

TMS320F2837xD Dual-Core Delfino Microcontrollers

Technical Reference Manual

Literature Number: SPRUHM8G
December 2013–Revised September 2017

Preface	81
1 C28x Processor	82
1.1 Overview	83
1.1.1 Floating-Point Unit	83
1.1.2 Trigonometric Math Unit	83
1.1.3 Viterbi, Complex Math, and CRC Unit II (VCU-II)	84
2 System Control	85
2.1 Introduction	86
2.2 System Control Functional Description	86
2.2.1 Device Identification	86
2.2.2 Device Configuration Registers	87
2.3 Resets	87
2.3.1 Reset Sources	87
2.3.2 External Reset (XRS)	88
2.3.3 Power-On Reset (POR)	88
2.3.4 Debugger Reset (SYSRS)	88
2.3.5 Watchdog Reset (WDRS)	89
2.3.6 NMI Watchdog Reset (NMIWDRS)	89
2.3.7 DCSM Safe Code Copy Reset (SCCRESET)	89
2.3.8 Hibernate Reset (HIBRESET)	89
2.3.9 Hardware BIST Reset (HWBISTR)	89
2.3.10 Test Reset (TRST)	89
2.4 Peripheral Interrupts	89
2.4.1 Interrupt Concepts	90
2.4.2 Interrupt Architecture	90
2.4.3 Interrupt Entry Sequence	91
2.4.4 Configuring and Using Interrupts	92
2.4.5 PIE Channel Mapping	95
2.4.6 Vector Tables	96
2.5 Exceptions and Non-Maskable Interrupts	102
2.5.1 Configuring and Using NMIs	102
2.5.2 Emulation Considerations	102
2.5.3 NMI Sources	103
2.5.4 Illegal Instruction Trap (ITRAP)	103
2.6 Safety Features	103
2.6.1 Write Protection on Registers	103
2.6.2 Missing Clock Detection Logic	104
2.6.3 PLLSLIP Detection	105
2.6.4 CPU1 and CPU2 PIE Vector Address Validity Check	105
2.6.5 NMIWDs	106
2.6.6 ECC and Parity Enabled RAMs, Shared RAMs Protection	106
2.6.7 ECC Enabled Flash Memory	106
2.6.8 ERRORSTS Pin	106
2.7 Clocking	107
2.7.1 Clock Sources	109

2.7.2	Derived Clocks	111
2.7.3	Device Clock Domains	111
2.7.4	XCLKOUT.....	112
2.7.5	Clock Connectivity	113
2.7.6	Clock Source and PLL Setup	114
2.8	32-Bit CPU Timers 0/1/2	117
2.9	Watchdog Timers	119
2.9.1	Servicing the Watchdog Timer	119
2.9.2	Minimum Window Check	120
2.9.3	Watchdog Reset or Watchdog Interrupt Mode.....	120
2.9.4	Watchdog Operation in Low Power Modes	121
2.9.5	Emulation Considerations	121
2.10	Low Power Modes	122
2.10.1	IDLE	122
2.10.2	STANDBY	122
2.10.3	HALT	123
2.10.4	HIB.....	123
2.11	Memory Controller Module	125
2.11.1	Functional Description	125
2.12	Flash and OTP Memory	133
2.12.1	Features.....	133
2.12.2	Flash Tools	133
2.12.3	Default Flash Configuration	134
2.12.4	Flash Bank, OTP and Pump	134
2.12.5	Flash Module Controller (FMC)	134
2.12.6	Flash and OTP Power-Down Modes and Wakeup.....	135
2.12.7	Flash and OTP Performance.....	137
2.12.8	Flash Read Interface	137
2.12.9	Erase/Program Flash.....	139
2.12.10	Error Correction Code (ECC) Protection	140
2.12.11	Reserved Locations Within Flash and OTP	144
2.12.12	Procedure to Change the Flash Control Registers	144
2.12.13	Flash Pump Ownership Semaphore.....	144
2.13	Dual Code Security Module (DCSM).....	146
2.13.1	Functional Description	146
2.13.2	CSM Impact on Other On-Chip Resources	152
2.13.3	Incorporating Code Security in User Applications	153
2.14	JTAG	157
2.15	Registers.....	159
2.15.1	Base Addresses	159
2.15.2	CPUTIMER_REGS Registers.....	160
2.15.3	PIE_CTRL_REGS Registers	167
2.15.4	WD_REGS Registers	219
2.15.5	NMI_INTRUPT_REGS Registers.....	225
2.15.6	XINT_REGS Registers.....	238
2.15.7	DMA_CLA_SRC_SEL_REGS Registers	247
2.15.8	FLASH_PUMP_SEMAPHORE_REGS Registers	254
2.15.9	DEV_CFG_REGS Registers	256
2.15.10	CLK_CFG_REGS Registers.....	323
2.15.11	CPU_SYS_REGS Registers.....	346
2.15.12	ROM_PREFETCH_REGS Registers	386
2.15.13	DCSM_Z1_OTP Registers.....	388
2.15.14	DCSM_Z2_OTP Registers.....	395

2.15.15	DCSM_Z1_REGS Registers	402
2.15.16	DCSM_Z2_REGS Registers	422
2.15.17	DCSM_COMMON_REGS Registers	442
2.15.18	MEM_CFG_REGS Registers	449
2.15.19	ACCESS_PROTECTION_REGS Registers	497
2.15.20	MEMORY_ERROR_REGS Registers	520
2.15.21	ROM_WAIT_STATE_REGS Registers	537
2.15.22	FLASH_CTRL_REGS Registers	539
2.15.23	FLASH_ECC_REGS Registers	548
2.15.24	CPU_ID_REGS Registers	571
2.15.25	UID_REGS Registers	573
3	ROM Code and Peripheral Booting	582
3.1	Introduction	583
3.2	Device Boot Philosophy	583
3.3	Device Boot Modes	583
3.4	Configuring Boot Mode Pins	584
3.5	Configuring Get Boot Options	585
3.6	Configuring Emulation Boot Options	586
3.7	Device Boot Flow Diagrams	588
3.7.1	Emulation Boot Flow Diagrams	589
3.7.2	Standalone and Hibernate Boot Flow Diagrams	591
3.8	Device Reset and Exception Handling	593
3.8.1	Reset Causes and Handling	593
3.8.2	Exceptions and Interrupts Handling	594
3.9	Boot ROM Description	594
3.9.1	Entry Points	594
3.9.2	Wait Points	595
3.9.3	Memory Maps	595
3.9.4	Boot Modes	598
3.9.5	Boot Data Stream Structure	611
3.9.6	GPIO Assignments	613
3.9.7	Boot IPC	615
3.9.8	Clock Initializations	618
3.9.9	Wait State Configuration	619
3.9.10	Boot Status information	619
3.9.11	ROM Version	621
4	Direct Memory Access (DMA)	623
4.1	Introduction	624
4.2	Architecture	625
4.2.1	Block Diagram	625
4.2.2	Common Peripheral Architecture	625
4.2.3	Peripheral Interrupt Event Trigger Sources	627
4.2.4	DMA Bus	632
4.3	Pipeline Timing and Throughput	632
4.4	CPU Arbitration	633
4.5	Channel Priority	634
4.5.1	Round-Robin Mode	634
4.5.2	Channel 1 High Priority Mode	635
4.6	Address Pointer and Transfer Control	636
4.7	Overrun Detection Feature	640
4.8	Register Descriptions	642
4.8.1	DMA Control Register (DMACTRL) — EALLOW Protected	643
4.8.2	Debug Control Register (DEBUGCTRL) — EALLOW Protected	644

4.8.3	Revision Register (REVISION).....	644
4.8.4	Priority Control Register 1 (PRIORITYCTRL1) — EALLOW Protected	645
4.8.5	Priority Status Register (PRIORITYSTAT)	646
4.8.6	Mode Register (MODE) — EALLOW Protected	647
4.8.7	Control Register (CONTROL) — EALLOW Protected	649
4.8.8	Burst Size Register (BURST_SIZE) — EALLOW Protected	651
4.8.9	BURST_COUNT Register	651
4.8.10	Source Burst Step Register Size (SRC_BURST_STEP) — EALLOW Protected	652
4.8.11	Destination Burst Step Register Size (DST_BURST_STEP) — EALLOW Protected	653
4.8.12	Transfer Size Register (TRANSFER_SIZE) — EALLOW Protected	653
4.8.13	Transfer Count Register (TRANSFER_COUNT)	654
4.8.14	Source Transfer Step Size Register (SRC_TRANSFER_STEP) — EALLOW Protected	654
4.8.15	Destination Transfer Step Size Register (DST_TRANSFER_STEP) — EALLOW Protected	655
4.8.16	Source/Destination Wrap Size Register (SRC/DST_WRAP_SIZE) — EALLOW protected)	655
4.8.17	Source/Destination Wrap Count Register (SCR/DST_WRAP_COUNT)	656
4.8.18	Source/Destination Wrap Step Size Registers (SRC/DST_WRAP_STEP) — EALLOW Protected .	656
4.8.19	Shadow Source Begin and Current Address Pointer Registers (SRC_BEG_ADDR_SHADOW/DST_BEG_ADDR_SHADOW) — All EALLOW Protected	657
4.8.20	Active Source Begin and Current Address Pointer Registers (SRC_BEG_ADDR/DST_BEG_ADDR)	657
4.8.21	Shadow Destination Begin and Current Address Pointer Registers (SRC_ADDR_SHADOW/DST_ADDR_SHADOW) — All EALLOW Protected	658
4.8.22	Active Destination Begin and Current Address Pointer Registers (SRC_ADDR/DST_ADDR).....	658
5	Control Law Accelerator (CLA)	659
5.1	Control Law Accelerator (CLA) Overview	660
5.2	CLA Interface	662
5.2.1	CLA Memory	662
5.2.2	CLA Memory Bus	663
5.2.3	Shared Peripherals and EALLOW Protection	663
5.2.4	CLA Tasks and Interrupt Vectors	664
5.2.5	CLA Software Interrupt to CPU	666
5.3	CLA and CPU Arbitration	666
5.3.1	CLA and CPU Arbitration	666
5.3.2	CLA Message RAM	666
5.4	CLA Configuration and Debug	668
5.4.1	Building a CLA Application	668
5.4.2	Typical CLA Initialization Sequence	668
5.4.3	Debugging CLA Code	670
5.4.4	CLA Illegal Opcode Behavior	671
5.4.5	Resetting the CLA	671
5.5	Pipeline.....	672
5.5.1	Pipeline Overview.....	672
5.5.2	CLA Pipeline Alignment.....	672
5.5.3	Parallel Instructions.....	675
5.6	Instruction Set	677
5.6.1	Instruction Descriptions	677
5.6.2	Addressing Modes and Encoding.....	679
5.6.3	Instructions	681
5.7	Registers.....	792
5.7.1	CLA Base Addresses.....	792
5.7.2	CLA_REGS Registers.....	793
5.7.3	CLA_SOFTINT_REGS Registers.....	828
6	Inter-Processor Communication (IPC)	833

6.1	Inter-Processor Communication	834
6.2	Message RAMs	835
6.3	IPC Flags and Interrupts	835
6.4	IPC Command Registers	835
6.5	Free-Running Counter	836
6.6	IPC Communication Protocol.....	837
6.7	Registers.....	838
6.7.1	IPC Base Addresses	838
6.7.2	IPC_REGS_CPU1 Registers.....	839
6.7.3	IPC_REGS_CPU2 Registers.....	872
7	General-Purpose Input/Output (GPIO)	905
7.1	GPIO Overview	906
7.2	Configuration Overview	907
7.3	Digital General-Purpose I/O Control.....	907
7.4	Input Qualification.....	909
7.4.1	No Synchronization (Asynchronous Input)	909
7.4.2	Synchronization to SYSCLKOUT Only.....	909
7.4.3	Qualification Using a Sampling Window	909
7.5	USB Signals	912
7.6	SPI Signals	912
7.7	GPIO and Peripheral Muxing.....	914
7.8	Internal Pullup Configuration Requirements.....	919
7.9	Registers	921
7.9.1	GPIO Base Addresses	921
7.9.2	GPIO_CTRL_REGS Registers.....	922
7.9.3	GPIO_DATA_REGS Registers	1087
8	Crossbar (X-BAR).....	1137
8.1	GPIO Input X-BAR	1138
8.2	ePWM and GPIO Output X-BAR	1139
8.2.1	ePWM X-BAR.....	1139
8.2.2	GPIO Output X-BAR	1142
8.2.3	X-BAR Flags	1143
8.3	X-BAR Registers	1145
8.3.1	X-BAR Base Addresses	1145
8.3.2	INPUT_XBAR_REGS Registers	1146
8.3.3	XBAR_REGS Registers	1165
8.3.4	EPWM_XBAR_REGS Registers	1178
8.3.5	OUTPUT_XBAR_REGS Registers	1271
9	Analog Subsystem	1372
9.1	Analog Subsystem	1373
9.1.1	Features	1373
9.1.2	Block Diagram	1373
9.1.3	Lock Registers	1376
9.2	Registers	1377
9.2.1	Analog Subsystem Base Addresses.....	1377
9.2.2	ANALOG_SUBSYS_REGS Registers.....	1378
10	Analog-to-Digital Converter (ADC).....	1387
10.1	Analog-to-Digital Converter (ADC)	1388
10.1.1	Features	1388
10.1.2	ADC Block Diagram.....	1388
10.1.3	ADC Configurability	1389
10.1.4	SOC Principle of Operation	1393

10.1.5	SOC Configuration Examples	1396
10.1.6	ADC Conversion Priority	1398
10.1.7	Burst Mode	1401
10.1.8	EOC and Interrupt Operation	1403
10.1.9	Post-Processing Blocks	1403
10.1.10	Opens/Shorts Detection Circuit (OSDETECT)	1406
10.1.11	Power-Up Sequence	1407
10.1.12	ADC Calibration	1407
10.2	ADC Timings	1408
10.2.1	ADC Timing Diagrams	1408
10.3	Additional Information	1413
10.3.1	Ensuring Synchronous Operation	1413
10.3.2	Choosing an Acquisition Window Duration	1417
10.3.3	Achieving Simultaneous Sampling	1418
10.3.4	Designing an External Reference Circuit	1418
10.3.5	Internal Temperature Sensor	1420
10.4	Registers	1421
10.4.1	ADC Base Addresses	1421
10.4.2	ADC_REGS Registers	1422
10.4.3	ADC_RESULT_REGS Registers	1560
11	Buffered Digital to Analog Converter (DAC)	1581
11.1	Buffered Digital to Analog Converter (DAC) Overview	1582
11.1.1	Features	1582
11.1.2	Block Diagram	1582
11.2	Using the DAC	1582
11.3	Lock Registers	1583
11.4	Registers	1583
11.4.1	DAC Base Addresses	1583
11.4.2	DAC_REGS Registers	1584
12	Comparator Subsystem (CMPSS)	1592
12.1	CMPSS Overview	1593
12.1.1	Features	1593
12.1.2	Block Diagram	1593
12.2	Comparator	1594
12.3	Internal DAC	1594
12.4	Ramp Generator	1595
12.5	Digital Filter	1596
12.6	Registers	1598
12.6.1	CMPSS Base Addresses	1598
12.6.2	CMPSS_REGS Registers	1599
13	Sigma Delta Filter Module (SDFM)	1624
13.1	SDFM Module Overview	1625
13.1.1	SDFM Features	1625
13.1.2	Block Diagram	1626
13.2	Configuring Device Pins	1627
13.3	Input Control Unit	1628
13.4	Comparator Unit	1629
13.5	Data Filter Unit	1630
13.5.1	32-bit or 16-bit Data Filter Output Representation	1632
13.5.2	Data Rate and Latency of the Sinc Filter	1633
13.6	Interrupt Unit	1634
13.7	Register Descriptions	1636
13.8	Registers	1637

13.8.1	SDFM Base Addresses.....	1637
13.8.2	SDFM_REGS Registers.....	1638
14	Enhanced Pulse Width Modulator (ePWM)	1674
14.1	Introduction.....	1675
14.1.1	Submodule Overview	1677
14.2	Configuring Device Pins	1682
14.3	Overview.....	1682
14.4	Time-Base (TB) Submodule	1684
14.4.1	Purpose of the Time-Base Submodule.....	1684
14.4.2	Controlling and Monitoring the Time-Base Submodule	1685
14.4.3	Calculating PWM Period and Frequency	1686
14.4.4	Phase Locking the Time-Base Clocks of Multiple ePWM Modules.....	1690
14.4.5	Simultaneous Writes to TBPRD and CMPx Registers Between ePWM Modules	1690
14.4.6	Time-Base Counter Modes and Timing Waveforms.....	1691
14.4.7	Global Load	1693
14.5	Counter-Compare (CC) Submodule	1695
14.5.1	Purpose of the Counter-Compare Submodule	1695
14.5.2	Controlling and Monitoring the Counter-Compare Submodule.....	1695
14.5.3	Operational Highlights for the Counter-Compare Submodule.....	1696
14.5.4	Count Mode Timing Waveforms	1698
14.6	Action-Qualifier (AQ) Submodule	1701
14.6.1	Purpose of the Action-Qualifier Submodule	1702
14.6.2	Action-Qualifier Submodule Control and Status Register Definitions	1702
14.6.3	Action-Qualifier Event Priority	1705
14.6.4	AQCTLA and AQCTLB Shadow Mode Operations	1706
14.6.5	Waveforms for Common Configurations	1708
14.7	Dead-Band Generator (DB) Submodule	1714
14.7.1	Purpose of the Dead-Band Submodule	1715
14.7.2	Dead-band Submodule Additional Operating Modes.....	1715
14.7.3	Operational Highlights for the Dead-Band Submodule.....	1716
14.8	PWM Chopper (PC) Submodule	1721
14.8.1	Purpose of the PWM Chopper Submodule	1721
14.8.2	Operational Highlights for the PWM Chopper Submodule.....	1721
14.8.3	Waveforms	1722
14.9	Trip-Zone (TZ) Submodule.....	1725
14.9.1	Purpose of the Trip-Zone Submodule	1725
14.9.2	Operational Highlights for the Trip-Zone Submodule.....	1725
14.9.3	Generating Trip Event Interrupts	1728
14.10	Event-Trigger (ET) Submodule.....	1730
14.10.1	Operational Overview of the ePWM Type 4 Event-Trigger Submodule	1731
14.11	Digital Compare (DC) Submodule	1736
14.11.1	Purpose of the Digital Compare Submodule	1737
14.11.2	Enhanced Trip Action	1738
14.11.3	Using CMPSS to Trip the ePWM on a Cycle-by-Cycle Basis	1738
14.11.4	Operation Highlights of the Digital Compare Submodule	1738
14.12	EPWM X-BAR	1744
14.13	Applications to Power Topologies	1745
14.13.1	Overview of Multiple Modules	1745
14.13.2	Key Configuration Capabilities	1746
14.13.3	Controlling Multiple Buck Converters With Independent Frequencies.....	1747
14.13.4	Controlling Multiple Buck Converters With Same Frequencies.....	1750
14.13.5	Controlling Multiple Half H-Bridge (HHB) Converters	1751
14.13.6	Controlling Dual 3-Phase Inverters for Motors (ACI and PMSM)	1753

14.13.7	Practical Applications Using Phase Control Between PWM Modules	1755
14.13.8	Controlling a 3-Phase Interleaved DC/DC Converter	1756
14.13.9	Controlling Zero Voltage Switched Full Bridge (ZVSFB) Converter.....	1759
14.13.10	Controlling a Peak Current Mode Controlled Buck Module.....	1760
14.13.11	Controlling H-Bridge LLC Resonant Converter.....	1761
14.14	Registers	1763
14.14.1	EPWM Base Addresses	1763
14.14.2	EPWM_REGS Registers	1764
14.14.3	EPWM_XBAR_REGS Registers.....	1900
14.14.4	SYNC_SOC_REGS Registers	1993
15	High-Resolution Pulse Width Modulator (HRPWM)	2001
15.1	Introduction.....	2002
15.2	Operational Description of HRPWM	2004
15.2.1	Controlling the HRPWM Capabilities	2004
15.2.2	Configuring the HRPWM	2007
15.2.3	Configuring Hi-Res in Deadband Rising Edge and Falling Edge Delay	2008
15.2.4	Principle of Operation.....	2008
15.2.5	Deadband High Resolution Operation	2018
15.2.6	Scale Factor Optimizing Software (SFO)	2019
15.2.7	HRPWM Examples Using Optimized Assembly Code.	2019
15.3	Appendix A: SFO Library Software - SFO_TI_Build_V7.lib.....	2025
15.3.1	Scale Factor Optimizer Function - int SFO()	2025
15.3.2	Software Usage	2026
16	Enhanced Capture (eCAP).....	2028
16.1	Introduction.....	2029
16.2	Description	2029
16.3	Configuring Device Pins for the eCAP	2029
16.4	Capture and APWM Operating Mode	2030
16.5	Capture Mode Description	2031
16.5.1	Event Prescaler.....	2032
16.5.2	Edge Polarity Select and Qualifier	2033
16.5.3	Continuous/One-Shot Control	2033
16.5.4	32-Bit Counter and Phase Control	2034
16.5.5	CAP1-CAP4 Registers	2035
16.5.6	Using SWSYNC with the ECAP Module	2035
16.5.7	Interrupt Control	2036
16.5.8	Shadow Load and Lockout Control	2038
16.5.9	APWM Mode Operation	2038
16.6	Application of the ECAP Module	2039
16.6.1	Example 1 - Absolute Time-Stamp Operation Rising Edge Trigger	2039
16.6.2	Example 2 - Absolute Time-Stamp Operation Rising and Falling Edge Trigger	2042
16.6.3	Example 3 - Time Difference (Delta) Operation Rising Edge Trigger	2044
16.6.4	Example 4 - Time Difference (Delta) Operation Rising and Falling Edge Trigger	2046
16.7	Application of the APWM Mode	2048
16.7.1	Example 1 - Simple PWM Generation (Independent Channel/s)	2048
16.8	Registers	2050
16.8.1	eCAP Base Addresses	2050
16.8.2	ECAP_REGS Registers	2051
17	Enhanced QEP (eQEP).....	2068
17.1	Introduction.....	2069
17.2	Configuring Device Pins	2071
17.3	Description	2071
17.3.1	EQEP Inputs	2071

17.3.2	Functional Description	2072
17.3.3	eQEP Memory Map	2073
17.4	Quadrature Decoder Unit (QDU)	2074
17.4.1	Position Counter Input Modes	2074
17.4.2	eQEP Input Polarity Selection	2077
17.4.3	Position-Compare Sync Output	2077
17.5	Position Counter and Control Unit (PCCU)	2077
17.5.1	Position Counter Operating Modes	2077
17.5.2	Position Counter Latch	2079
17.5.3	Position Counter Initialization	2081
17.5.4	eQEP Position-compare Unit	2082
17.6	eQEP Edge Capture Unit	2083
17.7	eQEP Watchdog.....	2087
17.8	Unit Timer Base	2087
17.9	eQEP Interrupt Structure	2088

21-16. McBSP Transmission Signal Activity	2251
21-17. Conceptual Block Diagram of the Sample Rate Generator.....	2253

