Individual Means** for **Input Method**, specify the **Mean Control** (μ_c) as 9 and **Noninferiority margin** (δ_0) as -3 and specify the

12 Normal Non-inferiority Two-Sample

Std. Deviation (σ) as 10. Specify 0 for **Difference in Means** (δ_1). The upper pane should appear as below:

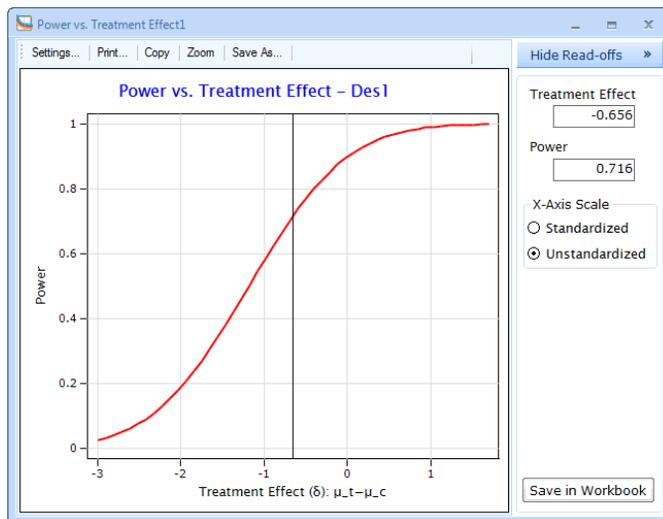

Click **Compute**. This will calculate the sample size for this design, and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (467 subjects) is highlighted in yellow.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | Input Method | δ_1 | δ_0 | μ_c | Mean Treatment (Alt.) | Mean Treatment (Null) | σ |
|------|----------------|--------------|-----------|--------------------|-------|-------|-------------|------------------|------------|------------|---------|-----------------------|-----------------------|----------|
| Des1 | Noninferiority | 1 | 1-Sided | 0.025 | 0.9 | 1 | 467 | Individual Means | 0 | -3 | 9 | 9 | 6 | 10 |

This design has default name Des 1. Select this design by clicking anywhere along the row in the **Output Preview** and click . In the **Output Preview** toolbar, click to save this design to Wbk1 in the **Library**. If you hover the cursor over Des 1 in the **Library**, a tooltip will appear that summarizes the input parameters of the design.

With Des 1 selected in the **Library**, click on the **Library** toolbar, and then click **Power vs Treatment Effect** (δ). The resulting power curve for this design will

appear.

You can save this chart to the Library by clicking **Save in Workbook**. In addition, you can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...** For now, you may close the chart before continuing.

12.1.2 Three-Look Design

Create a new design by selecting Des 1 in the **Library**, and clicking  on the **Library** toolbar. In the Input, change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab for **Boundary Info** should appear. Click this tab to reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. By default, there is an efficacy boundary (to reject H_0) selected, but no futility boundary (to reject H_1). The **Boundary Family** specified is of the **Spending Functions** type. The default **Spending function** is the **Lan-DeMets** (Lan & DeMets, 1983), with **Parameter OF** (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping

12 Normal Non-inferiority Two-Sample

boundaries of O'Brien and Fleming (1979).

Design Type: Noninferiority Number of Looks: 3

Design Parameters Boundary Info

| Mnemonic | MN-2S-DI | MN-2S-DI |
| Test Parameters | | |
| Design Type | Noninferiority | Noninferiority |
| No. of Looks | 1 | 3 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.025 | 0.025 |
| Power | 0.9 | 0.9 |
| Model Parameters | | |
| Input Method | Individual Means | Individual Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 0 | 0 |
| Noninf. Margin ($\delta_0 = \mu_{t0} - \mu_c$) | -3 | -3 |
| Mean Control (μ_c) | 9 | 9 |
| Mean Treatment (μ_t) | 9 | 9 |
| Mean Treatment (μ_{t0}) | 6 | 6 |
| Std. Deviation (σ) | 10 | 10 |
| Test Statistic | Z | Z |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Boundary Parameters | | |
| Efficacy Boundary | | LD (OF) |
| Spacing of Looks | | Equal |
| Sample Size | | |
| Maximum | 467 | 473 |
| Expected Under H0 | | 472.032 |
| Expected Under H1 | | 379.185 |

The maximum sample size with Des 2 is 473, which is only a slight increase over the fixed sample size in Des 1. However, the expected sample size with Des 2 is 379 patients under H_1 , a saving of almost 100 patients. In order to see the stopping probabilities, double-click Des 2 in the **Library**.

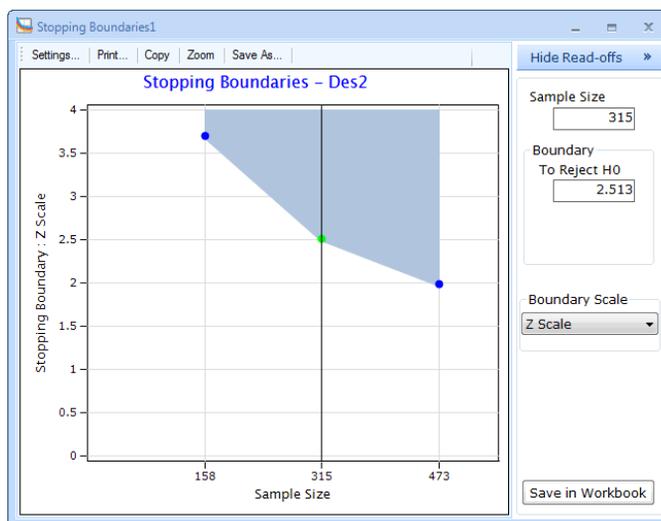

☺ **Stopping Boundaries: Look by Look**

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries Efficacy Z | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|--------------------------|---|----------|
| | | | | | Under H0 | Under H1 |
| | | | | | Efficacy | Efficacy |
| 1 | 0.334 | 158 | 1.053E-4 | 3.706 | 1.053E-4 | 0.034 |
| 2 | 0.666 | 315 | 0.006 | 2.513 | 0.006 | 0.525 |
| 3 | 1 | 473 | 0.025 | 1.993 | 0.019 | 0.341 |

The clear advantage of this sequential design resides in the high probability of stopping by the second look, if the alternative is true, with a sample size of 315 patients, which is well below the requirements for a fixed sample study (467 patients). Close the Output window before continuing.

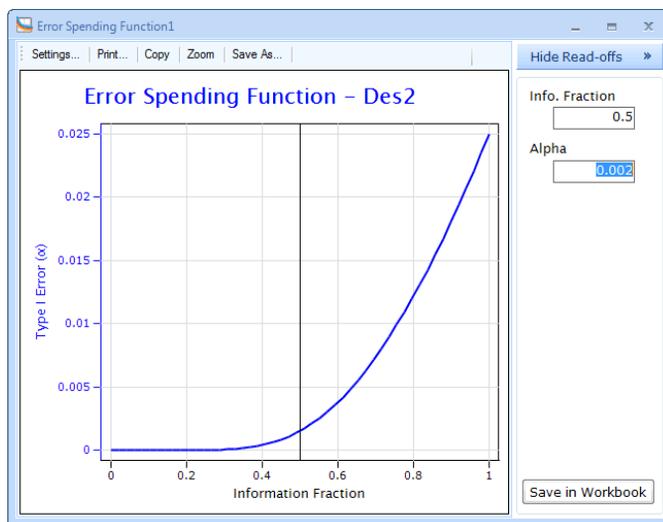

Examining stopping boundaries and spending functions

You can plot the boundary values of Des 2 by clicking  on the **Library** toolbar, and then clicking **Stopping Boundaries**. The following chart will appear:

12 Normal Non-inferiority Two-Sample

You can choose a different **Boundary Scale** from the corresponding drop down box. The available boundary scales include: Z scale, Score Scale, δ Scale, δ/σ Scale and p -value scale. To plot the error spending function for Des 2, select Des 2 in the **Library**, click the  in the toolbar, and then click **Error Spending**. The following chart will appear:

The above spending function is according to Lan and DeMets (1983) with O'Brien-Fleming flavor, and for one-sided tests has the following functional form:

$$\alpha(t) = 2 - 2\Phi\left(\frac{Z_{\alpha/2}}{\sqrt{t}}\right)$$

Observe that very little of the total type-1 error is spent early on, but more is spent rapidly as the information fraction increases, and reaches 0.025 at an information fraction of 1.

Feel free to explore other plots by clicking the  icon in the **Library** toolbar. Close all charts before continuing. To obtain the tables used to generate these plots, click the  icon.

Select Des 2 in the **Library**, and click  on the **Library** toolbar. In the **Boundary Info** tab, change the **Boundary Family** from **Spending Functions** to

Wang-Tsiatis. The Wang-Tsiatis (1989) power boundaries are of the form

$$c(t_j) = C(\Delta, \alpha, K)t_j^\Delta$$

for $j = 1, 2, \dots, K$, where Δ is a shape parameter that characterizes the boundary shape and $C(\Delta, \alpha, K)$ is a positive constant. The choice $\Delta = 0$ will yield the classic O'Brien-Fleming stopping boundary, whereas the $\Delta = 0.5$ will yield the classic Pocock stopping boundary. Other choices of parameters in the range -0.5 to 0.5 are also permitted. Accept the default parameter 0 and click **Compute** to obtain the sample size.

A new row will be added to the **Output Preview** with design name as Des 3.

Select all three rows in **Output Preview** using the Ctrl key and click  . All three designs will be displayed in the **Output Summary**.

12 Normal Non-inferiority Two-Sample

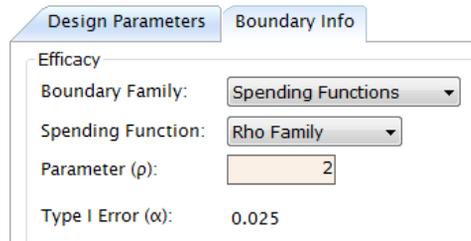

Note that the total sample size and the expected sample size under H_1 for Des 3 are close to those for Des 2. This is expected because the Wang-Tsiatis power family with shape parameter 0 yields the classic O'Brien-Fleming stopping boundaries. Save this design in the current workbook by selecting the corresponding row in **Output Preview** and clicking  on the **Output Preview** toolbar.

Select Des 2 in the **Library**, and click the  on the **Library** toolbar. In the **Boundary Info** tab, change the **Spending Function** from **Lan-DeMets** to **Rho Family**. The Rho spending function was first published by Kim and DeMets (1987) and was generalized by Jennison and Turnbull (2000). It has following functional form:

$$\alpha(t) = \alpha t^\rho \quad \rho > 0$$

When $\rho = 1$, the corresponding stopping boundaries resemble the Pocock stopping boundaries. When $\rho = 3$, the boundaries resemble the O'Brien-Fleming boundaries. Larger value of ρ yield increasingly conservative boundaries.

Specify parameter (ρ) as 2, and click **Compute**

| Design Parameters | | Boundary Info | |
|----------------------------|--------------------|---------------|--|
| Efficacy | | | |
| Boundary Family: | Spending Functions | | |
| Spending Function: | Rho Family | | |
| Parameter (ρ): | 2 | | |
| Type I Error (α): | 0.025 | | |

A new row will be added to the **Output Preview** with design name as Des 4. Select all four rows in **Output Preview** using the Ctrl key and click . All the designs will

be displayed in the **Output Summary**.

| | Des1 | Des2 | Des3 | Des4 |

Click **Simulate**. Once the simulation run has completed, East will add an additional

12 Normal Non-inferiority Two-Sample

row to the **Output Preview** labeled as Sim 1.

Select Sim 1 in the **Output Preview** and click . Double-click Sim 1 in the **Library**. The simulation output details will be displayed.

| Simulation Parameters | |
|--------------------------------|------------------|
| Simulation ID | Sim1 |
| Design Type | Noninferiority |
| Number of Looks | 3 |
| Test Type | 1-Sided |
| Sample Size (n) | 487 |
| Noninf. Margin (δ_0) | -3 |
| Test Statistic | t |
| Avg. Power at Termination | 0.899 |
| Response Generation Parameters | |
| Generate Data Using | Individual Means |
| Mean Control (μ_c) | 9 |
| Mean Treatment (μ_t) | 9 |
| SD Control (σ_c) | 10 |
| SD Treatment (σ_t) | 10 |
| Simulation Control Parameters | |
| Starting Seed | Clock |
| Number of Simulations | 10000 |

⊖ Average Sample Size

| Look # | Average Sample Size (n) |
|---------|-------------------------|
| 1 | 162 |
| 2 | 325 |
| 3 | 487 |
| Average | 350.215 |

⊖ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | Stopping For | Total Simulations | |
|--------|-----------------|------------|--------------|-------------------|---------|
| | | Efficacy | Efficacy | Count | % |
| 1 | 162 | 2.774 | 2026 | 2026 | 20.260% |
| 2 | 325 | 2.346 | 4379 | 4379 | 43.790% |
| 3 | 487 | 2.062 | 2580 | 3595 | 35.950% |
| Total | | | 8985 | 10000 | |
| % | | | 89.850% | | |

The upper efficacy stopping boundary was crossed around 90% of times, out of 10,000 simulated trials, which is consistent with the power of 90%. The exact result of the simulations may differ slightly, depending on the seed.

12.1.4 Interim Monitoring

Select Des 4 in the **Library**, and click  from the **Library** toolbar. Alternatively,

right-click on Des 4 and select **Interim Monitoring**.

| Enter Interim Data | | | | | | | | | | | Interim Monitoring: Des4 | | | | |

Error Spending

| Info. Fraction | α |
|----------------|----------|
| | |

Confidence Intervals

| Info. Fraction | RCI Upper | RCI Lower |
|----------------|-----------|-----------|
| | | |

The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

Although the study has been designed assuming three equally spaced analyses, departures from this strategy are permissible using the spending function methodology of Lan and DeMets (1983) and its extension to boundaries for early stopping in favor of H_0 proposed by Pampallona, Tsiatis and Kim (2001). At each interim analysis time point, East will determine the amount of type-1 error probability and type-2 error probability that it is permitted to spend based on the chosen spending functions specified in the design. East will then re-compute the corresponding stopping boundaries. This strategy ensures that the overall type-1 error does not exceed the nominal significance level α .

12 Normal Non-inferiority Two-Sample

Let us take the first look after accruing 200 subjects. The test statistic at look j for testing non-inferiority is given by

$$Z_j = \frac{\hat{\delta}_j - \delta_0}{SE(\hat{\delta}_j)}$$

where $\hat{\delta}_j$ and δ_0 indicate estimated treatment difference and the non-inferiority margin, respectively. SE denotes the standard error. Suppose we have observed $\hat{\delta}_j = 2.3033$ and $SE(\hat{\delta}_j) = 2.12132$. With $\delta_0 = -3$, the value of test statistic at first look would be $Z_1 = (2.3033 + 3)/2.12132$ or 2.5.

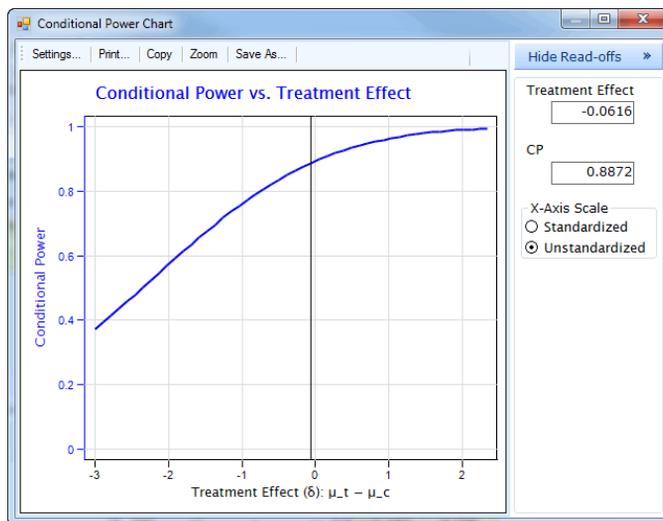

To pass these values to East, click **Enter Interim Data** to open the **Test Statistic Calculator**. Enter the following values: 200 for **Cumulative Sample Size**, 2.3033 as **Estimate of δ** and 2.12132 as **Standard Error of Estimate of δ** . Click **Recalc**, and then **OK**.

The screenshot shows a window titled "Test Statistic Calculator". It has a "Recalc" button on the left and "OK" and "Cancel" buttons on the right. The main area is titled "Editing Look #1" and contains a checkbox "Set Current Look as Last" which is unchecked. Below this are three input fields: "Cumulative Sample Size" with the value 200, "Estimate of δ " with the value 2.3033, and "Standard Error of Estimate of δ " with the value 2.1232. Below these are two output fields: "Estimate of $\delta - \delta_0$ " with the value 5.303 and "Test Statistic" with the value 2.498. The output fields have a yellow background.

The value of test statistic is 2.498, which is very close to the stopping boundary 2.634. The lower bound of 97.5% repeated confidence interval (RCI) for δ is -3.29.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|------------------------|--------|
| | | | | | | | Upper | Lower |
| 1 | 0.411 | 200 | 2.5 | 2.303 | 2.121 | 2.634 | Infinity | -3.285 |
| 2 | | | | | | | | |
| 3 | | | | | | | | |

Click the  icon in the **Conditional Power** chart located in lower part of the dashboard.

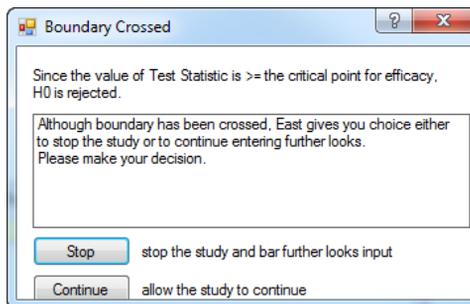

The conditional power at the current effect size 2.303 is over 99.3%.

Suppose we take the next interim look after accruing 350 subjects. Enter **350** for **Cumulative Sample Size**, **2.3033** for **Estimate of δ** and **1.71047** for **Standard Error of Estimate of δ** . Click **Recalc** and **OK** to update the charts and tables in the dashboard.

12 Normal Non-inferiority Two-Sample

Now the stopping boundary is crossed and the following dialog box appears.

Click **Stop**. The dashboard will now include the following table.

| Final Inference | |
|--|--------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0.005 |
| Adj. Pt. Est. for δ | 2.013 |
| Adj. 95% CI for δ | |
| Upper Confidence Bound | 5.486 |
| Lower Confidence Bound | -1.692 |
| Post-Hoc Power | |

The adjusted confidence interval and p-value are calculated according to the approach proposed by Tsiatis, Rosner and Mehta (1984) and later extension by Kim and DeMets (1987). The basic idea here is to search for the confidence bounds such that the p-value under the alternative hypothesis just becomes statistically significant.

12.1.5 Trial Design Using a t-Test (Single Look)

In Section 12.1 the sample size is obtained based on asymptotic approximation of the distribution of the test statistics

$$\frac{\hat{\delta} - \delta_0}{\sqrt{\text{var}[\hat{\delta}]}}$$

If the study under consideration is small, the above asymptotic approximation of the distribution may be poor. Using the student's t-distribution with $(n - 1)$ degrees of freedom, we may better size the trial to have appropriate power to reject the H_0 . In East, this can be done through specifying distribution of test statistic as t . We shall illustrate this by designing the study described in Section 12.1 that aims to demonstrate that the AII inhibitor is non-inferior to the ACE inhibitor.

Select Des 1 from the **Library**. Click  from the toolbar. Change the **Test Statistic** from **Z** to **t**. The entries for the other fields need not be changed. Click **Compute**. East will add an additional row to the **Output Preview** labeled as Des 5. The required sample size is 469. Select the rows corresponding to Des 1 and Des 5 and . This will display both designs in the **Output Summary**.

| | Des 1 | Des 5 |

| Sample Size | | |
| Maximum | 467 | 469 |

Des 5, which used the t distribution, requires us to commit a combined total of 469 patients to the study, up from 467 in Des 1, which used the normal distribution. The extra patients are needed to compensate for the extra variability due to estimation of the $\text{var}[\hat{\delta}]$.

12.2 Ratio of Means

12.2.1 Trial design

12.2.2 Designing the study

12.2.3 Simulation

Let μ_t and μ_c denote the means of the observations from the experimental treatment (T) and the control treatment (C), respectively, and let σ_t^2 and σ_c^2 denote the corresponding variances of the observations. It is assumed that $\sigma_t/\mu_t = \sigma_c/\mu_c$, i.e. the coefficient of variation $CV = \sigma/\mu$ is the same for t and c . Finally, let $\rho = \mu_t/\mu_c$.

For a non-inferiority trial with ratio of means we define the null hypothesis as

- $H_0 : \rho \leq \rho_0$ if $\rho_0 < 1$
- $H_0 : \rho \geq \rho_0$ if $\rho_0 > 1$

where ρ_0 denotes the noninferiority margin. Consider the case when $\rho_0 < 1$. Now define $\delta = \ln(\rho) = \ln(\mu_t) - \ln(\mu_c)$, so the null hypothesis becomes $H_0: \delta \leq \delta_0$ where $\delta_0 = \ln(\rho_0)$.

Since we can translate the ratio hypothesis into a difference hypothesis, we can perform the test for difference as discussed in section 12.1 on log-transformed data.

12 Normal Non-inferiority Two-Sample

Here, we need the standard deviation of log transformed data. If we are provided with the coefficient of variation (CV) instead, the standard deviation of log transformed data can be obtained using the relation $sd = \sqrt{\ln(1 + CV^2)}$.

12.2.1 Trial design

For illustration, we consider the example cited by Laster and Johnson (2003): A randomized clinical study of a new anti-hypertensive therapy known to produce fewer side-effects than a standard therapy but expected to be almost 95% effective ($\rho_1 = 0.95$). To accept the new therapy, clinicians want a high degree of assurance that it is at least 80% as effective in lowering blood pressure as the standard agent. Accordingly we plan to design the study to test:

$$H_0 : \mu_t / \mu_c \leq 0.8$$

against

$$H_1 : \mu_t / \mu_c > 0.8$$

Reductions in seated diastolic blood pressure are expected to average 10 mmHg ($= \mu_c$) with standard therapy with standard deviation as 7.5 mmHg ($= \sigma_c$). Therefore, CV in the standard therapy is $7.5/10 = 0.75$. We also assume that CV in both therapies are equal. We need to design a study that would have 90% power at $\rho_1 = 0.95$ under H_1 and maintains one-sided type I error at 5%.

12.2.2 Designing the study

Start East afresh. Click **Continuous: Two Samples**, under the **Design** tab, and then click **Parallel Design: Ratio of Means**.

In the input window, select **Noninferiority** for **Design Type**. Select **Individual Means** for **Input Method** and then specify the **Mean Control** (μ_c) as 10, **Noninferiority Margin** (ρ_0) as 0.8 and **Ratio of Means** (ρ_1) as 0.95. Specify 0.75

value for **Coeff. Var.**. The upper pane should appear as below:

Click **Compute**. This will calculate the sample size for this design, and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed total sample size (636 subjects) is highlighted in yellow.

| ID | Design Type | Test Type | Specified α | Power | Input Method | Sample Size | nt/nc | Test Statistic | ρ | μ_c | Mean Treatment (Alt.) | ρ_0 | C V of Data |
|-------|----------------|-----------|--------------------|-------|------------------|-------------|-------|----------------|--------|---------|-----------------------|----------|-------------|
| Des 1 | Noninferiority | 1-Sided | 0.025 | 0.9 | Individual Means | 636 | 1 | Z | 0.95 | 10 | 9.5 | 0.8 | 0.75 |

This design has default name Des 1. Select this design by clicking anywhere along the row in the **Output Preview** and click . Some of the design details will be

12 Normal Non-inferiority Two-Sample

displayed in the **Output Summary**.

|----------------|------|
| Critical Point | 1.96 |
|----------------|------|

Unequal allocation ratio

Since the profile of standard therapy is well established and comparatively little is known about the new therapy, you want to put more subjects on the new therapy. You can do this by specifying allocation ratio greater than 1. Suppose you want 50% more subjects on new therapy compared to standard one. Then we need to specify allocation ratio (n_t/n_c) as 1.5.

Create a new design by selecting Des 1 in the **Output Preview**, and clicking  on the Output toolbar. In the Input, change the **Allocation Ratio** from 1 to 1.5. Click **Compute** to obtain sample size for this design. A new row will be added labeled as Des 2.

Save this design in the current workbook by selecting the corresponding row in **Output Preview** and clicking  on the **Output Preview** toolbar. Select both rows in **Output Preview** using the Ctrl key and click .

Out of 10,000 simulations, close to 90% are rejected for non-inferiority. Therefore, the simulation result verifies that the design attains 90% power. The simulation result might vary depending on the starting seed value chosen.

12 Normal Non-inferiority Two-Sample

12.3 Difference of Means in Crossover Designs

12.3.1 Trial Design

In a 2×2 crossover design each subject is randomized to one of two sequence groups. Subjects in sequence group 1 receive the test drug (T) formulation in a first period, have their outcome variable, X recorded, wait out a washout period to ensure that the drug is cleared from their system, then receive the control drug formulation (C) in period 2 and finally have the measurement on X again. In sequence group 2, the order in which the T and C are assigned is reversed. The table below summarizes this type of trial design.

| Group | Period 1 | Washout | Period 2 |
|-------|----------|---------|----------|
| 1(TC) | Test | — | Control |
| 2(CT) | Control | — | Test |

The resulting data are commonly analyzed using a linear model. The response y_{ijk} in period j on subject k in sequence group i , where $i = 1, 2$, $j = 1, 2$, and $k = 1, \dots, n_i$ is modeled as a linear function of an overall mean response μ , formulation effect τ_t and τ_c , period effects π_1 and π_2 , and sequence effects γ_1 and γ_2 . The fixed effects model can be displayed as:

| Group | Period 1 | Washout | Period 2 |
|-------|-----------------------------------|---------|-----------------------------------|
| 1(TC) | $\mu + \tau_t + \pi_1 + \gamma_1$ | — | $\mu + \tau_c + \pi_2 + \gamma_1$ |
| 2(CT) | $\mu + \tau_c + \pi_1 + \gamma_2$ | — | $\mu + \tau_t + \pi_2 + \gamma_2$ |

Let $\mu_t = \mu + \tau_t$ and $\mu_c = \mu + \tau_c$ denote the means of the observations from the test and control formulations, respectively, and let MSE denote the mean-squared error.

In a noninferiority trial, we test $H_0 : \delta \leq \delta_0$ against $H_0 : \delta > \delta_0$ if $\delta_0 < 0$ or $H_0 : \delta \geq \delta_0$ against $H_0 : \delta < \delta_0$ if $\delta_0 > 0$, where δ_0 indicates the noninferiority margin.

East uses following test statistic to test the above null hypothesis

$$T_L = \frac{(\bar{y}_{11} - \bar{y}_{12} - \bar{y}_{21} + \bar{y}_{22})/2 - \delta_0}{\sqrt{\frac{\hat{\sigma}^2}{2} \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$$

where, \bar{y}_{ij} is the mean of the observations from group i and period j and $\hat{\sigma}^2$ is the estimate of error variance. T_τ is distributed with Student's t distribution with $(n_1 + n_2 - 2)$ degrees of freedom.

12.3.1 Trial Design

Consider a 2×2 crossover trial between a Test drug (T) and a Reference Drug (C) where the noninferiority need to be established in terms of some selected treatment response. Let μ_T and μ_C denote the mean of Test and Reference drugs, respectively. Let $\delta = \mu_t - \mu_c$ be the difference in averages. The noninferiority margin were set at -3. Accordingly we plan to design the study to test:

$$H_0 : \mu_t - \mu_c \leq -3$$

against

$$H_1 : \mu_t - \mu_c > -3$$

For this study, we consider $\mu_c = 21.62$ ng.h/mL and $\mu_t = 23.19$ ng.h/mL under H_1 . Further we assume mean squared error (MSE) would be 2.5. We want to design a study that would have 90% power at $\delta_1 = 23.19 - 21.62 = 1.57$ under H_1 . We want to perform this test at a one sided 0.025 level of significance.

Start East afresh. First, **Continuous: Two Samples** on the **Design** tab, and then click **Crossover Designs: Difference of Means**.

In the input window, select **Noninferiority** for **Design Type**. Select **Individual Means** for **Input Method** and then specify the **Mean Control (μ_c)** as 21.62 and **Mean Treatment (μ_t)** as 23.19. Enter the **Type I Error (α)** as 0.025. Select **Sqrt (MSE)** from the drop-down list and enter as 2.5. Finally, enter **Noninferiority Margin (δ_0)** as -3. The upper pane should appear as below:

Design: Continuous Endpoint: Two-Sample Test - Crossover Design - Difference of Means

12.4 Ratio of Means in Crossover Designs

12.4.1 Trial Design

We consider the same anti-hypertensive therapy example discussed in section 12.2, but this time we will assume that the data has come from a crossover design. We wish to test the following hypotheses:

$$H_0 : \mu_t / \mu_c \leq 0.8$$

against

$$H_1 : \mu_t / \mu_c > 0.8$$

We want the study to have at least 90% power at $\rho_1 = 0.95$ and maintains one-sided test I error at 5%. As before, we will consider $CV = 0.75$ for both treatment arms.

Start East afresh. First, click **Continuous: Two Samples** under the **Design** tab, and then click **Crossover Design: Ratio of Means**.

In the input window, select **Noninferiority** for **Design Type**. Select **Individual Means** for **Input Method** and then specify the **Noninferiority**

Margin (ρ_0) as 0.8, **Mean Control** (μ_c) as 10, and **Mean Treatment** (μ_t) as 9.5. Using the relationship between CV (=0.75) and standard deviation of log-transformed data mentioned in section 12.2, we have standard deviation for log-transformed data as 0.45. Specify 0.45 for **Sqrt. of MSE Log**. The upper pane should appear as below:

Click **Compute**. The sample size required for this design is highlighted in yellow in the Output Preview pane. Save this design in the current workbook by selecting the corresponding row in **Output Preview** and clicking on the **Output Preview** toolbar. Select Des 1 in **Library** and click . This will display the design details.

12 *Normal Non-inferiority Two-Sample*

In general, a crossover design requires fewer subjects compared to its parallel design counterpart, and may be preferred whenever it is feasible.

13

Normal Equivalence Two-Sample

In many cases, the goal of a clinical trial is neither superiority nor non-inferiority, but equivalence. In Section 13.1, the problem of establishing the equivalence with respect to the difference of the means of two normal distributions using a parallel-group design is presented. The corresponding problem of establishing equivalence with respect to the log ratio of means is presented in Section 13.2. For the crossover design, the problem of establishing equivalence with respect to the difference of the means is presented in Section 13.3, and with respect to the log ratio of means in Section 13.4.

13.1 Difference in Means

13.1.1 Trial design

13.1.2 Simulation

In some experimental situations, we want to show that the means of two normal distributions are “close”. For example, a test formulation of a drug (T) and the control (or reference) formulation of the same drug (C) are considered to be bioequivalent if the rate and extent of absorption are similar. Let μ_t and μ_c denote the means of the observations from the test and reference formulations, respectively, and let σ^2 denote the common variance of the observations. The goal is to establish that $\delta_L < \mu_t - \mu_c < \delta_U$, where δ_L and δ_U are a-priori specified values used to define equivalence. The two one-sided tests (TOST) procedure of Schuirmann (1987) is commonly used for this analysis, and is employed in this section for a parallel-group study.

Let $\delta = \mu_t - \mu_c$ denote the true difference in the means. The null hypothesis $H_0: \delta \leq \delta_L$ or $\delta \geq \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L < \delta < \delta_U$ at level α , using TOST. Here we perform the following two tests together:

- Test1: $H_{0L}: \delta \leq \delta_L$ against $H_{1L}: \delta > \delta_L$ at level α
- Test2: $H_{0U}: \delta \geq \delta_U$ against $H_{1U}: \delta < \delta_U$ at level α

H_0 is rejected in favor of H_1 at level α if and only if both H_{0L} and H_{0U} are rejected. Note that this is the same as rejecting H_0 in favor of H_1 at level α if the $(1 - 2\alpha)$ 100% confidence interval for δ is completely contained within the interval (δ_L, δ_U) .

Let N be the total sample size and $\hat{\mu}_t$ and $\hat{\mu}_c$ denote the estimates of the means T and C, respectively. Let $\hat{\delta} = \hat{\mu}_t - \hat{\mu}_c$ denote the estimated difference with standard error $se(\hat{\delta})$

We use the following two test statistics to apply Test1 and Test2, respectively:

$$T_L = \frac{(\hat{\delta} - \delta_L)}{se(\hat{\delta})}, T_U = \frac{(\hat{\delta} - \delta_U)}{se(\hat{\delta})}$$

13 Normal Equivalence Two-Sample

T_L and T_U are assumed to follow Student's t-distribution with $(N - 2)$ degrees of freedom under H_{0L} and H_{0U} , respectively. H_{0L} is rejected if $T_L \geq t_{1-\alpha, (N-2)}$, and H_{0U} is rejected if $T_U \leq t_{\alpha, (N-2)}$.

The null hypothesis H_0 is rejected in favor of H_1 if $T_L \geq t_{1-\alpha, (N-2)}$ and $T_U \leq t_{\alpha, (N-2)}$, or in terms of confidence intervals: Reject H_0 in favor of H_1 at level α if

$$\delta_L + t_{1-\alpha, (N-2)} 2\hat{\sigma} / \sqrt{N} < \hat{\delta} < \delta_U + t_{\alpha, (N-2)} 2\hat{\sigma} / \sqrt{N}. \quad (13.1)$$

We see that decision rule (13.1) is the same as rejecting H_0 in favor of H_1 if the $(1 - 2\alpha)$ 100% confidence interval for δ is entirely contained within interval (δ_L, δ_U) .

The above inequality (13.1) cannot hold if $4t_{1-\alpha, (N-2)} \hat{\sigma} / \sqrt{N} \geq (\delta_U - \delta_L)$, in which case H_0 is not rejected in favor of H_1 . Thus, we assume that $4t_{1-\alpha, (N-2)} \hat{\sigma} / \sqrt{N} < (\delta_U - \delta_L)$. The impact of this assumption was examined by Bristol (1993a).

The power or sample size of such a trial design is determined for a specified value of δ , denoted δ_1 , for a single-look study only. The choice $\delta_1 = 0$, i.e. $\mu_t = \mu_c$, is common. For a specified value of δ_1 , the power is given by

$$\Pr(\text{Reject } H_0) = 1 - \tau_\nu(t_{\alpha, \nu} | \Delta_1) + \tau_\nu(-t_{\alpha, \nu} | \Delta_2) \quad (13.2)$$

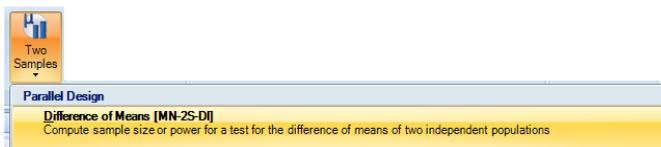

where $\nu = N - 2$ and Δ_1 and Δ_2 are non-centrality parameters given by $\Delta_1 = (\delta_1 - \delta_L) / se(\hat{\delta})$ and $\Delta_2 = (\delta_1 - \delta_U) / se(\hat{\delta})$, respectively. $t_{\alpha, \nu}$ denotes the upper $\alpha \times 100\%$ percentile from a Student's t distribution with ν degrees of freedom. $\tau_\nu(x | \Delta)$ denotes the distribution function of a non-central t distribution with ν degrees of freedom and non-centrality parameter Δ , evaluated at x .

Since we don't know the sample size N ahead of time, we cannot characterize the bivariate t-distribution. Thus solving for sample size must be performed iteratively by equating the formula (13.2) to the power $1 - \beta$.

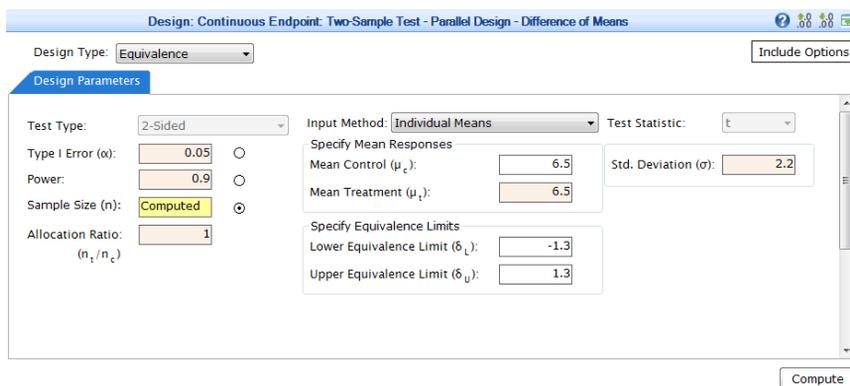

13.1.1 Trial design

Consider the situation where we need to establish equivalence between a test formulation of capsules (T) with the marketed capsules (C). The response variable is the change from baseline in total symptom score. Based on the studies conducted during the development program, it is assumed that $\mu_c = 6.5$. Based on this value, equivalence limits were set as $-\delta_L = \delta_U = 1.3 (= 20\% \mu_c)$. We assume that the common standard deviation is $\sigma = 2.2$. We want to have 90% power at $\mu_t = \mu_c$.

Start East afresh. Click **Continuous: Two Samples** on the **Design** tab and then click **Parallel Design: Difference of Means**.

This will launch a new window. The upper pane of this window displays several fields with default values. Select **Equivalence** for **Design Type**, and **Individual Means** for **Input Method**. Enter 0.05 for **Type I Error**. Specify both **Mean Control** (μ_c) and **Mean Treatment** (μ_t) as 6.5. We have assumed $\sigma = 2.2$. Enter this value for **Std. Deviation** (σ). Also enter -1.3 for **Lower Equivalence Limit** (δ_L) and 1.3 for **Upper Equivalence Limit** (δ_U). The upper pane should appear as below:

Click **Compute**. The output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (126 subjects) is highlighted in yellow.

| ID | Design Type | Test Type | Specified α | Power | nt/nc | Sample Size | Input Method | δ_L | μ_c | Mean Treatment (Alt.) | δ_L | δ_U | σ | Test Statistic |
|------|-------------|-----------|--------------------|-------|-------|-------------|------------------|------------|---------|-----------------------|------------|------------|----------|----------------|
| Des1 | Equivalence | 2-Sided | 0.05 | 0.902 | 1 | 126 | Individual Means | 0 | 6.5 | 6.5 | -1.3 | 1.3 | 2.2 | t |

This design has default name Des 1. Select this design and click  in the **Output Preview** toolbar. Some of the design details will be displayed in the upper pane,

13 Normal Equivalence Two-Sample

labeled as **Output Summary**.

| Des 1 | |

| Std. Deviation (σ) | 2.2 |
| Test Statistic | t |
| Allocation Ratio (nt / nc) | 1 |
| Sample Size | |
| Maximum | 126 |

A total of 126 subjects must be enrolled in order to achieve the desired 90% power under the alternative hypothesis. Of these 126 subjects 63 will be randomized to the test formulation, and the remaining 63 to the marketed formulation. In the **Output Preview** toolbar, select Des 1 and click  to save this design to Wbk1 in the **Library**.

Suppose that this sample size is not economically feasible and we want to examine power for a total sample size of 100. Select Des 1 in the **Library**, and click  on the **Library** toolbar. In the Input, click the radiobutton for **Power**, and enter **Sample Size** (n) as 100.

Design Parameters

Test Type: 2-Sided ▾

Type I Error (α): 0.05

Power: Computed

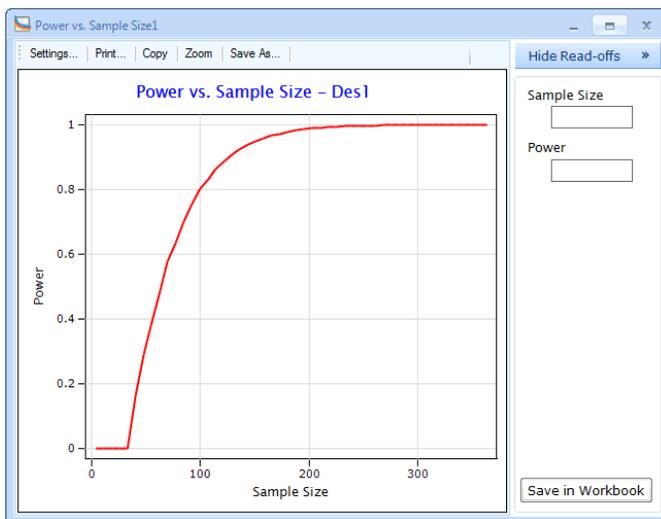

Sample Size (n): 100

Allocation Ratio: 1
(n_t / n_c)

Click **Compute**. This will add a new row to the **Output Preview** and the calculated power is highlighted in yellow. We see that a power of 80.3% can be achieved with 100 subjects.

| ID | Design Type | Test Type | Specified α | Power | nt/nc | Sample Size |
|------|-------------|-----------|--------------------|-------|-------|-------------|
| Des1 | Equivalence | 2-Sided | 0.05 | 0.902 | 1 | 126 |
| Des2 | Equivalence | 2-Sided | 0.05 | 0.803 | 1 | 100 |

Suppose we want to see how the design parameters such as power, sample size and treatment effect are interrelated. To visualize any particular relationship for Des 1, first select Des 1 from **Library** and then click  in the toolbar. You will see a list of options available. To plot power against sample size, click **Power vs Sample Size**.

Feel free to explore other plots and options available with them. Close the charts before continuing.

13.1.2 Simulation

We wish to make sure that Design 1 has the desired power of 90%, and maintains the type I error of 5%. This examination can be conducted using simulation. Select Des 1 in the **Library**, and click  in the toolbar. Alternatively, right-click Des 1 and

13 Normal Equivalence Two-Sample

select **Simulate**. A new Simulation window will appear. Click on the **Response Generation Info** tab. We will first simulate under H_1 . Leave the default values as below, and click **Simulate**.

| Simulation Parameters | | Response Generation Info | | Simulation Control Info | |
|-----------------------------|------------------|---|-----|-------------------------|--|
| Generate Data Using: | Individual Means | <input checked="" type="checkbox"/> Common Standard Deviation | | | |
| Mean Control (μ_c): | 6.5 | SD Control (σ_c): | 2.2 | | |
| Mean Treatment (μ_t): | 6.5 | SD Treatment (σ_t): | 2.2 | | |

Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1.

Select Sim 1 in the **Output Preview** and click . Now double-click on Sim 1 in the **Library**. The simulation output details, including the table below, will be displayed.

Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | | Stopping For | | Total Simulations | |
|--------|-----------------|------------|--------|----------------|----------------|-------------------|----------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 126 | 1.657 | -1.657 | 9031 | 0 | 10000 | 100.000% |
| Total | | | | 9031 | 0 | 10000 | |
| % | | | | 90.310% | 0.000% | | |

Observe that out of the 10,000 simulated trials, the null hypothesis was around 90% of the time. (Note: The numbers on your screen might differ slightly because you might be using a different starting seed for your simulations.)

Next we will simulate from a point that belongs to the null hypothesis. Consider $\mu_c = 6.5$ and $\mu_t = 7.8$. Select Sim 1 in **Library** and click  icon. Go to the **Response Generation Info** tab in the upper pane and specify: **Mean Control** (μ_c) = 6.5 and **Mean Treatment** (μ_t) = 7.8.

| Simulation Parameters | | Response Generation Info | | Simulation Control Info | |
|-----------------------------|------------------|---|-----|-------------------------|--|
| Generate Data Using: | Individual Means | <input checked="" type="checkbox"/> Common Standard Deviation | | | |
| Mean Control (μ_c): | 6.5 | SD Control (σ_c): | 2.2 | | |
| Mean Treatment (μ_t): | 7.8 | SD Treatment (σ_t): | 2.2 | | |

Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 2. Select Sim 2 in the **Output Preview** and click . Now double-click on Sim 2 in the **Library**. You can see that when H_0 is true, the simulated power is close to the specified type I error of 5%.

13.2 Ratio of Means

13.2.1 Trial design

13.2.2 Simulation

For some pharmacokinetic parameters, the ratio of the means is a more appropriate measure of the distance between the treatments. Let μ_t and μ_c denote the means of the observations from the test formulation (T) and the reference (C), respectively, and let σ_t^2 and σ_c^2 denote the corresponding variances of the observations. It is assumed that $\sigma_t/\mu_t = \sigma_c/\mu_c$, i.e. the coefficient of variation $CV = \sigma/\mu$ is the same for T and C. Finally, let $\rho = \mu_t/\mu_c$.

The goal is to establish that $\rho_L < \rho < \rho_U$, where ρ_L and ρ_U are specified values used to define equivalence. In practice, ρ_L and ρ_U are often chosen such that $\rho_L = 1/\rho_U$. The two one-sided tests procedure of Schuirmann (1987) is commonly used for this analysis, and is employed here for a parallel-group study.

The null hypothesis $H_0: \rho \leq \rho_L$ or $\rho \geq \rho_U$ is tested against the two-sided alternative hypothesis $H_1: \rho_L < \rho < \rho_U$ at level α , using two one-sided tests. Schuirmann (1987) proposed working this problem on the natural logarithm scale. Thus, we are interested in the parameter $\delta = \ln(\rho) = \ln(\mu_t) - \ln(\mu_c)$ and the null hypothesis $H_0: \delta \leq \delta_L$ or $\delta \geq \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L < \delta < \delta_U$ at level α , using two one-sided t-tests. Here $\delta_L = \ln(\rho_L)$ and $\delta_U = \ln(\rho_U)$.

Since we have translated the ratio hypothesis into a difference hypothesis, we can perform the test for difference as discussed in section 13.1. Note that we need the standard deviation for log transformed data. However, if we are provided with information on CV instead, the standard deviation of log transformed data can be obtained using the relation $sd = \sqrt{\ln(1 + CV^2)}$.

13.2.1 Trial design

Suppose that the logarithm of area under the curve (AUC), a pharmacokinetic parameter related to the efficacy of a drug, is to be analyzed to compare the two formulations of a drug. We want to show that the two formulations are bioequivalent by showing that the ratio of the means satisfies $0.8 < \mu_t/\mu_c < 1.25$. Thus $\rho_L = 0.8$ and $\rho_U = 1.25$. Also, based on previous studies, it is assumed that the coefficient of variation is $CV = 0.25$.

13 Normal Equivalence Two-Sample

Start East afresh. Click **Continuous: Two Samples** on the **Design** tab and then click **Parallel Design: Ratio of Means**.

This will launch a new window. The upper pane of this window displays several fields with default values. Select **Equivalence** for **Trial Type**, and enter 0.05 for the **Type I Error**. For the **Input Method**, specify **Ratio of Means**. Enter 1 for **Ratio of Means** (ρ_1), 0.8 for **Lower Equivalence Limit** (ρ_L) and 1.25 for **Upper Equivalence Limit** (ρ_U). Specify 0.25 for **Coeff. Var.**. The upper pane should appear as below:

Click **Compute**. The output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed total sample size (55 subjects) is highlighted in yellow.

| ▲ | ID | Design Type | Test Type | Specified α | Power | Input Method | Sample Size | nt/nc | Test Statistic | ρ | ρ_L | ρ_U | C V of Data |
|---|------|-------------|-----------|--------------------|-------|----------------|-------------|-------|----------------|--------|----------|----------|-------------|
| 📄 | Des1 | Equivalence | 2-Sided | 0.05 | 0.906 | Ratio of Means | 55 | 1 | t | 1 | 0.8 | 1.25 | 0.25 |

In the **Output Preview** toolbar, click  to save this design to Wbk1 in the **Library**. Double-click Des 1 in the **Library** to see the details of the designs. Close

this output window before continuing.

13.3 Difference of Means in Crossover Designs

13.3.1 Trial design

13.3.2 Simulation

Crossover trials are widely used in clinical and medical research. The crossover design is often preferred over a parallel design, because in the former, each subject receives all the treatments and thus each subject acts as their own control. This leads to the requirement of fewer subjects in a crossover design. In this chapter, we show how East supports the design and simulation of such experiments with endpoint as difference of means.

In a 2×2 crossover design each subject is randomized to one of two sequence groups (or, treatment sequences). Subjects in sequence group 1 receive the test drug (T) formulation in a first period, have their outcome variable, X recorded, wait out a washout period to ensure that the drug is cleared from their system, then receive the control drug formulation (C) in period 2 and finally have the measurement on X again. In sequence group 2, the order in which the T and C are assigned is reversed. The table below summarizes this type of trial design.

| Group | Period 1 | Washout | Period 2 |
|-------|----------|---------|----------|
| 1(TC) | Test | — | Control |
| 2(CT) | Control | — | Test |

The resulting data are commonly analyzed using a linear model. The response y_{ijk} on the k th subject in period j of sequence group i , where $i = 1, 2, j = 1, 2$, and $k = 1, \dots, n_i$ is modeled as a linear function of an overall mean response μ , formulation effect τ_t and τ_c , period effects π_1 and π_2 , and sequence effects γ_1 and γ_2 . The fixed effects model can be displayed as:

| Group | Period 1 | Washout | Period 2 |
|-------|-----------------------------------|---------|-----------------------------------|
| 1(TC) | $\mu + \tau_t + \pi_1 + \gamma_1$ | — | $\mu + \tau_c + \pi_2 + \gamma_1$ |
| 2(CT) | $\mu + \tau_c + \pi_1 + \gamma_2$ | — | $\mu + \tau_t + \pi_2 + \gamma_2$ |

Let $\mu_t = \mu + \tau_t$ and $\mu_c = \mu + \tau_c$ denote the means of the observations from the test and control formulations, respectively, and let MSE denote the mean-squared error of the log data obtained from fitting the model. This is nothing other than the MSE from a crossover ANOVA model for the 2×2 design (2 periods and 2 sequences).

13 Normal Equivalence Two-Sample

In an equivalence trial, the goal is to establish $\delta_L < \mu_t - \mu_c < \delta_U$, where δ_L and δ_U are specified values used to define equivalence. In practice, δ_L and δ_U are often chosen such that $\delta_L = -\delta_U$. The two one-sided tests (TOST) procedure of Schuirmann (1987) is commonly used for this analysis, and is employed here for a crossover study.

Let $\delta = \mu_t - \mu_c$ denotes the true difference in the means. The null hypothesis $H_0: \delta \leq \delta_L$ or $\delta \geq \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L < \delta < \delta_U$ at level α , using TOST. Here we perform the following two tests together:

- Test1: $H_{0L}: \delta \leq \delta_L$ against $H_{1L}: \delta > \delta_L$ at level α
- Test2: $H_{0U}: \delta \geq \delta_U$ against $H_{1U}: \delta < \delta_U$ at level α

H_0 is rejected in favor of H_1 at level α if and only if both H_{0L} and H_{0U} are rejected. Note that this is the same as rejecting H_0 in favor of H_1 at level α if the $(1 - 2\alpha)$ 100% confidence interval for δ is completely contained within the interval (δ_L, δ_U) .

East uses following test statistic to test the above two null hypotheses

$$T_L = \frac{(\bar{y}_{11} - \bar{y}_{12} - \bar{y}_{21} + \bar{y}_{22})/2 - \delta_L}{\sqrt{\frac{MSE}{2} \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$$

and

$$T_U = \frac{(\bar{y}_{11} - \bar{y}_{12} - \bar{y}_{21} + \bar{y}_{22})/2 - \delta_U}{\sqrt{\frac{MSE}{2} \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$$

where, \bar{y}_{ij} is the mean of the observations from group i and period j . Both T_L and T_U are distributed as Student's t distribution with $(n_1 + n_2 - 2)$ degrees of freedom.

The power of the test (i.e. probability of declaring equivalence) depends on the true value of $\mu_t - \mu_c$. The sample size (or power) is determined at a specified value of this difference, denoted δ_1 . The choice $\delta_1 = 0$, i.e. $\mu_t = \mu_c$, is common. Note that the power and the sample size depend only on δ_L , δ_U , δ_1 , and \sqrt{MSE} .

13.3.1 Trial design

Standard 2×2 crossover designs are often recommended in regulatory guidelines to establish bioequivalence of a generic drug with off patent brand-name drug. Consider a 2×2 bioequivalence trial between a Test drug (T) and a Reference Drug (C) where equivalence needs to be established in terms of the pharmacokinetic parameter Area Under the Curve (AUC). Let μ_T and μ_c denote the average AUC for Test and

Reference drugs, respectively. Let $\delta = \mu_t - \mu_c$ be the difference. To establish average bioequivalence, the calculated 90% confidence interval of δ should fall within a pre-specified bioequivalence limit. The bioequivalence limits are set at -3 and 3. Accordingly we plan to design the study to test:

$$H_0 : \mu_t - \mu_c \leq -3 \text{ or } \mu_t - \mu_c \geq 3$$

against

$$H_1 : -3 < \mu_t - \mu_c < 3$$

From this study, we consider $\mu_c = 21.62$ ng.h/mL and $\mu_t = 23.19$ ng.h/mL under H_1 . Further, we assume that the mean squared error (MSE) from ANOVA would be 2.5. We wish to design a study that would have 90% power at $\delta_1 = 23.19 - 21.62 = 1.57$ under H_1 .

Start East afresh. Click **Continuous: Two Samples** on the **Design** tab and then click **Crossover Design: Difference of Means**.

This will launch a new window. The upper pane displays several fields with default values. Select **Equivalence** for **Design Type**, and **Individual Means** for **Input Method**. Enter 0.05 for **Type I Error**. Specify the **Mean Control** (μ_c) as 21.62 and **Mean Treatment** (μ_t) as 23.19. Select **Sqrt (MSE)** from the drop-down list and specify as 2.5. Also specify the **Lower Equiv. Limit** (δ_L) and **Upper Equiv. Limit** (δ_U) as -3 and 3, respectively. The upper pane should appear as below:

Click **Compute**. The output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (54 subjects) is highlighted in

13 Normal Equivalence Two-Sample

yellow.

13.4 Ratio of Means in Crossover Designs

Often in crossover designs, an equivalence hypothesis is tested in terms of ratio of means. These types of trials are very popular in establishing bioavailability or bioequivalence between two formulations in terms of pharmacokinetic parameters (FDA guideline on BA/BE studies for orally administered drug products, 2003). In particular, the FDA considers two products bioequivalent if the 90% confidence interval of the ratio of two means lie within (0.8, 1.25). In this chapter, we show how East supports the design and simulation of such experiments with endpoint as ratio of means.

In a 2×2 crossover design each subject is randomized to one of two sequence groups. We have already discussed 2×2 crossover design in section 13.3. However, unlike section 13.3, we are interested in the ratio of means. Let μ_t and μ_c denote the means of the observations from the experimental treatment (T) and the control treatment (C), respectively. In an equivalence trial with endpoint as ratio of means, the goal is to establish $\rho_L < \rho < \rho_U$, where ρ_L and ρ_U are specified values used to define equivalence. In practice, ρ_L and ρ_U are often chosen such that $\rho_L = 1/\rho_U$

The null hypothesis $H_0: \rho \leq \rho_L$ or $\rho \geq \rho_U$ is tested against the two-sided alternative hypothesis $H_1: \rho_L < \rho < \rho_U$ at level α , using two one-sided tests. Schuirmann (1987) proposed working this problem on the natural logarithm scale. Thus, we are interested in the parameter $\delta = \ln(\rho) = \ln(\mu_t) - \ln(\mu_c)$ and the null hypothesis $H_0: \delta \leq \delta_L$ or

13 Normal Equivalence Two-Sample

$\delta \geq \delta_U$ is tested against the two-sided alternative hypothesis $H_1: \delta_L < \delta < \delta_U$ at level α , using two one-sided t-tests. Here $\delta_L = \ln(\rho_L)$ and $\delta_U = \ln(\rho_U)$.

Since we have translated the ratio hypothesis into a difference hypothesis, we can perform the test for difference as discussed in section 13.1. Note that we need the standard deviation for log transformed data. However, if we are provided with information on CV instead, the standard deviation of log transformed data can be obtained using the relation $sd = \sqrt{\ln(1 + CV^2)}$.

13.4.1 Trial design

Standard 2×2 crossover designs are often recommended in regulatory guidelines to establish bioequivalence of a generic drug with off patent brand-name drug. Consider a 2×2 bioequivalence trial between a Test drug (T) and a Reference Drug (C) where the equivalence need to be established in terms of pharmacokinetic parameter Area Under the Curve (AUC). Let μ_T and μ_C denote the average AUC for Test and Reference drugs, respectively. Let $\rho = \mu_t/\mu_c$ be the ratio of averages. To establish average bioequivalence, the calculated 90% confidence interval of ρ should fall within a pre-specified bioequivalence limit. The bioequivalence limits are set at 0.8 and 1.25. Accordingly we plan to design the study to test:

$$H_0 : \mu_t/\mu_c \leq 0.8 \text{ or } \mu_t/\mu_c \geq 1.25$$

against

$$H_1 : 0.8 < \mu_t/\mu_c < 1.25$$

From this study, we consider $\mu_c = 21.62$ ng.h/mL and $\mu_t = 23.19$ ng.h/mL under H_1 . Further, we assume that the coefficient of variation (CV), or intrasubject variability, is 17%. For a lognormal population, the mean squared error (MSE) from ANOVA of log-transformed data, and CV, are related by: $MSE = \log(1 + CV^2)$. Thus in this case MSE is 0.0285 and its square-root is 0.169. We wish to design a study that would have 90% power at $\rho_1 = 23.19/21.62 = 1.073$ under H_1 .

Start East afresh. Click **Continuous: Two Samples** on the **Design** tab and then click **Crossover Design: Ratio of Means**.

This will launch a new window. The upper pane displays several fields with default values. Select **Equivalence** for **Design Type**, and **Individual Means** for **Input Method**. Enter 0.05 for **Type I Error**. Then specify the **Mean Control** (μ_c) as 21.62 and **Mean Treatment** (μ_t) as 23.19. Specify 0.169 for **Sqrt. of MSE Log**. Also

specify the **Lower Equiv. Limit** (ρ_L) and **Upper Equiv. Limit** (ρ_U) as 0.8 and 1.25, respectively. The upper pane should appear as below:

Click **Compute**. The output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (23 subjects) is highlighted in yellow.

| ID | Design Type | Test Type | Specified α | Power | Input Method | Sample Size | ntc/nct | Test Statistic | μ_c | Mean Treatment (Alt.) | ρ_L | ρ_U | Sqrt MSE Log |

14

Normal: Many Means

In this section, we will illustrate various tests available for comparing more than two continuous means in East.

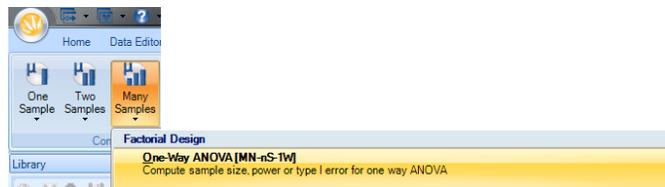

14.1 One Way ANOVA

14.1.1 One Way Contrast

In a one-way ANOVA test, we wish to test the equality of means across R independent groups. The two sample difference of means test for independent data is a one-way ANOVA test for 2 groups. The null hypothesis $H_0 : \mu_1 = \mu_2 = \dots = \mu_R$ is tested against the alternative hypothesis H_1 : for at least one pair (i, j) , $\mu_i \neq \mu_j$, where $i, j = 1, 2, \dots, R$.

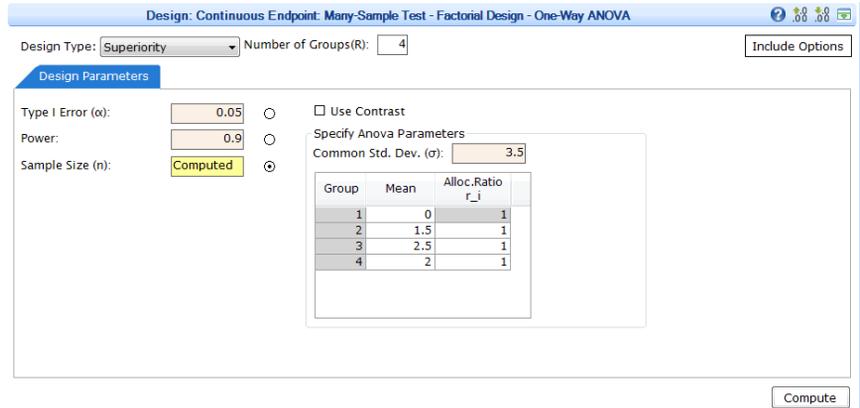

Suppose n patients have been allocated randomly to R treatments. We assume that the data of the R treatment groups comes from R normally distributed populations with the same variance σ^2 , and with population means $\mu_1, \mu_2, \dots, \mu_R$.

To design a one-way ANOVA study in East, first click **Continuous: Many Samples** on the **Design** tab, and then click **Factorial Design: One Way ANOVA**.

In the upper pane of this window is the input dialog box. Consider a clinical trial with four groups. Enter 4 in **Number of Groups(R)**. The trial is comparing three different doses of a drug against placebo in patients with Alzheimer's disease. The primary objective of the study is to evaluate the efficacy of these three doses, where efficacy is assessed by *difference from placebo* in cognitive performance measured on a 13-item cognitive subscale. On the basis of pilot data, the expected mean responses are 0, 1.5, 2.5, and 2, for Groups 1 to 4, respectively. The common standard deviation within each group is $\sigma = 3.5$. We wish to compute the required sample size to achieve 90% power with a type-1 error of 0.05. Enter these values into the dialog box as shown below.

Then, click **Compute**.

The design is shown as a row in the **Output Preview**, located in the lower pane of the window. The computed sample size (203) is highlighted in yellow.

| ▲ | ID | Design Type | Specified α | Power | Sample Size | Δ | Groups | σ | Variance of Means |
|---|------|-------------|--------------------|-------|-------------|----------|--------|----------|-------------------|
| | Des1 | Superiority | 0.05 | 0.901 | 203 | 0.071 | 4 | 3.5 | 0.875 |

Select this row, then click in the **Output Preview** toolbar to save this design to Workbook1 in the **Library**. With Des1 selected in the **Library**, click to

14 Normal: Many Means

display the following output.

| 2 | 1.5 | 1 |
| 3 | 2.5 | 1 |
| 4 | 2 | 1 |

The output indicates that 51 patients per group is necessary to achieve the desired power. Close this output window before continuing.

14.1.1 One Way Contrast

A contrast of the population means is a linear combination of the μ_i 's. Let c_i denote the coefficient for population mean μ_i in the linear contrast. For a single contrast test of many means in a one-way ANOVA, the null hypothesis is $H_0 : \sum c_i \mu_i = 0$ versus a two-sided alternative $H_1 : \sum c_i \mu_i \neq 0$, or a one-sided alternative $H_1 : \sum c_i \mu_i < 0$ or $H_1 : \sum c_i \mu_i > 0$.

With Des1 selected in the **Library**, click . In the input dialog box, click the checkbox titled **Use Contrast**, and select a two-sided test. Ensure that the means for each group are the same as those from Des1 (0, 1.5, 2.5, and 2). In addition, we wish the test the following contrast: $-3, 1, 1, 1$, which compares the placebo group with the average of the three treatment groups. Finally, we may enter unequal allocation ratios such as: $1, 2, 2, 2$, which implies that twice as many patients will be assigned to each

treatment group as in the placebo group. Click **Compute**.

Use Contrast

Specify Anova Parameters

Common Std. Dev. (σ):

| Group | Mean | Contrast Coefficient | Alloc. Ratio r_i |
|-------|------|----------------------|--------------------|
| 1 | 0 | -3 | 1 |
| 2 | 1.5 | 1 | 2 |
| 3 | 2.5 | 1 | 2 |
| 4 | 2 | 1 | 2 |

The following row will be added to the **Output Preview**.

| ▲ | ID | Design Type | Specified α | Power | Sample Size | Δ | Groups | σ | Variance of Means | Test Type | Contrast | Scale |
|---|------|-------------|--------------------|-------|-------------|----------|--------|----------|-------------------|-----------|----------|-------|
| | Des1 | Superiority | 0.05 | 0.901 | 203 | 0.071 | 4 | 3.5 | 0.875 | | | |
| | Des2 | Superiority | 0.05 | 0.9 | 265 | 0.529 | 4 | 3.5 | | 2-Sided | 6 | 3.24 |

Given the above contrast and allocation ratios, this study would require a total of 265 patients to achieve 90% power.

14.2 One Way Repeated Measures (Const. Correlation) ANOVA

As with the one-way ANOVA discussed in subsection 14.1, the repeated measures ANOVA also tests for equality of means. However, in a repeated measures setting, all patients are measured under all levels of the treatment. As the sample is exposed to each condition in turn, the measurement of the dependent variable is repeated. Thus, there is some correlation between observations from the same patient, which needs to be accounted for. The constant correlation assumption means we assume that the correlation between observations from the same patient is constant for all patients. The correlation parameter (ρ) is an additional parameter that needs to be specified in the one way repeated measures study design.

Start East afresh. To design a repeated measure ANOVA study, click **Continuous: Many Samples**, and click **Factorial Design: One Way Repeated Measures (Constant Correlation) ANOVA**.

A specific type of repeated measures design is a longitudinal study in which patients are followed over a series of time points. As an illustration, we will consider a

14 Normal: Many Means

hypothetical study that investigated the effect of a dietary intervention on weight loss. The endpoint is decrease in weight (in kilograms) from baseline, measured at four time points: baseline, 4 weeks, 8 weeks, and 12 weeks. For **Number of Levels**, enter 4. We wish to compute the required sample size to achieve 90% power with a type-1 error of 0.05. The means at each of the four levels are: 0, 1.5, 2.5, 2 for Levels 1, 2, 3, and 4, respectively. Finally, enter $\sigma = 5$ and $\rho = 0.2$, and click **Compute**.

Sample Size Information

Sample Size (n) 330

Critical Points

Critical Point 2.642

Sample Size: Group by Group

| Group # | Sample Size Per Group |
|---------|-----------------------|
| 1 | 83 |
| 2 | 82 |
| 3 | 83 |
| 4 | 82 |

ANOVA Parameters Table Values:

| Level | Mean |
|-------|------|
| 1 | 0 |
| 2 | 1.5 |
| 3 | 2.5 |
| 4 | 2 |

The output indicates that 83 patients per group is necessary to achieve the desired power.

14.3 Two Way ANOVA

In a two-way ANOVA, there are two factors to consider, say A and B. We can design a study to test equality of means across factor A, factor B, or the interaction between of A and B. In addition to the common standard deviation σ , you also need to specify the cell means.

For example, consider a study to determine the combined effects of sodium restriction and alcohol restriction on lowering of systolic blood pressure in hypertensive men (Parker et al., 1999). Let **Factor A** be sodium restriction and **Factor B** be alcohol restriction. There are two levels of each factor (restricted vs usual sodium intake, and restricted vs usual alcohol intake), producing four groups. Each patient is randomly assigned to one of these four groups.

Start East afresh. Click **Continuous: Many Samples**, and click **Factorial Design: Two-Way ANOVA**.

14 Normal: Many Means

Enter a type-1 error of 0.05. Then enter the following values in the input dialog box as shown below: **Number of Factor A Levels** as 2, **Number of Factor B Levels** as 2, **Common Std. Dev.** as 2, **A1/B1** as 0.5, **A1/B2** as 4.7, **A2/B1** as 0.4, and **A2/B2** as 6.9. We will first select **Power for A**, then click **Compute**.

Leaving the same input values, click **Compute** after selecting **Power for B** in the input window. Similarly, click **Compute** after selecting **Power for AB**. The **Output Preview** should now have three rows, as shown below.

| ID | Specified α | Specified Power A | Specified Power B | Specified Power AB | Attained Power A | Attained Power B | Attained Power AB | Sample Size | #Factor A Levels | #Factor B Levels | σ | Var VA | Var VB | Var VAB |
|------|-------------|-------------------|-------------------|--------------------|------------------|------------------|-------------------|-------------|------------------|------------------|---|--------|--------|---------|
| Des1 | 0.05 | 0.9 | NA | NA | 0.903 | 1 | 0.946 | 156 | 2 | 2 | 2 | 0.276 | 7.156 | 0.331 |
| Des2 | 0.05 | NA | 0.9 | NA | 0.127 | 0.981 | 0.142 | 12 | 2 | 2 | 2 | 0.276 | 7.156 | 0.331 |
| Des3 | 0.05 | NA | NA | 0.9 | 0.849 | 1 | 0.906 | 132 | 2 | 2 | 2 | 0.276 | 7.156 | 0.331 |

In order to achieve at least 90% power to detect a different across means in factor A, factor B, as well as the interaction, a sample size of 156 patients is necessary (i.e., Des1). Select Des1 in the **Output Preview**, then click  in the toolbar to save to Workbook1 in the **Library**. With Des1 selected in the **Library**, click  to

display the following output.

Design: Continuous Endpoint: Many-Sample Test - Factorial Design - Two-Way ANOVA

| Test Parameters | |
|--------------------------------|----------------|
| Design ID | Des1 |
| Specified α | 0.05 |
| Attained α : | 0.05 |

| A2 | 0.4 | 6.9 | 3.65 |
| Column Mean | 0.45 | 5.8 | 3.125 |

The output indicates that 39 patients per group is necessary to achieve 90% power to test the main effect of A.

15 *Multiple Comparison Procedures for Continuous Data*

It is often the case that multiple objectives are to be addressed in one single trial. These objectives are formulated into a family of hypotheses. Formal statistical hypothesis tests can be performed to see if there is strong evidence to support clinical claims. Type I error is inflated when one considers the inferences together as a family. Failure to compensate for multiplicities can have adverse consequences. For example, a drug could be approved when actually it is not better than placebo. Multiple comparison (MC) procedures provides a guard against inflation of type I error due to multiple testing. Probability of making at least one type I error is known as family wise error rate (FWER). East supports several parametric and p-value based MC procedures. In this chapter we explain how to design a study using a chosen MC procedure that strongly maintains FWER.

In East, one can calculate the power from the simulated data under different MC procedures. With the information on power, one can choose the right MC procedure that provides maximum power yet strongly maintains the FWER. MC procedures included in East strongly control FWER. Strong control of FWER refers to preserving the probability of incorrectly claiming at least one null hypothesis. To contrast strong control with weak control of FWER, the latter controls the FWER under the assumption that all hypotheses are true. East supports following MC procedures based on continuous endpoint.

| Category | Procedure | Reference |
|---------------|-------------------------------|-----------------------------------|
| Parametric | Dunnett's Single Step | Dunnett CW (1955) |
| | Dunnett's Step Down | Dunnett CW and Tamhane AC (1991) |
| | Dunnett's Step Up | Dunnett CW and Tamhane AC (1992) |

15.1 Parametric Procedures

15.1.1 Dunnett's single step

15.1.2 Dunnett's step-down and step-up procedures

Assume that there are k arms including the placebo arm. Let n_i be the number of subjects for i -th treatment arm ($i = 0, 2, \dots, k - 1$). Let $N = \sum_{i=0}^{k-1} n_i$ be the total sample size and the arm 0 refers to placebo. Let Y_{ij} be the response from subject j in treatment arm i and y_{ij} be the observed value of Y_{ij} ($i = 0, 2, \dots, k - 1, j = 1, 2, \dots, n_i$). Suppose that

$$Y_{ij} = \mu_i + e_{ij} \tag{15.1}$$

where $e_{ij} \sim N(0, \sigma^2)$. We are interested in the following hypotheses:

- For the right tailed test: $H_i : \mu_i - \mu_0 \leq 0$ vs $K_i : \mu_i - \mu_0 > 0$
- For the left tailed test: $H_i : \mu_i - \mu_0 \geq 0$ vs $K_i : \mu_i - \mu_0 < 0$

For the global null hypothesis at least one of the H_i is rejected in favor of K_i after controlling for FWER. Here H_i and K_i refer to null and alternative hypotheses, respectively, for comparison of i -th arm with the placebo arm.

East supports three parametric MC procedures - single step Dunnett test (Dunnett, 1955), step-down Dunnett test and step-up Dunnett test. These procedures make two parametric assumptions - normality and homoscedasticity. Let \bar{y}_i be the sample mean for treatment arm i and s^2 be the pooled sample variance for all arms. The test statistic for comparing treatment effect of arm i with placebo can be defined as

$$T_i = \frac{\bar{y}_i - \bar{y}_0}{s \sqrt{\frac{1}{n_i} + \frac{1}{n_0}}} \tag{15.2}$$

Let t_i be the observed value of T_i and these observed values for $K - 1$ treatment arms can be ordered as $t_{(1)} \geq t_{(2)} \geq \dots \geq t_{(k-1)}$.

Detailed formula to obtain critical boundaries for single step Dunnett and step-down Dunnett tests are discussed in Appendix H.

In single step Dunnett test, the critical boundary remains same for all the $k - 1$ individual tests. Let c_α be the critical boundary that maintains FWER of α and \tilde{p}_i be the adjusted p -value associated with comparison of i -th arm and placebo arm. Then for a right tailed test, H_i is rejected if $t_i > c_\alpha$ and for a left tailed test H_i is rejected if $t_i < c_\alpha$.

Unlike in single step Dunnett test, the critical boundary does not remain same for all the $k - 1$ individual tests in step-down Dunnett test. Let c_i be the critical boundary and \tilde{p}_i be the adjusted p -value associated with comparison of i -th arm and placebo arm. For a right tailed test $H_{(i)}$ is rejected if $t_{(i)} > c_i$ and $H_{(1)}, \dots, H_{(c-i)}$ have been

15 Multiple Comparison Procedures for Continuous Data

already rejected. For a left tailed test $H_{(i)}$ is rejected if $t_{(i)} < c_{k-i}$ and $H_{(i-1)}, \dots, H_{(k-1)}$ have been already rejected.

Unlike step-down test, step-up Dunnett procedure starts with the least significant test statistic i.e., $t_{(k-1)}$. Let c_i be the critical boundary and \tilde{p}_i be the adjusted p-value associated with comparison of i -th arm and placebo arm. The i -th test statistic in order i.e., $t_{(i)}$ will be tested if and only if none of $H_{(i+1)}, \dots, H_{(k-1)}$ are rejected. If $H_{(i)}$ is rejected then stop and reject all of $H_{(i)}, \dots, H_{(1)}$. For a right tailed test, $H_{(i)}$ is rejected if $t_{(i)} > c_{(i)}$ and for a left tailed test $H_{(i)}$ is rejected if $t_{(i)} < c_{(i)}$.

For both single step Dunnett and step-down Dunnett tests, the global null hypothesis is rejected in favor of at least one right tailed alternative if $H_{(1)}$ is rejected and in favor of at least one left tailed alternative if $H_{(k-1)}$ is rejected .

Single step Dunnett test and step-down Dunnett test can be seen as the parametric version of Bonferroni procedure and Holm procedure, respectively. Parametric tests are uniformly more powerful than the corresponding p-value based tests when the parametric assumption holds or at least approximately holds, especially when there are a large number of hypotheses. Parametric procedures may not control FWER if the standard deviations are different.

15.1.1 Dunnett's single step

Dunnett's Single Step procedure is described below with an example.

Example: Alzheimer's Disease Clinical Trial

In this section, we will use an example to illustrate how to design a study using the MCP module in East. This is a randomized, double-blind, placebo-controlled, parallel study to assess three different doses (0.3 mg, 1 mg and 2 mg) of a drug against placebo in patients with mild to moderate probable Alzheimer's disease. The primary objective of this study is to evaluate the safety and efficacy of the three doses. The drugs are administered daily for 24 weeks to subjects with Alzheimer's disease who are either receiving concomitant treatment or not receiving any co-medication. The efficacy is assessed by cognitive performance based on the Alzheimer's disease assessment scale-13-item cognitive sub-scale. From previous studies, it is estimated that the common standard deviation of the efficacy measure is 5. It is expected that the dose-response relationship follows straight line within the dose range we are interested.

We would like to calculate the power for a total sample size of 200. This will be a balanced study with a one-sided 0.025 significance level to detect at least one dose

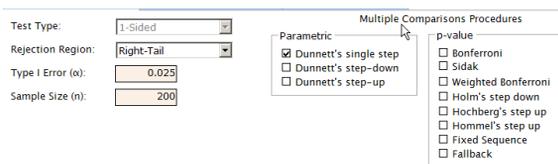

with significant difference from placebo. We will show how to simulate the power of such a study using the multiple comparison procedures listed above.

Designing the study

First, click  (**Continuous: Many Samples**) on the **Design** tab and then click **Multi-Arm Design: Pairwise Comparisons to Control - Difference of Means**. This will launch a new window.

There is a box at the top with the label **Number of Arms**. For our example, we have 3 treatment groups plus a placebo. So enter 4 for **Number of Arms**. Under the **Design Parameters** tab, there are several fields which we will fill in. First, there is a box with the label **Side**. Here you need to specify whether you want a one-sided or two-sided test. Currently, only one-sided tests are available. Under it you will see the box with label **Sample Size (n)**. For now skip this box and move to the next dropdown box with the label **Rejection Region**. If left tail is selected, the critical value for the test is located in the left tail of the distribution of the test statistic. Likewise, if right tail is selected the critical value for the test is located in the right tail of the distribution of the test statistic. For our example, we will select **Right Tail**. Under that, there is a box with the label **Type - 1 Error (α)**. This is where you need to specify the FWER. For our example, enter 0.025. Now go to the box with the label **Total Sample Size**. Here we input the total number of subjects, including those in the placebo arm. For this example, enter 200.

To the right, there will be a heading with the title **Multiple Comparison Procedures**. In the parametric grouping, check the box next to **Dunnett's single step**, as this is the multiple comparison procedure we are illustrating in this subsection. After entering these parameters your screen should now look like this:

| | |
|----------------------------|------------|
| Test Type: | 1-Sided |
| Rejection Region: | Right-Tail |
| Type I Error (α): | 0.025 |
| Sample Size (n): | 200 |

| Multiple Comparison Procedures | |
|---|--|
| Parametric | p-value |
| <input checked="" type="checkbox"/> Dunnett's single step | <input type="checkbox"/> Bonferroni |
| <input type="checkbox"/> Dunnett's step-down | <input type="checkbox"/> Sidak |
| <input type="checkbox"/> Dunnett's step-up | <input type="checkbox"/> Weighted Bonferroni |
| | <input type="checkbox"/> Holm's step down |
| | <input type="checkbox"/> Hochberg's step up |
| | <input type="checkbox"/> Hommel's step up |
| | <input type="checkbox"/> Fixed Sequence |
| | <input type="checkbox"/> Fallback |

Now click on **Response Generation Info** tab. You will see a table titled **Table of Proportions**. In this table we can specify the labels for treatment arms. Also you have to specify the dose level if you want to generate means through dose-response curve. Since we are comparing placebo and 3 dose groups, enter **Placebo**, **Dose1**, **Dose2** and **Dose3** in the 4 cells in first column labeled as **Arm**.

15 Multiple Comparison Procedures for Continuous Data

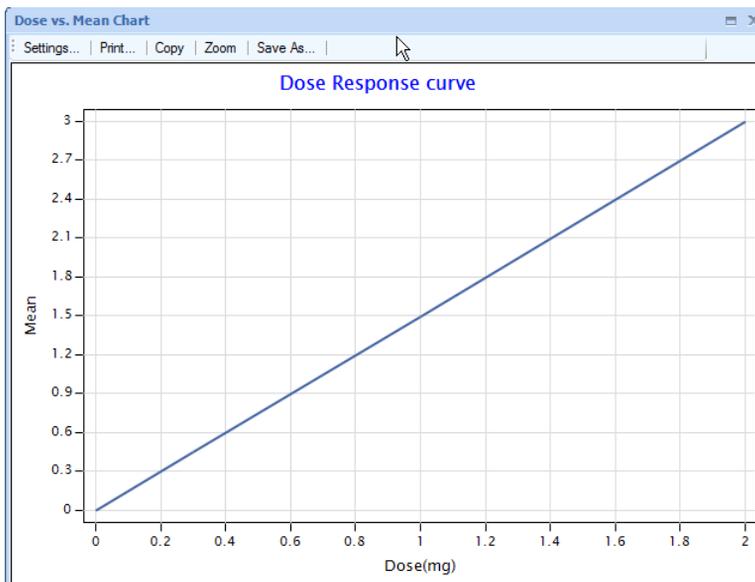

The table contains the default mean and standard deviation for each arm which we will change later. There are two check boxes in this tab above the table. The first is labeled **Generate Means through DR Curve**. There are two ways to specify the mean response for each arm: 1) generate means for each arm through a dose-response curve or 2) Specify the mean directly in the **Table of Proportions**. To specify the mean directly just enter the mean value for each arm in the table in **Mean** column. However, in this example, we will generate means through dose response curve. In order to do this, check **Generate Means through DR Curve** box. Once you check this box you will notice two things. First, an additional column with label **Dose** will appear in the table. Here you need to enter the dose levels for each arm. For this example, enter 0, 0.3, 1 and 2 for Placebo, Dose1, Dose2 and Dose3 arms, respectively. Secondly, you will notice an additional section will appear to the right which provides the option to generate the mean response from four families of parametric curves which are Four Parameter Logistic, Emax, Linear and Quadratic. The technical details about each curve can be found in the Appendix H.

Here you need to choose the appropriate parametric curve from the drop-down list under **Dose Response Curve** and then you have to specify the parameters associated with these curves. For the Alzheimer's disease example, suppose the dose response follows a linear curve with intercept 0 and slope 1.5. To do this, we would need to select "Linear" from the dropdown list. To right of this dropdown box, specify the parameter values of the selected curve family by inputting 0 for **Intercept(E0)** and 1.5 for **Slope(δ)**. After specifying this, the mean values in the table will be changed accordingly. Here we are generating the means using the following linear dose-response curve:

$$E(Y|Dose) = E0 + \delta \times Dose \quad (15.3)$$

For placebo, the mean can be obtained by specifying *Dose* as 0 in the above equation. This gives the mean for placebo arm as 0. For arm Dose1, mean would be $0 + 1.5 \times 0.3$ or 0.45. Similarly the means for the arm Dose2 and Dose3 will be obtained as 1.5 and 3. You can verify that the values in **Mean** column is changed to 0, 0.45, 1.5 and 3 for the four arms, respectively.

Now click **Plot DR Curve** to see the plot of means against the dose levels.

You will see the linear dose response curve that intersects the Y-axis at 0. Now close this window. The dose response curve generates means, but still we have to specify the standard deviation. Standard deviation for each arm could be either equal or different. To specify the common standard deviation, check the box with label **Common Standard Deviation** and specify the common standard deviation in the field next to it. When standard deviations for different arms are not all equal, the standard deviations need to be directly specified in the table in column labeled with **Std. Dev.**. In this example, we are considering a common standard deviation of 5. So check the box for **Common Standard Deviation** and specify 5 in the field next to it. Now the column **Std.Dev.** will be updated with 5 for all the four arms. As we have finished specifying all the fields in the **Response Generation Info** tab, this should appear as below.

Generate Means Through DR Curve

Common Standard Deviation

Table of Means

| Arm | Dose | Mean | Std.Dev. |
|---------|------|------|----------|
| Control | 0 | 0 | 5 |
| 1 | 0.3 | 0.45 | 5 |
| 2 | 1 | 1.5 | 5 |
| 3 | 2 | 3 | 5 |

Dose Response Curve:

Parameters

Intercept(E_0) Slope(β)

[Plot DR Curve](#)

15 Multiple Comparison Procedures for Continuous Data

Click on the **Include Options** button located in the right-upper corner in the Simulation window and check **Randomized Info**. This will add an additional tab - **Randomization Info**. Now click on the **Randomization Info** tab. Second column of the **Table of Allocation** table displays the allocation ratio of each treatment arm to that of control arm. The cell for control arm is always one and is not editable. Only those cells for treatment arms other than control need to be filled in. The default value for each treatment arm is one which represents a balanced design. For the Alzheimer's disease example, we consider a balanced design and leave the default values for the allocation ratios unchanged. Your screen should now look like this:

Randomization Method:

Table of Allocation

| Arm | $r_i = n_i/n_1$ |
|---------|-----------------|
| Control | 1.000 |
| 1 | 1.000 |
| 2 | 1.000 |
| 3 | 1.000 |

The last tab is **Simulation Control Info**. Specify 10000 as **Number of Simulations** and 1000 as **Refresh Frequency** in this tab. The box labeled **Random Number Generator** is where you can set the seed for the random number generator. You can either use the clock as the seed or choose a fixed seed (in order to replicate past simulations). The default is the **clock** and we will use that. The box on the right hand side is labeled **Output Options**. This is where you can choose to save summary statistics for each simulation run and/or to save subject level data for a specific number of simulation runs. To save the output for each simulation, check the box with label **Save summary statistics for every simulation run**. Now click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 1.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim 1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |

Note that a simulation node Sim 1 is created in the library. Also note that another node is appended to the simulation node with label **SummaryStat** which contains detailed simulation summary statistics for each simulation run. Select Sim 1 in the **Output Preview** and click  icon to save the simulation in the library. Now double-click on

Sim 1 in the **Library**. The simulation output details will be displayed in the right pane.

Summary
 Using Dunnett's single step test, this study has 0.75 global power to detect at least one treatment arm which is different from control arm given a total sample size 200. This test has conjunctive power 0.019 to detect all treatment arms which are truly different from control arm. This test provides disjunctive power 0.75 to detect at least one treatment arm which is truly different from control arm.

The first section in the output is the **Hypothesis** section. In our situation, we are testing 3 hypotheses. We are comparing the mean score on the Alzheimer's disease assessment scale (13-item cognitive sub-scale) for each dose with that of placebo. That is, we are testing the 3 hypotheses:

$$H_1 : \mu_1 = \mu_0 \quad \text{vs} \quad K_1 : \mu_1 > \mu_0$$

$$H_2 : \mu_2 = \mu_0 \quad \text{vs} \quad K_2 : \mu_2 > \mu_0$$

$$H_3 : \mu_3 = \mu_0 \quad \text{vs} \quad K_3 : \mu_3 > \mu_0$$

Here, μ_P , μ_1 , μ_2 and μ_3 represent the population mean score on the Alzheimer's disease assessment scale for the placebo, 0.3 mg, 1 mg and 2 mg dose groups, respectively. Also, H_i and K_i are the null and alternative hypotheses, respectively, for the i -th test.

The **Input Parameters** section provides the design parameters that we specified earlier. The next section **Overall Power** gives us estimated power based on the

15 Multiple Comparison Procedures for Continuous Data

simulation. The second line gives us the global power, which is about 75%. Global power indicates the power to reject global null $H_0 : \mu_1 = \mu_2 = \mu_3 = \mu_0$. Thus, the global power indicates that 75% of times the global null will be rejected. In other words, at least one of the H_1 , H_2 and H_3 is rejected in about 75% of the occasion. Global power is useful to show the existence of dose-response relationship and dose-response may be claimed if any of the doses in the study is significantly different from placebo.

The next line displays the conjunctive power. Conjunctive power indicates the proportion of cases in the simulation where all the H_i 's, which are truly false, were rejected. In this example, all the H_i 's are false. Therefore, for this example, conjunctive power is the proportion of cases where all of the H_1 , H_2 and H_3 were rejected. For this simulation conjunctive power is only about 2.0% which means that only in 2.0% of time, all of the H_1 , H_2 and H_3 were rejected.

Disjunctive power indicates the proportion of rejecting at least one of those H_i 's where H_i is truly false. The main distinction between global and distinctive power is that the former finds any rejection whereas the latter look for rejection only among those H_i 's which are false. Since here all of the H_1 , H_2 and H_3 are false, therefore, global and disjunctive power ought to be the same.

The next section gives us the marginal power for each hypothesis. Marginal power finds the proportion of times when a particular hypothesis is rejected after applying multiplicity adjustment. Based on simulation results, H_1 is rejected about 3% of times, H_2 is rejected about 20% of times and H_3 is rejected a little more than 70% of times.

Recall that we have asked East to save the simulation results for each simulation run—. Open this file by clicking on **SummaryStat** in the library and you will see that it contains 10,000 rows - each rows represents results for a single simulation. Find the 3 columns with labels **Rej_Flag_1**, **Rej_Flag_2** and **Rej_Flag_3**, respectively. These columns represents the rejection status for H_1 , H_2 and H_3 , respectively. A value of 1 is indicator of rejection on that particular simulation, otherwise the null is not rejected. Now the proportion of 1's in **Rej_Flag_1** indicates the marginal power to reject H_1 . Similarly we can find out the marginal power for H_2 and H_3 from **Rej_Flag_2** and **Rej_Flag_3**, respectively. To obtain the global and disjunctive power, count the total number of cases where at least one of the H_1 , H_2 and H_3 have been rejected and then divide by the total number of simulations of 10,000. Similarly, to obtain the conjunctive power count the total number of cases where all of the H_1 , H_2 and H_3 have been rejected and then divide by the total number of simulations of 10,000.

Next we will consider an example to show how global and disjunctive power are different from each other. Select Sim 1 in **Library** and click . Now go to the **Response Generation Info** tab and uncheck the **Generate Means Through DR Curve** box. The table will now have only three columns. Specify **Dose1**, **Dose2** and **Dose3** in the 4 cells in first column labeled as **Arm** and enter 0, 0, 1 and 1.2 in the 4 cells in second column labeled as **Mean**.

Generate Means Through DR Curve

Common Standard Deviation

Table of Proportions

| Arm | Mean | Std.Dev. |
|---------|------|----------|
| Placebo | 0 | 5 |
| Dose1 | 0 | 5 |
| Dose2 | 1 | 5 |
| Dose3 | 1.2 | 5 |

Here we are generating response for placebo from distribution $N(0, 5^2)$, for Dose1 from distribution $N(0, 5^2)$, for Dose2 from distribution $N(1, 5^2)$ and for Dose3 from distribution $N(1.2, 5^2)$. Now click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 2.

| | ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|--|------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| | Sim1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |
| | Sim2 | Dunnett's single step | 1-Sided | 0.025 | 0.009 | 3 | 200 | Right-Tail | 0.179 | 0.029 | 0.176 | 200 |

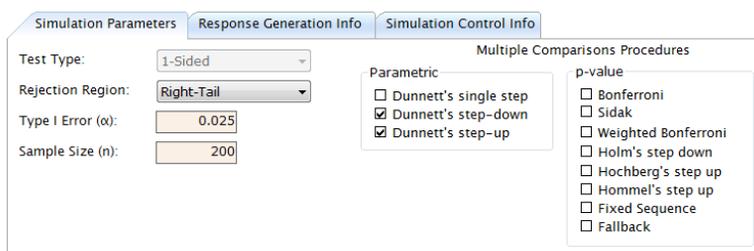

For Sim 2, the global power and disjunctive power are 17.9% and 17.6%, respectively. To understand why, we need to open the saved simulation data for Sim 2. The total number of cases where at least one of H_1 , H_2 and H_3 is rejected is 1790 and dividing this by total number of simulation 10,000 gives the global power of 17.9%. Again, the total number of cases where at least one of H_2 and H_3 are rejected is 1760 and dividing this by total number of simulation 10,000 gives the disjunctive power of 17.6%. The exact result of the simulations may differ slightly, depending on the seed.

15 Multiple Comparison Procedures for Continuous Data

15.1.2 Dunnett's step-down and step-up procedures

Dunnett's Step-Down procedure is described below using the same Alzheimer's Disease example from the previous section 15.1.1 on Dunnett's Single Step.

Since the other design specification remains same except that we are using Dunnett's step-down in place of single step Dunnett's test, we can design simulation in this section with only little effort. Select Sim 1 in **Library** and click . Now go to the **Design Parameters** tab. There in the **Multiple Comparison Procedures** box, uncheck the **Dunnett's single step** box and check the **Dunnett's step-down** and **Dunnett's step-up** box.

The screenshot shows a software interface with three tabs: "Simulation Parameters", "Response Generation Info", and "Simulation Control Info". The "Simulation Parameters" tab is active, showing "Test Type" as "1-Sided", "Rejection Region" as "Right-Tail", "Type I Error (α)" as "0.025", and "Sample Size (n)" as "200". The "Simulation Control Info" tab is also visible, showing the "Multiple Comparisons Procedures" section. Under "Parametric", "Dunnett's single step" is unchecked, while "Dunnett's step-down" and "Dunnett's step-up" are checked. Under "p-value", "Bonferroni", "Sidak", "Weighted Bonferroni", "Holm's step down", "Hochberg's step up", "Hommel's step up", "Fixed Sequence", and "Fallback" are all unchecked.

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add two additional rows to the **Output Preview** labeled as Sim 3 and Sim 4.

Dunnett step-down procedure and step-down have global and disjunctive power of close to 75% and conjunctive power of close to 4%. To see the marginal power for each test, select Sim 3 and Sim 4 in the **Output Preview** and click  icon. Now, double-click on Sim 3 in the **Library**. The simulation output for Dunnett step-down

procedure details will be displayed in the right pane.

Simulation: Continuous Endpoint: Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Differences of Means

Hypothesis:
 $H_1: \mu_1 - \mu_0 \leq 0$ Vs. $K_1: \mu_1 - \mu_0 > 0$ for $i = 1, 2, \dots, k-1$ where k is the total number of arms.

| Simulation Parameters | |
|-----------------------------------|----------------------|
| Simulation ID | Sim3 |

| Elapsed Time | 00:00:05 |

Summary
 Using Dunnnett's step-down test, this study has 0.746 global power to detect at least one treatment arm which is different from control arm given a total sample size 200. This test has conjunctive power 0.042 to detect all treatment arms which are truly different from control arm. This test provides disjunctive power 0.746 to detect at least one treatment arm which is truly different from control arm.

The marginal power for comparison of Dose1, Dose2 and Dose3 using Dunnnett step-down procedure are close to 5%, 23% and 74%, respectively. Similarly one can find the marginal power for individual tests in Dunnnett step-up procedure.

15.2 p-value based Procedures

15.2.1 Single step MC procedures

15.2.2 Data-driven step-down MC procedure

15.2.3 Data-driven step-up MC procedures

15.2.4 Fixed-sequence stepwise MC procedures

p-value based procedures strongly control the FWER regardless of the joint distribution of the raw p-values as long as the individual raw p-values are legitimate p-values. Assume that there are k arms including the placebo arm. Let n_i be the number of subjects for i -th treatment arm ($i = 0, 2, \dots, k-1$). Let $N = \sum_{i=0}^{k-1} n_i$ be the total sample size and the arm 0 refers to placebo. Let Y_{ij} be the response from subject j in treatment arm i and y_{ij} be the observed value of Y_{ij} ($i = 0, 2, \dots, k-1, j = 1, 2, \dots, n_i$). Suppose that

$$Y_{ij} = \mu_i + e_{ij} \tag{15.4}$$

where $e_{ij} \sim N(0, \sigma_i^2)$. We are interested in the following hypotheses:

- For the right tailed test: $H_i: \mu_i - \mu_0 \leq 0$ vs $K_i: \mu_i - \mu_0 > 0$
- For the left tailed test: $H_i: \mu_i - \mu_0 \geq 0$ vs $K_i: \mu_i - \mu_0 < 0$

15 Multiple Comparison Procedures for Continuous Data

For the global null hypothesis at least one of the H_i is rejected in favor of K_i after controlling for FWER. Here H_i and K_i refer to null and alternative hypotheses, respectively, for comparison of i -th arm with the placebo arm.

Let \bar{y}_i be the sample mean for treatment arm i , s_i^2 be the sample variance from i -th arm and s^2 be the pooled sample variance for all arms. For the unequal variance case, the test statistic for comparing treatment effect of arm i with placebo can be defined as

$$T_i = \frac{\bar{y}_i - \bar{y}_0}{\sqrt{\frac{1}{n_i} s_i^2 + \frac{1}{n_0} s_0^2}} \quad (15.5)$$

For the equal variance case, one need to replace s_i^2 and s_0^2 by the pooled sample variance s^2 . For both the case, T_i is distributed as Student's t distribution. However, the degrees of freedom varies for equal variance and unequal variance case. For equal variance case the degrees of freedom would be $N - k$. For the unequal variance case, the degrees of freedom is subject to Satterthwaite correction.

Let t_i be the observed value of T_i and these observed values for $K - 1$ treatment arms can be ordered as $t_{(1)} \geq t_{(2)} \geq \dots \geq t_{(k-1)}$. For the right tailed test the marginal p-value for comparing the i -th arm with placebo is calculated as $p_i = P(T > t_i)$ and for left tailed test $p_i = P(T < t_i)$, where T is distributed as Student's t distribution. Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the ordered p-values.

15.2.1 Single step MC procedures

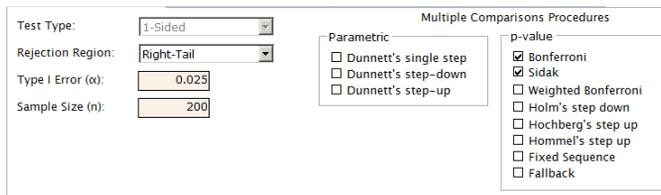

East supports three p-value based single step MC procedures - Bonferroni procedure, Sidak procedure and weighted Bonferroni procedure. For the Bonferroni procedure, H_i is rejected if $p_i < \frac{\alpha}{k-1}$ and the adjusted p-value is given as $\min(1, (k-1)p_i)$. For the Sidak procedure, H_i is rejected if $p_i < 1 - (1 - \alpha)^{\frac{1}{k-1}}$ and the adjusted p-value is given as $1 - (1 - p_i)^{k-1}$. For the weighted Bonferroni procedure, H_i is rejected if $p_i < w_i \alpha$ and the adjusted p-value is given as $\min(1, \frac{p_i}{w_i})$. Here w_i denotes the proportion of α allocated to the H_i such that $\sum_{i=1}^{k-1} w_i = 1$. Note that, if $w_i = \frac{1}{k-1}$, then the Bonferroni procedure is reduced to the regular Bonferroni procedure.

Bonferroni and Sidak procedures

Bonferroni and Sidak procedures are described below using the same Alzheimer's Disease example from the section 15.1.1 on Dunnett's Single Step.

Since the other design specification remains same except that we are using Bonferroni and Sidak in place of single step Dunnett's test, we can design simulation in this

section with only little effort. Select Sim 1 in **Library** and click . Now go to the **Design Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Dunnett's single step** box and check the **Bonferroni** and **Sidak** boxes.

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add two additional rows to the **Output Preview**. Bonferroni and Sidak procedures have disjunctive and global powers of close to 73% and conjunctive power of about 1.8%. Now select Sim 5 and Sim 6 in the **Output Preview** using the Ctrl key and click  icon. This will save Sim 5 and Sim 6 in the Wbk1 in **Library**.

Weighted Bonferroni procedure

As before we will use the same Alzheimer's Disease example to illustrate weighted Bonferroni procedure. Select Sim 1 in **Library** and click . Now go to the **Design Parameters** tab. There in the **Multiple Comparison Procedures** box, uncheck the **Dunnett's single step** box and check the **Weighted Bonferroni** box.

Table of Means

| Arm | Dose | Mean | Std.Dev. | Proportion of Alpha |
|---------|------|------|----------|---------------------|
| Control | 0 | 0 | 5 | |
| 1 | 0.3 | 0.45 | 5 | 0.333 |
| 2 | 1 | 1.5 | 5 | 0.333 |
| 3 | 2 | 3 | 5 | 0.333 |

Next click on **Response Generation Info** tab and look at the **Table of Proportions**. You will see an additional column with label **Proportion of Alpha** is added. Here you have to specify the proportion of total alpha you want to spend in each test. Ideally, the values in this column should add up to 1; if not, then East will normalize it to add them up to 1. By default, East distributes the total alpha equally among all tests. Here we have 3 tests in total, therefore each of the tests have proportion of alpha as 1/3 or 0.333. You can specify other proportions as well. For this example, keep the equal

15 Multiple Comparison Procedures for Continuous Data

proportion of alpha for each test. Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 7. The weighted Bonferroni MC procedure has global and disjunctive power of 73.7% and conjunctive power of 1.6%. Note that, the powers in the weighted Bonferroni procedure is quite close to the Bonferroni procedure. This is because the weighted Bonferroni procedure with equal proportion is equivalent to the simple Bonferroni procedure. The exact result of the simulations may differ slightly, depending on the seed. Now select Sim 7 in the **Output Preview** and click  icon. This will save Sim 7 in Wbk1 in **Library**.

15.2.2 Data-driven step-down MC procedure

In the single step MC procedures, the decision to reject any hypothesis does not depend on the decision to reject other hypotheses. On the other hand, in the stepwise procedures decision of one hypothesis test can influence the decisions on the other tests of hypotheses. There are two types of stepwise procedures. One type of procedures proceed in data-driven order. The other type proceeds in a fixed order set a priori. Stepwise tests in a data-driven order can proceed in step-down or step-up manner. East supports Holm step-down MC procedure which start with the most significant comparison and continue as long as tests are significant until the test for certain hypothesis fails. The testing procedure stops at the first time a non-significant comparison occurs and all remaining hypotheses will be retained. In i -th step, $H_{(k-i)}$ is rejected if $p_{(k-i)} \leq \frac{\alpha}{i}$ and go to the next step.

Holm's step-down

As before we will use the same Alzheimer's Disease example to illustrate Holm's step-down procedure. Select Sim 1 in **Library** and click . Now go to the **Design Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Dunnett's single step** box and check the **Holm's Step-down** box.

| | | | |
|-------------------|------------|--|--|
| Test Type: | 1-Sided | Multiple Comparisons Procedures | |
| Rejection Region: | Right-Tail | Parametric | p-value |
| Type I Error (α): | 0.025 | <input type="checkbox"/> Dunnett's single step | <input type="checkbox"/> Bonferroni |
| Sample Size (n): | 200 | <input type="checkbox"/> Dunnett's step-down | <input type="checkbox"/> Sidak |
| | | <input type="checkbox"/> Dunnett's step-up | <input type="checkbox"/> Weighted Bonferroni |
| | | | <input checked="" type="checkbox"/> Holm's step down |
| | | | <input type="checkbox"/> Hochberg's step up |
| | | | <input type="checkbox"/> Hommel's step up |
| | | | <input type="checkbox"/> Fixed Sequence |
| | | | <input type="checkbox"/> Fallback |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will

add an additional row to the **Output Preview** labeled as Sim 8.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |
| Sim3 | Dunnett's step-down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.746 | 0.042 | 0.746 | 200 |
| Sim4 | Dunnett's step-up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.741 | 0.045 | 0.741 | 200 |
| Sim5 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.729 | 0.017 | 0.729 | 200 |
| Sim6 | Sidak | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.732 | 0.018 | 0.732 | 200 |
| Sim7 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.016 | 0.737 | 200 |
| Sim8 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.74 | 0.045 | 0.74 | 200 |

Holm's step-down procedure has global and disjunctive power of 74% and conjunctive power of 4.5%. The exact result of the simulations may differ slightly, depending on the seed. Now select Sim 8 in the **Output Preview** and click  icon. This will save Sim 8 in Wbk1 in **Library**.

Simulation: Continuous Endpoint: Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Differences of Means

Summary

Using Holm's step down test, this study has 0.74 global power to detect at least one treatment arm which is different from control arm given a total sample size 200. This test has conjunctive power 0.045 to detect all treatment arms which are truly different from control arm. This test provides disjunctive power 0.74 to detect at least one treatment arm which is truly different from control arm.

15.2.3 Data-driven step-up MC procedures

Step-up tests start with the least significant comparison and continue as long as tests are not significant until the first time when a significant comparison occurs and all remaining hypotheses will be rejected. East supports two such MC procedures -

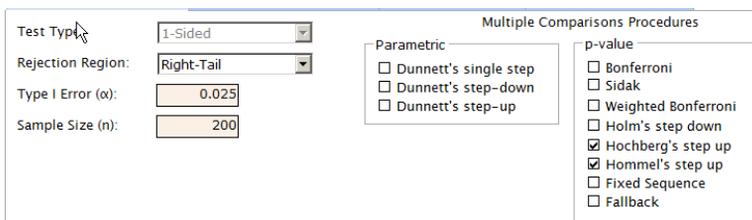

15 Multiple Comparison Procedures for Continuous Data

Hochberg step-up and Hommel step-up procedures. In the Hochberg step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-i)} > \frac{\alpha}{i}$. In the Hommel step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-j)} > \frac{i-j+1}{i} \alpha$ for $j = 1, \dots, i$. Fixed sequence test and fallback test are the types of tests which proceed in a prespecified order.

Hochberg's and Hommel's step-up procedures

Hochberg's and Hommel's step-up procedures are described below using the same Alzheimer's Disease example from the section 15.1.1 on Dunnett's Single Step.

Since the other design specification remains same except that we are using Hocheberg and Hommel step-up procedures in place of single step Dunnett's test we can design simulation in this section with only little effort. Select Sim 1 in **Library** and click . Now go to the **Design Parameters** tab. There in the **Multiple Comparison Procedures** box, uncheck the **Dunnett's single step** box and check the **Hochberg's step-up** and **Hommel's step-up** boxes.

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add two additional rows to the **Output Preview** labeled as Sim 9 and Sim 10.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|

Hocheberg and Hommel procedures have disjunctive and global powers of close to 74

15.2.4 Fixed-sequence stepwise MC procedures

In data-driven stepwise procedures, we don't have any control on the order of the hypotheses to be tested. However, sometimes based on our preference or prior knowledge we might want to fix the order of tests a priori. Fixed sequence test and fallback test are the types of tests which proceed in a pre-specified order. East supports both of these procedures.

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is pre-specified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the associated raw marginal p-values. In the fixed sequence testing procedure, for $i = 1, \dots, k - 1$, in i -th step, if $p_i < \alpha$, reject H_i and go to the next step; otherwise retain H_i, \dots, H_{k-1} and stop.

Fixed sequence testing strategy is optimal when early tests in the sequence have largest treatment effect and performs poorly when early hypotheses have small treatment effect or are nearly true (Westfall and Krishen 2001). The drawback of fixed sequence test is that once a hypothesis is not rejected no further testing is permitted. This will lead to lower power to reject hypotheses tested later in the sequence.

Fallback test alleviates the above undesirable feature for fixed sequence test. Let w_i be the proportion of α for testing H_i such that $\sum_{i=1}^{k-1} w_i = 1$. In the fixed sequence testing procedure, in i -th step ($i = 1, \dots, k - 1$), test H_i at $\alpha_i = \alpha_{i-1} + \alpha w_i$ if H_{i-1} is rejected and at $\alpha_i = \alpha w_i$ if H_{i-1} is retained. If $p_i < \alpha_i$, reject H_i ; otherwise retain it. Unlike the fixed sequence testing approach, the fallback procedure can continue testing even if a non-significant outcome is encountered by utilizing the fallback strategy. If a hypothesis in the sequence is retained, the next hypothesis in the sequence is tested at the level that would have been used by the weighted Bonferroni procedure. With $w_1 = 1$ and $w_2 = \dots = w_{k-1} = 0$, the fallback procedure simplifies to fixed sequence procedure.

Fixed sequence testing procedure

As before we will use the same Alzheimer's Disease example to illustrate fixed sequence testing procedure. Select Sim 1 in **Library** and click . Now go to the **Design Parameters** tab. There in the **Multiple Comparison Procedures** box,

15 Multiple Comparison Procedures for Continuous Data

uncheck the **Dunnett's single step** box and check the **Fixed Sequence** box.

Next click on **Response Generation Info** tab and look at the **Table of Proportions**. You will see an additional column with label **Test Sequence** is added. Here you have to specify the order in which the hypotheses will be tested. Specify 1 for the test that will be tested first, 2 for the test that will be tested next and so on. By default East specifies 1 to the first test, 2 to the second test and so on. For now we will keep the default which means that H_1 will be tested first followed by H_2 and finally H_3 will be tested.

Table of Means

| Arm | Dose | Mean | Std.Dev. | Test Sequence |
|---------|------|------|----------|---------------|
| Control | 0 | 0 | 5 | |
| 1 | 0.3 | 0.45 | 5 | 1 |
| 2 | 1 | 1.5 | 5 | 2 |
| 3 | 2 | 3 | 5 | 3 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 11.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |
| Sim3 | Dunnett's step-down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.746 | 0.042 | 0.746 | 200 |
| Sim4 | Dunnett's step-up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.741 | 0.045 | 0.741 | 200 |
| Sim5 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.729 | 0.017 | 0.729 | 200 |
| Sim6 | Sidak | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.732 | 0.018 | 0.732 | 200 |
| Sim7 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.016 | 0.737 | 200 |
| Sim8 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.74 | 0.045 | 0.74 | 200 |
| Sim9 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.739 | 0.051 | 0.739 | 200 |
| Sim10 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.048 | 0.737 | 200 |
| Sim11 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.068 | 0.05 | 0.068 | 200 |

The fixed sequence procedure with the specified sequence has global and disjunctive power of less than 7% and conjunctive power of 5%. The reason for small global and

disjunctive power is due to the smallest treatment effect is tested first and the magnitude of treatment effect increases gradually for the remaining tests. For optimal power in fixed sequence procedure, the early tests in the sequence should have larger treatment effects. In our case, Dose3 has largest treatment effect followed by Dose2 and Dose1. Therefore, to obtain optimal power, H_3 should be tested first followed by H_2 and H_1 .

Select Sim 11 in the **Output Preview** and click  icon. Select Sim 11 in **Library**, click  and go to the **Response Generation Info** tab. In **Test Sequence** column in the table, specify 3 for Dose1, 2 for Dose2 and 1 for Dose3.

Table of Means

| Arm | Dose | Mean | Std.Dev. | Test Sequence |
|---------|------|------|----------|---------------|
| Control | 0 | 0 | 5 | |
| 1 | 0.3 | 0.45 | 5 | 3 |
| 2 | 1 | 1.5 | 5 | 2 |
| 3 | 2 | 3 | 5 | 1 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional rows to the **Output Preview** labeled as Sim 12.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comparisons | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|--------------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |
| Sim3 | Dunnett's step-down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.746 | 0.042 | 0.746 | 200 |
| Sim4 | Dunnett's step-up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.741 | 0.045 | 0.741 | 200 |
| Sim5 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.729 | 0.017 | 0.729 | 200 |
| Sim6 | Sidak | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.732 | 0.018 | 0.732 | 200 |
| Sim7 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.016 | 0.737 | 200 |
| Sim8 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.74 | 0.045 | 0.74 | 200 |
| Sim9 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.739 | 0.051 | 0.739 | 200 |
| Sim10 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.048 | 0.737 | 200 |
| Sim11 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.068 | 0.05 | 0.068 | 200 |
| Sim12 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.849 | 0.046 | 0.849 | 200 |

Now the fixed sequence procedure with the pre-specified sequence (H_3, H_2, H_1) has global and disjunctive power close to 85% and conjunctive power close to 5%. This example illustrates that fixed sequence procedure is powerful provided the hypotheses are tested in a sequence of descending treatment effects. Fixed sequence procedure controls the FWER because for each hypothesis, testing is conditional upon rejecting all hypotheses earlier in sequence. The exact result of the simulations may differ slightly, depending on the seed. Select Sim 12 in the **Output Preview** and click .

15 Multiple Comparison Procedures for Continuous Data

icon to save it in **Library**.

Fallback procedure

Again we will use the same Alzheimer’s Disease example to illustrate the fallback procedure. Select Sim 1 in **Library** and click . There in the **Multiple Comparison Procedures** box, uncheck the **Dunnett’s single step** box and check the **Fallback** box.

| | | | |
|-------------------|------------|--|--|
| Test Type: | 1-Sided | Multiple Comparisons Procedures | |
| Rejection Region: | Right-Tail | Parametric | p-value |
| Type I Error (α): | 0.025 | <input type="checkbox"/> Dunnett’s single step | <input type="checkbox"/> Bonferroni |

| | | | <input type="checkbox"/> Fixed Sequence |
| | | | <input checked="" type="checkbox"/> Fallback |

Next click on **Response Generation Info** tab and look at the **Table of Proportions**. You will see two additional columns with label **Test Sequence** and **Proportion of Alpha**. In the column **Test Sequence**, you have to specify the order in which the hypotheses will be tested. Specify 1 for the test that will be tested first, 2 for the test that will be tested next and so on. By default East specifies 1 to the first test, 2 to the second test and so on. For now we will keep the default which means that H_1 will be tested first followed by H_2 and finally H_3 will be tested.

In the column **Proportions of Alpha**, you have to specify the proportion of total alpha you want to spend in each test. Ideally, the values in this column should add up to 1; if not, then East will normalize it to add them up to 1. By default East distributes the total alpha equally among the all tests. Here we have 3 tests in total, therefore each of the tests have proportion of alpha as $1/3$ or 0.333 . You can specify other proportions as well. For this example, keep the equal proportion of alpha for each test.

Table of Means

| Dose | Mean | Std.Dev. | Test Sequence | Proportion of Alpha |
|------|------|----------|---------------|---------------------|
| 0 | 0 | 5 | | |
| 0.3 | 0.45 | 5 | 1 | 0.333 |
| 1 | 1.5 | 5 | 2 | 0.333 |
| 2 | 3 | 5 | 3 | 0.333 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional rows to the **Output Preview** labeled as Sim 13.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |
| Sim3 | Dunnett's step-down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.746 | 0.042 | 0.746 | 200 |
| Sim4 | Dunnett's step-up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.741 | 0.045 | 0.741 | 200 |
| Sim5 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.729 | 0.017 | 0.729 | 200 |
| Sim6 | Sidak | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.732 | 0.018 | 0.732 | 200 |
| Sim7 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.016 | 0.737 | 200 |
| Sim8 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.74 | 0.045 | 0.74 | 200 |
| Sim9 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.739 | 0.051 | 0.739 | 200 |
| Sim10 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.048 | 0.737 | 200 |
| Sim11 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.068 | 0.05 | 0.068 | 200 |
| Sim12 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.849 | 0.046 | 0.849 | 200 |
| Sim13 | Fallback | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.02 | 0.737 | 200 |

Now we will consider a sequence where H_3 will be tested first followed by H_2 and H_1 because in our case, Dose3 has largest treatment effect followed by Dose2 and Dose1.

Select Sim 13 in the **Output Preview** and click  icon. Select Sim 12 in **Library**, click  and go to the **Response Generation Info** tab. In **Test Sequence** column in the table, specify 3 for Dose1, 2 for Dose2 and 1 for Dose3.

Table of Means

| Dose | Mean | Std.Dev. | Test Sequence | Proportion of Alpha |
|------|------|----------|---------------|---------------------|
| 0 | 0 | 5 | | |
| 0.3 | 0.45 | 5 | 3 | 0.333 |
| 1 | 1.5 | 5 | 2 | 0.333 |
| 2 | 3 | 5 | 1 | 0.333 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will

15 Multiple Comparison Procedures for Continuous Data

add an additional rows to the **Output Preview** labeled as Sim 14.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |
| Sim3 | Dunnett's step-down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.746 | 0.042 | 0.746 | 200 |
| Sim4 | Dunnett's step-up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.741 | 0.045 | 0.741 | 200 |
| Sim5 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.729 | 0.017 | 0.729 | 200 |
| Sim6 | Sidak | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.732 | 0.018 | 0.732 | 200 |
| Sim7 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.016 | 0.737 | 200 |
| Sim8 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.74 | 0.045 | 0.74 | 200 |
| Sim9 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.739 | 0.051 | 0.739 | 200 |
| Sim10 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.048 | 0.737 | 200 |
| Sim11 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.068 | 0.05 | 0.068 | 200 |
| Sim12 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.849 | 0.046 | 0.849 | 200 |
| Sim13 | Fallback | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.02 | 0.737 | 200 |
| Sim14 | Fallback | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.735 | 0.045 | 0.735 | 200 |

Note that the fallback test is more robust to the misspecification of the test sequence but fixed sequence test is very sensitive to the test sequence. If the test order is misspecified, fixed sequence test has very poor performance.

15.3 Comparison of MC procedures

We have obtained the power (based on the simulation) for different MC procedures for the Alzheimer's Disease example from the section 15.1.1. Now the obvious question is which MC procedure to choose. To compare all the MC procedure, we will perform simulation for all the MC procedures under the following scenario.

- Treatment arms: placebo, dose1 (dose=0.3 mg), dose2 (dose=1 mg) and dose3 (dose=2 mg) with respective groups means as 0, 0.45, 1.5 and 3, respectively.
- common standard deviation = 5
- Type I Error: 0.025 (right-tailed)
- Number of Simulations:10000
- Total Sample Size:200
- Allocation ratio: 1 : 1 : 1 : 1

For comparability of simulation results, we have used similar seed for simulation under all MC procedures. Following output displays the powers under different MC

procedures.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim12 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.849 | 0.046 | 0.849 | 200 |
| Sim1 | Dunnett's single step | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.75 | 0.019 | 0.75 | 200 |
| Sim3 | Dunnett's step-down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.746 | 0.042 | 0.746 | 200 |
| Sim4 | Dunnett's step-up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.741 | 0.045 | 0.741 | 200 |
| Sim8 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.74 | 0.045 | 0.74 | 200 |
| Sim9 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.739 | 0.051 | 0.739 | 200 |
| Sim10 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.048 | 0.737 | 200 |
| Sim7 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.016 | 0.737 | 200 |
| Sim13 | Fallback | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.737 | 0.02 | 0.737 | 200 |
| Sim14 | Fallback | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.735 | 0.045 | 0.735 | 200 |
| Sim6 | Sidak | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.732 | 0.018 | 0.732 | 200 |
| Sim5 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.729 | 0.017 | 0.729 | 200 |
| Sim11 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 200 | Right-Tail | 0.068 | 0.05 | 0.068 | 200 |

Here we have used equal proportions for weighted Bonferroni and Fallback procedures. For the two fixed sequence testing procedures (fixed sequence and fallback) two sequences have been used - (H_1, H_2, H_3) and (H_3, H_2, H_1) . As expected, Bonferroni and weighted Bonferroni procedures provides similar powers. It appears that fixed sequence procedure with the pre-specified sequence (H_3, H_2, H_1) provides the power of close to 85% which is the maximum among all the procedures. However, fixed sequence procedure with the pre-specified sequence (H_1, H_2, H_3) provides power of less than 7%. Therefore, power in fixed sequence procedure is largely dependent on the specification of sequence of testing and a mis-specification might result in huge drop in power. For this reason, fixed sequence procedure may not be considered as appropriate MC procedure to go with.

Dunnett's single step, step-down and step-up procedures are the next in order after fixed sequence procedure with the pre-specified sequence (H_3, H_2, H_1) . All the three procedures attain close to 75% of disjunctive power, respectively. However, all these three procedures assume that all the treatment arms have equal variance. Therefore, if homogeneity of variance between the treatment arms is a reasonable assumption, Dunnett's step-down or single step procedure should be the best option based on these simulation results. However, when the assumption of equal variance is not met, Dunnett's procedure may not be the appropriate procedure as the type I error might not be strongly controlled.

Next in the list are the fallback procedures and both of them provides a little more than 73% power which is very close to the power attained by Dunnett's procedures. Therefore, unlike fixed sequence procedure, fallback procedure does not depend much on the order of the hypotheses they are tested. Moreover, this does not require the

15 Multiple Comparison Procedures for Continuous Data

assumption of equal variance among the treatment arms to be met. For all these reasons, fallback procedure seems to be the most appropriate MC procedure for the design we are interested in.

Now, we will perform the comparison but this time with unequal variance between the treatment arms. Precisely, we simulate data under the following scenario to see the type I error rate control of different procedures.

- Treatment arms: placebo, dose1 (dose=0.3 mg), dose2 (dose=1 mg) and dose3 (dose=2 mg) with respective groups means as 0, 0, 0 and 0, respectively.
- standard deviation for placebo, dose1 and dose2 is 5; standard deviation for dose3 is 10
- Type I Error: 0.025 (right-tailed)
- Number of Simulations:1000000
- Total Sample Size:200
- Allocation ratio: 1 : 1 : 1 : 1

Following output displays the type I error rate under different MC procedures for the unequal variance case.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. Pairwise Comps. | Sample Size | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|---------------------|-------------|------------------|--------------|-------------------|-------------------|---------------------|
| Sim15 | Dunnett's single step | 1-Sided | 0.025 | 0.027 | 3 | 200 | Right-Tail | 0.027 | 0 | 0 | 200 |
| Sim16 | Dunnett's step-down | 1-Sided | 0.025 | 0.027 | 3 | 200 | Right-Tail | 0.027 | 0 | 0 | 200 |
| Sim17 | Dunnett's step-up | 1-Sided | 0.025 | 0.026 | 3 | 200 | Right-Tail | 0.026 | 0 | 0 | 200 |
| Sim13 | Fixed Sequence | 1-Sided | 0.025 | 0.025 | 3 | 200 | Right-Tail | 0.025 | 0 | 0 | 200 |
| Sim12 | Hommel's step up | 1-Sided | 0.025 | 0.024 | 3 | 200 | Right-Tail | 0.024 | 0 | 0 | 200 |
| Sim10 | Hochberg's step up | 1-Sided | 0.025 | 0.024 | 3 | 200 | Right-Tail | 0.024 | 0 | 0 | 200 |
| Sim6 | Sidak | 1-Sided | 0.025 | 0.023 | 3 | 200 | Right-Tail | 0.023 | 0 | 0 | 200 |
| Sim9 | Holm's step down | 1-Sided | 0.025 | 0.023 | 3 | 200 | Right-Tail | 0.023 | 0 | 0 | 200 |
| Sim7 | Weighted Bonferroni | 1-Sided | 0.025 | 0.023 | 3 | 200 | Right-Tail | 0.023 | 0 | 0 | 200 |
| Sim14 | Fallback | 1-Sided | 0.025 | 0.023 | 3 | 200 | Right-Tail | 0.023 | 0 | 0 | 200 |
| Sim5 | Bonferroni | 1-Sided | 0.025 | 0.023 | 3 | 200 | Right-Tail | 0.023 | 0 | 0 | 200 |

Note that the Dunnett tests slightly inflate type I error rate but all other procedures control the type I error rate below the nominal level 0.025.

16 *Multiple Endpoints-Gatekeeping Procedures*

16.1 *Introduction*

Clinical trials are often designed to assess benefits of a new treatment compared to a control treatment with respect to multiple clinical endpoints which are divided into hierarchically ordered families. Typically, the primary family of endpoints defines the overall outcome of the trial, provides the basis for regulatory claim and is included in the product label. The secondary families of endpoints play a supportive role and provide additional information for physicians, patients, payers and hence are useful for enhancing product label. Gatekeeping procedures are specifically designed to address this type of multiplicity problems by explicitly taking into account the hierarchical structure of the multiple objectives. The terminology-gatekeeping indicates the hierarchical decision structure where the higher ranked families serve as gatekeepers for the lower ranked family. The lower ranked families won't be tested if the higher ranked families are not passed. Two types of gatekeeping procedures are described in this chapter. One is serial gatekeeping procedure and the other one is parallel gatekeeping procedure. In the next few sections, specific examples will be provided to illustrate how to design trials with each type of gatekeeping procedures. For more information about applications of gatekeeping procedures in a clinical trial setting and literature review on this topic, please refer to Dmitrienko and Tamhane (2007).

16.2 *Simulate Serial Gatekeeping Design*

Serial gatekeeping procedures were studied by Maurer, Hothorn and Lehman (1995), Bauer et al. (1998) and Westfall and Krishen (2001). Serial gatekeepers are encountered in trials where endpoints are usually ordered from most important to least important. Reisberg et al. 2003 reported a study designed to investigate memantine, an N-methyl-D-aspartate (NMDA) antagonist, for the treatment of Alzheimer's disease in which patients with moderate-to-severe Alzheimer's disease were randomly assigned to receive placebo or 20 mg of memantine daily for 28 weeks. The two primary efficacy variables were: (1) the Clinician's Interview-Based Impression of Change Plus Caregiver Input (CIBIC-Plus) global score at 28 weeks, (2) the change from base line to week 28 in the Alzheimer's Disease Cooperative Study Activities of Daily Living Inventory modified for severe dementia (ADCS-ADLsev). The CIBIC-Plus measures overall global change relative to base line and is scored on a seven-point scale ranging from 1 (markedly improved) to 7 (markedly worse). For illustration purpose, we redefine the primary endpoint of clinician's global assessment score as 7 minus the CIBIC-Plus score so that a larger value indicates improvement (0 markedly worse and 6 markedly improved). The secondary efficacy endpoints included the Severe Impairment Battery and other measures of cognition, function, and behavior. Suppose that the trial is declared successful only if the treatment effect is demonstrated on both endpoints. If the trial is successful, it is of interest to assess the two secondary endpoints: (1) Severe Impairment Battery (SIB), (2) Mini-Mental State Examination

16 Multiple Endpoints-Gatekeeping Procedures

(MMSE). The SIB was designed to evaluate cognitive performance in advanced Alzheimer' disease. A 51-item scale, it assesses social interaction, memory, language, visuospatial ability, attention, praxis, and construction. The scores range from 0 (greatest impairment) to 100. The MMSE is a 30-point scale that measures cognitive function. The means of the endpoints for subjects in the control group and experimental group and the common covariance matrix are as follows

| | Mean Treatment | Mean Control |
|-------------|----------------|--------------|
| CIBIC-Plus | 2.6 | 2.3 |
| ADCS-ADLsev | -2.5 | -4.5 |
| SIB | -6.5 | -10 |
| MMSE | -0.4 | -1.2 |

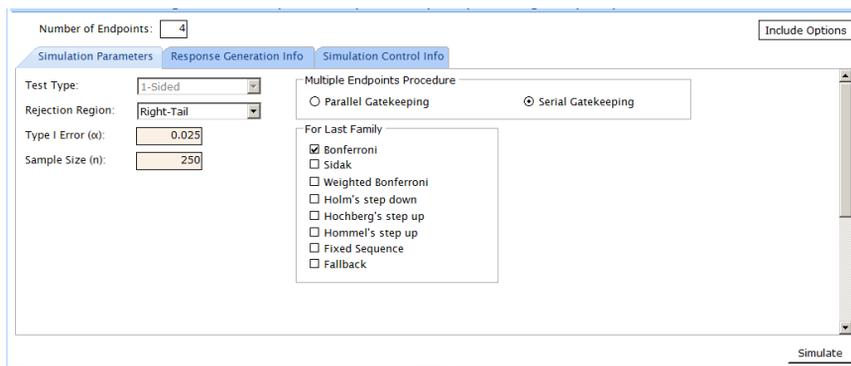

| CIBIC-Plus | ADCS-ADLsev | SIB | MMSE |
|------------|-------------|-----|------|
| 1.2 | 3.6 | 6.8 | 1.6 |
| 3.6 | 42 | 38 | 9.3 |
| 6.8 | 38 | 145 | 17 |
| 1.6 | 9.3 | 17 | 8 |

Typically there are no analytical ways to compute the power for gatekeeping procedures. Simulations can be used to assess the operating characteristics of different designs. For example, one could simulate the power for given sample sizes. To start the simulations, click [Two Samples](#) in the [Design](#) tab and select [Multiple Comparisons-Multiple Endpoints](#) to see the following input windows

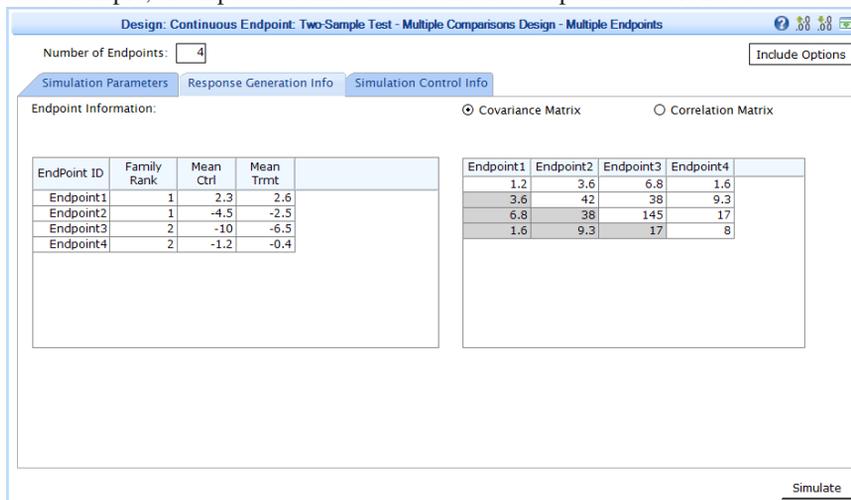

The screenshot displays the 'Design: Continuous Endpoint: Two-Sample Test - Multiple Comparisons Design - Multiple Endpoints' window. The 'Number of Endpoints' is set to 4. The 'Simulation Parameters' tab is active, showing 'Test Type' as 1-Sided, 'Rejection Region' as Right-Tail, 'Type I Error (α)' as 0.025, and 'Sample Size (n)' as 100. The 'Multiple Endpoints Procedure' section has 'Serial Gatekeeping' selected. The 'For Last Family' section has 'Bonferroni' checked, with other options like Sidak, Weighted Bonferroni, Holm's step down, Hochberg's step up, Hommel's step up, Fixed Sequence, and Fallback unchecked. A 'Simulate' button is located at the bottom right.

On the top of this input window, one needs to specify the total number of endpoints and other input parameters such as Rejection Region, Type I Error, Sample Size. One also needs to select the multiple comparison procedure which will be used to test the last family of endpoints. The type I error specified on this screen is the nominal level of the familywise error rate which is defined as the probability of falsely declaring the efficacy of the new treatment compared to control with respect to any endpoint. For the Alzheimer's disease example, CIBIC-Plus and ADCS-ADlsev form the primary family, and the other endpoints SIB and MMSE form the secondary family. Suppose that we would like to see the power for a sample size of 250 at a nominal type I error rate 0.025 using Bonferroni test for the secondary family, then the input window looks as follows

16 Multiple Endpoints-Gatekeeping Procedures

Behind the window for **Simulation Parameters**, there is another window tab labeled as **Response Generation Info**. The window for **Response Generation Info** tab shown below allows one to specify the underlying joint distribution among the multiple endpoints for control arm and for experimental arm. The joint distribution among the endpoints are assumed to be multivariate normal with common covariance matrix. One also needs to specify which family each endpoint belongs to in the column with label **Family Rank**. One can also customize the label for each endpoint. For the Alzheimer’s disease example, the inputs for this window should be specified as follows

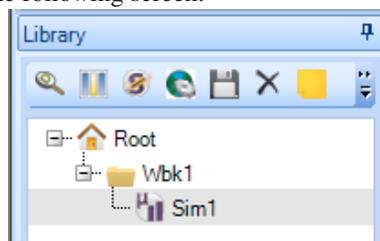

One can specify the number of simulations to be performed on the window with the

label **Simulation Control Info**. By default, 10000 simulations will be performed. One can also save the summary statistics for each simulated trial or save subject-level data by checking the appropriate box in the output option area. To simulate this design, click the **Simulate** button at the bottom right of the screen to see the preliminary output displayed in the output preview area as seen in the following screen. All the results displayed in the yellow cells are summary outputs generated from simulations. For example, the actually FWER, number of families, conjunctive power for the primary family, conjunctive power and disjunctive power for the last family.

| Output Preview | | | | | | | | | | | |
|----------------|--------------------------------|-----------|--------------------|--------------------|--------------|------------------|-----------------|-------------|------------------|-------------------------------|-------------------------------|
| ID | Multiple Comparisons Procedure | Test Type | Design Type | Specified α | Overall FWER | No. of Endpoints | No. of Families | Sample Size | Rejection Region | Conjunctive Power Last Family | Disjunctive Power Last Family |
| Sim1 | Bonferroni | 1-Sided | Serial Gatekeeping | 0.025 | 0 | 4 | 2 | 250 | Right-Tail | 0.259 | 0.417 |

To view the detailed output, first save the simulation into a workbook in the library by clicking on the tool button  and you will notice that a simulation node appears in the library as shown in the following screen.

Now double click on the simulation node **Sim1** to see the detailed output as shown in the following screen. The detailed output summarizes all the main input parameters such as the multiple comparison procedure used for the last family of endpoints, the nominal type I error level, total sample size, mean values for each endpoint in the control arm and that in the experimental arm etc. It also displays the attained overall FWER, conjunctive power, disjunctive power, the FWER and conjunctive power for each gatekeeper family, the FWER and conjunctive power and disjunctive power for the last family. The definitions of different types of power are as follows:

Overall Power and FWER:

Global: probability of declaring significance on any of the endpoints

Conjunctive: probability of declaring significance on all of the endpoints for which the

16 Multiple Endpoints-Gatekeeping Procedures

treatment arm is truly better than the control arm

Disjunctive: probability of declaring significance on any of the endpoints for which the treatment arm is truly better than the control arm

FWER: probability of making at least one type I error among all the endpoints

Power and FWER for Individual Gatekeeper Family except the Last Family:

Conjunctive Power: probability of declaring significance on all of the endpoints in the particular gatekeeper family for which the treatment arm is truly better than the control arm

FWER: probability of making at least one type I error when testing the endpoints in the particular gatekeeper family

Power and FWER for the Last Family:

Conjunctive Power: probability of declaring significance on all of the endpoints in the last family for which the treatment arm is truly better than the control arm

Disjunctive Power: probability of declaring significance on any of the endpoints in the last family for which the treatment arm is truly better than the control arm

FWER: probability of making at least one type I error when testing the endpoints in the last family

Marginal Power: probability of declaring significance on the particular endpoint

For the Alzheimer's disease example, the conjunctive power, which characterizes the power for the study, is 46.9% for a total sample size of 250. Using Bonferroni test for the last family, the design has 40.5% probability (disjunctive power for the last family) to detect the benefit of memantine with respect to at least one of the two secondary endpoints, SIB and MMSE. It has 25.1% chance (conjunctive power for the last family)

to declare the benefit of memantine with respect to both of the secondary endpoints.

Simulation: Continuous Endpoint: Two-Sample Test - Multiple Comparisons Design - Multiple Endpoints - Serial Gatekeeping

Hypothesis:
 $H_1: \mu_{i1} - \mu_{i0} \leq 0$ Vs. $K_i: \mu_{i1} - \mu_{i0} > 0$ for $i = 1, 2, \dots, n$ where n is the total number of endpoints.

| Simulation Parameters | |

| Endpoint1 | 1 | 2.3 | 2.6 | 1.095 |

One can find the sample size to achieve a target power by simulating multiple designs in a batch mode. For example, one could simulate a batch of designs for a range of

16 Multiple Endpoints-Gatekeeping Procedures

sample size changing from 250 to 500 in step of 50 as shown in the following window.

Note that a total sample size somewhere between 450 to 500 provides 80% power to detect the mean differences for both primary endpoints CIBIC-Plus and ADCS-ADLsev as seen in the following window.

| ID | Multiple Endpoints Procedure for Last Family | Test Type | Design Type | Specified α | Overall FWER | Global Power | Conjunctive Power | Disjunctive Power | No. of Endpoints | No. of Families | Sample Size | Rejection Region | Conjunctive Power First Family |
|------|--|-----------|-------------|--------------------|--------------|--------------|-------------------|-------------------|------------------|-----------------|-------------|------------------|--------------------------------|
| Sim2 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.472 | 0.254 | 0.472 | 4 | 2 | 250 | Right-Tail | 0.472 |
| Sim3 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.563 | 0.336 | 0.563 | 4 | 2 | 300 | Right-Tail | 0.563 |
| Sim4 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.65 | 0.433 | 0.65 | 4 | 2 | 350 | Right-Tail | 0.65 |
| Sim5 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.715 | 0.511 | 0.715 | 4 | 2 | 400 | Right-Tail | 0.715 |
| Sim6 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.783 | 0.598 | 0.783 | 4 | 2 | 450 | Right-Tail | 0.783 |
| Sim7 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.828 | 0.668 | 0.828 | 4 | 2 | 500 | Right-Tail | 0.828 |

To get a more precise sample size to achieve 80% power, one could simulate a bunch of designs with the sample size ranging from 450 to 500 in step of 10. One will notice that a sample size of 480 provides over 80% power to claim the significant differences with respect to both primary endpoints.

| ID | Multiple Endpoints Procedure for Last Family | Test Type | Design Type | Specified α | Overall FWER | Global Power | Conjunctive Power | Disjunctive Power | No. of Endpoints | No. of Families | Sample Size | Rejection Region | Conjunctive Power First Family |
|------|--|-----------|-------------|--------------------|--------------|--------------|-------------------|-------------------|------------------|-----------------|-------------|------------------|--------------------------------|
| Sim2 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.783 | 0.597 | 0.783 | 4 | 2 | 450 | Right-Tail | 0.783 |
| Sim3 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.793 | 0.612 | 0.793 | 4 | 2 | 460 | Right-Tail | 0.793 |
| Sim4 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.803 | 0.627 | 0.803 | 4 | 2 | 470 | Right-Tail | 0.803 |
| Sim5 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.801 | 0.627 | 0.801 | 4 | 2 | 480 | Right-Tail | 0.801 |
| Sim6 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.818 | 0.648 | 0.818 | 4 | 2 | 490 | Right-Tail | 0.818 |
| Sim7 | Bonferroni | 1-Sided | Serial | 0.025 | 0 | 0.827 | 0.663 | 0.827 | 4 | 2 | 500 | Right-Tail | 0.827 |

One could compare the multiple designs side by side by clicking on the tool button  in the output preview area as follows:

There is a special case where all the endpoints belong to one single family. The software handle this special case in a particular manner. Intersection-Union test will be applied to a single family of endpoints and the selected MCP for the last family in the Simulation Parameter tab is not applicable for this special case. For the Alzheimer disease example, if we are only interested in testing the two endpoints (CIBIC-Plus and ADCS-ADLsev) as co-primary endpoints as indicated by the family rank in the window for Response Generation Info, then the Intersection-Union test will be applied to the two endpoints so that each endpoint is tested at nominal level α . The detailed output window is slightly different in case of single family of endpoints as seen in the

16 Multiple Endpoints-Gatekeeping Procedures

following window.

Simulation: Continuous Endpoint: Two-Sample Test - Multiple Comparisons Design - Multiple Endpoints - Serial Gatekeeping

Hypothesis:
 $H_1: \mu_{iT} - \mu_{iC} \leq 0$ Vs. $K_i: \mu_{iT} - \mu_{iC} > 0$ for $i = 1, 2, \dots, n$ where n is the total number of endpoints.

16.3 Simulate Parallel Gatekeeping Design

Parallel gatekeeping procedures are often used in clinical trials with several primary objectives where each individual objective can characterize a successful trial outcome. In other words, the trial can be declared to be successful if at least one primary objective is met. Consider a randomized, double blinded and parallel group designed clinical trial to compare two vaccines against the human papilloma virus. Denote vaccine T the new vaccine and vaccine C the comparator. The primary objective of this study is to demonstrate that vaccine T is superior to vaccine C for the antigen type 16 or 18 which account for 70% of cervical cancer cases globally. If the new vaccine shows superiority over the comparator with respect to either antigen type 16 or 18, it is of interest to test the superiority of vaccine T to vaccine C for the antigen type 31 or 45. The two types of vaccines are compared based on the immunological response, i.e. the number of T-cell in the blood, seven months after the vaccination. Assume that the log transformed data is normally distributed with mean μ_{iT} or μ_{iC} ($i = 1, 2, 3, 4$) where the index 1, 2, 3, and 4 represent the four antigen types respectively. The null

Table 16.1: Mean response and Standard Deviation

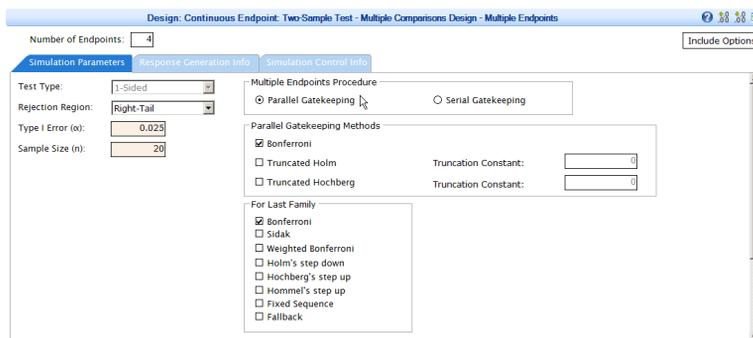

| Endpoints | Mean for Vaccine C | Mean for Vaccine T | Standard Deviation |
|-----------|--------------------|--------------------|--------------------|
| Type 16 | 4 | 4.57 | 0.5 |
| Type 18 | 3.35 | 4.22 | 0.5 |
| Type 31 | 2 | 2.34 | 0.6 |
| Type 45 | 1.42 | 2 | 0.3 |

hypotheses and alternative hypotheses can be formulated as

$$H_{i0} : \mu_{iT} - \mu_{iC} \leq 0 \text{ vs } H_{i1} : \mu_{iT} - \mu_{iC} > 0$$

The parallel gatekeeping test strategy is suitable for this example. The two null hypotheses H_{10} and H_{20} for antigen type 16 and 18 constitute the primary family which serves as the gatekeeper for the second family of hypotheses which contains H_{30} and H_{40} . Assume that the means and the standard deviations for all four antigen types are as follows:

Assume that the total sample size is 20 and one-sided significance level is 0.025. To assess the operating characteristics of the parallel gatekeeping procedures, we first need to open the simulation window for multiple endpoints. To this end, click on the **Design** menu, choose **Two Sample** for continuous endpoint and then select **Multiple Endpoints** from the drop-down list and the following screen will show up.

On the top of the above screen, one need to specify the total number of endpoints. The

16 Multiple Endpoints-Gatekeeping Procedures

lower part of the above screen is the **Simulation Parameters** tab which allows one to specify the important design parameters including the nominal type I error rate, total sample size, multiple comparison procedures. Now select **Parallel Gatekeeping** and choose **Bonferroni** for the parallel gatekeeping methods. For the last family, select **Bonferroni** as the multiple testing procedure. Next to the **Simulation Parameters** tab are two additional tabs: **Response Generation Info** and **Simulation Control Info**. We need to specify the mean responses for each endpoint for both treatment and control arm as well as the covariance structure among the endpoints. In addition, we need to specify which family each specific endpoint belongs to in the column with the label **Family Rank** in the same table for specifying the mean responses. There are two ways of specifying the covariance structure: **Covariance Matrix** or **Correlation Matrix**. If the **Correlation Matrix** option is selected, one needs to input the standard deviation for each endpoint in the same table for specifying the mean responses. There is a simpler way to input the standard deviation for each endpoint if all the endpoints share a common standard deviation. This can be done by checking the box for **Common Standard Deviation** and specify the value of the common standard deviation in the box to the right hand side. One also need to specify the correlations among the endpoints in the table to the right hand side. Similarly, if all the endpoints have a common correlation, then we can just check the box for **Common Correlation** and specify the value of the common correlation in the box to the right. For the vaccine example, assume the endpoints share a common mild correlation 0.3. Then the window with completed inputs for generating data looks like the following screen.

Design: Continuous Endpoint: Two-Sample Test - Multiple Comparisons: Design - Multiple Endpoints

Number of Endpoints: Include Options

Simulation Parameters | **Response Generation Info** | Simulation Control Info

Endpoint Information:

Common Standard Deviation:

| EndPoint ID | Family Rank | Mean Ctrl | Mean Trmt | Std. Dev. |
|-------------|-------------|-----------|-----------|-----------|
| Endpoint1 | 1 | 4 | 4.57 | 0.5 |
| Endpoint2 | 1 | 3.35 | 4.22 | 0.5 |
| Endpoint3 | 2 | 2 | 2.34 | 0.5 |
| Endpoint4 | 2 | 1.42 | 2 | 0.3 |

Covariance Matrix Correlation Matrix

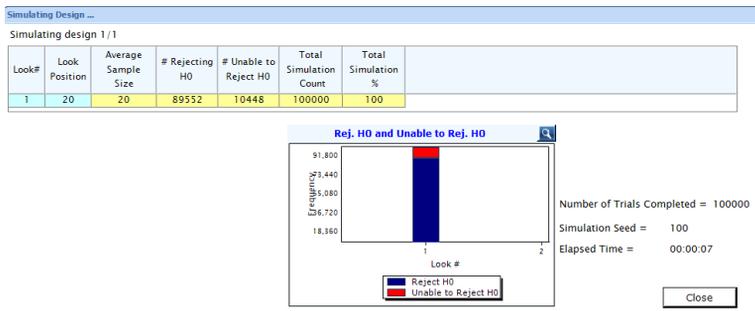

Common Correlation:

| Endpoint1 | Endpoint2 | Endpoint3 | Endpoint4 |
|-----------|-----------|-----------|-----------|
| 1 | 0.3 | 0.3 | 0.3 |
| 0.3 | 1 | 0.3 | 0.3 |
| 0.3 | 0.3 | 1 | 0.3 |
| 0.3 | 0.3 | 0.3 | 1 |

Simulate

In the window for **Simulation Control Info**, we can specify the total number of simulations, refresh frequency, type of random number seed. We can also choose to save the simulation data for more advanced analyses. After finishing specifying all the

input parameter values, click on the **Simulate** button on the bottom right of the window to run the simulations. The progress window will report how many simulations have been completed as seen in the following screen.

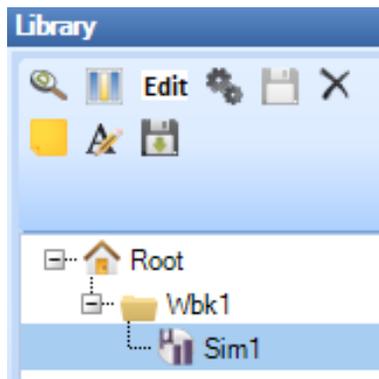

When all the requested simulations have been completed, click on the **Close** button at the right bottom of the progress report screen and the preliminary simulation summary will show up in the output preview window where one can see overall power summary and the power summary for the primary family as well as the attained overall FWER etc.

| ID | Multiple Endpoints Procedure for Last Family | Parallel Gatekeeping Method | Test Type | Design Type | Specified α | Overall FWER | Global Power | Conjunctive Power | Disjunctive Power | No. of Endpoints | No. of Families | Sample Size |
|------|--|-----------------------------|-----------|-------------|--------------------|--------------|--------------|-------------------|-------------------|------------------|-----------------|-------------|
| Sim1 | Bonferroni | Bonferroni | 1-Sided | Parallel | 0.025 | 0 | 0.945 | 0.101 | 0.945 | 4 | 2 | 20 |

To see the detailed output, we need to save the simulation in the workbook by clicking on the icon  on the top of the output preview window. A simulation node will be

16 Multiple Endpoints-Gatekeeping Procedures

appended in the corresponding workbook in the library as seen in the follow window.

Next double click on the simulation node in the library and the detailed outputs will be displayed accordingly.

Simulation: Continuous Endpoint: Two-Sample Test - Multiple Comparisons Design - Multiple Endpoints - Parallel Gatekeeping

Hypothesis:

In case of testing multiple endpoints, the power definition is not unique. East provides the overall power summary and the power summary for each specific family. In the

overall power summary table, the following types of power are provided with the overall FWER: global power, conjunctive power and disjunctive power, which capture the overall performance of this gatekeeping procedure. The definitions of the powers are given below:

Overall Power and FWER:

Global: probability of declaring significance on any of the endpoints

Conjunctive: probability of declaring significance on all of the endpoints for which the treatment arm is truly better than the control arm

Disjunctive: probability of declaring significance on any of the endpoints for which the treatment arm is truly better than the control arm

FWER: probability of making at least one type I error among all the endpoints

Power and FWER for Individual Gatekeeper Families except the Last Family:

Conjunctive Power: probability of declaring significance on all of the endpoints in the particular gatekeeper family for which the treatment arm is truly better than the control arm

Disjunctive Power: probability of declaring significance on any of the endpoints in the particular gatekeeper family for which the treatment arm is truly better than the control arm

FWER: probability of making at least one type I error when testing the endpoints in the particular gatekeeper family

Power and FWER for the Last Gatekeeper Family:

Conjunctive Power: probability of declaring significance on all of the endpoints in the last family for which the treatment arm is truly better than the control arm

Disjunctive Power: probability of declaring significance on any of the endpoints in the last family for which the treatment arm is truly better than the control arm

FWER: probability of making at least one type I error when testing the endpoints in the last family

Marginal Power: probability of declaring significance on the particular endpoint

For the vaccine example, we see that the gatekeeping procedure using Bonferroni test for both the primary family and the secondary family provides 94.49% power to detect the difference in at least one of the two antigen types 16 and 18. It provides 52.19% power to detect the differences in both antigen types. Also note that this gatekeeping procedure only provides 89.55% power to detect the response difference in any of the other two antigen types 31 or 45 and only 12.53% to detect both antigen types 31 and 45. The marginal power table displays the probabilities of declaring significance on the

16 Multiple Endpoints-Gatekeeping Procedures

Table 16.2: Power Comparisons under Different Correlation Assumptions

| Correlation | Primary Family | | Secondary Family | | Overall Power | |
|-------------|----------------|-----------|------------------|-----------|---------------|-----------|
| | Disjunct. | Conjunct. | Disjunct. | Conjunct. | Disjunct. | Conjunct. |
| 0.3 | 0.9449 | 0.5219 | 0.8955 | 0.1253 | 0.9449 | 0.1012 |
| 0.5 | 0.9324 | 0.5344 | 0.8867 | 0.1327 | 0.9324 | 0.1192 |
| 0.8 | 0.9174 | 0.5497 | 0.8855 | 0.1413 | 0.9174 | 0.1402 |

particular endpoint after multiplicity adjustment. For example, the power of detecting antigen type 16 is 55.22%.

If it is of interest to assess the robustness of this procedure with respect to the correlation among the different endpoints, we can go back to the input window to change the correlations and run simulation again. To this end, right click on the Sim1 node in the library and select [Edit Simulation](#) from the dropdown list. Next click on the [Response Generation Info](#) tab, change the common correlation to 0.5 and click [Simulate](#) button. We can repeat this for a common correlation 0.8. The following table summarizes the power comparisons under different correlation assumptions. Note that the disjunctive power decreases as the correlation increases and conjunctive power increases as the correlation increases.

There are three available parallel gatekeeping methods: Bonferroni, Truncated Holm and Truncated Hochberg. The multiple comparison procedures applied to the gatekeeper families need to satisfy the so-called separable condition. A multiple comparison procedure is separable if the type I error rate under partial null configuration is strictly less than the nominal level α . Bonferroni is a separable procedure. However, the regular Holm and Hochberg procedure are not separable and can't be applied directly to the gatekeeper families. The truncated versions obtained by taking the convex combinations of the critical constants for the regular Holm/Hochberg procedure and Bonferroni procedure are separable and more powerful than Bonferroni test. The truncation constant leverages the degree of conservativeness. The larger value of the truncation constant results in more powerful procedure. If the truncation constant is set to be 1, it reduces to the regular Holm or Hochberg test. To see this, let's simulate the design using the truncated Holm procedure for the primary family and Bonferroni test for the second family for the vaccine example with common correlation 0.3. Table 3 compares the conjunctive power and disjunctive power for each family and the overall ones for different truncation parameter values. As the value of the truncation parameter increases, the conjunctive power for the primary family increases and the disjunctive power remain unchanged. Both the conjunctive power

Table 16.3: Impact of Truncation Constant in Truncated Holm Procedure on Overall Power and Power for Each Family

| Truncation Constant | Primary Family | | Secondary Family | | Overall Power | |
|---------------------|----------------|-----------|------------------|-----------|---------------|-----------|
| | Conjunct. | Disjunct. | Conjunct. | Disjunct. | Conjunct. | Disjunct. |
| 0 | 0.5219 | 0.9449 | 0.1253 | 0.8955 | 0.1012 | 0.9449 |
| 0.25 | 0.5647 | 0.9449 | 0.1229 | 0.8872 | 0.1065 | 0.9449 |
| 0.5 | 0.5988 | 0.9449 | 0.1212 | 0.8747 | 0.1108 | 0.9449 |
| 0.8 | 0.6327 | 0.9449 | 0.1188 | 0.84 | 0.115 | 0.9449 |

Table 16.4: Impact of Truncation Constant in Truncated Holm Procedure on Marginal Power

| Truncation Constant | Primary Family | | Secondary Family | |
|---------------------|----------------|---------|------------------|---------|
| | Type 16 | Type 18 | Type 31 | Type 45 |
| 0 | 0.5522 | 0.9146 | 0.127 | 0.8938 |
| 0.25 | 0.5886 | 0.921 | 0.1246 | 0.8855 |
| 0.5 | 0.6183 | 0.9254 | 0.1227 | 0.8731 |
| 0.8 | 0.6483 | 0.9293 | 0.1203 | 0.8385 |

and disjunctive power for the secondary family decrease as we increase the truncation parameter. The overall conjunctive power also increases but the overall disjunctive power remains the same with the increase of truncation parameter. Table 4 shows the marginal powers of this design for different truncation parameter values. The marginal powers for the two endpoints in the primary family increase. On the other hand, the marginal powers for the two endpoints in the secondary family decrease.

Table 5 and Table 6 displays the operating characteristics for truncation Hochberg test with different truncation constant values. Note that both the conjunctive and disjunctive powers for the primary family increase as the truncation parameter increases. However, the power for the secondary family decreases with the larger truncation parameter value. The marginal powers for the primary family and for the secondary family behave similarly. The overall conjunctive and disjunctive powers also increase as we increase the truncation parameter.

If all the endpoints belong to one single family, the selected multiple testing procedures for the last family (Bonferroni, Sidak, Weighted Bonferroni, Holm’s step

16 Multiple Endpoints-Gatekeeping Procedures

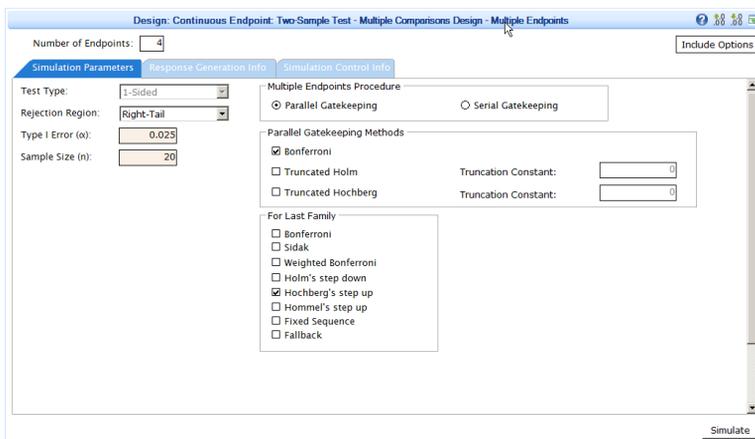

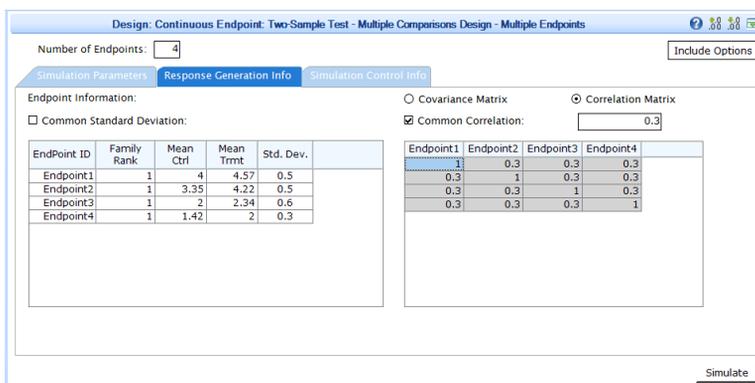

Table 16.5: Impact of Truncation Constant in Truncated Hochberg Procedure on Overall Power and Power for Each Family

| Truncation Constant | Primary Family | | Secondary Family | | Overall Power | |

| 0.8 | 0.6525 | 0.9335 | 0.1205 | 0.8424 |

down, Hochberg’s step up, Hommel’s step up, Fixed Sequence or Fallback) will be applied for multiplicity adjustment. For example, if all the four antigen types in the vaccine example are treated as primary endpoints as indicated by the family rank in the window for Response Generation Info and Hochberg’s step up test is selected for the last family in the window for Simulation Parameters, then the regular Hochberg test will be applied to the four endpoints for multiplicity adjustment. The detailed output window is slightly different in case of single family of endpoints as seen in the following window.

16 Multiple Endpoints-Gatekeeping Procedures

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

17.1 Design

Consider designing a placebo controlled, double blind and randomized trial to evaluate the efficacy, pharmacokinetics, safety and tolerability of a new therapy given as multiple weekly infusions in subjects with a recent acute coronary syndrome. There are four dose regimens to be investigated. The treatment effect is assessed through the change in PAV (percent atheroma volume) from baseline to Day 36 post-randomization, as determined by IVUS (intravascular ultrasound). The expected change in PAV for placebo group and the four dose regimens are: 0, 1, 1.1, 1.2 and 1.3 and the common standard deviation is 3. The objective of the study is to find the optimal dose regimen based on the totality of the evidence including benefit-risk assessment and cost considerations.

To design such a study in EAST, we first need to invoke the design dialog window. To this end, one needs to click on the Design menu on the top of EAST window, select Many Samples for continuous type of response and then select Multiple Looks-Group Sequential in the drop-down list as shown in the following screen shot

After selecting the design, we will see a dialog window for the user to specify the main design parameters. On the top of the window, we need to specify the number of arms including the control arm and the number of looks. We also need to specify the

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

nominal significance level, power or sample size, mean response for each arm, standard deviation for each arm and allocation ratio of each arm to control arm. Suppose we would like to compute the sample size to achieve 90% power at one-sided 0.025 significance level. After filling in all the inputs, the design dialog window looks as follows:

Design: Continuous Endpoint: Many-Sample Test - Pairwise Comparisons to Control - Difference of Means - Multi-

Number of Arms: 5 Number of Looks: 1

Test Parameters

Type I Error (α): 0.025 Common Standard Deviation: 3

Power: 0.9 ○

Sample Size (n): Computed ⊕

| Arm | Mean | Std. Dev. | Allocation Ratio ($n_i : n_c$) |
|-------------|------|-----------|-------------------------------------|
| Control | 0 | 3.000 | 1.000 |
| Treatment 1 | 1 | 3.000 | 1.000 |
| Treatment 2 | 1.1 | 3.000 | 1.000 |
| Treatment 3 | 1.2 | 3.000 | 1.000 |
| Treatment 4 | 1.3 | 3.000 | 1.000 |

Compute

Now click on the compute button at the bottom right of the window to see the total sample size. Note that we need 519 subjects. Here the power is the probability of successfully detecting significant difference for at least one active treatment group

compared to control arm.

Design: Continuous Endpoint: Many-Sample Test - Pairwise Comparisons to Control - Difference of Means - Multiple Look-Group Sequential

Number of Arms: 5 Number of Looks: 1

Test Parameters

Type I Error (α): 0.025 Common Standard Deviation: 3

Power: 0.9 ○

Sample Size (n): 519 ⊕

| Arm | Mean | Std. Dev. | Allocation Ratio (n _i : n _c) |
|-------------|------|-----------|---|
| Control | 0 | 3.000 | 1.000 |
| Treatment 1 | 1 | 3.000 | 1.000 |
| Treatment 2 | 1.1 | 3.000 | 1.000 |
| Treatment 3 | 1.2 | 3.000 | 1.000 |
| Treatment 4 | 1.3 | 3.000 | 1.000 |

Suppose that now we would like to do a group sequential design with interim looks so that the trial can be terminated earlier if one or more of the treatment groups demonstrate overwhelming efficacy. To do this, we change the number of looks to 3. Note that there is another tab showing up beside the Test Parameter tab. This new tab with label Boundary is to specify efficacy boundary, futility boundary and the spacing of looks. Suppose we want to take two interim looks with equally spacing using O'Brien Fleming spending function from Lan-DeMats 1984. The input window looks

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

like the following

Design: Continuous Endpoint: Many-Sample Test - Pairwise Comparisons to Control - Difference of Means - Multip...   

Number of Arms: Number of Looks:

Test Parameters Boundary

Efficacy

Boundary Family: Futility (Non-Binding)

Spending Function: Boundary Family:

Type I Error (α): 0.025

Spacing of Looks Equal Unequal Efficacy Boundary:  

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|---------------------|-------------------|
| 1 | 0.333 | 0.000 | 4.049 |
| 2 | 0.667 | 0.006 | 2.931 |
| 3 | 1.000 | 0.025 | 2.477 |

One can view the boundaries in terms of other scales including score, δ and p-value scale by clicking the drop-down box for boundary scale. For example, the δ scale boundary for this study is 2.904, 1.486 and 1.026.

Now click on the compute button on the bottom right of the window to create the design. Note that the total sample size to achieve 90% power is now 525 compared to 519 for the fixed sample design created earlier. The power definition here is the probability of successfully detecting any active treatment group which is significantly

different from control group at any look.

Design: Continuous Endpoint: Many-Sample Test - Pairwise Comparisons to Control - Difference of Means - Multiple Look-Group

5 3

Test Parameters Boundary

| Treatment 4 | 1.3 | 3 | 1 |

The first table shows the sample size information including the maximum sample size

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

if the trial goes all the way to the end and the sample size per arm. It also shows that the expected sample size under the global null where none of the active treatment group is different from control group and the expected sample size under the design alternative specified by the user. The secondary table displays the look-by-look information including sample size, cumulative type I error, boundaries, boundary crossing probability under the global null and under user-specified design alternative. The boundary crossing probability at each look shows the likelihood of at least one active treatment group crossing the boundary at that particular look. The third table shows the Z scale boundary.

One can also add a futility boundary to the design by clicking on the drop-down box for the futility boundary family. There are three families of boundary for futility: Spending Function, p value, δ which can be seen as in the following screen

Design: Continuous Endpoint: Many-Sample Test - Pairwise Comparisons to Control - Differen

Number of Arms: 5 Number of Looks: 3

Test Parameters **Boundary**

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.025

Futility (Non-Binding)

Boundary Family: Spending Functions

Spending Function: None

Parameter: p-value

Type II Error (β): 0.1

Spacing of Looks: Equal Unequal Boundary Scale: Z Scale

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Cum. β Spent | Futility Boundary |
|--------|----------------|-------------------------------------|-------------------------------------|---------------------|-------------------|--------------------|-------------------|
| 1 | 0.333 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.000 | 4.049 | 0.005 | 0.178 |
| 2 | 0.667 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.006 | 2.931 | 0.045 | 1.642 |
| 3 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.025 | 2.477 | 0.102 | 2.477 |

Now click on recalc button to see the cumulative α , efficacy boundary, cumulative β and futility boundary displayed in the boundary table. The futility boundary is non-binding and the details on the computation of futility boundary is provided in Section J.2. The futility boundary is computed such that the probability for the best performed arm (compared to control arm) to cross the futility boundary at any look is equal to the incremental β . For example, the probability for the best performed treatment arm crossing 0.178 is 0.005 under the design alternative. The probability for the trial to stay in the continuous region at the first look but cross the futility boundary

1.647 at second look is 0.04 which is the incremental β spent.

Number of Arms: 5 Number of Looks: 3

Test Parameters Boundary

Efficacy
 Boundary Family: Spending Functions
 Spending Function: Lan-DeMets
 Parameter: OF
 Type I Error (α): 0.025

Futility (Non-Binding)

| Treatment 2 | 1.1 | 3 | 1 |
| Treatment 3 | 1.2 | 3 | 1 |
| Treatment 4 | 1.3 | 3 | 1 |

One can also build a futility boundary based on δ . For example, one might want to terminate the study if negative δ is observed. It can be seen that such futility boundary is more conservative than the one constructed based on O'Brien-Fleming spending function in the sense that it terminates the trial earlier for futility with smaller

probability.

17.2 Simulation

Multi-arm multi-stage design is complex study design with pros and cons. One of the pros is that it saves subjects compared to conducting separate studies to assess each treatment to control. It may also be advantageous in terms of enrolment. One of the cons is that the hurdle for demonstrating statistical significance is higher due to multiplicity. One needs to evaluate the operating characteristics of such designs through intensive simulations and to assess the pros and cons of using such design. To simulate a MAMS design, select the design node in the library and click on the

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

simulation icon located at the top of the library window

This will open the simulation dialog window. There are four windows for inputting values for simulation parameters: Test Parameters, Boundary, Response Generation and Simulation Controls. The Test Parameters window provides the total sample size, test statistics and variance type to be used in simulations. The boundary tab has similar inputs as that for design. The default inputs for boundary are carried from the design. One can modify the boundary in the simulation mode without having to go back to design. One can even add a futility boundary. The next screen is Response Generation tab where one needs to specify the underlying mean, standard deviation and allocation ratio for different treatment arm. The last tab, Simulation Control, allows one to specify the total number of simulations to be run and to save the intermediate simulation data for further analysis. For example, we can run simulation under the

design alternative where the mean differences from control are 1,1.1,1.2 and 1.3.