21-18. Possible Inputs to the Sample Rate Generator and the Polarity Bits	2255
21-19. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 1.....	2257
21-20. CLKG Synchronization and FSG Generation When GSYNC = 1 and CLKGDV = 3.....	2258
21-21. Overrun in the McBSP Receiver	2260
21-22. Overrun Prevented in the McBSP Receiver	2261
21-23. Possible Responses to Receive Frame-Synchronization Pulses	2261
21-24. An Unexpected Frame-Synchronization Pulse During a McBSP Reception	2262
21-25. Proper Positioning of Frame-Synchronization Pulses	2263
21-26. Data in the McBSP Transmitter Overwritten and Thus Not Transmitted.....	2263
21-27. Underflow During McBSP Transmission	2264
21-28. Underflow Prevented in the McBSP Transmitter	2265
21-29. Possible Responses to Transmit Frame-Synchronization Pulses	2265
21-30. An Unexpected Frame-Synchronization Pulse During a McBSP Transmission	2266
21-31. Proper Positioning of Frame-Synchronization Pulses	2267
21-32. Alternating Between the Channels of Partition A and the Channels of Partition B	2269
21-33. Reassigning Channel Blocks Throughout a McBSP Data Transfer	2270
21-34. McBSP Data Transfer in the 8-Partition Mode	2271
21-35. Activity on McBSP Pins for the Possible Values of XMCM	2274
21-36. Typical SPI Interface	2275
21-37. SPI Transfer With CLKSTP = 10b (No Clock Delay), CLKXP = 0, and CLKRP = 0	2277
21-38. SPI Transfer With CLKSTP = 11b (Clock Delay), CLKXP = 0, CLKRP = 1	2277
21-39. SPI Transfer With CLKSTP = 10b (No Clock Delay), CLKXP = 1, and CLKRP = 0	2277
21-40. SPI Transfer With CLKSTP = 11b (Clock Delay), CLKXP = 1, CLKRP = 1	2277
21-41. SPI Interface with McBSP Used as Master	2279
21-42. SPI Interface With McBSP Used as Slave	2280
21-43. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 0.....	2287
21-44. Unexpected Frame-Synchronization Pulse With (R/X)FIG = 1.....	2287
21-45. Companding Processes for Reception and for Transmission	2288
21-46. Range of Programmable Data Delay	2289
21-47. 2-Bit Data Delay Used to Skip a Framing Bit.....	2289
21-48. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge ..	2294
21-49. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods.....	2295
21-50. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge ..	2297
21-51. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 0	2307
21-52. Unexpected Frame-Synchronization Pulse With (R/X) FIG = 1	2307
21-53. Companding Processes for Reception and for Transmission	2308
21-54. μ -Law Transmit Data Companding Format	2308
21-55. A-Law Transmit Data Companding Format.....	2309
21-56. Range of Programmable Data Delay	2310
21-57. 2-Bit Data Delay Used to Skip a Framing Bit.....	2310
21-58. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge ..	2314
21-59. Frame of Period 16 CLKG Periods and Active Width of 2 CLKG Periods.....	2314
21-60. Data Clocked Externally Using a Rising Edge and Sampled by the McBSP Receiver on a Falling Edge ..	2316
21-61. Four 8-Bit Data Words Transferred To/From the McBSP.....	2320
21-62. One 32-Bit Data Word Transferred To/From the McBSP	2320
21-63. 8-Bit Data Words Transferred at Maximum Packet Frequency	2321
21-64. Configuring the Data Stream of as a Continuous 32-Bit Word.....	2321
21-65. Receive Interrupt Generation	2322
21-66. Transmit Interrupt Generation	2322

21-67. Data Receive Registers (DRR2 and DRR1)	2326
21-68. Data Transmit Registers (DXR2 and DXR1)	2326
21-69. Serial Port Control 1 Register (SPCR1)	2327
21-70. Serial Port Control 2 Register (SPCR2)	2330
21-71. Receive Control Register 1 (RCR1)	2332
21-72. Receive Control Register 2 (RCR2)	2333
21-73. Transmit Control 1 Register (XCR1)	2335
21-74. Transmit Control 2 Register (XCR2)	2336
21-75. Sample Rate Generator 1 Register (SRGR1)	2338
21-76. Sample Rate Generator 2 Register (SRGR2)	2338
21-77. Multichannel Control 1 Register (MCR1)	2340
21-78. Multichannel Control 2 Register (MCR2)	2342
21-79. Pin Control Register (PCR)	2344
21-80. Receive Channel Enable Registers (RCERA...RCERH)	2346
21-81. Transmit Channel Enable Registers (XCERA...XCERH)	2348
21-82. McBSP Interrupt Enable Register (MFFINT)	2350
22-1. CAN Block Diagram	2353
22-2. CAN Core in Silent Mode	2357
22-3. CAN Core in Loopback Mode	2358
22-4. CAN Core in External Loopback Mode	2359
22-5. CAN Core in Loopback Combined with Silent Mode	2359
22-6. Initialization of a Transmit Object	2362
22-7. Initialization of a single Receive Object for Data Frames	2363
22-8. Initialization of a single Receive Object for Remote Frames	2363
22-9. CPU Handling of a FIFO Buffer (Interrupt Driven)	2368
22-10. Bit Timing	2369
22-11. The Propagation Time Segment	2370
22-12. Synchronization on Late and Early Edges	2372
22-13. Filtering of Short Dominant Spikes	2373
22-14. Structure of the CAN Core's CAN Protocol Controller	2374
22-15. Data Transfer Between IF1 / IF2 Registers and Message RAM	2377
22-16. Structure of a Message Object	2378
22-17. Message RAM Representation in Debug Mode	2382
22-18. CAN_CTL Register	2386
22-19. CAN_ES Register	2389
22-20. CAN_ERRC Register	2391
22-21. CAN_BTR Register	2392
22-22. CAN_INT Register	2394
22-23. CAN_TEST Register	2395
22-24. CAN_PERR Register	2397
22-25. CAN_RAM_INIT Register	2398
22-26. CAN_GLB_INT_EN Register	2399
22-27. CAN_GLB_INT_FLG Register	2400
22-28. CAN_GLB_INT_CLR Register	2401
22-29. CAN_ABOTR Register	2402

22-35. CAN_IPEN_21 Register	2408
22-36. CAN_MVAL_X Register	2409
22-37. CAN_MVAL_21 Register	2410
22-38. CAN_IP_MUX21 Register	2411
22-39. CAN_IF1CMD Register	2412
22-40. CAN_IF1MSK Register	2416
22-41. CAN_IF1ARB Register	2417
22-42. CAN_IF1MCTL Register	2419
22-43. CAN_IF1DATA Register	2422
22-44. CAN_IF1DATB Register	2423
22-45. CAN_IF2CMD Register	2424
22-46. CAN_IF2MSK Register	2428
22-47. CAN_IF2ARB Register	2429
22-48. CAN_IF2MCTL Register	2431
22-49. CAN_IF2DATA Register	2434
22-50. CAN_IF2DATB Register	2435
22-51. CAN_IF3OBS Register	2436
22-52. CAN_IF3MSK Register	2438
22-53. CAN_IF3ARB Register	2439
22-54. CAN_IF3MCTL Register	2440
22-55. CAN_IF3DATA Register	2442
22-56. CAN_IF3DATB Register	2443
22-57. CAN_IF3UPD Register	2444
23-1. USB Block Diagram	2446
23-2. USB Scheme	2447
23-3. Function Address Register (USBFADDR)	2473
23-4. Power Management Register (USBPOWER) in Host Mode	2474
23-5. Power Management Register (USBPOWER) in Device Mode	2474
23-6. USB Transmit Interrupt Status Register (USBTXIS)	2476
23-7. USB Transmit Interrupt Status Register (USBRXIS)	2478
23-8. USB Transmit Interrupt Status Enable Register (USBTXIE)	2480
23-9. USB Transmit Interrupt Status Enable Register (USBRXIE)	2482
23-10. USB General Interrupt Status Register (USBIS) in Host Mode	2484
23-11. USB General Interrupt Status Register (USBIS) in Device Mode	2485
23-12. USB Interrupt Enable Register (USBIE) in Host Mode	2486
23-13. USB Interrupt Enable Register (USBIE) in Device Mode	2487
23-14. Frame Number Register (FRAME)	2488
23-15. USB Endpoint Index Register (USBEPIDX)	2488
23-16. USB Test Mode Register (USBTEST) in Host Mode	2489
23-17. USB Test Mode Register (USBTEST) in Device Mode	2489
23-18. USB FIFO Endpoint <i>n</i> Register (USBFIFO[<i>n</i>])	2491
23-19. USB Device Control Register (USBDEVCTL)	2492
23-20. USB Transmit Dynamic FIFO Sizing Register (USBTXFIFOSZ)	2494
23-21. USB Receive Dynamic FIFO Sizing Register (USBRXFIFOSZ)	2495
23-22. USB Transmit FIFO Start Address Register (USBTXFIFOADDR)	2496
23-23. USB Receive FIFO Start Address Register (USBRXFIFOADDR)	2497
23-24. USB Connect Timing Register (USBCONTIM)	2498
23-25. USB Full-Speed Last Transaction to End of Frame Timing Register (USBFSEOF)	2499

23-26. USB Low-Speed Last Transaction to End of Frame Timing Register (USBLSEOF)	2499
23-27. USB Transmit Functional Address Endpoint <i>n</i> Registers (USBTXFUNCADDR[<i>n</i>])	2500
23-28. USB Transmit Hub Address Endpoint <i>n</i> Registers (USBTXHUBADDR[<i>n</i>]).....	2501
23-29. USB Transmit Hub Port Endpoint <i>n</i> Registers (USBTXHUBPORT[<i>n</i>]).....	2502
23-30. USB Receive Functional Address Endpoint <i>n</i> Registers (USBFIFO[<i>n</i>])	2503
23-31. USB Receive Hub Address Endpoint <i>n</i> Registers (USBRXHUBADDR[<i>n</i>])	2504
23-32. USB Transmit Hub Port Endpoint <i>n</i> Registers (USBRXHUBPORT[<i>n</i>])	2505
23-33. USB Maximum Transmit Data Endpoint <i>n</i> Registers (USBTXMAXP[<i>n</i>]).....	2506
23-34. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Host Mode	2507
23-35. USB Control and Status Endpoint 0 Low Register (USBCSRL0) in Device Mode	2508
23-36. USB Control and Status Endpoint 0 High Register (USBCSRH0) in Host Mode	2509
23-37. USB Control and Status Endpoint 0 High Register (USBCSRH0) in Device Mode	2509
23-38. USB Receive Byte Count Endpoint 0 Register (USBCOUNT0).....	2510
23-39. USB Type Endpoint 0 Register (USBTTYPE0)	2510
23-40. USB NAK Limit Register (USBNAKLMT)	2511
23-41. USB Transmit Control and Status Endpoint <i>n</i> Low Register (USBTXCSRL[<i>n</i>]) in Host Mode.....	2512
23-42. USB Transmit Control and Status Endpoint <i>n</i> Low Register (USBTXCSRL[<i>n</i>]) in Device Mode	2513
23-43. USB Transmit Control and Status Endpoint <i>n</i> High Register (USBTXCSRH[<i>n</i>]) in Host Mode.....	2515
23-44. USB Transmit Control and Status Endpoint <i>n</i> High Register (USBTXCSRH[<i>n</i>]) in Device Mode	2516
23-45. USB Maximum Receive Data Endpoint <i>n</i> Registers (USBRXMAXP[<i>n</i>])	2517
23-46. USB Receive Control and Status Endpoint <i>n</i> Low Register (USBCSRL[<i>n</i>]) in Host Mode	2518
23-47. USB Control and Status Endpoint <i>n</i> Low Register (USBCSRL[<i>n</i>]) in Device Mode	2519
23-48. USB Receive Control and Status Endpoint <i>n</i> High Register (USBCSRH[<i>n</i>]) in Host Mode	2520
23-49. USB Control and Status Endpoint <i>n</i> High Register (USBCSRH[<i>n</i>]) in Device Mode.....	2521
23-50. USB Maximum Receive Data Endpoint <i>n</i> Registers (USBRXCOUNT[<i>n</i>])	2522
23-51. USB Host Transmit Configure Type Endpoint <i>n</i> Register (USBTXTYPE[<i>n</i>])	2523
23-52. USB Host Transmit Interval Endpoint <i>n</i> Register (USBTXINTERVAL[<i>n</i>])	2524
23-53. USB Host Configure Receive Type Endpoint <i>n</i> Register (USBRXTYPE[<i>n</i>])	2525
23-54. USB Host Receive Polling Interval Endpoint <i>n</i> Register (USBRXINTERVAL[<i>n</i>])	2526
23-55. USB Request Packet Count in Block Transfer Endpoint <i>n</i> Registers (USBRQPKTCOUNT[<i>n</i>])	2527
23-56. USB Receive Double Packet Buffer Disable Register (USBRXDPKTBUFDIS).....	2528

21-22. Register Bits Used to Enable/Disable the Clock Stop Mode	2283
21-23. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme	2284
21-24. Register Bit Used to Enable/Disable the Receive Multichannel Selection Mode	2284
21-25. Register Bit Used to Choose One or Two Phases for the Receive Frame	2284
21-26. Register Bits Used to Set the Receive Word Length(s).....	2285
21-27. Register Bits Used to Set the Receive Frame Length.....	2285
21-28. How to Calculate the Length of the Receive Frame	2286
21-29. Register Bit Used to Enable/Disable the Receive Frame-Synchronization Ignore Function	2286
21-30. Register Bits Used to Set the Receive Companding Mode.....	2287
21-31. Register Bits Used to Set the Receive Data Delay	2288
21-32. Register Bits Used to Set the Receive Sign-Extension and Justification Mode.....	2290
21-33. Example: Use of RJUST Field With 12-Bit Data Value ABCh.....	2290
21-34. Example: Use of RJUST Field With 20-Bit Data Value ABCDEh.....	2290
21-35. Register Bits Used to Set the Receive Interrupt Mode	2291
21-36. Register Bits Used to Set the Receive Frame Synchronization Mode	2291
21-37. Select Sources to Provide the Receive Frame-Synchronization Signal and the Effect on the FSR Pin.....	2292
21-38. Register Bit Used to Set Receive Frame-Synchronization Polarity.....	2293
21-39. Register Bits Used to Set the SRG Frame-Synchronization Period and Pulse Width	2294
21-40. Register Bits Used to Set the Receive Clock Mode	2295
21-41. Receive Clock Signal Source Selection	2296
21-42. Register Bit Used to Set Receive Clock Polarity.....	2296
21-43. Register Bits Used to Set the Sample Rate Generator (SRG) Clock Divide-Down Value.....	2298
21-44. Register Bit Used to Set the SRG Clock Synchronization Mode	2298
21-45. Register Bits Used to Set the SRG Clock Mode (Choose an Input Clock)	2299
21-46. Register Bits Used to Set the SRG Input Clock Polarity	2300
21-47. Register Bits Used to Place Transmitter in Reset Field Descriptions	2301
21-48. Register Bit Used to Enable/Disable the Digital Loopback Mode.....	2302
21-49. Receive Signals Connected to Transmit Signals in Digital Loopback Mode	2302
21-50. Register Bits Used to Enable/Disable the Clock Stop Mode	2302
21-51. Effects of CLKSTP, CLKXP, and CLKRP on the Clock Scheme	2303
21-52. Register Bits Used to Enable/Disable Transmit Multichannel Selection	2304
21-53. Register Bit Used to Choose 1 or 2 Phases for the Transmit Frame	2305
21-54. Register Bits Used to Set the Transmit Word Length(s)	2305
21-55. Register Bits Used to Set the Transmit Frame Length.....	2306
21-56. How to Calculate Frame Length.....	2306
21-57. Register Bit Used to Enable/Disable the Transmit Frame-Synchronization Ignore Function	2307
21-58. Register Bits Used to Set the Transmit Companding Mode	2308
21-59. Register Bits Used to Set the Transmit Data Delay	2309
21-60. Register Bit Used to Set the Transmit DXENA (DX Delay Enabler) Mode	2311
21-61. Register Bits Used to Set the Transmit Interrupt Mode	2311
21-62. Register Bits Used to Set the Transmit Frame-Synchronization Mode	2312
21-63. How FSXM and FSGM Select the Source of Transmit Frame-Synchronization Pulses	2312
21-64. Register Bit Used to Set Transmit Frame-Synchronization Polarity	2313
21-65. Register Bits Used to Set SRG Frame-Synchronization Period and Pulse Width	2314
21-66. Register Bit Used to Set the Transmit Clock Mode.....	2315
21-67. How the CLKXM Bit Selects the Transmit Clock and the Corresponding Status of the MCLKX pin.....	2315

21-68. Register Bit Used to Set Transmit Clock Polarity	2315
21-69. McBSP Emulation Modes Selectable with FREE and SOFT Bits of SPCR2.....	2317
21-70. Reset State of Each McBSP Pin	2317
21-71. Receive Interrupt Sources and Signals	2322
21-72. Transmit Interrupt Sources and Signals.....	2322
21-73. Error Flags	2323
21-74. McBSP Mode Selection	2323
21-75. McBSP Base Address Table.....	2325
21-76. McBSP Register Summary.....	2325
21-77. Serial Port Control 1 Register (SPCR1) Field Descriptions	2327
21-78. Serial Port Control 2 Register (SPCR2) Field Descriptions.....	2330
21-79. Receive Control Register 1 (RCR1) Field Descriptions	2332
21-80. Frame Length Formula for Receive Control 1 Register (RCR1)	2333
21-81. Receive Control Register 2 (RCR2) Field Descriptions	2333
21-82. Frame Length Formula for Receive Control 2 Register (RCR2)	2334
21-83. Transmit Control 1 Register (XCR1) Field Descriptions	2335
21-84. Frame Length Formula for Transmit Control 1 Register (XCR1)	2335
21-85. Transmit Control 2 Register (XCR2) Field Descriptions	2336
21-86. Frame Length Formula for Transmit Control 2 Register (XCR2)	2337
21-87. Sample Rate Generator 1 Register (SRGR1) Field Descriptions.....	2338
21-88. Sample Rate Generator 2 Register (SRGR2) Field Descriptions.....	2339
21-89. Multichannel Control 1 Register (MCR1) Field Descriptions	2340
21-90. Multichannel Control 2 Register (MCR2) Field Descriptions	2342
21-91. Pin Control Register (PCR) Field Descriptions.....	2344
21-92. Pin Configuration	2346
21-93. Receive Channel Enable Registers (RCERA...RCERH) Field Descriptions.....	2346
21-94. Use of the Receive Channel Enable Registers	2347
21-95. Transmit Channel Enable Registers (XCERA...XCERH) Field Descriptions	2348
21-96. Use of the Transmit Channel Enable Registers	2349
21-97. McBSP Interrupt Enable Register (MFFINT) Field Descriptions	2350
22-1. CAN Register Access From Software	2354
22-2. CAN Register Access From CCS	2355
22-3. PIE Nomenclature for Interrupts.....	2361
22-4. Programmable Ranges Required by CAN Protocol	2369
22-5. Message Object Field Descriptions	2378
22-6. Message RAM Addressing in Debug Mode	2381
22-7. CAN Base Addresses Table	2383

About This Manual

This Technical Reference Manual (TRM) details the integration, the environment, the functional description, and the programming models for each peripheral and subsystem in the device.

The TRM should not be considered a substitute for the data manual, rather a companion guide that should be used alongside the device-specific data manual to understand the details to program the device. The primary purpose of the TRM is to abstract the programming details of the device from the data manual. This allows the data manual to outline the high-level features of the device without unnecessary information about register descriptions or programming models.

Notational Conventions

This document uses the following conventions.

- Hexadecimal numbers may be shown with the suffix h or the prefix 0x. For example, the following number is 40 hexadecimal (decimal 64): 40h or 0x40.
- Registers in this document are shown in figures and described in tables.
 - Each register figure shows a rectangle divided into fields that represent the fields of the register. Each field is labeled with its bit name, its beginning and ending bit numbers above, and its read/write properties with default reset value below. A legend explains the notation used for the properties.
 - Reserved bits in a register figure can have one of multiple meanings:
 - Not implemented on the device
 - Reserved for future device expansion
 - Reserved for TI testing
 - Reserved configurations of the device that are not supported
 - Writing nondefault values to the Reserved bits could cause unexpected behavior and should be avoided.

Glossary

[TI Glossary](#) — This glossary lists and explains terms, acronyms, and definitions.

Related Documentation From Texas Instruments

For a complete listing of related documentation and development-support tools for these devices, visit the Texas Instruments website at <http://www.ti.com>. Additionally, the *TMS320C28x CPU and Instruction Set Reference Guide* ([SPRU430](#)) and *TMS320C28x Floating Point Unit and Instruction Set Reference Guide* ([SPRUE02](#)) must be used in conjunction with this TRM.

C28x Processor

This chapter contains a modified description of the C28x Processor and provides links to access their respective references guides.

Topic	Page
1.1 Overview	83

1.1 Overview

The CPU is a 32-bit fixed-point processor. This device draws from the best features of digital signal processing; reduced instruction set computing (RISC); and microcontroller architectures, firmware, and tool sets.

The CPU features include a modified Harvard architecture and circular addressing. The RISC features are single-cycle instruction execution, register-to-register operations, and modified Harvard architecture. The microcontroller features include ease of use through an intuitive instruction set, byte packing and unpacking, and bit manipulation. The modified Harvard architecture of the CPU enables instruction and data fetches to be performed in parallel. The CPU can read instructions and data while it writes data simultaneously to maintain the single-cycle instruction operation across the pipeline. The CPU does this over six separate address/data buses.

For more information on CPU architecture and instruction set, see the *TMS320C28x CPU and Instruction Set Reference Guide* (literature number [SPRU430](#)). For more information on the C28x Floating Point Unit (FPU), Trigonometric Math Unit, and Viterbi, Complex Math, and CRC Unit II (VCU-II) instruction sets, see the *TMS320C28x Extended Instruction Sets Technical Reference Guide* (literature number [SPRUHS1](#)). A brief overview of the FPU, TMU, and VCU-II are provided here.

1.1.1 Floating-Point Unit

The C28x plus floating-point (C28x+FPU) processor extends the capabilities of the C28x fixed-point CPU by adding registers and instructions to support IEEE single-precision floating point operations.

Devices with the C28x+FPU include the standard C28x register set plus an additional set of floating-point unit registers. The additional floating-point unit registers are the following:

- Eight floating-point result registers, RnH (where n = 0–7)
- Floating-point Status Register (STF)
- Repeat Block Register (RB)

All of the floating-point registers, except the repeat block register, are shadowed. This shadowing can be used in high-priority interrupts for fast context save and restore of the floating-point registers.

1.1.2 Trigonometric Math Unit

The TMU extends the capabilities of a C28x+FPU by adding instructions and leveraging existing FPU instructions to speed up the execution of common trigonometric and arithmetic operations listed in [Table 1-1](#).

Table 1-1. TMU Supported Instructions

INSTRUCTIONS	C EQUIVALENT OPERATION	PIPELINE CYCLES
MPY2PIF32 RaH,RbH	$a = b * 2\pi$	2/3
DIV2PIF32 RaH,RbH	$a = b / 2\pi$	2/3
DIVF32 RaH,RbH,RcH	$a = b/c$	5
SQRTF32 RaH,RbH	$a = \sqrt{b}$	5
SINPUF32 RaH,RbH	$a = \sin(b*2\pi)$	4
COSPUF32 RaH,RbH	$a = \cos(b*2\pi)$	4
ATANPUF32 RaH,RbH	$a = \tan(b)/2\pi$	4
QUADF32 RaH,RbH,RcH,RdH	Operation to assist in calculating ATANPU2	5

No changes have been made to existing instructions, pipeline or memory bus architecture. All TMU instructions use the existing FPU register set (R0H to R7H) to carry out their operations.

1.1.3 Viterbi, Complex Math, and CRC Unit II (VCU-II)

The VCU-II is the second-generation Viterbi, Complex Math, and CRC extension to the C28x CPU. The VCU-II extends the capabilities of the C28x CPU by adding registers and instructions to accelerate the performance of FFTs and communications-based algorithms. The C28x+VCU-II supports the following algorithm types:

- **Viterbi Decoding**

Viterbi decoding is commonly used in baseband communications applications. The Viterbi decode algorithm consists of three main parts: branch metric calculations, compare-select (Viterbi butterfly), and a traceback operation. Table 1-2 shows a summary of the VCU performance for each of these operations.

Table 1-2. Viterbi Decode Performance

VITERBI OPERATION	VCU CYCLES
Branch Metric Calculation (code rate = 1/2)	1
Branch Metric Calculation (code rate = 1/3)	2p
Viterbi Butterfly (add-compare-select)	2 ⁽¹⁾
Traceback per Stage	3 ⁽²⁾

⁽¹⁾ C28x CPU takes 15 cycles per butterfly.

⁽²⁾ C28x CPU takes 22 cycles per stage.

- **Cyclic Redundancy Check**

Cyclic redundancy check (CRC) algorithms provide a straightforward method for verifying data integrity over large data blocks, communication packets, or code sections. The C28x+VCU can perform 8-bit, 16-bit, 24-bit, and 32-bit CRCs. For example, the VCU can compute the CRC for a block length of 10 bytes in 10 cycles. A CRC result register contains the current CRC, which is updated whenever a CRC instruction is executed.

- **Complex Math**

Complex math is used in many applications, a few of which are:

- Fast Fourier Transform (FFT)

The complex FFT is used in spread spectrum communications, as well as in many signal processing algorithms.

- Complex filters

Complex filters improve data reliability, transmission distance, and power efficiency. The C28x+VCU can perform a complex I and Q multiply with coefficients (four multiplies) in a single cycle. In addition, the C28x+VCU can read/write the real and imaginary parts of 16-bit complex data to memory in a single cycle.

Table 1-3. Complex Math Performance

COMPLEX MATH OPERATION	VCU CYCLES	NOTES
Add or Subtract	1	32 +/- 32 = 32-bit (Useful for filters)
Add or Subtract	1	16 +/- 32 = 15-bit (Useful for FFT)
Multiply	2p	16 x 16 = 32-bit
Multiply and Accumulate (MAC)	2p	32 + 32 = 32-bit, 16 x 16 = 32-bit
RPT MAC	2p+N	Repeat MAC. Single cycle after the first operation.

NOTE: Only the CRC-related VCU instructions will be supported in future devices. FFT algorithms are available for the C28x+FPU.

System Control

This chapter explains system control and interrupts found on this MCU. The system control module configures and manages the overall operation of the device and provides information about the device status. Configurable features in system control include reset control, NMI operation, power control, clock control, and low-power modes.

Topic	Page
2.1 Introduction	86
2.2 System Control Functional Description	86
2.3 Resets	87

2.1 Introduction

On this device, the CPU1 subsystem acts as a master, and by default (upon reset), it owns all the configuration and control. Through software running on CPU1, peripherals and I/Os can be configured to be accessible by the CPU2 subsystem and the configuration so chosen could be locked.

The PLL clock configuration is also owned by the CPU1 subsystem by default, but a clock control semaphore is provided by which CPU2 can grab access to the clock configuration registers.

Each CPU has its own NMI module to handle different exceptions during run time. If the NMI was on CPU1, any NMI exception that is unhandled before the NMI Watchdog (NMIWD) timer expiration will reset the entire device. If the NMI was on the CPU2 subsystem, then the CPU2 subsystem alone will be reset, in which case the CPU1 subsystem will be informed by another NMI that the CPU2 subsystem was reset because of NMIWD timer expiration.

Each CPU subsystem has its own watchdog timer module for software to use. Watchdog timer expiration on CPU2 will reset the CPU2 subsystem alone when configured to generate a reset, but watchdog timer expiration on CPU1 will reset the entire device.

Except for a CPU2 standalone internal reset such as CPU2.NMIWD or CPU2.WD each time the device is reset, the CPU2 subsystem will be held under reset until the CPU1 subsystem brings it out of reset. This is done by the boot ROM software running on the CPU1 core.

The register space of the device system control module is divided into three categories and will be explained further in this chapter. They are:

1. System Control Device Configuration Registers (DEV_CFG_REGS). These registers are mapped to CPU1 only. The base address of these registers on the CPU1 address space begins at 0x5D000.
2. System Control Clock Configuration Registers (CLK_CFG_REGS). These registers are mapped to both CPU1 and CPU2 address space but access control is based on a Clock Control Semaphore register. The base address of these registers on both the CPU subsystems begins at 0x5D200.
3. System control CPU Subsystem Registers (CPU_SYS_REGS). These registers are mapped to both the CPU subsystems. The base address of these registers on both the CPU subsystems begins at 0x5D300.

This chapter explains the system control module on both the CPU subsystems.

2.2 System Control Functional Description

The system control module provides the following capabilities:

- Device identification and configuration registers
- Reset control
- Exceptions and Interrupt control
- Safety and error handling features of the device
- Power control
- Clock control
- Low Power modes
- Security module
- Inter-Processor Communication (IPC)

2.2.1 Device Identification

Device identification registers provide information on device class, device family, revision, part number, pin count, operating temperature range, package type, pin count, and device qualification status.

All of the device information is part of the DEV_CFG_REGS space and is accessible only by the software running on the CPU1 subsystem.

The control subsystem device identification registers are: PARTIDL, PARTIDH, and REVID.

A 256-bit Unique ID (UID) is available in UID_REGS. The 256 bits are separated into these registers:

- UID_PSRAND0-5: 192 bits of pseudo-random data
- UID_UNIQUE: 32-bit unique data, the value in this register will be unique across all devices with the same PARTIDH
- UID_CHECKSUM: 32-bit fletcher checksum of UID_PSRAND0-5 and UID_UNIQUE
- CPU ID: 16-bit location in OTP. The value at this location provides the information about CPU (CPU1 or CPU20. Please refer to the device datasheet, for more detail.

2.2.2 Device Configuration Registers

Several registers provide users with configuration information for debug and identification purposes on this MCU. This information includes the features of the peripheral and how much RAM and FLASH memory is available on this part.

These registers are part of DEV_CFG_REGS space and are accessible only by the software running on the CPU1 subsystem.

- DC0 – DC20: Device Configuration or Capabilities registers.
If a particular bit in these registers is set to '1' then the associated/feature or module is available in the device.
- PERCNF: Peripheral configuration register.
This register configures ADC capabilities, and enables or disables the USB internal PHY.
- CPUID: CPU identification register

This register is available for software to identify on which CPU it is executing.

2.3 Resets

This section explains the types and effects of the different resets on this device.

2.3.1 Reset Sources

Table 2-1 summarizes the various reset signals and their effect on the device.

Table 2-1. Reset Signals

Reset Source	CPU1 Core Reset (C28x, TMU, FPU, VCU)	CPU1 Peripheral s Reset	CPU2 Core Reset (C28x, TMU, FPU, VCU)	CPU2 Peripheral s Reset	CPU2 Held In Reset	JTAG / Debug Logic Reset	IOs	XRS Output
POR	Yes	Yes	Yes	Yes	Yes	Yes	Hi-Z	Yes
XRS Pin	Yes	Yes	Yes	Yes	Yes	No	Hi-Z	-
CPU1.WDRS	Yes	Yes	Yes	Yes	Yes	No	Hi-Z	Yes
CPU1.NMIWDRS	Yes	Yes	Yes	Yes	Yes	No	Hi-Z	Yes
CPU1.SYSRS (Debugger Reset)	Yes	Yes	Yes	Yes	Yes	No	Hi-Z	No
CPU1.SCCRESET	Yes	Yes	Yes	Yes	Yes	No	Hi-Z	No
CPU2.SYSRS (Debugger Reset)	No	No	Yes	Yes	No	No	-	No
CPU2.WDRS	No	No	Yes	Yes	No	No	-	No
CPU2.NMIWDRS	No	No	Yes	Yes	No	No	-	No
CPU2.SCCRESET	No	No	Yes	Yes	No	No	-	No
HIBRESET	Yes	Yes	Yes	Yes	Yes	Yes	Isolated	No
CPU1.HWBISTRs	Yes	No	No	No	No	No	-	No
CPU2.HWBISTRs	No	No	Yes	No	No	No	-	No
TRST	No	No	No	No	No	Yes	-	No

The resets can be divided into a few groups:

- Chip-level resets ($\overline{XRS}$, POR, CPU1. $\overline{WDRS}$, and CPU1. $\overline{NMIWDRS}$), which reset all or almost all of the device.
- System resets (CPU1. $\overline{SYSRS}$ and CPU1. $\overline{SCCRESET}$), which reset a large subset of the device but maintain some system-level configuration.
- CPU2 subsystem resets (CPU2. $\overline{SYSRS}$, CPU2. $\overline{WDRS}$, CPU2. $\overline{NMIWDRS}$, and CPU2. $\overline{SCCRESET}$), which reset only CPU2 and its peripherals.
- Special resets ($\overline{HIBRESET}$, CPU1. $\overline{HWBISTR}$, CPU2. $\overline{HWBISTR}$, and $\overline{TRST}$), which enable specific device functions.

Whenever the CPU1 subsystem is reset, CPU2 and its peripherals are also reset, and CPU2 is held in reset. CPU1 brings it out of reset by writing to the CPU2RESCTL register. This is normally done by the boot ROM. For more details on the boot process, refer to the *ROM Code and Peripheral Booting* chapter.

After a reset, the reset cause register (RESC) is updated with the reset cause. The bits in this register maintain their state across multiple resets. They can only be cleared by a power-on reset (POR) or by writing ones to the register. Each CPU has its own RESC register, referred to as CPU1.RESC and CPU2.RESC.

Many peripheral modules have individual resets accessible through the system control registers. For information about a module's reset state, refer to the appropriate chapter for that module.

After a POR, XRS, CPU1. $\overline{WDRS}$, CPU1. $\overline{NMIWDRS}$, or $\overline{HIBRESET}$, the boot ROMs will clear all of the system and message RAMs on both CPUs. After a CPU2. $\overline{WDRS}$ or CPU2. $\overline{NMIWDRS}$, CPU2's boot ROM will clear all of the CPU2 system and message RAMs.

2.3.2 External Reset ($\overline{XRS}$)

The external reset ($\overline{XRS}$) is the main chip-level reset for the device. It resets both CPUs, all peripherals and I/O pin configurations, and most of the system control registers. It also holds CPU2 in reset. There is a dedicated open-drain pin for $\overline{XRS}$. This pin may be used to drive reset pins for other ICs in the application, and may itself be driven by an external source. The $\overline{XRS}$ is driven internally during watchdog, NMI, and power-on resets. In hibernate mode, toggling $\overline{XRS}$ will produce a $\overline{HIBRESET}$.

The XRSn bit in the RESC register will be set whenever $\overline{XRS}$ is driven low for any reason. This bit is then cleared by the boot ROM.

2.3.3 Power-On Reset (POR)

The power-on reset (POR) circuit creates a clean reset throughout the device during power-up, suppressing glitches on the GPIOs. The $\overline{XRS}$ pin is held low for the duration of the POR. In most applications, $\overline{XRS}$ is held low long enough to reset other system ICs, but some applications may require a longer pulse. In these cases, $\overline{XRS}$ can be driven low externally to provide the correct reset duration. A POR resets everything that $\overline{XRS}$ does, along with a few other registers – the reset cause register (RESC), the NMI shadow flag register (NMISHDFLG), the X1 clock counter register (X1CNT), and the hibernate configuration registers (HIBBOOTMODE, IORESTOREADDR, and LPMCR.M0M1MODE).

After a POR, the POR and XRSn bits in RESC are set. These bits are then cleared by the boot ROM.

2.3.4 Debugger Reset ($\overline{SYSRS}$)

During development, it is sometimes necessary to reset the CPU and its peripherals without disconnecting the debugger or disrupting the system-level configuration. To facilitate this, each CPU has its own subsystem reset, which can be triggered by a debugger using Code Composer Studio. CPU2's subsystem reset (CPU2. $\overline{SYSRS}$) resets only CPU2, its peripherals, and its clock gating and LPM configuration. It does not hold CPU2 in reset. CPU1's subsystem reset (CPU1. $\overline{SYSRS}$) resets CPU1, its peripherals, many system control registers (including its clock gating and LPM configuration and the peripherals' CPU ownership), and all I/O pin configurations. It also produces a CPU2. $\overline{SYSRS}$ and holds CPU2 in reset.

Neither $\overline{SYSRS}$ resets the ICEpick debug module, the device capability registers, the clock source and PLL configurations, the missing clock detection state, the PIE vector fetch error handler address, the NMI flags, the analog trims, or anything reset only by a POR (see [Section 2.3.3](#)).

2.3.5 Watchdog Reset ($\overline{WDRS}$)

Each CPU has a watchdog timer that can optionally trigger a reset that lasts for 512 INTOSC1 cycles. CPU1's watchdog reset (CPU1. $\overline{WDRS}$) produces an $\overline{XRS}$. CPU2's watchdog reset (CPU2. $\overline{WDRS}$) produces a CPU2.SYSRS and triggers an NMI on CPU1.

After a watchdog reset, the WDRSn bit in RESC is set.

2.3.6 NMI Watchdog Reset ($\overline{NMIWDRS}$)

Each CPU has a non-maskable interrupt (NMI) module that detects hardware errors in the system. Each NMI module has a watchdog timer that triggers a reset if the CPU does not respond to an error within a user-specified amount of time. CPU1's NMI watchdog reset (CPU1. $\overline{NMIWDRS}$) produces an $\overline{XRS}$. CPU2's NMI watchdog reset (CPU2. $\overline{NMIWDRS}$) produces a CPU2.SYSRS and triggers an NMI on CPU1.

After an NMI watchdog reset, the NMIWDRSn bit in RESC is set.

2.3.7 DCSM Safe Code Copy Reset ($\overline{SCCRESET}$)

Each CPU has a dual-zone code security module (DCSM) that blocks read access to certain areas of the flash memory. To facilitate CRC checks and copying of CLA code, TI provides ROM functions to securely access those memory areas. To prevent security breaches, interrupts must be disabled before calling these functions. If a vector fetch occurs in a safe copy or CRC function, the DCSM triggers a reset. CPU1's security reset (CPU1. $\overline{SCCRESET}$) is similar to a CPU1.SYSRS, and CPU2's security reset (CPU2. $\overline{SCCRESET}$) is similar to a CPU2.SYSRS. However, the security reset also resets the debug logic to deny access to a potential attacker.

After a security reset, the SCCRESETn bit in RESC is set.

2.3.8 Hibernate Reset ($\overline{HIBRESET}$)

Hibernate is a chip-level low-power mode that gates power to large portions of the device. Waking up from hibernate involves a special reset ($\overline{HIBRESET}$). This reset is similar to a POR except that the I/O pins remain isolated and the $\overline{XRS}$ pin is not toggled. (An external $\overline{XRS}$ toggle during hibernate will trigger a $\overline{HIBRESET}$). I/O isolation is disabled in software as part of a special boot ROM flow. For more information on hibernate, refer to [Section 2.10](#).

After a hibernate reset, the HIBRESETn bit in RESC is set. This bit is then cleared by the boot ROM.

2.3.9 Hardware BIST Reset ($\overline{HWBISTRs}$)

Each CPU has a Hardware Built-In Self Test (HWBIST) module that tests the functionality of the CPU. At the end of the test, it resets the CPU to return it to a working state. This reset ($\overline{HWBISTRs}$) only affects the CPU itself. The peripherals and system control remain as previously configured. The CPU state is restored in software as part of a special boot ROM flow. For more information on the HWBIST flow, contact your local TI representative.

After a HWBIST reset, the HWBISTn bit in RESC is set. This bit is then cleared by the boot ROM.

2.3.10 Test Reset ($\overline{TRST}$)

The ICEPick debug module and associated JTAG logic has its own reset ($\overline{TRST}$) which is controlled by a dedicated pin. This reset is normally active unless the user connects a debugger to the device. For more information on the debug module, see the TI Processors Wiki page on ICEPick: <http://processors.wiki.ti.com/index.php/ICEPICK>.

The $\overline{TRST}$ does not have a normal RESC bit, but the TRSTn_pin_status bit indicates the state of the pin.

2.4 Peripheral Interrupts

This section explains the peripheral interrupt handling on the device. Non-maskable interrupts are covered in [Section 2.5](#). Software interrupts and emulation interrupts are not covered in this document. For information on those, see the *TMS320C28x CPU and Instruction Set Reference Guide* ([SPRU430](#)).

2.4.1 Interrupt Concepts

An interrupt is a signal that causes the CPU to pause its current execution and branch to a different piece of code known as an interrupt service routine (ISR). This is a useful mechanism for handling peripheral events, and involves less CPU overhead or program complexity than register polling. However, because interrupts are asynchronous to the program flow, care must be taken to avoid conflicts over resources that are accessed both in interrupts and in the main program code.

Interrupts propagate to the CPU through a series of flag and enable registers. The flag registers store the interrupt until it is processed. The enable registers block the propagation of the interrupt. When an interrupt signal reaches the CPU, the CPU fetches the appropriate ISR address from a list called the vector table.

2.4.2 Interrupt Architecture

The C28x CPU has fourteen peripheral interrupt lines. Two of them (INT13 and INT14) are connected directly to CPU timers 1 and 2, respectively. The remaining twelve are connected to peripheral interrupt signals through the enhanced Peripheral Interrupt Expansion module (ePIE, or PIE as a shortened version). The PIE multiplexes up to sixteen peripheral interrupts into each CPU interrupt line. It also expands the vector table to allow each interrupt to have its own ISR. This allows the CPU to support a large number of peripherals.

An interrupt path is divided into three stages – the peripheral, the PIE, and the CPU. Each stage has its own enable and flag registers. This system allows the CPU to handle one interrupt while others are pending, implement and prioritize nested interrupts in software, and disable interrupts during certain critical tasks.

Figure 2-1 shows the interrupt architecture for this device.

Figure 2-1. Device Interrupt Architecture

2.4.2.1 Peripheral Stage

Each peripheral has its own unique interrupt configuration, which is described in that peripheral's chapter. Some peripherals allow multiple events to trigger the same interrupt signal. For example, a communications peripheral might use the same interrupt to indicate that data has been received or that there has been a transmission error. The cause of the interrupt can be determined by reading the peripheral's status register. Often, the bits in the status register must be cleared manually before another interrupt will be generated.

2.4.2.2 PIE Stage

The PIE provides individual flag and enable register bits for each of the peripheral interrupt signals, which are sometimes called PIE channels. These channels are grouped according to their associated CPU interrupt. Each PIE group has one 16-bit enable register (PIEIERx), one 16-bit flag register (PIEIFRx), and one bit in the PIE acknowledge register (PIEACK). The PIEACK register bit acts as a common interrupt mask for the entire PIE group.

When the CPU receives an interrupt, it fetches the address of the ISR from the PIE. The PIE returns the vector for the lowest-numbered channel in the group that is both flagged and enabled. This gives lower-numbered interrupts a higher priority when multiple interrupts are pending.

If no interrupt is both flagged and enabled, the PIE returns the vector for channel 1. This condition will not happen unless software changes the state of the PIE while an interrupt is propagating. [Section 2.4.4](#) contains procedures for safely modifying the PIE configuration once interrupts have been enabled.

2.4.2.3 CPU Stage

Like the PIE, the CPU provides flag and enable register bits for each of its interrupts. There is one enable register (IER) and one flag register (IFR), both of which are internal CPU registers. There is also a global interrupt mask, which is controlled by the INTM bit in the ST1 register. This mask can be set and cleared using the CPU's SETC instruction. In C code, controlSUITE's DINT and EINT macros can be used for this purpose.

Writes to IER and INTM are atomic operations. In particular, if INTM is cleared, the next instruction in the pipeline will run with interrupts disabled. No software delays are needed.

2.4.2.4 Dual-CPU Interrupt Handling

Each CPU has its own PIE. Both PIEs must be configured independently.

Some interrupts come from shared peripherals that can be owned by either CPU, such as the ADCs and SPIs. These interrupts are sent to both PIEs regardless of the peripheral's ownership. Thus, a peripheral owned by one CPU can cause an interrupt on the other CPU if that interrupt is enabled in the other CPU's PIE.

2.4.3 Interrupt Entry Sequence

[Figure 2-2](#) shows how peripheral interrupts propagate to the CPU.

Figure 2-2. Interrupt Propagation Path

When a peripheral generates an interrupt (on PIE group x, channel y), it triggers the following sequence of events:

1. The interrupt is latched in PIEIFRx.y.
2. If PIEIERx.y is set, the interrupt propagates.
3. If PIEACK.x is clear, the interrupt propagates and PIEACK.x is set.
4. The interrupt is latched in IFR.x.
5. If IER.x is set, the interrupt propagates.
6. If INTM is clear, the CPU receives the interrupt.
7. Any instructions in the D2 or later stage of the pipeline are run to completion. Instructions in earlier stages are flushed.
8. The CPU saves its context on the stack.
9. IFR.x and IER.x are cleared. INTM is set. EALLOW is cleared.
10. The CPU fetches the ISR vector from the PIE. PIEIFRx.y is cleared.
11. The CPU branches to the ISR.

The interrupt latency is the time between PIEIFRx.y latching the interrupt and the first ISR instruction entering the execution stage of the CPU pipeline. The minimum interrupt latency is 14 SYSCLK cycles. Wait states on the ISR or stack memories will add to the latency. External interrupts add a minimum of two SYSCLK cycles for GPIO synchronization plus extra time for input qualification (if used). Loops created using the C28x RPT instruction cannot be interrupted.

2.4.4 Configuring and Using Interrupts

At power-up, no interrupts are enabled by default. The PIEIER and IER registers are cleared and INTM is set. The application code is responsible for configuring and enabling all peripheral interrupts.

2.4.4.1 Enabling Interrupts

To enable a peripheral interrupt, perform the following steps:

1. Disable interrupts globally (DINT or SETC INTM).
2. Enable the PIE by setting the ENPIE bit of the PIECTRL register.
3. Write the ISR vector for each interrupt to the appropriate location in the PIE vector table, which can be found in [Table 2-2](#).
4. Set the appropriate PIEIERx bit for each interrupt. The PIE group and channel assignments can be

found in [Table 2-2](#).

5. Set the CPU IER bit for any PIE group containing enabled interrupts.
6. Enable the interrupt in the peripheral.
7. Enable interrupts globally (EINT or CLRC INTM).

Step 4 does not apply to the Timer1 and Timer2 interrupts, which connect directly to the CPU.

2.4.4.2 Handling Interrupts

ISRs are similar to normal functions, but must do the following:

1. Save and restore the state of certain CPU registers (if used).
2. Clear the PIEACK bit for the interrupt group.
3. Return using the IRET instruction.

Requirements 1 and 3 are handled automatically by the TMS320C28x C compiler if the function is defined using the `__interrupt` keyword. For information on this keyword, see the Keywords section of the *TMS320C28x Optimizing C/C++ Compiler v6.2.4 User's Guide* ([SPRU514](#)). For information on writing assembly code to handle interrupts, see the Standard Operation for Maskable Interrupts section of the *TMS320C28x CPU and Instruction Set Reference Guide* ([SPRU430](#)).

The PIEACK bit for the interrupt group must be cleared manually in user code. This is normally done at the end of the ISR. If the PIEACK bit is not cleared, the CPU will not receive any further interrupts from that group. This does not apply to the Timer1 and Timer2 interrupts, which do not go through the PIE.

2.4.4.3 Disabling Interrupts

To disable all interrupts, set the CPU's global interrupt mask via DINT or SETC INTM. It is not necessary to add NOPs after setting INTM or modifying IER – the next instruction will execute with interrupts disabled.

Individual interrupts can be disabled using the PIEIERx registers, but care must be taken to avoid race conditions. If an interrupt signal is already propagating when the PIEIER write completes, it may reach the CPU and trigger a spurious interrupt condition. To avoid this, use the following procedure:

1. Disable interrupts globally (DINT or SETC INTM).
2. Clear the PIEIER bit for the interrupt.
3. Wait 5 cycles to make sure that any propagating interrupt has reached the CPU IFR register.
4. Clear the CPU IFR bit for the interrupt's PIE group.
5. Clear the PIEACK bit for the interrupt's PIE group.
6. Enable interrupts globally (EINT or CLRC INTM).

Interrupt groups can be disabled using the CPU IER register. This cannot cause a race condition, so no special procedure is needed.

PIEIFR bits must never be cleared in software since the read/modify/write operation may cause incoming interrupts to be lost. The only safe way to clear a PIEIFR bit is to have the CPU take the interrupt. The following procedure can be used to bypass the normal ISR:

1. Disable interrupts globally (DINT or SETC INTM).
2. Modify the PIE vector table to map the PIEIFR bit's interrupt vector to an empty ISR. This ISR will only contain a return from interrupt instruction (IRET).
3. Disable the interrupt in the peripheral registers.
4. Enable interrupts globally (EINT or CLRC INTM).
5. Wait for the pending interrupt to be serviced by the empty ISR.
6. Disable interrupts globally.
7. Modify the PIE vector table to map the interrupt vector back to its original ISR.
8. Clear the PIEACK bit for the interrupt's PIE group.
9. Enable interrupts globally.