Trt Select **Simulation: Continuous Endpoint: Many-Sample Test -**

Number of Arms: 5 Number of Looks: 3

Test Parameters Boundary Response Generation Simulation Controls

Common Standard Deviation: 3

| Arm | Mean | Std. Dev. | Allocation Ratio (n _i : n _c) |
|-------------|------|-----------|---|
| Control | 0 | 3.000 | 1.000 |
| Treatment 1 | 1 | 3.000 | 1.000 |
| Treatment 2 | 1.1 | 3.000 | 1.000 |
| Treatment 3 | 1.2 | 3.000 | 1.000 |
| Treatment 4 | 1.3 | 3.000 | 1.000 |

After filling in all the inputs, click on the Simulation button on the right bottom of the window. After the simulation is completed, it will show up in the output preview area. To view the detailed simulation output, we can save it into the library and double click the simulation node.

Note: The trial is terminated if any arm enters the efficacy region.

The first table in the detailed output shows the overall power including global power, conjunctive power, disjunctive power and FWER. The definitions for different powers

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

are as follows.

- Global Power: probability of demonstrating statistical significance on one or more treatment groups
- Conjunctive Power: probability of demonstrating statistical significance on all treatment groups which are truly effective
- Disjunctive Power: probability of demonstrating statistical significance on at least one treatment group which is truly effective
- FWER: probability of incorrectly demonstrating statistical significance on at least one treatment group which is truly ineffective

For this example, the global power is about 90% which confirms the design power. The conjunctive power is about 8%.

The second table for probability of trial termination at each look displays the average sample size, information fraction, cumulative α spent, boundary information, probability of trial termination at each look. For this example, the chance of terminating the trial at the very first look is less than 3%. The trial has about 55% chance to stop early by the second look. It can be seen that the average sample size for the trial is about 424 which is shown in the last entry of the average sample size column.

In MAMS design, when the trial stops for efficacy, there might be one or more treatments crossing the efficacy boundary. Such information is valuable in some situations. For example, when multiple dose options are desired for patients with different demographic characteristics, it might be beneficial to approve multiple doses on the product label which will give physicians the options to prescribe the appropriate dose for a specific patient. In this case, we are not only interested in the overall power of the study but also interested in the power of claiming efficacy on more than one dose groups. Such information is summarized in the third table. This table shows the probability of demonstrating significance on specific number of treatments at each look and across all looks. For example, the trial has about 90% overall power. With 39% probability out of 90%, it successfully shows significance on only one treatment, 26% probability on two treatments, 17% on three treatments and about 8.5% for all four treatments. It also shows such breakdown look by look.

The fourth table summarizes the marginal power for each treatment group look by look and across all looks. For example, the trial has a marginal power of 29% successfully demonstrating efficacy for Treatment 1, 38% for Treatment 2, 49% for Treatment 3 and 60% for Treatment 4. The detailed efficacy outcome table as seen in the following screen provides further efficacy details pertinent to treatment identities. For example,

the trial has about 3.77% probability of demonstrating efficacy only on Treatment 1, 1.34% for both treatment 1 and 2, 1.7% for treatment 1, 2 and 3. It has 8.5% probability of showing significance on all four treatments.

⊖ Detailed Efficacy Outcomes

| Efficacy Outcome | Count | % |
|--|---------|----------|
| Treatment 1 only | 37715 | 3.772% |
| Treatment 2 only | 64134 | 6.413% |

17.2.1 Futility Stopping and Dropping the Losers

In the simulation mode, the futility boundary can be utilized in two different manners. Futility boundary can be used to terminate the trial earlier if the best performing treatment isn't doing well. It can also be used to drop arms which are futile along the way and only continue those treatments which are performing well. The two options can be accessed through the two radio buttons below the boundary table as seen in the

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

following screen.

Terminate Trial if at least one treatment crosses efficacy boundary

Futility Options: Terminate Trial if all treatments cross futility boundary
 Drop treatment arm if it crosses futility boundary

Restore Original Design

Suppose we want to see how often the trial will be terminated early for futility if none of the treatments are effective. Click on the Simulate button on the right bottom of the window to start simulation. The detailed output is shown below. Note that the trial will have about 20% probability of stopping early for futility at the very first look and a little more than 9% chance of stopping for futility at the second look. The average

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

sample size is about 437 compared to 523 for the design without futility boundary.

Note: The trial is terminated if any arm enters the efficacy region or all arms enter the futility region.

Under the design alternative, there is a very small probability (less than 0.5%) to terminate the trial early for futility as seen from the following table.

Probability of Trial Termination at Each Look

| Look # | Average Sample Size (n) | Info. Fraction (n/n _{max}) | Cumulative α Spent | Cumulative β Spent | Boundaries | | Probability (Incremental) of Trial Termination | | | | | |
|---------|-------------------------|--------------------------------------|--------------------|--------------------|------------|------------|--|----------------|--------|-------------|---------|---------|
| | | | | | Efficacy Z | Futility δ | Efficacy Count | Futility Count | % | Total Count | % | |
| 1 | 175 | 0.333 | 1.035E-4 | 0.003 | 4.049 | 0 | 38650 | 3.865% | 2844 | 0.284% | 41494 | 4.149% |
| 2 | 350 | 0.667 | 0.006 | 0.003 | 2.931 | 0 | 516605 | 51.661% | 106 | 0.011% | 516711 | 51.671% |
| 3 | 525 | 1 | 0.025 | 0.103 | 2.477 | 1.026 | 344240 | 34.424% | 97555 | 9.756% | 441795 | 44.180% |
| Overall | 420.053 | | | | | | 899495 | 89.950% | 100505 | 10.051% | 1000000 | |

Note: The trial is terminated if any arm enters the efficacy region or all arms enter the futility region.

For the big companies, a more aggressive futility boundary might be desirable so that trials for treatments with small effect can be terminated early and resources can be deployed to other programs. Suppose that a futility boundary based on $\delta = 0.5$ to be used. Under the global null hypothesis, there is almost 70% chance for the trial to stop early for futility. The average sample size for the study is about 316 compared to 437

for the design with futility based δ of zero.

⊖ Probability of Trial Termination at Each Look

| Overall | 437.603 | | | | | | 26540 | 2.654% | 973460 | 97.346% | 1000000 | |

Note: The trial is terminated if any arm enters the efficacy region or all arms enter the futility region.

The other use of the futility boundary is to drop those arms which are ineffective along the way. Such design would be more efficient if it is anticipated that there is a strong heterogeneity among different treatment arms. Suppose that two of the four treatment regimens have relative smaller treatment effect. For example, the mean difference from control might be 0.1, 0.1, 1.2, 1.3. Without applying any futility, the trial has about 85% and average sample size of 437. If we drop those doses which cross the futility boundary based on δ of 0.5, the trial has about 82% power and average sample size 328. From the table for probability of trial termination at each look, we can see that the trial has about 8% chance stopping early at the first interim look of which a little more than 2% for efficacy and about 5% chance for futility. The trial has 46% chance stopping earlier at the second look with about 45% for efficacy and less than 2% for futility. From the table for additional details of probability of trial termination at each look, we can see that the trial has 2.78% chance stopping for efficacy at the first look of which 2.55% probability the trial demonstrates significance on only one treatment. At the second look, the trial has about 45% probability stopping early for efficacy of which 29% probability it demonstrates significance on one treatment, 15% probability on two treatments and less than 1% probability on three or four treatments. This design has marginal power about 50% to detect significance on Treatment 3 and more than 60% probability on Treatment 4. Treatment 1 and Treatment 2 each has 70% chance being terminated at look 1 for futility. The marginal probability for futility stopping for each treatment counts those simulated trials for which the particular treatment crosses the futility boundary but it doesn't counts those trials for which the particular treatment

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

falls into the continuous region.

Probability of Trial Termination at Each Look

| Look # | Average Sample Size (n) | Info. Fraction (n/n_max) | Cumulative α Spent | Cumulative β Spent | Boundaries | | Probability (Incremental) of Trial Termination | | | | | | | | | |
|---------|-------------------------|--------------------------|---------------------------|--------------------------|------------|----------|--|---------|-------|---------|----------|---------|-------|---|-------|--|

| Total | 0.385% | 87.319% | 0.397% | 87.287% | 49.759% | 33.743% | 61.655% | 27.562% |

Note: The trial is terminated if any arm enters the efficacy region and an arm is dropped when it enters futility region.

The second table in the above screen shows the probability of demonstrating significance on specific number of treatments. However it doesn't provide information on the likelihood of showing efficacy on specific treatment combinations. Such information is provided in the table for detailed efficacy outcomes. For example, the trial has about 20% probability of success with Treatment 3 only, 32% with Treatment

4 only, 30% with both Treatment 3 and Treatment 4.

 Detailed Efficacy Outcomes

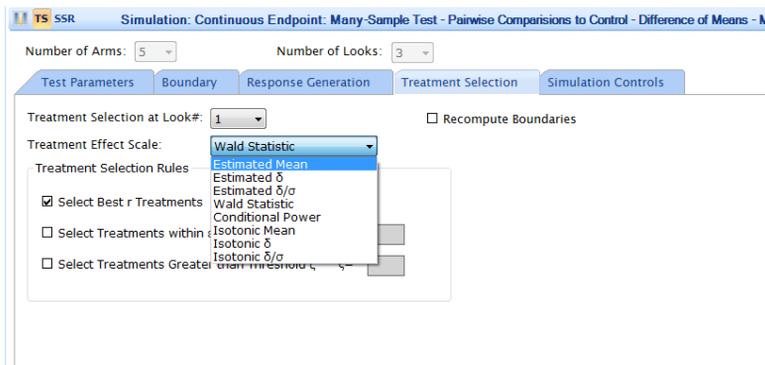

| Efficacy Outcome | Count | % |
|--|--------|----------|
| Treatment 1 only | 16 | 0.016% |
| Treatment 2 only | 15 | 0.015% |
| Treatment 3 only | 19896 | 19.896% |
| Treatment 4 only | 31566 | 31.566% |
| Treatment 1 & Treatment 2 only | 0 | 0.000% |

| Treatment 1 & Treatment 3 & Treatment 4 only | 239 | 0.239% |
| Treatment 2 & Treatment 3 & Treatment 4 only | 259 | 0.259% |
| All 4 treatments | 27 | 0.027% |
| None | 18467 | 18.467% |
| Total | 100000 | 100.000% |

17.2.2 Interim Treatment Selection

It might be desirable to select promising dose/treatment groups and drop those ineffective or unsafe groups after reviewing the interim data. In general, there are no analytical approach to evaluate such complex design. EAST provides the option to evaluate such adaptive design through intensive simulations. The treatment selection option can be incorporated by clicking on the  icon located on the top bar of the main simulation dialog window. The treatment selection window screen looks as follows. It takes several inputs from the user. The first input is the drop-down box for the user to specify the look position for performing treatment selection. The next input is drop-down box for the treatment effect scale. There is a list of treatment effect scale available as seen in the following screen including Wald Statistic, Estimated Mean,

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

Estimated δ etc.

EAST provides three different dose/treatment selection rules: (1) Select best r treatment, (2) Select treatments within ϵ of the best treatment, (3) Select treatments greater than threshold ζ where r, ϵ, ζ accept inputs from the user. For the same example, suppose we select two best treatments at the second interim look. The inputs

are as follows:

Number of Arms: 5 Number of Looks: 3

Now click on simulation button to run simulations. When the simulation is done, save it into the library and view the detailed output as in the following screen. We can see that the trial has about 85% overall power to detect significance on at least one treatment group with an average sample size of 400 (Overall Powers). It has about 50% probability of stopping early by the second look (Prabability of Trial Termination at Each Look). From the third table (Additional Details of Probability of Trial Termination at Each Look), it can be seen that the trial has about 52% power to show significance on only one treatment and 33% probability on two treatments, less than 1% probability on three or four treatments. Marginally Treatment 3 has 53% chance of

success and Treatment 4 has 66% chance of success.

| | # of Treatments Claiming Efficacy | | | | # of Treatments Continuing | | | |
| | One | Two | Three | Four | One | Two | Three | Four |
| 1 | 2.605% | 0.239% | 0.006% | 0.000% | 0.000% | 0.000% | 0.000% | 97.153% |
| 2 | 31.925% | 15.481% | 0.387% | 0.014% | 0.000% | 52.193% | 0.000% | 0.000% |
| 3 | 51.764% | 33.322% | 0.387% | 0.014% | | | | |
| Total | 51.764% | 33.322% | 0.387% | 0.014% | | | | |

Note: The trial is terminated if any arm enters the efficacy region.

Marginal Probability of Trial Termination by Treatment at Each Look

| Look # | Efficacy Boundary | | | |
|--------|-------------------|-------------|-------------|-------------|
| | Treatment 1 | Treatment 2 | Treatment 3 | Treatment 4 |
| 1 | 0.018% | 0.016% | 1.272% | 1.789% |
| 2 | 0.289% | 0.290% | 28.076% | 35.449% |
| 3 | 0.344% | 0.338% | 53.374% | 65.569% |
| Total | 0.344% | 0.338% | 53.374% | 65.569% |

Note: The trial is terminated if any arm enters the efficacy region.

When we select two best treatments, the sample size for the selected two treatments remains the same as the designed one. However we can reallocate the remaining sample size from the dropped groups to the selected arm to gain more power. If the sample size for the dropped arms are reallocated to the selected arms, the efficacy stopping boundary for the remaining looks will have to be recomputed in order to preserve the type I error. This can be achieved by checking the box for Reallocating remaining sample size to selected arm on the Treatment Selection tab as seen in the

17 Continuous Endpoint: Multi-arm Multi-stage (MaMs) Designs

following window.

Number of Arms: 5 Number of Looks: 3

Treatment Effect Scale: Estimated δ

Reallocate remaining sample size to selected arm

Treatment Selection Rules

Select Best r Treatments $r =$ 2

Select Treatments within ϵ of Best Treatment $\epsilon =$

Select Treatments Greater than Threshold ζ $\zeta =$

The simulation output is shown in the following screen. Note that the power of the study is almost 92% in exchange of a higher average sample size 436 compared to the design without sample size reallocation (85% power and 400 average sample size). Also with sample size reallocation, the study has a higher power 43% of demonstrating significance on both Treatment 3 and Treatment 4 compared to the design without sample size reallocation which has 33% power.

18 Two-Stage Multi-arm Designs using p -value combination

18.1 Introduction

In the drug development process, identification of promising therapies and inference on selected treatments are usually performed in two or more stages. The procedure we will be discussing here is an adaptive two-stage design that can be used for the situation of multiple treatments to be compared with a control. This will allow integration of both the stages within a single confirmatory trial controlling the multiple level type-I error. After the interim analysis in the first stage, the trial may be terminated early or continued with a second stage, where the set of treatments may be reduced due to lack of efficacy or presence of safety problems with some of the treatments. This procedure in East is highly flexible with respect to stopping rules and selection criteria and also allows re-estimation of the sample size for the second stage. Simulations show that the method may be substantially more powerful than classical one-stage multiple treatment designs with the same total sample size because second stage sample size is focused on evaluating only the promising treatments identified in the first stage. This procedure is available for continuous as well discrete endpoint studies. The current chapter deals with the continuous endpoint studies only; discrete endpoint studies are handled similarly.

18.2 Study Design

18.2.1 Introduction to the Study

18.2.2 Methodology

18.2.3 Study Design Inputs

18.2.4 Simulating under Different Alternatives

This section will explore different design options available in East with the help of an example.

18.2.1 Introduction to the Study

Consider designing a placebo controlled, double blind, randomized trial to evaluate the efficacy, pharmacokinetics, safety and tolerability of a New Chemical Entity (NCE) given as multiple weekly infusions in subjects with a recent acute coronary syndrome. There are four dose regimens to be investigated. The treatment effect is assessed through the change in PAV (percent atheroma volume) from baseline to Day 36 post-randomization, as determined by IVUS (intravascular ultrasound). The expected change in PAV for placebo group and the four dose regimens are: 0, 1, 1.1, 1.2, 1.3 and the common standard deviation is 3. The objective of the study is to find the optimal dose regimen based on the totality of the evidence including benefit-risk assessment and cost considerations.

18.2.2 Methodology

This is a randomized, double-blind, placebo-controlled study conducted in two parts using a 2-stage adaptive design. In Stage 1, approximately 250 eligible subjects will be randomized equally to one of four treatment arms (NCE [doses: 1, 2.5, 5 or 10 mg]) and matching placebo (which is 50 subjects/dose group) After all subjects in Stage 1

18 Two-Stage Multi-arm Designs using p-value combination

have completed treatment period or discontinued earlier, an interim analysis will be conducted to

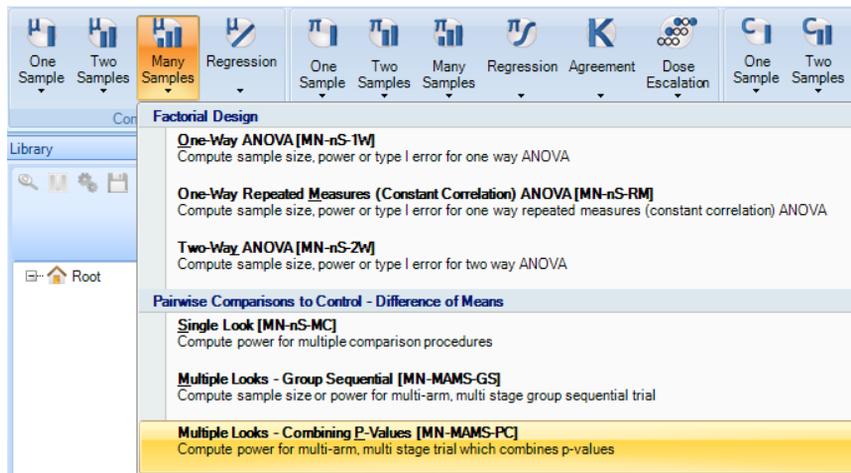

1. compare the means each dose group
2. assess safety within each dose group and
3. drop the less efficient doses

Based on the interim analysis, Stage 2 of the study will either continue with additional subjects enrolling into 1/2/3 arms (placebo and 1/2/3 favorable, active doses) or the study will be halted completely if unacceptable toxicity has been observed.

In this example, we will have the following workflow to cover different options available in East:

1. Start with four arms (4 doses + Placebo)
2. Evaluate the four doses at the interim analysis and based on the **Treatment Selection Rules** carry forward some of the doses to the next stage
3. While we select the doses, also increase the sample size of the trial by using **Sample Size Re-estimation (SSR)** tool to improve conditional power if necessary
In a real trial, both the above actions (early stopping as well as sample size re-estimation) will be performed after observing the interim data.
4. See the final design output in terms of different powers, probabilities of selecting particular dose combinations
5. See the early stopping boundaries for efficacy and futility on adjusted p-value scale
6. Monitor the actual trial using the **Interim Monitoring** tool in East.

Start East. Click Design tab, then click **Many Samples** in the **Continuous** category, and then click **Multiple Looks- Combining p-values** test.

This will bring up the input window of the design with some default values. Enter the inputs as discussed below.

18.2.3 Study Design Inputs

The four doses of the treatment- *1mg*, *2.5mg*, *5mg*, *10mg* will be compared with the Placebo arm based on their treatment means. Preliminary sample size estimates are provided to achieve an overall study power of at least 90% at an overall, adequately adjusted 1-sided type-1 or alpha level of 2.5%, after taking into account all interim and final hypothesis tests. Note that we always use 1-sided alpha since dose-selection rules are usually 1-sided.

In Stage 1, 250 subjects are initially planned for enrollment (5 arms with 50 subjects each). Following an interim analysis conducted after all subjects in Stage 1 have completed treatment period or discontinued earlier, an additional 225 subjects will be enrolled into three doses for Stage 2 (placebo and two active doses). So we start with the total of $250+225 = 475$ subjects.

The multiplicity adjustment methods available in East to compute the adjusted p-value (p-value corresponding to global NULL) are *Bonferroni*, *Sidak*, *Simes*. For discrete endpoint test, *Dunnnett Single Step* is not available since we will be using Z-statistic. Let us use the *Bonferroni* method for this example. The p-values obtained from both the stages can be combined by using the “Inverse Normal” method. In the “Inverse

18 Two-Stage Multi-arm Designs using p-value combination

Normal” method, East first computes the weights as follows:

$$w^{(1)} = \sqrt{\frac{n^{(1)}}{n}} \tag{18.1}$$

And

$$w^{(2)} = \sqrt{\frac{n^{(2)}}{n}} \tag{18.2}$$

where $n^{(1)}$ and $n^{(2)}$ are the total sample sizes corresponding to Stage 1 and stage 2 respectively and n is the total sample size.

EAST displays these weights by default but they are editable and user can specify any other weights as long as

$$w^{(1)^2} + w^{(2)^2} = 1 \tag{18.3}$$

Final p-value is given by

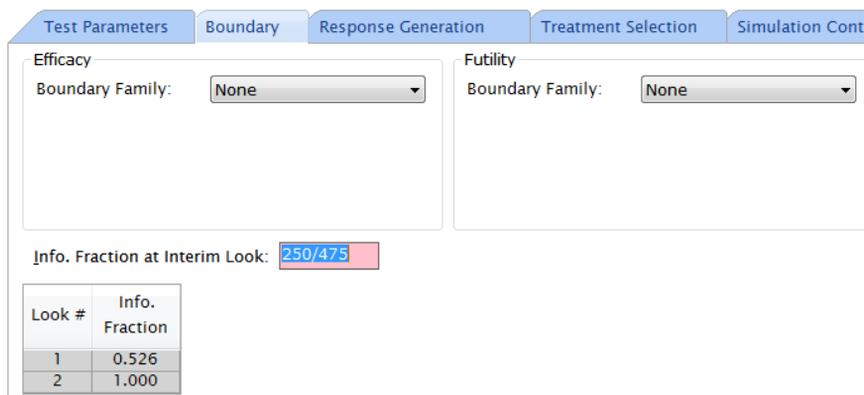

$$p = 1 - \Phi\left(w^{(1)}\Phi^{-1}(1 - p^{(1)}) + w^{(2)}\Phi^{-1}(1 - p^{(2)})\right) \tag{18.4}$$

The weights specified on this tab will be used for p-value computation. $w^{(1)}$ will be used for data before interim look and $w^{(2)}$ will be used for data after interim look. Thus, according to the samples sizes planned for the two stages in this example, the weights are calculated as $\sqrt{(250/475)}$ and $\sqrt{(225/475)}$. **Note :** These weights are updated by East once we specify the first look position as 250/475 in the **Boundary** tab. So leave these as default values for now. Set the *Number of Arms* as 5 and enter the rest of the inputs as shown below:

| | | | |
|---|------------|--------------------------|----------------|
| Number of Arms: | 5 | Number of Looks: | 2 |
| <div style="display: flex; justify-content: space-between;"> Test Parameters Boundary Response Generation Treatment Selection Simulation Controls </div> | | | |
| Test Type: | 1-Sided | Multiplicity Adjustment: | Bonferroni |
| Rejection Region: | Right-Tail | p-value Combination: | Inverse Normal |
| Type I Error (α): | 0.025 | Weight1: | 0.707 |
| Total Sample Size (n): | 475 | Weight2: | 0.707 |
| | | Test Statistic: | t |
| | | Variance: | Equal |

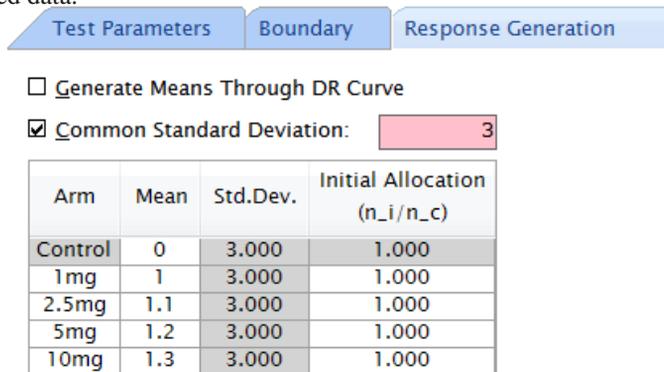

We can certainly have early stopping boundaries for efficacy and/or futility. But generally, in designs like this, the objective is to select the best dose(s) and not stop early. So for now, select the **Boundary** tab and set both the boundary families to “None”. Also, set the timing of the interim analysis as 0.526 which will be after

observing the data on 250 subjects out of 475. Enter 250/475 as shown below. Notice the updated weights on the bf Test Parameters tab.

| Look # | Info. Fraction |
|--------|----------------|
| 1 | 0.526 |
| 2 | 1.000 |

The next tab is **Response Generation** which is used to specify the true underlying means on the individual dose groups and the initial allocation from which to generate the simulated data.

| Arm | Mean | Std.Dev. | Initial Allocation (n _i /n _c) |
|---------|------|----------|--|
| Control | 0 | 3.000 | 1.000 |
| 1mg | 1 | 3.000 | 1.000 |
| 2.5mg | 1.1 | 3.000 | 1.000 |
| 5mg | 1.2 | 3.000 | 1.000 |
| 10mg | 1.3 | 3.000 | 1.000 |

One can also generate the mean response for all the arms using a dose-response curve like 4PL or Emax or Linear or Quadratic. It can be done by checking the box for **Generate Means through DR Curve** and entering appropriate parameters for DR

18 Two-Stage Multi-arm Designs using p -value combination

model selected.

The screenshot shows the 'Response Generation' tab with the following table and settings:

| Arm | Dose | Mean | Std.Dev. | Initial Allocation (n ₁ /n _c) |
|---------|-------|-------|----------|--|
| Control | 1.000 | 5.005 | 3.000 | 1.000 |
| 1mg | 2.000 | 5.037 | 3.000 | 1.000 |
| 2.5mg | 3.000 | 5.27 | 3.000 | 1.000 |
| 5mg | 4.000 | 6.788 | 3.000 | 1.000 |
| 10mg | 5.000 | 12.5 | 3.000 | 1.000 |

Settings: Generate Means Through DR Curve, Common Standard Deviation: 3.
 Dose Response Curve: Four Parameter Logistic (selected), Four Parameter Logistic, Emax, Linear, Quadratic.
 Parameters: $\theta = 5$, $\tau = 0.5$.
 Button: Plot DR Curve

For this example, we will use the given means and standard deviation and not generate them using a DR curve. Make sure the means are 0, 1, 1.1, 1.2, 1.3 and SD is 3.

Before we update the **Treatment Selection** tab, go to the **Simulation Control Parameters** tab where we can specify the number of simulations to run, the random number seed and also to save the intermediate simulation data. For now, enter the inputs as shown below and keep all other inputs as default.

The screenshot shows the 'Simulation Controls' tab with the following settings:

Number of Simulations: 10000
 Refresh Frequency: 1000
 Random Number Seed: Clock, Fixed (100)
 Suppress All Intermediate Output
 Pause after Refresh
 Pause at End

Output Options:
 Output Type: Case Data
 Save summary statistics for every simulation run
 Save subject level data for 1 simulation runs
 Note: Max. 100,000 records will be saved.

Click on the **Treatment Selection** tab. This tab is to select the scale to compute the treatment-wise effects. For selecting treatments for the second stage, the treatment effect scale will be required, but the control treatment will not be considered for selection. It will always be there in the second stage. The list under **Treatment Effect Scale** allows you to set the selection rules on different scales. Select **Estimated δ** from this list. It means that all the selection rules we specify on this tab will be in terms of the estimated value of treatment effect, δ , i.e., difference from

placebo. Here is a list of all available treatment effect scales: Estimated Mean, Estimated δ , Estimated δ/σ , Test Statistic, Conditional Power, Isotonic Mean, Isotonic δ , Isotonic δ/σ .

For more details on these scales, refer to the Appendix **K** chapter on this method.

The next step is to set the treatment selection rules for the second stage.

Select Best r Treatments: The best treatment is defined as the treatment having the highest or lowest mean effect. The decision is based on the rejection region. If it is “Right-Tail” then the highest should be taken as best. If it is “Left-Tail” then the lowest is taken as best. Note that the rejection region does not affect the choice of treatment based on conditional power.

Select treatments within ϵ of Best Treatment: Suppose the treatment effect scale is **Estimated δ** . If the best treatment has a treatment effect of δ_b and ϵ is specified as 0.1 then all the treatments which have a δ as $\delta_b - 0.1$ or more are chosen for Stage 2.

Select treatments greater than threshold ζ : The treatments which have the treatment effect scale greater or less than the threshold (ζ) specified by the user according to the rejection region. But if the treatment effect scale is chosen as the conditional power then it will be greater than all the time.

Use R for Treatment Selection: If you wish to define any customized treatment selection rules, it can be done by writing an R function for those rules to be used within East. This is possible due to the R Integration feature in East. Refer to the appendix chapter on **R Functions** for more details on syntax and use of this feature. A template file for defining treatment selection rules is also available in the subfolder **RSamples** under your East installation directory.

| Tasks | File Name | Function Name |
|--------------------------|-----------|---------------|
| Treatment Selection | | |
| Initialize R Environment | | |

For more details on using R to define Treatment selection rules, refer to section **O.10**.

18 Two-Stage Multi-arm Designs using p-value combination

Selecting multiple doses (arms) for Stage 2 would be more effective than selecting just the best one. For this example, select the first rule **Select Best r treatments** and set $r = 2$ which indicates that East will select the best two doses for Stage 2 out the four. We will leave the Allocation Ratio after Selection as 1 to yield equal allocation between the control and selected doses in Stage 2.

Click the **Simulate** button to run the simulations. When the simulations are over, a row gets added in the **Output Preview** area. Save this row to the **Library** by clicking the  icon in the toolbar. Rename this scenario as **Best2**. Double click it to see the detailed output.

Marginal Probabilities of Selection and Efficacy

| Label | Average Sample Size | Marginal Probability of Selection | | Marginal Probability of Efficacy | |
|-------|---------------------|-----------------------------------|---------|----------------------------------|---------|
| | | Count | % | Count | % |
| 1mg | 76.805 | 3574 | 35.740% | 2611 | 26.110% |
| 2.5mg | 82.933 | 4391 | 43.910% | 3485 | 34.850% |
| 5mg | 91.648 | 5553 | 55.530% | 4634 | 46.340% |
| 10mg | 98.615 | 6482 | 64.820% | 5605 | 56.050% |

The first table in the detailed output shows the overall power including global power, conjunctive power, disjunctive power and FWER. The definitions for different powers are as follows:

- Global Power: probability of demonstrating statistical significance on one or

- more treatment groups
- Conjunctive Power: probability of demonstrating statistical significance on all treatment groups which are truly effective
- Disjunctive Power: probability of demonstrating statistical significance on at least one treatment group which is truly effective
- FWER: probability of incorrectly demonstrating statistical significance on at least one treatment group which is truly ineffective

For our example, there is 88% global power which is the probability of this design to reject any null hypothesis, where the set of null hypothesis are the TRUE proportion of responders at each dose equals that of control. Also shown is conjunctive and disjunctive power, as well as Family Wise Error Rate (FWER).

The **Lookwise Summary** table summarizes the number of simulated trials that ended with a conclusion of efficacy, i.e., rejected any null hypothesis, at each look. In this example, no simulated trial stopped at the interim analysis with an efficacy conclusion since there were no stopping boundaries, but 8845 simulations yielded an efficacy conclusion via the selected dose after Stage 2. This is consistent with the global power.

The table **Detailed Efficacy Outcomes for all 10000 Simulations** summarizes the number of simulations for which each individual dose group or pairs of doses were selected for Stage 2 and yielded an efficacy conclusion. For example, the pair (2.5mg, 10mg only) was observed to be efficacious in approximately 16% of the trials (1576/10000).

The next table **Marginal Probabilities of Selection and Efficacy**, summarizes the number and percent of simulations in which each dose was selected for Stage 2, regardless of whether it was found significant at end of Stage 2 or not, as well as the number and percent of simulations in which each dose was selected and found significant. Average sample size is also shown. It tells us how frequently the dose (either alone or with some other dose) was selected and efficacious. For example, dose 10mg was selected in approximately 65% trials and was efficacious in approximately 56% trials. (which is the sum of 631, 1144, 1576, 2254 simulations from previous table.)

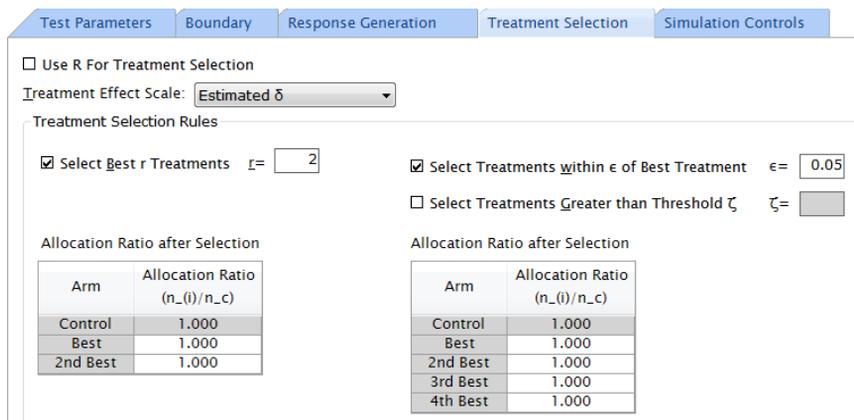

The advantage of 2-stage “treatment selection design” or “drop-the-loser” design is that it allows to drop the less performing/futile arms based on the interim data and still preserves the type-1 error as well as achieve the desired power.

In the **Best2** scenario, we dropped two doses ($r = 2$). Suppose, we had decided to proceed to stage 2 without dropping any doses. In this case, Power would have

18 Two-Stage Multi-arm Designs using p -value combination

dropped significantly. To verify this in East, click the  button on the bottom left corner of the screen. This will take us back to the input window of the last simulation scenario. Go to **Treatment Selection** tab and set $r = 4$ and save it to **Library**. Rename this scenario as **All4**. Double click it to see the detailed output. We can observe that the power drops from 88% to 78%. That is because the sample size of 225 is being shared among five arms as against three arms in the **Best2** case.

Now go back to **Treatment Selection** tab, set $r = 2$ as before. Select one more rule, **Select Treatments within ϵ of Best Treatment** and set the ϵ value as 0.05. The tab should look as shown below.

Use R For Treatment Selection
 Treatment Effect Scale: Estimated δ

Treatment Selection Rules

Select Best r Treatments $r =$

Select Treatments within ϵ of Best Treatment $\epsilon =$

Select Treatments Greater than Threshold ζ $\zeta =$

Allocation Ratio after Selection

| Arm | Allocation Ratio (n _(i) /n _c) |
|----------|--|
| Control | 1.000 |
| Best | 1.000 |
| 2nd Best | 1.000 |

Allocation Ratio after Selection

| Arm | Allocation Ratio (n _(i) /n _c) |
|----------|--|
| Control | 1.000 |
| Best | 1.000 |
| 2nd Best | 1.000 |
| 3rd Best | 1.000 |
| 4th Best | 1.000 |

Also set the Starting Seed on **Simulation Controls** tab to 100. **Note that since we have selected two treatment selection rules, East will simulate two different scenarios, one for each rule.** As we want to compare the results from these two scenarios, we use the same starting seed. That will ensure same random number generation and the only difference in results will be the effect of the two rules.

Save these two scenarios in the **Library** as **r=2** and **epsilon=0.05**, select them and click the  icon in the toolbar to see them side-by-side.

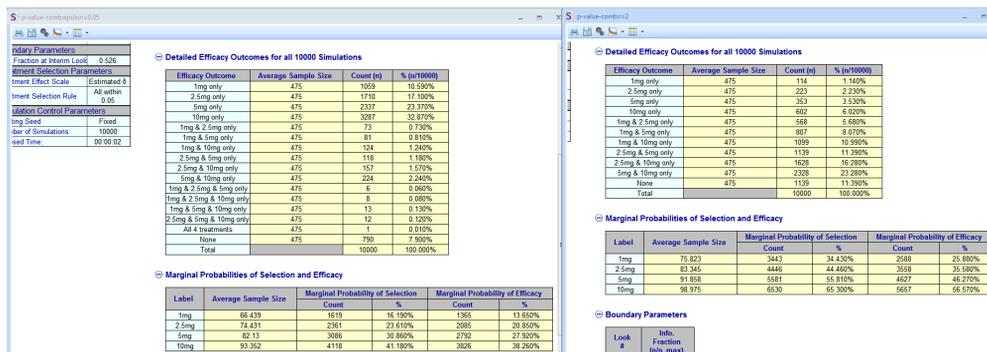

| | p-value-comb:r=2 | p-value-comb:epsilon=... |

Boundary Parameters

| Look # | Info. Fraction (info_max) |
|--------|---------------------------|
| 1 | |

Notice from this comparison, due to a more general rule based on ϵ , we can select multiple doses and not just two. At the same time, the marginal probability of selection as well as efficacy for each dose drops significantly.

18.2.4 Simulating under Different Alternatives

Since this is a simulation based design, we can perform sensitivity analyses by changing some of the inputs and observing effects on the overall power and other output. Let us first make sure that this design preserves the total type I error. It can be done by running the simulations under “Null” hypothesis.

Select the last design created which would be **epsilon = 0.05** in the Library and click the  icon. This will take you to the input window of that design. Go to **Response Generation** tab and enter the inputs as shown below. Notice that all the means are 0

which means the simulations will be run under NULL assumption.

Test Parameters
Boundary
Response Generation

Generate Means Through DR Curve

Common Standard Deviation:

| Arm | Mean | Std.Dev. | Initial Allocation (n _i /n _c) |
|---------|-------|----------|---|
| Control | 0.000 | 3.000 | 1.000 |
| 1mg | 0.000 | 3.000 | 1.000 |
| 2.5mg | 0.000 | 3.000 | 1.000 |
| 5mg | 0.000 | 3.000 | 1.000 |
| 10mg | 0.000 | 3.000 | 1.000 |

Run the simulations and go to the detailed output by saving the row from **Output Preview** to the **Library**. Notice the global power and the simulated FWER is less than 0.025 which means the overall type1 error is preserved.

18.3 Sample Size Re-estimation

As seen in the previous scenario, the desired power of approximately 92% is achieved with the sample size of 475 if the initial assumptions ($\mu_c = 0$, $\mu_{1mg} = 1$, $\mu_{2.5mg} = 1.1$, $\mu_{5mg} = 1.2$ and $\mu_{10mg} = 1.3$) hold true. But if they do not, then the original sample size of 475 may be insufficient to achieve 92% power. The adaptive sample size re-estimation is suited to this purpose. In this approach we start out with a sample size of 475 subjects, but take an interim look after data are available on 250 subjects. The purpose of the interim look is not to stop the trial early but rather to examine the interim data and continue enrolling past the planned 475 subjects if the interim results are promising enough to warrant the additional investment of sample size. This strategy has the advantage that the sample size is finalized only after a thorough examination of data from the actual study rather than through making a large up-front sample size commitment before any data are available. Furthermore, if the sample size may only be increased but never decreased from the originally planned 475 subjects, there is no loss of efficiency due to overruns. Suppose the mean responses on the five doses are as shown below. Update the **Response Generation** tab

18 Two-Stage Multi-arm Designs using p -value combination

accordingly and also set the seed as 100 in the **Simulation Controls** tab.

Test Parameters Boundary Response Generation

Generate Means Through DR Curve

Common Standard Deviation:

| Arm | Mean | Std.Dev. | Initial Allocation (n _i /n _c) |
|---------|------|----------|---|
| Control | 0 | 3.000 | 1.000 |
| 1mg | 0.8 | 3.000 | 1.000 |
| 2.5mg | 0.95 | 3.000 | 1.000 |
| 5mg | 1 | 3.000 | 1.000 |
| 10mg | 1 | 3.000 | 1.000 |

Run 10000 simulations and save the simulation row to the **Library** by clicking the

icon in the toolbar. See the details.

Overall Powers

| | |
|---|-------|
| Global (Reject any Hi) | 0.779 |
| Conjunctive (Reject all Hi where $\mu_i > \mu_0$) | 2E-4 |
| Disjunctive (Reject at least one Hi where $\mu_i > \mu_0$) | 0.779 |
| FWER (Reject any Hi where $\mu_i \leq \mu_0$) | 0 |

Lookwise Summary

| Look # | Average Total Sample Size (n) | Trial Termination | |
|---------|-------------------------------|-------------------|---------|
| | | Efficacy | |
| | | Count | % |
| 1 | 250 | 0 | 0.000% |
| 2 | 475 | 7785 | 77.850% |
| OverAll | | 7785 | 77.850% |

Notice that the global power has dropped from 92% to 78%. Let us re-estimate the sample size to achieve the desired power. Add the **Sample Size Re-estimation** tab by clicking the button . A new tab gets added as shown below.

SSR At: For a K -look group sequential design, one can decide the time at which conditions for adaptations are to be checked and actual adaptation is to be

18 Two-Stage Multi-arm Designs using p -value combination

carried out. This can be done either at some intermediate look or after some specified information fraction. The possible values of this parameter depend upon the user choice. The default choice for this design is always the **Look #**. and is fixed to 1 since it is always a 2-look design.

Target CP for Re-estimating Sample Size: The primary driver for increasing the sample size at the interim look is the desired (or target) conditional power or probability of obtaining a positive outcome at the end of the trial, given the data already observed. For this example we have set the conditional power at the end of the trial to be 92%. East then computes the sample size that would be required to achieve this conditional power.

Maximum Sample Size if Adapt (multiplier; total): As just stated, a new sample size is computed at the interim analysis on the basis of the observed data so as to achieve some target conditional power. However the sample size so obtained will be overruled unless it falls between pre-specified minimum and maximum values. For this example, let us use the multiplier as 2 indicating that we intend to double the original sample size if the results are promising. The range of allowable sample sizes is [475, 950]. If the newly computed sample size falls outside this range, it will be reset to the appropriate boundary of the range. For example, if the sample size needed to achieve the desired 90% conditional power is less than 475, the new sample size will be reset to 475. In other words we will not decrease the sample size from what was specified initially. On the other hand, the upper bound of 950 subjects demonstrates that the sponsor is prepared to double the sample size in order to achieve the desired 90% conditional power. But if 90% conditional power requires more than 950 subjects, the sample size will be reset to 950, the maximum allowed.

Promising Zone Scale: One can define the promising zone as an interval based on conditional power, test statistic, or estimated δ/σ . The input fields change according to this choice. The decision of altering the sample size is taken based on whether the interim value of conditional power / test statistic / δ/σ lies in this interval or not. Let us keep the default scale which is Conditional Power.

Promising Zone: Minimum/Maximum Conditional Power (CP): The sample size will only be altered if the estimate of CP at the interim analysis lies in a pre-specified range, referred to as the “Promising Zone”. Here the promising zone is 0.30 – 0.90. The idea is to invest in the trial in stages. Prior to the interim analysis the sponsor is only committed to a sample size of 475 subjects. If, however, the results at the interim analysis appear reasonably promising, the

sponsor would be willing to make a larger investment in the trial and thereby improve the chances of success. Here we have somewhat arbitrarily set the lower bound for a promising interim outcome to be $CP = 0.30$. An estimate $CP < 0.30$ at the interim analysis is not considered promising enough to warrant a sample size increase. It might sometimes be desirable to also specify an upper bound beyond which no sample size change will be made. Here we have set that upper bound of the promising zone at $CP = 0.90$. In effect we have partitioned the range of possible values for conditional power at the interim analysis into three zones; *unfavorable* ($CP < 0.3$), *promising* ($0.3 \leq CP < 0.9$), and *favorable* ($CP \geq 0.9$). Sample size adaptations are made only if the interim CP falls in the promising zone at the interim analysis. The promising zone defined on the Test Statistic scale or the Estimated δ/σ scale works similarly.

SSR Function in Promising Zone: The behavior in the promising zone can either be defined by a continuous function or a step function. The default is continuous where East accepts the two quantities - (Multiplier, Target CP) and re-estimates the sample size depending upon the interim value of CP/test statistic/effect size. The SSR function can be defined as a step-function as well. This can be done with a single piece or with multiple pieces. For each piece, define the step function in terms of:

- the interval of CP/test statistic/ δ/σ . This depends upon the choice of promising zone scale.
- the value of re-estimated sample size in that interval.
- for single piece, just the total re-estimated sample size is required as an input.

If the interim value of CP/ test statistic/ δ/σ lies in the promising zone then the re-estimation will be done using this step function.

Let us set the inputs on **Sample Size Re-estimation** tab as shown below. Just for the comparison purpose, also run the simulations without adaptation. Both the scenarios

18 Two-Stage Multi-arm Designs using p -value combination

can also be run together by entering two values 1, 2 in the cell for Multiplier.

Promising Zone defined as 0.3 <= CP < 0.9

We observe from the table the power of adaptive implementation is approximately

85% which is almost 8% improvement over the non-adaptive design. This increase in power has come at an average cost of 540-475 = 65 additional subjects. Next we observe from the **Zone-wise Averages** table that 1610 of 10000 trials (16%) underwent sample size re-estimation (Total Simulation Count in the “Promising Zone”) and of those 1610 trials, 89% were able to reject the Global null hypothesis. The average sample size, conditional on adaptation is 882.

18.4 Adding Early Stopping Boundaries

One can also incorporate stopping boundaries to stop at the interim early for efficacy or futility. The efficacy boundary can be defined based on **Adjusted p-value** scale whereas futility boundary can be on **Adjusted p-value** or δ/σ scale.

Click the  button on the bottom left corner of the screen. This will take you back to the input window of the last simulation scenario. Go to **Boundary** tab and set Efficacy and Futility boundaries to “Adjusted p-value”. These boundaries are for

18 Two-Stage Multi-arm Designs using p-value combination

early stopping at look1. As the note on this tab says:

- If any one adjusted p-value is \leq efficacy p-value boundary then stop the trial for efficacy
- If only all the adjusted p-values are $>$ futility p-value then stop the trial for futility. Else carry forward all the treatments to the next step of treatment selection.

Stopping early for efficacy or futility is step which is carried out before applying the treatment selection rules. The simulation output has the same explanation as above except the **Lookwise Summary** table may have some trials stopped at the first look due to efficacy or futility.

18.5 Interim Monitoring with Treatment Selection

Select the simulation node with **SSR** implementation and click the **IM** icon. It will invoke the **Interim Monitoring** dashboard. Click the **Enter Interim Data** icon to open the **Test Statistic Calculator**. The “Sample Size” column is filled out according to the originally planned design (50/arm). Enter the data as shown below:

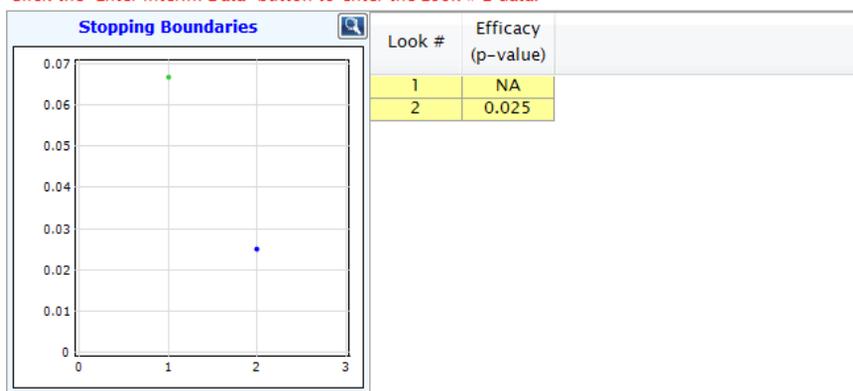

| Arm | Sample Size | Mean | Std. Deviation | Test Statistic | Raw p-values |
|---------|-------------|-------|----------------|----------------|--------------|
| Control | 50 | 0.005 | 3.000 | NA | NA |
| 1mg | 50 | 0.9 | 3.000 | 1.492 | 0.069 |
| 2.5mg | 50 | 1.15 | 3.000 | 1.908 | 0.030 |
| 5mg | 50 | 1.22 | 3.000 | 2.025 | 0.023 |
| 10mg | 50 | 1.3 | 3.000 | 2.158 | 0.017 |

Click **Recalc** to calculate the test statistic as well as the raw p-values. Notice that the

p-values for *1mg* and *2.5mg* are 0.069 and 0.030 respectively which are greater than 0.025. We will drop these doses in the second stage. On clicking **OK**, it updates the dashboard. The overall adjusted p-value is 0.067.

| Look # | Number of Arms | Adjusted p-value for Best Treatment | Prespecified Weights | Prespecified Efficacy Boundary (p-value) |
|--------|----------------|-------------------------------------|----------------------|--|
| 1 | 5 | 0.067 | 0.725 | NA |
| 2 | | | 0.688 | 0.025 |

Click the "Enter Interim Data" button to enter the Look # 2 data.

Open the test statistic calculator for the second look and enter the following information and also drop the two doses *1mg* and *2.5mg* using the dropdown of

18 Two-Stage Multi-arm Designs using p-value combination

“Action”. Click **Recalc** to calculate the test statistic as well as the raw p-values.

Test Statistic Calculator

Editing Look #2 (Incremental Data)

Terminate Trial for Futility

| Arm | Action | Sample Size | Mean | Std. Deviation | Test Statistic | Raw p-values |
|---------|----------|-------------|-------|----------------|----------------|--------------|
| Control | NA | 75 | 0.009 | 3.000 | NA | NA |
| 1mg | Drop | | | | | |
| 2.5mg | Drop | | | | | |
| 5mg | Continue | 75 | 1.23 | 3.000 | 2.492 | 0.007 |
| 10mg | Continue | 75 | 1.29 | 3.000 | 2.615 | 0.005 |

Recalc OK Cancel

On clicking **OK**, it updates the dashboard. Observe that the adjusted p-value for *10mg* crosses the efficacy boundary. It can also be observed in the **Stopping Boundaries** chart.

| Look # | Number of Arms | Adjusted p-value for Best Treatment | Prespecified Weights | Prespecified Efficacy Boundary (p-value) |
|--------|----------------|-------------------------------------|----------------------|--|
| 1 | 5 | 0.067 | 0.725 | NA |
| 2 | 3 | 0.004 | 0.688 | 0.025 |

Click the "Edit Interim Data" button to edit the Look # 2 data.

Stopping Boundaries

| Look # | Efficacy (p-value) |
|--------|--------------------|
| 1 | NA |
| 2 | 0.025 |

The final p-value adjusted for multiple treatments is 0.00353.

19 Normal Superiority Regression

Linear regression models are used to examine the relationship between a response variable and one or more explanatory variables assuming that the relationship is linear. In this chapter, we discuss the design of three types of linear regression models. In Section 19.1, we examine the problem of testing a single slope in a simple linear regression model involving one continuous covariate. In Section 19.2, we examine the problem of testing the equality of two slopes in a linear regression model with only one observation per subject. Finally, in Section 19.3, we examine the problem of testing the equality of two slopes in a linear regression repeated measures model, applied to a longitudinal setting.

19.1 Linear Regression, Single Slope

19.1.1 Trial Design

We assume that the observed value of a response variable Y is a linear function of an explanatory variable X plus random noise. For each of the $i = 1, \dots, n$ subjects in a study

$$Y_i = \gamma + \theta X_i + \epsilon_i$$

Here the ϵ_i are independent normal random variables with $E(\epsilon_i) = 0$ and $Var(\epsilon_i) = \sigma_\epsilon^2$. We follow Dupont et al. (1998) and emphasize a slight distinction between observational and experimental studies. In an observational study, the values X_i are attributes of randomly chosen subjects and their possible values are not known to the investigator at the time of a study design. In an experimental study, a subject is randomly assigned (with possibly different probabilities) to one of the predefined experimental conditions. Each of these conditions is characterized by a certain value of explanatory variable X that is completely defined at the time of the study design. In both cases the value X_i characterizing either an attribute or experimental exposure of subject i is a random variable with a variance σ_x^2 .

We are interested in testing that the slope θ is equal to a specified value θ_0 . Thus we test the null hypothesis $H_0: \theta = \theta_0$ against the two-sided alternative $H_1: \theta \neq \theta_0$ or a one-sided alternative hypothesis $H_1: \theta < \theta_0$ or $H_1: \theta > \theta_0$.

Let $\hat{\theta}$ denote the estimate of θ , and let $\hat{\sigma}_\epsilon^2$ and $\hat{\sigma}_x^2$ denote the estimates of σ_ϵ^2 and σ_x^2 based on n observations. The variance of $\hat{\theta}$ is

$$\sigma^2 = \frac{\sigma_\epsilon^2}{n\sigma_x^2}. \tag{19.1}$$

The test statistic is defined as

$$Z = (\hat{\theta} - \theta_0) / \hat{\sigma}, \tag{19.2}$$

where

$$\hat{\sigma}^2 = \frac{\hat{\sigma}_\epsilon^2}{n\hat{\sigma}_x^2}$$

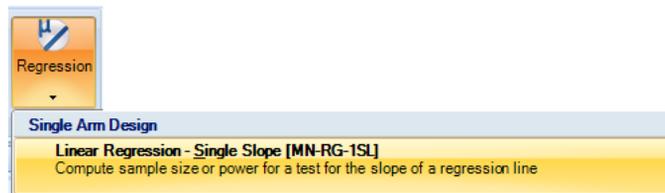

is the estimate of the variance of $\hat{\theta}$ based on n observations. Notice that the test statistic is centered so as to have a mean of zero under the null hypothesis.

We want to design the study so the power is attained when $\theta = \theta_1$. The power depends on θ_0 , θ_1 , σ_x , and σ_ϵ through $\theta_0 - \theta_1$ and σ_x/σ_ϵ .

19.1.1 Trial Design

During the development of medications, we often want to model the dose-response relationship, which may be done by estimating the slope of the regression, where Y is the appropriate response variable and the explanatory variable X is a set of specified doses. Consider a clinical trial involving four doses of a medication. The doses and randomization of subjects across the doses have been chosen so that the standard deviation $\sigma_x = 9$. Based on prior studies, it is assumed that $\sigma_\epsilon = 15$. If there is no dose response, the slope is equal to 0. Thus we will test the null hypothesis $H_0: \theta = 0$ against a two-sided alternative $H_1: \theta \neq 0$. The study is to be designed to have 90% power at the alternative $\theta_1 = 0.5$ with a type-1 error rate of 5%.

Start East afresh. Click **Continuous: Regression** on the **Design** tab and then click **Single-Arm Design: Linear Regression - Single Slope**.

This will launch a new input window. Select the **2-Sided** for **Test Type**. Enter 0.05 and 0.9 for **Type I Error (α)** and **Power**, respectively. Enter the values of $\theta_0 = 0$,

19 Normal Superiority Regression

$$\theta_1 = 0.5, \sigma_x = 9, \text{ and } \sigma_\epsilon = 15.$$

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (119 subjects) is highlighted in yellow.

| ID | Design Type | Test Type | Specified α | Power | Sample Size | Std. Dev. | Std. Dev. of Residual | Null Hypothesis Slope | Alternative Hypothesis Slope |

19.2 Linear Regression for Comparing Two Slopes

19.2.1 Trial Design

In some experimental situations, we are interested in comparing the slopes of two regression lines. The regression model relates the response variable Y to the explanatory variable X using the model $Y_{il} = \gamma + \theta_i X_{il} + \epsilon_{il}$, where the error ϵ_{il} has a normal distribution with mean zero and an unknown variance σ_ϵ^2 for Subject l in Treatment i , $i = c, t$ and $l = 1, \dots, n_i$. Let σ_{xc}^2 and σ_{xt}^2 denote the variance of the explanatory variable X for control (c) and treatment (t), respectively. We are interested in testing the equality of the slopes θ_c and θ_t . Thus we test the null hypothesis

19 Normal Superiority Regression

$H_0: \theta_c = \theta_t$ against the two-sided alternative $H_1: \theta_c \neq \theta_t$ or a one-sided alternative hypothesis $H_1: \theta_c < \theta_t$ or $H_1: \theta_c > \theta_t$.

Let $\hat{\theta}_c$ and $\hat{\theta}_t$ denote the estimates of θ_c and θ_t , and let $\hat{\sigma}_\epsilon^2$, $\hat{\sigma}_{xc}^2$, and $\hat{\sigma}_{xt}^2$, denote the estimates of σ_ϵ^2 , σ_{xc}^2 , and σ_{xt}^2 , based on n_c and n_t observations, respectively. The variance of $\hat{\theta}_i$ is

$$\sigma_i^2 = \frac{\sigma_\epsilon^2}{n_i \sigma_{xi}^2}.$$

Let $n = n_c + n_t$ and let $r = n_t/n$. Then, the test statistic is

$$Z_j = \frac{n^{1/2}(\hat{\theta}_t - \hat{\theta}_c)}{\hat{\sigma}_\epsilon \left(\frac{1}{(1-r)\hat{\sigma}_{xc}^2} + \frac{1}{r\hat{\sigma}_{xt}^2} \right)^{1/2}}. \quad (19.3)$$

19.2.1 Trial Design

We want to design the study so the power is attained for specified values of θ_c and θ_t . The power depends on $\theta_t, \theta_c, \sigma_{xc}, \sigma_{xt}$, and σ_ϵ through $\theta_t - \theta_c, \sigma_{xc}/\sigma_\epsilon$, and $\sigma_{xt}/\sigma_\epsilon$.

Suppose that a medication was found to have a response that depends on the level of a certain laboratory parameter. It was decided to develop a new formulation for which this interaction is decreased. The explanatory variable is the baseline value of the laboratory parameter. The study is designed with $\theta_t = 0.5, \theta_c = 1, \sigma_{xc} = \sigma_{xt} = 6$, and $\sigma_\epsilon = 10$. We examine the slopes of the two regressions by testing the null hypothesis $H_0: \theta_t = \theta_c$. Although we hope to decrease the slope, we test the null hypothesis against the two-sided alternative $H_1: \theta_t \neq \theta_c$.

Start East afresh. Click **Continuous: Regression** on the **Design** tab and then click **Parallel Design: Linear Regression - Difference of Slopes**.

This will launch a new input window. Select **2-Sided** for **Test Type**. Enter 0.05 and 0.9 for **Type I Error (α)** and **Power**, respectively. Select **Individual Slopes** for **Input Method**, and enter the values of $\theta_c = 1, \theta_t = 0.5, \sigma_{xc} = 6, \sigma_{xt} = 6$, and

$$\sigma_{\epsilon} = 10.$$

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The computed sample size (469) is highlighted in yellow.

| ID | Design Type | Test Type | Specified α | Power | Sample Size | Slope under Control | Slope under Treatment | nt/nc | Std. Dev. of Covariates under Control | Std. Dev. of Covariates under Treatment | Std. Dev. of Residual |

19.3 Repeated Measures for Comparing Two Slopes

In many clinical trials, each subject is randomized to one of two groups, and responses are collected at various timepoints on the same individual over the course of the trial. In these “longitudinal” trials, we are interested in testing the equality of slopes, or mean response changes per unit time, between the treatment group (t) and the control group (c). A major difficulty associated with designing such studies is the fact that the data are independent across individuals, but the repeated measurements on the same individual are correlated. The sample size computations then depend on within – and between – subject variance components that are often unknown at the design stage. One way to tackle this problem is to use prior estimates of these variance components (also known as nuisance parameters) from other studies, or from pilot data.

Suppose each patient is randomized to either group c or group t . The data consist of a series of repeated measurements on the response variable for each patient over time. Let M denote the total number of measurements, inclusive of the initial baseline measurement, intended to be taken on each subject. These M measurements will be taken at times $v_m, m = 1, 2, \dots, M$, relative to the time of randomization, where $v_1 = 0$. A linear mixed effects model is usually adopted for analyzing such data. Let Y_{ilm} denote the response of subject l , belonging to group i , at time point v_m . Then the model asserts that

$$Y_{clm} = \gamma_c + \theta_c v_m + a_l + b_l v_m + e_{ilm} \tag{19.4}$$

for the control group, and

$$Y_{tlm} = \gamma_t + \theta_t v_m + a_l + b_l v_m + e_{ilm} \tag{19.5}$$

for the treatment group, where the random effect $(a_l, b_l)'$ is multivariate normal with mean $(0, 0)'$ and variance-covariance matrix

$$G = \begin{bmatrix} \sigma_a^2 & \sigma_{ab} \\ \sigma_{ab} & \sigma_b^2 \end{bmatrix},$$

and the e_{lm} 's are all iid $N(0, \sigma_w^2)$. In this model, σ_w^2 denotes the “within – subject” variability, attributable to repeated measurements on the same subject, while G denotes the “between – subjects” variability, attributable to the heterogeneity of the population being studied.

Define

$$\delta = \theta_t - \theta_c$$

We are interested in testing

$$H_0: \delta = 0$$

against the two-sided alternative

$$H_1: \delta \neq 0$$

or against one-sided alternative hypotheses of the form

$$H_1: \delta > 0 \text{ or } H_1: \delta < 0$$

Let $(\hat{\theta}_C, \hat{\theta}_T)$ be the maximum likelihood estimates of (θ_C, θ_T) , based on an enrollment of (n_C, n_T) , respectively. The estimate of the difference of slopes is

$$\hat{\delta} = \hat{\theta}_T - \hat{\theta}_C \tag{19.6}$$

and its standard error is denoted by $se(\hat{\delta})$. The test statistic is the familiar Wald statistic

$$Z = \frac{\hat{\delta}}{se(\hat{\delta})} \tag{19.7}$$

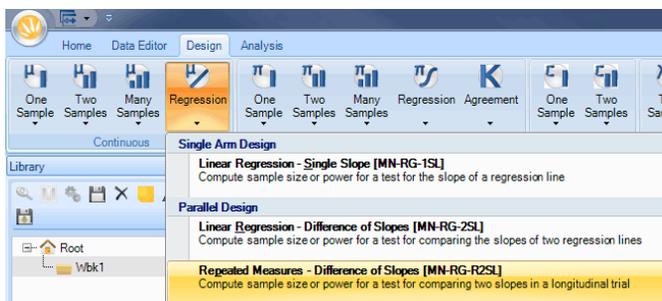

19.3.1 Trial Design

Consider a trial to compare an analgesic to placebo in the treatment of chronic pain using a 10 cm visual analogue scale (VAS). Measurements are taken on each subject at baseline and once a month for six months. Thus $M = 7$ and $S = 6$. It is assumed from past data that $\sigma_w = 4$ and $\sigma_b = 6$. We wish to test the null hypothesis $H_0: \theta_t = \theta_c$

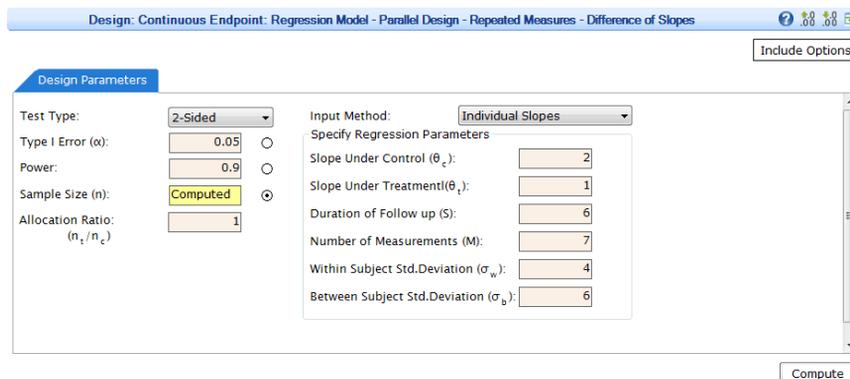

19 Normal Superiority Regression

with a two-sided level-0.05 test having 90% power to detect a 1 cm/month decline in slope, with $\theta_c = 2$ and $\theta_t = 1$ under H_1 .

Start East afresh. Click **Continuous: Regression** on the **Design** tab, and then click **Parallel Design: Repeated Measures - Difference of Slopes**.

This will launch a new input window. Select **2-Sided** for **Test Type**. Enter 0.05 and 0.9 for **Type I Error (α)** and **Power**, respectively. Select **Individual Slopes** for **Input Method**. Enter the values of $\theta_c = 2$, $\theta_t = 1$, **Duration of Follow up (S)** = 6, **Number of Measurements (M)** = 7, $\sigma_w = 4$, and $\sigma_b = 6$.

Click **Compute**. This will calculate the sample size for this design and the output is shown as a row in the **Output Preview** located in the lower pane of this window. The

computed sample size (1538) is highlighted in yellow.

| ▲ | ID | Test Type | Specified α | Power | Sample Size | Slope under Control | Slope under Treatment | nt/nc | Duration of Follow Up | Number of Measurements | Std. Dev. Within Subjects | Std. Dev. Between Subjects |
|---|------|-----------|--------------------|-------|-------------|---------------------|-----------------------|-------|-----------------------|------------------------|---------------------------|----------------------------|
| ☒ | Des1 | 2-Sided | 0.05 | 0.9 | 1538 | 2 | 1 | 1 | 6 | 7 | 4 | 6 |

Des 1 requires 1538 completers in order to attain 90% power. Select this design by clicking anywhere along the row in the **Output Preview** and click . Some of the design details will be displayed in the upper pane, labeled as **Output Summary**.

20 *Introduction to Volume 3*

This volume describes the procedures for discrete endpoints (binomial) applicable to one-sample, two-samples, many-samples, regression and agreement situations. All the three type of designs - superiority, non-inferiority and equivalence are discussed in detail.

Chapter 21 introduces you to East on the Architect platform, using an example clinical trial to test difference of proportions.

Chapter 22 deals with the design and interim monitoring of two types of tests involving binomial response rates that can be described as superiority one sample situation. Section 22.1 discusses designs in which an observed binomial response rate is compared to a fixed response rate, possibly derived from historical data. Section 22.2 deals with McNemar's test for comparing matched pairs of binomial responses. Chapter 38 discusses in detail the Simon's Two stage design.

Chapter 23 discusses the superiority two-sample situation where the aim is to compare independent samples from two populations in terms of the proportion of sampling units presenting a given trait. East supports the design and interim monitoring of clinical trials in which this comparison is based on the difference of proportions, the ratio of proportions, or the odds ratio of the two populations, common odds ratio of the two populations. The four cases are discussed in Sections 23.1, 23.2, 23.3 and 23.4, respectively. Section 23.5 discusses the Fisher's exact test for single look design.

Chapter 24 presents an account of designing and monitoring non-inferiority trials in which the non-inferiority margin is expressed as either a difference, a ratio, or an odds ratio of two binomial proportions. The difference is examined in Section 24.1. This is followed by two formulations for the ratio: the Wald formulation in Section 24.2 and the Farrington-Manning formulation in Section 24.3. The odds ratio formulation is presented in Section 24.4.

Chapter 25 narrates the details of the design and interim monitoring in equivalence two-sample situation where the goal is neither establishing superiority nor non-inferiority, but equivalence. Examples of this include showing that an aggressive therapy yields a similar rate of a specified adverse event to the established control, such as the bleeding rates associated with thrombolytic therapy or cardiac outcomes with a new stent.

Chapter 26 details the design and interim monitoring superiority k-sample experimental situations where there are several binomial distributions indexed by an

ordinal variable and where it is required to examine changes in the probabilities of success as the levels of the indexing variable changes. Examples of this include the examination of a dose-related presence of a response or a particular side effect, dose-related tumorigenicity, or presence of fetal malformations relative to levels of maternal exposure to a particular toxin, such as alcohol, tobacco, or environmental factors.

Chapter 27 details the Multiple Comparison Procedures (MCP) for discrete data. It is often the case that multiple objectives are to be addressed in one single trial. These objectives are formulated into a family of hypotheses. Multiple comparison (MC) procedures provide a guard against inflation of type I error while testing these multiple hypotheses. East supports several parametric and p-value based MC procedures. This chapter explains how to design a study using a chosen MC procedure that strongly maintains FWER.

Chapter 30 describes how East may be used to design and monitor two-arm randomized clinical trials with a binomial endpoints, while adjusting for the effects of covariates through the logistic regression model. These methods are limited to binary and categorical covariates only. A more general approach, not limited to categorical covariates, is to base the design on statistical information rather than sample size. This approach is further explained in Chapter 59

Chapter 31 discusses the tests available to check the inter-rater reliability. In some experimental situations, to check inter-rater reliability, independent sets of measurements are taken by more than one rater and the responses are checked for agreement. For a binary response, Cohen's Kappa test for binary ratings can be used to check inter-rater reliability.

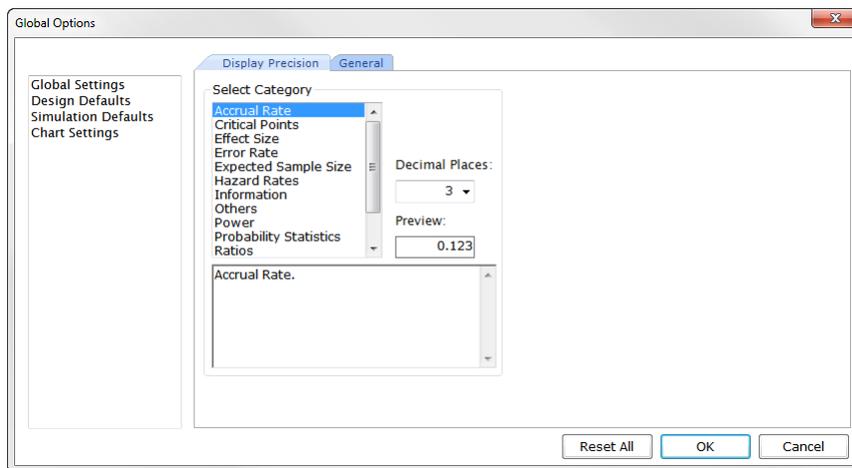

Chapter 32 deals with the design, simulation, and interim monitoring of Phase 1 dose escalation trials. One of the primary goals of Phase I trials in oncology is to find the maximum tolerated dose (MTD). Sections 32.1, 32.2, 32.3 and 32.4 discusses the four commonly used dose escalation methods - 3+3, Continual Reassessment Method (CRM), modified Toxicity Probability Interval (mTPI) and Bayesian Logistic Regression Model (BLRM).

20 Introduction to Volume 3

20.1 Settings

Click the **Global Options** icon in the **Home** menu to adjust default values in East 6.

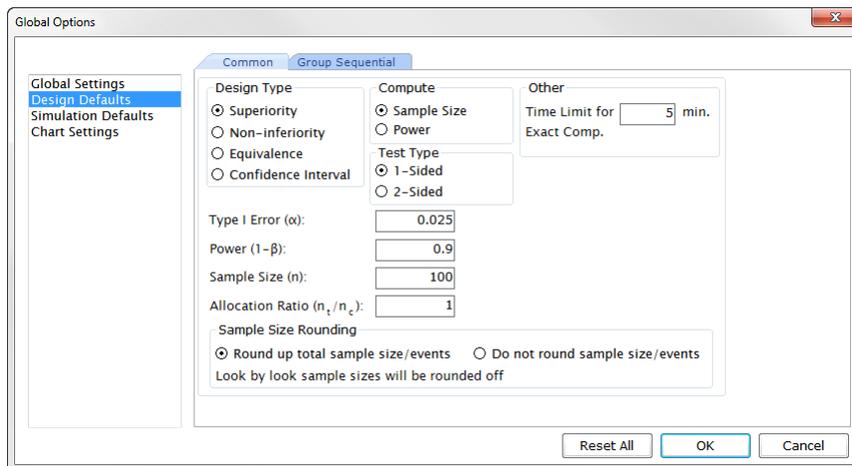

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

The **Design Defaults** is where the user can change the settings for trial design:

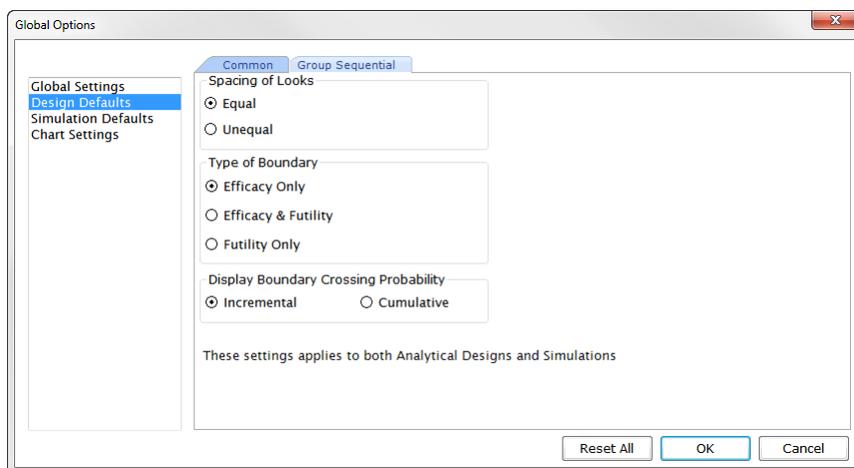

Under the **Common** tab, default values can be set for input design parameters.

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

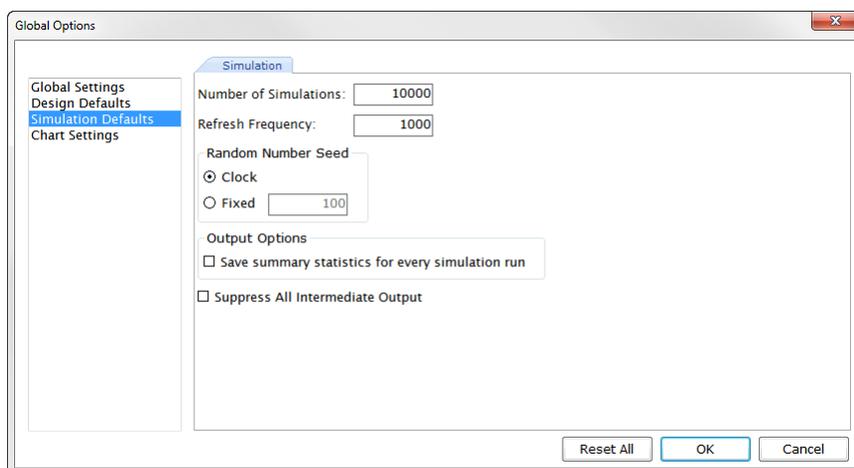

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

20 Introduction to Volume 3

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

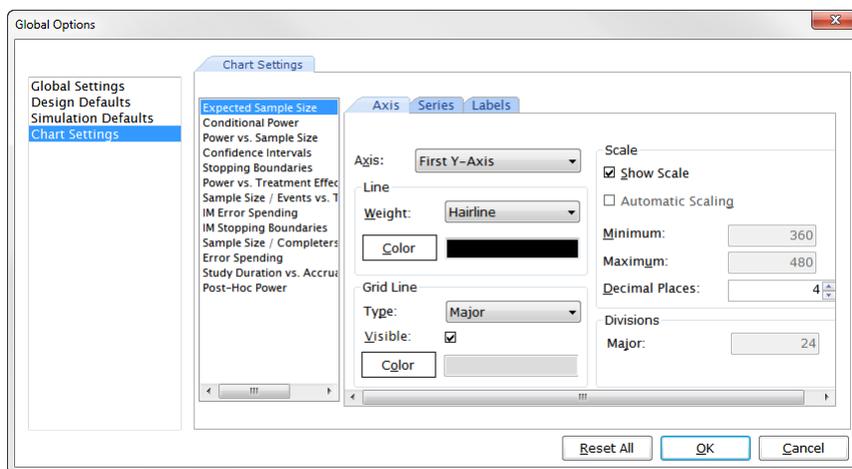

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

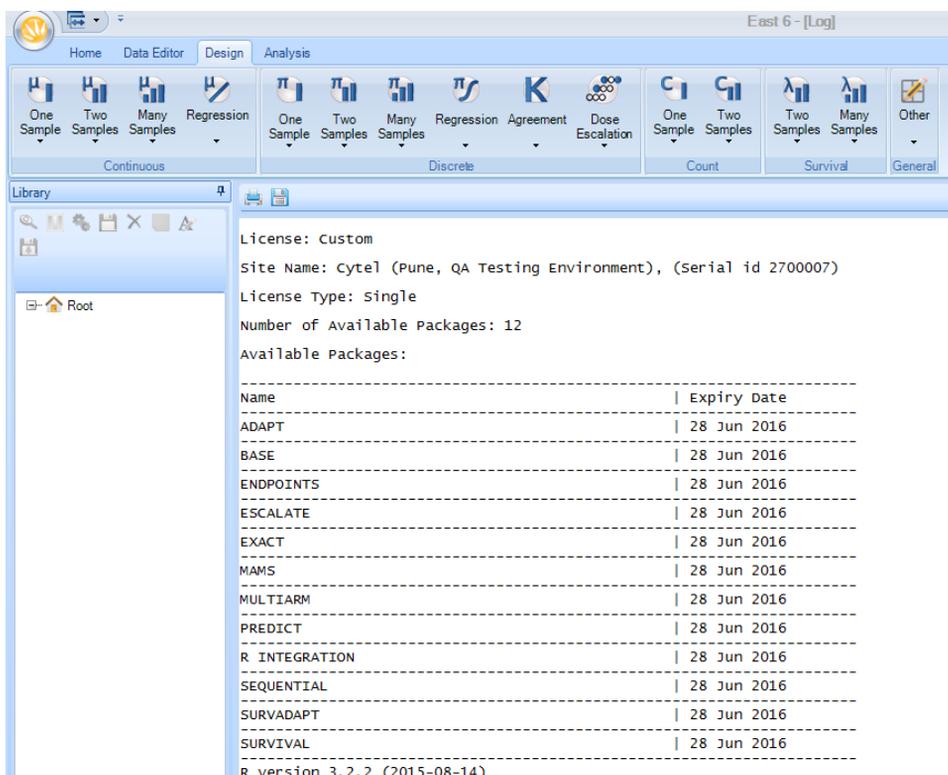

We suggest that you do not alter the defaults until you are quite familiar with the software.

21 *Tutorial: Binomial Endpoint*

This tutorial introduces you to East on the Architect platform, using an example clinical trial to test difference of proportions.

21.1 *Fixed Sample Design*

When you open East, you will see the following screen below.

By default, the Design tab in the ribbon will be active. The items on this tab are grouped under the following categories of endpoints: Continuous, Discrete, Count, Survival, and General. Click **Discrete: Two Samples**, and then **Parallel Design: Difference of Proportions**.

The following input window will appear.

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Design Type: Superiority Number of Looks: 1

Test Parameters

Test Type: 1-Sided

Type I Error (α): 0.025

Power: 0.9

Sample Size (n): Computed

Allocation Ratio: 1
(n_t/n_c)

Specify Proportion Response
 Prop. under Control (π_c): 0.1

Specify Alternative Hypothesis
 Prop. under Treatment (π_t): 0.5
 Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): 0.4

Perform Exact Computations

Specify Variance
 Pooled Estimate
 Unpooled Estimate

Use Casagrande-Pike-Smith
 Correction (Ignored if alloc. ratio is not 1)

Assurance (Probability of Success):

By default, the radio button for **Sample Size (n)** is selected, indicating that it is the variable to be computed. The default values shown for **Type I Error** and **Power** are 0.025 and 0.9. Keep the same for this design. Since the default inputs provide all of the necessary input information, you are ready to compute sample size by clicking the **Compute** button. The calculated result will appear in the **Output Preview** pane, as shown below.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | π_c | Prop. Treatment (Alt.) | δ_1 | Variance |
|------|-------------|--------------|-----------|--------------------|-------|-------|-------------|---------|------------------------|------------|-------------------|
| Des1 | Superiority | 1 | 1-Sided | 0.025 | 0.902 | 1 | 45 | 0.1 | 0.5 | 0.4 | Unpooled Estimate |

This single row of output contains relevant details of inputs and the computed result of total sample size (and total completers) of 45. Select this row and save it in the **Library** under a workbook by clicking icon. Select this node in the Library, and click icon to display a summary of the design details in the upper pane

21 Tutorial: Binomial Endpoint

(known as **Output Summary**).

| Wbk1:Des1 | |
|--|-------------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |

| Proportion under Treatment (π_t) | 0.5 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0.4 |
| Variance | Unpooled Estimate |
| Sample Size | |
| Maximum | 45 |

The discussion so far gives you a quick feel of the software for computing sample size for a single look design. We will describe further features in an example for a group sequential design in the next section.

21.2 Group Sequential Design for a Binomial Superiority Trial

21.2.1 Study Background

Design objectives and interim results from CAPTURE, a prospective randomized trial of placebo versus Abciximab for patients with refractory unstable angina were presented at a workshop on clinical trial data monitoring committees (Anderson, 2002). The primary endpoint was reduction in death or MI within 30 days of entering the study. The study was designed for 80% power to detect a reduction in the event rate from 15% on the placebo arm to 10% on the Abciximab arm. A two-sided test with a type-1 error of 5% was used. We will illustrate various design, simulation and interim monitoring features of East for studies with binomial endpoints with the help of this example.

Let us modify Des1 to enter above inputs and create a group sequential design for CAPTURE trial. Select the node for Des1 in the **Library** and click the  icon. This will take you back to the input window of Des1. Alternatively, you can also click

the  button on the left hand bottom of East screen to go to the latest

input window.

Select **2-Sided** for **Test Type**, enter **0.05** for **Type I Error**, **0.8** for **Power**, specify the **Prop. under Control** be **0.15**, the **Prop. under Treatment** to be **0.1**. Next, change the **Number of Looks** to be **3**. You will see a new tab, **Boundary Info**, added to the input dialog box.

Design Type: Superiority Number of Looks: 3

Test Parameters

Test Type: 1-Sided

Type I Error (α): 0.05

Power: 0.8

Sample Size (n): Computed

Allocation Ratio: 1 (n_1/n_2)

Specify Proportion Response

Prop. under Control (π_c): 0.15

Specify Alternative Hypothesis

Prop. under Treatment (π_t): 0.1

Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): -0.05

Specify Variance

Pooled Estimate

Unpooled Estimate

Use Casagrande-Pike-Smith Correction (ignored if alloc. ratio is not 1)

Assurance (Probability of Success):

Click the **Boundary Info** tab, and you will see the following screen. On this tab, you can choose whether to specify stopping boundaries for efficacy, or futility, or both. For this trial, choose efficacy boundaries only, and leave all other default values. We will implement the Lan-Demets (O'Brien-Fleming) spending function, with equally spaced looks.

Design Type: Superiority Number of Looks: 3

Boundary

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks Equal Unequal

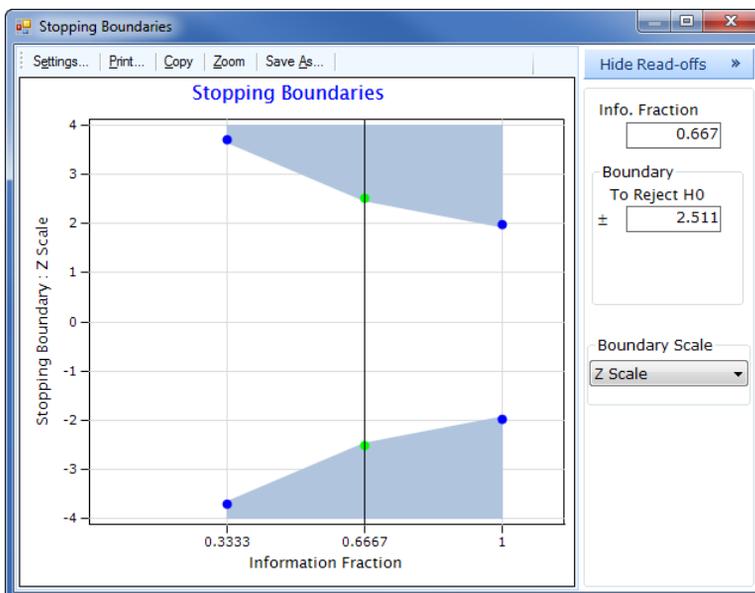

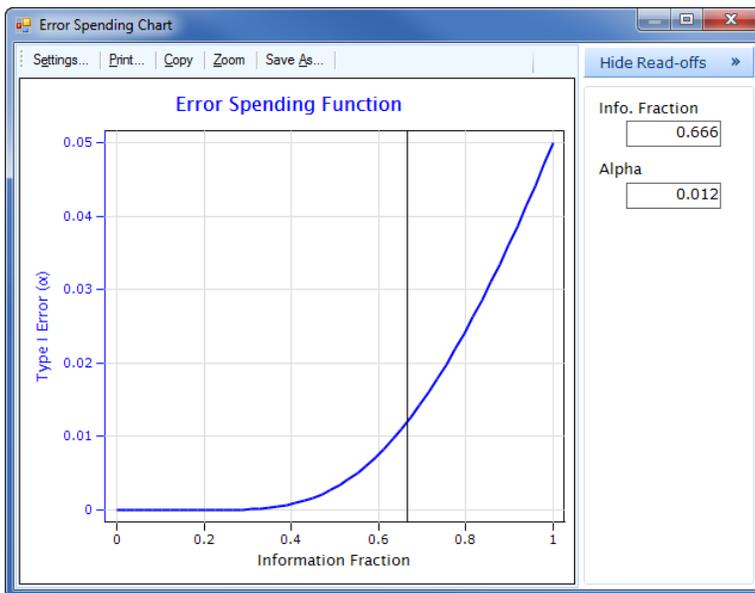

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|---------------------|-------------------|
| 1 | 0.333 | 0.001 | -3.200 |
| 2 | 0.667 | 0.016 | -2.141 |
| 3 | 1.000 | 0.050 | -1.695 |

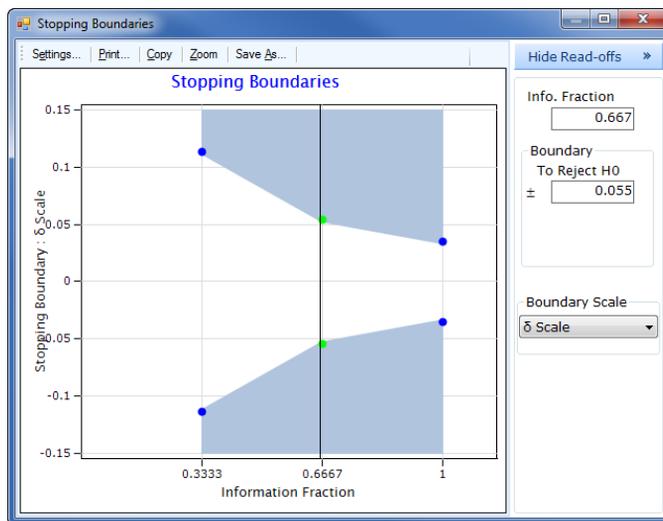

On the **Boundary Info** tab, click on the icons  or , to generate the

21 Tutorial: Binomial Endpoint

following charts.

You can also view these boundaries on different scales like δ scale or p-value scale. Select the desired scale from the dropdown. Let us see the boundaries on δ scale.

Click **Compute**. This will add another row for Des2 in the **Output Preview** area.

The maximum sample size required under this design is 1384. The expected sample sizes under H0 and H1 are 1378 and 1183, respectively. Click  in the **Output Preview** toolbar to save this design to Wbk1 in the **Library**. Double-click on Des2 to generate the following output.

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

21 Tutorial: Binomial Endpoint

21.2.2 Creating multiple designs easily

In East, it is easy to create multiple designs by inputting multiple parameter values. In the trial described above, suppose we want to generate designs for all combinations of the following parameter values: **Power** = 0.8, 0.9, and **Difference in Proportions** = -0.04, -0.03, -0.02, -0.01. The number of such combinations is $2 \times 4 = 8$.

East can create all 8 designs by a single specification in the input dialog box. Select Des2 and click  icon. Enter the above values in the **Test Parameters** tab as shown below. The values of **Power** have been entered as a list of comma-separated values, while **Difference in Proportions** has been entered as a colon-separated range of values: -0.04 to -0.01 in steps of 0.01.

Test Type: 2-Sided

Type I Error (α): 0.05

Power: 0.8, 0.9

Sample Size (n): Computed

Allocation Ratio: 1
(n_1 / n_2)

Specify Proportion Response

Prop. under Control (π_c): 0.15

Specify Alternative Hypothesis

Prop. under Treatment (π_t): Computed

Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): -0.04:-0.01

Specify Variance

Pooled Estimate

Unpooled Estimate

Use Casagrande-Pike-Smith Correction (Ignored if alloc. ratio is not 1)

Now click compute. East computes all 8 designs Des3-Des10, and displays them in the **Output Preview** as shown below. Click  to maximize the **Output Preview**.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt / nc | Sample Size | π_c | Prop. Treatment (Alt.) | δ_1 | Variance | Spacing of Looks | Efficacy Boundary | Expected SS (H0) | Expected SS (H1) |

 Total Number of Simulations: 10000
 Elapsed Time: 00:00:10

In 80.46% of the simulated trials, the null hypothesis was rejected. This tells us that the design power of 80% is achieved. **Simulations** is a tool which can be used to assess the study design under various scenarios. The next section will explore interim monitoring with this design.

21.2.4 Interim Monitoring

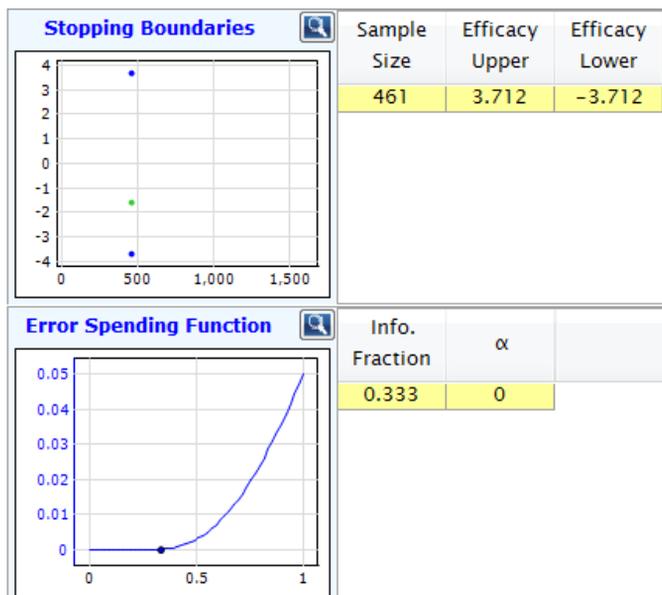

Right-click Des2 in the **Library** and select **Interim Monitoring**. Click the **Enter Interim Data** to open the **Test Statistic Calculator**. Suppose that after 461 subjects, at the first look, you have observed 34 out of 230 responding on Control arm and 23 out of 231 responding on Treatment arm. The calculator computes the difference in proportions as -0.048 and its standard error of 0.031 .

Click **OK** to update the IM Dashboard.

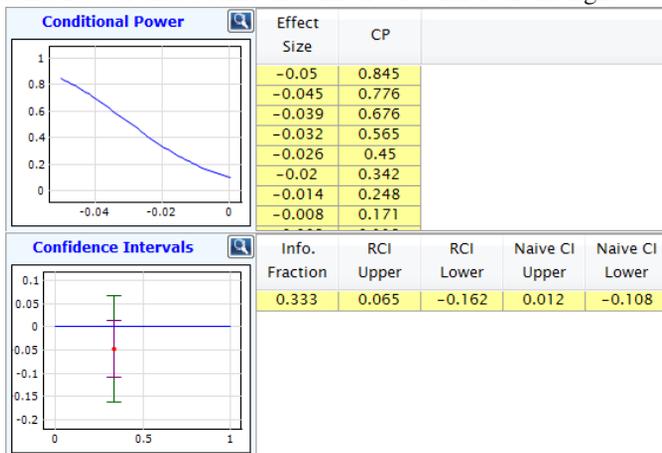

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | | 95% RCI for δ | | Repeat ... p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|--------|----------------------|-------|--------------------|-------|------------------|
| | | | | | | Upper | Lower | Lower | Upper | | | |
| 1 | 0.333 | 461 | -1.578 | -0.048 | 0.031 | 3.712 | -3.712 | -0.162 | 0.065 | 0.545 | 0.823 | 0.705 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

The **Stopping Boundaries** and **Error Spending Function** charts on the left:

21 Tutorial: Binomial Endpoint

The **Conditional Power** and **Confidence Intervals** charts on the right:

Suppose that after 923 subjects, at the second look, you have observed 69 out of 461 responding on Control arm and 23 out of 462 responding on Treatment arm. The

calculator computes the difference in proportions as -0.1 and its standard error of 0.019 .

| | Control | Treatment |
|-------------------------|---------|-----------|
| Cumulative Sample Size: | 461 | 462 |
| Cumulative Response: | 69 | 23 |

Cumulative Sample Size: 923

Estimate of δ : -0.1

$\delta = (\pi_t - \pi_c)$

Standard Error of Estimate of δ : 0.019

Test Statistic: -5.135

Click **Recalc**, and then **OK** to update the IM Dashboard. In this case, a boundary has been crossed, and the following window appears.

Since the value of Test Statistic is \leq the critical point for efficacy, H_0 is rejected.

Although boundary has been crossed, East gives you choice either to stop the study or to continue entering further looks. Please make your decision.

Stop stop the study and bar further looks input

Continue allow the study to continue

Click **Stop** to complete the trial. The IM Dashboard will be updated accordingly, and a

21 Tutorial: Binomial Endpoint

table for **Final Inference** will be displayed as shown below.

| Final Inference | |
|--|--------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0 |
| Adj. Pt. Est. for δ | -0.094 |
| Adj. 95% CI for δ | |
| Upper Confidence Bound | -0.047 |
| Lower Confidence Bound | -0.135 |
| Post-Hoc Power | |

22 Binomial Superiority One-Sample

This chapter deals with the design, simulation, and interim monitoring of two types of tests involving binomial response rates. In Section 22.1, we discuss group sequential designs in which an observed binomial response rate is compared to a fixed response rate, possibly derived from historical data. Section 22.2 deals with McNemar’s test for comparing matched pairs of binomial responses in a group sequential setting.

22.1 Binomial One Sample

22.1.1 Trial Design

22.1.2 Trial Simulation

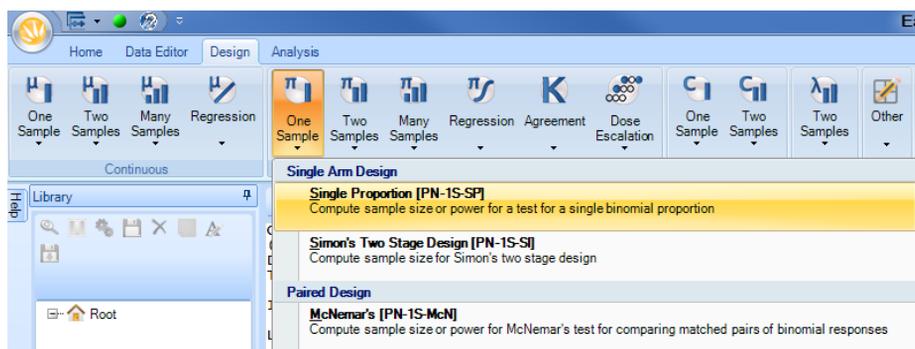

22.1.3 Interim Monitoring

In experimental situations, where the variable of interest has a binomial distribution, it may be of interest to determine whether the response rate π differs from a fixed value π_0 . Specifically we wish to test the null hypothesis $H_0: \pi = \pi_0$ against the two sided alternative hypothesis $H_1: \pi \neq \pi_0$ or against one sided alternatives of the form $H_1: \pi > \pi_0$ or $H_1: \pi < \pi_0$. The sample size, or power, is determined for a specified value of π which is consistent with the alternative hypothesis, denoted π_1 .

22.1.1 Trial Design

Consider the design of a single-arm oncology trial in which we wish to determine if the tumor response rate of a new cytotoxic agent is at least 15%. Thus, it is desired to test the null hypothesis $H_0: \pi = 0.15$ against the one-sided alternative hypothesis $H_1: \pi > 0.15$. We will design this trial with a one sided test that achieves 80% power at $\pi = \pi_1 = 0.25$ with a one-sided level 0.05 test.

Single-Look Design To begin, click **Design** tab, then **Single Sample** under **Discrete** group, and then click **Single Proportion**.

In the ensuing dialog box, choose the test parameters as shown below. We first consider a single-look design, so leave the default value for **Number of Looks** to 1. In the drop down menu, next to **Test Type** select 1-Sided. Enter 0.8 for **Power**. Enter

22 Binomial Superiority One-Sample

0.15 in the box next to **Prop. Response under Null** (π_0) and 0.25 in the box next to **Prop. Response under Alt** (π_1). This dialog box also asks us to specify whether we wish to standardize the test statistic (for performing the hypothesis test of the null hypothesis $H_0: \pi = 0.15$) with the null or the empirical variance. We will discuss the test statistic and the method of standardization in the next subsection. For the present, select the default radio button **Under Null Hypothesis**.

Now click **Compute**. The design is shown as a row in the **Output Preview** located in the lower pane of this window. The sample size required in order to achieve the desired 80% power is 91 subjects.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | Sample Size | π_0 | π_1 | Variance |
|------|-------------|--------------|-----------|--------------------|-------|-------------|---------|---------|-----------------------|
| Des1 | Superiority | 1 | 1-Sided | 0.05 | 0.801 | 91 | 0.15 | 0.25 | Under Null Hypothesis |

You can select this design by clicking anywhere on the row in the **Output Preview**. Click  icon to get the design output summary displayed in the upper pane. In the **Output Preview** toolbar, click  icon to save this design Des1 to workbook Wbk1 in the **Library**. If you hover the cursor over the node Des1 in the Library, a

tooltip will appear that summarizes the input parameters of the design.

The screenshot shows the 'Library' window with a tree view containing 'Root', 'Wbk1', and 'Des1'. A tooltip is displayed over 'Des1' with the following text:

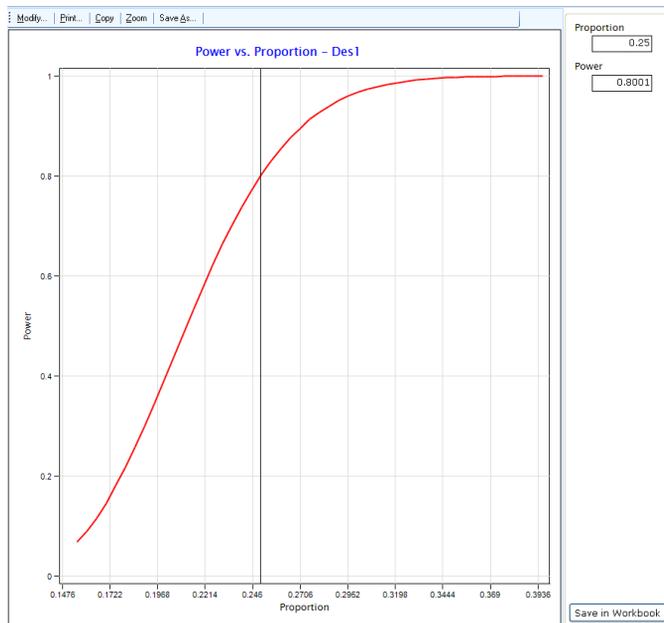

```

Design Type = Superiority
No. of Looks = 1
Test Type = 1-Sided
Specified  $\alpha$  = 0.05
Power = 0.801
Sample Size = 91
Prop. Response under Null ( $\pi_0$ ) = 0.15
Prop. Response under Alt. ( $\pi_1$ ) = 0.25
Variance of Standardized Test Statistic = Under Null Hypothesis
    
```

To the right, a table titled 'Wbk1:Des1' lists parameters:

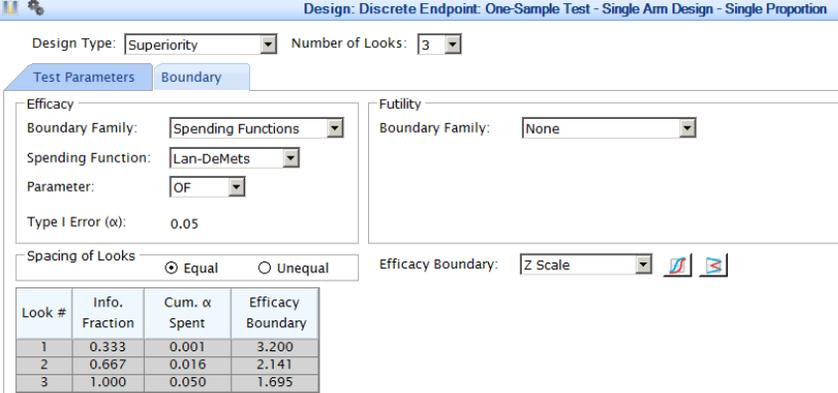

| Wbk1:Des1 | |
|---|-----------------------|
| Mnemonic | PN-1S-SP |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |
| Specified α | 0.05 |
| Power | 0.801 |
| Model Parameters | |
| Prop. Response under Null (π_0) | 0.15 |
| Prop. Response under Alt. (π_1) | 0.25 |
| Variance of Standardized Test Statistic | Under Null Hypothesis |
| Sample Size | |
| Maximum | 91 |

With the design Des1 selected in the Library, click icon on the Library toolbar, and then click **Power vs. Treatment Effect (δ)**. The power curve for this design will be displayed. You can save this chart to the Library by clicking **Save in Workbook**. Alternatively, you can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...**. For now, you may close the chart before continuing.

22 Binomial Superiority One-Sample

Three-Look Design In order to reach an early decision and enter into comparative trials, let us plan to conduct this single-arm study as a group sequential trial with a maximum of 3 looks. Create a new design by selecting Des1 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab **Boundary** will appear. Clicking on this tab will reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side for the **Futility** boundary. By default, there is an efficacy boundary (to reject H0) selected, but no futility boundary (to reject H1). The **Boundary Family** specified is of the **Spending Functions** type. The default **Spending function** is the **Lan-DeMets** (Lan & DeMets, 1983), with **Parameter** OF (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O'Brien and Fleming (1979). Technical details of these stopping boundaries are available in Appendix F.

Design: Discrete Endpoint: One-Sample Test - Single Arm Design - Single Proportion

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks

Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary |
|--------|----------------|--------------|-------------------|
| 1 | 0.333 | 0.001 | 3.200 |
| 2 | 0.667 | 0.016 | 2.141 |
| 3 | 1.000 | 0.050 | 1.695 |

Return to the test parameters by clicking **Test Parameters** tab. The dialog box requires us to make a selection in the section labeled **Variance of Standardized Test Statistic**. We are being asked to specify to East how we intend to standardize the test statistic when we actually perform the hypothesis tests at the various monitoring time points. There are two options: **Under Null Hypothesis** and **Empirical Estimate**. To understand the difference between these two options, let $\hat{\pi}_j$ denote the estimate of π based on n_j observations, up to and including the j th monitoring time point.

Under Null Hypothesis The test statistic to be used for the interim monitoring is

$$Z_j^{(N)} = \frac{\hat{\pi}_j - \pi_0}{\sqrt{\pi_0(1 - \pi_0)/n_j}} \quad (22.1)$$

Empirical The test statistic to be used for the interim monitoring is

$$Z_j^{(E)} = \frac{\hat{\pi}_j - \pi_0}{\sqrt{\hat{\pi}_j(1 - \hat{\pi}_j)/n_j}} \quad (22.2)$$

The choice of variance should not make much of a difference to the type 1 error or power for studies in which the sample size is large. In the present case however, it might matter. We shall therefore examine both the options. First, we select the **Under Null Hypothesis** radio button.

Click **Compute** button to generate output for Design Des2. With Des2 selected in the **Output Preview**, click  icon to save Des2 to the **Library**. In order to see the stopping probabilities, as well as other characteristics, select Des2 in the **Library**, and click  icon. The cumulative boundary stopping probabilities are shown in the **Stopping Boundaries** table. We see that for Des2 the maximum sample size is 91 subjects, with 90 expected under the null hypothesis $H_0: \pi = 0.15$ and 73 expected when the true value is $\pi=0.25$.

Design: Discrete Endpoint: One-Sample Test - Single Arm Design - Single Proportion

Next, click **Compute**. With Des3 selected in the **Output Preview**, click  icon. In the **Library**, select the nodes Des2 and Des3, by holding the Ctrl key, and then click  icon. The upper pane will display the summary details of the two designs side-by-side:

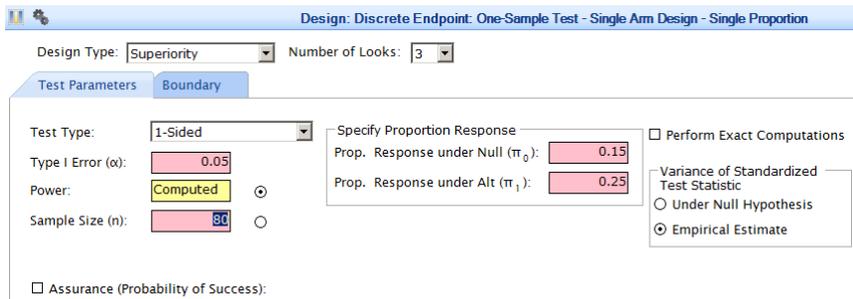

| | Wbk1:Des2 | Wbk1:Des3 |
|---|-----------------------|--------------------|
| Mnemonic | PN-1S-SP | PN-1S-SP |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 3 | 3 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.801 | 0.802 |
| Model Parameters | | |
| Prop. Response under Null (π_0) | 0.15 | 0.15 |
| Prop. Response under Alt. (π_1) | 0.25 | 0.25 |
| Variance of Standardized Test Statistic | Under Null Hypothesis | Empirical Estimate |
| Boundary Parameters | | |
| Spacing of Looks | Equal | Equal |
| Efficacy Boundary | LD (OF) | LD (OF) |
| Sample Size | | |
| Maximum | 91 | 119 |
| Expected Under H0 | 90.48 | 118.326 |
| Expected Under H1 | 72.823 | 98.803 |

The maximum sample size needed for 80% power is 119, and the expected sample size is 99 under the alternative hypothesis H_1 with $\pi_1 = 0.25$, if we intend to standardize the test statistic with the empirical variance. The corresponding maximum and

22 Binomial Superiority One-Sample

expected sample sizes if the null variance is to be used for the standardization are 91 and 73, respectively. Thus, for this configuration of design parameters, it would appear preferable to specify in advance that the test statistic will be standardized by the null variance. Evidently, this is the option with the smaller maximum and expected sample size. These results, however, are based on the large sample theory developed in Appendix B. Since the sample sizes in both Des2 and Des3 are fairly small, it would be advisable to verify that the power and type 1 error of both the plans are preserved by simulating these designs. We show how to simulate these plans in Section 22.1.2.

In some situations, the sample size is subject to external constraints. Then, the power can be computed for a specified maximum sample size. Suppose that in the above situation, using the observed estimates for the computation of the variance, the total sample size is constrained to be at most, 80 subjects. Select Des3 in the **Library** and click  on the **Library** toolbar. Change the selections in the ensuing dialog box so that the trial is now designed to compute power for a maximum sample size of 80 subjects, as shown below.

Design: Discrete Endpoint: One-Sample Test - Single Arm Design - Single Proportion

Assurance (Probability of Success):

Click **Compute** button to generate the output for Design Des4. With Des4 selected in the **Output Preview**, click  icon. In the **Library**, select the nodes for Des2, Des3, and Des4 by holding the Ctrl key, and then click  icon. The upper pane

will display the summary details of the three designs side-by-side:

| | Wbk1-Des2 | Wbk1-Des3 | Wbk1-Des4 |
|---|-----------------------|--------------------|--------------------|
| Mnemonic | PN-1S-SP | PN-1S-SP | PN-1S-SP |
| Test Parameters | | | |
| Design Type | Superiority | Superiority | Superiority |
| No. of Looks | 3 | 3 | 3 |
| Test Type | 1-Sided | 1-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 | 0.05 |
| Power | 0.801 | 0.802 | 0.655 |
| Model Parameters | | | |
| Prop. Response under Null (π_0) | 0.15 | 0.15 | 0.15 |
| Prop. Response under Alt. (π_1) | 0.25 | 0.25 | 0.25 |
| Variance of Standardized Test Statistic | Under Null Hypothesis | Empirical Estimate | Empirical Estimate |
| Boundary Parameters | | | |
| Spacing of Looks | Equal | Equal | Equal |
| Efficacy Boundary | LD (OF) | LD (OF) | LD (OF) |
| Sample Size | | | |
| Maximum | 91 | 119 | 80 |
| Expected Under H0 | 90.48 | 118.326 | 79.548 |
| Expected Under H1 | 72.823 | 98.803 | 70.711 |

From this, we can see that Des4 has only 65.5 % power.

22.1.2 Trial Simulation

In Section 22.1.1, we created group sequential designs with two different assumptions for the manner in which the test would be standardized at the interim monitoring stage. Under Des2, we assumed that the null variance, and hence the test statistic (22.1) would be used for the interim monitoring. This plan required a maximum sample size of 91 subjects. Under Des3, we assumed that the empirical variance, and hence the test statistic (22.2) would be used for the interim monitoring. This plan required a maximum sample size of 119 subjects. Since the sample sizes for both plans are fairly small and the calculations involved the use of large sample theory, it would be wise to verify the operating characteristics of these two plans by simulation.

Select Des2 in the **Library**, and click the  icon from **Library** toolbar. Alternatively, right-click on Des2 node and select **Simulate**. A new Simulation

22 Binomial Superiority One-Sample

worksheet will appear.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z |
|--------|----------------|---------------------|------------|
| 1 | 0.330 | 0.001 | 3.220 |
| 2 | 0.670 | 0.017 | 2.133 |
| 3 | 1.000 | 0.050 | 1.696 |

Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled Sim1. Select Sim1 row in the **Output Preview** and click icon. Note that some of the simulation output details will be displayed in the upper pane. Click icon to save it to the **Library**. Double-click on Sim1 node in the **Library**. The simulation output details will be displayed.

However, when we run the simulations under $H_0: \pi = 0.15$, we obtain a type 1 error of about 3% instead of the specified 5% as shown below. While this ensures that the type 1 error is preserved, it also suggests that the use of the empirical variance rather than the null variance to standardize the test statistic might be problematic with small sample sizes.

Assurance (Probability of Success):

Click **Compute** to generate the output for Des5. In the **Output Preview**, we see that Des5 requires a sample size of 1035 subjects. To verify whether the use of the empirical variance will indeed produce the correct type-1 error for this large trial, select Des5 in the **Output Preview** and click  icon. In the **Library**, select Des5 and click  icon from **Library** toolbar . First, run 10,000 trials with $\pi = 0.15$. On the **Response Generation** tab, change **Proportion Response** from 0.18 to 0.15. Next click **Simulate**. Observe that the type-1 error obtained by simulating Des5 is about 4.4%, an improvement over the corresponding type 1 error obtained by simulating Des3.

This example has demonstrated the importance of simulating a design to verify that it does indeed possess the operating characteristics that are claimed for it. Since these operating characteristics were derived by large-sample theory, they might not hold for small sample sizes, in which case, the sample size or type-1 error might have to be adjusted appropriately.

22.1.3 Interim Monitoring

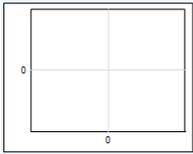

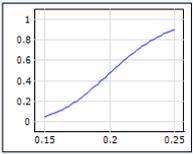

Consider interim monitoring of Des3, the design that has 80% power when the empirical estimate of variance is used to standardize the test statistic. Select Des3 in the **Library**, and click **IM** icon from the Library toolbar. Alternatively, right-click on Des3 and select **Interim Monitoring**. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the

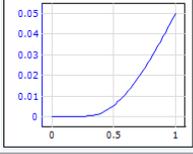

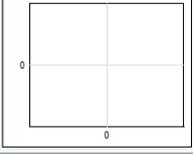

clinical trial and are useful tools for decision making by a data monitoring committee.

Simulation Details | IM Interim Monitoring

At the first interim look, when 40 subjects have enrolled, suppose that the observed response rate is 0.35. Click **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. In the box next to **Cumulative Sample Size** enter 40. Enter 0.35 in the box next to **Estimate of π** . In the box next to **Standard Error of Estimate of π** enter

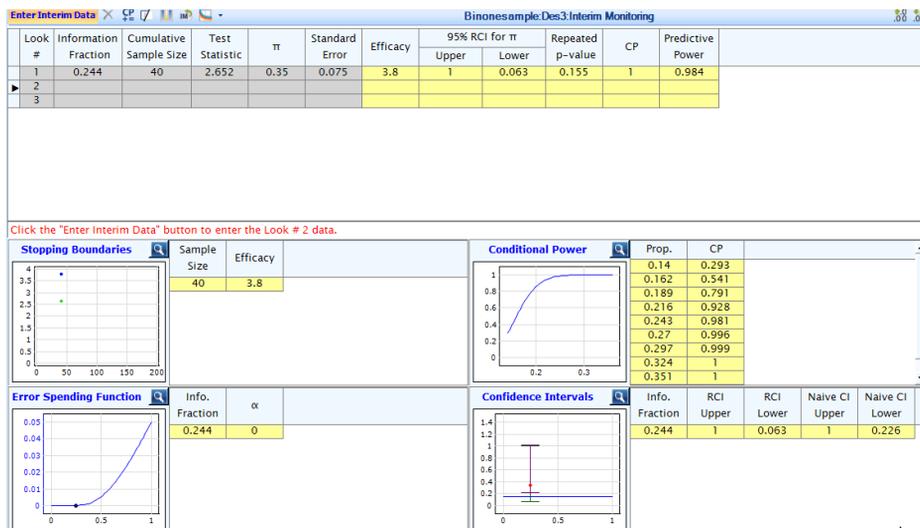

22 Binomial Superiority One-Sample

0.07542. Next click **Recalc**.

The screenshot shows a dialog box titled "Test Statistic Calculator". At the top right, there are two small icons with ".00" below them. The main area is titled "Editing Look #1" and contains a checkbox "Set Current Look as Last" which is unchecked. Below this are three input fields: "Cumulative Sample Size" with the value 40, "Estimate of π " with the value 0.35, and "Standard Error of Estimate of π " with the value 0.07542. These three fields are grouped under the heading "Input for Binomial end point". Below this is an "Output" section with two fields: "Estimate of $\pi - \pi_0$ " with the value 0.2, and "Test Statistic" with the value 2.652. At the bottom of the dialog are three buttons: "Recalc", "OK", and "Cancel".

Observe that upon pressing the **Recalc** button, the test statistic calculator automatically computes the value of the test statistic as 2.652.

Clicking **OK** results in the following output.

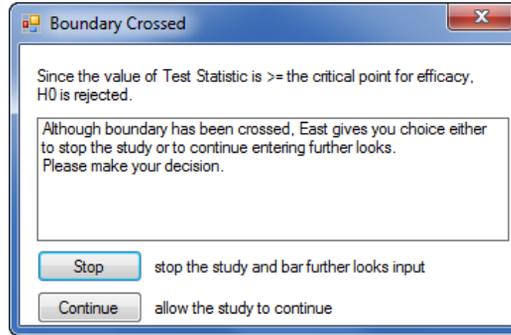

Since our test statistic, 2.652, is smaller than the stopping boundary, 3.185, the trial continues.

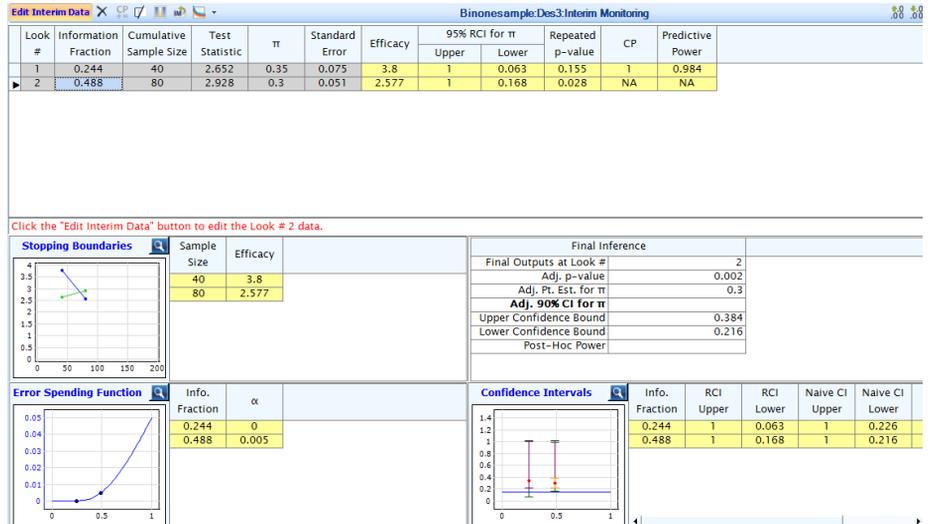

At the second interim monitoring time point, after 80 subjects have enrolled, suppose that the estimate of $\hat{\pi}$ based on all data up to that point is 0.30. Click on the second row in the table in the upper section. Then click **Enter Interim Data** icon. In the box next to **Cumulative Sample Size** enter 80. Enter 0.30 in the box next to **Estimate of π** . In the box next to **Standard Error of Estimate of π** enter 0.05123. Next click **Recalc**. Upon clicking **OK** we observe that the stopping boundary is crossed and the following

22 Binomial Superiority One-Sample

message is displayed.

We can conclude that $\pi > 0.15$ and terminate the trial. Clicking **Stop** yields the following output.

22.2 McNemar's Test

McNemar's Test is used in experimental situations where paired comparisons are observed. In a typical application, two binary response measurements are made on each subject – perhaps from two different treatments, or from two different time points. For example, in a comparative clinical trial, subjects are matched on baseline demographics and disease characteristics and then randomized with one subject in the

pair receiving the experimental treatment and the other subject receiving the control. Another example is the cross over clinical trial in which each subject receives both treatments. By random assignment, some subjects receive the experimental treatment followed by the control while others receive the control followed by the experimental treatment. Let π_c and π_t denote the response probabilities for the control and experimental treatments, respectively. The probability parameters for McNemar's test are displayed in Table 22.1.

Table 22.1: A 2 x 2 Table of Probabilities for McNemar's Test

| Control | Experimental | | Total Probability |
|-------------------|--------------|------------|-------------------|
| | No Response | Response | |
| No Response | π_{00} | π_{01} | $1 - \pi_c$ |
| Response | π_{10} | π_{11} | π_c |
| Total Probability | $1 - \pi_t$ | π_t | 1 |

The null hypothesis

$$H_0: \pi_c = \pi_t$$

is tested against the alternative hypothesis

$$H_1: \pi_c \neq \pi_t$$

for the two sided testing problem or the alternative hypothesis

$$H_1: \pi_c > \pi_t$$

(or $H_1: \pi_c < \pi_t$) for the one-sided testing problem. Since $\pi_t = \pi_c$ if and only if $\pi_{01} = \pi_{10}$, the null hypothesis is also expressed as

$$H_0: \pi_{01} = \pi_{10},$$

and is tested against corresponding one and two sided alternatives. The power of this test depends on two quantities:

1. The difference between the two discordant probabilities (which is also the difference between the response rates of the two treatments)

$$\delta = \pi_{01} - \pi_{10} = \pi_t - \pi_c;$$

22 Binomial Superiority One-Sample

2. The sum of the two discordant probabilities

$$\xi = \pi_{10} + \pi_{01} .$$

East accepts these two parameters as inputs at the design stage.

We next specify the test statistic to be used during the interim monitoring stage. Suppose we intend to execute McNemar's test a maximum of K times in a group sequential setting. Let the cumulative data up to and including the j th interim look consist of $N(j)$ matched pairs arranged in the form of the following 2×2 contingency table of counts:

Table 22.2: 2×2 Contingency Table of Counts of Matched Pairs at Look j

| Control | Experimental | | Total Probability |
|-------------------|--------------|-------------|-------------------|
| | No Response | Response | |
| No Response | $n_{00}(j)$ | $n_{01}(j)$ | $r_0(j)$ |
| Response | $n_{10}(j)$ | $n_{11}(j)$ | $r_1(j)$ |
| Total Probability | $c_0(j)$ | $c_1(j)$ | $N(j)$ |

For $a = 0, 1$ and $b = 0, 1$ define

$$\hat{\pi}_{ab}(j) = \frac{n_{ab}(j)}{N(j)} \tag{22.3}$$

Then the sequentially computed McNemar test statistic at look j is

$$Z_j = \frac{\hat{\delta}_j}{\text{se}(\hat{\delta}_j)} \tag{22.4}$$

where

$$\hat{\delta}_j = \hat{\pi}_{01}(j) - \hat{\pi}_{10}(j) \tag{22.5}$$

and

$$\text{se}(\hat{\delta}_j) = \frac{\sqrt{[n_{01}(j) + n_{10}(j)]}}{N(j)} \tag{22.6}$$

We now show how to use East to design and monitor a clinical trial based on McNemar's test.

22.2.1 Trial Design

Consider a trial in which we wish to determine whether a transdermal delivery system (TDS) can be improved with a new adhesive. Subjects are to wear the old TDS (control) and new TDS (experimental) in the same area of the body for one week each. A response is said to occur if the TDS remains on for the entire one week observation period. From historical data, it is known that control has a response rate of 85% ($\pi_c = 0.85$). It is hoped that the new adhesive will increase this to 95% ($\pi_t = 0.95$). Furthermore, of the 15% of the subjects who did not respond on the control, it is hoped that 87% will respond on the experimental system. That is, $\pi_{01} = 0.87 \times 0.15 = 0.13$. Based on these data, we can fill in all the entries of Table 22.1 as displayed in Table 22.2.

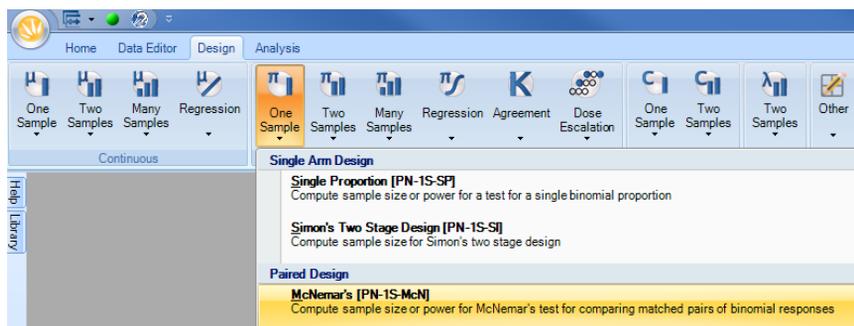

Table 22.3: McNemar Probabilities for the TDS Trial

| Control | Experimental | | Total Probability |
|-------------------|--------------|----------|-------------------|
| | No Response | Response | |
| No Response | 0.02 | 0.13 | 0.15 |
| Response | 0.03 | 0.82 | 0.85 |
| Total Probability | 0.05 | 0.95 | 1 |

Although it is expected that the new adhesive will increase the adherence rate, the comparison is posed as a two-sided testing problem, testing $H_0: \pi_c = \pi_t$ against $H_1: \pi_c \neq \pi_t$ at the 0.05 level. We wish to determine the sample size to have 90% power for the values displayed in Table 22.3. To design this trial, click **Design** tab, then **Single Sample** on the **Discrete** group, and then click **McNemar's Test for**

22 Binomial Superiority One-Sample

Matched Pairs.

Single-Look Design First, consider a study with no interim analyses, and 90% power for two sided test at $\alpha = 0.05$. Choose the design parameters as shown below. We first consider a single-look design, so leave the default value for **Number of Looks** to 1. Enter 0.9 for **Power**. As shown in Table 22.2, we must specify $\delta_1 = \pi_t - \pi_c = 0.1$ and $\xi = \pi_{01} + \pi_{10} = 0.16$.

Design Type: Superiority Number of Looks: 1

Test Parameters

Test Type: 2-Sided
 Type I Error (α): 0.05
 Power: 0.9
 Sample Size (n): Computed

Difference in Probabilities (δ_1): $(\delta_1 = \pi_t - \pi_c)$ 0.1
 Prop. of Discordant Pairs (ξ): $(\xi = \pi_{01} + \pi_{10})$ 0.16

Perform Exact Computations

Probability Allocation: Row = Control, Column = Treatment

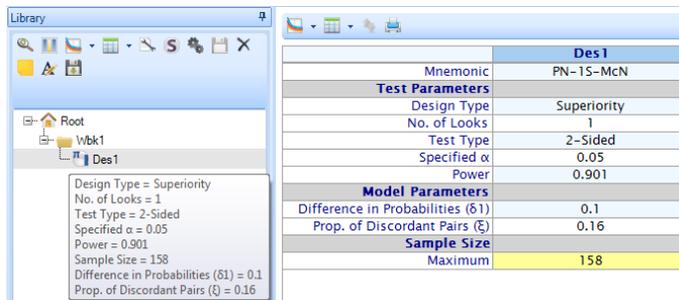

| | | | |
|-------------|-------------|------------|-------------|
| | No Response | Response | Total |
| No Response | π_{00} | π_{01} | $1 - \pi_c$ |
| Response | π_{10} | π_{11} | π_c |
| Total | $1 - \pi_t$ | π_t | 1 |

Click **Compute**. The design Des1 is shown as a row in the Output Preview located in the lower pane of this window. A total of 158 subjects is required to have 90% power.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | Sample Size | δ_1 | ξ |
|------|-------------|--------------|-----------|--------------------|-------|-------------|------------|-------|
| Des1 | Superiority | 1 | 1-Sided | 0.025 | 0.901 | 158 | 0.1 | 0.16 |

You can select this design by clicking anywhere on the row in the **Output Preview**.

Click on  icon to get the output summary displayed in the upper pane. In the **Output Preview** toolbar, click the  icon to save this design Des1 to workbook Wbk1 in the **Library**. If you hover the cursor over Des1 in the Library, a tooltip will appear that summarizes the input parameters of the design.

Five-Look Design Now consider the same design with a maximum of 5 looks, using the default Lan-DeMets (O'Brien-Fleming) spending function. Create a new design by selecting Des1 in the **Library**, and clicking  icon on the **Library** toolbar. Change the **Number of Looks** from 1 to 5, to generate a study with four interim looks and a final analysis. A new tab **Boundary** will appear. Clicking on this tab will reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side for the **Futility** boundary. By default, there is an efficacy boundary (to reject H0) selected, but no futility boundary (to reject H1). The **Boundary Family** specified is of the Spending Functions type. The default **Spending function** is the Lan-DeMets (Lan & DeMets, 1983), with **Parameter** OF (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O'Brien and Fleming (1979).

22 Binomial Superiority One-Sample

Technical details of these stopping boundaries are available in Appendix F.

Design Type: Number of Looks:

Test Parameters **Boundary**

Efficacy
 Boundary Family:
 Spending Function:
 Parameter:
 Type I Error (α): 0.05

Futility
 Boundary Family:

Spacing of Looks Equal Unequal Efficacy Boundary:

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.200 | 0.000 | 4.877 | -4.877 |
| 2 | 0.400 | 0.001 | 3.357 | -3.357 |
| 3 | 0.600 | 0.008 | 2.680 | -2.680 |
| 4 | 0.800 | 0.024 | 2.290 | -2.290 |
| 5 | 1.000 | 0.050 | 2.031 | -2.031 |

Click **Compute** to generate output for Des2. With Des2 selected in the **Output Preview**, click the icon to save Des2 to the **Library**. In the **Library**, select the nodes for both Des1 and Des2, by holding the Ctrl key, and then click the icon. The upper pane will display the output summary of the two designs side-by-side:

| | Des1 | Des2 |
|--|-------------|-------------|
| Mnemonic | PN-1S-McN | PN-1S-McN |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 1 | 5 |
| Test Type | 2-Sided | 2-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.901 | 0.901 |
| Model Parameters | | |
| Difference in Probabilities (δ_1) | 0.1 | 0.1 |
| Prop. of Discordant Pairs (ξ) | 0.16 | 0.16 |
| Boundary Parameters | | |
| Spacing of Looks | | Equal |
| Efficacy Boundary | | LD (OF) |
| Sample Size | | |
| Maximum | 158 | 162 |
| Expected Under H0 | | 160.935 |
| Expected Under H1 | | 119.965 |

There has been a slight inflation in the maximum sample size, from 158 to 162. However, the expected sample size is 120 subjects if the alternative hypothesis of $\delta_1 = 0.10$ and $\xi = 0.16$ holds. The stopping boundary, spending function, and Power

vs. Sample Size charts can all be displayed by clicking on the appropriate icons from the **Library** toolbar.

22.2.2 Interim Monitoring

Consider interim monitoring of Des2. Select Des2 in the **Library**, and click **IM** icon from the Library toolbar. Alternatively, right-click on Des2 and select **Interim Monitoring**. A new IM worksheet will appear.

Suppose, that the results are to be analyzed after results are available for every 32 subjects. After the first 32 subjects were enrolled, one subject responded on the control arm and did not respond on the treatment arm; four subjects responded on the treatment arm but did not respond on the control arm; 10 subjects did not respond on either treatment; 17 subjects responded on both the arms. This information is sufficient to complete all the entries in Table 22.3 and hence to evaluate the test statistic value.

Click **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. In the box next to **Cumulative Sample Size** enter 32. Enter the values in the table as shown below and click **Recalc**.

Test Statistic Calculator

Editing Look #1

Input for Binomial end point

Row = Control, Column = Treatment

| | No Response | Response | Total |
|-------------|-------------|----------|-------|
| No Response | 10 | 4 | 14 |
| Response | 1 | 17 | 18 |
| Total | 11 | 21 | 32 |

Output
 Test Statistic: 1.342

Recalc OK Cancel

22 Binomial Superiority One-Sample

Clicking **OK** results in the following entry in the first look row.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | | 95% RCI for δ | | Repeat... p-value | CP | Predict... |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|--------|----------------------|--------|-------------------|-------|------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.198 | 32 | 1.342 | 0.094 | 0.07 | 4.909 | -4.909 | 0.437 | -0.249 | 0.902 | 0.874 | 0.703 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |
| 4 | | | | | | | | | | | | |
| 5 | | | | | | | | | | | | |

As you can see the value of the test statistic, 1.342, is within the stopping boundaries, (4.909,-4.909). Thus, the trial continues.

The second interim analysis was performed after data were available for 64 subjects. A total of two subjects responded on the control arm and failed to respond on the treatment arm; seven subjects responded on the treatment arm and failed to respond on the control arm; 20 subjects responded on neither arm; 35 subjects responded on both the arms.

Click on the second row in the table in the upper section. Then click **Enter Interim Data** icon. Enter the appropriate values in the table as shown below and click **Recalc**.

While it is often difficult to specify the absolute difference of the discordant probabilities, δ_1 , it is even more difficult to specify the sum of the discordant probabilities, ξ . Simulation can be used to examine the effects of misspecification of ξ . Run the simulations again, now with $\delta_1=0.10$ and $\xi=0.2$. The results are given below.

Notice that this provides a power of approximately 81%. Larger values of ξ would further decrease the power. However, values of $\xi > 0.2$ with $\delta_1 = 0.1$ would be inconsistent with the initial assumption of $\pi_c = 0.85$ and $\pi_t = 0.95$. Additional simulations for various values of δ and ξ can provide information regarding the consequences of misspecification of the input parameters.

23 Binomial Superiority Two-Sample

In experiments based on binomial data, the aim is to compare independent samples from two populations in terms of the proportion of sampling units presenting a given trait. In medical research, outcomes such as the proportion of patients responding to a therapy, developing a certain side effect, or requiring specialized care, would satisfy this definition. East supports the design, simulation, and interim monitoring of clinical trials in which this comparison is based on the difference of proportions, the ratio of proportions, or the odds ratio of the two populations. The three cases are discussed in the following sections.

23.1 Difference of Two Binomial Proportions

23.1.1 Trial Design

23.1.2 Interim Monitoring

23.1.3 Pooled versus Unpooled Designs

Let π_c and π_t denote the binomial probabilities for the control and treatment arms, respectively, and let $\delta = \pi_t - \pi_c$. Interest lies in testing the null hypothesis that $\delta = 0$ against one and two-sided alternatives. A special characteristic of binomial designs is the dependence of the variance of a binomial random variable on its mean. Because of this dependence, even if we keep all other test parameters the same, the maximum sample size required to achieve a specified power will be affected by how we intend to standardize the difference of binomial response rates when computing the test statistic at the interim monitoring stage. There are two options for computing the test statistic – use either the **unpooled** or **pooled** estimate of variance for standardizing the observed treatment difference. Suppose, for instance, that at the j th interim look the observed response rate on the treatment arm is $\hat{\pi}_{tj}$, and the observed response rate on the control arm is $\hat{\pi}_{cj}$. Let n_{tj} and n_{cj} be the number of patients on the treatment and control arms, respectively. Then the test statistic based on the unpooled variance is

$$Z_j^{(u)} = \frac{\hat{\pi}_{tj} - \hat{\pi}_{cj}}{\sqrt{\frac{\hat{\pi}_{tj}(1-\hat{\pi}_{tj})}{n_{tj}} + \frac{\hat{\pi}_{cj}(1-\hat{\pi}_{cj})}{n_{cj}}}} \tag{23.1}$$

In contrast, the test statistic based on the pooled variance is

$$Z_j^{(p)} = \frac{\hat{\pi}_{tj} - \hat{\pi}_{cj}}{\sqrt{\hat{\pi}_j(1-\hat{\pi}_j)\left[\frac{1}{n_{tj}} + \frac{1}{n_{cj}}\right]}}, \tag{23.2}$$

where

$$\hat{\pi}_j = \frac{n_{tj}\hat{\pi}_{tj} + n_{cj}\hat{\pi}_{cj}}{n_{tj} + n_{cj}}. \tag{23.3}$$

It can be shown that $[Z_j^{(p)}]^2$ is the familiar Pearson chi-square statistic computed from all the data accumulated by the j th look.

The maximum sample size required to achieve a given power depends on whether, at the interim monitoring stage, we intend to use the unpooled statistic (23.1) or the pooled statistic (23.2) to determine statistical significance. The technical details of the sample size computations for these two options are given in Appendix B, Section B.2.5. The CAPTURE clinical trial is designed in Section 23.1.1 and monitored in Section 23.1.2 under the assumption that the unpooled statistic will be used for interim monitoring. In Section 23.1.3, however, the same trial is re-designed, on the basis of the pooled variance. It is seen that the difference in sample size due to the two design assumptions is almost negligible. This is because the CAPTURE trial utilized balanced randomization. We show further in Section 23.1.3 that if the randomization is unbalanced, the difference in sample size based on the two design assumptions can be substantial.

23.1.1 Trial Design

Design objectives and interim results from CAPTURE, a prospective randomized trial of placebo versus Abciximab for patients with refractory unstable angina were presented at a workshop on clinical trial data monitoring committees (Anderson, 2002). The primary endpoint was reduction in death or MI within 30 days of entering the study. The study was designed for 80% power to detect a reduction in the event rate from 15% on the placebo arm to 10% on the Abciximab arm. A two-sided test with a type-1 error of 5% was used. We will illustrate various design and interim monitoring features of East for studies with binomial endpoints with the help of this example. Thereby this example can serve as a model for designing and monitoring your own binomial studies.

Single Look Design To begin, click **Design** tab, then **Two Samples** on the **Discrete** group, and then click **Difference of Proportions**.

The goal of this study is to test the null hypothesis, H_0 , that the Abciximab and placebo arms both have an event rate of 15%, versus the alternative hypothesis, H_1 , that Abciximab reduces the event rate by 5%, from 15% to 10%. It is desired to have a two sided test with three looks at the data, a type-1 error of $\alpha = 0.05$ and a power of $(1 - \beta) = 0.8$.

Choose the test parameters as shown below. We first consider a single-look design, so leave the default value for **Number of Looks** to 1. Enter 0.8 for the **Power**. To specify the appropriate effect size, enter 0.15 for the **Prop. Under Control** and 0.10 for the **Prop. Under Treatment**. Notice that you have the option to select the manner in which the test statistic will be standardized at the hypothesis testing stage. If you choose **Unpooled Estimate**, the standardization will be according to equation (23.1).

23 Binomial Superiority Two-Sample

If you choose **Pooled Estimate**, the standardization will be according to equation (23.2). For the present, choose the **Unpooled Estimate** option. The other choice in this dialog box is whether or not to use the Casagrande-Pike-Smith (1978) correction for small sample sizes. This is not usually necessary as can be verified by the simulation options in East. The dialog box containing the test parameters will now look as shown below.

Design Type: Superiority Number of Looks: 1

Test Parameters

Test Type: 2-Sided

Type I Error (α): 0.05

Power: 0.8

Sample Size (n): Computed

Allocation Ratio: 1 (n_1/n_2)

Specify Proportion Response

 Specify Variance
 Pooled Estimate
 Unpooled Estimate

Use Casagrande-Pike-Smith Correction (Ignored if alloc. ratio is not 1)

Assurance (Probability of Success):

Next, click **Compute** button. The design is shown as a row in the Output Preview located in the lower pane of this window. The computed sample size (1366 subjects) is highlighted in yellow.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | π_c | Prop. Treatment (Alt.) | δ_1 | Variance |
|------|-------------|--------------|-----------|--------------------|-------|-------|-------------|---------|------------------------|------------|-------------------|
| Des1 | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 1366 | 0.15 | 0.1 | -0.05 | Unpooled Estimate |

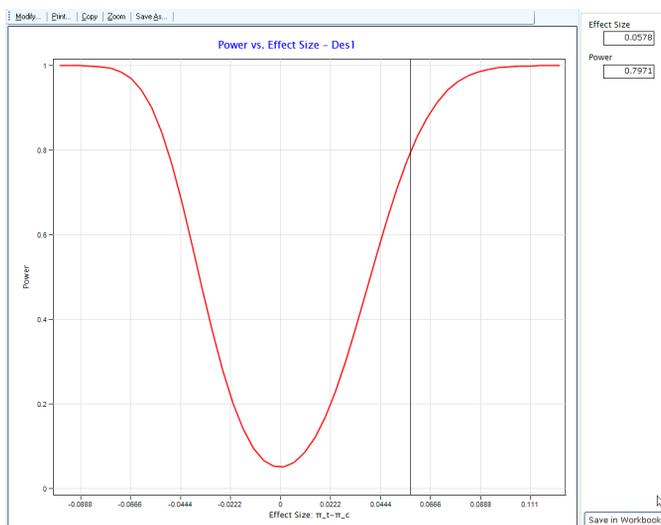

You can select this design Des1 by clicking anywhere on the row in the **Output Preview**. Now you can click  icon to see the output summary displayed in the upper pane. In the **Output Preview** toolbar, click  icon to save this design Des1 to Workbook Wbk1 in the **Library**. If you hover the cursor over Des1 in the Library, a

tooltip will appear that summarizes the input parameters of the design.

The screenshot shows a software window with a 'Library' pane on the left and a parameter table on the right. The 'Library' pane shows a tree structure with 'Root', 'Wbk1', and 'Des1'. A tooltip for 'Des1' lists the following parameters: Design Type = Superiority, No. of Looks = 1, Test Type = 2-Sided, Specified α = 0.05, Power = 0.8, Allocation Ratio (nt/nc) = 1, Sample Size = 1366, Proportion under Control (π_c) = 0.15, Proportion under Treatment (π_t) = 0.1, Diff. in Prop. ($\pi_t - \pi_c$) = -0.05, and Variance = Unpooled Estimate.

| Des 1 | |
|--|-------------------|
| Mnemonic | PN-25-DI |

| Maximum | 1366 |

With Des1 selected in the **Library**, click the icon on the **Library** toolbar, and then click **Power vs Treatment Effect** (δ). The resulting power curve for this design is shown. You can save this chart to the **Library** by clicking **Keep**. Alternatively, you can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...** For now, you may close the chart before continuing.

Group Sequential Design Create a new design by selecting Des1 in the **Library**,

23 Binomial Superiority Two-Sample

and clicking  icon on the **Library** toolbar. Change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab **Boundary** will appear. Clicking on this tab will reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side for the **Futility** boundary. By default, there is an efficacy boundary (to reject H0) selected, but no futility boundary (to reject H1). The **Boundary Family** specified is of the **Spending Functions** type. The default **Spending function** is the Lan-DeMets (Lan & DeMets, 1983), with **Parameter OF** (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O'Brien and Fleming (1979). Technical details of these stopping boundaries are available in Appendix F.

Click **Boundary** tab to see the details of cumulative alpha spent, and the boundary values, in the **Look Details** table.

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: None

Spacing of Looks Equal Unequal

Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.333 | 0.000 | 3.710 | -3.710 |
| 2 | 0.667 | 0.012 | 2.511 | -2.511 |
| 3 | 1.000 | 0.050 | 1.993 | -1.993 |

Click **Compute** to generate output for a new design Des2. The 3-look group sequential design displayed in Des2 requires an upfront commitment of up to a maximum of 1384 patients. That is 18 patients more than the fixed sample design displayed in Des1. Notice, however, that under the alternative hypothesis of a 5% drop in the event rate, the expected sample size is only 1183 patients – a saving of 201 patients relative to the fixed sample design. This is because the test statistic could cross a stopping boundary at one of the interim looks.

With Des2 selected in the **Output Preview**, click  icon to save Des2 to the **Library**. In order to see the stopping probabilities, as well as other characteristics,

select Des2 in the **Library**, and click  icon. The cumulative boundary stopping probabilities are shown in the **Stopping Boundaries** table.

Close the Output window before continuing. The stopping boundary chart can be brought up by clicking  icon on the **Library** toolbar, and then clicking **Stopping Boundaries**. The following chart will appear.

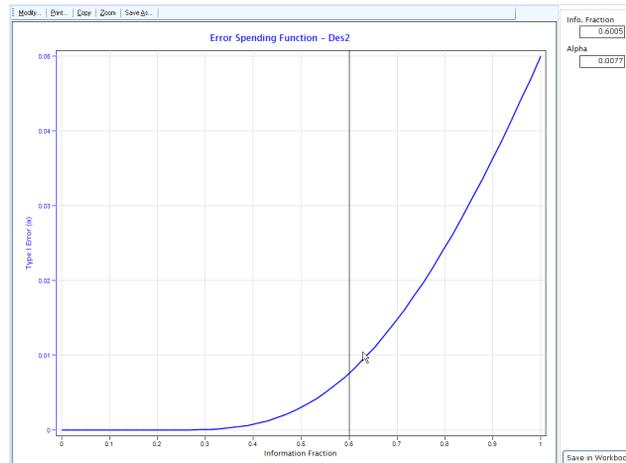

Lan-DeMets Spending Function: O'Brien-Fleming Version

Close this chart, and click  icon in the **Library** toolbar and then **Error**

23 Binomial Superiority Two-Sample

Spending The following chart will appear.

This spending function was proposed by Lan and DeMets (1983), and for two-sided tests has the following functional form :

$$\alpha(t) = 4 - 4\Phi\left(\frac{z_{\alpha/4}}{\sqrt{t}}\right) . \quad (23.4)$$

Notice that hardly any type-1 error is spent in the early stages of the trial but the rate of error spending increases rapidly as the trial progresses. This is reflected in the corresponding stopping boundaries. The upper and lower boundary values are rather wide apart initially (± 3.712 standard deviations) but come closer together with each succeeding interim look until at the last look the standardized test statistic crosses the boundary at ± 1.993 standard deviations. This is not too far off from the corresponding boundary values, ± 1.96 , required to declare statistical significance at the 0.05 level for a fixed sample design. For this reason this spending function is often adopted in preference to other spending functions that spend the type-1 error more aggressively and thereby reduce the expected sample size under H_1 by a greater amount.

Lan-DeMets Spending Function: Pocock Version

A more aggressive spending function, also proposed by Lan and DeMets (1983), is **PK** which refers to Pocock. This spending function captures the spirit of the Pocock (1977) stopping boundary belonging to the Wang and Tsatis (1987) power family, and

has the functional form

$$\alpha(t) = \alpha \log(1 + (e - 1)t) . \tag{23.5}$$

Select Des2 in the **Library**, and click  icon on the **Library** toolbar. On the **Boundary** tab, change the **Parameter** from OF to PK, and click **Compute** to create design Des3. With Des3 selected in the **Output Preview**, click the  icon. In the **Library**, select the nodes for both Des2 and Des3, by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the two designs side-by-side:

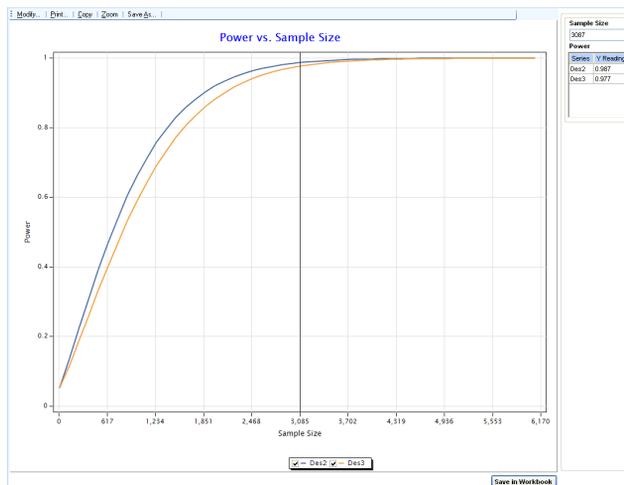

| | Des2 | Des3 |
|--|-------------------|-------------------|
| Mnemonic | PN-2S-DI | PN-2S-DI |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 3 | 3 |
| Test Type | 2-Sided | 2-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.8 | 0.8 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Proportion under Control (π_c) | 0.15 | 0.15 |
| Proportion under Treatment (π_t) | 0.1 | 0.1 |
| Diff. in Prop. ($\pi_t - \pi_c$) | -0.05 | -0.05 |
| Variance | Unpooled Estimate | Unpooled Estimate |
| Boundary Parameters | | |
| Spacing of Looks | Equal | Equal |
| Efficacy Boundary | LD (OF) | LD (PK) |
| Sample Size | | |
| Maximum | 1384 | 1599 |
| Expected Under H0 | 1378.32 | 1566.588 |
| Expected Under H1 | 1182.678 | 1119.294 |

Under Des3, you must make an up-front commitment of up to 1599 patients, considerably more than you would need for a fixed sample design. However, because the type-1 error is spent more aggressively in the early stages, the expected sample size is only 1119 patients.

For now, close this output window, and click  icon on the **Library** toolbar to

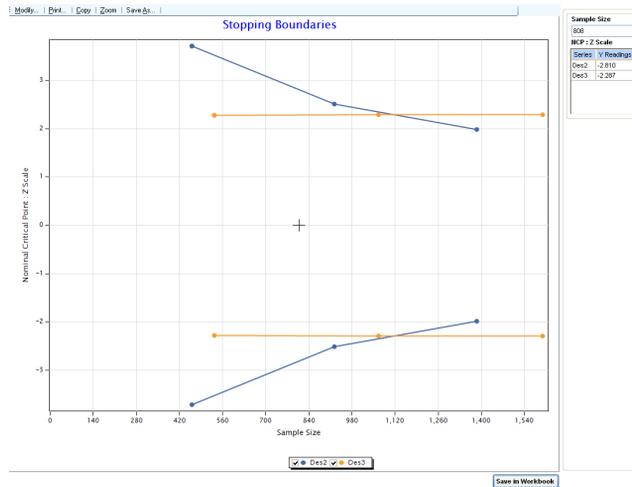

23 Binomial Superiority Two-Sample

compare the two designs according to Power vs. Sample Size.

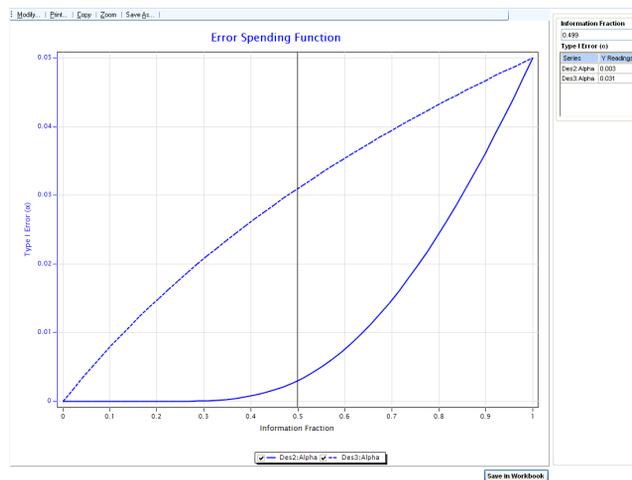

Using the same icon, select Stopping Boundaries. Notice, by moving the cursor from right to left in the stopping boundary charts, that the stopping boundary derived from the PK spending function is approximately flat, requiring ± 2.28 standard deviations at the first look and ± 2.29 standard deviations at the second and ± 2.30 third looks. In contrast, the stopping boundary derived from the OF spending function requires ± 3.71 standard deviations at the first look, ± 2.51 standard deviations at the second look and ± 1.99 standard deviations at the third look. This translates into a smaller expected sample size under H_1 for Des3 than for Des2. This advantage is, however, offset by at least two drawbacks of the stopping boundary derived from the PK spending function; the large up-front commitment of 1599 patients, and the large standardized test statistic of 2.295 (corresponding to a two-sided p value of 0.0217)

required at the last look in order to declare statistical significance.

Using the same icon, select Error Spending to compare the two designs graphically in terms of error spending functions. Des3 (PK) spends the type-1 error probability at a much faster rate than Des2 (OF). Close the chart before continuing.

23 Binomial Superiority Two-Sample

Wang and Tsiatis Power Boundaries

The stopping boundaries generated by the Lan-Demets OF and PK functions closely resemble closely the classical O'Brien-Fleming and Pocock stopping boundaries, respectively. These classical boundaries are a special case of a family of power boundaries proposed by Wang and Tsiatis (1987). For a two-sided α level test, using K equally spaced looks, the power boundaries for the standardized test statistic Z_j at the j -th look are of the form

$$Z_j \geq \frac{C(\Delta, \alpha, K)}{(j/K)^{0.5-\Delta}} \quad (23.6)$$

The normalizing constant $C(\Delta, \alpha, K)$ is evaluated by recursive integration so as to ensure that the K -look group sequential test has type-1 error equal to α .

Select Des3 in the **Library** and click  on the **Library** toolbar. On the **Boundary** tab, change the **Boundary Family** from Spending Functions to Wang-Tsiatis. Leave the default value of Δ as 0 and click **Compute** to create design Des4.

Efficacy

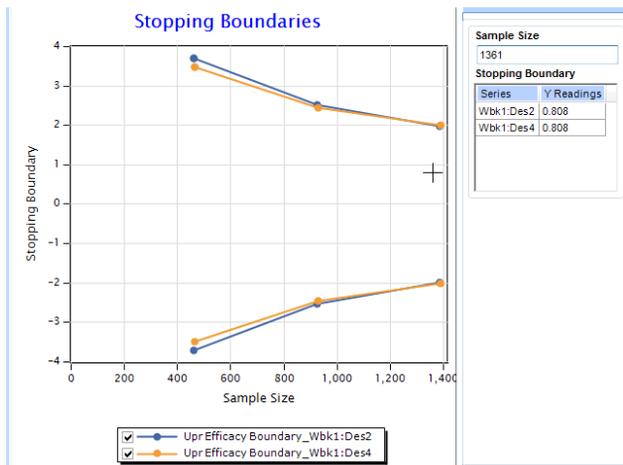

Boundary Family: Wang-Tsiatis

Shape Parameter (Δ):

Type I Error (α): 0.05

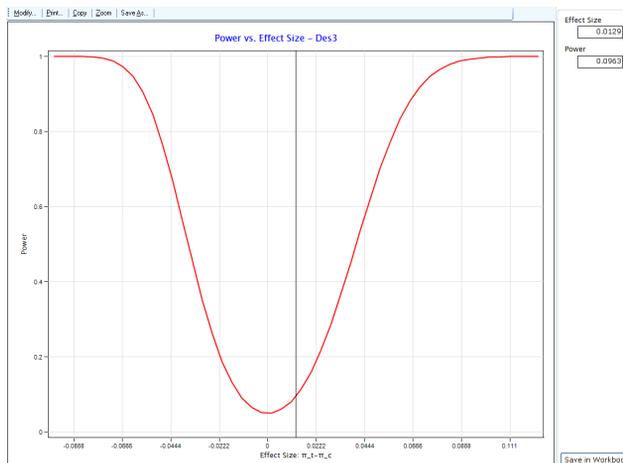

With Des4 selected in the **Output Preview**, click the  icon. In the **Library**, select both Des2 and Des4 by holding the Ctrl key. Click  icon, and under **Select Chart** on the right, select Stopping Boundaries. As expected, the boundary values for Des2 (Lan-Demets, OF) and Des4 (Wang-Tsiatis, $\Delta = 0$) are very similar.

Close the chart before continuing.

The Power Chart and the ASN Chart

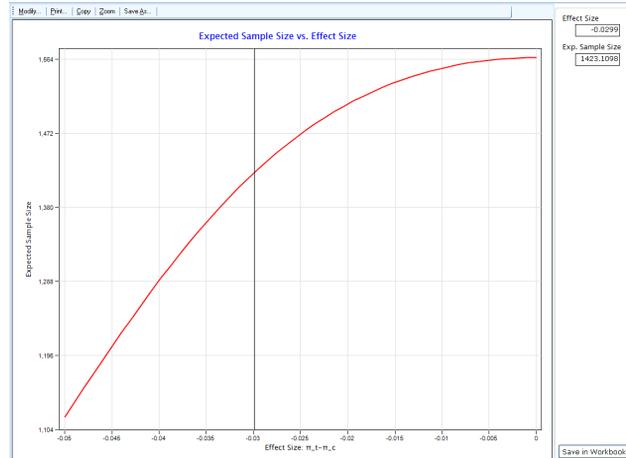

East provides some additional tools for evaluating study designs. Select Des3 in the **Library**, click the  icon, and then click **Power vs. Treatment effect (δ)**. By scrolling from left to right with the vertical line cursor, one can observe the power for various values of the effect size.

Close this chart, and with Des3 selected, click the  icon again. Then click

23 Binomial Superiority Two-Sample

Expected Sample Size. The following chart appears:

This chart displays the Expected Sample Size as a function of the effect size and confirms that for Des3 the average sample size is 1566 under H_0 (effect size, zero) and 1120 under H_1 (effect size, -0.05).

Unequally spaced analysis time points

In the above designs, we have assumed that analyses were equally spaced. This assumption can be relaxed if you know when interim analyses are likely to be performed (e.g. for administrative reasons). In either case, departures from this assumption are allowed during the actual interim monitoring of the study, but sample size requirements will be more accurate if allowance is made for this knowledge.

With Des3 selected in the **Library**, click the  icon. Under **Spacing of Looks** in the **Boundary** tab, click the **Unequal** radio button. The column titled **Info. Fraction** in the **Look Details** table can be edited to modify the relative spacing of the analyses. The information fraction refers to the proportion of the maximum (yet unknown) sample size. By default, this table displays equal spacing, but suppose that the two interim analyses will be performed with 0.25 and 0.5 (instead of 0.333 and 0.667) of the maximum sample size. Enter these new information fraction values and click **Compute** to create design Des5. Select Des5 in the **Output Preview** and click  icon to save it in the **Library** for now.

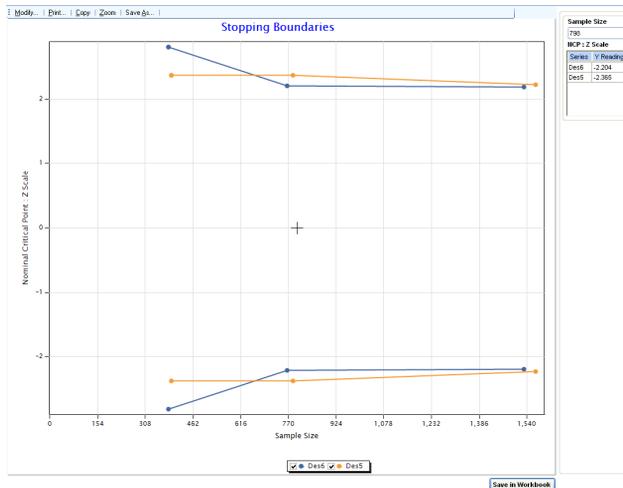

Arbitrary amounts of error probability to be spent at each analysis

Another feature of East is the possibility to specify arbitrary amounts of cumulative error probability to be used at each look. This option can be combined with the option of unequal spacing of the analyses. With Des5 selected in the **Library**, click the  icon on the **Library** toolbar. Under the **Boundary** tab, select **Interpolated** for the **Spending Function**. In the column titled **Cum. α Spent**, enter 0.005 for the first look and 0.03 for the second look, and click **Compute** to create design Des6.

Look Details:

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|-------|
| | | | Upper | Lower |
| 1 | 0.250 | 0.0050 | | |
| 2 | 0.500 | 0.0300 | | |
| 3 | 1.000 | 0.0500 | | |

Select Des6 in the **Output Preview** and click  icon. From the **Library**, select Des5 and Des6 by holding the Ctrl key. Click  icon, and under **Select Chart** on the right, select **Stopping Boundaries**. The following chart will be displayed.

Computing power for a given sample size

When sample size is a given design constraint, East can compute the achieved power, given the other test parameters. Select Des6 in the **Library** and click  icon. On the **Test Parameters** tab, click the radio button for **Power(1 - β)**. You will notice that

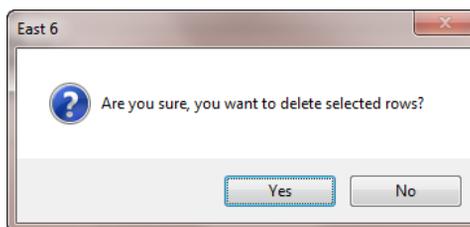

23 Binomial Superiority Two-Sample

the field for power will contain the word **Computed**. You may now enter a value for the sample size: 1250, and click **Compute**.

The following output will appear in **Output Preview** in Des7 row, where, as expected, the achieved power is less than 0.9, namely 0.714.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | tTC | Prop. Treatment (Alt.) | δ_1 | Variance | Spacing of Looks | Efficacy Boundary | Expected SS (H0) | Expected SS (H1) |

To delete this design, click Des7 in the **Output Preview**, and click icon in the text **Output Preview** toolbar. East will display a warning to make sure that you want to delete the selected row. Click **Yes** to continue.

Stopping Boundaries for Early Rejection of H_0 or H_1 Although both Des2 and Des3 reduce the expected sample size substantially by rejecting H_0 when H_1 is true, they are unable to do so if H_0 is true. It is, however, often desirable to terminate a study early if H_0 is true since that would imply that the new treatment is no different than the standard treatment. East can produce stopping boundaries that result in early termination either under either H_0 or H_1 . Stopping boundaries for early termination if

H_1 is true are known as **efficacy boundaries**. They are obtained by choosing an appropriate α -spending function. These boundaries ensure that the type 1 error does not exceed the pre-specified significance level α . East can also construct stopping boundaries for rejecting H_1 and terminating early if H_0 is true. These stopping boundaries are known as **futility boundaries**. They are obtained by choosing an appropriate β spending function. These boundaries ensure that the type 2 error does not exceed β and thereby ensure that the power of the study is preserved at $1 - \beta$ despite the possibility of early termination for futility. Pampallona and Tsiatis (1994) have extended the error spending function methodology of Lan and DeMets (1983) so as to spend both α , the type-1 error, and β , the type-2 error, and thereby obtain efficacy and futility boundaries simultaneously. East provides you with an entire catalog of published spending functions from which you can take your pick for generating both the H_0 and H_1 boundaries.

For various reasons, investigators usually prefer to be very conservative about early stopping for efficacy but are likely to be more aggressive about cutting their losses and stopping early for futility. Suppose then that you wish to use the conservative Lan-DeMets (OF) spending function for early termination to reject H_0 in favor of H_1 , but use a more aggressive spending function for early termination to reject H_1 in favor of H_0 . Possible choices for spending functions to reject H_1 that are more aggressive than Lan-DeMets(OF) but not as aggressive as Lan-DeMets(PK) are members of the Rho family (Jennison and Turnbull, 2000) and the Gamma family (Hwang, Shih and DeCani, 1990). For illustrative purposes we will use the **Gamam(-1)** spending function from the Gamma family.

Select Des2 in the **Library** and click  icon. For the futility boundary on the **Boundary** tab, select Spending Functions and then select Gamma Family. Set the **Parameter** to -1 . Also, click on the **Binding** option to the right. The screen

23 Binomial Superiority Two-Sample

will look like this:

Efficacy

Boundary Family: Spending Functions

Spending Function: Lan-DeMets

Parameter: OF

Type I Error (α): 0.05

Futility

Boundary Family: Spending Functions

Spending Function: Gamma Family

Parameter (γ): -1

Type II Error (β): 0.2

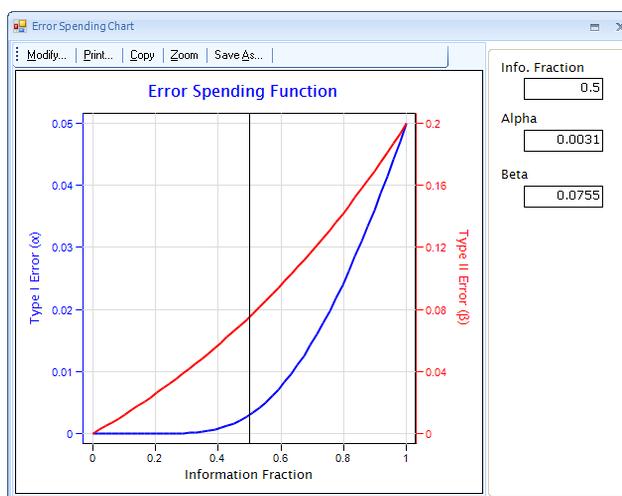

Non-Binding
 Binding

Spacing of Looks: Equal Unequal

Boundary Scale: Z Scale

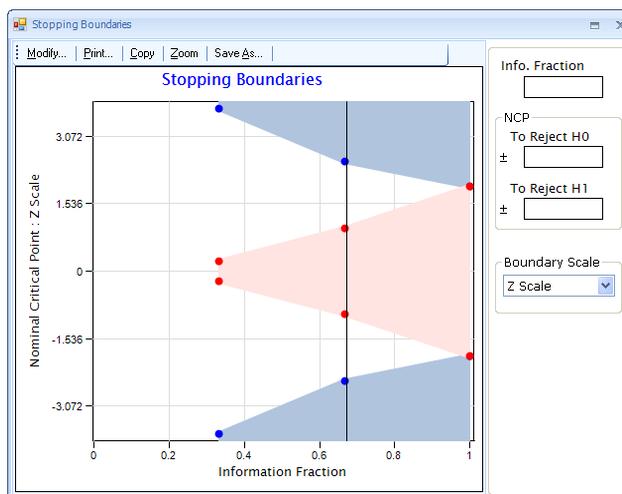

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | | Cum. β Spent | Futility Boundary | |
|--------|----------------|-------------------------------------|-------------------------------------|---------------------|-------------------|--------|--------------------|-------------------|--------|
| | | | | | Upper | Lower | | Upper | Lower |
| 1 | 0.333 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.000 | 3.710 | -3.710 | 0.046 | 0.232 | -0.232 |
| 2 | 0.667 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.012 | 2.509 | -2.509 | 0.110 | 0.979 | -0.979 |
| 3 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.050 | 1.933 | -1.933 | 0.200 | 1.933 | -1.933 |

On the **Boundary** tab, you may click icon, or icon to view plots of the error spending functions, or stopping boundaries, respectively.

Observe that the β -spending function (upper in red) spends the type-2 error

substantially faster than the α -spending function (lower in blue).

These stopping boundaries are known as **inner-wedge** stopping boundaries. They divide the sample space into three zones corresponding to three possible decisions. If the test statistic enters the lower blue zone, we terminate the trial, reject H_0 , and conclude that the new treatment (Abciximab) is beneficial relative to the placebo. If the test statistic enters the upper blue zone, we terminate the trial, reject H_0 , and conclude that the new treatment is harmful relative to the placebo. If the test statistic enters the center (pink) zone, we terminate the trial, reject H_1 , and conclude that Abciximab offers no benefit relative to placebo. Assuming that the event rate is 0.15 for the placebo arm, this strategy has a 2.5% chance of declaring benefit and a 2.5% chance of declaring harm when the event rate for the Abciximab arm is also 0.15. Furthermore this strategy has a 20% chance of entering the pink zone and declaring no benefit when there actually is a substantial benefit with Abciximab, resulting in a drop in the event rate from 0.15 to 0.1. In other words, Des7 has a two-sided type-1 error of 5% and 80% power.

Click **Compute** and with Des7 selected in the **Output Preview**, click the  icon.

To view the design details, click the  icon. Des7 requires an up-front commitment of 1468 patients, but the expected sample size is 1028 patients under H_0 , and 1164 patients under H_1 . You may wish to save this output (e.g., in HTML format)

by clicking on the  icon, or to print by clicking on the  icon. Close the

23 Binomial Superiority Two-Sample

output window before continuing.