2.4.4.4 Nesting Interrupts

By default, interrupts do not nest. It is possible to nest and prioritize interrupts via software control of the IER and PIEIERx registers. Documentation and example code can be found in controlSUITE and on the TI Processors wiki:

http://processors.wiki.ti.com/index.php/Interrupt_Nesting_on_C28x

2.4.5 PIE Channel Mapping

Table 2-2 shows the PIE group and channel assignments for each peripheral interrupt. Each row is a group, and each column is a channel within that group. When multiple interrupts are pending, the lowest-numbered channel is the lowest-numbered group is serviced first. Thus, the interrupts at the top of the table have the highest priority, and the interrupts at the bottom have the lowest priority.

Table 2-2. PIE Channel Mapping

	INTx.1	INTx.2	INTx.3	INTx.4	INTx.5	INTx.6	INTx.7	INTx.8	INTx.9	INTx.10	INTx.11	INTx.12	INTx.13	INTx.14	INTx.15	INTx.16

2.4.6 Vector Tables

Table 2-3 shows the CPU interrupt vector table. The vectors for INT1 – INT12 are not used in this device. The reset vector is fetched from the boot ROM instead of from this table.

Table 2-3. CPU Interrupt Vectors

Name	Vector ID	Address	Size (x16)	Description	Core priority	ePIE group Priority
Reset	0	0x0000 0D00	2	Reset is always fetched from location 0x003F_FFC0 in Boot ROM	1 (Highest)	-
INT1	1	0x0000 0D02	2	Not used. See PIE Group 1	5	-
INT2	2	0x0000 0D04	2	Not used. See PIE Group 2	6	-
INT3	3	0x0000 0D06	2	Not used. See PIE Group 3	7	-
INT4	4	0x0000 0D08	2	Not used. See PIE Group 4	8	-
INT5	5	0x0000 0D0A	2	Not used. See PIE Group 5	9	-
INT6	6	0x0000 0D0C	2	Not used. See PIE Group 6	10	-
INT7	7	0x0000 0D0E	2	Not used. See PIE Group 7	11	-
INT8	8	0x0000 0D10	2	Not used. See PIE Group 8	12	-
INT9	9	0x0000 0D12	2	Not used. See PIE Group 9	13	-
INT10	10	0x0000 0D14	2	Not used. See PIE Group 10	14	-
INT11	11	0x0000 0D16	2	Not used. See PIE Group 11	15	-
INT12	12	0x0000 0D18	2	Not used. See PIE Group 12	16	-
INT13	13	0x0000 0D1A	2	CPU TIMER1 Interrupt	17	-

2.5 Exceptions and Non-Maskable Interrupts

This section describes system-level error conditions that can trigger a non-maskable interrupt (NMI). The interrupt allows the application to respond to the error.

2.5.1 Configuring and Using NMIs

Each CPU has its own NMI module. An incoming NMI sets a status bit in the NMIFLG register and starts the NMI watchdog counter. This counter is clocked by the SYSCLK, and if it reaches the value in the NMIWDPRD register, it triggers an NMI watchdog reset (NMIWDRS). To prevent this, the NMI handler must clear the flag bit using the NMIFLGCLR register. Once all flag bits are clear, the NMIINT bit in the NMIFLG register may also be cleared to allow future NMIs to be taken.

The NMI module is enabled by the boot ROM during the startup process. To respond to NMIs, an NMI handler vector must be written to the PIE vector table.

2.5.2 Emulation Considerations

The NMI watchdog counter behaves as follows under debug conditions:

CPU Suspended	When the CPU is suspended, the NMI watchdog counter will be suspended.
Run-Free Mode	When the CPU is placed in run-free mode, the NMI watchdog counter will resume operation as normal.
Real-Time Single-Step Mode	When the CPU is in real-time single-step mode, the NMI watchdog counter will be suspended. The counter remains suspended even within real-time interrupts.
Real-Time Run-Free Mode	When the CPU is in real-time run-free mode, the NMI watchdog counter operates as normal.

2.5.3 NMI Sources

There are several types of hardware errors that can trigger an NMI. Additional information about the error is usually available from the module that detects it.

2.5.3.1 Missing Clock Detection

The missing clock detection logic monitors OSCCLK for failure. If the OSCCLK source stops, the PLL is bypassed, OSCCLK is connected to INTOSC1, and NMIs are fired to both CPUs. For more information on missing clock detection, see [Section 2.6.2](#).

2.5.3.2 RAM Uncorrectable ECC Error

A single-bit parity error, double-bit ECC data error, or single-bit ECC address error in a RAM read will trigger an NMI. This applies to CPU, CLA, and DMA reads. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on RAM error detection, see [Section 2.11.1.8](#).

2.5.3.3 Flash Uncorrectable ECC Error

A double-bit ECC data error or single-bit ECC address error in a flash read will trigger an NMI. Single-bit ECC data errors do not trigger an NMI, but can optionally trigger a normal peripheral interrupt. For more information on flash error detection, see [Section 2.12.10](#).

2.5.3.4 NMI Vector Fetch Mismatch

Each CPU's Peripheral Interrupt Expansion module (PIE) has redundant vector tables. If a mismatch in these tables is detected during a vector fetch, a user-specified error handler is run instead of the ISR. If the vector fetch was caused by an NMI, a second NMI is fired to the other CPU. Mismatches for other interrupts do not trigger an NMI. For more information about the vector address check, see [Section 2.6.4](#).

2.5.3.5 CPU2 Watchdog or NMI Watchdog Reset

A watchdog reset or NMI watchdog reset on CPU2 will trigger an NMI on CPU1. Since a CPU1 reset also resets CPU2, this NMI source is not available on CPU2.

Watchdog interrupts do not trigger an NMI.

2.5.4 Illegal Instruction Trap (ITRAP)

If the CPU tries to execute an illegal instruction, it generates a special interrupt called an illegal instruction trap (ITRAP). This interrupt is non-maskable and has its own vector in the PIE vector table. For more information about ITRAPs, see the Illegal-Instruction Trap section of the *TMS320C28x DSP CPU and Instruction Set Reference Guide* ([SPRU430](#)).

NOTE: A RAM fetch access violation will trigger an ITRAP in addition to the normal peripheral interrupt for RAM access violations. The CPU will handle the ITRAP first.

2.6 Safety Features

This section gives details on features that monitor device operation during run-time to detect any error in operation.

2.6.1 Write Protection on Registers

2.6.1.1 LOCK Protection on System Configuration Registers

Several system configuration registers are protected from spurious CPU writes by "LOCK" registers. Once these associated LOCK register bits are set the respective locked registers can no longer be modified by software. See specific register descriptions for details.

2.6.1.2 EALLOW Protection

Several control registers are protected from spurious CPU writes by the EALLOW protection mechanism. The EALLOW bit in status register 1 (ST1) indicates the state of protection as shown in Table 2-5.

Table 2-5. Access to EALLOW-Protected Registers

EALLOW Bit	CPU Writes	CPU Reads	JTAG Writes	JTAG Reads
0	Ignored	Allowed	Allowed ⁽¹⁾	Allowed
1	Allowed	Allowed	Allowed	Allowed

⁽¹⁾ The EALLOW bit is overridden via the JTAG port, allowing full access of protected registers during debug from the Code Composer Studio interface.

At reset, the EALLOW bit is cleared, enabling EALLOW protection. While protected, all writes to protected registers by the CPU are ignored and only CPU reads, JTAG reads, and JTAG writes are allowed. If this bit is set, by executing the EALLOW instruction, the CPU is allowed to write freely to protected registers. After modifying registers, they can once again be protected by executing the EDIS instruction to clear the EALLOW bit.

2.6.2 Missing Clock Detection Logic

The missing clock detect (MCD) logic detects OSCCLK failure, using INTOSC1 as the reference clock source. This circuit only detects complete loss of OSCCLK and doesn't do any detection of frequency drift on the OSCCLK.

This circuit monitors the OSCCLK (primary clock) using the 10 MHz clock provided by the INTOSC1 (secondary clock) as a backup clock. This circuit functions as below:

1. The primary clock (OSCCLK) clock keeps ticking a 7-bit counter (named as MCDPCNT). This counter is asynchronously reset with $\overline{XRS}$.
2. The secondary clock (INTOSC1) clock keeps ticking a 13-bit counter (named as MCDSCNT). This counter is asynchronously reset with $\overline{XRS}$.
3. Each time MCDPCNT overflows, the MCDSCNT counter is reset. Thus, if OSCCLK is present or not slower than INTOSC1 by a factor of 64, MCDSCNT will never overflow.
4. If OSCCLK stops for some reason, or is slower than INTOSC1 by at least a factor of 64, the MCDSCNT will overflow and a missing clock condition will be detected on OSCCLK.
5. The above check is continuously active, unless the MCD is disabled using MCDPCR register (by making the MCLKOFF bit 1)
6. If the circuit ever detects a missing OSCCLK, the following occurs:
 - The MCDSTS flag is set
 - The MCDSCNT counter is frozen to prevent further missing clock detection
 - The CLOCKFAIL signal goes high, which generates TRIP events to PWM modules and fires NMIs to CPU1.NMIWD and CPU2.NMIWD.
 - PLL is forcefully bypassed and OSCCLK is switched to INTOSC1 (after the PLLSYSCLK divider). PLLMULT is zeroed out automatically in this case.
 - While the MCDSTS bit is set, the OSCCLKSRCSEL bits have no effect and OSCCLK is forcefully connected to INTOSC1.
 - PLLRAWCLK going to the system is switched to INTOSC1 automatically
7. If the MCLKCLR bit is written (this is a W=1 bit), MCDSTS bit will be cleared and OSCCLK source will be decided by the OSCCLKSRCSEL bits. Writing to MCLKCLR will also clear the MCDPCNT and MCDSCNT counters to allow the circuit re-evaluate missing clock detection. If user wants to lock the PLL after missing clock detection, he needs to first switch the clock source to INTOSC1 (using OSCCLKSRCSEL register), do a MCLKCLR and re-lock the PLL.
8. The MCD is enabled at power up. There is no support for missing clock detection if INTOSC2 is failed from the device power-up.

Figure 2-3 shows the missing clock logic functional flow.

Figure 2-3. Missing Clock Detection Logic

2.6.3 PLLSLIP Detection

The PLL SLIP detection on this device can detect if the PLL reference clock goes too high or too slow while PLL is locked. An interrupt to both the CPUs is triggered as shown in the ePIE table in [Section 2.4](#). Apart from the interrupt to both the CPUs, the PLLSTS.SLIP bit is set for user software to check the error.

The SLIP detection is available on both SYSPLL and AUXPLL.

2.6.4 CPU1 and CPU2 PIE Vector Address Validity Check

The ePIE vector table on each CPU is duplicated into these two parts:

- Main ePIE Vector Table mapped from 0xD00 to 0xEFF in the C28x memory space
- Redundant ePIE Vector Table mapped from 0x1000D00 to 0x1000EFF in the C28x memory space

Following is the behavior of accesses to the ePIE memories:

- Data Writes to Main Vector Table: Writes to both memories
- Data Writes to Redundant Vector Table: Writes only to the Redundant Vector Table
- Vector Fetch: Data from both the vector tables are compared
- Data Read: Can read the Main and Redundant vector table separately

On every vector fetch from the ePIE, a hardware comparison (no cycle penalty is incurred to do the comparison) of both the vector table outputs is performed and if there is a mismatch between the two vector table outputs, the following occurs:

1. If the PIEVERRADDR register (default value 0x3F FFFF) is not initialized, the default error handler at address 0x3FFFBE gets executed.

But, when the PIEVERRADDR register is initialized to the address of the user-defined routine, the user-defined routine is executed instead of the default error handler.

Note: Each CPU has its own copy of the PIE Vector Fetch Error Handler register (CPU1.PIEVERRADDR and CPU2.PIEVERRADDR).

2. Hardware also generates EPWM Trip signals which will trip the PWM outputs using TRIPIN15.
3. An NMI to the other CPU is sent if the current mismatch is during a vector fetch. For example, on an NMI vector fetch error for CPU2, an NMI is also fired to CPU1.NMIWD.

If there is no mismatch, the correct vector is jammed onto the C28 program control.

2.6.5 NMIWDs

Each CPU has user-programmable NMIWD period registers, in which users can set a limit on how much time they want to allocate for the device to acknowledge the NMI. If the NMI is not acknowledged, it will cause a device reset.

2.6.6 ECC and Parity Enabled RAMs, Shared RAMs Protection

Each CPU subsystem has different RAM blocks. Few RAM blocks are ECC-enabled and others are parity-enabled. All single-bit errors in ECC RAM are auto-corrected and an error counter is incremented every time a single bit error is detected. If the error counter reaches a predefined user configured limit, an interrupt is generated to the corresponding CPU. Refer to [Section 2.11](#) for more details on RAM errors.

All uncorrectable double-bit errors end up triggering an NMI to corresponding CPUs.

2.6.7 ECC Enabled Flash Memory

When ECC is programmed and enabled, flash single-bit errors are corrected automatically by ECC logic before giving data to the CPU, but they are not corrected in flash memory. Flash memory will still contain wrong data until another erase/program operation happens to correct the flash contents. Irrespective of whether the error interrupt is enabled or disabled, single-bit errors are always corrected before giving data to the CPU. When the interrupt is disabled, users can check the single-bit error counter register for any single-bit error occurrences. The error counter stops incrementing once its value is equal to the threshold+1. It is always suggested to set the threshold register to a non-zero value so that the error counter can increment. It is up to the user to decide the threshold value at which they have to reprogram the flash with the correct data.

When ECC is programmed and enabled, flash uncorrectable errors end up triggering an NMI to the respective CPU. Please refer to [Section 2.11](#) for more details on flash error correction and error catching mechanisms.

2.6.8 ERRORSTS Pin

The ERRORSTS pin is an 'always output' pin and remains low until an error is detected inside the chip. On an error, the ERRORSTS pin goes high until the corresponding internal error status flag for that error source is cleared. [Figure 2-4](#) shows the functionality of the ERRORSTS pin.

The ERRORSTS pin will be tri-stated until the chip power rails ramp up to the lower operational limit. As the ERRORSTS pin is an active-high pin, users who care about the state of this pin during power-up should connect an external pull-down on this pin.

Figure 2-4. ERRORSTS Pin Diagram

2.7 Clocking

This section explains the clock sources and clock domains on this device, and how to configure them for application use. [Figure 2-5](#) provides an overview of the device's clocking system.

Figure 2-5. Clocking System

Note: The default/2 divider for ePWMs and EMIFs is not shown.

2.7.1 Clock Sources

All of the clocks in the device are derived from one of four clock sources.

2.7.1.1 Primary Internal Oscillator (INTOSC2)

At power-up, the device is clocked from an on-chip 10 MHz oscillator (INTOSC2). INTOSC2 is the primary internal clock source, and is the default system clock at reset. It is used to run the boot ROM and can be used as the system clock source for the application. Note that INTOSC2's frequency tolerance is too loose to meet the timing requirements for CAN and USB, so an external clock must be used to support those features.

2.7.1.2 Backup Internal Oscillator (INTOSC1)

The device also includes a redundant on-chip 10 MHz oscillator (INTOSC1). INTOSC1 is a backup clock source that normally only clocks the watchdog timers and missing clock detection circuit (MCD). If MCD is enabled and a missing system clock is detected, the system PLL is bypassed and all system clocks are connected to INTOSC1 automatically. INTOSC1 may also be manually selected as the system and auxiliary clock source for debug purposes.

2.7.1.3 External Oscillator (XTAL)

The dedicated X1 and X2 pins support an external clock source (XTAL), which can be used as the main system and auxiliary clock source. Frequency limits and timing requirements can be found in the device datasheet. Three types of external clock sources are supported:

- A single-ended 3.3V external clock. The clock signal should be connected to X1 while X2 is left unconnected, as shown in [Figure 2-6](#).

Figure 2-6. Single-ended 3.3V External Clock

- An external crystal. The crystal should be connected across X1 and X2 with its load capacitors connected to VSSOSC as shown in [Figure 2-7](#).

Figure 2-7. External Crystal

- An external resonator. The resonator should be connected across X1 and X2 with its ground connected to VSSOSC as shown in [Figure 2-8](#).

Figure 2-8. External Resonator

2.7.1.4 Auxiliary Clock Input (AUXCLKIN)

An additional external clock source is supported on GPIO133 (AUXCLKIN). This must be a single-ended 3.3V external clock. It can be used as the source for the USB and CAN bit clocks. Frequency limits and timing requirements can be found in the device datasheet. The external clock should be connected directly to the GPIO133 pin, as shown in [Figure 2-9](#).

Figure 2-9. AUXCLKIN

2.7.2 Derived Clocks

The clock sources discussed in the previous section can be multiplied (via PLL) and divided down to produce the desired clock frequencies for the application. This process produces a set of derived clocks, which are described in this section.

2.7.2.1 Oscillator Clock (OSCCLK)

One of INTOSC2, XTAL, or INTOSC1 must be chosen to be the master reference clock (OSCCLK) for the CPU and most of the peripherals. OSCCLK may be used directly or fed through the system PLL to reach a higher frequency. At reset, OSCCLK is the default system clock, and is connected to INTOSC2.

2.7.2.2 System PLL Output Clock (PLLRAWCLK)

The system PLL allows the device to run at its maximum rated operating frequency, and in most applications will generate the main system clock. This PLL uses OSCCLK as a reference, and features a fractional multiplier and slip detection. For configuration instructions, see [Section 2.7.6](#).

2.7.2.3 Auxiliary Oscillator Clock (AUXOSCCLK)

One of INTOSC2, XTAL, or AUXCLKIN may be chosen to be the auxiliary reference clock (AUXOSCCLK) for the USB module. (This selection does not affect the CAN bit clock, which uses AUXCLKIN directly). AUXOSCCLK may be used directly or fed through the auxiliary PLL to reach a higher frequency. At reset, AUXOSCCLK is connected to INTOSC2, but only an external oscillator can meet the USB timing requirements.

2.7.2.4 Auxiliary PLL Output Clock (AUXPLLRAWCLK)

The auxiliary PLL is used to generate a 60 MHz clock for the USB module. This PLL uses AUXOSCCLK as a reference, and features a fractional multiplier and slip detection. For configuration instructions, see [Section 2.7.6](#).

2.7.3 Device Clock Domains

The device clock domains feed the clock inputs of the various modules in the device. They are connected to the derived clocks, either directly or through an additional divider.

2.7.3.1 System Clock (PLLSYSCLK)

The system control registers, GS RAMs, IPC module, GPIO qualification, and NMI watchdog timers have their own clock domain (PLLSYSCLK). Despite the name, PLLSYSCLK may be connected to the system PLL (PLLRAWCLK) or to OSCCLK. The chosen clock source is run through a frequency divider, which is configured via the SYSCLKDIVSEL register. PLLSYSCLK is gated in HALT mode.

2.7.3.2 CPU Clock (CPUCLK)

Each CPU has its own clock (CPU1.CPUCLK and CPU2.CPUCLK) which is used to clock the CPU, its coprocessors, its private RAMs (M0, M1, D0, and D1), and its boot ROM and flash wrapper. This clock is identical to PLLSYSCLK, but is gated when the CPU enters IDLE, STANDBY, or HALT mode.

2.7.3.3 CPU Subsystem Clock (SYSCLK and PERx.SYSCLK)

Each CPU provides a clock (CPU1.SYSCLK and CPU2.SYSCLK) to its CLA, DMA, and most owned peripherals. This clock is identical to PLLSYSCLK, but is gated when the CPU enters STANDBY or HALT mode.

Each peripheral clock can be connected to either CPU1.SYSCLK or CPU2.SYSCLK. This selection is made by CPU1 via the CPUSELx registers. Each peripheral clock also has its own independent clock gating which is controlled by the CPU's PCLKCRx registers. By default, the ePWM, EMIF1, and EMIF2 clocks each have an additional /2 divider, which is required to support CPU frequencies over 100 MHz. At slower CPU frequencies, these dividers can be disabled via the PERCLKDIVSEL register.

2.7.3.4 Low-Speed Peripheral Clock (LSPCLK and PERx.LSPCLK)

The SCI, SPI, and McBSP modules can communicate at bit rates that are much slower than the CPU frequency. These modules are connected to a shared clock divider, which generates a low-speed peripheral clock (LSPCLK) derived from SYSCLK. LSPCLK uses a /4 divider by default, but the ratio can be changed via the LOSPCP register. Each SCI, SPI, and McBSP module's clock (PERx.LSPCLK) can be gated independently via the PCLKCRx registers.

2.7.3.5 USB Auxiliary Clock (AUXPLLCLK)

The USB module requires a fixed 60 MHz clock for bit sampling. Since the main system clock is usually not a multiple of 60 MHz, the correct frequency cannot be achieved with a simple divider. Instead, the USB clock is provided through an auxiliary clock path (AUXPLLCLK), which can use an independent clock source and PLL to generate the correct frequency.

USB clock tolerances are very tight. As stated in section 7.1.11 of the USB 2.0 specification, low-speed devices (1.50 Mb/s) have a tolerance of +/- 1.5% , while high-speed devices (12.000 Mb/s) have a tolerance of +/- 0.25%. Typically these tolerances are achieved by using an external crystal or resonator as the source for AUXOSCCLK.

2.7.3.6 CAN Bit Clock

The required frequency tolerance for the CAN bit clock depends on the bit timing setup and network configuration, and can be as tight as 0.1%. Since the main system clock (in the form of PERx.SYSCLK) may not be precise enough, the bit clock can also be connected to XTAL or AUXCLKIN via the CLKSRCCTL2 register. There is an independent selection for each CAN module.

2.7.3.7 CPU Timer2 Clock (TIMER2CLK)

CPU timers 0 and 1 are connected to PERx.SYSCLK. Timer 2 is connected to PERx.SYSCLK by default, but may also be connected to INTOSC1, INTOSC2, XTAL, or AUXPLLCLK via the TMR2CLKCTL register. This register also provides a separate prescale divider for timer 2. If a source other than SYSCLK is used, the SYSCLK frequency must be at least twice the source frequency to ensure correct sampling. Each CPU has its own independent CPU timers and TMR2CLKCTL register.

The main reason to use a non-SYSCLK source would be for internal frequency measurement. In most applications, timer 2 will run off of the SYSCLK.

2.7.4 XCLKOUT

It is sometimes necessary to observe a clock directly for debug and testing purposes. The external clock output (XCLKOUT) feature supports this by connecting a clock to an external pin, GPIO73. The available clock sources are PLLSYSCLK, PLLRAWCLK, CPU1.SYSCLK, CPU2.SYSCLK, AUXPLLRAWCLK, INTOSC1, and INTOSC2.

To use XCLKOUT, first select the clock source via the CLKSRCCTL3 register. Next, select the desired output divider via the XCLKOUTDIVSEL register. Finally, connect GPIO73 to mux channel 3 using the GPIO configuration registers.

2.7.5 Clock Connectivity

The tables below provide details on the clock connections of every module present in the device.

Table 2-6. Clock Connections Sorted by Clock Domain

Clock Domain	CPU1 Subsystem	CPU2 Subsystem	Shared Modules
CPUx.CPUCLK	CPU1 CPU1.VCU CPU1.FPU CPU1.TMU CPU1.M0 - M1 RAMs CPU1.D0 - D1 RAMs CPU1.BootROM CPU1.Flash	CPU2 CPU2.VCU CPU2.FPU CPU2.TMU CPU2.M0 - M1 RAMs CPU2.D0 - D1 RAMs CPU2.BootROM CPU2.Flash

Watchdog Timer	WDCLK (INTOSC1)

2.7.6 Clock Source and PLL Setup

The needs of the application are what ultimately determine the clock configuration. Specific concerns such as application performance, power consumption, total system cost, and EMC are beyond the scope of this document, but they should provide answers to the following questions:

1. What is the desired CPU frequency?
2. Is CAN required?
3. Is USB required?
4. What types of external oscillators or clock sources are available?

If CAN or USB is required, an external clock source with a precise frequency must be used as a reference clock. Otherwise, it may be possible to use only INTOSC2 and avoid the need for more external components.

2.7.6.1 Choosing PLL Settings

There are two settings to configure for each PLL – a multiplier and a divider. They obey the formulas:

$$f_{\text{PLLSYSCLK}} = f_{\text{OSCCLK}} * (\text{SYSPLLMULT.IMULT} + \text{SYSPLLMULT.FMULT}) / \text{SYSCLKDIVSEL.PLLSYSCLKDIV}$$

$$f_{\text{AUXPLLCLK}} = f_{\text{AUXOSCCLK}} * (\text{AUXPLLMULT.IMULT} + \text{AUXPLLMULT.FMULT}) / \text{AUXCLKDIVSEL.AUXPLLDIV}$$

where f_{OSCCLK} is the system oscillator clock frequency, $f_{\text{AUXOSCCLK}}$ is the auxiliary oscillator clock frequency, IMULT and FMULT are the integral and fractional parts of the multipliers, PLLSYSCLKDIV is the system clock divider, and AUXPLLDIV is the auxiliary clock divider. For the permissible values of the multipliers and dividers, see the documentation for their respective registers.

Many combinations of multiplier and divider can produce the same output frequency. However, the product of the reference clock frequency and the multiplier (known as the VCO frequency) must be in the range specified in the data manual.

NOTE: The system clock frequency (PLLSYSCLK) may not exceed the limit specified in the datasheet. This limit does not allow for oscillator tolerance.

The clock source and PLL configuration registers are shared between the two CPUs. Register access is controlled via a semaphore, which is described in the *Inter-Processor Communication* chapter.

2.7.6.2 System Clock Setup

Once the application requirements are understood, a specific clock configuration can be determined. The default configuration is for INTOSC2 to be used as the system clock (PLLSYSCLK) with a divider of 1. The following procedure should be used to set up the desired application configuration:

1. Select the reference clock source (OSCCLK) by writing to CLKSRCCTL1.OSCCLKSRCSEL.
2. Set up the system PLL: (see the InitSysPll() function in your devices controlSUITE installation for an example):
 - a. Bypass the PLL by clearing SYSPLLCTL1[PLLCLKEN].
 - b. Set the system clock divider to /1 to ensure the fastest PLL configuration by clearing SYSCLKDIVSEL[PLLSYSCLKDIV].
 - c. Set the integral and fractional multipliers by simultaneously writing them both to SYSPLLMULT. This will automatically enable the PLL. Be sure that the product of OSCCLK and the multiplier is in the range specified in the data manual.
 - d. Lock the PLL five times (see your device errata for details). This number can be increased depending on application requirements. A higher number of lock attempts helps to ensure a successful PLL start
 - e. Set the system clock divider one setting higher than the final desired value. For example ClkCfgRegs.SYSCLKDIVSEL.bit.PLLSYSCLKDIV = divsel + 1. This limits the current increase when switching to the PLL.
 - f. Set up the watchdog to reset the device. Note that the SCRS[WDOVERRIDE] bit should not be cleared prior to locking the PLL.
 - g. Set the SYSDBGCTL[BIT_0] bit. This bit is only reset by a POR reset. If the watchdog has to reset the device due to an issue with switching to the PLL, this bit can be checked in the reset handler to determine the reset was caused by a PLL error.
 - h. Switch to the PLL as the system clock by setting SYSPLLCTL1[PLLCLKEN].
 - i. Clear the SYSDBGCTL[BIT_0] bit.
 - j. Change the divider to the appropriate value.
 - k. Reconfigure the watchdog as needed for the application.

NOTE: If the CPU2 changes the OSCCLK source, it will not automatically bypass the PLL. The CPU2 must manually bypass the PLL first by writing a 0 to SYSPLLCTL1.PLLCLKEN.

2.7.6.3 USB Auxiliary Clock Setup

See the InitAuxPll() function in your device's controlSUITE installation for an example.

If USB functionality is needed, the auxiliary clock (AUXPLLCLK) must be configured to produce 60 MHz. The procedure is similar to the system clock setup:

1. Select the reference clock source (AUXOSCCLK) by writing to CLKSRCCTL2.AUXOSCCLKSRCSEL.
2. Wait two AUXOSCCLK cycles.
3. Set up the auxiliary PLL. If the PLL is not needed, bypass it and power it down by writing a 0 to AUXPLLCTL1.PLEN. To use the PLL:
 - a. Set the desired auxiliary clock divider by writing to AUXCLKDIVSEL.AUXPLLDIV.
 - b.) Configure CPU Timer 2 to be clocked from AUXPLL. Keep the counter frozen.
 - c.) Power down the AUXPLL by clearing AUXPLLCTL1[PLEN].
 - d. Set the integral and fractional multipliers simultaneously. This will automatically enable the PLL. Be sure that the product of AUXOSCCLK and the multiplier is in the range specified in the data manual..
 - e. Wait for the PLL to lock by polling the AUXPLLSTS.LOCKS bit. This will take 16 μ s plus 1024 AUXOSCCLK cycles.
 - f. Connect the auxiliary PLL output clock (AUXPLLRAWCLK) to AUXPLLCLK by writing a 1 to AUXPLLCTL1.PLLCLKEN.
 - g. Start CPU Timer 2. In a large for() loop, continue polling the TCR[TIF] overflow flag. If it sets, the AUXPLL started correctly. If not, repeat steps (c) through (g). The auxiliary clock configuration can be changed at run time. Changing the AUXOSCCLK source will automatically bypass the PLL and set the multiplier to zero. Changing the multiplier from one non-zero value to another will temporarily bypass the PLL until it re-locks.

The auxiliary clock configuration can be changed at run time. Changing the AUXOSCCLK source will automatically bypass the PLL and set the multiplier to zero. Changing the multiplier from one non-zero value to another will temporarily bypass the PLL until it re-locks.

NOTE: If the AUXOSCCLK source is changed on the same AUXOSCCLK cycle as the multiplier, the PLL will be disabled but the AUXPLLMULT register will show the written value. This can happen when the system PLL is enabled before configuring the auxiliary PLL (CPUCLK >> AUXOSCCLK). To avoid this issue, wait two AUXOSCCLK cycles between changing the clock source and writing to AUXPLLMULT.

2.7.6.4 Clock Configuration Examples

Example 1: Using a crystal (15 MHz) as a reference, generate a CPU frequency of 100 MHz and a USB clock of 60 MHz:

```
CLKSRCCTL1.OSCCLKSRCSEL = 0x1
SYSPLLMULT.IMULT = 26 (0x1A)
SYSPLLMULT.FMULT = .50 (0x2)
SYSCLKDIVSEL.PLLSYSCLKDIV = 4 (0x2)
SYSPLLCTL1.PLLCLKEN = 1
PERCLKDIVSEL.EPWMCLKDIV = 1 (0x0)
PERCLKDIVSEL.EMIF1CLKDIV = 1 (0x0)
PERCLKDIVSEL.EMIF2CLKDIV = 1 (0x0)
CLKSRCCTL2.AUXOSCCLKSRCSEL = 0x1
```

```
AUXPLLMULT.IMULT = 8 (0x08)
AUXPLLMULT.FMULT = .00 (0x0)
AUXCLKDIVSEL.AUXPLLDIV = 2 (0x1)
AUXPLLCTL1.PLLCLKEN = 1
```

This gives a PLLRAWCLK of 397.5 MHz and an AUXPLLRAWCLK of 120 MHz, both of which are in the acceptable range. The CPU frequency is 99.375 MHz. Crystals have tight frequency tolerances, which should keep the system clock from exceeding 100 MHz. The USB frequency is exactly 60 MHz. Since the CPU frequency is less than 100 MHz, the ePWM and EMIF clock dividers can be set to /1.

Example 2: Using INTOSC2 (10 MHz) as a reference, generate a CPU frequency of 200 MHz - 3%:

```
CLKSRCCTL1.OSCCLKSRCSEL = 0x0
SYSPLLMULT.IMULT = 38 (0x26)
SYSPLLMULT.FMULT = .75 (0x3)
SYSCLKDIVSEL.PLLSYSCLKDIV = 2 (0x1)
SYSPLLCTL1.PLLCLKEN = 1
```

2.8 32-Bit CPU Timers 0/1/2

This section describes the three 32-bit CPU-Timers (TIMER0/1/2) shown in [Figure 2-10](#).

CPU-Timer0 and CPU-Timer1 can be used in user applications. CPU-Timer2 is reserved for real-time operating system uses (for example, TI-RTOS). If the application is not using an operating system that utilizes this timer, then CPU-Timer2 can be used in the application. CPU-Timer0 and CPU-Timer1 run off of SYSCLK. CPU-Timer2 normally runs off of SYSCLK, but can also use INTOSC1, INTOSC2, XTAL, and AUXPLLCLK. The CPU-Timer interrupt signals (TINT0, TINT1, TINT2) are connected as shown in [Figure 2-11](#).

Figure 2-11. CPU-Timer Interrupts Signals and Output Signal

- A The timer registers are connected to the memory bus of the C28x processor.
- B The CPU Timers are synchronized to SYSCLKOUT.

The general operation of the CPU-Timer is as follows:

- The 32-bit counter register, TIMH:TIM, is loaded with the value in the period register PRDH:PRD
- The counter decrements once every (TPR[TDDRH:TDDR]+1) SYSCLKOUT cycles, where TDDRH:TDDR is the timer divider.
- When the counter reaches 0, a timer interrupt output signal generates an interrupt pulse.

The registers listed in [Section 2.15](#) are used to configure the timers.

2.9 Watchdog Timers

The watchdog module generates an output pulse 512 watchdog clocks (WDCLKs) wide whenever the 8-bit watchdog up counter has reached its maximum value. The watchdog clock source is INTOSC1. Software must periodically write a 0x55 + 0xAA sequence into the watchdog key register to reset the watchdog counter. The counter can also be disabled. Figure 2-12 shows the various functional blocks within the watchdog module.

Figure 2-12. CPU Watchdog Timer Module

2.9.1 Servicing the Watchdog Timer

The watchdog counter (WDCNTR) is reset when the proper sequence is written to the WDKEY register before the 8-bit watchdog counter overflows. The WDCNTR is reset-enabled when a value of 0x55 is written to the WDKEY. When the next value written to the WDKEY register is 0xAA, then the WDCNTR is reset. Any value written to the WDKEY other than 0x55 or 0xAA causes no action. Any sequence of 0x55 and 0xAA values can be written to the WDKEY without causing a system reset; only a write of 0x55 followed by a write of 0xAA to the WDKEY resets the WDCNTR.

Table 2-8. Example Watchdog Key Sequences

Step	Value Written to WDKEY	Result
1	0xAA	No action
2	0xAA	No action
3	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
4	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
5	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
6	0xAA	WDCNTR is reset.
7	0xAA	No action
8	0x55	WDCNTR is enabled to be reset if next value is 0xAA.

Table 2-8. Example Watchdog Key Sequences (continued)

Step	Value Written to WDKEY	Result
9	0xAA	WDCNTR is reset.
10	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
11	0x32	Improper value written to WDKEY. No action, WDCNTR no longer enabled to be reset by next 0xAA.
12	0xAA	No action due to previous invalid value.
13	0x55	WDCNTR is enabled to be reset if next value is 0xAA.
14	0xAA	WDCNTR is reset.

Step 3 in Table 2-8 is the first action that enables the WDCNTR to be reset. The WDCNTR is not actually reset until step 6. Step 8 again re-enables the WDCNTR to be reset and step 9 resets the WDCNTR. Step 10 again re-enables the WDCNTR to be reset. Writing the wrong key value to the WDKEY in step 11 causes no action, however the WDCNTR is no longer enabled to be reset and the 0xAA in step 12 now has no effect.

If the watchdog is configured to reset the device, then a WDCR overflow or writing the incorrect value to the WDCR[WDCHK] bits will reset the device and set the watchdog flag (WDRSn) in the reset cause register (RESC). After a reset, the program can read the state of this flag to determine whether the reset was caused by the watchdog. After doing this, the program should clear WDRSn to allow subsequent watchdog resets to be detected. Watchdog resets are not prevented when the flag is set.

2.9.2 Minimum Window Check

To complement the timeout mechanism, the watchdog also contains an optional "windowing" feature that requires a minimum delay between counter resets. This can help protect against error conditions that bypass large parts of the normal program flow but still include watchdog handling.

To set the window minimum, write the desired minimum watchdog count to the WDWCR register. This value will take effect after the next WDKEY sequence. From then on, any attempt to service the watchdog when WDCNTR is less than WDWCR will trigger a watchdog interrupt or reset. When WDCNTR is greater than or equal to WDWCR, the watchdog can be serviced normally.

At reset, the window minimum is zero, which disables the windowing feature.

2.9.3 Watchdog Reset or Watchdog Interrupt Mode

The watchdog can be configured in the SCSR register to either reset the device ($\overline{\text{WDRST}}$) or assert an interrupt ($\overline{\text{WDINT}}$) if the watchdog counter reaches its maximum value. The behavior of each condition is described below:

- **Reset mode:**

If the watchdog is configured to reset the device, then the $\overline{\text{WDRST}}$ signal will pull the device reset ($\overline{\text{XRS}}$) pin low for 512 OSCCLK cycles when the watchdog counter reaches its maximum value.

Note: After a CPU1 watchdog reset, the boot ROMs will clear all of the system and message RAMs on both CPUs. After a CPU2 watchdog reset, CPU2's boot ROM will clear all of the CPU2 system and message RAMs.

- **Interrupt mode:**

When the watchdog counter expires, it will assert an interrupt by driving the $\overline{\text{WDINT}}$ signal low for 512 OSCCLK cycles. The falling edge of $\overline{\text{WDINT}}$ triggers a WAKEINT interrupt in the PIE if it is enabled. Because the PIE is edge-triggered, re-enabling the WAKEINT while $\overline{\text{WDINT}}$ is active will not produce a duplicate interrupt.

To avoid unexpected behavior, software should not change the configuration of the watchdog while $\overline{\text{WDINT}}$ is active. For example, changing from interrupt mode to reset mode while $\overline{\text{WDINT}}$ is active will immediately reset the device. Disabling the watchdog while $\overline{\text{WDINT}}$ is active will cause a duplicate interrupt if the watchdog is later re-enabled. If a debug reset is issued while $\overline{\text{WDINT}}$ is active, the reset cause register (RESC) will show a watchdog reset. The WDINTS bit in the SCSR register can be read to determine the current state of $\overline{\text{WDINT}}$.

2.9.4 Watchdog Operation in Low Power Modes

In IDLE mode, the watchdog interrupt ($\overline{\text{WDINT}}$) signal can generate an interrupt to the CPU to take the CPU out of IDLE mode. As with any other peripheral, the watchdog interrupt will trigger a WAKEINT interrupt in the PIE during IDLE mode. User software must determine which peripheral caused the interrupt.

In STANDBY mode, all of the clocks to the peripherals are turned off within the CPU subsystem. The only peripheral that remains functional is the watchdog since the watchdog module runs off the oscillator clock (OSCCLK). The $\overline{\text{WDINT}}$ signal is fed to the Low Power Modes (LPM) block so that it can be used to wake the CPU from STANDBY low power mode. This feature is enabled by setting LPMCR.WDINTE = 1. See [Section 2.10](#) for details.

Note: If the watchdog interrupt is used to wake-up from an IDLE or STANDBY low power mode condition, software must make sure that the $\overline{\text{WDINT}}$ signal goes back high before attempting to reenter the IDLE or STANDBY mode. The $\overline{\text{WDINT}}$ signal will be held low for 512 OSCCLK cycles when the watchdog interrupt is generated. The current state of $\overline{\text{WDINT}}$ can be determined by reading the watchdog interrupt status bit (WDINTS) bit in the SCSR register. WDINTS follows the state of $\overline{\text{WDINT}}$ by two SYSCLKOUT cycles.

In HALT mode, the internal oscillators and CPU1 watchdog are kept active if the user sets CLKSRCCTL1.WDHALTI = 1. A watchdog reset can wake the system from HALT mode, but a watchdog interrupt cannot.

2.9.5 Emulation Considerations

The watchdog module behaves as follows under various debug conditions:

CPU Suspended:	When the CPU is suspended, the watchdog clock (WDCLK) is suspended
Run-Free Mode:	When the CPU is placed in run-free mode, then the watchdog module resumes operation as normal.
Real-Time Single-Step Mode:	When the CPU is in real-time single-step mode, the watchdog clock (WDCLK) is suspended. The watchdog remains suspended even within real-time interrupts.
Real-Time Run-Free Mode:	When the CPU is in real-time run-free mode, the watchdog operates as normal.

2.10 Low Power Modes

This device has three clock-gating, low-power modes and a special power-gating mode. All low-power modes are entered by setting the LPMCR register and executing the IDLE instruction. More information about this instruction can be found in the *TMS320C28x CPU and Instruction Set Reference Guide (SPRU430)*.

Low-power modes should not be entered into while a flash program or erase is ongoing.

The application should verify the following before entering STANDBY or HALT Mode:

1. Check the value of the GPIODAT register of the pin selected for STANDBY or HALT wake-up (GPIOLPMSEL0/1) prior to entering the Low-Power mode to ensure that the wake event has not already been asserted.
2. The LPMCR.QUALSTDBY register should be set to a value greater than the ratio of INTOSC1/PLLSYSCLK to ensure proper wake up. This is applicable to STANDBY only.

2.10.1 IDLE

IDLE is a standard feature of the C28x CPU. In this mode, the CPU clock is gated while all peripheral clocks are left running. IDLE can thus be used to conserve power while a CPU is waiting for peripheral events. When one CPU is in IDLE, there is no effect on the other CPU subsystem.

Any enabled interrupt will wake the CPU up from IDLE mode.

To enter IDLE mode, set LPMCR.LPM to 0x0 and execute the IDLE instruction.

2.10.2 STANDBY

STANDBY is a more aggressive low-power mode that gates both the CPU clock and any peripheral clocks derived from the CPU's SYSCLK. The watchdog however, is left active. Like IDLE, this mode affects only one CPU subsystem. The other CPU subsystem and all of its peripherals are unaffected. STANDBY is best suited for an application where the wake-up signal will come from an external system (or CPU subsystem) rather than a peripheral input.

IPC interrupt 1 (flag 0), an NMI fired to the other CPU, or (optionally) a watchdog interrupt, will wake the CPU subsystem up from STANDBY mode. Any of GPIO0-63 can also be configured to wake up the subsystem when they are driven active low. Upon wakeup, the CPU receives a WAKEINT interrupt, even if it was woken by an IPCINT1 signal.

To enter STANDBY mode:

1. Set LPMCR.LPM to 0x1.
2. Enable the WAKEINT interrupt in the PIE.
3. For watchdog interrupt wakeup, set LPMCR.WDINTE to 1 and configure the watchdog to generate interrupts.
4. For GPIO wakeup, set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module, and set LPMCR.QUALSTDBY to select the number of OSCCLK cycles for input qualification.
5. Execute the IDLE instruction to enter STANDBY.

To wake up from Standby mode:

1. Configure the desired GPIO to trigger the wakeup.
2. Drive the selected GPIO signal low; it must remain low for the number of OSCCLK cycles specified in the QUALSTDBY bits in the LPMCR register. If the signal is sampled high during this period, the count restarts.

At the end of the qualification period, the PLL enables the CLKIN to the CPU and the WAKEINT interrupt is latched in the PIE block. The WAKEINT interrupt can also be triggered by IPCINT1 sent from the other CPU and a watchdog interrupt.

The CPU is now out of STANDBY mode and can resume normal execution.

If CPU2 is in STANDBY mode, writing a 1 to the RESET bit of the CPU2RESCTL register will have no effect. CPU2 may be reset by any Chip-level reset (POR, XRSn, CPU1.WDRSn, or CPU1.NMIWDRSn) or HIBRESETn. Alternately CPU2 may be woken up by any configured wake-up event.

If CPU2 is in STANDBY mode and the debugger is connected, executing a debug reset on CPU2 will have no effect. In order to wake the CPU2 with the debugger, Click Run, Single Step, or Step over in the Debug toolbar. CCS will prompt the user requesting to bring the CPU out of the low-power mode. Click Yes. This will wake CPU2 from STANDBY and continue execution.

2.10.3 HALT

HALT is a global low-power mode that gates almost all system clocks and allows for power-down of oscillators and analog blocks. This mode affects both CPU subsystems. HALT can be used for additional power savings over putting both CPU subsystems in STANDBY, although the options for wakeup are more limited.

Similar to STANDBY, any of GPIO0-63 can be configured to wake up the system from HALT. No other wakeup option is available. However, CPU1's watchdog may still be clocked, and can be configured to produce a watchdog reset if a timeout mechanism is needed. On wakeup, both CPUs receive a WAKEINT interrupt.

To enter HALT mode:

1. Disable all interrupts with the exception of the WAKEINT interrupt on both CPUs. The other interrupts can be reenabled after the device is brought out of HALT mode.
2. Put CPU2 into IDLE mode. (Using STANDBY will cause a duplicate WAKEINT on CPU2). CPU1 should verify this by checking the LPMSTAT register.
3. Set LPMCR.LPM to 0x2. Set GPIOLPMSEL0 and GPIOLPMSEL1 to connect the chosen GPIOs to the LPM module.
4. Set CLKSRCCTL1.WDHALTI to 1 to keep the CPU1 watchdog active and INTOSC1 and INTOSC2 powered up in HALT.
5. Set CLKSRCCTL1.WDHALTI to 0 to disable the CPU1 watchdog and power down INTOSC1 and INTOSC2 in HALT.
6. Execute the IDLE instruction on CPU1 to enter HALT.

If an interrupt or NMI is received while the IDLE instruction is in the pipeline, the system will begin executing the WAKEINT ISR. After HALT wakeup, ISR execution will resume where it left off.

NOTE: Before entering HALT mode, if the system PLL is locked (SYSPLL.LOCKS = 1), it must also be connected to the system clock (PLLCTL1.PLLCLKEN = 1). Otherwise, the device will never wake up.

To wake up from HALT mode:

1. Drive the selected GPIO low for a minimum 5us. This will activate the CPU1.WAKEINT and CPU2.WAKEINT PIE interrupts.
2. Drive the wake-up GPIO high again to initiate the powering up of the SYSPLL and AUXPLL.
3. Wait 16us plus 1024 OSCCLK cycles to allow the PLLs to lock and the WAKEINT ISR to be latched.
4. Execute the WAKEINT ISR.

The device is now out of HALT mode and can resume normal execution.

2.10.4 HIB

Hibernate (HIB) is a global low-power mode that gates the supply voltages to most of the system. This mode affects both CPU subsystems. HIB is essentially a controlled power-down with remote wakeup capability, and can be used to save power during long periods of inactivity. Because gating the supply voltage corrupts the state of the logic, a reset is required to exit HIB. To prevent external systems from being affected by the reset, HIB provides isolation of the I/O pin states as well as low-power data retention via the M0 and M1 memories.

Unlike the clock-gating modes, HIB does not have a true wakeup. Instead, GPIO41 becomes $\overline{\text{HIBWAKE}}$, an asynchronous reset signal. When the boot ROM detects a HIB wakeup, it will avoid clearing M0 and M1 and call a user-specified I/O restore function. To prevent glitches on internal and external signals, $\overline{\text{XRS}}$ will also generate a $\overline{\text{HIBWAKE}}$ signal during HIB. The I/O restore function should set up the GPIO control registers to match their pre-HIB state, then write a 1 to LPMCR.IOISODIS to deactivate I/O isolation. If the restore function does not disable isolation, the boot ROM will do it.