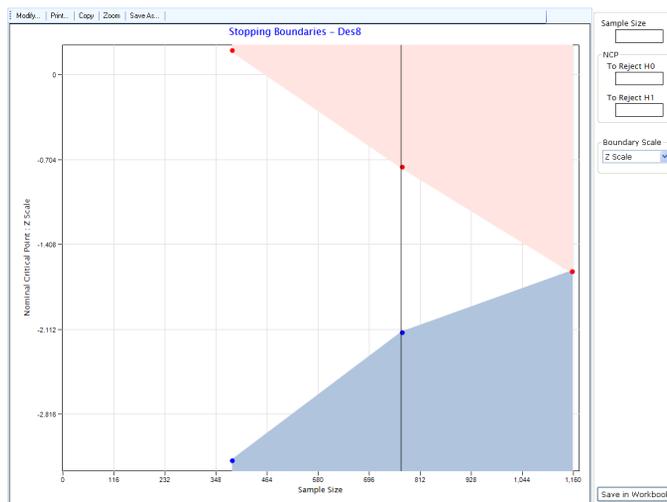

Boundaries with Early Stopping for Benefit or Futility

Next suppose you are interested in designing the clinical trial in such a way that you can reach only two conclusions, not three. You wish to demonstrate either that Abciximab is beneficial relative to placebo or that it offers no benefit relative to placebo, but there is no interest in demonstrating that Abciximab is harmful relative to placebo. To design this two-decision trial select Des7 in the **Library** and click the  icon. Change the entry in the **Test Type** cell from 2-Sided to 1-Sided. Check to ensure other specifications are same as in Des7. Click **Compute** to generate the design.

| | Des 7 | Des 8 |
|--|-------------------|-------------------|
| Mnemonic | PN-2S-DI | PN-2S-DI |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 3 | 3 |
| Test Type | 2-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.8 | 0.8 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Proportion under Control (π_c) | 0.15 | 0.15 |
| Proportion under Treatment (π_t) | 0.1 | 0.1 |
| Diff. in Prop. ($\pi_t - \pi_c$) | -0.05 | -0.05 |
| Variance | Unpooled Estimate | Unpooled Estimate |
| Boundary Parameters | | |
| Spacing of Looks | Equal | Equal |
| Efficacy Boundary | LD (OF) | LD (OF) |
| Futility Boundary | Gm (-1) (B) | Gm (-1) (B) |
| Sample Size | | |
| Maximum | 1468 | 1156 |
| Expected Under H0 | 1028.235 | 680.953 |
| Expected Under H1 | 1163.929 | 891.733 |

The error spending functions are the same but this time the stopping boundaries divide

the sample space into two zones only as shown below.

If the test statistic enters the lower (blue) zone, the null hypothesis is rejected in favor of concluding that Abciximab is beneficial relative to placebo. The probability of this event under H_0 is 0.05. If the test statistic enters the upper (pink) zone the alternative hypothesis is rejected in favor of concluding that Abciximab offers no benefit relative to placebo. The probability of this event under H_1 is 0.2. In other words, Design8 has a one sided type-1 error rate of 5% and 80% power. Since Design8 precludes the possibility of demonstrating that Abciximab is harmful relative to placebo, it requires far fewer patients. It only requires an up-front commitment of 1156 patients and the expected sample size is 681 if H_0 is true and 892 if H_1 is true.

Before continuing to the next section, we will save the current workbook, and open a new workbook. Select the workbook node in the **Library** and Click the  button in the top left hand corner, and click **Save**. Alternatively, select Workbook1 in the **Library** and right-click, then click **Save**. This saves all the work done so far on your directory.

Next, click the  button, click **New**, and then **Workbook**. A new workbook, Wbk2, should appear in the **Library**. Next, close the window to clear all designs from the **Output Preview**.

23 Binomial Superiority Two-Sample

Multiple designs for discrete outcomes East allows the user to easily create multiple designs by specifying a range of values for certain parameters in the design window. In studies with discrete outcomes, East supports the input of multiple key parameters at once to simultaneously create a number of different designs. For example, suppose in a multi-look study the user wants to generate designs for all combinations of the following parameter values in a two sample **Difference of Proportions** test: **Power** = 0.8 and 0.9, and **Alternative Hypothesis - Prop. under Treatment** = 0.4, 0.5 and 0.6. The number of combinations is $2 \times 3 = 6$. East creates all permutations using only a single specification under the **Test Parameters** tab in the design window. As shown below, the values for **Power** are entered as a list of comma separated values, while the **Prop. under Treatment** for the alternative hypothesis are entered as a colon separated range of values, 0.4. to 0.6 in steps of 0.1.

East computes all 6 designs and displays them in the **Output Preview** window:

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Sample Size | Expected SS (H0) | Expected SS (H1) | ttc | Prop. Treatment (Alt.) | δ_1 | Variance |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|-------------|------------------|------------------|-----|------------------------|------------|-------------------|
| Des1 | Superiority | 3 | 2-Sided | 0.05 | 0.805 | 1 | Equal | LD (OF) | 59 | 58.762 | 50.312 | 0.1 | 0.4 | 0.3 | Unpooled Estimate |
| Des2 | Superiority | 3 | 2-Sided | 0.05 | 0.802 | 1 | Equal | LD (OF) | 34 | 33.857 | 29.026 | 0.1 | 0.5 | 0.4 | Unpooled Estimate |
| Des3 | Superiority | 3 | 2-Sided | 0.05 | 0.8 | 1 | Equal | LD (OF) | 21 | 20.914 | 17.945 | 0.1 | 0.6 | 0.5 | Unpooled Estimate |
| Des4 | Superiority | 3 | 2-Sided | 0.05 | 0.9 | 1 | Equal | LD (OF) | 78 | 77.68 | 62.547 | 0.1 | 0.4 | 0.3 | Unpooled Estimate |
| Des5 | Superiority | 3 | 2-Sided | 0.05 | 0.905 | 1 | Equal | LD (OF) | 46 | 45.807 | 36.789 | 0.1 | 0.5 | 0.4 | Unpooled Estimate |
| Des6 | Superiority | 3 | 2-Sided | 0.05 | 0.909 | 1 | Equal | LD (OF) | 29 | 28.885 | 23.016 | 0.1 | 0.6 | 0.5 | Unpooled Estimate |

East provides the capability to analyze multiple designs in ways that make comparisons between the designs visually simple and efficient. To illustrate this, a selection of a few of the above designs can be viewed simultaneously in both the **Output Summary** section as well as in the various tables and plots. The following is a subsection of the designs computed from the above example with differing values for number of looks, power and proportion under treatment. Designs are displayed side by side, allowing details to be easily compared. Save these designs in the newly created workbook.

In addition East allows multiple designs to be viewed simultaneously either graphically or in tabular format: **Stopping Boundaries (table)**

Stopping Boundaries (plot)

Power vs. Treatment Effect (plot)

This capability allows the user to explore a greater space of possibilities when determining the best choice of study design.

Select individual looks

With Des8 selected in Wbk1, click  icon. In the **Spacing of Looks** table of the **Boundary** tab, notice that there are ticked checkboxes under the columns **Stop for Efficacy** and **Stop for Futility**. East gives you the flexibility to remove one of the stopping boundaries at certain looks, subject to the following constraints: (1) both boundaries must be included at the final two looks, (2) at least one boundary, either efficacy or futility, must be present at each look, (3) once a boundary has been selected all subsequent looks must include this boundary as well and (4) efficacy boundary for the penultimate look cannot be absent.

Untick the checkbox in the first look under the **Stop for Futility** column.

23 Binomial Superiority Two-Sample

Click **Recalc**, and click  icon to view the new boundaries. Notice that the futility boundary does not begin until the second look.

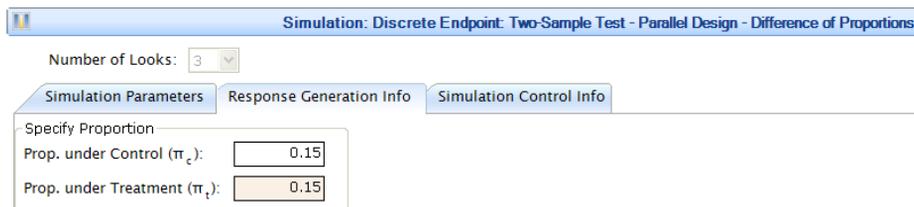

Simulation Tool

Let us verify the operating characteristics of Des8 from Wkbk1 through Simulations.

Select Des8 in the **Library**, and click  icon from **Library** toolbar. Alternatively, right-click on Des8 and select **Simulate**. A new Simulation worksheet will appear.

Let us first verify, by running 10,000 simulated clinical trials that the type-1 error is indeed 5%. That is, we must verify that if the event rate for both the placebo and treatment (Abciximab) arms is 0.15, only about 500 of these simulations will reject H_0 . Click on the **Response Generation** tab, and change the entry in the cell labeled **Prop. Under Treatment** from 0.1 to 0.15.

Next, click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled Sim1.

Select Sim1 in the **Output Preview**. Click  icon to save it to the **Library**. Double-click on Sim1 in the **Library**. The simulation output details will be displayed. In the **Details** output, notice that 487 of the 10,000 simulations rejected H_0 . (This number might vary, depending on the starting seed used for the simulations.) This confirms that the type-1 error is preserved (up to Monte Carlo accuracy) by these stopping boundaries.

Simulation Seed and Elapsed Time

Starting Seed: 1323107
Total Number of Simulations: 10000
Elapsed Time: 00:00:04

Next, run 10,000 simulations under the alternative hypothesis H_1 that the event rate for placebo is 0.15 but the event rate for Abciximab is 0.1. Right-click Sim1 in the Library and click Edit Simulation. In the **Response Generation** tab, enter 0.10 for **Prop. Under Treatment**. Leave all other values as they are, and click **Simulate** to create output Sim2. Select Sim2 in the **Output Preview** and save it to Workbook Wbk1. In the **Overall Simulation Result** table, notice that the lower efficacy stopping boundary was crossed in 7996 out of 10000 simulated trials, which is consistent with 80% power (up to Monte Carlo accuracy) for the original design. Moreover, 393 of these simulations were able to reject the null hypothesis at the very first look. Feel free to

23 Binomial Superiority Two-Sample

experiment further with other simulation options before continuing.

23.1.2 Interim Monitoring

The spending functions discussed above were for illustrative purposes only. They were not used in the actual CAPTURE trial. Instead, the investigators created their own spending function which is closely approximated by the Gamma spending function of Hwang, Shih and DeCani (1990) with parameter -4.5 . The investigators then used this spending function to generate two-sided boundaries for early stopping only to reject H_0 . Moreover since it was felt that the trial would enroll patients rapidly, the study was designed for three unequally spaced looks; one interim analysis after 25% enrollment, a second interim analysis after 50% enrollment, and a final analysis after all the patients had enrolled.

To design this trial, select Des2 in the **Library** and click  icon. In the **Boundary** tab, in the **Efficacy** box, set **Spending Function** to Gamma Family and change the **Parameter** (γ) to -4.5 . In the **Futility** Box, make sure **Boundary Family** is set to None. Click the radio button for **Unequal** in the **Spacing of Looks** box. In the **Looks Details** table change the **Info. Fraction** to 0.25 and 0.50 for Looks 1 and 2,

respectively.

Design Type: Superiority Number of Looks: 3

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|--------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.25 | 0.001 | 3.246 | -3.246 |
| 2 | 0.5 | 0.005 | 2.883 | -2.883 |
| 3 | 1 | 0.050 | 1.977 | -1.977 |

Click **Comptue**. In the **Output Preview** toolbar, click  icon to save this design to Wbk1 in the **Library**. Select Des9 in the **Library**, and click the **IM** icon from the **Library** toolbar. Alternatively, right-click on Des9 and select **Interim Monitoring** dashboard. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

Click on the **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. The first interim look was taken after accruing a total of 350 patients, 175 per treatment arm. There were 30 events on the placebo arm and 14 on the Abciximab arm. Based on these data, the event rate for placebo is $30/175 = 0.17143$ and the event rate for Abciximab is $14/175 = 0.08$. Hence the estimate of

$\delta = 0.08 - 0.17143 = -0.09143$. The unpooled estimate of the SE of $\hat{\delta}$ is

$$\sqrt{\frac{(14/175)(161/175)}{175} + \frac{(30/175)(145/175)}{175}} = 0.035103. \quad (23.7)$$

So the value of test statistic is

$$\frac{\hat{\delta}}{SE} = \frac{-0.09143}{0.035103} = -2.60457 \quad (23.8)$$

We will use the test statistic calculator and specify the values of $\hat{\delta}$ and SE in the same.

23 Binomial Superiority Two-Sample

The test statistic calculator will then compute the test statistic value and post it into the interim monitoring sheet. This process will ensure that the RCI and final adjusted estimates will be computed using the estimates of δ and SE obtained from the observed data.

Click on the **Estimate of δ and Std. Error of δ** radio button. Type in $(14/175) - (30/175)$ for **Estimate of δ** . The **Estimate of δ** is computed as -0.091429 . We can then enter the expression given by (23.7) for the **Std. Error of Estimate of δ** . Click on **Recalc** to get the **Test Statistic** value, then **OK** to continue.

The top panel of the interim monitoring worksheet displays upper and lower stopping boundaries and upper and lower 95% repeated confidence intervals. The lower stopping boundary for rejecting H_0 is -3.239 . Since the current value of the test statistic is -2.605 , the trial continues. The repeated confidence interval is $(-0.205, 0.022)$. We thus conclude, with 95% confidence, that Abciximab arm is unlikely to increase the event rate by any more than 2.2% relative to placebo and might actually reduce the event rate by as much as 20.5%.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | | 95% RCI for δ | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|--------|----------------------|--------|-------------------|----|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.254 | 350 | -2.605 | -0.091 | 0.035 | 3.239 | -3.239 | 0.022 | -0.205 | 0.383 | 1 | 0.97 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

Now click on the second row in the table in the upper section. Then click the **Enter Interim Data** icon. A second interim look was taken after accruing a total of 700 patients, 353 on placebo and 347 on Abciximab. By this time point there were a total of 55 events on the placebo arm and 37 events on the Abciximab arm.

Based on these data, the event rate for placebo is $55/353 = 0.15581$ and the event rate for Abciximab is $37/347 = 0.10663$. Hence the estimate of $\delta = 0.10663 - 0.15581 = -0.04918$. The unpooled estimate of the SE of $\hat{\delta}$ is

$$\sqrt{\frac{(37/347)(310/347)}{347} + \frac{(55/353)(298/353)}{353}} = 0.02544. \quad (23.9)$$

So the value of test statistic is

$$\frac{\hat{\delta}}{SE} = \frac{-0.04918}{0.02544} = -1.9332 \quad (23.10)$$

We will now enter the above values of $\hat{\delta}$ and SE in the test statistic calculator for posting the test statistic value into the interim monitoring sheet. Enter the appropriate values for **Cumulative SS** and **Cumulative Response**. Click the **Recalc** button. The calculator updates the fields - total sample size, δ and SE.

| 3 | | | | | | | | | | | | |

At this interim look, the stopping boundary for early rejection of H_0 is ± 2.868 and the 95% repeated confidence interval is still unable to exclude a difference of zero for the two event rates. Thus the study continues. The **Stopping Boundaries** chart of the dashboard displays the path traced out by the test statistic in relation to the upper and lower stopping boundaries at the first two interim looks. To expand this chart to full size, click the  icon located at the top right of the chart.

This full-sized chart displays stopping boundaries that have been recomputed on the basis of the error spent at each look, as shown on the **Error Spending** chart located at the bottom left of the dashboard. To display this full-sized chart, close the current chart

and click the  icon on the **Error Spending** chart.

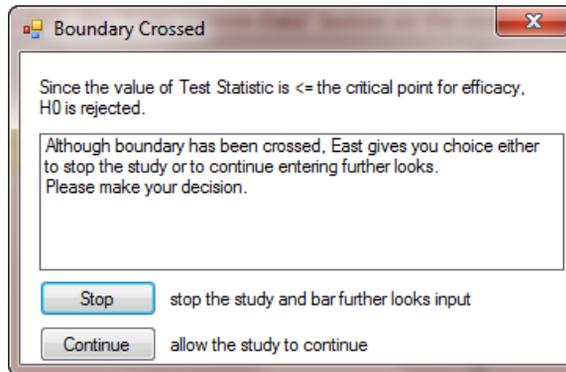

By moving the vertical cursor from left to right on this chart we observe that 0.0012 of the total error was spent by the first interim look and 0.005 of it was spent by the second interim look. Close this chart before continuing.

Although this study was designed for two interim looks and one final look, the data monitoring committee decided to take a third unplanned look after accruing 1050 patients, 532 on placebo and 518 on Abciximab. The error spending function methodology permits this flexibility. Both the timing and number of interim looks may be modified from what was proposed at the design stage. East will recompute the new stopping boundaries on the basis of the error actually spent at each look rather than the error that was proposed to be spent. There were 84 events on the placebo arm and 55 events on the Abciximab arm.

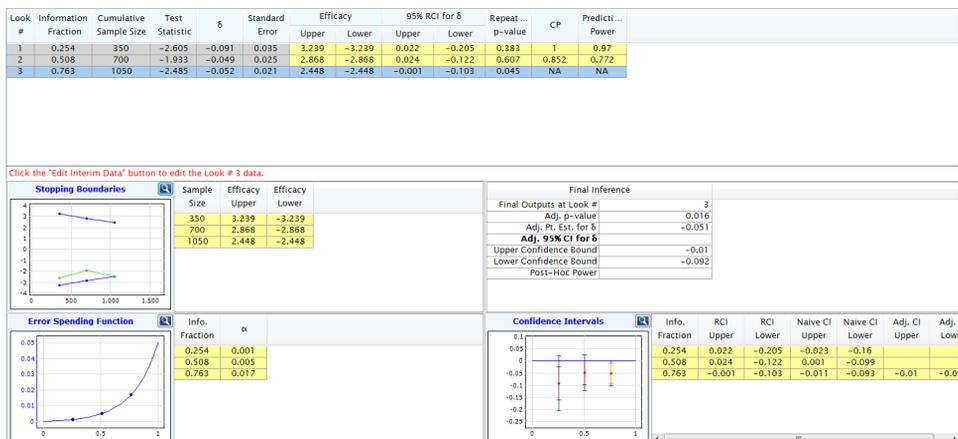

Hence the estimate of $\delta = 0.1062 - 0.1579 = -0.05171$. The unpooled estimate of the SE of δ is 0.02081. So the value of test statistic is -2.4849 . Click the third row of the table in the top portion and then click the **Enter Interim Data** icon. Upon entering this summary information, through the test statistic calculator, into the interim

23 Binomial Superiority Two-Sample

monitoring sheet we observe that the stopping boundary is crossed.

Press the **Stop** button and observe the results in the interim monitoring worksheet.

The 95% repeated confidence interval is $(-0.103, -0.011)$ and it excludes 0 thus confirming that the null hypothesis should be rejected. Once the study is terminated, East computes a final p-value, confidence interval and median unbiased point estimate, all adjusted for the multiple looks, using a stage wise ordering of the sample space as proposed by Tsiatis, Rosner and Mehta (1984). The adjusted p-value is 0.016. The adjusted confidence interval for the difference in event rates is $(-0.092, -0.010)$ and the median unbiased estimate of the difference in event rates is -0.051 . In general, the adjusted confidence interval produced at the end of the study is narrower than the final

repeated confidence interval although both intervals provide valid coverage of the unknown effect size.

23.1.3 Pooled versus Unpooled Designs

The manner in which the data will be analyzed at the interim monitoring stage should be reflected in the study design. We stated at the beginning of this chapter that the test statistic used to track the progress of a binomial endpoint study could be computed by using either the unpooled variance or the pooled variance to standardize the difference of binomial proportions. The design of the CAPTURE trial in Section 23.1.1 and its interim monitoring in Section 23.1.2 were both performed on the basis of the unpooled statistic. In this section we examine how the design would change if we intended to use the pooled statistic for the interim monitoring. It is seen that the change in sample size is negligible if the randomization is balanced. If, however, an unbalanced randomization rule is adopted, there can be substantial sample size differences between the unpooled and pooled designs.

Consider once more the design of the CAPTURE trial with a maximum of $K = 3$ looks, stopping boundaries generated by the **Gamma(-4.5)** Gamma family spending function, and 80% power to detect a drop in the event rate from 0.15 on the placebo arm to 0.1 on the Abciximab arm using a two sided level 0.05 test. We now consider the design of this trial on the basis of the pooled statistic.

Select Des9 in the **Library** and click  icon. Then under the **Test Parameters** tab, in the **Specify Variance** box, select the radio button for **Pooled Estimate**.

It is instructive to compare Des9 with Des10. It is important to remember that Des9 utilized the unpooled design while Des10 utilized the pooled design.

When we compare Des9 and Des10 side by side we discover that there is not much difference in terms of either the maximum or expected sample sizes. This is usually the case for balanced designs. If, however, we were to change the value of the **Allocation Ratio** parameter from 1 to 0.333 (which corresponds to assigning 25% of the patients to treatment and 75% to control), then we would find a substantial difference in the sample sizes of the two plans. In the picture below, Des11 utilizes the unpooled design

while Des12 utilizes the pooled design.

| Expected Under H0 | 1674.503 | 1902.894 |
| Expected Under H1 | 1504.039 | 1749.991 |

Notice that because of the unbalanced randomization the unpooled design is able to achieve 80% power with 229 fewer patients than the pooled design. Specifically, if we decide to monitor the study with the test statistic (23.2) we need to commit a maximum of 1908 patients (Des12), whereas if we decide to monitor the study with the test statistic (23.1) we need to commit a maximum of only 1679 patients (Des11). We can verify, by simulation that both Des11 and Des12 produce 80% power under the alternative hypothesis.

After saving Des11 and Des12 in Workbook1, select Des11 in the **Library** and click the  icon. Next, click the **Simulate** button. The results are displayed below and demonstrate that the null hypothesis was rejected 7710 times in 10,000 trials (77.10%),

23 Binomial Superiority Two-Sample

very close to the desired 80% power.

| Proportion under Treatment (π_t) | 0.1 | 0.1 |
| Diff. in Prop. ($\pi_t - \pi_c$) | -0.05 | -0.05 |
| Variance | Unpooled Estimate | Pooled Estimate |
| Boundary Parameters | | |
| Spacing of Looks | Unequal | Unequal |
| Efficacy Boundary | Gm (-4.5) | Gm (-4.5) |
| Sample Size | | |
| Maximum | 1995 | 1770 |
| Expected Under H0 | 1989.657 | 1765.263 |
| Expected Under H1 | 1787.135 | 1547.235 |

Now the pooled design (Des14) requires a maximum of 1770 patients whereas the unpooled des (Des13) requires a maximum of 1995 patients. This shows that when planning a binomial study with unbalanced randomization, it is important to try both the pooled and unpooled designs and choose the one that produces the same power with fewer patients. The correct choice will depend on the response rates of the control and treatment arms as well as on the value of the fraction assigned to the treatment arm.

23.2 Ratio of Proportions

23.2.1 Trial Design

23.2.2 Trial Simulation

23.2.3 Interim Monitoring

Let π_c and π_t denote the binomial probabilities for the control and treatment arms, respectively, and let $\rho = \pi_t/\pi_c$. We want to test the null hypothesis that $\rho = 1$ against one or two-sided alternatives. It is mathematically more convenient to express this hypothesis testing problem in terms of the difference of the (natural) logarithms. Thus we define $\delta = \ln(\pi_t) - \ln(\pi_c)$. On this metric, we are interested in testing $H_0: \delta = 0$ against one or two-sided alternative hypotheses. Let $\hat{\pi}_{ij}$ denote the estimate of π_i based on n_{ij} observations from Treatment i , up to and including the j th look, $j = 1, \dots, K$, $i = t, c$, where a maximum of K looks are to be taken. Then the estimate of δ at the j -th look is

$$\hat{\delta}_j = \ln(\hat{\pi}_{tj}) - \ln(\hat{\pi}_{cj}) \quad (23.11)$$

with estimated standard error

$$\hat{s}e_j = \left\{ \frac{(1 - \hat{\pi}_{tj})}{n_{tj}\hat{\pi}_{tj}} + \frac{(1 - \hat{\pi}_{cj})}{n_{cj}\hat{\pi}_{cj}} \right\}^{1/2} \quad (23.12)$$

if we use an unpooled estimate for the variance of $\hat{\delta}$ and estimated standard error

$$\hat{s}e_j = \left\{ \frac{(1 - \hat{\pi}_j)}{\hat{\pi}_j} (n_{tj}^{-1} + n_{cj}^{-1}) \right\}^{1/2}, \quad (23.13)$$

where

$$\hat{\pi}_j = \frac{n_{tj}\hat{\pi}_{tj} + n_{cj}\hat{\pi}_{cj}}{n_{tj} + n_{cj}},$$

if we use a pooled estimate for the variance of $\hat{\delta}$.

In general, for any twice-differentiable function $h(\cdot)$, with derivative $h'(\cdot)$, $h(\hat{\pi}_{ij})$ is approximately normal with mean $h(\pi_i)$ and variance $[h'(\pi_i)]^2 \pi_i(1 - \pi_i)/n_{ij}$ for large values of n_{ij} . Using this asymptotic approximation, the test statistic at the j th look is

$$Z_j^{(u)} = \frac{\ln(\hat{\pi}_{tj}) - \ln(\hat{\pi}_{cj})}{\left\{ \frac{(1 - \hat{\pi}_{tj})}{n_{tj}\hat{\pi}_{tj}} + \frac{(1 - \hat{\pi}_{cj})}{n_{cj}\hat{\pi}_{cj}} \right\}^{1/2}}, \quad (23.14)$$

i.e. the ratio of (23.11) and (23.12), if we use an unpooled estimate for the variance of $\ln(\hat{\pi}_{tj}) - \ln(\hat{\pi}_{cj})$ and

$$Z_j^{(p)} = \frac{\ln(\hat{\pi}_{tj}) - \ln(\hat{\pi}_{cj})}{\left\{ \frac{(1 - \hat{\pi}_j)}{\hat{\pi}_j} (n_{tj}^{-1} + n_{cj}^{-1}) \right\}^{1/2}}, \quad (23.15)$$

i.e. the ratio of (23.11) and (23.13), if we use a pooled estimate for the variance of $\ln(\hat{\pi}_{tj}) - \ln(\hat{\pi}_{cj})$.

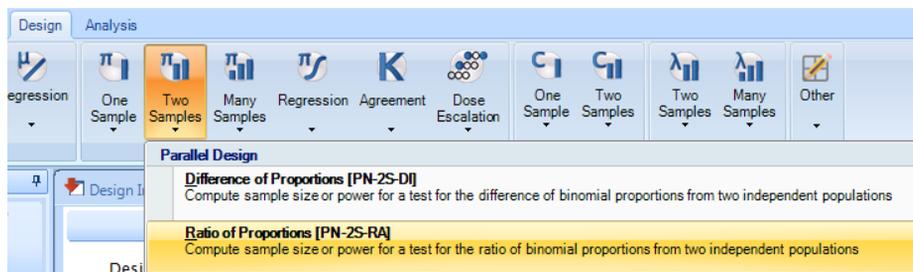

23.2.1 Trial Design

Design objectives and interim results were presented from PRISM, a prospective randomized trial of Heparin alone (control arm), Tirofiban alone (monotherapy arm), and Heparin plus Tirofiban (combination therapy arm), at a DIA Workshop on Flexible Trial Design (Snappin, 2003). The composite endpoint was refractory ischemia, myocardial infarct or death within seven days of randomization. The investigators were interested in comparing the two Tirofiban arms to the control arm with each test being conducted at the 0.025 level of significance (two sided). It was assumed that the control arm has a 30% event rate. Thus, $\pi_t = \pi_c = 0.3$ under H_0 . The investigators wished to determine the sample size to have power of 80% if there was a 25% decline

23 Binomial Superiority Two-Sample

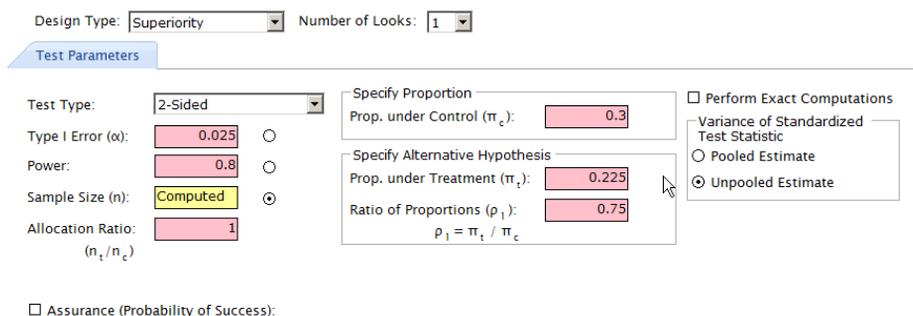

in the event rate, i.e. $\pi_t/\pi_c = 0.75$. It is important to note that the power of the test depends on π_c and π_t , not just the ratio, so different values of the pair (π_c, π_t) with the same ratio will have different solutions.

We will now design a two-arm study that compares the control arm, Heparin, to the combination therapy arm, Heparin plus Tirofiban. First click **Design** tab, then **Two Samples** on the **Discrete** group, and then click **Ratio of Proportions**.

We want to determine the sample size required to have power of 80% when $\pi_c=0.3$ and $\rho = \pi_t/\pi_c=0.75$, using a two-sided test with a type 1 error rate of 0.025.

Single-Look Design- Unpooled Estimate of Variance First consider a study with only one look and equal sample sizes in the two groups. Select the input parameters as displayed below.

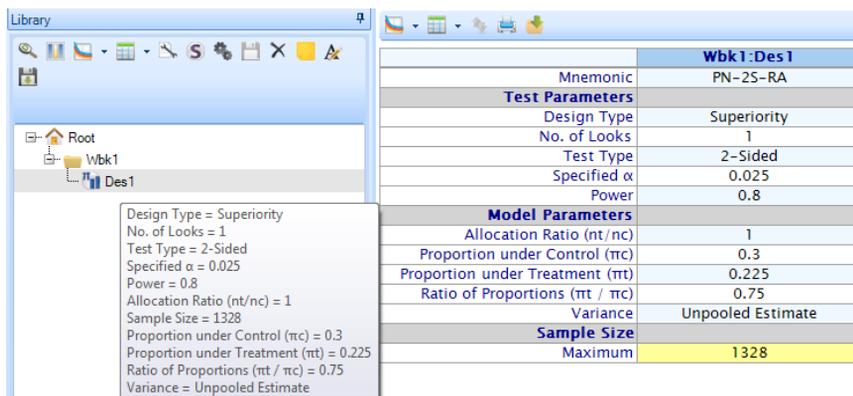

We will use the test statistic (23.14) with the unpooled estimate of the variance. Click the **Compute** button. The design Des1 is shown as a row in the **Output Preview**, located in the lower pane of this window. This single-look design requires a combined

total of 1328 subjects from both treatments in order to attain 80% power.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | π_c | Prop. Treatment (Alt.) | ρ_1 | Variance |
|------|-------------|--------------|-----------|--------------------|-------|-------|-------------|---------|------------------------|----------|-------------------|
| Des1 | Superiority | 1 | 2-Sided | 0.025 | 0.8 | 1 | 1328 | 0.3 | 0.225 | 0.75 | Unpooled Estimate |

You can select this design by clicking anywhere on the row in the **Output Preview**. If you click  , some of the design details will be displayed in the upper pane.

In the **Output Preview** toolbar, click  icon to save this design to Workbook wbk1 in the **Library**.

The screenshot shows the software interface. On the left is the 'Library' pane with a tree view containing 'Root', 'Wbk1', and 'Des1'. A tooltip is displayed over 'Des1' with the following text:

- Design Type = Superiority
- No. of Looks = 1
- Test Type = 2-Sided
- Specified α = 0.025
- Power = 0.8
- Allocation Ratio (nt/nc) = 1
- Sample Size = 1328
- Proportion under Control (π_c) = 0.3
- Proportion under Treatment (π_t) = 0.225
- Ratio of Proportions (π_t / π_c) = 0.75
- Variance = Unpooled Estimate

On the right is the 'Output Preview' pane showing a table for 'Wbk1:Des1' with the following parameters:

| Wbk1:Des1 | |
|--|-------------------|
| Mnemonic | PN-2S-RA |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 2-Sided |
| Specified α | 0.025 |
| Power | 0.8 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Proportion under Control (π_c) | 0.3 |
| Proportion under Treatment (π_t) | 0.225 |
| Ratio of Proportions (π_t / π_c) | 0.75 |
| Variance | Unpooled Estimate |
| Sample Size | |
| Maximum | 1328 |

Three-Look Design - Unpooled Estimate of Variance For the above study, suppose we wish to take up to two equally spaced interim looks and one final look at the accruing data, using the Lan-DeMets (O'Brien-Fleming) stopping boundary. Create a new design by selecting Des1 in the **Library**, and clicking the  icon. In the input, change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab for **Boundary** will appear. Click this tab to reveal the stopping boundary parameters. By default, the Lan-DeMets (O'Brien-Fleming)

23 Binomial Superiority Two-Sample

stopping boundary and equal spacing of looks are selected.

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary

Efficacy
 Boundary Family: Spending Functions
 Spending Function: Lan-DeMets
 Parameter: OF
 Type I Error (α): 0.025

Futility
 Boundary Family: None

Spacing of Looks Equal Unequal Efficacy Boundary: Z Scale

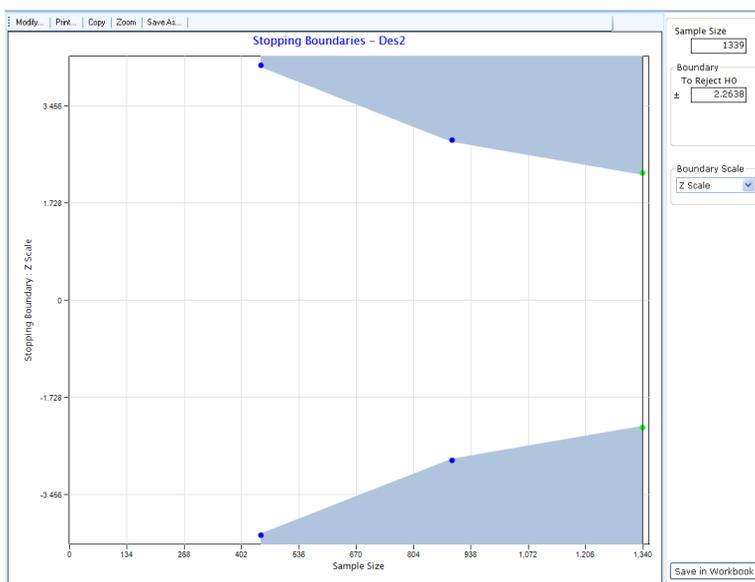

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.333 | 0.000 | 4.171 | -4.171 |
| 2 | 0.667 | 0.004 | 2.846 | -2.846 |
| 3 | 1.000 | 0.025 | 2.264 | -2.264 |

Click **Compute** to create design Des2. The results of Des2 are shown in the **Output Preview** window. With Des2 selected in the **Output Preview**, click  icon. In the **Library**, select the nodes for both Des1 and Des2, by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the two designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 |
|--|-------------------|-------------------|
| Mnemonic | PN-2S-RA | PN-2S-RA |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 1 | 3 |
| Test Type | 2-Sided | 2-Sided |
| Specified α | 0.025 | 0.025 |
| Power | 0.8 | 0.8 |
| Model Parameters | | |
| Proportion under Control (π_c) | 0.3 | 0.3 |
| Proportion under Treatment (π_t) | 0.225 | 0.225 |
| Ratio of Proportions (π_t / π_c) | 0.75 | 0.75 |
| Variance | Unpooled Estimate | Unpooled Estimate |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Boundary Parameters | | |
| Efficacy Boundary | | LD (OF) |
| Spacing of Looks | | Equal |
| Sample Size | | |
| Maximum | 1328 | 1339 |
| Expected Under H0 | | 1337.002 |
| Expected Under H1 | | 1167.474 |

Although, the maximum sample size has increased from 1328 to 1339, using three planned looks may result in a smaller sample size than that required for the single-look design, with an expected sample size of 1168 subjects under the alternative hypothesis ($\pi_c = 0.3, \rho = 0.75$), and still ensures that the power is 80%.

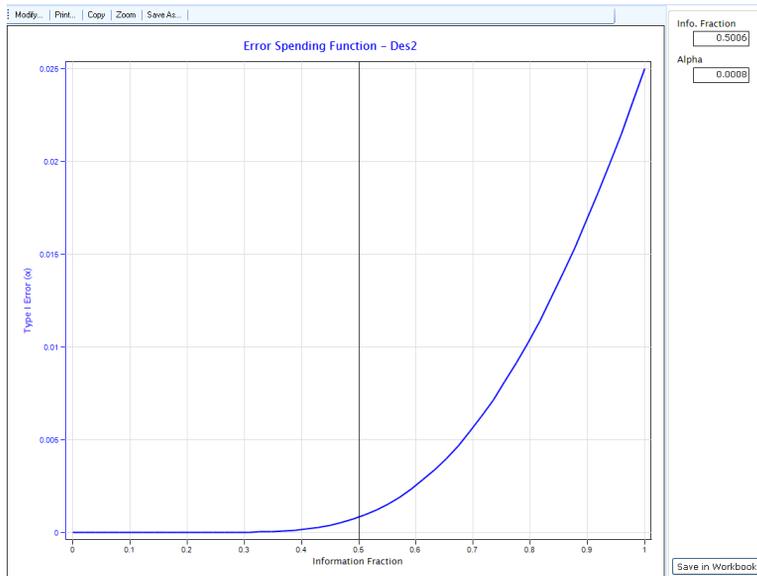

Additional information can also be obtained from Des2. The Lan-DeMets spending function corresponding to the O'Brien-Fleming boundary can be viewed by selecting Des2 in the **Library**, clicking on the  icon, and selecting **Stopping Boundaries**. The following chart will appear:

The alpha-spending function can be viewed by selecting Des2 in the **Library**, clicking

23 Binomial Superiority Two-Sample

on the  icon, and selecting **Error Spending**.

In order to see the stopping probabilities, as well as other characteristics, select Des2 in the **Library**, and click the  icon. The cumulative boundary stopping probabilities are shown in the **Stopping Boundaries** table.

 **Stopping Boundaries: Look by Look**

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | | Boundary Crossing Probability (Incremental) | | | |
|--------|--------------------------|-----------------|---------------------------|------------|--------|---|----------|----------|-------|

| 2 | 0.667 | 893 | 0.004 | 2.845 | -2.845 | 0.002 | 0.002 | 3.838E-8 | 0.368 |
| 3 | 1 | 1339 | 0.025 | 2.264 | -2.264 | 0.01 | 0.01 | 3.834E-8 | 0.424 |

Close this window before continuing.

Three-Look Design - Pooled Estimate of Variance We now consider this design using the statistic (23.15) with the pooled estimate of the variance. Create a new design by selecting Des2 in the **Library**, and clicking the  icon. Under the **Test Parameters** tab, select the radio button for **Pooled Estimate** in the **Variance of**

Standardized Test Statistic box. Leave everything else unchanged. Click the **Compute** button to generate the output for Des3. Save Des3 by selecting it in the **Output Preview** and clicking the  icon. In the **Library**, select the nodes for Des1, Des2, and Des3, by holding the Ctrl Key, and then click the  icon. The upper pane will display the details of the three designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 | Wbk1:Des3 |
|--|-------------------|-------------------|-----------------|
| Mnemonic | PN-25-RA | PN-25-RA | PN-25-RA |

| Power | 0.8 | 0.8 | 0.8 |
| Model Parameters | | | |
| Allocation Ratio (nt/nc) | 1 | 1 | 1 |
| Proportion under Control (π_c) | 0.3 | 0.3 | 0.3 |
| Proportion under Treatment (π_t) | 0.225 | 0.225 | 0.225 |
| Ratio of Proportions (π_t / π_c) | 0.75 | 0.75 | 0.75 |
| Variance | Unpooled Estimate | Unpooled Estimate | Pooled Estimate |
| Boundary Parameters | | | |
| Spacing of Looks | | Equal | Equal |
| Efficacy Boundary | | LD (OF) | LD (OF) |
| Sample Size | | | |
| Maximum | 1328 | 1339 | 1373 |
| Expected Under H0 | | 1337.002 | 1370.956 |
| Expected Under H1 | | 1167.474 | 1200.52 |

For this problem, the test statistic (23.14) with the unpooled estimate of the variance requires a smaller sample size than the test statistic (23.15) with the pooled estimate of the variance. Close this window before continuing.

23.2.2 Trial Simulation

Suppose we want to see the impact of π_t on the behavior of the test statistic (23.14) with the unpooled estimate of the variance. First we consider $\pi_t = 0.225$ as specified by the alternative hypothesis. With Des2 selected in the **Library**, click the  icon. Click on the **Simulate** button. The results of the simulation will appear under Sim1 in the **Output Preview**. Select Sim1 in the **Output Preview** and click  icon to save it to Wbk1. Double-click on Sim1 in the **Library** to display the results of the simulation. Although the actual values may differ, we see that the power is

23 Binomial Superiority Two-Sample

approximately 80% and the probability of stopping early is about 0.37.

Simulation: Discrete Endpoint: Two-Sample Test - Parallel Design - Ratio of Proportions

23.2.3 Interim Monitoring

Consider interim monitoring of Des2. Select Des2 in the **Library**, and click the **IM** icon from the **Library** toolbar. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right.

Suppose that the results are to be analyzed after results are available for every 450 subjects. Click on **Enter Interim Data** icon in the upper left to invoke the **Test Statistics Calculator**. Select the radio-button to enter $\hat{\delta}$ and its standard error. Enter 450 in the box next to **Cumulative Sample Size**. Suppose that after the data were available for first 450 subjects, 230 subjects were randomized to the control arm (c) and 220 subjects were randomized to the treatment arm (t). Of the 230 subjects in the control arm, there were 65 events; of the 220 subjects in the treatment arm, there were 45 events. In the box next to **Estimate of δ** enter: $\ln((45/220)/(65/230))$ and then hit Enter. EAST will compute the estimate of δ . Enter 0.169451 in the box next to **Std.**

23 Binomial Superiority Two-Sample

Error of δ . Next click **Recalc**. You should now see the following:

Test Statistic Calculator

Sample Size and Responses

| | Control | Treatment |
|-------------------------|---------|-----------|
| Cumulative Sample Size: | N/A | N/A |
| Cumulative Response: | N/A | N/A |

Cumulative Sample Size: 450

Input for Binomial end point

Estimate of δ : -0.323

$\delta = \ln(\pi_t / \pi_c)$

Standard Error of Estimate of δ : 0.169

Output

Test Statistic: -1.911

Recalc OK Cancel

Next, click **OK**. The following table will appear in the top section of the IM Dashboard.

| Look # | Information Fraction | Cumulative Completers | Test Statistic | Est. of p | Est. of δ | Std. Error of Est. of δ | Efficacy | | 97.5% RCI for p | | 97.5% RCI for δ | | Repeat ... p-value | CP | Predictive Power |
|--------|----------------------|-----------------------|----------------|-----------|------------------|--------------------------------|----------|--------|-----------------|-------|------------------------|--------|--------------------|-------|------------------|
| | | | | | | | Upper | Lower | Upper | Lower | Upper | Lower | | | |
| 1 | 0.336 | 450 | -1.908 | 0.724 | -0.323 | 0.169 | 4.153 | -4.153 | 1.463 | 0.358 | 0.38 | -1.027 | 0.407 | 0.899 | 0.771 |
| 2 | | | | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | | | | |

Note - Click on  icon to hide or unhide the columns of your interest. RCI for δ . Keeping all the four boxes checked can display RCI on both the scales.

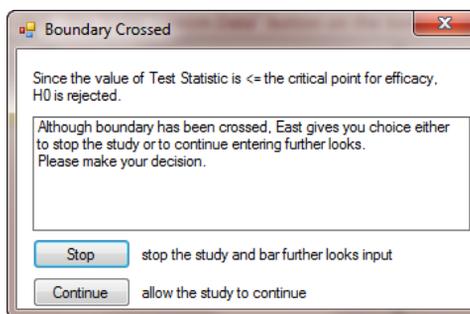

The boundary was not crossed as the value of the test statistic Test Statistic is -1.911, which is within the boundaries (-4.153, 4.153), so the trial continues. After data were available for an additional 450 subjects, the second analysis is performed. Suppose that among the 900 subjects, 448 were randomized to control (*c*) and 452 were randomized to (*t*). Of the 448 subjects in the control arm, there were 132 events; of the 452 subjects in the treatment arm, there were 90 events.

Click on the second row in the table in the upper section. Then click

Enter Interim Data

icon. Enter 900 box next to **Sample Size (Overall)**. Then in the box next to **Estimate of δ** enter: $\ln((90/452)/(132/448))$. Next hit **Enter**, then enter 0.119341 in the box next to **Std. Error of δ** . Click **Recalc** then **OK**.

The value of the test statistic is -3.284, which is less than -2.833, the value of the lower boundary, so the following dialog box appears.

Click on **Stop** to stop any further analyses. The **Final Inference** Table shows that the adjusted point estimate of $\ln(\rho)$ is -0.392 ($p = 0.001$) and the final adjusted 97.5% confidence interval for $\ln(\rho)$ is (-0.659, -0.124).

| Final Inference | |
|--|--------|
| Final Outputs at Look # | 2 |

| Adj. Pt. Est. for p | 0.676 |
| Adj. 97.5% CI for p | |
| Upper Confidence Bound | 0.883 |
| Lower Confidence Bound | 0.517 |
| Adj. Pt. Est. for δ | -0.392 |
| Adj. 97.5% CI for δ | |
| Upper Confidence Bound | -0.124 |
| Lower Confidence Bound | -0.659 |

23 Binomial Superiority Two-Sample

23.3 Odds Ratio of Proportions

23.3.1 Trial Design

23.3.2 Trial Simulation

23.3.3 Interim Monitoring

Let π_t and π_c denote the two binomial probabilities associated with the treatment and the control, respectively. Furthermore, let the odds ratio be

$$\psi = \frac{\pi_t/(1 - \pi_t)}{\pi_c/(1 - \pi_c)} = \frac{\pi_t(1 - \pi_c)}{\pi_c(1 - \pi_t)}. \quad (23.16)$$

We are interested in testing $H_0: \psi = 1$ against the two-sided alternative $H_1: \psi \neq 1$ or against a one-sided alternative $H_1: \psi < 1$ or $H_1: \psi > 1$. It is convenient to express this hypothesis testing problem in terms of the (natural) logarithm of ψ . Let $\hat{\pi}_{tj}$ and $\hat{\pi}_{cj}$ denote the estimates of π_t and π_c based on n_{tj} and n_{cj} observations from the treatment and the control, respectively, up to and including the j th look, $j = 1, \dots, K$, where a maximum of K looks are to be made.

The difference between treatments at the j th look is assessed using

$$\hat{\delta}_j = \ln(\hat{\pi}_{tj}/(1 - \hat{\pi}_{tj})) - \ln(\hat{\pi}_{cj}/(1 - \hat{\pi}_{cj})). \quad (23.17)$$

Using the asymptotic approximation presented in section 23.2, the estimate of the standard error of $\hat{\delta}_j$ at the j th look is

$$\hat{s}e_j = \{1/n_{tj}\hat{\pi}_{tj}(1 - \hat{\pi}_{tj}) + 1/n_{cj}\hat{\pi}_{cj}(1 - \hat{\pi}_{cj})\}^{1/2}, \quad (23.18)$$

and the test statistic at the j -th look is the ratio of $\hat{\delta}_j$, given by (23.17), and the estimate of the standard error of $\hat{\delta}_j$, given by (23.18), namely,

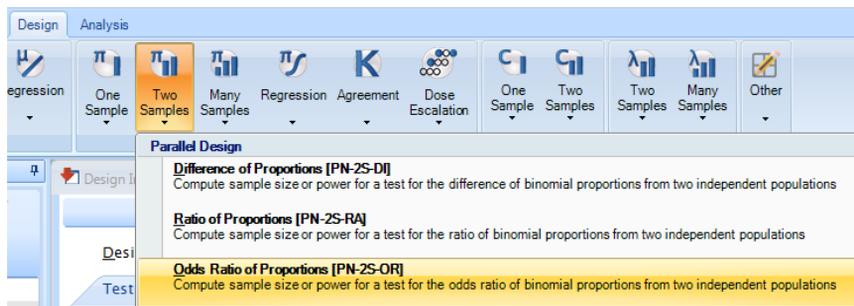

$$Z_j = \frac{\ln(\hat{\pi}_{tj}/(1 - \hat{\pi}_{tj})) - \ln(\hat{\pi}_{cj}/(1 - \hat{\pi}_{cj}))}{\{1/n_{tj}\hat{\pi}_{tj}(1 - \hat{\pi}_{tj}) + 1/n_{cj}\hat{\pi}_{cj}(1 - \hat{\pi}_{cj})\}^{1/2}}. \quad (23.19)$$

23.3.1 Trial Design

Suppose that the response rate for the control treatment is 10% and we hope that the experimental treatment can triple the odds ratio; that is, we desire to increase the response rate to 25%. Although we hope to increase the odds ratio, we solve this problem using a two-sided testing formulation. The null hypothesis $H_0: \psi = 1$ is tested against the two-sided alternative $H_1: \psi \neq 1$. The power of the test is computed at specified values of π_c and ψ . Note that the power of the test depends on π_c and ψ , or equivalently π_c and π_t , not just the odds ratio. Thus, different values of π_c with the same odds ratio will have different solutions.

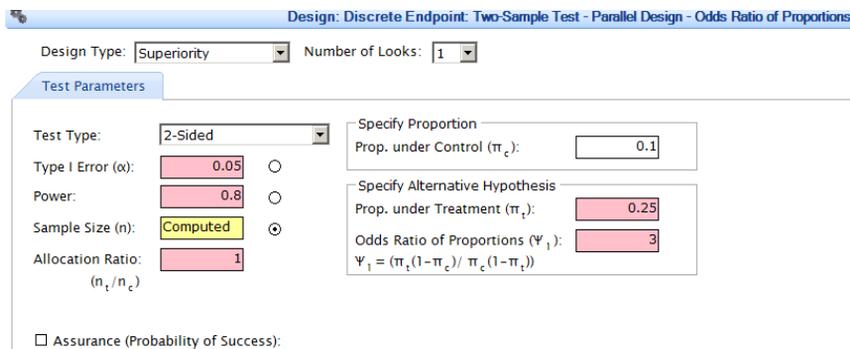

First, click **Design** tab, then click **Two Samples** in the **Discrete** group, and then click

Odds Ratio of Proportions.

Suppose we want to determine the sample size required to have power of 80% when $\pi_c = 0.1$ and $\psi_1 = 3$ using a two-sided test with a type-1 error rate of 0.05.

Single-Look Design First consider a study with only one look and equal sample sizes in the two groups. Enter the appropriate design parameters so that the dialog box appears as shown. Then click **Compute**.

The design Des1 is shown as a row in the **Output Preview**, located in the lower pane of this window. This single-look design requires a combined total of 214 subjects from

23 Binomial Superiority Two-Sample

both treatments in order to attain 80% power.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | π_c | Prop. Treatment (Alt.) | ψ_1 |
|------|-------------|--------------|-----------|--------------------|-------|-------|-------------|---------|------------------------|----------|
| Des1 | Superiority | 1 | 2-Sided | 0.05 | 0.8 | 1 | 214 | 0.1 | 0.25 | 3 |

You can select this design by clicking anywhere on the row in the **Output Preview**. If you click  icon, some of the design details will be displayed in the upper pane. In the **Output Preview** toolbar, click the  icon to save this design to Wbk1 in the **Library**.

| Expected Under H0 | | 216.106 |
| Expected Under H1 | | 185.392 |

Using three planned looks may result in a smaller sample size than that required for the single-look design, with an expected sample size of 186 subjects under the alternative hypothesis ($\pi_c = 0.1, \psi = 3$), and still ensures the power is 80%.

Additional information can also be obtained from Des2. The Lan-DeMets spending function corresponding to the O'Brien-Fleming boundary can be viewed by selecting Des2 in the **Library**, clicking on the  icon, and selecting **Stopping Boundaries**.

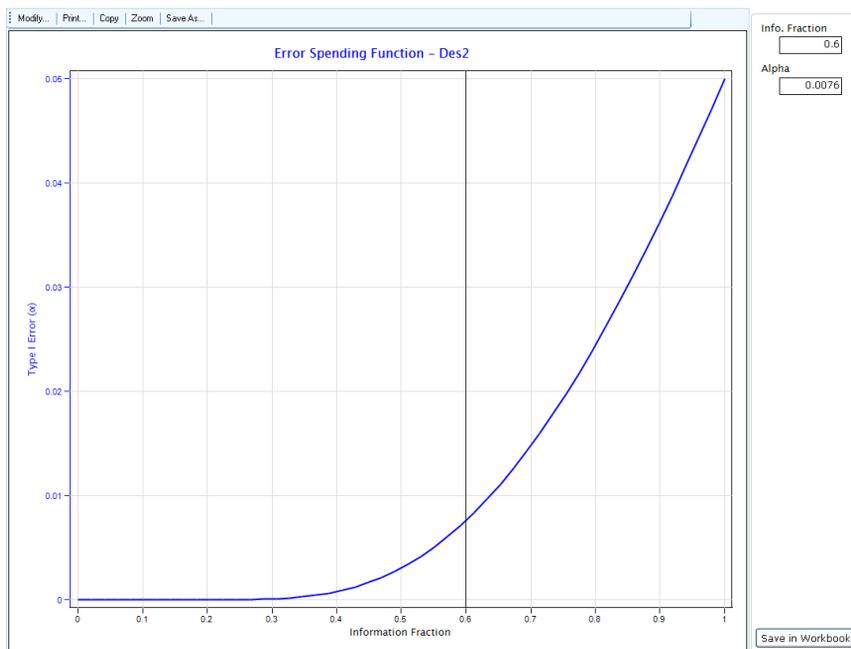

The following chart will appear:

The alpha-spending function can be viewed by selecting Des2 in the **Library**, clicking

23 Binomial Superiority Two-Sample

on the  icon, and selecting **Error Spending**.

In order to see the stopping probabilities, as well as other characteristics, select Des2 in the **Library**, and click the  icon. The cumulative boundary stopping probabilities are shown in the **Stopping Boundaries** table. East displays the stopping boundary, the type-1 error spent and the boundary crossing probabilities under $H_0: \pi_c = 0.1, \psi = 1$ and the alternative hypothesis $H_1: \pi_c = 0.1, \psi = 3$.

☯ **Stopping Boundaries: Look by Look**

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | | Boundary Crossing Probability (Incremental) | | | |
|--------|--------------------------|-----------------|--------------------|------------|--------|---|----------|----------|----------|
| | | | | | | Under H0 | | Under H1 | |
| | | | | Efficacy Z | | Efficacy | | Efficacy | |
| | | | | Upper | Lower | Upper | Lower | Upper | Lower |
| 1 | 0.332 | 72 | 1.995E-4 | 3.72 | -3.72 | 9.975E-5 | 9.975E-5 | 0.018 | 4.517E-8 |
| 2 | 0.668 | 145 | 0.012 | 2.508 | -2.508 | 0.006 | 0.006 | 0.403 | 7.326E-7 |
| 3 | 1 | 217 | 0.05 | 1.993 | -1.993 | 0.019 | 0.019 | 0.38 | 6.513E-7 |

Close this window before continuing.

23.3.2 Trial Simulation

Suppose we want to see the impact of π_t on the behavior of the test statistic (23.19). First we consider $\pi_t = 0.25$ as specified by the alternative hypothesis. With Des2 selected in the **Library**, click  icon. Next, click **Simulate** button. The results of the simulation will appear under Sim1 in the **Output Preview**. Highlight Sim1 in the **Output Preview** and click  icon to save it to workbook Wbk1. Double-click on Sim1 in the **Library** to display the results of the simulation. Although your results may differ slightly, we see that the power is approximately 83% and the probability of stopping early is about 0.39.

☰ Simulation Boundaries and Incremental Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | | Stopping For | | Total Simulations | |
|--------|-----------------|------------|--------|----------------|----------------|-------------------|---------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 72 | 3.72 | -3.72 | 0 | 0 | 0 | 0.000% |
| 2 | 145 | 2.508 | -2.508 | 3878 | 0 | 3878 | 38.780% |
| 3 | 217 | 1.993 | -1.993 | 4432 | 0 | 6122 | 61.220% |
| Total | | | | 8310 | 0 | 10000 | |
| % | | | | 83.100% | 0.000% | | |

Now we consider $\pi_t = 0.225$, which will provide us with the impact if we were too optimistic about the treatment effect. Select Sim1 in the **Library** and click  icon. Under the **Response Generation** tab, enter the value of 0.225 next to **Prop. Under Treatment** (π_t). Click **Simulate**. Although, the actual values may differ, we see that the power is approximately 68% and the probability of stopping early is about 0.26.

☰ Simulation Boundaries and Incremental Boundary Crossing Probabilities

| Look # | Sample Size (n) | Boundaries | | Stopping For | | Total Simulations | |
|--------|-----------------|------------|--------|----------------|----------------|-------------------|---------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |

| Total | | | | 6862 | 0 | 10000 | |
| % | | | | 68.620% | 0.000% | | |

23.3.3 Interim Monitoring

Consider interim monitoring of Des2. Select Des2 in the **Library**, and click 

23 Binomial Superiority Two-Sample

icon from the **Library** toolbar. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right.

Suppose that the results are to be analyzed after results are available for every 70 subjects. Click on **Enter Interim Data** icon in the upper left to invoke the **Test Statistics Calculator**. Select the second radio button on the calculator to enter values of $\hat{\delta}$ and its standard error. Before that enter 70 in the box next to **Cumulative Sample Size**. Suppose, after the data were available for first 70 subjects, 35 subjects were randomized to the control arm (c), of whom 5 experienced a response, and 35 subjects were randomized to the treatment arm (t), of whom 9 subjects experienced a response. In the box next to **Estimate of δ** enter 0.730888 and in the box next to **Std. Error of δ** enter 0.618794. Next click **Recalc**. You should now see the following:

Test Statistic Calculator

Editing Look #1

Set Current Look as Last

Sample Size and Responses

| | Control | Treatment |
|-------------------------|---------|-----------|
| Cumulative Sample Size: | N/A | N/A |
| Cumulative Response: | N/A | N/A |

Cumulative Sample Size: 70

Input for Binomial end point

Estimate of δ : 0.730888

$\delta = \ln(\pi_t(1 - \pi_c)/(\pi_c(1 - \pi_t)))$

Standard Error of Estimate of δ : 0.618794

Output

Test Statistic: 1.181

Recalc OK Cancel

Click **OK** and the following entry will appear in the top section of the IM Dashboard.

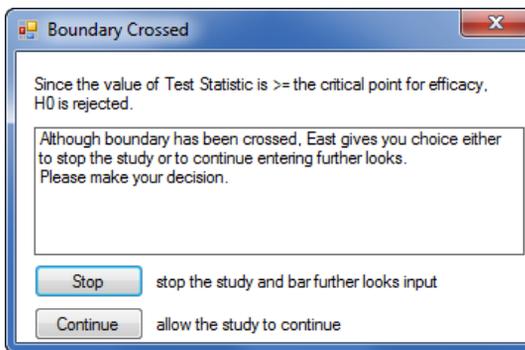

| Look # | Information Fraction | Cumulative Completers | Test Statistic | Est. of ψ | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for ψ | | 95% RCI for δ | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|-----------------------|----------------|----------------|------------------|--------------------------------|----------|--------|--------------------|-------|----------------------|--------|-------------------|-------|-------------------|
| | | | | | | | Upper | Lower | Upper | Lower | Upper | Lower | | | |
| 1 | 0.323 | 70 | 1.181 | 2.077 | 0.731 | 0.619 | 3.777 | -3.777 | 21.502 | 0.201 | 3.068 | -1.606 | 0.751 | 0.548 | 0.53 |
| 2 | | | | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | | | | |

Note - Click on  icon to hide or unhide the columns of your interest.

The boundary was not crossed, as value of the test statistic (1.181) is within the boundaries (-3.777, 3.777), so the trial continues. After data were available for an additional 70 subjects, the second analysis was performed. Suppose that among the 140 subjects, 71 were randomized to *c* and 69 were randomized to *t*.

Click on the second row in the table in the upper section. Then click **Enter Interim Data** icon. Enter 140 in the box next to **Cumulative Sample Size**. Then in the box next to **Estimate of δ** enter: 1.067841 and in the box next to **Std. Error of δ** enter: 0.414083. Next, click on **Recalc** then **OK**.

The test statistic 2.579 exceeds the upper boundary (2.56), so the following screen appears.

Click **Stop** to halt any further analyses. The **Final Inference** Table shows that the adjusted point estimate of $\ln(\psi)$ is 1.068 ($p = 0.01$) and the adjusted 95% confidence

23 Binomial Superiority Two-Sample

interval for $\ln(\psi)$ is (0.256, 1.879).

| Final Inference | |

| Adj. 95% CI for δ | |
| Upper Confidence Bound | 1.879 |
| Lower Confidence Bound | 0.256 |

23.4 Common Odds Ratio of Stratified Tables

23.4.1 Trial Design

23.4.2 Interim Monitoring

Some experiments are performed with several disjoint groups (strata) within each treatment group. For example, multicenter clinical trials are conducted using several investigator sites. Other situations include descriptive subsets, such as baseline and demographic characteristics. Let π_{tg} and π_{cg} denote the two binomial probabilities in Group g , $g = 1, \dots, G$, for the treatment and control, respectively. It is assumed that the odds ratio

$$\psi = \frac{\pi_{tg}/(1-\pi_{tg})}{\pi_{cg}/(1-\pi_{cg})} = \frac{\pi_{tg}(1-\pi_{cg})}{\pi_{cg}(1-\pi_{tg})} \quad (23.20)$$

is the same for each group (stratum). The Cochran-Mantel-Haensel test is used for testing $H_0: \psi = 1$ against the two-sided alternative $H_1: \psi \neq 1$ or against a one-sided alternative $H_1: \psi > 1$ or $H_1: \psi < 1$.

Let $\hat{\pi}_{tjg}$ and $\hat{\pi}_{c jg}$ denote the estimates of π_t and π_c based on n_{tjg} and $n_{c jg}$ observations in Group g from the treatment (t) and the control (c), respectively, up to and including the j th look, $j = 1, \dots, K$, where a maximum of K looks are to be taken.

Then the estimate of $\delta = \ln(\psi)$ from the g -th group at the j -th look is

$$\hat{\delta}_{jg} = \ln\left(\frac{\hat{\pi}_{tjg}}{1-\hat{\pi}_{tjg}}\right) - \ln\left(\frac{\hat{\pi}_{c jg}}{1-\hat{\pi}_{c jg}}\right).$$

Then the estimate of $\delta = \ln(\psi)$ at the j -th look is the average of $\hat{\delta}_{jg}$, $g = 1, \dots, G$;

namely,

$$\hat{\delta}_j = \frac{\sum_{g=1}^G \hat{\delta}_{jg}}{G}$$

or, equivalently,

$$\hat{\delta}_j = \frac{\sum_{g=1}^G (\ln(\frac{\hat{\pi}_{tjg}}{1-\hat{\pi}_{tjg}}) \ln(\frac{\hat{\pi}_{cjg}}{1-\hat{\pi}_{cjg}}))}{G}. \tag{23.21}$$

The estimate of the standard error of $\hat{\delta}_{jg}$ at the j th look is

$$\hat{se}_{jg} = \left\{ \frac{1}{n_{tjg} \hat{\pi}_{tjg} (1 - \hat{\pi}_{tjg})} + \frac{1}{n_{cjg} \hat{\pi}_{cjg} (1 - \hat{\pi}_{cjg})} \right\}^{1/2}.$$

The estimated variance of $\hat{\delta}$ at the j -th look is the average of the variances of $\hat{\delta}_{jg}, g = 1, \dots, G$. Thus,

$$\hat{se}_j = \left\{ \frac{\sum_{g=1}^G \hat{se}_{jg}^2}{G} \right\}^{1/2}. \tag{23.22}$$

The test statistic used at the j -th look is

$$Z_j = \frac{\hat{\delta}_j}{\hat{se}_j}. \tag{23.23}$$

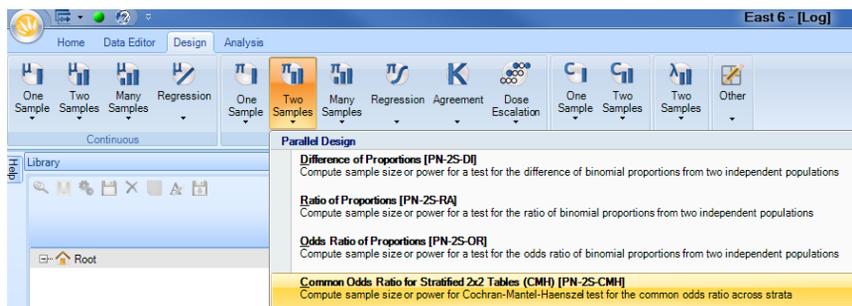

23.4.1 Trial Design

First consider a simple example with two strata, such as males and females, with an equal number of subjects in each stratum and the same response rate of 60% for the control in each stratum. We hope that the experimental treatment can triple the odds ratio. Although we hope to increase the odds ratio, we solve this problem using a two-sided testing formulation. The null hypothesis $H_0: \psi = 1$ is tested against the two-sided alternative $H_1: \psi \neq 1$. The power of the test is computed at specified values of $\pi_{cg}, g = 1, \dots, G$, and ψ .

To begin, click **Design** tab, then click **Two Samples** in the **Discrete** group, and then

23 Binomial Superiority Two-Sample

click **Common Odds Ratio for Stratified 2 x 2 Tables**.

Suppose that we want to determine the sample size required to have power of 80% when $\pi_{c1} = \pi_{c2} = 0.6$ and $\psi = 3$ using a two-sided test with a type-1 error rate of 0.05.

Single-Look Design - Equal Response Rates First consider a study with only one look and equal sample sizes in the two groups. Enter the appropriate test parameters so that the dialog box appears as shown. Then click **Compute**.

Design Type: Superiority Number of Looks: 1

Test Parameters

Test Type: 2-Sided Common Odds Ratio (Ψ): 3 Number of Strata: 2
 $\Psi = \pi_t (1 - \pi_c) / \pi_c (1 - \pi_t)$ (G)

Type I Error (α): 0.05 Power: 0.8

Sample Size (n): Computed Allocation Ratio: 1
 (n_t / n_c)

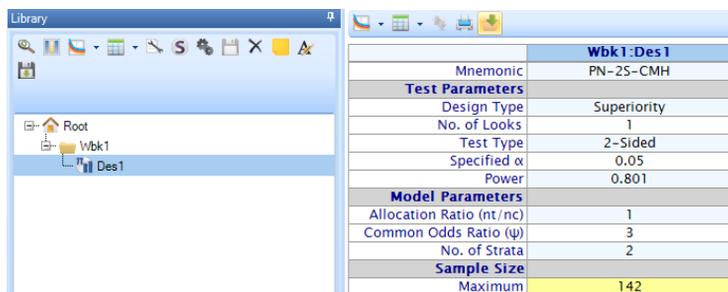

Stratum Specific Input: Equal Unequal

| Stratum # | Stratum Fraction | π_c | π_t |
|-----------|------------------|---------|---------|
| 1 | 0.500 | 0.6 | 0.818 |
| 2 | 0.500 | 0.6 | 0.818 |

The design is shown as a row in the **Output Preview**, located in the lower pane of this window. This single-look design requires a combined total of 142 subjects from both treatments in order to attain 80% power.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | ψ | No. of Strata |
|-------|-------------|--------------|-----------|--------------------|-------|-------|-------------|--------|---------------|
| Des 1 | Superiority | 1 | 2-Sided | 0.05 | 0.801 | 1 | 142 | 3 | 2 |

You can select this design by clicking anywhere on the row in the **Output Preview**. If you click  icon, some of the design details will be displayed in the upper pane. In the **Output Preview** toolbar, click  icon to save this design to workbook Wbk1 in the **Library**.

| Wbk1:Des1 | |
|------------------------------|-------------|
| Mnemonic | PN-2S-CMH |
| Test Parameters | |

| Common Odds Ratio (ψ) | 3 |
| No. of Strata | 2 |
| Sample Size | |
| Maximum | 142 |

Single-Look Design - Unequal Response Rates Now, we consider a more realistic clinical trial. Suppose that males and females respond differently, so that the response rate for males is $\pi_{c1} = 0.6$ and the response rate for females is $\pi_{c2} = 0.3$. First, we consider a study without any interim analyses.

Create a new design by selecting Des1 in the **Library**, and clicking the  icon. Change π_{c2} in the **Stratum Specific Input** table to 0.3 as shown below.

Design Type: Superiority Number of Looks: 1

Test Parameters

Test Type: 2-Sided Common Odds Ratio (Ψ): 3 Number of Strata: 2
 $\Psi = \pi_t (1 - \pi_c) / \pi_c (1 - \pi_t)$ (G)

Type I Error (α): 0.05

Power: 0.8

Sample Size (n): Computed

| Common Odds Ratio (ψ) | 3 | 3 |
| No. of Strata | 2 | 2 |
| Sample Size | | |
| Maximum | 142 | 127 |

This single-look design requires a combined total of 127 subjects from both treatments in order to attain 80% power.

Three-Look Design - Unequal Response Rates For the above study, suppose we wish to take up to two equally spaced interim looks and one final look at the accruing data, using the Lan-DeMets (O'Brien-Fleming) stopping boundary. Create a new design by selecting Des2 in the **Library**, and clicking the  icon. In the input, change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab for **Boundary** will appear. Click this tab to reveal the stopping boundary parameters. By default, the Lan-DeMets (O'Brien-Fleming) stopping boundary and equal spacing of looks are selected.

Design Type: Superiority Number of Looks:

| 2 | 0.667 | 0.012 | 2.511 | -2.511 |
| 3 | 1.000 | 0.050 | 1.993 | -1.993 |

Click the **Compute** button to generate output for Des3. The results of Des3 are shown in the **Output Preview** window. With Des3 selected in the **Output Preview**, click  icon. In the **Library**, select the nodes for Des1, Des2, and Des3 by holding the Ctrl Key, and then click the  icon. The upper pane will display the details of the three designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 | Wbk1:Des3 |
|------------------------------|-------------|-------------|-------------|
| Mnemonic | PN-2S-CMH | PN-2S-CMH | PN-2S-CMH |
| Test Parameters | | | |
| Design Type | Superiority | Superiority | Superiority |
| No. of Looks | 1 | 1 | 3 |
| Test Type | 2-Sided | 2-Sided | 2-Sided |
| Specified α | 0.05 | 0.05 | 0.05 |
| Power | 0.801 | 0.801 | 0.802 |
| Model Parameters | | | |
| Common Odds Ratio (ψ) | 3 | 3 | 3 |
| No. of Strata | 2 | 2 | 2 |
| Allocation Ratio (nt/nc) | 1 | 1 | 1 |
| Boundary Parameters | | | |
| Spacing of Looks | | | Equal |
| Efficacy Boundary | | | LD (OF) |
| Sample Size | | | |
| Maximum | 142 | 127 | 129 |
| Expected Under H0 | | | 128.471 |
| Expected Under H1 | | | 110.157 |

Using three planned looks requires an up-front commitment of 129 subjects, a slight increase over the single-look design, which required 127 subjects. However, the three look design may result in a smaller sample size than that required for the single look design, with an expected sample size of 111 subjects under the alternative hypothesis ($\pi_{c1} = 0.6, \pi_{c2} = 0.3, \psi = 3$), and still ensures that the power is 80%.

By selecting only Des3 in the **Library** and clicking  icon, East displays the stopping boundary, the type-1 error spent and the boundary crossing probabilities under $H_0: \pi_{c1} = 0.6, \pi_{c2} = 0.3, \psi = 1$ and the alternative hypothesis

23 Binomial Superiority Two-Sample

$$H_1: \pi_{c1} = 0.6, \pi_{c2} = 0.3, \psi = 3.$$

☰ Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | | Boundary Crossing Probability (Incremental) | | | |

Close this window before continuing.

Three-Look Design - Unequal Response Rates - Unequal Strata Sizes Some disorders have different prevalence rates across various strata. Consider the above example, but with the expectation that 30% of the subjects will be males and 70% of the subjects will be females. Create a new design by selecting Des3 in the **Library**, and clicking the  icon. Under the **Test Parameters** tab in the **Stratum Specific Input** box select the radio button **Unequal**. You can now edit the **Stratum Fraction** column for Stratum 1. Change this value from 0.5 to 0.3 as shown below.

Design Type: Superiority Number of Looks: 3

Test Parameters Boundary

Test Type: 2-Sided Common Odds Ratio (Ψ): 3 Number of Strata: 2

Type I Error (α): 0.05 $\Psi = \pi_t (1 - \pi_c) / \pi_c (1 - \pi_t)$ (G)

Power: 0.8 Equal Unequal

Sample Size (n): Computed

Allocation Ratio: 1 (n_t/n_c)

|-----------|------------------|---------|---------|
| 1 | 0.3 | 0.6 | 0.818 |
| 2 | 0.7 | 0.3 | 0.563 |

Click the **Compute** button to generate output for Des4. The results of Des4 are shown in the **Output Preview** window. With Des4 selected in the **Output Preview**, click the  icon. In the **Library**, select the rows for Des1, Des2, Des3, and Des4 by holding the Ctrl key, and then click  icon. The upper pane will display the details of the

four designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 | Wbk1:Des3 | Wbk1:Des4 |
|------------------------------|-------------|-------------|-------------|-------------|
| Mnemonic | PN-2S-CMH | PN-2S-CMH | PN-2S-CMH | PN-2S-CMH |
| Test Parameters | | | | |
| Design Type | Superiority | Superiority | Superiority | Superiority |
| No. of Looks | 1 | 1 | 3 | 3 |
| Test Type | 2-Sided | 2-Sided | 2-Sided | 2-Sided |
| Specified α | 0.05 | 0.05 | 0.05 | 0.05 |
| Power | 0.801 | 0.801 | 0.802 | 0.802 |
| Model Parameters | | | | |
| Common Odds Ratio (ψ) | 3 | 3 | 3 | 3 |
| No. of Strata | 2 | 2 | 2 | 2 |
| Allocation Ratio (nt/nc) | 1 | 1 | 1 | 1 |
| Boundary Parameters | | | | |
| Spacing of Looks | | | Equal | Equal |
| Efficacy Boundary | | | LD (OF) | LD (OF) |
| Sample Size | | | | |
| Maximum | 142 | 127 | 129 | 124 |
| Expected Under H0 | | | 128.471 | 123.487 |
| Expected Under H1 | | | 110.157 | 105.856 |

Note that, for this example, unequal sample sizes for the two strata result in a smaller total sample size than that required for equal sample sizes for the two strata.

23.4.2 Interim Monitoring

Consider interim monitoring of Des4. Select Des4 in the **Library**, and click the **IM** icon from the **Library** toolbar. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right.

Suppose that the results are to be analyzed after results are available for every 40 subjects. Click on the **Enter Interim Data** icon in the upper left to invoke the **Test Statistics Calculator**. Enter 40 in the box next to **Cumulative Sample Size**. Suppose that $\hat{\delta}_1 = 0.58$ and $\hat{s}e_1 = 0.23$. Enter these values and click on **Recalc**. You should

23 Binomial Superiority Two-Sample

now see the following:

Test Statistic Calculator

Recalc OK Cancel

Click **OK** and the following table will appear in the top section of the IM Dashboard.

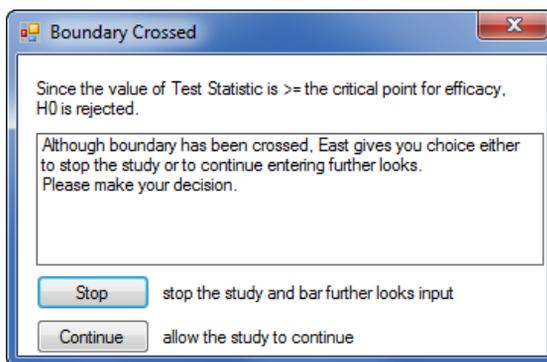

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | | 95% RCI for δ | | Repeat ... p-value | CP | Predicti... Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|--------|----------------------|--------|--------------------|-------|-------------------|
| | | | | | | Upper | Lower | Upper | Lower | | | |
| 1 | 0.323 | 40 | 2.522 | 0.58 | 0.23 | 3.777 | -3.777 | 1.449 | -0.289 | 0.235 | 0.999 | 0.959 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

The boundary was not crossed, as value of the test statistic (2.522) is within the boundaries (-3.777, 3.777), so the trial continues. Click on the second row in the table in the upper section. Then click the **Enter Interim Data** icon. Enter 80 in the box next to **Cumulative Sample Size**. Suppose that $\hat{\delta}_2 = 0.60$ and $\hat{s}e_2 = 0.21$. Enter these

values and click **Recalc**. You should now see the following:

Click the **OK** button. The test statistic 2.857 exceeds the upper boundary (2.56), so the following dialog box appears.

Click **Stop** to stop any further analyses. The **Final Inference** Table shows the adjusted point estimate of $\ln(\psi)$ is 0.600 ($p = 0.004$) and the adjusted 95% confidence interval

23 Binomial Superiority Two-Sample

for $\ln(\psi)$ is (0.188, 1.011).

| Final Inference | |

23.5 Fisher's Exact Test (Single Look)

23.5.1 Trial Design

In some experimental situations, the normal approximation to the binomial distribution may not be appropriate, such as the probabilities of interest are large or small. This may lead to incorrect p-values, and thus the incorrect conclusion. For this reason, Fisher's exact test may be used. Let π_t and π_c denote the two response probabilities for the treatment and the control, respectively. Interest lies in testing $H_0: \pi_t = \pi_c$ against the two-sided alternative $H_1: \pi_t \neq \pi_c$. Results are presented here only for the situation where there is a single analysis; that is, no interim analysis, for the two-sided test with equal sample sizes for the two treatments.

Let $\hat{\pi}_t$ and $\hat{\pi}_c$ denote the estimates of π_t and π_c , respectively, based on $n_t = n_c = 0.5N$ observations from the treatment (t) and the control (c). The parameter of interest is $\delta = \pi_t - \pi_c$, which is estimated by $\hat{\delta} = \hat{\pi}_t - \hat{\pi}_c$. The estimate of the standard error used in the proposed test statistic uses of the pooled estimate of the common value of π_t and π_c under H_0 , given by

$$\hat{s}e = \frac{2\{\hat{\pi}(1 - \hat{\pi})\}^{1/2}}{N}, \tag{23.24}$$

where $\hat{\pi} = 0.5(\hat{\pi}_t + \hat{\pi}_c)$.

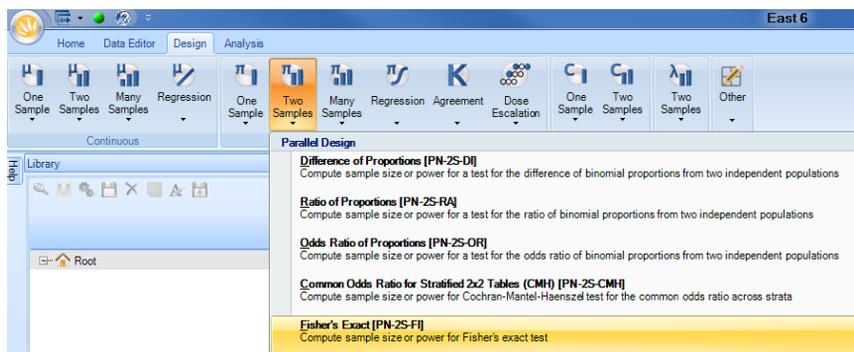

Incorporating a continuity correction factor, the test statistic is

$$Z = \frac{|\hat{\delta}|2/N}{\hat{s}e}. \tag{23.25}$$

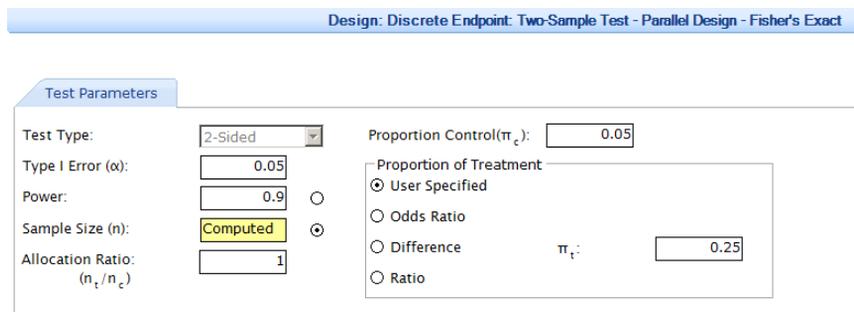

23.5.1 Trial Design

Consider the example where the probability of a response for the control is 5% and it is

hoped that the experimental treatment can increase this rate to 25%. First, in the **Discrete** area, click **Two Samples** on the **Design** tab, and then click **Fisher Exact Test**.

Suppose we want to determine the sample size required to have power of 90% when $\pi_c = 0.05$ and $\pi_t = 0.25$ using a two-sided test with a type-1 error rate of 0.05. Enter the appropriate test parameters so that the dialog box appears as shown. Then click **Compute**.

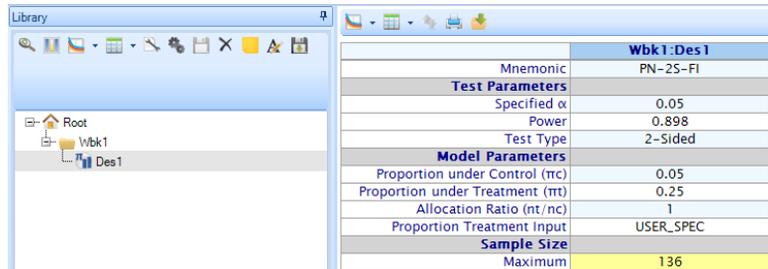

The design is shown as a row in the **Output Preview**, located in the lower pane of this window. This single-look design requires a combined total of 136 subjects from both treatments in order to attain 90% power.

| ID | Specified α | Power | Sample Size | Test Type | π_c | Prop. Treatment (Alt.) | nt / nc | Treat. Input |
|------|--------------------|-------|-------------|-----------|---------|------------------------|---------|--------------|
| Des1 | 0.05 | 0.898 | 136 | 2-Sided | 0.05 | 0.25 | 1 | USER_SPEC |

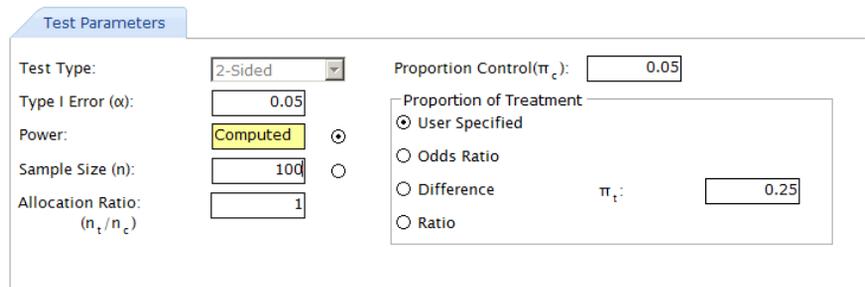

23 Binomial Superiority Two-Sample

You can select this design by clicking anywhere along the row in the **Output Preview**. If you click  icon, some of the design details will be displayed in the upper pane. In the **Output Preview** toolbar, click the  icon to save this design to Workbook1 in the **Library**.

| Wbk1:Des1 | |
|--|-----------|
| Mnemonic | PN-2S-FI |
| Test Parameters | |
| Specified α | 0.05 |
| Power | 0.898 |
| Test Type | 2-Sided |
| Model Parameters | |
| Proportion under Control (π_c) | 0.05 |
| Proportion under Treatment (π_t) | 0.25 |
| Allocation Ratio (n_t/n_c) | 1 |
| Proportion Treatment Input | USER_SPEC |
| Sample Size | |
| Maximum | 136 |

Suppose that this sample size is larger than economically feasible and it is desired to evaluate the power when a total of 100 subjects are enrolled. Create a new design by selecting Des1 in the **Library**, and clicking the  icon. In the input, select the radio button in the box next to **Power**. The box next to **Power** will now say Computed, since we wish to compute power. In the box next to **Sample Size (n)** enter 100.

Test Parameters

Test Type: 2-Sided

Click **Compute** to create design Des2. The results of Des2 are shown in the **Output Preview** window. With Des2 selected in the **Output Preview**, click the  icon. In the **Library**, select the rows for both Des1 and Des2, by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the two designs

side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 |
|--|-----------|-----------|
| Mnemonic | PN-2S-FI | PN-2S-FI |
| Test Parameters | | |
| Specified α | 0.05 | 0.05 |
| Power | 0.898 | 0.748 |
| Test Type | 2-Sided | 2-Sided |
| Model Parameters | | |
| Proportion under Control (π_c) | 0.05 | 0.05 |
| Proportion under Treatment (π_t) | 0.25 | 0.25 |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Proportion Treatment Input | USER_SPEC | USER_SPEC |
| Sample Size | | |
| Maximum | 136 | 100 |

Des2 yields a power of approximately 75% as shown. Noting that 100 subjects is economically feasible and yields reasonable power, the question arises as to the sample size required to have 80%, which might still be economically feasible. This can be accomplished by selecting Des1 in the **Library**, and clicking the  icon. In the input, change the **Power** from 0.9 to 0.8. Click **Compute** to generate the output for Des3. The results of Des3 are shown in the **Output Preview** window. With Des3 selected in the **Output Preview**, click the  icon. In the **Library**, select the rows for both Des1, Des2, and Des3 by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the three designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 | Wbk1:Des3 |
|--|-----------|-----------|-----------|

| Proportion Treatment Input | USER_SPEC | USER_SPEC | USER_SPEC |
| Sample Size | | | |
| Maximum | 136 | 100 | 110 |

23 Binomial Superiority Two-Sample

Entering 0.8 for the power yields a required sample size of 110 subjects.

23.6 Assurance (Probability of Success)

Assurance, or probability of success, is a Bayesian version of power, which corresponds to the (unconditional) probability that the trial will yield a statistically significant result. Specifically, it is the prior expectation of the power, averaged over a prior distribution for the unknown treatment effect (see O'Hagan et al., 2005). For a given design, East allows you to specify a prior distribution, for which the assurance or probability of success will be computed. First, enter the following values in the Input window: A 3-look design for testing the difference in proportions of two distinct populations with Lan-DeMets(OF) efficacy only boundary, Superiority Trial, 1-sided test, 0.025 type-1 error, 80% power, $\pi_c = 0.15$, and $\pi_t = 0.1$.

Select the **Assurance** checkbox in the Input window. The following options will appear as below.

To address our uncertainty about the treatment proportion, we specify a prior distribution for π_t . In the **Distribution** list, click **Beta**, and in the **Input Method** list, click **Beta Parameters (a and b)**. Enter the values of $a = 11$ and $b = 91$. Recall that the mode of the Beta distribution is $\frac{a-1}{a+b-2}$. Thus, these parameter values generate a Beta distribution that is peaked at 0.1, which matches the assumed treatment

proportion. Click **Compute**.

Assurance (Probability of Success) 0.597

Prior Distribution for: n_t Distribution: Beta

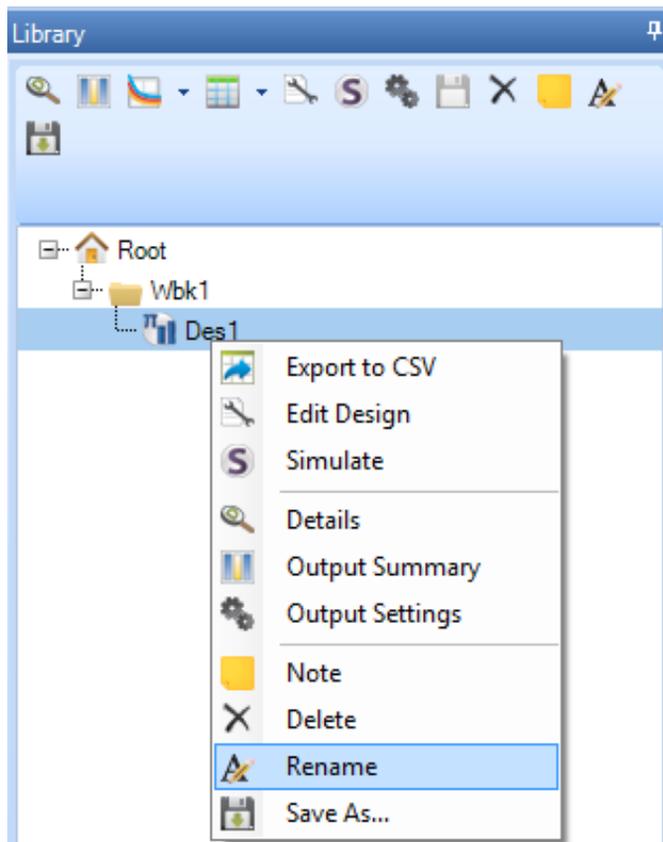

Input Method: Beta Parameters (a and b)

Parameters of Distribution of n_t

a: 11 b: 91

The computed probability of success (0.597) is shown above. Note that for this prior, assurance is very less than the specified power (0.8); incorporating the uncertainty about π_t has yielded a much less optimistic estimate of power. Save this design in the **Library** and rename it as Bayes1.

23 Binomial Superiority Two-Sample

East also allows you to specify an arbitrary prior distribution through a CSV file. In the **Distribution** list, click **User Specified**, and then click **Browse...** to select the CSV file where you have constructed a prior.

Assurance (Probability of Success) 0.735
 Prior Distribution for: n_t Distribution: User Specified
D:\Work\EAST6.3\Assurance_Prior.c Browse...

If you are specifying a prior for one parameter only (either π_c or π_t , but not both), then the CSV file should contain two columns, where the first column lists the grid points

for the parameter of interest, and the second column lists the prior probability assigned to each grid point. If you are specifying priors for both π_c and π_t , the CSV file should contain four columns (from left to right): values of π_c , probabilities for π_c , values of π_t , and probabilities for π_t . The number of points for π_c and number of points for π_t may differ. For example, we consider a 5-point prior for π_t only, with probability = 0.2 at each point.

| | A | B |
|---|------|-----|
| 1 | 0.08 | 0.2 |
| 2 | 0.09 | 0.2 |
| 3 | 0.1 | 0.2 |
| 4 | 0.11 | 0.2 |
| 5 | 0.12 | 0.2 |

Once the CSV filename and path has been specified, click **Compute** to calculate the assurance, which will be displayed in the box below:

Assurance (Probability of Success): 0.735

Prior Distribution for: n_t Distribution: User Specified

D:\Work\East62Manual\Assurance.c Browse...

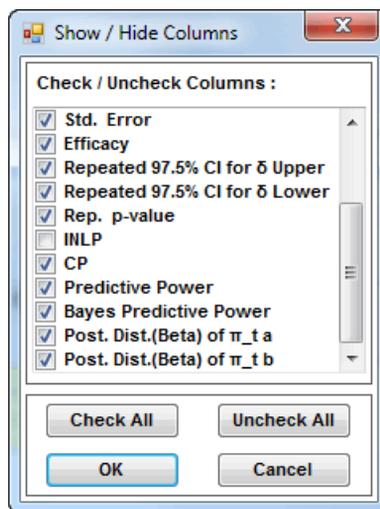

As stated in O’Hagan et al. (2005, p.190): “Assurance is a key input to decision-making during drug development and provides a reality check on other methods of trial design.” Indeed, it is not uncommon for assurance to be much lower than the specified power. The interested reader is encouraged to refer to O’Hagan et al. for further applications and discussions on this important concept.

23.7 Predictive Power and Bayesian Predictive Power

Similar Bayesian ideas can be applied to conditional power for interim monitoring. Rather than calculating conditional power for a single assumed value of the treatment effect, δ , such as at $\hat{\delta}$, we may account for the uncertainty about δ by taking a weighted average of conditional powers, weighted by the posterior distribution for δ . East calculates an average power, called the **predictive power** (Lan, Hu, & Proschan, 2009), assuming a diffuse prior for the drift parameter, η . In addition, if the user specified a beta prior distribution at the design stage to calculate assurance, then East will also calculate the average power, called **Bayesian predictive power**, for the corresponding posterior. We will demonstrate these calculations for the design renamed as Bayes1 earlier.

23 Binomial Superiority Two-Sample

In the **Library**, right-click Bayes1 and click **Interim Monitoring**, then click  in the toolbar of the IM Dashboard.

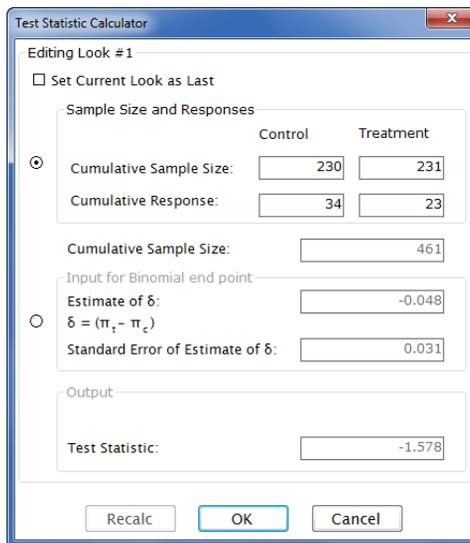

In the Show/Hide Columns window, make sure to show the columns for: CP (Conditional Power), Predictive Power, Bayes Predictive Power, Posterior Distribution of $\pi_t a$, and Posterior Distribution of $\pi_t b$, and click **OK**. The following columns will be added to the main grid of the IM Dashboard.

| CP | Predictive Power | Bayes Predictive Power | Post. Dist.(Beta) of π_t | |
|----|------------------|------------------------|------------------------------|---|
| | | | a | b |
| | | | | |
| | | | | |

In the toolbar of the IM Dashboard, open the Test Statistic Calculator by clicking **Enter Interim Data**. In order to appropriately update the posterior distribution, you will need to use the Test Statistic Calculator to enter the sample size and number of responses for each arm. Enter 34 events out of 230 patients in the control arm, and 23

out of 231 patients in the treatment arm, then click **OK**.

The main grid of the IM Dashboard will be updated as follows. In particular, notice the differing values for CP and the Bayesian measures of power.

| CP | Predictive Power | Bayes Predictive Power | Post. Dist.(Beta) of π_t | |
|-------|------------------|------------------------|------------------------------|-----|
| | | | a | b |
| 0.823 | 0.705 | 0.74 | 34 | 299 |
| | | | | |

24 *Binomial Non-Inferiority Two-Sample*

In a binomial non-inferiority trial the goal is to establish that the response rate of an experimental treatment is **no worse than** that of an active control, rather than attempting to establish that it is superior. A therapy that is demonstrated to be non-inferior to the current standard therapy for a particular indication might be an acceptable alternative if, for instance, it is easier to administer, cheaper, or less toxic. Non-inferiority trials are designed by specifying a non-inferiority margin. The amount by which the response rate on the experimental arm is worse than the response rate on the control arm must fall within this margin in order for the claim of non-inferiority to be sustained. In this chapter, we shall design and monitor non-inferiority trials in which the non-inferiority margin is expressed as either a difference, a ratio, or an odds ratio of two binomial proportions. The difference is examined in Section 24.1. This is followed by two formulations for the ratio: the Wald formulation in Section 24.2 and the Farrington-Manning formulation in Section 24.3. The odds ratio formulation is presented in Section 24.4.

24.1 *Difference of Proportions*

24.1.1 *Trial Design*

24.1.2 *Trial Simulation*

24.1.3 *Interim Monitoring*

Let π_c and π_t denote the response rates for the control and experimental treatments, respectively. Let $\delta = \pi_t - \pi_c$. The null hypothesis is specified as

$$H_0: \delta = \delta_0$$

and is tested against one-sided alternative hypotheses. If the occurrence of a response denotes patient benefit rather than harm, then $\delta_0 > 0$ and the alternative hypothesis is

$$H_1: \delta < \delta_0$$

or equivalently as

$$H_1: \pi_t > \pi_c - \delta_0 .$$

Conversely, if the occurrence of a response denotes patient harm rather than benefit, then $\delta_0 < 0$ and the alternative hypothesis is

$$H_1: \delta > \delta_0$$

or equivalently as

$$H_1: \pi_t < \pi_c - \delta_0 .$$

For any given π_c , the sample size is determined by the desired power at a specified value of $\delta = \delta_1$. A common choice is $\delta_1 = 0$ (or equivalently $\pi_t = \pi_c$) but East permits you to power the study at any value of δ_1 which is consistent with the choice of H_1 .

Let $\hat{\pi}_{tj}$ and $\hat{\pi}_{cj}$ denote the estimates of π_t and π_c based on n_{tj} and n_{cj} observations from the experimental and control treatments, respectively, up to and including j -th look, $j = 1, \dots, K$, where a maximum of K looks are to be made. The test statistic at the j -th look is

$$Z_j = \frac{\hat{\delta}_j - \delta_0}{\text{se}(\hat{\delta}_j)} \tag{24.1}$$

where

$$\hat{\delta}_j = \hat{\pi}_{cj} - \hat{\pi}_{tj} \tag{24.2}$$

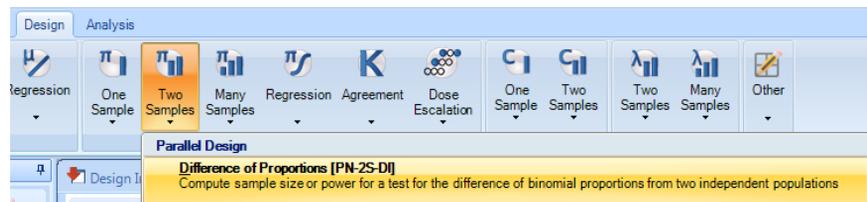

and

$$\text{se}(\hat{\delta}_j) = \sqrt{\frac{\hat{\pi}_{cj}(1 - \hat{\pi}_{cj})}{n_{cj}} + \frac{\hat{\pi}_{tj}(1 - \hat{\pi}_{tj})}{n_{tj}}} \tag{24.3}$$

24.1.1 Trial Design

The 24-week disease-free rate with a standard therapy for HIV is 80%. Suppose that the claim of non-inferiority for an experimental therapy can be sustained if its response rate is greater than 75%; i.e., the non-inferiority margin is $\delta_0 = 0.05$. For studies of this type, we specify inferiority as the null hypothesis, non-inferiority as the alternative hypothesis, and attempt to reject the null hypothesis using a one-sided test. We will specify to East that, under the null hypothesis H_0 , $\pi_c = 0.8$ and $\pi_t = 0.75$. We will test this hypothesis with a one-sided level 0.05 test. Suppose we require 90% power at the alternative hypothesis, H_1 , that both response rates are equal to the null response rate of the control arm, i.e. $\delta_1 = 0$. Thus, under H_1 , we have $\pi_c = \pi_t = 0.8$.

To begin click **Two Samples** on the **Design** tab in the **Discrete** group, and then click **Difference of Proportions**. inxxnon-inferiority,binomial

Single-Look Design Powered at $\delta = 0$ To begin with, suppose we will design a single-look study for rejection of H_0 only, with 90% power at a 0.025 significance level. Enter the relevant parameters into the dialog box as shown below. In the drop

24 Binomial Non-Inferiority Two-Sample

down box next to **Trial** be sure to select Noninferiority.

Assurance (Probability of Success)

Now click **Compute**. The design is shown as a row in the Output Preview located in the lower pane of this window. The single-look design requires a combined total of 2690 patients on both arms in order to attain 90% power. We can, however, reduce the expected sample size without any loss of power if we use a group sequential design. This is considered next.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | ttc | Prop. Treatment (Alt.) | Prop. Treatment (Null) | δ_1 | δ_0 |
|------|----------------|--------------|-----------|--------------------|-------|-------|-------------|-----|------------------------|------------------------|------------|------------|

Before continuing we will save Design1 to the **Library**. You can select this design by clicking anywhere along the row in the **Output Preview**. Some of the design details will be displayed in the upper pane, labeled **Compare Designs**. In the **Output Preview** toolbar, click the  icon to save this design to Workbook1 in the **Library**. If you hover the cursor over Design1 in the Library, a tooltip will appear that

summarizes the input parameters of the design.

Three-Look Design Powered at $\delta = 0$ For the above study, suppose we wish to take up to two interim looks and one final look at the accruing data. Create a new design by selecting Design1 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab **Boundary Info** will appear. Clicking on this tab will reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. By default, there is an efficacy boundary (to reject H0) selected, but no futility boundary (to reject H1). The **Boundary Family** specified is of the Spending Functions type. The default **Spending function** is the Lan-DeMets (Lan & DeMets, 1983), with **Parameter OF** (O’Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O’Brien and Fleming (1979).

Now suppose, in our example, that the three looks are unequally spaced, with the first look being taken after 50% of the committed accrual, and the second look being taken when after 75% of the committed accrual. Under **Spacing of Looks** in the **Boundary Info** tab, click the **Unequal** radio button. The column titled **Info. Fraction** in the **Look Details** table can be edited to modify the relative spacing of the analyses. The information fraction refers to the proportion of the maximum (yet unknown) sample size. By default, this table displays equal spacing. Enter the new information fraction values as shown below and click **Recalc** to see the updated values of the stopping

24 Binomial Non-Inferiority Two-Sample

boundaries populated in the **Look Details** table.

| Expected Under H_0 | | 2732.345 |
| Expected Under H_1 | | 2093.682 |

Let us examine the design output from Design2. The maximum number of subjects that we must commit to this study in order to achieve 90% power is 2740. That is 50 patients more than are needed for Design1. However, since Design1 is a single-look design, there is no prospect of saving resources if indeed H_1 is true and the two treatments have the same response rates. In contrast, Design2 permits the trial to stop early if the test statistic crosses the stopping boundary. For this reason, the expected sample size under H_1 is 2094, a saving of 596 patients relative to Design1. If H_0 is true, the expected sample size is 2732 and there is no saving of patient resources. In order to see the stopping probabilities, as well as other characteristics, select Design2 in the **Library**, and click the  icon. The cumulative boundary stopping

probabilities are shown in the **Stopping Boundaries** table.

To display a chart of average sample number (ASN) versus the effect size, $\pi_t - \pi_c$, select Design2 in the **Library** and click on the  icon and select **Average Sample Number (ASN)**. To display a chart of power versus treatment size, select Design2 in the **Library** and click on the  icon and select **Power vs. Treatment Effect (δ)**.

In Design2, we utilized Lan-DeMets (Lan & DeMets, 1983) spending function, with **Parameter** OF (O'Brien-Fleming) to generate the stopping boundary for early stopping under H_1 . One drawback of Design2 is the large expected sample size if H_0 is true. We can guard against this eventuality by introducing a futility boundary which will allow us to stop early if H_0 is true. A popular approach to stopping early for futility is to compute the conditional power at each interim monitoring time point and stop the study if this quantity is too low. This approach is somewhat arbitrary since there is no guidance as to what constitutes low conditional power. In East, we compute futility boundaries that protect β , the type-2 error, so that the power of the study will not deteriorate. This is achieved by using a β -spending function to generate the futility boundary. Thereby the type-2 error will not exceed β and the power of the study will be preserved. This approach was published by Pampallona and Tsiatis (1994).

Suppose we now wish to include a futility boundary. To design this trial select Design2 in the **Library** and click the  icon. In the **Boundary Info** tab, in the **Futility** box, set **Boundary Family** to Spending Function. Change the **Spending Function** to Gamma Family and change the **Parameter** (Γ) to -8 . This family is parameterized by the single parameter γ which can take all possible non-zero values.

24 Binomial Non-Inferiority Two-Sample

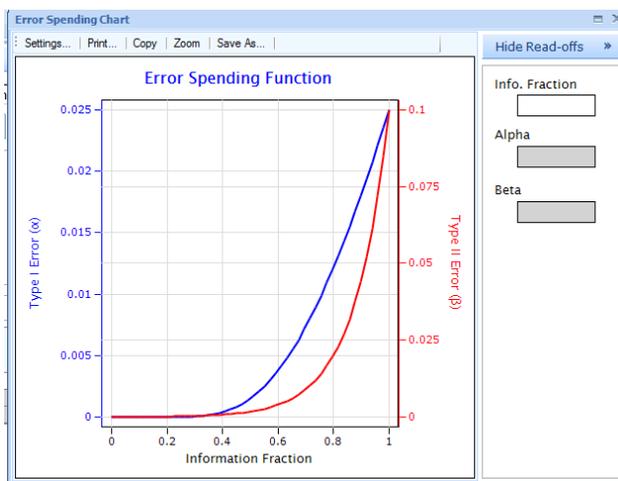

Its functional form is

$$\beta(t) = \frac{\beta(1 - e^{-\gamma t})}{(1 - e^{-\gamma})}. \tag{24.4}$$

Next click **Refresh Boundary**. Your screen should now look like the following:

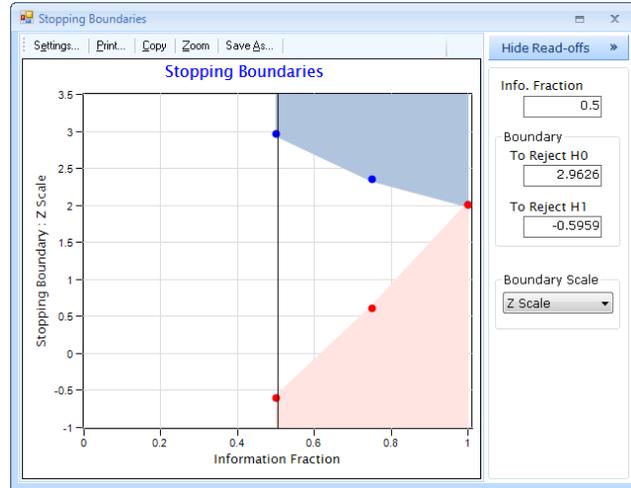

| Look # | Info. Fraction | Stop for Efficacy | Stop for Futility | Cum. α Spent | Efficacy Boundary | Cum. β Spent | Futility Boundary |
|--------|----------------|-------------------------------------|-------------------------------------|--------------|-------------------|--------------|-------------------|
| 1 | 0.500 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.002 | 2.963 | 0.002 | -0.596 |
| 2 | 0.750 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.010 | 2.359 | 0.014 | 0.611 |
| 3 | 1.000 | <input checked="" type="checkbox"/> | <input checked="" type="checkbox"/> | 0.025 | 2.014 | 0.100 | 2.014 |

On the **Boundary Info** tab, you may also click the or icons to view plots of the error spending functions, or stopping boundaries, respectively.

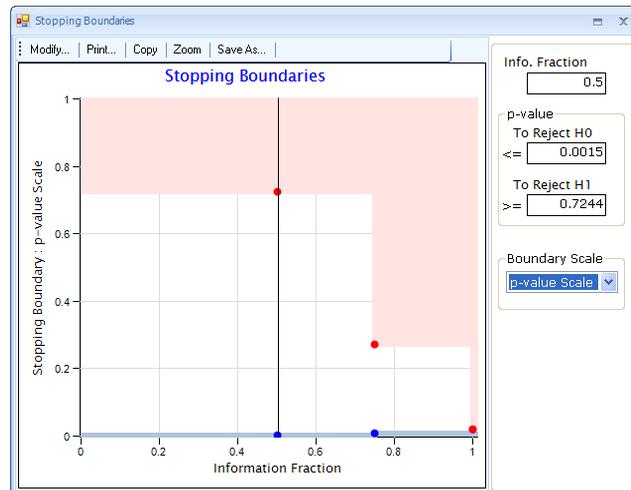

Notice how conservative the β -spending function is compared to the α -spending

function. Its rate of error spending is almost negligible until about 60% of the information has accrued.

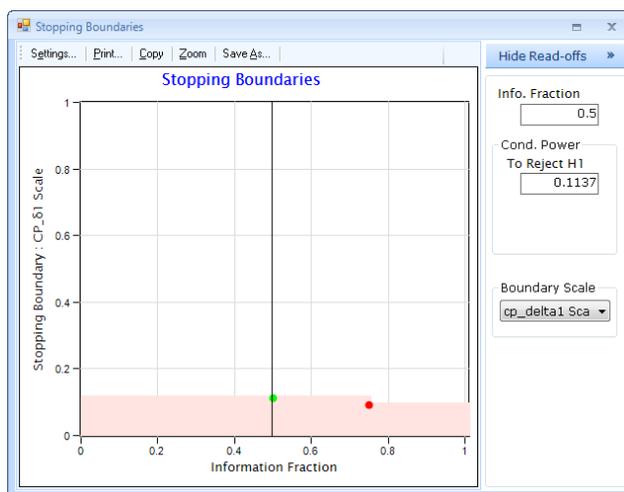

One can view the stopping boundaries on various alternative scales by selecting the appropriate scale from the drop-down list of boundary scales to the right of the chart. It is instructive to view the stopping boundaries on the p-value scale.

24 Binomial Non-Inferiority Two-Sample

By moving the vertical scroll bar from left to right in the above chart, one can observe the p-values required for early stopping at each look. The p-values needed to stop the study and declare non-inferiority at the first, second and third looks are, respectively, 0.0015, 0.0092 and 0.022. The p-values needed to stop the study for futility at the first and second looks are, respectively, 0.7244 and 0.2708.

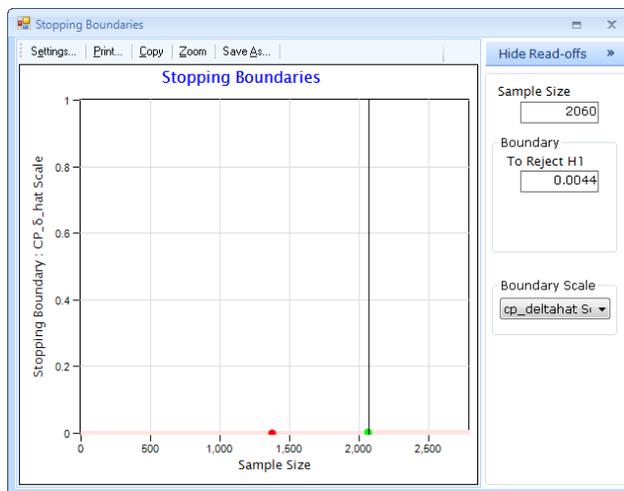

Other useful scales for displaying the futility boundary are the conditional power scales. They are the `cp_delta1` Scale and the `cp_delta1hat` scale. Here ‘cp’ refers to conditional power. The suffix ‘delta1’ implies that we will represent the futility boundary in terms of conditional power evaluated at the value of $\delta = \delta_1$ specified at the design stage under the alternative hypothesis. The suffix ‘delta1hat’ implies that we will represent the futility boundary in terms of conditional power evaluated at the value of $\hat{\delta}$ at which the test statistic $Z = \hat{\delta}/se(\hat{\delta})$ would just hit the futility boundary. The screenshot below represents the first two values of the futility boundary on the `cp_delta1` Scale.

For example, the stopping boundary at the first look is `cp_delta1=0.1137`. This is to be interpreted in the following way: if at the first look the value of the test statistic Z just falls on the futility boundary, then the conditional power, as defined by Section C.3 of Appendix C with $\delta = \delta_1 = 0$, will be 0.1137. This gives us a way to express the futility boundary in terms of conditional power.

The `cp_delta1` Scale might not give one an accurate picture of futility. This is because, on this scale, the conditional power is evaluated at the value of $\delta = \delta_1$

specified at the design stage. However, if the test statistic has actually fallen on the futility boundary, the data are more suggestive of the null than the alternative hypothesis and it is not very likely that $\delta = \delta_1$. Thus it might be more reasonable to evaluate conditional power at the observed value $\delta = \hat{\delta}$. The screenshot below represents the futility boundary on the `cp_deltahat` Scale.

For example, the stopping boundary at the second look is `cp_deltahat=0.0044`. This is to be interpreted in the following way: if at the second look, the value of test statistic Z just falls on the futility boundary, then the conditional power, as defined by Section C.3 of Appendix C with $\delta = \hat{\delta} = Z \times se(\hat{\delta})$, will be 0.0044. It is important to realize that the futility boundary has not changed. It is merely being expressed on a different scale. On the whole, it is probably more realistic to express the futility boundary on the `cp_deltahat` scale than on the `cp_delta1` scale since it is highly unlikely that the true value of δ is equal to δ_1 if Z has hit the futility boundary.

Close this chart before continuing. Click the **Compute** button to generate output for Design3. With Design3 selected in the **Output Preview**, click the  icon. In the **Library**, select the rows for Design1, Design2, and Design3, by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the three

24 Binomial Non-Inferiority Two-Sample

designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 | Wbk1:Des3 |

| Expected Under H0 | | 2732.345 | 2046.973 |
| Expected Under H1 | | 2093.682 | 2086.492 |

Observe that Design3 will stop with a smaller expected sample size under either H_0 or H_1 compared to Design2.

Three-Look Design Powered at $\delta \neq 0$ The previous designs were all powered to detect the alternative hypothesis that the new treatment and the active control have the same response rate ($\delta_1 = 0$). As is usually the case with non-inferiority trials, the distance between the non-inferiority margin $\delta_0 = 0.05$ and the alternative hypothesis $\delta_1 = 0$ is rather small, thereby resulting in a very large sample size commitment to this trial. Sometimes a new treatment is actually believed to have a superior response rate to the active control. However the anticipated treatment benefit might be too small to make it feasible to run a superiority trial. Suppose, for example, that it is anticipated that the treatment arm could improve upon the 80% response rate of the active control by about 2.5%. A single-look superiority trial designed for 90% power to detect this small of a difference would require over 12000 subjects. In this situation, the sponsor might prefer to settle for a non-inferiority claim. A non-inferiority trial in which the active control has a response probability of $\pi_c = 0.8$, the non-inferiority margin is $\delta_0 = -0.05$, and the alternative hypothesis is $\delta_1 = \pi_c - \pi_t = -0.025$ can be designed as follows.

Create a new design by selecting Design3 in the **Library**, and clicking the  icon on the **Library** toolbar. In the ensuing dialog box, choose the design parameters as

shown below.

Design Type: Number of Looks:

Test Parameters **Boundary**

Test Type:

Type I Error (α):

Power:

Sample Size (n):

Allocation Ratio: (n_1/n_2)

Specify Proportion Response
Prop. under Control (π_c):

Specify Null Hypothesis
Prop. under Treatment (π_{t0}):
Noninferiority Margin (δ_0):
 $(\delta_0 = \pi_{t0} - \pi_c)$

Specify Alternative Hypothesis
Prop. under Treatment (π_{t1}):
Diff. in Prop. ($\delta_1 = \pi_{t1} - \pi_c$):

Use Casagrande-Pike-Smith
 Correction (ignored if alloc. ratio is not 1)

Assurance (Probability of Success):

Click the **Compute** button to generate output for Design4. Notice that this design requires only 1161 subjects. This is 1585 fewer subjects than under Design3.

24.1.2 Trial Simulation

You can simulate Design 3 by selecting Design3 in the **Library**, and clicking the  icon from **Library** toolbar. Alternatively, right-click on Design3 and select **Simulate**.

24 Binomial Non-Inferiority Two-Sample

A new Simulation worksheet will appear.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z | Futility Z |
|--------|----------------|---------------------|------------|------------|
| 1 | 0.500 | 0.002 | 2.963 | -0.596 |
| 2 | 0.750 | 0.010 | 2.359 | 0.612 |
| 3 | 1.000 | 0.025 | 2.014 | 2.014 |

Try different choices for the simulation parameters to verify the operating characteristics of the study. For instance under the **Response Generation Info** tab, set **Prop. Under Control** to 0.8 and **Prop. Under Treatment** to 0.75. You will be simulating under the null hypothesis and should achieve a rejection rate of 2.5%. Now, click on the **Simulate** button.

Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled Simulation1. Select Simulation1 in the **Output Preview**. Note that some of the design details will be displayed in the upper pane, labeled **Compare Designs**. Click the  icon to save it to the **Library**. Double-click on Simulation1

in the **Library**. The simulation output details will be displayed.

Simulation Seed and Elapsed Time

Starting Seed: 747963
 Total Number of Simulations: 10000
 Elapsed Time: 00:00:05

We see above that we achieved a rejection rate of 2.5%.

Now suppose that the new treatment is actually slightly superior to the control treatment. For example, $\pi_c = 0.8$ and $\pi_t = 0.81$. Since this study is designed for 90% power when $\pi_c = \pi_t = 0.8$, we would expect the simulations to reveal power in excess of 90%.

Select Sim1 node in the **Library**, and click the  icon from **Library** toolbar. Under the **Response Generation Info** tab change the **Prop. Under Treatment** to 0.81. Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled Simulation2. Select Simulation2 in the **Output Preview**. Click the  icon to save it to the **Library**. Double-click on Simulation2 in the **Library**. The simulation output details will be

24 Binomial Non-Inferiority Two-Sample

displayed.

These results show that the power exceeds 97%.

The power of the study will deteriorate if the response rate of the control arm is less than 0.8, even if $\pi_c = \pi_t$. To see this, let us simulate with $\pi_c = \pi_t = 0.7$. The results

are shown below.

Simulation: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

Total Number of Simulations: 10000
Elapsed Time: 00:00:02

Notice that the power has dropped from 90% to 80% even though the new treatment and the control treatment have the same response rates. This is because the lower response rates for π_c and π_t induce greater variability into the distribution of the test statistic. In order to preserve power, the sample size must be increased. This can be achieved without compromising the type-1 error within the group sequential framework by designing the study for a maximum amount of (Fisher) information instead of a maximum sample size. We discuss maximum information studies later, in Chaper 59.

24.1.3 Interim Monitoring

Consider interim monitoring of Design3. Select Design3 in the **Library**, and click the **IM** icon from the Library toolbar. Alternatively, right-click on Design3 and select **Interim Monitoring**. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

Suppose that the trial is first monitored after accruing 500 subjects on each treatment arm, with 395 responses on the treatment arm and 400 responses on the control arm.

24 Binomial Non-Inferiority Two-Sample

Click on the **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. In the box next to **Cumulative Sample Size** enter 1000. Enter -0.01 in the box next to **Estimate of δ** . In the box next to **Std. Error of δ** enter 0.02553. Next click **Recalc**.

The screenshot shows a window titled "Test Statistic Calculator". It has a "Recalc" button on the left and "OK" and "Cancel" buttons on the right. The main area is divided into sections: "Editing Look #1" with a checkbox "Set Current Look as Last"; "Sample Size and Responses" with radio buttons for "Control" and "Treatment" and input boxes for "Cumulative Sample Size" and "Cumulative Response" (all showing "N/A"); "Input for Binomial end point" with a radio button selected and input boxes for "Estimate of δ " (value: -0.01) and "Standard Error of Estimate of δ " (value: 0.02553); and "Output" with input boxes for "Estimate of $\delta - \delta_0$ " (value: 0.04) and "Test Statistic" (value: 1.567).

Note that the test statistic is computed to be 1.567.

Upon clicking the **OK** button, East will produce the interim monitoring report shown below.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | Futility | 87.5% RCI for δ | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|----------|------------------------|-------|-------------------|-------|-------------------|
| | | | | | | | | Upper | Lower | | | |
| 1 | 0.364 | 1000 | 1.567 | -0.01 | 0.026 | 3.535 | -1.27 | 0.072 | -0.1 | 0.254 | 0.778 | 0.68 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

The stopping boundary for declaring non-inferiority is 3.535 whereas the value of the test statistic is only 1.567. Thus the trial should continue.

Suppose that the next interim look occurs after accruing 1250 patients on each arm with 1000 responses on the control arm and 990 responses on the treatment arm. Click on the second row in the table in the upper section. Then click the **Enter Interim Data** icon. The estimate of δ is -0.008 and the standard error is 0.016118. Enter the appropriate values as shown below and click **Recalc**.

Test Statistic Calculator

| 2 | 0.91 | 2500 | 2.606 | -0.008 | 0.016 | 2.08 | 1.467 | 0.018 | -0.042 | 0.007 | NA | NA |

Click the "Edit Interim Data" button to edit the Look # 2 data.

Stopping Boundaries

| Sample Size | Efficacy | Futility |
|-------------|----------|----------|
| 1000 | 3.535 | -1.27 |
| 2500 | 2.08 | 1.467 |

Final Inference

| | |
|----------------------------|--------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0.005 |
| Adj. Pt. Est. for δ | -0.008 |
| Adj. 95% CI for δ | |
| Upper Confidence Bound | 0.024 |
| Lower Confidence Bound | -0.04 |
| Post-Hoc Power | |

Error Spending Function

| Info. Fraction | α | β |
|----------------|----------|---------|
| 0.364 | 0 | 0.001 |
| 0.91 | 0.019 | 0.049 |

Confidence Intervals

| Info. Fraction | RCI Lower | RCI Upper | Naive CI Lower | Naive CI Upper | Adj. CI Upper |
|----------------|-----------|-----------|----------------|----------------|---------------|
| 0.364 | 0.072 | -0.1 | 1 | -0.06 | |
| 0.91 | 0.018 | -0.042 | 1 | -0.04 | 0.024 |

The lower bound on the 87.5% repeated confidence interval is -0.042, comfortably within the non-inferiority margin of -0.05 specified at the design stage.

East also provides a p-value, confidence interval and median unbiased point estimate for $\pi_t - \pi_c$ using stage-wise ordering of the sample space as described in Jennison and Turnbull (2000, page 179). This is located in the **Adjusted Inference Table**, located in the lower section of the IM Worksheet. In the present example, the lower confidence

bound is -0.040, slightly greater than the corresponding bound from the repeated confidence interval.

24.2 Ratio of Proportions: Wald Formulation

24.2.1 Trial Design

24.2.2 Trial Simulation

24.2.3 Interim Monitoring

Let π_c and π_t denote the response rates for the control and the experimental treatments, respectively. Let the difference between the two arms be captured by the ratio

$$\rho = \frac{\pi_t}{\pi_c} .$$

The null hypothesis is specified as

$$H_0: \rho = \rho_0$$

and is tested against one-sided alternative hypotheses. If the occurrence of a response denotes patient benefit rather than harm, then $\rho_0 < 1$ and the alternative hypothesis is

$$H_1: \rho > \rho_0$$

or equivalently as

$$H_1: \pi_t > \rho_0 \pi_c .$$

Conversely, if the occurrence of a response denotes patient harm rather than benefit, then $\rho_0 > 1$ and the alternative hypothesis is

$$H_1: \rho < \rho_0$$

or equivalently as

$$H_1: \pi_t < \rho_0 \pi_c .$$

For any given π_c , the sample size is determined by the desired power at a specified value of $\rho = \rho_1$. A common choice is $\rho_1 = 1$ (or equivalently $\pi_t = \pi_c$), but East permits you to power the study at any value of ρ_1 which is consistent with the choice of H_1 .

Let $\hat{\pi}_{tj}$ and $\hat{\pi}_{cj}$ denote the estimates of π_t and π_c based on n_{tj} and n_{cj} observations from the experimental and control treatments, respectively, up to and including j -th look, $j = 1, \dots, K$, where a maximum of K looks are to be made. It is convenient to express the treatment effect on the logarithm scale as

$$\delta = \ln \rho = \ln \pi_t - \ln \pi_c . \tag{24.5}$$

The test statistic at the j th look is then defined as

$$Z_j = \frac{\hat{\delta}_j - \delta_0}{\text{se}(\hat{\delta}_j)} \tag{24.6}$$

24 Binomial Non-Inferiority Two-Sample

where

$$\hat{\delta}_j = \ln \left(\frac{\hat{\pi}_{tj}}{\hat{\pi}_{cj}} \right), \quad (24.7)$$

$$\delta_0 = \ln(\rho_0) \quad (24.8)$$

and

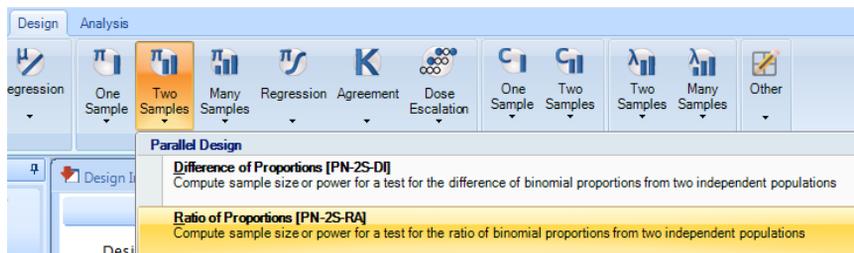

$$se(\hat{\delta}_j) = \sqrt{\frac{1 - \hat{\pi}_{cj}}{n_{cj}\hat{\pi}_{cj}} + \frac{1 - \hat{\pi}_{tj}}{n_{tj}\hat{\pi}_{tj}}}. \quad (24.9)$$

24.2.1 Trial Design

The Coronary Artery Revascularization in Diabetes (CARDia) trial (Kapur et. al., 2005) was designed to compare coronary bypass graft surgery (CABG) and percutaneous coronary intervention (PCI) as strategies for revascularization, with the goal of showing that PCI is noninferior to CABG. We use various aspects of that study to exemplify the methodology to test for inferiority. The endpoint is the one-year event rate, where an event is defined as the occurrence of death, nonfatal myocardial infarction, or cerebrovascular accident.

Suppose that the event rate for the CABG is $\pi_c = 0.125$ and that the claim of non-inferiority for PCI can be sustained if one can demonstrate statistically that the ratio $\rho = \pi_t/\pi_c$ is at most 1.3. In other words, PCI is considered to be non-inferior to CABG as long as $\pi_t < 0.1625$. Thus the null hypothesis $H_0: \rho = 1.3$ is tested against the one-sided alternative hypothesis $H_1: \rho < 1.3$. We want to determine the sample size required to have power of 80% when $\rho = 1$ using a one-sided test with a type-1 error rate of 0.05.

Single Look Design Powered at $\rho = 1$ First we consider a study with only one look and equal sample sizes in the two groups. To begin click **Two Proportions** on the **Design** tab under **Discrete**, and then click **Ratio of Proportions**.

In the ensuing dialog box, next to **Trial**, select *Noninferiority* from the drop down menu. Choose the remaining design parameters as shown below.

Design Type: Number of Looks:

Test Statistic
 Wald
 Score (Farrington Manning)

Make sure to select the radio button for **Wald** in the **Test Statistic** box. We will discuss the **Score (Farrington Manning)** test statistic in the next section.

Now click **Compute**. The design is shown as a row in the Output Preview located in the lower pane of this window. This single-look design requires a combined total of 2515 subjects from both treatments in order to attain 80% power.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | π_c | Prop. Treatment (Alt.) | Prop. Treatment (Null) | ρ^1 | ρ^0 | Test Statistic |
|------|----------------|--------------|-----------|--------------------|-------|-------|-------------|---------|------------------------|------------------------|----------|----------|----------------|
| Des1 | Noninferiority | 1 | 1-Sided | 0.05 | 0.8 | 1 | 2515 | 0.125 | 0.125 | 0.163 | 1 | 1.3 | Wald |

You can select this design by clicking anywhere along the row in the **Output Preview**. Some of the design details will be displayed in the upper pane, labeled **Compare Designs**. In the **Output Preview** toolbar, click the  icon to save this design to Workbook1 in the **Library**. If you hover the cursor over Design1 in the Library, a

24 Binomial Non-Inferiority Two-Sample

tooltip will appear that summarizes the input parameters of the design.

The screenshot shows a software interface with a 'Library' pane on the left and a parameter table on the right. The 'Library' pane shows a tree structure with 'Root', 'Wbk1', and 'Des1'. A tooltip is displayed over 'Des1', listing design parameters. The parameter table on the right is titled 'Wbk1:Des1' and lists various parameters under 'Test Parameters' and 'Model Parameters'.

Three-Look Design Powered at $\rho = 1$ For the above study, suppose we wish to take up to two equally spaced interim looks and one final look at the accruing data, using the Lan- DeMets (O'Brien-Fleming) stopping boundary. Create a new design by selecting Design1 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab **Boundary Info** will appear. Clicking on this tab will reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. By default, there is an efficacy boundary (to reject H_0) selected, but no futility boundary (to reject H_1). The **Boundary Family** specified is of the Spending Functions type. The default **Spending function** is the Lan-DeMets (Lan & DeMets, 1983), with **Parameter** OF (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O'Brien and Fleming

(1979). Technical details of these stopping boundaries are available in Appendix F.

| Maximum | 2515 | 2566 |
| Expected Under H0 | | 2551.404 |
| Expected Under H1 | | 2133.893 |

Using three planned looks requires an up-front commitment of 2566 subjects, a slight

24 Binomial Non-Inferiority Two-Sample

inflation over the single-look design which required 2515 subjects. However, the three-look design may result in a smaller sample size than that required for the single-look design, with an expected sample size of 2134 subjects under the alternative hypothesis ($\pi_c = 0.125, \rho = 1$), and still ensures that the power is 80%.

By selecting Design2 in the **Library** and clicking on the  icon, East displays the cumulative accrual, the stopping boundary, the type-1 error spent and the boundary crossing probabilities under the null hypothesis $H_0: \rho = 1.3$, and the alternative hypothesis $H_1: \rho = 1$.

☰ Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|------------|---|----------|
| | | | | Efficacy Z | Under H0 | Under H1 |
| | | | | | Efficacy | Efficacy |
| 1 | 0.333 | 855 | 6.852E-4 | -3.201 | 6.852E-4 | 0.04 |
| 2 | 0.667 | 1711 | 0.016 | -2.141 | 0.016 | 0.425 |
| 3 | 1 | 2566 | 0.05 | -1.695 | 0.034 | 0.335 |

Single-Look Design Powered at $\rho \neq 1$ Sample sizes for non-inferiority trials powered at $\rho = 1$ are generally rather large, because regulatory requirements usually impose small non-inferiority margins (see, for example, Wang et. al., 2001). Observe that both Design1 and Design2 were powered at $\rho = 1$ and required sample sizes in excess of 2500 subjects. However, based on Kapur et al (2005), it is reasonable to expect $\pi_t < \pi_c$. We now consider the same design as in Design1, but we will power at the alternative hypothesis $\rho_1 = 0.72$. That is, we will design this study to have 80% power to claim non-inferiority if $\pi_c = 0.125$ and $\pi_t = 0.72 \times 0.125 = 0.09$.

Create a new design by selecting Design1 in the **Library**, and clicking the  icon on the **Library** toolbar. In the ensuing dialog box, change the design parameters as

shown below.

Design Type: Number of Looks:

| Maximum | 2515 | 2566 | 607 |
| Expected Under H0 | | 2551.404 | |
| Expected Under H1 | | 2133.893 | |

This single-look design requires a combined total of 607 subjects from both treatments in order to attain 80% power. This is a considerable decrease from the 2515 subjects required to attain 80% power using Design1 with $\rho_1 = 1$.

Three-Look Design Powered at $\rho \neq 1$ We now consider the impact of multiple looks on Design3. Suppose we wish to take up to two equally spaced interim looks and one final look at the accruing data, using the Lan-DeMets (O'Brien-Fleming) stopping

24 Binomial Non-Inferiority Two-Sample

boundary.

Create a new design by selecting Design3 in the **Library**, and clicking the  icon on the **Library** toolbar. In the ensuing dialog box, change the **Number of Looks** to 3.

Design Type: Noninferiority Number of Looks: 3

This time the rejection rate is only 5% (up to Monte Carlo accuracy), as we would expect under the null hypothesis. You may experiment in this manner with different values of π_c and π_t and observe the rejection rates look by look as well as averaged over all looks.

24.2.3 Interim Monitoring

Select Design4 in the **Library**, and click the **IM** icon from the Library toolbar. Alternatively, right-click on Design4 and select **Create IM Dashboard**. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

Suppose that the trial is first monitored after accruing 125 subjects on each treatment

arm, with 15 responses on the control arm and 13 responses on the treatment arm.

Click on the **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. In the box next to **Cumulative Sample Size** enter 250. Enter -0.143101 in the box next to **Estimate of δ** . In the box next to **Std. Error of δ** enter 0.357197. Next click **Recalc**. Notice that the test statistic is computed to be -1.135 . This value for the test statistic was obtained by substituting the observed sample sizes and responses into equations (24.6) through (24.9).

Upon clicking the **OK** button, East will produce the interim monitoring report shown below.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | Est. of p | Est. of δ | Std. Error of Est. of δ | Efficacy | 95% RCI for p | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|-------------|------------------|--------------------------------|----------|-----------------|-------|------------------|-------|------------------|
| | | | | | | | | Upper | Lower | | | |
| 1 | 0.404 | 250 | -1.135 | 0.867 | -0.143 | 0.357 | -2.872 | 2.417 | 0 | 0.334 | 0.556 | 0.536 |
| 2 | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | |

24 Binomial Non-Inferiority Two-Sample

Note - Click on  icon to hide or unhide the columns of your interest.

The stopping boundary for declaring non-inferiority is -2.872 whereas the value of the test statistic is only -1.135. Thus the trial should continue.

This conclusion is supported by the value of the 97.5% upper confidence bound of the repeated confidence interval for $\delta = \ln(\rho)$. The non-inferiority claim could be sustained only if this bound were less than $\ln(1.3) = 0.262$. At the current interim look, however, the upper bound on δ is 0.883, indicating that the non-inferiority claim is not supported by the data.

Suppose that the next interim look occurs after accruing 250 patients on each arm with 31 responses on the control arm and 22 responses on the treatment arm. Click on the second row in the table in the upper section. Then click the **Enter Interim Data** icon. In the box next to **Cumulative Sample Size** enter 500. Enter -0.342945 in the box next to **Estimate of δ** . In the box next to **Std. Error of δ** enter 0.264031. Next click

Recalc. Notice that the test statistic is computed to be -2.293.

Final Inference

| Final Outputs at Look # | Value |
|----------------------------|--------|
| Final Outputs at Look # | 2 |
| Adj. p-value | 0.012 |
| Adj. Pt. Est. for ρ | 0.712 |
| Adj. 90% CI for ρ | |
| Upper Confidence Bound | 1.103 |
| Lower Confidence Bound | 0.461 |
| Adj. Pt. Est. for δ | -0.339 |
| Adj. 90% CI for δ | |
| Upper Confidence Bound | 0.098 |

Conf. Intervals for ρ

| Info. Fraction | RCI Upper | RCI Lower | Naive CI Upper | Naive CI Lower |
|----------------|-----------|-----------|----------------|----------------|
| 0.404 | 2.417 | 0 | 1.56 | 0 |
| 0.808 | 1.173 | 0 | 1.096 | 0 |

The upper bound on the 95.0% repeated confidence interval for δ is 0.159. Thus the upper confidence bound on ρ is $\exp(0.159) = 1.172$, comfortably within the non-inferiority margin $\rho_0 = 1.3$ specified at the design stage.

In the **Final Inference** Table in the bottom portion of the IM worksheet, East also provides a p-value, confidence interval and median unbiased point estimate for δ using stage-wise ordering of the sample space as described in Jennison and Turnbull (2000). This approach often yields narrower confidence intervals than the repeated confidence intervals approach although both approaches have the desired 95.0% coverage. In the present example, the upper confidence bound is 0.098, slightly less than the corresponding bound from the repeated confidence interval.

24.3 Ratio of Proportions: Farrington-Manning Formulation

24.3.1 Trial Design

24.3.2 Trial Simulation

24.3.3 Interim Monitoring

An alternative approach to establishing non-inferiority of an experimental treatment to the control treatment with respect to the ratio of probabilities was proposed by Farrington and Manning (1990). Let π_c and π_t denote the response rates for the control and the experimental treatments, respectively. Let the difference between the two arms be expressed by the ratio

$$\rho = \frac{\pi_t}{\pi_c}$$

The null hypothesis is specified as

$$H_0: \rho = \rho_0,$$

or equivalently

$$H_0: \pi_t = \rho_0 \pi_c,$$

which is tested against one-sided alternative hypotheses. If the occurrence of a response denotes patient benefit rather than harm, then $\rho_0 < 1$ and the alternative hypothesis is

$$H_1: \rho > \rho_0$$

or equivalently as

$$H_1: \pi_t > \rho_0 \pi_c .$$

Conversely, if the occurrence of a response denotes patient harm rather than benefit, then $\rho_0 > 1$ and the alternative hypothesis is

$$H_1: \rho < \rho_0$$

or equivalently as

$$H_1: \pi_t < \rho_0 \pi_c .$$

For any given π_c , the sample size is determined by the desired power at a specified value of $\rho = \rho_1$. A common choice is $\rho_1 = 1$ (or equivalently $\pi_t = \pi_c$), but East permits you to power the study at any value of ρ_1 which is consistent with the choice of H_1 .

Let $\hat{\pi}_{tj}$ and $\hat{\pi}_{cj}$ denote the estimates of π_t and π_c based on n_{tj} and n_{cj} observations from the experimental and control treatments, respectively, up to and including the j -th look, $j = 1, \dots, K$, where a maximum of K looks are to be made. The test statistic at the j -th look is defined as

$$Z_j = \frac{\hat{\pi}_{tj} - \rho_0 \hat{\pi}_{cj}}{\sqrt{\left[\frac{\hat{\pi}_{tj}(1-\hat{\pi}_{tj})}{n_{tj}} + \frac{\rho_0^2 \hat{\pi}_{cj}(1-\hat{\pi}_{cj})}{n_{cj}} \right]}} . \quad (24.10)$$

The choice of test statistic is the primary distinguishing feature between the above Farrington-Manning formulation and the Wald formulation of the non-inferiority test discussed in Section 24.2. The Wald statistic (24.6) measures the standardized difference between the observed ratio of proportions and the non-inferiority margin on the natural logarithm scale. The corresponding repeated one-sided confidence bounds displayed in the interim monitoring worksheet estimate $\ln(\pi_t/\pi_c)$ and may be converted to estimates of the ratio of proportions by exponentiation. On the other hand,

24 Binomial Non-Inferiority Two-Sample

the Farrington-Manning formulation focuses on the expression of the null hypothesis as

$$H_0: \pi_t - \rho_0 \pi_c = 0.$$

Thus, we consider

$$\delta = \pi_t - \rho_0 \pi_c \tag{24.11}$$

as the parameter of interest. The test statistic (24.10) is the standardized estimate of this difference obtained at the j -th look. A large difference in the direction of the alternative hypothesis is indicative of non-inferiority. The corresponding repeated one-sided confidence bounds displayed in the interim monitoring worksheet provide estimates of δ rather than directly estimating ρ or $\ln(\rho)$. The Farrington-Manning and Wald procedures are equally applicable for hypothesis testing since the null hypothesis $\delta = 0$ is rejected if and only if the corresponding null hypothesis $\rho = \rho_0$ is rejected.

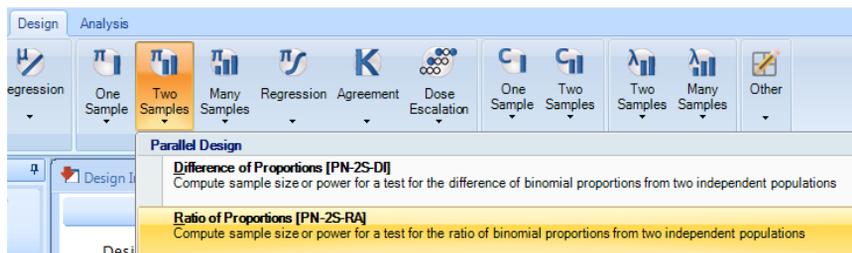

24.3.1 Trial Design

We consider the Coronary Artery Revascularization in Diabetes (CARDia) trial (Kapur et al, 2005) compared coronary bypass graft surgery (CABG) and percutaneous coronary intervention (PCI) as strategies for revascularization, with the goal of showing that PCI is noninferior to CABG, presented in Section 24.2. We use various aspects of that study to exemplify the use of the methodology to test for inferiority with respect to the one-year event rate where an "event" is the occurrence of death, nonfatal myocardial infarction, or cerebrovascular accident, using the Farrington-Manning formulation.

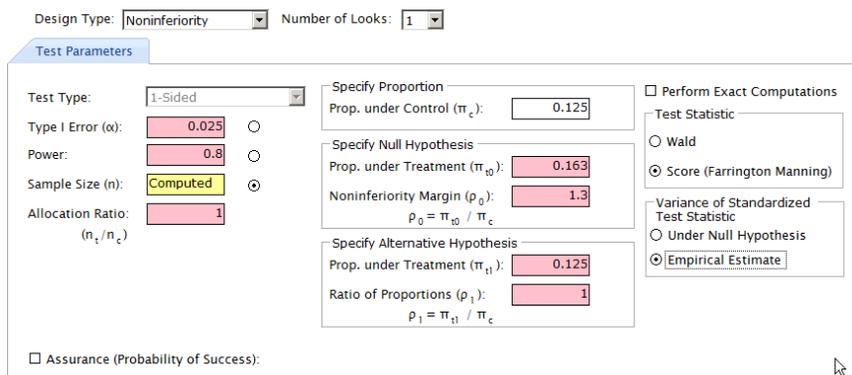

Suppose that the event rate for the CABG is $\pi_c = 0.125$ and that the claim of non-inferiority for PCI can be sustained if the ratio ρ is at most 1.3; that is, the event rate for the PCI (π_t) is at most 0.1625. The null hypothesis $H_0: \rho = 1.3$ is tested against the alternative hypothesis $H_1: \rho < 1.3$. We want to determine the sample size required to have power of 80% when $\rho = 1$ using a one-sided test with a type-1 error rate of 0.05.

Single Look Design Powered at $\rho = 1$ First we consider a study with only one look and equal sample sizes in the two groups. To begin click **Two Proportions** on the

Design tab, and then click **Ratio of Proportions**.

In the ensuing dialog box, next to **Trial**, select *Noninferiority* from the drop down menu. Choose the remaining design parameters as shown below.

Now click **Compute**. The design is shown as a row in the Output Preview located in the lower pane of this window. This single-look design requires a combined total of 2588 subjects from both treatments in order to attain 80% power.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | πc | Prop. Treatment (Alt.) | Prop. Treatment (Null) | ρ1 | ρ0 | Test Statistic | Variance |
|------|----------------|--------------|-----------|-------------|-------|-------|-------------|-------|------------------------|------------------------|----|-----|----------------|--------------------|
| Des1 | Noninferiority | 1 | 1-Sided | 0.025 | 0.8 | 1 | 3285 | 0.125 | 0.125 | 0.163 | 1 | 1.3 | Score (FM) | Empirical Estimate |

You can select this design by clicking anywhere along the row in the **Output Preview**. Some of the design details will be displayed in the upper pane, labeled **Compare Designs**. In the **Output Preview** toolbar, click the  icon to save this design to Workbook1 in the **Library**. If you hover the cursor over Design1 in the Library, a

24 Binomial Non-Inferiority Two-Sample

tooltip will appear that summarizes the input parameters of the design.

Three-Look Design Powered at $\rho = 1$ For the above study, suppose we wish to take up to two equally spaced interim looks and one final look at the accruing data, using the Lan- DeMets (O'Brien-Fleming) stopping boundary. Create a new design by selecting Design1 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab **Boundary Info** will appear. Clicking on this tab will reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. By default, there is an efficacy boundary (to reject H0) selected, but no futility boundary (to reject H1). The **Boundary Family** specified is of the Spending Functions type. The default **Spending function** is the Lan-DeMets (Lan & DeMets, 1983), with **Parameter** OF (O'Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of O'Brien and Fleming

(1979).

| Expected Under H1 | | 2195.332 |

Using three planned looks requires an up-front commitment of 2640 subjects, a slight inflation over the single-look design which required only 2588 subjects. However, the three-look design may result in a smaller sample size than that required for the single-look design, with an expected sample size of 2195 subjects under the alternative hypothesis ($\pi_c = 0.125, \rho = 1$), and still ensures that the power is 80%.

By selecting Design2 in the **Library** and clicking on the  icon, East displays the cumulative accrual, the stopping boundary, the type-1 error spent and the boundary crossing probabilities under the null hypothesis $H_0: \rho = 1.3$, and the alternative hypothesis $H_1: \rho = 1$.

⊖ Stopping Boundaries: Look by Look

| 3 | 1 | 2640 | 0.05 | -1.695 | 0.034 | 0.335 |

Single-Look Design Powered at $\rho \neq 1$ Sample sizes for non-inferiority trials powered at $\rho = 1$ are generally rather large because regulatory requirements usually impose small non-inferiority margins. Observe that both Design1 and Design2 were powered at $\rho = 1$ and required sample sizes in excess of 2500 subjects. However, based on Kapur et al (2005), it is reasonable to expect $\pi_t < \pi_c$. We now consider the same design as in Design1, but we will power at the alternative hypothesis $\rho_1 = 0.72$. That is, we will design this study to have 80% power to claim non-inferiority if $\pi_c = 0.125$ and $\pi_t = 0.72 \times 0.125 = 0.09$.

Create a new design by selecting Design1 in the **Library**, and clicking the  icon on the **Library** toolbar. In the ensuing dialog box, change the design parameters as shown below.

| Expected Under H1 | | 2195.332 | 2843.261 | 2195.332 |

Using three planned looks inflates the maximum sample size slightly, from 628 to 641 subjects. However it results in a smaller expected sample size under H_1 . Observe that the expected sample size is only 533 subjects under the alternative hypothesis ($\pi_c = 0.125, \rho = 0.72$), and still ensures the power is 80%.

24.3.2 Trial Simulation

You can simulate Design4 by selecting Design4 in the **Library** and clicking on the  icon. Try different choices for the simulation parameters to verify the operating characteristics of the study. For instance, under the **Response Generation Info** tab set **Prop. Under Control** to 0.125 and **Prop. Under Treatment** to $0.72 \times 0.125 = 0.09$.

This time the rejection rate is only 5% (up to Monte Carlo accuracy), as we would expect under the null hypothesis. You may experiment in this manner with different values of π_c and π_t and observe the rejection rates look by look as well as averaged over all looks.

24.3.3 Interim Monitoring

Select Design4 in the **Library**, and click the **IM** icon from the Library toolbar. Alternatively, right-click on Design4 and select **Interim Monitoring**. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

Suppose that the trial is first monitored after accruing 125 subjects on each treatment arm, with 15 responses on the control arm and 13 responses on the treatment arm.

Click on the **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. In the box next to **Cumulative Sample Size** enter 250. Enter -0.052 in the box next to **Estimate of δ** . In the box next to **Std. Error of δ** enter 0.046617. Next click **Recalc**.

24 Binomial Non-Inferiority Two-Sample

The test statistic is computed to be -1.115. This value for the test statistic was obtained by substituting the observed sample sizes and responses into equation (24.10).

| Cumulative Sample Size: | N/A | N/A |
| Cumulative Response: | N/A | N/A |

Cumulative Sample Size: 250

Input for Binomial end point

Estimate of δ : -0.052

$\delta = (\pi_t - \rho_0 * \pi_c)$

Standard Error of Estimate of δ : 0.046617

Output

$\delta - \delta_0$: -0.052

Test Statistic: -1.115

Recalc OK Cancel

Upon clicking the **OK** button, East will produce the interim monitoring report shown below.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|----------------------|-------|------------------|------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.095 | 250 | -1.115 | -0.052 | 0.047 | -6.262 | 0.24 | -1 | 0.643 | 0.98 | 0.738 |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

The stopping boundary for declaring non-inferiority is -2.929 whereas the value of the test statistic is only -1.115. Thus the trial should continue. This conclusion is also

supported by the upper confidence bound on

$$\delta = \pi_t - \rho_0 \pi_c$$

which at present equals 0.085. A necessary and sufficient condition for the stopping boundary to be crossed, and non-inferiority demonstrated thereby, is for this upper confidence bound to be less than zero.

Suppose that the next interim look occurs after accruing 250 patients on each arm with 31 responses on the control arm and 22 responses on the treatment arm. Click on the second row in the table in the upper section. Then click the **Enter Interim Data** icon. In the box next to **Cumulative Sample Size** enter 500. Enter -0.0732 in the box next to **Estimate of δ** . In the box next to **Std. Error of δ** enter 0.032486. Next click **Recalc**. Notice that the test statistic is computed to be -2.253.

The screenshot shows a 'Test Statistic Calculator' dialog box with the following fields and values:

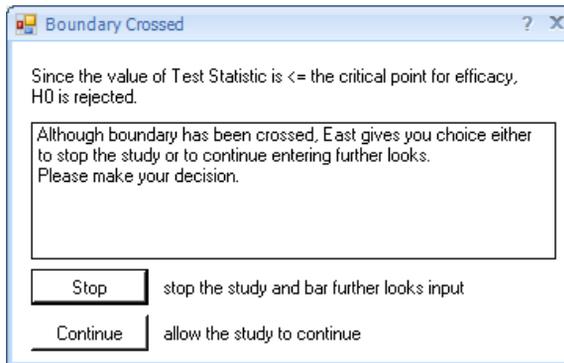

| Sample Size and Responses | | |
|--|----------|-----------|
| | Control | Treatment |
| Cumulative Sample Size: | N/A | N/A |
| Cumulative Response: | N/A | N/A |
| Cumulative Sample Size: | 500 | |
| Input for Binomial end point | | |

| $\delta = (\pi_t - \rho_0 * \pi_c)$ | | |
| Standard Error of Estimate of δ : | 0.032486 | |
| Output | | |
| $\delta - \delta_0$ | -0.073 | |
| Test Statistic: | -2.253 | |

Buttons: Recalc, OK, Cancel

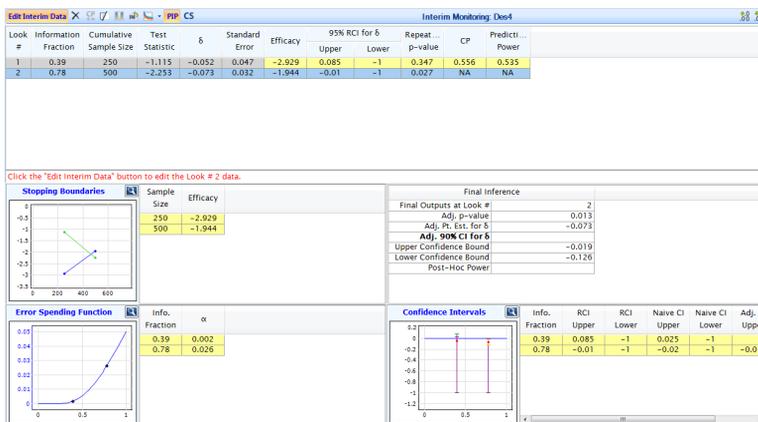

Click the **OK** button. This time the stopping boundary for declaring non-inferiority is

24 Binomial Non-Inferiority Two-Sample

crossed. The following message box appears.

Click the **Stop** button to stop the study. The analysis results are shown below. Notice that the upper confidence bound of the repeated confidence interval for δ excludes zero.

In the **Final Inference** Table in the bottom portion of the IM worksheet, East also provides a p-value, confidence interval and median unbiased point estimate for δ using stage-wise ordering of the sample space as described in Jennison and Turnbull (2000, page 179). The upper confidence bound for δ based on the stage-wise method likewise excludes zero.

24.4 Odds Ratio Test

Let π_t and π_c denote the two binomial probabilities associated with the treatment (t)

and the control (c). Let the difference between the two treatment arms be captured by the odds ratio

$$\psi = \frac{\pi_t/(1 - \pi_t)}{\pi_c/(1 - \pi_c)} = \frac{\pi_t(1 - \pi_c)}{\pi_c(1 - \pi_t)} .$$

The null hypothesis is specified as

$$H_0: \psi = \psi_0$$

and is tested against one-sided alternative hypotheses. If the occurrence of a response denotes patient benefit rather than harm, then $\psi_0 > 1$ and the alternative hypothesis is

$$H_1: \psi > \psi_0 .$$

Conversely, if the occurrence of a response denotes patient harm rather than benefit, then $\psi_0 < 1$ and the alternative hypothesis is

$$H_1: \psi < \psi_0 .$$

For any given π_c , the sample size is determined by the desired power at a specified value $\psi = \psi_1$. A common choice is $\psi_1 = 1$ (or equivalently $\pi_t = \pi_c$), but East permits you to power the study at any value of ψ_1 which is consistent with the choice of H_1 .

Let $\hat{\pi}_{tj}$ and $\hat{\pi}_{cj}$ denote the estimates of π_t and π_c based on n_{tj} and n_{cj} observations from the experimental and control treatments, respectively, up to and including j -th look, $j = 1, \dots, K$, where a maximum of K looks are to be made. It is convenient to express the treatment effect on the logarithmic scale as

$$\delta = \ln \psi . \quad (24.12)$$

The test statistic at the j th look is then defined as

$$Z_j = \frac{\hat{\delta}_j - \delta_0}{\text{se}(\hat{\delta}_j)} = \frac{\ln(\hat{\psi}_j) - \ln(\psi_0)}{\sqrt{\frac{1}{n_{tj}\hat{\pi}_{tj}(1-\hat{\pi}_{tj})} + \frac{1}{n_{cj}\hat{\pi}_{cj}(1-\hat{\pi}_{cj})}} . \quad (24.13)$$

24.4.1 Trial Design

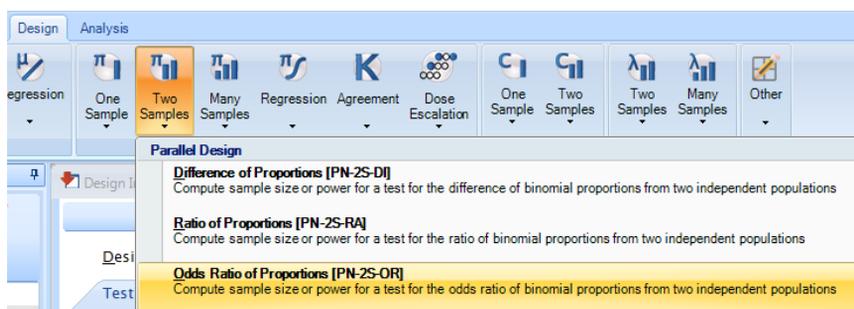

Suppose that the response rate for the control treatment is 90%, where higher response rates imply patient benefit. Assume that a claim of non-inferiority can be sustained if we can demonstrate statistically that the experimental treatment has a response rate of at least 80%. In other words the non-inferiority margin is

$$\psi_0 = \frac{0.8(1 - 0.9)}{0.9(1 - 0.8)} = 0.444 .$$

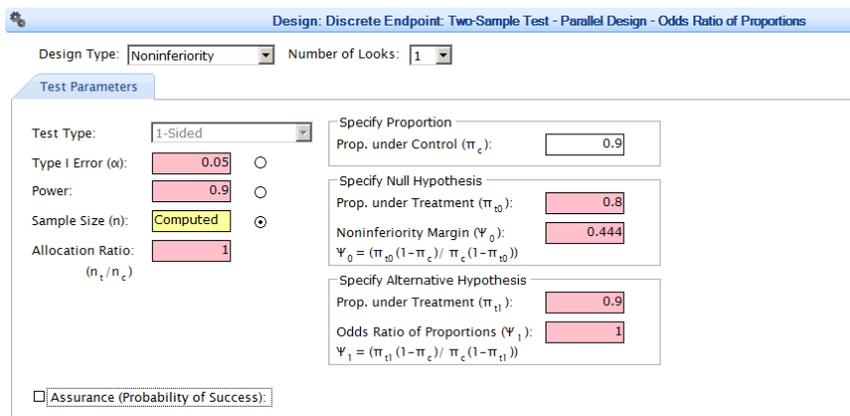

24 Binomial Non-Inferiority Two-Sample

The null hypothesis $H_0: \psi = 0.444$ is to be tested against the one-sided alternative $H_1: \psi > 0.444$. Suppose that we want to determine the sample size required to have power of 90% when $\pi_c = 0.9$ and $\psi_1 = 1$, i.e. $\pi_c = \pi_t$, using a test with a type-1 error rate of 0.05.

Single-Look Design Powered at $\psi = 1$ First we consider a study with only one look and equal sample sizes in the two groups. To begin click **Two Proportions** on the **Design** tab, and then click **Odds Ratio of Proportions**.

In the ensuing dialog box, next to **Trial**, select **Noninferiority** from the drop down menu. Choose the remaining design parameters as shown below.

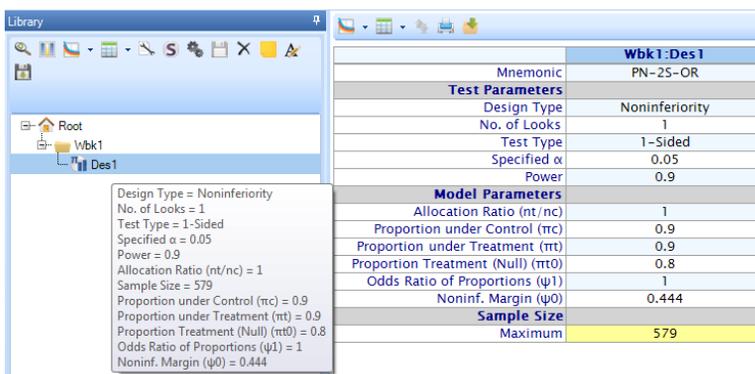

Now click **Compute**. The design is shown as a row in the Output Preview located in the lower pane of this window. This single-look design requires a combined total of

579 subjects from both treatments in order to attain 90% power.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | ttc | Prop. Treatment (Alt.) | Prop. Treatment (Null) | ψ_1 | ψ_0 |
|------|----------------|--------------|-----------|--------------------|-------|-------|-------------|-----|------------------------|------------------------|----------|----------|
| Des1 | Noninferiority | 1 | 1-Sided | 0.05 | 0.9 | 1 | 579 | 0.9 | 0.9 | 0.8 | 1 | 0.444 |

You can select this design by clicking anywhere along the row in the **Output Preview**. Some of the design details will be displayed in the upper pane, labeled **Compare Designs**. In the **Output Preview** toolbar, click the  icon to save this design to Workbook1 in the **Library**. If you hover the cursor over Design1 in the Library, a tooltip will appear that summarizes the input parameters of the design.

The screenshot shows the 'Library' window with a tree view containing 'Root', 'Wbk1', and 'Des1'. A tooltip is displayed over 'Des1' with the following text:

Design Type = Noninferiority
No. of Looks = 1
Test Type = 1-Sided
Specified α = 0.05
Power = 0.9
Allocation Ratio (nt/nc) = 1
Sample Size = 579
Proportion under Control (π_c) = 0.9
Proportion under Treatment (π_t) = 0.9
Proportion Treatment (Null) (π_{t0}) = 0.8
Odds Ratio of Proportions (ψ_1) = 1
Noninf. Margin (ψ_0) = 0.444

To the right, a table titled 'Wbk1:Des1' displays the parameters:

| Mnemonic | PN-25-OR |
|--|----------------|
| Test Parameters | |
| Design Type | Noninferiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |
| Specified α | 0.05 |
| Power | 0.9 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Proportion under Control (π_c) | 0.9 |
| Proportion under Treatment (π_t) | 0.9 |
| Proportion Treatment (Null) (π_{t0}) | 0.8 |
| Odds Ratio of Proportions (ψ_1) | 1 |
| Noninf. Margin (ψ_0) | 0.444 |
| Sample Size | |
| Maximum | 579 |

Three-Look Design Powered at $\psi = 1$ For the above study, suppose we wish to take up to two equally spaced interim looks and one final look at the accruing data, using the default Lan- DeMets (O’Brien-Fleming) stopping boundary. Create a new design by selecting Design1 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the **Number of Looks** from 1 to 3, to generate a study with two interim looks and a final analysis. A new tab **Boundary Info** will appear. Clicking on this tab will reveal the stopping boundary parameters. By default, the **Spacing of Looks** is set to **Equal**, which means that the interim analyses will be equally spaced in terms of the number of patients accrued between looks. The left side contains details for the **Efficacy** boundary, and the right side contains details for the **Futility** boundary. By default, there is an efficacy boundary (to reject H0) selected, but no futility boundary (to reject H1). The **Boundary Family** specified is of the Spending Functions type. The default **Spending function** is the Lan-DeMets (Lan & DeMets, 1983), with **Parameter** OF (O’Brien-Fleming), which generates boundaries that are very similar, though not identical, to the classical stopping boundaries of

24 Binomial Non-Inferiority Two-Sample

O'Brien and Fleming (1979). Technical details of these stopping boundaries are available in Appendix F.

Design Type: Number of Looks:

| 3 | 1.000 | 0.050 | 1.695 |

Click the **Compute** button to generate output for Design2. With Design2 selected in the **Output Preview**, click the  icon to save Design2 to the **Library**. In the **Library**, select the rows for Design1 and Design2, by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the two designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 |
|--|----------------|----------------|
| Mnemonic | PN-2S-OR | PN-2S-OR |
| Test Parameters | | |
| Design Type | Noninferiority | Noninferiority |
| No. of Looks | 1 | 3 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.9 | 0.9 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Proportion under Control (π_c) | 0.9 | 0.9 |
| Proportion under Treatment (π_t) | 0.9 | 0.9 |
| Proportion Treatment (Null) (π_{t0}) | 0.8 | 0.8 |
| Odds Ratio of Proportions (ψ_1) | 1 | 1 |
| Noninf. Margin (ψ_0) | 0.444 | 0.444 |
| Boundary Parameters | | |
| Spacing of Looks | | Equal |
| Efficacy Boundary | | LD (OF) |
| Sample Size | | |
| Maximum | 579 | 590 |
| Expected Under H0 | | 586.647 |
| Expected Under H1 | | 457.036 |

Using three planned looks requires an up-front commitment of 590 subjects, a slight inflation over the single-look design which required 579 subjects. However, the

three-look design may result in a smaller sample size than that required for the single-look design, with an expected sample size of 457 subjects under the alternative hypothesis ($\pi_c = 0.9, \psi = 1$), and still ensures that the power is 90%.

Single-Look Design Powered at $\psi \neq 1$ Suppose that it is expected that the new treatment is a bit better than the control, but it is unnecessary and unrealistic to perform a superiority test. The required sample size for $\psi_1 = 1.333$, i.e. $\pi_t = 0.92308$, is determined. Create a new design by selecting Design1 in the

Library, and clicking the  icon on the **Library** toolbar. In the ensuing dialog box, change the design parameters as shown below.

Design Type: Noninferiority Number of Looks: 1

Test Parameters

Test Type: 1-Sided

Specify Null Hypothesis
 Prop. under Treatment (π_{t0}): 0.8
 Noninferiority Margin (Ψ_0): 0.444
 $\Psi_0 = (\pi_{t0}(1-\pi_c) / \pi_c(1-\pi_{t0}))$

Specify Alternative Hypothesis
 Prop. under Treatment (π_{t1}): 0.923
 Odds Ratio of Proportions (Ψ_1): 1.333
 $\Psi_1 = (\pi_{t1}(1-\pi_c) / \pi_c(1-\pi_{t1}))$

Assurance (Probability of Success):

Click the **Compute** button to generate output for Design3. With Design3 selected in the **Output Preview**, click the  icon. In the **Library**, select the rows for Design1, Design2, and Design3, by holding the Ctrl key, and then click the .

24 Binomial Non-Inferiority Two-Sample

icon. The upper pane will display the details of the three designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des2 | Wbk1:Des3 |
|--|----------------|----------------|----------------|
| Mnemonic | PN-25-OR | PN-25-OR | PN-25-OR |
| Test Parameters | | | |
| Design Type | Noninferiority | Noninferiority | Noninferiority |
| No. of Looks | 1 | 3 | 1 |
| Test Type | 1-Sided | 1-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 | 0.05 |
| Power | 0.9 | 0.9 | 0.9 |
| Model Parameters | | | |
| Allocation Ratio (nt/nc) | 1 | 1 | 1 |
| Proportion under Control (mC) | 0.9 | 0.9 | 0.9 |
| Proportion under Treatment (mT) | 0.9 | 0.9 | 0.923 |
| Proportion Treatment (Null) (mT0) | 0.8 | 0.8 | 0.8 |
| Odds Ratio of Proportions (ψ_1) | 1 | 1 | 1.333 |
| Noninf. Margin (ψ_0) | 0.444 | 0.444 | 0.444 |
| Boundary Parameters | | | |
| Spacing of Looks | | Equal | |
| Efficacy Boundary | | LD (OF) | |
| Sample Size | | | |
| Maximum | 579 | 590 | 358 |
| Expected Under H0 | | 586.647 | |
| Expected Under H1 | | 457.036 | |

We observe that a single-look design powered at $\psi_1 = 1.333$ reduces the sample size considerably relative to the single-look design powered at $\psi_1 = 1$. The reduction in maximum sample size for the three-look design is approximately 38% $(=(579-358)/579)$. However, Design3 should be implemented after careful consideration, since its favorable operating characteristics are only applicable to the optimistic situation where $\psi_1 = 1.333$. If $\psi_1 < 1.33$, the power under Design3 decreases and may be too small to establish noninferiority, even if the true value > 1 , but is < 1.333 .

Three-Look Design Powered at $\psi \neq 1$ For the above study (Design3), suppose we wish to take up to two equally spaced interim looks and one final look at the accruing data, using the default Lan- DeMets (O'Brien-Fleming) stopping boundary. Create a new design by selecting Design3 in the **Library**, and clicking the  icon on the **Library** toolbar. In the ensuing dialog box, change the **Number of Looks** to 3. Click the **Compute** button to generate output for Design4.

| | Wbk1:Des1 | Wbk1:Des2 | Wbk1:Des3 | Wbk1:Des4 |
|--|----------------|----------------|----------------|----------------|
| Mnemonic | PN-25-OR | PN-25-OR | PN-25-OR | PN-25-OR |
| Test Parameters | | | | |
| Design Type | Noninferiority | Noninferiority | Noninferiority | Noninferiority |
| No. of Looks | 1 | 3 | 1 | 3 |
| Test Type | 1-Sided | 1-Sided | 1-Sided | 1-Sided |
| Specified α | 0.05 | 0.05 | 0.05 | 0.05 |
| Power | 0.9 | 0.9 | 0.9 | 0.9 |
| Model Parameters | | | | |
| Allocation Ratio (nt/nc) | 1 | 1 | 1 | 1 |
| Proportion under Control (mC) | 0.9 | 0.9 | 0.9 | 0.9 |
| Proportion under Treatment (mT) | 0.9 | 0.9 | 0.923 | 0.923 |
| Proportion Treatment (Null) (mT0) | 0.8 | 0.8 | 0.8 | 0.8 |
| Odds Ratio of Proportions (ψ_1) | 1 | 1 | 1.333 | 1.333 |
| Noninf. Margin (ψ_0) | 0.444 | 0.444 | 0.444 | 0.444 |
| Boundary Parameters | | | | |
| Spacing of Looks | | Equal | | Equal |
| Efficacy Boundary | | LD (OF) | | LD (OF) |
| Sample Size | | | | |
| Maximum | 579 | 590 | 358 | 365 |
| Expected Under H0 | | 586.647 | | 362.927 |
| Expected Under H1 | | 457.036 | | 282.621 |

Using three planned looks requires an up-front commitment of 365 subjects, a small inflation over the single-look design which required 358 subjects. However, the three-look design may result in a smaller sample size than that required for the single-look design, with an expected sample size of 283 subjects under the alternative hypothesis ($\pi_c = 0.9, \psi = 1.333$), and still ensures that the power is 90%.

24.4.2 Trial Simulation

You can simulate Design4 by selecting Design4 in the **Library** and clicking on the  icon. Try different choices for the simulation parameters to verify the operating characteristics of the study. First, we verify the results under the alternative hypothesis at which the power is to be controlled, namely $\pi_c = 0.9$ and $\pi_t = 0.92308$. Under the **Response Generation Info** tab set **Prop. Under Control** to 0.9 and **Prop. Under Treatment** to 0.92308.

Number of Looks:

Test Parameters Response Generation Simulation Controls

Specify Proportion

Prop. under Control (π_c):

Prop. under Treatment (π_t):

Click **Simulate** button. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled Simulation1. Select Simulation1 in the **Output Preview**. Note that some of the design details will be displayed in the upper pane, labeled **Compare Designs**. Click the  icon to save it to the **Library**. Double-click on Simulation1 in the **Library**. The simulation output details will be

24 Binomial Non-Inferiority Two-Sample

displayed.

Simulation: Discrete Endpoint: Two-Sample Test - Parallel Design - Odds Ratio of Proportions

| % | | | 74.120% | | |

Simulation Seed and Elapsed Time

Starting Seed: 1426296
 Total Number of Simulations: 10000
 Elapsed Time: 00:00:03

This results in a power of approximately 74%. From this we see that if that optimistic choice is incorrect, then the power to establish noninferiority has decreased to a possibly unacceptable value of 74%.

24.4.3 Interim Monitoring

Select Design4 in the **Library**, and click the **IM** icon from the Library toolbar. Alternatively, right-click on Design4 and select **Interim Monitoring**. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

Suppose that the trial is first monitored after accruing 60 subjects on each treatment arm, with 50 responses on the control arm and 52 responses on the treatment arm.

Click on the **Enter Interim Data** icon to invoke the **Test Statistic Calculator**. In the box next to **Cumulative Sample Size** enter 120. Enter 0.264231 in the box next to **Estimate of δ** . In the box next to **Std. Error of δ** enter 0.514034. Next click **Recalc**. Notice that the test statistic is computed to be 2.092. This value for the test statistic was

24 Binomial Non-Inferiority Two-Sample

obtained by substituting the observed sample sizes and responses into equation (24.13).

Upon clicking the **OK** button, East will produce the interim monitoring report shown below.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | Est. of δ | Std. Error of Est. of δ | Efficacy | 95% RCI for γ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|------------------|--------------------------------|----------|----------------------|-------|------------------|-------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.329 | 120 | 2.092 | 0.264 | 0.514 | 3.225 | Infinity | 0.248 | 0.176 | 0.993 | 0.922 |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |

Note - Click on  icon to hide or unhide the columns of your interest.

The critical value is 3.22, and since the observed value of the test statistic (24.13) is less than this value, the null hypothesis cannot be rejected. Therefore, noninferiority cannot as yet be concluded.

Suppose that the second look is made after accruing 120 subjects on each treatment

arm, with 112 responses on the control arm and 115 responses on the treatment arm. Click on the second row in the table in the upper section. Then click the **Enter Interim Data** icon. In the box next to **Cumulative Sample Size** enter 240. Enter 1.43848 in the box next to **Estimate of δ** . In the box next to **Std. Error of δ** enter 0.801501. Next click **Recalc**. Notice that the test statistic is computed to be 2.808. This value for the test statistic was obtained by substituting the observed sample sizes and responses into equation (24.13).

Estimate of $\delta - \delta_0$:

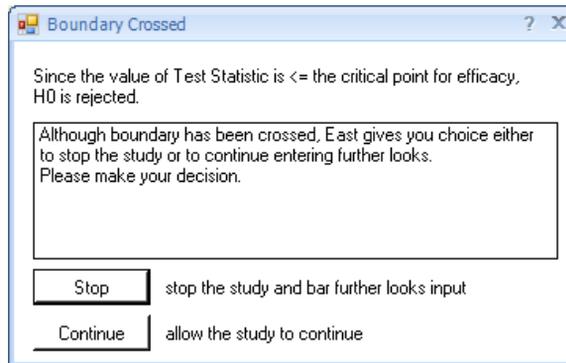

Test Statistic:

Recalc OK Cancel

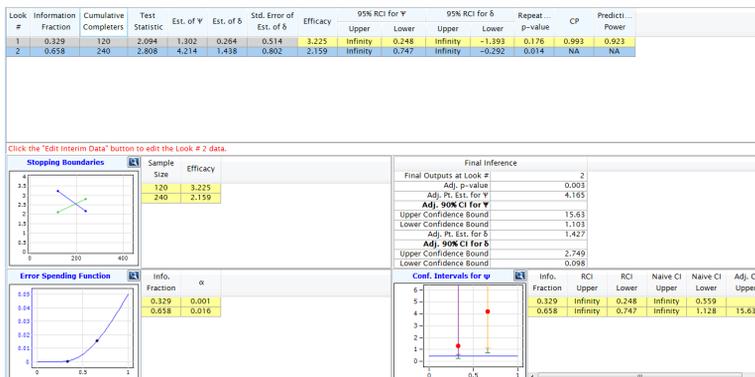

Click the **OK** button. This time the stopping boundary for declaring non-inferiority is

24 Binomial Non-Inferiority Two-Sample

crossed. The following message box appears.

Click the **Stop** button to stop the study. The analysis results are shown below.

The null hypothesis is rejected and we conclude that the treatment is noninferior to the control. In the **Final Inference** Table in the bottom portion of the IM worksheet, East also provides a stage-wise adjusted p-value, median unbiased point estimate and confidence interval for ψ as described in Jennison and Turnbull (2000) and in Appendix C of the East user manual. In the present example the adjusted p-value is 0.003, the point estimate for ψ is $\exp(1.427) = 4.166$ and the upper 95% confidence bound for ψ is $\exp(0.098) = 1.103$.

25 Binomial Equivalence Two-Sample

25.1 Equivalence Test

In some experimental situations, it is desired to show that the response rates for the control and the experimental treatments are "close", where "close" is defined prior to the collection of any data. Examples of this include showing that an aggressive therapy yields a similar rate of a specified adverse event to the established control, such as the bleeding rates associated with thrombolytic therapy or cardiac outcomes with a new stent. Let π_c and π_t denote the response rates for the control and the experimental treatments, respectively, and let $\hat{\pi}_t$ and $\hat{\pi}_c$ denote the estimates of π_t and π_c based on n_t and n_c observations from the experimental and control treatments. Furthermore, let

$$\delta = \pi_t - \pi_c, \tag{25.1}$$

which is estimated by

$$\hat{\delta} = \hat{\pi}_t - \hat{\pi}_c. \tag{25.2}$$

Finally, let the variance of $\hat{\delta}$ be

$$\sigma^2 = \frac{\pi_c(1 - \pi_c)}{n_c} + \frac{\pi_t(1 - \pi_t)}{n_t}, \tag{25.3}$$

which is estimated by

$$\hat{\sigma}^2 = \frac{\hat{\pi}_c(1 - \hat{\pi}_c)}{n_c} + \frac{\hat{\pi}_t(1 - \hat{\pi}_t)}{n_t}. \tag{25.4}$$

The null hypothesis $H_0: |\pi_t - \pi_c| = \delta_0$ is tested against the two-sided alternative hypothesis $H_1: |\pi_t - \pi_c| < \delta_0$, where $\delta_0 (> 0)$ is specified to define equivalence. Following Machin and Campbell (1987), we present the solution to this problem as a one-sided α -level test. The decision rule is to declare equivalence if

$$-\delta_0 + z_\alpha \hat{\sigma} \leq \hat{\pi}_t - \hat{\pi}_c \leq \delta_0 - z_\alpha \hat{\sigma}. \tag{25.5}$$

We see that decision rule (25.5) is the same as declaring equivalence if the $(1 - 2\alpha)$ 100% confidence interval for $\pi_t - \pi_c$ is entirely contained with the interval $(-\delta_0, \delta_0)$. The power or sample size are determined for a single-look study only. The extension to multiple looks is given in the next section. The sample size, or power, is determined at a specified difference $\pi_t - \pi_c$, denoted δ_1 , where $-\delta_0 < \delta_1 < \delta_0$. The probability of declaring equivalence depends on the true values of π_c and π_t . Based on the results of Machin and Campbell (1987), the required total sample size (N) is, for $n_t = rN$ and $n_c = (1 - r)N$,

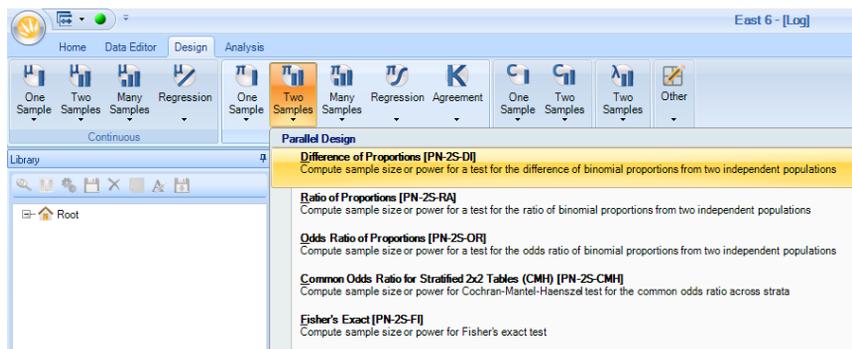

$$N = \frac{(z_\alpha + z_\beta)^2}{(\delta_0 - \delta_1)^2} \left(\frac{\pi_c(1 - \pi_c)}{1 - r} + \frac{(\pi_c + \delta_1)(1 - (\pi_c + \delta_1))}{r} \right). \tag{25.6}$$

25 Binomial Equivalence Two-Sample

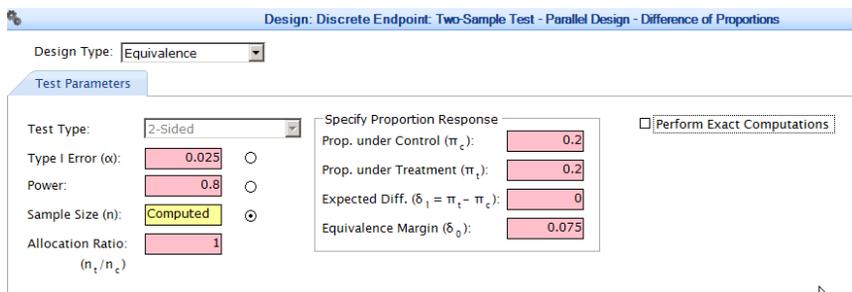

25.1.1 Trial Design

Consider the development of a new stent which is to be compared to the standard stent with respect to target vessel failure (acute failure, target vessel revascularization, myocardial infarction, or death) after one year. The standard stent has an assumed target vessel failure rate of 20%. Equivalence is defined as $\delta_0 = 0.075$. The sample size is to be determined with $\alpha = 0.025$ (one-sided) and power, i.e. probability of declaring equivalence, of $1 - \beta = 0.80$.

To begin click **Two Samples** on the **Design** tab, and then click **Difference of Proportions**.

Suppose that we want to determine the sample size required to have power of 80% when $\delta_1 = 0$. Enter the relevant parameters into the dialog box as shown below. In the drop down box next to **Trial Type** be sure to select **Equivalence**.

Click on the **Compute** button. The design is shown as a row in the Output Preview located in the lower pane of this window. The sample size required in order to achieve the desired 80% power is 1203 subjects.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | π_c | Prop. Treatment (Alt.) | δ_1 | Equivalence Margin | Expected Difference |
|------|-------------|--------------|-----------|--------------------|-------|-------|-------------|---------|------------------------|------------|--------------------|---------------------|
| Des1 | Equivalence | 1 | 2-Sided | 0.025 | 0.801 | 1 | 1203 | 0.2 | 0 | 0.075 | 0 | 0 |

You can select this design by clicking anywhere along the row in the **Output Preview**. If you double click anywhere along the row in the **Output Preview** some of the design details will be displayed in the upper pane, labeled **Output Summary**.

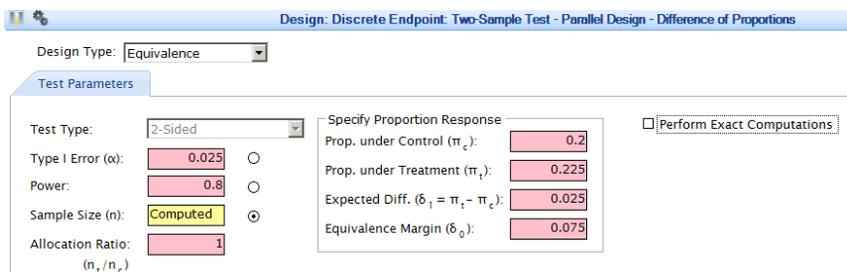

| Des1 | |
|--|-------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Equivalence |
| No. of Looks | 1 |
| Test Type | 2-Sided |
| Specified α | 0.025 |
| Power | 0.801 |
| Model Parameters | |
| Proportion under Control (π_c) | 0.2 |
| Proportion under Treatment (π_t) | 0.2 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0 |
| Equivalence Margin(δ_0) | 0.075 |
| Expected Difference($\pi_t - \pi_c$) | 0 |
| Allocation Ratio (nt/nc) | 1 |
| Sample Size | |
| Maximum | 1203 |

In the **Output Preview** toolbar, click the  icon to save this design to Workbook1 in the **Library**. If you hover the cursor over Des1 in the Library, a tooltip will appear that summarizes the input parameters of the design.

If the assumed difference δ_1 is not zero, it is more difficult to establish equivalence, in the sense that the power is lower and thus the required sample size is larger. Consider $\delta_1 = 0.025$, so that the new stent increases the rate to 22.5%. Create a new design

25 Binomial Equivalence Two-Sample

Des2 by selecting Des1 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the value of **Expected Diff.** from 0 to 0.025 as shown below.

Click on the **Compute** button. The design is shown as a row in the Output Preview located in the lower pane of this window. With Design2 selected in the **Output Preview**, click the  icon. In the **Library**, select the rows for Des1 and Des2, by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the two designs side-by-side:

| | Des1 | Des2 |
|---|-------------|-------------|
| Mnemonic | PN-2S-DI | PN-2S-DI |
| Test Parameters | | |
| Design Type | Equivalence | Equivalence |
| No. of Looks | 1 | 1 |
| Test Type | 2-Sided | 2-Sided |
| Specified α | 0.025 | 0.025 |
| Power | 0.801 | 0.8 |
| Model Parameters | | |
| Proportion under Control (π_c) | 0.2 | 0.2 |
| Proportion under Treatment (π_t) | 0.2 | 0.225 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0 | 0.025 |
| Equivalence Margin (δ_0) | 0.075 | 0.075 |
| Expected Difference ($\pi_t - \pi_c$) | 0 | 0.025 |
| Allocation Ratio (n_t/n_c) | 1 | 1 |
| Sample Size | | |
| Maximum | 1 203 | 21 20 |

This single-look design requires a combined total of 2120 subjects from both

treatments in order to attain 80% power.

Consider $\delta_1 = -0.025$, so that the new stent decreases the rate to 17.5%. Create a new design, as above, and change the value of **Expected Diff.** to -0.025 . Click the **Compute** button to generate the output for Des3. With Des3 selected in the **Output Preview**, click the  icon. In the **Library**, select the nodes for Des1, Des2, and Des3 by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the three designs side-by-side:

| | Des1 | Des2 | Des3 |
|---|-------------|-------------|-------------|
| Mnemonic | PN-2S-DI | PN-2S-DI | PN-2S-DI |
| Test Parameters | | | |
| Design Type | Equivalence | Equivalence | Equivalence |
| No. of Looks | 1 | 1 | 1 |
| Test Type | 2-Sided | 2-Sided | 2-Sided |
| Specified α | 0.025 | 0.025 | 0.025 |
| Power | 0.801 | 0.8 | 0.8 |
| Model Parameters | | | |
| Proportion under Control (π_c) | 0.2 | 0.2 | 0.2 |
| Proportion under Treatment (π_t) | 0.2 | 0.225 | 0.175 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0 | 0.025 | -0.025 |
| Equivalence Margin (δ_0) | 0.075 | 0.075 | 0.075 |
| Expected Difference ($\pi_t - \pi_c$) | 0 | 0.025 | -0.025 |
| Allocation Ratio (n_t/n_c) | 1 | 1 | 1 |
| Sample Size | | | |
| Maximum | 1203 | 2120 | 1940 |

Des3 yields a required total sample size of 1940 subjects. This asymmetry is due to the fact that the variance is smaller for values of $\pi_c + \delta_1$ further from 0.5.

25.1.2 Extension to Multiple Looks

Although the details presented in the previous section are related to a single-look design only, these results can be used to extend the solution to allow for multiple equally-spaced looks. We can use the General Design Module to generalize the solution to this problem to the study design with multiple looks. Details are given in Chapters 60 and 59.

Let $\hat{\pi}_{tj}$ and $\hat{\pi}_{cj}$ denote the estimates of π_t and π_c based on n_{tj} and n_{cj} observations from the experimental and control treatments, respectively, up to and including the j -th look, $j = 1, \dots, K$, where a maximum of K looks are to be used. Let $n_j = n_{cj} + n_{tj}$ and

$$\hat{\delta}_j = \hat{\pi}_{tj} - \hat{\pi}_{cj} \tag{25.7}$$

25 Binomial Equivalence Two-Sample

denote the estimate of δ , given by (25.1), and let

$$\hat{\sigma}_j^2 = \frac{\hat{\pi}_{c_j}(1 - \hat{\pi}_{c_j})}{n_{c_j}} + \frac{\hat{\pi}_{t_j}(1 - \hat{\pi}_{t_j})}{n_{t_j}} \quad (25.8)$$

denote the estimate of σ^2 , given by (25.3), using the data available at the j -th look.

At the j -th look, the inference is based on

$$Z_j = \frac{\hat{\delta}_j}{\hat{\sigma}_j}. \quad (25.9)$$

Let

$$\eta = \delta \sqrt{I_{max}},$$

where I_{max} is described in Chapter 59. Let $t_j = n_j/n_{max}, j = 1, \dots, K$. Then, using the multivariate normal approximation to the distribution of Z_1, \dots, Z_K , with the expected value of Z_j equal to $t_j^{1/2}\eta$ and the variance of Z_j equal to 1, the $(1 - \alpha)100\%$ repeated confidence intervals for η are

$$\left(\frac{Z_j + C_{Lj}}{t_j^{1/2}}, \frac{Z_j + C_{Uj}}{t_j^{1/2}} \right), \quad (25.10)$$

where C_{Lj} and C_{Uj} are the values specified by the stopping boundary. The corresponding $(1 - \alpha)100\%$ repeated confidence intervals for δ are

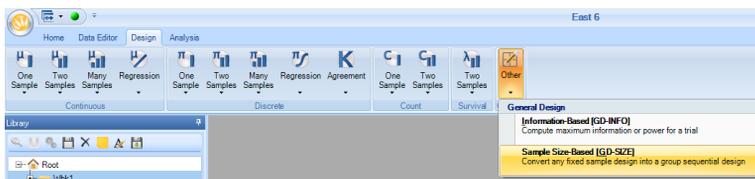

$$(\delta_j + C_{Lj}, \delta_j + C_{Uj}). \quad (25.11)$$

Using the General Design Module, East provides these repeated confidence intervals for η . By considering the decision rule (25.5) as declaring equivalence if the $(1 - 2\alpha)$ 100% confidence interval for $\pi_t - \pi_c$ is entirely contained with the interval $(-\delta_0, \delta_0)$, we generalize the decision rule to a multiple-look design by concluding equivalence and stopping the study the first time one of the repeated $(1 - 2\alpha)$ 100% confidence intervals for η is entirely contained within the interval $(-\eta_{0j}, \eta_{0j})$, where

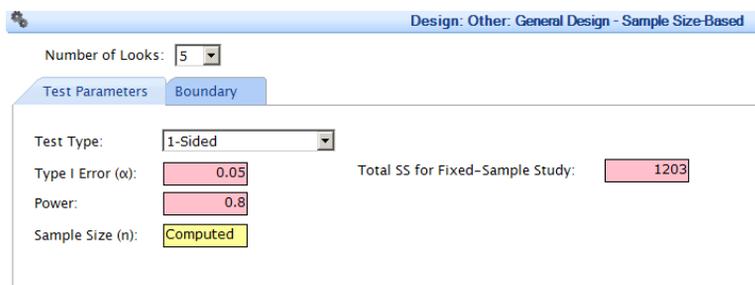

$$\eta_{0j} = \delta_0/t_j^{1/2}\hat{\sigma}_j.$$

Consider Design1 (i.e. $\pi_c = 0.20, \delta_0 = 0.075$, and $\delta_1 = 0$). As we saw above, a total of 1203 subjects are required for decision rule (25.5) to have power of 80% of declaring equivalence, using a 95% confidence interval.

To begin click on the **Other Designs** on the **Design** tab and then click **Sample Size-Based**.

Enter the parameters as shown below. For the **Sample Size for Fixed-Sample Study** enter **1203**, the value obtained from Des1. Also, be sure to set the **Number of Looks** to 5. Recall that the choice here is twice the (one-sided) value specified for the single-look design. The General Design Module is designed for testing the null hypothesis $H_{00}: \eta = 0$. Thus, the specified power of the test pertains to testing H_{00} and is not directly related to the procedure using the confidence interval. The expected sample sizes under H_0 and H_1 depend on the specified value of the power and pertain to the null hypothesis H_{00} and the corresponding alternative hypothesis $H_{10}: \eta \neq 0$ or a corresponding one-sided alternative. These expected sample sizes are not directly applicable to the equivalence problem of testing H_0 against H_1 .

Next click on the **Boundary Info** tab. The repeated confidence intervals for η depend on the choice of spending function boundaries. The sample size for this group sequential study also depends on the choice of the spending function, as well as the choice of the power. Although the boundaries themselves are not used in the decision rule, the width of the repeated confidence intervals for η are determined by the choice of the spending function. Here we will use the Lan- DeMets (O'Brien-Fleming)

25 Binomial Equivalence Two-Sample

stopping boundary, with the looks spaced equally apart, as shown below.

Number of Looks: 5

Click **Compute**. With Des4 selected in the **Output Preview**, click the  icon. In the **Library**, select the rows for Des1 and Des4, by holding the Ctrl key, and then click the  icon. The upper pane will display the summary details of the two designs side-by-side:

| | Wbk1:Des1 | Wbk1:Des4 |
|--|------------------|------------------|
| Mnemonic | PN-2S-DI | GD-SIZE |
| Test Parameters | | |
| Design Type | Equivalence | |
| No. of Looks | | 5 |
| Test Type | 2-Sided | 1-Sided |
| Specified α | 0.025 | 0.05 |
| Power | 0.801 | 0.8 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | |
| Proportion under Control (π_C) | 0.2 | |
| Proportion under Treatment (π_T) | 0.2 | |
| Diff. in Prop. ($\pi_T - \pi_C$) | 0 | |
| Equivalence Margin(δ_0) | 0.075 | |
| Expected Difference($\pi_T - \pi_C$) | 0 | |
| Fixed SS | | 1203 |
| Boundary Parameters | | |
| Spacing of Looks | | Equal |
| Efficacy Boundary | | LD (OF) |
| Sample Size | | |
| Maximum | 1203 | 1246 |
| Expected Under H0 | | 1235.595 |
| Expected Under H1 | | 971.512 |

We see that the extension of Des1 to a five-look design requires a commitment of 1233 subjects, a small inflation over the sample size of 1203 subjects required for Des1.

Select Design4 in the **Library**, and click the **IM** icon from the Library toolbar. Alternatively, right-click on Design4 and select **Create IM Dashboard**. This will invoke the interim monitoring worksheet, from which the repeated 95% confidence intervals will be provided.

The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

We want to perform up to five looks, as data becomes available for every 200 subjects. Suppose that, after 200 subjects, $\hat{\pi}_{c,j} = 18/100 = 0.18$ and $\hat{\pi}_{t,j} = 20/100 = 0.2$. Then, from (25.2) and (25.4), the estimates of δ and the standard error of $\hat{\delta}$ are 0.02 and 0.0555. Click on the  icon to invoke the **Test Statistic Calculator**. Enter the appropriate values as shown below and click **Recalc**. Notice that the test statistic is

25 Binomial Equivalence Two-Sample

computed to be 0.357.

Next click **OK** . The following screen is shown.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|----------------------|--------|------------------|-------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.161 | 200 | 0.36 | 0.02 | 0.056 | 4.754 | Infinity | -0.244 | 0.713 | 0.197 | 0.365 |
| 2 | | | | | | | | | | | |
| 3 | | | | | | | | | | | |
| 4 | | | | | | | | | | | |
| 5 | | | | | | | | | | | |

The first repeated 95% confidence interval for η is (-12.628, 14.402). Since this confidence interval is not contained in the interval (-3.357, 3.357), where

$$\eta_{01} = \frac{\delta_0}{t_1^{1/2} \hat{\sigma}_1} = \frac{0.075}{(0.162)^{1/2} (0.0555)} = 3.357,$$

we take a second look after 400 subjects. Click on the second row in the table in the upper section. Then click the  icon to invoke the **Test Statistic Calculator**. Suppose that $\hat{\pi}_{c_j} = 36/200 = 0.18$ and $\hat{\pi}_{t_j} = 38/200 = 0.19$. Then, from (25.2) and (25.4), the estimates of δ and the standard error of $\hat{\delta}$ are 0.01 and 0.0388. Enter these

values as shown below and click on the **Recalc** button.

Click on the **OK** button and the following values are presented in the interim monitoring worksheet.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|------|----------------|----------|---------------|--------|------------------|-------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.161 | 200 | 0.36 | 0.02 | 0.056 | 4.754 | Infinity | -0.244 | 0.713 | 0.197 | 0.365 |
| 2 | 0.321 | 400 | 0.026 | 0.01 | 0.388 | 3.268 | Infinity | -1.258 | 0.765 | 0.022 | 0.125 |
| 3 | | | | | | | | | | | |
| 4 | | | | | | | | | | | |
| 5 | | | | | | | | | | | |

The second repeated 95% confidence interval for η is (-6.159, 7.064) is not contained in the interval (-3.396, 3.396), where

$$\eta_{02} = \frac{\delta_0}{t_2^{1/2} \hat{\sigma}_2} = \frac{0.075}{(0.324)^{1/2} (0.0388)} = 3.396,$$

so we cannot conclude equivalence. Continue the study and we take a third look after 600 subjects. Click on the third row in the table in the upper section. Then click the  icon to invoke the **Test Statistic Calculator**. Suppose that $\hat{\pi}_{c,j} = 51/300 = 0.17$ and $\hat{\pi}_{t,j} = 60/300 = 0.2$. Then, from (25.2) and (25.4), the estimates of δ and the standard error of $\hat{\delta}$ are 0.03 and 0.0317. Enter these values as

25 Binomial Equivalence Two-Sample

shown below and click on the **Recalc** button. The following screen is shown.

Click on the **OK** button and the following values are presented in the interim monitoring worksheet.

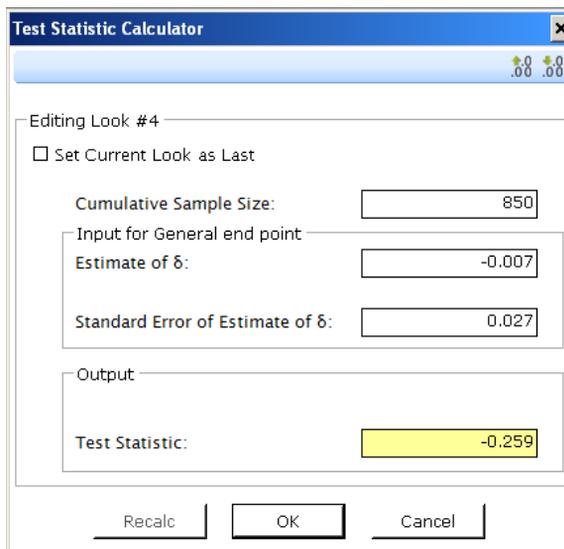

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|----------------------|--------|------------------|-------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.161 | 200 | 0.36 | 0.02 | 0.056 | 4.754 | Infinity | -0.244 | 0.713 | 0.197 | 0.365 |
| 2 | 0.321 | 400 | 0.026 | 0.01 | 0.388 | 3.268 | Infinity | -1.258 | 0.765 | 0.022 | 0.125 |
| 3 | 0.482 | 600 | 0.946 | 0.03 | 0.032 | 2.608 | Infinity | -0.053 | 0.382 | 0.316 | 0.369 |
| 4 | | | | | | | | | | | |
| 5 | | | | | | | | | | | |

The third repeated 95% confidence interval for η is (-2.965, 5.679) is not contained in the interval (-3.390, 3.390), where

$$\eta_{03} = \frac{\delta_0}{t_3^{1/2} \hat{\sigma}_3} = \frac{0.075}{(0.487)^{1/2} (0.0317)} = 3.390,$$

so we cannot conclude equivalence. Continue the study and we take a fourth look after 850 subjects. Click on the fourth row in the table in the upper section. Then click the  icon to invoke the **Test Statistic Calculator**. Suppose that $\hat{\pi}_{cj} = 91/450 = 0.2022$ and $\hat{\pi}_{tj} = 88/450 = 0.1956$. Then, from (25.2) and (25.4),

the estimates of δ and the standard estimate of δ are -0.007 and 0.027. Enter these values as shown below and click on the **Recalc** button. The following screen is shown.

Click on the **OK** button and the following values are presented in the interim monitoring worksheet.

| Look # | Information Fraction | Cumulative Sample Size | Test Statistic | δ | Standard Error | Efficacy | 95% RCI for δ | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|------------------------|----------------|----------|----------------|----------|----------------------|--------|------------------|-------|------------------|
| | | | | | | | Upper | Lower | | | |
| 1 | 0.161 | 200 | 0.36 | 0.02 | 0.056 | 4.754 | Infinity | -0.244 | 0.713 | 0.197 | 0.365 |
| 2 | 0.321 | 400 | 0.026 | 0.01 | 0.388 | 3.268 | Infinity | -1.258 | 0.765 | 0.022 | 0.125 |
| 3 | 0.482 | 600 | 0.946 | 0.03 | 0.032 | 2.608 | Infinity | -0.053 | 0.382 | 0.316 | 0.369 |
| 4 | 0.682 | 850 | -0.259 | -0.007 | 0.027 | 2.141 | Infinity | -0.065 | 0.873 | 0 | 0.001 |
| 5 | | | | | | | | | | | |

The fourth confidence interval is (-3.302, 2.678) is entirely contained in the interval (-3.346, 3.346), where

$$\eta_{04} = \frac{\delta_0}{t_4^{1/2} \hat{\sigma}_4} = \frac{0.075}{(0.689)^{1/2} (0.027)} = 3.346$$

and thus we conclude that the two treatments are equivalent. To express the results in terms of the δ , the final confidence interval for η can be transformed to a confidence interval for δ by multiplying the confidence limits by

$$t_4^{1/2} \hat{\sigma}_4 = (0.689)^{1/2} (0.027) = 0.0224,$$

25 *Binomial Equivalence Two-Sample*

resulting in a confidence interval for δ of $(-0.074, 0.060)$, which is entirely contained within the interval $(-0.075, 0.075)$.

26 Binomial Superiority n -Sample

26.1 Chi-Square for Specified Proportions in C Categories
 26.1.1 Trial Design

Let π_{0i} and π_{1i} for $i = 1, 2, \dots, C$ denote the response proportions under null and alternative hypotheses respectively where C denotes the number of categories. The null hypothesis states that the observed frequencies follow multinomial distribution with null proportions as probabilities. The test is performed for only two sided alternative. The sample size, or power, is determined for a specified value of the proportions which is consistent with the alternative hypothesis, denoted by π_{1i} .

Table 26.1: Table: Contingency Table

| Category\ Response | Cured | Not Cured |
|--------------------|----------|-----------|
| Age Group A | n_{11} | n_{21} |
| Age Group B | n_{12} | n_{22} |
| Age Group C | n_{13} | n_{23} |
| Marginal | $n_{1.}$ | $n_{2.}$ |

The null hypothesis is $H_0 : \pi_i = \pi_{0i}, i = 1, 2, 3, \dots, C$ and is tested against two-sided alternative.

The test statistic is given as,

$$\chi^2 = \sum_i \frac{(n_{1i} - \mu_i)^2}{\mu_i} \tag{26.1}$$

where $\mu_i = n_{1.}\pi_{0i}$

Let χ_0^2 be the observed value of χ^2 . For large samples, χ^2 has approximately Chi-squared distribution with d.f. $C - 1$. The p-value is approximated by $P(\chi_{c-1}^2 \geq \chi_0^2)$, where χ_{c-1}^2 denotes a Chi-squared random variable with d.f. = $C - 1$.

26.1.1 Trial Design

Consider the design of a single-arm trial with binary response - Cured and Not Cured. The responses for Cured population for three categories are of interest - Age group A, Age group B and Age group C. We wish to determine whether the proportion of cured in the three age groups are 0.25, 0.25, and 0.50 respectively. Thus it is desired to test $H_0 : \pi_A = 0.25, \pi_B = 0.25, \pi_C = 0.50$. We wish to design the trial with a two-sided

26 Binomial Superiority n-Sample

test that achieves 90% power at $H_1 : \pi_A = 0.3, \pi_B = 0.4, \pi_C = 0.3$ at level of significance 0.05.

Start East. Click **Design** tab, then click **Many Samples** in the **Discrete** group, and then click **Chi-Square Test of Specified Proportions in C Categories**.

In the upper pane of this window is the Input dialog box, which displays default input values.

Enter the **Number of Categories (C)** as 3. Under **Table of Proportion of Response**, enter the values of proportions under **Null Hypothesis** and **Alternative Hypothesis** for each category except the last one such that the sum of values in a row equals to 1. Enter the inputs as shown below and click **Compute**.

With Des1 selected in the **Library**, click  icon on the **Library** toolbar, and then click **Power vs. Sample Size**. The resulting power curve for this design is shown. You can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...** For now, you may close the chart before continuing.

26 Binomial Superiority n -Sample

26.2 Two-Group Chi-square for Proportions in C Categories

26.2.1 Trial Design

Let π_{1j} and π_{2j} denote the response proportions of group 1 and group 2 respectively for the j -th category, where $j = 1, 2, \dots, C$.

The null hypothesis $H_0 : \pi_{1j} = \pi_{2j} \forall j = 1, 2, \dots, C$ is tested against the alternative hypothesis that for at least one j , π_{1j} differs from π_{2j} .

Table 26.2: Table: Contingency Table

| Categories \ Groups | Group 1 | Group 2 | Marginal |
|---------------------|----------|----------|----------|
| A | n_{11} | n_{21} | n_{01} |
| B | n_{12} | n_{22} | n_{02} |
| C | n_{13} | n_{23} | n_{03} |
| Marginal | n_{10} | n_{20} | n |

The test statistic is given as,

$$\chi^2 = \sum_{ij} \frac{(n_{ij} - \mu_{ij})^2}{\mu_{ij}} \quad (26.2)$$

where $\mu_{ij} = \frac{n_{oj}n_{io}}{n}$, $j = 1, 2, \dots, C$ and $i = 1, 2$.

Let χ_0^2 be the observed value of χ^2 . For large samples, χ^2 has approximately Chi-squared distribution with d.f. $C - 1$. The p-value is approximated by $P(\chi_{C-1}^2 \geq \chi_0^2)$, where χ_{C-1}^2 denotes a Chi-squared random variable with d.f. = $C - 1$.

26.2.1 Trial Design

Suppose researchers want to investigate the relationship between different dose levels (level 1, level 2 and level 3) of a drug and the type adverse events (serious or not serious). The proportions who were treated with different dose levels will be compared using a Chi-square test. Suppose the expected proportions of patients for three different dose levels are 0.30, 0.35 and 0.35 where patients had no serious adverse events and the expected proportions are 0.20, 0.30 and 0.50 where patients had serious adverse events. We wish to design the trial with a two-sided test that achieves 90% power at level of significance 0.05.

Start East. Click **Design** tab, then click **Many Samples** in the **Discrete** group, and then click **Two-Group Chi-square for Proportions in C Categories**.

The Input dialog box, with default input values will appear in the upper pane.

Enter the **Number of Categories (C)** as 3. Under **Table of Proportion of Response**, enter the values of proportions under **Control** and **Treatment** for each category except the last one such that the sum of values in a row equals to 1. Enter the inputs as shown below and click **Compute**.

26 Binomial Superiority n -Sample

26.3 Nonparametric: Wilcoxon Rank Sum for Ordered Categorical Data

26.3.1 Trial Design

When we compare two treatments with respect to signs and symptoms associated with a disease, we may base the comparison on a variable that assesses degree of response or the degree of severity, using an ordinal categorical variable. For example, investigators may report the severity of an adverse event, or other abnormality, using a specified grading system or using a simple scale, such as "none", "mild", "moderate", or "severe". The latter rating scale might be used in an analgesia study to report the severity of pain. Although this four-point scale is often used and intuitively appealing, additional categories, such as "very mild" and "very severe", may be added. In other situations, the efficacy of the treatment is best assessed by the subject reporting response to therapy using a similar scale. The Wilcoxon test for ordered categories is a nonparametric test for use in such situations. East provides the power for a specified sample size for a single-look design using the constant proportional odds ratio model. Let π_{cj} and π_{tj} denote the probabilities for category j , $j = 1, 2, \dots, J$ for the control c and the treatment t respectively. Let $\gamma_{ci} = \sum_{j=1}^i \pi_{cj}$ and $\gamma_{ti} = \sum_{j=1}^i \pi_{tj}$. We assume that

$$\frac{\gamma_{ci}}{1-\gamma_{ci}} = e^{\psi} \frac{\gamma_{ti}}{1-\gamma_{ti}}, i = 1, 2, \dots, J - 1,$$

or, equivalently,

$$\psi = \ln(\gamma_{ci}) - \ln(1 - \gamma_{ci}) - (\ln(\gamma_{ti}) - \ln(1 - \gamma_{ti})) \quad (26.3)$$

We compare the two distributions by focusing on the parameter ψ . Thus we test the null hypothesis $H_0 : \psi = 0$ against the two-sided alternative $H_1 : \psi \neq 0$ or a one-sided alternative hypothesis $H_1 : \psi > 0$. East requires the specified value of ψ to be positive. Technical details can be found in Rabbee et al.,2003.

26.3.1 Trial Design

We consider here a placebo-controlled parallel-group study where subjects report the response to treatment as "none", "slight", "considerable", or "total". We expect that most of the subjects in the placebo group will report no response.

Start East. Click **Design** tab, then click **Many Samples** in the **Discrete** group, and then click **Non Parametric: Wilcoxon Rank Sum for Ordered Categorical Data**.

The Input dialog box, with default input values will appear in the upper pane.

We want to determine the power, using a two-sided test with a type-1 error rate of 0.05, with a total of 100 subjects, and equal sample sizes for the two groups. Enter **Number of Categories** as 4. We will use **User Specified for Specify Pop 1 Probabilities** and **Proportional Odd Model for Pop2 Probabilities** here. Click **Proportional Odds Model** radio button. A new field for **Shift** will appear. Enter 1.5 in this field. Based on the results of a pilot study, the values of 0.55, 0.3, 0.1, and 0.05 are used as **Pop 1 probabilities**. Enter the inputs as shown below and click **Compute**.

|  | Des1 | 2-Sided | 0.05 | 0.98 | 100 | 1 | 4 | 1.5 |

26.4 Trend in R Ordered Binomial Proportions

26.4.1 Trial Design

In some experimental situations, there are several binomial distributions indexed by an ordinal variable and we want to examine changes in the probabilities of success as the levels of the indexing variable changes. Examples of this include the examination of a dose-related presence of a response or a particular side effect, dose-related tumorigenicity, or presence of fetal malformations relative to levels of maternal exposure to a particular toxin, such as alcohol, tobacco, or environmental factors.

The test for trend in R ordered proportions is based on the Cochran Armitage trend test. Let π_j denote the probability of interest for the j -th category of the ordinal variable, $j = 1, 2, \dots, R$ and let scores be denoted by $\omega_1, \omega_2, \dots, \omega_R$. It is assumed that the odds ratio relating to j -th category to the $(j - 1)$ -th category satisfies

$$\frac{\pi_j}{1 - \pi_j} = \psi^{\omega_j - \omega_{j-1}} \frac{\pi_{j-1}}{1 - \pi_{j-1}} \quad (26.4)$$

or equivalently,

$$\ln\left(\frac{\pi_j}{1 - \pi_j}\right) = (\omega_j - \omega_{j-1}) \ln(\psi) + \ln\left(\frac{\pi_{j-1}}{1 - \pi_{j-1}}\right) \quad (26.5)$$

This assumption can also be equivalently expressed as a relationship between the odds ratio for the j -th category to that of the first category; namely,

$$\frac{\pi_j}{1 - \pi_j} = \psi^{\omega_j - \omega_1} \frac{\pi_1}{1 - \pi_1} \quad (26.6)$$

or equivalently,

$$\ln\left(\frac{\pi_j}{1 - \pi_j}\right) = (\omega_j - \omega_1) \ln(\psi) + \ln\left(\frac{\pi_1}{1 - \pi_1}\right) \quad (26.7)$$

It is assumed that $\pi_1 < \dots < \pi_R$ with $\psi > 1$ or $\pi_1 > \dots > \pi_R$ with $\psi < 1$.

We want to test the null hypothesis $H_0 : \psi = 1$ against the two sided alternative $H_1 : \psi \neq 1$ or against a one-sided alternative $H_1 : \psi > 1$ or $H_1 : \psi < 1$. The sample size required to achieve a specified power or the power for a specified sample size is determined for a single-look design with the specified parameters. The sample size calculation is conducted using the methodology presented below, which is similar to that described in Nam, 1987.

Let $n_j = r_j N$ denote the sample size for the j -th category where r_j is the j -th sample fraction and N is the total sample size. The determination of the sample size required to control the power of the test of H_0 is based on

$$W = \sum_{j=1}^R r_j (\omega_j - \bar{\omega}) \hat{\pi}_j \tag{26.8}$$

with $\bar{\omega} = \sum_{j=1}^R r_j \omega_j$

The expected value of W is

$$E(W) = \sum_{j=1}^R r_j (\omega_j - \bar{\omega}) \pi_j \tag{26.9}$$

and the variance of W is

$$V(W) = \sum_{j=1}^R r_j (\omega_j - \bar{\omega})^2 \pi_j (1 - \pi_j) \tag{26.10}$$

The expected value of W under H_0 is

$$E_0(W) = \pi \sum_{j=1}^R r_j (\omega_j - \bar{\omega}) \tag{26.11}$$

and the variance of W under H_0 is

$$V_0(W) = \pi(1 - \pi) \sum_{j=1}^R r_j (\omega_j - \bar{\omega})^2 \tag{26.12}$$

26 Binomial Superiority n-Sample

Where,

$$\pi = \sum_{j=1}^R r_j \pi_j \quad (26.13)$$

The test statistic used to determine the sample size is

$$Z = \frac{W - E_0(W)}{V_0(W)^{\frac{1}{2}}} \quad (26.14)$$

The total sample size required for a two-sided test with type-1 error rate of α to have power $1 - \beta$ when $\psi = \psi_1$ is

$$N = \frac{[z_{\alpha/2} V_0(W)^{\frac{1}{2}} + z_{\beta} V(W)^{\frac{1}{2}}]^2}{E(W)^2} \quad (26.15)$$

The total sample size required for a one-sided test with type-1 error rate of α to have power $1 - \beta$ when $\psi = \psi_1$ is determined from (1.11) with $\alpha/2$ replaced by α .

26.4.1 Trial Design

Consider the problem of comparing three durations of therapy for a specific disorder. We want to have sufficiently large power when 10% of subjects with shorter duration, 25% of subjects with intermediate duration and 50% of subjects with extensive duration will respond by the end of therapy. These parameters result in an odds ratio of $\psi = 3$ or equivalently $\ln(\psi) = 1.1$. We would like to determine the sample size to achieve 90% power when $\ln(\psi) = 1.1$ based on a two-sided test at significance level 0.05.

Start East. Click **Design** tab, then click **Many Samples** in the **Discrete** group, and then click **Trend in R Ordered Binomial Proportions**.

The Input dialog box, with default input values will appear in the upper pane.

Response probabilities can be specified in one of the two ways, selected from **Response Probabilities**: (1) User Specified Probabilities or (2) Model Based Probabilities. User can specify probabilities for each population if he or she chooses User Specified Probabilities whereas Model Based Probabilities are based on logit

transformation. We will use **Model Based Probabilities** here. Under **Response Probabilities**, click **Model Based Probabilities** radio button. A new field for **log of Common odds Ratio** will appear. Enter **1.1** in this field. Enter **0.1** in **Prop. of Response** field. One can specify the **Scores (W(i))** also in monotonically increasing order. We will use **Equally Spaced** here. Enter the inputs as shown below and click **Compute**.

With Des1 selected in the **Library**, click  icon on the **Library** toolbar, and then click **Power vs. Sample Size**. The resulting power curve for this design is shown. You can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...** For now, you may close the chart before continuing.

The default specification of equally spaced scores is useful when the categories are ordinal, but not numerical. If the categories are numerical, such as doses of a therapy, then the numerical value will be more appropriate. Consider three doses of 10, 20, and 30. One must exhibit care in specification of $\log(\psi)$ when the differences between scores for adjacent categories are equal, but this common difference is not equal to one. Although the differences are equal, user defined scores must be used. If the common difference is equal to a positive value A, then equating $\log(\psi)$ to $1/A$ of that for the default of equally spaced scores, with a common difference of one, will provide identical results. With three doses of (Scores $W(i)$) of 10, 20, and 30 and \log of Common odds Ratio = 0.11, the results are the same as those shown above. This is shown in the following screenshot.

Log of Common odds Ratio $\pi_i(1 - \pi_{i-1}) / (1 - \pi_i)\pi_{i-1}$: * $(W_i - W_{i-1})$

Specify Table of Scores

| Population #(i) | Population Fraction | Scores $W(i)$ | Prop. Of Response |
|-----------------|---------------------|---------------|-------------------|
| 1 | 0.333 | 10 | 0.1 |
| 2 | 0.333 | 20 | 0.25 |
| 3 | 0.333 | 30 | 0.501 |

26 Binomial Superiority n-Sample

The design output will be displayed in the Output Preview, with the computed sample size highlighted in yellow. A total of 75 subjects must be enrolled in order to achieve 90% power under the alternative hypothesis when $\log(\psi) = .11$ and $\pi_1 = 0.1$.

| ID ▲ | Test Type | Specified α | Power | Sample Size | No. of Population | Population Fraction | Scores | Response Probability |
|------|-----------|--------------------|-------|-------------|-------------------|---------------------|----------------|----------------------|
| Des1 | 2-Sided | 0.05 | 0.902 | 75 | 3 | Equal | User Specified | Model Based |
| Des2 | 2-Sided | 0.05 | 0.902 | 75 | 3 | Equal | User Specified | Model Based |

Similarly, if the differences between scores for adjacent categories are not equal, user defined scores must be used. Consider three doses of 10, 20, and 50, with **log of Common odds Ratio**= 0.11. Change the scores (**Scores W(i)**) to 10, 20, and 50 in the previous design. This is shown in the following screenshot.

Log of Common odds Ratio $\pi_1(1 - \pi_{i-1})/(1 - \pi_i)\pi_{i-1}$: * (W_i - W_{i-1})

Specify Table of Scores

| Population #(i) | Population Fraction | Scores W(i) | Prop. Of Response |
|-----------------|---------------------|-------------|-------------------|
| 1 | 0.333 | 10 | 0.1 |
| 2 | 0.333 | 20 | 0.25 |
| 3 | 0.333 | 50 | 0.9 |

The design output will be displayed in the Output Preview, with the computed sample size highlighted in yellow. A total of 16 subjects must be enrolled in order to achieve 90% power under the alternative hypothesis when $\log(\psi) = .11$ and $\pi_1 = 0.1$.

| ID ▲ | Test Type | Specified α | Power | Sample Size | No. of Population | Population Fraction | Scores | Response Probability |
|------|-----------|--------------------|-------|-------------|-------------------|---------------------|----------------|----------------------|
| Des1 | 2-Sided | 0.05 | 0.902 | 75 | 3 | Equal | User Specified | Model Based |
| Des2 | 2-Sided | 0.05 | 0.902 | 75 | 3 | Equal | User Specified | Model Based |
| Des3 | 2-Sided | 0.05 | 0.914 | 16 | 3 | Equal | User Specified | Model Based |

Although, a small sample size is usually desirable, here it may be due to a value of $\pi_3 (= 0.90)$ which may be too large to be meaningful. Then the power should be controlled at a smaller value of $\log(\psi)$. Consider $\log(\psi) = 0.07$. Change the **log of Common odds Ratio** value to 0.07. This is shown in the following screenshot.

Log of Common odds Ratio $\pi_1(1 - \pi_{i-1})/(1 - \pi_1)\pi_{i-1}$: * $(W_i - W_{i-1})$

Specify Table of Scores

| Population #(i) | Population Fraction | Scores W(i) | Prop. Of Response |
|-----------------|---------------------|-------------|-------------------|
| 1 | 0.333 | 10 | 0.1 |
| 2 | 0.333 | 20 | 0.183 |
| 3 | 0.333 | 50 | 0.646 |

The design output will be displayed in the Output Preview, with the computed sample size highlighted in yellow. A total of 37 subjects must be enrolled in order to achieve 90% power under the alternative hypothesis when $\log(\psi) = .07$ and $\pi_1 = 0.1$.

| ID ▲ | Test Type | Specified α | Power | Sample Size | No. of Population | Population Fraction | Scores | Response Probability |

| Des1 | 2-Sided | 0.05 | 0.902 | 75 | 3 | Equal | User Specified | Model Based |
| Des2 | 2-Sided | 0.05 | 0.902 | 75 | 3 | Equal | User Specified | Model Based |
| Des3 | 2-Sided | 0.05 | 0.914 | 16 | 3 | Equal | User Specified | Model Based |
| Des4 | 2-Sided | 0.05 | 0.902 | 37 | 3 | Equal | User Specified | Model Based |

The trend test is particularly useful in situations where there are several categories. Consider now an example of a dose-ranging study to examine the safety of a therapy, with respect to the occurrence of a specified adverse event (AE), such as a dose-limiting toxicity (DLT). Six doses (1, 2, 4, 8, 12, 16) have been selected. It is expected that approximately 5% on the lowest dose will experience the AE. The study is to be designed to have power of 90% if approximately 20% on the highest dose experience the AE. This suggests that the study should be designed with $\log(\psi)$ approximately $(\log(0.20) - \log(0.05))/15 = 0.092$. Enter **log of Common odds Ratio** as 0.1, **Prop. Of Response** as 0.05 and **Number of Populations** as 6. Enter the **Scores W(i)** as 1, 2, 4, 8, 12, and 16. Leave all other values as defaults, and click **Compute**.

This sample size may not be economically feasible, so we instead select the sample size to achieve a power of 80%. Selecting **Power(1- β)** as 0.8 yields the result shown in the following screen shot. This design requires a combined total of 298 subjects from all groups to attain 80% power when $\log(\psi) = 0.1$ and $\pi_1 = 0.05$.

26.5 Chi-Square for R Unordered Binomial Proportions
26.5.1 Trial Design

Let π_{ij} denote proportions of response in i -th group and j -th category with $i = 1, 2, \dots, R$ and $j = 1, 2$ where R denotes the number of groups. The null hypothesis of equality of proportions in all groups for every category is tested against the alternative that at least one proportion is different across all groups for any category.

The null hypothesis is defined as,

$$H_0 : \pi_{i1} = \pi_0 \forall i$$

The alternative is defined as,

$$H_1 : \pi_{i1} \neq \pi_0 \text{ for any } i = 1, 2, \dots, R$$

Table 26.3: Table: $R \times 2$ Contingency Table

| Rows | Col 1 | Col 2 | Row Total |
|-----------|----------|----------|-----------|
| Row 1 | n_{11} | n_{12} | m_1 |
| Row 2 | n_{21} | n_{22} | m_2 |
| . | . | . | . |
| . | . | . | . |
| Row R | n_{R1} | n_{R2} | m_R |
| Col Total | n_1 | n_2 | N |

The test statistic is given as,

$$\chi^2 = \sum_{i=1}^R \sum_{j=1}^2 \frac{(n_{ij} - \frac{m_i n_j}{N})^2}{\frac{m_i n_j}{N}} \tag{26.16}$$

Let χ_0^2 be the observed value of χ^2 . For large samples, χ^2 has approximately Chi-squared distribution with d.f. $R - 1$. The p-value is approximated by $P(\chi_{R-1}^2 \geq \chi_0^2)$, where χ_{R-1}^2 denotes a Chi-squared random variable with d.f. = $R - 1$.

26.5.1 Trial Design

Consider a 3-arm trial with treatments A, B and C. The response is the reduction in

26 Binomial Superiority n-Sample

blood pressure (BP). From historical data it is known that the response rates of treatment A, B and C are 37.5%, 59% and 40% respectively. That is, out of 40 individuals under treatment A, 15 had a reduction in BP, out of 68 individuals under treatment B, 40 had a reduction in BP and out of 30 individuals under treatment C, 12 had a reduction in BP. Based on these data we can fill the entries in the table of proportions.

Table 26.4: Table: Proportion of Response

| Groups\Categories: | Reduction in BP | No Reduction | Marginal |
|--------------------|-----------------|--------------|----------|
| Treatment A | 0.375 | 0.625 | 1 |
| Treatment B | 0.59 | 0.41 | 1 |
| Treatment C | 0.4 | 0.6 | 1 |

This can be posed as a two-sided testing problem for testing $H_0 : \pi_A = \pi_B = \pi_C (= \pi_0, \text{ say})$ against $H_1 : \pi_i \neq \pi_0$ (for at least any $i = A, B, C$) at 0.05 level. We wish to determine the sample size to have 90% power for the values displayed in the above table.

Start East. Click **Design** tab, then click **Many Samples** in the **Discrete** group, and then click **Chi-Square Test for Unordered Binomial Proportions**.

The Input dialog box, with default input values will appear in the upper pane.

Enter the values of **Response Proportion** in each group and **Alloc.Ratio** $r_i = n_i/n_1$ where **Alloc.Ratio** $r_i = n_i/n_1$ is the corresponding weights relative to the first group . Enter the inputs as shown below and click **Compute**.

Number of Groups(R):

Test Parameters

Type I Error (α):

With Des1 selected in the **Library**, click  icon on the **Library** toolbar, and then

26 Binomial Superiority n-Sample

click **Power vs Sample Size**. The resulting power curve for this design is shown. You can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As....** For now, you may close the chart before continuing

26.6 Chi-Square for R Unordered Multinomial Proportions

Let π_{ij} denote the response proportion in i -th group and j -th category. The null hypothesis $H_0 : \pi_{1j} = \pi_{2j} = \dots = \pi_{Rj} \forall j = 1, 2, \dots, C$ is tested against the alternative hypothesis that for at least one category, the response proportions in all groups are not same.

The test statistic is given as,

$$\chi^2 = \sum_{i=1}^R \sum_{j=1}^C \frac{(n_{ij} - \frac{m_i n_j}{N})^2}{\frac{m_i n_j}{N}} \quad (26.17)$$

Let χ_0^2 be the observed value of χ^2 . For large samples, χ^2 has approximately

Table 26.5: Table: Contingency Table

| Rows | Col 1 | Col 2 | . | . | Col C | Row Total |
|-----------|----------|----------|---|---|----------|-----------|
| Row 1 | n_{11} | n_{12} | . | . | n_{1C} | m_1 |

Chi-squared distribution with d.f. $(R - 1)(C - 1)$. The p-value is approximated by $P(\chi^2_{(R-1)(C-1)} \geq \chi_0^2)$, where $\chi^2_{(R-1)(C-1)}$ denotes a Chi-squared random variable with d.f. $= (R - 1)(C - 1)$.

26.6.1 Trial Design

Consider a 3-arm oncology trial with treatments A, B and C. The responses in 4 categories - CR (complete response), PR (partial response), SD (stable disease) and PD (disease progression) are of interest. We wish to determine whether the response proportion in each of the 4 categories is same for the three treatments. From historical data we get the following proportions for each category for the three treatments. Out of 100 patients, 30 were treated with treatment A, 35 were treated with treatment B and 35 were treated with treatment C. The response proportion information for each treatment is given below. Assuming equal allocation in each treatment arm, we wish to design a two-sided test which achieves 90% power at significance level 0.05.

Table 26.6: Table: Contingency Table

| Categories \ Treatment | Treatment A | Treatment B | Treatment C |
|------------------------|-------------|-------------|-------------|
| CR | 0.019 | 0.158 | 0.128 |
| PR | 0.001 | 0.145 | 0.006 |
| SD | 0.328 | 0.154 | 0.003 |
| PD | 0.652 | 0.543 | 0.863 |
| Marginal | 1 | 1 | 1 |

Start East. Click **Design** tab, then click **Many Samples** in the **Discrete** group, and then click **Chi-Square R Unordered Multinomial Proportions**.

26 Binomial Superiority n-Sample

The Input dialog box with default input values will appear in the upper pane of this window.

Enter **Number of Categories (C)** as 4. Enter the values of **Proportion of Response** and $r_i = n_i/n_1$ where $r_i = n_i/n_1$ is the corresponding weights relative to the first group. Enter the inputs as shown below and click **Compute**.

Number of Groups(R): Number of Categories(C):

26 Binomial Superiority n -Sample

27 Multiple Comparison Procedures for Discrete Data

Sometime it might be the case that multiple treatment arms are compared with a placebo or control arm in one single trial on the basis of a primary endpoint that is binary. These objectives are formulated into a family of hypotheses. Formal statistical hypothesis tests can be performed to see if there is strong evidence to support clinical claims. Type I error is inflated when one considers the inferences together as a family. Failure to compensate for multiplicities can have adverse consequences. For example, a drug could be approved when actually it is not better than placebo. Multiple comparison (MC) procedures provides a guard against inflation of type I error due to multiple testing. The probability of making at least one type I error is known as family wise error rate (FWER). East supports following MC procedures based on binary endpoint.

| Procedure | Reference |
|---------------------|------------------------------------|
| Bonferroni | Bonferroni CE (1935, 1936) |
| Sidak | Sidak Z (1967) |
| Weighted Bonferroni | Benjamini Y and Hochberg Y (1997) |
| Holm’s Step Down | Holm S (1979) |
| Hochberg’s Step Up | Hochberg Y (1988) |
| Hommel’s Step Up | Hommel G (1988) |
| Fixed Sequence | Westfall PH and Krishen A (2001) |
| Fallback | Wiens B, Dmitrienko A (2005) |

In this chapter we explain how to design a study using a MC procedure.

In East, one can calculate the power from the simulated data under different MC procedures. With the information on power, one can choose the right MC procedure that provides maximum power yet strongly maintains the FWER. MC procedures included in East strongly control FWER. Strong control of FWER refers to preserving the probability of incorrectly claiming at least one null hypothesis. To contrast strong control with weak control of FWER, the latter controls the FWER under the assumption that all hypotheses are true.

27.1 Bonferroni Procedure

27.1.1 Example: HIV Study

Bonferroni procedure is described below with an example.

Assume that there are k arms including the control where the treatments arms will be compared with placebo on the basis of a binary response variable X . Let n_i be the

27 Multiple Comparison Procedures for Discrete Data

number of subjects for i -th treatment arm ($i = 0, 2, \dots, k - 1$). Let $N = \sum_{i=0}^{k-1} n_i$ be the total sample size and the arm 0 refers to control. Also, assume π_i be the response probabilities in i -th arm. We are interested in the following hypotheses:

- For the right tailed test: $H_i : \pi_i - \pi_0 \leq 0$ vs $K_i : \pi_i - \pi_0 > 0$
- For the left tailed test: $H_i : \pi_i - \pi_0 \geq 0$ vs $K_i : \pi_i - \pi_0 < 0$

For the global null hypothesis at least one of the H_i is rejected in favor of K_i after controlling for FWER. Here H_i and K_i refer to the null and alternative hypotheses, respectively, for comparison of i -th arm with the control arm.

Let $\hat{\pi}_i$ be the sample proportion for treatment arm i and $\hat{\pi}_0$ be the sample proportion for the control arm. For unpooled variance case, the test statistic to compare i -th arm with control (i.e., H_i vs K_i) is defined as

$$T_i = \frac{\hat{\pi}_i - \hat{\pi}_0}{\sqrt{\frac{1}{n_i} \hat{\pi}_i (1 - \hat{\pi}_i) + \frac{1}{n_0} \hat{\pi}_0 (1 - \hat{\pi}_0)}} \quad (i = 0, 2, \dots, k - 1) \quad (27.1)$$

For the pooled variance case, one need to replace $\hat{\pi}_i$ and $\hat{\pi}_0$ by the pooled sample proportion $\hat{\pi}$. Pooled sample proportion $\hat{\pi}$ is defined as

$$\hat{\pi} = \frac{n_i \hat{\pi}_i + n_0 \hat{\pi}_0}{n_i + n_0} \quad (i = 0, 2, \dots, k - 1) \quad (27.2)$$

Let t_i be the observed value of T_i and these observed values for $K - 1$ treatment arms can be ordered as $t_{(1)} \geq t_{(2)} \geq \dots \geq t_{(k-1)}$. For the right tailed test the marginal p-value for comparing the i -th arm with placebo is calculated as $p_i = P(Z > t_i) = \Phi(-t_i)$ and for left tailed test $p_i = P(Z < t_i) = \Phi(t_i)$, where Z is distributed as standard normal and $\Phi(\cdot)$ is the the cumulative distribution function of a standard normal variable. Let $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(k-1)}$ be the ordered p-values.

East supports three single step MC procedures for comparing proportions- Bonferroni procedure, Sidak procedure and weighted Bonferroni procedure. For the Bonferroni procedure, H_i is rejected if $p_i < \frac{\alpha}{k-1}$ and the adjusted p-value is given as $\min(1, (k - 1)p_i)$.

27.1.1 Example: HIV Study

This is a randomized, double-blind, parallel-group, placebo-controlled, multi-center study to assess the efficacy and safety of 125mg, 250 mg, and 500 mg orally twice daily of a new drug for a treatment of HIV associated diarrhea. The primary efficacy endpoint is clinical response, defined as two or less watery bowel movements per

week, during at least two of the four weeks of the 4-week efficacy assessment period. The efficacy will be evaluated by comparing the proportion of responders in the placebo group to the proportion of responders in the three treatment groups at a one-sided alpha of 0.025. The estimated response rate in placebo group is 35%. The response rates in the treatment groups are expected to be 40% for 125mg, 45% for 250mg and 55% for 500 mg.

| Dose (mg) | Estimated proportion |
|-----------|----------------------|
| Placebo | 0.35 |
| 125 | 0.40 |
| 250 | 0.45 |
| 500 | 0.55 |

With the above underlying scenario, we would like to calculate the power for a total sample size of 500. This will be a balanced study with a one-sided 0.025 significance level to detect at least one dose with significant difference from placebo. We will show how to simulate the power of such a study using the multiple comparison procedures listed above.

Designing the Study

Start East. Click **Design** tab, then click **Many Samples** in the **Discrete** group, and then click **Single Look** under **Multiple Pairwise Comparisons to Control - Differences of Proportions**.

This will launch a new window which asks the user to specify the values of a few design parameters including the number of arms, overall type I error, total sample size and multiple comparison procedure. For our example, we have 3 treatment groups plus a placebo. So enter **4** for **Number of Arms**. Under the **Test Parameters** tab, there are several fields which we will fill in. First, there is a box with the label **Test Type**. Here you need to specify whether you want a one-sided or two-sided test. Currently, only one-sided tests are available. The next dropdown box has the label **Rejection Region**. If left tail is selected, the critical value for the test is located in the left tail of the distribution of the test statistic. Likewise, if right tail is selected the critical value for the test is located in the right tail of the distribution of the test statistic. For our example, we will select **Right Tail**. Under that, there is a box with the label **Type - 1 Error (α)**. This is where you need to specify the FWER. For our example, enter 0.025. Now go to the box with the label **Sample Size (n)**. Here we input the total number of subjects, including those in the placebo arm. For this example, enter 500. To the right, there will be a heading with the title **Multiple Comparison Procedures**.

27 Multiple Comparison Procedures for Discrete Data

Check the box next to **Bonferroni**, as this is the multiple comparison procedure we are illustrating in this subsection. After entering these parameters your screen should now look like this:

Number of Arms:

Test Parameters
Response Generation
Simulation Controls

Test Type:

Rejection Region:

Type I Error (α):

Sample Size (n):

Multiple Comparisons Procedures

p-value

Bonferroni Hochberg's step up

Sidak Hommel's step up

Weighted Bonferroni Fixed Sequence

Holm's step down Fallback

Now click on **Response Generation** tab. You will see a table titled **Table of Proportions**. In this table we can specify the labels for treatment arms. Also you have to specify the dose level if you want to generate proportions through dose-response curve.

There are two fields in this tab above the table. The first one is labeled as **Variance** and this has drop down list with two options - **Pooled** and **Unpooled**. Here you have to select whether you are considering pooled variance or unpooled variance for the calculation of test statistics for each test. For this example, select **Unpooled** for **Variance**.

Variance:

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Response Rate |
|---------|---------------|
| Control | 0.1 |
| 1 | 0.3 |
| 2 | 0.5 |
| 3 | 0.7 |

Next to the **Variance** there is check box labeled **Generate Proportions Through DR Curve**. If you want to generate response rate for each arm according to dose-response

curve, you need to check this box. Check the box **Generate Proportions Through DR Curve**. Once you check this box you will notice two things. First, an additional column with label **Dose** will appear in the table. Here you need to enter the dose levels for each arm. For this example, enter 0, 125, 250 and 500 for Placebo, Dose1, Dose2 and Dose3 arms, respectively. Secondly, you will notice an additional section will appear to the right which provides the option to generate the response rate from four families of parametric curves which are Four Parameter Logistic, Emax, Linear and Quadratic. The technical details about each curve can be found in the Appendix H. Here you need to choose the appropriate parametric curve from the drop-down list under **Dose Response Curve** and then you have to specify the parameters associated with these curves. Suppose the response rate follows the following four parameter logistic curve:

$$E(\pi|D) = \beta + \frac{\delta}{1 + \exp\left(\frac{\theta - D}{\tau}\right)} \quad (27.3)$$

where D indicates dose. The parameter for the logistic dose-response curve should be chosen with care. We want to parameterize the above logistic model such that the proportions from logistic model agrees as close as possible to the estimated proportions stated at the beginning of the example. We will consider a situation where the response rate at dose 0 is very close to the parameter β . In other words, β indicates the placebo effect. For this to hold, $\frac{\delta}{1 + \exp\left(\frac{\theta - D}{\tau}\right)}$ should be very close to 0 at $D = 0$. For now, assume that it holds and we will return to this later. We have assumed 35% response rate in placebo arm. Therefore, we specify β as 0.35. The parameter $\beta + \delta$ indicates the maximum response rate. Since the response rate cannot exceed 1, δ should be chosen such a way that $\beta + \delta \leq 1$. The situation where the 100% response rate can never be achieved, δ would be even less. For this example, the response rate for the highest dose of 550 mg is 55%. Therefore, we assume that maximum response rate with the new drug could be achieved as only 60%. Therefore, we specify the δ as 0.60 - 0.35 or 0.25. The parameter θ indicates the median dose that can produce 50% of maximum improvement in response rate or a response that is equal to $\beta + \frac{\delta}{2}$. With $\beta = 0.35$ and $\delta = 0.25$, $\beta + \frac{\delta}{2}$ is 0.475. Note that we have assumed the dose 250 mg can provide response rate of 45%. Therefore, we assume θ as 300. τ need to be selected in such a way that $\frac{\delta}{1 + \exp\left(\frac{\theta - D}{\tau}\right)}$ should be very close to 0 at $D = 0$. We can assure this condition by choosing any small value of τ . However, a very small τ is an indicator of sharp improvement in response rate around the median dose and negligible improvement for almost other doses. In the HIV example, the estimated response rates indicate improvement in all the dose levels. With τ as 75, $\frac{\delta}{1 + \exp\left(\frac{\theta - D}{\tau}\right)}$ is 0.0045 and the proportions from the logistic regression are close to the estimated proportions for the chosen doses. Therefore, $\beta = 0.35$, $\delta = 0.25$, $\theta = 300$ and $\tau = 75$ seems to be a reasonable for our example.

27 Multiple Comparison Procedures for Discrete Data

Select **Four Parameter Logistic** from drop-down list of **Dose Response Curve**. To the right of this dropdown box, Now we need to specify the 4 parameter values in the **Parameters** box. Enter 0.35 for β , 0.25 for δ , 250 for θ and 75 for τ . You can verify that the values in **Response Rate** column is changed to 0.359, 0.39, 0.475 and 0.591 for the four arms, respectively. These proportions are very close to the estimated proportions stated at the beginning of the example.

Variance:

Generate Proportions Through DR Curve

Dose Response Curve:

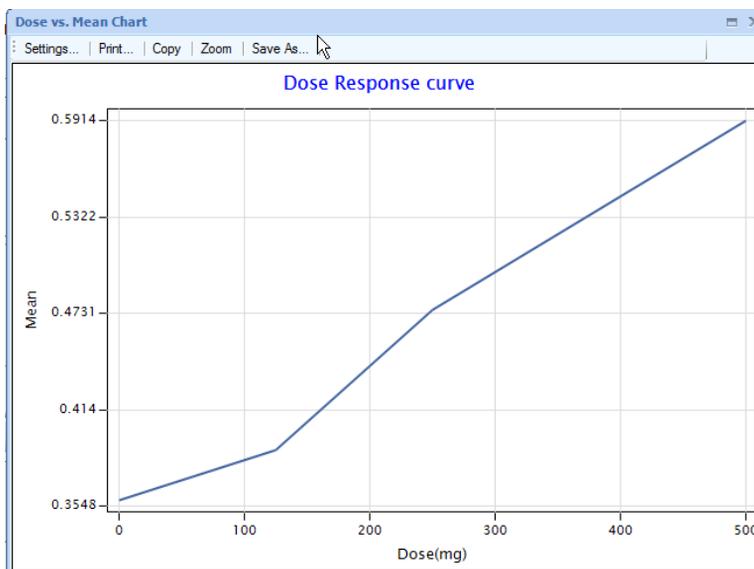

Parameters

| | | | |
|---------|----------|----------|--------|
| β | δ | θ | τ |
| 0.35 | 0.25 | 250 | 75 |

Table of Proportions

| Arm | Dose | Resp... Rate |
|---------|------|--------------|
| Control | 0 | 0.359 |
| 1 | 125 | 0.39 |
| 2 | 250 | 0.475 |
| 3 | 500 | 0.591 |

Now click **Plot DR Curve** located below the parameters to see the dose-response curve.

You will see the logistic dose response curve that intersects the Y-axis at 0.359. Close this plot. Since the response rates from logistic regression is close but not exactly

similar to the estimated proportions stated at the beginning of the example. Therefore, we will specify directly the estimated response rates in the **Table of Proportions**. In order to do this first uncheck **Generate Proportions Through DR Curve**. You will notice two things. First, the column with label **Dose** will disappear in the table. Second, the section in right will disappear as well. Now enter the estimated proportions in the **Response Rate** column. Enter 0.35, 0.40, 0.45 and 0.55 in this column. Now the **Response Generation** tab should appear as below.

Variance:

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Res... Rate | |
|---------|----------------|--|
| Control | 0.35 | |
| 1 | 0.4 | |
| 2 | 0.45 | |
| 3 | 0.55 | |

Click on the **Include Options** button located in the right-upper corner in the Simulation window and check **Randomized**. This will add **Randomization** tab. Now click on the **Randomization** tab. Second column of the **Table of Allocation** table displays the allocation ratio of each treatment arm to that of control arm. The cell for the control arm is always one and is not editable. Only those cells for treatment arms other than control need to be filled in. The default value for each treatment arm is one which represents a balanced design. For the HIV study example, we consider a balanced design and leave the default values for the allocation ratios unchanged. Your

27 Multiple Comparison Procedures for Discrete Data

screen should now look like this:

Randomization Method: Fixed Allocation

Table of Allocation

| Arm | $r_i = n_i/n_1$ |
|---------|-----------------|
| Control | 1.000 |
| 1 | 1.000 |
| 2 | 1.000 |
| 3 | 1.000 |

The last tab is **Simulation Control**. Specify 10000 as **Number of Simulations** and 1000 as **Refresh Frequency** in this tab. The box labeled **Random Number Seed** is where you can set the seed for the random number generator. You can either use the clock as the seed or choose a fixed seed (in order to replicate past simulations). The default is the **clock** and we will use that. The box besides that is labeled **Output Options**. This is where you can choose to save summary statistics for each simulation run and/or to save the subject level data for a specific number of simulation runs. To save the output for each simulation, check the box with label **Save summary statistics for every simulation run**.

Number of Simulations: 10000

Refresh Frequency: 1000

Random Number Seed

Clock

Fixed [100]

Suppress All Intermediate Output

Pause after Refresh

Stop At End

Output Options

Output Type: Case Data

Save summary statistics for every simulation run

Save subject level data for [1] simulation runs

Note: Max. 100,000 records will be saved.

Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim1.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |

Summary

Using Bonferroni test, this study has 0.807 global power to detect at least one treatment arm which is different from control arm given a total sample size 500. This test has conjunctive power 0.035 to detect all treatment arms which are truly different from control arm. This test provides disjunctive power 0.807 to detect at least one treatment arm which is truly different from control arm.

The first section in the output is the **Hypothesis** section. In our situation, we are testing 3 hypotheses. We are comparing the estimated response rate of each dose group with that of placebo. That is, we are testing the 3 hypotheses:

$$H_1 : \pi_1 = \pi_0 \quad \text{vs} \quad K_1 : \pi_1 > \pi_0$$

$$H_2 : \pi_2 = \pi_0 \quad \text{vs} \quad K_2 : \pi_2 > \pi_0$$

$$H_3 : \pi_3 = \pi_0 \quad \text{vs} \quad K_3 : \pi_3 > \pi_0$$

Here, π_0, π_1, π_2 and π_3 represent the population response rate for the placebo, 125 mg, 250 mg and 500 mg dose groups, respectively. Also, H_i and K_i are the null and alternative hypotheses, respectively, for the i -th test.

The **Input Parameters** section provides the design parameters that we specified earlier. The next section **Overall Power** gives us estimated power based on the simulation. The second line gives us the global power, which is 0.807. Global power indicates the power to reject global null $H_0 : \mu_1 = \mu_2 = \mu_3 = \mu_0$. Thus, the global power of 0.807 indicates that 80.7% of times the global null will be rejected. In other words, at least one of the H_1, H_2 and H_3 is rejected in 81.2% of the occasions. Global

27 Multiple Comparison Procedures for Discrete Data

power is useful to show the existence of dose-response relationship and the dose-response may be claimed if any of the doses in the study is significantly different from placebo.

The next line displays the conjunctive power. Conjunctive power indicates the proportion of cases in the simulation where all the H_i 's, which are truly false, were rejected. In this example, all the H_i 's are false. Therefore, for this example, conjunctive power is the proportion of cases where all of the H_1 , H_2 and H_3 were rejected. For this simulation conjunctive power is only 0.035 which means that only in 3.5% of time, all of the H_1 , H_2 and H_3 were rejected.

Disjunctive power indicates the proportion of rejecting at least one of those H_i 's where H_i is truly false. The main distinction between global and distinctive power is that the former finds any rejection whereas the latter looks for rejection only among those H_i 's which are false. Since here all of the H_1 , H_2 and H_3 are false, therefore, global and disjunctive power ought to be the same.

The next section gives us the marginal power for each hypothesis. Marginal power finds the proportion of times when a particular hypothesis is rejected. Based on simulation results, H_1 is rejected about 6% of times, H_2 is rejected about 22% of times and H_3 is rejected about 80% of times.

Recall that we have asked East to save the simulation results for each simulation run—. Open this file by clicking on **SummaryStat** in the library and you will see that it contains 10,000 rows - each rows represents results for a single simulation. Find the 3 columns with labels **Rej_Flag_1**, **Rej_Flag_2** and **Rej_Flag_3**, respectively. These columns represents the rejection status for H_1 , H_2 and H_3 , respectively. A value of 1 is indicator of rejection on that particular simulation, otherwise the null is not rejected. Now the proportion of 1's in **Rej_Flag_1** indicates the marginal power to reject H_1 . Similarly we can find out the marginal power for H_2 and H_3 from **Rej_Flag_2** and **Rej_Flag_3**, respectively. To obtain the global and disjunctive power, count the total number of cases where at least one of the H_1 , H_2 and H_3 have been rejected and then divide by the total number of simulations of 10,000. Similarly, to obtain the conjunctive power count the total number of cases where all of the H_1 , H_2 and H_3 have been rejected and then divide by the total number of simulations of 10,000.

Next we will consider an example to show how global and disjunctive power are different from each other. Select Sim 1 in **Library** and click . Now go to the the **Response Generation** tab and enter 0.35, 0.35, 0.38 and 0.42 in the 4 cells in second

column labeled as **Response Rate**.

Variance:

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Res... Rate |
|---------|----------------|
| Control | 0.35 |
| 1 | 0.35 |
| 2 | 0.38 |
| 3 | 0.42 |

Here we are generating response for placebo from distribution $\text{Bin}(125, 0.35)$, for Dose1 from distribution $\text{Bin}(125, 0.35)$, for Dose2 from distribution $\text{Bin}(125, 0.38)$ and for Dose3 from distribution $\text{Bin}(125, 0.42)$. Click **Simulate** to start the simulation. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 2.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Bonferroni | 1-Sided | 0.025 | 0.009 | 3 | 500 | Right-Tail | Un-pooled | 0.121 | 0.015 | 0.118 | 500 |

For Sim 2, the global power and disjunctive power are close to 12%. To understand why, click on **SummaryStat** in the library for Sim 2. The total number of cases where at least one of H_1 , H_2 and H_3 are rejected is about 1270 and dividing this by total number of simulation 10,000 gives the global power of 12.7%. Again, the total number of cases where at least one of H_2 and H_3 are rejected is close to 1230 and dividing this by total number of simulation 10,000 gives the disjunctive power of 12.3%. The exact result of the simulations may differ slightly, depending on the seed.

Now, delete the Sim 2 from the **Output Preview** because we have modified the design in HIV example to explain the difference between global power and disjunctive power. In order to do this, select row corresponding to Sim 2 in **Output Preview** and click  in the toolbar.

27 Multiple Comparison Procedures for Discrete Data

27.2 Weighted Bonferroni procedure

In this section we will cover the weighted Bonferroni procedure with the same HIV example.

For the weighted Bonferroni procedure, H_i is rejected if $p_i < w_i\alpha$ and the adjusted p-value is given as $\min(1, \frac{p_i}{w_i})$. Here w_i denotes the proportion of α allocated to the H_i such that $\sum_{i=1}^{k-1} w_i = 1$. Note that, if $w_i = \frac{1}{k-1}$, then the Bonferroni procedure is reduced to the regular Bonferroni procedure.

Since the other design specifications remain same except that we are using weighted Bonferroni procedure in place of Bonferroni procedure, we can design simulation in this section with only little effort. Select Sim 1 in **Library** and click . Now go to the **Test Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Bonferroni** box and check the **Weighted Bonferroni** box.

Next click on **Response Generation** tab and look at the **Table of Proportions**. You will see an additional column with label **Proportion of Alpha** is added. Here you have to specify the proportion of total alpha you want to spend in each test. Ideally, the values in this column should add up to 1; if not, then East will normalize it to add them up to 1. By default, East distributes the total alpha equally among all tests. Here we have 3 tests in total, therefore each of the tests have proportion of alpha as $1/3$ or 0.333. You can specify other proportions as well. For this example, keep the equal

proportion of alpha for each test.

Variance: Un-pooled

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Resp... Rate | Proportion of Alpha |
|---------|--------------|---------------------|
| Control | 0.35 | |
| 1 | 0.4 | 0.333 |
| 2 | 0.45 | 0.333 |
| 3 | 0.55 | 0.333 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim 2.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |

The weighted Bonferroni MC procedure has global and disjunctive power of 81% and conjunctive power of 3.4%. Note that, the powers in the weighted Bonferroni procedure is quite close to the Bonferroni procedure. This is because the weighted Bonferroni procedure with equal proportion is equivalent to the simple Bonferroni procedure. The difference in power between Bonferroni test in previous section and the weighted Bonferroni power in this section attributed to simulation error. The exact result of the simulations may differ slightly, depending on the seed. Now select Sim2 in the **Output Preview** and click the  icon. This will save Sim2 in Wbk1 in **Library**.

27 Multiple Comparison Procedures for Discrete Data

27.3 Sidak procedures

Sidak procedures are described below using the same HIV example from the section 27.1. For the Sidak procedure, H_i is rejected if $p_i < 1 - (1 - \alpha)^{\frac{1}{k-1}}$ and the adjusted p-value is given as $1 - (1 - p_i)^{k-1}$.

Select Sim1 in **Library** and click . Now go to the **Test Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Bonferroni** box and check the **Sidak** box.

Number of Arms:

Test Parameters

Type I Error (α):

Sample Size (n):

Multiple Comparisons Procedures

p-value

Bonferroni Hochberg's step up

Sidak Hommel's step up

Weighted Bonferroni Fixed Sequence

Holm's step down Fallback

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional rows to the **Output Preview** labeled as Sim3.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |
| Sim3 | Sidak | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.038 | 0.812 | 500 |

Sidak procedure has disjunctive and global powers of 81% and conjunctive powers of 3.8%. The exact result of the simulations may differ slightly, depending on the seed.

Now select Sim 3 in the **Output Preview** using the Ctrl key and click the  icon. This will save Sim 3 in the Wbk1 in **Library**.

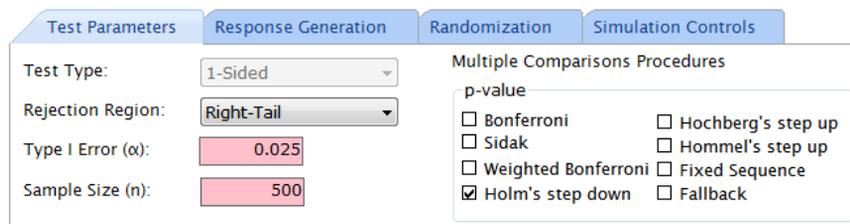

27.4 Holm's step-down procedure

In the single step MC procedures, the decision to reject any hypothesis does not depend on the decision to reject other hypotheses. On the other hand, in the stepwise procedures decision of one hypothesis test can influence the decisions on the other tests of hypotheses. There are two types of stepwise procedures. One type of procedures proceeds in data-driven order. The other type proceeds in a fixed order set a priori. Stepwise tests in a data-driven order can proceed in step-down or step-up manner. East supports Holm step down MC procedure which start with the most significant comparison and continue as long as tests are significant until the test for

certain hypothesis fails. The testing procedure stops at the first time a non-significant comparison occurs and all remaining hypotheses will be retained. In i -th step, $H_{(i)}$ is rejected if $p_{(i)} \leq \frac{\alpha}{k-i}$ and goes to the next step.

Holm's step down

As before we will use the same HIV example to illustrate Holm's step down procedure. Select Sim1 in **Library** and click . Now go to the the **Test Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Bonferroni** box and check the **Holm's Step down** box.

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim4.

| ID ▲ | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |
| Sim3 | Sidak | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.038 | 0.812 | 500 |
| Sim4 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.09 | 0.811 | 500 |

Holm's step down procedure has global and disjunctive power close to 81% and conjunctive power close to 9%. The exact result of the simulations may differ slightly, depending on the seed. Now select Sim4 in the **Output Preview** and click the  icon. This will save Sim4 in Wbk1 in **Library**.

27.5 Hocheberg and Hommel procedures

Step-up tests start with the least significant comparison and continue as long as tests are not significant until the first time when a significant comparison occurs and all remaining hypotheses will be rejected. East supports two such MC procedures - Hochberg step-up and Hommel step-up procedures. In the Hochberg step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-i)} > \frac{\alpha}{i}$. In the Hommel step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-j)} > \frac{i-j+1}{i} \alpha$ for $j = 1, \dots, i$. Fixed

27 Multiple Comparison Procedures for Discrete Data

sequence test and fallback test are the types of tests which proceed in a prespecified order.

Hochberg's and Hommel's step up procedures are described below using the same HIV example from the section 27.1 on Bonferroni procedure.

Since the other design specifications remain same except that we are using Dunnett's step down in place of single step Dunnett's test we can design simulation in this section with only little effort. Select Sim1 in **Library** and click . Now go to the **Test Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Bonferroni** box and check the **Hochberg's step up** and **Hommel's step up** boxes.

Holm's step down Fallback

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add two additional rows to the **Output Preview** labeled as Sim 5 and Sim 6.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |
| Sim3 | Sidak | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.038 | 0.812 | 500 |
| Sim4 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.09 | 0.811 | 500 |
| Sim5 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.097 | 0.812 | 500 |
| Sim6 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.814 | 0.097 | 0.814 | 500 |

The Hocheberg and Hommel procedures have disjunctive and global powers of 81.2% and 81.4%, respectively and conjunctive powers close to 10%. The exact result of the simulations may differ slightly, depending on the seed. Now select Sim5 and Sim6 in the **Output Preview** using Ctrl key and click the  icon. This will save Sim5 and Sim6 in Wbk1 in **Library**.

27.6 Fixed-sequence testing procedure

In data-driven stepwise procedures, we don't have any control on the order of the hypotheses to be tested. However, sometimes based on our preference or prior knowledge we might want to fix the order of tests a priori. Fixed sequence test and fallback test are the types of tests which proceed in a pre-specified order. East supports both of these procedures.

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is prespecified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the associated raw marginal p-values. In the fixed sequence testing procedure, for $i = 1, \dots, k - 1$, in i -th step, if $p_i < \alpha$, reject H_i and go to the next step; otherwise retain H_i, \dots, H_{k-1} and stop.

Fixed sequence testing strategy is optimal when early tests in the sequence have largest treatment effect and performs poorly when early hypotheses have small treatment effect or are nearly true (Westfall and Krishen 2001). The drawback of fixed sequence test is that once a hypothesis is not rejected no further testing is permitted. This will lead to lower power to reject hypotheses tested later in the sequence.

As before we will use the same HIV example to illustrate fixed sequence testing procedure. Select Sim 1 in **Library** and click . Now go to the the **Test Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Bonferroni** box and check the **Fixed Sequence** box.

Number of Arms:

| Test Parameters | Response Generation | Randomization | Simulation Controls |
|--|--|---------------|---------------------|
| Test Type: <input type="text" value="1-Sided"/> Rejection Region: <input type="text" value="Right-Tail"/> Type I Error (α): <input type="text" value="0.025"/> Sample Size (n): <input type="text" value="500"/> | Multiple Comparisons Procedures p-value <input type="checkbox"/> Bonferroni <input type="checkbox"/> Hochberg's step up <input type="checkbox"/> Sidak <input type="checkbox"/> Hommel's step up <input type="checkbox"/> Weighted Bonferroni <input checked="" type="checkbox"/> Fixed Sequence <input type="checkbox"/> Holm's step down <input type="checkbox"/> Fallback | | |

Next click on **Response Generation** tab and look at the **Table of Proportions**. You will see an additional column with label **Test Sequence** is added. Here you have to specify the order in which the hypotheses will be tested. Specify 1 for the test that will be tested first, 2 for the test that will be tested next and so on. By default East specifies 1 to the first test, 2 to the second test and so on. For now we will keep the default

27 Multiple Comparison Procedures for Discrete Data

which means that H_1 will be tested first followed by H_2 and finally H_3 will be tested.

Variance: Un-pooled

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Resp... Rate | Test Sequence |
|---------|-----------------|------------------|
| Control | 0.35 | |
| 1 | 0.4 | 1 |
| 2 | 0.45 | 2 |
| 3 | 0.55 | 3 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional row to the **Output Preview** labeled as Sim7.

| ID ▲ | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |
| Sim3 | Sidak | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.038 | 0.812 | 500 |
| Sim4 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.09 | 0.811 | 500 |
| Sim5 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.097 | 0.812 | 500 |
| Sim6 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.814 | 0.097 | 0.814 | 500 |
| Sim7 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.133 | 0.097 | 0.133 | 500 |

The fixed sequence procedure with the specified sequence has global and disjunctive power close to 13% and conjunctive power close to 10%. The reason for small global and disjunctive power is due to the smallest treatment effect is tested first and the magnitude of treatment effect increases gradually for the remaining tests. For optimal power in fixed sequence procedure, the early tests in the sequence should have larger treatment effects. In our case, Dose3 has largest treatment effect followed by Dose2 and Dose1. Therefore, to obtain optimal power, H_3 should be tested first followed by H_2 and H_1 .

Select Sim7 in the **Output Preview** and click the  icon. Now, select Sim7 in **Library**, click  and go to the the **Response Generation** tab. In **Test Sequence**

column in the table, specify 3 for Dose1, 2 for Dose2 and 1 for Dose3.

Variance:

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Resp... Rate | Test Sequence |
|---------|--------------|---------------|
| Control | 0.35 | |
| 1 | 0.4 | 3 |
| 2 | 0.45 | 2 |
| 3 | 0.55 | 1 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional rows to the **Output Preview** labeled as Sim8.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |
| Sim3 | Sidak | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.038 | 0.812 | 500 |
| Sim4 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.09 | 0.811 | 500 |
| Sim5 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.097 | 0.812 | 500 |
| Sim6 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.814 | 0.097 | 0.814 | 500 |
| Sim7 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.133 | 0.097 | 0.133 | 500 |
| Sim8 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.892 | 0.097 | 0.892 | 500 |

Now the fixed sequence procedure with the pre-specified sequence (H_3, H_2, H_1) has global and disjunctive power close to 89% and conjunctive power of 9.7%. This example illustrates that fixed sequence procedure is powerful provided the hypotheses are tested in a sequence of descending treatment effects. Fixed sequence procedure controls the FWER because for each hypothesis, testing is conditional upon rejecting all hypotheses earlier in sequence. The exact result of the simulations may differ slightly, depending on the seed. Select Sim8 in the **Output Preview** and click the  icon to save it in **Library**.

27.7 Fallback procedure

Fallback test alleviates the above undesirable feature for fixed sequence test. Let w_i be the proportion of α for testing H_i such that $\sum_{i=1}^{k-1} w_i = 1$. In the fixed sequence

27 Multiple Comparison Procedures for Discrete Data

testing procedure, in i -th step ($i = 1, \dots, k - 1$), test H_i at $\alpha_i = \alpha_{i-1} + \alpha w_i$ if H_{i-1} is rejected and at $\alpha_i = \alpha w_i$ if H_{i-1} is retained. If $p_i < \alpha_i$, reject H_i ; otherwise retain it. Unlike the fixed sequence testing approach, the fallback procedure can continue testing even if a non-significant outcome is encountered by utilizing the fallback strategy. If a hypothesis in the sequence is retained, the next hypothesis in the sequence is tested at the level that would have been used by the weighted Bonferroni procedure. With $w_1 = 1$ and $w_2 = \dots = w_{k-1} = 0$, the fallback procedure simplifies to fixed sequence procedure.

Again we will use the same HIV example to illustrate the fallback procedure. Select Sim 1 in **Library** and click . Now go to the **Test Parameters** tab. In the **Multiple Comparison Procedures** box, uncheck the **Dunnett's single step** box and check the **Fallback** box.

Number of Arms:

| Test Parameters | Response Generation | Randomization | Simulation Controls |
|--|--|---------------|---------------------|
| Test Type: <input type="text" value="1-Sided"/> Rejection Region: <input type="text" value="Right-Tail"/> Type I Error (α): <input type="text" value="0.025"/> Sample Size (n): <input type="text" value="500"/> | Multiple Comparisons Procedures p-value <input type="checkbox"/> Bonferroni <input type="checkbox"/> Hochberg's step up <input type="checkbox"/> Sidak <input type="checkbox"/> Hommel's step up <input type="checkbox"/> Weighted Bonferroni <input type="checkbox"/> Fixed Sequence <input type="checkbox"/> Holm's step down <input checked="" type="checkbox"/> Fallback | | |

Next click on **Response Generation** tab and look at the **Table of Proportions**. You will see two additional columns with label **Test Sequence** and **Proportion of Alpha**. In the column **Test Sequence**, you have to specify the order in which the hypotheses will be tested. Specify 1 for the test that will be tested first, 2 for the test that will be tested next and so on. By default East specifies 1 to the first test, 2 to the second test and so on. For now we will keep the default which means that H_1 will be tested first followed by H_2 and finally H_3 will be tested.

In the column **Proportions of Alpha**, you have to specify the proportion of total alpha you want to spend in each test. Ideally, the values in this column should add up to 1; if not, then East will normalize it to add them up to 1. By default East distributes the total alpha equally among the all tests. Here we have 3 tests in total, therefore each of the tests have proportion of alpha as $1/3$ or 0.333 . You can specify other proportions as

well. For this example, keep the equal proportion of alpha for each test.

Variance: Un-pooled

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Resp... Rate | Test Sequence | Proportion of Alpha |
|---------|--------------|---------------|---------------------|
| Control | 0.35 | | |
| 1 | 0.4 | 1 | 0.333 |
| 2 | 0.45 | 2 | 0.333 |
| 3 | 0.55 | 3 | 0.333 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional rows to the **Output Preview** labeled as Sim9.

| ID ▲ | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |
| Sim3 | Sidak | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.038 | 0.812 | 500 |
| Sim4 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.09 | 0.811 | 500 |
| Sim5 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.097 | 0.812 | 500 |
| Sim6 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.814 | 0.097 | 0.814 | 500 |
| Sim7 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.133 | 0.097 | 0.133 | 500 |
| Sim8 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.892 | 0.097 | 0.892 | 500 |
| Sim9 | Fallback | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.043 | 0.811 | 500 |

The fixed sequence procedure with the specified sequence had global and disjunctive power close to 13% and conjunctive power of 9%. With the same pre-specified order for testing hypotheses, fallback procedure has superior power compared to fixed sequence procedure. This is because the fallback procedure can continue testing even if a non-significant outcome is encountered whereas the fixed sequence procedure has to stop when a hypothesis in the sequence is not rejected. Now we will consider a sequence where H_3 will be tested first followed by H_2 and H_1 because in our case, Dose3 has largest treatment effect followed by Dose2 and Dose1.

Select Sim 9 in the **Output Preview** and click the  icon. Now, select Simulation 9 in **Library**, click  and go to the the **Response Generation** tab. In **Test Sequence**

27 Multiple Comparison Procedures for Discrete Data

column in the table, specify 3 for Dose1, 2 for Dose2 and 1 for Dose3.

Variance: Un-pooled ▼

Generate Proportions Through DR Curve

Table of Proportions

| Arm | Response Rate | Test Sequence | Proportion of Alpha |
|---------|---------------|---------------|---------------------|
| Control | 0.35 | | |
| 1 | 0.4 | 3 | 0.333 |
| 2 | 0.45 | 2 | 0.333 |
| 3 | 0.55 | 1 | 0.333 |

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional rows to the **Output Preview** labeled as Sim 10.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size |
|-------|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|------------------|-----------|--------------|-------------------|-------------------|---------------------|
| Sim1 | Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.807 | 0.035 | 0.807 | 500 |
| Sim2 | Weighted Bonferroni | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.81 | 0.034 | 0.81 | 500 |
| Sim3 | Sidak | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.038 | 0.812 | 500 |
| Sim4 | Holm's step down | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.09 | 0.811 | 500 |
| Sim5 | Hochberg's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.812 | 0.097 | 0.812 | 500 |
| Sim6 | Hommel's step up | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.814 | 0.097 | 0.814 | 500 |
| Sim7 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.133 | 0.097 | 0.133 | 500 |
| Sim8 | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.892 | 0.097 | 0.892 | 500 |
| Sim9 | Fallback | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.043 | 0.811 | 500 |
| Sim10 | Fallback | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.811 | 0.084 | 0.811 | 500 |

Now the fixed sequence procedure with the pre-specified sequence (H_3, H_2, H_1) had global and disjunctive power of 89% and conjunctive power of 9.7%. The obtained power is very close to Sim 9. Therefore, specification of sequence in descending treatment effect does not make much difference in terms of power. The exact result of

the simulations may differ slightly, depending on the seed. Select Sim10 in the **Output Preview** and click the  icon to save it in **Library**.

27.8 Comparison of MC procedures

We have obtained the power (based on the simulations) for different MC procedures for the HIV example in the previous sections. Now the obvious question is which MC procedure to choose. To compare all the MC procedure, we will perform simulations for all the MC procedures under the following scenario.

- Treatment arms: placebo, dose1 (dose=0.3 mg), dose2 (dose=1 mg) and dose3 (dose=2 mg) with respective proportions as 0.35, 0.4, 0.45 and 0.55, respectively.
- Variance: Unpooled
- Proportion of Alpha: Equal (0.333)
- Type I Error: 0.025 (right-tailed)
- Number of Simulations:10000
- Total Sample Size:500
- Allocation ratio: 1 : 1 : 1 : 1

For comparability of simulation results, we have used similar seed for simulation under all MC procedures (we have used seed as 5643). Following output displays the powers under different MC procedures. Clean up the **Output Preview** area, select all the checkboxes corresponding to the procedures and hit **Simulate**.

| ID | Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Rejection Region | Variance | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size | |

| <input type="checkbox"/> | Fixed Seq(1, 2, 3) | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.136 | 0.099 | 0.136 | 500 |
| <input type="checkbox"/> | Fallback (1, 2, 3) | Fallback | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.819 | 0.047 | 0.819 | 500 |
| <input type="checkbox"/> | Fixed Seq (3, 2, 1) | Fixed Sequence | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.895 | 0.099 | 0.895 | 500 |
| <input type="checkbox"/> | Fallback (3, 2, 1) | Fallback | 1-Sided | 0.025 | 0 | 3 | 500 | Right-Tail | Un-pooled | 0.819 | 0.085 | 0.819 | 500 |

Here we have used equal proportions for weighted Bonferroni and Fallback procedures. For the two fixed sequence testing procedures (fixed sequence and fallback) two sequences have been used - (H_1, H_2, H_3) and (H_3, H_2, H_1) . As expected, Bonferroni and weighted Bonferroni procedures provides similar powers. It appears that fixed sequence procedure with the pre-specified sequence (H_3, H_2, H_1) provides the power of 89.5% which is the maximum among all the procedures. However, fixed sequence procedure with the pre-specified sequence (H_1, H_2, H_3) provides power of 13.6%. Therefore, power in fixed sequence procedure is largely

27 *Multiple Comparison Procedures for Discrete Data*

dependent on the specification of sequence of testing and a mis-specification might result in huge drop in power.

All the remaining remaining procedures have almost equal global and disjunctive powers - about 82%. Now, in terms of conjunctive power, Hochberg's step-up and Hommel's step-up procedures have the highest conjunctive power of 9.9%. Therefore, we can choose either Hochberg's step-up or Hommel's step-up procedure for a prospective HIV study discussed in section [27.1](#).

28 *Multiple Endpoints-Gatekeeping Procedures for Discrete Data*

Clinical trials are often designed to assess benefits of a new treatment compared to a control treatment with respect to multiple clinical endpoints which are divided into hierarchically ordered families. Typically, the primary family of endpoints defines the overall outcome of the trial, provides the basis for regulatory claim and is included in the product label. The secondary families of endpoints play a supportive role and provide additional information for physicians, patients, payers and are useful for enhancing the product label. Gatekeeping procedures address multiplicity problems by explicitly taking into account the hierarchical structure of the multiple objectives. The term "gatekeeping" indicates the hierarchical decision structure where the higher ranked families serve as "gatekeepers" for the lower ranked family. Lower ranked families won't be tested if the higher ranked families have not passed requirements. Two types of gatekeeping procedures for discrete outcomes, parallel and serial, are described in this chapter. For more information about applications of gatekeeping procedures in a clinical trial setting and literature review on this topic, please refer to Dmitrienko and Tamhane (2007).

East uses simulations to assess the operating characteristics of different designs using gatekeeping procedures. For example, one could simulate the power for a variety of sample sizes in a simple batch procedure. It is important to note that when determining the sample size for a clinical trial with multiple co-primary endpoints, if the correlation among the endpoints is not taken into consideration, the sample size may be overestimated (Souza, et al 2010). East uses information about the correlation among the multiple endpoints in order to determine a more feasible sample size.

28.1 *MK-0974 (telcagepant) for Acute Migraine* Consider the randomized, placebo-controlled, double blind, parallel treatment clinical trial designed to compare two treatments for migraine, a common disease and leading cause of disability. Standard treatment includes the use of Triptans, which although generally well tolerated, have a vasoconstrictor effect, which can be problematic. This leaves a certain population of patients with underlying cardiovascular disease, uncontrolled hypertension or certain subtypes of migraine unable to access this treatment. In addition, for some patients this treatment has no or low beneficial effect and is associated with some undesirable side effects resulting in the discontinuation of the drug (Ho et al, 2008). In this study, multiple doses of the drug Telcagepant (300 mg, 150 mg), an antagonist of the CGRP receptor associated with migraine, and zolmitriptan (5mg) the standard treatment against migraine, are compared against a placebo. The five co-primary endpoints include pain freedom, pain relief, absence of photophobia (sensitivity to light), absence of phonophobia (sensitivity to sound), and absence of nausea two hours post treatment. Three co-secondary endpoints included more sustained measurements of pain freedom, pain relief, and total migraine freedom

28 Multiple Endpoints-Gatekeeping Procedures for Discrete Data

for up to a 24 hour period. The study employed a full analysis set where the multiplicity of endpoints was addressed using a step-down closed testing procedure. Due to the negative aspects of zolmitriptan, investigators were primarily interested in determining the efficacy of Telcagepant for the acute treatment of migraine with the hope of an alternative treatment with fewer associated side effects. This study will be used to illustrate the two gatekeeping procedures East provides for multiple discrete endpoints.

28.2 Serial Gatekeeping Design - Simulation for Discrete Outcomes

Serial gatekeeping procedures were studied by Maurer, Hothorn and Lehmacher (1995), Bauer et al. (1998) and Westfall and Krishen (2001). Serial gatekeepers are encountered in trials where endpoints are usually ordered from most important to least important. Suppose that a trial is declared successful only if the treatment effect is demonstrated on both primary and secondary endpoints. If endpoints in the primary trial are successful, it is only then of interest to assess the secondary endpoints. Correlation coefficients between the endpoints are bounded and East computes the valid range of acceptable values. As the number of endpoints increases, the restriction imposed on the valid range of correlation values is also greater. Therefore for illustration purpose, the above trial is simplified to consider three primary endpoints, pain freedom (PF), absence of phonophobia (phono) and absence of photophobia (photo) at two hours post treatment. Only one endpoint from the secondary family, sustained pain freedom (SPF), will be included in the example. Additionally, where the original trial studied multiple doses and treatments, this example will use only two groups to focus the comparison on the higher dose of Telcagepant of 300mg, and placebo. The example includes correlation values intended to represent zero, mild and moderate correlation accordingly, to examine its effect on power.

The efficacy, or response rate, of the endpoints for subjects in the treatment group and placebo group and a sample correlation matrix follows:

| | Response Telcagepant 300mg | Response Placebo |
|-------|----------------------------|------------------|
| PF | 0.269 | 0.096 |
| phono | 0.578 | 0.368 |
| photo | 0.51 | 0.289 |
| SPF | 0.202 | 0.05 |

| | ρ_{12} | ρ_{13} | ρ_{23} | ρ_{14} | ρ_{24} | ρ_{34} |
|--------|-------------|-------------|-------------|-------------|-------------|-------------|
| Sim 1 | 0 | 0 | 0 | 0 | 0 | 0 |
| Sim 2 | 0 | 0 | 0.3 | 0 | 0 | 0 |
| Sim 3 | 0 | 0 | 0.5 | 0 | 0 | 0 |
| Sim 4 | 0 | 0 | 0.8 | 0 | 0 | 0 |
| Sim 5 | 0.3 | 0.3 | 0.3 | 0 | 0 | 0 |
| Sim 6 | 0.3 | 0.3 | 0.5 | 0 | 0 | 0 |

At the top of this input window, the user must specify the total number of endpoints in the trial. Other input parameters such as Test Type, Type I Error (α), Sample Size (n), and whether or not a Common Rejection Region is to be used for the endpoints. If a different rejection region is desired for different endpoints, this information should be specified in the **Endpoint Information** box. Here the user can change the label, select the family rank for each endpoint and choose the rejection region (either right or left tailed).

As discussed above there are typically two types of gatekeeping procedures - serial and parallel. Parallel gatekeeping requires the rejection of at least one hypothesis test - that is only one of the families of endpoints must be significant, no matter the rank. Serial gatekeeping uses the fact that the families are hierarchically ordered, and subsequent families are only tested if the previously ranked families are significant. Once the **Gatekeeping Procedure** is selected, the user must then select the multiple comparison procedure which will be used to test the last family of endpoints. These tests are discussed in Chapter 27. If Parallel Gatekeeping is selected, the user must also specify a test for Gatekeeper Families, specifically Bonferonni, Truncated Holm or Truncated Hochberg, and is discussed more in the Parallel example which follows. The type I error specified on this screen is the nominal level of the family-wise error rate, which is defined as the probability of falsely declaring the efficacy of the new treatment compared to control with respect to any endpoint.

For the migraine example, **PF**, **phono**, and **photo** form the primary family, and **SPF** is the only outcome in the secondary family. Suppose that we would like to see the power for a sample size of 200 at a nominal type I error rate 0.025 using Bonferroni test for the secondary family. The input window will look as follows:

Simulate

The number of simulations to be performed and other simulation parameters can be specified in the Simulation Controls window. By default, 10000 simulations will be performed. The summary statistics for each simulated trial and subject-level data can be saved by checking the appropriate boxes in the Output Options area. Once all design parameters are specified, click the **Simulate** button at the bottom right of the screen. Preliminary output is displayed in the output preview area and all results

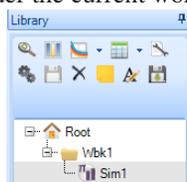

displayed in the yellow cells are summary outputs generated from simulations.

Summary

This serial gatekeeping procedure uses intersection-union test for the gatekeeping familie(s) and Bonferroni test for the last family of endpoints. The conjunctive power of 0.651 is achieved in detecting all the endpoints for which the treatment arm is truly better than the control arm for a total sample size of 100. The disjunctive power of 0.701 is achieved in detecting at least one endpoint for which the treatment arm is truly better than the control arm for a total sample size of 200.

For the migraine example, the conjunctive power, which characterizes the power for the study, is 0.701% for a total sample size of 200. Using Bonferroni test for the last family, the design has 0.651% probability (disjunctive power for the last family) to

28 Multiple Endpoints-Gatekeeping Procedures for Discrete Data

detect the benefit of Telcagepant 300mg with respect to at least one secondary endpoints. It has 0.651% chance (conjunctive power for the last family) to declare the benefit of Telcagepant 300 mg with respect to both of the secondary endpoints. For a sample size of 200 this relatively low power is typically undesirable. One can find the sample size to achieve a target power by simulating multiple designs in a batch mode. For example, the simulation of a batch of designs for a range of sample size 200 to 300 in steps of 20 is shown by the following.

The screenshot shows a software interface for configuring a simulation. At the top, 'Number of Endpoints' is set to 4. The 'Test Parameters' tab is active, showing 'Test Type' as 1-Sided, 'Type I Error (α)' as 0.025, and 'Sample Size (n)' as 200:300:25. The 'Simulation Controls' tab is also visible, showing 'Gatekeeping Procedure' set to Serial and 'Test for Last Family' options including Bonferroni, Sidak, Weighted Bonferroni, Hochberg's step up, Hommel's step up, Fixed Sequence, Holm's step down, and Fallback. A 'Common Rejection Region' is set to Right-Tail. Below this is an 'Endpoint Information' table:

| EndPoint ID | Family Rank | Rejection Region |
|-------------|-------------|------------------|
| PF | 1 | Right-Tail |
| phono | 1 | Right-Tail |
| photo | 1 | Right-Tail |
| SPF | 2 | Right-Tail |

A 'Simulate' button is located at the bottom right of the interface.

Multiple designs can be viewed side by side for easy comparison by selecting the simulations and clicking the  in the output preview area:

| Simulation Results (Overall) | | | | | |
| Average Sample Size | 200 | 225 | 250 | 275 | 300 |

For this example, to obtain a conjunctive power between 80% and 90% the study

would need to be constructed with somewhere between 250 and 300 subjects. For the remainder of this example, we will use sample size of 250 subjects under the correlation assumptions in the above table.

28.3 *Parallel Gatekeeping Design - Simulation for Discrete Outcomes*

A common concern in clinical trials with multiple primary endpoints, is whether or not statistical significance should be achieved on all endpoints. As the number of endpoints increases, this generally becomes more difficult. Parallel gatekeeping procedures are often used in clinical trials with multiple primary objectives where each individual objective can characterize a successful overall trial outcome. In other words, the trial can be declared to be successful if at least one primary objective is met.

Again, consider the same randomized, placebo-controlled, double blind, parallel treatment clinical trial designed to compare two treatments for migraine presented in the serial gatekeeping example. For the purpose of this example the trial is again simplified to study only three primary family endpoints, pain freedom (PF), absence of phonophobia (phono) and absence of photophobia (photo) at two hours post treatment. The singular endpoint in the secondary family is sustained pain freedom (SPF), and will be included in the example where, using East, power estimates will be computed via simulation. The example correlation values are intended to represent a common and moderate association among the endpoints. In general, serial gatekeeping designs require a larger sample size than parallel designs, therefore this example will use a total sample size of 125, at one-sided significance level of $\alpha = 0.025$.

The efficacy, or response rate, of the endpoints for subjects in the treatment group and placebo group and a sample correlation matrix are as follows:

| | Response Telcagepant 300mg | Response Placebo |
|-------|----------------------------|------------------|
| PF | 0.269 | 0.096 |
| phono | 0.578 | 0.368 |
| photo | 0.51 | 0.289 |
| SPF | 0.202 | 0.05 |

28 Multiple Endpoints-Gatekeeping Procedures for Discrete Data

| | ρ_{12} | ρ_{13} | ρ_{23} | ρ_{14} | ρ_{24} | ρ_{34} |
|-------|-------------|-------------|-------------|-------------|-------------|-------------|

Simulate

In the **Gatekeeping Procedure** box, keep the default of **Parallel** and **Bonferroni** for the **Test for Gatekeeper Families**. For the **Test for Last Family**, also ensure that **Bonferroni** is selected as the multiple testing procedure. In the **Endpoint Information** box, specify which family each specific endpoint belongs to using the

column with the label **Family Rank**.

In the **Response Generation** window the **Variance** can be specified to be either Pooled or Un-pooled. In the **Endpoint Information** box, the Response Rates for treatment and control for each endpoint are specified. If the endpoints share a common correlation, select the **Common Correlation** checkbox and enter the correlation value to the right. East will only allow a value within the **Valid Range**. Otherwise input the specific correlation for each pair of endpoints in the **Correlation Matrix**.

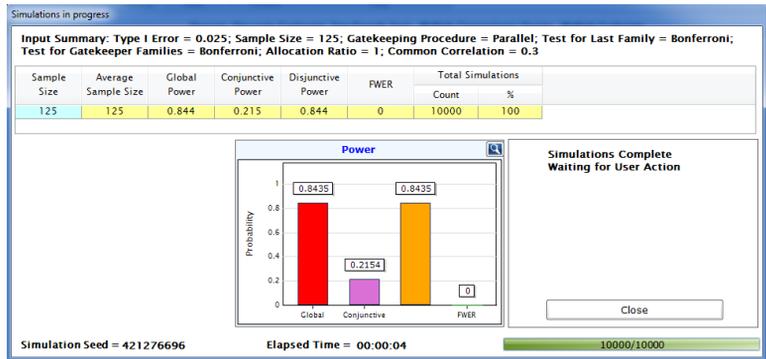

| EndPoint ID | Response Rate Control | Response Rate Treatment |
|-------------|-----------------------|-------------------------|
| PF | 0.096 | 0.269 |
| phono | 0.368 | 0.578 |
| photo | 0.289 | 0.51 |

Summary

This parallel gatekeeping procedure uses Bonferroni test for gatekeeping familie(s) and Bonferroni test for the last family. The conjunctive power of 0.215 is achieved in detecting all endpoints for which the treatment arm is truly better than the control arm for a total sample size of 125. The disjunctive power of 0.844 is achieved in detecting at least one endpoint for which the treatment arm is truly better than the control arm for a total sample size of 125.

28 Multiple Endpoints-Gatekeeping Procedures for Discrete Data

As with serial gatekeeping, East provides following types of power:

Overall Power and FWER:

Global: probability of declaring significance on any of the endpoints.

Conjunctive: probability of declaring significance on all of the endpoints for which the treatment arm is truly better than the control arm.

Disjunctive: probability of declaring significance on any of the endpoints for which the treatment arm is truly better than the control arm.

FWER: probability of making at least one type I error among all the endpoints.

Power and FWER for Individual Gatekeeper Families except the Last Family:

Conjunctive Power: probability of declaring significance on all of the endpoints in the particular gatekeeper family for which the treatment arm is truly better than the control arm.

Disjunctive Power: probability of declaring significance on any of the endpoints in the particular gatekeeper family for which the treatment arm is truly better than the control arm.

FWER: probability of making at least one type I error when testing the endpoints in the particular gatekeeper family.

Power and FWER for the Last Gatekeeper Family:

Conjunctive Power: probability of declaring significance on all of the endpoints in the last family for which the treatment arm is truly better than the control arm.

Disjunctive Power: probability of declaring significance on any of the endpoints in the last family for which the treatment arm is truly better than the control arm.

FWER: probability of making at least one type I error when testing the endpoints in the last family.

Marginal Power: probability of declaring significance on the particular endpoint.

For the migraine example under the lower common correlation assumption, we see that the gatekeeping procedure using the Bonferroni test for both the primary family and the secondary family provides 84.4% power to detect the difference in at least one of the three primary measures of migraine relief. It only provides 24.1% power to detect the differences in all types of relief. The marginal power table displays the probabilities of declaring significance on the particular endpoint after multiplicity adjustment. For example, the power to detect sustained pain relief beyond 2 hours for a dose of 300 mg of telecapant is 60.3

To assess the robustness of this procedure with respect to the correlation among the

Table 28.1: Power Comparisons under Different Correlation Assumptions

| Correlation | Primary Family | | Secondary Family | | Overall Power | |

The following table summarizes the power comparisons under different correlation assumptions. Note that the disjunctive power decreases as the correlation increases and conjunctive power increases as the correlation increases.

There are three available parallel gatekeeping methods: Bonferroni, Truncated Holm and Truncated Hochberg. The multiple comparison procedures applied to the gatekeeper families need to satisfy the so-called separable condition. A multiple comparison procedure is separable if the type I error rate under partial null configuration is strictly less than the nominal level α . Bonferroni is a separable

28 Multiple Endpoints-Gatekeeping Procedures for Discrete Data

Table 28.2: Impact of Truncation Constant on Power in the Truncated Holm Procedure

| Truncation Constant | Primary Family | | Secondary Family | | Overall Power | |
|---------------------|----------------|-----------|------------------|-----------|---------------|-----------|
| | Conjunct. | Disjunct. | Conjunct. | Disjunct. | Conjunct. | Disjunct. |
| 0 | 0.234 | 0.84 | 0.59 | 0.59 | 0.21 | 0.84 |
| 0.25 | 0.28 | 0.833 | 0.569 | 0.569 | 0.248 | 0.833 |
| 0.5 | 0.315 | 0.836 | 0.542 | 0.542 | 0.275 | 0.836 |
| 0.8 | 0.383 | 0.838 | 0.488 | 0.488 | 0.334 | 0.838 |

procedure, however, the regular Holm and Hochberg procedure are not separable and can't be applied directly to the gatekeeper families. The truncated versions obtained by taking the convex combinations of the critical constants for the regular Holm/Hochberg procedure and Bonferroni procedure are separable and more powerful than Bonferroni test. The truncation constant leverages the degree of conservativeness. The larger value of the truncation constant results in more powerful procedure. If the truncation constant is set to be 1, it reduces to the regular Holm or Hochberg test.

To see this, simulate the design using the truncated Holm procedure for the primary family and Bonferroni test for the second family for the migraine example with common correlation 0.3. The table below compares the conjunctive power and disjunctive power for each family and the overall ones for different truncation parameter values. As the value of the truncation parameter increases, the conjunctive power for the primary family increases and the disjunctive power remain unchanged. Both the conjunctive power and disjunctive power for the secondary family decrease as we increase the truncation parameter. The overall conjunctive power also increases but the overall disjunctive power remains the same with the increase of truncation parameter.

The next table shows the marginal powers of this design for different truncation parameter values. The marginal powers for the two endpoints in the primary family increase. On the other hand, the marginal powers for the endpoint in the secondary family decrease.

The last two tables display the operating characteristics for the Hochberg test with different truncation constant values. Note that both the conjunctive and disjunctive powers for the primary family increase as the truncation parameter increases. However, the power for the secondary family decreases with the larger truncation

Table 28.3: Impact of Truncation Constant on Marginal Power in the Truncated Holm Procedure

| Truncation Constant | Primary Family | | | Secondary Family |

29 Two-Stage Multi-arm Designs using p -value combination

29.1 Introduction

In the drug development process, identification of promising therapies and inference on selected treatments are usually performed in two or more stages. The procedure we will be discussing here is an adaptive two-stage design that can be used for the situation of multiple treatments to be compared with a control. This will allow integration of both the stages within a single confirmatory trial controlling the multiple level type-I error. After the interim analysis in the first stage, the trial may be terminated early or continued with a second stage, where the set of treatments may be reduced due to lack of efficacy or presence of safety problems with some of the treatments. This procedure in East is highly flexible with respect to stopping rules and selection criteria and also allows re-estimation of the sample size for the second stage. Simulations show that the method may be substantially more powerful than classical one-stage multiple treatment designs with the same total sample size because second stage sample size is focused on evaluating only the promising treatments identified in the first stage. This procedure is available for continuous as well discrete endpoint studies. The current chapter deals with the discrete endpoint studies only; continuous endpoint studies are handled similarly.

29.2 Study Design

29.2.1 Introduction to the Study

29.2.2 Methodology

29.2.3 Study Design Inputs

29.2.4 Simulating under Different Alternatives

This section will explore different design options available in East with the help of an example.

29.2.1 Introduction to the Study

A new chemical entity (NCE) is being developed for the treatment of reward deficiency syndrome, specifically alcohol dependence and binge eating disorder. Compared with other orally available treatments, NCE was designed to exhibit enhanced oral bioavailability, thereby providing improved efficacy for the treatment of alcohol dependence.

- Primary Objective: To evaluate the safety and efficacy of NCE compared with placebo when administered daily for 12 weeks to adults with alcohol dependence.
- Secondary Objective: To determine the optimal dose or doses of NCE.

The **primary endpoint** is defined as the percent of subjects abstinent from heavy drinking during Weeks 5 through 12 of treatment based on self-report of drinking activity. A heavy drinking day is defined as 4 or more standard alcoholic drinks in 1 day for females and 5 or more standard alcoholic drinks in 1 day for males. The endpoint is based on the patient-reported number of standard alcoholic drinks per day, transformed into a binary outcome measure, abstinence from heavy drinking.

29 Two-Stage Multi-arm Designs using p-value combination

29.2.2 Methodology

This is a multicenter, randomized, double-blind, placebo-controlled study conducted in two parts using a 2-stage adaptive design. In Stage 1, approximately 400 eligible subjects will be randomized equally among four treatment arms (NCE [doses: 1, 2.5, or 10 mg]) and matching placebo. After all subjects in Stage 1 have completed the 12-week treatment period or discontinued earlier, an interim analysis will be conducted to

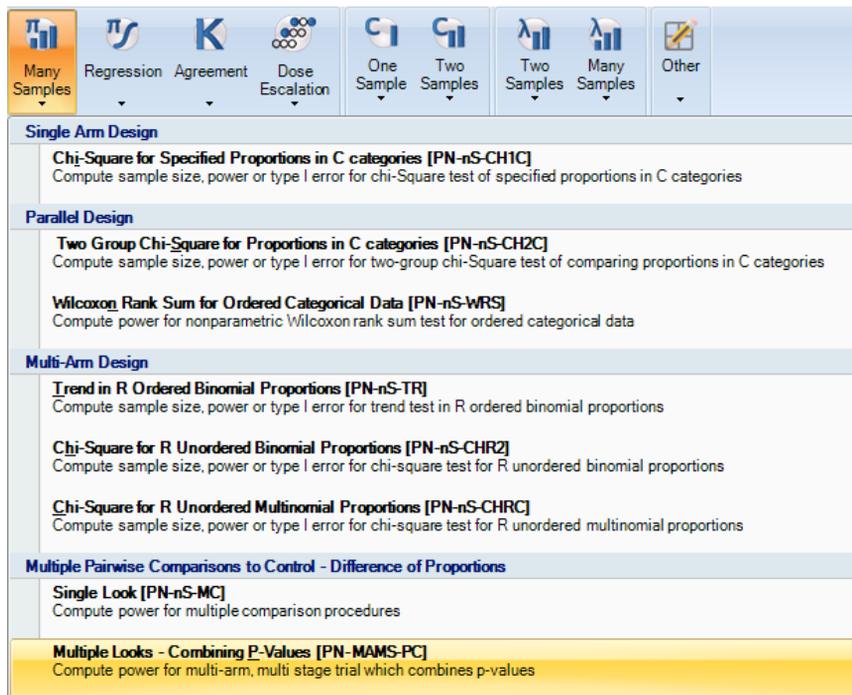

1. compare the proportion of subjects in each dose group who have achieved abstinence from heavy drinking during Weeks 5 through 12,
2. to assess safety within each dose group and
3. drop the less efficient doses.

Based on the interim analysis, Stage 2 of the study will either continue with additional subjects enrolling into 2 or 3 arms (placebo and 1 or 2 favorable, active doses) or the study will be halted completely if unacceptable toxicity has been observed.

In this example, we will have the following workflow to cover different options available in East:

1. Start with four arms (3 doses + Placebo)
2. Evaluate the three doses at the interim analysis and based on the **Treatment Selection Rules** carry forward one or two of the doses to the next stage
3. While we select the doses, also increase the sample size of the trial by using **Sample Size Re-estimation (SSR)** tool to improve conditional power if necessary
In a real trial, both the above actions (early stopping as well as sample size re-estimation) will be performed after observing the interim data.
4. See the final design output in terms of different powers, probabilities of selecting particular dose combinations
5. See the early stopping boundaries for efficacy and futility on adjusted p-value scale
6. Monitor the actual trial using the **Interim Monitoring** tool in East.

Start East. Click Design tab, then click **Many Samples** in the **Discrete** category, and then click **Multiple Looks- Combining p-values** test.

This will bring up the input window of the design with some default values. Enter the inputs as discussed below.

29.2.3 Study Design Inputs

Let us assume that three doses of the treatment *1mg*, *2.5mg*, *10mg* are compared with the Placebo arm. Preliminary sample size estimates are provided to achieve an overall study power of at least 80% at an overall, adequately adjusted 1-sided type-1 or alpha level of 2.5%, after taking into account all interim and final hypothesis tests. Note that we always use 1-sided alpha since dose-selection rules are usually 1-sided.

In Stage 1, 400 subjects are initially planned for enrollment (4 arms with 100 subjects each). Following an interim analysis conducted after all subjects in Stage 1 have completed 12 weeks of treatment or discontinued earlier, an additional 200 subjects will be enrolled into 2 doses for Stage 2 (placebo and one active dose). So we start with the total of 400+200 = 600 subjects.

The multiplicity adjustment methods available in East to compute the adjusted p-value

29 Two-Stage Multi-arm Designs using p-value combination

(p-value corresponding to global NULL) are *Bonferroni*, *Sidak*, *Simes*. For discrete endpoint test, *Dunnnett Single Step* is not available since we will be using Z-statistic. Let us use the *Bonferroni* method for this example. The p-values obtained from both the stages can be combined by using the “Inverse Normal” method. In the “Inverse Normal” method, East first computes the weights as follows:

$$w^{(1)} = \sqrt{\frac{n^{(1)}}{n}} \tag{29.1}$$

And

$$w^{(2)} = \sqrt{\frac{n^{(2)}}{n}} \tag{29.2}$$

where $n^{(1)}$ and $n^{(2)}$ are the total sample sizes corresponding to Stage 1 and stage 2 respectively and n is the total sample size.

EAST displays these weights by default but these values are editable and user can specify any other weights as long as

$$w^{(1)^2} + w^{(2)^2} = 1 \tag{29.3}$$

Final p-value is given by

$$p = 1 - \Phi\left(w^{(1)}\Phi^{-1}(1 - p^{(1)}) + w^{(2)}\Phi^{-1}(1 - p^{(2)})\right) \tag{29.4}$$

The weights specified on this tab will be used for p-value computation. $w^{(1)}$ will be used for data before interim look and $w^{(2)}$ will be used for data after interim look. Thus, according to the samples sizes planned for the two stages in this example, the weights are calculated as $\sqrt{(400/600)}$ and $\sqrt{(200/600)}$. **Note :** These weights are updated by East once we specify the first look position as 400/600 in the **Boundary** tab. So leave these as default values for now. Set the *Number of Arms* as 4 and enter the rest of the inputs as shown below:

Number of Arms: 4 Number of Looks: 2

Test Parameters Boundary Response Generation Treatment Selection Simulation Controls

Test Type: 1-Sided Multiplicity Adjustment: Bonferroni Specify Variance
 Rejection Region: Right-Tail p-value Combination: Inverse Normal Pooled Estimate
 Type I Error (α): 0.025 Weight1: 0.707 Unpooled Estimate
 Total Sample Size (n): 600 Weight2: 0.707

We can certainly have early stopping boundaries for efficacy and/or futility. But generally, in designs like this, the objective is to select the best dose(s) and not stop

early. So for now, select the **Boundary** tab and set both the boundary families to “None”. Also, set the timing of the interim analysis as 0.667 which will be after observing the data on 400 subjects out of 600. Enter 400/600 as shown below. Notice the updated weights on the bf Test Parameters tab.

Number of Arms: 4 Number of Looks: 2

Test Parameters Boundary Response Generation Treatment Selection Simulation Controls

Efficacy
 Boundary Family: None

Futility
 Boundary Family: None

Info. Fraction at Interim Look: 400/600

| Look # | Info. Fraction |
|--------|----------------|
| 1 | 0.667 |
| 2 | 1.000 |

The next tab is **Response Generation** which is used to specify the true underlying proportion of response on the individual dose groups and the initial allocation from which to generate the simulated data.

Test Parameters Boundary Response Generation

Generate Response Proportions Through DR Curve

| Treatment Label | Response Proportion | Initial Allocation (n _i /n _c) |
|-----------------|---------------------|--|
| Control | 0.1 | 1.000 |
| 1 mg | 0.14 | 1.000 |
| 2.5 mg | 0.18 | 1.000 |
| 10 mg | 0.22 | 1.000 |

Before we update the **Treatment Selection** tab, go to the **Simulation Control Parameters** tab where we can specify the number of simulations to run, the random number seed and also to save the intermediate simulation data. For now, enter the

29 Two-Stage Multi-arm Designs using p -value combination

inputs as shown below and keep all other inputs as default.

Click on the **Treatment Selection** tab. This tab is to select the scale to compute the treatment-wise effects. For selecting treatments for the second stage, the treatment effect scale will be required, but the control treatment will not be considered for selection. It will always be there in the second stage. The list under **Treatment Effect Scale** allows you to set the selection rules on different scales. Select **Estimated δ** from this list. It means that all the selection rules we specify on this tab will be in terms of the estimated value of treatment effect, δ , i.e., difference from placebo.

Here is a list of all available treatment effect scales:

Estimated Proportion, Estimated δ , Test Statistic, Conditional Power, Isotonic Proportion, Isotonic δ .

For more details on these scales, refer to the Appendix **K** chapter on this method.

The next step is to set the treatment selection rules for the second stage.

Select Best r Treatments: The best treatment is defined as the treatment having the highest or lowest mean effect. The decision is based on the rejection region. If it is “Right-Tail” then the highest should be taken as best. If it is “Left-Tail” then the lowest is taken as best. Note that the rejection region does not affect the choice of treatment based on conditional power.

Select treatments within ϵ of Best Treatment: Suppose the treatment effect scale is **Estimated δ** . If the best treatment has a treatment effect of δ_b and ϵ is specified

as 0.1 then all the treatments which have a δ as $\delta_b - 0.1$ or more are chosen for Stage 2.

Select treatments greater than threshold ζ : The treatments which have the treatment effect scale greater or less than the threshold (ζ) specified by the user according to the rejection region. But if the treatment effect scale is chosen as the conditional power then it will be greater than all the time.

Use R for Treatment Selection: If you wish to define any customized treatment selection rules, it can be done by writing an R function for those rules to be used within East. This is possible due to the R Integration feature in East. Refer to the appendix chapter on **R Functions** for more details on syntax and use of this feature. A template file for defining treatment selection rules is also available in the subfolder **RSamples** under your East installation directory.

| Tasks | File Name | Function Name |
|--------------------------|-----------|---------------|
| Treatment Selection | | |
| Initialize R Environment | | |

For more details on using R to define Treatment selection rules, refer to section [O.10](#).

For this example, select the first rule **Select Best r treatments** and set $r = 1$ which indicates that East will select the best dose for Stage 2 out the three doses. We will leave the default allocation ratio selections to yield equal allocation between the

29 Two-Stage Multi-arm Designs using p -value combination

control and selected best dose in Stage 2.

Test Parameters Boundary Response Generation **Treatment Selection** Simulation Controls

Use R For Treatment Selection

⊖ Marginal Probabilities of Selection and Efficacy

| Label | Average Sample Size | Marginal Probability of Selection | | Marginal Probability of Efficacy | |
|-------|---------------------|-----------------------------------|---------|----------------------------------|---------|
| | | Count | % | Count | % |
| 1mg | 103.82 | 382 | 3.820% | 167 | 1.670% |
| 2.5mg | 122.98 | 2298 | 22.980% | 1593 | 15.930% |
| 10mg | 173.2 | 7320 | 73.200% | 6323 | 63.230% |

The first table in the detailed output shows the overall power including global power, conjunctive power, disjunctive power and FWER. The definitions for different powers are as follows:

- Global Power: probability of demonstrating statistical significance on one or more treatment groups
- Conjunctive Power: probability of demonstrating statistical significance on all treatment groups which are truly effective
- Disjunctive Power: probability of demonstrating statistical significance on at least one treatment group which is truly effective
- FWER: probability of incorrectly demonstrating statistical significance on at

29 Two-Stage Multi-arm Designs using p -value combination

least one treatment group which is truly ineffective

For our example, there is 0.8 global power, i.e., the probability of this design to reject any null hypothesis, where the set of null hypothesis are the TRUE proportion of responders at each dose equals that of control. Also shown are conjunctive and disjunctive power, as well as Family Wise Error Rate (FWER).

The **Lookwise Summary** table summarizes the number of simulated trials that ended with a conclusion of efficacy, i.e., rejected any null hypothesis, at each look. In this example, no simulated trial stopped at the interim analysis with an efficacy conclusion since there were no stopping boundaries, but 8083 simulations yielded an efficacy conclusion via the selected dose after Stage 2. This is consistent with the global power.

The next table **Detailed Efficacy Outcomes for all 10000 Simulations**, summarizes the number of simulations for which each dose was selected for Stage 2 and yielded an efficacy conclusion. For example, the dose 10mg was observed to be efficacious in 63% of simulated trials whereas none of the three doses were efficacious in 19% of trials.

The last output table **Marginal Probabilities of Selection and Efficacy**, summarizes the number and percent of simulations in which each dose was selected for Stage 2, regardless of whether it was found significant at end of Stage 2 or not, as well as the number and percent of simulations in which each dose was selected and found significant. Average sample size is also shown. Note that since this design only selected the single best dose, this table gives almost the same information as the above one.

Selecting multiple doses (arms) for Stage 2 would be of more effective than selecting just the best one.

Click the  button on the bottom left corner of the screen. This will take us back to the input window of the last simulation scenario. Go to **Treatment Selection** tab and set $r = 2$. It means that we are interested in carrying forward the two best doses out of the three. Run the simulations by keeping the sample size fixed as 600. The simulated power drops to approximately 73%. Note that the loss of power for this 2-best-doses-choice scenario in comparison to the previous example which chose only the best dose. This is because of the smaller sample sizes per dose in stage 2 for this 2-best-doses scenario since the sample size is split in Stage 2 among 2 doses and control instead of between only 1 dose and control in the best dose scenario.

Now go to **Test Parameters** tab and change the sample size to 700 assuming that each of the two doses and Placebo will get 100 subjects in Stage 2. Accordingly, update the look position on **Boundaries** tab to 400/700 as well. Click the **Simulate** button to run the simulations. When the simulations are over, a row gets added in the **Output**

Preview area. Save this row to the **Library** by clicking the  icon in the toolbar. Rename this scenario as **Best2**. Double click it to see the detailed output.

⊖ Overall Powers

| | |
|--|-------|
| Global (Reject any H_i) | 0.809 |
| Conjunctive (Reject all H_i where $\pi_i > \pi_0$) | 0 |
| Disjunctive (Reject at least one H_i where $\pi_i > \pi_0$) | 0.809 |
| FWER (Reject any H_i where $\pi_i \leq \pi_0$) | 0 |

⊖ Lookwise Summary

| Look # | Average Total Sample Size (n) | Trial Termination | |
|---------|-------------------------------|-------------------|---------|

⊖ Detailed Efficacy Outcomes for all 10000 Simulations

| Efficacy Outcome | Average Sample Size | Count (n) | %(n/10000) |
|-------------------|---------------------|-----------|------------|
| 1mg only | 700 | 10 | 0.100% |
| 2.5mg only | 700 | 250 | 2.500% |
| 10mg only | 700 | 3067 | 30.670% |
| 1mg & 2.5mg only | 700 | 130 | 1.300% |
| 1mg & 10mg only | 700 | 555 | 5.550% |
| 2.5mg & 10mg only | 700 | 4076 | 40.760% |
| None | 700 | 1912 | 19.120% |
| Total | | 10000 | 100.000% |

⊖ Marginal Probabilities of Selection and Efficacy

| Label | Average Sample Size | Marginal Probability of Selection | | Marginal Probability of Efficacy | |
|-------|---------------------|-----------------------------------|---------|----------------------------------|---------|
| | | Count | % | Count | % |
| 1mg | 124.66 | 2466 | 24.660% | 695 | 6.950% |
| 2.5mg | 179.93 | 7993 | 79.930% | 4456 | 44.560% |
| 10mg | 195.41 | 9541 | 95.410% | 7698 | 76.980% |

The interpretation of first two tables is same as described above. It restores the power to 80% and also gives us the design details when two of the three doses were selected.

29 Two-Stage Multi-arm Designs using p -value combination

The table **Detailed Efficacy Outcomes for all 10000 Simulations** summarizes the number of simulations for which each individual dose group or pairs of doses were selected for Stage 2 and yielded an efficacy conclusion. For example, the pair (2.5mg, 10mg only) was observed to be efficacious in 41% of the trials (4076/10000).

The next table **Marginal Probabilities of Selection and Efficacy**, summarizes the number and percent of simulations in which each dose was selected for Stage 2, regardless of whether it was found significant at end of Stage 2 or not, as well as the number and percent of simulations in which each dose was selected and found significant. Average sample size is also shown. It tells us how frequently the dose (either alone or with some other dose) was selected and efficacious. For example, dose 1mg was selected in approximately 25% trials and was efficacious in approximately 7% trials (which is the sum of 10, 130 and 555 simulations from previous table.)

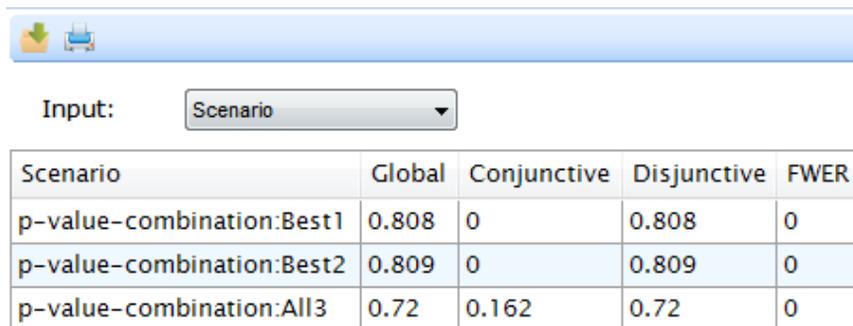

The advantage of 2-stage “treatment selection design” or “drop-the-loser” design is that it allows to drop the less performing/futile arms based on the interim data and still preserves the type-1 error as well as achieve the desired power.

In the **Best1** scenario, we dropped two doses ($r = 1$) and in the **Best2** scenario, we dropped one dose ($r = 2$). Suppose, we had decided to proceed to stage 2 without dropping any doses. In this case, Power would have dropped significantly. To verify this in East, run the above scenario with $r = 3$ and save it to **Library**. Rename this scenario as **All3**. Double click it to see the detailed output. We can observe that the power drops from 80% to 72%.

The three scenarios created so far can be compared in the tabular manner as well.

Select the three nodes in the **Library**, click the  icon in the toolbar and select

“Power” from the dropdown. A table as shown below will be created by East.

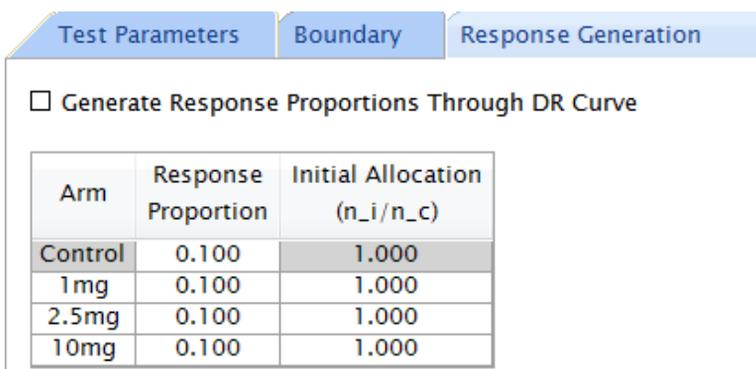

Input: Scenario

| Scenario | Global | Conjunctive | Disjunctive | FWER |
|---------------------------|--------|-------------|-------------|------|
| p-value-combination:Best1 | 0.808 | 0 | 0.808 | 0 |
| p-value-combination:Best2 | 0.809 | 0 | 0.809 | 0 |
| p-value-combination:All3 | 0.72 | 0.162 | 0.72 | 0 |

29.2.4 Simulating under Different Alternatives

Since this is a simulation based design, we can perform sensitivity analyses by changing some of the inputs and observing effects on the overall power and other output. Let us first make sure that this design preserves the total type1 error. It can be done by running the simulations under “Null” hypothesis.

Click the  button on the bottom left corner of the screen. Go to **Response Generation** tab and enter the inputs as shown below:

Generate Response Proportions Through DR Curve

| Arm | Response Proportion | Initial Allocation (n _i /n _c) |
|---------|---------------------|--|
| Control | 0.100 | 1.000 |
| 1mg | 0.100 | 1.000 |
| 2.5mg | 0.100 | 1.000 |
| 10mg | 0.100 | 1.000 |

Also set $r = 2$ in the **Treatment Selection** tab. Run the simulations and go to the

29 Two-Stage Multi-arm Designs using p-value combination

detailed output by saving the row from **Output Preview** to the **Library**. Notice the global power and simulated FWER is less than design type I error which means the overall type I error is preserved.

29.3 Sample Size Re-estimation

As we have seen above, the desired power of 80% is achieved with the sample size of 700 if the initial assumptions ($\pi_c = 0.1, \pi_{1mg} = 0.14, \pi_{2.5mg} = 0.18, \pi_{10mg} = 0.22$) hold true. But if they do not, then the original sample size of 700 may be insufficient to achieve 80% power. The adaptive sample size re-estimation is suited to this purpose. In this approach we start out with a sample size of 700 subjects, but take an interim look after data are available on 400 subjects. The purpose of the interim look is not to stop the trial early but rather to examine the interim data and continue enrolling past the planned 700 subjects if the interim results are promising enough to warrant the additional investment of sample size. This strategy has the advantage that the sample size is finalized only after a thorough examination of data from the actual study rather than through making a large up-front sample size commitment before any data are available. Furthermore, if the sample size may only be increased but never decreased from the originally planned 700 subjects, there is no loss of efficiency due to overruns. Suppose the proportions of response on the four arms are as shown below. Update the **Response Generation** tab accordingly and also set the seed as 100 in the **Simulation Controls** tab.

Generate Response Proportions Through DR Curve

| Arm | Response Proportion | Initial Allocation (n _i /n _c) |
|---------|---------------------|--|
| Control | 0.100 | 1.000 |
| 1mg | 0.130 | 1.000 |
| 2.5mg | 0.170 | 1.000 |
| 10mg | 0.200 | 1.000 |

Run 10000 simulations and save the simulation row to the **Library** by clicking the

icon in the toolbar.

Overall Powers

| | |
|---|------|
| Global (Reject any Hi) | 0.67 |
| Conjunctive (Reject all Hi where $\pi_i > \pi_0$) | 0 |
| Disjunctive (Reject at least one Hi where $\pi_i > \pi_0$) | 0.67 |
| FWER (Reject any Hi where $\pi_i \leq \pi_0$) | 0 |

Lookwise Summary

| Look # | Average Total Sample Size (n) | Trial Termination | |
|---------|-------------------------------|-------------------|---------|
| | | Efficacy | |
| | | Count | % |
| 1 | 400 | 0 | 0.000% |
| 2 | 700 | 6703 | 67.030% |
| OverAll | | 6703 | 67.030% |

Notice that the global power has dropped from 80% to 67%. Let us re-estimate the sample size to achieve the desired power. Add the **Sample Size Re-estimation** tab by

clicking the button . A new tab is added as shown below.

Test Parameters | Boundary | Response Generation | Treatment Selection | **Sample Size Re-estimation**

SSR At: Look # 1

Max. Sample Size if Adapt (multiplier; total #): 1 700

Target CP for Re-estimating Sample Size: 0.9

Promising Zone Scale: (Based on Current Winner) Cond. Power CP

Promising Zone: Min. CP: 0.3 Max. CP: 0.9

SSR Function in Promising Zone: Continuous

SSR At: For a *K*-look group sequential design, one can decide the time at which conditions for adaptations are to be checked and actual adaptation is to be carried out. This can be done either at some intermediate look or after some specified information fraction. The possible values of this parameter depend

29 Two-Stage Multi-arm Designs using p -value combination

upon the user choice. The default choice for this design is always the **Look #**. and is fixed to 1 since it is always a 2-look design.

Target CP for Re-estimating Sample Size: The primary driver for increasing the sample size at the interim look is the desired (or target) conditional power or probability of obtaining a positive outcome at the end of the trial, given the data already observed. For this example we have set the conditional power at the end of the trial to be 80%. East then computes the sample size that would be required to achieve this desired conditional power.

Maximum Sample Size if Adapt (multiplier; total): As just stated, a new sample size is computed at the interim analysis on the basis of the observed data so as to achieve some target conditional power. However the sample size so obtained will be overruled unless it falls between pre-specified minimum and maximum values. For this example, the range of allowable sample sizes is [700, 1400]. If the newly computed sample size falls outside this range, it will be reset to the appropriate boundary of the range. For example, if the sample size needed to achieve the desired 80% conditional power is less than 700, the new sample size will be reset to 700. In other words we will not decrease the sample size from what was specified initially. On the other hand, the upper bound of 1400 subjects demonstrates that the sponsor is prepared to increase the sample size up to double the initial investment in order to achieve the desired 80% conditional power. But if 80% conditional power requires more than 1400 subjects, the sample size will be reset to 1400, the maximum allowed.

Promising Zone Scale: One can define the promising zone as an interval based on conditional power, test statistic, or estimated δ . The input fields change according to this choice. The decision of altering the sample size is taken based on whether the interim value of conditional power / test statistic / δ lies in this interval or not. Let us keep the default scale which is Conditional Power.

Promising Zone: Minimum/Maximum Conditional Power (CP): The sample size will only be altered if the estimate of CP at the interim analysis lies in a pre-specified range, referred to as the “Promising Zone”. Here the promising zone is 0.30 – 0.80. The idea is to invest in the trial in stages. Prior to the interim analysis the sponsor is only committed to a sample size of 700 subjects. If, however, the results at the interim analysis appear reasonably promising, the sponsor would be willing to make a larger investment in the trial and thereby improve the chances of success. Here we have somewhat arbitrarily set the lower bound for a promising interim outcome to be $CP = 0.30$. An estimate

$CP < 0.30$ at the interim analysis is not considered promising enough to warrant a sample size increase. It might sometimes be desirable to also specify an upper bound beyond which no sample size change will be made. Here we have set that upper bound of the promising zone at $CP = 0.80$. In effect we have partitioned the range of possible values for conditional power at the interim analysis into three zones; *unfavorable* ($CP < 0.3$), *promising* ($0.3 \leq CP < 0.8$), and *favorable* ($CP \geq 0.8$). Sample size adaptations are made only if the interim CP falls in the promising zone at the interim analysis. The promising zone defined on the Test Statistic scale or the Estimated δ scale works similarly.

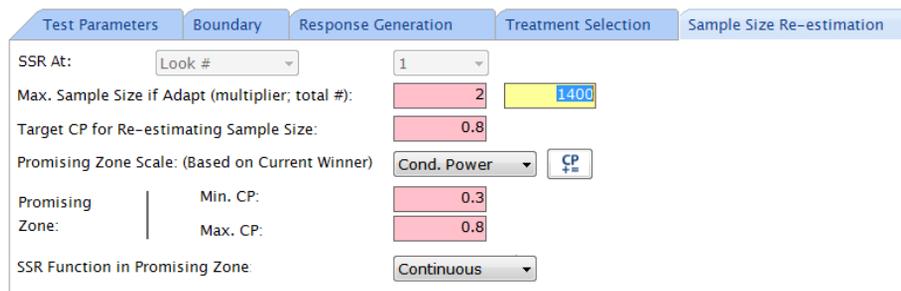

SSR Function in Promising Zone: The behavior in the promising zone can either be defined by a continuous function or a step function. The default is continuous where East accepts the two quantities - (Multiplier, Target CP) and re-estimates the sample size depending upon the interim value of CP/test statistic/effect size. The SSR function can be defined as a step-function as well. This can be done with a single piece or with multiple pieces. For each piece, define the step function in terms of:

- the interval of CP/test statistic/effect size. This depends upon the choice of promising zone scale.
- the value of re-estimated sample size in that interval.
- for single piece, just the total re-estimated sample size is required as an input.

If the interim value of CP/ test statistic/effect size lies in the promising zone then the re-estimation will be done using this step function.

Let us set the inputs on **Sample Size Re-estimation** tab as shown below:

29 Two-Stage Multi-arm Designs using p -value combination

| Test Parameters | | Boundary | Response Generation | Treatment Selection | Sample Size Re-estimation |
|--|-------------|----------|---------------------|---------------------|---------------------------|
| SSR At: | Look # | | 1 | | |
| Max. Sample Size if Adapt (multiplier; total #): | 2 | | | | 1400 |
| Target CP for Re-estimating Sample Size: | 0.8 | | | | |
| Promising Zone Scale: (Based on Current Winner) | Cond. Power | | | | CP |
| Promising Zone: | Min. CP: | 0.3 | | | |
| | Max. CP: | 0.8 | | | |
| SSR Function in Promising Zone: | | | Continuous | | |

Run 10000 simulations and see the Details. Just for the comparison purpose, re-run the simulations but this time, set the multiplier in the **Sample Size Re-estimation** tab to 1 which means we are not interested in sample size re-estimation. Both the scenarios can also be run by entering two values 1, 2 in the cell for Multiplier.

Promising Zone defined as 0.3 ≤ CP < 0.8

We observe from the table the power of adaptive implementation is approximately 75%

which is almost 8% improvement over the non-adaptive design. This increase in power has come at an average cost of 805-700 = 105 additional subjects. Next we observe from the **Zone-wise Averages** table that 1563 of 10000 trials (16%) underwent sample size re-estimation and of those 1563 trials, 84% were able to reject the Global null hypothesis. The average sample size, conditional on adaptation is 1376.

29.4 Adding Early Stopping Boundaries

One can also incorporate stopping boundaries to stop at the interim early for efficacy or futility. The efficacy boundary can be defined based on **Adjusted p-value** scale whereas futility boundary can be on **Adjusted p-value** or δ scale.

Click the  button on the bottom left corner of the screen. This will take you back to the input window of the last simulation scenario. Go to **Boundary** tab and set Efficacy and Futility boundaries to “Adjusted p-value”. These boundaries are for

29 Two-Stage Multi-arm Designs using p-value combination

early stopping at look1. As the note on this tab says:

- If any one adjusted p-value is \leq efficacy p-value boundary then stop the trial for efficacy
- If only all the adjusted p-values are $>$ futility p-value then stop the trial for futility. Else carry forward all the treatments to the next step of treatment selection.

Stopping early for efficacy or futility is step which is carried out before treatment selection rules are applied. The simulation output has the same explanation as above except the **Lookwise Summary** table may have some trials stopped at the first look due to efficacy or futility.

29.5 Monitoring this trial

Select the simulation node with **SSR** implementation and click the **IM** icon. It will invoke the **Interim Monitoring** dashboard. Click the **Enter Interim Data** icon to open the **Test Statistic Calculator**. Enter the data as shown below:

| Arm | Sample Size | Proportion | Test Statistic | Raw p-values |
|---------|-------------|------------|----------------|--------------|
| Control | 100 | 0.09 | NA | NA |
| 1mg | 100 | 0.15 | 1.311 | 0.095 |
| 2.5mg | 100 | 0.17 | 1.694 | 0.045 |
| 10mg | 100 | 0.18 | 1.879 | 0.030 |

Click **Recalc** to calculate the test statistic as well as the raw p-values. Notice that the p-value for *1mg* is 0.095 which is greater than 0.025. We will drop this dose in the second stage. On clicking **OK**, it updates the dashboard.

| Look # | Number of Arms | Adjusted p-value for Best Treatment | Prespecified Weights | Prespecified Efficacy Boundary (p-value) |
|--------|----------------|-------------------------------------|----------------------|--|
| 1 | 4 | 0.09 | 0.756 | NA |
| 2 | | | 0.655 | 0.025 |

Click the "Edit Interim Data" button to edit the Look # 1 data.

Stopping Boundaries

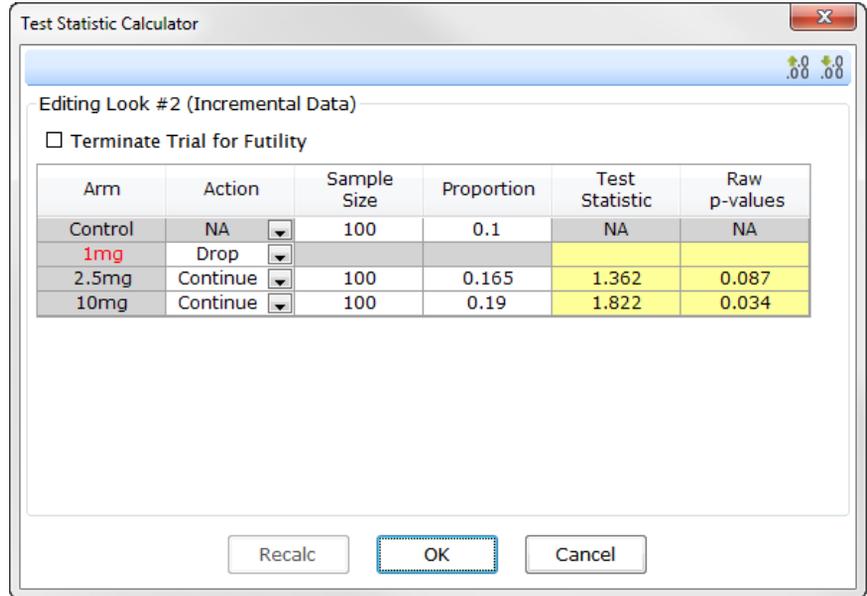

The plot shows a grid with x-axis from 0 to 3 and y-axis from 0 to 0.1. A green dot is at (1, 0.09) and a blue dot is at (2, 0.025).

| Look # | Efficacy (p-value) |
|--------|--------------------|
| 1 | NA |
| 2 | 0.025 |

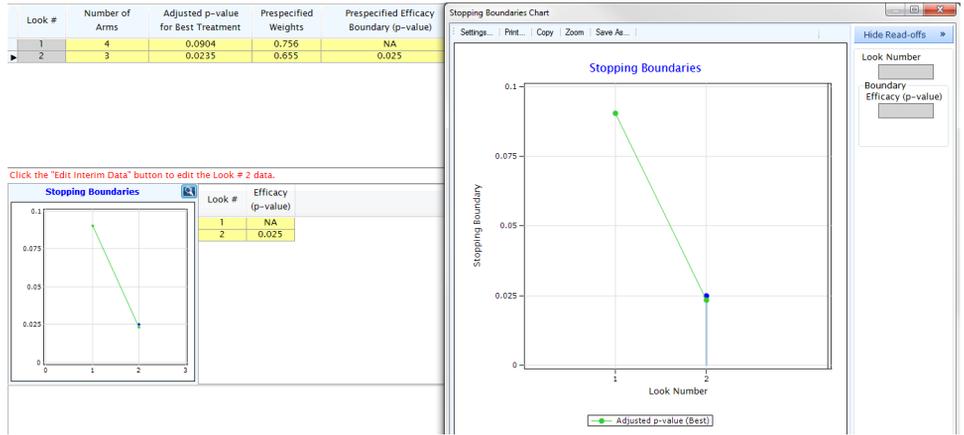

Open the test statistic calculator for the second look and enter the following information and also drop the dose 1mg. Click **Recalc** to calculate the test statistic as

29 Two-Stage Multi-arm Designs using p-value combination

well as the raw p-values.

On clicking **OK**, it updates the dashboard. Observe that the adjusted p-value for *10mg* crosses the efficacy boundary. It can also be observed in the **Stopping Boundaries** chart.

30 *Binomial Superiority Regression*

30.1 *Logistic Regression with Single Normal Covariate*

Logistic regression is widely used for modeling the probability of a binary response in the presence of covariates. In this section we will show how East may be used to design clinical trials with binomial endpoints, while adjusting for the effects of covariates through the logistic regression model. The sample size calculations for the logistic regression models discussed here and implemented in East are based on the methods of Hsieh et al., 1997. We note, however, that these methods are limited to continuous covariates only. When the covariate is normal, the log odds value β_1 is zero if and only if the group means between the two response categories are the same assuming equal variances.

Suppose in a logistic regression model, Y is a binary response variable and X_1 is a covariate related to Y . The model is given by

$$\log\left(\frac{P}{1-P}\right) = \beta_0 + \beta_1 X_1 \tag{30.1}$$

where $P = P(Y = 1)$. The null hypothesis that the coefficient of the covariate β_1 is zero is tested against the two sided alternative hypothesis that β_1 is not equal to zero. The slope coefficient β_1 is the change in log odds for every one unit increase in X_1 . The sample size required for a two sided test with type-I error rate of α to have a power $1 - \beta$ is

$$n = \frac{(Z_{1-\frac{\alpha}{2}} + Z_{1-\beta})^2}{P_1(1 - P_1)\beta^{*2}} \tag{30.2}$$

Where β^* is the effect size to be tested, P_1 is the event rate at the mean of X and Z_u is the upper u -th percentile of the standard normal distribution.

30.1.1 *Trial Design*

We use a Department of Veterans Affairs Cooperative Study entitled 'A Psychophysiological Study of Chronic Post-Traumatic Stress Disorder' to illustrate the preceding sample size calculation for logistic regression with continuous covariates. The study developed and validated a logistic regression model to explore the use of certain psychophysiological measurements for the prognosis of combat-related

post-traumatic stress disorder (PTSD). In the study, patients' four psychophysiological measurements-heart rate, blood pressures, EMG and skin conductance- were recorded while patients were exposed to video tapes containing combat and neutral scenes. Among the psychophysiological variables, the difference of the heart rates obtained while viewing the combat and the neutral tapes (DCNHR) is considered a good predictor of the diagnosis of PTSD. The prevalence rate of PTSD among the Vietnam veterans was assumed to be 20 per cent. Therefore, we assumed a four to one sample size ratio for the non-PTSD versus PTSD groups. The effect size of DCNHR is approximately 0.3 which is the difference of the group means divided by the standard deviation. We would like to determine the sample size to achieve 90% power based on a two-sided test at significance level 0.05 (Hsieh et. al.,1998).

Start East. Click **Design** tab, then click **Regression** in the **Discrete** group, and then click **Logistic Regression - Odds Ratio**.

The input dialog box, with default input values will appear in the upper pane of this window. Enter 0.2 in **Proportion Success at $X = \mu, (P_0)$** and 1.349 in **Odds Ratio $P_1(1 - P_0)/P_0(1 - P_1)$** field.

Enter the rest of the inputs as shown below and click **Compute**.

Test Parameters

| | | | |
|----------------------------|------------|---|-------|
| Test Type: | 2-Sided ▾ | Proportion Successes at $X = \mu, (P_0)$: | 0.2 |
| Type I Error (α): | 0.05 ○ | Proportion Successes at $X = \mu + \sigma, (P_1)$: | 0.252 |
| Power: | 0.9 ○ | Odds Ratio[$P_1(1 - P_0)/[P_0(1 - P_1)]$]: | 1.349 |
| Sample Size (n): | Computed ⊕ | <input type="checkbox"/> Other Covariates | |

The design output will be displayed in the Output Preview, with the computed sample size highlighted in yellow. A total of 733 subjects must be enrolled in order to achieve 90% power under the alternative hypothesis. Besides sample size, one can also compute the power and the level of significance for this design.

| | ID | Test Type | Specified α | Power | Sample Size | Δ | Prop P0 | Prop P1 | Odds Ratio |
|---|------|-----------|--------------------|-------|-------------|----------|---------|---------|------------|
| π | Des1 | 2-Sided | 0.05 | 0.9 | 733 | 0.299 | 0.2 | 0.252 | 1.349 |

You can select this design by clicking anywhere on the row in the Output Preview. If

30 Binomial Superiority Regression

you click on  icon, some of the design details will be displayed in the upper pane. In the Output Preview toolbar, click the  icon, to save this design to workbook Wbk1 in the **Library**. If you hover the cursor over Des1 in the **Library**, a tooltip will appear that summarizes the input parameters of the design.

Sample Size Information

Sample Size (n) 733

Critical Points

Lower Critical Point -1.96
 Upper Critical Point 1.96

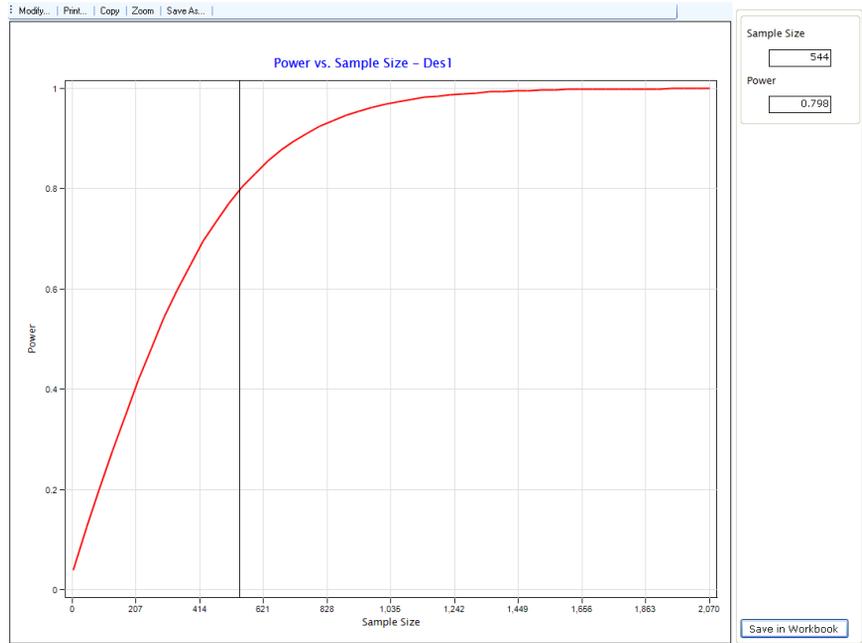

Summary

A total sample size of 733 is required in a study to detect a significant effect of the continuous covariate on response proportions between the treatment and control group with desired power 90.01%. The test is based on a 2-Sided test for significance of the covariate in a logistic regression with significance level 0.05. The proportion of successes expected at a covariate value equal to its mean is 0.2. The proportion of successes expected at a covariate value equal to its mean plus one standard deviation is 0.252. The odds ratio is 1.349 and the log odds ratio is 0.299, equal to the coefficient of the covariate in the logistic regression under the alternative hypothesis.

Observe that this kind output gives us the summary of the output as well.

With Des1 selected in the **Library**, click  icon, on the **Library** toolbar, and then click **Power vs. Sample Size**. The resulting power curve for this design is shown. You can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As....** For now, you may close the chart before continuing

30 Binomial Superiority Regression

31 Agreement

31.1 Cohen's Kappa

31.1.1 Trial Design

In some experimental situations, to check inter-rater reliability, independent sets of measurements are taken by more than one rater and the responses are checked for agreement. For a binary response, Cohen's Kappa test for binary ratings can be used to check inter-rater reliability. Conventionally, the kappa coefficient is used to express the degree of agreement between two raters when the same two raters rate each of a sample of n subjects independently, with the ratings being on a categorical scale consisting of k categories (Fleiss, 1981). A simple example is given in the below table where two tests **Test 1** and **Test 2** ($k = 2$) were performed. In the below table, π_{ij} denotes the true population proportion in the i -th row and the j -th column category.

Table 31.1: Table of proportions of two raters

| Test 1 \ Test 2 | Test 2(+) | Test 2(-) | Marginal Probability |
|----------------------|------------|------------|----------------------|
| Test 1(+) | π_{11} | π_{12} | $\pi_{1.}$ |
| Test 1(-) | π_{21} | π_{22} | $\pi_{2.}$ |
| Marginal Probability | $\pi_{.1}$ | $\pi_{.2}$ | 1 |

The Kappa coefficient (κ) is defined by

$$\kappa = \frac{\pi_0 - \pi_e}{1 - \pi_e} \tag{31.1}$$

where $\pi_0 = \sum_{i=1}^2 \pi_{ii}$ and $\pi_e = \sum_{i=1}^2 \pi_{i.}\pi_{.i}$.