To enter HIB mode:

1. Save any necessary state to the M0 and M1 memories of both CPUs.
2. Put all I/Os in the desired state for isolation and deactivate any analog modules in use.
3. Write the address of the I/O restore function for each CPU to its IORESTOREADDR register.
4. Put CPU2 in reset, IDLE, or STANDBY.
5. Bypass the PLL by setting PLLCLKEN to 0.
6. Set CPU1's LPMCR.LPM to 0x3 and execute the IDLE instruction.

Any debugger connection will be lost on HIB entry since the JTAG logic is powered down.

Due to the loss of system state on HIB entry, it is possible for error information to be lost if an NMI is triggered while the IDLE instruction is in the pipeline. The ERRORSTS pin will be set and remain set until I/O isolation is disabled, but there will be no way to tell what caused the error.

To wake the device from HIB mode:

1. Assert the dedicated $\overline{\text{GPIOHIBWAKE}}$ pin (GPIO41) low to enable the power-up of the device clock sources.
2. Assert $\overline{\text{GPIOHIBWAKE}}$ pin high again. This triggers the power-up of the rest of the device.
3. Boot ROM code will execute on HIB wake-up. Boot ROM will read CPU1.RESC.HIBRESTn bit to determine this is a wakeup from HIB.
4. Boot ROM calls the I/O context restore routine. This I/O restore function should reconfigure the I/O configuration and do any other necessary application setup.

Since waking up from HIB mode is a type of reset, the device will enter the main function. The device is now out of HIB mode and can normal execution.

NOTE: The bootROM uses locations 0x02-0x122 on CPU1's M0 RAM and locations 0x02-0x80 on CPU2's M0 RAM. To prevent losing any data during HIB wake-up, avoid saving any critical data to these locations.

NOTE: The application must bypass the PLL before executing the IDLE instruction to enter HIB. If the PLL is not bypassed when entering HIB, there will be a brief current spike on the Vdd supply that may cause the device to reset.

2.11 Memory Controller Module

For these devices, the RAMs have different characteristics. Some are:

- dedicated to each CPU (M0, M1, and Dx RAMs),
- shared between the CPU and its own CLA (LSx RAM),
- shared between the CPU and DMA of both subsystems (GSx RAM), and
- used to send and receive messages between processors (MSGRAM).

All these RAMs are highly configurable to achieve control for write access and fetch access from different masters. There are also RAMs - called IPC MSGRAMs - that are used for interprocessor communication. All dedicated RAMs are enabled with the ECC feature (both data and address) and shared RAMs, as well as IPC MSGRAMs, are enabled with the PARITY (both data and address) feature. Some of the dedicated memories are secure memory as well. Refer to [Section 2.13](#) for more details. Each RAM has its own controller which takes care of the access protection/security related checks and ECC/Parity features for that RAM. [Figure 2-13](#) shows the configuration of these RAMs.

Figure 2-13. Memory Architecture

NOTE: All RAMs on these devices are SRAMs.

2.11.1 Functional Description

This section further defines and discusses the dedicated RAMs, shared RAMs, and MSG RAMs on this device.

2.11.1.1 Dedicated RAM (Dx RAM)

Each CPU subsystem has four dedicated RAM blocks: M0, M1, D0, and D1. M0/M1 memories are small blocks of memory which are tightly coupled with the CPU. Only the CPU has access to these memories. No other masters (including DMA) have any access to these memories.

All dedicated RAMs have the ECC feature. All dedicated memories (except for M0/M1) are secure memory and also have the access protection (CPU write protection/CPU fetch protection) feature. Each type of access protection for each RAM block can be enabled/disabled by configuring the specific bit in the access protection register, allocated to each subsystem (DxACCPROT).

2.11.1.2 Local Shared RAM (LSx RAM)

RAM blocks which are dedicated to each subsystem and are accessible to its CPU and CLA only, are called local shared RAMs (LSx RAMs). All such memories are secure memory and have the parity feature. By default, these memories are dedicated to the CPU only, and the user could choose to share these memories with the CLA by appropriately configuring the MSEL_LSx bit field in the LSxMSEL register. Further, when these memories are shared between the CPU and CLA, the user could choose to use these memories as CLA program memory by configuring the CLAPGM_LSx bit field in the LSxCLAPGM registers. CPU access to all memory blocks, which are programmed as CLA program memory, are blocked.

All these RAMs have the access protection (CPU write/CPU fetch) feature. Each type of access protection for each RAM block can be enabled or disabled by configuring the specific bit in the local shared RAM access protection registers, mapped to each CPU subsystem. [Table 2-9](#) shows the LSx RAM features.

Table 2-9. Local Shared RAM

MSEL_LSx	CLAPGM_LSx	CPUx Allowed Access	CPUx.CLA1 Allowed Access	Comment
00	X	All	-	LSx memory is configured as CPU dedicated RAM
01	0	All	Data Read Data Write	LSx memory is shared between CPU and CLA1
01	1	Emulation Read Emulation Write	Fetch Only	LSx memory is CLA1 program memory

2.11.1.3 Global Shared RAM (GSx RAM)

RAM blocks which are accessible from both the CPU and their respective DMA are called global shared RAMs (GSx RAMs). Each shared RAM can be owned by either CPU subsystem based on the configuration of their respective bits (one bit for each GSx memory) in the GSxMSEL register. When a particular GSx RAM block is owned by the CPU1 subsystem, CPU1 and CPU1.DMA have full access to that RAM block, whereas CPU2 and CPU2.DMA have only read access to it (no fetch/write access). Similarly, when a particular GSx RAM block is owned by the CPU2 subsystem, CPU1 and CPU1.DMA will have only read access (no fetch/write access) to that RAM block, whereas CPU2 and CPU2.DMA will have full access to it. [Table 2-10](#) shows the features of the GSx RAM.

Table 2-10. Global Shared RAM

GSxMSEL	CPU1	CPU1	CPU1	CPU1.DMA	CPU1.DMA	CPU2	CPU2	CPU2	CPU2.DMA	CPU2.DMA
	Fetch	Read	Write	Read	Write	Fetch	Read	Write	Read	Write
0	Yes	Yes	Yes	Yes	Yes	No	Yes	No	Yes	No
1	No	Yes	No	Yes	No	Yes	Yes	Yes	Yes	Yes

Like other shared RAM, these RAMs also have a different levels of access protection which can be enabled or disabled by configuring specific bits in the GSxACCPROT registers mapped in each subsystem.

Master select and access protection configuration for each GSx RAM block can be individually locked by the user to prevent further update to these bit fields. The user can also choose to permanently lock the configuration to individual bit fields by setting the specific bit fields in the GSxCOMMIT register (refer to the register description for more details). Once configuration is committed for a particular GSx RAM block, it can not be changed further until CPUx.SYSRS is issued. Only the CPU1 SW can change the master select configuration by writing into the GSxMSEL register, mapped on the CPU1. The GSxMSEL register, which is mapped to the CPU2 subsystem, is a status register which can only be used by CPU2 SW to know the master ownership for each GSx RAM block.

2.11.1.4 CPU Message RAM (CPU MSG RAM)

These RAM blocks can be used to share data between CPU1 and CPU2. Since these RAMs are used for interprocessor communication, they are also called IPC RAMs. The CPU MSGRAMs have CPU/DMA read/write access from its own CPU subsystem, and CPU/DMA read only access from the other subsystem.

This RAM has parity.

2.11.1.5 CLA Message RAM (CLA MSGRAM)

These RAM blocks are be used to share data between the CPU and CLA. The CLA has read and write access to the "CLA to CPU MSGRAM." The CPU has read and write access to the "CPU to CLA MSGRAM." The CPU and CLA both have read access to both MSGRAMs.

This RAM has parity.

2.11.1.6 Access Arbitration

For a shared RAM, multiple accesses can happen at a given time. The maximum number of accesses to any shared RAM at any given time depends on the type of shared RAM. On this device, a combination of a fixed and round robin scheme is followed to arbitrate multiple access at any given time. Accesses from the same masters are arbitrated in a fixed priority manner, but the accesses from different masters are arbitrated using the round robin scheme.

The following is the order of fixed priority for CPU accesses:

1. Data Write/Program Write
2. Data Read
3. Program Read/Program Fetch

The following is the order of fixed priority for CLA accesses:

1. Data Write
2. Data Read/Program Fetch

Figure 2-14 represents the arbitration scheme on global shared memories:

Figure 2-14. Arbitration Scheme on Global Shared Memories

Figure 2-15 represents the arbitration scheme on local shared memories.

Figure 2-15. Arbitration Scheme on Local Shared Memories

2.11.1.7 Access Protection

All RAM blocks except for M0/M1 on both subsystems have different levels of protection. This feature allows the user to enable or disable specific access to individual RAM blocks from individual masters. There is no protection for read accesses, hence reads are always allowed from all the masters which have access to that RAM block.

The following sections describe the different kinds of protection available for RAM blocks on this device.

Note: For debug accesses, all the protections are disabled.

2.11.1.7.1 CPU Fetch Protection

A CPU has execution permission from a memory, only if that memory is dedicated to that CPU or its respective subsystem is master for that memory (in case of GSx memory). When fetch accesses are allowed based on the mastership, it can be further protected by setting the FETCHPROTx bit of the specific register to '1.' If fetch access is done by the CPU to a memory where CPU fetch protection is enabled, a fetch protection violation occurs.

There are two types of fetch protection violations:

- Non-master CPU fetch protection violation
- Master CPU fetch protection violation

If a fetch access is made to a memory by a non-master CPU, it is called a non-master fetch protection violation. If a fetch access is made to a dedicated or shared memory by the master CPU, and FETCHPROTx is set to '1' for that memory, the violation is called a master CPU fetch protection violation.

If a fetch protection violation occurs, it results in an ITRAP for CPU. A flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, get latched into the appropriate CPU fetch access violation address register.

2.11.1.7.2 CPU Write Protection

A CPU has write permission to a memory only if that memory is dedicated to that CPU, or if its respective subsystem is the master for that memory (in case of GSx memory). When write accesses are allowed based on the mastership, it can be further protected by setting the CPUWRPROTx bit of the specific register to '1.' If write access is done by a CPU to memory where it is protected, a write protection violation occurs.

There are two types of CPU write protection violations:

- Non-master CPU write protection violation
- Master CPU write protection violation

If a write access is made to a dedicated or shared memory by the master CPU and CPUWRPROTx is set to '1' for that memory, it's called a master CPU write protection violation.

If a write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU write access violation address register. Also, an access violation interrupt is generated if enabled in the interrupt enable register.

2.11.1.7.3 CPU Read Protection

For local shared RAM, if memory is shared between the CPU and its CLA, the CPU will only have access if the memory is configured as data RAM for the CLA. If it is programmed as program RAM, all the access from the CPU, including a read, will be blocked and the violation will be considered as a non-master access violation.

If a read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CPU read access violation address register. Also, an access violation interrupt is generated, if enabled in the interrupt enable register.

2.11.1.7.4 CLA Fetch Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as data RAM for the CLA, any fetch access from the CLA to that particular LSx RAM results in a CLA fetch protection violation, which is a non-master access violation.

If a CLA fetch protection violation occurs, it results in a MSTOP, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA fetch access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

2.11.1.7.5 CLA Write Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data write access from the CLA to that particular LSx RAM results in a CLA write protection violation, which is a non-master access violation.

If a CLA write protection violation occurs, write gets ignored, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA write access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

2.11.1.7.6 CLA Read Protection

If local shared RAM is configured as dedicated RAM for the CPU, or if it is configured as program RAM for the CLA, any data read access from the CLA to that particular LSx RAM results in a CLA read protection violation, which is a non-master access violation.

If a CLA read protection violation occurs, a flag gets set into the appropriate access violation flag register, and the memory address for which the access violation occurred, gets latched into the appropriate CLA read access violation address register. Also, an access violation interrupt is generated to the master CPU if enabled in the interrupt enable register.

2.11.1.7.7 DMA Write Protection

The CPU1 or CPU2 DMA has write permission to a GSx memory only if its respective subsystem is master for that memory. When write accesses from a DMA are allowed based on the mastership, it can be further protected by setting the DMAWRPROTx bit of a specific register to '1.' If write access is done by the DMA to protected memory, a write protection violation occurs.

There are two types of DMA write protection violations:

- Non-master DMA write protection violation (only applicable to Sx memories)
- Master DMA write protection violation

If a write access is made to GSx memory by a non-master DMA, it is called a non-master write protection violation. If a write access is made to a dedicated or shared memory by a master DMA, and DMAWRPROTx is set to '1' for that memory, it is called a master DMA write protection violation.

If a write protection violation occurs on CPU1, write is ignored and a DMAERR interrupt gets generated, whereas in the case of CPU2, a write is ignored and an access violation interrupt is generated if enabled in the interrupt enable register. A flag gets set in the DMA access violation flag register, and the memory address where the violation happened gets latched in the DMA fetch access violation address register. These are dedicated registers for each subsystem.

- Note 1:** All access protections are ignored during debug accesses. Write access to a protected memory will go through when it is done via the debugger, irrespective of the write protection configuration for that memory.
- Note 2:** Access protection is not implemented for M0 and M1 memories.
- Note 3:** In the case of local shared RAM, if memory is shared between the CPU and its CLA, the CPU will only have access if the memory is configured as data RAM for the CLA. If it is programmed as program RAM, all the access from the CPU (including read) and data access from the CLA will be blocked, and violation will be considered as a non-master access violation. If the memory is configured as dedicated to the CPU, all access from the CLA will be blocked and the violation will be considered a non-master access violation.

2.11.1.8 Memory Error Detection, Correction and Error Handling

These devices have memory error detection and correction features to satisfy safety standards requirements. These requirements warrant the addition of detection mechanisms for finite dangerous failures.

In this device, all dedicated RAMs support error correction code (ECC) protection and the shared RAMs have parity protection. The ECC scheme used is Single Error Correction Double Error Detection (SECCDED). The parity scheme used is even parity. ECC/Parity will cover the data bits stored in memory as well as address.

ECC/Parity calculation is done inside the memory controller module and then calculated. ECC/Parity is written into the memory along with the data. ECC/Parity is computed for 16-bit data; hence, for each 32-bit data, there will be three 7-bit ECC codes (or 3-bit parity), two of which are for data and a third one for the address.

2.11.1.8.1 Error Detection and Correction

Error detection is done while reading the data from memory. The error detection is performed for data as well as address. For parity memory, only a single-bit error gets detected, whereas in case of ECC memory, along with a single-bit error, a double-bit error also gets detected. These errors are called correctable error and uncorrectable errors. The following are characteristics of these errors:

- Parity errors are always uncorrectable errors
- Single-bit ECC errors are correctable errors
- Double-bit ECC errors are uncorrectable errors
- Address ECC errors are also uncorrectable errors

Correctable errors get corrected by the memory controller module and then correct data is given back as read data to the master. It is also written back into the memory to prevent double-bit error due to another single-bit error at the same memory address.

2.11.1.8.2 Error Handling

For each correctable error, the count in the correctable error count register will increment by one. When the value in this count register becomes equal to the value configured into the correctable error threshold register, an interrupt is generated to the respective CPU, that is, if the interrupt is enabled in the correctable interrupt enable register. The user needs to configure the correctable error threshold register based on the system requirements. Also, the address for which the error occurred, gets latched into the master-specific status register and a flag gets set. Each of these registers are dedicated for each CPU subsystem.

If there are uncorrectable errors, an NMI gets generated for the respective CPU. In this case, the address for which the error occurred, also gets latched into the master-specific address status register, and a flag gets set.

[Table 2-11](#) summarizes different error situations that can arise. These need to be handled appropriately in the software, using the status and interrupt indications provided.

Table 2-11. Error Handling in Different Scenarios

Access Type	Error Found In	Error Type	Status Indication	Error Notification
Reads	Data read from memory	Uncorrectable Error (Single-bit error for Parity RAMs OR Double bit Error for ECC RAMs)	Yes - CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Error Address Register Data returned to CPUx/CPUx.DMA/CPUx.CLA1 is incorrect	NMI for CPUx access NMI for CPUx.DMA access NMI to CPU for CPUx.CLA1 access
Reads	Data read from memory	Single-bit error for ECC RAMs	Yes - CPUx/CPUx.DMA CPU/DMA Read Error Address Register Increment single error counter	Interrupt when error counter reaches the user programmable threshold for single errors
Reads	Address	Address error	Yes - CPUx/CPUx.DMA/CPUx.CLA1 CPU/DMA/CLA Read Address Error Register Data returned to CPUx/CPUx.DMA/CPUx.CLA1 is incorrect	NMI to CPU for CPUx access NMI to CPU for CPUx.DMA access NMI to CPU for CPUx.CLA1 access

NOTE: In the case of an uncorrectable error during fetch on the CPU, there is the possibility of getting an ITRAP before an NMI exception, since garbage instructions enter into the CPU pipeline before the NMI gets generated.

During debug accesses, correctable as well as uncorrectable errors are masked.

2.11.1.9 Application Test Hooks for Error Detection and Correction

Since error detection and correction logic is part of safety critical logic, safety applications may need to ensure that the logic is always working fine (during run time also). To enable this, a test mode is provided, in which a user can modify the data bits (without modifying the ECC/Parity bits) or ECC/Parity bits directly. Using this feature, an ECC/Parity error could be injected into data.

NOTE: The memory map for ECC/Parity bits and data bits are the same. The user must choose a different test mode to access ECC/Parity bits.

The following table shows the bit mapping for the ECC/Parity bits when they are read in RAMTEST mode using their respective addresses.

Table 2-12. Mapping of ECC Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (ECC Memory)
6:0	ECC Code for lower 16 bits of data
7	Not Used
14:8	ECC Code for upper 16 bits of data
15	Not Used
22:16	ECC Code for address
31:23	Not Used

Table 2-13. Mapping of Parity Bits in Read Data from ECC/Parity Address Map

Data Bits Location in Read Data	Content (Parity Memory)
0	Parity for lower 16 bits of data
7:1	Not Used
8	Parity for upper 16 bits of data
15:9	Not Used
16	Parity for address
31:17	Not Used

2.11.1.10 RAM Initialization

To ensure that read/fetch from uninitialized RAM locations do not cause ECC or parity errors, the RAM_INIT feature is provided for each memory block. Using this feature, any RAM block can be initialized with 0x0 data and respective ECC/Parity bits accordingly. This can be initiated by setting the INIT bit to '1' for the specific RAM block in INIT registers. To check the status of RAM initialization, SW should poll for the INITDONE bit for that RAM block in the INITDONE register to be set. Unless this bit gets set, no access should be made to that RAM memory block.

In the case of GSx memory, only the CPU of the subsystem that is configured as the master for the particular GSx RAM block can initiate the RAM initialization.

NOTE: None of the masters should access the memory while initialization is taking place. If memory is accessed before RAMINITDONE is set, the memory read/write as well as initialization will not happen correctly.

2.12 Flash and OTP Memory

Flash is an electrically erasable/programmable nonvolatile memory that can be programmed and erased many times to ease code development. Flash memory can be used primarily as a program memory for the core, and secondarily as static data memory.

This section describes the proper sequence to configure the wait states and operating mode of flash. It also includes information on flash and OTP power modes, how to improve flash performance by enabling the flash prefetch/cache mode, and the SECDDED safety feature.

2.12.1 Features

Features of flash memory include:

- Dedicated flash bank in the CPU1 subsystem (refer to the device data manual for the size of flash bank)
- Dedicated flash bank in the CPU2 subsystem (refer to the device data manual for the size of flash bank)
- Dedicated flash module controller (FMC) in the CPU1 and CPU2 subsystems for each bank
- 128 bits (bank width) can be programmed at a time along with ECC
- Multiple sectors providing the option of leaving some sectors programmed and only erasing specific sectors
- User-programmable OTP locations for configuring security, OTP boot-mode and boot-mode select pins (if the user is unable to use the factory-default boot-mode select pins)
- Single-flash pump shared by the CPU1 and CPU2 subsystems
- Hardware flash pump semaphore to control ownership of the pump between the two FMCs.
- Enhanced performance using the code-prefetch mechanism and data cache in CPU1-FMC and CPU2-FMC
- Configurable wait states to give the best performance for a given execution speed
- Safety Features
 - SECDDED-single error correction and double error detection is supported in both FMCs
 - Address bits are included in ECC
 - Test mode to check the health of ECC logic
- Supports low-power modes for flash bank and pump for power savings
- Built-in power mode control logic
- Integrated flash program/erase state machine (FSM) in both FMCs
 - Simple flash API algorithms
 - Fast erase and program times (refer to the device data manual for details)
- Code Security Module (CSM) to prevent access to the flash by unauthorized persons (refer to [Section 2.13](#) for details)

2.12.2 Flash Tools

Texas Instruments provides the following tools for flash:

- Code Composer Studio (CCS) - the development environment with integrated flash plugin
- F021 Flash API Library - a set of software peripheral functions to erase/program flash
- UniFlash - standalone tool to erase/program/verify the flash content through JTAG. No CCS is required.
- CCS On-Chip Flash Plugin and UniFlash tools developed for these devices support AutoEccGeneration (see *TMS320F2837xD Flash API Version 1.54 Reference Guide* , [SPNU629](#)). But they do not support the program of ECC generated by the linker -ecc options.
- Users must check and install available updates for CCS On-Chip Flash Plugin and UniFlash tools.

2.12.3 Default Flash Configuration

The following are flash module configuration settings at power-up in both CPU1 and CPU2 subsystems:

- Dedicated flash banks are in sleep power mode
- Shared pump is in sleep mode
- ECC is enabled
- Wait-states are set to the maximum (0xF)
- Code-prefetch mechanism and data cache are disabled in both FMCs

During the boot process, the boot ROM performs a dummy read of the Code Security Module (CSM) password locations in the OTP. This read is performed to unlock a new (or erased) device that has no password stored in it, so that flash programming or loading of code into CSM-protected SARAM can be performed. On devices with a password, this read has no effect and the device remains locked. One effect of this read is that the flash will transition from the sleep (reset) state to the active state.

User application software must initialize wait-states using the FRDCNTL register, and configure cache/prefetch features using the RD_INTF_CTRL register, to achieve optimum system performance. Software that configures flash settings like wait-states, cache/prefetch features, and so on, must be executed only from RAM memory, **not** from flash memory.

NOTE: Before initializing wait-states, turn off the pre-fetch and data caching in the FRD_INTF_CTRL register.

2.12.4 Flash Bank, OTP and Pump

There is a dedicated flash bank in the CPU1 subsystem called the CPU1 flash bank and a dedicated flash bank in the CPU2 subsystem called the CPU2 flash bank. Also, there is a one-time programmable (OTP) memory on the CPU1 subsystem called USER OTP, which the user can program only once and cannot erase. Flash and OTP are uniformly mapped in both program and data memory space.

Both the CPU1 subsystem and CPU2 subsystem have a TI-OTP which contains manufacturing information like settings used by the flash state machine for erase and program operations, and so on. Users may read TI-OTP but it cannot be programmed or erased. For memory map and size information of the CPU1-Bank, CPU1 TI-OTP, CPU1 USER OTP, CPU2 flash bank, CPU2 TI-OTP, CPU2 USER-OTP and corresponding ECC locations, please refer to the device data manual.

The CPU1 flash bank/USER OTP and CPU2 flash bank/USER OTP share a common flash pump. A hardware semaphore, called the flash pump semaphore, is provided to control the access of the flash pump between the CPU1 subsystem and CPU2 subsystem.

[Figure 2-22](#) depicts the user-programmable OTP locations in CPU1 USER-OTP and CPU2 USER-OTP. For more information on the functionality of these fields, please refer to [Section 2.13](#) and the *ROM Code and Peripheral Booting* chapter.

2.12.5 Flash Module Controller (FMC)

There is a dedicated flash module controller in both the CPU1 subsystem (CPU1-FMC) and the CPU2 subsystem (CPU2-FMC). The CPU1 in the CPU1 subsystem interfaces with the CPU1 flash module controller (CPU1-FMC), which in turn, interfaces with the CPU1 flash bank and shared pump to perform erase/program operations as well as to read data/execute code from the CPU1 flash bank.