We want to test the null hypothesis $H_0 : \kappa \leq \kappa_0$ against $H_1 : \kappa > \kappa_0$ where $\kappa_0 > 0$. The total sample size required for a test with type-I error rate of α to have a power $1 - \beta$ is

$$n = \frac{(z_\alpha + z_\beta)^2 (E + F - G)}{[(1 - \pi_e)^2 (\kappa - \kappa_0)]^2} \tag{31.2}$$

31 Agreement

where

$$E = \sum_{i=1}^2 \pi_{ii} [(1 - \pi_e) - (\pi_{.i} + \pi_{i.})(1 - \pi_0)]^2 \quad (31.3)$$

$$F = (1 - \pi_0)^2 \sum_{i=1}^2 \sum_{j \neq i} \pi_{ij} (\pi_{.i} + \pi_{j.})^2 \quad (31.4)$$

and

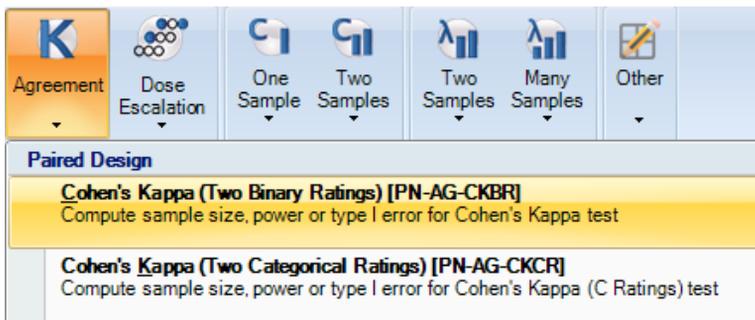

$$G = [\pi_0(1 + \pi_e) - 2\pi_e]^2 \quad (31.5)$$

We can calculate power, sample size or level of significance for your Cohen's Kappa test for two ratings.

31.1.1 Trial Design

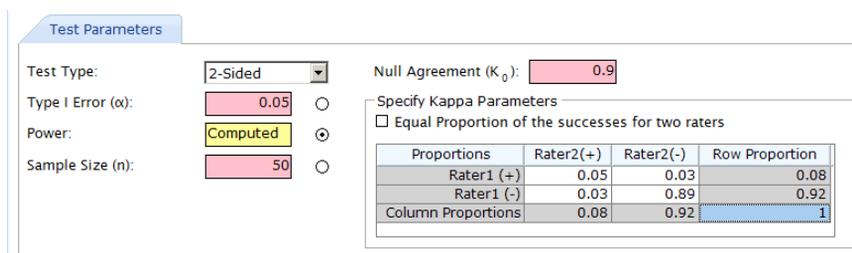

Consider responses from two raters. The example is based on a study to develop and validate a set of clinical criteria to identify patients with minor head injury who do not undergo a CT scan (Haydel, et al., 2000). In the study, CT scan was first reviewed by a staff neuroradiologist. An independent staff radiologist then reviewed 50 randomly selected CT scans and the two sets of responses checked for agreement. Let κ denote the level of agreement. The null hypothesis is $H_0 : \kappa = 0.9$ versus the one-sided alternative hypothesis $H_1 : \kappa < 0.9$. We wish to compute the power of the test at the alternative value $\kappa_1 = 0.6$. We expect each rater to identify 8% of CT scans to be positive. Also we expect 5% of the positive CT scans were rated by both the raters.

Start East. Click **Design** tab, then click Agreement in the **Discrete** group, and then click **Cohen's Kappa (Two Binary Ratings)** .

The input dialog box, with default input values will appear in the upper pane of this window.

Enter 0.9 in **Null Agreement** (κ_0) field. Specify the $\alpha = 0.05$, sample size and the kappa parameter values as shown below. Enter the rest of the inputs as shown below and click **Compute**.

The design output will be displayed in the Output Preview, with the computed power highlighted in yellow. The power of the test is 64.9% given a sample size of 50 scans to establish agreement of ratings by the two radiologists. Besides power, one can also compute the sample size for this study design.

| ID | Test Type | Specified α | Power | Sample Size | Prop Rater 1 | Prop Rater 2 | Kappa 0 | Kappa 1 |
|------|-----------|--------------------|-------|-------------|--------------|--------------|---------|---------|
| Des2 | 2-Sided | 0.05 | 0.649 | 50 | 0.08 | 0.08 | 0.9 | 0.592 |

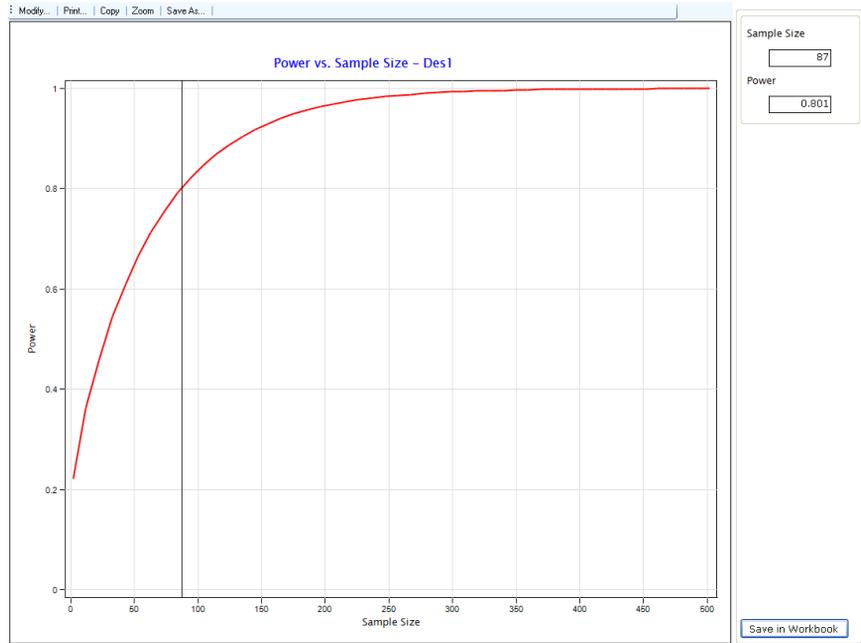

You can select this design by clicking anywhere on the row in the Output Preview. If you click  icon, some of the design details will be displayed in the upper pane. In

31 Agreement

the Output Preview toolbar, click  icon, to save this design to workbook Wbk1 in the **Library**. If you hover the cursor over Des1 in the **Library**, a tooltip will appear that summarizes the input parameters of the design.

| | Des 1 |
|-------------------------|--------------|

| Maximum | 50 |

With Des1 selected in the **Library**, click  icon on the **Library** toolbar, and then click **Power vs. Sample Size**. The resulting power curve for this design is shown. You can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As....** For now, you may close the chart before continuing

31.2 Cohen's Kappa (C Ratings)

Let κ denotes the measure of agreement between two raters who each classify n objects into C mutually exclusive ratings (categories). Here the null hypothesis is $H_0 : \kappa = \kappa_0$ is tested against two-sided hypothesis $H_1 : \kappa \neq \kappa_0$ or one sided hypothesis $H_1 : \kappa > \kappa_0$ or $H_1 : \kappa < \kappa_0$. The total sample size required for a test with type-I error rate of α to have a power $1 - \beta$ when $\kappa = \kappa_1$ is

$$n \geq \left\lceil \frac{Z_{1-\alpha} \max \tau(\hat{\kappa} | \kappa = \kappa_0) + Z_{1-\beta} \max \tau(\hat{\kappa} | \kappa = \kappa_1)}{\kappa_1 - \kappa_0} \right\rceil \quad (31.6)$$

Where

$$\tau(\hat{\kappa}) = \frac{(Q_1 + Q_2 - 2Q_3 - Q_4)^{\frac{1}{2}}}{(1 - \pi_e)^2} \quad (31.7)$$

and

31 Agreement

$$\begin{aligned}
 Q_1 &= \pi_0(1 - \pi_e)^2, \\
 Q_2 &= (1 - \pi_0)^2 \sum_{i=1}^C \sum_{j=1}^C \pi_{ij}(\pi_i + \pi_j)^2, \\
 Q_3 &= 2(1 - \pi_0)(1 - \pi_e) \sum_{i=1}^C \pi_{ij}(\pi_i + \pi_j), \\
 Q_4 &= (\pi_0\pi_e - 2\pi_e + \pi_0)^2.
 \end{aligned}$$

π_{ij} is the proportion of subjects that Rater 1 places in category i but Rater 2 places in category j , π_0 is the proportion of agreement and π_e is the expected proportion of agreement.

The power of the test is given by

$$\text{Power} = \Phi\left[\frac{\sqrt{n}(\kappa_1 - \kappa_0) - Z_{1-\alpha} \max \tau(\hat{\kappa}|\kappa = \kappa_0)}{\max \tau(\hat{\kappa}|\kappa = \kappa_1)}\right] \quad (31.8)$$

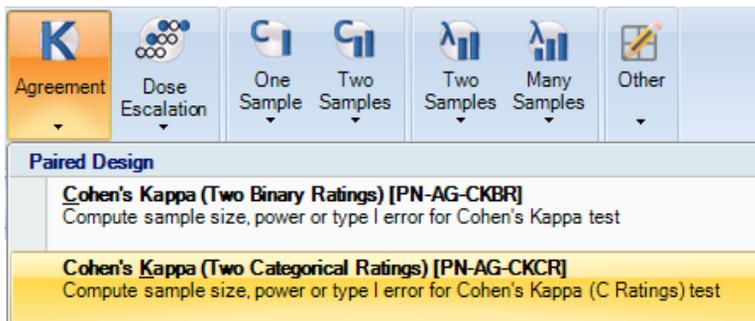

31.2.1 Trial Design

Consider a hypothetical problem of physical health ratings from two different raters-health instructor and subject's general practitioner. 360 subjects were randomly selected and the two sets of responses were checked for agreement. Let κ denote the level of agreement. The null hypothesis is $H_0 : \kappa = 0.6$ versus the one-sided alternative hypothesis $H_1 : \kappa < 0.6$. We wish to compute the power of the test at the alternative value $\kappa_1 = 0.5$.

Table 31.2: Table: Contingency Table

| General Petitioner \ Health Instructor | Poor | Fair | Good | Excellent | Total |
|--|------|------|------|-----------|-------|
| Poor | 2 | 12 | 8 | 0 | 22 |
| Fair | 9 | 35 | 43 | 7 | 94 |
| Good | 4 | 36 | 103 | 40 | 183 |
| Excellent | 1 | 8 | 30 | 22 | 61 |
| Total | 16 | 91 | 184 | 69 | 360 |

Start East. Click **Design** tab, then click Agreement in the **Discrete** group, and then click **Cohen's Kappa (Two Categorical Ratings)**.

The input dialog box, with default input values will appear in the upper pane of this window.

Enter **Number of Ratings (C)** as 4. Enter 0.6 in **Null Agreement (κ_0)** field and 0.5 in **Alternative Agreement (κ_1)**. Click **Marginal Probabilities** and specify the marginal probabilities calculated from the above table. Specify the **sample size**. Leave all other values as defaults, and click **Compute**.

Test Parameters

Test Type: 2-Sided

Type I Error (α): 0.05

Power: Computed

Sample Size (n): 360

Number of Ratings (C): 4

Specify Kappa Parameters

Alternative Agreement (κ_1): 0.5

Null Agreement (κ_0): 0.6

Marginal Probabilities

Cell Probabilities

| Ratings | 1 | 2 | 3 | 4 | Marginal Prop |
|---------------|-------|-------|-------|-------|---------------|
| 1 | 0.044 | 0 | 0 | 0 | 0.044 |
| 2 | 0 | 0.094 | 0.159 | 0 | 0.253 |
| 3 | 0 | 0.159 | 0.352 | 0 | 0.511 |
| 4 | 0 | 0 | 0 | 0.192 | 0.192 |
| Marginal Prop | 0.044 | 0.253 | 0.511 | 0.192 | 1 |

The design output will be displayed in the Output Preview, with the computed power highlighted in yellow. The power of the test is 73.3% given a sample size of 360 subjects to establish agreement of ratings by the two raters. Besides power, one can also compute the sample size for this study design.

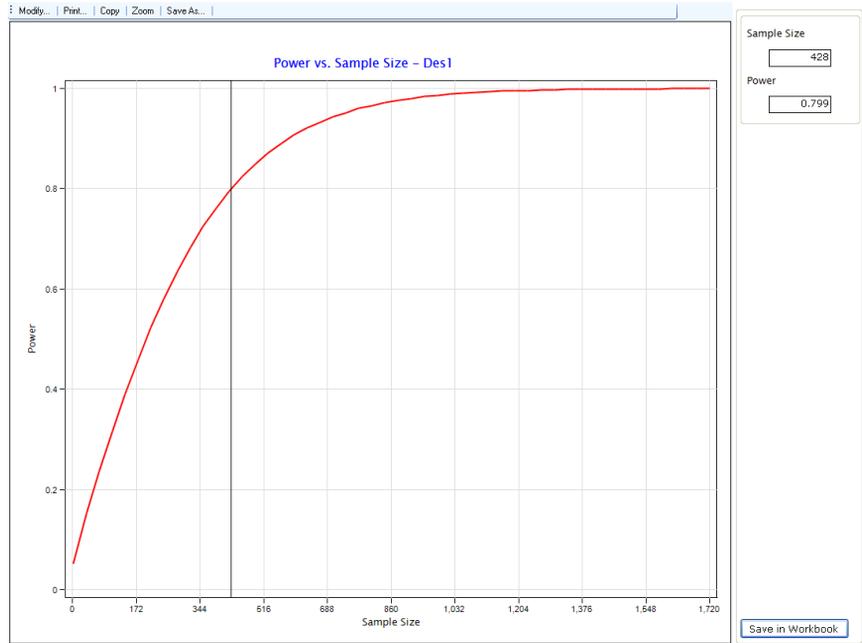

| ▲ | ID | Test Type | Specified α | Power | Sample Size | Kappa 0 | Kappa 1 | Kappa Rating |
|---|------|-----------|--------------------|-------|-------------|---------|---------|--------------|
| K | Des2 | 2-Sided | 0.05 | 0.733 | 360 | 0.6 | 0.5 | 4 |

31 Agreement

You can select this design by clicking anywhere on the row in the Output Preview. If you click  icon, some of the design details will be displayed in the upper pane. In the Output Preview toolbar, click  icon to save this design to workbook Wbk1 in the **Library**. If you hover the cursor over Des1 in the **Library**, a tooltip will appear that summarizes the input parameters of the design.

You can export the chart in one of several image formats (e.g., Bitmap or JPEG) by clicking **Save As...** For now, you may close the chart before continuing.

32

Dose Escalation

This chapter deals with the design, simulation, and interim monitoring of Phase 1 dose escalation trials. A brief overview of the designs is given below; more technical details are available in the Appendix N.

One of the primary goals of Phase I trials in oncology is to find the maximum tolerated dose (MTD). Currently, the vast majority of such trials have employed traditional dose escalation methods such as the 3+3 design. The 3+3 design starts by allocating three patients typically to the lowest dose level, and then adaptively moves up and down in subsequent cohorts until either the MTD is obtained, or the trial is stopped for excessive toxicity. In addition to the 3+3, East also provides the Continual Reassessment Method (CRM), the modified Toxicity Probability Interval (mTPI) method, and the Bayesian logistic regression model (BLRM) for single agent designs. Compared to the 3+3, these modern methods may offer a number of advantages, which can be explored systematically via simulation and interim monitoring.

The CRM (Goodman et al., 1995; O’Quigley et al., 1990) is a Bayesian model-based method that uses all available information from all doses to guide dose assignment. One first specifies a target toxicity, a one-parameter dose response curve and corresponding prior distribution. The posterior mean and predictions for the probability of toxicity at each dose are updated as the trial progresses. The next recommended dose is the one whose toxicity probability is closest to the target toxicity.

The mTPI method (Ji et al., 2010) is Bayesian like the CRM, but rule-based like the 3+3. In this way, the mTPI represents a useful compromise between the other methods. An independent beta distribution is assumed for the probability of toxicity at each dose. A set of decision intervals are specified, and subsequent dosing decisions (up, down, or stay) are determined by computing the normalized posterior probability in each interval at the current dose. The normalized probability for each interval is known as the unit probability mass (UPM).

A more advanced version of the CRM is the BLRM (Neuenschwander et al., 2008; Sweeting et al., 2013), which assumes a two-parameter logistic dose response curve. In addition to a target toxicity, one specifies a set of decision intervals, and optional associated losses, for guiding dosing decisions.

For dual-agent combination designs, East provides a combination version of the BLRM (Neuenschwander et al., 2014), as well as the PIPE (product of independent beta probabilities escalation) method (Mander & Sweeting, 2015).

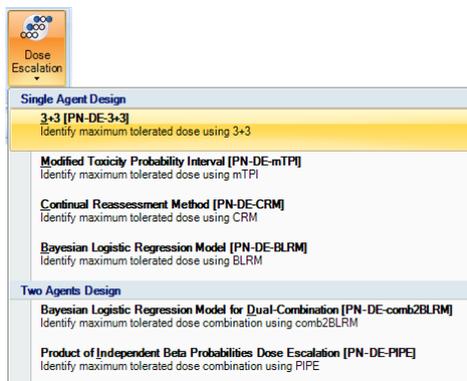

32.1 3+3

32.1.1 Simulation

32.1.2 Interim Monitoring

32.1.1 Simulation

Click **Discrete: Dose Escalation** on the Design tab, and then click **Single Agent Design: 3+3**.

This window is the Input dialog box, which is separated into three tabs: **Design Parameters**, **Response Generation**, and **Simulation Control**. First, you may specify the **Max. Number of Doses** as 7.

In the **Design Parameters** tab, enter 30 as the **Max. Sample Size**. For the 3+3 design, the **Cohort Size** is fixed at 3.

There are three variants of 3+3 offered: L and H and L(modified). The key differences between these variants can be seen in the respective **Decision Rules** table. Select 3+3

32 Dose Escalation

L.

Max. Number of Doses:

Design Parameters
Response Generation
Simulation Controls

Max. Sample Size:

Cohort Size:

Start With Accelerated Titration

Decision Rules

3+3 variant:

Target Probability of Toxicity (P_T): 1/6

| # Subjects with DLTs at Current Dose D_i | Decision 3+3 L |
|--|--|
| 0/3 | Escalate to $D_{[i+1]}$ |
| 1/3 | Stay at $D_{[i]}$ & treat 3 more |
| 2/3 or 3/3 | De-escalate to $D_{[i-1]}$; If $D_{[i-1]}$ already has 6 subjects, stop & choose $D_{[i-1]}$ as MTD |
| 0/3 + {0/3 or 1/3} | Stop & choose $D_{[i]}$ as MTD |
| 1/3 + 0/3 | Escalate to $D_{[i+1]}$ |
| {1/3 + 1/3} or {0/3 + 2/3} | De-escalate to $D_{[i-1]}$; If $D_{[i-1]}$ already has 6 subjects, stop & choose $D_{[i-1]}$ as MTD |
| 1/3 + {2/3 or 3/3} | De-escalate to $D_{[i-1]}$; If $D_{[i-1]}$ already has 6 subjects, stop & choose $D_{[i-1]}$ as MTD |

You also have the option of starting with an Accelerated Titration design (Simon et al., 1997), which escalates with single-patient cohorts until the first DLT is observed, after which the cohort is expanded at the current dose level with two more patients.

In the **Response Generation** tab, you can specify a set of true dose response curves from which to simulate. For the **Starting Dose**, select the lowest dose (5). In the row titled *Dose*, you can specify the dose levels (e.g., in mg). In the row titled *GCI*, you can edit the true probabilities of toxicity at each dose. You can also rename the profile by directly editing that cell. For now, leave all entries at their default values.

You can add a new profile generated from a parametric curve family. For example, click on the menu **Curve Family** and select **Emax**. You may construct a

four-parameter Emax curve by adjusting its parameters, then click **Add Profile**.

Specify True Probability of Toxicity

Curve Family: **Emax**

Parameters

| | | | |
|------|------|------|------|
| E0 | EMax | ED50 | Hill |
| 0.05 | 0.75 | 50 | 1 |

| GC1 | 0.05 | 0.1 | 0.2 | 0.3 | 0.35 | 0.4 | 0.45 |
| EM1 | 0.118 | 0.175 | 0.223 | 0.3 | 0.383 | 0.425 | 0.459 |

Starting Dose: **5**

Plot Profiles

Click **Plot Profiles** to plot the two dose toxicity curves in this grid.

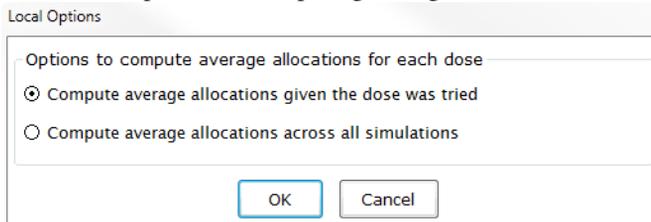

Dose Toxicity Curve

In the **Simulation Control** tab, check the boxes corresponding to **Save summary statistics** and **Save subject-level data**. These options will provides access to several charts derived from these more detailed levels of simulated data. If you wish to display subject-level plots for more than one simulation, you can increase the number. For now, leave this at 1 to save computation time.

32 Dose Escalation

You may also like to examine the **Local Options** button of the input window toolbar. This gives you different options for computing average allocations for each dose.

Click **Simulate**. East will simulate data generated from the two profiles you specified, and apply the 3+3 design to each simulation data set. Once completed, the two simulations will appear as two rows in the **Output Preview**. Select both rows in the **Output Preview** and click the  icon in the toolbar. The two simulations will be displayed side by side in the **Output Summary**.

Dose-wise Summary

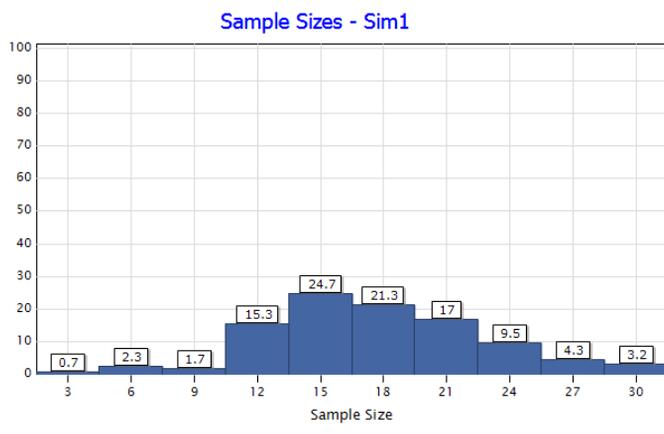

With Sim1 selected in the **Library**, click the Plots icon to access a wide range of available plots. Below is an example of the MTD plot, showing the percentage of simulations that each dose level was selected as the MTD. The "true" MTD is displayed as the second dose level. This is the dose whose true probability of DLT

32 Dose Escalation

(0.1) was closest to and below the target probability (1/6).

Another useful plot is that showing the possible sample sizes, shown as percentages over all simulations.

Close each plot after viewing, or save them by clicking **Save in Workbook**.

Finally, to save the workbook to disk, right-click Wbk1 in the **Library** and then **Save**

As...

32.1.2 Interim Monitoring

Right-click one of the Simulation nodes in the Library, and select **Interim Monitoring**. This will open an empty interim monitoring dashboard.

| Cohort # | Dose Assigned | #Subjects | #DLTs | Recommended Dose |
|----------|---------------|-----------|-------|------------------|
| 1 | | | | |
| 2 | | | | |
| 3 | | | | |

32 Dose Escalation

32.2 Continual Reassessment Method (CRM)

32.2.1 Simulation

32.2.2 Interim Monitoring

32.2.1 Simulation

Click **Discrete: Dose Escalation** on the Design tab, and then click **Single Agent Design: Continual Reassessment Method**.

This window is the Input dialog box, which is separated into four tabs: **Design Parameters**, **Stopping Rules**, **Response Generation**, and **Simulation Control**.

In the **Design Parameters** tab, enter **30** as the **Maximum Sample Size**, and **3** for **Cohort Size**. If you were to check the box **Start With**, then you would be simulating from the 3+3 or Accelerated Titration design first, before switching to the CRM. For this tutorial, however, leave the box unchecked.

Enter **0.25** for the **Target Probability of Toxicity**, and **0.3** for the **Target Probability Upper Limit**. This will ensure that the next dose assignment is that whose posterior mean toxicity probability is closest to **0.25**, and below **0.3**.

Target Probability of Toxicity (P_T):

Toxicity Probability Upper Limit (UL):

Assign the dose whose toxicity probability is closest to P_T , and below UL.

Click the **Posterior Sampling...** button. By default, CRM requires the posterior mean only. If instead you wish to sample from the posterior distribution (using a

Metropolis-Hastings algorithm), you will be able to compute and plot the posterior probabilities of being the MTD for each dose. Note that this option will increase the simulation time.

Click the **Dose Skipping...** button. As was recommended in later variations of CRM, in the interests of promoting safety, leave the default options: No untried doses will be skipped while escalating, and no dose escalation will occur when the most recent subject experienced a DLT.

For **Model Type**, select **Power**, with a Gamma($\alpha = 1, \beta = 1$) prior for θ . Other model types available include the **Logistic** and the **Hyperbolic Tangent**. Finally, for the prior probabilities of toxicity of all doses (known as the *skeleton*), enter: 0.05, 0.1,

32 Dose Escalation

0.2, 0.3, 0.35, 0.4, and 0.45.

Model Type: Power

Prior

Distribution: Gamma θ

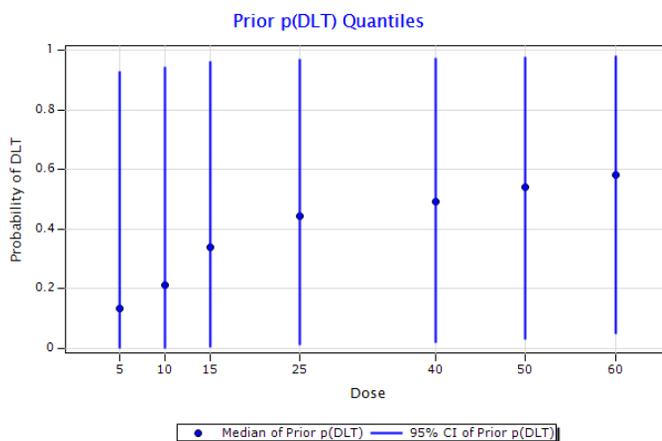

α (shape):

β (rate):

| Dose ID | Probability of Toxicity |
|---------|-------------------------|
| D1 | 0.050 |
| D2 | 0.100 |
| D3 | 0.200 |
| D4 | 0.300 |
| D5 | 0.350 |
| D6 | 0.400 |
| D7 | 0.450 |

Click the  icon to generate a chart of the 95% prior intervals at each dose for probability of DLT.

In the **Stopping Rules** tab, you may specify various rules for stopping the trial. Enter

the following inputs as below.

| | | |
|--|---|----------------|
| Stop Trial Early (MTD not determined) if | | Min SS on Dose |
| <input checked="" type="checkbox"/> | MTD Below Lowest Dose: Prob.($P_l > P_T$ data) > | 0.8 6 |
| <input checked="" type="checkbox"/> | MTD Above Highest Dose: Prob.($P_h < P_T$ data) > | 0.9 6 |
| Stop Trial Early (MTD determined) if | | Min SS on Dose |
| <input type="checkbox"/> | Minimum SS Observed in the Trial >= | |
| <input checked="" type="checkbox"/> | Allocation Rule: SS Already Allocated at Current MTD >= | 9 |

The early stopping rules are divided into two types: Those where the MTD is not determined, and those where the MTD is determined. The former case may arise when the MTD is estimated to be below the lowest dose or above the highest dose. Thus, if the posterior probability of overdosing (toxicity at the lowest dose is greater than target toxicity) exceeds 0.8, then the trial will be stopped. Similarly, if the posterior probability of underdosing (toxicity at the highest dose is lower than target toxicity) exceeds 0.9, then the trial will be stopped. A minimum of 6 subjects will need to be observed on a dose before either of these two rules is activated. A further stopping rule is based on the **Allocation Rule**: If the number of subjects already allocated to the current MTD is at least 9, the trial will be stopped.

In the **Response Generation** tab, you can specify a set of true dose response curves from which to simulate. For the **Starting Dose**, select the lowest dose (5). Leave the default profile as shown below. If you wish to edit or add additional profiles (dose

32 Dose Escalation

response curves), see the corresponding section for the 3+3 design.

Specify True Probability of Toxicity

Curve Family:
 General

Add Profile

True Probability of Toxicity (Profiles)

| Profile\Dose ID | D1 | D2 | D3 | D4 | D5 | D6 | D7 |
|-----------------|------|-----|-----|-----|------|-----|------|
| Dose | 5 | 10 | 15 | 25 | 40 | 50 | 60 |
| GC1 | 0.05 | 0.1 | 0.2 | 0.3 | 0.35 | 0.4 | 0.45 |

Starting Dose: 5

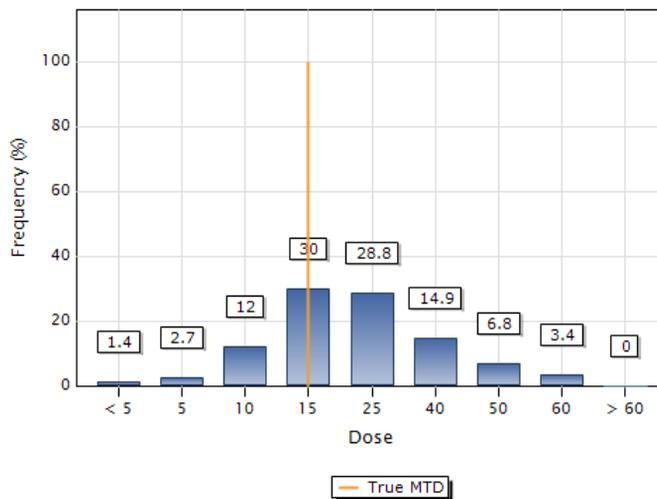

Plot Profiles

In the **Simulation Control** tab, check the boxes corresponding to **Save summary statistics** and **Save subject-level data**. These options will provides access to several charts derived from these more detailed levels of simulated data. If you wish to display subject-level plots for more than one simulation, you can increase the number. For now, leave this at 1 to save computation time.

Click **Simulate** to simulate the CRM design. In the **Output Preview** toolbar, click the  icon to save the simulation to the **Library**. Double-click the simulation node in the **Library** to display the simulation output details. Click the Plots icon in the **Library** to access a wide range of available plots.

Below is an example of the MTD plot, showing the percentage of simulations that each dose level was selected as the MTD. The true MTD is displayed as the third dose level (15). This is the dose whose true probability of DLT (0.2) was closest to and below the

target probability (0.25).

32.2.2 Interim Monitoring

Right-click the Simulation node in the Library, and select **Interim Monitoring**. This will open an empty interim monitoring dashboard.

Click **Enter Interim Data** to open a window in which to enter data for the first cohort: in particular, the **Dose Assigned** and the **DLTs Observed**. Click **OK** to continue.

Continue in this manner by clicking **Enter Interim Data**, entering the following doses, and the corresponding number of DLTs.

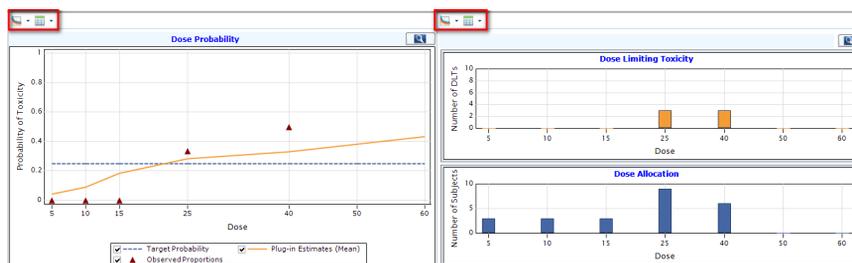

| Cohort # | Dose Assigned | #Subjects | #DLTs | Recommended Dose | Posterior Mean (Θ) |
|----------|---------------|-----------|-------|------------------|--------------------|
| 1 | 5 | 3 | 0 | 10 | 1.493 |
| 2 | 10 | 3 | 0 | 15 | 1.773 |
| 3 | 15 | 3 | 0 | 25 | 2.074 |
| 4 | 25 | 3 | 1 | 40 | 1.509 |
| 5 | 40 | 3 | 1 | 40 | 1.375 |
| 6 | 40 | 3 | 2 | 25 | 1.105 |
| 7 | 25 | 3 | 1 | 25 | 1.072 |
| 8 | 25 | 3 | 1 | 25 | 1.049 |

32 Dose Escalation

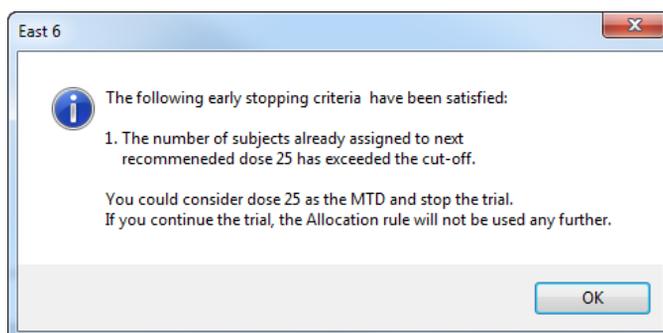

If you click **Display by Dose**, you will see the data grouped by dose level. You may click **Display by Cohort** to return to the original view.

| Dose # | Dose Assigned | Standardized Dose | #Subjects | Prop. Of Subjects | #DLTs | Prop. Of DLTs | Posterior Probability of Toxicity |
|--------|---------------|-------------------|-----------|-------------------|-------|---------------|-----------------------------------|
| 1 | 5 | 0.05 | 3 | 0.125 | 0 | 0 | 0.043 |
| 2 | 10 | 0.1 | 3 | 0.125 | 0 | 0 | 0.089 |
| 3 | 15 | 0.2 | 3 | 0.125 | 0 | 0 | 0.185 |
| 4 | 25 | 0.3 | 9 | 0.375 | 3 | 0.333 | 0.283 |
| 5 | 40 | 0.35 | 6 | 0.25 | 3 | 0.5 | 0.333 |
| Total | | | 24 | | 6 | | |

After each cohort, East will update the Interim Monitoring Dashboard. You may replace the IM dashboard plots with any other plots or corresponding tables, by clicking on the associated icons at the top left of each panel.

At this point, East recommends that you stop the trial.

Click **Stop Trial** to generate a table for final inference.

| Final Inference | |
|-------------------------|---------------------------|
| Final Output at Cohort# | 8 |
| MTD | 25 (using stopping rules) |
| Fitted MTD | 21.662 |

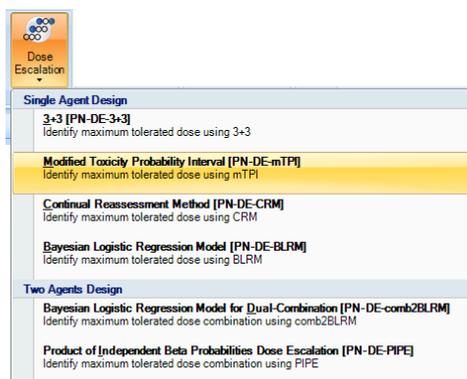

32.3 modified Toxicity Probability Interval (mTPI)

32.3.1 Simulation

32.3.2 Interim Monitoring

32.3.1 Simulation

Click **Discrete: Dose Escalation** on the Design tab, and then click **Single Agent Design: Modified Toxicity Probability Interval**.

This window is the Input dialog box, which is separated into five tabs: **Design Parameters**, **Stopping Rules**, **Trial Monitoring Table**, **Response Generation**, and **Simulation Control**.

In the **Design Parameters** tab, enter 30 as the **Maximum Sample Size**, and 3 for **Cohort Size**. If you were to check the box **Start With**, then you would be simulating from the 3+3 or Accelerated Titration design first, before switching to the mTPI. For this tutorial, however, leave the box unchecked.

Enter 0.25 for the **Target Probability of Toxicity**, 0.2 for the upper limit of the **Under**

32 Dose Escalation

dosing interval, and 0.3 for the upper limit of **Proper dosing** interval.

Target Probability of Toxicity (P_T):

| Toxicity Intervals | Lower Limit | Upper Limit |
|--------------------|-------------|-------------|
| Under dosing | 0.000 | 0.2 |
| Proper dosing | 0.200 | 0.3 |
| Over dosing | 0.300 | 1 |

These entries imply that toxicity probabilities within this interval [0.2 to 0.3] can be regarded as equivalent to the target toxicity (0.25) as far as dosing decisions are concerned. Finally, we will assume a uniform Beta($a = 1, b = 1$) prior distribution for all doses.

Prior

$P_i \sim \text{Beta}(a, b)$ 

P_i : True Toxicity Probability at Dose i

a (Prior Toxicity):

b (Prior Non-Toxicity):

In the **Stopping Rules** tab, enter the following inputs as below.

Design Parameters
Stopping Rules
Trial Monitoring Table
Response Generation
Simulation Controls

Stop Trial Early (MTD not determined) if

| | | |
|---|-----------------------------------|--------------------------------|
| Dose Exclusion Rule: $\text{Prob.}(P_i > P_T \text{data}) >$ | <input type="text" value="0.95"/> | <input type="text" value="3"/> |
| <input checked="" type="checkbox"/> MTD Above Highest Dose: $\text{Prob.}(P_h < P_T \text{data}) >$ | <input type="text" value="0.9"/> | <input type="text" value="3"/> |

Stop Trial Early (MTD determined) if

| | |
|---|----------------------|
| <input type="checkbox"/> Minimum SS Observed in the Trial \geq <input type="text"/> | <input type="text"/> |
| <input type="checkbox"/> Target Rule: $\text{Prob.}(\text{Target Toxicity}) >$ <input type="text"/> | <input type="text"/> |
| <input type="checkbox"/> CI Rule: <input type="text"/> % CI for P(DLT) at MTD $>$ <input type="text"/> and $<$ <input type="text"/> | <input type="text"/> |
| <input type="checkbox"/> Allocation Rule: SS Already Allocated at Current MTD \geq <input type="text"/> | <input type="text"/> |

Stopping Rules Combination

R1 Or R2

| # | Stopping Rule | And/Or |
|----|------------------------|-------------------------------------|
| R1 | Dose Exclusion Rule | Or <input type="button" value="v"/> |
| R2 | MTD Above Highest Dose | <input type="button" value="v"/> |

P_i : Probability of Toxicity at Dose i
 P_h : Probability of Toxicity at Highest Dose
 P_T : Target Probability of Toxicity

For the mTPI design, the stopping rule is based on dose exclusion rules. This states that if there is greater than a 0.95 posterior probability that toxicity for a given dose is greater than the target toxicity, that dose and all higher doses will be excluded in subsequent cohorts. When this dose exclusion rule applies to the lowest dose, then all doses are excluded, and hence the trial will be stopped for excessive toxicity.

Furthermore, the dose exclusion rule is not activated until at least 3 subjects are observed on a dose. A similar idea can be applied to the highest dose: If there is a greater than 95% posterior probability that the toxicity at the highest dose is less than the target toxicity, then stop the trial early.

The remaining stopping rules allow one to stop the trial early with MTD determined. The **Allocation Rule** requires a certain number of subjects already allocated to the next recommended dose. The **CI Rule** requires that the credible interval for probability of DLT at the MTD is within some range. The **Target Rule** requires that the posterior probability of being in the target toxicity, or proper dosing interval, exceeds some threshold. Finally, any of these rules can be combined with **Minimum Ss Observed in the Trial**.

In the **Trial Monitoring Table** tab, you can view the decision table corresponding to the inputs entered in the previous tabs.

Design Parameters | Stopping Rules | Trial Monitoring Table | Response Generation | Simulation Controls

| 14 | | | | | | | | | | | | | | | DU | DU | DU | DU | DU | D |

Number of Toxicities

- E = Escalate to the next higher dose
- S = Stay at the current dose
- D = De-escalate to the next lower dose
- DU = The current dose is unacceptably toxic

Target Toxicity (%) = 25%
Sample Size = 30

East also provides the option of creating and simulating from a customized trial monitoring table. If you click **Edit Trial Monitoring Table**, you can click on any cell

32 Dose Escalation

in the grid to edit and change the dose assignment rule for that cell.

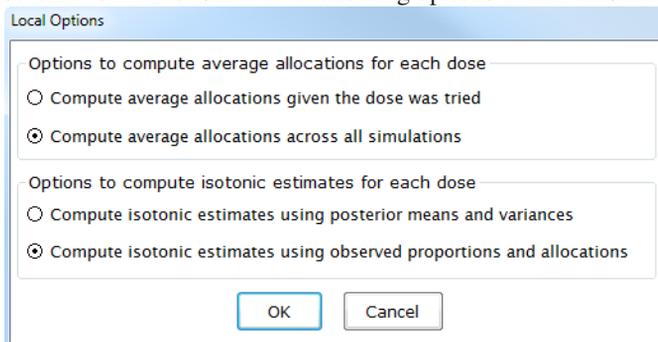

Number of patient

| r\n | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
|-----|----|----|----|----|----|----|----|----|
| 0 | E | E | E | E | E | E | E | E |
| 1 | E | S | S | S | S | S | E | E |
| 2 | D | DU | D | D | S | S | S | S |
| 3 | S | | DU | DU | DU | D | S | S |
| 4 | DU | | | DU | DU | DU | DU | DU |
| 5 | | | | | DU | DU | DU | DU |

In the **Response Generation** tab, you can specify a set of true dose response curves from which to simulate. For the **Starting Dose**, select the lowest dose (5). Leave the default profile as shown below. If you wish to edit or add additional profiles (dose response curves), see the corresponding section for the 3+3 design.

In the **Simulation Control** tab, check the boxes corresponding to **Save summary statistics** and **Save subject-level data**. These options will provide access to several charts derived from these more detailed levels of simulated data. If you wish to display subject-level plots for more than one simulation, you can increase the number. For now, leave this at 1 to save computation time.

Click the **Local Options** button at the top left corner of the input window toolbar. This gives you different options for computing average allocations for each dose, and for computing isotonic estimates. Select the following options and click OK.

Click **Simulate** to simulate the mTPI design. In the **Output Preview** toolbar, click the

 icon to save the simulation to the **Library**. Double-click the simulation node in the **Library** to display the simulation output details. For example, the true MTD was D3 (15), and this dose was selected as MTD the most often (43% of the time).

⊖ **MTD Analysis**

| | True | Median | Mean | Mode |
|------------|------|--------|--------|------|
| MTD | 15 | 15 | 20.756 | 15 |
| Fitted MTD | 20 | 18.992 | 21.538 | NA |

⊖ **% of Simulations selecting each dose as MTD**

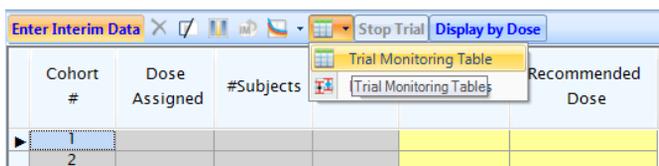

| Dose ID | Below lowest dose | D1 | D2 | D3 | D4 | D5 | D6 | D7 | Above highest dose |
|------------|-------------------|------|-------|-------|-------|------|-----|------|--------------------|
| Dose | | 5 | 10 | 15 | 25 | 40 | 50 | 60 | |
| Percentage | 0.01 | 0.94 | 13.29 | 43.46 | 29.57 | 9.41 | 2.9 | 0.42 | 0 |

Click the Plots icon in the **Library** to access a wide range of available plots.

32.3.2 Interim Monitoring

Right-click one of the Simulation nodes in the Library, and select **Interim Monitoring**. This will open an empty interim monitoring dashboard.

In the interim monitoring toolbar, click the chart icon, and **Trial Monitoring Table** to generate a table to guide dosing decisions for this trial.

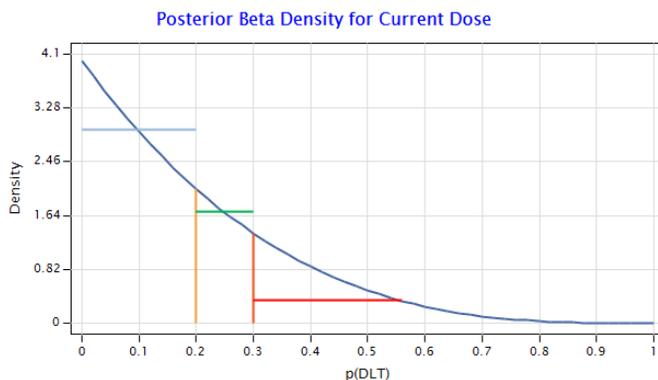

Click **Enter Interim Data** to open a window in which to enter data for the first cohort:

32 Dose Escalation

in particular, the **Dose Assigned** and the **DLTs Observed**. Click **OK** to continue.

The screenshot shows a dialog box titled "Enter Interim Data". Inside, there is a section for "Editing Cohort #1". It contains three input fields: "Dose Assigned" is a dropdown menu showing "5"; "#Subjects Allocated" is a text box containing "3"; and "#DLTs Observed" is a text box containing "0". At the bottom of the dialog are two buttons: "OK" and "Cancel".

The dashboard will be updated accordingly. The decision for the next cohort is based on the highest Unit Probability Mass (UPM): the posterior probability for each toxicity interval divided by the length of the interval. The underdosing interval corresponds to an E (Escalate) decision, the proper dosing interval corresponds to an S (Stay) decision, and the overdosing interval corresponds to a D (De-escalate) decision. In this case, the UMP for underdosing is highest.

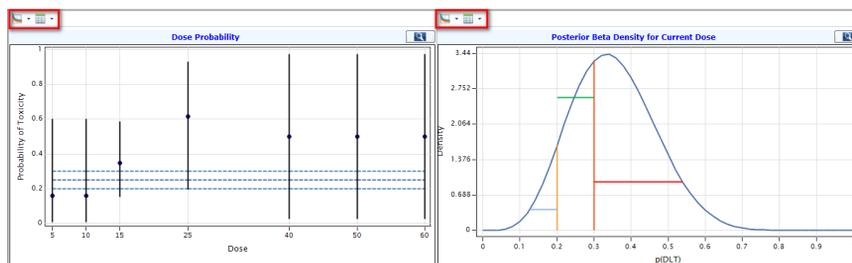

Thus, the recommendation is to escalate to dose 10.

Continue in this manner by entering data for each subsequent cohort, and observe how the interim monitoring dashboard updates.

One example is given below.

| Cohort # | Dose Assigned | #Subjects | #DLTs | Decision | Recommended Dose |
|----------|---------------|-----------|-------|----------|------------------|
| 1 | 5 | 3 | 0 | E | 10 |
| 2 | 10 | 3 | 0 | E | 15 |
| 3 | 15 | 3 | 0 | E | 25 |
| 4 | 25 | 3 | 2 | D | 15 |
| 5 | 15 | 3 | 2 | S | 15 |
| 6 | 15 | 3 | 1 | S | 15 |
| 7 | 15 | 3 | 2 | S | 15 |
| 8 | 15 | 3 | 0 | S | 15 |

After each cohort, East will update the Interim Monitoring Dashboard. You may replace the IM dashboard plots with any other plots or corresponding tables, by clicking on the associated icons at the top left of each panel.

Suppose we wished to end the study after 8 cohorts (24 patients). Click **Stop Trial** to end the study and generate a table of final inference.

| Final Inference | |
|-------------------------|-------|
| Final Output at Cohort# | 8 |
| MTD | 15 |
| Fitted MTD | 13.75 |

32.4 Bayesian logistic regression model (BLRM)

32.4.1 Simulation

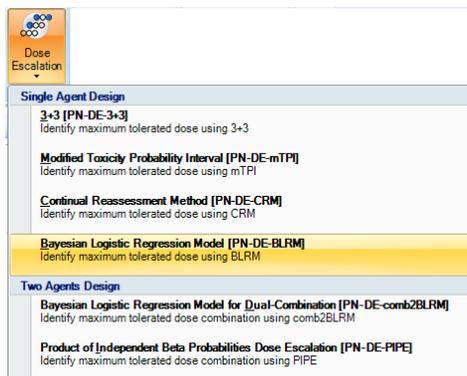

32.4.2 Interim Monitoring

32.4.1 Simulation

Click **Discrete: Dose Escalation** on the Design tab, and then click **Single Agent**

32 Dose Escalation

Design: Bayesian Logistic Regression Model.

This window is the Input dialog box, which is separated into four tabs: **Design Parameters**, **Stopping Rules**, **Response Generation**, and **Simulation Control**.

In the **Design Parameters** tab, enter 30 as the **Maximum Sample Size**, and 3 for **Cohort Size**. If you were to check the box **Start With**, then you would be simulating from the 3+3 or Accelerated Titration design first, before switching to the BLRM. For this tutorial, however, leave the box unchecked.

The next step is to choose a **Dose Selection Method**: either by **Bayes Risk** or by **Max Target Toxicity**. For the next cohort, the Bayes risk method selects the dose that minimizes the posterior expected loss, aka Bayes risk. In contrast, Max Target Toxicity method selects the dose that maximizes the posterior probability of targeted toxicity. For both methods, the dose selected must not exceed the EWOC (Escalation With Overdose Control) threshold: the posterior probability of overdosing,

either excessive or unacceptable toxicity, is less than the threshold (e.g., 0.25).

Target Probability of Toxicity (P_T):

Dose Selection Method
 Max Targeted Toxicity Bayes Risk

| Toxicity Intervals | Lower Limit | Upper Limit |
|-----------------------|-------------|-------------|
| Under dosing | 0.000 | 0.200 |
| Targeted toxicity | 0.200 | 0.350 |
| Excessive toxicity | 0.350 | 1.000 |
| Unacceptable toxicity | | |

EWOC: Prob. (Overdosing) <

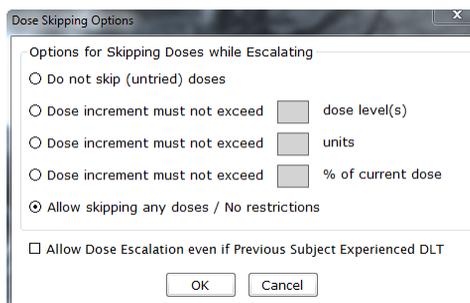

Reference Dose (D^*):

Recall that the BLRM method applies the following model:

$$\text{logit}(\pi_d) = \log(\alpha) + \beta \log(d/d^*) \tag{32.1}$$

The **Reference Dose (D^*)** is the dose at which the odds of observing a DLT is α .

Click the **Dose Skipping** button, and select **Allow skipping any doses / No Restrictions**.

You can specify the prior directly in terms of a bivariate normal distribution for $\log(\alpha)$

32 Dose Escalation

and $\log(\beta)$.

Prior Specification

Prior Calculator...

| | | | |
|--------------|-------------------------------------|------------------------------------|---|
| | ln (α) | ln (β) | |
| Mean: | <input type="text" value="-0.847"/> | <input type="text" value="0.265"/> |  |
| SD: | <input type="text" value="1.275"/> | <input type="text" value="1.981"/> | |
| Correlation: | <input type="text" value="0"/> | | |

Alternatively, if you click **Prior Calculator**, a calculator will appear allowing you to specify a prior indirectly by one of three methods: (1) lowest dose and reference dose, (2) lowest dose and highest dose, or (3) lowest dose and MTD. Click **Recalc** to convert the prior inputs into matching bivariate normal parameter values, and click **OK** to paste these values into the input window. Appendix N of the manual, and Appendix A of Neuenschwander et al. (2008) describes some of these methods.

Prior Distribution Calculator x

Specify Prior on: Lowest Dose and Reference Dose

Input

Prob. (DLT) at D1:

Prob. (DLT) at D*:

$P[\pi(D1) \leq \text{ }] = \text{ }$

$P[\pi(D*) \leq \text{ }] = \text{ }$

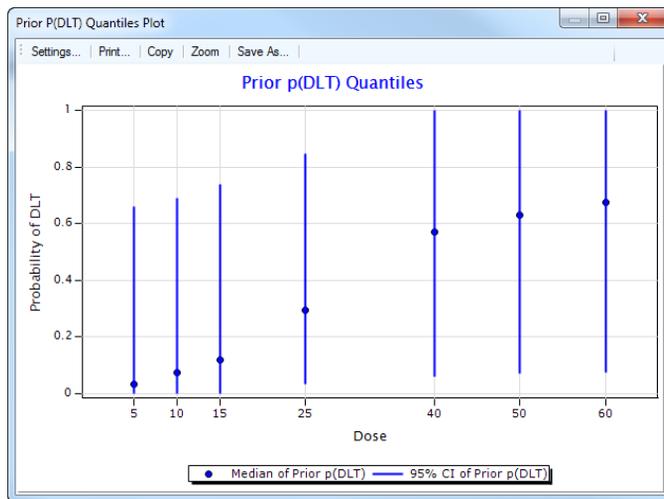

D1: Lowest Dose D*: Reference Dose

Output

| | | | |
|--------------|-------------------------------------|------------------------------------|--|
| | ln (α) | ln (β) | |
| Mean: | <input type="text" value="-0.847"/> | <input type="text" value="0.265"/> |  |
| SD: | <input type="text" value="1.275"/> | <input type="text" value="1.981"/> | |
| Correlation: | <input type="text" value="0"/> | | |

Click the  icon to generate a chart of the 95% prior intervals at each dose for

probability of DLT.

Click **Posterior Sampling Methods** to select from one of two methods: Metropolis Hastings, or direct Monte Carlo. For this tutorial, click **OK** to select **Direct**.

The dialog box is titled "Posterior Sampling Methods". It has two radio buttons: "Direct" (selected) and "Metropolis Hastings". Below the radio buttons are two input fields: "In (α)" with value "30" and "In (β)" with value "30". There are also two input fields: "# Points:" with value "30" and "Steady state simulations:" with value "1000". At the bottom are "Ok" and "Cancel" buttons.

In the **Stopping Rules** tab, you can specify multiple rules for stopping the trial. The trial is stopped early and MTD not determined if there is evidence of underdosing. This rule is identical to that from mTPI: If there is a greater than some threshold posterior probability that the toxicity at the highest dose is less than the target toxicity, then stop the trial early.

The remaining stopping rules allow one to stop the trial early with MTD determined. The **Allocation Rule** requires a certain number of subjects already allocated to the

32 Dose Escalation

next recommended dose. The **CI Rule** requires that the credible interval for probability of DLT at the MTD is within some range. The **Target Rule** requires that the posterior probability of being in the target toxicity exceeds some threshold. Finally, any of these rules can be combined with **Minimum Ss Observed in the Trial**. Check the appropriate boxes and enter values as below.

Stop Trial Early (MTD not determined) if

MTD Above Highest Dose: Prob.($P_n < P_T$ | data) > Min SS on Dose

Stop Trial Early (MTD determined) if

Minimum SS Observed in the Trial >= Min SS on Dose

Target Rule: Prob.(Target Toxicity) > Min SS on Dose

CI Rule: % CI for P(DLT) at MTD > and < Min SS on Dose

Allocation Rule: SS Already Allocated at Current MTD >=

Stopping Rules Combination
(R1 Or R2)

| # | Stopping Rule | And/Or |
|----|-----------------|--------|
| R1 | Target Rule | Or |
| R2 | Allocation Rule | |

In the **Response Generation** tab, you can specify a set of true dose response curves from which to simulate. For the **Starting Dose**, select the lowest dose (5). Leave the default profile as shown below. If you wish to edit or add additional profiles (dose response curves), see the corresponding section for the 3+3 design.

In the **Simulation Control** tab, check the boxes corresponding to **Save summary statistics**, **Save subject-level data**, and **Save final posterior samples**. These options will provides access to several charts derived from these more detailed levels of simulated data. If you wish to display subject-level plots, or posterior distribution plots, for more than one simulation, you can increase the number. For now, leave both of these at 1 to save computation time.

Note: Max. 100,000 records will be saved.

Click **Simulate** to simulate the BLRM design. In the **Output Preview** toolbar, click

the  icon to save the simulation to the **Library**. Double-click the simulation node in the **Library** to display the simulation output details. Click the Plots icon in the **Library** to access a wide range of available plots.

32.4.2 Interim Monitoring

Right-click the Simulation node in the Library, and select **Interim Monitoring**. This will open an empty interim monitoring dashboard. Click **Enter Interim Data** to open a window in which to enter data for the first cohort: in particular, the **Dose Assigned** and the **DLTs Observed**. Click **OK** to continue.

The dialog box titled "Enter Interim Data" contains the following fields and controls:

- Editing Cohort #1
- Dose Assigned:
- #Subjects Allocated:
- #DLTs Observed:
- OK button
- Cancel button

The dashboard will be updated accordingly.

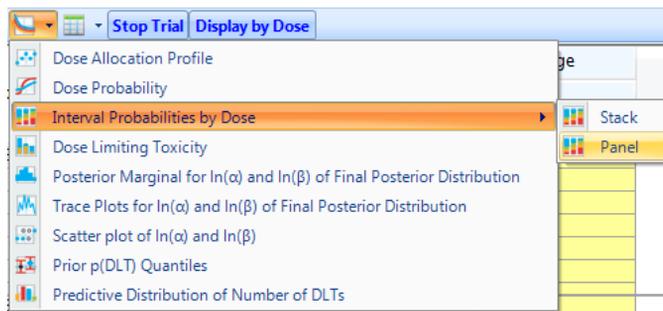

The acceptable dose range is on a continuous scale between the minimum and maximum doses. The upper limit of the acceptable dose range is the largest dose whose probability of overdosing is less than the EWOC threshold. The lower limit of the acceptable range is the dose whose DLT rate is equal to the lower limit of the targeted toxicity interval. When the computed lower limit exceeds the recommended

32 Dose Escalation

dose, it is set to the recommended dose.

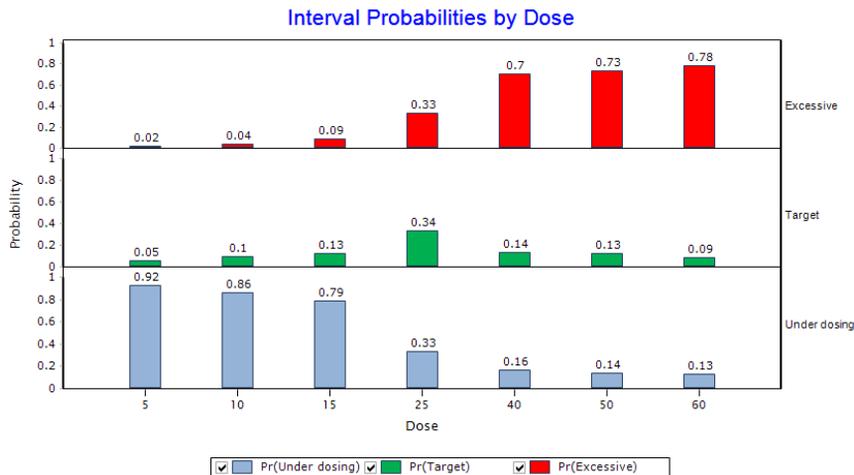

| Cohort # | Dose Assigned | #Subjects | #DLTs | Recommended Dose | Acceptable Dose Range | |
|----------|---------------|-----------|-------|------------------|-----------------------|-------------|
| | | | | | Lower Limit | Upper Limit |
| 1 | 5 | 3 | 0 | 15 | 15 | 23.221 |
| 2 | | | | | | |
| 3 | | | | | | |
| 4 | | | | | | |
| 5 | | | | | | |
| 6 | | | | | | |
| 7 | | | | | | |
| Total | | 3 | 0 | | | |

In the IM toolbar, click the Plots icon, then **Interval Probabilities by Dose** and **Panel**.

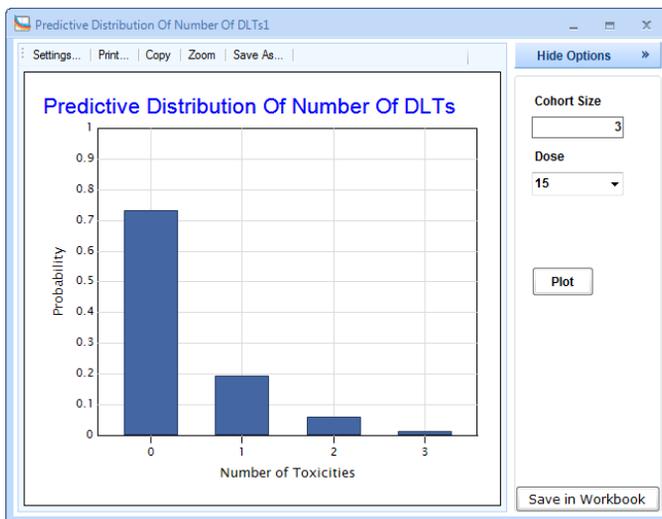

Notice that for all doses greater than or equal to 25, the posterior probability of overdosing exceeds the EWOC threshold (0.25). Of the remaining doses, dose 15 maximizes the probability of targeted toxicity, and is therefore the next recommended

dose.

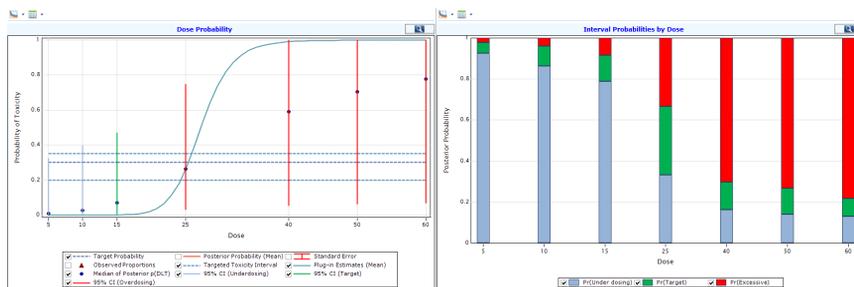

In the IM toolbar, click the Plots icon, then **Predictive Distribution of Number of DLTs**. You can enter a planned cohort size and select a next dose, to plot the posterior predictive probability of the number of DLTs to be observed in next cohort.

32 Dose Escalation

After each cohort, East will update the Interim Monitoring Dashboard. You may replace the IM dashboard plots with any other plots or corresponding tables, by clicking on the associated icons at the top left of each panel.

Continue entering data for each subsequent cohort, and observe how the interim monitoring dashboard updates. One example is given below.

| | Cohort # | Dose Assigned | #Subjects | #DLTs | Recommended Dose |
|---|----------|---------------|-----------|-------|------------------|
| | 1 | 5 | 3 | 0 | 15 |
| | 2 | 15 | 3 | 0 | 25 |
| | 3 | 25 | 3 | 0 | 25 |
| | 4 | 25 | 3 | 0 | 25 |
| | 5 | 25 | 3 | 1 | 25 |
| ▶ | 6 | | | | |
| | 7 | | | | |
| | Total | | 15 | 1 | |

Click **Stop Trial** to generate final inference table.

32.5 Bayesian logistic regression model for dual-combination (comb2BLRM)

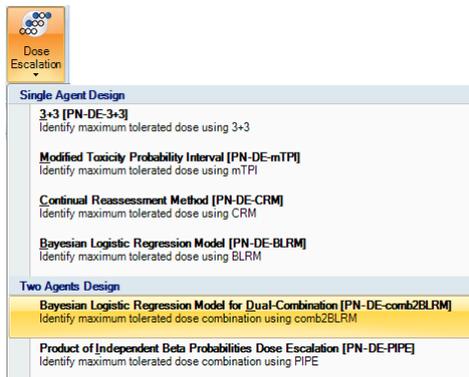

32.5.1 Simulation

32.5.2 Interim Monitoring

32.5.1 Simulation

Click **Discrete: Dose Escalation** on the Design tab, and then click **Two Agents**

Design: Bayesian Logistic Regression Model for Dual-Combination.

Set the **Max. Number of Doses** as 4 for both Agent 1 and Agent 2, the **Max. Sample Size** as 60, the **Cohort Size** as 3.

Set the target toxicity interval to 16-35%, with an EWOC criterion of 0.25. Set the reference doses to 290 and 20 for Agents 1 and 2, respectively.

Design Parameters Stopping Rules Response Generation Simulation Controls

Max. Sample Size:

Cohort Size:

| Toxicity Intervals | Lower Limit | Upper Limit |
|--------------------|-------------|-------------|
| Under dosing | 0.000 | 0.160 |
| Targeted toxicity | 0.160 | 0.350 |
| Overdosing | 0.350 | 1.000 |

EWOC: Prob. (Overdosing) <

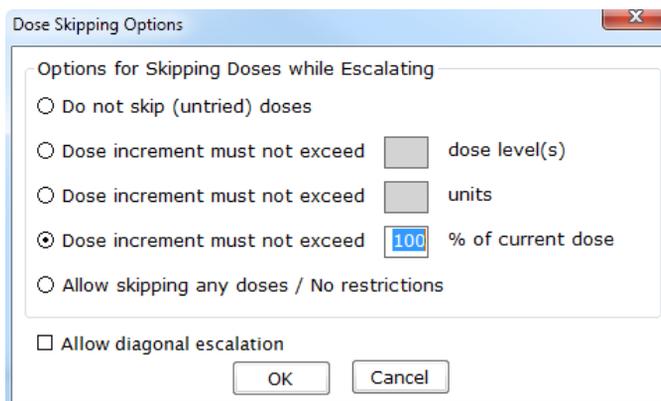

Reference Dose for Agent 1:

Reference Dose for Agent 2:

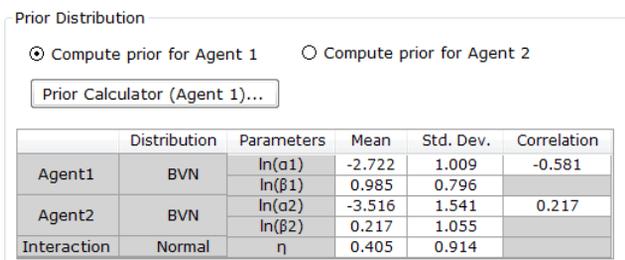

Click the button for **Dose Skipping**. These options imply that the dose of only one compound can be increased for the next cohort (no diagonal escalation), with a

32 Dose Escalation

maximum increment of 100

The prior distribution is an extension of that for the single-agent BLRM, but includes a normal prior for the interaction term. As with the single-agent BLRM, you can use the calculator to transform prior information on particular dose levels to a bivariate normal for either Agent 1 or Agent 2. In this tutorial, we will simply enter the following values adapted from Neuenschwander et al. (2015).

In the **Stopping Rules** tab, you may specify various rules for stopping the trial. The logical operators (And/Or) follow left-to-right precedence, beginning with the top-most rule in the table. The order of the stopping rules is determined by the order of selection.

Enter the following inputs as below. Select the **Minimum Ss** rule first, followed by the **Target Rule**, followed by the **Allocation Rule**. Be sure to select the appropriate logical operators. This combination of rules implies the MTD dose combination declared will meet the following conditions: (1) At least 6 patients have already been allocated to this combination, and (2) This dose satisfies one of the following: (i) The

probability of targeted toxicity at this combination exceeds 0.5, or (ii) A minimum of 15 subjects have already been observed in the trial.

Stop Trial Early (MTD determined) if

Minimum SS Observed in the Trial >=

Target Rule: Prob.(Target Toxicity) >

Allocation Rule: SS Already Allocated at Current MTD >=

Stopping Rules Combination
 ((R1 Or R2) And R3)

| # | Stopping Rule | And/Or |
|----|---------------------------|--------|
| R1 | Minimum Subjects in Trial | Or |
| R2 | Target Rule | And |
| R3 | Allocation Rule | |

In the **Response Generation** tab, enter the following inputs. Make sure that the starting dose combination is the lowest dose level for each agent.

32 Dose Escalation

In the **Output Preview** toolbar, click the  icon to Sim1 to the **Library**. Double-click Sim1 in the **Library** to display the simulation output details.

With Sim1 selected in the **Library**, click the Plots icon to access a wide range of available plots. Below is an example of the MTD plot, showing the percentage of simulations that each dose combination was selected as the MTD. The combinations whose true DLT rates were below, within, and above the target toxicity interval (0.16 – 0.35) are colored blue, green, and red, respectively.

32.5.2 Interim Monitoring

Right-click the Simulation node in the Library, and select **Interim Monitoring**. This will open an empty interim monitoring dashboard. Click **Enter Interim Data** to open a window in which to enter data for the first cohort: in particular, the **Dose Assigned** for

each agent, the **Subjects Allocated** and the **DLTs Observed**. Click **OK** to continue.

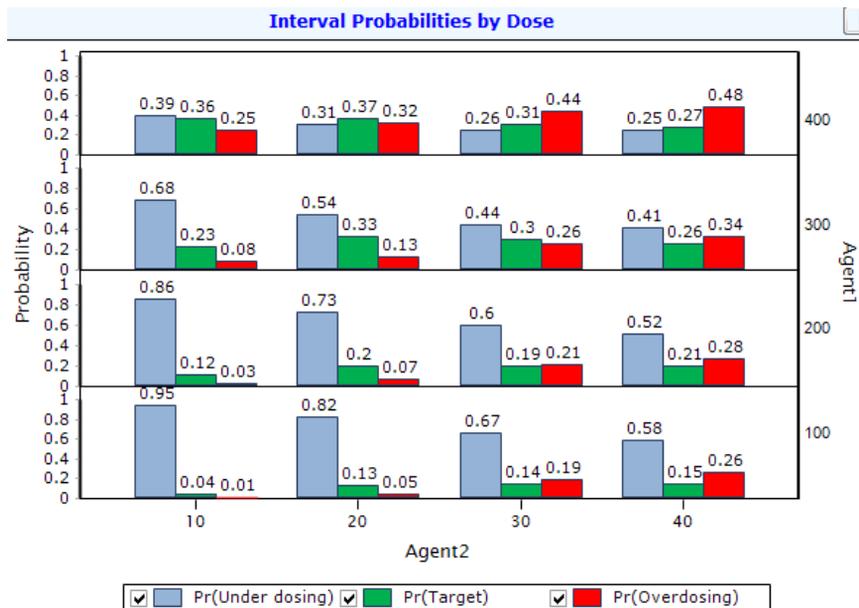

The next recommended dose is 100 mg for Agent 1 and 20 mg for Agent 2.

| Cohort # | Dose Assigned | | #Subjects | #DLTs | Recommended Dose | |
|----------|---------------|--------|-----------|-------|------------------|--------|
| | Agent1 | Agent2 | | | Agent1 | Agent2 |
| 1 | 100 | 10 | 3 | 0 | 100 | 20 |
| 2 | | | | | | |
| 3 | | | | | | |
| 4 | | | | | | |
| 5 | | | | | | |
| 6 | | | | | | |
| 7 | | | | | | |
| Total | | | 3 | 0 | | |

Recall that the dose skipping constraints are that the dose increment cannot exceed 100% of the current dose, and that only one compound can be increased. Of the eligible dose combinations, the recommended one has the highest probability of

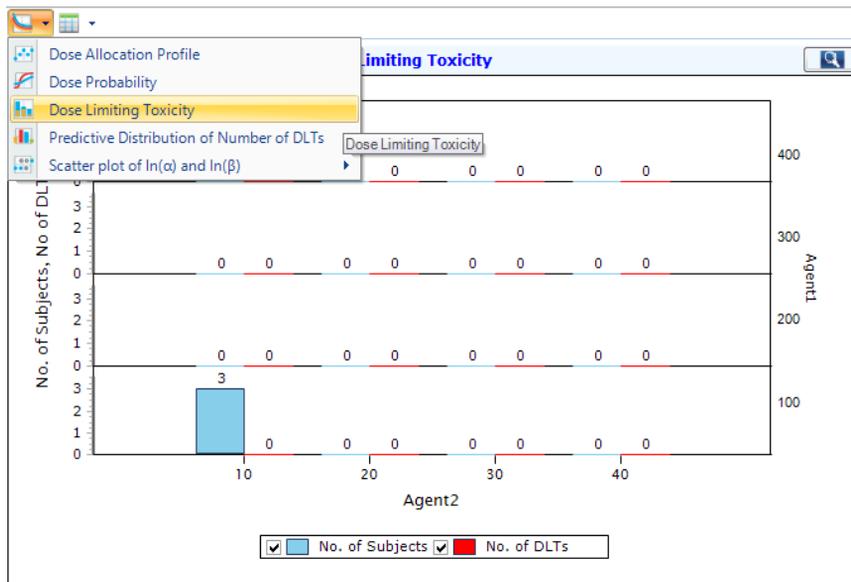

32 Dose Escalation

targeted toxicity.

You may replace the IM dashboard plots with any other plots or corresponding tables, by clicking on the associated icons at the top left of each panel. For example, change the left-hand plot to **Dose Limiting Toxicity** to view the number of subjects and DLTs

observed at each dose combination.

Continue in this manner by clicking **Enter Interim Data**, entering the following doses, and the corresponding number of DLTs.

| Cohort # | Dose Assigned | | #Subjects | #DLTs | Recommended Dose | |
|----------|---------------|--------|-----------|-------|------------------|----------|
| | Agent1 | Agent2 | | | Agent1 | Agent2 |
| 1 | 100 | 10 | 3 | 0 | 100 | 20 |
| 2 | 100 | 20 | 3 | 0 | 100 | 40 |
| 3 | 100 | 40 | 3 | 1 | 200 | 40 |
| 4 | 200 | 40 | 3 | 2 | 200 | 30 |
| 5 | 200 | 30 | 3 | 1 | 200 | 30 |
| 6 | 200 | 30 | 3 | 1 | 100 | 30 |
| 7 | 100 | 30 | 3 | 0 | MTD = 200 | MTD = 30 |
| 8 | | | | | | |
| 9 | | | | | | |
| 10 | | | | | | |
| 11 | | | | | | |
| Total | | | 21 | 5 | | |

The recommended MTD combination is 200 mg for Agent 1 and 30 mg for Agent 2.

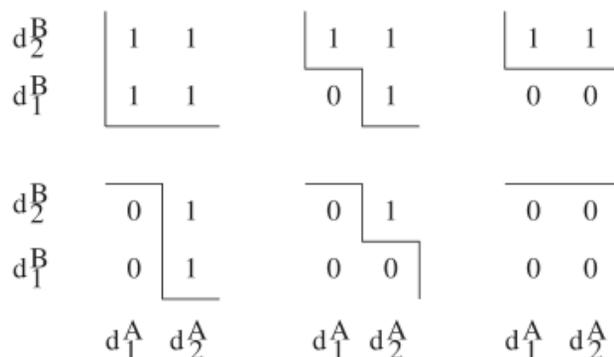

32 Dose Escalation

32.6 Product of Independent beta Probabilities dose Escalation (PIPE)

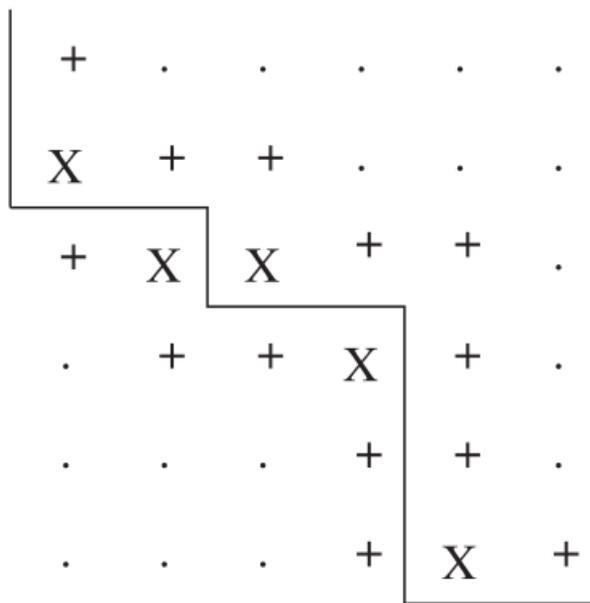

32.6.1 Simulation

One of the core concepts underlying the PIPE method is the maximum tolerated contour (MTC), a line partitioning the dose combination space into toxicity probabilities either less than or greater than the target. The recommended dose combination at the end of the trial is the dose combination closest from below to the MTC. The following figures from Mander and Sweeting (2015) illustrate the MTC, and the related concepts of admissible dose combinations (adjacent or closest) and dose skipping options (neighborhood vs non-neighborhood constraint).

This figure below shows six monotonic MTCs for two agents, each with two dose levels.

After each cohort, the most likely contour is selected before applying a dose selection strategy. The next dose combination is chosen from a set of admissible doses, which are either *closest* to the most likely contour, or *adjacent*. In the figure below, all the (X) and (+) symbols are considered *adjacent*. Of these, the (X) symbols represent the *closest* doses.

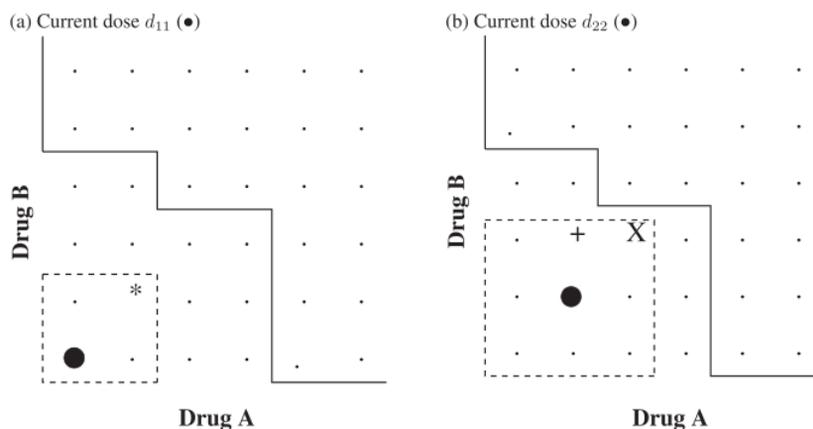

Of the admissible doses, the next dose combination chosen is that with the **minimum sample size**, where sample size is defined as the prior and trial sample size combined. The **weighted randomization method** selects one of the admissible doses at random, with selection probabilities weighted by the inverse of their sample size.

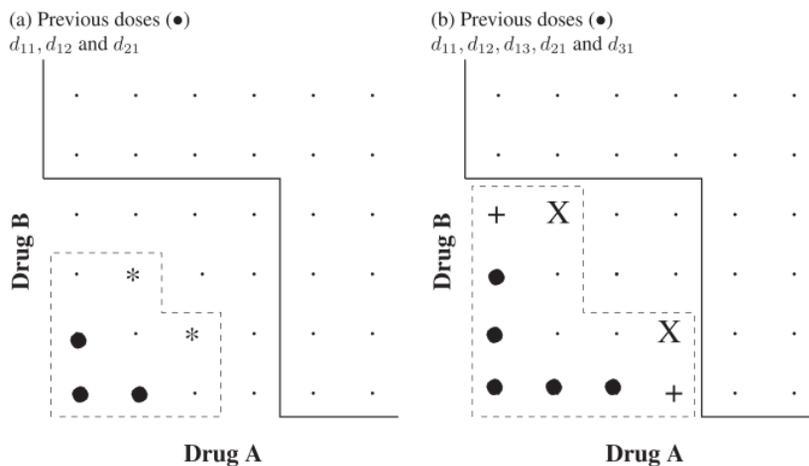

For dose skipping options, one can choose between a neighborhood constraint, or a non-neighborhood constraint. The **neighborhood constraint** restricts the set of admissible doses to those a single dose level higher or lower than the current dose for both agents, while the **non-neighborhood constraint** restricts the set of admissible doses to a single dose level higher or lower than any previously administered dose combination.

This figure below illustrates the neighborhood constraint, at two different cohorts. Only those combinations within the dashed box are admissible. The asterisk symbol on the left represents the admissible dose combination closest to the MTC.

32 Dose Escalation

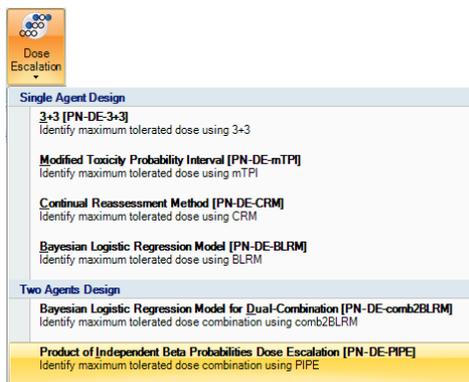

This figure below illustrates the non-neighborhood constraint. The set of admissible doses is now larger because all previously administered doses are included.

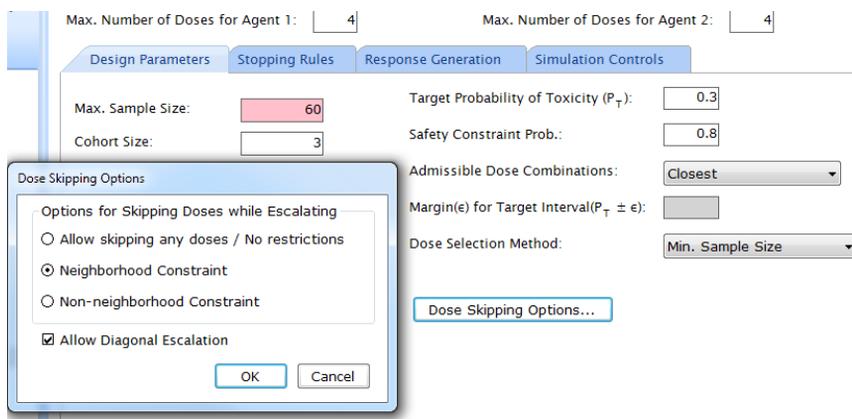

Finally, there is a safety constraint threshold to avoid overdosing. Averaging over the posterior distribution of all monotonic contours, the expected probability of being above the MTC is calculated for all dose combinations. Those dose combinations whose expected probabilities exceed the safety threshold are excluded from the admissible set.

Click **Discrete: Dose Escalation** on the Design tab, and then click **Two Agents Design: Product of Independent Beta Probabilities Dose Escalation**.

In the **Design Parameters** tab, select the following options.

In addition to the **Closest** and **Adjacent** options for **Admissible Dose Combinations**, there is also an **Interval** option. This allows you to specify a margin ϵ around the target toxicity level to define the admissible dose set, rather than relying on the MTC. Dose combinations whose posterior mean toxicity risk lies in the specified target interval ($P_T \pm \epsilon$) are considered admissible.

For the prior specification, enter the following values. When entering the same prior

32 Dose Escalation

sample size for each dose combination, a value of 1 considered a *strong* prior, whereas a value of 1 divided by the number of combinations can be considered a *weak* prior (Mander & Sweeting, 2015).

Specify Prior Using: Prior P(DLT) and Prior SS

Prior Specification

Prior P(DLT):

| | | Agent2 | | | |
|--------|----|--------|-------|-------|-------|
| Doses | | D1 | D2 | D3 | D4 |
| Agent1 | D1 | 0.098 | 0.145 | 0.240 | 0.335 |
| | D2 | 0.145 | 0.190 | 0.280 | 0.370 |
| | D3 | 0.240 | 0.280 | 0.360 | 0.440 |
| | D4 | 0.335 | 0.370 | 0.440 | 0.510 |

Prior Sample Size:

| | | Agent2 | | | |
|--------|----|--------|-------|-------|-------|
| Doses | | D1 | D2 | D3 | D4 |
| Agent1 | D1 | 1.000 | 1.000 | 1.000 | 1.000 |
| | D2 | 1.000 | 1.000 | 1.000 | 1.000 |
| | D3 | 1.000 | 1.000 | 1.000 | 1.000 |
| | D4 | 1.000 | 1.000 | 1.000 | 1.000 |

In the **Stopping Rules** tab, there are a number of options similar to those from other designs. However, for this tutorial, leave these options unchecked.

Design Parameters | **Stopping Rules** | Response Generation | Simulation Controls

Stop Trial Early (MTD not determined) if

MTD Below Lowest Dose: Prob.($P_1 > P_T$ | data) > Min SS on Dose

Stopping Rule | And/Or

| Stopping Rule | And/Or |
|---------------|--------|
| | ▼ |
| | ▼ |

Stop Trial Early (MTD determined) if

Minimum SS Observed in the Trial >=

Allocation Rule: SS Already Allocated to Next Recommended Dose >=

Similarly, leave the default options in the **Response Generation** tab. In this tutorial, the true probabilities of toxicity will be in agreement with the prior medians specified

above.

The screenshot shows the 'Simulation Controls' tab with two sections for 'Specify True Probability of Toxicity'. The first section is for 'Agent1' and the second for 'Agent2'. Both sections have a 'Curve Family' dropdown set to 'General' and a 'Starting Dose' dropdown. The 'Agent1' starting dose is 100, and the 'Agent2' starting dose is 10. A 'Recalc>>' button is located between the two sections. To the right, a 'True Probability of Toxicity (Profiles)' window shows a table for 'Agent2' with columns for Doses (10, 20, 30, 40) and rows for Dose (100, 200, 300, 400). The table contains numerical values representing toxicity probabilities.

| | | Agent2 | | | | |
|--------|------|--------|-------|-------|------|-------|
| | | Doses | 10 | 20 | 30 | 40 |
| Agent1 | Dose | 100 | 0.098 | 0.145 | 0.24 | 0.335 |
| | GC1 | 200 | 0.145 | 0.19 | 0.28 | 0.37 |
| | 300 | 0.24 | 0.28 | 0.36 | 0.44 | |
| | 400 | 0.335 | 0.37 | 0.44 | 0.51 | |

In the **Simulation Controls** tab, you can run 1000 simulations, although the PIPE method runs relatively quickly.

The screenshot shows the 'Simulation Controls' tab with 'Number of Simulations' set to 1000 and 'Refresh Frequency' set to 100. Under 'Random Number Seed', the 'Clock' radio button is selected. There are checkboxes for 'Suppress All Intermediate Output', 'Pause after Refresh', and 'Stop at End'. On the right, the 'Output Options' section shows 'Output Type' set to 'Case Data' and checkboxes for 'Save summary statistics for every simulation run' and 'Save subject level data for 1 simulation runs'. A note states: 'Note: Max. 100,000 records will be saved.'

In the **Output Preview** toolbar, click the  icon to save the simulation to the **Library**. Double-click the simulation node in the **Library** to display the simulation output details.

In the **MTD Analysis** table, you can see that the (Agent 1, Agent 2) dose combinations selected most often as MTD were: (300, 10) at 22.1% and (300, 20) at 20.8%. The true

32 Dose Escalation

probabilities of toxicity at these combinations were 0.24 and 0.28, respectively.

⊖ MTD Analysis

| Dose_1 | Dose_2 | True Prob. of Toxicity | % of Sims selected as MTD | Average Allocations | Average No. of DLTs |
|--------|--------|------------------------|---------------------------|---------------------|---------------------|
| 100 | 10 | 0.098 | 0.1 | 9 | 0 |
| 100 | 20 | 0.145 | 0.4 | 10.5 | 1.75 |
| 100 | 30 | 0.24 | 0.7 | 12.429 | 1.857 |
| 100 | 40 | 0.335 | 0.4 | 15.75 | 3.75 |
| 200 | 10 | 0.145 | 5 | 6.78 | 0.8 |
| 200 | 20 | 0.19 | 9.7 | 10.763 | 1.546 |
| 200 | 30 | 0.28 | 8.1 | 14.889 | 2.667 |
| 200 | 40 | 0.37 | 1.8 | 17.5 | 3.889 |
| 300 | 10 | 0.24 | 22.1 | 9.339 | 1.412 |
| 300 | 20 | 0.28 | 20.8 | 12.649 | 2.188 |
| 300 | 30 | 0.36 | 5.6 | 13.018 | 2.5 |
| 300 | 40 | 0.44 | 0.3 | 14 | 3.667 |
| 400 | 10 | 0.335 | 16.1 | 9.783 | 1.665 |
| 400 | 20 | 0.37 | 8 | 9.938 | 1.688 |
| 400 | 30 | 0.44 | 0.7 | 9.429 | 1.143 |
| 400 | 40 | 0.51 | 0 | NA | NA |

32.6.2 Interim Monitoring

Right-click the Simulation node in the Library, and select **Interim Monitoring**. This will open an empty interim monitoring dashboard. Click **Enter Interim Data** to open a window in which to enter data for the first cohort: in particular, the **Dose Assigned** for

each agent, the **Subjects Allocated** and the **DLTs Observed**. Click **OK** to continue.

The next recommended dose is 200 mg for Agent 1 and 20 mg for Agent 2.

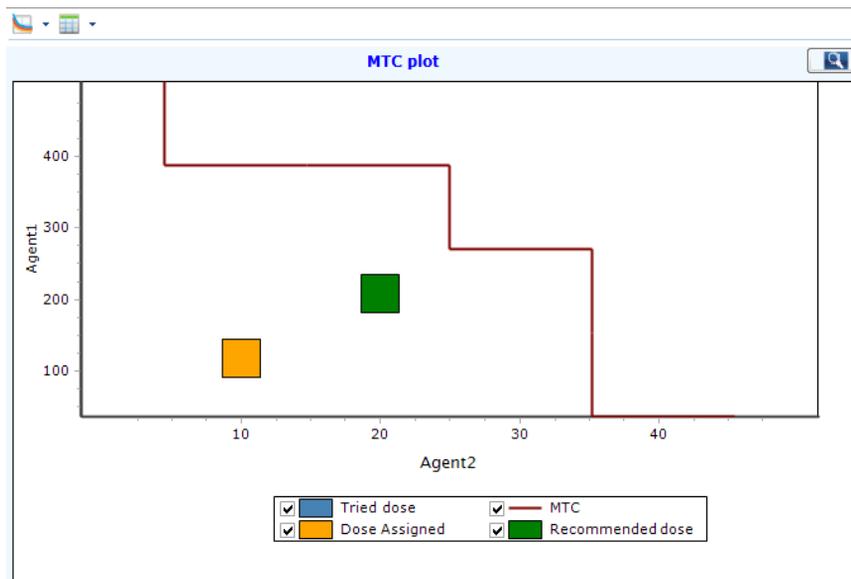

| Cohort # | Dose Assigned | | #Subjects | #DLTs | Recommended Dose | |
|----------|---------------|--------|-----------|-------|------------------|--------|
| | Agent1 | Agent2 | | | Agent1 | Agent2 |
| 1 | 100 | 10 | 3 | 0 | 200 | 20 |
| 2 | | | | | | |
| 3 | | | | | | |
| 4 | | | | | | |
| 5 | | | | | | |
| 6 | | | | | | |
| 7 | | | | | | |
| Total | | | 3 | 0 | | |

Recall that the dose skipping constraints allow for **diagonal escalation** (that is, escalation on both agents at the same time), but the **neighborhood constraint** restricts the set of admissible doses to a single dose level higher or lower than the current dose. Given these constraints, the dose combination (200, 10) is the only combination **closest** to the most probable MTC.

The **MTC plot** allows you to view the most probable MTC, the current dose, the

32 Dose Escalation

recommended dose, and all tried doses.

You may replace the IM dashboard plots with any other plots or corresponding tables, by clicking on the associated icons at the top left of each panel.

Continue in this manner by clicking **Enter Interim Data**, entering the following doses, and the corresponding number of DLTs.

| Cohort # | Dose Assigned | | #Subjects | #DLTs | Recommended Dose | |
|----------|---------------|--------|-----------|-------|------------------|--------|
| | Agent1 | Agent2 | | | Agent1 | Agent2 |
| 1 | 100 | 10 | 3 | 0 | 200 | 20 |
| 2 | 200 | 20 | 3 | 1 | 300 | 20 |
| 3 | 300 | 20 | 3 | 1 | 300 | 10 |
| 4 | 300 | 10 | 3 | 1 | 200 | 20 |
| 5 | 200 | 20 | 3 | 2 | 200 | 10 |
| 6 | 200 | 10 | 3 | 1 | 100 | 20 |
| 7 | 100 | 20 | 3 | 1 | 100 | 30 |
| 8 | 100 | 30 | 3 | 2 | 100 | 20 |
| 9 | | | | | | |
| Total | | | 24 | 9 | | |

Click **Stop Trial**. The recommended MTD combination is 200 mg for Agent 1 and 10

mg for Agent 2. The recommended MTD combination must meet three criteria: (i) closest to MTC from below, (ii) have been experimented on, and (iii) below safety threshold. If there is no dose combination satisfying all three criteria, the MTD will be undetermined.

Volume 4 *Exact Binomial Designs*

| | |
|---|------------|

| <i>37 Binomial Equivalence Two-Sample – Exact</i> | <i>767</i> |
| <i>38 Binomial Simon’s Two-Stage Design</i> | <i>774</i> |

33 *Introduction to Volume 8*

This volume describes various cases of clinical trials using binomial endpoints where the asymptotic normal approximation to the test statistic may fail. This is often the case in situations where the trial sample size is too small, however testing and analysis based on the exact binomial distribution would provide valid results. Asymptotic tests may also fail when proportions are very close to the boundary, namely zero or one. These exact methods can be applied in situations where the normal approximation is adequate, in which case the solutions to both the exact and asymptotic method would converge to the same result.

Using exact computations, Chapter 34 deals with the design and interim monitoring of a one sample test of superiority for proportion. The first section discusses a fixed and group sequential design in which an observed binomial response rate is compared to a fixed response rate. The following section illustrates how, for a fixed sample, McNemar's conditional test can be used to compare matched pairs of binomial responses.

Chapters 35 through 37 illustrates how to use East to design two-sample exact tests of superiority, non-inferiority and equivalence, including examples for both the difference and ratio of proportions.

Chapter 38 describes Simon's two stage design in an exact setting, which computes the expected minimal sample size of a trial that may be stopped due to futility or continue to a second stage to further study efficacy and safety.

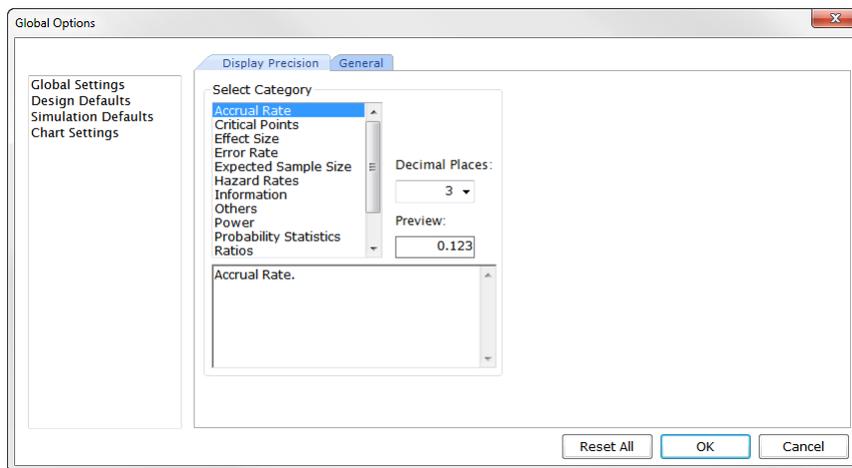

It is important to note that all exact tests work with only integer values for sample size, and will override the **Design Defaults - Common: Do not round off sample size/events** flag in the **Options** menu. Whenever the **Perform Exact Computations** check box is selected in the **Design Input Output** dialog box, resulting sample sizes will be converted to an integer value for all computations, including power and chart/table values.

33 Introduction to Volume 8

33.1 Settings

Click the icon in the **Home** menu to adjust default values in East 6.

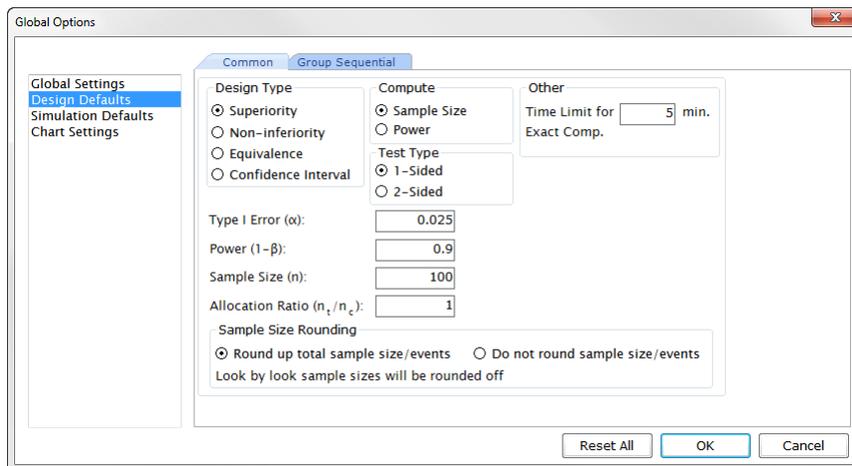

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

The **Design Defaults** is where the user can change the settings for trial design:

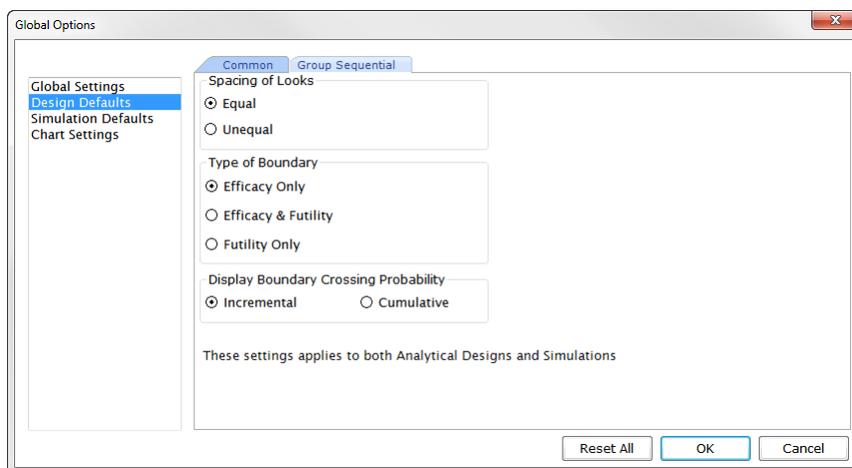

Under the **Common** tab, default values can be set for input design parameters.

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

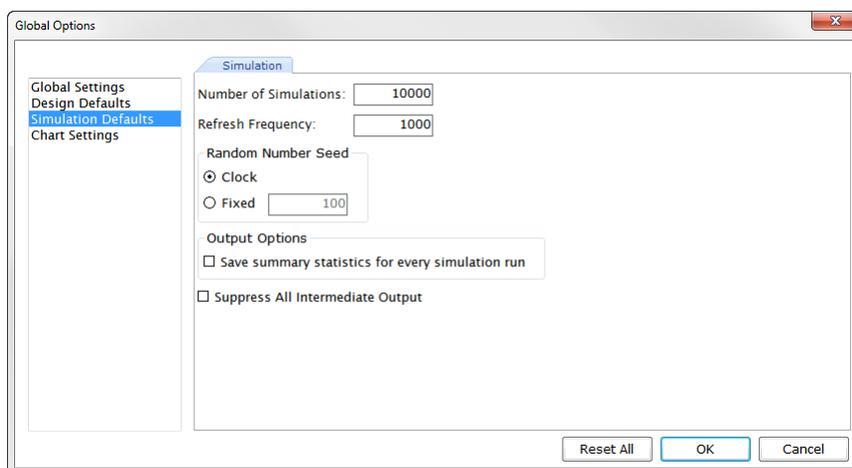

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

33 Introduction to Volume 8

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

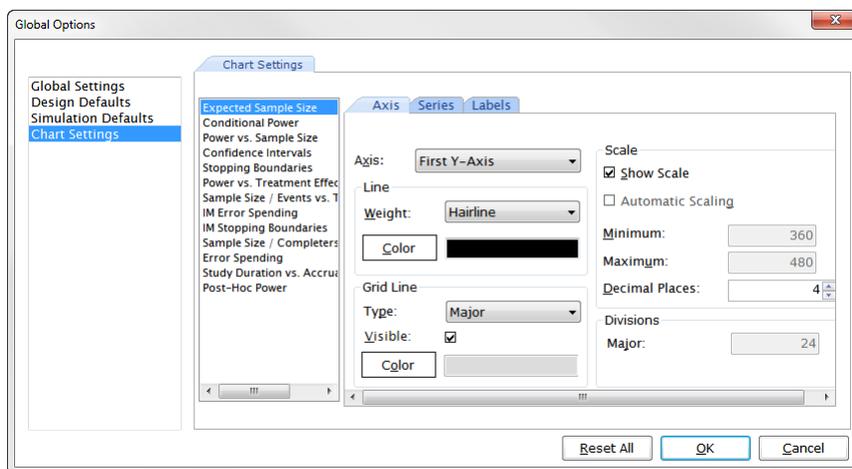

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

We suggest that you do not alter the defaults until you are quite familiar with the software.

34 Binomial Superiority One-Sample – Exact

This chapter deals with the design and interim monitoring of tests involving binomial response rates using exact computations. Section 34.1 discusses a fixed sample and group sequential design in which an observed binomial response rate is compared to a fixed response rate. In Section 34.2, McNemar’s conditional test for comparing matched pairs of binomial responses for a fixed sample is discussed.

34.1 Binomial One-Sample

34.1.1 Trial Design

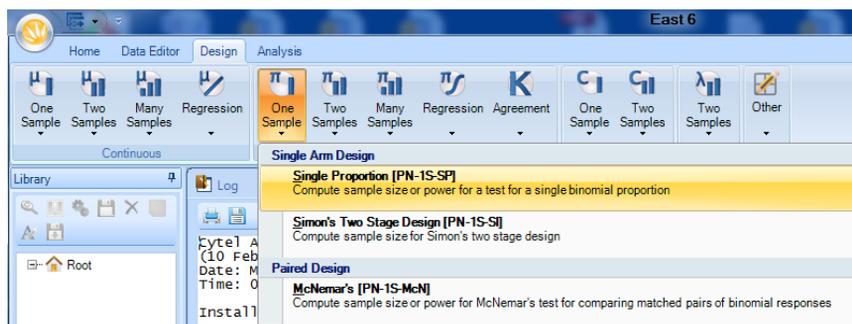

34.1.2 Interim Monitoring

In experimental situations where the variable of interest has a binomial distribution, it may be of interest to determine whether the response rate π differs from a fixed value π_0 . Specifically, we wish to test the null hypothesis $H_0: \pi = \pi_0$ against one-sided alternatives of the form $H_1: \pi > \pi_0$ or $H_1: \pi < \pi_0$. Either the sample size or power is determined for a specified value of π which is consistent with the alternative hypothesis, denoted as π_1 .

34.1.1 Trial Design

Consider a single-arm oncology trial designed to determine if the tumor response rate for a new cytotoxic agent is at least 15%. Thus it is desired to test the null hypothesis $H_0: \pi = 0.15$ against the one-sided alternative hypothesis $H_1: \pi > 0.15$. The trial will be designed using a one-sided test that achieves 80% power at $\pi = \pi_1 = 0.25$ with a level $\alpha = 0.05$ test.

Single-Look Design To illustrate this example, in **East** under the **Design** ribbon for **Discrete** data, click **One Sample** and then choose **Single Arm Design: Single Proportion**:

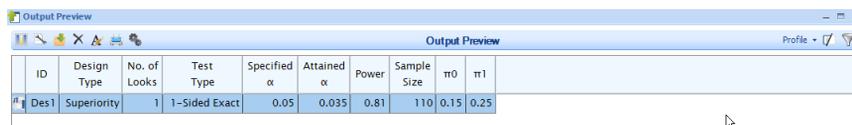

This will launch the following input window:

Leave the default values of **Design Type: Superiority** and **Number of Looks: 1**. In the **Design Parameters** dialog box, select the **Perform Exact Computations** checkbox and enter the following parameters:

- Test Type: 1 sided
- Type I Error (α): 0.05
- Power: 0.8
- Sample Size (n): Computed (select radio button)
- Prop. Response under Null (π_0): 0.15
- Prop. Response under Alt (π_1): 0.25

34 Binomial Superiority One-Sample – Exact

Click **Compute**. The sample size for this design is calculated and the results are shown as a row in the **Output Preview** window:

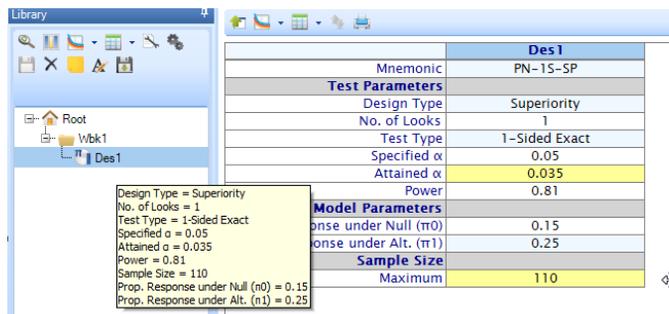

| ID | Design Type | No. of Looks | Test Type | Specified α | Attained α | Power | Sample Size | π_0 | π_1 |
|------|-------------|--------------|---------------|--------------------|-------------------|-------|-------------|---------|---------|
| Des1 | Superiority | 1 | 1-Sided Exact | 0.05 | 0.035 | 0.81 | 110 | 0.15 | 0.25 |

The sample size required in order to achieve 80% power is 110 subjects. Note that because of the discreteness involved in performing exact computations, the attained type-1 error is 0.035, less than the specified value of 0.05. Similarly, the attained power is 0.81, slightly larger than the specified value of 0.80.

As is standard in **East**, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the **Output Preview** toolbar. The design details will be displayed in the upper pane, labeled **Output Summary**. This can be saved to the **Library** by selecting **Des 1** and

clicking the  icon.

| Des1 | |
|---------------------------------------|---------------|

- ⊖ Sample Size Information
 - Sample Size (n) 110
- ⊖ Critical Points
 - Critical Point 24

The critical point, or the boundary set for the rejection of H_0 is 24 (on the # response scale). Therefore out of 110 subjects, if the observed number of patients responding to the new treatment exceeds 24, the null hypothesis will be rejected in favor of declaring the new treatment to be superior. This can also be seen using both a response scale and proportion scale in either the **Stopping Boundaries** chart or table, available in the

34 Binomial Superiority One-Sample – Exact

Library

Stopping Boundaries .00 .00

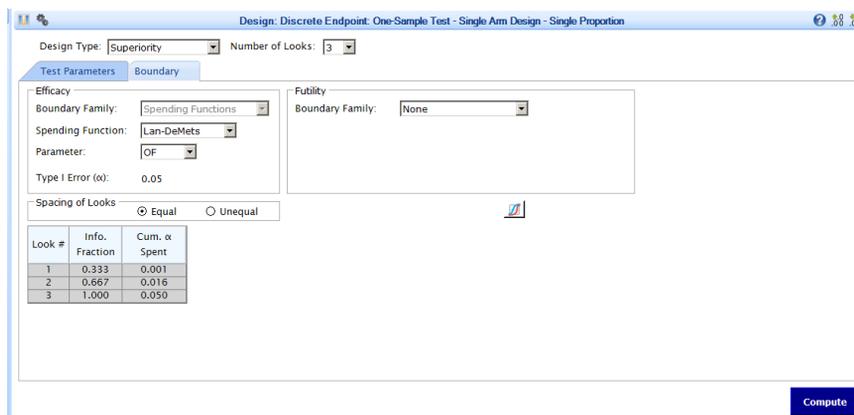

Boundary Scales : # Resp. Scale Settings...

Des1

| Look # | Info. Fraction | Sample Size | Cum. α Spent | Boundaries | |
|--------|----------------|-------------|---------------------|-------------------|--|
| | | | | Efficacy Boundary | |
| 1 | 1 | 110 | 0.05 | 24 | |

Three-Look Design In order to reach an early decision and enter into comparative trials, conduct this single-arm study as a group sequential trial with a maximum of 3

looks. Create a new design by selecting **Des1** in the **Library**, and clicking the  icon on the **Library** toolbar. To generate a study with two interim looks and a final analysis, change the **Number of Looks** from 1 to 3. A **Boundary Info** tab will appear, which allows the specification of parameters for the **Efficacy** and **Futility** boundary families. By default, an efficacy boundary to reject H_0 is selected, however there is no futility boundary to reject H_1 . The **Boundary Family** specified is of the **Spending Functions** type and the default **Spending Function** is the Lan-DeMets (Lan & DeMets, 1983), with **Parameter** OF (O'Brien-Fleming). The default **Spacing of Looks** is **Equal**, therefore the interim analyses will be equally spaced by the number of patients accrued between looks.

Return to the the **Design Parameters** dialog box. The binomial parameters $\pi_0 = 0.15$

34 Binomial Superiority One-Sample – Exact

and $\pi_1 = 0.25$ are already specified. Click **Compute** to generate this exact design:

| Output Preview | | | | | | | | | | | | | |
|----------------|-------------|--------------|---------------|--------------------|-------------------|-------|-------------|---------|---------|------------------|-------------------|------------------|------------------|
| ID | Design Type | No. of Looks | Test Type | Specified α | Attained α | Power | Sample Size | π_0 | π_1 | Spacing of Looks | Efficacy Boundary | Expected SS (H0) | Expected SS (H1) |
| Des1 | Superiority | 1 | 1-Sided Exact | 0.05 | 0.035 | 0.81 | 110 | 0.15 | 0.25 | | | | |
| Des2 | Superiority | 3 | 1-Sided Exact | 0.05 | 0.038 | 0.814 | 110 | 0.15 | 0.25 | Equal | LD (OF) | 109.604 | 90.706 |

The maximum sample size is again 110 subjects with 110 also expected under the null hypothesis $H_0: \pi = 0.15$ and 91 expected when the true value is $\pi=0.25$. Save this design to the **Library**.

☰ Sample Size Information

| Sample Size (n) | Total |
|-----------------|---------|
| Maximum | 110 |
| Expected H1 | 90.706 |
| Expected H0 | 109.604 |

☰ Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries Efficacy # Resp. | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|--------------------------------|---|----------|
| | | | | | Under H0 | Under H1 |
| 1 | 0.336 | 37 | 7.264E-4 | 14 | 5.746E-4 | 0.058 |
| 2 | 0.664 | 73 | 0.016 | 19 | 0.01 | 0.408 |
| 3 | 1 | 110 | 0.05 | 24 | 0.028 | 0.348 |

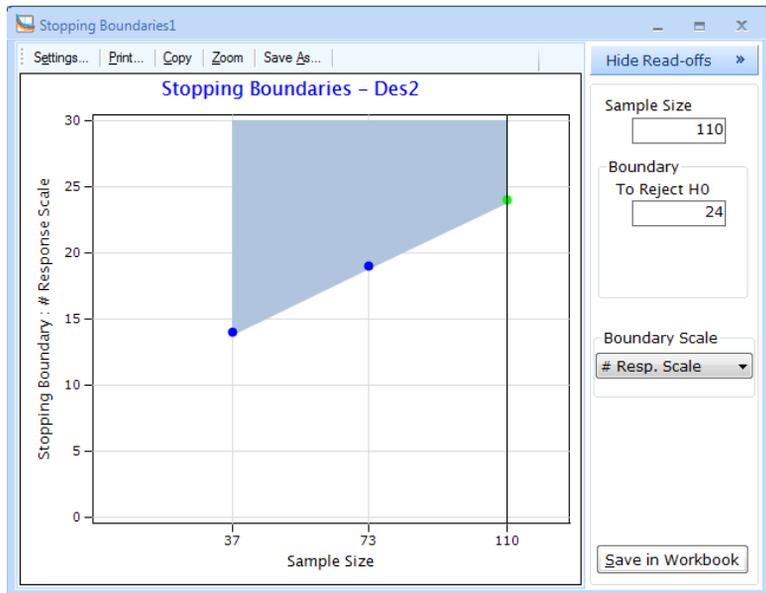

Here we can see the cumulative sample size and cumulative type 1 error (α) spent at each of the three looks. The boundaries set for the rejection of H_0 at each look are 14, 19 and 24 (on the # response scale). For example, at the second look with a cumulative 73 subjects, if the observed number of patients responding to the new treatment exceeds 19, the null hypothesis would be rejected in favor of declaring the new treatment to be superior. In addition, the incremental boundary crossing probabilities under both the null and alternative are displayed for each look.

The cumulative boundary stopping probabilities can also be seen in the **Stopping Boundaries** chart and table. Select **Des 2** in the **Library**, click the  icon and

34 Binomial Superiority One-Sample – Exact

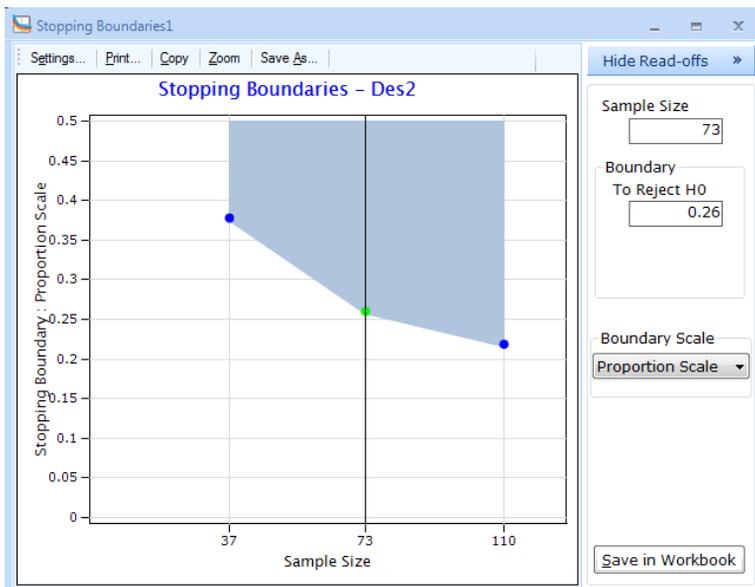

choose **Stopping Boundaries**.

chosen from the drop-down list **Boundary Scale** in the chart.

To examine the **Error Spending** function click the  icon in the **Library** and

34 Binomial Superiority One-Sample – Exact

choose **Error Spending**.

When the sample size for a study is subject to external constraints, power can be computed for a specified maximum sample size. Suppose for the previous design the total sample size is constrained to be at most 80 subjects. Create a new design by editing **Des2** in the **Library**. Change the parameters so that the trial is now designed to compute power for a maximum sample size of 80 subjects, as shown below.

Design: Discrete Endpoint, One-Sample Test - Single Arm Design - Single Proportion

Power vs Sample size-Sawtooth paradigm Generate the **Power vs. Sample Size** graph for **Des 2**. You will get the following power chart which is commonly described in the literature as a *sawtooth* chart.

This chart illustrates that it is possible to have designs with different sample sizes but all with the same power. What is not apparent is that for designs with the same power, the attained significance level may vary. Upon examination, the sample sizes of 43 and 55 seem to have the same power of about 0.525. The data can also be displayed in a

34 Binomial Superiority One-Sample – Exact

chart form by selecting the  icon in the **Library**, and can be printed from here as well. Compute the power for two new designs based on **Des 2** with sample sizes of 43 and 55 respectively.

| | Des4 | Des5 |
|---------------------------------------|---------------|---------------|
| Mnemonic | PN-1S-SP | PN-1S-SP |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 3 | 3 |
| Test Type | 1-Sided Exact | 1-Sided Exact |
| Specified α | 0.05 | 0.05 |
| Attained α | 0.049 | 0.031 |
| Power | 0.525 | 0.524 |
| Model Parameters | | |
| Prop. Response under Null (π_0) | 0.15 | 0.15 |
| Prop. Response under Alt. (π_1) | 0.25 | 0.25 |
| Boundary Parameters | | |
| Spacing of Looks | Equal | Equal |
| Efficacy Boundary | LD (OF) | LD (OF) |
| Sample Size | | |
| Maximum | 43 | 55 |
| Expected Under H0 | 42.89 | 54.877 |
| Expected Under H1 | 40.508 | 51.11 |

Although sample sizes of 43 and 55 attain nearly same power, the attained significance levels are different, at 0.049 and 0.031 respectively. Though both are less than the design specification of 0.05, the plan with lower sample size of 43 pays a higher penalty in terms of type-1 error than the plan with a larger sample size of 55.

34.1.2 Interim Monitoring

Consider the interim monitoring of **Des 2**, which has 80% power. Select this design

from the **Library** and click the **IM** icon.

The screenshot shows the 'Interim Monitoring: Des2' window. At the top, there is a toolbar with an 'Enter Interim Data' button. Below the toolbar is a table for data entry:

| Look # | Information Fraction | Cumulative Sample Size | Cumulative Response | Efficacy | CP |
|--------|----------------------|------------------------|---------------------|----------|----|
| 1 | | | | | |
| 2 | | | | | |
| 3 | | | | | |

Below the table, the hypothesis is defined as $H1: \pi_1 = 0.1$. A red instruction reads: 'Select the Look # 1 row for which data entry is desired and click the "Enter Interim Data" button on the toolbar.'

The interface is divided into four main monitoring panels:

- Stopping:** Contains a plot of cumulative response vs. sample size and a table with columns 'Sample Size' and 'Efficacy'.
- Conditional:** Contains a plot of cumulative response vs. sample size and a table with columns 'Prop.' and 'CP'.
- Error Spending:** Contains a plot of error spending vs. information fraction and a table with columns 'Info. Fraction' and ' α '.

Suppose at the first interim look, when 40 subjects have enrolled, the observed cumulative response is 12. Click the **Enter Interim Data** button at the top left of the **IM Interim Monitoring** window. Enter 40 for the **Cumulative Sample Size** and 12

34 Binomial Superiority One-Sample – Exact

for the **Cumulative Response** in the **Test Statistic Calculator** window.

Test Statistic Calculator

Editing Look #1

| Lower Confidence Bound | 0.172 |

34.2 McNemar's Conditional Exact Test

McNemar's conditional test is used in experimental situations where paired comparisons are observed. In a typical application, two binary response measurements are made on each subject – perhaps from two different treatments, or from two different time points. For example, in a comparative clinical trial, subjects are matched on baseline demographics and disease characteristics and then randomized with one subject in the pair receiving the experimental treatment and the other subject receiving the control. Another example is the crossover clinical trial in which each subject receives both treatments. By random assignment, some subjects receive the experimental treatment followed by the control while others receive the control followed by the experimental treatment. Let π_c and π_t denote the response probabilities for the control and experimental treatments, respectively. The probability parameters for this test are displayed in Table 34.1.

34 Binomial Superiority One-Sample – Exact

Table 34.1: A 2 x 2 Table of Probabilities for McNemar’s Conditional Exact Test

| Control | Experimental | | Total Probability |
|-------------------|--------------|------------|-------------------|
| | No Response | Response | |
| No Response | π_{00} | π_{01} | $1 - \pi_c$ |
| Response | π_{10} | π_{11} | π_c |
| Total Probability | $1 - \pi_t$ | π_t | 1 |

The null hypothesis

$$H_0: \pi_c = \pi_t$$

is tested against the alternative hypothesis

$$H_1: \pi_c > \pi_t$$

(or $H_1: \pi_c < \pi_t$) for the one-sided testing problem. Since $\pi_t = \pi_c$ if and only if $\pi_{01} = \pi_{10}$, the null hypothesis is also expressed as

$$H_0: \pi_{01} = \pi_{10} ,$$

is tested against corresponding one-sided alternative. The power of this test depends on two quantities:

1. The difference between the two discordant probabilities (which is also the difference between the response rates of the two treatments)

$$\delta = \pi_{01} - \pi_{10} = \pi_t - \pi_c ;$$

2. The sum of the two discordant probabilities

$$\xi = \pi_{10} + \pi_{01} .$$

East accepts these two parameters as inputs at the design stage.

34.2.1 Trial Design

Consider a trial in which we wish to determine whether a transdermal delivery system (TDS) can be improved with a new adhesive. Subjects are to wear the old TDS (control) and new TDS (experimental) in the same area of the body for one week each. A response is said to occur if the TDS remains on for the entire one-week observation

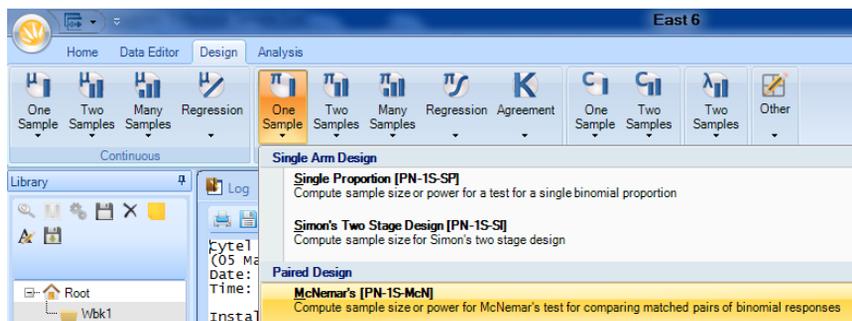

period. From historical data, it is known that control has a response rate of 85% ($\pi_c = 0.85$). It is hoped that the new adhesive will increase this to 95% ($\pi_t = 0.95$). Furthermore, of the 15% of the subjects who did not respond on the control, it is hoped that 87% will respond on the experimental system. That is, $\pi_{01} = 0.87 \times 0.15 = 0.13$. Based on these data, we can fill in all the entries of Table 34.1 as displayed in Table 34.2.

Table 34.2: McNemar Probabilities for the TDS Trial

| Control | Experimental | | Total Probability |
|-------------------|--------------|----------|-------------------|
| | No Response | Response | |
| No Response | 0.02 | 0.13 | 0.15 |
| Response | 0.03 | 0.82 | 0.85 |
| Total Probability | 0.05 | 0.95 | 1 |

As it is expected that the new adhesive will increase the adherence rate, the comparison is posed as a one-sided testing problem, testing $H_0: \pi_c = \pi_t$ against $H_1: \pi_c < \pi_t$ at the 0.05 level. We wish to determine the sample size to have 90% power for the values displayed in Table 34.2.

To illustrate this example, in East under the Design ribbon for Discrete data, click **One Sample** and then choose **Paired Design: McNemar's**:

34 Binomial Superiority One-Sample – Exact

This will launch the following input window:

Sample Size Information

Sample Size (n) 139

Critical Points

Critical Point 1.645

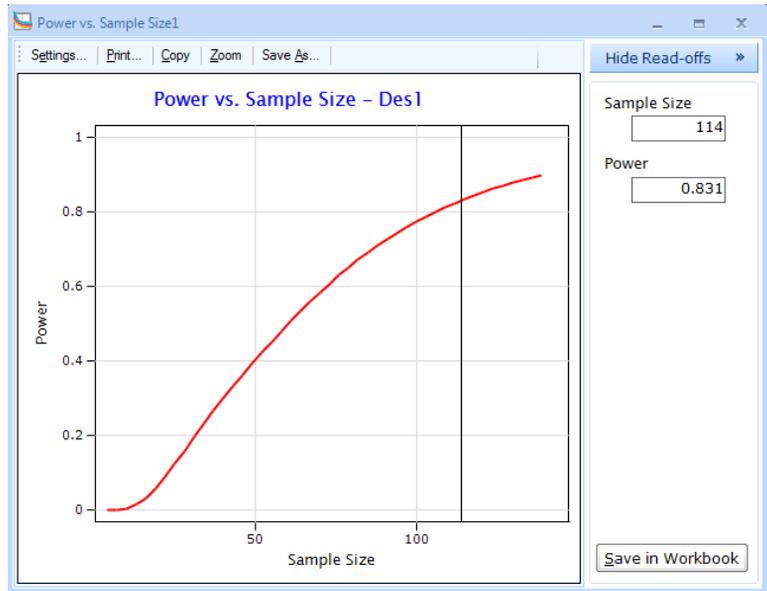

Sample sizes have been rounded.

Due to discreteness the displayed sample size may not be unique. Use the 'Power Vs Sample Size' chart from charts menu to find all other sample sizes that guarantee desired power.

The critical point, or the boundary set for the rejection of H_0 is 1.645

It is important to note that in this exact computation the displayed sample size may not be unique due to the discreteness of the distribution. This can be seen in the **Power Vs Sample Size** graph, which is a useful tool along with its corresponding table, and can be used to find all other sample sizes that guarantee the desired power. These visual

tools are available in the **Library** under the **Plots** and **Tables** menus.

35 *Binomial Superiority Two-Sample – Exact*

In many experiments based on binomial data, the aim is to compare independent samples from two populations in terms of the proportion of sampling units presenting a given trait. In medical research, outcomes such as the proportion of patients responding to a therapy, developing a certain side effect, or requiring specialized care, would satisfy this definition. Exact tests support the design and monitoring of clinical trials in which this comparison is based on either the difference of proportions or ratio of proportions of the two populations. These two cases are discussed in Sections 35.1, and 35.2 respectively.

Caution: The methods presented in this chapter are computationally intensive and could consume several hours of computer time if the exact sample sizes are very large. Here are some guidelines:

1. Estimate the likely sample size under the Exact method by first determining the asymptotic sample size
2. If the exact sample size is likely to be larger than 1000, computing power is preferable to computing the sample size

35.1 *Difference of Two Binomial Proportions*

35.1.1 *Trial Design*

Let π_c and π_t denote the binomial probabilities for the control and treatment arms, respectively, and let $\delta = \pi_t - \pi_c$. Interest lies in testing the null hypothesis that $\delta = 0$ against one and two-sided alternatives.

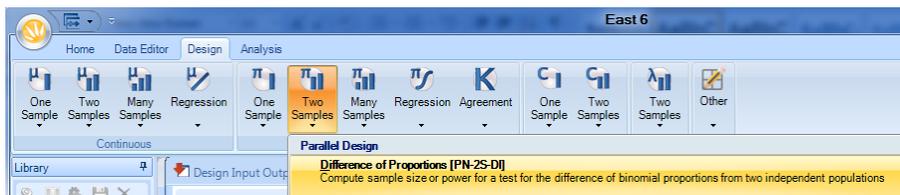

The technical details of the sample size computations for this option are given in Appendix V.

35.1.1 *Trial Design*

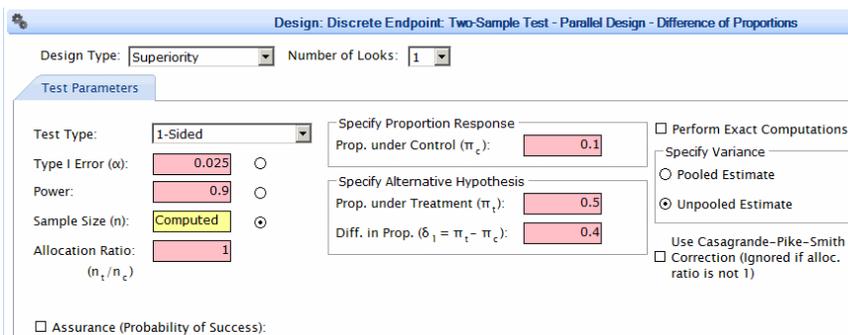

In a clinical study, an experimental drug coded Y73 is to be compared with a control drug coded X39 to treat chronic hepatitis B infected adult patients. The primary end point is histological improvement as determined by Knodell Scores at week 48 of treatment period. It is estimated that the proportion of patients who are likely to show histological improvement under treatment X39 to be 25% and under the treatment Y73, as much as 60%. A one-sided fixed sample study is to be designed with $\alpha = 0.05$ and 90% power.

Single Look Design To illustrate this example, in **East** under the **Design** ribbon for **Discrete** data, click **Two Samples** and then choose **Parallel Design: Difference of**

Proportions:

This will launch the following input window:

The goal of this study is to test the null hypothesis, H_0 , that the X39 and Y73 arms both have an event rate of 25%, versus the alternative hypothesis, H_1 , that Y73 increases the event rate by 35%, from 25% to 60%. This will be a one-sided test with a single fixed look at the data, a type-1 error of $\alpha = 0.05$ and a power of $(1 - \beta) = 0.9$.

Leave the default values of **Design Type: Superiority** and **Number of Looks: 1**. In the **Design Parameters** dialog box, select the **Perform Exact Computations** checkbox and enter the following parameters:

- Test Type: 1 sided (required)
- Type 1 Error (α): 0.05
- Power: 0.9
- Sample Size (n): Computed (select radio button)
- Prop. under Control (π_c): 0.25
- Prop. under Treatment (π_t): 0.6
- Diff. in Prop. ($\delta_1 = \pi_t - \pi_c$): (will be calculated)

35 Binomial Superiority Two-Sample – Exact

Click **Compute**. The sample size for this design is calculated and the results are shown as a row in the **Output Preview** window:

| Output Preview | | | | | | | | | | | | |
|----------------|-------------|--------------|---------------|--------------------|-------------------|-------|-------|-------------|---------|------------------------|------------|--|
| ID | Design Type | No. of Looks | Test Type | Specified α | Attained α | Power | nt/nc | Sample Size | π_c | Prop. Treatment (Alt.) | δ_1 | |
| Des 1 | Superiority | 1 | 1-Sided Exact | 0.05 | 0.049 | 0.905 | 1 | 68 | 0.25 | 0.6 | 0.35 | |

The sample size required in order to achieve 90% power is 68 subjects. Note that because of the discreteness involved in performing exact computations, the attained type-1 error is 0.049, slightly less than the specified value of 0.05. Similarly, the attained power is 0.905, slightly larger than the specified value of 0.90.

As is standard in **East**, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the **Output Preview** toolbar. The design details will be displayed in the upper pane, labeled **Output Summary**. This can be saved to the **Library** by selecting **Des 1** and

clicking the  icon.

35 Binomial Superiority Two-Sample – Exact

The critical point, or the boundary set for the rejection of H_0 is 1.715 attained at $\pi_U = 0.371$ (on the Z scale) and 0.176 (on the δ scale). If the observed test statistic exceeds this boundary the null will be rejected in favor of declaring the new treatment to be superior. This can also be seen in the **Stopping Boundaries** chart and table, available in the **Library**.

Stopping Boundaries

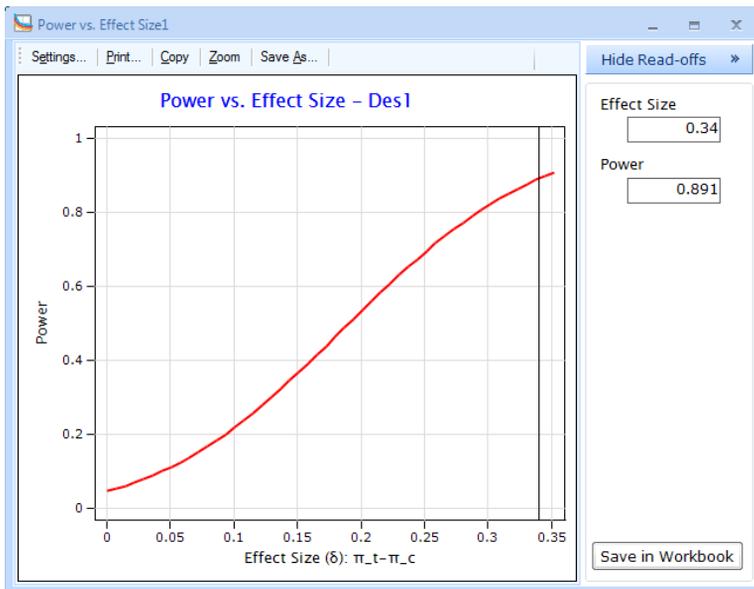

Boundary Scales : δ Scale

Des1

| Look # | Info. Fraction | Sample Size | Cum. α Spent | Boundaries | |
|--------|----------------|-------------|---------------------|------------|----------|
| | | | | Efficacy | Boundary |
| 1 | 1 | 68 | 0.05 | 0.176 | |

The **Power vs. Treatment Effect** chart dynamically generates power under this design for all values of treatment effect $\delta = \pi_t - \pi_c$. Here it is easy to see how as treatment effect size increases (H_1 : alternative treatment is superior) the power of the study

reaches the desired 90%. This is available in tabular form as well.

35.2 Ratio of Two Binomial Proportions

Let π_c and π_t denote the binomial probabilities for the control and treatment arms, respectively, and let $\rho = \pi_t/\pi_c$. It is of interest to test the null hypothesis that $\rho = 1$ against a one-sided alternative.

The technical details of the sample size computations for this option are given in Appendix V.

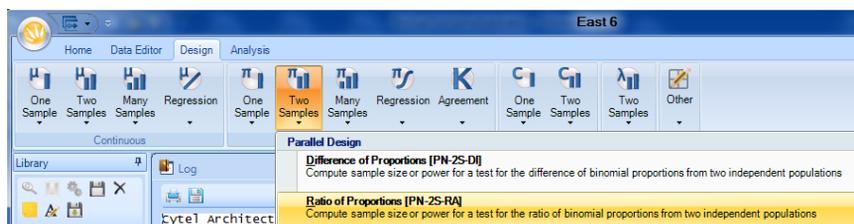

35.2.1 Trial Design

In a clinical study, an experimental drug coded Y73 is to be compared with a control drug coded X39 to treat chronic hepatitis B infected adult patients. The primary end point is histological improvement as determined by Knodell Scores at week 48 of treatment period. It is estimated that the proportion of patients who are likely to show histological improvement under treatment coded X39 to be 25% and under the treatment coded Y73 as much as 60%, that is 2.4 times the rate for X39. A single look, one-sided fixed sample study is to be designed with $\alpha = 0.05$ and 90% power.

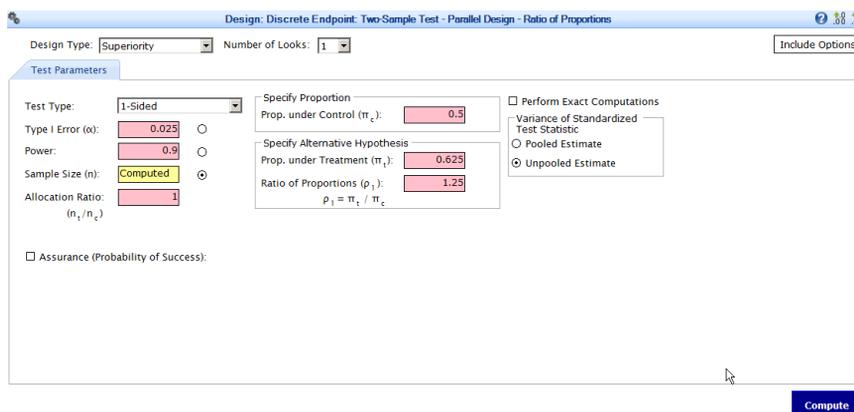

Single Look Design

35 Binomial Superiority Two-Sample – Exact

To illustrate this example, in **East** under the **Design** ribbon for **Discrete** data, click **Two Samples** and then choose **Parallel Design: Ratio of Proportions**:

This will launch the following input window:

Leave the default values of **Design Type: Superiority** and **Number of Looks: 1**. In the **Design Parameters** dialog box, select the **Perform Exact Computations** checkbox and enter the following parameters:

- Test Type: 1 sided (required)
- Type 1 Error (α): 0.05
- Power: 0.9
- Sample Size (n): Computed (select radio button)
- Prop. under Control (π_c): 0.25
- Prop. under Treatment (π_t): (will be calculated to be 0.6)
- Ratio of Proportions (ρ_1): 2.4

Click **Compute**. The sample size for this design is calculated and the results are shown as a row in the **Output Preview** window:

| Output Preview | | | | | | | | | | | | |
|----------------|-------------|--------------|---------------|--------------------|-------------------|-------|-------------|---------|---------|------------------------|----------|--|
| ID | Design Type | No. of Looks | Test Type | Specified α | Attained α | Power | Sample Size | nt / nc | π_c | Prop. Treatment (Alt.) | ρ_1 | |
| Des8 | Superiority | 1 | 1-Sided Exact | 0.05 | 0.046 | 0.903 | 72 | 1 | 0.25 | 0.6 | 2.4 | |

The sample size required in order to achieve 90% power is 72 subjects. Note that because of the discreteness involved in performing exact computations, the attained type-1 error is 0.046, less than the specified value of 0.05. Similarly, the attained power is 0.903, slightly larger than the specified value of 0.90.

As is standard in **East**, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the **Output Preview** toolbar. The design details will be displayed in the upper pane, labeled **Output Summary**. This can be saved to the **Library** by selecting **Des 1** and

35 Binomial Superiority Two-Sample – Exact

clicking the  icon.

The critical point, or the boundary set for the rejection of H_0 is 1.813 (on the Z scale). If the observed test statistic exceeds this boundary the null will be rejected in favor of declaring the new treatment to be superior. This boundary can be seen in terms of the observed ratio (0.916 on the $\ln(\rho)$ scale and 2.5 on the ρ scale) in the **Stopping**

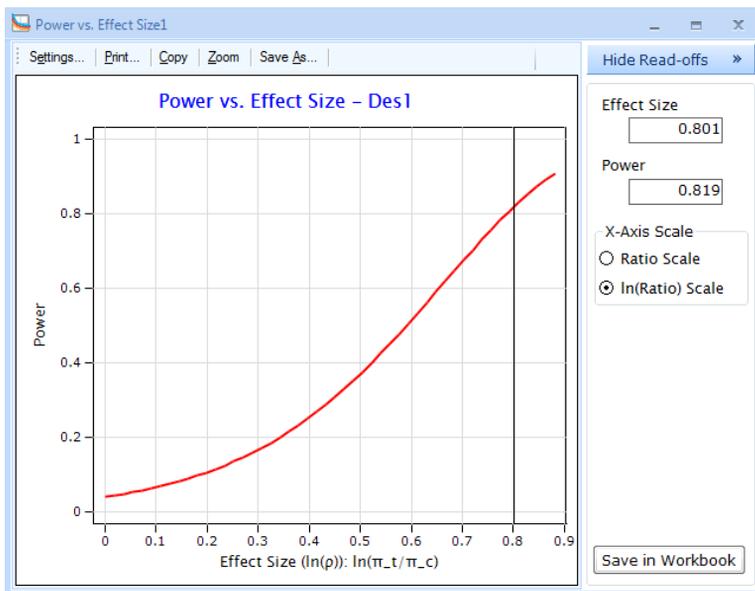

Boundaries chart and table, available in the **Library**.

The **Power vs. Treatment Effect** chart dynamically generates power under this design for all values of treatment effect (ratio or ln(ratio) scale). Here it is easy to see how as the ratio (treatment effect size) increases (H_1 : the new treatment is superior) the power

35 Binomial Superiority Two-Sample – Exact

of the study reaches the desired 0.9%. This is available in tabular form as well.

36 Binomial Non-Inferiority Two-Sample – Exact

In a non-inferiority trial, the goal is to establish that the response rate of an experimental treatment is **no worse than** that of an established control. A therapy that is demonstrated to be non-inferior to the current standard therapy might be an acceptable alternative if, for instance, it is easier to administer, cheaper, or less toxic. Non-inferiority trials are designed by specifying a non-inferiority margin, which is the acceptable amount by which the response rate on the experimental arm can be less than the response rate on the control arm. If the experimental response rate falls within this margin, the new treatment can claim to be non-inferior. This chapter presents the design of non-inferiority trials in which this margin is expressed as either the difference between or the ratio of two binomial proportions. The difference is examined in Section 36.1 and is followed by two formulations for the ratio in Section 36.2.

Caution: The methods presented in this chapter are computationally intensive and could consume several hours of computer time if the exact sample sizes are very large. Here are some guidelines:

1. Estimate the likely sample size under the Exact method by first determining the asymptotic sample size
2. If the exact sample size is likely to be larger than 1000, computing power is preferable to computing the sample size

36.1 Difference of Proportions

36.1.1 Trial Design

Let π_c and π_t denote the response rates for the control and experimental treatments, respectively. Let $\delta = \pi_t - \pi_c$. The null hypothesis is specified as

$$H_0: \delta = \delta_0$$

and is tested against one-sided alternative hypotheses. If the occurrence of a response denotes patient harm rather than benefit, then $\delta_0 > 0$ and the alternative hypothesis is

$$H_1: \delta < \delta_0$$

or equivalently as

$$H_1: \pi_c > \pi_t - \delta_0 .$$

Conversely, if the occurrence of a response denotes patient benefit rather than harm, then $\delta_0 < 0$ and the alternative hypothesis is

$$H_1: \delta > \delta_0$$

or equivalently as

$$H_1: \pi_c < \pi_t - \delta_0 .$$

36 Binomial Non-Inferiority Two-Sample – Exact

For any given π_c , the sample size is determined by the desired power at a specified value of $\delta = \delta_1$. A common choice is $\delta_1 = 0$ (or equivalently $\pi_t = \pi_c$) but East allows the study to be powered at any value of δ_1 which is consistent with the choice of H_1 .

Let $\hat{\pi}_t$ and $\hat{\pi}_c$ denote the estimates of π_t and π_c based on n_t and n_c observations from the experimental and control treatments, respectively. The test statistic is

$$Z = \frac{\hat{\delta} - \delta_0}{\text{se}(\hat{\delta})} \tag{36.1}$$

where

$$\hat{\delta} = \hat{\pi}_t - \hat{\pi}_c \tag{36.2}$$

and

$$\text{se}(\hat{\delta}) = \sqrt{\frac{\tilde{\pi}_t(1 - \tilde{\pi}_t)}{n_t} + \frac{\tilde{\pi}_c(1 - \tilde{\pi}_c)}{n_c}}. \tag{36.3}$$

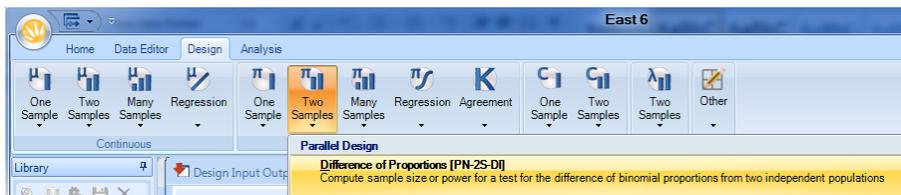

Here $\tilde{\pi}_t$ and $\tilde{\pi}_c$ are the restricted maximum likelihood estimates of π_t and π_c . For more details refer to Appendix V.

36.1.1 Trial Design

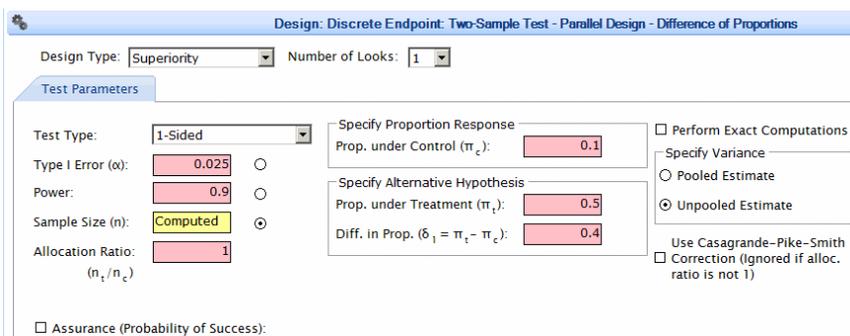

To evaluate the efficacy and safety of drug A vs. drug B in antiretroviral naive HIV-infected individuals, a phase3, 52 week double-blind randomized study is conducted. The primary response measure is the proportion of patients with HIV-RNA levels \leq 50 copies/mL. The study is a non-inferiority designed trial where a standard drug A is expected to have a response rate of 80% and a new experimental drug B is to be compared under a non-inferiority margin of 20% ($\delta_0 = 0.20$). For these studies, inferiority is assumed as the null hypothesis and is to be tested against the alternative of non-inferiority using a one-sided test. Therefore under the null hypothesis H_0 : $\pi_c = 0.8$ and $\pi_t = 0.60$. We will test this hypothesis against H_1 , that both response rates are equal to the null response rate of the control arm, i.e. $\delta_1 = 0$. Thus, under H_1 , we have $\pi_c = \pi_t = 0.8$. East will be used to conduct a one-sided $\alpha = 0.025$ level test with 90% power.

Single Look Design To illustrate this example, in **East** under the **Design** ribbon for **Discrete** data, click **Two Samples** and then choose **Parallel Design: Difference of**

Proportions:

This will launch the following input window:

Change **Design Type: Noninferiority** and keep **Number of Looks: 1**. In the **Design Parameters** dialog box, select the **Perform Exact Computations** checkbox and enter the following parameters:

The **Power vs. Treatment Effect** chart dynamically generates power under this design for all values of treatment effect $\delta = \pi_t - \pi_c$. Here it is easy to see how as treatment effect size approaches zero (H_1 : no difference between the two treatments) the power

36 Binomial Non-Inferiority Two-Sample – Exact

of the study reaches the desired 90%. This is available in tabular form as well.

36.2 Ratio of Proportions

Let π_c and π_t denote the response rates for the control and the experimental treatments, respectively. Let the difference between the two arms be captured by the ratio

$$\rho = \frac{\pi_t}{\pi_c}.$$

The null hypothesis is specified as

$$H_0: \rho = \rho_0$$

and is tested against one-sided alternative hypotheses. If the occurrence of a response denotes patient benefit rather than harm, then $\rho_0 < 1$ and the alternative hypothesis is

$$H_1: \rho > \rho_0$$

or equivalently as

$$H_1: \pi_t > \rho_0 \pi_c.$$

Conversely, if the occurrence of a response denotes patient harm rather than benefit, then $\rho_0 > 1$ and the alternative hypothesis is

$$H_1: \rho < \rho_0$$

or equivalently as

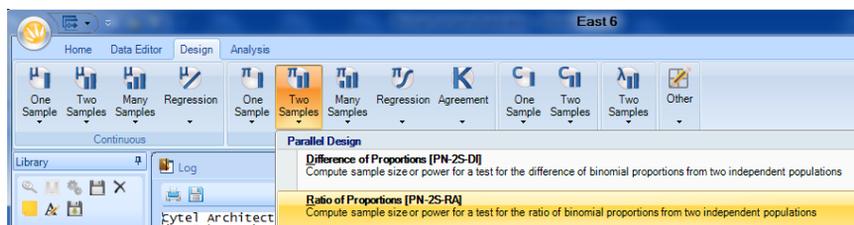

$$H_1: \pi_t < \rho_0 \pi_c .$$

For any given π_c , the sample size is determined by the desired power at a specified value of $\rho = \rho_1$. A common choice is $\rho_1 = 1$ (or equivalently $\pi_t = \pi_c$), but East permits you to power the study at any value of ρ_1 which is consistent with the choice of H_1 .

36.2.1 Trial Design

Suppose with a rare disease condition, the cure rate with an expensive treatment A is estimated to be 90%. The claim of non-inferiority for an inexpensive new treatment B can be held if it can be statistically proven that the ratio $\rho = \pi_t / \pi_c$ is at least 0.833. In other words, B is considered to be non-inferior to A as long as $\pi_t > 0.75$. Thus the null hypothesis $H_0: \rho = 0.833$ is tested against the one-sided alternative hypothesis $H_1: \rho > 0.833$. We want to determine the sample size required to have power of 80% when $\rho = 1$ using a one-sided test with a type-1 error rate of 0.05.

Single Look Design Powered at $\rho = 1$ Consider a one look study with equal sample sizes in the two groups. In **East** under the **Design** ribbon for **Discrete** data, click **Two Samples** and then choose **Parallel Design: Ratio of Proportions**:

The **Power vs. Treatment Effect** chart dynamically generates power under this design for all values of treatment effect (ratio or ln(ratio) scale). Here it is easy to see how as treatment effect size approaches zero (H_1 : no difference between the two

36 Binomial Non-Inferiority Two-Sample – Exact

treatments) the power of the study reaches the desired 0.8%. This is available in tabular form as well.

37 Binomial Equivalence Two-Sample – Exact

37.1 Equivalence Test

In some experimental situations, it is desired to show that the response rates for the control and the experimental treatments are "close", where "close" is defined prior to the collection of any data. It may be of interest to show that the rate of an adverse event associated with an aggressive therapy is similar to that of the established control. For example, the bleeding rate associated with thrombolytic therapy or cardiac outcomes with a new stent. Let π_c and π_t denote the response rates for the control and the experimental treatments, respectively and let

$$\delta = \pi_t - \pi_c. \quad (37.1)$$

The null hypothesis $H_0: |\pi_t - \pi_c| = \delta_0$ is tested against the two-sided alternative $H_1: |\pi_t - \pi_c| < \delta_0$, where $\delta_0 (> 0)$ defines equivalence. The theory is presented in Section V.4 of Appendix V.

Caution: The methods presented in this chapter are computationally intensive and could consume several hours of computer time if the exact sample sizes are very large.

Here are some guidelines:

1. Estimate the likely sample size under the Exact method by first determining the asymptotic sample size
2. If the exact sample size is likely to be larger than 1000, computing power is preferable to computing the sample size

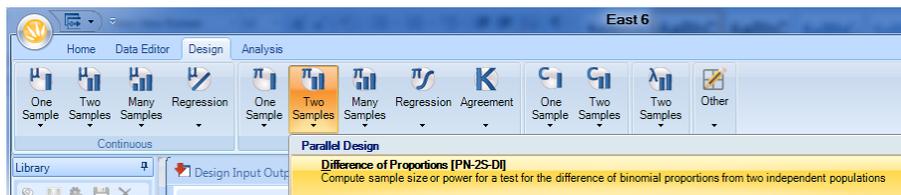

37.1.1 Trial Design

Burgess et al. (2005) describe a randomized controlled equivalence trial, in which the objective is to evaluate the efficacy and safety of a 4% dimeticone lotion for treatment of head lice infestation, relative to a standard treatment. The success rate of the standard treatment is estimated to be about 77.5%. Equivalence is defined as $\delta_0 = 0.20$. The sample size is to be determined with $\alpha = 0.025$ (two-sided) and power, i.e. probability of declaring equivalence, of $1 - \beta = 0.90$.

To illustrate this example, in **East** under the **Design** ribbon for **Discrete** data, click

37 Binomial Equivalence Two-Sample – Exact

Two Samples and then choose **Parallel Design: Difference of Proportions**:

This will launch the following input window:

38 *Binomial Simon's Two-Stage Design*

The purpose of a phase II trial is to determine if a new drug has sufficient efficacy against a specific disease or condition to either warrant further development within Phase II, or to advance onto a Phase III study. In a two-staged design, a fixed number of patients are recruited and treated initially, and if the protocol is considered effective the second stage will continue to enroll additional patients for further study regarding efficacy and safety.

This chapter presents an example for the widely used two-stage optimal and minimax designs developed by Simon (1989). In addition, East supports the framework of an admissible two-stage design, a graphical method geared to search for an alternative with more favorable features (Jung, et al. 2004). The underlying theory is examined in Appendix U.

38.1 *An Example*

During a Phase II study of an experimental drug, a company determined that a response rate of 10% or less is to be considered poor, whereas a response rate is 40% or more is to be considered promising or good. Requirements call for a two-stage study with the following hypotheses:

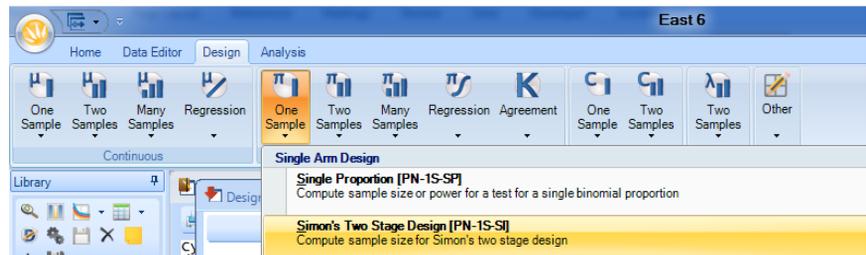

$$H_0 : \pi \leq 0.10$$

$$H_1 : \pi \geq 0.40$$

and design parameters $\alpha = 0.05$ and $1 - \beta = 0.90$.

38.1.1 *Trial Design*

To illustrate this example, in **East** under the **Design** ribbon for **Discrete** data, click **One Sample** and then choose **Single Arm Design: Simon's Two Stage Design**:

This will launch the following input window:

Design: Discrete Endpoint - One-Sample Test - Single Arm Design - Simon's Two Stage Design

Design Type: Minimax

Test Parameters

Test Type: 1-Sided

Type I Error (α): 0.025

Power: 0.9

| Look2 Futility | 4 |
| Sample Size | |
| Maximum | 20 |
| Expected Under H0 | 11.477 |

Under the optimal design, the combined maximum sample size for both stages is computed to be 20. The boundary parameter for futility at the first look is 1, and at the second look it is 4. What this means can be further explained using the **Stopping**

Boundaries chart available under the **Plots**  menu.

The scale of the stopping boundaries can be displayed using either number of responses (**# Resp. Scale**) or **Proportion Scale**. The above graph uses the number of responses, which tells us that at the first look, when the cumulative sample size is 9, the trial could be stopped for futility if no more than one patient shows a favorable response to treatment. At the second stage, when all 20 patients are enrolled, the boundary response to reject H_1 is 4 or less. The **Stopping Boundaries** table under the **Tables**  menu also tells us that the probability of crossing the stopping

38 Binomial Simon's Two-Stage Design

boundary, thus warranting early termination, is 0.775.

Stopping Boundaries
0.00 0.00

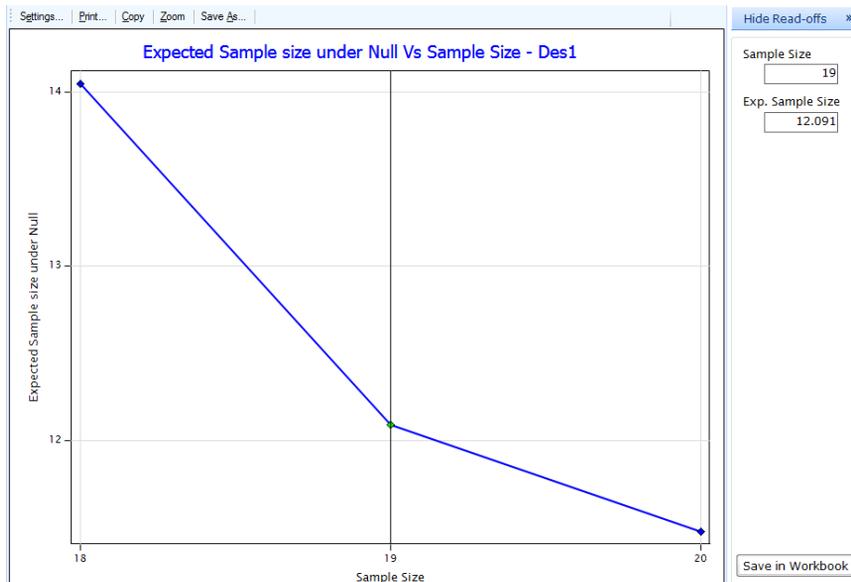

Boundary Scales : # Resp. Scale Settings...

☰ Weights

| Design # | Total Sample Size (n) | Interval for w | |
|----------|-----------------------|----------------|-------|
| | | Lower | Upper |
| Minimax | 18 | 0.662 | 1 |
| 2 | 19 | 0.381 | 0.662 |
| Optimal | 20 | 0 | 0.381 |

Note: Interval for w is the set of values w such that the design minimizes $w * n + (1 - w) * EN0$

For the optimal design the expected sample size under the null, which assumes the drug performs poorly, is 11.447, which can also be seen in the **Admissible Designs** table, available under the **Tables**  menu:

| Admissible Designs | | | | | |
|---------------------------------|-------------------|-------------------|-------------------|-------|-------------------------------|
| Boundary Scales : # Resp. Scale | | | | | |
| Des1 | | | | | |
| Design # | Total Sample Size | Look1 Sample Size | Futility Boundary | | Expected Sample Size H0 (EN0) |
| | | | Look1 | Look2 | |
| Minimax | 18 | 12 | 1 | 4 | 14.046 |
| 2 | 19 | 6 | 0 | 4 | 12.091 |
| Optimal | 20 | 9 | 1 | 4 | 11.477 |

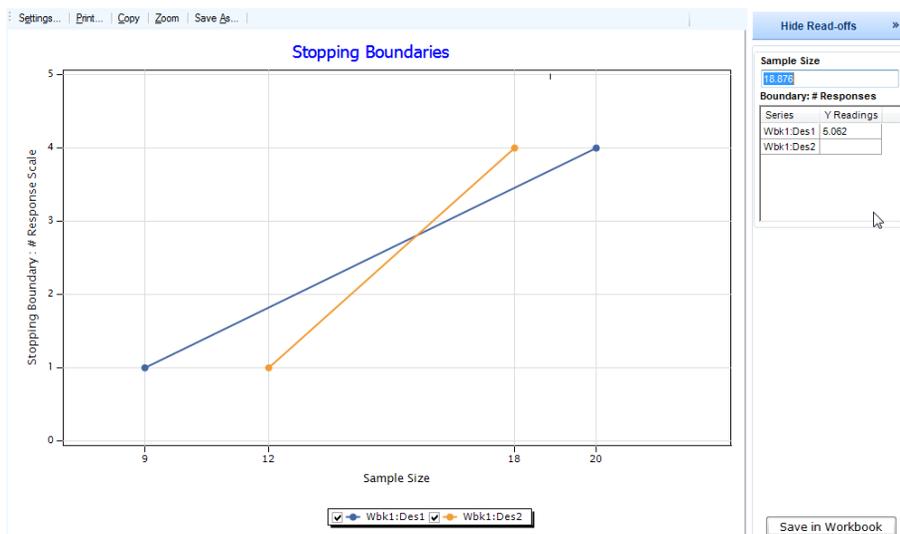

To regenerate the study using a minimax design, select the **Edit Design**  icon. Select **Design Type: Minimax**, leave all design parameters the same and click **Compute**. The cumulative maximum sample size for both stages using this design is 18. As with the optimal design, the first stage boundary response to reject H_1 is 1 or

less and the second stage boundary response to reject H_1 is 4 or less.

| Output Preview | | | | | | | | | | | | | |
|----------------|-------------|--------------|---------------|--------------------|-------------------|-------|-------------|---------|---------|------------------|----------------|----------------|----------------|
| ID | Design Type | No. of Looks | Test Type | Specified α | Attained α | Power | Sample Size | π_0 | π_1 | Expected SS (H0) | SS Upper Limit | Look1 Futility | Look2 Futility |
| Des1 | Optimal | 2 | 1-Sided Exact | 0.05 | 0.035 | 0.902 | 20 | 0.1 | 0.4 | 11.477 | 100 | 1 | 4 |
| Des2 | Minimax | 2 | 1-Sided Exact | 0.05 | 0.028 | 0.903 | 18 | 0.1 | 0.4 | 14.046 | 100 | 1 | 4 |

Save this design to the **Library** by selecting **Des 2** and clicking the  icon. Design details, graphs and tables can be attained as with the optimal design described above.

East provides the capability to visually compare stopping boundaries for both methods simultaneously using a compare plots graph. From the **Library** select both designs, click the  icon, and select **Stopping Boundaries**.

38 Binomial Simon's Two-Stage Design

These stopping boundaries can be compared in tabular format as well:

Boundary Scales : # Resp. Scale ▾

Wbk1:Des1

| Look # | Sample Size | Boundaries | Incremental Boundary Crossing Probabilities |
|--------|-------------|-------------------|---|
| | | Futility Boundary | Futility |
| | | 1 | 9 |
| 2 | 20 | 4 | NA |

Wbk1:Des2

| Look # | Sample Size | Boundaries | Incremental Boundary Crossing Probabilities |
|--------|-------------|-------------------|---|
| | | Futility Boundary | Futility |
| | | 1 | 12 |
| 2 | 18 | 4 | NA |

Although the two futility boundaries are the same for both designs, the cumulative sample size at both stages differ. We also see that the probability of early stopping for futility is higher under the optimal design (0.775) than with the minimax design (0.659). However the cumulative sample size at stage one for the optimal design is only 9 whereas the minimax design requires 12 subjects for the first stage. Referring to the design details generated for the optimal design above, we see that an admissible design (labeled **Design # 2**) requires a total sample size of 19. Here, the cumulative number of subjects required at the end of stage one is only 6 and offers a probability of early stopping of 0.531, less than both the optimal and minimax designs. It is also worthy to note that for the admissible design, the boundary parameter for futility at the first look is 0. This means that only one patient has to show a promising result for the study to proceed to a second stage, whereas at least two successes are required for both

the optimal and minimax designs to warrant a second stage.

Volume 5 Poisson and Negative Binomial Endpoints

39 Introduction to Volume 4 **785**

40 Count Data One-Sample **790**

41 Count Data Two-Samples **799**

39 *Introduction to Volume 4*

This volume describes various cases of clinical trials involving count data. This is often useful in medical research due to its nature of modeling events counted in terms of whole numbers, particularly events that may be considered rare. Typically, interest lies in the rate of occurrence of a particular event during a specific time interval or other unit of space.

Chapter 40 describes the design of tests involving count or Poisson response rates in which an observed response rate is compared to a fixed response rate, possibly derived from historical data.

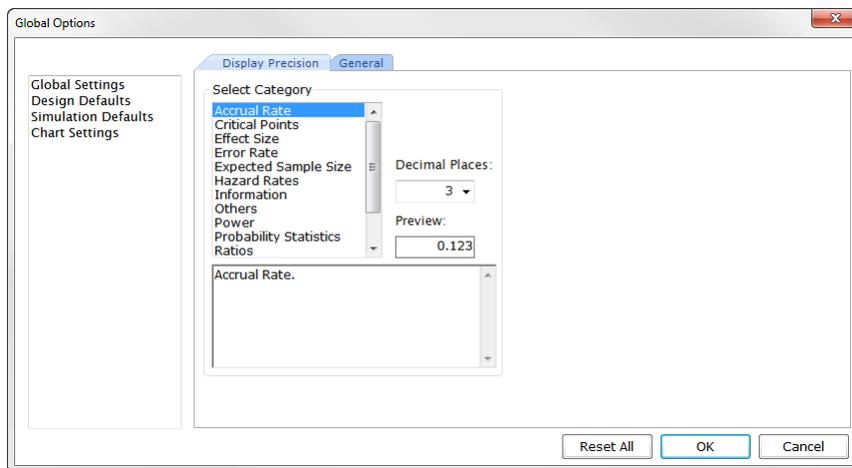

Chapter 41 deals with the comparison of independent samples from two populations in terms of the rate of occurrence of a particular outcome. It supports the design of clinical trials in which this comparison is based on the ratio of rates, assuming a Poisson or Negative Binomial distribution.

39 Introduction to Volume 4

39.1 Settings

Click the icon in the **Home** menu to adjust default values in East 6.

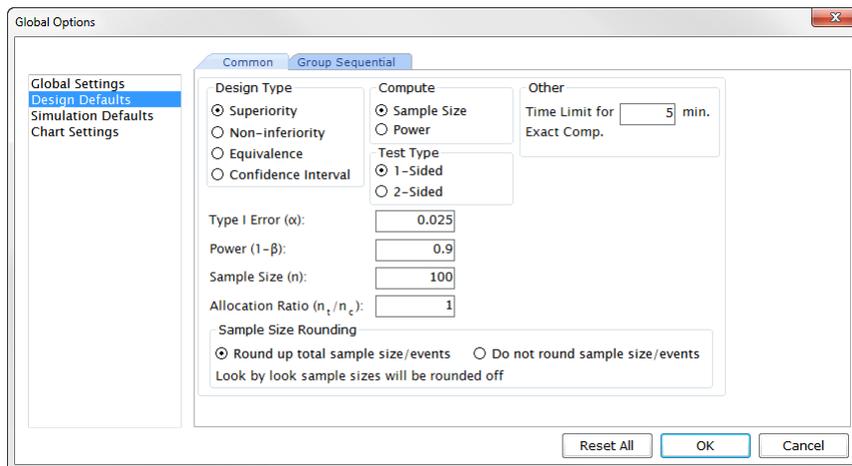

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

The **Design Defaults** is where the user can change the settings for trial design:

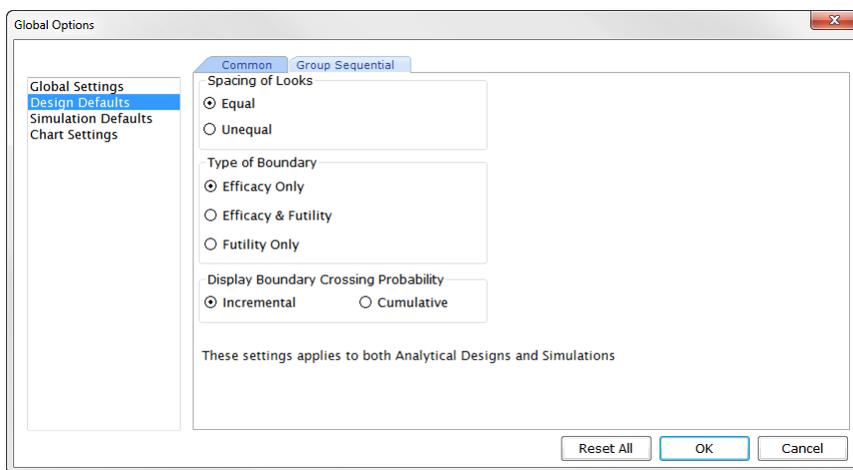

Under the **Common** tab, default values can be set for input design parameters.