Figure 2-16. FMC Interface with Core, Bank and Pump

The CPU2 in the CPU2 subsystem interfaces with the CPU2 flash module controller (CPU2-FMC) which in turn, interfaces with the CPU2 flash bank and shared pump to perform erase/program operations as well as to read data/execute code from the CPU2 flash bank. Control signals to the flash pump will be controlled by either CPU2-FMC or CPU1-FMC, depending on who gains the flash pump semaphore.

There is a state machine in both CPU1-FMC and CPU2-FMC which generates the erase/program sequences in hardware. This simplifies the Flash API software which configures control registers in the FMC to perform flash erase and program operations (see *TMS320F2837xD Flash API Version 1.54 Reference Guide*, [SPNU629](#), for details on Flash API).

[Section 2.12.6](#) through [Section 2.12.10](#) describe FMC in detail.

2.12.6 Flash and OTP Power-Down Modes and Wakeup

The flash bank and pump consume a significant amount of power when active. The flash module provides a mechanism to power-down flash banks and pump. Special timers automatically sequence the power-up of the CPU1 flash bank and CPU2 flash bank independently of each other. The shared charge pump module has its own independent power-up timer as well.

The flash bank and OTP operate in three power modes: Sleep (lowest power), Standby, and Active (highest power)

- **Sleep State**
This is the state after a device reset. In this state, a CPU data read or opcode fetch will automatically initiate a change in power mode to the standby state and then to the active state. During this transition time to the active state, the CPU will automatically be stalled.
- **Standby State**
This state uses more power than the sleep state, but takes a shorter time to transition to the active or read state. In this state, a CPU data read or opcode fetch will automatically initiate a change in power mode to the active state. During this transition time to the active state, the CPU will automatically be stalled. Once the flash/OTP has reached the active state, the CPU access will complete as normal.
- **Active or Read State**
In this state, the bank and pump are in active power mode state (highest power)

The charge pump operates in two power modes:

- Sleep (lowest power)
- Active (highest power)

Any access to any flash bank/OTP causes the charge pump to go into active mode, if it is in sleep mode. An erase or program command causes the charge pump and bank to become active. If any bank is in active or in standby mode, the charge pump will be in active mode, independent of the pump power mode control configuration (PMPPWR bit field in the FPAC1 register).

To power down the Flash pump, both the CPU1 and CPU2 must each power down the Flash Pump without any Flash accesses in between. The Flash Pump will not enter low-power mode if the below sequence is not followed.

1. When the system is ready to power down the Flash completely, synchronize CPU1 and CPU2. CPU2 will enter its Flash power-down phase (steps 2, 3, 4, and 5) while the CPU1 will be waiting for it to complete.
2. Acquire the Pump Semaphore with the CPU2.
3. Assign a value of 0x14 to CPU2 VREADST (refer to the FBAC register) to ensure the requisite delay needed for the flash pump/bank to come out of low-power mode later: FBAC.VREADST = 0x14
4. Change the CPU2 Flash Bank Fall Back power mode to Sleep: FBFALLBACK.BNKPWR = 0.
5. Change the CPU2 Flash Charge Pump Fall Back power mode to Sleep: FPAC1.PMPPWR = 0. CPU2 should notify CPU1 that it has completed the above sequence. It should wait until CPU1 completes steps 6, 7, 8, 9 and 10.
6. Acquire the Pump Semaphore with the CPU1.
7. Assign a value of 0x14 to CPU1 VREADST (refer to FBAC register) to ensure the requisite delay needed for the flash pump/bank to come out of low-power mode later: FBAC.VREADST = 0x14
8. Change the CPU1 Flash Bank Fall Back power mode to Sleep: FBFALLBACK.BNKPWR = 0.
9. Change the CPU1 Flash Charge Pump Fall Back power mode to Sleep: FPAC1.PMPPWR = 0.
10. Release the Pump Semaphore from the CPU1. CPU1 should notify CPU2 that it has completed the power-down sequence so that both subsystems may continue.

The above listed procedure should be executed from RAM and not from Flash. Note that exclusive control of the Flash pump should be gained by a CPU (using Flash pump semaphore PUMPREQUEST) before configuring the PMPPWR bit field of the FPAC1 register as shown in the above sequence. As the charge pump is shared between CPU1-FMC and CPU2-FMC, the effective PMPPWR value used when powering down the pump will be of the FMC (out of CPU1-FMC and CPU2-FMC) which owns the pump. The application software can check the current power mode of the flash bank by reading the FBPRDY register. The PUMPRDY bit in the FBPRDY register in CPU1-FMC and CPU2-FMC together reflect the power mode of the charge pump. A value of 0 in the PUMPRDY bit in both CPU1-FMC and CPU2-FMC indicates that the charge pump is in sleep mode. A value of 1 in the PUMPRDY bit in either CPU1-FMC or CPU2-FMC or in both CPU1-FMC and CPU2-FMC indicates that the charge pump is in active mode. Refer to the register descriptions, [Section 2.15](#), for detailed information.

While the pump is in sleep state, a charge pump sleep down counter holds a user configurable value (PSLEEP bit field in the FPAC1 register) and when the charge pump exits sleep power mode, the down counter delays from 0 to PSLEEP prescaled SYSCLK clock cycles (prescaled clock is SYSCLK/2) before putting the charge pump into active power mode. Note that the configured PSLEEP value should yield at least a delay of 20us for the pump to go to active mode. Refer to the register descriptions, [Section 2.15](#), for detailed information.

Below are the number of cycles it will take for the Bank and pump to wake up from low power modes.

1. Pump sleep to active = PSLEEP * (SYSCLK/2) cycles
2. Bank sleep to standby = 425 Flash clock cycles
3. Bank standby to active = 90 Flash clock cycles

Where in Flash clock = SYSCLK/(RWAIT+1)

2.12.7 Flash and OTP Performance

Once the flash bank and pump are in the active power state, a read or fetch access can be classified as a flash access (access to an address location in flash) or an OTP access (access to an address location in OTP). Once the CPU throws an access to a flash memory address, data is returned after RWAIT+1 number of SYSCLK cycles. For a USER-OTP access, data is returned after 11 SYSCLK cycles.

RWAIT defines the number of random access wait-states and is configurable using the RWAIT bit-field in the FRDCNTL register. At reset, the RWAIT bit-field defaults to a worst-case wait-state count (15), and therefore needs to be initialized for the appropriate number of wait states to improve performance, based on the CPU clock rate and the access time of the flash. The flash supports 0-wait accesses when the RWAIT bits are set to zero. This assumes that the CPU speed is low enough to accommodate the access time.

For a given system clock frequency, RWAIT has to be configured using below formula:

$$\text{RWAIT} = \text{ceiling}[(\text{SYSCLK}/\text{FCLK})-1]$$

where SYSCLK is the system operating frequency

FCLK is flash clock frequency. FCLK should be $\leq \text{FCLK}_{\text{max}}$, allowed maximum flash clock frequency at RWAIT=0.

If RWAIT results in a fractional value when calculated using the above formula, RWAIT has to be rounded up to the nearest integer.

2.12.8 Flash Read Interface

This section provides details about the data read modes to access flash bank/OTP and the configuration registers which control the read interface. In addition to a standard read mode, the FMC has a built-in prefetch and cache mechanism to allow increased clock speeds and CPU throughput wherever applicable.

2.12.8.1 FMC Flash Read Interface

2.12.8.1.1 Standard Read Mode

Standard read mode is defined as the read mode in effect when code prefetch-mechanism and data cache are disabled. It is also the default read mode after reset. During this mode, each read access to flash is decoded by the flash wrapper to fetch the data from the addressed location and the data is returned after the RWAIT+1 number of cycles.

Prefetch buffers associated with prefetch mechanism and data cache are bypassed in standard read mode; therefore, every access to the flash/OTP is used by the CPU immediately, and every access creates a unique flash bank access.

Standard read mode is the recommended mode for lower system frequency operation in which RWAIT can be set to zero to provide single-cycle access operation. The FMC can operate at higher frequencies using standard read mode at the expense of adding wait states. At higher system frequencies, it is recommended to enable cache and prefetch mechanisms to improve performance. Refer to the device specific data manual to determine the maximum flash frequency allowed in standard read mode (that is, maximum flash clock frequency with RWAIT=0, FCLK_{MAX}).

2.12.8.1.2 Prefetch Mode

Flash memory is typically used to store application code. During code execution, instructions are fetched from sequential memory addresses, except when a discontinuity occurs. Usually the portion of the code that resides in sequential addresses makes up the majority of the application code and is referred to as linear code. To improve the performance of linear code execution, a flash prefetch-mechanism has been implemented in the FMC. [Figure 2-17](#) illustrates how this mode functions.

Figure 2-17. Flash Prefetch Mode

This prefetch mechanism does a look-ahead prefetch on linear address increments starting from the address of the last instruction fetch. The flash prefetch mechanism is disabled by default. Setting the PREFETCH_EN bit in the FRD_INTF_CTRL register enables this prefetch mode.

An instruction fetch from the flash or OTP reads out 128 bits per access. The starting address of the access from flash is automatically aligned to a 128-bit boundary, such that the instruction location is within the 128 bits to be fetched. With the flash prefetch mode enabled, the 128 bits read from the instruction fetch are stored in a 128-bit wide by 2-level deep instruction prefetch buffer. The contents of this prefetch buffer are then sent to the CPU for processing as required.

Up to four 32-bit or eight 16-bit instructions can reside within a single 128-bit access. The majority of C28x instructions are 16 bits, so for every 128-bit instruction fetch from the flash bank, it is likely that there are up to eight instructions in the prefetch buffer ready to process through the CPU. During the time it takes to process these instructions, the flash prefetch mechanism automatically initiates another access to the flash bank to prefetch the next 128 bits. In this manner, the flash prefetch mechanism works in the background to keep the instruction prefetch buffers as full as possible. Using this technique, the overall efficiency of sequential code execution from flash or OTP is improved significantly. If the prefetch mechanism is enabled, then the last row of 128 bits in the bank should not be used, because the prefetch logic which does a look-ahead prefetch, will try to fetch from outside the bank and would result in an ECC error.

The flash prefetch is aborted only on a PC discontinuity caused by executing an instruction such as a branch, BANTZ, call, or loop. When this occurs, the prefetch mechanism is aborted and the contents of the prefetch buffer are flushed. There are two possible scenarios when this occurs:

1. If the destination address is within the flash or OTP, the prefetch aborts and then resumes at the destination address.
2. If the destination address is outside of the flash and OTP, the prefetch is aborted and begins again only when a branch is made back into the flash or OTP. The flash prefetch mechanism only applies to instruction fetches from program space. Data reads from data memory and from program memory do not utilize the prefetch buffer capability and thus bypass the prefetch buffer. For example, instructions such as MAC, DMAC, and PREAD read a data value from program memory. When this read happens,

the prefetch buffer is bypassed but the buffer is not flushed. If an instruction prefetch is already in progress when a data read operation is initiated, then the data read will be stalled until the prefetch completes.

Note that the prefetch mechanism gets bypassed when RWAIT is configured as zero.

2.12.8.1.2.1 Data Cache

Along with the prefetch mechanism, a data cache of 128 bits wide is also implemented to improve data-space read performance. This data cache will not be filled by the prefetch mechanism. When any kind of data-space read is made by the CPU from an address in the bank, and if the data corresponding to the requested address is not in the data cache, then 128 bits of data will be read from the bank and loaded in the data cache. This data is eventually sent to the CPU for processing. The starting address of the access from flash is automatically aligned to a 128-bit boundary such that the requested address location is within the 128 bits to be read from the bank. By default, this data cache is disabled and can be enabled by setting DATA_CACHE_EN bit in the FRD_INTF_CTRL register. Note that the data cache gets bypassed when RWAIT is configured as zero.

Some other points to keep in mind when working with flash/ OTP:

- Reads of the USER OTP locations are hardwired for 10 wait states. The RWAIT bits have no effect on these locations.
- CPU writes to the flash or OTP memory map areas are ignored. They complete in a single cycle.
- If a security zone is in the locked state and the respective password lock bits are not all 1s, then,
 - Data reads to Zx-CSMPSWD will return 0
 - Program space reads to Zx-CSMPSWD will return 0
 - Program fetches to Zx-CSMPSWD will return 0
- When the Code Security Module (CSM) is secured, reads to the flash/OTP memory map area from outside the secure zone take the same number of cycles as a normal access. However, the read operation returns a zero.
- The arbitration scheme in FMC prioritizes CPU accesses in the fixed priority order of data read (highest priority), program space read and program fetches/program prefetches (lowest priority).
- When FSM interface is active for erase/program operations, data in the prefetch buffers and data cache in FMC will be flushed.
- When data cache is enabled, the debugger memory window open to Flash/OTP space will invoke data caching. Hence, debugger memory window should not be left open for Flash/OTP space when benchmarking the code for performance.

2.12.9 Erase/Program Flash

Flash memory may be programmed either by using the CCS Flash plugin or by using Uniflash. If these methods are not feasible in an application, the API may be used. The Flash memory should be programmed, erased, and verified only by using the F021 Flash API library. These functions are written, compiled and validated by Texas Instruments. The flash module contains a flash state machine (FSM) to perform program and erase operations. This section only provides a high level description for these operations, therefore, refer to the *TMS320F2837xD Flash API Version 1.54 Reference Guide* ([SPNU629](#)) for more information. Note that Flash API execution is interruptible. However, there should not be any read/fetch access from the Flash bank on which an erase/program operation is in progress. Flash API must be executed from RAM.

A typical flow to program flash is:

Erase → Program → Verify

Always refer to the device-specific support folder in controlSUITE™ for the latest Flash API library.

2.12.9.1 Erase

When the target flash is erased, it reads as all 1's. This state is called 'blank.' The erase function must be executed before programming. The user should NOT skip erase on sectors that read as 'blank' because these sectors may require additional erasing due to marginally erased bits columns. The FSM provides an "Erase Sector" command to erase the target sector. The erase function erases the data and the ECC together. This command is implemented by the following Flash API function:

```
Fapi_issueAsyncCommandWithAddress();
```

The Flash API provides the following function to determine if the flash bank is 'blank':

```
Fapi_doBlankCheck();
```

2.12.9.2 Program

The FSM provides a command to program the USER OTP and Flash. This command is also used to program ECC check bits.

This command is implemented by the following Flash API function:

```
Fapi_issueProgrammingCommand();
```

The Program function provides the options to program data without ECC, data along with user-provided ECC data, data along with ECC calculated by API software , and to program ECC only.

2.12.9.3 Verify

After programming, the user must perform verify using API function Fapi_doVerify(). This function verifies the flash contents against supplied data.

Application software typically perform a CRC check of the Flash memory contents during power-up and at regular intervals during runtime (as needed). Apart from this, ECC logic, when enabled (enabled by default), catches single-bit errors, double-bit errors, and address errors whenever the CPU reads/fetches from a Flash address.

2.12.10 Error Correction Code (ECC) Protection

CPU1-FMC and CPU2-FMC contain an embedded single error correction and double error detection (SECDDED) module. SECDDED, when enabled, provides the capability to screen out memory faults. SECDDED can detect and correct single-bit data errors and detect address errors/double-bit data errors. For every 64 bits of flash/OTP data (aligned on a 64-bit memory boundary) that is programmed, eight ECC check bits have to be calculated and programmed in ECC memory space. Refer to the device data manual for the Flash/OTP ECC memory map. SECDDED works with a total of eight user-calculated error correction code (ECC) check bits associated with each 64-bit wide data word and its corresponding 128-bit memory-aligned address. Users must program ECC check bits along with flash data. TI recommends using the AutoEccGeneration option available in Plugin/API to program ECC. Users can use the F021 Flash API to calculate and program ECC data along with flash data. Flash API uses hardware ECC logic in the device to generate the ECC data for the given Flash data. The Flash Plugin, the Flash programming tool integrated with Code Composer Studio, uses Flash API to generate and program ECC data).

Figure 2-18 illustrates the ECC logic inputs and outputs.

Figure 2-18. ECC Logic Inputs and Outputs

During an instruction fetch or a data read operation, the 19 most significant address bits (three least significant bits of address are not considered), together with the 64-bit data/8-bit ECC read-out of flash banks/ECC memory map area, pass through the SECDED logic and the eight checkbits are produced in FMC. These eight calculated ECC check bits are then XORed with the stored check bits (user programmed check bits) associated with the address and the read data. The 8-bit output is decoded inside the SECDED module to determine one of three conditions:

- No error occurred
- A correctable error (single bit data error) occurred
- A non-correctable error (double bit data error or address error) occurred

If the SECDED logic finds a single-bit error in the address field, then it is considered to be a non-correctable error.

NOTE: Since ECC is calculated for an entire 64-bit data, a non 64-bit read such as a byte read or a half-word read will still force the entire 64-bit data to be read and calculated, but only the byte or half-word will be actually used by the CPU.

This ECC (SECDED) feature is enabled at reset. The ECC_ENABLE register can be used to configure (enable/disable) the ECC feature. The ECC for the application code must be programmed.. There are two SECDED modules in each FMC. Out of the 128-bit data (aligned on a 128-bit memory boundary) read from the bank/OTP address, the lower 64-bits of data and corresponding 8 ECC bits (read from user programmable ECC memory area) are fed as inputs to one SECDED module along with 128-bit aligned 19-bit address from where data has been read. The upper 64-bits of data and corresponding 8 ECC bits are fed as inputs to another SECDED module in parallel, along with 128-bit aligned 19-bit address. Each of the SECDED modules evaluate their inputs and determine if there is any single-bit data error or double-bit data error/address error.

ECC logic will be bypassed when the 64 data bits and the associated ECC bits fetched from the bank are either all ones or zeros.

2.12.10.1 Single-Bit Data Error

This section provides information for both single-bit data errors and single-bit ECC check bit errors. If there is a single bit flip (0 to 1 or 1 to 0) in flash data or in ECC data, then it is considered as a single-bit data error. The SECCDED module detects and corrects single-bit errors, if any, in the 64-bit flash data or eight ECC check bits read from the flash/ECC memory map before the read data is provided to the CPU.

When SECCDED finds and corrects single bit data errors, the following information is logged in the ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the single-bit error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address will be captured in the SINGLE_ERR_ADDR_LOW register. If the single-bit error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address will be captured in the SINGLE_ERR_ADDR_HIGH register.
- Whether the error occurred in data bits or ECC bits – the ERR_TYPE_L and ERR_TYPE_H bit fields in the ERR_POS register indicate whether the error occurred in data bits or ECC bits of the lower 64-bits, or the upper 64-bits respectively, of a 128-bit memory-aligned data.
- Bit position at which error occurred – the ERR_POS_L and ERR_POS_H bit fields in the ERR_POS register indicate the bit position of the error in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC respectively, of a 128-bit memory-aligned data.
- Whether the corrected value is 0 (FAIL_0_L, FAIL_0_H flags in ERR_STATUS register)
- Whether the corrected value is 1 (FAIL_1_L, FAIL_1_H flags in ERR_STATUS register)
- A single bit error counter that increments on every single bit error occurrence (ERR_CNT register) until a user-configurable threshold (see ERR_THRESHOLD) is met
- A flag that gets set when one or more single-bit errors occurs after ERR_CNT equals ERR_THRESHOLD (SINGLE_ERR_INT_FLG flag in the ERR_INTFLG register)

When the ERR_CNT value equals THRESHOLD+1 value and a single bit error occurs, the SINGLE_ERR_INT flag is set, and an interrupt (FLASH_CORRECTABLE_ERR on C28x PIE has to be enabled for interrupt, if needed) is fired. The SINGLE_ERR interrupt will not be fired again until the SINGLE_ERR_INTFLG is cleared. If the single error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR_INTCLR register, the error interrupt will not come again, as this is an edge-based interrupt.

When multiple single-bit errors get caught by ECC logic, Flash ECC registers will hold the information related to the latest ECC error. When multiple single-bit errors get caught, both FAIL_0_L and FAIL_1_L (and/or FAIL_0_H and FAIL_1_H) might get set, indicating that single-bit fail0/fail1 occurred in different 64-bit aligned addresses.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash memory will cause the single-bit error flag to get set when there is a single-bit error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

2.12.10.2 Uncorrectable Error

Uncorrectable errors include address errors and double-bit errors in data/ECC. When SECCDED finds uncorrectable errors, the following information is logged in ECC registers if the ECC feature is enabled:

- Address where the error occurred – if the uncorrectable error occurs in the lower 64-bits of a 128-bit memory-aligned data, the lower 64-bit memory-aligned address will be captured in the UNC_ERR_ADDR_LOW register. If the uncorrectable error occurs in the upper 64-bits of a 128-bit memory-aligned data, the upper 64-bit memory-aligned address will be captured in the UNC_ERR_ADDR_HIGH register.
- A flag is set indicating that an uncorrectable error occurred – the UNC_ERR_L and UNC_ERR_H flags in the ERR_STATUS register indicate the uncorrectable error occurrence in the lower 64-bits/lower 8-bit ECC, or the upper 64-bits/upper 8-bit ECC, respectively, of a 128-bit memory-aligned data.
- A flag is set indicating that an uncorrectable error interrupt is fired (UNC_ERR_INTFLG in ERR_INTFLG register)

When an uncorrectable error occurs, the UNC_ERR_INTFLG bit is set and an uncorrectable error interrupt is fired. This uncorrectable error interrupt generates an NMI, if enabled. If an uncorrectable error interrupt flag is not cleared using the corresponding error interrupt clear bit in the ERR_INTCLR register, an error interrupt will not come again, as this is an edge based interrupt.

Although ECC is calculated on 64-bit basis, a read of any address location within a 128-bit aligned Flash memory will cause the uncorrectable error flag to get set when there is a uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data. NMI will occur on the CPU for a read of any address location within a 128-bit aligned Flash memory, when there is an uncorrectable error in both or in either one of the lower 64 and upper 64 bits (or corresponding ECC check bits) of that 128-bit data.

2.12.10.3 SECEDED Logic Correctness Check

Since error detection and correction logic are part of safety-critical logic, safety applications may need to ensure that the SECEDED logic is always working properly. For these safety concerns, in order to ensure the correctness of the SECEDED logic, an ECC test mode is provided to test the correctness of ECC logic periodically. In this ECC test mode, data/ECC and address inputs to the ECC logic are controlled by the ECC test mode registers FDATAH_TEST, FDATAL_TEST, FECC_TEST, and FADDR_TEST, respectively. Using this test mode, users can introduce single-bit errors, double-bit errors, or address errors and check whether or not SECEDED logic is catching those errors. Users can also check if SECEDED logic is reporting any false errors when no errors are introduced.

This ECC test mode can be enabled by setting the ECC_TEST_EN bit in the FECC_CTRL register. When ECC test mode is enabled, the CPU cannot read the data from flash and instead the CPU gets data from the ECC test mode registers (FDATAH_TEST/FDATAL_TEST). This is because ECC test mode registers (FDATAH_TEST, FDATAL_TEST, FECC_TEST) are multiplexed with data from the flash. Hence, the CPU should not read/fetch from Flash when ECC test mode is enabled. For this reason, ECC test mode code should be executed from RAM and not from flash.

Only one of the SECEDED modules (out of the two SECEDED modules that work on lower 64 bits and upper 64 bits of a read 128-bit data) at a time can be tested. The ECC_SELECT bit in the FECC_CTRL register can be configured by users to select one of the SECEDED modules for test.