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

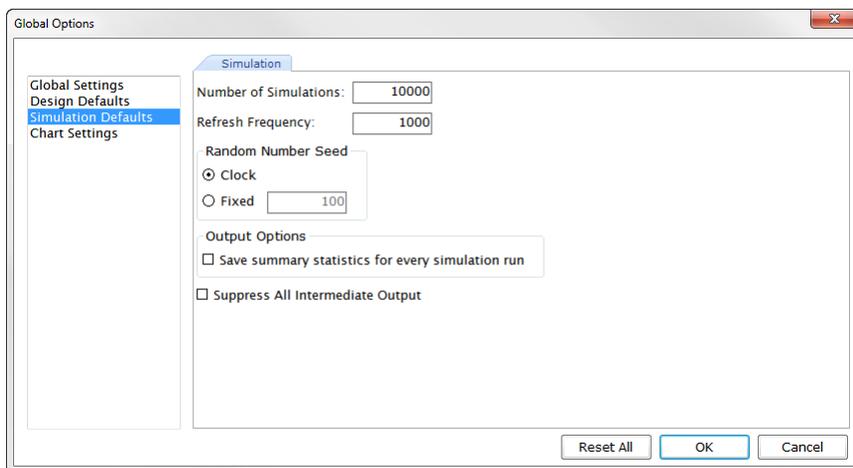

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

39 Introduction to Volume 4

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

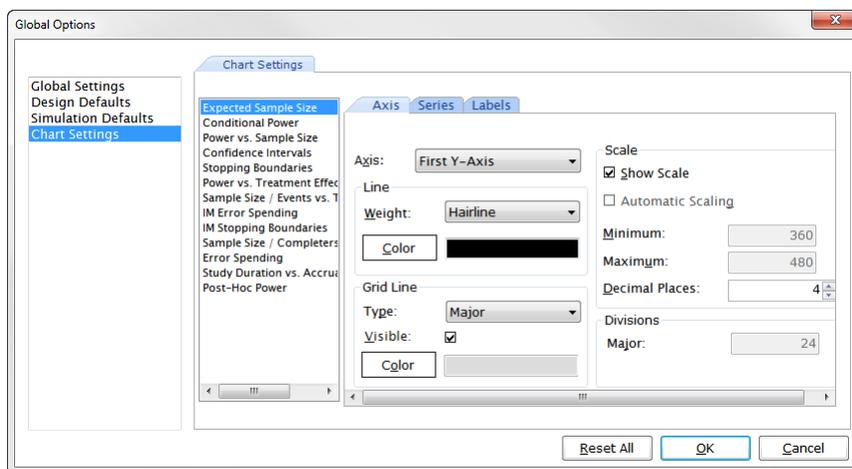

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

We suggest that you do not alter the defaults until you are quite familiar with the software.

40

Count Data One-Sample

This chapter deals with the design of tests involving count or Poisson response rates. Here, independent outcomes or events under examination can be counted in terms of whole numbers, and typically are considered rare. In other words, a basic assumption of the Poisson distribution is that the probability of an event occurring is proportional to the length of time under consideration. The longer the time interval, the more likely the event will occur. Therefore, in this context interest lies in the rate of occurrence of a particular event during a specified period. Section 40.1 focuses on designs in which an observed Poisson response rate is compared to a fixed response rate, possibly derived from historical data.

40.1 Single Poisson Rate

Data following a Poisson distribution are non-negative integers, and the probability that an outcome occurs exactly k times can be calculated as:

$$P(k) = \frac{e^{-\lambda} \lambda^k}{k!}, k = 0, 1, 2, \dots \text{ where } \lambda \text{ is the average rate of occurrence.}$$

When comparing a new protocol or treatment to a well-established control, a preliminary single-sample study may result in valuable information prior to a full-scale investigation. In experimental situations it may be of interest to determine whether the response rate λ differs from a fixed value λ_0 . Specifically we wish to test the null hypothesis $H_0: \lambda = \lambda_0$ against the two sided alternative hypothesis $H_1: \lambda \neq \lambda_0$ or against one sided alternatives of the form $H_1: \lambda > \lambda_0$ or $H_1: \lambda < \lambda_0$. The sample size, or power, is determined for a specified value of λ which is consistent with the alternative hypothesis, denoted λ_1 .

40.1.1 Trial Design

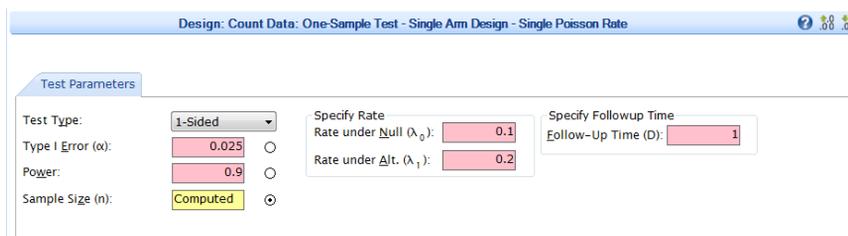

Consider the design of a single-arm clinical trial in which we wish to determine if the positive response rate of a new acute pain therapy is at least 30% per single treatment cycle. Thus, it is desired to test the null hypothesis $H_0: \lambda = 0.2$ against the one-sided alternative hypothesis $H_1: \lambda \geq 0.3$. The trial will be designed such that a one sided $\alpha = 0.05$ test achieves 80% power at $\lambda = \lambda_1 = 0.3$.

In the **Design** tab under the **Count** group choose **One Sample** and then **Single Poisson**

Rate.

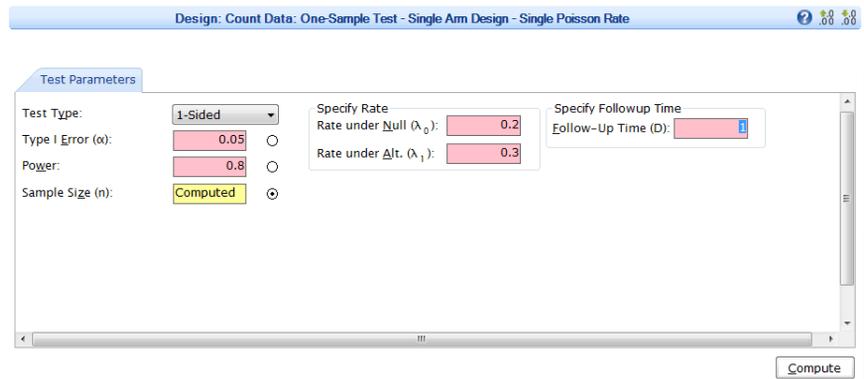

This will launch the following input window:

Enter the following design parameters:

- Test Type: 1 sided
- Type 1 Error (α): 0.05
- Power: 0.8
- Sample Size (n): Computed (select radio button)
- Rate under Null (λ_0): 0.2
- Rate under Alt. (λ_1): 0.3
- Follow-up Time (D): 1

40 Count Data One-Sample

Click **Compute**. The design is shown as a row in the **Output Preview** window:

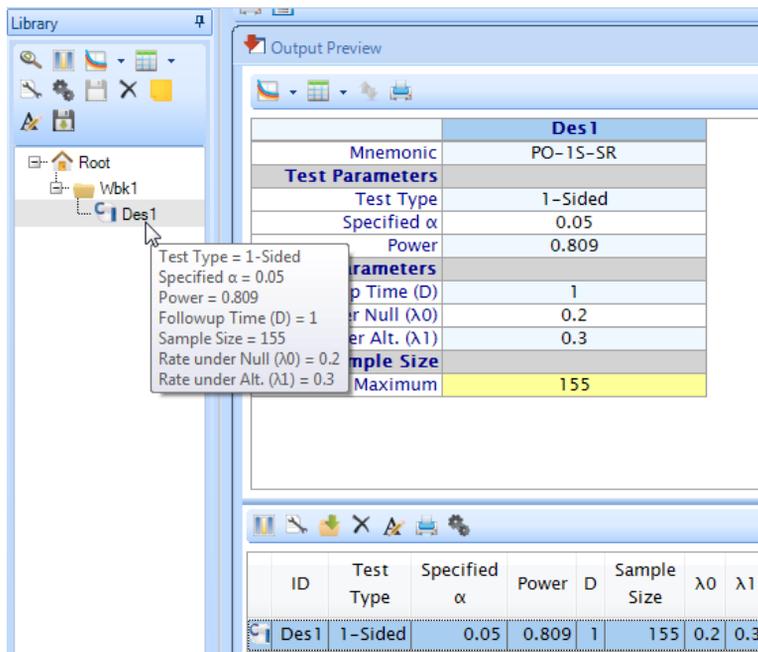

| ID | Test Type | Specified α | Power | D | Sample Size | λ_0 | λ_1 |
|-------|-----------|--------------------|-------|---|-------------|-------------|-------------|
| Des 1 | 1-Sided | 0.05 | 0.809 | 1 | 155 | 0.2 | 0.3 |

The sample size required in order to achieve the desired 80% power is 155 subjects. As is standard in East, this design has the default name **Des 1**. To see a summary of the output of this design, click anywhere in the row and then click the  icon in the Output Preview toolbar. The design details are displayed labeled **Output Summary**.

| Des1 | |

| Rate Under Alt. (λ_1) | 0.3 |
| Follow-Up Time (D) | 1 |

Sample Size Information
Sample Size (n) 155

Critical Points
Critical Point 1.645

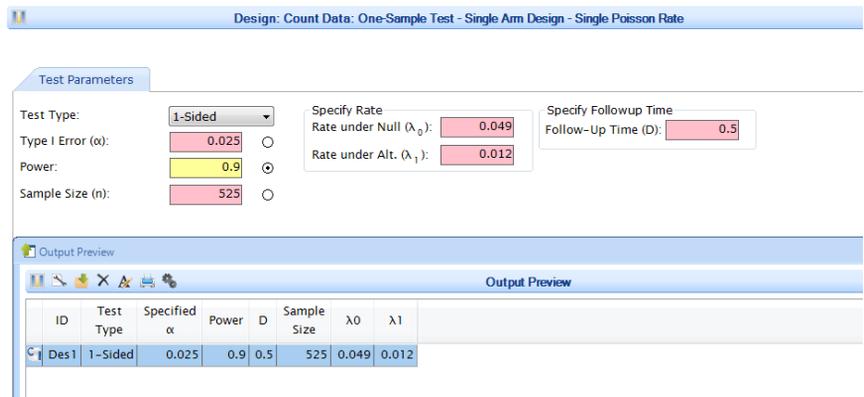

Summary
A total sample size of 155 is required in a study to achieve 0.8 power at 0.05 level of significance when average response rates under null and alternative are 0.2 and 0.3 respectively. Here, the subjects are followed up to 1 units of time.

In addition to the **Power vs. Sample** size chart and table, East also provides the efficacy boundary in the **Stopping Boundaries** chart and table.

Alternatively, East allows the computation of either the **Type-1 error** (α) or **Power** for a given sample size. Using the **Design Input/Output** window as described above, simply enter the desired sample size and click **Compute** to calculate the resulting power of the test.

Power vs Sample Size: Sawtooth paradigm Consider the following design which uses East to compute power assuming a one sample, single Poisson rate.

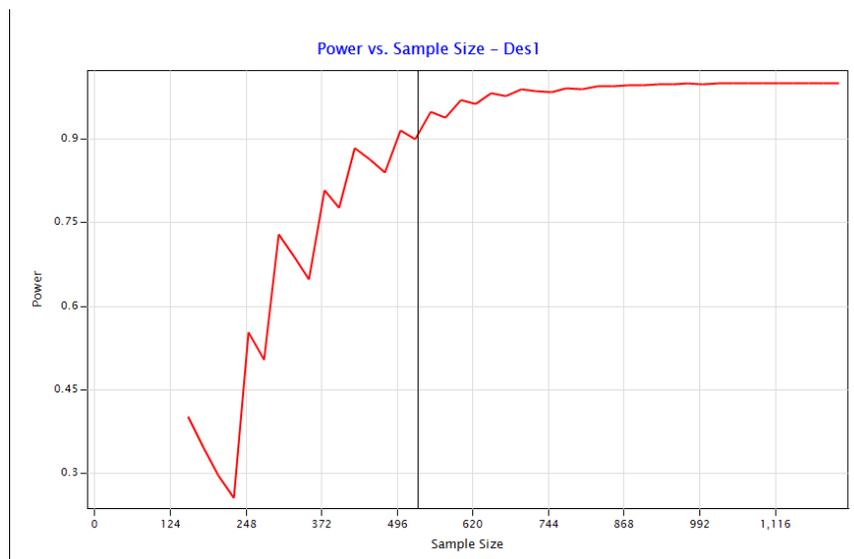

Test Type: 1 sided
 Type 1 Error (α): 0.025
 Power: Computed
 Sample Size (n): 525
 Rate under Null (λ_0): 0.049
 Rate under Alt. (λ_1): 0.012
 Follow-up Time (D): 0.5

Save the design to a workbook, and then generate the **Power vs. Sample Size** graph to obtain the power chart. The resulting curve is commonly described in the literature as a

40 Count Data One-Sample

sawtooth chart.

This chart illustrates that it is possible to have a design where different sample sizes could obtain the same power. As with the binomial distribution, the Poisson distribution is discrete. For power and sample size computations for discrete data, the so called "Saw tooth" phenomena occurs.

The data can also be displayed in a chart form by selecting the  icon in the

Library, and can be printed or saved as case data.

| Range for Sample Size | | |
|-----------------------|-----|-----------|
| From | To | Step Size |
| 525 | 600 | 5 |

Tabulate

| Sample Size | Power_Des 1 |
|-------------|-------------|
| 525 | 0.9 |
| 530 | 0.897 |
| 535 | 0.955 |
| 540 | 0.953 |
| 545 | 0.951 |
| 550 | 0.949 |
| 555 | 0.947 |
| 560 | 0.945 |
| 565 | 0.943 |
| 570 | 0.941 |
| 575 | 0.938 |
| 580 | 0.936 |
| 585 | 0.934 |
| 590 | 0.972 |
| 595 | 0.97 |
| 600 | 0.969 |

It is important to note that for designs with the same power, the attained significance level may vary. For example, the sample sizes of 565 and 580 seem to have a similar power of about 0.94. Upon computing two new designs based on the above design with sample sizes of 565 and 580 respectively, it is apparent that the attained significance levels are different. The design with a lower sample size of 565 pays a higher penalty in terms of type-1 error ($\alpha = 0.03$) than the plan with a larger sample

40 Count Data One-Sample

size of 580 ($\alpha = 0.016$).

| | ID | Test Type | Specified α | Power | D | Sample Size | λ_0 | λ_1 | Attained α |

Count Data Two-Samples

Often in experiments based on count data, the aim is to compare independent samples from two populations in terms of the rate of occurrence of a particular outcome. In medical research, outcomes such as the number of times a patient responds to a therapy, develops a certain side effect, or requires specialized care, are of interest. Or perhaps a therapy is being evaluated to determine the number of times it must be applied until an acceptable response rate is observed. East supports the design of clinical trials in which this comparison is based on the ratio of rates, assuming a Poisson or Negative Binomial distribution. These two cases are presented in Sections 41.1 and 41.2, respectively.

41.1 Poisson - Ratio of Rates

41.1.1 Trial Design

41.1.2 Example - Coronary Heart Disease

Let λ_c and λ_t denote the Poisson rates for the control and treatment arms, respectively, and let $\rho_1 = \lambda_t/\lambda_c$. We want to test the null hypothesis that $\rho_1 = 1$ against one or two-sided alternatives. The sample size, or power, is determined to be consistent with the alternative hypothesis, that is $H_1 : \lambda_t \neq \lambda_c$, $H_1 : \lambda_t > \lambda_c$, or $H_1 : \lambda_t < \lambda_c$.

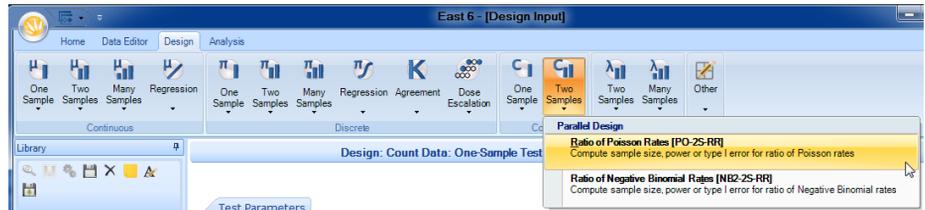

41.1.1 Trial Design

Suppose investigators are preparing design objectives for a prospective randomized trial of a standard treatment (control arm) vs. a new combination of medications (therapy arm) to present at a clinical trials workshop. The endpoint of interest is the number of abnormal ECGs (electrocardiogram) within seven days. The investigators were interested in comparing the therapy arm to the control arm with a two sided test conducted at the 0.025 level of significance. It can be assumed that the rate of abnormal ECGs in the control arm is 30%, thus $\lambda_t = \lambda_c = 0.3$ under H_0 . The investigators wish to determine the sample size to attain power of 80% if there is a 25% decline in the event rate, that is $\lambda_t/\lambda_c = 0.75$. It is important to note that the power of the test depends on λ_c and λ_t , not just the ratio, so different values of the pair (λ_c, λ_t) with the same ratio will yield different solutions.

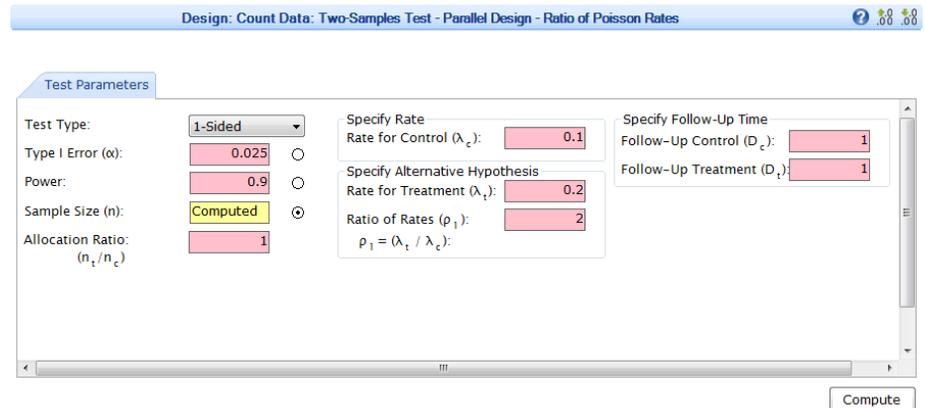

We will now design a study that compares the control arm to the combination therapy arm. In the **Design** tab under the **Count** group choose **Two Samples** and then **Parallel**

41 Count Data Two-Samples

Design - Ratio of Poisson Rates.

This will launch the following input window:

Enter the following design parameters:

- Test Type: 2-sided
- Type 1 Error (α): 0.05
- Power: 0.8
- Sample Size (n): Computed (select radio button)
- Allocation Ratio (n_t/n_c): 1
- Rate for Control (λ_c): 0.3
- Rate for Treatment (λ_t): 0.225 (will be automatically calculated)
- Ratio of Rates $\rho_1 = (\lambda_t/\lambda_c)$: 0.75
- Follow-up Control (D_c): 7
- Follow-up Treatment (D_t): 7

Design: Count Data: Two-Samples Test - Parallel Design - Ratio of Poisson Rates

Follow-Up Treatment (D_t): 7

Compute

The Allocation Ratio ($n_t : n_c$) describes the ratio of patients to each arm. For example, an allocation ratio of 3:1 indicates that 75% of the patients are randomized to the treatment arm as opposed to 25% to the control. Here we assume the same number of patients in both arms. Click **Compute**. The design is shown as a row in the **Output Preview** window:

Output Preview

| ID | Test Type | Specified α | Power | Sample Size | λ_c | λ_t | ρ_1 | D_c | D_t | n_t / n_c |

Summary

A total sample size of 211 is required in a study to achieve 0.8 power at 0.05 level of significance when response rates for Control group and Treatment group are 0.3 and 0.225 respectively. Here, the subjects from the two groups are followed up to 7 and 7 units of time.

In addition to the **Power vs. Sample** size chart and table, East also provides the efficacy boundary in the **Stopping Boundaries** chart and table.

Alternatively, East allows the computation of either the **Type-1 error** (α) or **Power** for a given sample size. Using the **Design Input Output** window as described above, simply enter the desired sample size and click **Compute** to calculate the resulting power of the test.

41.1.2 Example - Coronary Heart Disease

The following example is presented in the paper by Gu, et al. (2008) which references a prospective study reported by Stampfer and Willett (1985) examining the relationship between post-menopausal hormone use and coronary heart disease (CHD). Researchers were interested if the group using hormone replacement therapy exhibited less coronary heart disease. The study did show strong evidence that the incidence rate of CHD in the group who did not use hormonal therapy was higher than that in the group who did use post-menopausal hormones. The authors then determined the sample size necessary for the two groups when what they referred to as the ratio of sampling frames is 2, known as the allocation ratio in East. The study assumed an observation time of 2 years, and that the incidence rate of CHD for those using the

hormone therapy is 0.0005. The following excerpt from the paper presents the required sample sizes for the participants using hormone therapy in order to achieve 90% power at $\alpha = 0.05$, for multiple different test procedures:

Table 6 The values of $\lambda_1 = t_1\gamma_1$ and the required sample sizes for the example with $1 - \beta = 0.9$, $\alpha = 0.05$, $R = 1$, $R' = 4$, $\gamma_1 = 0.0005$.

| Test Procedure | λ_1 | Required sample size |
|------------------------------|-------------|----------------------|
| $p_1^{(A)}$ | 8.53 | 8527 |
| $p_2^{(A)}$ | 6.86 | 6860 |
| $p_3^{(A)}$ | 6.66 | 6655 |
| $p_4^{(A)}$ | 6.66 | 6655 |
| $p_5^{(A)}$ | 8.63 | 8627 |
| $p_j^{(P)}, j = 1, \dots, 5$ | 6.59 | 6590 |
| $p^{(C)}$ | 7.26 | 7260 |
| $p^{(M)}$ | 6.58 | 6580 |
| $p^{(L)}$ | 6.37 | 6370 |

The epidemiologist would like to know the required sample size for the two groups when the ratio of sampling frames is 2 ($d = 2$). Suppose also that the observation time domain is 2 years, from the previous study that the incidence rate of CHD for those using the hormone is 0.0005 ($\gamma_1 = 0.0005$), and R' is 4. From formulae (6)–(12), the values of $\lambda_1 = t_1\gamma_1$ and the required sample sizes for the hormone using group to achieve 90% power at $\alpha = 0.05$ for different test procedures are presented in Table 6. The smallest are for $p_3^{(A)}$ and $p_4^{(A)}$.

It is first necessary to determine the difference in notation between the referenced paper and that used by East:

| Gu et al. (2008) | East |
|------------------|----------------------|
| γ_1 | λ_t |
| γ_0 | λ_c |
| $R' = 4$ | $1/\rho_1 = 0.25$ |
| D | Allocation Ratio = 2 |

Once again in the **Design** tab under the **Count** group choose **Two Samples** and then **Parallel Design - Ratio of Poisson Rates**. Enter the following design parameters:

- Test Type: 1-sided
- Type 1 Error (α): 0.05
- Power: 0.9
- Sample Size (n): Computed (select radio button)
- Allocation Ratio (n_t/n_c): 2

41 Count Data Two-Samples

Rate for Control (λ_c): 0.002
 Rate for Treatment (λ_t): 0.0005
 Ratio of Rates $\rho_1 = (\lambda_t/\lambda_c)$: 0.25
 Follow-up Control (D_c): 2
 Follow-up Treatment (D_t): 2

Design: Count Data: Two-Samples Test - Parallel Design - Ratio of Poisson Rates

| Follow-Up Treatment (D_t) | 2 |
| Allocation Ratio (n_t/n_c) | 2 |

| Sample Size Information | |
|-----------------------------|-------|
| Sample Size (n) | 10027 |
| Treatment (n _t) | 6685 |
| Control (n _c) | 3342 |

| Critical Points | |
|-----------------|--------|
| Critical Point | -1.645 |

Summary
 A total sample size of 10027 is required in a study to achieve 0.9 power at 0.05 level of significance when response rates for Control group and Treatment group are 0.002 and 0 respectively. Here, the subjects from the two groups are followed up to 2 and 2 units of time.

Table 6 in the referenced paper shows the number of subjects required for the treatment group. The East results show that the total number of subjects required for the entire study is 10027. Given that the allocation ratio is 2, the number of subjects required for the control group is $10027/3=3342$ and the treatment group is therefore 6685. This falls in the range of the sample sizes presented in the referenced paper (and close to the minimum of 6655), which again calculates these sizes using a number of different methods.

41.2 Negative Binomial Ratio of Rates

In experiments where the data follows a binomial distribution, the number of successful outcomes for a fixed number of trials is of importance when determining the sample size to adequately power a study. Suppose instead that it is of interest to observe a fixed number of successful outcomes (or failures), but the overall number of trials necessary to achieve this is unknown. In this case, the data is said to follow a Negative Binomial Distribution. There are two underlying parameters of interest. As with the Poisson distribution, λ denotes the average rate of response for a given outcome. In addition, a **shape** parameter γ specifies the desired number of observed "successes". As with the Poisson distribution, the Negative Binomial distribution can be useful when designing a trial where one must wait for a particular event. Here, we are waiting for a specific number of successful outcomes to occur. A Poisson regression analysis assumes a common rate of events for all subjects within a stratum, as well as equal mean and variance (equidispersion). With over dispersed count data, estimates of standard error from these models can be invalid, leading to difficulties in planning a clinical trial. Increased variability resulting from over dispersed data requires a larger sample size in order to maintain power. To address this issue of allowing variability between patients, East provides valid sample size and power calculations for count data using a negative binomial model, resulting in a better evaluation of study design and increased likelihood of trial success.

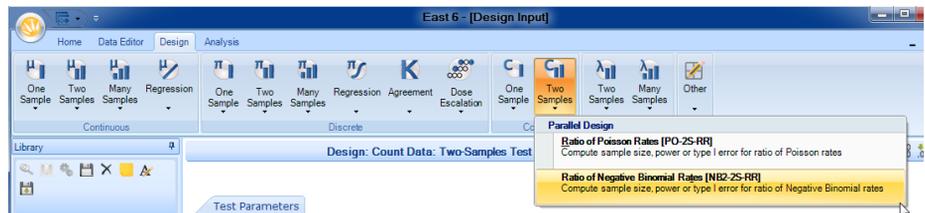

41.2.1 Trial Design

Suppose that a hypothetical manufacturer of robotic prostheses, those that require several components to fully function, has an order to produce a large quantity of artificial limbs. According to historical data, about 20% of the current limbs fail the rigorous quality control test and therefore cannot be shipped to patients. For each order, the manufacturer must produce more than requested; in fact they must continue to produce the limbs until the desired quantity passes quality control. Given that there is a high cost in producing these prosthetic limbs, it is of great interest reduce the number of those that fail the test.

41 Count Data Two-Samples

The company plans to introduce a new feature to the current model, the goal being the probability of failure is reduced to 10%. It is safe to assume that the enhancement will not cause a decline in the original success rate. In this scenario, we wish to test the null hypothesis $H_0: \lambda_c = \lambda_t = 0.2$ against the one sided alternative of the form $H_1: \lambda_c > \lambda_t$. Quality control investigators wish to conduct a one-sided test at the $\alpha = 0.05$ significance level to determine the sample size required obtain 90% power to observe a 50% decline in the event rate, i.e. $\lambda_t/\lambda_c = 0.5$. It is important to note that the power of the test depends on λ_c and λ_t , not just the ratio, so different values of the pair (λ_c, λ_t) with the same ratio will have different solutions. The same holds true for the shape parameter. Different values of (γ_c, γ_t) will result in different sample sizes or power calculations. East allows user specific shape parameters for both the treatment and control groups, however for this example assume that the desired number of successful outcomes for both groups is 10.

The following illustrates the design of a two-arm study comparing the control arm, which the current model of the prosthesis, to the treatment arm, which is the enhanced model. In the **Design** tab under the **Count** group choose **Two Samples** and then **Parallel Design - Ratio of Negative Binomial Rates**.

This will launch the following input window:

The screenshot shows a software window titled "Design: Count Data: Two-Samples Test - Parallel Design - Ratio of Negative Binomial Rates". The "Test Parameters" tab is active. The parameters are as follows:

- Test Type: 1-Sided (dropdown menu)
- Type I Error (α): 0.025 (input field)
- Power: 0.9 (input field)
- Sample Size (n): Computed (input field)
- Allocation Ratio: 1 (input field)
- Specify Rate: Rate for Control (λ_c): 0.2 (input field)
- Specify Alternative Hypothesis: Rate for Treatment (λ_t): 0.1 (input field)
- Ratio of Rates (ρ): 0.5 (input field)
- Specify Follow-Up Time: Follow-Up Time (D): 1 (input field)
- Specify Shape Parameter: Shape Control (γ_c): 1 (input field)
- Shape Treatment (γ_t): 1 (input field)

A "Compute" button is located at the bottom right of the window.

Enter the following design parameters:

- Test Type: 1 sided
- Type 1 Error (α): 0.05
- Power: 0.9
- Sample Size (n): Computed (select radio button)
- Allocation Ratio (n_t/n_c): 1
- Rate for Control (λ_c): 0.2
- Rate for Treatment (λ_t): 0.1
- Ratio of Rates $\rho = (\lambda_t/\lambda_c)$: 0.5
- Follow-up Time (D): 1
- Shape Control (γ_c): 10
- Shape Treatment (γ_t): 10

With the design **Des1** selected in the Library, click icon on the Library toolbar, and then click **Power vs. Sample Size**. The power curve for this design will be displayed. You can save this chart to the Library by clicking **Save in Workbook**. Alternatively, you can export the chart in one of several image formats (e.g., Bitmap or

41 Count Data Two-Samples

JPEG) by clicking **Save As...** or **Export** into a PowerPoint presentation.

Close the Power vs. Sample Size chart. To view all computed characteristics of this

design, select **Des1** in the **Library**, and click  icon.

Summary
 A total sample size of 1248 is required in a study to achieve 0.9 power at 0.05 level of significance when response rates for Control group and Treatment group are 0.2 and 0.1 respectively and the shape parameters for the two groups are 10 and 10 respectively. Here, the subjects from the two groups are followed up to 1 units of time.

In addition to the **Power vs. Sample** size chart and table, East also provides the efficacy boundary in the **Stopping Boundaries** chart and table.

For a specific desired sample size, East allows the computation of either the **Type-1 error** (α) or **Power** for a test. Using the **Design Input Output** window and methods as described above, simply enter the desired sample size and click **Compute** to calculate the resulting power of the test.

In addition to this example, consider the following illustration of the benefit of using the negative binomial model in clinical trials. In real life settings, the variance of count data observed between patients is typically higher than the observed mean. The negative binomial model accommodates between subject heterogeneity according to a Gamma distribution. For example:

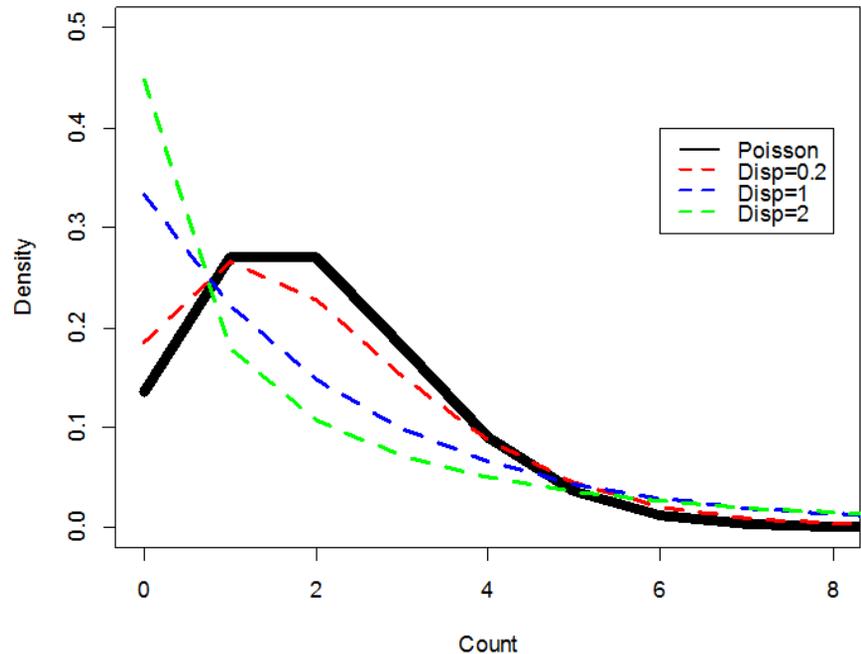

Poisson: $Y \sim Poisson(\lambda)$

Negative Binomial: $Y_i \sim Poisson(\lambda k_i)$ where $k_i \sim Gamma(k)$

In the case of no overdispersion ($k = 0$) the negative binomial model reduces to the

41 Count Data Two-Samples

Poisson model. In the figure below, the Poisson and negative binomial models are displayed under various values of the dispersion parameter.

Assuming the above parameterization, the variance of the negative binomial model is $\lambda + k\lambda^2$. The inflation in variance is thus linear by the factor $1 + k * \lambda$ and dependent on the mean. Depending on the distributional assumption used and its impact on the variance, sample size and power can vary widely.

In multiple sclerosis (MS) patients, magnetic resonance imaging (MRI) is used as a marker of efficacy by means of serial counts of lesions appearing on the brain. Exacerbations rates as a primary endpoint are frequently used in MS as well as in chronic obstructive pulmonary disease (COPD) and asthma (Keene *et al.* 2007). Poisson regression could be considered, however this model would not address variability between patients, resulting in over dispersion. The negative binomial model offers an alternative approach.

TRISTAN (Keene *et al.* 2007) was a double-blind, randomized study for COPD comparing the effects of the salmeterol/fluticasone propionate combination product

(SFC) to salmeterol alone, fluticasone proprionate alone and placebo. Although the primary end-point was pre-bronchodilator FEV1, the number of exacerbations was an important secondary endpoint.

Suppose we are to design a new trial to be observed over a period of 1 to 2 years. The primary objective is the reduction of the rate of exacerbations, defined as a worsening of COPD symptoms that require treatment with antibiotics, cortisone or both, with the combination product SFC versus placebo. Based on the TRISTAN results, we aim to reduce the incidence of events by 33%. Suppose the exacerbation rate is 1.5 per year, and can expect to detect a rate of 1.0 in the combination group. Assume a 2-sided test with a 5% significance level and 90% power. Using a Poisson model, a total of 214 patients are needed to be enrolled in the study.

For the TRISTAN data, the estimate of the overdispersion parameter was 0.46 (95% CI: 0.34-0.60). Using a negative binomial model with overdispersion of 0.33, 0.66, 1

41 Count Data Two-Samples

and 2, the increase in sample size ranged from 298 to 725, respectively.

Exacerbation rates are calculated as number of exacerbations divided by the length of time in treatment in years. EAST can be used to illustrate the impact of a one versus two year study by changing the follow-up duration.

For 382 patients and a shape parameter of 0.66, power is increased from 90% to 97%

when follow-up time is doubled :

The number of patients required for a two year study powered at 90% is 277, whereas 382 patients would be required to achieve the same power for a study period of one

41 Count Data Two-Samples

year.

Negative binomial models are increasing in popularity for medical research, and as the industry standard for trial design, East continues to evolve by incorporating sample size methods for count data. These models allow the count to vary around the mean for groups of patients instead of the population means. Additionally, increased variability does lead to a larger test population; consequently the balance between power, sample size and duration of observation needs to be evaluated.

42 *Introduction to Volume 6*

The chapters in this volume deal with clinical trials where the endpoint of interest is the time from entry into the study until a specific event –for example, death, tumour recurrence, or heart attack – occurs. Such trials are also referred to as survival trials, time-to-event trials, or time-to-failure trials. Long-term mortality trials in oncology, cardiology or HIV usually select time-to-event as the primary endpoint. The group sequential methodology is particularly appropriate for such trials because of the potential to shorten the study duration and thereby bring beneficial new therapies to patients sooner than would be possible by a conventional single-look design. In contrast to studies involving normal and binomial endpoints, the statistical power of a time-to-event study is determined, not by the number of individuals accrued, but rather by the number of events observed. Accruing only as many individuals as the number of events required to satisfy power considerations implies having to wait until all individuals have reached the event. This will probably make the trial extend over an unacceptably long period of time. Therefore one usually accrues a larger number of patients than the number of events required, so that the study may be completed within a reasonable amount of time. East allows the user a high degree of flexibility in this respect.

This volume contains Chapters 42 through 47. Chapter 42 is the present chapter. It describes the contents of the remaining chapters of Volume 6.

Chapter 43 introduces you to East on the Architect platform, using an example clinical trial to compare survival in two groups.

In Chapter 44 we discuss the Randomized Aldactone Evaluation Study (RALES) for decreasing mortality in patients with severe heart failure (Pitt et al., 1999). The chapter illustrates how East may be used to design and monitor a group sequential two-sample superiority trial with a time-to-event endpoint. We begin with the simple case of a constant enrollment rate, exponential survival and no drop-outs. The example is then extended to cover non-uniform enrollment, non-constant hazard rates for survival, and differential drop-out rates between the treatment and control arms. The role of simulation in providing additional insights is discussed. Simulations in presence of non-proportional hazard rates, stratification variables are explained. The trial was designed so that every subject who had not dropped out or reached the stated endpoint would be followed until the trial was terminated. This is an example of a **variable follow-up design**, because subjects who are enrolled at the beginning of the enrollment phase are followed for a longer time than subjects who are enrolled later.

In contrast to Chapter 44, Chapter 45 deals with the **fixed follow-up design**. Here we

design a trial in which each subject can only be followed for a maximum of one year and then goes off study. We use East to design such a trial basing the design parameters on the PASSION and TYPHOON trials – two recently published studies of drug eluting stents (Spaulding et al., 2006; Laarman et al., 2006). The impact of variable accrual patterns and drop-outs is also taken into account.

Chapter 46 shows how to use East to design a non-inferiority trial with a time-to-event endpoint. The setting is a clinical trial to demonstrate the non-inferiority of Xeloda to 5-FU+LV in patients with metastatic colorectal cancer (Rothman et al., 2003). Part of the discussion in this chapter is about the choice of the non-inferiority margin.

Chapter 47 will illustrate through a worked example how to design, monitor and simulate a two-sample non-inferiority trial with a time-to-event endpoint in which each subject who has not dropped out or experienced the event is followed for a fixed duration only. This implies that each subject who does not drop-out or experience the event within a given time interval, as measured from the time of randomization, will be administratively censored at the end of that interval. In East we refer to such designs as **fixed follow-up designs**.

Chapters 48 and 49 handle the trade-off between patient accruals and study duration in a different way from the previous chapters. In contrast to publicly funded trials, which usually lack the resources to exert control over the accrual rate of a trial, industry trials are often run with a fixed timeframe as the constraint. Industry sponsors would rather adjust the patient recruitment rate by opening and closing investigator sites than delay the end of a study and therefore their entire drug development program, time to market, and revenue. Chapters 48 and 49 illustrate how to design superiority and non-inferiority trials in East given a fixed accrual period and fixed study duration. Additionally, these design options provide the users with many useful graphs that chart the relationship between power, sample size, number of events, accrual duration, and study duration.

Also note that Chapter 44 contains a section that guides the user through the powerful survival simulation tool available in East.

Chapter 50 is a note which gives details on specifying dropout parameters for survival studies in East with the help of an example.

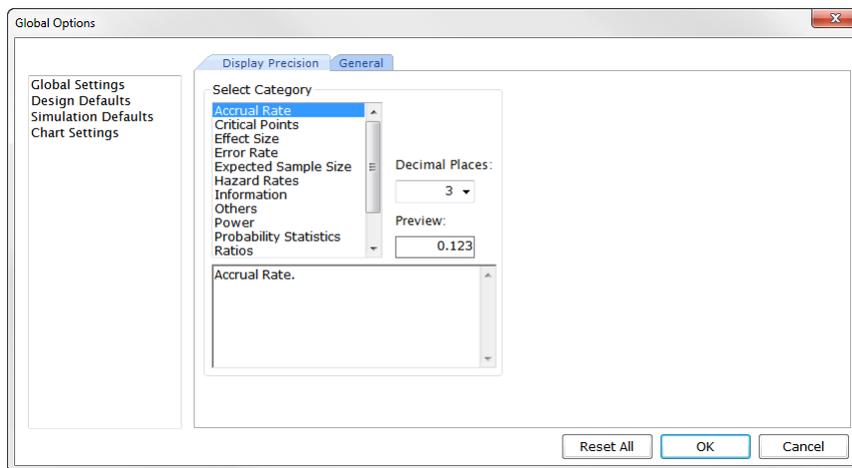

A unified formula for calculating the expected number of events $d(l)$ in a time-to-event trial can be found in the Appendix D.

42 Introduction to Volume 6

42.1 Settings

Click the **Global Options** icon in the **Home** menu to adjust default values in East 6.

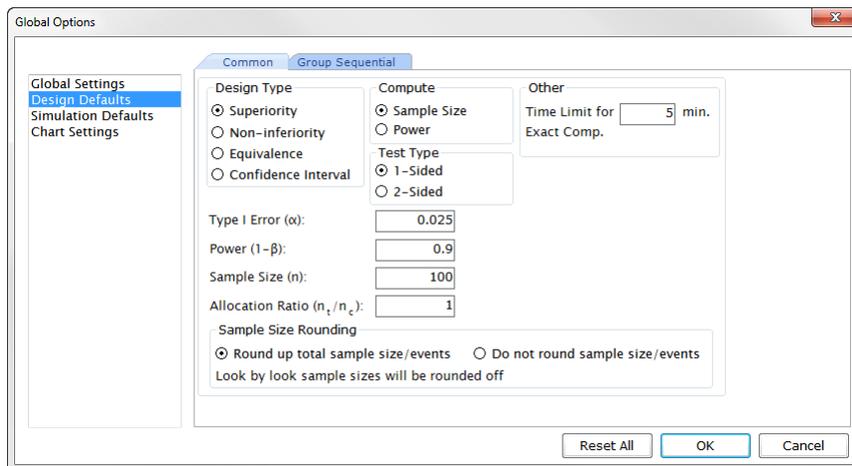

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

The **Design Defaults** is where the user can change the settings for trial design:

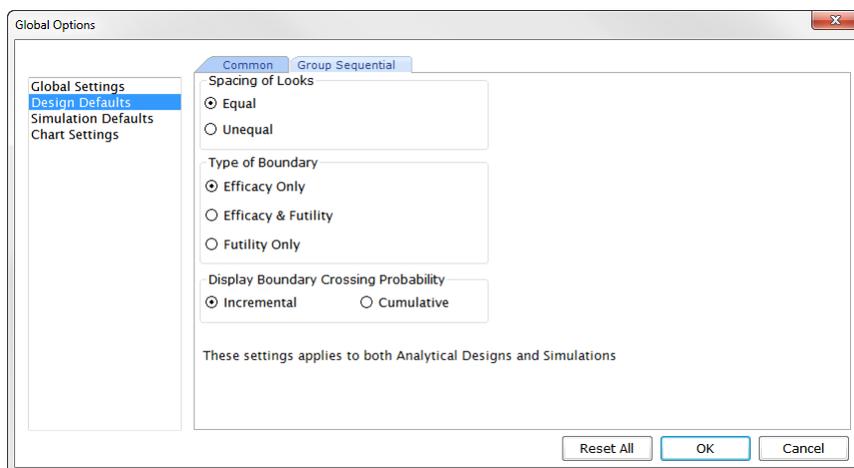

Under the **Common** tab, default values can be set for input design parameters.

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

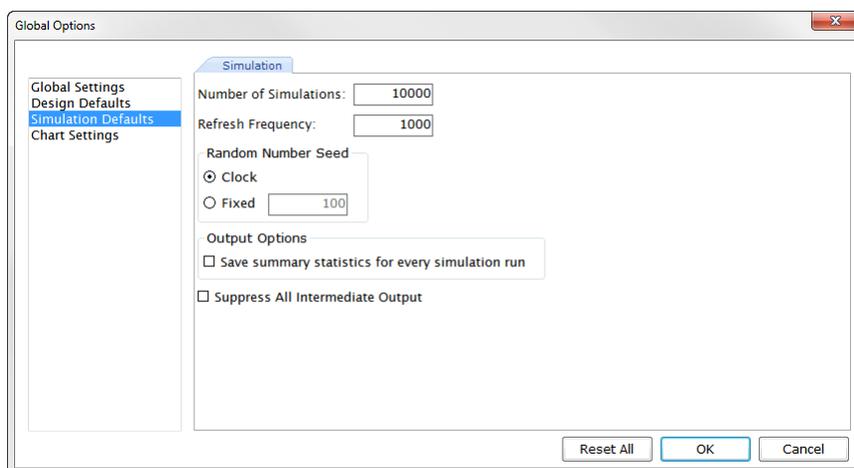

- **Time Limit for Exact Computation**
 This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
 If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
 Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

42 Introduction to Volume 6

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

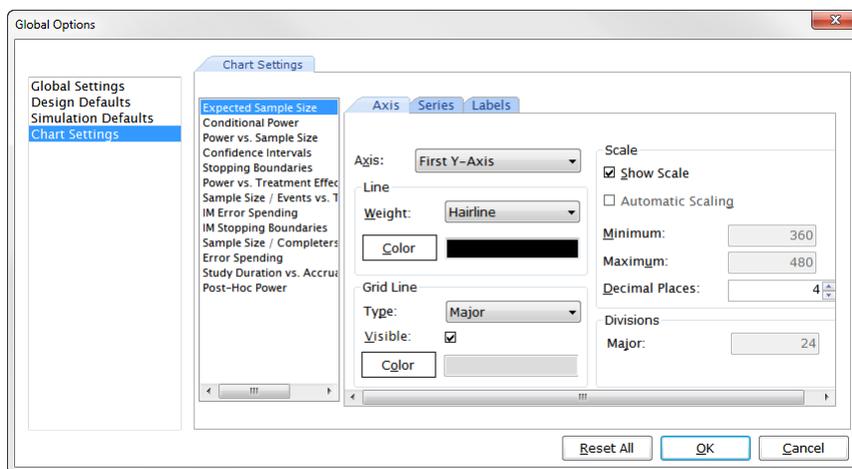

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

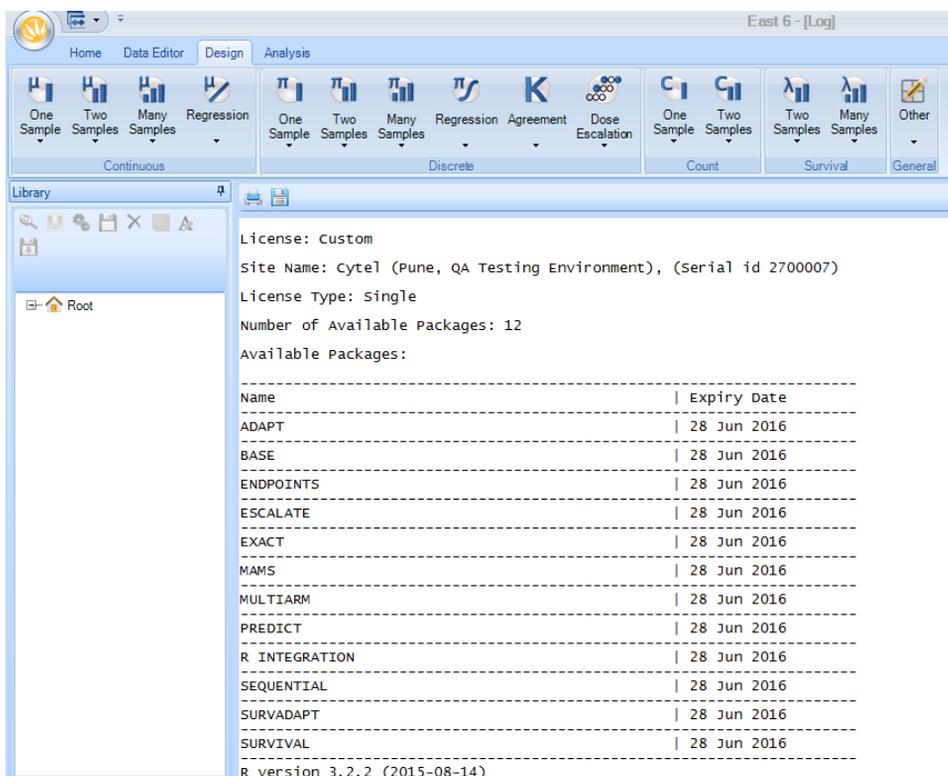

We suggest that you do not alter the defaults until you are quite familiar with the software.

43 *Tutorial: Survival Endpoint*

This tutorial introduces you to East 6, using examples for designing a clinical trial to compare survival in two groups. It is suggested that you go through the tutorial while you are at the computer, with East 6 running in it.

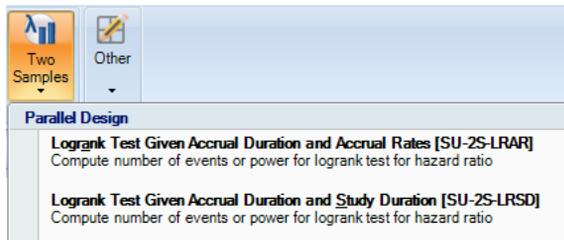

43.1 *A Quick Feel of the Software*

When you open East 6, the screen will look as shown below.

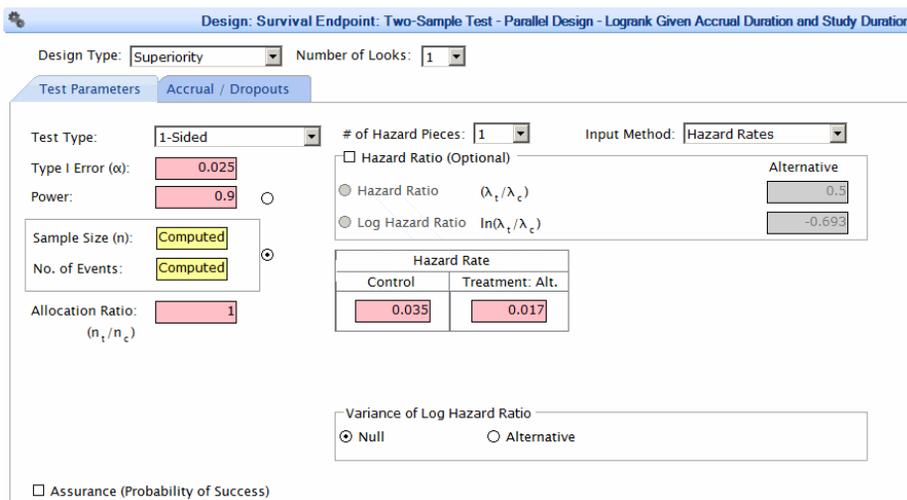

In the tabs bar at the top of the ribbon, Design tab is already selected. Each tab has its own ribbon. All the commands buttons under Design tab are displayed in its ribbon, with suggestive icons. These commands have been grouped under the categories of Continuous, Discrete, Count, Survival and General. For this tutorial, let us explore the command **Two Samples** under **Survival** category. In East, we use the terms 'time to event' and 'survival' interchangeably. Click on **Two Samples**. You will see a list of

action items, which are dialog box launchers.

Click on **Logrank Test Given Accrual Duration and Study Duration**. You will get the following dialog box in the work area.

This dialog box is for computing Sample Size (n) and Number of Events. All the default input specifications under the tab Design Parameters are on display: Design Type=Superiority, Number of Looks=1, Test Type=1-Sided, Type-1 Error (α)=0.025, Power ($1-\beta$)=0.9, Allocation Ratio (n_t/n_c)=1, # of Hazard Pieces=1, Input Method=Hazard Rates, Hazard Ratio (λ_t/λ_c)=0.5, Log Hazard Ratio $\ln(\lambda_t/\lambda_c)$ =-0.693, Hazard Rate (Control)=0.0347, Hazard Rate (Treatment)=0.0173, and Variance of Log-Hazard Ratio=Null. There are two radio buttons in this dialog box, one at the side of Power ($1-\beta$) box and the second at the side of the combined boxes for Sample Size (n) and Number of Events. By default, the latter radio button is

43 Tutorial: Survival Endpoint

selected indicating that the items against this radio button are to be computed using all other inputs. Similarly, if the first radio button is selected, then Power will be computed using all other inputs.

Now click on the tab Accrual/Dropout and you will see the following dialog box.

The default specifications in this dialog box are: Subjects are followed=Until End of Study, Accrual Duration=22, Study Duration=38, # of Accrual Periods=1, and no Dropouts. Now accept all the default specifications that are displayed for this single look design and be ready to compute the Sample Size (n) and the Number of Events for the design. Click Compute.

At the end of the computation, you will see the results appearing at the bottom of the screen, in the Output Preview pane, as shown below.

| Output Preview | | | | | | | | | | | | | | |
|----------------|-------------|--------------|-----------|--------------------|-------|---------|-------------|------------------|------------------|----------------|------------------|------------------|--------------------|----------------------------|
| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt / nc | Sample Size | Expected SS (H0) | Expected SS (H1) | Maximum Events | Exp. Events (H0) | Exp. Events (H1) | Comm. Accr. (Dur.) | Exp. Accrual Duration (H0) |
| Des1 | Superiority | 1 | 1-Sided | 0.025 | 0.902 | 1 | 182 | 182 | 182 | 88 | 88 | 88 | 22 | 22 |

| Exp. Accrual Duration (H1) | Hazard Ratio (Alt.) | Study Duration | Exp. Study Duration (H0) | Exp. Study Duration (H1) | Var (Log HR) | No. of Accrual Periods |
|----------------------------|---------------------|----------------|--------------------------|--------------------------|--------------|------------------------|
| 22 | 0.5 | 38 | 30.758 | 37.959 | Null | 1 |

This single row of output preview contains relevant details of all the inputs and the computed results for events and accruals. The maximum value for events is 88 and the committed accrual is 182 subjects. Since this is a fixed-look design, the expected events are same as the maximum required. Click anywhere in this row, and then click on the icon to get a detailed display in the upper pane of the screen as shown

below.

| | Des2 |
|---|--------------------|
| Mnemonic | SU-25-LRSD |
| Test Parameters | |
| Design Type | Superiority |

| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.902 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Hazard Ratio (Alt.) | 0.5 |
| Var (Log HR) | Null |
| Accrual & Dropout Parameters | |
| Subjects are Followed | Until End of Study |
| No. of Accrual Periods | 1 |
| No. of Dropout Pieces | 0 |
| Sample Size | |
| Maximum | 182 |
| Expected Under H0 | 182 |
| Expected Under H1 | 182 |
| Events | |
| Maximum | 88 |
| Expected Under H0 | 88 |
| Expected Under H1 | 88 |
| Study Duration | |
| Maximum | 38 |
| Expected Under H0 | 30.758 |
| Expected Under H1 | 37.959 |
| Accrual Duration | |
| Maximum | 22 |
| Expected Under H0 | 22 |
| Expected Under H1 | 22 |

The contents of this output, displayed in the upper pane, are the same as what is contained in the output preview row for Design1 shown in the lower pane, but the upper pane display is easier to read and comprehend. The title of the upper pane display is **Output Summary**. This is because, you can choose more than one design in the Output Preview pane and the display in the upper pane will show the details of all the selected designs in juxtaposed columns.

43 Tutorial: Survival Endpoint

The discussion so far gives you a quick feel of the software for computing the required events and sample size for a single look survival design. We have not discussed about all the icons in the output preview pane or the library pane or the hidden Help pane in the screen. We will describe them taking an example for a group sequential design in the next section.

43.2 Group Sequential Design for a Survival Superiority Trial

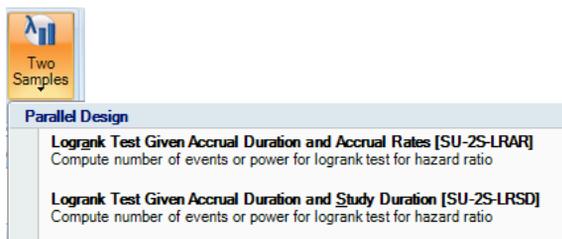

- 43.2.1 Background Information on the study
- 43.2.2 Creating the design in East
- 43.2.3 Design Outputs
- 43.2.4 East icons explained
- 43.2.5 Saving created designs
- 43.2.6 Displaying Detailed Output
- 43.2.7 Comparing Multiple Designs
- 43.2.8 Events vs. Time plot
- 43.2.9 Simulation
- 43.2.10 Interim Monitoring

43.2.1 Background Information on the study

The randomized aldactone evaluation study (RALES) was a double-blind multicenter clinical trial of aldeosterone-receptor blocker vs. placebo published in New England Journal of Medicine (vol 341, 10, pages 709-717, 1999). This trial was open to patients with severe heart failure due to systolic left ventricular dysfunction. The Primary endpoint was all-causes mortality. The anticipated accrual rate was 960 patients/year. The mortality rate for the placebo group was 38%. The investigators wanted 90% power to detect a 17% reduction in the mortality hazard rate for the Aldactone group (from 0.38 to 0.3154) with $\alpha = 0.05$, 2-sided test. Six DMC meetings were planned. The dropout rate in both the groups is expected to be 5% each year. The patient accrual period is planned to be 1.7 years and the total study duration to be 6 years.

43.2.2 Creating the design in East

For our purpose, let us create our own design from the basic details of this study. Now start afresh East. On the Design tab, click on **Two Samples** under **Survival** category. You will see a list of action items, which are dialog box launchers.

Click on the second option **Logrank Test Given Accrual Duration and Study**

Duration. You will get the following dialog box in the work area.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Design Type: Superiority Number of Looks: 1

Test Parameters Accrual / Dropouts

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Hazard Rates

Type I Error (α): 0.025

Power: 0.9

Sample Size (n): Computed

No. of Events: Computed

Allocation Ratio: 1 (n_1/n_2)

Hazard Ratio (Optional)

Hazard Ratio (λ_1/λ_2) Alternative: 0.5

Log Hazard Ratio $\ln(\lambda_1/\lambda_2)$ Alternative: -0.693

| Hazard Rate | |
|-------------|-----------------|
| Control | Treatment: Alt. |
| 0.035 | 0.017 |

Variance of Log Hazard Ratio

Null Alternative

Assurance (Probability of Success)

All the specifications you see in this dialog box are default values, which you will have to modify for the study under consideration.

Now, let the Design Type be Superiority.

Design Type: Superiority

Superiority

Noninferiority

Next, enter 6 in the Number of Looks box. You can see the range of choices for the

43 Tutorial: Survival Endpoint

number of looks is from 1 to 20.

Number of Looks:

1 ▲

2

3

4

5

6

7

8

9

10 ▼

Immediately after this selection, you will see a new tab **Boundary Info** added to the input dialog box. We will look into this tab, after you complete the filling of current tab **Design Parameters**.

Next, choose 2-Sided in the Test Type box.

Test Type:

2-Sided ▼

1-Sided

2-Sided

2-Sided (Asymmetric)

Next, enter 0.05 in the Type-1 Error (α) box, and 0.9 in the Power box.

Type I Error (α):

Power:

Next enter the specifications for survival parameters. Keep **# of Hazard Pieces** as 1. Click on the check box against Hazard Ratio and choose Hazard Rates as the Input Method. Enter 0.83 as the Hazard Ratio and 0.38 as the Hazard Rate (Control). East computes and displays the Hazard Rate (Treatment) as 0.3154. Keep the default choice of Null for Variance of Log-Hazard Ratio. Now the dialog box will look as shown

below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Design Type: Superiority Number of Looks: 6

Test Parameters Boundary **Accrual / Dropouts**

Test Type: 2-Sided # of Hazard Pieces: 1 Input Method: Hazard Rates

Type I Error (α): 0.05

Variance of Log Hazard Ratio

Null Alternative

Assurance (Probability of Success)

Next click the tab **Accrual/Dropout** . Keep the specification ‘Until End of Study’ for **Subjects are followed**. Enter 1.7 as **Accrual Duration** and 6 as **Study Duration**. Keep **# of Accrual Periods** as 1. Change the **# of Pieces** for dropouts to 1. Choose ‘Prob. of Dropout’ as the **Input Method** for entering information on dropouts. Enter 0.05 as probability of dropout at end of 1 year for both the groups. Now the dialog box will appear as shown below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Design Type: Superiority Number of Looks: 6

Test Parameters Boundary **Accrual / Dropouts**

Subjects are followed: Until End of Study

Accrual Info

Accrual Duration: 1.7 Study Duration: 6

of Accrual Periods: 1

| Period # | By Time | Cum. % Accrued |
|----------|---------|----------------|
| 1 | 1.700 | 100.000 |

Piecewise Dropout Information

of Pieces: 1 Input Method: Hazard Rates

Hazard Rate (Control): 0.05

Hazard Rate (Treatment): 0.05

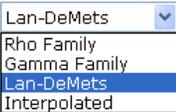

Now click on the **Boundary** tab. In the dialog box of this tab, you can specify stopping boundaries for efficacy or futility or both. For this trial, let us consider only Efficacy boundaries only. Choose ‘Spending Functions’ as the Efficacy Boundary Family.

Boundary Family: Spending Functions

- None
- Spending Functions**
- Haybittle Peto (p-value)
- Wang-Tsiatis

43 Tutorial: Survival Endpoint

Choose 'Lan-DeMets' in the Spending Function box.

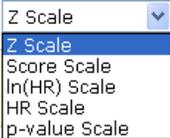

Spending Function: 

Choose 'OF' in the Parameter box.

Parameter: 

Next, click the radio button near 'Equal' for Spacing of Looks.

Choose 'Z Scale' in the Efficacy Boundary Scale box.

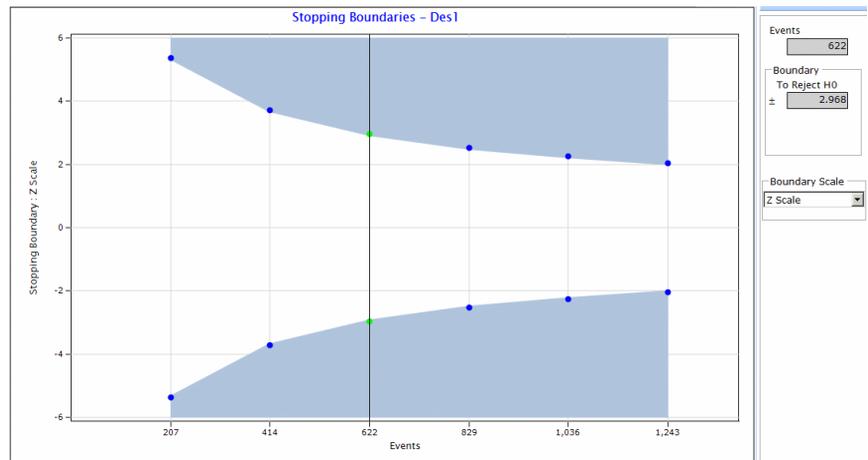

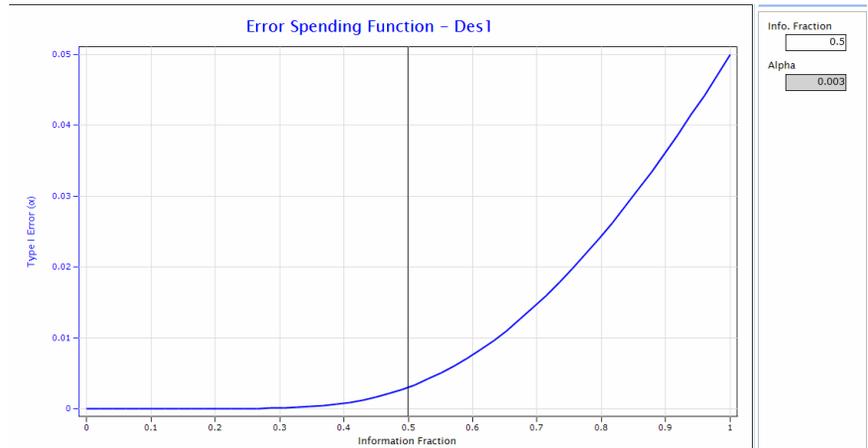

Efficacy Boundary: 

In the table below of look-wise details, the columns - Info Fraction, Cumulative Alpha Spent, and the upper and lower efficacy boundaries are computed and displayed as shown here. Scroll a little bit to see the sixth look details.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|---------|
| | | | Upper | Lower |
| 1 | 0.167 | 0.0000 | 5.3666 | -5.3666 |
| 2 | 0.333 | 0.0002 | 3.7103 | -3.7103 |
| 3 | 0.500 | 0.0031 | 2.9697 | -2.9697 |
| 4 | 0.667 | 0.0121 | 2.5387 | -2.5387 |
| 5 | 0.833 | 0.0282 | 2.2522 | -2.2522 |

The two icons  and  represent buttons for Error Spending Function chart and Stopping Boundaries chart respectively. Click these two buttons one by one to see

the following charts.

43 Tutorial: Survival Endpoint

43.2.3 Design Outputs

Now you have completed specifying all the inputs required for a group sequential trial design and you are ready to compute the required events and sample size or accruals for the trial. Click on the **Compute** button. After the computation is over, East will show in the Output Preview pane the following results:

| Output Preview | | | | | | | | | | | | | | |
|----------------|-------------|--------------|-----------|--------------------|-------|-------|-------------|------------------|------------------|----------------|------------------|------------------|--------------------|----------------------------|
| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | Expected SS (H0) | Expected SS (H1) | Maximum Events | Exp. Events (H0) | Exp. Events (H1) | Comm. Accr. (Dur.) | Exp. Accrual Duration (H0) |
| Des1 | Superiority | 6 | 2-Sided | 0.05 | 0.9 | 1 | 1642 | 1641.997 | 1641.986 | 1243 | 1233.984 | 903.595 | 1.7 | 1.7 |

| Exp. Accrual Duration (H1) | Hazard Ratio (Alt.) | Study Duration | Exp. Study Duration (H0) | Exp. Study Duration (H1) | Var (Log HR) | No. of Accrual Periods | Spacing of Looks | Efficacy Boundary |
|----------------------------|---------------------|----------------|--------------------------|--------------------------|--------------|------------------------|------------------|-------------------|
| 1.7 | 0.83 | 6 | 5.359 | 3.729 | Null | 1 | Equal | LD (OF) |

This single row of output preview contains relevant details of all the inputs and the computed results for events and accruals. The maximum required Events is computed as 1243 and the Committed Accrual to be 1646 subjects. The expected Events under H0 and H1 are estimated to be 1234 and 904 respectively. The expected Study Duration under H0 and H1 are 5.359 and 3.729 respectively.

Click anywhere in this Output Preview row and then click on  icon to get a

summary in the upper pane of the screen as shown below.

| | Des 1 |
|---|--------------------|
| Mnemonic | SU-2S-LRSD |

| Accrual Duration | |
| Maximum | 1.7 |
| Expected Under H0 | 1.7 |
| Expected Under H1 | 1.7 |

43.2.4 East icons explained

In the 'Output Preview' pane, you see the following icons in the upper row.

The functions of the above icons are as indicated below. The tooltips also will indicate their functions.

43 Tutorial: Survival Endpoint

-  Output Summary (The output summary of selected design(s) will appear in the upper pane)
-  Edit Design (The input dialog box of a selected design will appear in the upper pane)
-  Save in Workbook (Save one or more selected designs in a workbook)
-  Delete (Delete one or more selected designs)
-  Rename (Rename Design names)
-  Print (Print selected designs)
-  Display Precision (Local Settings)
-  Filter (Filter and select designs according to specified conditions)
-  Show/Hide Columns (Show/Hide Columns of the designs in the Output Preview panel)

The following icons can be seen at the right end of Output Preview pane and Output Summary or Input/Output window respectively. Their functions are:

-  Maximize Output Preview Pane
-  Minimize Output Preview Pane

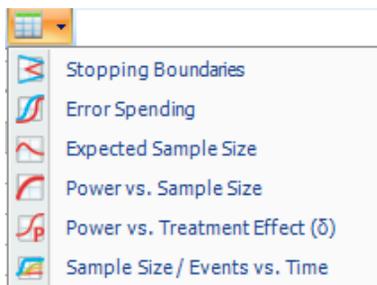

You may also notice a row of icons at the top of Output Summary window as shown below.

The first icon is for Plot (Plots of a selected design will appear in a pop-up window).

The second icon is for Show Tables (The data for different plots can be displayed in tabular form in pop-up windows).

If you have multiple designs in the output summary window, the third icon becomes active and can be used to move the order of those columns in the Output Summary.

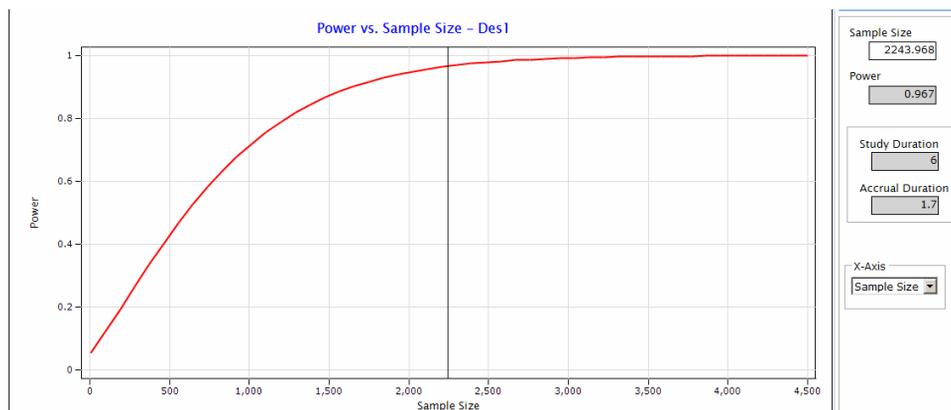

The fourth icon is to print the Output Summary window.

As an example, if you click Power vs. Sample Size under Plot icon, you will get the

43 Tutorial: Survival Endpoint

following chart.

If you want to see the data underlying the above chart, click Show Table icon and click

Power vs. Sample Size. You will see the following table in a pop-up window.

| Range for No. of Events | | | Input |
|-------------------------|------|-----------|-----------------|
| From | To | Step Size | No. of Events |
| 4 | 3200 | 65.2245 | ▼ |
| | | | Tabulate |

| No. of Events | Power_Des1 |
|---------------|------------|
| 4 | 0.0538 |
| 69.224 | 0.1183 |
| 134.449 | 0.1853 |
| 199.673 | 0.2529 |
| 264.898 | 0.3194 |
| 330.122 | 0.3838 |
| 395.347 | 0.4452 |
| 460.571 | 0.503 |
| 525.796 | 0.5568 |
| 591.02 | 0.6065 |
| 656.245 | 0.652 |
| 721.469 | 0.6934 |
| 786.694 | 0.7308 |
| 851.918 | 0.7644 |
| 917.143 | 0.7944 |

You can customize the format of the above table and also save it as case data in a workbook. You may experiment with all the above icon / buttons to understand their functions.

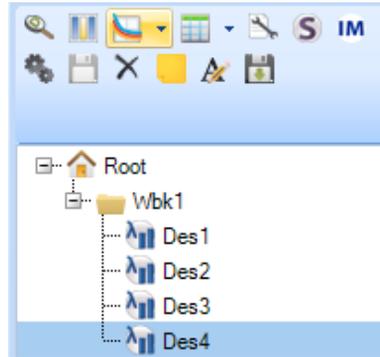

43.2.5 Saving created Designs in the library and hard disk

In the Output Preview pane, select one or more design rows and click the  icon,

The selected design(s) will then get added as a node(s) in the current workbook, as

43 Tutorial: Survival Endpoint

shown below.

The above action only adds the design to the workbook node in the library and it is not saved in the hard disk. For saving in the hard disk, you may either save the entire workbook or only the design by right-clicking on the desired item and choosing save or save as options.

Here in the library also, you see rows of icons.

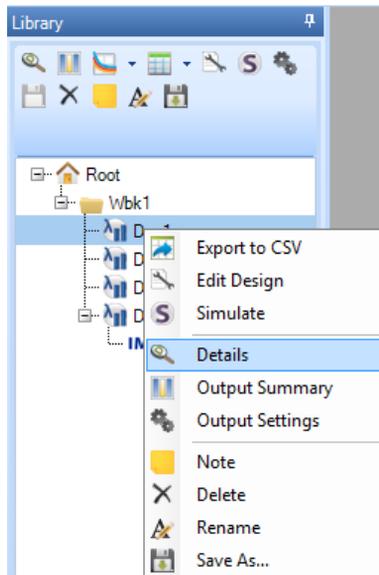

Some of these icons you have already seen. The functions of other icons are:

-  Details (Details of a selected design will appear on the upper pane in the work area)
-  Output Settings (Output Settings can be changed here)
-  Simulate (Start the simulation process for any selected design node)
-  Interim Monitoring (Start the Interim Monitoring process for any selected design)

43.2.6 Displaying Detailed Output

Select the design from the Library and click the  icon or Right-click on the Des1

node in the library and click Details.

You will see the detailed output of the design displayed in the Work area.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

43.2.7 Comparing Multiple Designs

Click on Des1 row and then click Edit icon  . You will get the input dialog box in the upper pane. Change the Power value to 0.8 and then click Compute.

You will see now Des2 is created and a row added to Output Preview pane as shown below.

| Output Preview | | | | | | | | | | | | | | |
|----------------|-------------|--------------|-----------|--------------------|-------|-------|-------------|------------------|------------------|----------------|------------------|------------------|--------------------|----------------------------|
| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | Expected SS (H0) | Expected SS (H1) | Maximum Events | Exp. Events (H0) | Exp. Events (H1) | Comm. Accr. (Dur.) | Exp. Accrual Duration (H0) |
| Des1 | Superiority | 6 | 2-Sided | 0.05 | 0.9 | 1 | 1642 | 1641.997 | 1641.986 | 1243 | 1233.984 | 903.595 | 1.7 | 1.7 |
| Des2 | Superiority | 6 | 2-Sided | 0.05 | 0.8 | 1 | 1230 | 1229.997 | 1229.995 | 931 | 924.247 | 736.316 | 1.7 | 1.7 |

Click on Des1 row and then keeping Ctrl key pressed, click on Des2 row. Now both the rows will be selected. Next, click the Output Summary icon  .

Now you will see the output details of these two designs displayed in the upper pane Compare Designs in juxtaposed columns, as shown below.

| | Des 1 | Des 2 |
|---|--------------------|--------------------|
| Power | 0.9 | 0.8 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Hazard Ratio (Alt.) | 0.83 | 0.83 |
| Var (Log HR) | Null | Null |

| Expected Under H0 | 5.359 | 5.358 |
| Expected Under H1 | 3.729 | 4.207 |
| Accrual Duration | | |
| Maximum | 1.7 | 1.7 |
| Expected Under H0 | 1.7 | 1.7 |
| Expected Under H1 | 1.7 | 1.7 |

In a similar way, East allows the user to easily create multiple designs by specifying a range of values for certain parameters in the design window. For example, in a survival trial the **Logrank Test given Accrual Duration and Study Duration** design allows the input of multiple key parameters at once to simultaneously create a number of different designs. For example, suppose in a multi-look study the user wants to generate designs for all combinations of the following parameter values: **Power** = 0.8 and 0.9, and **Hazard Ratio - Alternative** = 0.6, 0.7, 0.8 and 0.9. The number of combinations is 2 x 4 = 8. East creates all permutations using only a single specification under the **Design Parameters** tab in the design window. As shown below, the values for **Power** are entered as a list of comma separated values, while the alternative hazard ratios are entered as a colon separated range of values, 0.6 to 0.9 in

43 Tutorial: Survival Endpoint

steps of 0.1.

East computes all 8 designs and displays them in the **Output Preview** window:

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Sample Size | Expected SS (H0) | Expected SS (H1) | Maximum Events | Exp. Events (H0) | Exp. Events (H1) | Comm. Accr. (Dur.) | Exp. Accrual Duration (H0) |
|-------|-------------|--------------|-----------|--------------------|-------|-------|-------------|------------------|------------------|----------------|------------------|------------------|--------------------|----------------------------|
| Des3 | Superiority | 6 | 2-Sided | 0.05 | 0.801 | 1 | 125 | 124.489 | 111.053 | 124 | 123.101 | 98.054 | 22 | 21.91 |

East provides the capability to analyze multiple designs in ways that make comparisons between the designs visually simple and efficient. To illustrate this, a selection of a few of the above designs can be viewed simultaneously in both the **Output Summary** section as well as in the various tables and plots. The following is a subsection of the designs computed from the above example with differing values for number of looks, power and hazard ratio. Designs are displayed side by side, allowing

details to be easily compared:

| | Des3 | Des4 | Des5 | Des6 |

Save as Case Data

Power vs. Sample Size (plot)

Total Sample Size / Events vs. Time (plot)

This capability allows the user to explore a greater space of possibilities when determining the best choice of study design.

43.2.8 Events vs. Time plot

For survival studies, East provides a variety of charts and plots to visually validate and

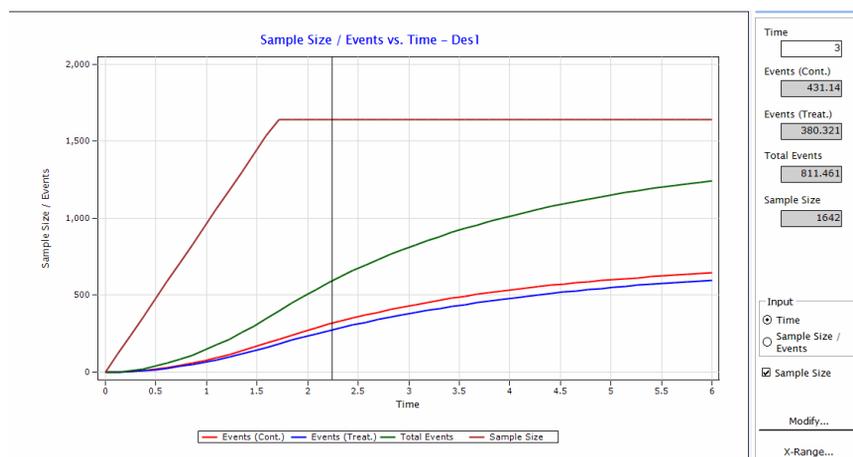

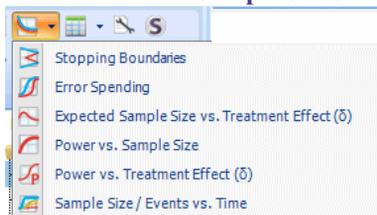

43 Tutorial: Survival Endpoint

analyze the design. For example, the **Sample Size / Events vs. Time** plot allows the user to see the rate of increase in the number of events (control and treatment) over time (accrual duration, study duration). An additional feature of this particular chart is that a user can easily update key input parameters to determine how multiple different scenarios can directly impact a study. This provides significant benefits during the design phase, as the user can quickly examine how a variety of input values affect a study before the potentially lengthy task of simulation is employed.

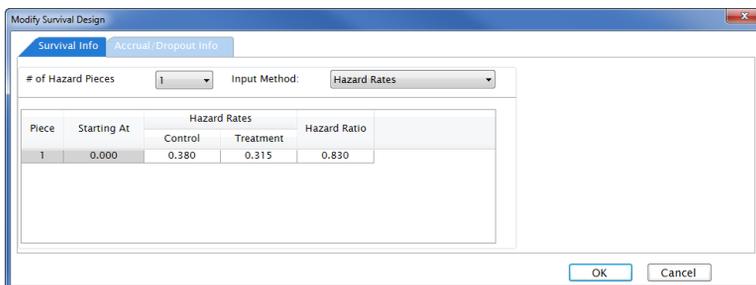

To illustrate this feature what follows is the example from the RALES study. For study details, refer to subsection **Background Information on the study** of this tutorial.

Currently there are ten designs in the **Output Preview** area. Select Des1 from them and save it to the current workbook. You may delete the remaining ones at this point.

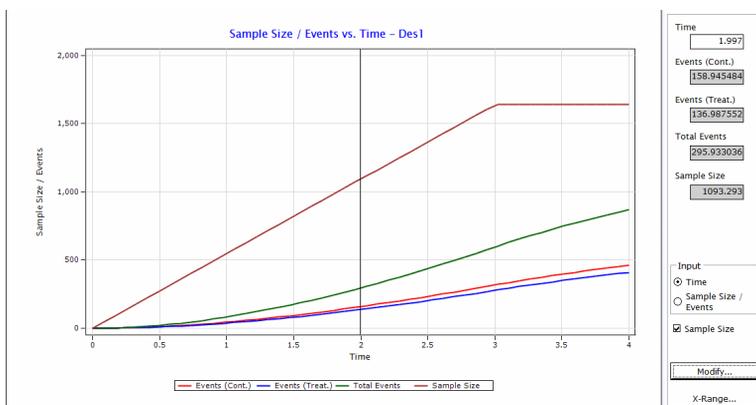

To view the **Sample Size / Events vs. Time** plot, select the corresponding node in the **Library** and under the **Charts** icon choose **Sample Size / Events vs. Time**:

Survival parameters for this design can be edited directly through this chart by clicking the **Modify** button. The **Modify Survival Design** window is then displayed for the user to update design parameters:

To illustrate the benefit of the modification feature, suppose at design time there is potential flexibility in the accrual and duration times for the study. To see how this may affect the number of subsequent events, modify the design to change the **Accrual Duration** to 3 and **Study Duration** to 4. Re-create the plot to view the effect of these new values on the shape and magnitude of the curves by clicking **OK**:

Similar steps can be taken to observe the effect of changing other parameter values on the number of events necessary to adequately power a study.

43 Tutorial: Survival Endpoint

43.2.9 Simulation

In the library, right-click on the node **Des1** and click **Simulate**. You will be presented with the following Simulation sheet.

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Number of Looks: 6

Test Parameters | Response Generation | Accrual / Dropouts | Simulation Controls

Trial Type: Superiority
 Test Type: 2-Sided
 Fix at Each Look: Total No. of Events
 Total No. of Events: 1243

Test Statistic: Logrank

| Look # | Info. Fraction | Cum. α Spent | | Efficacy Z | |
|--------|----------------|---------------------|-------|------------|--------|
| | | Upper | Lower | Upper | Lower |
| 1 | 0.167 | 0.000 | 0.000 | 5.369 | -5.369 |
| 2 | 0.333 | 0.000 | 0.000 | 3.712 | -3.712 |
| 3 | 0.500 | 0.002 | 0.002 | 2.968 | -2.968 |
| 4 | 0.667 | 0.006 | 0.006 | 2.538 | -2.538 |
| 5 | 0.833 | 0.014 | 0.014 | 2.252 | -2.252 |

This sheet has four tabs - Test Parameters, Response Generation, Accrual/Dropout, and Simulation Controls. Additionally, you can click **Include Options** and add some more tabs like Site, Randomization, User Defined R Function and Stratification. The first three tabs essentially contain the details of the parameters of the design. In the Simulation Control tab, you can specify the number of simulations to carry out and specify the file for storing simulation data. Let us first carry out 1000 simulations to check whether the design can reach the specified power of 90%. The Response Generation tab, by default, shows the hazard rates for control and treatment. We will use these values in our simulation.

Survival Information

of Hazard Pieces: 1 | Input Method: Hazard Rates

| Hazard Rate | | Hazard Ratio |
|-------------|-----------|--------------|
| Control | Treatment | |
| 0.38 | 0.315 | 0.83 |

In the Simulation Control tab, specify the number of simulations as 1000. Use the

Random number seed as Fixed 12345.

Let us keep the values in other tabs as they are and click **Simulate**. The progress of simulation process will appear in a temporary window as shown below.

43 Tutorial: Survival Endpoint

In the top row, you see a few icons. For now, we will discuss only the first icon [Enter Interim Data](#) which represents Test Statistic Calculator. Using this calculator, you will enter the details of interim look data analysis results into the IM dashboard.

Suppose we have the following data used by the Data Monitoring Committee during the first 5 looks of interim monitoring.

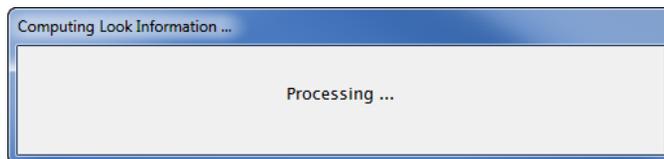

| Date | Total Deaths | $\hat{\delta}$ | SE($\hat{\delta}$) | Z-Statistic |
|--------|--------------|----------------|----------------------|-------------|
| Aug 96 | 125 | -0.283 | 0.179 | -1.581 |
| Mar 97 | 299 | -0.195 | 0.116 | -1.681 |
| Aug 97 | 423 | -0.248 | 0.097 | -2.557 |
| Mar 98 | 545 | -0.259 | 0.086 | -3.012 |
| Aug 98 | 670 | -0.290 | 0.077 | -3.766 |

The first look was taken at 125 events and the analysis of the data showed the value of $\hat{\delta} = -0.283$ and $SE(\hat{\delta}) = 0.179$. First, click the blank row in the IM Dashboard and then click the [Enter Interim Data](#) icon. Now you can enter the first analysis results into the TS calculator and click Recalc. The Test Statistic value will be computed and the TS

calculator will appear as shown below.

Now click on the button 'OK' to get the first look details into IM Dashboard. The following message will appear that some required computations are being carried out.

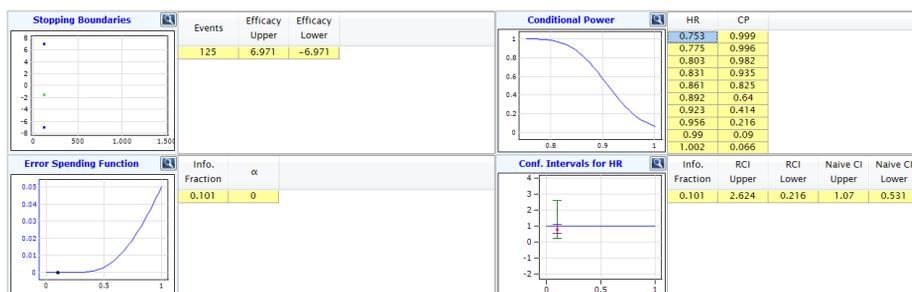

After the computations are over, the output for the first look will appear in the IM

43 Tutorial: Survival Endpoint

Dashboard as shown below.

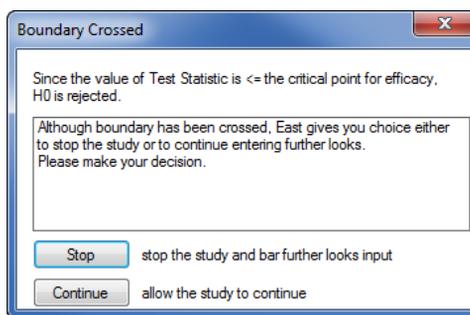

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of HR | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for HR | | 95% RCI for δ | | Repeat... p-value | CP | Predicti... Power |
|--------|----------------------|-------------------|----------------|------------|------------------|--------------------------------|----------|--------|----------------|-------|----------------------|--------|-------------------|-------|-------------------|
| | | | | | | | Upper | Lower | Upper | Lower | Upper | Lower | | | |
| 1 | 0.101 | 125 | -1.581 | 0.754 | -0.283 | 0.179 | 6.971 | -6.971 | 2.624 | 0.216 | 0.965 | -1.531 | 1 | 0.999 | 0.853 |
| 2 | | | | | | | | | | | | | | | |
| 3 | | | | | | | | | | | | | | | |
| 4 | | | | | | | | | | | | | | | |
| 5 | | | | | | | | | | | | | | | |
| 6 | | | | | | | | | | | | | | | |

For the first look at total number of events, 125, the Information Fraction works out to be 0.101. The efficacy boundaries for this information fraction are newly computed. The Repeated 95% Confidence Interval limits and Repeated p-value are computed and displayed. You may also see that the charts at the bottom of the IM Dashboard have been updated with relevant details appearing on the side.

In a similar way, enter the interim analysis results for the next 4 looks in the IM Dashboard.

At the fifth look, the boundary is crossed. A message window appears as shown below.

Click Stop and you will see the details of all the looks in the IM Dashboard as shown below.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of HR | Est. of δ | Std. Error of Est. of δ | Efficacy | | 95% RCI for HR | | 95% RCI for δ | | Repeat... p-value | CP | Predicti... Power |

| 3 | 0.34 | 423 | -2.557 | 0.78 | -0.248 | 0.097 | 3.672 | -3.672 | 1.114 | 0.547 | 0.108 | -0.604 | 0.212 | 0.999 | 0.962 |
| 4 | 0.438 | 545 | -3.012 | 0.772 | -0.259 | 0.086 | 3.206 | -3.206 | 1.017 | 0.586 | 0.017 | -0.535 | 0.069 | 1 | 0.993 |
| 5 | 0.539 | 670 | -3.766 | 0.748 | -0.29 | 0.077 | 2.872 | -2.872 | 0.933 | 0.6 | -0.069 | -0.511 | 0.008 | NA | NA |

The final Adjusted Inference output also appears as displayed below.

| Final Inference | |
|--|--------|
| Final Outputs at Look # | 5 |
| Adj. p-value | 0.001 |
| Adj. Pt. Est. for HR | 0.767 |
| Adj. 95% CI for HR | |
| Upper Confidence Bound | 0.902 |
| Lower Confidence Bound | 0.655 |
| Adj. Pt. Est. for δ | -0.266 |
| Adj. 95% CI for δ | |
| Upper Confidence Bound | -0.104 |
| Lower Confidence Bound | -0.424 |

One important point to note here is that this study got over almost about 2 years ahead of planned schedule, because of the very favorable interim analysis results.

This completes the Interim Monitoring exercise in this trial.

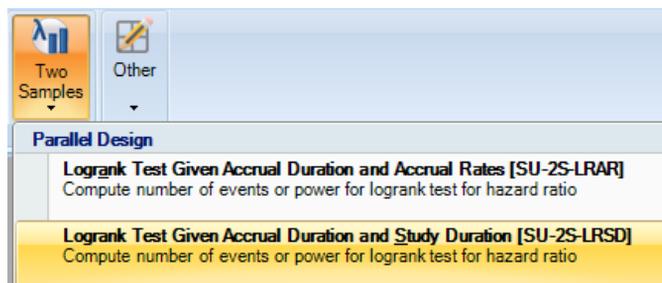

43.3 User Defined R Function

East allows you to customize simulations by inserting user-defined R functions for one or more of the following tasks: generate response, compute test statistic, randomize subjects, generate arrival times, and generate dropout information. The R functionality for arrivals and dropouts will be available only if you have entered such information at the design stage. Although the R functions are also available for all normal and binomial endpoints, we will illustrate this functionality for a time-to-event endpoint. Specifically, we will use an R function to generate Weibull survival responses.

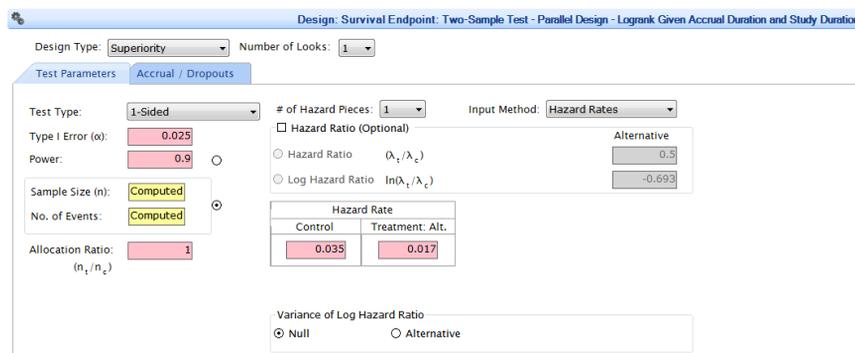

Start East afresh. On the **Design** tab, click **Survival: Two Samples** and then **Logrank**

43 Tutorial: Survival Endpoint

Test Given Accrual Duration and Study Duration.

Choose the design parameters as shown below. In particular, select a one sided test with type-1 error of $\alpha = 0.025$.

Click **Compute** and save this design (Des1) to the **Library**. Right-click Des1 in the **Library** and click **Simulate**. In the **Simulation Control Info** tab, check the box for **Suppress All Intermediate Output**. Type 10000 for **Number of**

Simulations and select **Clock** for **Random Number Seed**.

Test Parameters | Response Generation | Accrual / Dropouts | **Simulation Controls**

Number of Simulations:
 Refresh Frequency:
 Random Number Seed
 Clock
 Fixed
 Suppress All Intermediate Output

Output Options
 Output Type:
 Save summary statistics for every simulation run
 Save subject level data for simulation runs
 Note: Max. 100,000 records will be saved.

In the top right-hand corner for the input window, click **Include Options**, and then click **User Defined R Function**.

Include Options

- Site Info
- Randomization Info
- User Defined R Function
- Stratification Info

Go to the **User Defined R Function** tab. For now, leave the box **Initialize R simulation (optional)** unchecked. This optional task can be used to load required libraries, set seeds for simulations, and initialize global variables.

Select the row for **Generate Response**, click **Browse...**, and navigate to the folder containing your R file. Select the file and click **Open**. The path should now be displayed under **File Name**.

Test Parameters | Response Generation | Accrual / Dropouts | **User Defined R Function** | Simulation Controls

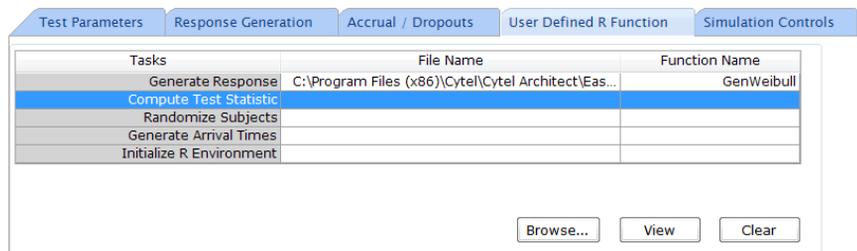

| Tasks | File Name | Function Name |
|--------------------------|---|---------------|
| Generate Response | C:\Program Files (x86)\Cytel\Cytel Architect\Eas... | |
| Compute Test Statistic | | |
| Randomize Subjects | | |
| Generate Arrival Times | | |
| Initialize R Environment | | |

43 Tutorial: Survival Endpoint

Click **View** to open a notepad application to view your R file. In this example, we are generating survival responses for both control and treatment arms from a Weibull with shape parameter = 2 (i.e. exponential), with the same hazard rate in both arms. This sample file is available in the folder named **R Samples** under installation directory of East 6.

```
SurvivalWeibull.r - Notepad
File Edit Format View Help
GenWeibull <- function(NumSub, NumArm, TreatmentID, SurvMethod, NumPrd, PrdTime, SurvParam)
{
  time <- c()
  null.rate <- SurvParam[1,1]
  for(m in 1:NumSub)
  {
    j <- TreatmentID[m]
    time[m] <- rweibull(n=1, shape=2, scale=1 / null.rate)
  }
  return(list(SurvivalTime = as.double(time), ErrorCode = as.integer(0)) )
}
```

Copy the function name (in this case *GenWeibull*) and paste it into the cell for **Function Name**. Save and close the R file, and click **Simulate**.

Return to the tab for **User Defined R Function**, select the **Generate Response** row, and click **View**. In the R function, change the shape parameter = 1, to generate responses from a Weibull distribution with increasing hazards. Save and close the R

file, and click **Simulate**. You may have to save this file on some other location.

```
SurvivalWeibull.r - Notepad
File Edit Format View Help
GenWeibull <- function(NumSub, NumArm, TreatmentID, SurvMethod, NumPrd, PrdTime, SurvParam)
{
  time <- c()
  null.rate <- SurvParam[1,1]
  for(m in 1:NumSub)
  {
    j <- TreatmentID[m]
    time[m] <- rweibull(n=1, shape=1, scale=1 / null.rate)
  }
  # time[m] <- rweibull(n=1, shape=1, scale=1 / SurvParam[1, j+1])
  return(list(SurvivalTime = as.double(time), ErrorCode = as.integer(0)) )
}
```

Select both simulations (Sim1 and Sim2) from the **Output Preview**, and on the toolbar, click  to display in the **Output Summary**.

| | Sim1 | Sim2 |
|-------------------------------------|--------------------|--------------------|
| Mnemonic | SU-2S-LRSD | SU-2S-LRSD |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| Test Type | 1-Sided | 1-Sided |
| Power | 0.027 | 0.026 |
| No. of Looks | 1 | 1 |
| Test Statistic | Logrank | Logrank |
| Model Parameters | | |
| No. of Hazard Pieces | 1 | 1 |
| Hazard Ratio | 0.5 | 0.5 |
| Sample Size | | |
| Maximum | 182 | 182 |
| Events | | |
| Maximum | 88 | 88 |
| Simulation Results (Overall) | | |
| Average Study Duration | 34.624 | 30.708 |
| Average Sample Size | 182 | 182 |
| Other Parameters | | |
| Subjects Followed-up | Until End of Study | Until End of Study |

Notice that the type-1 error appears to be controlled in both cases. When we simulated from the exponential (Sim2), the average study duration (30.7 months) was close to what was calculated at Des1 for the expected study duration under the null. However, when we simulated from the Weibull with decreasing hazards (Sim1), the average study duration increased to 34.6 months.

43 *Tutorial: Survival Endpoint*

The ability to use custom R functions for many simulation tasks allows considerable flexibility in performing sensitivity analyses and assessment of key operating characteristics.

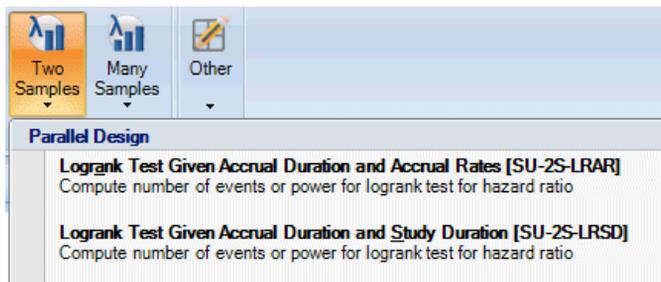

44 Superiority Trials with Variable Follow-Up

This chapter will illustrate through a worked example how to design, monitor and simulate a two-sample superiority trial with a time-to-event trial endpoint. Each subject who has not dropped out or experienced the event is followed until the trial ends. This implies that a subject who is enrolled earlier could potentially be followed for a longer time than a subject who is enrolled later on in the trial. In East we refer to such designs as **variable follow-up designs**.

44.1 The RALES Clinical Trial: Initial Design

The RALES trial (Pitt et al., 1999) was a double blind study of aldosterone-receptor blocker spironolactone at a daily dose of 25 mg in combination with standard doses of an ACE inhibitor (treatment arm) versus standard therapy of an ACE inhibitor (control arm) in patients who had severe heart failure as a result of systolic left ventricular dysfunction. The primary endpoint was death from any cause. Six equally-spaced looks at the data using the Lan-DeMets-O'Brien-Fleming spending function were planned. The trial was designed to detect a hazard ratio of 0.83 with 90% power at a two-sided 0.05 level of significance. The hazard rate of the control arm was estimated to be 0.38/year. The trial was expected to enroll 960 patients/year.

We begin by using East to design RALES under these basic assumptions. Open East, click **Design** tab and then **Two Samples** button in **Survival** group. You will see the following screen.

Note that there are two choices available in the above list; **Logrank Test Given Accrual Duration and Accrual Rates** and **Logrank Test Given Accrual Duration and Study Duration**. The option **Logrank Test Given Accrual Duration and Study Duration** is explained later in Chapter 48. Now click **Logrank Test Given Accrual**

44 Superiority Trials with Variable Follow-Up

Duration and Accrual Rates and you will get the following input dialog box.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Design Type: Superiority Number of Looks: 1

Test Parameters Accrual / Dropouts

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Hazard Rates

Type I Error (α): 0.025

Power: 0.9

No. of Events: Computed

Allocation Ratio: 1
(n_1/n_2)

Hazard Ratio (Optional) Alternative

Hazard Ratio (λ_t/λ_c) 0.5

Log Hazard Ratio $\ln(\lambda_t/\lambda_c)$ -0.693

| Hazard Rate | |
|-------------|-----------------|
| Control | Treatment: Alt. |
| 0.035 | 0.017 |

Variance of Log Hazard Ratio

Null Alternative

Assurance (Probability of Success)

In the above dialog box, enter 6 for **Number of Looks**, keep the default choices of **Design Type: Superiority**, change the **Test Type to 2-Sided**, **Type I Error (α) to 0.05**, **Power : 0.9**, and the **Allocation Ratio: 1**.

Further, keep the default choices of **# of Hazard Pieces** as 1 and the **Input Method:** as **Hazard Rates**. Click the check box against **Hazard Ratio** and enter the **Hazard Ratio** as 0.83. Enter **Hazard Rate (Control)** as 0.38. You will see the **Hazard Rate (Treatment:Alt)** computed as 0.3154. Also, keep the **Variance of Log Hazard Ratio** to be used as under **Null**. Now the **Test Parameters** tab of the input

dialog will appear as shown below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Design Type: Superiority Number of Looks: 6

Test Parameters Boundary Accrual / Dropouts

Test Type: 2-Sided # of Hazard Pieces: 1 Input Method: Hazard Rates

Type I Error (α): 0.05
 Power: 0.9
 No. of Events: Computed
 Allocation Ratio: 1
 (n_1/n_2)

Hazard Ratio (Optional) Alternative
 Hazard Ratio (λ_1/λ_2) 0.83
 Log Hazard Ratio $\ln(\lambda_1/\lambda_2)$ -0.186

| Hazard Rate | |
|-------------|-----------------|
| Control | Treatment: Alt. |
| 0.38 | 0.315 |

Variance of Log Hazard Ratio
 Null Alternative

Assurance (Probability of Success)

Now click on the tab **Boundary**. You will see the following input dialog box.

Design Parameters Boundary Info Accrual / Dropout Info

Efficacy
 Boundary Family: Spending Functions
 Spending Function: Lan-DeMets
 Parameter: OF
 Type I Error (α): 0.05

Futility
 Boundary Family: None

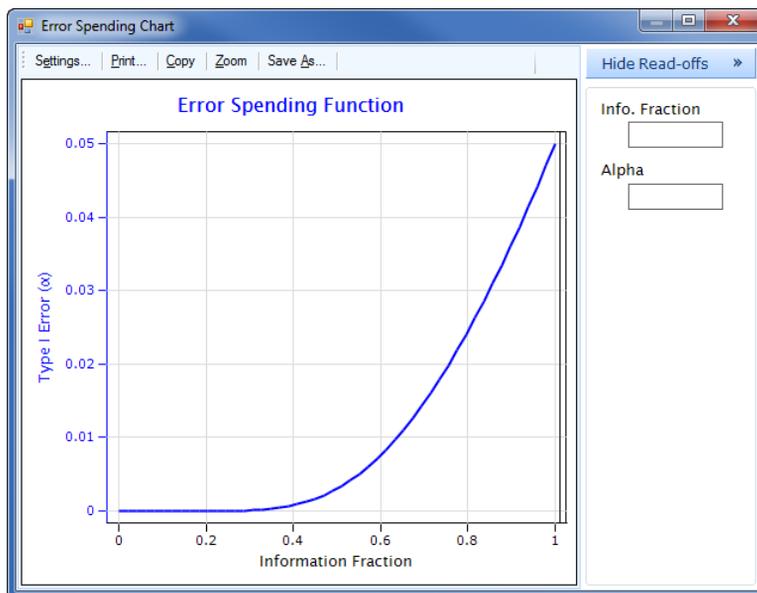

Spacing of Looks Equal Unequal Efficacy Boundary: Z Scale

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.167 | 0.000 | 5.367 | -5.367 |
| 2 | 0.333 | 0.000 | 3.710 | -3.710 |
| 3 | 0.500 | 0.003 | 2.970 | -2.970 |
| 4 | 0.667 | 0.012 | 2.539 | -2.539 |
| 5 | 0.833 | 0.028 | 2.252 | -2.252 |

Keep all the default specifications for the boundaries to be used in the design. You can

44 Superiority Trials with Variable Follow-Up

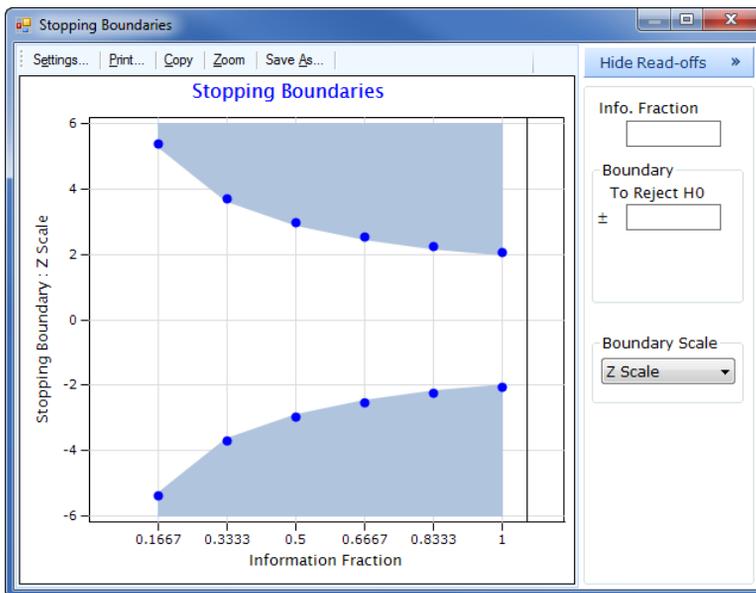

look at the Error Spending Chart by clicking on the icon 

Close this chart.

If you click on the boundary chart icon , you will see the boundary chart as

displayed below.

Close this chart.

Now click **Accrual/Dropouts** tab. Keep the default choice **Until End of Study** for the input **Subjects are followed:**. Keep the **# of Accrual Periods** as 1 and enter 960/year as the accrual rate. For this example, assume no dropouts. The dialog box

44 Superiority Trials with Variable Follow-Up

will look as shown below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Design Type: Superiority Number of Looks: 6

Test Parameters Boundary Accrual / Dropouts

Subjects are followed: Until End of Study

Accrual Info

of Accrual Periods: 1

Accrual Rate: 960

Piecewise Dropout Information

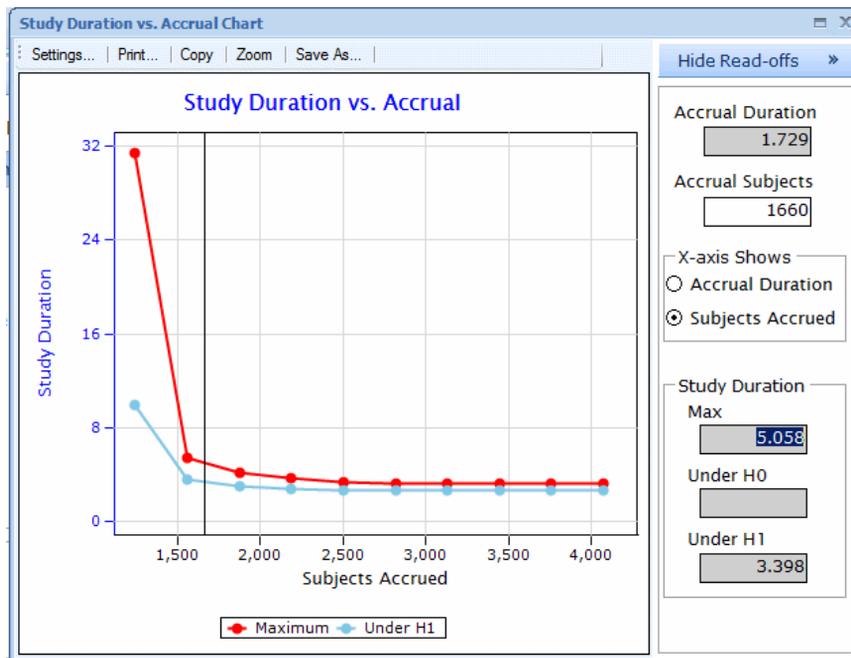

of Pieces: 0

Accrual

| | Min. | Comtd. | Sugg. Max. |
|--|-------|--------|------------|
| <input type="radio"/> Duration: | 1.295 | 2.268 | 3.241 |
| <input checked="" type="radio"/> Subjects: | 1243 | 2177 | 3111 |

Under the **Accrual** section and in column titled **Comtd.** (committed), you see two radio buttons **Durations** and **Subjects** with the latter selected by default. The selected item will appear as the x-axis item in the **Study Duration vs. Accrual** chart, which you can get by clicking on the icon displayed on the side. Against **Durations** and **Subjects** you see two rows of three cells each. The first and third cells will show the min and max values for the row item and the middle cell, mid value between min and max values. From these results, you see that any sample size in the range 1243 to 3111 will suffice to attain the desired 90% power and selects 2177, the mid-point of the allowable range, as the default sample size. Depending on the needs of the study, you may wish to use a different sample size within the allowable range. The choice of sample size generally depends on how long you wish the study to last. The larger you make the patient accrual the shorter will be the total study duration, consisting of accrual time plus follow up time. To understand the essence of this trade-off, bring up

the **Study Duration vs. Accrual** chart by clicking on the icon  .

Based on this chart, a sample size of 1660 subjects is selected. Close the chart and enter 1660 for **Committed Accrual (subjects)**. Click on **Compute** and see the results in the new design created under **Output Preview**. Click the  icon to see the design summary. This sample size ensures that the maximum study duration will be slightly more than 4.9 years. Additionally, under the alternative hypothesis, the

44 Superiority Trials with Variable Follow-Up

expected study duration will be only about 3.3 years.

| Sample Size | |
|-------------------|----------|
| Maximum | 1660 |
| Expected Under H0 | 1659.987 |
| Expected Under H1 | 1659.985 |
| Events | |
| Maximum | 1243 |
| Expected Under H0 | 1233.984 |
| Expected Under H1 | 903.595 |
| Study Duration | |
| Maximum | 4.905 |
| Expected Under H0 | 4.506 |
| Expected Under H1 | 3.337 |
| Accrual Duration | |
| Maximum | 1.729 |
| Expected Under H0 | 1.729 |
| Expected Under H1 | 1.729 |

44.2 Incorporating Drop-Outs

The investigators expect 5% of the patients in both the groups to drop out each year. To incorporate this drop-out rate into the design, in the **Piecewise Constant Dropout Rates** tab, select 1 for the number of pieces and change the Input Method from **Hazard Rates** to **Prob. of Dropout**. Then enter 0.05 as the probability of dropouts at 1 year for both the groups.

Piecewise Dropout Information

of Pieces: Input Method:

By Time:

Prob. of Dropout (Control)

Prob. of Dropout (Treatment)

Note: Period 1 hazard rates apply after time 1.

To make Des1 and Des2 comparable, change the sample size of Des2 to 1660 by

typing this value into the **Committed Accrual (Subjects)** cell. Click on **Compute** and see the results in the new design created under **Output Preview**. Select the two designs and click on  icon to see them side-by-side.

| | Des1 | Des2 |
|---|--------------------|--------------------|
| Mnemonic | SU-2S-LRAR | SU-2S-LRAR |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 6 | 6 |
| Test Type | 2-Sided | 2-Sided |
| Specified α | 0.05 | 0.05 |
| Power | 0.9 | 0.9 |
| Model Parameters | | |
| Hazard Ratio (Alt.) | 0.83 | 0.83 |
| Var (Log HR) | Null | Null |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Boundary Parameters | | |
| Spacing of Looks | Equal | Equal |
| Efficacy Boundary | LD (OF) | LD (OF) |
| Accrual & Dropout Parameters | | |
| Accrual Rate | 960 | 960 |
| Subjects are Followed | Until End of Study | Until End of Study |
| No. of Accrual Periods | 1 | 1 |
| No. of Dropout Pieces | 0 | 1 |
| Sample Size | | |
| Maximum | 1660 | 1660 |
| Expected Under H0 | 1659.987 | 1659.992 |
| Expected Under H1 | 1659.985 | 1659.986 |
| Events | | |
| Maximum | 1243 | 1243 |
| Expected Under H0 | 1233.984 | 1233.984 |
| Expected Under H1 | 903.595 | 903.595 |
| Study Duration | | |
| Maximum | 4.905 | 5.87 |
| Expected Under H0 | 4.506 | 5.258 |
| Expected Under H1 | 3.337 | 3.687 |
| Accrual Duration | | |
| Maximum | 1.729 | 1.729 |
| Expected Under H0 | 1.729 | 1.729 |
| Expected Under H1 | 1.729 | 1.729 |

A comparison of two designs reveals that, because of the drop-outs, the maximum study duration will be prolonged from 4.9 years under Des1 to 5.9 years under Des2. The expected study duration will likewise be prolonged from 3.3 years to 3.7 years under the alternative hypothesis, and from 4.5 years to 5.3 years under the null hypothesis.

44 Superiority Trials with Variable Follow-Up

44.3 Incorporating Non-Constant Accrual Rates

In many clinical trials, the enrollment rate is low in the beginning and reaches its maximum expected level a few months later when all the sites enrolling patients have been recruited. Suppose that patients are expected to enroll at an average rate of 400/year for the first six months and at an average rate of 960/year thereafter. Click on

the **Input** icon on the bottom of your screen to go back to the input window of Des2. Now in **Accrual** section, specify that there are two accrual periods and enter the accrual rate for each period in the dialog box as shown below.

Accrual Info

of Accrual Periods:

| Period # | Starting At | Accrual Rate |
|----------|-------------|--------------|
| 1 | 0 | 400.000 |
| 2 | 0.5 | 960.000 |

Accrual

| | | | | |
|--|------------------------------------|------------------------------------|------------------------------------|--|
| | Min. | Comtd. | Sugg. Max. | |
| <input type="radio"/> Duration: | <input type="text" value="1.779"/> | <input type="text" value="2.021"/> | <input type="text" value="3.618"/> | |
| <input checked="" type="radio"/> Subjects: | <input type="text" value="1428"/> | <input type="text" value="1660"/> | <input type="text" value="3193"/> | |

Once again let the sample size be 1660 to make Des3 comparable to the other two designs. Click on **Compute** to complete the design. Select all the three designs in the

Output Preview area and click on  icon to see them side-by-side.

| | Des1 | Des2 | Des3 |
|---|--------------------|--------------------|--------------------|
| Mnemonic | SU-2S-LRAR | SU-2S-LRAR | SU-2S-LRAR |

| Accrual & Dropout Parameters | | | |
| Accrual Rate | 960 | 960 | Multiple |
| Subjects are Followed | Until End of Study | Until End of Study | Until End of Study |
| No. of Accrual Periods | 1 | 1 | 2 |
| No. of Dropout Pieces | 0 | 1 | 1 |
| Sample Size | | | |
| Maximum | 1660 | 1660 | 1660 |
| Expected Under H0 | 1659.987 | 1659.992 | 1659.99 |
| Expected Under H1 | 1659.985 | 1659.986 | 1659.985 |
| Events | | | |
| Maximum | 1243 | 1243 | 1243 |
| Expected Under H0 | 1233.984 | 1233.984 | 1233.984 |
| Expected Under H1 | 903.595 | 903.595 | 903.595 |
| Study Duration | | | |
| Maximum | 4.905 | 5.87 | 6.15 |
| Expected Under H0 | 4.506 | 5.258 | 5.538 |
| Expected Under H1 | 3.337 | 3.687 | 3.966 |
| Accrual Duration | | | |
| Maximum | 1.729 | 1.729 | 2.021 |
| Expected Under H0 | 1.729 | 1.729 | 2.021 |
| Expected Under H1 | 1.729 | 1.729 | 2.021 |

Notice that the enrollment period has increased from 1.7 years to 2 years. Likewise, the maximum study duration and the expected study durations under H_0 and H_1 have also increased relative to Designs 1 and 2. Now the maximum study duration is 6.15 years.

44.4 Incorporating Piecewise Constant Hazards

Prior studies had suggested that the survival curves might not follow an exponential distribution. Suppose it is believed that the hazard rate for failure on the control arm decreases after the first 12 months from 0.38 to 0.35. We will assume that the hazard ratio is still 0.83. We can enter the appropriate piecewise hazard rates into East as

follows. Click on  icon on the bottom of your screen to go back to

44 Superiority Trials with Variable Follow-Up

the input window and go to **Test Parameters** tab.

of Hazard Pieces: Input Method:

Hazard Ratio

Hazard Ratio (λ_t / λ_c) Alternative

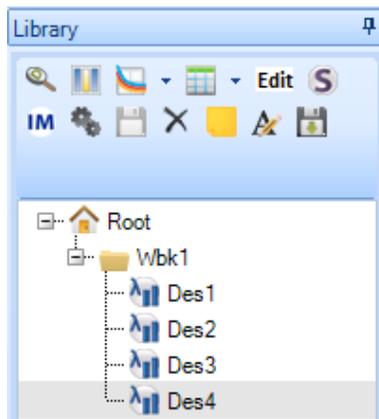

Log Hazard Ratio $\ln(\lambda_t / \lambda_c)$

| Period # | Starting at Time | Hazard Rate (Control) | Hazard Rate (Treatment: Alt.) |
|----------|------------------|-----------------------|-------------------------------|
| 1 | 0.000 | 0.38 | 0.315 |
| 2 | 1.000 | 0.35 | 0.291 |

Change the sample size to 1660 on **Accrual/Dropouts** tab for comparability with the previous designs. Click on **Compute** and see the results of the design in the **Output Summary** mode.

| Expected Under H1 | 3.337 | 3.687 | 3.966 | 4.136 |
| Accrual Duration | | | | |
| Maximum | 1.729 | 1.729 | 2.021 | 2.021 |
| Expected Under H0 | 1.729 | 1.729 | 2.021 | 2.021 |
| Expected Under H1 | 1.729 | 1.729 | 2.021 | 2.021 |

We observe that the impact of changing from a constant hazard rate to a piecewise constant hazard rate is substantial. The maximum study duration has increased from 6.15 years for Des3 to 6.56 years for Des4. Before proceeding further, save all the four designs in the workbook.

44.5 Simulating a Trial with Proportional Hazards

44.5.1 Simulation Worksheet

44.5.2 Simulating Under H_1

44.5.3 Simulating...

It would be useful to verify the operating characteristics of the various designs created in the previous section by simulation. The new survival simulation capabilities in East permit this. Let us use these capabilities to simulate Des4. Save this design in the workbook. Right-click on this design node and select the menu item **Simulate**. You'll see the following **Survival Simulation** worksheet.

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Number of Looks: 6

Test Parameters | Response Generation | Accrual / Dropouts | Simulation Controls

Trial Type: Superiority
 Test Type: 2-Sided
 Fix at Each Look: Total No. of Events
 Total No. of Events: 1243

Test Statistic: Logrank

| Look # | Info. Fraction | Cum. α Spent | | Efficacy Z | |
|--------|----------------|--------------|-------|------------|--------|
| | | Upper | Lower | Upper | Lower |
| 1 | 0.167 | 0.000 | 0.000 | 5.369 | -5.369 |
| 2 | 0.333 | 0.000 | 0.000 | 3.712 | -3.712 |
| 3 | 0.500 | 0.002 | 0.002 | 2.968 | -2.968 |
| 4 | 0.667 | 0.006 | 0.006 | 2.538 | -2.538 |
| 5 | 0.833 | 0.014 | 0.014 | 2.252 | -2.252 |

44.5.1 Components of the Simulation Worksheet

This simulation worksheet consists four tabs - **Test Parameters**, **Response Generation**, **Accrual/Dropouts**, and **Simulation Controls**. The **Test Parameters** tab displays all the parameters of the simulation. If desired, you may modify one or more

44 Superiority Trials with Variable Follow-Up

of these parameter values before carrying out simulation. The second tab **Response Generation** will appear as shown below.

Survival Information

of Hazard Pieces: 2 Input Method: Hazard Rates

Hazard Ratio

| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
|-------|------------------|--------------|-----------|--------------|
| | | Control | Treatment | |
| 1 | 0.000 | 0.380 | 0.315 | 0.830 |
| 2 | 1.000 | 0.350 | 0.291 | 0.830 |

In this tab, you may modify values of response parameters before carrying out simulation. The third tab **Accrual/Dropouts** will display information relating to accrual and dropouts.

Sample Size: 1660
 Total No. of Events: 1243
 Subjects are followed: Until End of Study

Distribution of Accrual Time: Uniform

Accrual Info

of Accrual Periods: 2 Input Method: Accrual Rates

| Period # | Starting at Time | Accrual Rate |
|----------|------------------|--------------|
| 1 | 0 | 400.000 |
| 2 | 0.5 | 960.000 |

Piecewise Dropout Information

of Pieces: 1 Input Method: Prob. of Dropout

By Time: 1

Probability of Dropout - Control: 0.05
 Probability of Dropout - Treatment: 0.05

Note: Period 1 hazard rates apply after time 1.

As in the case of other tabs, you may modify one or more values appearing in this tab before simulation is carried out.

In the **Simulation Controls**, you may specify the simulation parameters like

number of simulations required and the desired simulation seed etc.

The screenshot shows the 'Simulation Controls' tab of a software interface. It contains several input fields and checkboxes. On the left, there are fields for 'Number of Simulations' (10000) and 'Refresh Frequency' (1000). Below these is a 'Random Number Seed' section with radio buttons for 'Clock' (selected) and 'Fixed' (100). Further down are checkboxes for 'Suppress All Intermediate Output', 'Pause after Refresh', and 'Pause at End' (checked). On the right, there is an 'Output Options' section with a dropdown for 'Output Type' (Case Data) and two checkboxes: 'Save summary statistics for every simulation run' and 'Save subject level data for' (1) simulation runs. A note below states 'Note: Max. 100,000 records will be saved.'

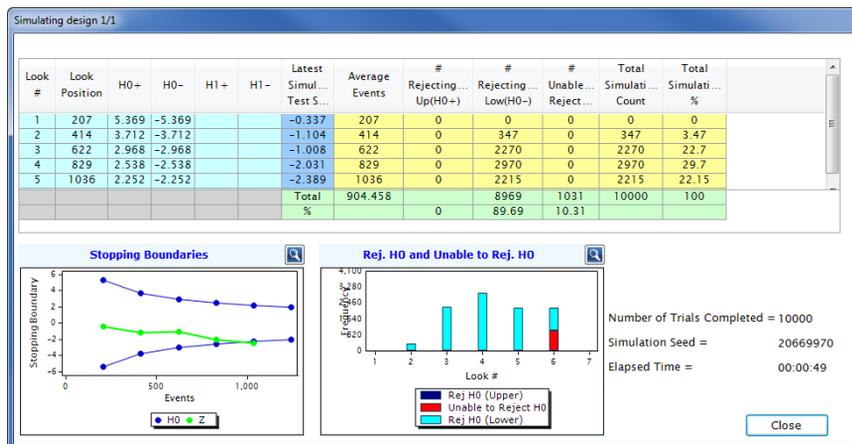

Also optionally, you may bring out one more tab **Randomization** by clicking on **Include Options** button on the right hand top corner. In the **Randomization**, you may alter the allocation ratio of the design before carrying out simulation. The other tabs under the **Include Options** will be discussed elsewhere in this manual.

The screenshot shows the 'Randomization' tab of the software interface. It features a dropdown menu for 'Randomization Method' set to 'Complete Randomized Design' and a text input field for 'Allocation Ratio (n₁/n_c):' with the value '1' entered.

Keeping all the default parameter values same as in the different tabs, click **Simulate**. You can see the progress of the simulation process summarized as shown in the following screen shot. The complete summary of simulations will be displayed

44 Superiority Trials with Variable Follow-Up

at the end of simulations.

Close this window. The simulation results appear in a row in the **Output Preview** as shown below.

| ID | Design Type | No. of Looks | Test Type | Specified α | Power | nt/nc | Spacing of Looks | Efficacy Boundary | Accrual Rate | Sample Size | Expected SS (H0) | Expected SS (H1) | Maximum Events | Average Study Duration | Average Events |
|------|-------------|--------------|-----------|--------------------|-------|-------|------------------|-------------------|--------------|-------------|------------------|------------------|----------------|------------------------|----------------|
| Sim1 | Superiority | 6 | 2-Sided | | 0.897 | 1 | User Specified | User Specified | Multiple | 1660 | | | 1243 | 4.136 | 904.458 |

The output summary can be seen by clicking on the icon  after selecting the

simulation row in the Output Preview.

| | Sim1 |
|---|--------------------|
| Mnemonic | SU-2S-LRAR |
| Test Parameters | |
| Design Type | Superiority |
| Test Type | 2-Sided |
| Power | 0.897 |
| No. of Looks | 6 |
| Test Statistic | Logrank |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| No. of Hazard Pieces | 2 |
| Boundary Parameters | |
| Spacing of Looks | User Specified |
| Efficacy Boundary | User Specified |
| Accrual & Dropout Parameters | |
| Subjects Followed-up | Until End of Study |
| Accrual Rate | Multiple |
| No. of Accrual Periods | 2 |
| Sample Size | |

| % | | | | 0.000% | 89.660% | | |

44.5.2 Simulating Under H_1

Notice that in the above simulations, we did not change anything on the **Response Generation** tab which indicates that we executed 10000 simulations under the designs assumptions or in other words, under alternative hypothesis.

Let us examine these 10000 simulations more closely. The actual values may differ from the manual, depending on the starting seed used.

The column labeled **Events** in the second table, displays the number of events after which each interim look was taken. The column labeled **Avg. Look Time** in the first table, displays the average calendar times at which each interim look was taken. Thus, the first interim look (taken after observing 207 events) occurred after an average elapse of about 1.5 years; the second interim look (taken after observing 414 events) occurred after an average elapse of about 2.1 years; and so on. The remaining columns of the simulation output are self-explanatory. The columns labeled **Stopping For** show that 8966 of the 10000 simulations crossed the lower stopping boundary, thus confirming (up to Monte Carlo accuracy) that this design has 90% power. The detailed output tables also show how the events, drop-outs, accruals, and average follow-up times were observed at each interim analysis.

44.5.3 Simulating Under H_0

To simulate under the null hypothesis we must go back to the input window of Sim1 and then to the **Response Generation** tab. In this pane change the hazard rate for the treatment arm to 0.38 for the first piece and to 0.35 for the second piece of the hazard function.

| Survival Information | | | | |
|---------------------------------------|-------------|----------------------------|-----------|--------------|
| # of Hazard Pieces | 2 | Input Method: Hazard Rates | | |
| <input type="checkbox"/> Hazard Ratio | | | | |
| Piece | Starting At | Hazard Rates | | Hazard Ratio |
| | | Control | Treatment | |
| 1 | 0.000 | 0.380 | 0.38 | 1.000 |
| 2 | 1.000 | 0.350 | 0.35 | 1.000 |

This change implies that we will be simulating under the null hypothesis. Click on the **Simulate** button. A new row in Output Preview will be added now. Select this row and add to the library node. By double-clicking on this node, you will see the detailed simulation output as shown below. The results are displayed below.

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Simulation Boundaries and Incremental Boundary Crossing Probabilities

| Look # | Events | Boundaries Efficacy | | Stopping For | | Total Simulations | |
|--------|--------|---------------------|--------|----------------|----------------|-------------------|---------|
| | | Upper | Lower | Upper Efficacy | Lower Efficacy | Count | % |
| | | | | | | | |
| 2 | 414 | 3.712 | -3.712 | 1 | 2 | 3 | 0.030% |
| 3 | 622 | 2.968 | -2.968 | 15 | 8 | 23 | 0.230% |
| 4 | 829 | 2.538 | -2.538 | 61 | 49 | 110 | 1.100% |
| 5 | 1036 | 2.252 | -2.252 | 80 | 69 | 149 | 1.490% |
| 6 | 1243 | 2.045 | -2.045 | 112 | 120 | 9715 | 97.150% |
| Total | | | | 269 | 249 | 10000 | |
| % | | | | 2.690% | 2.480% | | |

Out of 10000 simulated trials only 27 crossed the upper stopping boundary and 25 crossed the lower stopping boundary thus confirming (up to Monte Carlo accuracy) that the type-1 error is preserved for this design.

44 Superiority Trials with Variable Follow-Up

44.6 Simulating a Trial with Non-Proportional Hazards

44.6.1 Single-Look Design

44.6.2 Single-Look Design

44.6.3 Group Seq. Design

A new agent is to be tested against placebo in a large cardiovascular study with the endpoint being time to stroke, MI or death. The control arm has a 12-month event-free rate of 97%. We wish to design the study to detect a hazard ratio of 0.75 with 90% power, using a two-sided test conducted at the 0.05 level. An important design consideration is that treatment differences are expected to emerge only after one year of therapy. Subjects will enroll at the rate of 1000/month and be followed to the end of the study. The dropout rate is expected to be 10% per year for both treatment arms. Finally, the study should be designed for maximum study duration of 50 months.

The usual design options in East are not directly applicable to this trial because they require the hazard ratio to be constant under the alternative hypothesis. Here, however, we are required to power the trial to detect a hazard ratio of 0.75 that only emerges after patients have been on the study for 12 months. The simulation capabilities of East can help us with the design.

44.6.1 Single-Look Design with Proportional Hazards

We begin by creating a single-look design powered to detect hazard ratio of 0.75, ignoring the fact that the two survival curves separate out only after 12 months. Open a new survival design worksheet by clicking on **Design>Survival>Logrank Test Given Accrual Duration and Accrual Rates**. In the resulting **Test Parameters** tab, enter the parameters values as shown below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Design Type: Superiority Number of Looks: 1

Test Parameters Accrual / Dropouts

Test Type: 2-Sided # of Hazard Pieces: 1 Input Method: Cum. % Survival

Type I Error (α): 0.05

Power: 0.9

No. of Events: Computed

Allocation Ratio: 1 (n_1/n_2)

Hazard Ratio (Optional) Alternative

Hazard Ratio (λ_1/λ_2) 0.75

Ratio of % Survivals at Period # 1 (S_1/S_2) 1.008

| By Time | Cum. % Survival | |
|---------|-----------------|-----------------|
| | Control | Treatment: Alt. |
| 12 | 97 | 97.741 |

Note: Period 1 hazard rates apply after time 12.

Variance of Log Hazard Ratio

Null Alternative

Assurance (Probability of Success)

Click on the tab **Accrual/Dropouts** and enter the values as shown below,

excluding the Accrual tab.

Design Type: Superiority Number of Looks: 1

Test Parameters | **Accrual / Dropouts**

Subjects are followed: Until End of Study

Accrual Info

of Accrual Periods: 1

Accrual Rate: 1000

Piecewise Dropout Information

of Pieces: 1 Input Method: Prob. of Dropout

By Time: 12

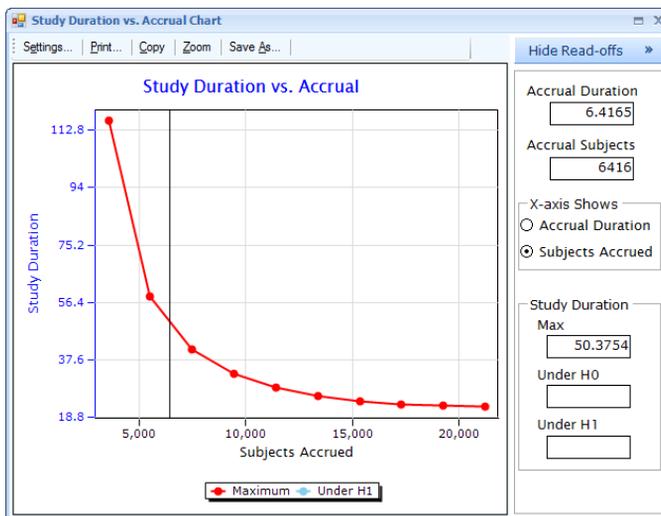

Prob. of Dropout (Control): 0.1

Prob. of Dropout (Treatment): 0.1

Note: Period 1 hazard rates apply after time 12.

| Accrual | Min. | Comtd. | Sugg. Max. |
|--|-------|--------|------------|
| <input type="radio"/> Duration: | 2.524 | 12.392 | 22.26 |
| <input checked="" type="radio"/> Subjects: | 2524 | 12392 | 22260 |

East informs you in the Accrual tab, that any sample size in the range 2524 to 22260 will suffice to attain the desired 90% power. However, the study will end sooner if we enroll more patients. Recall that we wish the trial to last no more than 50 months, inclusive of accrual and follow-up. The **Accrual-Duration** chart can provide guidance on sample size selection. This chart reveals that if 6400 subjects are enrolled, the expected maximum duration of a trial is close to 50 months.

44 Superiority Trials with Variable Follow-Up

Now change the **Comtd.** number of subjects to 6400 and click on **Compute** to complete the design. A new row is added for this design in the Output Preview. Select this row and add it to a library node under a workbook. Now you double-click on this node, you will see the detailed output. A section of it is shown below:

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

| Critical Points | |
|----------------------|------|
| Lower Critical Point | 1.96 |
| Upper Critical Point | 1.96 |

Variable Follow-Up Design: All subjects are followed until failure, drop out or end of study.

We can verify the operating characteristics of Des1 by simulation. With the cursor on Des1 node, Click on Simulation icon from the library menu bar. You'll be taken to the survival simulation worksheet. In the **Simulation Control** tab, specify the number of simulations to be 1000. Now click on **Simulate** button. This will generate 1000 simulations from the survival curves specified in the design. Each simulation will consist of survival data on 6400 subjects entering the trial uniformly at the rate of 1000/month. Events (failures) will be tracked and the simulated trial will be terminated when the total number of events equals 508. Subjects surviving past this termination time point will have their survival times censored. The resulting survival data will be summarized in terms of the logrank test statistic. Each simulation records two important quantities:

- the calendar time at which the last of the specified 508 events arrived;
- whether or not the logrank test statistic rejected the null hypothesis.

We would expect that, on average, the 508 events will occur in about 48.7 months and about 90% of the simulations will reject the null hypothesis. The simulation summary

is shown in the following screen shot.

| | Sim3 |
|---|--------------------|
| Mnemonic | SU-2S-LRAR |
| Test Parameters | |
| Design Type | Superiority |
| Test Type | 2-Sided |
| Power | 0.913 |
| No. of Looks | 1 |
| Test Statistic | Logrank |
| Model Parameters | |
| No. of Hazard Pieces | 1 |
| Hazard Ratio | 0.75 |
| Accrual & Dropout Parameters | |
| Subjects Followed-up | Until End of Study |
| Accrual Rate | 1000 |
| Sample Size | |
| Maximum | 6400 |
| Events | |
| Maximum | 508 |
| Simulation Results (Overall) | |
| Average Study Duration | 48.691 |
| Average Sample Size | 6400 |

Indeed we observe that the average study duration for this set of 1000 simulations was 48.691 months, and that 913 of the 1000 simulated trials crossed the critical value and rejected H_0 and hence the power attained is 0.913. This serves as an independent verification of the operating characteristics of Des1, up to Monte Carlo accuracy.

44.6.2 Single-Look Design with Non-Proportional Hazards

Were it not for the fact that the hazard ratio of 0.75 only emerges after 12 months of therapy, Des1 would meet the goals of this study. However, the impact of the late separation of the survival curves must be taken into consideration. This is accomplished, once again, by simulation. Click the Edit Simulation icon while the cursor is on the last simulation node. In the resulting simulation sheet click on **Response Generation** tab. In this tab, specify that the hazard rates for the control and treatment arms are identical and equal to 0.0025 for the first 12 months and the hazard ratio is 0.75 thereafter. This is done by making appropriate entries in this

44 Superiority Trials with Variable Follow-Up

tab as shown below.

| Survival Information | | | | |
|---------------------------------------|------------------|----------------------------|-----------|--------------|
| # of Hazard Pieces | 2 | Input Method: Hazard Rates | | |
| <input type="checkbox"/> Hazard Ratio | | | | |
| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
| | | Control | Treatment | |
| 1 | 0.000 | 0.0025 | 0.0025 | 1.015 |
| 2 | 12.000 | 0.0025 | 0.0019 | 0.75 |

Click on the **Simulate** button. This will generate 10000 simulations from survival curves specified in the **Survival Parameters Pane**. As before, each simulation will consist of survival data on 6400 subjects entering the trial uniformly at the rate of 1000/month. Events (failures) will be tracked and the simulated trial will be terminated when the total number of events equals 508. The summary output of this simulation

run as shown below.

| | |
|---|--------------------|
| | Sim2 |
| Mnemonic | SU-2S-LRAR |
| Test Parameters | |
| Design Type | Superiority |
| Test Type | 2-Sided |
| Power | 0.522 |
| No. of Looks | 1 |
| Test Statistic | Logrank |
| Model Parameters | |
| No. of Hazard Pieces | 2 |
| Accrual & Dropout Parameters | |
| Followup Duration | Until End of Study |
| Accrual Rate | 1000 |
| No. of Accrual Periods | 1 |
| Sample Size | |
| Maximum | 6400 |
| Events | |
| Maximum | 508 |
| Simulation Results (Overall) | |
| Average Study Duration | 46.962 |
| Average Sample Size | 6400 |
| Average Events | 508 |

This time only 522 of the 1000 trials were able to reject H_0 . The drop in power is of course due to the fact that the two survival curves do not separate out until 12 months have elapsed. Thus events that arise within the first 12 months arrive at the same rate for both arms and are not very informative about treatment differences.

We need to increase the power of the study to 90%. This can be accomplished in one of two ways:

1. Prolonging the study duration until a sufficient number of events are obtained to achieve 90% power.
2. Increasing the sample size.

The first approach cannot be used because the study duration is not permitted to exceed 50 months. The simulations have shown that the study duration is already almost 50 months, and it has only achieved 56.5% power. Thus we must resort to increasing the sample size.

44 Superiority Trials with Variable Follow-Up

Now if we increase the sample size while keeping the total number of events fixed at 508, the average study duration will drop. The power, however, may not increase. In fact it might even decrease since a larger fraction of the 508 events will arise in the first 12 months, before the two survival curves have separated. To see this, increase the sample size from 6400 to 10000 in the **Accrual/Dropouts** tab. Then click on **Simulate** button. From this simulation run, you will get the output summary as shown below.

| | Sim3 |
|---|--------------------|
| Mnemonic | SU-2S-LRAR |
| Test Parameters | |
| Design Type | Superiority |
| Test Type | 2-Sided |
| Power | 0.261 |
| No. of Looks | 1 |
| Test Statistic | Logrank |
| Model Parameters | |
| No. of Hazard Pieces | 2 |
| Accrual & Dropout Parameters | |
| Followup Duration | Until End of Study |
| Accrual Rate | 1000 |
| No. of Accrual Periods | 1 |
| Sample Size | |
| Maximum | 10000 |
| Events | |
| Maximum | 508 |
| Simulation Results (Overall) | |
| Average Study Duration | 29.668 |
| Average Sample Size | 10000 |
| Average Events | 508 |

Notice that the average study duration has dropped to 29.7 months. But the power has dropped also. This time only 261 of the 10000 simulations could reject the null hypothesis.

To increase power we must increase sample size while keeping the study duration fixed at about 50 months. This is accomplished by selecting the **Look Time** option from the drop-down box in the **Fix at Each Look** section of the **Survival Parameters Pane** and choosing a 50 month Total Study Durn., while keeping the

sample size increase from 6400 to 10000.

The screenshot shows a software interface with two tabs: "Test Parameters" and "Response Generation". The "Response Generation" tab is active. Below the tabs, there are four settings:

- Number of Looks: 1 (dropdown menu)
- Trial Type: Superiority (dropdown menu)
- Test Type: 2-Sided (dropdown menu)
- Fix at Each Look: Look Time (dropdown menu)
- Study Duration: 50 (text input field)

We will now run 10000 simulations in each of which 10000 subjects are enrolled at the rate of 1000/year. Each simulated trial will be terminated at the end of 50 months of calendar time and a logrank test statistic will be derived from the data. Click on the **Simulate** button. Add the simulation run output to library node and see the

44 Superiority Trials with Variable Follow-Up

following output summary.

| | Sim4 |
|---|--------------------|
| Mnemonic | SU-2S-LRAR |
| Test Parameters | |
| Design Type | Superiority |
| Test Type | 2-Sided |
| Power | 0.735 |
| No. of Looks | 1 |
| Test Statistic | Logrank |

| Followup Duration | Until End of Study |
| Accrual Rate | 1000 |
| No. of Accrual Periods | 1 |
| Sample Size | |
| Maximum | 10000 |
| Events | |
| Maximum | 810.638 |
| Simulation Results (Overall) | |
| Average Study Duration | 50 |
| Average Sample Size | 10000 |
| Average Events | 810.638 |

For more details, you can click  icon after selecting the saved simulation node.

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

| Simulation Parameters | |
|-------------------------------|-------------|
| Simulation ID | Sim4 |
| Design Type | Superiority |
| Number of Looks | 1 |
| Test Type | 2-Sided |
| Sample Size (n) | 10000 |
| Fix at Each Look | Look Time |
| Test Statistic | Logrank |
| Average Events | 810.638 |
| Total Accrual Duration | 10 |
| Avg. Power at Termination | 0.735 |
| Simulation Control Parameters | |
| Starting Seed | Clock |
| Number of Simulations | 10000 |

☞ Average Sample Size, Dropouts and Look Times

| Look # | Average Sample Size | Average Events | | Average Dropouts | | Average Look Time | Average Follow up |
|---------|---------------------|----------------|-----------|------------------|-----------|-------------------|-------------------|
| | | Control | Treatment | Control | Treatment | | |
| 1 | 10000 | 440.811 | 369.827 | 1547.908 | 1557.214 | 50 | 35.373 |
| Average | 10000 | 440.811 | 369.827 | 1547.908 | 1557.214 | 50 | 35.373 |

☞ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Look Time | Boundaries Efficacy | | Stopping For | | Total Simulations | |
|--------|-----------|---------------------|-------|----------------|----------------|-------------------|---|
| | | Upper | Lower | Upper Efficacy | Lower Efficacy | Count | % |
| | | | | | | | |
| Total | | | | 0 | 7345 | 10000 | |
| % | | | | 0.000% | 73.450% | | |

☞ Response Generation Parameters

No. of Hazard Pieces: 2
 Input Method: Hazard Rates

| Piece # | Starting at Time | Control | Treatment | Hazard Ratio |
|---------|------------------|---------|-----------|--------------|
| 1 | 0 | 0.003 | 0.003 | 1.015 |
| 2 | 12 | 0.003 | 0.002 | 0.75 |

Now you can see, the power of the study has increased to 73.5%. On average 811 events occurred during the 50 months that the study remained open. Since we require 90% power, the sample size must be increased even further. This can be done by trial and error over several simulation experiments. Eventually we discover that a sample size of 18000 patients will provide about 90% power with an average of 1358 events.

| 1 | 0 | 0.003 | 0.003 | 1.015 |
| 2 | 12 | 0.003 | 0.002 | 0.75 |

It is evident from these simulations that the proportional hazards assumption is simply not appropriate if the survival curves separate out late. In the present example the

44 Superiority Trials with Variable Follow-Up

proportional hazards assumption would have led to a sample size of 6400 whereas the sample size actually needed was 18000.

44.6.3 Group Sequential Design with Non-Proportional Hazards

The single-look design discussed in the previous section required a sample size of 17200 subjects. A group sequential design, monitored by an independent data monitoring committee, is usually more efficient for large studies of this type. Such a trial can be designed with efficacy stopping boundaries or with efficacy and futility stopping boundaries. Consider first a design with five equally spaced efficacy boundaries. Go back to the library, click on Des1 node, and then click on  . In the resulting design input dialog window, change the entry in the **Number of Looks** cell from 1 to 5. Click on **Compute** button and save the plan as Des2 in the library. Select Des1 and Des2 nodes and then click on  to see the following

details for both the designs.

| | Wbk2:Des1 | Wbk2:Des2 |

| Expected Under H1 | 6400 | 12554.1223 |
| Events | | |
| Maximum | 508 | 520 |
| Expected Under H0 | 508 | 516.5858 |
| Expected Under H1 | 508 | 385.5073 |
| Accrual Duration | | |
| Maximum | 6.4 | 12.555 |
| Expected Under H0 | 6.4 | 12.555 |
| Expected Under H1 | 6.4 | 12.5541 |
| Study Duration | | |
| Maximum | 48.677 | 27.2317 |
| Expected Under H0 | 41.817 | 24.2646 |
| Expected Under H1 | 48.677 | 21.4502 |

Des2 reveals that a group sequential design, with five equally spaced looks, taken after observing 104, 208, 312, 416 and 520 events, respectively, utilizing the default Lan-DeMets-O'Brien-Fleming (LD (OF)) spending function, achieves 90% power with a maximum sample size of 12555 and a maximum study duration of 27.232 months. The expected study duration under H_1 is 21.451 months. However, these operating characteristics are based on the assumption that the hazard ratio is constant and equals 0.75. Since in fact the hazard ratio is 0.75 only after 12 months of treatment, the actual power of this design is unlikely to be 90%. We can use simulation to determine the actual power. With the cursor in any cell of Des2 node, select 

44 Superiority Trials with Variable Follow-Up

from the menu bar. You will be taken to the simulation worksheet. In the **Response Generation** tab, make the changes in the hazard rates as shown below.

| Survival Information | | | | |
|---------------------------------------|------------------|---------------|--------------|--------------|
| # of Hazard Pieces | 2 | Input Method: | Hazard Rates | |
| <input type="checkbox"/> Hazard Ratio | | | | |
| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
| | | Control | Treatment | |
| 1 | 0.000 | 0.0025 | 0.0025 | 1.000 |
| 2 | 12.000 | 0.0025 | 0.0019 | 0.760 |

After changing the number of simulations as 1000 in the **Simulation Control**, click on the **Simulate** button to run 1000 simulations of Des2 with data being generated from the survival distributions that were specified in the **Response Generation** tab.

The results of this simulation run are as shown below.

| Wbk2:Des2:Sim6 | |
|---|--------------------|
| Mnemonic | SU-2S-LRAR |
| Test Parameters | |
| Design Type | Superiority |
| Test Type | 2-Sided |
| Test Statistic | Logrank |
| Power | 0.187 |
| No. of Looks | 5 |
| Model Parameters | |
| No. of Hazard Pieces | 2 |
| Boundary Parameters | |
| Efficacy Boundary | User Specified |
| Spacing of Looks | User Specified |
| Accrual & Dropout Parameters | |
| Followup Duration | Until End of Study |
| Accrual Rate | 1000 |
| No. of Accrual Periods | 1 |
| Sample Size | |
| Maximum | 12555 |
| Events | |
| Maximum | 520 |
| Study Duration | |
| Maximum | 25.2768 |

Only 187 of the 1000 simulated trials were able to reject the null hypothesis indicating that the study is grossly underpowered. We can improve on this performance by extending the total study duration so that additional events may be observed. To increase study duration, go to the **Simulation Parameters** tab and select the **Look Time** option under **Fix at Each Look**. We had specified at the outset that the total study duration should not exceed 50 months. Let us therefore fix the total study duration at 50 months and space each interim look 10 months apart by editing

44 Superiority Trials with Variable Follow-Up

the **Study Duration**.

The screenshot shows the 'Test Parameters' tab of a trial design software. The 'Trial Type' is set to 'Superiority', 'Test Type' is '2-Sided', and 'Fix at Each Look' is 'Look Time'. The 'Study Duration' is set to 50. The 'Test Statistic' is 'Logrank'. Below the settings is a table showing efficacy Z values for 5 looks.

| Look # | Analysis Time | Efficacy Z | |
|--------|---------------|------------|--------|
| | | Upper | Lower |
| 1 | 10.000 | 4.877 | -4.877 |
| 2 | 20.000 | 3.357 | -3.357 |
| 3 | 30.000 | 2.680 | -2.680 |
| 4 | 40.000 | 2.290 | -2.290 |
| 5 | 50.000 | 2.031 | -2.031 |

We are now ready to simulate a 5-look group sequential trial in which the **LD (OF)** stopping boundaries are applied and the looks are spaced 10 months apart. Each simulated trial will enroll 12555 subjects at the rate of 1000/month. The simulation data will be generated from survival distributions in which the hazard rates of both arms are 0.0025 for the first 12 months and the hazard ratio is 0.75 thereafter. To generate 1000 simulations of this design click on the **Simulate** button. These simulations do indeed show a substantial increase in power, from 18.7% previously to 79.9% .

| | Wbk2:Des2:Sim6 | Wbk2:Des2:Sim7 |
|---|--------------------|--------------------|
| Mnemonic | SU-2S-LRAR | SU-2S-LRAR |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| Test Type | 2-Sided | 2-Sided |
| Test Statistic | Logrank | Logrank |
| Power | 0.187 | 0.799 |
| No. of Looks | 5 | 5 |
| Model Parameters | | |
| No. of Hazard Pieces | 2 | 2 |

| Events | | |
| Maximum | 520 | 879.219 |
| Study Duration | | |
| Maximum | 25.2768 | 50 |

The design specifications stated, however, that the trial should have 90% power. In order to achieve this amount of power we will have to increase the sample size. By trial and error, upon increasing the sample size to 18200 on the **Simulation Parameters** tab we observe that the power has increased to 90 % (up to Monte Carlo accuracy).

44 Superiority Trials with Variable Follow-Up

44.7 Simulating a Trial with Stratification variables

The data presented in Appendix I of Kalbfleisch and Prentice (1980) on lung cancer patients were used as a basis for this example. We will design a trial to compare two treatments (Standard and Test) in a target patient group where patients had some prior therapy. The response variable is the survival time in days of lung cancer patients. First, we will create a design for 3 looks, to compare the two treatment groups. Next, using this design, we will carry out simulation with stratification variables. Three covariates in the data are used here as stratum variables: a) type of cancer cell (small, adeno, large, squamous,), b) age in years (≤ 50 , > 50), and c) performance status score (≤ 50 , > 50 and ≤ 70 , > 70).

The input data for base design are as follows: Trial type:superiority; test type:2-sided; type I error:0.05; power:0.90; allocation ratio:1; hazard rate (control):0.009211; hazard rate (treatment):0.004114; number of looks:3; Boundary family:spending functions; spending function:Lan-DeMets (OF); subjects are followed:until end of study; subjects accrual rate:12 per day.

The input data for stratified simulation are as given below: The number of stratum variables=3 (cell type; age group; performance status score).

Table 44.1: Input data for stratified simulation

| Cell type | Proportion | Hazard ratio |
|--------------------------------|------------|--------------|
| small | 0.28 | Baseline |
| adeno | 0.13 | 2.127 |
| large | 0.25 | 0.528 |
| squamous | 0.34 | 0.413 |
| Age group | Proportion | Hazard ratio |
| ≤ 50 years | 0.28 | Baseline |
| > 50 years | 0.72 | 0.438 |
| Performance status score group | Proportion | Hazard ratio |
| ≤ 50 | 0.43 | Baseline |
| > 50 and ≤ 70 | 0.37 | 0.164 |
| > 70 | 0.20 | 0.159 |

44.7.1 Creating the design

First we will create a design using the input data. Open East, click **Design** tab and then **Two Samples** button in **Survival** group. Now click **Logrank Test: Given Accrual Duration and Accrual Rates**. In the resulting screen, enter the input data in the dialog

boxes under the different tabs. Finally click on **Compute** button. Now the dialog boxes under the different tabs will appear as shown below.

The **Test Parameters** tab is shown below, where you can see the computed value of **No.of Events**.

44.7.2 Running Stratified Simulation

After selecting the design node, click on **Simulate** icon. You will see simulation screen with the dialog boxes under different tabs. Click on **Include Options** and select **Stratification**.

44 Superiority Trials with Variable Follow-Up

The dialog box under **Test Parameters** will be as shown below. Keep the default test statistic **LogRank** and the default choice of **Use Stratified Statistic**.

| Look # | Info. Fraction | Cum. α Spent | | Efficacy Z | |
|--------|----------------|--------------|-------|------------|--------|
| | | Upper | Lower | Upper | Lower |
| 1 | 0.333 | 0.000 | 0.000 | 3.710 | -3.710 |
| 2 | 0.667 | 0.006 | 0.006 | 2.511 | -2.511 |
| 3 | 1.000 | 0.025 | 0.025 | 1.993 | -1.993 |

After entering the stratification input information, the dialog box under **Stratification** will appear as shown below.

| Cell type | Level | Fraction | Age group | Level | Fraction | PerfStatus | Level | Fraction |
|-----------|---------|----------|-----------|---------|----------|------------|-------|----------|
| small | <=50... | 0.28 | > 50... | <=50... | 0.28 | Perf_1 | 0.43 | |
| | adeno | 0.13 | | > 50... | 0.72 | Perf_2 | 0.37 | |
| large | large | 0.25 | squa... | large | 0.34 | Perf_3 | 0.2 | |
| | squa... | 0.34 | | Perf_3 | 0.2 | | | |

| Stratum ID | Label | Fraction |
|------------|---------------------------|----------|
| SID01 | small <=50 yrs Perf_1 | 0.034 |
| SID02 | small <=50 yrs Perf_2 | 0.029 |
| SID03 | small <=50 yrs Perf_3 | 0.016 |
| SID04 | small > 50 yrs Perf_1 | 0.087 |
| SID05 | small > 50 yrs Perf_2 | 0.075 |
| SID06 | small > 50 yrs Perf_3 | 0.040 |
| SID07 | adeno <=50 yrs Perf_1 | 0.016 |
| SID08 | adeno <=50 yrs Perf_2 | 0.013 |
| SID09 | adeno <=50 yrs Perf_3 | 0.007 |

After entering adding response related input information, the dialog box under

Response Generation will display details as shown in the following screen shots.

The screenshot shows a software interface with several tabs: Simulation Parameters, Stratification Info, Response Generation Info, Accrual/Dropout Info, and Simulation Control Info. The 'Response Generation Info' tab is active. It displays 'Survival Information' with a dropdown for 'Stratum ID' set to 'SID01:small | <=50 yrs | Perf_1'. There are radio buttons for 'Using Hazard Rates' (selected) and 'Using Cum. % Survival'. Below this is a table showing 'Hazard Rates' for 'Control' and 'Treatment' across different strata.

| Piece | Starting At | Hazard Rates | | Hazard Ratio |
|-------|-------------|--------------|-----------|--------------|
| | | Control | Treatment | |
| 1 | 0.0000 | 0.0092 | 0.0041 | 0.4466 |

Below the main interface, three detailed views of the 'Specify Hazard Ratio' table are shown for different variables: Cell type, Age group, and PerfStatus.

Variables: Treatment, Cell type, Age group, PerfStatus

Specify Hazard Ratio:

| Cell type | | |
|-----------|----------|--------------|
| Level | Fraction | Hazard Ratio |
| small | 0.280 | Baseline |
| adeno | 0.130 | 2.127 |
| large | 0.250 | 0.528 |
| squamous | 0.340 | 0.413 |

Variables: Treatment, Cell type, Age group, PerfStatus

Specify Hazard Ratio:

The stratified simulation results show that the attained power 0.856 is slightly less than the design specified power of 0.90.

45 Superiority Trials with Fixed Follow-Up

This chapter will illustrate through a worked example how to design, monitor and simulate a two-sample superiority trial with a time-to-event endpoint in which each subject who has not dropped out or experienced the event is followed for a fixed duration only. This implies that each subject who does not drop-out or experience the event within a given time interval, as measured from the time of randomization, will be administratively censored at the end of that interval. In East we refer to such designs as **fixed follow-up designs**.

45.1 Clinical Trial of Drug Eluting Stents

Drug-eluting coronary-artery stents were shown to decrease the risks of death from cardiac causes, myocardial infarction and target-vessel revascularization as compared to uncoated stents in patients undergoing primary percutaneous coronary intervention (PCI) in two randomized clinical trials published in the September 14, 2006 issue of the New England Journal of Medicine. In the Paclitaxel-Eluting Stent versus Conventional Stent in Myocardial Infarction with ST-Segment Elevation (PASSION) trial, Laarman et al. (2006) randomly assigned 619 patients to receive either a paclitaxel-eluting stent or an uncoated stent. The primary endpoint was the percentage of cardiac deaths, recurrent myocardial infarctions or target-lesion revascularizations at 12 months. A marginally lower 12-month failure rate was observed in the paclitaxel-stent group compared with the uncoated-stent group (8.8% versus 12.8%, $p = 0.09$). The Trial to Assess the Use of the Cypher Stent in Acute Myocardial Infarction Treated with Balloon Angioplasty (TYPHOON), (Spaulding et al., 2006) showed even more promising results. In this trial of 712 patients the sirolimus-eluting stents had a significantly lower target-vessel failure rate at 12 months than the uncoated stents (7.3% versus 14.3%, $p = 0.004$). Based on these results an editorial by Van de Werf (2006) appeared in the same issue of the New England Journal of Medicine as the Typhoon and PASSION trials, recommending that studies with a larger sample size and a hard clinical endpoint be conducted so that drug-eluting stents might be routinely implanted in patients undergoing PCI. In this chapter we will use East to design and monitor a possible successor to the PASSION trial using a time-to-event endpoint with one year of fixed follow-up for each subject.

45.2 Single-Look Design

45.2.1 Initial Design

The primary endpoint for the trial is the time to target-vessel failure, with a failure being defined as target-vessel related death, recurrent myocardial infarction, or target-vessel revascularization. Each subject will be followed for 12 months. Based on the PASSION data we expect that 87.2% of subjects randomized to the uncoated stents will be event-free at 12 months. We will design the trial for 90% power to detect an increase to 91.2% in the paclitaxel-stents group, using a two-sided level-0.05 test. Enrollment is expected to be at the rate of 30 subjects per month.

45.2.1 Initial Design

We begin by opening a new East Workbook and selecting **Logrank Test Given Accrual Duration and Accrual Rates**.

This will open the input window for the design as shown below. Select **2-Sided** for **Test Type**, and enter **0.05** for **Type I error**.

The right hand side panel of this input window is to be used for entering the relevant time-to-event information.

| Test Parameters | Accrual / Dropouts |
|------------------------------------|--------------------|
| Test Type: | 2-Sided |
| Type I Error (α): | 0.05 |
| Power: | 0.9 |
| No. of Events: | Computed |
| Allocation Ratio: (n_1/n_2) | 1 |

The default values in the above dialog box must be changed to reflect the time-to-event parameters specified for the design. Select **% Cumulative Survival** for the **Input**

45 Superiority Trials with Fixed Follow-Up

Method and enter the relevant 12-month event-free percentages.

of Hazard Pieces: Input Method:

Hazard Ratio (Optional) Alternative

Hazard Ratio (λ_t / λ_c)

Ratio of % Survivals at Period # 1 (S_t / S_c)

| By Time | Cum. % Survival | |
|---------------------------------|-----------------------------------|-----------------------------------|
| | Control | Treatment: Alt. |
| <input type="text" value="12"/> | <input type="text" value="87.2"/> | <input type="text" value="91.2"/> |

Note: Period 1 hazard rates apply after time 12.

Change the **Input Method** to Hazard Rates. You will see the information you entered converted as shown below. Note that you may need to change the decimal display options for hazard rates using the  icon to see these numbers with more decimal places.

of Hazard Pieces: Input Method:

Hazard Ratio (Optional) Alternative

Hazard Ratio (λ_t / λ_c)

Log Hazard Ratio $\ln(\lambda_t / \lambda_c)$

| Hazard Rate | |
|-------------------------------------|-------------------------------------|
| Control | Treatment: Alt. |
| <input type="text" value="0.0114"/> | <input type="text" value="0.0077"/> |

Another parameter to be decided is the **Variance** which specifies whether the calculation of the required number of events is to be based on the variance estimate of log hazard ratio under the null hypothesis or the alternative hypothesis. The default choice in East is **Null**. Most textbooks recommend this choice as well (see, for example Collett, 1994, equation (2.21) specialized to no ties). It will usually not be necessary to change this default. For a technical discussion of this issue refer to

Appendix B, Section B.5.3

The second tab, labeled **Accrual/Dropouts** is used to enter the patient accrual rate and, for fixed follow-up designs, the duration of patient follow-up and the dropout information. In this example the clinical endpoint is progression-free survival for 12 months. Patients who are still on study at month 12 and who have not experienced the endpoint will be treated as censored. Therefore, in the first panel out of two, we select the entry from the dropdown that indicates that subjects are followed **For Fixed Period** and enter the number 12 in the corresponding edit box. Suppose that the anticipated rate of enrollment is 30 patients per month. This number is also entered into the dialog box as shown below. Let the committed accrual of subjects be same as 2474.

Test Parameters | **Accrual / Dropouts**

| Expected Under H0 | 2269.642 |
| Expected Under H1 | 2474 |
| Events | |
| Maximum | 268 |
| Expected Under H0 | 268 |
| Expected Under H1 | 268 |
| Study Duration | |
| Maximum | 94.467 |
| Expected Under H0 | 75.655 |
| Expected Under H1 | 94.467 |
| Accrual Duration | |
| Maximum | 82.467 |
| Expected Under H0 | 75.655 |
| Expected Under H1 | 82.467 |

East reveals that 268 events are required in order to obtain 90% power. If each patient can only be followed for a maximum of 12 months, we must commit to enrolling a total of 2474 patients over a period of 82.5 months. With this commitment we expect to see the required 268 events within 12 months of the last patient being enrolled. So the total study duration is expected to be $82.5 + 12 = 94.5$ months. To see how the

events are expected to arrive over time, invoke a plot of **Sample Size/ Events vs. Time** by clicking the **Plots** icon  from the toolbar.

Uncheck the **Sample Size** box, to see the events graphs on a larger scale as shown below.

45.3 Shortening the Study Duration

45.3.1 Increasing the Sample Size

45.3.2 Patient Follow-Up

45.3.3 Increasing the Rate of Enrollment

Under Des1 the trial will last for 94.5 months, with 82.5 months of patient enrollment (i.e., a sample size of 2474 subjects). This is not considered to be satisfactory to the trial sponsor. There are three possible ways in which the study duration might be shortened; by increasing the sample size, by increasing the duration of patient follow-up, or by increasing the rate of patient enrollment.

45.3.1 Increasing the Sample Size

45 Superiority Trials with Fixed Follow-Up

Unlike trials with variable patient follow-up, in a fixed follow-up design the gain from increasing the sample size is limited. This is evident from the relatively narrow range between the minimum accrual duration (82.5 months) and the suggested maximum accrual duration (88.3 months).

| Accrual | | | |
|--|--------|--------|------------|
| | Min. | Comtd. | Sugg. Max. |
| <input type="radio"/> Duration: | 82.467 | 82.467 | 88.267 |
| <input checked="" type="radio"/> Subjects: | 2474 | 2474 | 2648 |

Notice that if we were to increase the enrollment duration to the say, 88.3 months, the total study duration would only decrease by 5.9 months; from 94.5 months to 88.6 months. To see this, edit Des1 and create Des2 and enter the number 88.267 into the cell for **Committed Accrual (Duration)** as shown below:

| Accrual | | | |
|--|--------|--------|------------|
| | Min. | Comtd. | Sugg. Max. |
| <input type="radio"/> Duration: | 82.467 | 88.267 | 88.267 |
| <input checked="" type="radio"/> Subjects: | 2474 | 2648 | 2648 |

Des2 is created in the **Output Preview** pane upon clicking the **Compute** button.

Click on  icon to save the design in a workbook. Select Des1 and Des2 in the workbook and click on  icon to see the side-by-side comparison of the two

designs.

| Maximum | 82.467 | 88.267 |
| Expected Under H0 | 75.655 | 75.655 |
| Expected Under H1 | 82.467 | 88.267 |

The calculation of the minimum and maximum of the range of accrual durations is discussed on page 2308 of Appendix B, section B.5.2.

East has determined that if the enrollment (at the pre-specified rate of 30 patients per month) is stopped **before** 82.467 months have elapsed, and every patient still on study is followed for precisely 12 months, we will obtain fewer than 268 events on average, and the trial will be underpowered. Therefore East specifies that the minimum duration of enrollment must be 82.467 months. The user has the option to increase the enrollment duration beyond 82.467 months. In that case, however, if all patients still on study are followed for 12 months, more than 268 events will accumulate, on average, by the time the trial is terminated. Therefore it will not be necessary to follow the later enrollees for the entire 12 month period. In the extreme case, if we extend the enrollment duration to 88.267 months, the required 268 events will arrive, on average, by the end of the enrollment period itself thus making it unnecessary to have any follow-up after the last patient has been enrolled. The study duration cannot be shortened any further by increasing the enrollment beyond 88.267 months (i.e., extending the sample size beyond 2648). For these reasons, for fixed follow-up

45 Superiority Trials with Fixed Follow-Up

designs, East selects the **minimum** of the range of enrollment durations (in this case 82.467) as the default enrollment duration. We note that in contrast, for variable follow-up designs, East selects the **mid-point** of the range of suggested enrollment durations as the default. Of course, the user is free to change the default enrollment duration for both types of designs.

45.3.2 Increasing the Length of Patient Follow-Up

Since this is a fixed follow-up design we might consider increasing the length of

patient follow-up, at present equal to 12 months. Edit Des1 by clicking the icon  to create Des3. Increase the length of patient follow-up from 12 months to 18 months, and commit to the minimum sample size 1698.

| Expected Under H1 | 74.6 |
| Accrual Duration | |
| Maximum | 56.6 |
| Expected Under H0 | 56.6 |
| Expected Under H1 | 56.6 |

By increasing the duration of patient follow-up to 18 months, the required 268 events can be obtained with fewer patients. It is now only necessary to have enrollment duration of 56.6 months. The study is expected to terminate 18 months after the last patient has enrolled for total study duration of 74.6. Increasing the length of patient follow-up has indeed shortened the total study duration. We note, however, that it might not always be feasible to increase patient follow-up in this manner, particularly if the clinical endpoint of interest determines how long one should wait for the endpoint to occur.

45 Superiority Trials with Fixed Follow-Up

45.3.3 Increasing the Rate of Enrollment

In cases where the primary endpoint determines the duration of the fixed follow-up, the option to shorten the study duration by increasing the follow-up duration is not available. In that case the only possibility is to increase the rate of enrollment by opening up more sites. Edit Des1 to create Des4 and increase the rate of enrollment from 30 patients/month to 45 patients/month, while committing to accruing the minimum number of subjects 2474.

Subjects are followed: For Fixed Period 12

Accrual Info

of Accrual Periods: 1

Accrual Rate: 45

| Accrual | Min. | Comtd. | Sugg. Max. |
|--|--------|--------|------------|
| <input type="radio"/> Duration: | 54.978 | 54.978 | 60.8 |
| <input checked="" type="radio"/> Subjects: | 2474 | 2474 | 2736 |

With this enrollment rate East calculates that an enrollment duration of 55 (sample size of 2474) and 12 additional months of follow-up will produce the desired 268 events on average. Thus the total study duration is expected to be 67 months.

| | Des4 |
|---|-----------------------|
| Mnemonic | SU-2S-LRAR |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 2-Sided |
| Specified α | 0.05 |
| Power | 0.901 |
| Model Parameters | |
| Allocation Ratio (nt/nc) | 1 |
| Hazard Ratio (Alt.) | 0.673 |
| Var (Log HR) | Null |

| Accrual Duration | |
| Maximum | 54.978 |
| Expected Under H0 | 52.391 |
| Expected Under H1 | 54.978 |

Now try an enrollment rate of 51.5 patients/month, and remember to maintain the 2474 accrual. At this enrollment rate the study is fully powered with a sample size of 2474 subjects, enrolled over a period of 48 months. The required 268 events will arrive on average 12 months after the last patient has enrolled so that the trial is expected to terminate at month 60.

| Expected Under H1 | 60.039 | 43.892 |
| Accrual Duration | | |
| Maximum | 48.039 | 49.146 |
| Expected Under H0 | 46.518 | 47.156 |
| Expected Under H1 | 48.039 | 40.849 |

We note that the 5-look design requires an up-front commitment of 274 events compared to the 268 events for the single-look design. At an enrollment rate of 51.5 subjects/month we need to enroll 2531 subjects over 49.1 months. The maximum study duration is expected to be 61.1 months, only 1.1 months longer than the single-look design. However, because of the possibility of early stopping the expected study duration, under the alternative hypothesis that the negative of the log hazard ratio is $\ln(0.673) = -0.397$, is only 43.9 months a savings of more than 16 months.

45.4.1 Incorporating Drop-Outs

The sample size will have to be increased appropriately if we expect drop-outs. Suppose we expect a drop out rate of 0.05 by 12 months for each treatment arm. Edit Des6 and enter the drop-out rates in the appropriate design dialog box as shown below.

| Expected Under H0 | 47.156 | 48.148 |
| Expected Under H1 | 40.849 | 41.734 |

The 5% drop-out rate has resulted in a sample size increase from 2531 subjects to 2595

subjects. However, the impact on maximum study duration and expected study duration is small. Under the alternative hypothesis the study is expected to last for 44.7 months in Des7 as compared to 43.9 months in Des6.

45.4.2 Incorporating Non-Constant Accrual Rates

Des7 was designed with the assumption that patients would be enrolled at the rate of 51.5/month. Suppose that this enrollment rate cannot be achieved from the get-go. Instead, assume that for the first 12 months patients are enrolled at an average rate of 25/month and thereafter the average enrollment rate is 51.5/month. To see the impact of this change on the study design, edit Des7, enter the two enrollment rates into the appropriate dialog box as shown below and create Des8.

| Expected Under H0 | 48.148 | 54.323 |
| Expected Under H1 | 41.734 | 47.909 |

The total sample size has not changed between Des7 and Des8. However, the total duration of the enrollment phase has increased by about six months. Moreover, because of the slower enrollment rate for the first 12 months, the maximum total study duration has increased from 62.4 months to 68.6 months and the expected study duration under the alternative hypothesis has increased from 44.7 months to 50.9 months.

45.4.3 Incorporating Piece-Wise Exponential Survival

Suppose that the mechanism of action of the stents is such that the hazard rate for failure decreases after the first six months. We will assume that the average hazard rate for the uncoated stents arm is 0.0114 for the first six months and decreases thereafter to an average rate of 0.0075. We will continue to assume that the hazard ratio is unchanged, at 0.673. Therefore the hazard rate for the coated stents arm decreases from $0.673 * 0.0114 = 0.0077$ to $0.673 * 0.0075 = 0.005$. Edit Des8 as shown below

to create Des9.

of Hazard Pieces: Input Method:

Hazard Ratio

Hazard Ratio (λ_t/λ_c) Alternative

Log Hazard Ratio $\ln(\lambda_t/\lambda_c)$

| Maximum | 68.563 | 78.272 |
| Expected Under H0 | 54.323 | 61.816 |
| Expected Under H1 | 50.951 | 57.712 |
| Accrual Duration | | |
| Maximum | 56.563 | 66.272 |
| Expected Under H0 | 54.323 | 61.816 |
| Expected Under H1 | 47.909 | 54.669 |

Since the hazard ratio is unchanged, Des8 and Des9 require the same number of events, 274, in order to achieve the desired 90% power. Observe, however, that in order for these 274 events to arrive on average 12 months after the last patient has enrolled, Des9

45 Superiority Trials with Fixed Follow-Up

requires a sample size of 3095 subjects; 500 patients more than were required under Des8. The study duration is likewise prolonged. This is because the hazard rate slows down after the first six months on study. If, for example, the change in hazard rate were to occur after 12 months instead of after 6 months, the change would have no impact on sample size or study duration. To verify this, make the following change in Des9:

of Hazard Pieces: Input Method:

Hazard Ratio

Hazard Ratio (λ_t/λ_c) Alternative

Log Hazard Ratio $\ln(\lambda_t/\lambda_c)$

| Period # | Starting at Time | Hazard Rate (Control) | Hazard Rate (Treatment: Alt.) |

Notice that Des8 and Des10 are now identical.

45.5 Verification by Simulation

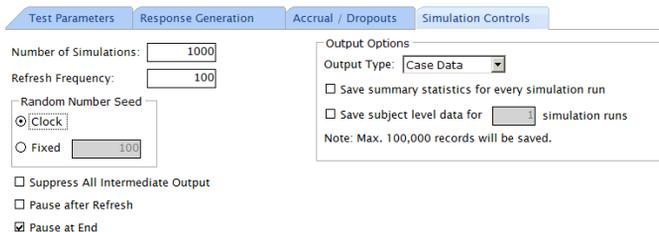

Click on the Des10 node in the **Library** click on  from the toolbar. A simulation input window comprising of four tabs - **Test Parameters**, **Response Generation**, **Accrual/Dropouts** and **Simulation Controls** is now invoked.

We will run simulations under different assumptions about the manner in which the data are generated.

45.5.1 Simulation Under the Alternative Hypothesis

We first run the simulations without making any changes to the default settings of the simulation input tabs. To see the default inputs for the simulations, click the tabs mentioned above.

Change the number of simulations to be run as 1000 on the last tab, **Simulation Control** and click **Simulate** button to run the simulations.

The screenshot shows the 'Simulation Controls' tab of a simulation input window. It contains the following settings:

- Number of Simulations: 1000
- Refresh Frequency: 100
- Random Number Seed:
 - Clock
 - Fixed: 100
- Suppress All Intermediate Output
- Pause after Refresh
- Pause at End
- Output Options:
 - Output Type: Case Data
 - Save summary statistics for every simulation run
 - Save subject level data for [] simulation runs
 - Note: Max. 100,000 records will be saved.

An entry for the simulation output gets added in the **Output Preview** pane. Save it in the workbook. Since we simulated Des10, a node named Sim1 will get associated with Des10. Double click on this node and see the detailed simulation output.

45 Superiority Trials with Fixed Follow-Up

Let us examine the results. Notice first that we have selected the option to fix the number of events for each look at their pre-planned values in the **Look Information** section. This can be seen in the **Simulation Parameters** tab.

Fix at Each Look: Total No. of Events ▾

Upon examining the simulation results in detail, however, we observe that the actual number of events at the final look is slightly lower than the pre-planned number of 274.

☉ Average Sample Size, Dropouts and Look Times

| Look # | Average Sample Size | Average Events | | Average Dropouts | | Average Look Time | Average Follow up |
|---------|---------------------|----------------|-----------|------------------|-----------|-------------------|-------------------|
| | | Control | Treatment | Control | Treatment | | |
| 1 | 816.757 | 32.647 | 22.353 | 12.395 | 12.38 | 22.04 | 7.042 |
| 2 | 1344.949 | 65.138 | 44.862 | 24.692 | 24.893 | 32.303 | 8.578 |
| 3 | 1860.36 | 96.361 | 67.639 | 36.735 | 36.902 | 42.293 | 9.261 |
| 4 | 2368.408 | 125.772 | 93.228 | 48.63 | 49.139 | 52.228 | 9.661 |
| 5 | 2594.008 | 150.064 | 118.223 | 59.426 | 59.985 | 64.739 | 10.784 |
| Average | 2176.262 | 121.205 | 83.385 | 45.596 | 46.244 | 50.637 | 9.739 |

This is observed consistently. If you edit this simulation node and simulate this scenario again and again with different starting seeds, you will notice that the actual number of events at which the first four looks are taken match the corresponding pre-planned values, whereas there appears to be a systematic bias towards taking the fifth and final look with slightly fewer events than was pre-planned. As a result the trial is slightly underpowered.

In practice, the slight loss of power due to the systematic decrease in the number of events at the final look relative to the pre-planned number is of very little consequence. It is instructive, however, to understand why it arises at all. The reason for the small amount of systematic bias is that the maximum follow-up time for each patient is 12 months. Thus, no further follow-up is possible once 12 months have elapsed after the last subject has enrolled. Since the duration of the enrollment period has been fixed at 56.5 months, the trial must be terminated at the latest in $56.5 + 12 = 68.5$ months. Observe that the selection in the **Simulation Parameters** tab, that in the row titled Fixed at Each Look, the choice **Total No. of Events** has been selected from the drop down list.

This means that East has been instructed to perform simulations in which each look is taken after a fixed number of events has been observed, as pre-specified in the design. Specifically, the looks should be taken after 55, 110, 164, 219 and 274 events have been observed. The trial should be terminated early if a boundary is crossed at one of the

first four looks; otherwise it should continue until all 274 events have been obtained.

☰ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Events | Boundaries | | Stopping For | | Total Simulations | |
|--------|--------|------------|--------|----------------|----------------|-------------------|---------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 55 | 4.868 | -4.868 | 0 | 0 | 0 | 0.000% |
| 2 | 110 | 3.35 | -3.35 | 0 | 84 | 84 | 8.400% |
| 3 | 164 | 2.684 | -2.684 | 0 | 333 | 333 | 33.300% |
| 4 | 219 | 2.291 | -2.291 | 0 | 318 | 318 | 31.800% |
| 5 | 274 | 2.031 | -2.031 | 0 | 99 | 265 | 26.500% |
| Total | | | | 0 | 834 | 1000 | |
| % | | | | 0.000% | 83.400% | | |

We thus have two conflicting restrictions for the maximum study duration. The fixed follow-up design implies that the trial cannot proceed beyond month 68.5 whereas the **Planned # of Events** restriction implies that the trial cannot proceed beyond 274 events. East resolves the conflict by fixing the maximum study duration at the **earlier** of 68.5 months or the time at which 274 events have been observed. Thereby the average number of events at the fifth and final look becomes a random variable with an upper bound of 274 and an expected value that is slightly less than 274.

To get around this bias one should specify in the **Look Information** section that we will **Fix at Each Look** the **Look Time** rather than the **Total No. of Events**.

Fix at Each Look:

| Look # | Analysis Ti... | Efficacy Z | |
|--------|----------------|------------|--------|
| | | Upper | Lower |
| 1 | 22.070 | 4.868 | -4.868 |
| 2 | 32.283 | 3.350 | -3.350 |
| 3 | 42.238 | 2.684 | -2.684 |
| 4 | 52.377 | 2.291 | -2.291 |
| 5 | 68.563 | 2.031 | -2.031 |

With this specification the looks will occur at fixed calendar times of 22.1, 32.3, 42.2, 52.4, and 68.5 months regardless of the number of events that have been obtained at these looks. Although the actual number of events obtained at each of these five looks are now random variables, the **average** number of events obtained in repeated simulations will be 55, 110, 164, 219 and 274, respectively, under the alternative hypothesis. The bias due to fixing the maximum number of events at 274 will no longer occur and the study will be fully powered. To see this, run the simulations

45 Superiority Trials with Fixed Follow-Up

10,000 times after fixing the **Look Time** rather than the **# of Events**

The appropriate number of events is obtained at each look on average and the study is fully powered, up to Monte Carlo accuracy.

45.5.2 Simulation Under the Null Hypothesis

It is important to verify by simulation that the type-1 error is preserved. Accordingly, edit the node Sim2 and switch to the **Response Generation** tab. We may now make changes to the design by editing the entries in the cells that are white in color.

| Survival Information | | | | |
|---------------------------------------|------------------|----------------------------|-----------|--------------|
| # of Hazard Pieces | 2 | Input Method: Hazard Rates | | |
| <input type="checkbox"/> Hazard Ratio | | | | |
| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
| | | Control | Treatment | |
| 1 | 0.000 | 0.0114 | 0.0077 | 0.673 |
| 2 | 12.000 | 0.0075 | 0.0050 | 0.673 |

To simulate under the null hypothesis we must set the hazard rates of the Control and Treatment groups to be the same, as shown below:

| Survival Information | | | | |
|---------------------------------------|------------------|----------------------------|-----------|--------------|
| # of Hazard Pieces | 2 | Input Method: Hazard Rates | | |
| <input type="checkbox"/> Hazard Ratio | | | | |
| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
| | | Control | Treatment | |
| 1 | 0.000 | 0.0114 | 0.0114 | 1.000 |
| 2 | 12.000 | 0.0075 | 0.0075 | 1.000 |

Then click on the **Simulate** button to generate 10000 simulated trials under the null

hypothesis.

⊖ **Simulation Boundaries and Boundary Crossing Probabilities**

| Look # | Look Time | Boundaries | | Stopping For | | Total Simulations | |
|--------|-----------|------------|--------|----------------|----------------|-------------------|---------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 22.07 | 4.868 | -4.868 | 0 | 0 | 0 | 0.000% |
| 2 | 32.283 | 3.35 | -3.35 | 3 | 5 | 8 | 0.080% |
| 3 | 42.238 | 2.684 | -2.684 | 33 | 36 | 69 | 0.690% |
| 4 | 52.377 | 2.291 | -2.291 | 85 | 69 | 154 | 1.540% |
| 5 | 68.563 | 2.031 | -2.031 | 140 | 111 | 9769 | 97.690% |
| Total | | | | 261 | 221 | 10000 | |
| % | | | | 2.610% | 2.210% | | |

The type-1 error has been preserved, with an overall two-sided false positive rate less than 5%. The above simulations were run with fixed look times rather than with fixed numbers of events at each look. It is interesting to note that, for the same fixed look times, the average number of events at each look under the null hypothesis greatly exceeds the corresponding average number of events at each look under the alternative hypothesis. This is so because the events arrive faster when the treatment arm is no more effective than the control arm.

46 *Non-Inferiority Trials Given Accrual Duration and Accrual Rates*

This chapter will illustrate through a worked example how to design, monitor and simulate a two-sample non-inferiority trial with a time-to-event trial endpoint, when the accrual duration and accrual rates are fixed.

46.1 *Establishing the Non-Inferiority Margin*

The first step in designing a non-inferiority trial is to establish a suitable non-inferiority margin. This is typically done by performing a meta-analysis on past clinical trials of the active control versus placebo. Regulatory agencies then require the sponsor of the clinical trial to demonstrate that a fixed percentage of the active control effect (usually 50%) is retained by the new treatment. A further complication arises because the active control effect can only be estimated with error. We illustrate below with an example provided by reviewers at the FDA.

Rothman et al. (2003) have discussed a clinical trial to establish the non-inferiority of the test drug Xeloda (treatment t) relative to the active control (treatment c) consisting of 5-fluorouracil with leucovorin (5FU+LV) for metastatic colorectal cancer. In order to establish a suitable non-inferiority margin for this trial it is necessary to first establish the effect of 5FU+LV relative to the reference therapy of 5FU alone (treatment p , here regarded as placebo). To establish this effect the FDA conducted a ten-study random effects meta-analysis (FDA Medical-Statistical review for Xeloda, NDA 20-896, April 2001) of randomized comparisons of 5-FU alone versus 5-FU+LV. Letting λ_t , λ_c and λ_p denote the constant hazard rates for the new treatment, the active control and the placebo, respectively, the FDA meta-analysis established that

$$\ln(\widehat{\lambda_p/\lambda_c}) = 0.234$$

with standard error

$$\text{se}[\ln(\widehat{\lambda_p/\lambda_c})] = 0.075 .$$

Thus with 100 γ % confidence the active control effect lies inside the interval

$$\left[0.234 - 0.075\Phi^{-1}\left(\frac{1+\gamma}{2}\right), 0.234 + 0.075\Phi^{-1}\left(\frac{1+\gamma}{2}\right)\right] \quad (46.1)$$

The new study is required to demonstrate that some fraction (usually 50%) of the active control effect is retained. Rothman et al. (2003) state that the claim of non-inferiority for the new treatment relative to the active control can be demonstrated if the upper limit of a two-sided 100(1 - α)% confidence interval for $\ln(\lambda_t/\lambda_c)$ is less than a pre-specified fraction of the lower limit of a two-sided 100 γ % confidence interval for the active control effect established by the meta-analysis. This is known as

the “two confidence intervals procedure”. Specifically in order to claim non-inferiority in the current trial it is necessary to show that

$$\begin{aligned} & \ln(\widehat{\lambda_t/\lambda_c}) + \Phi^{-1}(1 - \alpha/2)\text{se}[\ln(\widehat{\lambda_t/\lambda_c})] \\ & < (1 - f_0)\{\ln(\widehat{\lambda_p/\lambda_c}) - \Phi^{-1}(\frac{1 + \gamma}{2})\text{se}[\ln(\widehat{\lambda_p/\lambda_c})]\} . \end{aligned} \quad (46.2)$$

We may re-write the non-inferiority condition (46.2) in terms of a one-sided Wald test of the form

$$\frac{\ln(\widehat{\lambda_t/\lambda_c}) - \delta_0}{\text{se}[\ln(\widehat{\lambda_t/\lambda_c})]} < \Phi^{-1}(1 - \alpha/2) , \quad (46.3)$$

where

$$\delta_0 = (1 - f_0)\{\ln(\widehat{\lambda_p/\lambda_c}) - \Phi^{-1}(\frac{1 + \gamma}{2})\text{se}[\ln(\widehat{\lambda_p/\lambda_c})]\} \quad (46.4)$$

is the non-inferiority margin.

The choice $f_0 = 1$ implies that the entire active control effect must be retained in the new trial and amounts to running a superiority trial. At the other end of the spectrum, the choice $f_0 = 0$ implies that none of the active control effect need be retained; i.e., the new treatment is only required to demonstrate effectiveness relative to placebo. The usual choice is $f_0 = 0.5$, implying that the new treatment is required to retain at least 50% of the active control effect. The usual choice for α is $\alpha = 0.05$. A conservative choice for the coefficient γ is $\gamma = (1 - \alpha) = 0.95$. Rothman et al. (2003) refer to this method of establishing the non-inferiority margin as the “two 95 percent two-sided confidence interval procedure” or the “95-95 rule”. In general this approach leads to rather tight margins unless the active control effect is substantial. Rothman et al. (2003) have also proposed more lenient margins that vary with the amount of power desired. Fleming (2007), however, argues for the stricter 95-95 rule on the grounds that it offers greater protection against an ineffective medical compound being approved in the event that the results of the previous trials used to establish the active control effect are of questionable relevance to the current setting. Accordingly we evaluate (46.4) with $\gamma = 0.95$, $f_0 = 0.5$, $\ln(\widehat{\lambda_p/\lambda_c}) = 0.234$ and $\text{se}[\ln(\widehat{\lambda_p/\lambda_c})] = 0.075$ thereby obtaining the non-inferiority margin to be $\delta_0 = 0.044$ for the log hazard ratio and $\exp(0.044) = 1.045$ for the hazard ratio.

46 Non-Inferiority Trials Given Accrual Duration and Accrual Rates

46.2 Design of Metastatic Colorectal Cancer Trial

46.2.1 Single-Look Design

46.2.2 Early Stopping for Futility

In this section we will use East to design a single-look non-inferiority trial comparing the test drug Xeloda (treatment t) to the active control 5FU+LV (treatment c) for the treatment of metastatic colorectal cancer. On the basis of a meta-analysis of ten previous studies of the active control versus placebo (Rothman et al., 2003), a non-inferiority margin of 1.045 for λ_t/λ_c has been established. Thus we are interested in testing the null hypothesis of inferiority $H_0: \lambda_t/\lambda_c \geq 1.045$ versus the one-sided alternative hypothesis that $\lambda_t/\lambda_c < 1.045$. Subjects are expected to enroll at the rate of 60/month and the median survival time for patients randomized to the active control arm is expected to be 18 months.

46.2.1 Single-Look Design

We will use East to create an initial single-look design having 80% power to detect the alternative hypothesis $H_1: \lambda_t/\lambda_c = 1$ with a one sided level 0.025 non-inferiority test.

To begin click **Survival: Two Samples** on the **Design** tab and then click **Parallel Design: Log Rank Test Given Accrual Duration and Accrual Rates**.

A new screen will appear. Enter the appropriate design parameters into the dialog box as shown below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

Design Type: Noninferiority Number of Looks: 1

| <input checked="" type="radio"/> Hazard Ratio (λ_t/λ_c) | 1.045 | 1 |
| <input type="radio"/> Ratio of Medians (m_t/m_c) | 0.957 | 1 |

| | Med.Surv.Time | |
|---------|-----------------|-----------------|
| Control | Treatment: Null | Treatment: Alt. |
| 18 | 17.225 | 18 |

Assurance (Probability of Success)

Variance of Log Hazard Ratio

Null Alternative

The box labeled **Variance of Log Hazard Ratio** specifies whether the calculation of the required number of events is to be based on the variance estimate of the log hazard ratio under the null hypothesis or the alternative hypothesis. The default choice in East is **Null**. Most textbooks recommend this choice as well (see, for example Collett,

1994, equation (2.21) specialized to no ties). It will usually not be necessary to change this default. For a technical discussion of this issue refer to Appendix B, Section B.5.3.

Next click on the **Accrual/Dropouts** tab. Here we will specify the accrual information and dropout rates. Enter an accrual rate of 60. Suppose that there are 5% drop-outs per year in each arm. Enter these values as shown below.

Test Parameters | **Accrual / Dropouts**

Subjects are followed:

Accrual Info

of Accrual Periods:

Accrual Rate:

Piecewise Dropout Information

| Accrual | | Min. | Comtd. | Sugg. Max. |
|--|--|--------|---------|------------|
| <input type="radio"/> Duration: | | 300.05 | 311.733 | 323.4 |
| <input checked="" type="radio"/> Subjects: | | 18003 | 18704 | 19404 |

On the bottom of this screen is where you can specify the accrual duration or number of subjects. East automatically computes a range that is necessary to achieve the desired power of the study and selects the midpoint of the range, as the committed accrual duration or subjects. If your study has a restriction on accrual duration or subject accrual, you may enter this value in the **Comtd.** column. In our example, East computes a minimum accrual duration of 300.05 months and a suggested maximum of 323.4 months. Also, if you click the  icon a chart which shows the relationship between accrual duration (or subject accrual, depending on whether you choose to

46 Non-Inferiority Trials Given Accrual Duration and Accrual Rates

specify accrual duration or subject accrual) and study duration.

Looking at this chart, choosing an accrual duration longer than 315 months will not result in a substantial decrease in study duration. Thus, we commit to an accrual duration of 315 months. Close this chart, select the radio button next to **Duration** and enter 315 in the **Comtd.** column.

Click on **Compute** to complete the design. The design is shown as a row in the **Output Preview** located in the lower pane of this window. You can select this design by clicking anywhere along the row in the **Output Preview**. With Des1 selected, click the  icon to display the details of this design in the upper pane, which are shown below. You may also wish to save this design. Select Des1 in the **Output Preview**

window and click the  to save this design to Workbook1 in the **Library**.

It is immediately evident that Des1 is untenable. It requires 16,205 events to be fully powered. The problem lies with trying to power the trial to detect a hazard ratio of 1 under the alternative hypothesis. Suppose instead that the investigators actually believe that the treatment is slightly superior to the active control, but the difference is too small to be detected in a superiority trial. In that case a non-inferiority design powered at a hazard ratio less than 1 (0.95, say) would be a better option because such a trial would require fewer events.

To see this create a new design by selecting Des1 in the **Library**, and clicking the  icon on the **Library** toolbar. Then edit this design by specifying a hazard ratio of 0.95

46 Non-Inferiority Trials Given Accrual Duration and Accrual Rates

under the alternative hypothesis as shown below.

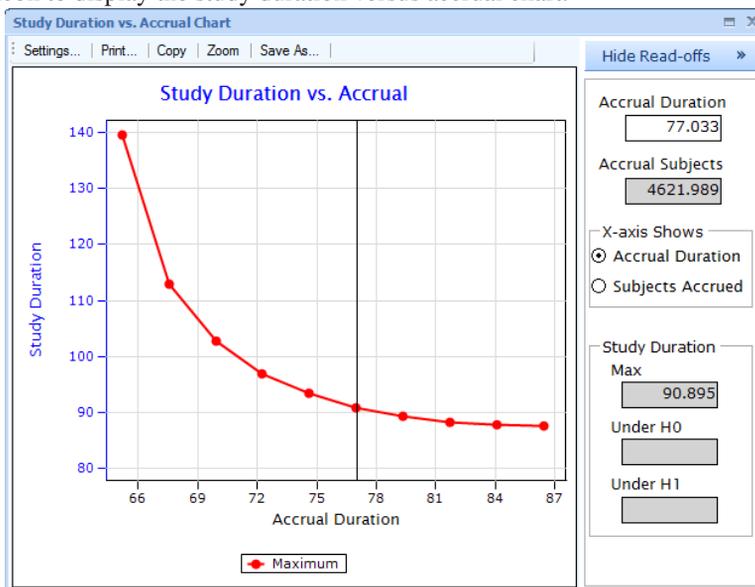

of Hazard Pieces: Input Method:

| Expected Under H1 | 315 | 77 |

46 Non-Inferiority Trials Given Accrual Duration and Accrual Rates

Des2 is clearly easier to implement than Des1. It requires only 3,457 events and 4620 subjects to be fully powered. Also note the marked decrease in study duration under either the null or alternative hypothesis. Nevertheless, Des2 is also unsatisfactory. The maximum study duration for Des2 (accrual plus follow-up) is 90.9 months with 77 months of that amount of time being utilized to enroll 4620 patients. It is necessary to shorten the maximum study duration further. One possible way to shorten the maximum study duration is to increase the rate of enrollment. Suppose that additional sites can be enlisted to enroll patients after the study is activated so that six months later the average rate of enrollment is increased to 110/month. To see the impact of the increased rate of enrollment select Des2 in the **Library**, and click on the  icon on the **Library** toolbar.

Next, click on the **Accrual/Dropouts** tab. Change the accrual rates as shown below.

The screenshot shows a software interface with two main panels. The left panel, titled 'Accrual Info', has a dropdown menu for 'Subjects are followed:' set to 'Until End of Study'. Below it, '# of Accrual Periods:' is set to '1'. The 'Accrual Rate:' is set to '110'. The right panel, titled 'Piecewise Dropout Information', has '# of Pieces:' set to '1' and 'Input Method:' set to 'Prob. of Dropout'. Under 'By Time:', there is a text box with '12'. Below that, 'Prob. of Dropout (Control)' is set to '0.05' and 'Prob. of Dropout (Treatment)' is set to '0.05'. A note at the bottom right says 'Note: Period 1 hazard rates apply after time 12.' At the bottom of the interface, there is an 'Accrual' table with columns 'Min.', 'Comtd.', and 'Sugg. Max.' and rows for 'Duration' and 'Subjects'.

| | Min. | Comtd. | Sugg. Max. |
|-----------|------|--------|------------|
| Duration: | 35 | 49 | 56.664 |
| Subjects: | 3850 | 5390 | 6233 |

Notice how East automatically updates the accrual duration and subject accrual. An accrual duration in the range of 35 to 56.664 months is sufficient to achieve the desired power. Suppose that after examining the study duration versus accrual chart, we decide on an accrual duration of 49 months. Enter 49 in the **Comtd.** column.

Click the **Compute** button to generate output for Des3. With Des3 selected in the **Output Preview**, click the  icon to save Des3 to the **Library**. In the **Library**, select the rows for Des1, Des2, and Des3 by holding the Ctrl key, and then click the

The upper pane will display the details of the three designs side-by-side:

| Maximum | 315 | 77 | 49 |
| Expected Under H0 | 315 | 77 | 49 |
| Expected Under H1 | 315 | 77 | 49 |

Des3 also requires 3457 events. However, because of the faster rate of enrollment the time that it takes to obtain these events is cut down to 58.5 months.

46.2.2 Early Stopping for Futility

Under the null hypothesis Des3, with 3457 events, has an expected study duration of 57.2 months. This is a very long time commitment for a trial that is unlikely to be successful. Therefore it would be a good idea to introduce a futility boundary for possible early stopping. Since we wish to be fairly aggressive about early stopping for futility we will generate the futility boundary from the Gamma(-1) β -spending function. On the other hand, since there is no interest in early stopping for efficacy, we will not use an efficacy boundary.

Create a new design by selecting Des3 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the number of looks from 1 to 3. Next, click on the **Boundary** tab. Enter the parameters as shown below. Be sure to select the **Non-Binding** option. This choice gives us the flexibility to continue the trial even if a futility boundary has been crossed. Data monitoring committees usually want this

46 Non-Inferiority Trials Given Accrual Duration and Accrual Rates

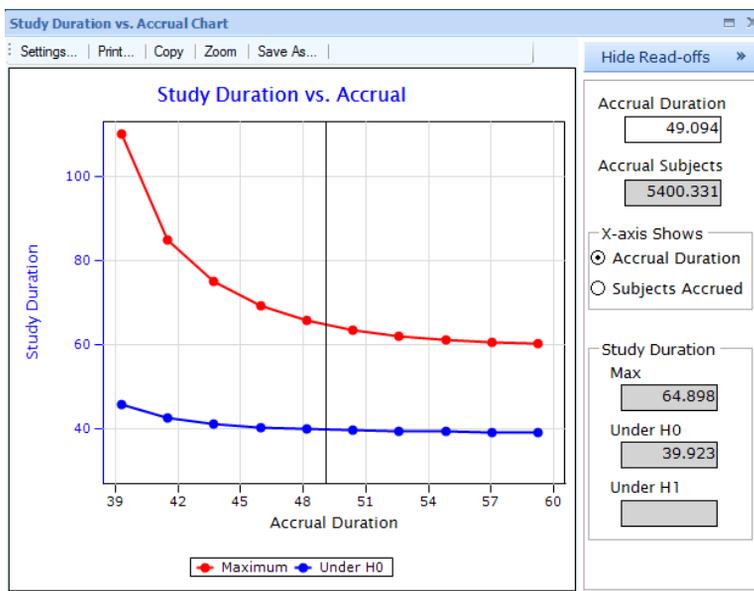

flexibility; for example, to follow a secondary endpoint.

The screenshot shows the 'Accrual / Dropouts' configuration window. It is divided into 'Efficacy' and 'Futility' sections. The 'Efficacy' section has 'Boundary Family' set to 'None'. The 'Futility' section has 'Boundary Family' set to 'Spending Functions', 'Spending Function' set to 'Gamma Family', 'Parameter (γ)' set to '-1', 'Type II Error (β)' set to '0.2', and 'Futility Boundary' set to 'Z Scale'. There are also radio buttons for 'Non-Binding' (selected) and 'Binding'. Below these settings is a table for 'Spacing of Looks'.

| Look # | Info. Fraction | Cum. β Spent | Futility Boundary |
|--------|----------------|--------------------|-------------------|
| 1 | 0.333 | 0.046 | -0.007 |
| 2 | 0.667 | 0.110 | -1.056 |
| 3 | 1.000 | 0.200 | -1.960 |

Next click on the **Accrual/Dropouts** tab. Once again, East automatically computes the minimum and suggested maximum values for the accrual duration and subject accrual.

Click the  icon to display the study duration versus accrual chart. Notice that another line is added to the chart. Now, we can see the maximum study duration vs accrual under the null hypothesis.

Suppose that after examining this chart, you decide to set the accrual duration at 49

months. Any increase in accrual duration past 49 months will not result in a substantial decrease in study duration. Close this chart. Select the radio button for **Duration** and enter 49 in the **Comtd.** column.

Click the **Compute** button to generate output for Des4. With Des4 selected in the **Output Preview**, click the  icon to save Des4 to the **Library**. In the **Library**, select the rows for Des3 and Des4 by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the two designs side-by-side:

| | Des 3 | Des 4 |
|---|--------------------|--------------------|
| Design Type | Noninferiority | Noninferiority |
| No. of Looks | 1 | 3 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.025 | 0.025 |
| Attained α | | 0.022 |
| Power | 0.8 | 0.8 |
| Model Parameters | | |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Hazard Ratio (Null) | 1.045 | 1.045 |
| Hazard Ratio (Alt.) | 0.95 | 0.95 |
| Var (Log HR) | Null | Null |
| Boundary Parameters | | |
| Spacing of Looks | | Unequal |
| Futility Boundary | | Gm (-1) (NB) |
| Accrual & Dropout Parameters | | |
| Accrual Rate | 110 | 110 |
| Subjects are Followed | Until End of Study | Until End of Study |
| No. of Accrual Periods | 1 | 1 |
| No. of Dropout Pieces | 1 | 1 |
| Sample Size | | |
| Maximum | 5390 | 5390 |
| Expected Under H0 | 5390 | 4140.262 |
| Expected Under H1 | 5390 | 5271.053 |
| Events | | |
| Maximum | 3457 | 3780 |
| Expected Under H0 | 3457 | 2056.327 |
| Expected Under H1 | 3457 | 3583.036 |
| Study Duration | | |
| Maximum | 58.523 | 64.893 |
| Expected Under H0 | 57.158 | 39.546 |
| Expected Under H1 | 58.523 | 62.059 |
| Accrual Duration | | |
| Maximum | 49 | 49 |
| Expected Under H0 | 49 | 37.639 |
| Expected Under H1 | 49 | 47.919 |

Observe that while the maximum study duration has been inflated by about 6 months compared to Des3, the expected study duration under H_0 has been cut down by almost 18 months.

It would be useful to simulate Des4 under a variety of scenarios for the hazard ratio. Select Des4 in the **Library** and click the  icon. You will be taken to the

46 Non-Inferiority Trials Given Accrual Duration and Accrual Rates

following simulation worksheet.

Number of Looks: 3

Test Parameters | **Response Generation** | Accrual / Dropouts | Simulation Controls

Trial Type: Noninferiority
 Test Type: 1-Sided
 Fix at Each Look: Total No. of Events
 Total No. of Events: 3780

Noninf. Margin (ln(HR0)): 0.044
 Test Statistic: Logrank

| Look # | Info. Fraction | Futility Z |
|--------|----------------|------------|
| 1 | 0.333 | -0.007 |
| 2 | 0.667 | -1.056 |
| 3 | 1.000 | -1.960 |

We wish to simulate this trial under the null hypothesis that the hazard ratio is $\exp(0.044) = 1.045$. To this end click on the **Response Generation** tab. In this tab change the hazard ratio to 1.045.

Survival Information

of Hazard Pieces: 1 | Input Method: Median Survival Times

| Med.Surv.Time | | Hazard Ratio |
|---------------|-----------|--------------|
| Control | Treatment | |
| 18 | 17.225 | 1.045 |

Next, click the **Simulate** button to simulate 10000 trials. A new row labeled Sim1 will appear in the **Output Preview** window. Select Sim1 in the **Output Preview** and click the  icon to save it to the **Library**. In the **Library**, double-click Sim1. A portion of the output is displayed below. (The actual values may differ, depending on the

starting seed used).

Simulation Seed and Elapsed Time

Starting Seed: 2272863
 Total Number of Simulations: 10000
 Elapsed Time: 00.01:15

Note that 234 out of the 10000 simulations rejected the null hypothesis when it was true. Thus confirming (up to Monte Carlo accuracy) that this design achieves a type-1 error of 2.5%. Also, observe that 50% of these trials have crossed the futility boundary at the very first interim look after only 29 months of study duration.

46.3 Interim Monitoring

Suppose we have adopted Des4. Let us monitor the trial with the help of the Interim Monitoring Worksheet. Select Des4 in the **Library**, and click the **IM** icon from the Library toolbar. Alternatively, right-click on Des4 and select **Interim Monitoring**. The interim monitoring dashboard contains various controls for monitoring the trial, and is divided into two sections. The top section contains several columns for displaying output values based on the interim inputs. The bottom section contains four charts, each with a corresponding table to its right. These charts provide graphical and numerical descriptions of the progress of the clinical trial and are useful tools for decision making by a data monitoring committee.

Suppose that the first interim look is taken after observing 1300 events. The observed hazard ratio is 1.15 and the standard error of the log hazard ratio is 0.06. Enter this information into the interim monitoring worksheet using Test Statistic calculator. Click

46 Non-Inferiority Trials Given Accrual Duration and Accrual Rates

on **Enter Interim Data** and enter the data in the test statistic calculator as shown below.

[Recalc] [OK] [Cancel]

Next, click **Recalc** and then **OK**. East will indicate that the H_1 (futility) boundary has been crossed and hence, the alternative hypothesis of non-inferiority is rejected in

favor of the null hypothesis of inferiority.

Click the **Stop** button to terminate the trial. You will see the IM sheet output including Final Inference details as shown below.

| Look # | Information Fraction | Cumulative Events | Test Statistic | Est. of... | Est. of δ | Std. Error of Est. of δ | Futility | 97.5% RCI for HR | | Repeated p-value | CP | Predictive Power |
|--------|----------------------|-------------------|----------------|------------|------------------|--------------------------------|----------|------------------|-------|------------------|----|------------------|
| | | | | | | | | Upper | Lower | | | |
| ▶ 1 | 0.344 | 1300 | 1.596 | 1.15 | 0.14 | 0.06 | -0.051 | NA | NA | NA | NA | NA |

Observe that the upper 97.5% Naive confidence bound for δ , 0.257, is above the non-inferiority margin of 0.044 (on the log hazard ratio scale).

Note - Click on  icon to hide or unhide the columns of your interest.

47 *Non-Inferiority Trials with Fixed Follow-Up*

This chapter will illustrate through a worked example how to design, monitor and simulate a two-sample non-inferiority trial with a time-to-event endpoint in which each subject who has not dropped out or experienced the event is followed for a fixed duration only. This implies that each subject who does not drop-out or experience the event within a given time interval, as measured from the time of randomization, will be administratively censored at the end of that interval. In East we refer to such designs as **fixed follow-up designs**.

47.1 *Type II Diabetes Trial*

A randomized non-inferiority clinical trial of a new monotherapy agent (treatment ‘t’) versus an active control (treatment ‘c’) is being planned for the treatment of type II diabetes. The primary endpoint is time to treatment failure, as measured by an elevated level of the HbA1c biomarker (greater than 8%). Each patient will be followed for up to 18 months or failure, whichever comes first. It is estimated that 50% of subjects on the active control will fail within four years. A major issue for non-inferiority trials is the selection of the non-inferiority margin for the new therapy. Since this question was discussed at length in Chapter 46, we will not repeat the discussion here. (See also, Rothman et al., 2003). Instead we will assume that, on the basis of an appropriate meta-analysis, the claim of non-inferiority can be sustained by demonstrating statistically that the treatment arm is at most 10% more hazardous than the control arm. This establishes a non-inferiority margin of $\lambda_t/\lambda_c = 1.1$ for the hazard ratio. Patient accrual will be at the rate of 1000/month for the first six months and 1500/month thereafter. The annual drop-out rate is expected to be 8% on each treatment arm.

We will design this trial to test the null hypothesis, $H_0: \lambda_t/\lambda_c \geq 1.1$, against the one sided alternative hypothesis, $H_1: \lambda_t/\lambda_c < 1.1$, with 90% power when $\lambda_t/\lambda_c = 1$. The investigators wish to select sample size that will enable the study to be completed within two years.

47.2 *Single-Look Design*

We begin by creating a single-look design for this study. To begin click **Survival: Two Samples** on the **Design** tab and then click **Parallel Design: Logrank Test Given Accrual Duration and Accrual Rates**.

This will open the input window for the design as shown below. Select **Noninferiority** from the **Design Type** dropdown. The right hand side panel of this input window is to be used for entering the relevant time-to event information. It appears with a default hazard ratio and default hazard rates for the control and treatment arms. Enter the survival information as mentioned in the design description.

- The hazard ratio under the null hypothesis (of non-inferiority) is 1.1. The hazard ratio under the alternative hypothesis at which 90% power is desired is 1.

Design Type: **Noninferiority** Number of Looks: **1**

Test Parameters | **Accrual / Dropouts**

Test Type: **1-Sided** # of Hazard Pieces: **1** Input Method: **Hazard Rates**

| 48 | 50 | 46.652 | 50 |

Note: Period 1 hazard rates apply after time 48.

To see the conversion of this information into hazard rates, select as input method the **Hazard Rates** option. The cumulative % survival will be converted into hazard rates.

Another parameter to be decided is the **Variance** which specifies whether the null or alternative hypothesis variance will be used to convert information into sample size. Leave it at its default value. (If interested in the technical details of the choice of

47 Non-Inferiority Trials with Fixed Follow-Up

variance, refer to Appendix B, Section B.5.3.

Variance of Log Hazard Ratio

Nll Alternative

The second tab, labeled **Accrual/Dropout** is used to enter the patient accrual rate and, for fixed follow-up designs, the duration of patient follow-up and the dropout information

- In this study, each subject will be followed for up to 18 months. Therefore select the **For Fixed Period** entry from the dropdown of **Subjects are Followed** and enter 18 in the edit box.
- Enrollment begins at the rate of 1000/month and increases to 1500/month six months later. Enter this information as shown below.

Subjects are followed: **For Fixed Period**

Accrual Info

of Accrual Periods:

| Period # | Starting at Time | Accrual Rate |
|----------|------------------|--------------|
| 1 | 0.000 | 1000.000 |
| 2 | 6.000 | 1500.000 |

The second panel, labeled **Piecewise Constant Dropout Rates**, is used to enter the rate at which we expect patients to drop out of the study. Make the **# of Pieces** as 1, change the **Input Method** to **Dropout Rates** and enter the information that the annual drop-out rate is 8%, as shown below.

Piecewise Dropout Information

By Time:

Prob. of Dropout (Control)

Prob. of Dropout (Treatment)

Also, make the **Committed # of Subjects** equal to the **Min. Suggested**, 21446.

| Accrual Duration | |
| Maximum | 16.297 |
| Expected Under H0 | 16.297 |
| Expected Under H1 | 16.297 |

East reveals that any sample size between 21,446 and 34,080 will satisfy the 90% power requirement. With 21,446 patients enrolled the expected study duration is 34.3 months, consisting of 16.3 months during the enrollment phase and an additional 18 months of fixed follow-up for each patient - including the last one - to be enrolled. At the end of that 34.3 month period we expect 4627 events. This is the number of events needed to fully power the study. To see how the events arrive over time, click on the

Sample Size/Events vs. Time chart.

If you increase the sample size beyond 21,446, the total study duration will be shortened. For example consider increasing the sample to 30,000 patients by editing

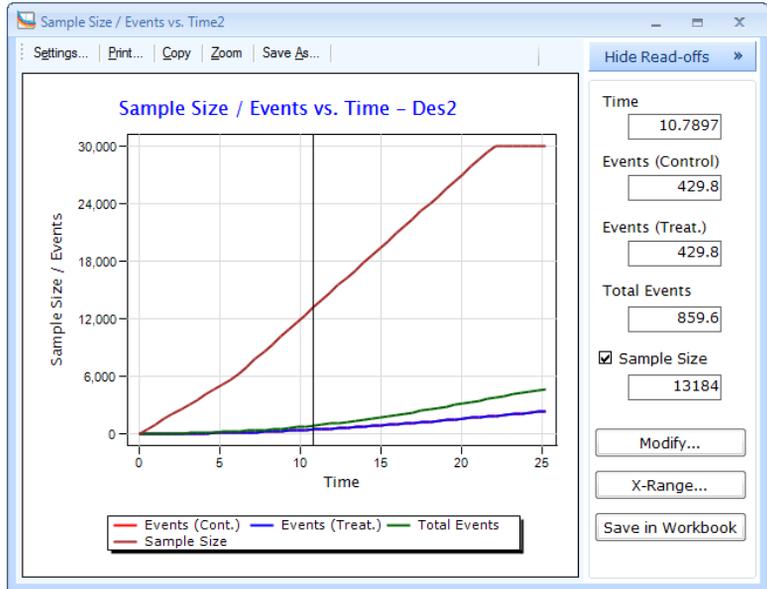

47 Non-Inferiority Trials with Fixed Follow-Up

Des1 ( icon) and creating Des2 with a new sample size.

| | Des1 | Des2 |
|---|-----------------------|-----------------------|
| Mnemonic | SU-2S-LRAR | SU-2S-LRAR |
| Test Parameters | | |

| Accrual Rate | Multiple | Multiple |
| Subjects are Followed | For Fixed Period (18) | For Fixed Period (18) |
| No. of Accrual Periods | 2 | 2 |
| No. of Dropout Pieces | 1 | 1 |
| Sample Size | | |
| Maximum | 21446 | 30000 |
| Expected Under H0 | 21446 | 30000 |
| Expected Under H1 | 21446 | 30000 |
| Events | | |
| Maximum | 4627 | 4627 |
| Expected Under H0 | 4627 | 4627 |
| Expected Under H1 | 4627 | 4627 |
| Accrual Duration | | |
| Maximum | 16.297 | 22 |
| Expected Under H0 | 16.297 | 22 |
| Expected Under H1 | 16.297 | 22 |
| Study Duration | | |
| Maximum | 34.297 | 25.021 |
| Expected Under H0 | 29.268 | 24.28 |
| Expected Under H1 | 34.297 | 25.021 |

Now the total study duration is 25 months where the accrual phase alone lasts for 22

months.

In this case, every patient will not have been followed for the full 18 months by the time the 4627 events needed to fully power the study have arrived and the study has been closed. Only those who were enrolled early will have been followed for 18 months. The later enrollees will have been followed for a shorter time.

47 Non-Inferiority Trials with Fixed Follow-Up

47.3 Three-Look Design

Next we consider extending Des1 by permitting two equally spaced interim looks at the accruing data with a view to possible early stopping. Edit Des1, change the number of looks from 1 to 3 as shown below.

Design Type: **Noninferiority** Number of Looks: **3**

47 Non-Inferiority Trials with Fixed Follow-Up

Because the default Lan-DeMets-O’Brien-Fleming spending function **LD (OF)** was used in this design, the maximum study duration has been inflated very slightly, from 34.3 to 34.5 months. However, if the alternative hypothesis is true we expect to terminate the trial in 26.4 months, a savings of about 8 months. This can be seen from the table **Sample Size Information** of the design details window.

⊖ Sample Size Information

| | Control Arm | Treatment Arm | Total |
|--------------------------------|-------------|---------------|-----------|

| Expected H0 | 16.467 | 29.351 |

47.4 Three-Look Design with Superiority Alternative

The preceding design required 21,701 subjects. This enormous up-front commitment might not be necessary if one actually believes that the new treatment is superior to the control treatment. Suppose that although the trial is still intended to reject the null hypothesis of inferiority at a non-inferiority margin of $\lambda_t/\lambda_c = 1.1$, it is believed that in fact λ_t/λ_c is less than 1; i.e., the treatment is actually superior to the active control. Ordinarily one would design a superiority trial in this situation. But now, suppose that the value λ_t/λ_c is believed to be about 0.95 under the alternative hypothesis. It would be very difficult to design a trial to prove superiority with this large a hazard ratio. (An extremely large sample size would be needed.) We can, however, use East to design a non-inferiority having 90% power at this alternative hypothesis. Edit Des3 and create Des4 by modifying the hazard ratio under the alternative hypothesis from 1 to 0.95 as shown below and **Committed Sample Size** equal to 9379.

Design Type: **Noninferiority** Number of Looks: **3**

Test Parameters Boundary Accrual / Dropouts

Test Type: **1-Sided** # of Hazard Pieces: **1** Input Method: **Hazard Rates**

| Study Duration | |
| Maximum | 26.253 |
| Expected Under H0 | 21.956 |
| Expected Under H1 | 20.176 |

Des4 can achieve 90% power with only 9379 patients, and 1979 events. The maximum study duration is 26.3 months and the expected study duration is 20 months under the alternative hypothesis. When compared to Des3, the savings in sample size are enormous.

47.5 *Simulating a Non-Inferiority Trial*

Let us simulate Des4. Activate Des4 in the **Library** and click on  icon. You will be taken to the Simulation Input window.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z |
|--------|----------------|---------------------|------------|
| 1 | 0.334 | 0.000 | -3.709 |
| 2 | 0.666 | 0.006 | -2.512 |
| 3 | 1.000 | 0.025 | -1.993 |

To view the default simulation inputs for this design, navigate across the four tabs. The inputs are as follows:

The hazard rates displayed in the **Response Generation** tab are the ones that were specified under the alternative hypothesis; i.e., $\lambda_c = 0.0144$ and $\lambda_t = 0.0137$. Hence we expect the trial to have 90% power. To verify this click the **Simulate** button and observe that in 10000 simulated trials the null hypothesis of inferiority was rejected

47 Non-Inferiority Trials with Fixed Follow-Up

8958 times. Also note that the Average Study Duration is 19.765 months.

| Total | | | 8753 | 10000 | |
| % | | | 87.530% | | |

Next let us verify that this design also preserves the type-1 error. Edit the node Sim1 by clicking  icon. We now specify the hazard rates under the null hypothesis; i.e., $\lambda_c = 0.0144$ and $\lambda_t = 0.0144 * 1.1 = 0.0159$. We enter these hazard rates into the table labeled **Piecewise Hazards** as shown below. (Note - Consider taking the exact values of hazard rates with full precision to reproduce the results in this User Manual)

Survival Information

of Hazard Pieces: Input Method:

Hazard Ratio

| Piece | Starting at Time | Hazard Rates | | Hazard Ratio |
|-------|------------------|--------------|-----------|--------------|
| | | Control | Treatment | |
| 1 | 0.000 | 0.014 | 0.016 | 1.1 |

Generate 10000 simulated trials by clicking on the **Simulate** button.

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Accrual Rates

☉ Average Sample Size, Dropouts and Look Times

| Look # | Average Sample Size | Average Events | | Average Dropouts | | Average Look Time | Average Follow up |
|---------|---------------------|----------------|-----------|------------------|-----------|-------------------|-------------------|
| | | Control | Treatment | Control | Treatment | | |
| 1 | 9379 | 315.008 | 344.992 | 151.63 | 150.898 | 9.45 | 4.642 |
| 2 | 9379 | 630.637 | 688.363 | 303.606 | 301.186 | 14.936 | 9.278 |
| 3 | 9379 | 947.641 | 1031.354 | 456.285 | 450.992 | 22.047 | 13.919 |
| Average | 9379 | 946.199 | 1029.298 | 455.527 | 450.21 | 22.009 | 13.895 |

☉ Simulation Boundaries and Boundary Crossing Probabilities

| Look # | Events | Boundaries | Stopping For | Total Simulations | |
|--------|--------|------------|--------------|-------------------|---------|
| | | Efficacy | Efficacy | Count | % |
| 1 | 660 | -3.709 | 1 | 1 | 0.010% |
| 2 | 1319 | -2.512 | 51 | 51 | 0.510% |
| 3 | 1979 | -1.993 | 173 | 9948 | 99.480% |
| Total | | | 225 | 10000 | |
| % | | | 2.250% | | |

We observe that only 225 of the 10000 trials rejected the null hypothesis thus confirming (up to Monte Carlo accuracy) that the type-1 error of 0.025 is preserved.

48 Superiority Trials Given Accrual Duration and Study Duration

This chapter will illustrate through a worked example how to design and simulate a two-sample superiority trial with a time-to-event trial endpoint, where the accrual duration and study duration are constrained. Most trials in the pharmaceutical industry setting are designed in this manner, time being a more rigid constraint than the accrual rate of patients. The duration of a clinical trial impacts the duration of a drug development program, and thus time to market and potential revenues. Therefore it is of interest to fix the study duration as well as the accrual duration to finish the clinical trial according to schedule. The option to design a trial in this way is available in East.

48.1 Calculating a Sample Size

For this design, East obtains the maximum number of events D_{max} from the maximum information I_{max} , as described in Appendix sections B.5 and B.5.3. To calculate the sample size, we first equate the expected number of events $d(S_a + S_f)$ (as calculated in Appendix D which depends on the accrual duration (S_a) and the duration of follow-up (S_f) to the maximum number of events D_{max} .

$$d(S_a + S_f) = D_{max} \quad (48.1)$$

In this type of design the accrual duration S_a and the study duration $S_a + S_f$ are given as input. East iterates between sample sizes, increasing onwards from a minimum value of D_{max} , enrolled over a duration of S_a until D_{max} events are found to occur within a study duration of $S_a + S_f$. The result is the unique sample size required to obtain the proper power for the study.

48.2 The RALES Clinical Trial: Initial Design

The RALES trial (Pitt et. al., 1999) was a double blind study of aldosterone-receptor blocker spironolactone at a daily dose of 25 mg in combination with standard doses of an ACE inhibitor (treatment arm) versus standard therapy of an ACE inhibitor (control arm) in patients who had severe heart failure as a result of systolic left ventricular dysfunction. The primary endpoint was death from any cause. Six equally-spaced looks at the data using the Lan-DeMets-O'Brien-Fleming spending function were planned. The trial was designed to detect a hazard ratio of 0.83 with 90% power at a two-sided 0.05 level of significance. The hazard rate of the control arm was estimated to be 0.38.

Randomization was scheduled to begin in March 1995 and complete in December 1996 for a total of 1.8 years of enrollment. Follow-up was planned through December

1999, so that the total study duration from first patient enrolled to last patient visit should be 4.8 years.

We begin by using East to design RALES under these basic assumptions. To begin click **Survival: Two Samples** on the **Design** tab and then click **Parallel Design: Logrank Test Given Accrual Duration and Study Duration**.

A new screen will appear. Enter the appropriate design parameters into the dialog box as shown below.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Design Type: Superiority Number of Looks: 6

Test Parameters Boundary Accrual / Dropouts

Test Type: 2-Sided # of Hazard Pieces: 1 Input Method: Hazard Rates

Type I Error (α): 0.05 Hazard Ratio (Optional) Alternative

Power: 0.9 Hazard Ratio (λ₁/λ₂) 0.83

Sample Size (n): Computed Log Hazard Ratio ln(λ₁/λ₂) -0.186

No. of Events: Computed

| Hazard Rate | |
|-------------|-----------------|
| Control | Treatment: Alt. |
| 0.38 | 0.3154 |

Allocation Ratio: 1 (n₁/n₂)

Variance of Log Hazard Ratio

Null Alternative

The box labeled **Variance of Log Hazard Ratio** specifies whether the calculation of the required number of events is to be based on the variance estimate of the log hazard ratio under the null hypothesis or the alternative hypothesis. The default choice in East is **Null**. Most textbooks recommend this choice as well (see, for example Collett, 1994, equation (2.21) specialized to no ties). It will usually not be necessary to change this default. For a technical discussion of this issue refer to Appendix B, Section B.5.3.

Next, click on the **Boundary Info** tab. We will take six equally spaced looks at the data using the Lan-DeMets O’Brien-Fleming spending function. These are the default

48 Superiority Trials Given Accrual Duration and Study Duration

setting in East.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Boundary | |
|--------|----------------|---------------------|-------------------|--------|
| | | | Upper | Lower |
| 1 | 0.167 | 0.000 | 5.367 | -5.367 |
| 2 | 0.333 | 0.000 | 3.710 | -3.710 |
| 3 | 0.500 | 0.003 | 2.970 | -2.970 |
| 4 | 0.667 | 0.012 | 2.539 | -2.539 |
| 5 | 0.833 | 0.028 | 2.252 | -2.252 |
| 6 | 1.000 | 0.050 | 2.045 | -2.045 |

Note that we do not select a futility boundary in this case. Next click on the **Accrual/Dropout Info** tab. Here we will specify the accrual information and dropout rates. The software allows a specification of piecewise constant hazards and variable accrual rates but we start by looking at an example that does not require any of these options. In the drop-down menu next to **Subjects are followed:** select **Until End of Study**. Set the **Accrual Duration** to 1.8 years and the **Study Duration** to 4.8 years. Notice that East has changed the settings so that at 1.8 years the study should be 100% accrued. Keep the number of accrual periods equal to the default of 1. To the right of the **Accrual Info** box is the **Piecewise Constant Dropout Rates** box. This box is used to enter that rate at which we expect patients to drop out of the study. For the present we will assume that there are no drop-outs.

| Period # | By Time | Cum. % Accrued |
|----------|---------|----------------|
| 1 | 1.800 | 100.000 |

Click on **Compute** to complete the design. The design is shown as a row in the

Output Preview located in the lower pane of this window. You can select this design by clicking anywhere along the row in the **Output Preview**. With Des1 selected, click the  icon to display the details of this design in the upper pane, which are shown below. You may also wish to save this design. Select Des1 in the **Output Preview** window and click the  to save this design to Workbook1 in the **Library**.

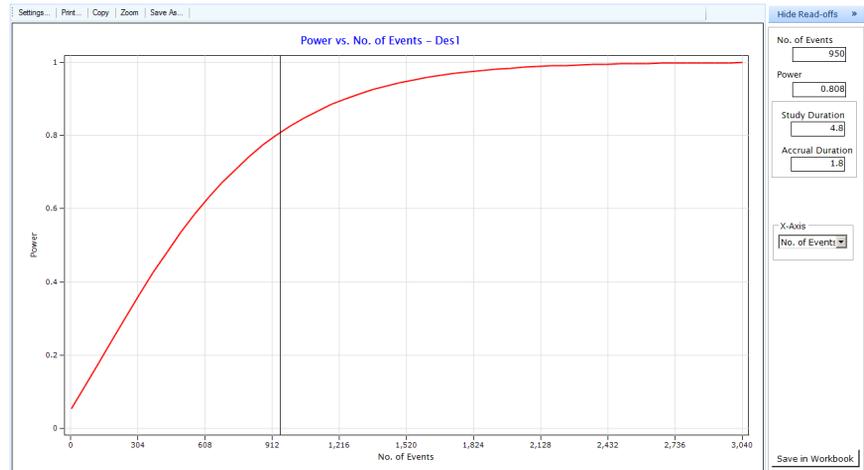

| Des 1 | |

| Expected Under H0 | 4.416 |
| Expected Under H1 | 3.304 |
| Accrual Duration | |
| Maximum | 1.8 |
| Expected Under H0 | 1.8 |
| Expected Under H1 | 1.798 |

East notifies you that 1243 events and a sample size of 1689 are required to attain the desired 90% power in the allotted time.

East provides charts to examine the trade-offs between power and accrual duration, study duration, sample size or number of events. Select Des1 in the **Library** click the  icon and select **Power vs. Sample Size**.

48 Superiority Trials Given Accrual Duration and Study Duration

Switch the **X-Axis** to **No. of Events**. The power of the study is really tied to the number of events that are observed. This chart shows the direct relationship between power and number of events.

Note that 950 events give us about 81% power. You may wish to save this chart to the **Library** by clicking on the **Save in Workbook** button.

48.3 Incorporating Drop-Outs

The investigators expect 5% of the patients in the spironolactone group and the control group to drop out each year. Create a new design by selecting Des1 in the **Library**, and clicking the  icon on the **Library** toolbar. Next, click on the **Accrual/Dropout Info** tab. In the **Piecewise Constant Dropout Rates** box, select 1 for the number of pieces and change the **Input Method** from **Hazard Rates** to **Prob. of Dropout**. Then enter 0.05 dropouts by 1 year for the treatment and

control arm as shown below.

Piecewise Dropout Information

of Pieces: Input Method:

By Time:

Prob. of Dropout (Control)

Prob. of Dropout (Treatment)

Note: Period 1 hazard rates apply after time 1.

Click the **Compute** button to generate output for Des2. With Des2 selected in the **Output Preview**, click the  icon to save Des2 to the **Library**. In the **Library**, select the rows for Des1 and Des2, by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the two designs side-by-side.

A comparison of the two plans reveals that, because of the drop-outs, we require 1,824 subjects to be enrolled under Des2 rather than 1689 under Des1. Also, the expected study duration will not change much under the alternative and null hypotheses between Des1 and Des2.

48.4 Incorporating Non-Constant Accrual Rates

In many clinical trials the enrollment rate is low in the beginning and reaches its maximum expected level a few months later when all the sites enrolling patients are onboard. Suppose that 20% of the total accrual is expected to occur during the first six months with the rest happening during the remaining 1.3 years. Create a new design by selecting Des2 in the **Library**, and clicking the  icon on the **Library** toolbar. Next, click on the **Accrual/Dropout Info** tab. Specify that there are two accrual periods and enter the cumulative accrual for each period in the dialog box as shown

48 Superiority Trials Given Accrual Duration and Study Duration

below.

Accrual Info

Accrual Duration: Study Duration:

of Accrual Periods:

| Period # | By Time | Cum. % Accrued |
|----------|---------|----------------|
| 1 | 0.5 | 20.000 |
| 2 | 1.8 | 100.000 |

Click the **Compute** button to generate output for Des3. With Des3 selected in the **Output Preview**, click the  icon to save Des3 to the **Library**. In the **Library**, select the rows for Des1, Des2, and Des3 by holding the Ctrl key, and then click the  icon. The upper pane will display the details of the three designs side-by-side.

Notice that we now need 1837 subjects to be enrolled to compensate for the overall later enrollment of subjects.

48.5 Simulation

48.5.1 Simulating Under H_1

48.5.2 Simulating Under H_0

It would be useful to verify the operating characteristics of the various plans created in the previous section by simulation. Select Des3 in the **Library** and click the  icon. You will be taken to the following simulation worksheet.

Simulation: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Number of Looks:

Test Parameters | Response Generation | **Accrual / Dropouts** | Simulation Controls

Trial Type: Test Statistic:

Test Type:

Fix at Each Look:

Total No. of Events:

| Look # | Info. Fraction | Cum. α Spent | | Efficacy Z | |
|--------|----------------|--------------|-------|------------|--------|
| | | Upper | Lower | Upper | Lower |
| 1 | 0.167 | 0.000 | 0.000 | 5.369 | -5.369 |
| 2 | 0.333 | 0.000 | 0.000 | 3.712 | -3.712 |
| 3 | 0.500 | 0.002 | 0.002 | 2.968 | -2.968 |

48.5.2 Simulating Under H0

To simulate under the null hypothesis we must go to the **Response Generation Info** tab in the simulation worksheet. In this tab change the hazard rate for the treatment arm to 0.38.

Test Parameters
Response Generation
Accrual / Dropouts
Sir

Survival Information

of Hazard Pieces
Input Method:

| Hazard Rate | | Hazard Ratio |
|-------------|-----------|--------------------------------|
| Control | Treatment | |
| 0.38 | 0.38 | <input type="text" value="1"/> |

This change implies that we will be simulating under the null hypothesis. Next, click

on the **Test Parameters** tab and make sure that the **Total No. of Events** is fixed at each look. Next, click the **Simulate** button to simulate 10000 trials. A portion of the results are displayed below.

☰ **Simulation Boundaries and Cumulative Boundary Crossing Probabilities**

| Look # | Events | Boundaries | | Stopping For | | Total Simulations | |
|---------|--------|------------|--------|----------------|----------------|-------------------|----------|
| | | Efficacy | | Upper Efficacy | Lower Efficacy | Count | % |
| | | Upper | Lower | | | | |
| 1 | 207 | 5.369 | -5.369 | 0 | 0 | 0 | 0.000% |
| 2 | 414 | 3.712 | -3.712 | 0 | 2 | 2 | 0.020% |
| 3 | 622 | 2.968 | -2.968 | 9 | 22 | 31 | 0.310% |
| 4 | 829 | 2.538 | -2.538 | 55 | 76 | 131 | 1.310% |
| 5 | 1036 | 2.252 | -2.252 | 128 | 151 | 279 | 2.790% |
| 6 | 1243 | 2.045 | -2.045 | 245 | 258 | 10000 | 100.000% |
| Total % | | | | 2.450% | 2.580% | | |

Out of 10000 simulated trials 245 crossed the upper stopping boundary and 258 crossed the lower stopping boundary thus confirming (up to Monte Carlo accuracy) that the type-1 error is preserved for this design.

48.6 User Defined R Function

East allows you to customize simulations by inserting user-defined R functions for one or more of the following tasks: generate response, compute test statistic, randomize subjects, generate arrival times, and generate dropout information. The R functionality for arrivals and dropouts will be available only if you have entered such information at the design stage. Although the R functions are also available for all normal and binomial endpoints, we will illustrate this functionality for a time-to-event endpoint. Specifically, we will use an R function to generate Weibull survival responses.

Start East afresh. On the **Design** tab, click **Survival: Two Samples** and then **Logrank Test Given Accrual Duration and Study Duration**.

Choose the design parameters as shown below. In particular, select a one sided test

48 Superiority Trials Given Accrual Duration and Study Duration

with type-1 error of $\alpha = 0.025$.

Design: Survival Endpoint: Two-Sample Test - Parallel Design - Logrank Given Accrual Duration and Study Duration

Refresh Frequency: 1000

Random Number Seed

Clock

Fixed 100

Suppress All Intermediate Output

Output Options

Output Type: Case Data

Save summary statistics for every simulation run

Save subject level data for 1 simulation runs

Note: Max. 100,000 records will be saved.

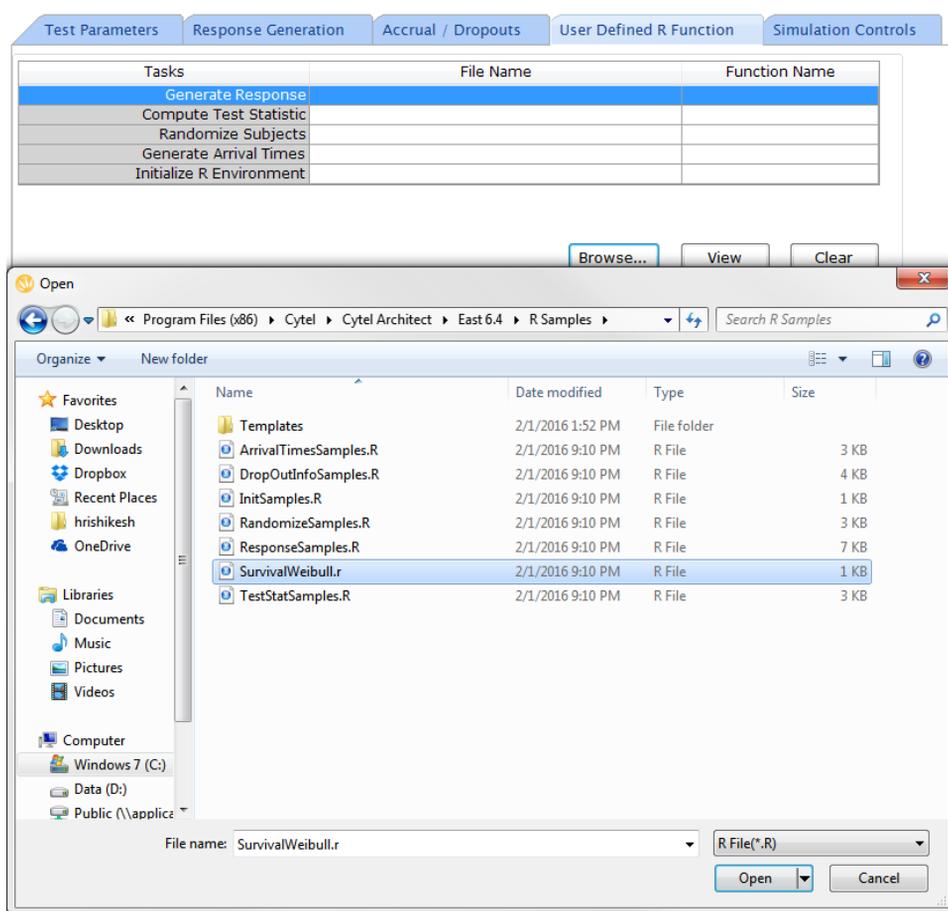

In the top right-hand corner for the input window, click **Include Options**, and then click **User Defined R Function**.

Include Options

- Site Info
- Randomization Info
- User Defined R Function
- Stratification Info

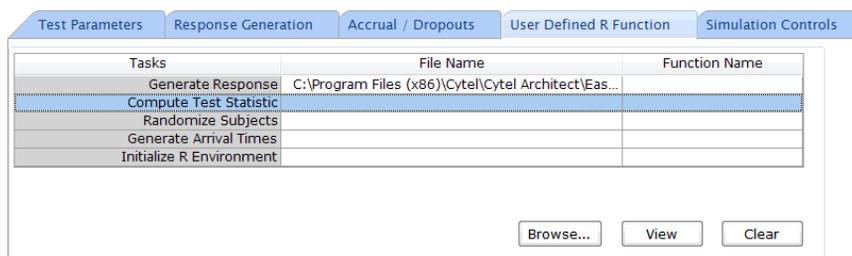

For now, leave the row **Initialize R Environment** blank. This optional task can be useful for loading required libraries, setting seeds for simulations, and initializing global variables.

Select the row for **Generate Response**, click **Browse...**, and navigate to the folder containing your R file.

48 Superiority Trials Given Accrual Duration and Study Duration

Select the file and click **Open**. The path should now be displayed under **File Name**.

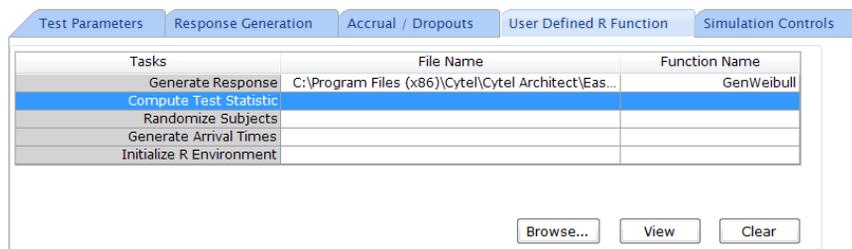

Click on the first row and then click **View** to open a notepad application to view your R file. In this example, I am generating survival responses for both control and treatment arms from a Weibull with shape parameter = 2 (i.e. exponential), with the same hazard rate in both arms.

```

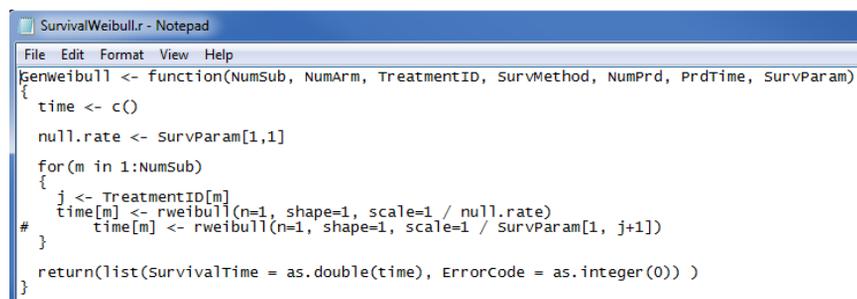

SurvivalWeibull.r - Notepad
File Edit Format View Help
GenWeibull <- function(NumSub, NumArm, TreatmentID, SurvMethod, NumPrd, PrdTime, SurvParam)
{
  time <- c()
  null.rate <- SurvParam[1,1]
  for(m in 1:NumSub)
  {
    j <- TreatmentID[m]
    time[m] <- rweibull(n=1, shape=2, scale=1 / null.rate)
  }
  return(list(SurvivalTime = as.double(time), ErrorCode = as.integer(0)) )
}
    
```

Copy the function name (in this case *GenWeibull*).

Close the R file and paste the function name in the cell for **Function Name**. Click **Simulate**.

Return to the tab for **User Defined R Function**, select the **Generate Response** row, and click **View**. In the R function, change the shape parameter = 1, to generate responses from a Weibull distribution with decreasing hazards. Save and close the R file. You may not be able to save the file in the C: drive due to administrative privileges. So save the updated file somewhere else, say the Desktop.

```
SurvivalWeibull.r - Notepad
File Edit Format View Help
GenWeibull <- function(NumSub, NumArm, TreatmentID, SurvMethod, NumPrd, PrdTime, SurvParam)
{
  time <- c()
  null.rate <- SurvParam[1,1]
  for(m in 1:NumSub)
  {
    j <- TreatmentID[m]
    time[m] <- rweibull(n=1, shape=1, scale=1 / null.rate)
    # time[m] <- rweibull(n=1, shape=1, scale=1 / SurvParam[1, j+1])
  }
  return(list(SurvivalTime = as.double(time), ErrorCode = as.integer(0)) )
}
```

Browse to the new file on the Desktop. The function name is same so no need to change that. Click **Simulate**.

Select both simulations (Sim1 and Sim2) from the **Output Preview**, and on the

48 Superiority Trials Given Accrual Duration and Study Duration

toolbar, click  to display in the **Output Summary**.

| | Sim1 | Sim2 |
|-------------------------------------|--------------------|--------------------|
| Mnemonic | SU-2S-LRSD | SU-2S-LRSD |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| Test Type | 1-Sided | 1-Sided |
| Power | 0.027 | 0.026 |
| No. of Looks | 1 | 1 |
| Test Statistic | Logrank | Logrank |
| Model Parameters | | |
| No. of Hazard Pieces | 1 | 1 |
| Hazard Ratio | 0.5 | 0.5 |
| Sample Size | | |
| Maximum | 182 | 182 |
| Events | | |
| Maximum | 88 | 88 |
| Simulation Results (Overall) | | |
| Average Study Duration | 34.624 | 30.708 |
| Average Sample Size | 182 | 182 |
| Other Parameters | | |
| Subjects Followed-up | Until End of Study | Until End of Study |

Notice that the type-1 error appears to be controlled in both cases. When we simulated from the exponential (Sim2), the average study duration (30.7 months) was close to what was calculated at Des1 for the expected study duration under the null. However, when we simulated from the Weibull with increasing hazards (Sim1), the average study duration increased to 34.6 months.

Appendix O contains detailed specifications for the required inputs and outputs of R functions for each task and endpoint. The ability to use custom R functions for many simulation tasks allows considerable flexibility in performing sensitivity analyses and assessment of key operating characteristics.

48.7 Assurance for Survival

Assurance, or probability of success, is a Bayesian version of power, which corresponds to the (unconditional) probability that the trial will yield a statistically significant result. Specifically, it is the prior expectation of the power, averaged over a prior distribution for the unknown treatment effect (see O’Hagan et al., 2005). For a given design, East allows you to specify a prior distribution, for which the assurance or probability of success will be computed. In this section, we will replicate and extend

an example from Sabin et al. (2014).

Start East afresh. Click **Survival: Two Samples** on the **Design** tab and then click **Parallel Design: Logrank Test Given Accrual Duration and Study Duration**. Compute the following design: Design Type = Superiority, Test Type = 1-sided, Type-1 error = 0.025, Power = 80%, Hazard ratio = 0.75.

Design Type: Superiority Number of Looks: 1

Test Parameters Accrual / Dropouts

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Hazard Rates

Type I Error (α): 0.025 Hazard Ratio (Optional) Alternative 0.75

Power: 0.8 Hazard Ratio (λ_t / λ_c) -0.288

Log Hazard Ratio $\ln(\lambda_t / \lambda_c)$

| Hazard Rate | |
|-------------|-----------------|
| Control | Treatment: Alt. |
| 0.035 | 0.026 |

Sample Size (n): 694

No. of Events: 380

Allocation Ratio: 1 (n_t / n_c)

Variance of Log Hazard Ratio

Null Alternative

Assurance (Probability of Success)

This design requires 380 events to achieve 80% power. However, this value of power depends on the assumption that the HR is precisely 0.75, or that $\delta = \ln(\text{HR}) = -0.288$. Sabin et al. (2014) explored various prior distributions derived from Phase 2 data. In one example, they used a Normal prior distribution for $\ln(\text{HR})$, with a mean of -0.183 , and a standard deviation of 0.135.

Select the **Assurance** checkbox in the Input window. In the **Distribution** list, click **Normal**, and in the **Input Method** list, click **E(δ) and SD(δ)**.

48 Superiority Trials Given Accrual Duration and Study Duration

Assurance (Probability of Success) 0.458

Prior Distribution for: Log Hazard Ratio (δ) Distribution: Normal

Input Method: E(δ) and SD(δ)

User Specified

E(δ): -0.183

SD(δ): 0.135

This replicates their reported *Probability of Ph 3 success* of 0.46.

East also allows you to specify an arbitrary discrete prior distribution through an R function. In the **Distribution** list, click **User Specified-R**, and then click **Browse...** to select the R file where you have constructed a prior. Click **View...** to open the R file.

```

InHR - Notepad
File Edit Format View Help
}nHR = function() {
  Error <- 0

  mean <- (-0.183)
  sd <- 0.135

  min <- mean - 4*sd
  max <- mean + 4*sd
  points.total <- 31
  step <- (max - min)/(points.total - 1)
  points <- seq(from=min, to=max, length=points.total)
  mid.points <- (points + (step/2))[-points.total]
  out.points <- c(-Inf, mid.points, Inf)
  L <- 1 : points.total
  R <- 2 : (points.total+1)

  weights <- pnorm(out.points[R], mean, sd) - pnorm(out.points[L], mean, sd)

  points <- c(0, points)
  weights <- c(1, weights)

  return(list(Delta = as.double(points), Prob = as.double(weights), ErrorCode = as.integer(Error)))
}
  
```

In this R file, we have constructed a discretized Normal distribution with the same mean and standard deviation as above, but added a lump of equal weight at the null hypothesis. Type the function name (in this case, InHR) into the **R Function** field, and click **Compute**. The resulting probability of success (0.241) is even lower due to the prior weight on the null hypothesis.

Assurance (Probability of Success)
Prior Distribution for: Distribution:

49 *Non Inferiority Trials Given Accrual Duration and Study Duration*

This chapter will illustrate through a worked example how to design and simulate a two-sample non inferiority trial with a time to event trial endpoint, when the accrual duration and study duration are fixed.

49.1 *Calculating a Sample Size*

For this design, East obtains the maximum number of events D_{max} from the maximum information I_{max} , as described in Appendix sections B.5 and B.5.3. To calculate the sample size, we first equate the expected number of events $d(S_a + S_f)$ (as calculated in Appendix D which depends on the accrual duration (S_a) and the duration of follow-up (S_f) to the maximum number of events D_{max} .

$$d(S_a + S_f) = D_{max} \tag{49.1}$$

In this type of design the accrual duration S_a and the study duration $S_a + S_f$ are given as input. East iterates between sample sizes, increasing onwards from a minimum value of D_{max} , enrolled over a duration of S_a until D_{max} events are found to occur within a study duration of $S_a + S_f$. The result is the unique sample size required to obtain the proper power for the study.

49.2 *The Non Inferiority Margin*

The first step in designing a non-inferiority trial is to establish a suitable non inferiority margin. This is typically done by performing a meta-analysis on past clinical trials of the active control versus placebo. Regulatory agencies then require the sponsor of the clinical trial to demonstrate that a fixed percentage of the active control effect (usually 50%) is retained by the new treatment. A further complication arises because the active control effect can only be estimated with error. We illustrate below with an example provided by reviewers at the FDA.

Rothman et al. (2003) have discussed a clinical trial to establish the non inferiority of the test drug Xeloda (treatment t) relative to the active control (treatment c) consisting of 5 fluorouracil with leucovorin (5FU+LV) for metastatic colorectal cancer. In order to establish a suitable non inferiority margin for this trial it is necessary to first establish the effect of 5FU+LV relative to the reference therapy of 5FU alone (treatment p , here regarded as placebo). To establish this effect the FDA conducted a ten study random effects meta analysis (FDA Medical Statistical review for Xeloda, NDA 20 896, April 2001) of randomized comparisons of 5-FU alone versus 5-FU+LV.

Letting λ_t, λ_c and λ_p denote the constant hazard rates for the new treatment, the active control and the placebo, respectively, the FDA meta analysis established that

$$\ln(\widehat{\lambda_p/\lambda_c}) = 0.234$$

with standard error

$$\text{se}[\ln(\widehat{\lambda_p/\lambda_c})] = 0.075 .$$

Thus with $100\gamma\%$ confidence the active control effect lies inside the interval

$$[0.234 - 0.075\Phi^{-1}(\frac{1+\gamma}{2}), 0.234 + 0.075\Phi^{-1}(\frac{1+\gamma}{2})] \quad (49.2)$$

The new study is required to demonstrate that some fraction (usually 50%) of the active control effect is retained. Rothman et al. (2003) state that the claim of non inferiority for the new treatment relative to the active control can be demonstrated if the upper limit of a two sided $100(1 - \alpha)\%$ confidence interval for $\ln(\lambda_t/\lambda_c)$ is less than a pre specified fraction of the lower limit of a two sided $100\gamma\%$ confidence interval for the active control effect established by the meta-analysis. This is known as the “two confidence intervals procedure”. Specifically in order to claim non inferiority in the current trial it is necessary to show that

$$\ln(\widehat{\lambda_t/\lambda_c}) + \Phi^{-1}(1 - \alpha/2)\text{se}[\ln(\widehat{\lambda_t/\lambda_c})] < (1 - f_0)\{\ln(\widehat{\lambda_p/\lambda_c}) - \Phi^{-1}(\frac{1+\gamma}{2})\text{se}[\ln(\widehat{\lambda_p/\lambda_c})]\} . \quad (49.3)$$

We may re-write the non inferiority condition (49.3) in terms of a one-sided Wald test of the form

$$\frac{\ln(\widehat{\lambda_t/\lambda_c}) - \delta_0}{\text{se}[\ln(\widehat{\lambda_t/\lambda_c})]} < \Phi^{-1}(1 - \alpha/2) , \quad (49.4)$$

where

$$\delta_0 = (1 - f_0)\{\ln(\widehat{\lambda_p/\lambda_c}) - \Phi^{-1}(\frac{1+\gamma}{2})\text{se}[\ln(\widehat{\lambda_p/\lambda_c})]\} \quad (49.5)$$

is the non inferiority margin.

The choice $f_0 = 1$ implies that the entire active control effect must be retained in the new trial and amounts to running a superiority trial. At the other end of the spectrum, the choice $f_0 = 0$ implies that none of the active control effect need be retained; i.e., the new treatment is only required to demonstrate effectiveness relative to placebo. The usual choice is $f_0 = 0.5$, implying that the new treatment is required to retain at least 50% of the active control effect. The usual choice for α is $\alpha = 0.05$. A conservative choice for the coefficient γ is $\gamma = (1 - \alpha) = 0.95$. Rothman et al. (2003) refer to this method of establishing the non inferiority margin as the “two 95 percent

49 Non Inferiority Trials Given Accrual Duration and Study Duration

two sided confidence interval procedure” or the “95-95 rule”. In general this approach leads to rather tight margins unless the active control effect is substantial. Rothman et al. (2003) have also proposed more lenient margins that vary with the amount of power desired. Fleming (2007), however, argues for the stricter 95-95 rule on the grounds that it offers greater protection against an ineffective medical compound being approved in the event that the results of the previous trials used to establish the active control effect are of questionable relevance to the current setting. Accordingly we evaluate (49.5) with $\gamma = 0.95$, $f_0 = 0.5$, $\ln(\widehat{\lambda_p/\lambda_c}) = 0.234$ and $\text{se}[\ln(\widehat{\lambda_p/\lambda_c})] = 0.075$ thereby obtaining the non inferiority margin to be $\delta_0 = 0.044$ for the log hazard ratio and $\exp(0.044) = 1.045$ for the hazard ratio.

49.3 Design of Metastatic Colorectal Cancer Trial

In this section we will use East to design a single-look non inferiority trial comparing the test drug Xeloda (treatment t) to the active control 5FU+LV (treatment c) for the treatment of metastatic colorectal cancer. On the basis of a meta analysis of ten previous studies of the active control versus placebo (Rothman et. al. 2003), a non inferiority margin of 1.045 for λ_t/λ_c has been established. Thus we are interested in testing the null hypothesis of inferiority $H_0: \lambda_t/\lambda_c \geq 1.045$ versus the one-sided alternative hypothesis that $\lambda_t/\lambda_c < 1.045$. Suppose the trial is planned to enroll for 30 months and finish within 70 months of the last patient enrolled.

49.3.1 Single-Look Design

We will use East to create an initial single-look design having 80% power to detect the alternative hypothesis $H_1: \lambda_t/\lambda_c = 1$ with a one sided level-0.025 non-inferiority test.

To begin click **Survival: Two Samples** on the **Design** tab and then click **Parallel Design: Logrank Test Given Accrual Duration and Study Duration** as shown below.

A new screen will appear. Enter the appropriate design parameters into the dialog box

as shown below.

Design Type: **Noninferiority** Number of Looks: **1**

Test Parameters | **Accrual / Dropouts**

Test Type: **1-Sided** # of Hazard Pieces: **1** Input Method: **Median Survival Times**

| <input type="radio"/> Ratio of Medians (m_t/m_c) | 0.957 | 1 |

| | Med.Surv.Time | |
|-----------|----------------|-----------------|
| Control | Treatment:Null | Treatment: Alt. |
| 18 | 17.225 | 18 |

Variance of Log Hazard Ratio

Null Alternative

The box labeled **Variance of Log Hazard Ratio** specifies whether the calculation of the required number of events is to be based on the variance estimate of the log hazard ratio under the null hypothesis or the alternative hypothesis. The default choice in East is **Null**. Most textbooks recommend this choice as well (see, for example Collett, 1994, equation (2.21) specialized to no ties). It will usually not be necessary to change this default. For a technical discussion of this issue refer to Appendix B, Section B.5.3.

Next click on the **Accrual/Dropout** tab. Here we will specify the accrual information and dropout rates. Set the accrual duration to **30** months and the study duration to **100** months in the **Accrual** box. Also, suppose that there are **5%** drop-outs per year in each arm. Enter these values as shown below.

| Expected Under H1 | 30 |

It is immediately evident that Des1 is untenable. It requires 16,205 events to be fully powered and 18,527 subjects to obtain those events within the course of the study. The problem lies with trying to power the trial to detect a hazard ratio of 1 under the alternative hypothesis. Suppose instead that the investigators actually believe that the treatment is slightly superior to the active control, but the difference is too small to be detected in a superiority trial. In that case a non-inferiority design powered at a hazard ratio less than 1 (0.95, say) would be a better option because such a trial would require fewer events.

To see this create a new design by selecting Des1 in the **Library**, and clicking the  icon on the **Library** toolbar. Then edit this design by specifying a hazard ratio of 0.95 under the alternative hypothesis as shown below.

| Expected Under H1 | 30 | 30 |

Des2 is clearly easier to implement than Des1. It requires only 3,457 events to be fully powered. This can be achieved with only 3,973 patients enrolled in the study.

49.3.2 Early Stopping for Futility

Under the null hypothesis, Des2, with 3,457 events, has expected study duration of 93.2 months. This is a very long time commitment for a trial that is unlikely to be successful. Therefore it would be a good idea to introduce a futility boundary for possible early stopping. Since we wish to be fairly aggressive about early stopping for futility we will generate the futility boundary from the Gamma(-1) β spending function. On the other hand since there no interest in early stopping for efficacy we will not use an efficacy boundary.

Create a new design by selecting Des2 in the **Library**, and clicking the  icon on the **Library** toolbar. Change the number of looks from 1 to 3.

Next, click on the **Boundary** tab. Enter the parameters as shown below. Be sure to select the **Non Binding** option. This choice gives us the flexibility to continue the trial even if a futility boundary has been crossed. Data monitoring committees usually want this flexibility; for example, to follow a secondary endpoint.

Efficacy

| Expected Under H1 | 30 | 30 | 29.784 |

49 Non Inferiority Trials Given Accrual Duration and Study Duration

Observe that while the sample size has been inflated to 4,344 subjects compared to Des2, the expected study duration under H_0 has been cut down to 39.6 months and the expected sample size under H_0 is 3,965. It would also be useful to simulate Des3 under a variety of scenarios for the hazard ratio. Select Des3 in the **Library** and click the  icon. You will be taken to the following simulation worksheet.

| Test Parameters | | Response Generation | | Accrual / Dropouts | | Simulation Controls | |
|----------------------|---------------------|---------------------|--|---------------------------|--|---------------------|--|
| Trial Type: | Noninferiority | | | Noninf. Margin (ln(HR0)): | | 0.044 | |
| Test Type: | 1-Sided | | | Test Statistic: | | Logrank | |
| Fix at Each Look: | Total No. of Events | | | | | | |
| Total No. of Events: | 3780 | | | | | | |
| Look # | Info. Fraction | Futility Z | | | | | |
| 1 | 0.333 | -0.007 | | | | | |
| 2 | 0.667 | -1.056 | | | | | |
| 3 | 1.000 | -1.960 | | | | | |

We wish to simulate this trial under the null hypothesis that the hazard ratio is $\exp(0.044) = 1.045$. To do this go to the **Response Generation** tab in the simulation worksheet. In this tab change the hazard ratio to 1.045 as shown below.

| Survival Information | | |
|----------------------|-----------|-------------------------------------|
| # of Hazard Pieces | 1 | Input Method: Median Survival Times |
| Med.Surv.Time | | Hazard Ratio |
| Control | Treatment | |
| 18 | 18.947 | 1.045 |

Next, click the **Simulate** button to simulate 10000 trials. A new row labeled Sim1 will appear in the **Output Preview** window. Select Sim1 in the **Output Preview** and click the  icon to save it to the **Library**. In the **Library**, double-click Sim1. A portion of the output is displayed below. (The actual values may differ, depending on the

starting seed used).

Simulation Seed and Elapsed Time

Starting Seed: 988853
 Total Number of Simulations: 10000
 Elapsed Time: 00.01.02

Note that 238 out of the 10000 simulations rejected the null hypothesis when it was true, thus confirming (up to Monte Carlo accuracy) that this design achieves a type-1 error of 2.5%. Also, observe that 50% of these trials have crossed the futility boundary at the very first interim look after only 24.7 months of study duration.

50 *A Note on Specifying Dropout parameters in Survival Studies*

This note gives details on specifying dropout parameters for survival studies in East. Dropout in a survival study is a competing risk. You may specify dropout rate as a hazard rate or as a probability of a subject dropping out within a specific period after entering the study. Very often, people, based on their past experience in a particular therapeutic area, are in a position to estimate likely dropout rates in a future study in the same therapeutic area. Their past experience may be that a specific percentage of subjects like 5% or 10% drop out of a study. We will explain with an example, how such estimates can be used in specifying input parameters for dropout rates in East.

Example 1: Logrank Test Given Accrual Duration and Study Duration Suppose we are designing a survival study with the following parameters:

Design Type: Superiority
Number of Looks: 3
Test Type: 1-sided
Type I Error: 0.025
Power: 0.9
Allocation Ratio: 1
Hazard Rate (Control): 0.03466 (default)
Hazard Ratio: 0.7
Hazard Rate (Treatment): 0.024 (this is computed by East given the above two inputs)
Variance of Log Hazard Ratio: Null
Boundary specification: Spending Function -Lan-DeMets (OF)
Accrual Duration: 20 months
Study Duration: 40 months

Further, it is expected that about 10% of the subjects are likely to drop out by end of the study. Now the problem is how to translate this estimate to either a hazard rate or a probability of dropout in a specific period, in the light of the facts that subjects accrue over a time period and the risk set for dropouts will be diminishing due to subjects leaving the study because of events. One way to find the right specification for dropout rate is by trial and error method. We make an initial guess and compute the design. The detailed output for the design will show estimates for sample size and maximum dropouts. If the estimated dropouts is closer to 10% of the sample size, then we can stop there. Otherwise, we have to increase or decrease the input specification for dropout rate and try again till we are able to see the estimated maximum dropouts is about 10% of the estimated maximum sample size.

We can try to create a design with the above input parameters, by entering the input values in the dialog box, in the usual way. For dropout specification, suppose, we

specify the probability of dropout as 0.1 by time 40, the study duration. This implies that the probability of a subject dropping out of the study within 40 months after entering the study is 0.1. The input dialog box for dropout information will be as shown below.

The screenshot shows a dialog box titled "Piecewise Dropout Information". It contains the following fields:

- # of Pieces: 1 (dropdown)
- Input Method: Prob. of Dropout (dropdown)
- By Time: 40 (text input)
- Prob. of Dropout (Control): 0.1 (text input)
- Prob. of Dropout (Treatment): 0.1 (text input)

Note: Period 1 hazard rates apply after time 40.

The equivalent specification in terms of hazard rate can be seen by choosing the item 'Hazard Rates' in the Input Method drop down box, which is shown below. Please apply **Increase Decimal** precision available at the top right corner of the Input dialog to get the exact results.

The screenshot shows a dialog box titled "Piecewise Dropout Information". It contains the following fields:

- # of Pieces: 1 (dropdown)
- Input Method: Hazard Rates (dropdown)
- Hazard Rate (Control): 0.00263 (text input)
- Hazard Rate (Treatment): 0.00263 (text input)

Now Compute this design and save it to a library node. If you double-click on this

50 A Note on Specifying Dropout parameters in Survival Studies

node, part of the detailed output will appear as shown below.

Sample Size Information

| | Control Arm | Treatment Arm | Total |
|-------------------------------|-------------|---------------|---------|
| Sample Size (n) | | | |
| Maximum | 300 | 302 | 602 |
| Expected H1 | 299.65 | 299.65 | 599.3 |
| Expected H0 | 300.994 | 300.994 | 601.988 |
| Events (s) | | | |
| Maximum | 186 | 149 | 335 |
| Expected H1 | 154.934 | 120.51 | 268.466 |
| Expected H0 | 167.223 | 167.223 | 334.315 |
| Dropouts (d) | | | |
| Maximum | 14 | 17 | 31 |
| Expected H1 | 11.588 | 13.468 | 25.056 |
| Expected H0 | 12.97 | 12.976 | 25.945 |
| Maximum Information (I):83.75 | | | |

The above results show that the the maximum dropouts is only 5.1% (31/602) of maximum sample size and not the desired value of 10%. Since all the subjects are not accrued at the beginning of this 40 month duration study, specifying a subject's probability of dropping out as 0.1 within 40 months may not be appropriate. As the accrual duration is 20 months and if we assume that the average accrual duration of the subjects is 10 months, a subject may be in the study on the average for a maximum of 30 months since the maximum study duration is 40 months. So let us specify the probability of dropout in 30 months period as 0.1 as shown below.

Piecewise Dropout Information

of Pieces: Input Method:

By Time:

Prob. of Dropout (Control)

Prob. of Dropout (Treatment)

For this design, the detailed output shows the following results.

⊖ **Sample Size Information**

| | Control Arm | Treatment Arm | Total |
|-------------------------------|-------------|---------------|---------|
| Sample Size (n) | | | |
| Maximum | 304 | 305 | 609 |
| Expected H1 | 303.099 | 303.099 | 606.198 |
| Expected H0 | 304.494 | 304.494 | 608.987 |
| Events (s) | | | |
| Maximum | 186 | 149 | 335 |
| Expected H1 | 155.103 | 120.559 | 268.466 |
| Expected H0 | 167.224 | 167.224 | 334.315 |
| Dropouts (d) | | | |
| Maximum | 19 | 22 | 41 |
| Expected H1 | 15.434 | 17.28 | 32.714 |
| Expected H0 | 16.963 | 16.969 | 33.933 |
| Maximum Information (I):83.75 | | | |

Now the maximum dropouts observed is 6.7% (41/609) of the maximum sample size. So we need to increase the dropout probability to a suitable value. Let us try out 0.15 as the probability of dropout by time 30.

Piecewise Dropout Information

of Pieces: Input Method:

By Time:

Prob. of Dropout (Control)

Prob. of Dropout (Treatment)

The design obtained with the above specification for dropout rate gives the following

50 A Note on Specifying Dropout parameters in Survival Studies

results.

⊖ Sample Size Information

| | Control Arm | Treatment Arm | Total |
|--------------------------------|-------------|---------------|---------|
| Sample Size (n) | | | |
| Maximum | 311 | 313 | 624 |
| Expected H1 | 310.491 | 310.491 | 620.982 |
| Expected H0 | 311.993 | 311.993 | 623.987 |
| Events (s) | | | |
| Maximum | 186 | 149 | 335 |
| Expected H1 | 155.473 | 120.676 | 268.466 |
| Expected H0 | 167.228 | 167.228 | 334.315 |
| Dropouts (d) | | | |
| Maximum | 29 | 34 | 63 |
| Expected H1 | 23.616 | 26.902 | 50.518 |
| Expected H0 | 25.945 | 26.945 | 52.89 |
| Maximum Information (I): 83.75 | | | |

Now the percentage of maximum dropouts to maximum sample size is 10.1% and it satisfies our aim.

Note: Some users may prefer to specify dropout rates upfront in terms of dropout hazard rates instead of probability of dropout. In either case, they may want to carry out the trial and error process, described above, in terms of dropout hazard rates instead of using probability of dropout.

51 Multiple Comparison Procedures for Survival Data

As with both continuous and discrete data, it is often desired to address multiple objectives during one single trial for a survival analysis. Here, the outcome of interest is typically the time from entry until a specific event is observed (i.e. death, recurrence, medical event). As with other data outcomes, formal statistical hypothesis tests are used to support or disprove clinical claims for survival data. When objectives are formulated into a family of hypotheses, as is the case with multiple comparison procedures, type I error is inflated. Failure to compensate for this can have adverse consequences. For example, a drug could be approved even when it is no better than placebo. Multiple comparison (MC) procedures guard against this inflation of type I error due to multiple testing.

East supports the calculation of power from simulated survival data using multiple different MC procedures. The user can choose the most relevant MC procedure that provides maximum power while maintaining the FWER. East maintains strong control of FWER, which refers to the preservation of the probability of incorrectly claiming at least one null hypothesis. The difference between strong control and weak control of FWER is that weak control of FWER assumes that all hypotheses are true.

The following MC procedures are available for survival endpoints in East.

| Category | Procedure | Reference |
|---------------|-------------------------------|------------------------------------|
| P-value Based | Bonferroni | Bonferroni CE (1935, 1936) |
| | Sidak | Sidak Z (1967) |
| | Weighted Bonferroni | Benjamini Y and Hochberg Y (1997) |
| | Holm’s Step Down | Holm S (1979) |
| | Hochberg’s Step Up | Hochberg Y (1988) |
| | Hommel’s Step Up | Hommel G (1988) |
| | Fixed Sequence | Westfall PH, Krishen A (2001) |
| Fallback | Wiens B, Dimitrienko A (2005) | |

P-value based procedures strongly control the FWER regardless of the joint distribution of the raw p-values as long as the individual raw p-values are legitimate p-values. A thorough discussion on calculating the expected number of events $d(l)$ in a time-to-event trial can be found in the Appendix D.

51.0.3 Single step MC procedures

East provides p-value based single step MC procedures to compute power for a

51 Multiple Comparison Procedures for Survival Data

survival data analysis. As with continuous outcomes, these include the Bonferroni procedure, the Sidak procedure, and the weighted Bonferroni procedure.

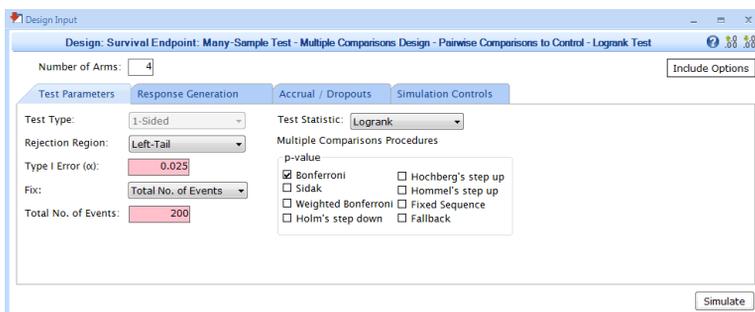

Example: STAMPEDE study

The STAMPEDE study is an ongoing, open-label, 5-stage, 6-arm randomized controlled trial using multi-arm, multi-stage (MAMS) methodology for men with prostate cancer. Started in 2005, it was the first trial of this design to use multiple arms and stages synchronously. The study population consists of men with high-risk localized or metastatic prostate cancer, who are being treated for the first time with long-term androgen deprivation therapy (ADT) or androgen suppression. The study started with 5 treatment groups:

- Standard of care (SOC) = ADT
- SOC + zoledronic acid (IV)
- SOC + docetaxel (IV)
- SOC + celecoxib, an orally administered cox-2 inhibitor
- SOC + zoledronic acid + docetaxel
- SOC + zoledronic acid + celecoxib

MAMS trials allow for the simultaneous assessment of a number of research treatments against a single control arm. By assessing several treatments in one trial, information can be acquired more quickly and with smaller numbers of patients. By combining multiple stages, this adaptive design allows continuing investments to be focused on treatments that show promise. Any therapy with insufficient evidence of activities is discontinued.

The Bonferroni and Sidak procedures in East are presented using relevant data from the STAMPEDE trial for a fixed-sample design. Under the **Design** tab in the **Survival** group, select **Many Samples - Pairwise Comparisons to Control - Logrank Test**. The following screen is displayed.

Change the default **Number of Arms:** to 6. Under the current tab, **Test Parameters**, keep the **Rejection Region:** assigned to Left-Tail, keep the default **Type I Error (α)** to 0.025, ensure that **Fix:** is set to the total number of events, and enter the value 1200. The type of **Test Statistic** used to calculate power can be identified as either the Logrank, Wilcoxon-Gehan, or Harrington-Fleming. Keep the default value of Logrank. Select both **Bonferroni** and **Sidak** for the choice of **Multiple Comparisons Procedures**.

Design: Survival Endpoint: Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Logrank Test

Number of Arms: 6

Simulate

This is where the user can specify the **Response Distribution:** to be either Exponential, Weibull, Lognormal, or R function. The **Input Method** can be set to either Median Survival Times, Cum. % Survival, or Hazard Rates. In addition the **Time Unit** can be selected to be either days, weeks, months or years. Keep the **Response Distribution:** as Exponential, set the **Input Method** to Hazard Rates, and the **Time Unit** to years. Enter the following information into the **Survival**

51 Multiple Comparison Procedures for Survival Data

Information table:

| Arm | Hazard Rates (Per Year) | Hazard Ratio |
|---------|-------------------------|--------------|
| Control | 0.139 | |
| Arm1 | 0.104 | 0.750 |
| Arm2 | 0.104 | 0.750 |
| Arm3 | 0.104 | 0.750 |
| Arm4 | 0.104 | 0.750 |
| Arm5 | 0.104 | 0.750 |

In the next tab, **Accrual/Dropouts**, the user sees the following input dialog box which allows the specification of sample size, duration of follow-up, as well as **Accrual info** and **Piecewise Dropout Information**.

Design: Survival Endpoint: Many-Sample Test - Multiple Comparisons Design - Pairwise Comparisons to Control - Logrank Test

Number of Arms: 4 Include Options

Test Parameters | Response Generation | **Accrual / Dropouts** | Simulation Controls

Sample Size: 400
 Total No. of Events: 200
 Subjects are followed: Until End of Study
 Distribution of Accrual Time: Uniform

Accrual Info

Accrual Duration Time Unit: Weeks
 # of Accrual Periods: 1 Input Method: Accrual Rates

| Period # | Starting at Time (Weeks) | Accr. Rate (Per Week) |
|----------|--------------------------|-----------------------|
| 1 | 0.0000 | 8.000 |

Piecewise Dropout Information

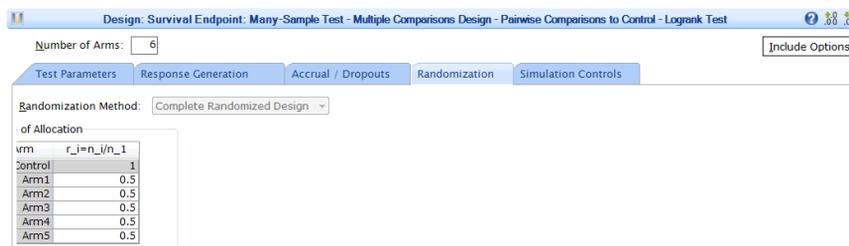

of Pieces: 0

Simulate

Set the **Sample Size** to 3400 and ensure that the **Subjects are followed**: dropdown is selected to be “Until End of Study”. The **Accrual Duration Time Unit**: is “Years”, the number of Accrual Periods is 1, and the Input Method is “Accrual Rates”. The Accrual Rate per Year is 500, starting at time 0. There is no **Piecewise Dropout Information** therefore keep the **Number of Pieces**: set to 0.

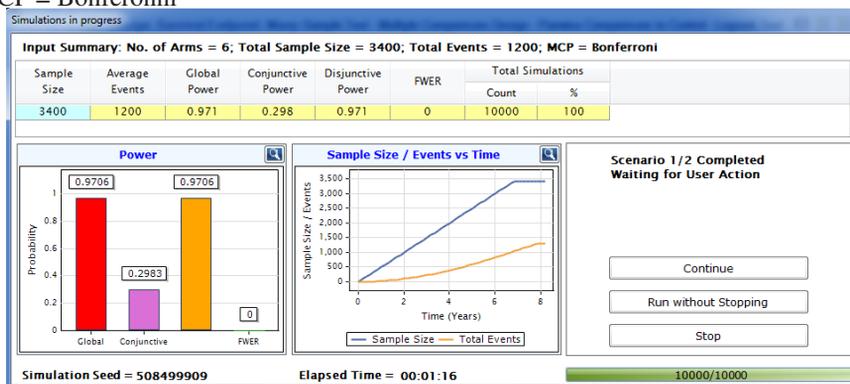

In the upper right hand of the Simulation Window, click the **Include Options** button,

and select “Randomization”. In the now new **Randomization** tab, the second column of the **Table of Allocation** table displays the allocation ratio of each treatment arm to that of control arm. The cell for control arm is always one and is not editable. Only those cells for treatment arms other than control need to be entered. The default value for each treatment arm is 1, which represents a balanced design. For the STAMPEDE, change the allocation ratio of the treatment arms to all be 0.5.

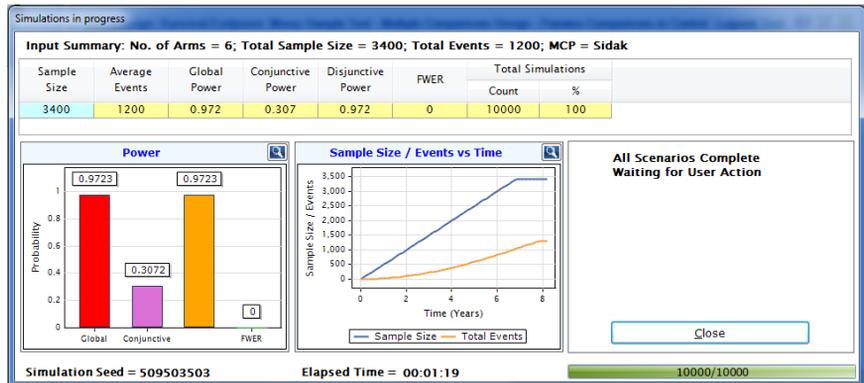

The last tab is the **Simulation Controls**. For this example, all simulation defaults can be maintained. The **Output Options** box is where the user can choose to save summary statistics for each simulation run or to save subject level data for a specific number of runs. Click **Simulate** to start the simulations. Once completed, East will add an additional row to the **Output Preview**, labeled as Sim 1.

MCP = Bonferonni

MCP = Sidak

51 Multiple Comparison Procedures for Survival Data

Note that two new simulations are displayed in the **Output Preview** window. Select the corresponding rows and save to the **Library**. Again select the two simulations and

click the **Output Summary** icon:

| | Stampede:Sim2 | Stampede:Sim3 |

| Arm3 | 0.2 |
| Arm4 | 0.2 |
| Arm5 | 0.2 |

An additional table **Treatment Arms** has been added which includes a column labeled **Proportion of Alpha**. This is where to specify the proportion of total alpha to be spent in each test. If necessary, East will normalize the column total to add up to 1, and the default is to distribute the total alpha equally among all tests. Here we have 5 tests in total, therefore each of the tests have proportion of alpha as $1/5$ or 0.2 . Other proportions can be specified as well. For this example, keep the equal proportion of alpha for each test. All other values can remain the same as in the previous example. Click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional row to the **Output Preview**.

The weighted Bonferroni MC procedure has global and disjunctive power of 96.9% and conjunctive power of 29.8%. Note that, the powers in the weighted Bonferroni procedure is quite close to the Bonferroni procedure. This is because the weighted Bonferroni procedure with equal proportion is equivalent to the simple Bonferroni procedure. The exact result of the simulations may differ slightly, depending on the seed. Select the simulation in the **Output Preview** and click  icon. This will save the simulation to the workbook in the **Library**.

51.0.4 Data-driven step-down MC procedure

In the single step MC procedures, the decision to reject any hypothesis does not depend on the decision to reject other hypotheses. On the other hand, in the stepwise procedures the decision of one hypothesis test can influence the decisions on the other tests. There are two types of stepwise procedures. The first proceeds in data-driven order. The other type follows a pre-defined fixed order. Stepwise tests that are in data-driven order can proceed in either a step-down or step-up manner. East supports the Holm step-down MC procedure, which starts with the most significant comparison and continues until the test for a certain hypothesis fails. The testing procedure stops at the first non-significant comparison, and all remaining hypotheses are retained.

Holm's step-down

The STAMPEDE example will be used to illustrate Holm's step-down procedure.

Select Sim 1 in **Library** and click . In the **Design Parameters** tab under the **Multiple Comparison Procedures** box, uncheck the **Weighted Bonferonni** box and check the **Holm's Step-down** box.

Number of Arms:

| Average Accrual Duration (Years) | 6.798 |
| Average Study Duration (Years) | 7.446 |

51.0.5 Data-driven step-up MC procedures

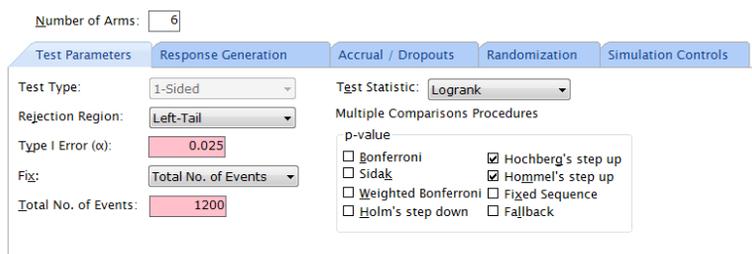

Step-up tests start with the least significant comparison and continue as long as tests are not significant until the first time when a significant comparison occurs and all remaining hypotheses will be rejected. East supports two such MC procedures for time to event data, the Hochberg step-up and the Hommel step-up. In the Hochberg step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-i)} > \frac{\alpha}{i}$. In the Hommel step-up procedure, in i -th step $H_{(k-i)}$ is retained if $p_{(k-j)} > \frac{i-j+1}{i} \alpha$ for $j = 1, \dots, i$. Fixed sequence test and fallback test are the types of tests which proceed in a predetermined

51 Multiple Comparison Procedures for Survival Data

order.

Hochberg's and Hommel's step-up procedures

Hochberg's and Hommel's step-up procedures are described below using the STAMPEDE example from the previous sections. All other design specification remains same except that we are using Hocheberg and Hommel step-up procedures in place of Holm's Step Down. Select Sim 1 in **Library** and click . In the **Design Parameters** tab, under the **Multiple Comparison Procedures** box, uncheck the **Holm's Step Down** box and check the **Hochberg's step-up** and **Hommel's step-up** boxes.

Number of Arms: 6

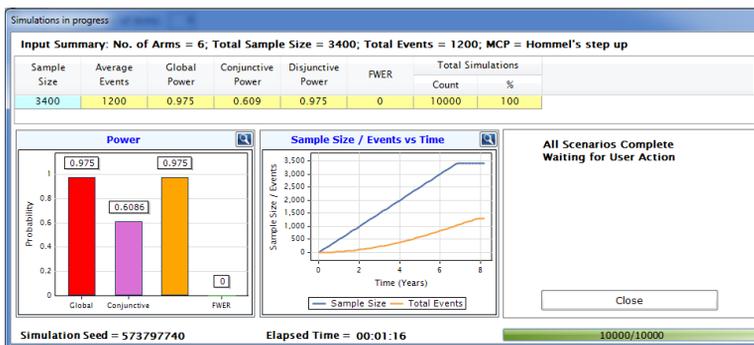

Test Parameters: Test Type: 1-Sided, Rejection Region: Left-Tail, Type I Error (α): 0.025, Fix: Total No. of Events, Total No. of Events: 1200

Response Generation: Test Statistic: Logrank

Multiple Comparisons Procedures (p-value):

- Bonferroni
- Sidak
- Weighted Bonferroni
- Holm's step down
- Hochberg's step up
- Hommel's step up
- Fixed Sequence
- Fallback

Now click **Simulate** to obtain power. Once the simulation run has completed, East will add two additional rows to the **Output Preview** window.

Hocheberg and Hommel procedures both have disjunctive and global powers of about 75% and conjunctive power about 6%. The exact result of the simulations may differ slightly, depending on the seed. Select these simulations in the **Output Preview** using Ctrl key and click  icon. This will save them to the corresponding workbook in the

Library.

51.0.6 Fixed-sequence stepwise MC procedures

In data-driven stepwise procedures, we don't have any control on the order of the hypotheses to be tested. However, sometimes based on our preference or prior knowledge we might want to fix the order of tests a priori. Fixed sequence test and fallback test are the types of tests which proceed in a pre-specified order. East supports both of these procedures for survival, or time to event data.

Assume that H_1, H_2, \dots, H_{k-1} are ordered hypotheses and the order is pre-specified so that H_1 is tested first followed by H_2 and so on. Let p_1, p_2, \dots, p_{k-1} be the associated raw marginal p-values. In the fixed sequence testing procedure, for $i = 1, \dots, k - 1$, in i -th step, if $p_i < \alpha$, reject H_i and go to the next step; otherwise retain H_i, \dots, H_{k-1} and stop.

Fixed sequence testing strategy is optimal when early tests in the sequence have largest treatment effect and performs poorly when early hypotheses have small treatment effect or are nearly true (Westfall and Krishen 2001). The drawback of fixed sequence test is that once a hypothesis is not rejected no further testing is permitted. This will

51 Multiple Comparison Procedures for Survival Data

lead to lower power to reject hypotheses tested later in the sequence.

Fallback test alleviates the above undesirable feature for fixed sequence test. Let w_i be the proportion of α for testing H_i such that $\sum_{i=1}^{k-1} w_i = 1$. In the fixed sequence testing procedure, in i -th step ($i = 1, \dots, k - 1$), test H_i at $\alpha_i = \alpha_{i-1} + \alpha w_i$ if H_{i-1} is rejected and at $\alpha_i = \alpha w_i$ if H_{i-1} is retained. If $p_i < \alpha_i$, reject H_i ; otherwise retain it. Unlike the fixed sequence testing approach, the fallback procedure can continue testing even if a non-significant outcome is encountered by utilizing the fallback strategy. If a hypothesis in the sequence is retained, the next hypothesis in the sequence is tested at the level that would have been used by the weighted Bonferroni procedure. With $w_1 = 1$ and $w_2 = \dots = w_{k-1} = 0$, the fallback procedure simplifies to fixed sequence procedure.

Fixed sequence testing procedure

The STAMPEDE example is used to illustrate fixed sequence testing procedure. Select Sim 1 in **Library** and click . Under the **Design Parameters** tab in the **Multiple Comparison Procedures** box, uncheck the **Bonferonni** box and check the **Fixed Sequence** box.

Number of Arms:

|---------|---------------|
| Control | |
| Arm1 | 1 |
| Arm2 | 2 |
| Arm3 | 3 |
| Arm4 | 4 |
| Arm5 | 5 |

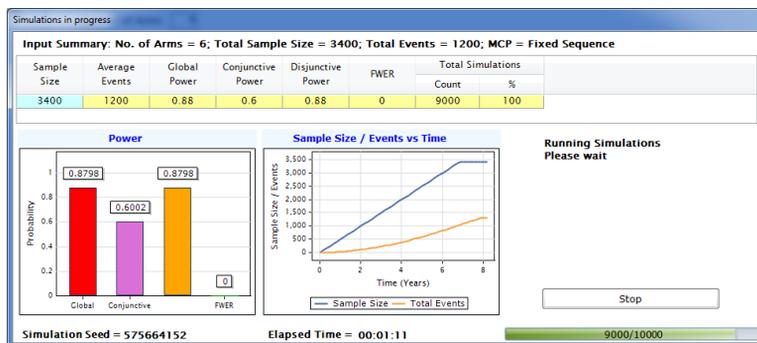

Notice that in the **Test Parameters** window a table called **Treatment Arms** has been added, which includes a column labeled **Test Sequence**. This is where the order of hypothesis tests are determined. Specify 1 for the test that will be tested first, 2 for the test that will be tested next and so on. By default East specifies 1 to the first test, 2 to the second test and so on. For optimal power in fixed sequence procedure, the early tests in the sequence should have larger treatment effects. For now we will keep the default which means that H_1 will be tested first followed by H_2 and finally H_3 will be

tested.

Number of Arms:

| Test Parameters | Response Generation | Accrual / Dropouts | Randomization | Simulation Controls | | | | | | | | | | | | | | |

| Average Accrual Duration (Years) | 6.798 |
| Average Study Duration (Years) | 7.449 |

It is worthwhile to note that the fixed sequence procedure is powerful provided the hypotheses are tested in a sequence of descending treatment effects. Fixed sequence procedure controls the FWER because for each hypothesis, testing is conditional upon rejecting all hypotheses earlier in sequence. As usual, the exact result of the simulations may differ slightly, depending on the seed.

Fallback procedure

The STAMPEDE example is used to illustrate the fallback procedure. Select Sim 1 in

Library and click . Under the **Design Parameters** tab in the **Multiple Comparison Procedures** box, uncheck the **Bonferonni** box and select the **Fallback** box.

Number of Arms:

Test Parameters
Response Generation
Accrual / Dropouts
Randomization

Treatment Arms

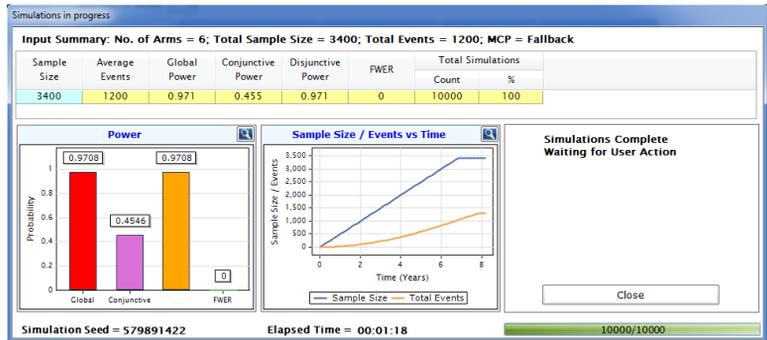

| Arm | Test Sequence | Proportion of Alpha |
|---------|---------------|---------------------|
| Control | | |
| Arm1 | 1 | 0.2 |
| Arm2 | 2 | 0.2 |
| Arm3 | 3 | 0.2 |
| Arm4 | 4 | 0.2 |
| Arm5 | 5 | 0.2 |

Notice that in the **Test Parameters** window a table called **Treatment Arms** has been added, which includes a columns labeled **Test Sequence** and **Proportion of Alpha**. In the column **Test Sequence**, the user specifies the order in which the hypotheses will be tested. Specify 1 for the test that will be tested first, 2 for the test that will be tested next and so on. By default East specifies 1 to the first test, 2 to the second test and so on. Keep the default, which means that H_1 will be tested first followed by H_2 and so on until H_5 is tested.

In the column **Proportions of Alpha**, the user specifies the proportion of total alpha to spend in each test. Ideally, the values in this column should add up to 1; if not, then East will normalize to add to 1. By default East, distributes the total alpha equally among the all tests. There are 5 tests in total, therefore each of the tests have proportion of alpha as $1/5$ or 0.2. Other proportions can be specified, however for this example, keep the equal proportion of alpha for each test. Click **Simulate** to obtain power. Once the simulation run has completed, East will add an additional row to the

51 Multiple Comparison Procedures for Survival Data

Output Preview.

The fallback procedure with the specified sequence has global and disjunctive power of 97.1% and conjunctive power of 45.5%. Select the simulation in the **Output Preview**

and click  icon to save to the workbook in the **Library**.

| Stampede:Sim8 | |
|---|---------------------|
| Mnemonic | SU-nS-MC |
| Test Parameters | |
| Multiple Comparison Procedure | Fallback |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| No. Pairwise Comps. | 5 |
| Rejection Region | Left-Tail |
| Fix | Total No. of Events |
| Test Statistic | Logrank |
| Model Parameters | |
| No. of Hazard Pieces | 1 |
| Accrual & Dropout Parameters | |
| Subject Followup | Until End of Study |
| Accrual Rate (Per Year) | 500 |
| No. of Accrual Periods | 1 |
| MCP Results | |
| Overall FWER | 0 |
| Global Power | 0.971 |
| Conjunctive Power | 0.455 |
| Disjunctive Power | 0.971 |
| Sample Size | |
| Maximum | 3400 |
| Events | |
| Maximum | 1200 |
| Simulation Results (Overall) | |
| Average Sample Size | 3400 |
| Average Events | 1200 |
| Average Accrual Duration (Years) | 6.798 |
| Average Study Duration (Years) | 7.45 |

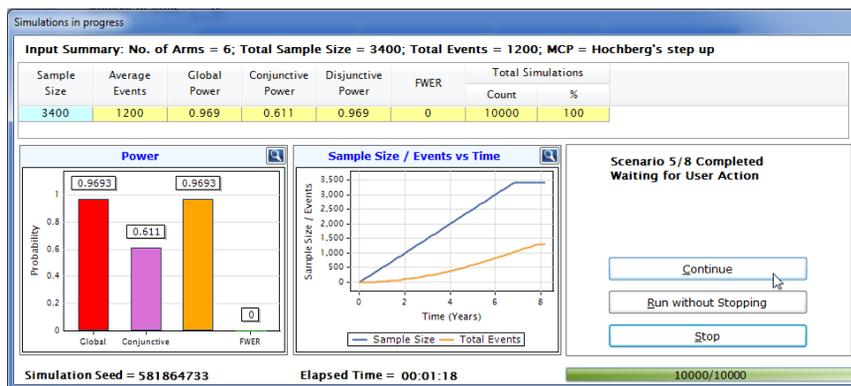

It is worthy to note that the fallback test is more robust to the misspecification of the test sequence while fixed sequence test is very sensitive to the test sequence. If the test order is incorrectly specified, fixed sequence test has very poor performance.

51.1 Comparison of MC procedures

East allows the capability of running all simulations at once in order to choose the most appropriate MC procedure. For the STAMPEDE example, Select Sim 1 in **Library** and click . Under the **Design Parameters** tab in the **Multiple**

51 Multiple Comparison Procedures for Survival Data

Comparison Procedures box, check the all boxes. Select **Simulate** and choose **Continue** as each simulation completes.

Following output displays the powers under different MC procedures.

| Multiple Comparison Procedure | Test Type | Specified α | Overall FWER | No. of Pairwise Comps. | Sample Size | Maximum Events | Rejection Region | Global Power | Conjunctive Power | Disjunctive Power | Average Sample Size | Average Events |
|-------------------------------|-----------|--------------------|--------------|------------------------|-------------|----------------|------------------|--------------|-------------------|-------------------|---------------------|----------------|
| Bonferroni | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.974 | 0.311 | 0.974 | 3400 | 1200 |
| Sidak | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.973 | 0.305 | 0.973 | 3400 | 1200 |
| Weighted Bonferroni | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.971 | 0.301 | 0.971 | 3400 | 1200 |
| Holm's step down | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.971 | 0.583 | 0.971 | 3400 | 1200 |
| Hochberg's step up | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.969 | 0.611 | 0.969 | 3400 | 1200 |
| Hommel's step up | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.977 | 0.619 | 0.977 | 3400 | 1200 |
| Fixed Sequence | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.882 | 0.615 | 0.882 | 3400 | 1200 |
| Fallback | 1-Sided | 0.025 | 0 | 5 | 3400 | 1200 | Left-Tail | 0.973 | 0.459 | 0.973 | 3400 | 1200 |

Here we have used equal proportions for weighted Bonferroni and Fallback procedures. For the two fixed sequence testing procedures (fixed sequence and fallback), just one sequence has been used: the default (H_1, H_2, H_3). The fixed sequence procedure results in the lowest power at 88.2%. Therefore, the fixed sequence procedure easily may not be considered as most appropriate. For this example, most all procedures result in approximately 97% global and disjunctive powers. The step-up and fixed sequence procedures produce the highest conjunctive power at approximately 62% each.

52 *Introduction To Adaptive Features*

This volume describes the adaptive features that can be used in the design of late stage adaptive clinical trials. The adaptive features are fully integrated into East and are invoked through simulation and calculation tools that will be described in the chapters of this volume.

The PhRMA Adaptive Design Working Group defines an adaptive trial as any clinical trial which uses accumulating data, possibly combined with external information, to modify aspects of the design without undermining the validity and integrity of the trial (see Gallo et. al.,2006). This definition is too broad for our purposes. It covers a very wide range of adaptations including dose response strategies in phase I trials, randomized play the winner rules for dose selection in early phase II trials, combination phase II/III designs, and mid-course data-dependent alterations to the later stage phase II and phase III designs. Adaptive features in East deal mainly with the last case. They extend the group sequential methodology of East in a natural way toward data-dependent changes in sample size, number of events (for event-driven trials). These adaptive extensions of group sequential designs are included in the list of adaptive methods discussed in the newly released FDA Guidance For Industry on Adaptive Design Clinical Trials for Drugs and Biologics (2010).

This volume contains Chapters 52 through 57. Chapter 52, the current chapter, describes the availability of adaptive features in East and contents of the remaining chapters in this volume. Chapter 53 provides the motivation for making adaptive changes to a late phase II or phase III trial. Three examples of actual case studies are included in this chapter; for continuous, discrete and survival endpoints, respectively. East provides two different methods for controlling type-1 error after an adaptive design change. These methods are described in the Chapter 54 and Chapter 55 respectively. They may be used to make sample size modifications for trials with normal or binomial endpoints and to make sample size and event modifications for trials with time-to-event or survival endpoints.

The third method, described in Chapter 56, offers considerable additional flexibility. All three methods are able to preserve the type-1 error in the face of data dependent changes to the study design. Each of these chapters is self-contained with a discussion of the statistical methodology followed by one or more worked examples.

A common feature in all these adaptive methods is their reliance on conditional power for making the adaptive modifications. We have developed special conditional power calculators for this purpose. The worked examples within each chapter illustrate the use of these calculators. Additionally, Chapter 57 is devoted entirely to describing how

to invoke and use the conditional power calculators.

The first adaptive method in East is the "weighted combinations" method due to Cui, Hung and Wang (1999), and Lehmacher and Wassmer (1999). In East this is referred to as the **CHW** method. In this method, the test statistic used to determine statistical significance at each interim look is a weighted combination of independent Wald statistics with pre-specified weights. This method is available for designs under Continuous, Discrete and Survival endpoints. The CHW method can be implemented at any interim look in a group sequential trial and can also be implemented multiple times. We provide simulation tools for evaluating the operating characteristics of the CHW design. This tool for the CHW method only permit sample adaptive size increases, not decreases. A special CHW Interim Monitoring Worksheet is provided to facilitate the interim monitoring and final analysis of such a trial.

The second adaptive method was proposed initially by Chen, DeMets and Lan (2004) and has now been extended by Gao, Ware and Mehta (2008) and Mehta and Pocock (2010). It is referred to as the **CDL** method. this method can be used to make sample size modifications for trials with normal or binomial endpoints and to make sample size and event modifications for trials with time-to-event or survival endpoints. The main advantage of the CDL method over the CHW method is that it permits data dependent sample size changes and event changes without the need to adjust the final test statistic with pre-specified weights. This is an attractive feature because the trial results can be presented in a conventional manner without artificially weighting the data from the two stages in ways that are difficult to explain to investigators who might be unfamiliar with the technical details of adaptive methodology. The method is, however, only applicable to two-stage adaptive designs or to multi-stage adaptive designs in which the sample size or number of events is changed at the penultimate stage. Furthermore the simulation tools for the CDL method only permit sample adaptive size increases, not decreases. This is in keeping with the recommendation of the FDA Guidance Document on Adaptive Design (2010).

The third adaptive method is referred to as the **Müller and Schäfer method**. It is based on preserving the conditional type-1 error computed at the time of the adaptation. Many authors have arrived independently at this key idea for making adaptive changes to a clinical trial. For example, it is central to the two-stage designs of Proschan and Hunsberger (1995), and the recursive combination tests of Brannath, Posch and Bauer (2002). Jennison and Turnbull (2003) claim that any fully flexible adaptive approach must respect this principle. The most general application of this principle is due to Müller and Schäfer (2001). These authors have shown explicitly that it is permissible to make any desired data dependent change to an ongoing group sequential clinical trial, possibly more than once, by the simple process of preserving the conditional type-1 error of the remainder of the trial after each change. When the

52 Introduction To Adaptive Features

only adaptive change is a change in sample size, the Müller and Schäfer method can be shown to be equivalent to the CHW method. However, the Müller and Schäfer method is not restricted to sample size changes exclusively.

The following table displays the types of designs for which adaptive methods are available in East with indications of their limitations.

Table 52.1: Adaptive Methods - Designs Applicable

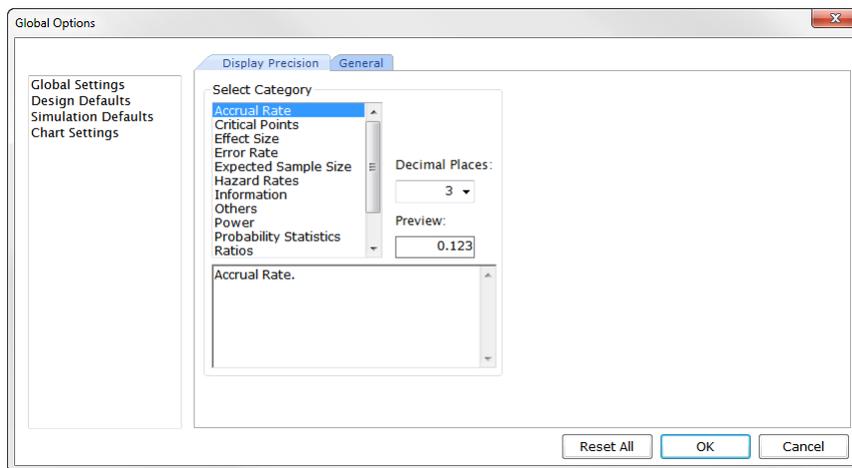

| Multi-look Design | <i>Adaptive Method^a</i> | | |
|--|------------------------------------|------------|------------|
| | CHW | CDL | MS |
| Continuous-Two Samples-Difference of Means-Superiority | <i>yes</i> | <i>yes</i> | <i>yes</i> |
| Discrete-Two Samples-Difference of Proportions-Superiority | <i>yes</i> | <i>yes</i> | <i>yes</i> |
| Discrete-Two Samples-Ratio of Proportions-Superiority | <i>yes</i> | <i>yes</i> | <i>yes</i> |
| Survival-Two Samples-Both Designs-Superiority | <i>yes</i> | <i>yes</i> | <i>yes</i> |

(a) H_0 only (1-sided); H_0 or H_1 (1-sided, binding/non-binding)

52.1 Settings

Click the **Global Options** icon in the **Home** menu to adjust default values in East 6.

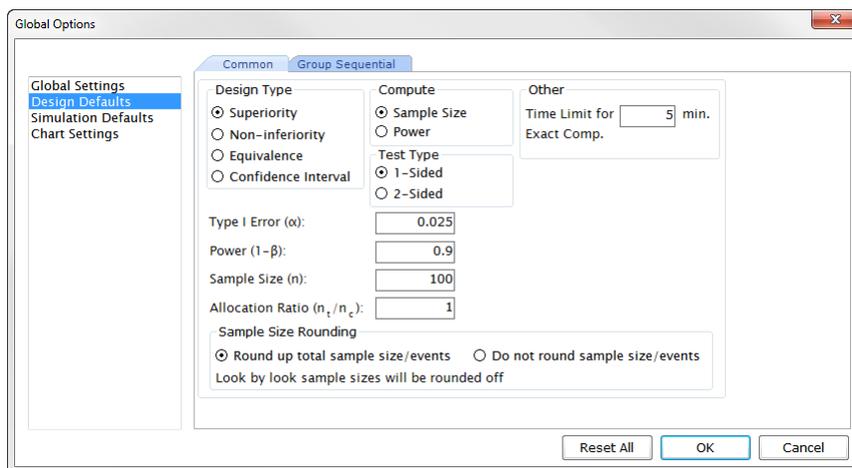

The options provided in the **Display Precision** tab are used to set the decimal places of numerical quantities. The settings indicated here will be applicable to all tests in East 6 under the **Design** and **Analysis** menus.

All these numerical quantities are grouped in different categories depending upon their usage. For example, all the average and expected sample sizes computed at simulation or design stage are grouped together under the category "Expected Sample Size". So to view any of these quantities with greater or lesser precision, select the corresponding category and change the decimal places to any value between 0 to 9.

The **General** tab has the provision of adjusting the paths for storing workbooks, files, and temporary files. These paths will remain throughout the current and future sessions even after East is closed. This is the place where we need to specify the installation directory of the R software in order to use the feature of R Integration in East 6.

52 Introduction To Adaptive Features

The **Design Defaults** is where the user can change the settings for trial design:

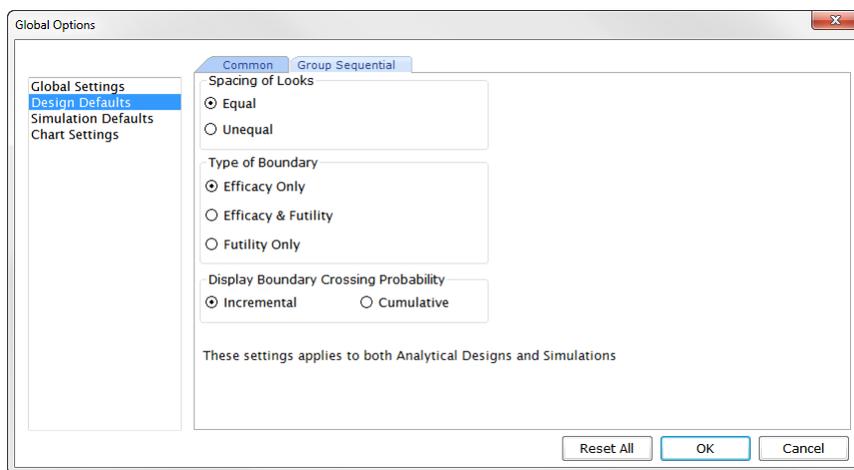

Under the **Common** tab, default values can be set for input design parameters.

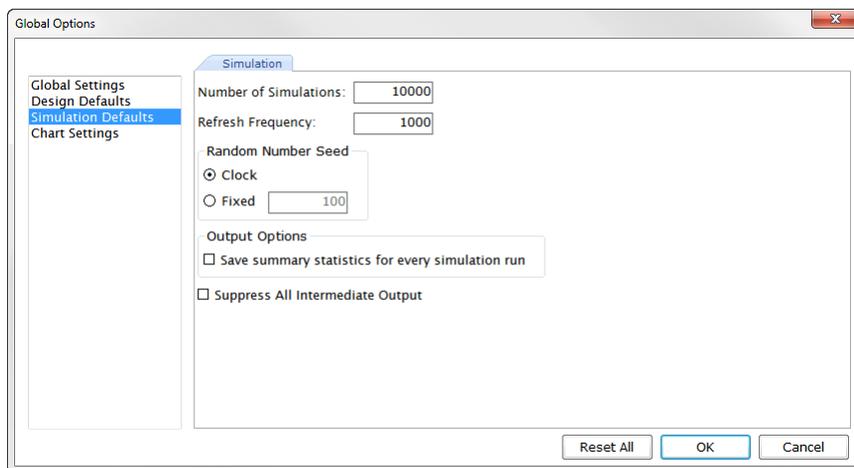

You can set up the default choices for the design type, computation type, test type and the default values for type-I error, power, sample size and allocation ratio. When a new design is invoked, the input window will show these default choices.

- **Time Limit for Exact Computation**
This time limit is applicable only to exact designs and charts. Exact methods are computationally intensive and can easily consume several hours of computation time if the likely sample sizes are very large. You can set the maximum time available for any exact test in terms of minutes. If the time limit is reached, the test is terminated and no exact results are provided. Minimum and default value is 5 minutes.
- **Type I Error for MCP**
If user has selected 2-sided test as default in global settings, then any MCP will use half of the alpha from settings as default since MCP is always a 1-sided test.
- **Sample Size Rounding**
Notice that by default, East displays the integer sample size (events) by rounding up the actual number computed by the East algorithm. In this case, the look-by-look sample size is rounded off to the nearest integer. One can also see the original floating point sample size by selecting the option "Do not round sample size/events".

Under the **Group Sequential** tab, defaults are set for boundary information. When a new design is invoked, input fields will contain these specified defaults. We can also set the option to view the Boundary Crossing Probabilities in the detailed output. It can be either Incremental or Cumulative.

Simulation Defaults is where we can change the settings for simulation:

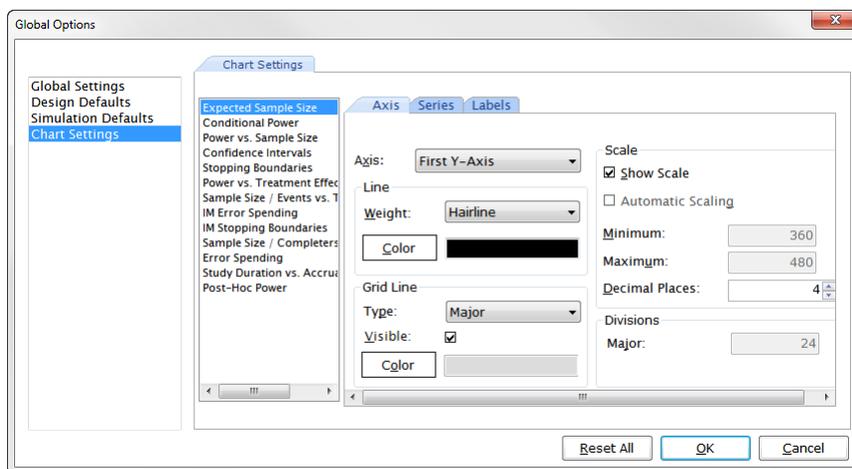

If the checkbox for "Save summary statistics for every simulation" is checked, then East simulations will by default save the per simulation summary data for all the

52 Introduction To Adaptive Features

simulations in the form of a case data.

If the checkbox for "Suppress All Intermediate Output" is checked, the intermediate simulation output window will be always suppressed and you will be directed to the **Output Preview** area.

The **Chart Settings** allows defaults to be set for the following quantities on East6 charts:

We suggest that you do not alter the defaults until you are quite familiar with the software.

53 *The Motivation for Adaptive Sample Size Changes*

In this chapter, we will highlight, through some prototypical examples, the motivation for making adaptive changes to the **sample size** in an on-going clinical trial.

Sample size is a key design input for any randomized clinical trial. Unfortunately, it is often computed in the face of inadequate knowledge about σ^2 the inter-subject variance, and δ the effect size. Economic pressures, possibly combined with competition for patients, then encourage trial investigators to make optimistic decisions about these two design parameters, a tendency that frequently results in underpowered studies. An underpowered trial is extremely undesirable, for it places human subjects at risk with a low probability of reaching a positive scientific conclusion and diverts resources that could be better utilized elsewhere. Therefore, in recent years there has been a considerable amount of research on more flexible clinical trials where the sample size is re-estimated after the clinical trial is underway, on the basis of updated information about σ^2 and δ . The updated information may arise either from external sources, from interim results of the on-going trial, or from a combination of the two. Sample size re-estimation based exclusively on updated information about σ^2 is covered in Chapter 59 in Special Topics volume of the East Manual, dealing with information based design. Here we are concerned primarily with sample size re-estimation due to updated information about δ after the study is activated.

Although statistical methods are available to make data dependent mid-course changes to sample size, the appropriateness of such sample size re-estimation has generated some debate. Critics of this type of design revision argue that the same end – ensuring adequate power at the appropriate value of δ – can be achieved more efficiently through a group sequential design (Tsiatis and Mehta, 2003; Jennison and Turnbull, 2003). This is a valid argument in settings where one is prepared to pre-specify a minimum clinically meaningful value of δ , commit a large maximum sample size to the trial up-front, and forgo the option to make data driven design changes as the trial progresses. There may be situations, however, where the flexibility to learn from the interim data and adapt the future course of the trial offsets the improved efficiency of the group sequential approach. Furthermore if the primary endpoint of the study is only measured after a lengthy follow-up, the sample size saving available through a group sequential design might be rather small. Finally, for two-stage design in which the sample size is only increased if the interim results fall in a promising zone, there may be no loss of efficiency whatsoever. We provide an example of this type at the end of Chapter 55.

53 The Motivation for Adaptive Sample Size Changes

53.1 The Benefits of Adaptive Designs

- 53.1.1 Rescuing an Underpowered On-Going Study
- 53.1.2 Designing a Study
- 53.1.3 Availing of Data from External Sources After the Study is Activated
- 53.1.4 Reducing the Sponsor's Risk

There are several reasons why it might be beneficial to allow for the possibility of a sample size increase in the middle of a group sequential clinical trial. Below we present a few real examples that we have encountered either in publications or in our consulting practice.

53.1.1 Rescuing an Underpowered On-Going Study

Cui, Hung and Wang (1999) discuss a phase III group sequential clinical trial for evaluating the effect of a new drug for prevention of myocardial infarction in patients undergoing coronary artery bypass graft surgery. The study was planned to detect a reduction in the incidence rate from 22% for placebo to 11% for the new drug with 95% power on a 1-sided level 0.025 test. The study was planned for one interim and one final look. On this basis the maximum sample size was computed to be 591 patients. There was, considerable uncertainty about the incidence rates at which the study was powered because, at that time, very little data were available on the new drug. The interim analysis results were less optimistic than was hoped at the design stage. The incidence rate in the placebo group was close to the rate specified at design, but the incidence rate in the treatment group was only 16.5%. The drop in the incidence of myocardial infarction due to the treatment was only half of what was expected. At that time, there was no valid method in the literature for increasing the sample size in mid-stream based on the observed efficacy outcome at the interim analysis. Thus the sample size was not increased and the trial eventually failed.

53.1.2 Designing a Study Given Limited Data About the Efficacy Endpoint

Consider the design of a two-arm schizophrenia trial for subjects with negative symptoms. For reasons of confidentiality, we will not reveal the names of the two drugs being tested, but will simply refer to them as the control and treatment arms, respectively. The primary clinical endpoint is the change from baseline in the Negative Symptom Assessment (NSA) at six months. There is, however, a second regulatory requirement that the new treatment must also show benefit in functional outcome as measured by a 21-item clinician rated Quality of Life Scale (QLS) measuring psychosocial functioning. The design of this trial poses inherent difficulties for the sponsor because there is very limited data from previous trials on NSA, and no data whatsoever on QLS, for patients with negative symptoms. Therefore it is not clear what values of δ one should use for calculating sample size. A pure group sequential strategy would be powered at the smallest clinically meaningful value of δ . This option is impractical in the current situation because there exists no previous experience with QLS in negative symptoms patients, and hence no notion of what constitutes a clinically meaningful effect. A second option is to run a preliminary phase II study and then follow up with a separate phase III study using the results of the earlier study, possibly combined with newly available external information, as inputs for specifying

δ and σ . This is a safe conservative choice but it does delay the time taken to reach a final conclusion about the new product. Also, with this option, the data from the phase II study cannot be combined with the data from the phase III study. A third option is to combine the phase II and phase III designs into a single integrated trial using one of the three adaptive methods provided in EastAdapt. In this option, one would start out with an initial group sequential design, powered using a sample size that reflects a compromise between the **scientific goal** of detecting the smallest clinically meaningful value of δ and the **pragmatic goal** of staying within budgetary constraints. This compromise is justified because there is still considerable uncertainty about the precise value of δ that should be used to perform the sample size calculation. Therefore the study is activated with the understanding that the current sample size assessment is preliminary and will be re-visited at a future interim analysis time point, when reliable data on the NSA and QLS endpoints become available.

53.1.3 Availing of Data from External Sources After the Study is Activated

A long-term clinical trial was activated comparing adjuvant chemotherapy to placebo in an oncology trial where the primary endpoint was survival. A retrospective analysis of historical data conducted at the design stage suggested that the study should be powered to detect a hazard ratio of 0.7. However, two years into the trial, a publication in a peer reviewed medical journal suggested that the quality of care in this disease had greatly improved, suggesting a decline in the hazard rate for the placebo arm. The investigators were very concerned by this report because it suggested that their study might now be underpowered. Although enrollment had been completed, there remained the option to adaptively extend the study duration, to see a larger number of events than had been planned at the design stage.

53.1.4 Reducing the Sponsor's Risk

From the sponsor's perspective a very attractive feature of an adaptive design is the opportunity it gives to invest in the trial in stages and thereby reduce risk. Under this scenario, the initial (first stage) investment of sample size resources might be small. The second stage investment would then be contingent on seeing promising results from the first stage. The sponsor risk is thereby reduced since the request for additional sample size resources, if made, would imply that the trial has a good chance of success. Many small biotechnology companies rely on outside investors to finance their trials. Creative adaptive designs of this type might make the financing easier.

In the remainder of the Chapter we illustrate all the above points through three case studies of actual phase 3 adaptive trials. In Section 53.2 we discuss a normal endpoint clinical trial of schizophrenia. In Section 53.3 we discuss a binomial endpoint clinical trial of acute coronary syndromes. In Section 53.4 we discuss a time-to-event

53 The Motivation for Adaptive Sample Size Changes

(survival) endpoint trial of lung cancer. These three examples will be carried forward to Chapters 54 and 55 where they will be used to demonstrate trial design and interim monitoring in East.

53.2 Normal Endpoint: Schizophrenia Trial

53.2.1 Fixed Sample Design

53.2.2 Group Sequential Design

53.2.3 The Problem of Overruns

53.2.4 Adaptive Design

53.2.4 Adaptive Sample Size Increase

53.2.5 Adaptive Design

Consider a two-arm trial to determine if there is an efficacy gain for an experimental drug relative to the industry standard treatment for negative symptoms schizophrenia. The primary endpoint is the improvement from baseline to week 26 in the Negative Symptoms Assessment (NSA), a 16-item clinician-rated instrument for measuring the negative symptomatology of schizophrenia. Let μ_t denote the difference between the mean NSA at baseline and the mean NSA at week 26 for the treatment arm and let μ_c denote the corresponding difference of means for the control arm. Denote the efficacy gain by $\delta = \mu_t - \mu_c$. The trial will be designed to test the null hypothesis $H_0: \delta = 0$ versus the one-sided alternative hypothesis that $\delta > 0$. It is expected from limited data on related studies that $\delta \geq 2$ and σ , the between-subject standard deviation, is believed to be about 7.5. In the discussion that follows we shall focus our attention on adaptive sample size adjustments due to uncertainty surrounding the true value of δ . Even though the statistical methods discussed here are applicable when there is uncertainty about either δ or σ , the adaptive approach requires careful justification primarily when δ is involved. Adaptive sample size adjustments relating to uncertainty about σ are fairly routine and non-controversial.

We shall consider fixed-sample, group sequential and adaptive design options for this study. There are advantages and disadvantages to each option with no single approach dominating over the others. We are interested, however, in exploring whether the adaptive methodology can add value to the better established fixed sample and group sequential approaches to trial design. We will see that an adaptive design alleviates to some extent the problem of “overruns” encountered by group sequential designs when the primary endpoint is observed after a lengthy follow-up period as is the case here. Additionally, we will see that an adaptive design may, in certain settings, have a more favorable risk versus benefit trade-off.

53.2.1 Fixed Sample Design

Since it is believed a priori that $\delta \geq 2$, we first create Des 1, a single-look design with 80% power to detect $\delta = 2$ using a one-sided level 0.025 test, given $\sigma = 7.5$. With these design parameters we can show that Des 1 will be fully powered if a total of 442 subjects are enrolled (221/arm). There is, however, considerable uncertainty about the true value of δ , and to a lesser extent about σ . Nevertheless it is believed that even if the true value of δ were as low as 1.6 on the NSA scale, that would constitute a clinically meaningful effect. We therefore also create Des 2, having 80% power to detect $\delta = 1.6$ using a one-sided level-0.025 test, given $\sigma = 7.5$. Des 2 requires a total

sample size of 690 subjects.

We have now proposed two design options. Under Des 1 we would enroll 442 subjects and hope that the study is adequately powered, which it will be if $\delta = 2$ and $\sigma = 7.5$. If, however $\delta = 1.6$ the power drops from 80% to 61%. There is thus a risk of launching an underpowered study for an effective drug under Des 1. Under Des 2 we will enroll 690 subjects, thereby ensuring 80% power at the smallest clinically meaningful value, $\delta = 1.6$, and rising to 94% power at $\delta = 2$. The operating characteristics of Des 1 and Des 2 are displayed side by side in Table 53.1 for values of δ between 1.6 and 2.0.

Table 53.1: Operating Characteristics of Des 1 and Des 2

| δ | Des 1 | | Des 2 | |
|----------|-------------|-------|-------------|-------|
| | Sample Size | Power | Sample Size | Power |
| 1.6 | 442 | 61% | 690 | 80% |
| 1.7 | 442 | 66% | 690 | 84% |
| 1.8 | 442 | 71% | 690 | 88% |
| 1.9 | 442 | 76% | 690 | 91% |
| 2.0 | 442 | 80% | 690 | 94% |

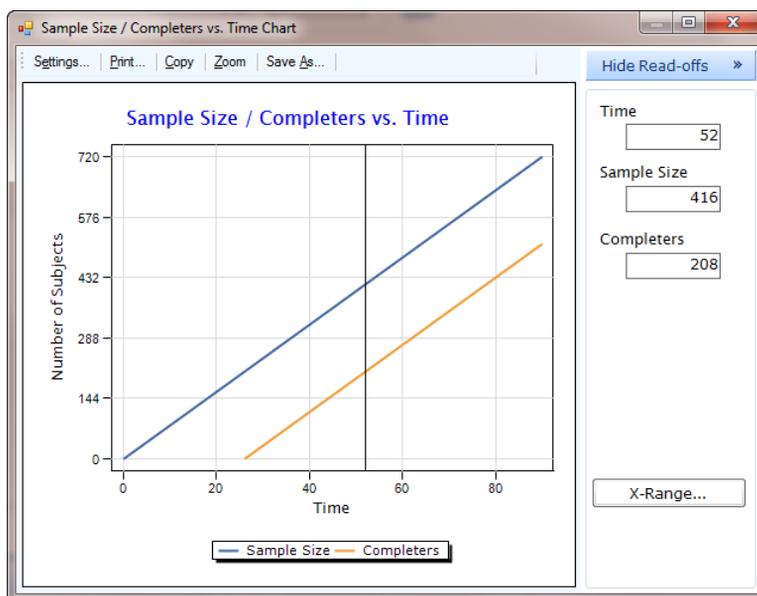

If resources were plentiful, Des 2 would clearly be the preferred option. The sponsor must, however, allocate scarce resources over a number of studies and in any case is not in favor of designing an overpowered trial. This leads naturally to considering a design that might be more flexible with respect to sample size than either of the above two single-look fixed sample designs. We will consider two types of flexible designs; group sequential and adaptive.

53.2.2 Group Sequential Design

When sample size flexibility is desired for late-stage trials, it is often appropriate to first explore the group sequential option. Let us then construct a group sequential design with one interim look and 80% power to detect $\delta = 1.6$ such that if in fact $\delta = 2$, the trial will stop early. While this would appear to be an attractive option, it is important to consider not just the saving in study duration but also the saving in the actual number of subjects randomized to the study. Since the efficacy endpoint for this trial will only be observed at week 26, the actual saving in sample size will be affected by the enrollment rate. In the current study it is anticipated that subjects will enroll at an average rate of 8 per week. The number of subjects enrolled and the number of completers over time are displayed graphically in Figure 53.1

53 The Motivation for Adaptive Sample Size Changes

Figure 53.1: Impact of Enrollment Rate and Length of Follow-Up on Trial Completion

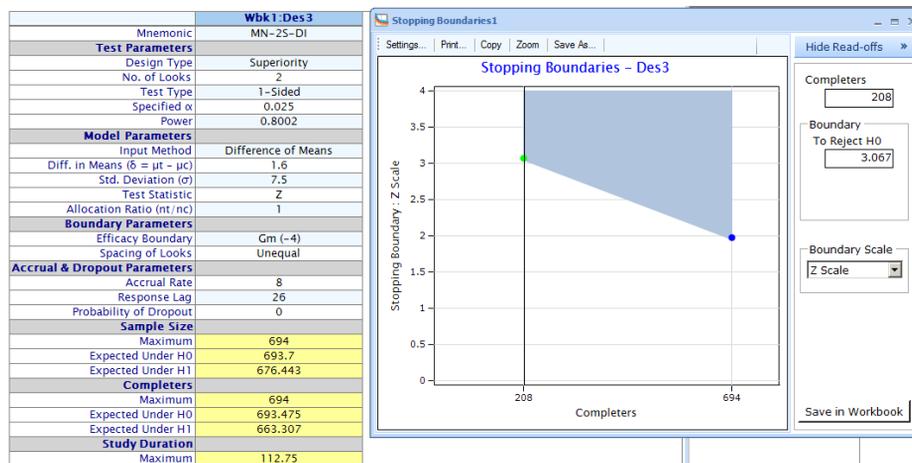

Observe that there is a 26-week horizontal separation between the two parallel lines depicting, respectively, the graph for enrollment and the graph for study completion. This 26-week gap must be taken into consideration when evaluating the savings achieved by utilizing a group sequential design.

The two major design parameters to be specified for a two-look group sequential design are the timing of the interim analysis and the amount of type-1 error to be spent. We will assume that data must be available for at least 200 completers before the trial can be terminated for efficacy so that an adequate safety profile may be developed for the study drugs. Therefore a suitable time point for the interim analysis is week 52, when we will have enrolled 416 subjects with data on 208 completers. Next we must decide on the amount of type-1 error to spend (see Lan and DeMets, 1983) for the early stopping boundary. It is generally held that the type-1 error should be spent conservatively in the early stages of a trial so as to ensure that results based on premature termination will be compelling and have the capacity to change medical practice (see Pocock, 2005). Suppose then that we use the $\gamma(-4)$ error spending function proposed by Hwang, Shih and DeCani (1990) to obtain the early stopping

boundary. The boundary thus produced resembles the conservative O’Brien-Fleming (1979) boundary. The corresponding group sequential design, having a sample size of 694, is displayed in Figure 53.2 as Des 3.

Figure 53.2: Group Sequential Design Denoted as Des 3

In Des 3 the nominal critical point for early stopping is 3.067 standard deviations. The one sided p-value corresponding to this early stopping boundary is $1 - \Phi(3.067) = 0.0011$ which, if met, would indeed be compelling enough to justify premature termination. Both Des 2 and Des 3 have 80% power to detect $\delta = 1.6$ with a one-sided level-0.025 test. Their sample size commitments too are almost the same. However, under Des 2 there is no possibility of early stopping whereas under Des 3, it is possible to stop early and thereby save on sample size. Figure 53.2 shows that the expected number of completers if in truth $\delta = 1.6$, is 663 subjects, a saving of 61 subjects compared to the maximum sample size of 694. The saving will be even more if the true value of δ is greater than 1.6. These expected savings in sample size are discussed next along with the problem of "overruns".

53.2.3 The Problem of Overruns

Care must be taken when estimating the actual sample size savings of a group sequential design. Even if the early stopping boundary is crossed at week 52 on the basis of the data from the 208 completers, we must still take into account the additional 208 randomized subjects who enrolled between week 26 and week 52 for whom the week 26 endpoint will not yet have been attained. These additional 208 subjects are

53 The Motivation for Adaptive Sample Size Changes

referred to as the "overruns". When the overruns are accounted for, the saving in sample size due to early stopping is only $694 - 416 = 278$ subjects, rather than $694 - 208 = 486$ subjects. The power and expected sample size values of the group sequential Des 3 for different choices of δ are displayed in Table 53.2. The table shows the impact of overruns on the expected sample size. For comparison we have also included corresponding power and sample size values for the fixed sample Des 2 in Table 53.2.

Table 53.2: Operating Characteristics of Plan3 (Group Sequential) and Plan2 (Fixed Sample)

| δ | Plan3 (Group Sequential) | | | | Plan2 (Fixed Sample) | |
|----------|-------------------------------|----------------------|---------------|-------|----------------------|-------|
| | Probability of Early Stopping | Expected Sample Size | | Power | SampSiz | Power |
| | | No Overruns | With Overruns | | | |
| 1.6 | 6.6% | 662 | 676 | 80% | 690 | 80% |
| 1.7 | 7.9% | 656 | 672 | 84% | 690 | 85% |
| 1.8 | 9.3% | 649 | 668 | 88% | 690 | 88% |
| 1.9 | 11.0% | 640 | 663 | 91% | 690 | 91% |
| 2.0 | 13.0% | 631 | 658 | 94% | 690 | 94% |

It is seen from Table 53.2 that Des 3 offers a modest benefit relative to Des 2. After accounting for the overruns, the expected sample sizes under Des 3 range between 658 and 676 for corresponding values of δ between 2 and 1.6, as compared to a fixed sample size of 690 under Plan2. In terms of power, Des 2 and Des 3 are practically identical. For the current trial a group sequential design with conservative error spending offers no substantial advantage over a conventional single look design with a fixed sample size. One is still faced with the dilemma of committing excessive sample size resources up front in order to ensure adequate power at $\delta = 1.6$, with limited prospects of saving on sample size in the event that $\delta = 2$.

Although in general group sequential designs do offer savings in expected sample size, their actual benefit may be diminished if a study enrolls subjects very rapidly but the primary endpoint can only be observed after a lengthy follow-up. In the current example we assumed that subjects are enrolled at the rate of 8 per week and the endpoint is observed after 26 weeks of follow-up for each subject. This resulted in 208 additional subjects being on-study who were not yet followed for 26 weeks at the time of the interim analysis. The efficiency loss due to an overrun of this magnitude was difficult to overcome. If instead the enrollment rate were to be halved to 4 subjects per week, and the endpoint were to be observed after only 12 weeks instead of 26 weeks,

there would only be an overrun of 48 subjects, and the resulting operating characteristics of the two group sequential designs would be more favorable relative to the corresponding fixed sample design. The accrual rate and the duration of follow-up are thus two extremely important design parameters for a group sequential trial.

We next consider adopting an adaptive design for this study. This is a radically different approach to trial design in which the difficulties encountered by group sequential designs – rapid accrual, delayed endpoint, and large up-front commitment of patient resources – can to some extent be mitigated.

53.2.4 Adaptive Design

To motivate the adaptive design let us recall that although the actual value of δ is unknown, the investigators believe that $\delta \geq 2$. For this reason Des 1 was constructed to have 80% power to detect $\delta = 2$. Des 2 on the other hand was constructed to have 80% power to detect $\delta = 1.6$, the smallest clinically meaningful treatment effect. If there were no resource constraints one would of course prefer to design the study for 80% power at $\delta = 1.6$ since that would imply even more power at $\delta = 2$. However, as we saw in Table 53.1, this conservative strategy carries as its price a substantially larger up-front sample size commitment which is, moreover, unnecessary if in truth $\delta = 2$. Des 3 was therefore constructed as a group sequential alternative to Des 2. Des 3 also has 80% power to detect $\delta = 1.6$ but there is a possibility of early stopping. We have seen, however, that due to the overruns problem, the expected sample size savings realized by Des 3 is small while the up-front sample size commitment is large.

The above difficulties lead us to consider whether Des 1, which was intended to detect $\delta = 2$ with 80% power and hence does not have such a large up-front sample size commitment, might be improved so as to provide some insurance against substantial power loss in the event that $\delta = 1.6$. The adaptive approach is suited to this purpose. In this approach we start out with a sample size of 442 subjects as in Des 1, but take an interim look after data are available on 208 completers. The purpose of the interim look is not to stop the trial early but rather to examine the interim data and continue enrolling past the planned 442 subjects if the interim results are promising enough to warrant the additional investment of sample size. This strategy has the advantage that the sample size is finalized only after a thorough examination of data from the actual study rather than through making a large up-front sample size commitment before any data are available. Furthermore if the sample size may only be increased but never decreased from the originally planned 442 subjects, there is no loss of efficiency due to overruns. The technical problem of avoiding inflating the type-1 error despite increasing the sample size in a data dependent manner has been solved by, among others, Cui, Hung and Wang (1999).

53 The Motivation for Adaptive Sample Size Changes

Selecting the Criteria for an Adaptive Sample Size Increase

The operating characteristics of an adaptive design depend in a complicated way on the criteria for increasing the sample size after observing the interim data. These criteria may combine objective information such as the current estimate of δ or the current conditional power with assessments of safety and with information available from other clinical trials that was not available at the start of the study. The adaptive approach provides complete flexibility to modify the sample size without having to pre-specify a precise mathematical formula for computing the new sample size based on the interim data. Therefore the full benefit of the flexibility offered by an adaptive design cannot be quantified ahead of time. Nevertheless it is instructive to investigate power and expected sample size by simulating the trial under different values of δ and applying precise pre-specified rules for increasing the sample size on the basis of the observed interim results. This will provide at least some idea, at the design stage, of the trade-off between the fixed sample or group sequential approaches and the adaptive approach. To this end we create Des 4, a design with 80% power to detect $\delta = 2$ with a one-sided level-0.025 test, based on a planned enrollment of 442 subjects. Des 4 specifies, in addition, that there will be one interim analysis after 26 weeks of follow-up data are available on the first 208 subjects enrolled. The purpose of the interim analysis is not to stop the trial early but rather to examine the interim data and decide whether a sample size increase is warranted. If no action were taken at the interim look, Des 4 would be identical to Des 1. The timing of the interim look reflects a preference for performing the interim analysis as late as possible but nevertheless while the trial is still enrolling subjects since, once the enrollment sites have closed down, it will be difficult to start them up again. Under the assumption that subjects enroll at the rate of 8 per week we will have enrolled 416 subjects by week 52; 208 of them will have completed the required 26 weeks of follow-up for the primary endpoint, and an additional 208 subjects will comprise the overruns. Only the data from the 208 completers will be used in making the decision to increase the sample size. After this decision is taken, enrollment will continue until the desired sample size is attained. The primary efficacy analysis will be based on the full 26 weeks of follow-up data from all enrolled subjects. It should be noted that unlike the group sequential setting, where the 208 overruns played no role in the early stopping decision but were still added to the final sample size, here the data from the 208 overruns will be fully utilized in the primary efficacy analysis which will only occur when all enrolled subjects have completed 26 weeks of follow-up. This is one of the advantages of the adaptive approach relative to the group sequential approach for trials with lengthy follow-up.

It remains to specify the criteria for increasing the sample size at the interim look. A well planned trial should pre-specify as far as possible the decision rules to be adopted for increasing the sample size once the interim data are available. Thereby the operating characteristics of the trial can be studied through simulation and if they are

unsatisfactory, the rules for sample size adaptation can be modified. It should be stressed, however, that in practice there is flexibility to overrule these pre-specified rules should unexpected results, either internal or external to the trial, be encountered at the time of the interim analysis. Nevertheless a precise formula for increasing the sample size must be pre-specified for purposes of simulation. While there are an infinite number of ways to construct such a formula it must address the following three questions:

- For what range of interim outcomes should a sample size increase be contemplated?
- How should the magnitude of the new sample size be calculated?
- What should be the upper limit to the sample size increase?

The answers to these questions might be driven by both clinical and business concerns, and will depend on the importance the investigators place on avoiding a false negative outcome for the current trial.

Range of Interim Outcomes for a Sample Size Increase

It is convenient to partition the sample space of possible interim outcomes into three zones; *unfavorable, promising and favorable*. An adaptive strategy is built on the premise that if the interim outcome lies in either the unfavorable or favorable zones, it is unnecessary to alter the sample size. In one case it would be risky to invest further in what appears to be a failed trial, while in the other case the trial appears slated to succeed anyway, without an additional sample size investment. Thus an adaptive sample size increase is only intended to help studies whose interim results fall in a promising zone, between these two extremes. How might these three zones be identified? One could use the interim estimate $\hat{\delta}$ or its standardized version $z = \hat{\delta}/se(\hat{\delta})$ to partition the sample space into the three zones. Alternatively one could rely on the conditional power or *probability of obtaining a positive outcome at the end of the trial, given the data already observed*. The conditional power approach is favored by most practitioners because it has a meaningful interpretation that is independent of the type of endpoint being measured, and incorporates both the current estimate of treatment effect as well as its standard error. Accordingly for the present trial we pre-specify that a sample size increase will only be contemplated if the conditional power at the interim look lies between 30% and 80%. That is, the unfavorable zone is characterized by conditional power values at most equal to 30%, the promising zone by conditional power values between 30% and 80% and the favorable zone by conditional power values at least equal to 80%.

Computing the Required Sample Size Increase

Just as at the design stage of a trial the sample size is determined by the desired power

53 The Motivation for Adaptive Sample Size Changes

(80%, say) to detect an anticipated value of δ , so also at the time of the interim analysis the new sample size may be determined by the desired conditional power (also 80%, say) to detect an anticipated value of δ . Now, however, data from the actual trial are available, and may be used to update the anticipated value of δ at which to power the trial. One could, if desired, incorporate prior beliefs, external information and current data into a value of δ at which to power the study. For simplicity however, we shall use the estimate of δ obtained at the interim analysis to recompute the sample size needed to hit the target of 80% conditional power. It is possible that this calculation could result in a reduction in the total sample size. This is permitted by the statistical methodology of adaptive designs. For the current example, however, we do not wish to decrease the sample size. Therefore if the recomputed sample size constitutes a decrease, the original sample size of 442 subjects will be used.

Specifying an Upper Limit to the Sample Size Increase

Since resources are limited, there must be an upper limit to the sample size increase, no matter what sample size is required to attain 80% conditional power. This upper limit is usually restricted to between 150% and 200% of the original sample size and is pre-specified at the start of the trial. Larger sample size increases are undesirable since they could yield statistically significant outcomes that are clinically non-significant. For the current trial we pre-specify an upper limit of 884 subjects. That is, we are prepared to double our investment in the trial, but only if the interim estimate of conditional power falls in the promising zone.

Finally, the design specifications of the adaptive Des 4 are as follows:

1. The initial sample size is 442 subjects, and has 80% power to detect $\delta = 2$ with a one-sided level-0.025 test.
2. An interim analysis is performed after data are available on 208 completers with 26 weeks of follow-up data.
3. At the interim analysis the conditional power is computed using the estimated value $\hat{\delta}$ as though it were the true value of δ . If the conditional power lies between 30% and 80%, the interim outcome is deemed to be promising.
4. If the interim outcome is promising, the sample size is re-computed so as to achieve 80% conditional power at the estimated value, $\hat{\delta}$. The original sample size is then updated to the re-computed sample size, subject to the constraint in item 5 shown below.
5. If the re-computed sample size is less than 442, the original sample size of 442 subjects is used. If the re-computed sample size exceeds 884, the sample size is curtailed to 884 subjects.

53.2.5 Operating Characteristics of Adaptive Design

Due to the complex adaptive scheme for re-computing sample size, the operating characteristics of Des 4 can best be evaluated by simulation. Table 53.3 displays power and expected sample sizes for selected values of δ between 1.6 and 2.0, based on 100,000 simulations of Des 4. For comparative purposes, corresponding power and sample size values for Des 1 are also displayed. The power of the adaptive Des 4 has

Table 53.3: Operating Characteristics of Des 1 (Fixed Sample) and Des 4 (Adaptive)

| Value of δ | Des 1(Fixed Sample) | | Des 4 (Adaptive) | |
|-------------------|---------------------|----------------------|------------------|----------------------|
| | Power | Expected Sample Size | Power | Expected Sample Size |
| 1.6 | 61% | 442 | 67% | 507 |
| 1.7 | 66% | 442 | 72% | 503 |
| 1.8 | 71% | 442 | 76% | 501 |
| 1.9 | 76% | 442 | 81% | 498 |
| 2.0 | 80% | 442 | 84% | 495 |

All Des 4 results are based on 100,000 simulated trials

increased by 6% at $\delta = 1.6$ and by 4% at $\delta = 2$ compared to Des 1. These power gains were obtained at the cost of corresponding average sample size increases of 67 subjects at $\delta = 1.6$ and 57 subjects at $\delta = 2$. The gains in power appear to be fairly modest, especially as they are offset by corresponding sample size increases. However, Des 4 offers a significant benefit in terms of risk reduction, not reflected in Table 53.3. To see this it is important to note that the sample size under Des 4 is only increased when the interim results are promising; i.e., when the conditional power at the interim analysis is greater than 30% but less than 80%. This is the very situation in which it is advantageous to increase the sample size and thereby avoid an underpowered trial. When the interim results are unfavorable (conditional power $\leq 30\%$) or favorable (conditional power $\geq 80\%$), a sample size increase is not warranted and hence the sample size is unchanged at 442 subjects for both Des 1 and Des 4. But when the interim results are promising (conditional power between 30% and 80%) the sample size is increased under Des 4 in an attempt to boost the conditional power back to 80%. It is this feature of the adaptive design that makes it more attractive than the simpler fixed sample design.

Table 53.4 displays the probability of falling into the following zones: unfavorable+futility, promising and Fav + Eff at the interim look, along with the power and expected sample size, conditional on falling into each zone, under both Des 1 and Des 4. The table highlights the key advantage of the adaptive Des 4 compared to the fixed sample Des 1; i.e., the ability to invest in the trial in stages, with the second stage

53 The Motivation for Adaptive Sample Size Changes

Table 53.4: Operating Characteristics of Des 1 and Des 4 Conditional on Interim Outcome

| δ | Interim Outcome | Probability of Interim Outcome | Power Conditional on Interim Outcome | | Expected Sample Size | |
|---|-----------------|--------------------------------|--------------------------------------|-------|----------------------|-------|
| | | | Des 1 | Des 4 | Des 1 | Des 4 |
| 1.6 | Unfav + Fut | 33% | 28% | 28% | 442 | 442 |
| | Promising | 27% | 61% | 83% | 442 | 696 |
| | Fav + Eff | 40% | 87% | 88% | 442 | 435 |
| 1.7 | Unfav + Fut | 30% | 32% | 32% | 442 | 442 |
| | Promising | 26% | 65% | 86% | 442 | 693 |
| | Fav + Eff | 45% | 89% | 90% | 442 | 435 |
| 1.8 | Unfav + Fut | 26% | 36% | 35% | 442 | 442 |
| | Promising | 25% | 69% | 89% | 442 | 691 |
| | Fav + Eff | 48% | 91% | 92% | 442 | 434 |
| 1.9 | Unfav + Fut | 23% | 41% | 39% | 442 | 442 |
| | Promising | 25% | 72% | 91% | 442 | 688 |
| | Fav + Eff | 52% | 93% | 93% | 442 | 434 |
| 2.0 | Unfav + Fut | 21% | 45% | 46% | 442 | 442 |
| | Promising | 24% | 76% | 92% | 442 | 685 |
| | Fav + Eff | 56% | 94% | 95% | 442 | 433 |
| All results are based on 100,000 simulated trials | | | | | | |

of the investment being required only if promising results are obtained at the first stage. This feature of Des 4 makes it far more attractive as an investment strategy than Des 1 which has no provision for increasing the sample size if a promising interim outcome is obtained. Suppose, for example that $\delta = 1.6$, the smallest clinically meaningful treatment effect. The trial sponsor only commits the resources needed for 442 subjects at the start of the trial, at which point the chance of success is 61%, as shown in Table 53.3. The additional sample size commitment is forthcoming only if promising results are obtained at the interim analysis, and in that case the sponsor's risk is substantially reduced because the chance of success jumps to 83%, as shown in Table 53.4. Similar results are observed for the other values of δ .

The probabilities of entering the unfavorable, promising and favorable zones at the interim analysis, displayed in Table 53.4, are instructive. Consider again the case $\delta = 1.6$. At this value of δ there is a 26% chance of landing in the promising zone and

thereby obtaining a substantial power boost under Des 4 as compared to Des 1. That is, 27% of the time the adaptive strategy can rescue a trial that is underpowered at the interim look. The chance of entering the favorable zone is 40%. That is, 40% of the time the sponsor will be lucky and have a well powered trial at the interim look without the need to increase the sample size. The remaining 33% of the time the sponsor will be unlucky and will enter the unfavorable zone from which also there is no sample size increase, and the chance of success is only 28%. These odds improve with larger values of δ .

53.3 Binomial Endpoint: Acute Coronary Syndromes Trial

53.3.1 Group Sequential Design

53.3.2 Adaptive Group Sequential Design

53.3.3 Adaptive Group Sequential Design

53.3.4 Adding a Futility Boundary

Consider a two-arm, placebo controlled randomized clinical trial for subjects with acute cardiovascular disease undergoing percutaneous coronary intervention (PCI). The primary endpoint is a composite of death, myocardial infarction or ischemia-driven revascularization during the first 48 hours after randomization. We assume on the basis of prior knowledge that the event rate for the placebo arm is 8.7%. The investigational drug is expected to reduce the event rate by at least 20%. The investigators are planning to randomize a total of 8000 subjects in equal proportions to the two arms of the study. It is easy to show that a conventional fixed sample design enrolling a total of 8000 subjects will have 83% power to detect a 20% risk reduction with a one-sided level-0.025 test of significance. The actual risk reduction is expected to be larger, but could also be as low as 15%, a treatment effect that would still be of clinical interest given the severity and importance of the outcomes. In addition, there is some uncertainty about the magnitude of the placebo event rate. For these reasons the investigators wish to build into the trial design some flexibility for adjusting the sample size. Two options under consideration are, a group sequential design with the possibility of early stopping in case the risk reduction is large, and an adaptive design with the possibility of increasing the sample size in case the risk reduction is small. In the remainder of this section we shall discuss these two options and show how they may be combined into a single design that captures the benefits of both.

53.3.1 Group Sequential Design

We first transform the fixed sample design into an 8000 person group sequential design with two interim looks, one after 4000 subjects are enrolled (50% of total information) and the second after 5600 subjects are enrolled (70% of total information). Early stopping efficacy boundaries are derived from the Lan and DeMets (1983) O'Brien-Fleming type error spending function. Let us denote this group sequential design as GSD1. The operating characteristics of GSD1 are displayed in Table 53.5. The first column of Table 53.5 is a list of potential risk reductions, defined as $100 \times (1 - \rho)\%$ where $\rho = \pi_t / \pi_c$, π_t is the event rate for the treatment arm, and π_c is the event rate for the control arm. The remaining columns display early stopping probabilities, power and expected sample size. Since the endpoint is observed within

53 The Motivation for Adaptive Sample Size Changes

48 hours, the problem of overruns that we encountered in the schizophrenia trial is negligible and may be ignored.

Table 53.5: Operating Characteristics of GSD1, a Three-Look 8000-Person Group Sequential Design

| Risk Reduction $100 \times (1 - \rho)$ | Probability of Crossing Efficacy Boundary | | | Overall Power | Expected Sample Size |
|---|---|-----------------------------|---------------------------------|---------------|----------------------|
| | At Look 1 ($N = 4000$) | At Look 2 ($N = 5600$) | At Final Look ($N = 8000$) | | |
| 15% | 0.074 | 0.183 | 0.309 | 57% | 7264 |
| 17% | 0.109 | 0.235 | 0.335 | 68% | 7002 |
| 20% | 0.181 | 0.310 | 0.330 | 82% | 6535 |
| 23% | 0.279 | 0.362 | 0.275 | 92% | 6017 |
| 25% | 0.357 | 0.376 | 0.222 | 96% | 5671 |

Table 53.5 shows that GSD1 is well powered, with large savings of expected sample size for risk reductions of 20% or more. It is thus a satisfactory design if, as is initially believed, the magnitude of the risk reduction is in the range 20% to 25%. This design does not, however, offer as good protection against a false negative conclusion for smaller risk reductions. In particular, even though 15% is still a clinically meaningful risk reduction, GSD1 offers only 57% power to detect this treatment effect. One possibility then is to increase the up-front sample size commitment of the group sequential design so that it has 80% power if the risk reduction is 15%. This leads to GSD2, a three-look group sequential design with a maximum sample size commitment of 13,853 subjects, one interim look after 6926 subjects (50% of total information) and a second interim look after 9697 subjects (70% of total information). GSD2 has 80% power to detect a risk reduction of 15% with a one-sided level-0.025 test.

Table 53.6 displays operating characteristics of GSD2 for risk reductions between 15%, and 25%. Notice that by attempting to provide adequate power at 15% risk reduction, the low end of clinically meaningful treatment effects, we have significantly over-powered the trial for values of risk reduction in the expected range of risk reductions, 20% to 25%. If, as expected, the risk reduction exceeds 20%, the large up-front sample size commitment of 13,853 subjects under GSD2 is unnecessary. GSD1 with an up-front commitment of only 8000 subjects will provide sufficient power in this setting.

From this point of view, GSD2 is not a very satisfactory design. It commits the investigators to a very large and expensive trial in order to provide adequate power in

Table 53.6: Operating Characteristics of GSD2, a Three-Look 13,853-Person Grp Sequential Design

| Risk Reduction $100 \times (1 - \rho)$ | Probability of Crossing Efficacy Boundary | | | Overall Power | Expected Sample Size |
|---|---|-----------------------------|-----------------------------------|---------------|----------------------|
| | At Look 1 ($N = 6926$) | At Look 2 ($N = 9697$) | At Final Look ($N = 13,853$) | | |
| 15% | 0.167 | 0.298 | 0.335 | 80% | 11,456 |
| 17% | 0.246 | 0.349 | 0.296 | 89% | 10,699 |
| 20% | 0.395 | 0.375 | 0.196 | 97% | 9558 |
| 23% | 0.565 | 0.329 | 0.099 | 99.3% | 8574 |
| 25% | 0.675 | 0.269 | 0.054 | 99.8% | 8061 |

the pessimistic range of risk reductions, without any evidence that the true risk reduction does indeed lie in the pessimistic range. Evidently a single group sequential design cannot provide adequate power for the "worst-case" scenario, and at the same time avoid overpowering the more optimistic range of scenarios. This leads us to consider building an adaptive sample size re-estimation option into the group sequential design GSD1, such that the adaptive component will provide the necessary insurance for the worst-case scenario, and thereby free the group sequential component to provide adequate power for the expected scenario, without a large and unnecessary up-front sample size commitment.

53.3.2 Adaptive Group Sequential Design

We convert the three-look group sequential design GSD1 into an adaptive group sequential design by inserting into it the option to increase the sample size at look 2, when 5600 subjects have been enrolled. Denote the modified design by A-GSD1. The rules governing the sample size increase for A-GSD1 are similar to the rules specified in Section 53.2.4 for the schizophrenia trial, but tailored to the needs of the current trial. The idea is to identify unfavorable, promising and favorable zones for the interim results at look 2, based on the attained conditional power. Sample size should only be increased if the interim results fall in the promising zone. Subject to an upper limit, the sample size should be increased by just the right amount to boost the current conditional power to some desired level (say 80%). The following are the design specifications for A-GSD1:

1. The starting design is GSD1 with a sample size of 8000 subjects, one interim look after enrolling 4000 subjects and a second interim look after enrolling 5600 subjects. The efficacy stopping boundaries at these two interim looks are derived from the Lan and DeMets (1983) error spending function of the

53 The Motivation for Adaptive Sample Size Changes

O'Brien-Fleming type.

2. At the second interim analysis, with data available on 5600 subjects, the conditional power is computed using the estimated value $\hat{\rho}$ as though it were the true relative risk ρ . If the conditional power is no greater than 30% the outcome is deemed to be unfavorable. If the conditional power is between 30% and 80%, the outcome is deemed to be promising. If the conditional power is at least 80%, the outcome is deemed to be favorable.
3. If the interim outcome is promising, the sample size is re-computed so as to achieve 80% conditional power at the estimated value $\hat{\rho}$. The original sample size is then updated to the re-computed sample size, subject to the constraint in item 4 shown below.
4. If the re-computed sample size is less than 8000, the original sample size of 8000 subjects is used. If the re-computed sample size exceeds 16,000, the sample size is curtailed at 16,000 subjects .

Some features of this adaptive strategy are worth pointing out. First, the sample size is re-computed on the basis of data from 5600 subjects from the trial itself. Therefore the estimate of ρ available at the interim analysis is substantially more reliable than the estimate that was used at the start of the trial to compute an initial sample size of 8000 subjects. The latter estimate is typically derived from smaller pilot studies or from other phase 3 studies in which the patient population might not be exactly the same as that of the current trial. Second, a sample size increase is only requested if the interim results are promising, in which case the trial sponsor should be willing to invest the additional resources needed to power the trial adequately. In contrast GSD2 increases the sample size substantially at the very beginning of the trial, before any data are available to determine if the large sample size is justified.

53.3.3 Operating Characteristics of Adaptive Group Sequential Design

Table 53.7 displays the power and expected sample size of the adaptive group sequential design A-GSD1. For comparative purposes corresponding power and sample size values of GSD1 are also provided.

If there is a 15% risk reduction, A-GSD1 has 6% more power than GSD1 but utilizes an additional 1093 subjects on average. It is seen that as the risk reduction parameter increases the power advantage and additional sample size requirement of A-GSD1 are reduced relative to GSD1.

The power and sample size entries in Table 53.7 were computed unconditionally, and for that reason do not reveal the real benefit that design A-GSD1 offers compared to design GSD1. As discussed previously in the schizophrenia example, the real benefit of an adaptive design is the opportunity it provides to invest in the trial in stages with

Table 53.7: Operating Characteristics of GSD1 (Group Sequential) and A-GSD1 (Adaptive Group Sequential) Designs

| Risk Reduction $100 \times (1 - \rho)$ | GSD1 (Group Sequential) | | A-GSD1 (Adaptive Group Sequential) | |
|--|-------------------------|----------------------|------------------------------------|----------------------|
| | Power | Expected Sample Size | Power | Expected Sample Size |
| 15% | 57% | 7264 | 62% | 8253 |
| 17% | 68% | 7002 | 73% | 7945 |
| 20% | 82% | 6535 | 86% | 7294 |
| 23% | 92% | 6017 | 94% | 6531 |
| 25% | 96% | 5671 | 97% | 6036 |
| All results for A-GSD1 are based on 100,000 simulated trials | | | | |

the second stage investment forthcoming only if promising results are obtained at the first stage. To explain this better it is necessary to display power and expected sample size results conditional on the zone (unfavorable, promising or favorable) into which the results of the trial fall at the second interim analysis. Accordingly Table 53.8 displays the operating characteristics of both GSD1 and A-GSD1 conditional on the zone into which the conditional power falls at the second interim analysis. The table reveals substantial gains in power for A-GSD1 compared to GSD1 at all values of risk reduction if the second interim outcome falls in the promising zone, thereby leading to an increase in the sample size. Outside this zone the two designs have the same operating characteristics since the sample size does not change. If the second interim outcome falls in the unfavorable zone, the trial appears to be headed for failure and an additional sample size investment would be risky. If the second interim outcome falls in the favorable zone, the trial is headed for success without the need to increase the sample size. Thus the adaptive design provides the opportunity to increase the sample size only when the results of the second interim analysis fall in the promising zone. This is precisely when the trial can most benefit from a sample size increase.

53.3.4 Adding a Futility Boundary

One concern with design A-GSD1 is that it lacks a futility boundary. There is thus the risk of proceeding to the end, possibly with a sample size increase, when the magnitude of the risk reduction is small and unlikely to result in a successful trial. In particular, suppose that the null hypothesis is true. In that case we can show that the power (i.e., the type-1 error) is 2.5% and the expected sample size under A-GSD1 is 8253 subjects. It might thus be desirable to include some type of futility stopping rule for the trial. In this trial the investigators proposed the following futility stopping rules at the two interim analysis time points:

53 The Motivation for Adaptive Sample Size Changes

Table 53.8: Operating Characteristics of GSD1 (Group Sequential) and A-GSD1 (Adaptive Group Sequential) Designs Conditional on Second Interim Outcome

| Risk Reduction $100 \times (1 - \rho)$ | Second Interim Outcome | Probability of Interim Outcome | Power Conditional on Second Interim Outcome | | Expected Sample Size | |
|---|------------------------|--------------------------------|---|--------|----------------------|--------|
| | | | GSD1 | A-GSD1 | GSD1 | A-GSD1 |
| 15% | Unfav + Fut | 36% | 15% | 15% | 8000 | 8000 |
| | Promising | 24% | 57% | 81% | 8000 | 12099 |
| | Fav + Eff | 40% | 94% | 94% | 6152 | 6152 |
| 17% | Unfav + Fut | 27% | 19% | 20% | 8000 | 8000 |
| | Promising | 24 % | 64% | 87% | 8000 | 11956 |
| | Fav + Eff | 49 % | 96% | 96% | 5992 | 5992 |
| 20% | Unfav + Fut | 16% | 29% | 30% | 8000 | 8000 |
| | Promising | 20% | 73% | 93% | 8000 | 11780 |
| | Fav + Eff | 64% | 98% | 98 % | 5721 | 5726 |
| 23% | Unfav + Fut | 9% | 40% | 40% | 8000 | 8000 |
| | Promising | 14% | 81% | 96% | 8000 | 11606 |
| | Fav + Eff | 77% | 99% | 99% | 5440 | 5440 |
| 25% | Unfav + Fut | 5% | 48% | 48% | 8000 | 8000 |
| | Promising | 11% | 85% | 98% | 8000 | 11449 |
| | Fav + Eff | 85% | 99.6% | 99.5% | 5250 | 5247 |

All results are based on 100,000 simulated trials

1. Stop for futility at the first interim analysis ($N = 4000$) if the estimated event rate for the experimental arm is at least 1% higher than the estimated event rate for the control arm
2. Stop for futility at the second interim analysis ($N = 5600$) if the conditional power, based on the estimated risk ratio $\hat{\rho}$, is no greater than 20%

The impact of the futility boundary on the unconditional operating characteristics of the A-GSD1 design are displayed in Table 53.9. The inclusion of the futility boundary has resulted in a dramatic saving of nearly 3000 subjects, on average, at the null hypothesis of no risk reduction. Furthermore, notwithstanding a small power loss of 2-3%, the trial continues to have well over 80% power for risk reductions of 20% or more. The trial suffers a power loss of 4% if the magnitude of the risk reduction is 15%, the low end of the range of clinical interest. In this situation, however, the unconditional power is inadequate (only 63%) even without a futility boundary. To

Table 53.9: Operating Characteristics of the A-GSD1 Design with and without a Futility Boundary

| Risk Reduction $100 \times (1 - \rho)$ | A-GSD1 with No Futility Boundary | | A-GSD1 with Futility Boundary | |
|---|----------------------------------|----------------------|-------------------------------|----------------------|

fully appreciate the impact of the futility boundary on power and expected sample size, it is necessary to study the operating characteristics of the trial conditional on the results of the second interim analysis. These results are displayed in Table 53.10.

53 The Motivation for Adaptive Sample Size Changes

Table 53.10: Operating Characteristics of A-GSD1 Design with and without a Futility Boundary, Conditional on the Second Interim Outcome

|---|------------------------|--------------------------------|---|----------|----------------------|----------|
| | | | No Fut | With Fut | No Fut | With Fut |
| 0% | Unfav + Fut | 93% | 0.5% | 0.1% | 8000 | 4370 |
| | Promising | 5% | 15% | 15% | 13030 | 12916 |
| | Fav + Eff | 2% | 65% | 64% | 7017 | 6928 |
| 15% | Unfav + Fut | 38% | 15% | 5% | 8000 | 5093 |
| | Promising | 23 % | 81% | 81% | 12099 | 11950 |
| | Fav + Eff | 39 % | 94% | 94% | 5992 | 6152 |
| 20% | Unfav + Fut | 18% | 30% | 9% | 8000 | 5264 |
| | Promising | 18% | 93% | 92% | 11780 | 11670 |
| | Fav + Eff | 64% | 98% | 98% | 5726 | 5711 |
| 25% | Unfav + Fut | 6% | 48% | 14% | 8000 | 5354 |
| | Promising | 10% | 98% | 97% | 11449 | 11370 |
| | Fav + Eff | 84% | 99.5% | 99.5% | 5247 | 5274 |
| All results are based on 100,000 simulated trials | | | | | | |

It is seen that the presence of the futility boundary does not cause any loss of power for trials that enter the promising or favorable zones at the second interim analysis. Additionally the presence of the futility boundary causes the average sample size to be reduced substantially in the unfavorable zone while remaining the same in the other two zones. In effect the futility boundary terminates a proportion of trials that enter the unfavorable zone thereby preventing them from proceeding to conclusion. It has no impact on trials that enter the promising or favorable zones.

53.4 Survival Endpoint: Lung Cancer Trial

A two-arm multi-center randomized clinical trial is planned for subjects with advanced metastatic non-small cell lung cancer with the goal of comparing the current standard second line therapy (docetaxel+cisplatin) to a new docetaxel containing combination regimen. The primary endpoint is overall survival (OS). The study is required to have one-sided $\alpha = 0.025$, and 90% power to detect an improvement in median survival, from 8 months on the control arm to 11.4 months on the experimental arm, which corresponds to a hazard ratio of 0.7. A group sequential design is adopted with an efficacy boundary derived from the Lan and DeMets (1983) O'Brien-Fleming type spending function and a futility boundary derived from the γ -spending function of Hwang, Shih and DeCani (1990) with parameter $\gamma = -5$. It is decided, with the help of the East software, to keep the study open for a maximum of 334 OS events, with one interim analysis after 167 events (50% of the total information), whereby a 1-sided level-0.025 group sequential logrank test will have 90% power to detect a hazard ratio of 0.7. As this is an event-driven trial, sample size does not play a direct role in the above power calculation. Nevertheless the rate of accrual, duration of accrual and duration of follow-up will affect the total study duration or time needed to obtain 334 events. Again, with the help of East, it is determined that by enrolling 483 subjects over a two year period and following them for an additional 6 months, the required 334 OS events can be expected to arrive by the end of the follow-up period.

Now the assumption of 8 months for median survival on the control arm is based on published results from a previously completed large, well-controlled trial. There is less data available on the experimental arm. It is thus possible, either because the new treatment is somewhat less effective than anticipated or because of improved standard of care for patients on the control arm, that the underlying hazard ratio could be larger than 0.7. If this were the case, the study would be underpowered. For example, if the true hazard ratio was 0.77, an effect that is still considered clinically meaningful, the power of a 483-subject study would drop from 90% to 67.2%. Thus one possibility would be to design the trial from the very beginning to have 90% power to detect a hazard ratio of 0.77. East shows that such a trial would require 621 events. In order to complete the trial in 30 months it would be necessary to enroll 878 subjects over 24 months with an additional 6 months of follow-up.

The sponsor is either unable or unwilling to make such a large sample size commitment up-front purely on the basis of the limited prior data available on the new compound. However, since an independent data monitoring committee (DMC) will be reviewing the interim efficacy data in an unblinded fashion at 50% of the total information, the sponsor might be prepared to authorize the investment of additional resources on the recommendation of this committee. In a manner analogous to the pre-specification of group sequential boundaries for early stopping, the sponsor must pre-specify to the DMC the precise data dependent rules for increasing the number of

53 The Motivation for Adaptive Sample Size Changes

events and sample size at the time of the interim analysis.

These rules follow the same basic structure as was adopted in Section 53.2 for the schizophrenia trial and in Section 53.3 for the acute coronary syndromes trial. The sample space of possible interim outcomes is partitioned into three zones; *unfavorable/futility*, *promising*, *favorable/efficacy*. The partitioning utilizes conditional power (CP) evaluated at the current estimate of hazard ratio with the initial specification of 334 events. The promising zone is of the form $CP_{\min} \leq CP < CP_{\max}$. To the left of the promising zone lies the unfavorable/futility zone while to the right of the promising zone lies the favorable/efficacy zone. If the data fall in the promising zone the number of events and sample size are increased by a pre-specified formula that is written into the DMC charter. If the interim data fall in the unfavorable/futility zone there is either no change in the initial design or an early termination because the futility boundary is crossed. Similarly if the interim data fall in the favorable/efficacy zone, there is either no change in the initial design or an early termination because the efficacy boundary is crossed. The choice of CP_{\min} , CP_{\max} and the rules for increasing resources in the promising zone require are best determined with the help of the simulation tools available in East. In Chapter 54, Section 54.5.3 we demonstrate how the EastSurvAdapt module of East may be used to simulate different criteria for increasing event and sample size resources and thereby obtain an adaptive design that best satisfies the goals of the trial within the resource constraints imposed on the sponsor. Based on these simulation results it has been decided to implement an adaptive increase in the number of events by 50% (from 334 to 501) if the interim results fall in the promising zone, here defined as conditional power between $CP_{\min} = 30\%$ and $CP_{\max} = 90\%$. It has further been decided that the sample size will be increased in the same ratio as the increase in events.

The operating characteristics of the lung cancer trial are displayed in Tables 53.11 and 53.12 and 53.13 for underlying hazard ratios of 0.77, 0.75 and 0.70 respectively. In each table the classical group sequential design and the adaptive group sequential design are compared with respect to power, average study duration and average number of subjects.

Table 53.11: Operating Characteristics of Optimistic Design (powered to Detect HR=0.70) under the Pessimistic Scenario (true HR=0.77)

| 10,000 Simulations Under the Pessimistic Scenario that HR = 0.77 | | | | | | | |
|--|---------|---------|-------|-------------------|--------|---------------|-------|
| Zone | P(Zone) | Power | | Duration (months) | | # of Subjects | |
| | | NonAdpt | Adapt | NonAdpt | Adapt | NonAdpt | Adapt |
| Unf+Fut | 30% | 29% | 29% | 27.8 | 27.82 | 469 | 468 |
| Prom | 34% | 69% | 85% | 29.2 | 31.03 | 483 | 712 |
| Fav+Effic | 36% | 92% | 94% | 26.2 | 26.18 | 450 | 451 |
| Total | — | 66% | 71% | 27.7 | 28.713 | 467 | 548 |

Table 53.12: Operating Characteristics of Optimistic Design (powered to Detect HR=0.70) under the Semi-Pessimistic Scenario (true HR=0.75)

| 10,000 Simulations Under the Semi-Pessimistic Scenario that HR = 0.75 | | | | | | | |
|---|---------|---------|-------|-------------------|-------|---------------|-------|
| Zone | P(Zone) | Power | | Duration (months) | | # of Subjects | |
| | | NonAdpt | Adapt | NonAdpt | Adapt | NonAdpt | Adapt |
| Unf+Fut | 24% | 35% | 36% | 28.2 | 28.3 | 471 | 471 |
| Prom | 34% | 73% | 89% | 29.4 | 32.1 | 483 | 712 |
| Fav+Effic | 42% | 96% | 95% | 25.8 | 25.9 | 446 | 446 |
| Total | — | 74% | 79% | 27.6 | 28.6 | 465 | 542 |

The results follow a similar pattern to what was observed in the previous two examples. Let us focus first on the simulation results when the underlying hazard ratio is 0.77. This is the setting where the adaptive design can play an important role since a hazard ratio of 0.77 is still clinically meaningful, and yet the sponsor is unable to command the resources that would be required to guarantee 90% power with a non-adaptive design. Row 4 of Table 53.11 shows that the adaptive design produces about a 6% gain in overall power, from 66% to 71%, at an average cost of about 1 additional month of study duration and 81 additional subjects. The real appeal of the adaptive design, however, is more evident when the overall simulation results are partitioned into the three zones. It is then seen from Table 53.11 that the interim outcome will fall in the unfavorable/futility zone 30% of the time, in which case the prospects for a successful trial are equally bleak for both the classical and adaptive designs, but no additional resources are committed to the adaptive trial. The interim outcome will fall in the favorable/efficacy zone 36% of the time, in which case the

53 The Motivation for Adaptive Sample Size Changes

Table 53.13: Operating Characteristics of Optimistic Design (powered to Detect HR=0.70) under the Optimistic Scenario (true HR=0.70)

| 10,000 Simulations Under the Optimistic Scenario that HR = 0.70 | | | | | | | |
|---|---------|---------|-------|-------------------|-------|---------------|-------|
| Zone | P(Zone) | Power | | Duration (months) | | # of Subjects | |
| | | NonAdpt | Adapt | NonAdpt | Adapt | NonAdpt | Adapt |
| Unf+Fut | 12% | 54% | 56% | 28.9 | 29.1 | 475 | 476 |
| Prom | 27% | 87% | 97% | 29.8 | 32.4 | 483 | 712 |
| Fav+Effic | 61% | 98% | 98% | 25.1 | 25.1 | 436 | 436 |
| Total | — | 90% | 93% | 26.9 | 27.6 | 454 | 516 |

prospects are excellent for both the classical and adaptive designs, and again, no additional resources are committed to the adaptive trial. The remaining 34% of the time the interim outcome will fall in the promising zone and this is where the adaptive design will help by boosting up the power from 69% to 85%. To be sure the study duration and sample size will also increased in the promising zone. Presumably, however, the power gain justifies the use of these additional resources. In summary, the additional resources will be called up to boost power only if they can make a difference to the chance of a successful outcome for the trial. Table 53.12 demonstrates that these results are similarly compelling if the true hazard ratio is 0.75. If, however, the true hazard ratio is 0.7 Table 53.13 shows that the trial as initially designed has adequate power without the need for any adaptation of events or sample size. There is now a 27% chance of landing in the promising zone and adding resources in order to boost power from 87% to 97%. In this setting the trial would be overpowered and some of the additional resources might not have been needed. The sponsor cannot of course know what the true hazard ratio is, and must weigh the likelihood of incurring these additional costs against the possibility of a loss to the patient population, and also a financial loss to the sponsor, if the study should fail despite the treatment difference being clinically meaningful.

53.5 Concluding Remarks

Many small companies with new molecules or technologies under development often rely on outside investors or large pharmaceutical companies for financing their phase 3 trials. The two-stage nature of the investment, with the second installment being obligated only if the interim results have significantly increased the odds of success, might make the adaptive design more attractive to outside investors than a conventional design requiring a fixed investment up-front, even when the two designs have an equivalent unconditional risk profiles. Simulations, performed prior to starting the

trial, are necessary to quantify the risks and benefits involved in selecting an adaptive design in preference to a conventional fixed sample or group sequential design, and to enable the sponsor to make an informed decision.

A major additional benefit of the adaptive approach is flexibility. The adaptive methodology controls the type-1 error even if the pre-specified criteria for increasing the sample size are overruled at the interim analysis. This might be desirable for a variety of reasons both internal and external to the current trial. For example, in addition to observing a promising outcome at the interim time analysis, the safety profile for the test drug might turn out to be far superior to what was originally anticipated, and this might make the new drug more competitive in the marketplace. One could therefore justify increasing the sample size by a larger amount than that determined by the pre-specified rules, and thereby further reduce the chances of a false negative outcome. Another possible situation in which one might overrule the pre-specified criteria for sample size change would be if compelling results from other clinical trials on comparable populations, treated with the same class of drugs became available and caused the sponsor to revise the value of δ at which to power the current study. Ideally one would wish to adhere strictly to the pre-specified criteria for sample size change since the operating characteristics of the design would change if they were overruled. This would certainly be the preference of regulatory authorities. As a practical matter, however, it is not possible to anticipate every contingency under which a sample size change is desirable. It is a strength of the adaptive approach that the validity of the statistical test at the end of the trial is not affected by unanticipated developments arising over the course of the clinical trial that necessitate making changes to the pre-specified criteria for sample size adaptation.

Adaptive trials require very careful up-front planning. An independent interim analysis review committee (IARC) must be appointed with the responsibility to actually implement the adaptive decision rules. A charter listing the members of the IARC, describing their roles and responsibilities, and providing the details of the proposed adaptations must be created. The charter should also discuss the steps that will be taken to ensure that the interim results remain confidential, as premature disclosure of interim results to the trial investigators could compromise the trial. Finally, regulatory approval must be secured in advance through a special protocol assessment (SPA). For this purpose the sponsor is required to submit the protocol, the charter and the simulations backing up the statistical validity of the proposed adaptive approach in good time.

Logistical and operational issues must also be considered. In a fixed sample study the total sample size is determined in advance. In a traditional group sequential study, the

53 *The Motivation for Adaptive Sample Size Changes*

maximum sample size is determined in advance. In an adaptive study, however, the maximum sample size might be increased at an interim look thereby further complicating the management of the trial, especially as it relates to patient recruitment and drug supply. Because of all these complexities an adaptive design might not always be the right choice. The more established fixed sample and group sequential designs should always be evaluated alongside an adaptive design. Simulations play a crucial role in understanding the operating characteristics of an adaptive design and deciding whether it is an appropriate choice for the trial under consideration. There should be a tangible, quantifiable benefit arising from the decision to take the adaptive route.

54

The Cui, Hung and Wang Method

This chapter discusses the Cui, Hung and Wang (1999) (CHW) method for adaptive sample size modification of an on-going two-arm, K -look group sequential clinical trial. The method is based on making a sample size modification, if required, each time that an interim analysis is performed. The interim monitoring continues in this way until either a boundary is crossed or the K looks are exhausted. Since the changes to the sample size may be based on unblinded analyses of the accruing data, the test statistic is not the usual Wald statistic utilized for monitoring a conventional group sequential design. Instead the test statistic comprises of a weighted sum of incremental Wald statistics with weights that are pre-specified and chosen appropriately so as to preserve the type-1 error. This test statistic was proposed independently by Cui, Hung and Wang (1999) and by Lehmacher and Wassmer (1999). We shall refer to this test statistic as the CHW statistic and to this method of making adaptive sample size modifications as the CHW method. The CHW method is only valid for adaptive designs involving data dependent alterations in the sample size. The operating characteristics of any CHW design are obtained through simulation using a special **Sample Size Re-estimation** tab. Interim monitoring is performed through a special **CHW Interim Monitoring** dashboard.

In Section 54.1, we provide a quick review of the underlying theory for normal and binomial endpoints. In Section 54.2 we show how these same results can be extended for trials with survival or time-to-event endpoints. (Hereafter we shall use the terms "survival" or "time-to-event" synonymously.) In Section 54.3, we illustrate the method for a normal endpoint adaptive design. In Section 54.4 we illustrate the method for a binomial endpoint adaptive design. In Section 54.5 we illustrate the method for a time-to-event adaptive design. These three designs were discussed at length in Chapter 53. Here we illustrate how to use the adaptive modules of East to simulate and monitor them. As already stated in the introductory chapter to this volume, we provide two such adaptive packages, East[®] Adapt and East[®] SurvAdapt. The East[®] Adapt package is required for studies with normal or binomial endpoints while the East[®] SurvAdapt package is required for studies with time-to-event endpoints. Since these packages do not function independently of East we will refer to the software as "East" rather than "EastAdapt" or "EastSurvAdapt" throughout this volume. The context will clarify which adaptive module must be available to the core East program in order to run a specific example.

54.1 Statistical Method: Normal and Binomial

54.1.1 Hypothesis Testing

54.1.2 RCI's and RPV's

54.1.3 Conditional Power

54.1.4 East Defaults

In this section, we discuss hypothesis testing, confidence interval and p-value estimation, and computation of conditional power for a group sequential trial that permits adaptive sample size changes at the interim looks.

54.1.1 Hypothesis Testing

Consider a level- α test of the null hypothesis

$$H_0: \delta = 0$$

versus the two-sided alternative hypothesis

$$H_1: \delta \neq 0$$

for a two-arm randomized clinical trial. Before any data are obtained we pre-specify that this hypothesis will be tested by a group sequential trial designed for up to K looks, at cumulative sample sizes n_1, n_2, \dots, n_K , with corresponding level- α stopping boundaries b_1, b_2, \dots, b_K derived from some spending function. Although we have pre-specified the initial sample sizes look by look, there is full flexibility to adapt based on either external information, information from the trial itself, or a combination of the two. Accordingly let $n_1^*, n_2^*, \dots, n_K^*$ denote the altered cumulative sample sizes at the K looks after sample size adaptation. For adaptive designs it is convenient to express sample sizes, and parameter estimates that depend on sample size, in terms of incremental quantities as well as cumulative ones. Thus, for $j = 1, 2, \dots, K$ we define $n^{(j)} = n_j - n_{j-1}$ and $n^{*(j)} = n_j^* - n_{j-1}^*$ to be the incremental sample sizes for the pre-specified and altered designs, respectively, with $n_0 = n_0^* = 0$. In keeping with this notation, we will hereafter index all statistics computed from cumulative sample sizes with subscripts and all statistics computed from incremental sample sizes with superscripts. Additionally we will assign a superscript “*” to all statistics that are computed with the altered sample sizes $n_j^*, j = 1, 2, \dots, K$, rather than the pre-specified sample sizes $n_j, j = 1, 2, \dots, K$.

Suppose we are at look j . Denote the j incremental Wald statistics by

$$Z^{*(l)} = \frac{\hat{\delta}^{*(l)}}{\text{se}(\hat{\delta}^{*(l)})} = \hat{\delta}^{*(l)} \sqrt{I^{*(l)}}, \quad l = 1, 2, \dots, j, \quad (54.1)$$

where $\hat{\delta}^{*(l)}$ and $I^{*(l)} = [\text{se}(\hat{\delta}^{*(l)})]^{-2}$ are, respectively, the point estimate and Fisher information about δ based only on data from the incremental $n^{*(l)}$ observations obtained between look $(l - 1)$ and look l . The CHW statistic at look j , sometimes referred to as the *weighted* statistic, is constructed by combining these incremental Wald statistics with the *pre-specified* weights

$$w^{(l)} = \frac{n^{(l)}}{n_K} \quad l = 1, 2, \dots, j$$

as shown below:

$$Z_{j,\text{chw}}^* = \frac{\sqrt{w^{(1)}}Z^{*(1)} + \sqrt{w^{(2)}}Z^{*(2)} + \dots + \sqrt{w^{(j)}}Z^{*(j)}}{\sqrt{w^{(1)} + w^{(2)} + \dots + w^{(j)}}} . \quad (54.2)$$

This statistic is asymptotically normally distributed with mean

$$E(Z_{j,\text{chw}}^*) = \frac{\delta \sum_{l=1}^j \sqrt{w^{(l)} I^{*(l)}}}{\sqrt{\sum_{l=1}^j w^{(l)}}}$$

and unit variance. Interim monitoring proceeds just as it would in a conventional group sequential trial, and with the same stopping boundaries. The null hypothesis is rejected at the first look j which is such that $|Z_{j,\text{chw}}^*| \geq b_j$.

Both Cui, Hung and Wang (1999) and Lehman and Wassmer (1999) have shown that the CHW statistic preserves the type-1 error despite the data dependent changes in the sample sizes at the interim looks. That is,

$$P_0\left(\bigcup_{j=1}^K |Z_{j,\text{chw}}^*| \geq b_j\right) = \alpha .$$

Now consider the conventional Wald statistic

$$Z_{j,\text{wald}}^* = \frac{\hat{\delta}_j^*}{\text{se}(\hat{\delta}_j^*)} = \hat{\delta}_j \sqrt{I_j^*} , \quad (54.3)$$

where $\hat{\delta}_j^*$ and $I_j^* = [\text{se}(\hat{\delta}_j^*)]^{-2}$ are, respectively, the point estimate and Fisher information about δ based on data from all the n_j^* observation obtained up to and including look j . Because of the data dependent changes in sample size at each stage of the trial, the type-1 error may not be preserved; in general,

$$P_0\left(\bigcup_{j=1}^K |Z_{j,\text{wald}}^*| \geq b_j\right) \neq \alpha .$$

The conventional Wald statistic (54.3) is sometimes referred to as the *unweighted* statistic. This is really a misnomer because we can represent (54.3) at any look j as a weighted sum of j incremental Wald statistics (54.1) using weights

$$w^{*(l)} = \frac{n^{*(l)}}{n_K^*}, \quad l = 1, 2, \dots, j,$$

54 The Cui, Hung and Wang Method

that depend on the actual rather than the pre-specified sample sizes as shown below:

$$Z_{j,\text{wald}}^* = \frac{\sqrt{w^{*(1)}}Z^{*(1)} + \sqrt{w^{*(2)}}Z^{*(2)} + \dots + \sqrt{w^{*(j)}}Z^{*(j)}}{\sqrt{w^{*(1)} + w^{*(2)} + \dots + w^{*(j)}}}. \quad (54.4)$$

The statistics (54.3) and (54.4) are functionally equivalent for the normally distributed data with known variance. In all other settings the two statistics are asymptotically equivalent. It follows that if there is no sample size change one may use either the unweighted or weighted statistic for the interim monitoring since, in that case $w^{(j)} = w^{*(j)}$ for all j , and hence $Z_{j,\text{chw}}^* = Z_{j,\text{wald}}^*$ for all j , and

$$P_0\left(\bigcup_{j=1}^K |Z_{j,\text{chw}}^*| \geq b_j\right) = P_0\left(\bigcup_{j=1}^K |Z_{j,\text{wald}}^*| \geq b_j\right) = \alpha.$$

Although the above hypothesis testing procedure was described for two-sided tests with symmetric boundaries, the modifications to accommodate two-sided tests with asymmetric boundaries and one-sided tests with or without futility boundaries is straightforward.

54.1.2 Repeated Confidence Intervals and Repeated P-Values

The confidence intervals and p-values described in this section are generalizations of the repeated confidence intervals (RCI's) and repeated p-values (RVP's) discussed by Jennison and Turnbull (2000, Chapter 9) for classical group sequential designs. The extension to the adaptive setting is discussed in Lehmacher and Wassmer (1999) and more generally in Mehta, Bauer, Posch and Brannath (2007). All the RCI's and RPV's in this chapter utilize the method of Lehmacher and Wassmer (1999). Like the CHW method with which they are associated, these RCI's and RPV's are only valid for adaptive changes in the sample size. They are not applicable if additional adaptive changes are made to the initial design, such as data dependent changes to the number and spacing of the interim looks, or changes to the error spending function.

Lehmacher and Wassmer (1999) have shown that the K RCI's for δ are given by

$$\frac{(Z_{j,\text{chw}}^* \pm b_j)\sqrt{s_j}}{\sum_{l=1}^j \sqrt{w^{(l)}I^{*(l)}}}, \quad j = 1, 2, \dots, K \quad (54.5)$$

where $s_j = n_j/n_K$ is the information fraction at look j based on the pre-specified sample sizes, are repeated confidence intervals (RCI's). Thus, if δ_0 is the true value of

δ then, for all $j = 1, 2, \dots, K$,

$$P_{\delta_0} \left\{ \bigcap_{i=1}^j \left(\frac{(Z_{i,\text{chw}}^* - b_i)\sqrt{s_i}}{\sum_{l=1}^i \sqrt{w^{(l)}I^{*(l)}}} \leq \delta_0 \leq \frac{(Z_{i,\text{chw}}^* + b_i)\sqrt{s_i}}{\sum_{l=1}^i \sqrt{w^{(l)}I^{*(l)}}} \right) \right\}. \quad (54.6)$$

Following the development in Jennison and Turnbull (2000, page 202) we can use (54.6) to obtain a repeated p-value at any look j . This is accomplished by iteratively altering the significance level of the hypothesis test for δ until a level \tilde{p}_j , say, is obtained such that one of the two extremes of the corresponding RCI (54.5), with confidence coefficient $1 - p_j$, just excludes zero. To be specific, let $b_j(q)$, $j = 1, 2, \dots, K$ represent any level- q two-sided stopping boundaries derived from some spending function. That is,

$$P_0 \left(\bigcup_{j=1}^K |Z_{j,\text{chw}}^*| \geq b_j(q) \right) = q$$

Let $z_{j,\text{chw}}^*$ be the observed value of $Z_{j,\text{chw}}^*$ at look j . Then the two-sided repeated p-value at look j is the probability \tilde{p}_j that satisfies the relationship

$$z_{j,\text{chw}}^* - b_j(\tilde{p}_j) = 0 \quad \text{if } \hat{\delta}_j \geq 0 \quad (54.7)$$

$$z_{j,\text{chw}}^* + b_j(\tilde{p}_j) = 0 \quad \text{if } \hat{\delta}_j < 0. \quad (54.8)$$

These results can be readily modified to accommodate two-sided asymmetric tests and one-sided tests with or without futility boundaries. Suppose, for example that we have obtained the asymmetric two-sided boundaries (a_j, b_j) , $j = 1, 2, \dots, K$ such that

$$P_0 \left\{ \bigcup_{i=1}^{j-1} (a_i < Z_{i,\text{chw}}^* < b_i) \cap (Z_{j,\text{chw}}^* \leq a_j), j = 1, 2, \dots, K \right\} = \alpha_l$$

and

$$P_0 \left\{ \bigcup_{i=1}^{j-1} (a_i < Z_{i,\text{chw}}^* < b_i) \cap (Z_{j,\text{chw}}^* \geq b_j), j = 1, 2, \dots, K \right\} = \alpha_u$$

where $\alpha_l + \alpha_u = \alpha$. Then the K repeated confidence intervals for δ are given by

$$\left[\frac{(Z_{j,\text{chw}}^* - b_j)\sqrt{s_j}}{\sum_{l=1}^j \sqrt{w^{(l)}I^{*(l)}}}, \frac{(Z_{j,\text{chw}}^* - a_j)\sqrt{s_j}}{\sum_{l=1}^j \sqrt{w^{(l)}I^{*(l)}}} \right] \quad j = 1, 2, \dots, K$$

To compute the two-sided repeated p-values let q be any probability and let $(a_j(q), b_j(q))$, $j = 1, 2, \dots, K$, be any level- q asymmetric two-sided stopping

54 The Cui, Hung and Wang Method

boundaries derived from a pair of level- q asymmetric spending functions $(\alpha_l(q), \alpha_u(q))$ which have the same functional form as the spending functions used in the original asymmetric level- α trial design. That is,

$$P_0 \left\{ \bigcup_{i=1}^{j-1} (a_i(q) < Z_{i,\text{chw}}^* < b_i(q)) \cap (Z_{j,\text{chw}}^* \leq a_j(q)), j = 1, 2, \dots, K \right\} = \alpha_l(q)$$

and

$$P_0 \left\{ \bigcup_{i=1}^{j-1} (a_i(q) < Z_{i,\text{chw}}^* < b_i(q)) \cap (Z_{j,\text{chw}}^* \geq b_j(q)), j = 1, 2, \dots, K \right\} = \alpha_u(q)$$

Note: In this notation, if $q = \alpha$, then $\alpha_l(q) = \alpha_l$, $\alpha_u(q) = \alpha_u$, $\alpha_l(q) + \alpha_u(q) = \alpha_l + \alpha_u = \alpha$, and $(a_j(q), b_j(q)) = (a_j, b_j)$, $j = 1, 2, \dots, K$.

Let $z_{j,\text{chw}}^*$ be the observed value of $Z_{j,\text{chw}}^*$ at look j . The two-sided repeated p-value at look j is the probability \tilde{p}_j that satisfies the relationship

$$z_{j,\text{chw}}^* - a_j(\tilde{p}_j) = 0 \quad \text{if } \hat{\delta}_j \geq 0 \tag{54.9}$$

$$z_{j,\text{chw}}^* + b_j(\tilde{p}_j) = 0 \quad \text{if } \hat{\delta}_j < 0. \tag{54.10}$$

54.1.3 Conditional Power

Suppose that an on-going trial has reached some interim look $L < K$, and the observed value of the CHW test statistic is $Z_{L,\text{chw}}^* = z_L$. Having examined the data so far obtained, suppose it is planned to proceed through the remaining stages of the trial with cumulative sample sizes $n_{L+1}^*, n_{L+2}^*, \dots, n_K^*$ that are possibly different than the cumulative sample sizes $n_{L+1}, n_{L+2}, \dots, n_K$ pre-specified at the start of the trial. We define the conditional power at look L as the probability of attaining statistical significance **in the direction of the alternative hypothesis** at any future look, given $z_{(L)}$. Thus, if we are testing the null hypothesis that $\delta = 0$ against the alternative that $\delta > 0$, the conditional power is defined as

$$\text{CP}_\delta(z_L) = P_\delta \left\{ \bigcup_{j=L+1}^K (Z_{j,\text{chw}}^* \geq b_j | z_L) \right\} \tag{54.11}$$

whereas if the alternative hypothesis is that $\delta < 0$, then the conditional power is defined as

$$\text{CP}_\delta(z_L) = P_\delta \left\{ \bigcup_{j=L+1}^K (Z_{j,\text{chw}}^* \leq b_j | z_L) \right\}. \tag{54.12}$$

For two sided tests the conditional power is given by

$$CP_{\delta}(z_L) = P_{\delta}\left\{ \bigcup_{j=L+1}^K (|Z_{j,\text{chw}}^*| \geq b_j | z_L) \right\} \quad (54.13)$$

These probabilities are obtained by recursive integration in East. Special East calculators are available from within the CHW interim monitoring dashboard and the CHW adaptive simulations to compute the conditional power for any specified value of δ . Use of these calculators will be demonstrated in the worked examples that form part of this chapter as well as in a separate chapter of the current user manual.

We conclude this section with some additional remarks about conditional power:

- Although equations (54.11) through (54.13) are expressed in terms of δ , their dependence on σ for normally distributed data is implicit through the expression (54.2) for $Z_{j,\text{chw}}^*$. In fact for the normal case one can show that conditional power depends only on the ratio δ/σ .
- By increasing the sample size of the remainder of the trial after look L one increases the conditional power. The calculators in East can be used to determine the magnitude of the sample size increase that is needed to achieve any desirable conditional power, for any assumed value of δ (and σ).
- Each simulation performed in the CHW adaptive simulations implements a one-time adaptive increase in sample size at a specified look L of the K -look group sequential design. The magnitude of the sample size increase is determined by a pre-specified conditional power, say $1 - \beta$, that the user desires to achieve. In order to speed up the simulations, this sample size is computed by an approximation to equation (54.11) (or (54.12)) that assumes that the next time the data are monitored will be at look K , and all the intermediate looks $L + 1, L + 2, \dots, K - 1$ will be skipped. Specifically the approximate conditional power calculation is given by

$$CP_{\delta}(z_L) = 1 - \Phi \left\{ b_K \sqrt{1 + \frac{n_L}{n_K - n_L}} - z_L \sqrt{\frac{n_L}{n_K - n_L}} - \frac{\delta \sqrt{r(1-r)} \sqrt{n_K^* - n_L}}{\sigma} \right\} \quad (54.14)$$

where r is the fraction randomized to the experimental arm. The approximate sample size needed to achieve conditional power $1 - \beta$ is then obtained by finding the value of n_K^* that satisfies

$$1 - \Phi \left\{ b_K \sqrt{1 + \frac{n_L}{n_K - n_L}} - z_L \sqrt{\frac{n_L}{n_K - n_L}} - \frac{\delta \sqrt{r(1-r)} \sqrt{n_K^* - n_L}}{\sigma} \right\} = 1 - \beta. \quad (54.15)$$

The operating characteristics of the adaptive design under this approximate way of computing conditional power are almost the same as the operating

54 The Cui, Hung and Wang Method

characteristics that would be obtained by using say equation (54.11) to evaluate conditional power at each simulation. The simulations are, however, speeded up substantially thereby.

54.1.4 Adaptive Simulations Defaults

It will be useful to discuss now, the default settings used for adaptive simulation procedures in East, and the options available to you if you want to change them. If you click on the button **Include Options** and check **Sample Size Re-estimation**, you will see the following additional tab called **Sample Size Re-estimation** on the screen.

| | | | |
|--|---------------------------|--|------------|
| Use Adaptation Method | | | |
| <input checked="" type="radio"/> CHW | <input type="radio"/> CDL | <input type="radio"/> Müller and Schäfer | Weights... |
| Adapt at: | Look # | 1 | |
| Max. Sample Size if Adapt (multiplier; total #): | | 1 | 694 |
| Target CP for Re-estimating Sample Size: | | 0.8 | |
| Promising Zone Scale: | | Cond. Power | CP |
| Promising Zone: | Min. CP: | 0.3 | |
| | Max. CP: | 0.8 | |
| CP Computation Based on: | | Estimated δ/σ | |

All the parameters on this tab will explained in detail in the subsequent sections. Here, we explain the default settings on this tab.

Three adaptation methods are implemented in this version of East - Cui-Hung-Wang, Chen-DeMets-Lan, and Müller and Schäfer methods. The default method selected is Cui-Hung-Wang.

By default, the adaptation happens at a specified look number. One can also perform adaptation after a specified sample size or information fraction.

By default, the promising zone is defined on the Conditional Power scale. One can also define it on the Test Statistic scale or Estimated δ scale.

The default settings for CP Computations are:

Estimated δ/σ for Normal Endpoint

Estimated (π_c, π_t) for Binomial Endpoint

Estimated HR for Survival Endpoint

We recommend that you do not alter these settings except for research purposes. The choices you make in this dialog box will determine how the adaptive simulations are conducted. Because changes to these settings can substantially alter the operating characteristics of the adaptive simulations, East will revert back to the default values each time the East session is terminated. For Binomial Endpoint designs, there are only two choices: **Estimated** (π_c, π_t) and **Design** (π_c, π_t). Depending on the selection you make, the conditional power computation at the specified interim look (Or sample size Or information fraction) will be based either on the estimated value of π_c and π_t or the values that have been used for creating the study design. An example of a binomial endpoint design is shown below.

| | |
|--|-------------------|
| | Wbk1:bin |
| Mnemonic | PN-25-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 3 |
| Test Type | 1-Sided |
| Variance | Unpooled Estimate |
| Specified α | 0.025 |
| Power | 0.901 |
| Model Parameters | |
| Proportion under Control (π_c) | 0.25 |
| Proportion under Treatment (π_t) | 0.4 |
| Diff. in Prop. ($\pi_t - \pi_c$) | 0.15 |
| Allocation Ratio (n_t/n_c) | 1 |
| Boundary Parameters | |
| Efficacy Boundary | LD (OF) |
| Spacing of Looks | Equal |
| Sample Size | |
| Maximum | 405 |
| Expected Under H0 | 404.169 |
| Expected Under H1 | 324.601 |

The design parameters in the above plan are $\pi_c = 0.25$ and $\pi_t = 0.40$. If you have chosen the setting **Design** (π_c, π_t) for conditional power computation in the **Sample Size Re-estimation** tab, then in any adaptive simulations, the conditional power at the interim analysis will be computed using the design values, $\pi_c = 0.25$ and

54 *The Cui, Hung and Wang Method*

$\pi_t = 0.40$, regardless of the estimated values obtained for these parameters at the time of the interim analysis.

For Normal Endpoint designs, the conditional power depends on δ and σ only through the ratio δ/σ . You may choose either **Design** δ/σ or **Estimated** δ/σ in the **Sample Size Re-estimation** tab and the conditional power at the interim analysis in any adaptive simulation will be computed accordingly. The sigma used for the computing test statistic is determined by the choice of sigma made in the **Simulation Parameters** tab. If this choice is Z then **design** σ is used otherwise **Estimated** σ is used in the test statistic computation.

Survival Endpoint designs are discussed in Section 54.2. For such designs the treatment effect δ is defined to be the log hazard ratio. You may choose either the Design HR or Estimated HR for purposes of computing conditional power at the interim look.

We end this section with an example that shows how the choice of Design or Estimated parameter values for conditional power computation at an interim look can alter the operating characteristics of an adaptive design. Consider the normal endpoint design

shown below.

| | Wbk1:Des1 |
|---|------------------|
| Mnemonic | MN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 3 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.901 |
| Model Parameters | |
| Input Method | Individual Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 15 |
| Mean Control (μ_c) | 0 |
| Mean Treatment (μ_t) | 15 |
| Std. Deviation (σ) | 30 |
| Test Statistic | Z |
| Allocation Ratio (nt/nc) | 1 |
| Boundary Parameters | |
| Efficacy Boundary | LD (OF) |
| Spacing of Looks | Equal |
| Sample Size | |
| Maximum | 171 |
| Expected Under H0 | 170.649 |
| Expected Under H1 | 136.959 |

The design parameters for the above plan are $\delta = 15$ and $\sigma = 30$. Suppose you have chosen **Design** δ/σ for the conditional power computation on the **Sample Size**

54 The Cui, Hung and Wang Method

Re-estimation tab:

| | | | |
|--|---------------------------|--|-----|
| Use Adaptation Method | | Weights... | |
| <input checked="" type="radio"/> CHW | <input type="radio"/> CDL | <input type="radio"/> Müller and Schäfer | |
| Adapt at: | Look # | 2 | |
| Max. Sample Size if Adapt (multiplier; total #): | | 1 | 171 |
| Target CP for Re-estimating Sample Size: | | 0.9 | |
| Promising Zone Scale: | | Cond. Power | CP |
| Promising Zone: | Min. CP: | 0.3 | |
| | Max. CP: | 0.9 | |
| CP Computation Based on: | | Design δ/σ | |

and the test statistic as Z on **Simulation Parameters** tab:

| | |
|------------------------------|----|
| Test Statistic: | Z |
| Std. Deviation (σ): | 30 |

Then, in every adaptive simulation you carry out for this design, the conditional power at the interim analyses will be based on the ratio $\delta/\sigma = 15/30 = 0.5$ and the test statistic will be computed under the assumption that design $\sigma = 30$, rather than estimating these quantities from the actual data generated at the interim look.

In order to explore the impact of changes to these simulation settings, change the choice of the test statistic to t in **Simulation Parameters** tab as shown below:

| | |
|-----------------|-------|
| Test Statistic: | t |
| Variance: | Equal |

Change the value of δ_1 under **Response Generation Info** to 10 and keep the σ_1 value same as 30.

| Simulation Parameters | Response Generation Info | Sample Size Re-estimation |
|---------------------------------------|--------------------------|---|
| Generate Data Using: Individual Means | | <input checked="" type="checkbox"/> Common Standard Deviation |
| Mean Control (μ_c): | 0 | SD Control (σ_c): 30 |
| Mean Treatment (μ_t): | 10 | SD Treatment (σ_t): 30 |

Also make changes on the **Sample Size Re-estimation** tab as shown below.

| Use Adaptation Method | | Weights... | |
|--|---------------------------|--|-----------------------------------|
| <input checked="" type="radio"/> CHW | <input type="radio"/> CDL | <input type="radio"/> Müller and Schäfer | |
| Adapt at: | Look # | 2 | |

| Promising Zone | 0.3 <= CP < 0.9 |
| Simulation Results (Overall) | |
| Average Sample Size | 191.238 |
| Simulation Results (Promising) | |
| Average Sample Size | 273.782 |

Remember that these results were obtained when the values of δ/σ and σ were both set to **Estimated** values. Now you can change your settings for these two parameters to **Estimated** and **Design** respectively. It can be done by editing the current simulation node. Select the simulation node in the **Library** and click the  icon. you will be taken **Simulation Parameters** tab. Here, select the Test statistic as Z from its dropdown. Run the simulation and get new results. Similarly you can carry out other two simulations with the combinations **Design-Estimated** and **Design-Design** for the two parameters δ/σ and σ and obtain the results. So now you will have four sets of results for the four assumptions on the two parameters. These results are all obtained by simulating under the values of $\delta_1 = 10$ and $\sigma_1 = 30$. Carry out two more sets of similar analyses using the combinations of $\delta_1 = 8$ & $\sigma_1 = 40$ and $\delta_1 = 12$ & $\sigma_1 = 24$. You may compare the various resulting values from

54 The Cui, Hung and Wang Method

the simulations, like power, average combined sample size, average adapted sample size, etc. As an example, let us compare the values of power, from the different simulations carried out, as tabulated below.

Table 54.1: Results for different assumptions of East Settings for Adaptive Simulation

(Design parameters: $\delta = 15, \sigma = 30$)

| Settings for | | Estimates of Power under different simulation parameters | | | |
|-------------------|----------------|--|------------------------------------|-------------------------------------|------------------------------------|
| Conditional Power | Test Statistic | $\delta_1 = 10,$ $\sigma_1 = 30$ | $\delta_1 = 8,$ $\sigma_1 = 40$ | $\delta_1 = 12,$ $\sigma_1 = 24$ | $\delta_1 = 0,$ $\sigma_1 = 30$ |
| δ/σ | σ | | | | |
| Estimated | Estimated | 66.25% | 30.8% | 93.24% | 2.65% |
| Estimated | Design | 65.93% | 48.96% | 85.81% | 2.5% |
| Design | Estimated | 67.12% | 30.66% | 94.42% | 2.5% |
| Design | Design | 67.27% | 49.21% | 87.78% | 2.44% |

We can also compare multiple simulation scenarios in East itself. It can be by selecting from the **Library** the scenarios to be compared and clicking the  icon to see the comparison. Let us compare first four scenarios from the above table.

| | Wbk1:Des1:CHWSim1 | Wbk1:Des1:CHWSim2 | Wbk1:Des1:CHWSim3 | Wbk1:Des1:CHWSim4 |
|---|----------------------------------|----------------------------------|-------------------------------|-------------------------------|

| Method of Adaptation | Cui-Hung-Wang | Cui-Hung-Wang | Cui-Hung-Wang | Cui-Hung-Wang |
| Adaptation Stage | Look # : 2 | Look # : 2 | Look # : 2 | Look # : 2 |
| Max. Sample Size if Adapt | 342 | 342 | 342 | 342 |
| Target CP | 0.9 | 0.9 | 0.9 | 0.9 |
| CP Computation Based on Promising Zone | Estimated δ/σ 0.3 <= CP < 0.9 | Estimated δ/σ 0.3 <= CP < 0.9 | Design δ/σ 0.3 <= CP < 0.9 | Design δ/σ 0.3 <= CP < 0.9 |
| Simulation Results (Promising) | | | | |
| Average Sample Size | 275.034 | 274.842 | 236.222 | 235.744 |

By comparing the power estimates across rows or columns in the above table, you will be able to gauge the effect due to different parameters/computations assumptions. Our recommendation is to leave these parameters at their default values except for exploratory purposes.

54.2 Statistical Method: Survival

For studies involving survival (time-to-event) endpoints the parameter δ denoting the treatment effect is defined to be the logarithm of the hazard ratio of the treatment arm to the control arm; $\delta = \ln(\text{HR})$. Under proportional hazards, $\delta < 0$ implies longer survival times for the treatment arm than for the control arm. In order to test the null hypothesis

$$H_0: \delta = 0$$

versus one and two-sided alternatives we exploit the independent increment structure of the sequentially computed logrank statistic (Tsiatis, 1981; Jennison and Turnbull, 1997). Before any data are obtained we pre-specify that the null hypothesis will be tested by a K -look group sequential design at potential stopping times D_1, D_2, \dots, D_K , where D_j denotes the **cumulative** number of events obtained at look j and b_j is the corresponding level- α stopping boundary derived from some spending function. The CHW method permits data dependent alterations to the cumulative events at which these looks occur. Accordingly let $D_1^*, D_2^*, \dots, D_K^*$ denote the altered cumulative events at the K looks resulting from an adaptation of the original design. Analogous to the notation developed for normal and binomial endpoints let $D^{(j)} = D_j - D_{j-1}$ and $D^{*(j)} = D_j^* - D_{j-1}^*$ be the incremental increase in the number of events between looks $j - 1$ and j .

54 The Cui, Hung and Wang Method

Let $Z_{j,cum}^*$ denote the Z-score based by either a logrank statistic or the treatment effect estimate obtained by fitting the Cox proportional hazard model to the cumulative data available at look j . Then the results of Tsiatis(1981) and Jennison and Turnbull (1997) show that the incremental statistics

$$Z^{*(j)} = \frac{\sqrt{I_j^*} Z_{j,cum}^* - \sqrt{I_{j-1}^*} Z_{j-1,cum}^*}{\sqrt{I_j^* - I_{j-1}^*}}, \text{ for } j = 1, \dots, K, \quad (54.16)$$

are asymptotically independent and normally distributed with mean

$$E \left[Z^{*(j)} \right] \approx \delta \sqrt{I_j^* - I_{j-1}^*} \quad (54.17)$$

and unit variance, where r is the fraction randomized to the treatment arm. In the simulation module $Z_{j,cum}^*$ comes from the log-rank test and we assume that

$$I_j^* \approx r(1-r)D_j^* \quad (54.18)$$

Here r is the proportion of subjects in the active treatment group. In the interim monitoring module we use an approximation (54.18) as default and use a slightly different approximation

$$I_j^* = \frac{1}{\left(\widehat{se}(\hat{\delta}_j) \right)^2} \quad (54.19)$$

if the monitoring relies on the estimates of treatment effect $\hat{\delta}_j$ and $\widehat{se}(\hat{\delta}_j)$ provided by fitting the Cox proportional hazard model to the cumulative data at look j . Let

$$w^{(j)} = \frac{D^{(j)}}{D^{(K)}}, \text{ for } j = 1, 2, \dots, K,$$

be pre-specified weights. Following Wassmer (2006), the CHW statistic for survival designs is constructed by combining the independent incremental statistics (54.16) with these weights:

$$Z_{j,chw}^* = \frac{\sqrt{w^{(1)}} Z^{*(1)} + \sqrt{w^{(2)}} Z^{*(2)} + \dots + \sqrt{w^{(j)}} Z^{*(j)}}{\sqrt{w^{(1)} + w^{(2)} + \dots + w^{(j)}}}. \quad (54.20)$$

The CHW statistic (54.20) for survival endpoints has the same asymptotic distribution as the CHW statistic (54.2) for normal and binomial endpoints. Thus all the distributional results, repeated confidence intervals, p-values, and conditional power calculations derived in Section 54.1.1, Section 54.1.2, and Section 54.1.3 for normal and binomial endpoints also hold for time-to-event endpoints with $\delta = \ln(\text{HR})$, $\sigma = 1$, $D^{*(j)}$ substituting for $n^{*(j)}$.

In particular equation (54.14), depicting the conditional power if $Z_{L,\text{chw}}^* = z_L$ at look L and D_K^* cumulative events are required at the K th look, can be re-expressed in the form

$$\text{CP}_\delta(z_L) = 1 - \Phi \left\{ b_K \sqrt{1 + \frac{D_L}{D_K - D_L}} - z_L \sqrt{\frac{D_L}{D_K - D_L}} - \delta \sqrt{r(1-r)} \sqrt{D_K^* - D_L} \right\}. \tag{54.21}$$

Since the true value of δ is unknown it is customary to substitute either its look L estimate $\hat{\delta}_L$,

$$\hat{\delta}_L^* = \frac{Z_{L,\text{cum}}^*}{\sqrt{r(1-r)} D_L^*} \tag{54.22}$$

or else the value δ_1 specified under the alternative hypothesis at the design stage, in the above expression for conditional power. East provides the user with both options. Note that like equation (54.14), equation (54.21) also involves the simplifying assumption that the next look following look L will be the last look, and all intermediate looks $L + 1, L + 2, \dots, K - 1$ will be skipped. This assumption yields an approximate conditional power that can be computed rapidly and is sufficiently accurate for use in simulation experiments such as those discussed in Section 54.5.3. However, special calculators documented in Chapter 57 are available if a more accurate conditional power computation that respects the actual stopping boundaries at looks $L + 1, L + 2, \dots, K - 1$ is desired.

54.3 Normal Endpoint: Schizophrenia Trial

54.3.1 Fixed Sample Design

54.3.2 Adaptive Design

54.3.3 Interim Monitoring

Consider a two-arm trial to determine if there is an efficacy gain for an experimental drug relative to the industry standard treatment for negative symptoms schizophrenia. The primary endpoint is the improvement from baseline to week 26 in the Negative Symptoms Assessment (NSA), a 16-item clinician-rated instrument for measuring the negative symptomatology of schizophrenia. Let μ_t denote the difference between the mean NSA at baseline and the mean NSA at week 26 for the treatment arm and let μ_c denote the corresponding difference of means for the control arm. Denote the efficacy gain by $\delta = \mu_t - \mu_c$. The trial will be designed to test the null hypothesis $H_0: \delta = 0$ versus the one-sided alternative hypothesis that $\delta > 0$. It is expected, from limited data on related studies, that $\delta \geq 2$ and σ , the between-subject standard deviation, is believed to be about 7.5. In the discussion that follows, we shall focus our attention on

54 The Cui, Hung and Wang Method

the uncertainty about δ . Even though the statistical methods discussed here are applicable when there is uncertainty about either δ or σ , the adaptive approach requires careful justification primarily when δ is involved. Adaptive sample size adjustments relating to uncertainty about σ are fairly routine and non-controversial. One way to eliminate the uncertainty due to σ is to re-parameterize the treatment effect in terms of δ/σ , since it turns out that the sample size, power and conditional power are all dependent on δ and σ only through this ratio. Although we shall not follow that approach here, we wish to point out that it is supported by the EastAdapt software.

This example is discussed in detail in Chapter 53, Section 53.2, where the relative merits of the fixed sample, group sequential and adaptive designs are compared. We have re-introduced this example in the present chapter in order to illustrate how to use the adaptive features in East software to design, simulate and monitor an adaptive clinical trial that will test the null hypothesis $\delta = 0$ and estimate the parameter δ .

54.3.1 Fixed Sample Design

Since it is believed a priori that $\delta \geq 2$, we first create Des 1, a single-look design with 80% power to detect $\delta = 2$ using a one-sided level 0.025 test, given $\sigma = 7.5$.

| | CHW:Des 1 |
|---|---------------------|
| Mnemonic | MN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.8 |
| Model Parameters | |
| Input Method | Difference of Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 2 |
| Std. Deviation (σ) | 7.5 |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | Z |
| Allocation Ratio (nt/nc) | 1 |
| Sample Size | |
| Maximum | 442 |

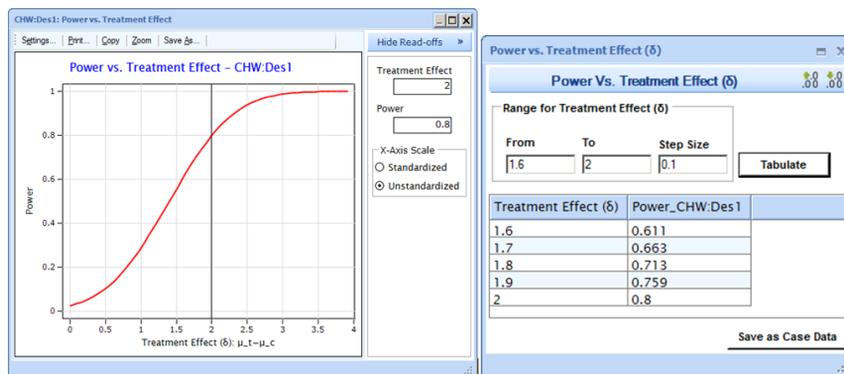

Des 1 shows that if the assumptions about δ and σ are correct, the trial will achieve 80% power with a total sample size of 442 subjects. There is, however, considerable

uncertainty about the true value of δ , and to a lesser extent about σ . Nevertheless it is believed that even if the true value of δ were as low as 1.6 on the NSA scale, that would constitute a clinically meaningful effect. Des 2, displayed below, shows that if 690 subjects are enrolled the power to detect $\delta = 1.6$ is 80%.

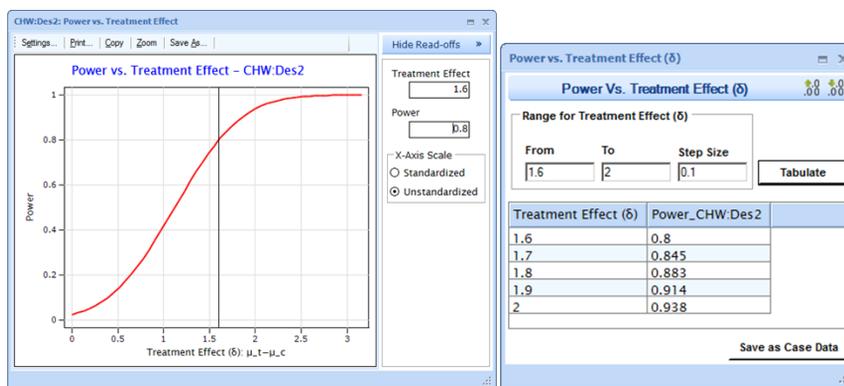

| | CHW:Des1 | CHW:Des2 |
|---|---------------------|---------------------|
| Mnemonic | MN-2S-DI | MN-2S-DI |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 1 | 1 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.025 | 0.025 |
| Power | 0.8 | 0.8 |
| Model Parameters | | |
| Input Method | Difference of Means | Difference of Means |
| Diff. in Means ($\delta = \mu_t - \mu_c$) | 2 | 1.6 |
| Std. Deviation (σ) | 7.5 | 7.5 |
| Test Statistic | Z | Z |
| Allocation Ratio (nt/nc) | 1 | 1 |
| Sample Size | | |
| Maximum | 442 | 690 |

So far we have proposed two design options. Under Des 1 we would enroll 442 subjects and hope that the study is adequately powered, which it will be if $\delta = 2$ and $\sigma = 7.5$. If, however $\delta = 1.6$ the power drops from 80% to 61%.

54 The Cui, Hung and Wang Method

There is thus a risk of launching an underpowered study for an effective drug under Des 1, even if $\sigma = 7.5$. Under Des 2 we will enroll 690 subjects, thereby ensuring 80% power at the smallest clinically meaningful value, $\delta = 1.6$, and rising to 94% power at $\delta = 2$.

The operating characteristics of Des 1 and Des 2 are displayed side by side in Table 54.2.

If resources were plentiful, Des 2 would clearly be the preferred option. The sponsor must, however, allocate scarce resources over a number of studies and in any case is not in favor of designing an overpowered trial. This leads naturally to considering a design that might be more flexible with respect to sample size than either of the above

Table 54.2: Operating Characteristics of Des 1 and Des 2

| δ | Des 1 | | Des 2 | |
|----------|-------------|-------|-------------|-------|
| | Sample Size | Power | Sample Size | Power |
| 1.6 | 442 | 61% | 690 | 80% |
| 1.7 | 442 | 66% | 690 | 85% |
| 1.8 | 442 | 71% | 690 | 88% |
| 1.9 | 442 | 76% | 690 | 91% |
| 2.0 | 442 | 80% | 690 | 94% |

two single-look fixed sample designs. Two options for providing this greater flexibility are the group sequential design and the adaptive design. In the group sequential design one starts out with a large up-front commitment by powering the study to detect the smallest clinically meaningful treatment effect $\delta = 1.6$, but the expected sample size is reduced by means of early stopping boundaries. In the adaptive design, one starts out with a smaller initial sample size by powering the study to detect the optimistic treatment effect $\delta = 2$, but reserves the option to increase the sample size on the basis of the data obtained at an interim look, should it appear advantageous to do so.

Group sequential designs are discussed extensively elsewhere in the East manual and hence this option need not be illustrated in the current chapter. We refer the user to Chapter 53, Section 53.2 of this user manual for a thorough discussion of the relative merits of the group sequential and adaptive options as they relate to the present example. It is seen that the relatively long follow-up (26 weeks) before the primary endpoint is observed leads to patient overruns which offset some of the advantages of the group sequential design. We shall accordingly confine our discussion to adaptive design for the remainder of this section.

54.3.2 Adaptive Design

To motivate the adaptive design let us recall that although the actual value of δ is unknown, the investigators believe that $\delta \geq 2$. For this reason Des 1 was constructed to have 80% power to detect $\delta = 2$. Des 2 on the other hand was constructed to have 80% power to detect $\delta = 1.6$, the smallest clinically meaningful treatment effect. If there were no resource constraints one would of course prefer to design the study for 80% power at $\delta = 1.6$ since that would imply even more power at $\delta = 2$. However, as can be seen from Table 54.2, this conservative strategy carries as its price a substantially larger up-front sample size commitment which is, moreover, unnecessary if in truth $\delta = 2$.

54 The Cui, Hung and Wang Method

The above difficulties lead us to consider whether Des 1, which was intended to detect $\delta = 2$ with 80% power and hence does not have such a large up-front sample size commitment, might be improved so as to provide some insurance against substantial power loss in the event that $\delta = 1.6$. The adaptive approach is suited to this purpose. In this approach we start out with a sample size of 442 subjects as in Des 1, but take an interim look after data are available on 208 completers. The purpose of the interim look is not to stop the trial early but rather to examine the interim data and continue enrolling past the planned 442 subjects if the interim results are promising enough to warrant the additional investment of sample size. This strategy has the advantage that the sample size is finalized only after a thorough examination of data from the actual study rather than through making a large up-front sample size commitment before any data are available. Furthermore, if the sample size may only be increased but never decreased from the originally planned 442 subjects, there is no loss of efficiency due to overruns. For the final analysis we adopt the CHW statistic described in Section 54.1, so as to avoid inflating the type-1 error.

Selecting the Criteria for an Adaptive Sample Size Increase

The operating characteristics of an adaptive design depend in a complicated way on the criteria for increasing the sample size after observing the interim data. These criteria may combine objective information such as the current estimate of δ or the current conditional power with assessments of safety and with information available from other clinical trials that was not available at the start of the study. The adaptive approach provides complete flexibility to modify the sample size without having to pre-specify a precise mathematical formula for computing the new sample size based on the interim data. Therefore the full benefit of the flexibility offered by an adaptive design cannot be quantified ahead of time. Nevertheless it is instructive to investigate power and expected sample size by simulating the trial under different values of δ and applying precise pre-specified rules for increasing the sample size on the basis of the observed interim results. This will provide at least some idea, at the design stage, of the trade-off between the fixed sample or group sequential approaches and the adaptive approach.

To this end we create Des 3 as a 2-look design with 80% power to detect $\delta = 2$ with a one-sided level-0.025 test, and one interim analysis utilizing the $\gamma(-24)$ spending function after data are available on 208 completers. The $\gamma(-24)$ early stopping boundary selected for Des 3 is so conservative that for all practical purposes there is no early stopping at all. The specification of this early stopping boundary is simply an artificial device for permitting an interim look at which one may adaptively increase

the sample size. Therefore Des 3 may be viewed as an extension of Des 1.

Design: Continuous Endpoint: Two-Sample Test - Parallel Design - Difference of Means

| Test Parameters | |
|--------------------------------|------------------|

Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries Efficacy Z | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|-----------------------|---|----------|
| | | | | | Under H0 | Under H1 |
| | | | | | Efficacy | Efficacy |
| 1 | 0.471 | 208 | 7.583E-8 | 5.251 | 7.583E-8 | 4.38E-4 |
| 2 | 1 | 442 | 0.025 | 1.96 | 0.025 | 0.8 |

At the start of the trial, both plans have the same sample size of 442 subjects and 80% power at $\delta = 2$, deteriorating to 61% power at $\delta = 1.6$.

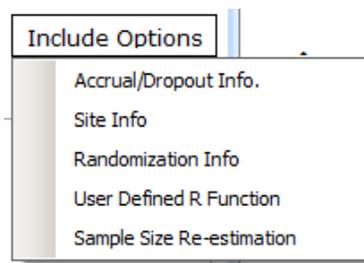

Des 3 stipulates, however, that an interim look will be taken after 26 weeks of follow-up data are available on 208 of the planned 442 subjects. At that interim look the sample size may be increased. The timing of the interim look reflects a preference for performing the interim analysis as late as possible but nevertheless while the trial is still enrolling subjects since, once the enrollment sites have closed down, it will be difficult to start them up again. Under the assumption that subjects enroll at the rate of 8 per week we will have enrolled 416 subjects by week 52; 208 of them will have

54 The Cui, Hung and Wang Method

completed the required 26 weeks of follow-up for the primary endpoint, and an additional 208 subjects will comprise the overruns. Only the data from the 208 completers will be used in making the decision to increase the sample size. After this decision is taken, enrollment will continue until the desired sample size is attained. The primary efficacy analysis will be based on the full 26 weeks of follow-up data from all enrolled subjects and will utilize the CHW test, thereby ensuring that the type-1 error is preserved despite the data dependent sample size change at the interim look. It should be noted that, unlike the group sequential setting where the 208 overruns at the time of the interim look played no role in the early stopping decision, here the data from the 208 overruns will be fully utilized in the primary efficacy analysis which will only occur when all enrolled subjects have completed 26 weeks of follow-up. This is one of the advantages of the adaptive approach relative to the group sequential approach for trials with lengthy follow-up.

The East software provides a simulation tool for studying the consequences of increasing the sample size of Des 3 at the interim look. To implement this tool we must add the sample size re-estimation tab for Des 3. Select Des 3 in the **Library** and click the **S** icon. In addition to the default tabs appearing by default on inserting Simulations, one can add more tabs to enter information available on randomization, stratification and sample size re-estimation. This can be done by clicking the **Include Options** button on this right hand top corner of the screen.

Select Sample Size Re-estimation from the list. This will add a tab named as **Sample Size Re-estimation** as shown below:

Let us focus on these tabs. Several parameters on these four tabs shown below play important role in simulation and adaptation of a design. The three tabs **Simulation Parameters**, **Response Generation Info** and **Simulation Control Info** contain all the

information about the design Des 3 in the absence of any adaptive change. It is a two-look design with a sample size of 442 and an interim look after 208 completers. The early stopping boundary generated by the $\gamma(-24)$ spending function equals 5.251 standard deviations on the Wald statistic scale. With this extremely conservative boundary there is practically no chance of early stopping even at the alternative hypothesis that $\delta = 2$. This design is for all practical purposes the same as Des 1.

The fourth tab **Sample Size Re-estimation** is used to specify the rules of adaptation for modifying the initial sample size of Des 3, based on the data at the interim analysis. Before running the simulations we must input suitable values into the cells of this tab. We have made the following choices in different tabs:

The **Response Generation Info** tab:

| | |
|---------------------------------------|---|
| Generate Data Using: Individual Means | <input checked="" type="checkbox"/> Common Standard Deviation |
| Mean Control (μ_c): 0 | SD Control (σ_c): 7.5 |
| Mean Treatment (μ_t): 1.6 | SD Treatment (σ_t): 7.5 |

The **Sample Size Re-estimation** tab:

| | | |
|--|---------------------------|--|
| Use Adaptation Method | | Weights... |
| <input checked="" type="radio"/> CHW | <input type="radio"/> CDL | <input type="radio"/> Müller and Schäfer |
| Adapt at: | Look # | 1 |
| Max. Sample Size if Adapt (multiplier; total #): | 2 | 884 |
| Target CP for Re-estimating Sample Size: | 0.8 | |
| Promising Zone Scale: | Cond. Power | <input checked="" type="radio"/> CP |
| Promising Zone: | Min. CP: | 0.3 |
| | Max. CP: | 0.8 |
| CP Computation Based on: | Estimated δ/σ | |

Most of these simulation parameters are self-explanatory. Some of them need further explanation. This is provided below.

Adapt at: For a K -look group sequential design, one can decide the time at which

54 The Cui, Hung and Wang Method

conditions for adaptations are to be checked and actual adaptation is to be carried out. This can be done either at some intermediate look or after some specified information fraction. The possible values of this parameter depends upon the choice of the user. If it is **Look no.**, then this parameter can be any integer number from 1 to $K - 1$. If the adaptation is to be carried out after reaching specified information fraction then this parameter can be a fraction between 0 and 1. The default choice in East is **Look no.** to decide the time of adaptation.

Adapt at:

Target CP for Re-estimating Sample Size: The primary driver for increasing the sample size at the interim look is the desired (or target) conditional power or probability of obtaining a positive outcome at the end of the trial, given the data already observed. For this example we have set the conditional power at the end of the trial to be 80%. East then computes the sample size that would be required to achieve this desired conditional power. The computation assumes that the estimated $\hat{\delta}$ obtained at the interim look is the true δ . Refer to Section 54.1.3 for the relevant formula for this computation.

Maximum Sample Size if Adapt (multiplier; total): As just stated, a new sample size is computed at the interim analysis on the basis of the observed data so as to achieve some target conditional power. However the sample size so obtained will be overruled unless it falls between pre-specified minimum and maximum values. For this example, the range of allowable sample sizes is [442, 884]. If the newly computed sample size falls outside this range, it will be reset to the appropriate boundary of the range. For example, if the sample size needed to achieve the desired 80% conditional power is less than 442, the new sample size will be reset to 442. In other words we will not decrease the sample size from what was specified initially. On the other hand, the upper bound of 884 subjects demonstrates that the sponsor is prepared to increase the sample size up to double the initial investment in order to achieve the desired 80% conditional power. But if 80% conditional power requires more than 884 subjects, the sample size will be reset to 884, the maximum allowed.

Promising Zone Scale: One can define the promising zone as an interval based on conditional power or test statistic or δ/σ . The input fields change according to this choice. The decision of altering the sample size is taken based on whether the interim value of conditional power / test statistic / δ/σ lies in this interval or not.

Let us keep the default scale which is Conditional Power.

Promising Zone: Minimum/Maximum Conditional Power (CP): The sample size

will only be altered if the estimate of CP at the interim analysis lies in a pre-specified range, referred to as the "Promising Zone". Here the promising zone is stipulated to be $0.30 - 0.80$. The idea is to invest in the trial in stages. Prior to the interim analysis the sponsor is only committed to a sample size of 442 subjects. If, however, the results at the interim analysis appear reasonably promising, the sponsor would be willing to make a larger investment in the trial and thereby improve the chances of success. Here we have somewhat arbitrarily set the lower bound for a promising interim outcome to be $CP = 0.30$. An estimate $CP < 0.30$ at the interim analysis is not considered promising enough to warrant a sample size increase. It might sometimes be desirable to also specify an upper bound beyond which no sample size change will be made. Here we have set that upper bound of the promising zone at $CP = 0.80$. In effect we have partitioned the range of possible values for conditional power at the interim analysis into three zones; *unfavorable* ($CP \leq 0.3$), *promising* ($0.3 \leq CP < 0.8$), and *favorable* ($CP \geq 0.8$). Sample size adaptations are attempted only if CP (with no sample size adaptation) falls in the promising zone at the interim analysis.

The promising zone defined on the Test Statistic scale or δ/σ scale work on the similar lines.

The **Simulation Control Info** tab:

| | |
|--|-------------------------------------|
| Number of Simulations: | <input type="text" value="100000"/> |

| % | | | 67.052% | | |

The results from the 100,000 simulated trials are displayed in three tables titled **Simulation Boundaries and Boundary Crossing Probabilities**, **Average Sample Size and Look Times** and **Simulation Results by Zone**. We observe from the table that the power of the adaptive implementation of Des 3 at $\delta = 1.6$ is 67.05%, an improvement of about 6% over the power of Des 1 at the same value of δ . This increase in power has come at an average cost of $510 - 442 = 68$ additional subjects. Next we observe from the **Simulation Results by Zone** that 26,488 of the 100,000 trials (26.49%) underwent a sample size adaptation and of these 26,488 trials, 21,986 (83%) were able to reject the null hypothesis. The average sample size, conditional on adaptation was 697.41. To examine these same results in more details, we see the table **Zone-wise Averages**.

This table contains the results from all the six zones - Futility, Unfavorable, Promising, Favorable, Efficacy and All Trials.

The simulations fall in the unfavorable zone, promising, favorable and efficacy zones

32.52%, 26.49%, 40.97% and 0.022% of the time respectively. Observe that while the overall probability of obtaining a significant result is only 67.05%, this probability jumps up to 83.0% conditional on falling in the promising zone.

We repeat these simulations with other values of δ between 1.6 and 2. The operating characteristics for the adaptive Des 3, are compared to those of the fixed sample Des 1 in Table 54.3. All results for Des 3 are based on 100,000 simulated trials and rounded to the nearest percentage point.

Table 54.3: Operating Characteristics of Des 1 (Fixed Sample) and Des 3 (Adaptive)

| Value of δ | Des 1(Fixed Sample) | | Des 3- Sim 1 to Sim 5(Adaptive) | |
|-------------------|---------------------|---------------------|---------------------------------|----------------------|
| | Power | Expected SampleSize | Power | Expected Sample Size |
| 1.6 | 61% | 442 | 67% | 509 |
| 1.7 | 66% | 442 | 72% | 508 |
| 1.8 | 71% | 442 | 77% | 506 |
| 1.9 | 76% | 442 | 81% | 502 |
| 2.0 | 80% | 442 | 84% | 499 |

The power of the adaptive Des 3 has increased by about 6% at $\delta = 1.6$ and by about 4% at $\delta = 2$ compared to Des 1. These power gains were obtained at the cost of corresponding average sample size increases of 67 subjects at $\delta = 1.6$ and 57 subjects at $\delta = 2$. Although these power gains appear fairly modest, Des 3 offers a significant benefit in terms of risk reduction, not reflected in Table 54.3. To see this, it is important to note that the sample size under Des 3 is only increased when the interim results are promising; i.e., when the conditional power at the interim analysis is greater than or equal to 30% but less than 80%. This is the very situation in which it is advantageous to increase the sample size and thereby avoid an underpowered trial. When the interim results are unfavorable (conditional power $< 30\%$) or favorable (conditional power $\geq 80\%$), a sample size increase is not warranted and hence it is unchanged at 442 subjects for both Des 1 and Des 3. But when the interim results are promising (conditional power between 30% and 80%) the sample size is increased under Des 3 in an attempt to boost the conditional power back to 80%. It is this feature of the adaptive design that makes it more attractive than the simpler fixed sample design.

In order to compare Des 1(the fixed sample design) with Des 3 (the group sequential design designed with adaptive simulations) conditional on zone, let us edit the simulations inputs associated with Des 3. Select Simulation node in the **Library** and click the  icon and make the changes as below:

Here we are simulating the same design except that we will not make any modification to the sample size at the interim look. Des 3 stipulates, however, that an interim look will be taken after 26 weeks of follow-up data are available on 208 of the planned 442 subjects. At that interim look the sample size may be increased. But in this modified setup, we will not increase the sample size at the interim look.

Note that we have kept the cap on max. sample size after adaptation as 442 under modified setup, compared to 884 under Sim 1. Now we can run the adaptive simulation under this modified setup and make a comparison of the results with the results obtained under Sim 1. Table 54.4 displays the probability of falling into the unfavorable, promising and favorable zones at the interim look, along with the power and expected sample size, conditional on falling into each zone, under various values of δ .

The table highlights the key advantage of the adaptive design (Sim 1 to Sim 5) compared to the traditional group sequential (Sim 6 to Sim 10) i.e., the ability to invest

Table 54.4: Operating Characteristics of Traditional Group Sequential Trial and an Adaptive Group Sequential Trial Conditional on Interim Outcome

| δ | Interim Outcome | Probability of Interim Outcome | Power Conditional on Interim Outcome | | Expected Sample Size | |

| All results are based on 100,000 simulated trials | | | | | | |

in the trial in stages, with the second stage of the investment being required only if promising results are obtained at the first stage. This feature of adaptive design makes it far more attractive as an investment strategy than fixed sample or non-adaptive group sequential design which has no provision for increasing the sample size if a promising interim outcome is obtained. Suppose, for example that $\delta = 1.6$, the smallest clinically meaningful treatment effect. The trial sponsor only commits the resources needed for 442 subjects at the start of the trial, at which point the chance of success is 61%, as shown in Table 54.3. The additional sample size commitment is forthcoming only if promising results are obtained at the interim analysis, and in that case the sponsor's risk is substantially reduced because the chance of success jumps to 83%, as shown in Table 54.4. Similar results are observed for the other values of δ .

The probabilities of entering the unfavorable, promising and favorable zones at the interim analysis, displayed in Table 54.4, are instructive. Consider again the case

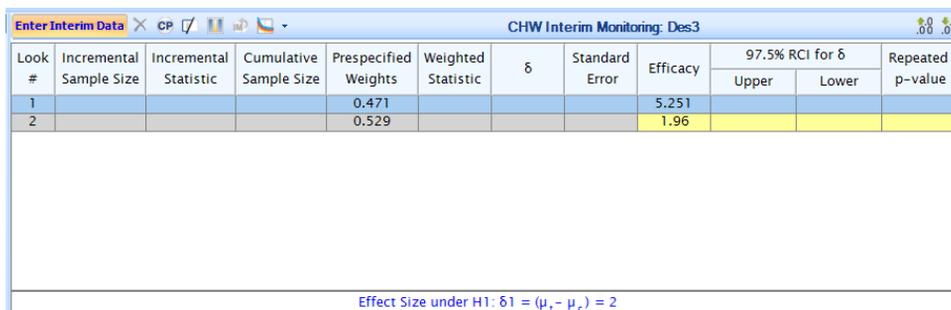

54 The Cui, Hung and Wang Method

$\delta = 1.6$. At this value of δ there is a 26% chance of landing in the promising zone and thereby obtaining a substantial power boost under adaptive setup as compared to non-adaptive. That is, 26% of the time the adaptive strategy can rescue a trial that is underpowered at the interim look. The chance of entering the favorable + efficacy zone is 41%. That is, 41% of the time the sponsor will be lucky and have a well powered trial at the interim look without the need to increase the sample size. The remaining 32% of the time the sponsor will be unlucky and will enter the unfavorable zone from which also there is no sample size increase, and the chance of success is only 28%. These odds improve with larger values of δ . The adaptive implementation satisfies the objective of powering the study primarily for $\delta = 2$ while providing a hedge against substantial power loss if $1.6 \leq \delta < 2$. It is thus a good compromise between Des 1 which is powered to detect $\delta = 2$ without any means of improving power if $\delta = 1.6$, and Des 2 which is powered to detect $\delta = 1.6$ but utilizes excessive sample size resources if $\delta = 2$.

54.3.3 Interim Monitoring

Now we will discuss the interim monitoring procedure taking the example of Des 3. Accordingly we invoke the CHW IM dashboard associated with Des 3 by clicking on the  icon from the toolbar.

The following dashboard appears.

| Look # | Incremental Sample Size | Incremental Statistic | Cumulative Sample Size | Prespecified Weights | Weighted Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeated p-value |
|--------|-------------------------|-----------------------|------------------------|----------------------|--------------------|----------|----------------|----------|------------------------|-------|------------------|
| | | | | | | | | | Upper | Lower | |
| 1 | | | | 0.471 | | | | 5.251 | | | |
| 2 | | | | 0.529 | | | | 1.96 | | | |

Effect Size under H1: $\delta_1 = (\mu_1 - \mu_c) = 2$

This dashboard differs from the usual interim monitoring dashboard for a classical group sequential trial in the following major ways: The Pre-specified Nominal Critical Points (stopping boundaries) are written into the dashboard as soon as it is invoked, and are non-editable. Patient accruals and corresponding test statistics are entered incrementally for each look, rather than cumulatively for all looks taken thus far. The weighted statistic is obtained by combining these incremental test statistics using Pre-specified Weights that are written into the dashboard as soon as it is invoked. One

is free to change the incremental sample size at each look from what was originally specified at the design stage. But if the sample sizes that correspond to the original study design are entered, then the weighted statistic is the same as the usual Wald statistic used for conventional (non-adaptive) interim monitoring

Suppose the first look is taken as planned after enrolling 208 subjects. Suppose we observe $\hat{\delta} = 1.7$ and $\hat{\sigma} = 7.6$ thus leading to a standard error of $\sqrt{(4 * 7.6^2 / 208)} = 1.0539$. The incremental statistic at the first look is thus $(1.7 / 1.0539) = 1.613$. Invoke the Test Statistic Calculator by clicking on the **Enter Interim Data** button. We enter these quantities into the Test Statistic Calculator as shown below.

| Editing Look # 1 For Incremental Sample Size | |
|--|--------|
| Sample Size: | 208 |
| Input for Normal end point | |
| Estimate of δ : $\delta = (\mu_t - \mu_c)$ | 1.7 |
| Standard Error of Estimate of δ : | 1.0539 |
| Output | |
| Weighted Statistic: | 1.613 |
| Incremental Statistic: | 1.613 |

Buttons: Recalc, OK, Cancel

Since the nominal critical value for early stopping is 5.251, the trial continues. We now need to decide on the sample size to use for the second and final look. We invoke the

54 The Cui, Hung and Wang Method

conditional power calculator to assist with this decision.

The screenshot shows a dialog box titled "Conditional Power Calculator" with a close button (X) in the top right corner. The dialog is divided into two main sections: "Input" and "Input/Output".

Input Section:

- Look #:
- Cumulative Sample Size:
- Weighted Test Statistic:

Input/Output Section:

- Value of δ :
- Value of σ :
- Value of δ/σ :
- Computed Conditional Power:
- Sample Size (Overall):

*Use radio button to select the quantity to be computed.

At the bottom of the dialog, there are four buttons: "Recalc", "Plot", "Details...", and "Close".

Suppose we specify to the calculator that we wish to obtain 80% conditional power to detect $\delta=1.6$ with a hypothesized value of 7.5 for sigma. Upon entering these terms

into the calculator we obtain a final (overall) sample size of 564.7 subjects.

Conditional Power Calculator

Input

Look #:

Cumulative Sample Size:

Weighted Test Statistic:

Input/Output

Value of δ :

Value of σ :

Value of δ/σ :

Desired Conditional Power:

Computed Sample Size (Overall):

*Use radio button to select the quantity to be computed.

Based on the guidance provided by the calculator, suppose we decide to enroll a total of 565 subjects. This implies that the incremental number to be entered into the interim monitoring dashboard is $565 - 208 = 357$ subjects.

Suppose that, based only on these 357 incremental subjects, the estimate of delta is 1.5 and the estimate of sigma is 7.7. The standard error of $\hat{\delta}$ is thus

54 The Cui, Hung and Wang Method

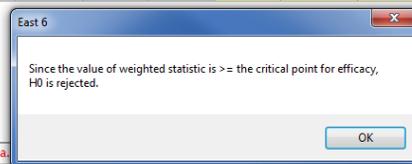

$\sqrt{(4 * 7.7^2 / 357)} = 0.8151$, leading to an incremental test statistic of 1.8404.

| Field | Value |
|--|--------|
| Sample Size: | 357 |
| Estimate of δ : $\delta = (\mu_t - \mu_c)$ | 1.5 |
| Standard Error of Estimate of δ : | 0.8151 |
| Weighted Statistic: | 2.446 |
| Incremental Statistic: | 1.84 |

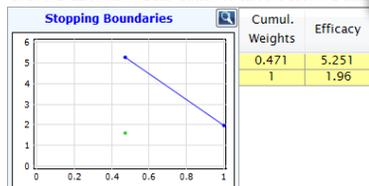

Upon pressing the OK button the incremental test statistic is entered into the interim monitoring dashboard and the weighted statistic that combines the two incremental statistics by the square roots of the pre-specified weights (as described in Section 54.1, equation 54.4) is computed as 2.446. Since the weighted statistic exceeds the nominal critical value, the null hypothesis is rejected. The confidence interval for delta is (0.3146, infty) and the p-value is 0.0072. These estimates are based on the methods described in Section 54.1 and are appropriately adjusted to preserve their validity in

the face of adaptive sample size changes.

| Look # | Incremental Sample Size | Incremental Statistic | Cumulative Sample Size | Prespecified Weights | Weighted Statistic | δ | Standard Error | Efficacy | 97.5% RCI for δ | | Repeat... p-value |
|--------|-------------------------|-----------------------|------------------------|----------------------|--------------------|----------|----------------|----------|------------------------|--------|-------------------|
| | | | | | | | | | Upper | Lower | |
| 1 | 208 | 1.613 | 208 | 0.471 | 1.613 | 1.7 | 1.054 | 5.251 | Infinity | -3.834 | 1 |
| 2 | 357 | 1.84 | 565 | 0.529 | 2.446 | 1.5 | 0.815 | 1.96 | Infinity | 0.315 | 0.007 |

Click the "Edit Interim Data" button to edit the Look # 2 data.

54.4 Binomial Endpoint: Acute Coronary Syndromes

54.4.1 Fixed Sample Design

54.4.2 Group Sequential Design

54.4.3 Adaptive Group Sequential Design

54.4.4 Operating Characteristics

54.4.5 Adding a Futility Boundary

Consider a two-arm, placebo controlled randomized clinical trial for subjects with acute cardiovascular disease undergoing percutaneous coronary intervention (PCI). The primary endpoint is a composite of death, myocardial infarction or ischemia-driven revascularization during the first 48 hours after randomization. We assume on the basis of prior knowledge that the event rate for the placebo arm is 8.7%. The investigational drug is expected to reduce the event rate by at least 20%. The investigators are planning to randomize a total of 8000 subjects in equal proportions to the two arms of the study.

54.4.1 Fixed Sample Design

We show with the help of East that a conventional fixed sample design enrolling a total of 8000 subjects will have 83% power to detect a 20% risk reduction with a one-sided level-0.025 test of significance (with 0.087 on the control arm and

54 The Cui, Hung and Wang Method

$0.8 \times 0.087 = 0696$ on the treatment arm).

| | Des 1 |
|--|-------------------|
| Mnemonic | PN-2S-DI |
| Test Parameters | |
| Design Type | Superiority |
| No. of Looks | 1 |
| Test Type | 1-Sided |
| Variance | Unpooled Estimate |
| Specified α | 0.025 |
| Power | 0.8259 |
| Model Parameters | |
| Proportion under Control (π_c) | 0.087 |
| Proportion under Treatment (π_t) | 0.07 |
| Diff. in Prop. ($\pi_t - \pi_c$) | -0.017 |
| Allocation Ratio (n_t/n_c) | 1 |
| Sample Size | |
| Maximum | 8000 |

The actual risk reduction is expected to be larger, but could also be as low as 15%, a treatment effect that would still be of clinical interest given the severity and importance of the outcomes. In addition, there is some uncertainty about the magnitude of the placebo event rate. For these reasons the investigators wish to build into the trial design some flexibility for adjusting the sample size. Two options under consideration are, a group sequential design with the possibility of early stopping in case the risk reduction is large, and an adaptive design with the possibility of increasing the sample size in case the risk reduction is small. In the remainder of this section we shall discuss these two options and show how they may be combined into a single design that captures the benefits of both.

54.4.2 Group Sequential Design

We first transform the fixed sample design into an 8000 person group sequential design with two interim looks, one after 4000 subjects are enrolled (50% of total information) and the second after 5600 subjects are enrolled (70% of total information). Early stopping efficacy boundaries are derived from the Lan and DeMets (1983) O'Brien-Fleming type error spending function. This group sequential design is shown as Des 2 in the following screen shot. Along with this plan, its operating characteristics

are also shown by the side.

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

| Test Parameters | |
|-----------------------------------|-------------------|
| Design ID | Des5 |
| Design Type | Superiority |
| Number of Looks | 3 |
| Test Type | 1-Sided |
| Specified α | 0.025 |
| Power | 0.82 |
| Model Parameters | |
| Prop. under Control (π_c) | 0.087 |
| Prop. under Treatment (π_t) | 0.07 |
| $\delta = \pi_t - \pi_c$ | |
| Under H0 | 0 |
| Under H1 | -0.017 |
| Allocation Ratio (n_t/n_c) | 1 |
| Variance | Unpooled Estimate |
| Boundary Parameters | |
| Spacing of Looks | Unequal |
| Efficacy Boundary | LD (OF) |

⊖ Sample Size Information

| | Control Arm | Treatment Arm | Total |
|------------------------------------|-------------|---------------|----------|
| Sample Size (n) | | | |
| Maximum | 4000 | 4000 | 8000 |
| Expected H1 | 3267.517 | 3267.517 | 6535.034 |
| Expected H0 | 3989.918 | 3989.918 | 7979.837 |
| Maximum Information (I): 27741.783 | | | |

⊖ Stopping Boundaries: Look by Look

| Look # | Info. Fraction (n/n_max) | Sample Size (n) | Cumulative α Spent | Boundaries | Boundary Crossing Probability (Incremental) | |
|--------|--------------------------|-----------------|---------------------------|------------|---|----------|
| | | | | Efficacy Z | Under H0 | Under H1 |
| | | | | | Efficacy | Efficacy |
| 1 | 0.5 | 4000 | 0.002 | -2.963 | 0.002 | 0.181 |
| 2 | 0.7 | 5600 | 0.007 | -2.462 | 0.006 | 0.31 |
| 3 | 1 | 8000 | 0.025 | -2.002 | 0.018 | 0.33 |

The output tells us that for this design, where the risk reduction is 20%; the probabilities of crossing boundary at Look1 (N=4000) is 0.181, at Look2 (N=5600) 0.31, and at Final Look 0.33; the overall power is 82%.

We can also create different designs by changing the value of risk reduction in Des 2 and obtain their corresponding results. A summary of such results is displayed in Table 54.5. The first column of Table 54.5 is a list of potential risk reductions, defined as $100 \times (1 - \rho)\%$ where $\rho = \pi_t/\pi_c$, π_t is the event rate for the treatment arm, and π_c is the event rate for the control arm. The remaining columns display early stopping probabilities, power and expected sample size. Since the endpoint is observed with 48 hours, the problem of overruns that we encountered in the schizophrenia trial is negligible and may be ignored.

54 The Cui, Hung and Wang Method

Table 54.5: Operating Characteristics of Des 2, a Three-Look 8000-Person Group Sequential Design

| Risk Reduction $100 \times (1 - \rho)$ | Probability of Crossing Efficacy Boundary | | | Overall Power | Expected Sample Size |
|---|---|-----------------------------|---------------------------------|---------------|----------------------|
| | At Look 1 ($N = 4000$) | At Look 2 ($N = 5600$) | At Final Look ($N = 8000$) | | |
| 15% | 0.074 | 0.183 | 0.309 | 57% | 7264 |
| 17% | 0.109 | 0.235 | 0.335 | 68% | 7002 |
| 20% | 0.181 | 0.310 | 0.330 | 82% | 6535 |
| 23% | 0.279 | 0.362 | 0.275 | 92% | 6017 |
| 25% | 0.357 | 0.376 | 0.222 | 95% | 5671 |

Table 54.5 shows that Des 2 is well powered, with large savings of expected sample size for risk reductions of 20% or more. It is thus a satisfactory design if, as is initially believed, the magnitude of the risk reduction is in the range 20% to 25%. This design does not, however, offer as good protection against a false negative conclusion for smaller risk reductions. In particular, even though 15% is still a clinically meaningful risk reduction, Des 2 offers only 57% power to detect this treatment effect. One possibility then is to increase the up-front sample size commitment of the group sequential design so that it has 80% power if the risk reduction is 15%. This leads to Des 3, a three-look group sequential design with a maximum sample size commitment of 13,853 subjects, one interim look after 6927 subjects (50% of total information) and a second interim look after 9697 subjects (70% of total information). Des 3 has 80% power to detect a risk reduction of 15% with a one-sided level-0.025 test.

Design: Discrete Endpoint: Two-Sample Test - Parallel Design - Difference of Proportions

| | | | | | Efficacy | Efficacy |
| 1 | 0.5 | 6927 | 0.002 | -2.962 | 0.002 | 0.167 |
| 2 | 0.7 | 9697 | 0.007 | -2.462 | 0.006 | 0.298 |
| 3 | 1 | 13853 | 0.025 | -2.002 | 0.018 | 0.335 |

Table 54.6 displays operating characteristics of Des 3 for risk reductions between 15%, and 25%, while keeping the maximum sample size as 13,853 . Notice that by attempting to provide adequate power at 15% risk reduction, the low end of clinically meaningful treatment effects, we have significantly over-powered the trial for values of risk reduction in the expected range of risk reductions, 20% to 25% . If, as expected, the risk reduction exceeds 20%, the large up-front sample size commitment of 13,853 subjects under Des 3 is unnecessary. Des 2 with an up-front commitment of only 8000 subjects will provide sufficient power in this setting. From this point of view, Des 3 is

Table 54.6: Operating Characteristics of Des 3, a Three-Look 13,853-Person Grp Sequential Design

| Risk Reduction $100 \times (1 - \rho)$ | Probability of Crossing Efficacy Boundary | | | Overall Power | Expected Sample Size |
|---|---|-----------------------------|------------------------------------|---------------|----------------------|
| | At Look 1 ($N = 6926$) | At Look 2 ($N = 9697$) | At Final Look ($N = 13, 853$) | | |
| 15% | 0.167 | 0.298 | 0.335 | 80% | 11,456 |
| 17% | 0.246 | 0.349 | 0.296 | 89% | 10,699 |
| 20% | 0.395 | 0.375 | 0.196 | 97% | 9558 |
| 23% | 0.565 | 0.329 | 0.099 | 99.3% | 8574 |
| 25% | 0.675 | 0.269 | 0.054 | 99.8% | 8061 |

not a very satisfactory design. It commits the investigators to a very large and expensive trial in order to provide adequate power in the pessimistic range of risk reductions, without any evidence that the true risk reduction does indeed lie in the pessimistic range. Evidently a single group sequential design cannot provide adequate power for the "worst-case" scenario, and at the same time avoid overpowering the more optimistic range of scenarios. This leads us to consider building an adaptive sample size re-estimation option into the group sequential design Des 2, such that the adaptive component will provide the necessary insurance for the worst-case scenario, and thereby free the group sequential component to provide adequate power for the expected scenario, without a large and unnecessary up-front sample size commitment.

54.4.3 Adaptive Group Sequential Design

We convert the three-look group sequential design Des 2 into an adaptive group sequential design by inserting into it the option to increase the sample size at look 2, when 5600 subjects have been enrolled. Recreate the Des 2 by clicking on the  icon and just clicking **Compute** button. This will create Des 4 in the **Output Preview** pane. Save it in the workbook. The sample size re-estimation or adaptation can be done through simulations. The rules governing the sample size increase for Des 4 are

54 The Cui, Hung and Wang Method

similar to the rules specified in Section 53.2.4 for the schizophrenia trial, but tailored to the needs of the current trial. The idea is to identify unfavorable, promising and favorable zones for the interim results at look 2, based on the attained conditional power. Sample size should only be increased if the interim results fall in the promising zone. Subject to an upper limit, the sample size should be increased by just the right amount to boost the current conditional power to some desired level (say 80%). The following are the design specifications for Des 4:

1. The starting design is Des 2 with a sample size of 8000 subjects, one interim look after enrolling 4000 subjects and a second interim look after enrolling 5600 subjects. The efficacy stopping boundaries at these two interim looks are derived from the Lan and DeMets (1983) error spending function of the O'Brien-Fleming type.
2. At the second interim analysis, with data available on 5600 subjects, the conditional power is computed using the estimated value $\hat{\rho}$ as though it were the true relative risk ρ . If the conditional power is no greater than 30%, the outcome is deemed to be unfavorable. If the conditional power is between 30% and 80%, the outcome is deemed to be promising. If the conditional power is at least 80%, the outcome is deemed to be favorable.
3. If the interim outcome is promising, the sample size is re-computed so as to achieve 80% conditional power at the estimated value $\hat{\rho}$. The original sample size is then updated to the re-computed sample size, subject to the constraint in item 4 shown below.
4. If the re-computed sample size is less than 8000, the original sample size of 8000 subjects is used. If the re-computed sample size exceeds 16,000, the sample size is curtailed at 16,000 subjects.

Some features of this adaptive strategy are worth pointing out. First, the sample size is re-computed on the basis of data from 5600 subjects from the trial itself. Therefore the estimate of ρ available at the interim analysis is substantially more reliable than the estimate that was used at the start of the trial to compute an initial sample size of 8000 subjects. The latter estimate is typically derived from smaller pilot studies or from other phase 3 studies in which the patient population might not be exactly the same as that of the current trial. Second, a sample size increase is only requested if the interim results are promising, in which case the trial sponsor should be willing to invest the additional resources needed to power the trial adequately. In contrast Des 3 increases the sample size substantially at the very beginning of the trial, before any data are available to determine if the large sample size is justified.

54.4.4 Operating Characteristics of Adaptive Group Sequential Design

The East software provides a simulation tool for studying the consequences of increasing the sample size of Des 4 at the interim look. To implement this tool we must add the sample size re-estimation tab for Des 4. Select Des 4 in the **Library** and click the **S** icon. Click the **Include Options** button and select Sample Size Re-Estimation from the list. This will add a tab named as **Sample Size Re-estimation** as shown below:

The first two tabs **Simulation Parameters** and **Response Generation Info** contains all the information about the design Des 4 in the absence of any adaptive change. It is a three-look design with a sample size of 8000 and first interim look after 4000 subjects, second interim look after 5600 subjects and the last look after 8000 subjects. The early stopping boundaries generated by the $LD(OF)$ spending function equals -2.963 and -2.462 at the first look and the second look respectively.

The third tab **Sample Size Re-estimation** is used to specify the rules for modifying the initial sample size of Des 4, based on the data at the interim analysis. The description of these parameters is similar to what is described for the normal endpoint example in section 54.3.2. We will run simulations for different risk reduction values (15% to 25%) by changing the proportion response (treatment) values correspondingly from 0.85×0.087 to 0.75×0.087 . Before running the simulations we must input suitable values into the cells of this tab. enter the following values of proportion under treatment as 0.07395, 0.07221, 0.0696, 0.06699, 0.06525. The **Response Generation Info** Tab:

Specify Proportion

Prop. under Control (π_c):

Prop. under Treatment (π_t):

Table 54.7: Operating Characteristics of Des 2 (Group Sequential) and Des 4 (Adaptive Group Sequential) Designs

| All results for Des 4 are based on 100,000 simulated trials | | | | |

design Des 2. As discussed previously in the schizophrenia example, the real benefit of an adaptive design is the opportunity it provides to invest in the trial in stages with the second stage investment forthcoming only if promising results are obtained at the first stage. To explain this better it is necessary to display power and expected sample size results conditional on the zone (unfavorable, promising or favorable) into which the results of the trial fall at the second interim analysis. To this end we run through the entire set of 100,000 simulations for Des 4 twice. In the first run we do not allow the sample size to change even when the conditional power lies in the promising zone. In effect we are simulating Des 2. The choice of simulation parameters for adaptation is as shown below:

Use Adaptation Method
 CHW CDL Müller and Schäfer Weights...

Adapt at: Look # 2

Max. Sample Size if Adapt (multiplier; total #): 1 8000

Target CP for Re-estimating Sample Size: 0.8

Promising Zone Scale: Cond. Power CP

| | | |

Similar simulation operations were carried out for other values of risk reduction under both the designs. Finally all these results representing the operating characteristics of both Des 2 and Des 4 conditional on the zone into which the conditional power falls at the second interim analysis, are displayed in Table 54.8.

(or) The table reveals substantial gains in power for Des 4 compared to Des 2 at all values of risk reduction if the second interim outcome falls in the promising zone, thereby leading to an increase in the sample size. Outside this zone the two designs have the same operating characteristics since the sample size does not change. If the second interim outcome falls in the unfavorable zone, the trial appears to be headed for failure and an additional sample size investment would be risky. If the second interim outcome falls in the favorable zone, the trial is headed for success without the need to increase the sample size. Thus the adaptive design provides the opportunity to increase the sample size only when the results of the second interim analysis fall in the promising zone. This is precisely when the trial can most benefit from a sample size increase.

54 The Cui, Hung and Wang Method

Table 54.8: Operating Characteristics of Des 2 (Group Sequential) and Des 4 (Adaptive Group Sequential) Designs Conditional on Second Interim Outcome

| Risk Reduction $100 \times (1 - \rho)$ | Second Interim Outcome | Probability of Interim Outcome | Power Conditional on Second Interim Outcome | | Expected Sample Size | |
|---|------------------------|--------------------------------|---|-------|----------------------|-------|

All results are based on 100,000 simulated trials

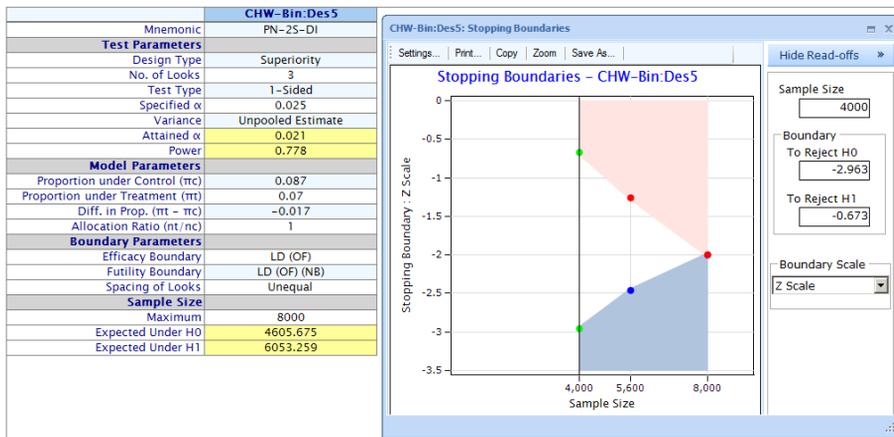

54.4.5 Adding a Futility Boundary

One concern with design Des 4 is that it lacks a futility boundary. There is thus the risk of proceeding to the end, possibly with a sample size increase, when the magnitude of the risk reduction is small and unlikely to result in a successful trial. In particular, suppose that the null hypothesis is true. In that case we can show that the power (i.e., the type-1 error) is 2.5% and the expected sample size under Des 4 is 8293 subjects. It might thus be desirable to include some type of futility stopping rule for the trial. In this trial the investigators proposed the following futility stopping rules at the two interim analysis time points:

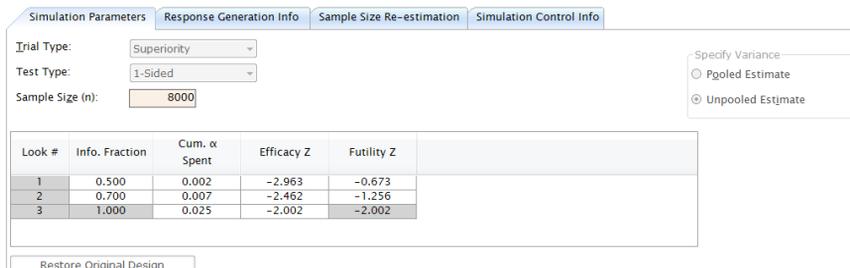

1. Stop for futility at the first interim analysis ($N = 4000$) if the estimated event rate for the experimental arm is at least 1% higher than the estimated event rate for the control arm
2. Stop for futility at the second interim analysis ($N = 5600$) if the conditional

power, based on the estimated risk ratio $\hat{\rho}$, is no greater than 20%

We will implement these futility rules by simulation. To this end create Des 5 with the same **LD (OF)** efficacy boundaries as Des 4, but also include non-binding **LD (OF)** futility boundaries after selecting Des 4 in the **Library** and clicking the  icon.

The futility boundary of Des 5 is not the one we intend to use. This is not a problem, however, since East permits us to edit all the boundaries in any of the simulation tabs. Accordingly we invoke the Simulations for Des 5 and add the **Sample Size Re-estimation** by selecting from the **Include Options** button. The following screen appears.

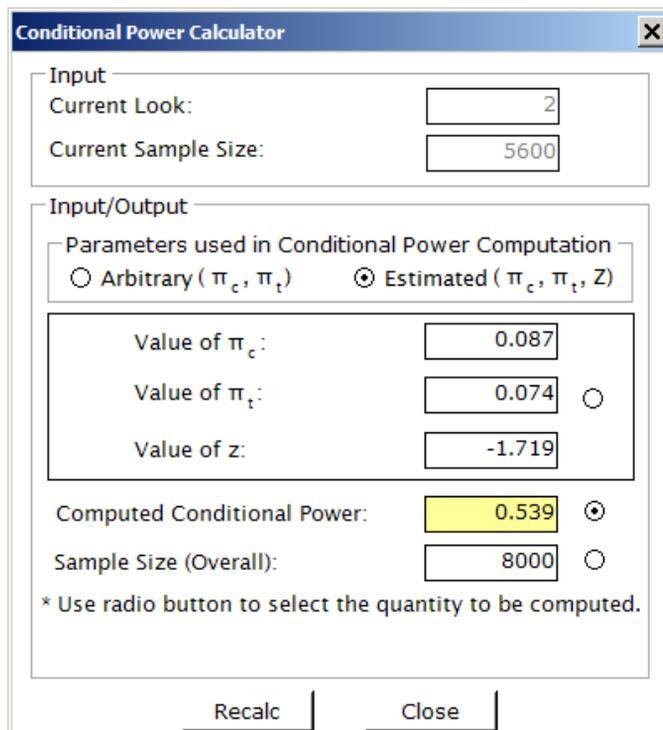

The first step is to edit the futility boundaries. The futility boundary for the first look, using the rule 1 mentioned at the beginning of this section, can be calculated manually as shown below:

54 The Cui, Hung and Wang Method

$$\begin{aligned} N &= 4000 \\ \pi_c &= 0.087 \\ \pi_t = 1.01\pi_c &= 0.08787 \\ \delta = \pi_t - \pi_c &= 0.00087 \\ se = \sqrt{\pi_c(1 - \pi_c)/2000 + \pi_t(1 - \pi_t)/2000} &= 0.008932521 \\ z = \delta/se &= 0.097396916 \end{aligned}$$

We will thus use 0.0974 as the futility boundary for the first interim look. Before we make this change and run CHW Simulations, however, we must determine the futility boundary for the second interim look, under rule 2. This is achieved by using the conditional power calculator available on the **Sample Size Re-estimation** tab. Click

on the  button for invoking CP Calculator. The following calculator appears.

| Field | Value |
|----------------------------|--------|
| Current Look | 2 |
| Current Sample Size | 5600 |
| Value of π_c | 0.087 |
| Value of π_t | 0.074 |
| Value of z | -1.719 |
| Computed Conditional Power | 0.539 |
| Sample Size (Overall) | 8000 |

We make the following changes to this dialog box. At the top of the **Input /Output** section we select the radio button that indicates that conditional power will be based on the values estimated at the interim look and not based on user-defined values. We choose the radio button from the three available at the right hand side of the dialog box that specifies what it is that we wish to compute. In the present case we wish to compute the Z-statistic that corresponds to a conditional power of 0.2, and so we select the top radio button from the three that are available. Finally, we edit box for Conditional Power and enter 0.2, since this is the conditional power for which we wish

54 The Cui, Hung and Wang Method

to determine the corresponding futility boundary.

The image shows a software dialog box titled "Conditional Power Calculator". It is divided into several sections:

- Input:** Contains two text input fields: "Current Look:" with the value "2" and "Current Sample Size:" with the value "5600".
- Input/Output:** Contains a sub-section titled "Parameters used in Conditional Power Computation" with two radio buttons: "Arbitrary (π_c, π_t)" (unselected) and "Estimated (π_c, π_t, Z)" (selected). Below this are three rows of input/output fields:
 - "Value of π_c :" with the value "0.087".
 - "Computed value of π_t :" with the value "Computed" and a radio button.
 - "Computed value of z:" with the value "Computed".
- Below the Input/Output section are two more text input fields: "Conditional Power:" with the value "0.2" and "Sample Size (Overall):" with the value "8000", each followed by an unselected radio button.
- At the bottom, there are two buttons: "Recalc" and "Close".

Below the input fields, there is a red asterisk followed by the text: "* Use radio button to select the quantity to be computed." and "* Please click the Recalc button."

Upon pressing the **Recalc** button, the calculator is updated.

We see that the Z-statistic corresponding to the futility boundary at look 2 is equal to -1.289. We may now edit the futility boundaries at look 1 and look 2 as shown below. Click on **Simulation Parameters** tab and edit the boundaries as given below:

Trial Type: Superiority
 Test Type: 1-Sided
 Sample Size (n): 8000

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z | Futility Z |
|--------|----------------|--------------|------------|------------|
| 1 | 0.500 | | -2.963 | 0.0974 |
| 2 | 0.700 | | -2.462 | -1.2891 |
| 3 | 1.000 | | -2.002 | -2.0018 |

54 The Cui, Hung and Wang Method

We now proceed to simulate this trial as before. The other parameters on **Sample Size Re-estimation** tab are set as below:

| | | | |
|--|---------------------------|--|-------|
| Use Adaptation Method | | Weights... | |
| <input checked="" type="radio"/> CHW | <input type="radio"/> CDL | <input type="radio"/> Müller and Schäfer | |
| Adapt at: | Look # | 2 | |
| Max. Sample Size if Adapt (multiplier; total #): | | 2 | 16000 |
| Target CP for Re-estimating Sample Size: | | 0.8 | |
| Promising Zone Scale: | | Cond. Power | CP |
| Promising Zone: | Min. CP: | 0.3 | |
| | Max. CP: | 0.8 | |
| CP Computation Based on: | | Estimated (n_c, n_t) | |

The impact of the futility boundary on the unconditional operating characteristics of the Des 4 design are displayed in Table 54.9.

Table 54.9: Operating Characteristics of the Des 4 Design with and without a Futility Boundary

| Risk Reduction $100 \times (1 - \rho)$ | Des 4 with No Futility Boundary | | Des 4 with Futility Boundary | |
|---|---------------------------------|----------------------|------------------------------|----------------------|
| | Power | Expected Sample Size | Power | Expected Sample Size |
| 0% | 2.5% | 8259 | 2.81% | 5339 |
| 15% | 63% | 8265 | 59% | 7440 |
| 20% | 86% | 7289 | 83% | 6939 |
| 25% | 97% | 6027 | 95% | 5928 |
| All results are based on 100,000 simulated trials | | | | |

The inclusion of the futility boundary has resulted in a dramatic saving of more than 3000 subjects, on average, at the null hypothesis of no risk reduction. Furthermore, notwithstanding a small power loss of 2-5%, the trial continues to have well over 80% power for risk reductions of 20% or more. The trial suffers a power loss of 7% if the magnitude of the risk reduction is 15%, the low end of the range of clinical interest. In this situation, however, the unconditional power is inadequate (only 63%) even without a futility boundary.

To fully appreciate the impact of the futility boundary on power and expected sample size, it is necessary to study the operating characteristics of the trial conditional on the results of the second interim analysis. These results are displayed in Table 54.10.

54 The Cui, Hung and Wang Method

Table 54.10: Operating Characteristics of Des 4 Design with and without a Futility Boundary, Conditional on the Second Interim Outcome

| Risk Reduction $100 \times (1 - \rho)$ | Second Interim Outcome | Prob. of Interim Outcome | Power Conditional on Second Interim Outcome | | Expected Sample Size | |
|---|------------------------|--------------------------|---|----------|----------------------|----------|
| | | | No Fut | With Fut | No Fut | With Fut |
| 0% | Unfav + Fut | 92% | 0.44% | 0.14% | 8000 | 4851 |
| | Promising | 6% | 15% | 16% | 12985 | 12946 |
| | Fav + Eff | 2% | 64% | 64% | 6918 | 6923 |
| 15% | Unfav + Fut | 36% | 15% | 5 % | 8000 | 5705 |
| | Promising | 24 % | 81% | 81% | 12098 | 12098 |
| | Fav + Eff | 40 % | 94% | 94% | 6147 | 6139 |
| 20% | Unfav + Fut | 16% | 30% | 10.2% | 8000 | 5930 |
| | Promising | 20% | 93% | 93% | 11781 | 11746 |
| | Fav + Eff | 64% | 98% | 98% | 5738 | 5729 |
| 25% | Unfav + Fut | 5% | 47% | 18% | 8000 | 6106 |
| | Promising | 10% | 98% | 97% | 11443 | 11443 |
| | Fav + Eff | 85% | 99.5% | 99.5% | 5251 | 5245 |
| All results are based on 100,000 simulated trials | | | | | | |

It is seen that the presence of the futility boundary does not cause any loss of power for trials that enter the promising or favorable zones at the second interim analysis. Additionally the presence of the futility boundary causes the average sample size to be reduced substantially in the unfavorable zone, moderately in the promising zone while remaining the same in the favorable zone. In effect, the futility boundary terminates a proportion of trials that enter the unfavorable zone thereby preventing them from proceeding to conclusion. It has no impact on trials that enter the favorable zone.

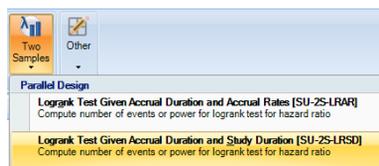

54.5 Survival Endpoint: Lung Cancer Trial

A two-arm multi-center randomized clinical trial is planned for subjects with advanced metastatic non-small cell lung cancer with the goal of comparing the current standard second line therapy (docetaxel+cisplatin) to a new docetaxel containing combination regimen. The primary endpoint is Overall Survival (OS). The study is required to have one-sided $\alpha = 0.025$, and 90% power to detect an improvement in median survival, from 8 months on the control arm to 11.4 months on the experimental arm, which corresponds to a hazard ratio of 0.7. We shall first create a group sequential design for this study in East, and shall then show how the design may be improved by permitting an increase in the number of events and sample size at the time of the interim analysis.

54.5.1 Group Sequential Design

We begin by constructing a two-look group sequential design with an efficacy boundary derived from the Lan and DeMets (1983) O’Brien-Fleming type spending function, a futility boundary derived from the γ -spending function of Hwang, Shih and DeCani (1990) with parameter $\gamma = -5$, and an interim analysis at 50% of the total information. It is required to enroll subjects over 24 months and extend the follow-up for six additional months, thereby completing the study in 30 months.

We begin by using East to design a trial under these basic assumptions. First, click **Survival: Two Samples** on the **Design** tab and then click **Parallel Design: Logrank Test Given Accrual Duration and Study Duration** as shown below.

This will launch a new input window. Enter the appropriate design parameters into the dialog box as shown below. Enter median survival times of 8 months for the Control arm and a hazard ratio of 0.7

Design Type: Superiority Number of Looks: 2

Design Parameters Boundary Info Accrual/Dropout Info

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Median Survival Times

Type I Error (α): 0.025 Hazard Ratio (Optional) Alternative

Power: 0.9 Hazard Ratio (λ_t/λ_c) 0.7

Sample Size (n): Computed Ratio of Medians (m_t/m_c) 1.429

No. of Events: Computed

| Period # | Med. Surv. Time (Control) | Med. Surv. Time (Treatment: Alt.) |
|----------|---------------------------|-----------------------------------|
| 1 | 8.000 | 11.429 |

Allocation Ratio: 1 (n_t/n_c)

Variance of Log Hazard Ratio Null Alternative

Next, click on the **Boundary Info** tab. Be sure to select the nonbinding futility

54 The Cui, Hung and Wang Method

boundary as below:

| | | | | | | | |
|--|----------------|-------------------------------------|-------------------------------------|---|-------------------|--------------------|-------------------|
| Efficacy Boundary Family: Spending Functions Spending Function: Lan-DeMets Parameter: OF Type I Error (α): 0.025 | | | | Futility Boundary Family: Spending Functions Spending Function: Gamma Family Parameter (γ): -5 Type II Error (β): 0.1 | | | |

| Maximum | 24 |
| Expected Under H0 | 20.954 |
| Expected Under H1 | 22.543 |

Des 1 requires an up-front commitment of 334 events to achieve 90% power. With an enrollment of 483 subjects over 24 months, the required 334 events are expected to arrive within 30 months. An interim analysis will be performed after 167 events are obtained (50% of the total information). Under the alternative hypothesis that the hazard ratio is 0.7, the chance of crossing the efficacy boundary at the interim look is about 26% leading to an expected sample size of 454 subjects and an expected study duration of 27 months. Keeping the cursor on Des1 node, if you click on the 

54 The Cui, Hung and Wang Method

icon, you will see the following output.

⊖ Sample Size Information

| | Control Arm | Treatment Arm | Total |
|------------------------------|-------------|---------------|---------|
| Sample Size (n) | | | |
| Maximum | 241 | 242 | 483 |

| Events (s) | | | |
| Maximum | 180 | 154 | 334 |
| Expected H1 | 162.827 | 135.155 | 290.11 |
| Expected H0 | 130.437 | 130.437 | 258.635 |
| Maximum Information (I):83.5 | | | |

⊖ Accrual and Study Duration

| | Accrual Duration | Study Duration |
|-------------|------------------|----------------|
| Maximum | 24 | 29.984 |
| Expected H1 | 22.543 | 26.954 |
| Expected H0 | 20.954 | 22.92 |

54.5.2 Adaptive Design: Motivation

Des1 is adequately powered to detect a hazard ratio of 0.7. It is possible however, either because the new treatment is somewhat less effective than anticipated or because of improved standard of care for patients on the control arm, that the underlying hazard ratio could be larger. If this were the case, the study would be underpowered. For example, if the true hazard ratio was 0.77, an effect that is still considered clinically meaningful, the power of a 483-subject study would drop from 90% to 67.2% as

shown below under Des2.

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Median Survival Times

Type I Error (α): 0.025

Power: Computed

Sample Size (n): 483

No. of Events: Computed

Allocation Ratio: 1 (n_1/n_2)

Hazard Ratio (Optional) Alternative 0.77

Hazard Ratio (λ_1/λ_2)

Ratio of Medians (m_1/m_2) 1.299

| Period # | At | Med. Surv. Time (Control) | Med. Surv. Time (Treatment: Alt.) |
|----------|----|---------------------------|-----------------------------------|
| 1 | | 8.000 | 10.390 |

Variance of Log Hazard Ratio

Null Alternative

| | Wbk1:Des1 | Wbk1:Des2 |
|------------------------|-------------|-------------|
| Mnemonic | SU-2S-LRSD | SU-2S-LRSD |
| Test Parameters | | |
| Design Type | Superiority | Superiority |
| No. of Looks | 2 | 2 |
| Test Type | 1-Sided | 1-Sided |
| Specified α | 0.025 | 0.025 |
| Attained α | 0.025 | 0.025 |
| Power | 0.901 | 0.672 |

Thus one possibility would be to design the trial from the very beginning to have 90% power to detect a hazard ratio of 0.77.

Test Type: 1-Sided # of Hazard Pieces: 1 Input Method: Median Survival Times

Type I Error (α): 0.025

The sponsor is either unable or unwilling to make such a large sample size commitment up-front purely on the basis of the limited prior data available on the new compound. However, since an independent data monitoring committee (DMC) will be reviewing the interim efficacy data in an unblinded fashion at 50% of the total information, the sponsor might be prepared to authorize the investment of additional resources on the recommendation this committee. In a manner analogous to the pre-specification of group sequential boundaries for early stopping, the sponsor must pre-specify to the DMC the precise data dependent rules for increasing the number of events and sample size at the time of the interim analysis. (Note, however, that these rules may be modified at the time of the interim analysis if the DMC believes it is in the best interests of the patients to modify them. The statistical methodology described in this volume permits such modifications without type-1 error inflation.) These rules are best constructed with the help of the simulation tools available in East as we now show.

54.5.3 Adaptive Design: Construction

The starting point for constructing the adaptive design is the group sequential design, Des1. This design is entirely satisfactory if the true hazard ratio is 0.7 but is unsatisfactory if the hazard ratio is 0.77, a hazard ratio that is still clinically meaningful. Designing a group sequential trial to detect a hazard ratio of 0.77, as in Des 3 above, is unfortunately not an option, for it requires too large a commitment of resources up front. It is possible, however, for the sponsor to start out with Des1, requiring only 334 events and 483 subjects, but build in the option for an increase in the number of events and subjects if the results obtained at the interim analysis are promising.

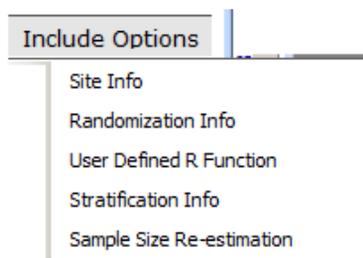

The adaptive design is constructed by means of simulation. Select Des1 in the **Library** and click the  icon. You will be taken to the following simulation input window.

Trial Type: Superiority
 Test Type: 1-Sided
 Maximum Events: 334
 Fix at Each Look: Total No. of Events
 Test Statistic: LogRank

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z | Futility Z |
|--------|----------------|---------------------|------------|------------|
| 1 | 0.500 | 0.002 | -2.963 | 0.126 |
| 2 | 1.000 | 0.025 | -1.969 | -1.969 |

Restore Original Design

In addition to the four tabs appearing by default on inserting Simulations, one can add more tabs to enter information available on randomization, stratification and sample size re-estimation. This can be done by clicking the **Include Options** button on this right hand top corner of the screen.

The **Sample Size Re-estimation** tab is added by clicking the appropriate option as shown above. Let us focus on five such tabs shown below. Several parameters on these

54 The Cui, Hung and Wang Method

tabs can play vital role in simulation and adaptation of a design.

The default values on the **Simulation Parameters** tab are those that were specified at the design stage. However, all the entries in the white cells are editable and can be used to alter the simulation parameters. Thus we could alter the **Info Fraction**, **Cum. α** spent and the **Simulation Boundaries** as well.

| Look # | Info. Fraction | Cum. α Spent | Efficacy Z | Futility Z |
|--------|----------------|---------------------|------------|------------|
| 1 | 0.500 | 0.002 | -2.963 | 0.126 |
| 2 | 1.000 | 0.025 | -1.969 | -1.969 |

or we could alter the **Survival Information** on the **Response Generation Info** tab

Survival Information

Using Hazard Rates
 Using Cum. % Survival

of Hazard Pieces

| Piece | Starting At | Hazard Rates | | Hazard Ratio |
|-------|-------------|--------------|-----------|--------------|
| | | Control | Treatment | |
| 1 | 0.000 | 0.0866 | 0.0607 | 0.700 |

or we could alter the Accrual and Dropout Information on the **Accrual/Dropout Info** tab.

Sample Size:

Subjects are followed:

Accrual Info

Accrual Duration:

of Accrual Periods: Input Method:

| Period # | At | Cum. % Accrued |
|----------|--------|----------------|
| 1 | 24.000 | 100.000 |

Distribution of Accrual Time: Uniform

Piecewise Constant Dropout Rates

of Pieces: Input Method:

| Period # | Starting At | Hazard Rate (Control) | Hazard Rate (Treatment) |
|----------|-------------|-----------------------|-------------------------|
| | | | |

and so on. Suppose, for example that we wish to edit the input parameters in the **Survival Information** panel. The current panel displays hazard rates of 0.0866

and 0.0607 for the Control and Treatment arms, respectively, implying a hazard ratio of 0.7

We know from the design Des 1 that a hazard ratio of 0.7 will yield 90% power. But what if the true hazard ratio was 0.77? The resultant deterioration in power can be evaluated by simulation. Accordingly we shall alter the Treatment cell, containing the hazard 0.0607, by replacing it with $0.77 * 0.0866 = 0.0667$.

Survival Information

of Hazard Pieces: Input Method:

| 95 | | | | | | | |

On running the simulations, an entry for Simulation output gets added in the **Output**

Preview pane and the detailed output can be seen in the Output Summary of Simulations.

The input quantities in the **Sample Size Re-estimation** tab are described below in detail.

1. **Adaptation at:** For a K -look group sequential design, one can decide the time at which conditions for adaptations are to be checked and actual adaptation is to be carried out. This can be done either at some intermediate look or after accumulating data on specified number of events or after some specified information fraction. The value of this parameter depends upon the choice of the user. If it is **Look no.** then this parameter can be any integer number from 1 to $K - 1$. If the adaptation is to be carried out after observing specified events then this parameter can be some integer between [4, No. of events at design stage] and so on. The default choice in East is **look number** to decide the time of adaptation.

Adapt at:

2. **Max Number of Events if Adapt :** This quantity is a multiplier with value ≥ 1 for specifying the upper limit (or cap) on the increase in the number of events, should an adaptive increase be called for based on the target conditional power. Notice that, in keeping with the FDA Guidance on Adaptive Clinical Trials (2010), East does not permit an adaptive decrease in the number of events. Therefore multipliers less than 1 are not accepted in this cell. For example, if you use the multiplier 1.5 and if adaptation takes place, the modified number of events is capped at 501. The 501-event cap becomes effective only if the increased number of events (as calculated by the criteria of cells 4, 5 and 6) exceed 501.

Max. # of Events if Adapt (multiplier; total #):

| | |
|-----|-----|
| 1.5 | 501 |
|-----|-----|

3. **Max Subjects if Adapt :** This quantity is a multiplier with value ≥ 1 for specifying the upper limit (or cap) on the number of subjects to be enrolled in the study. Although the power of the trial is determined by the number of events

54 The Cui, Hung and Wang Method

and not the number of subjects, the number of subjects play a role in determining how long it will take to observe the required number of events, and hence for determining the study duration. The number of subjects may only be increased, never decreased. Therefore multipliers less than 1 are not accepted in this cell. For example, if you use the multiplier 1.5 and if adaptation takes place, the modified number of subjects is capped at 724 subjects. The trial will continue to enroll subjects until either the required number of events is reached or the cap on the number of subjects is reached.

Max. Sample Size if Adapt (multiplier; total #):

- Upper Limit on Study Duration :** An event driven trial ordinarily continues until the required number of events arrive. This input parameter is provided merely as a safety factor in order to prevent the trial from being prolonged excessively should the required number of events be very large or their rate of arrival be very slow. Its default value is set at three times the expected study duration obtained from the initial design of the trial. Consequently, if the scenarios being simulated are realistic, the required number of events will almost always be attained much before this upper limit parameter becomes operational. It is recommended to leave this parameter unchanged at least for the initial set of simulation experiments since it would interfere with the operating characteristics of the study if it were to become operational.

Upper Limit on Study Duration:

- Target Conditional Power for Re-estimating Events :** This parameter ranges between 0 and 1 and is the *target conditional power* desired at the end of the study. Suppose, for example that the Target CP is set at 0.9.

Target CP for Re-estimating # of Events:

Let the value of the test statistic obtained in the current simulation be z_L at

look L , where an adaptive increase in the number of events is being considered.

Then, by setting the left hand side of equation (54.21) to 0.9 we have:

$$0.9 = 1 - \Phi \left\{ b_K \sqrt{1 + \frac{D_L}{D_K - D_L}} - z_L \sqrt{\frac{D_L}{D_K - D_L}} - \delta \sqrt{r(1-r)} \sqrt{D_K^* - D_L} \right\}. \quad (54.23)$$

Upon solving equation (56.11) for D_K^* we obtain the increased number of events that are needed to achieve the target conditional power of 0.9 in this simulation. Let us illustrate with Des 1. In Des 1 $K = 2, L = 1, r = 0.5$ and the critical value for declaring statistical significance at the end of the trial is $b_2 = -1.9687$, as can be seen by examining the stopping boundaries displayed in the **Simulation Parameters** tab. The interim analysis is performed when $D_1 = 167$ events are obtained. In the absence of any adaptive change, the trial will terminate when $D_2 = 334$ events are obtained. Suppose the current simulation generates a value $z_1 = 1.5$ for the logrank statistic at look 1. Since the target conditional power is 0.9, equation (56.11) takes the form

$$0.9 = 1 - \Phi \left\{ -1.9687 \sqrt{1 + \frac{167}{334 - 167}} - 1.5 \sqrt{\frac{167}{334 - 167}} - 0.5\delta \sqrt{D_2^* - 167} \right\}. \quad (54.24)$$

In order to evaluate D_2^* , however, it is necessary to specify a value for the log hazard ratio δ in equation (56.12). This parameter is of course unknown. East gives you the option to perform simulations with either the current estimate $\hat{\delta}_1$ or to use the value of δ specified under the alternative hypothesis at the design stage. The choice can be made by selecting **Estimated HR** or **Design HR** from a drop-down list of the quantity **CP Computation Based on** of the **Sample Size Re-estimation** tab.

The default value is **Estimated HR**, (or equivalently $\hat{\delta}_1 = \ln \hat{HR}_1$) and we recommend using this default until you have gained some experience with the simulation output and can judge for yourselves which option provides better operating characteristics for your studies. East uses the formula

$$\hat{\delta}_1 = \frac{z_1}{\sqrt{r(1-r)}D_1}$$

to obtain the current estimate of δ . Upon substituting $z_1 = 1.5, D_1 = 167$ and $r = 0.5$ in the above expression we obtain $\hat{\delta}_1 = 0.232$, or equivalently a hazard ratio estimate of $\exp(0.232) = 1.2611$. Substituting the estimate of $\hat{\delta}_1$ into equation (56.12) and solving for D_2^* yields $D_2^* = 656$. Since the maximum number of events has been capped at 501, this simulation will terminate the trial when the number of events reaches 501 instead of going all the way to 656 events. In this case the desired target conditional power of 0.9 will not be met.

54 The Cui, Hung and Wang Method

Indeed in this case the conditional power (with $\hat{\delta}_1$ being used in place of the unknown true δ) is only

$$1 - \Phi \left\{ 1.9687 \sqrt{1 + \frac{167}{333 - 167}} - 1.5 \sqrt{\frac{333}{333 - 167}} - 0.5\delta \sqrt{500 - 167} \right\} = 0.798$$

For a more detailed discussion of conditional power, including the use of a special conditional power calculator that computes conditional power accurately without relying on the approximate assumption that the next look will be the last one, see Chapter 57.

6. **Promising Zone Scale :** Promising Zone is such that the number of events will only be increased if the conditional power at the interim look falls in this zone. East asks you to select the scale on which the promising zone is to be defined. It can be defined based on the conditional power or the test statistic or the estimated effect size and should be specified by entering the minimum and maximum of these quantities.
Let us go ahead with the default option which is Conditional Power.
7. **Promising Zone – Min CP :** In this cell you specify the minimum conditional power (in the absence of any adaptive change) at which you will entertain an increase in the number of events. That is, you specify the lower limit of the promising zone.
8. **Promising Zone – Max CP :** In this cell you specify the maximum conditional power (in the absence of any adaptive change) at which you will entertain an increase in the number of events. That is, you specify the upper limit of the promising zone.
Suppose, for example, that the number of events is only increased in a promising zone specified by the range $0.45 \leq CP < 0.8$, and suppose that in that case, the number of events is re-estimated so as to achieve a target conditional power of 0.99. Then the Input Parameters Table will contain the entries shown below.

| | |
|--|---------------|
| <u>T</u> arget CP for Re-estimating # of Events: | 0.99 |
| <u>P</u> romising Zone Scale: | Cond. Power ▼ |
| Promising Zone: Min. CP: | 0.45 |
| Max. CP: | 0.8 |

The zone to the left of the *promising zone* ($CP < 0.45$) is known as the

unfavorable zone. The zone to the right of the *promising zone* ($CP \geq 0.8$) is known as the *favorable zone*. In a group sequential design that includes early stopping boundaries for futility and efficacy, the unfavorable zone contains within it an even more extreme region for early futility stopping and the favorable zone contains within it an even more extreme region for early efficacy stopping.

9. **HR Used in CP Computations:** In this cell you specify whether the simulations should utilize conditional power based on $\hat{\delta}_L$ estimated at the time of the interim analysis or should utilize the value of δ specified under the alternative hypothesis, in equations (54.21) and (56.11). The adaptive design will have rather different operating characteristics in each case. The default is to use the estimated value $\hat{\delta}_L$.

CP Computation Based on:

Estimated HR ▼

10. **Accrual Rate After Adaptation :** East gives you the option to alter the rate of enrollment after an adaptive increase in the number of events. This feature would be useful, for example, to evaluate the extent to which the follow-up time and hence the total study duration can be shortened if the rate of enrollment is increased after the adaptive change is implemented.

Accrual Rate After Adaptation:

No Change ▼

54 The Cui, Hung and Wang Method

Required Events Chart

The upper chart at the extreme right of the **Sample Size Re-estimation** tab is called the Required Events Chart. The X-axis of this chart, labeled **CP(Dsgn.Events, Est.HR)**, tracks the conditional power obtained at the interim look based on the total number of events D_K specified at the design stage (334 events under Des 1) and the interim estimate $\hat{\delta}_L$ of the log hazard ratio. To be specific,

$$= 1 - \Phi \left\{ b_K \sqrt{1 + \frac{D_L}{D_K - D_L}} - z_L \sqrt{\frac{D_L}{D_K - D_L}} - \hat{\delta}_L \sqrt{r(1-r)} \sqrt{D_K - D_L} \right\} \quad \text{CP(Dsgn.Events, Est.HR)} \quad (54.25)$$

Since $\hat{\delta}_L$ and z_L are related through the relationship

$$\hat{\delta}_L = \frac{z_L}{\sqrt{r(1-r)} D_L},$$

equation (54.25) shows that there is a one-to-one correspondence between **CP(Dsgn.Events, Est.HR)**, $\hat{\delta}_L$ and z_L . It is thus reasonable to use any one of these three variables on the X-axis of the Required Events Chart. We have chosen **CP(Dsgn.Events, Est.HR)** because it has a natural interpretation that is easily understood by non-statisticians. The Y-axis, labeled **Required Events** displays the number of events that are required to complete the trial. This number is computed as the minimum of the re-estimated number of events and the cap on the maximum number of events. To be specific, let D_{\max} be the maximum number of events permitted if an adaptation occurs. (This is the entry to the right of the multiplier in cell 1 of the Input Parameters Table.)

Max. # of Events if Adapt (multiplier; total #): Let D_K^* be the solution to the equation

$$\text{Target CP} = 1 - \Phi \left\{ b_K \sqrt{1 + \frac{D_L}{D_K - D_L}} - z_L \sqrt{\frac{D_L}{D_K - D_L}} - \hat{\delta}_L \sqrt{r(1-r)} \sqrt{D_K^* - D_L} \right\}, \quad (54.26)$$

where **Target CP** is the entry in cell 4.

Target CP for Re-estimating # of Events:

Then

$$\text{RequiredEvents} = \min(D_{\max}, D_K^*)$$

We will illustrate with a couple of examples.

Example 1: Suppose the input parameters are as displayed below:

| | | | |
|--|-------------------------------------|---|---------------------------------|
| Adapt at: | <input type="text" value="Look #"/> | <input type="text" value="1"/> | |
| Max. # of Events if Adapt (multiplier; total #): | <input type="text" value="1.5"/> | <input type="text" value="501"/> | |
| Max. Sample Size if Adapt (multiplier; total #): | <input type="text" value="1.5"/> | <input type="text" value="724"/> | |
| Upper Limit on Study Duration: | <input type="text" value="90"/> | | |
| Target CP for Re-estimating # of Events: | <input type="text" value="0.8"/> | | |
| Promising Zone Scale: | | <input type="text" value="Cond. Power"/> | <input type="text" value="CP"/> |
| Promising Zone: | Min. CP: | <input type="text" value="0.45"/> | |
| | Max. CP: | <input type="text" value="0.8"/> | |
| CP Computation Based on: | | <input type="text" value="Estimated HR"/> | |
| Accrual Rate After Adaptation: | | <input type="text" value="No Change"/> | |

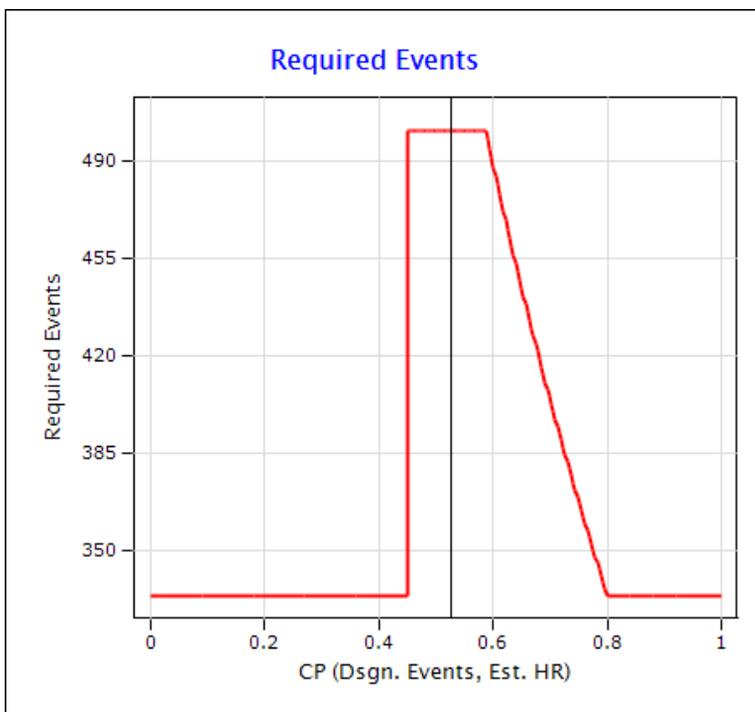

With these inputs the **Required Events** will be re-computed for values of **CP(Dsgn.Events, Est.HR)** that fall in the promising zone, specified by $0.45 \leq \text{CP}(\text{Dsgn.Events}, \text{Est.HR}) < 0.8$. For all values of **CP(Dsgn.Events, Est.HR)** outside this zone, the **Required Events** will remain the unchanged at 334, the number specified at the design stage. Inside the promising zone, however, East will re-estimate D_2^* , the number events that are needed to achieve the target conditional power of 0.8 displayed in cell 4, using equation (54.26). It can be shown that for values of **CP(Dsgn.Events, Est.HR)** on the X-axis between 0.45 and 0.58, the value of D_2^* needed to boost the conditional power to the 0.8 target exceeds 501. Since the cap on the number of events is set at $D_{\max} = 501$, East will set

$$\text{Required Events} = \min(501, D_2^*) = 501$$

in the chart for all $0.45 \leq \text{CP}(\text{Dsgn.Events}, \text{Est.HR}) \leq 0.58$. However, at values of **CP(Dsgn.Events, est.HR)** on the X-axis that exceed 0.59, the re-estimated number

54 The Cui, Hung and Wang Method

of events D_2^* is less than 500, and hence the **Required Events** gradually drops down until it reaches 334 at $CP(Dsgn.Events, Est.HR) = 0.8$. Thereafter the **Required Events** remains constant at 334. Thus the shape of the Required Events Chart is as shown below.

The shape of the Required Events Chart depends on the value of the target conditional power that is one of the inputs. To see this, consider the next example.

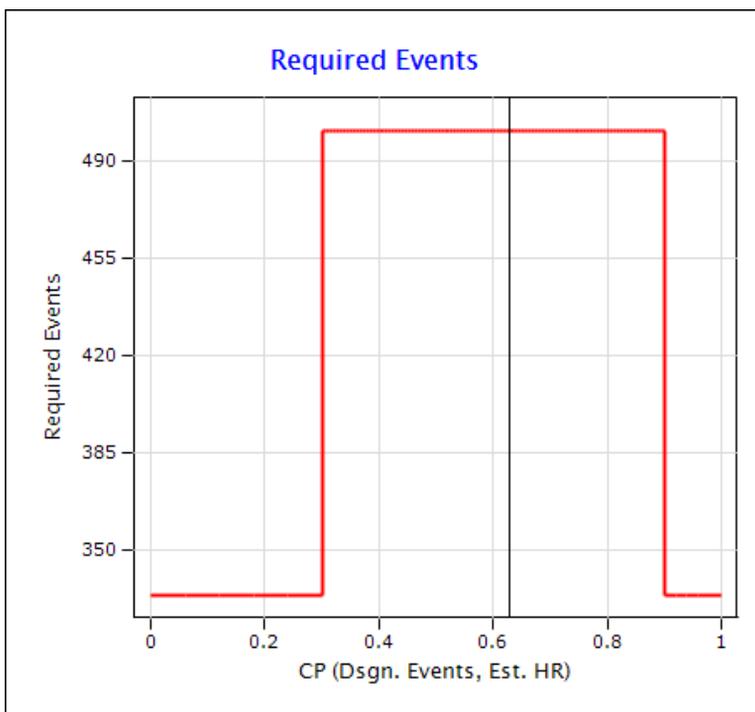

Example 2 : Suppose the input parameters are as displayed below:

| | | | |
|--|-------------------------------------|---|-----------------------------------|
| Adapt at: | <input type="text" value="Look #"/> | <input type="text" value="1"/> | |
| Max. # of Events if Adapt (multiplier; total #): | <input type="text" value="1.5"/> | <input type="text" value="501"/> | |
| Max. Sample Size if Adapt (multiplier; total #): | <input type="text" value="1.5"/> | <input type="text" value="724"/> | |
| Upper Limit on Study Duration: | <input type="text" value="90"/> | | |
| Target CP for Re-estimating # of Events: | <input type="text" value="0.99"/> | | |
| Promising Zone Scale: | | <input type="text" value="Cond. Power"/> | <input type="button" value="CP"/> |
| Promising Zone: | Min. CP: | <input type="text" value="0.3"/> | |
| | Max. CP: | <input type="text" value="0.9"/> | |
| CP Computation Based on: | | <input type="text" value="Estimated HR"/> | |
| Accrual Rate After Adaptation: | | <input type="text" value="No Change"/> | |

This time the promising zone ranges from 0.3 to 0.9. The target conditional power (Shape Parameter) is 0.99. It can be shown that more than 501 events (the cap in cell 1) will be needed to reach this target, for all values of **CP(Dsgn.Events, Est.HR)** in the promising zone. Therefore the Required Events Chart will be a step function taking on values 334 outside the promising zone and taking on values 501 inside the promising

54 The Cui, Hung and Wang Method

zone.

Thus by entering different target conditional power values as input in cell 4 and pressing **Refresh Charts** button, you can experiment with different shapes on the Required Events Chart. The step function shape is favored in many trials both for its simplicity and because it prevents "reverse engineering" the precise value of **CP(Dsgn.Events, est.HR)** by anyone who, for regulatory reasons, has to remain blind to the interim results. For example, suppose it is known that the number of events has increased from 334 to 501. Even then all one can conclude is that **CP(Dsgn.Events, est.HR)** falls between 0.3 and 0.9.

The Conditional Power Chart

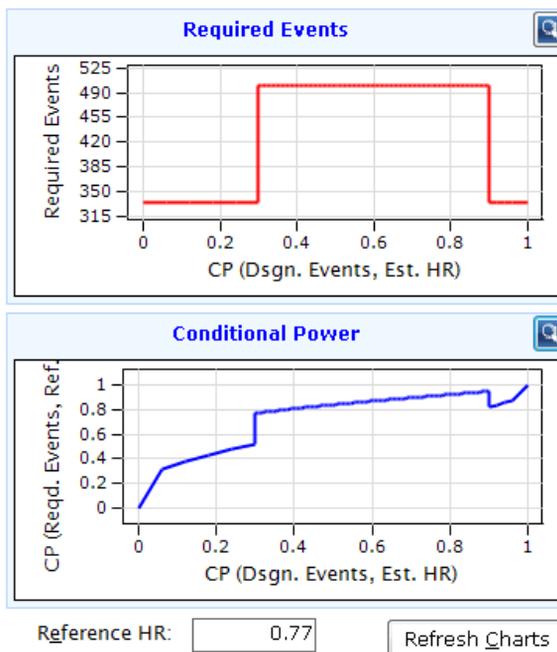

The lower chart on the right side panel of the **Sample Size Re-estimation** tab is called the Conditional Power Chart. As the name suggests, this chart plots the actual conditional power of the study given the observed data at the interim analysis. As was the case for the Required Events Chart, the data at interim analysis results are summarized in terms of **CP(Desgn.Events, Est.HR)** and displayed on the X-axis. The Y-axis, titled **CP(Req.Events, Ref.HR)** then plots the actual conditional power for the reference hazard ratio contained in the edit box below this chart, where **Req.Events** refers to the **Required Events** displayed in the chart above the conditional power chart. Consider again the inputs that were entered into the input parameter table in Example 2.

| | | | |
|--|-------------------------------------|---|-----------------------------------|
| Adapt at: | <input type="text" value="Look #"/> | <input type="text" value="1"/> | |
| Max. # of Events if Adapt (multiplier; total #): | <input type="text" value="1.5"/> | <input type="text" value="501"/> | |
| Max. Sample Size if Adapt (multiplier; total #): | <input type="text" value="1.5"/> | <input type="text" value="724"/> | |
| Upper Limit on Study Duration: | <input type="text" value="90"/> | | |
| Target CP for Re-estimating # of Events: | <input type="text" value="0.99"/> | | |
| Promising Zone Scale: | | <input type="text" value="Cond. Power"/> | <input type="button" value="CP"/> |
| Promising Zone: | Min. CP: | <input type="text" value="0.3"/> | |
| | Max. CP: | <input type="text" value="0.9"/> | |
| CP Computation Based on: | | <input type="text" value="Estimated HR"/> | |
| Accrual Rate After Adaptation: | | <input type="text" value="No Change"/> | |

For these inputs the conditional power chart looks as shown below if the Reference HR

54 The Cui, Hung and Wang Method

is equal to 0.77.