To test the ECC logic using ECC test mode, users can follow the steps below:

1. Obtain the ECC for a given Flash address (128-bit aligned) and 64-bit data by using the Auto ECC generation option provided in Flash API .
2. Develop an application to test ECC logic using the above data. In this application
 - Write the 128-bit aligned 19-bit Flash address in FADDR_TEST
 - Write 64-bit data in FDATAx_TEST (FDATAL_TEST or FDATAH_TEST depending on which ECC logic the user wants to test) register
 - Write the corresponding 8-bit ECC in the FECC_TEST register
 - In any of the above three steps, users can insert errors (single-bit data error or double-bit data error or address error or single-bit ECC error or double-bit ECC error) so that they can check whether or not ECC logic is able to catch the errors
 - Select the ECC logic block (lower 64-bits or upper 64-bits) which needs to be tested using the ECC_SELECT bit in the FECC_CTRL register
 - Enable ECC test mode using the ECC_TEST_EN bit in FECC_CTRL register
 - Write a value of 1 in the DO_ECC_CALC bit in FECC_CTRL register to enable ECC test logic for a single cycle to evaluate the address, data, ECC in FADDR_TEST, FDATAx_TEST and FECC_TEST registers for ECC errors

Once the above ECC test mode registers are written by the user:

- The FECC_OUTH register holds the data output bits 63:32 from the SECEDED block under test
- The FECC_OUTL register holds the data output bits 31:0 from the SECEDED block under test
- The FECC_STATUS register holds the status of single-bit error occurrence, uncorrectable error occurrence, and error position of single-bit error in data/check bits

2.12.10.4 Reading ECC Memory From a Higher Address Space

In these devices, ECC memory for Flash and OTP is allocated at a higher address space (address width more than 22 bits). C2000 Codegen tools (6.2 and onwards) are updated to include the below intrinsics to read ECC space.

For 16-bit read:

```
unsigned int variable = __addr32_read_uint16(unsigned long address);
```

For 32-bit read:

```
unsigned long variable = __addr32_read_uint32(unsigned long address);
```

2.12.11 Reserved Locations Within Flash and OTP

When allocating code and data to flash and OTP memory, keep the following reserved locations in mind:

- The entire OTP has reserved user-configurable locations for security and boot process. For more details on the functionality of these fields, please refer to [Section 2.13](#), and the *ROM Code and Peripheral Booting* chapter.
- Refer to the *ROM Code and Peripheral Booting* chapter for reserved locations in flash for real-time operating system usage and a boot-to-flash entry point. A boot-to-flash entry point is reserved for an entry-into-flash branch instruction. When the boot-to-flash boot option is used, the boot ROM will jump to this address in flash. If the user programs a branch instruction here, that will then redirect code execution to the entry point of the application.

2.12.12 Procedure to Change the Flash Control Registers

During flash configuration, no accesses to the flash or OTP can be in progress. This includes instructions still in the CPU pipeline, data reads, and instruction prefetch operations. To be sure that no access takes place during the configuration change, you should follow the procedure shown below for any code that modifies the flash control registers.

1. Start executing application code from RAM/Flash/OTP.
2. Branch to or call the flash configuration code (that writes to flash control registers) in RAM. This is required to properly flush the CPU pipeline before the configuration change. The function that changes the flash configuration cannot execute from the Flash or OTP. It must reside in RAM.
3. Execute the flash configuration code (should be located in RAM) that writes to flash control registers like FRDCNTL, FRD_INTF_CTRL, and so on.
4. At the end of the flash configuration code execution, wait eight cycles to let the write instructions propagate through the CPU pipeline. This must be done before the return-from-function call is made.
5. Return to the calling function which might reside in RAM or Flash/OTP and continue execution.

2.12.13 Flash Pump Ownership Semaphore

Each CPU subsystem has its own flash bank, which it can read, program, and erase. Both flash banks share a single charge pump for program and erase operations. Hence, only one CPU can program or erase its flash at any given time. A CPU can read data and execute code from its flash even when the other CPU is programming or erasing. The flash pump ownership semaphore allows one CPU to take control of the pump without being interrupted by the other CPU.

The pump ownership semaphore is implemented as a two-bit field in a PUMPREQUEST register with special write protections. This register requires a key field to be written at the same time as the semaphore bits. The possible semaphore states are:

00 or 11	Either CPU may write to the semaphore. CPU1 has control of the resource by default. 00 is the reset state.
01	CPU2 has exclusive control of the resource and exclusive write access to the semaphore.
10	CPU1 has exclusive control of the resource and exclusive write access to the semaphore.

Each CPU is only allowed to take control of the pump for itself. Direct transfer between the 01 and 10 states is not allowed. However, CPU1 may force both semaphores into the default state (00) at any time by putting CPU2 into reset. [Figure 2-19](#) shows the allowed states and state transitions.

Figure 2-19. Flash Pump Semaphore (PUMPREQUEST) States and State Transitions

2.12.13.1 Clock Configuration Semaphore

Both CPUs can access the PLL and peripheral clock configuration registers. The clock configuration semaphore allows one CPU to access the registers without being interrupted by the other CPU.

The clock configuration semaphore is implemented as a two-bit field in a register with special write protections. This register requires a key field to be written at the same time as the semaphore bits. The possible semaphore states are:

00 or 11	Either CPU may write to the semaphore. CPU1 has control of the clock configuration registers by default. 00 is the reset state.
01	CPU2 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.
10	CPU1 has exclusive control of the clock configuration registers and exclusive write access to the semaphore.

Each CPU is only allowed to take control of the clock configuration registers for itself. However, CPU1 may force both semaphores into the default state (00) at any time by putting CPU2 into reset. [Figure 2-20](#) shows the allowed states and state transitions.

Figure 2-20. Clock Configuration Semaphore (CLKSEM) State Transitions

2.13 Dual Code Security Module (DCSM)

The dual code security module (DCSM) is a security feature incorporated in this device. It prevents access and visibility to on-chip secure memories (and other secure resources) to unauthorized persons. It also prevents duplication and reverse engineering of proprietary code. The term “secure” implies access to on-chip secure memories and resources are blocked. The term “unsecure” implies access is allowed (the contents of the memory could be read by any means); for example, through a debugging tool such as Code Composer Studio™.

There are two CPUs on this device and each CPU subsystem has its own CSM for code protection. Each CPU subsystem's CSM has dual-zone security, which means the CPU1 subsystem has two zones (zone1/zone2) and CPU2 also has two zones (zone1/zone2).

2.13.1 Functional Description

The security module restricts the CPU access to on-chip secure memory and resources without interrupting or stalling CPU execution. When a read occurs to a secure memory location, the read returns a zero value and CPU execution continues with the next instruction. This, in effect, blocks read and write access to secure memories through the JTAG port or external peripherals.

The code security mechanism offers protection for two zones, Zone 1 (Z1) and Zone 2 (Z2). The security mechanism for both the zones is identical. Each zone has its own dedicated secure resource and allocated secure resource. The following are different secure resources available on this device:

- **OTP:** Each zone has its own dedicated secure OTP (USER OTP). This contains the security configurations for the individual zone. If a zone is secure, its USER OTP content (including CSM passwords) can be read (execution not allowed) only if the zone is unlocked using the password match flow (PMF).
- **CLA:** The CLA is a secure resource which can be allocated to either zone by configuring the GRABRAM location in the USER OTP. CLA configuration can only be performed by code running from the zone to which it has been allocated. The CLA message RAMs also belong to the same zone.
- **RAM:** All Dx and LSx RAMs can be secure RAM on this device. These RAMs can be allocated to either zone by configuring the respective GRABRAM location in the USER OTP.
- **Flash Sectors:** Flash Sectors can be secure on this device. Each Flash sector can be allocated to either zone by configuring the respective GRABSECT location in the USER OTP.
- **Secure ROM:** This device also has secure ROM which is EXEONLY-protected. This ROM contains specific function for the user, provided by TI.

Table 2-14 shows the status of a RAM block based on the configuration in GRABRAM register.

Table 2-14. RAM Status

GRAM_RAMx Bits in Z1_GRABRAMR Register	GRAM_RAMx Bits in Z2_GRABRAMR Register	Ownership
00	XX	GRAM_RAMx is inaccessible
XX	00	GRAM_RAMx is inaccessible
Differential Value (01/10)	Differential Value (01/10)	GRAM_RAMx is inaccessible
Differential Value (01/10)	11	GRAM_RAMx belongs to Z1
11	Differential Value (01/10)	GRAM_RAMx belongs to Z2
11	11	GRAM_RAMx is Non-Secure

The security of each zone is ensured by its own 128-bit (four 32-bit words) password (CSM password). The password for each zone is stored in its dedicated OTP location based on a zone-specific link pointer. A zone can be unsecured by executing the password match flow (PMF), described in Section 2.13.3.3.2.

There are three types of accesses: data/program reads, JTAG access, and instruction fetches (calls, jumps, code executions, ISRs). Instruction fetches are never blocked. JTAG accesses are always blocked when a memory is secure. Data reads to a secure memory are always blocked unless the program is executing from a memory which belongs to the same zone. Data reads to unsecure memory are always allowed. Table 2-15 shows the levels of security.

Table 2-15. Security Levels

PMF Executed With Correct Password?	Operating Mode of the Zone	Program Fetch Location	Security Description
No	Secure	Outside secure memory	Only instruction fetches by the CPU are allowed to secure memory. In other words, code can still be executed, but not read.
No	Secure	Inside secure memory	CPU has full access (except for EXEONLY memories where read is not allowed). JTAG port cannot read the secured memory contents.
Yes	Non-Secure	Anywhere	Full access for CPU and JTAG port to secure memory of that zone.

If the password locations of a zone have all 128 bits as ones, the zone is considered unsecure. Since new Flash devices have erased Flash (all ones), only a read of the password locations is required to bring any zone into unsecure mode. If the password locations of a zone have all 128 bits as zeros, the zone is secure, regardless of the contents of the CSMKEY registers. This means the zone can't be unlocked using PMF, the password match flow described in [Section 2.13.3.3.2](#). Therefore, the user should never use all zeros as a password. A password of all zeros will prevent debug of secure code or reprogramming the Flash.

CSMKEY registers are user-accessible registers that are used to unsecure the zones.

2.13.1.1 Emulation Code Security Logic (ECSL)

In addition to the CSM, the emulation code security logic (ECSL) has been implemented using a 64-bit password (part of existing CSM password) for each zone to prevent unauthorized users from stepping through secure code. A halt in secure code while the emulator is connected will trip the ECSL and break the emulation connection to the specific CPU subsystem for which the ECSL violation occurred. To allow emulation of secure code, while maintaining the CSM protection against secure memory reads, the user must write the correct 64-bit password into the CSMKEY (0/1) registers, which matches the password value stored in the USER OTP of that zone. This will disable the ECSL for the specific zone.

When initially debugging a device with the password locations in OTP programmed (secured), the emulator takes some time to take control of the CPU. During this time, the CPU will start running and may execute an instruction that performs an access to a protected ECSL area and if the CPU is halted when the program counter (PC) is pointing to a secure location, the ECSL will trip and cause the emulator connection to be broken.

The solution to this problem is:

- Use the Wait Boot Mode boot option. In this mode, the CPU will be in a loop and hence will not jump to the user application code. Using this BOOTMODE, the user can connect to CCS and debug the code.

2.13.1.2 CPU Secure Logic

The CPU Secure Logic (CPUSL) on this device prevents a hacker from reading the CPU registers in a watch window while code is running in a secure zone. All accesses to CPU registers when the PC points to a secure location are blocked by this logic. The only exception to this is read access to the PC. It is highly recommended not to write into the CPU register in this case, because proper code execution may get affected. If the CSM is unlocked using the CSM password match flow, the CPUSL logic also gets disabled.

2.13.1.3 Execute-Only Protection

To achieve a higher level of security on secure Flash sectors and RAM blocks that store critical user code (instruction opcodes), the Execute-Only protection feature is provided. When the Execute-Only protection is turned on for any secure Flash sector or RAM block, data reads to that Flash sectors are disallowed from any code (even from secure code). Execute-only protection for a Flash sector and RAM block can be turned on by configuring the bit field associated for that particular sector/RAM block in the zone's (which has ownership of that sector/RAM block) EXEONLYSECT and EXEONLYRAM register, respectively.

2.13.1.4 Password Lock

The password locations for each zone can be locked by programming the zone's PSWDLOCK field with any value other than "1111" (0xF) at the PSWDLOCK location in OTP. Until the passwords of a zone are locked, password locations will not be secure and can be read from the debugger as well as code running from non-secure memory. This feature can be used by the user to avoid accidental locking of the zone while programming the Flash sectors during the software development phase. On a fresh device the value for password lock fields for all zones at the PSWDLOCK location in OTP will be "1111" which means the password for all zones will be unlocked.

NOTE: Password unlock only makes password locations non-secure. All other secure memories and other locations of Flash sectors, which contain a password, remains secure as per security settings. But since passwords are non-secure, anyone can read the password and make the zone non-secure by running through PMF.

2.13.1.5 Link Pointer and Zone Select

For each of the two security zones of each CPU subsystem on this device, a dedicated OTP block exists that holds the configuration related to zone's security. The following are the available programmed configurations:

- Zx-LINKPOINTER1
- Zx-LINKPOINTER2
- Zx-LINKPOINTER3
- Zx-PSWDLOCK
- Zx-CRCLOCK
- Zx-BOOTCTRL
- Zx-EXEONLYRAM
- Zx-EXEONLYSECT
- Zx-GRABRAM
- Zx-GRABSECT
- Zx-CSMPASSWORD

Since OTP can't be erased, to provide flexibility of configuring some of the security settings like CSM passwords, allocation of RAM/Flash sectors and their attributes, multiple times by the user, the following configurations are placed in zone select regions of each zone's OTP Flash.

- Zx-EXEONLYRAM
- Zx-EXEONLYSECT
- Zx-GRABRAM
- Zx-GRABSECT
- Zx-CSMPASSWORD

The location of the zone select region in OTP is decided based on the value of three 29-bit link pointers (Zx-LINKPOINTERx) programmed in the OTP of each zone of both CPU subsystems. All OTP locations except link pointer locations are protected with ECC. Since the link pointer locations are not protected with ECC, three link pointers are provided that need to be programmed with the same value. The final value of the link pointer is resolved in hardware when a dummy read is done to all the link pointers by comparing

all the three values (bit-wise voting logic). Since in OTP, a '1' can be flipped by the user to '0' but '0' can't be flipped to '1' (no erase operation for OTP), the most significant bit position in the resolved link pointer which is '0', defines the valid base address for the zone select region. While generating the final link pointer value, if the bit patterns is not one of those listed in [Figure 2-21](#), the final link pointer value becomes All_1 (0xFFFF_FFFF) which selects the Zone-Select-Block1 (also known as the default zone select block).

Figure 2-21. Storage of Zone-Select Bits in OTP

Zx-LINKPOINTER	Addr Offset Of Zone-Select Block
32'bxxx11111111111111111111111111111111	0x20
32'bxxx11111111111111111111111111111111 0	0x30
32'bxxx11111111111111111111111111111111 0x	0x40
32'bxxx11111111111111111111111111111111 0xx	0x50

Zone Select Block	
Addr Offset	32-Bit Content
0x0	Zx-EXEONLYRAM
0x2	Zx-EXEONLYSECT
0x4	Zx-GRABRAM
0x6	Zx-GRABSECT
0x8	Zx-CSMPSWD0
0xa	Zx-CSMPSWD1
0xc	Zx-CSMPSWD2
0xe	Zx-CSMPSWD3

NOTE: Address locations for other security settings (PSWDLCK/CRCLOCK) that are not part of Zone Select blocks) can be programmed only once; therefore, the user should program them towards end of the development cycle.

Figure 2-22. Location of Zone-Select Block Based on Link-Pointer

2.13.1.5.1 C Code Example to get Zone Select Block Addr for Zone1

```

unsigned long LinkPointer;
unsigned long *Zone1SelBlockPtr;
int Bitpos = 28;
int ZeroFound = 0;

// Read Z1-Linkpointer register of DCSM module.
LinkPointer = *(unsigned long *)0x5F000;

// Bits 31 30 and 29 as most-significant 0 are reserved LinkPointer options

LinkPointer = LinkPointer << 2;

while ((ZeroFound == 0) && (bitpos > -1))
{
    if ((LinkPointer & 0x80000000) == 0)
    {
        ZeroFound = 1;
        Zone1SelBlockPtr = (unsigned long *) (0x78000 + ((bitpos + 3)*16));
    } else
    {
        bitpos--;
        LinkPointer = LinkPointer << 1;
    }
}
if (ZeroFound == 0)
{

```

```
//Default in case there is no zero found.
Zone1SelBlockPtr = (unsigned long *)0x78020;
}
```

2.13.1.6 Flash and OTP Erase/Program

On this device, OTP as well as normal Flash, are secure resources. Each zone has its own dedicated OTP, whereas normal Flash sectors can be allocated to any zone based on the value programmed in the GRABSECT location in OTP. Each zone has its own CSM passwords; read and write accesses are not allowed to resources owned by Z1 from code running from memory allocated to Z2 and vice versa. Before programming any secure Flash sector, the user must either unlock the zone to which that particular sector belongs, using PMF or execute the Flash programming code from secure memory which belongs to the same zone. The same is the case for erasing any secure Flash sector. To program the security settings in OTP Flash, the user must unlock the CSM of the respective zone. Unless the zone is unlocked, security settings in OTP Flash cannot be updated. The OTP content cannot be erased.

This device has only one Flash pump used for erase/program operation of normal Flash and OTP Flash. A semaphore mechanism is provided to avoid the conflict between Zone1 and Zone2. A zone needs to grab this semaphore to successfully complete the erase/program operation on the Flash sectors allocated to that zone. A semaphore can be grabbed by a zone by writing the appropriate value in the SEM field of the FLSEM register. For further details of this field, see the register description.

NOTE: If there is a loss of power or a reset of any nature during the flash programming operation, there is high probability of some (or possibly all) of the 128 bits in the corresponding 128-bit aligned address getting corrupted. If this happens while programming the password locations in USER OTP, the passwords may get corrupted.

2.13.1.7 Safe Copy Code

In some applications, the user may want to copy the code from secure Flash to secure RAM for better performance. The user cannot do this for EXEONLY flash sectors because EXEONLY secure memories cannot be read from anywhere. TI provides specific “Safe Copy Code” library functions for each zone to enable the user to copy content from EXEONLY secure flash sectors to EXEONLY RAM blocks. These functions do the copy-code operation in a highly secure environment and allow a copy to be performed only when the following conditions are met:

- The secure RAM block and the secure flash sector belong to the same zone.
- Both the secure RAM block and the secure flash sector have EXEONLY protection enabled.

For further usage of these library functions, see the device-specific Boot ROM documentation.

2.13.1.8 SafeCRC

Since reads from EXEONLY memories are not allowed, the user cannot calculate the CRC for content in EXEONLY memories using the VCU-II. But in some safety-critical applications, the user may have to calculate the CRC on these memories as well. To enable this without compromising on security, TI provides specific “SafeCRC” library functions for each zone. These functions do the CRC calculation in highly secure environment and allow a CRC calculation to be performed only when the following conditions are met:

- The source address should be modulo the number of words (based on length_id) for which the CRC needs to be calculated.
- The destination address should belong to the same zone as the source address.

For further usage of these library functions, see the device-specific Boot ROM documentation.

NOTE: The user must disable all the interrupts before calling the safe copy code and the safeCRC function. If there is a vector fetch during copy code operation, the CPU gets reset immediately.

Disclaimer: Code Security Module Disclaimer The Code Security Module (CSM) included on this device was designed to password protect the data stored in the associated memory and is warranted by Texas Instruments (TI), in accordance with its standard terms and conditions, to conform to TI's published specifications for the warranty period applicable for this device. TI DOES NOT, HOWEVER, WARRANT OR REPRESENT THAT THE CSM CANNOT BE COMPROMISED OR BREACHED OR THAT THE DATA STORED IN THE ASSOCIATED MEMORY CANNOT BE ACCESSED THROUGH OTHER MEANS. MOREOVER, EXCEPT AS SET FORTH ABOVE, TI MAKES NO WARRANTIES OR REPRESENTATIONS CONCERNING THE CSM OR OPERATION OF THIS DEVICE, INCLUDING ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL TI BE LIABLE FOR ANY CONSEQUENTIAL, SPECIAL, INDIRECT, INCIDENTAL, OR PUNITIVE DAMAGES, HOWEVER CAUSED, ARISING IN ANY WAY OUT OF YOUR USE OF THE CSM OR THIS DEVICE, WHETHER OR NOT TI HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. EXCLUDED DAMAGES INCLUDE, BUT ARE NOT LIMITED TO LOSS OF DATA, LOSS OF GOODWILL, LOSS OF USE OR INTERRUPTION OF BUSINESS OR OTHER ECONOMIC LOSS.

2.13.2 CSM Impact on Other On-Chip Resources

On this device, M0/M1 and GSx memories are not secure. To avoid any potential hacking when the device is in the default state (post reset), accesses (all types) to all memories (secure as well as non-secure, except BOOT-ROM and OTP) are disabled until proper security initialization is done. This means that after reset none of the memory resources except BOOT_ROM and OTP is accessible to the user.

The following steps are required after reset (any type of reset) to initialize the security on each CPU subsystem.

- Dummy Read to address location of SECDC (0x703F0, TI-reserved register) in TI OTP
- Dummy Read to address location of Z1_LINKPOINTER1 in Z1 OTP
- Dummy Read to address location of Z1_LINKPOINTER2 in Z1 OTP
- Dummy Read to address location of Z1_LINKPOINTER3 in Z1 OTP
- Dummy Read to address location of Z1_PSWDLOCK in Z1 OTP
- Dummy Read to address location of Z1_CRCLOCK in Z1 OTP
- Dummy Read to address location 0x78018 in Z1 OTP
- Dummy Read to address location of Z1_BOOTCTRL in Z1 OTP
- Read to memory map register of Z1_LINKPOINTER in DCSM module to calculate the address of zone select block for Z1
- Dummy read to address location of Z1_EXEONLYRAM in Z1 OTP
- Dummy read to address location of Z1_EXEONLYSECT in Z1 OTP
- Dummy read to address location of Z1_GRABRAM in Z1 OTP
- Dummy read to address location of Z1_GRABSECT in Z1 OTP
- Dummy Read to address location of Z2_LINKPOINTER1 in Z2 OTP
- Dummy Read to address location of Z2_LINKPOINTER2 in Z2 OTP
- Dummy Read to address location of Z2_LINKPOINTER3 in Z2 OTP
- Dummy Read to address location of Z2_PSWDLOCK in Z2 OTP
- Dummy Read to address location of Z2_CRCLOCK in Z2 OTP
- Dummy Read to address location 0x78218 in Z2 OTP
- Dummy Read to address location of Z2_BOOTCTRL in Z2 OTP
- Read to memory map register of Z2_LINKPOINTER in DCSM module to calculate the address of zone select block for Z2
- Dummy read to address location of Z2_EXEONLYRAM in Z2 OTP
- Dummy read to address location of Z2_EXEONLYSECT in Z2 OTP
- Dummy read to address location of Z2_GRABRAM in Z2 OTP
- Dummy read to address location of Z2_GRABSECT in Z2 OTP

2.13.3 Incorporating Code Security in User Applications

Code security is typically not required in the development phase of a project. However, security is needed once a robust code is developed for a zone. Before such a code is programmed in the Flash memory, a CSM password should be chosen to secure the zone. Once a CSM password is in place for a zone, the zone is secured (programming a password at the appropriate locations and either performing a device reset or setting the FORCESEC bit (Zx_CR.15) is the action that secures the device). From that time on, access to debug the contents of secure memory by any means (via JTAG, code running off external/on-chip memory, and so forth) requires a valid password. A password is not needed to run the code out of secure memory (such as in a typical end-user usage); however, access to secure memory contents for debug purposes, requires a password.

2.13.3.1 Environments That Require Security Unlocking

The following are the typical situations under which unsecuring can be required:

- Code development using debuggers (such as Code Composer Studio). This is the most common environment during the design phase of a product.
- Flash programming using TI's Flash utilities such as Code Composer Studio On-Chip Flash Programmer plug-in or the Uniflash tool. Flash programming is common during code development and testing. Once the user supplies the necessary password, the flash utilities disable the security logic before attempting to program the Flash. The flash utilities can disable the code security logic in new devices without any authorization, since new devices come with an erased Flash. However, reprogramming devices that already contain a custom password require the password to be supplied to the flash utilities in order to unlock the device to enable programming. In custom programming solutions that use the Flash API supplied by TI, unlocking the CSM can be avoided by executing the Flash programming algorithms from secure memory.
- Custom environment defined by the application
In addition to the above, access to secure memory contents can be required in situations such as:
 - Using the on-chip bootloader to load code or data into secure SARAM or to erase and program the Flash.
 - Executing code from on-chip unsecure memory and requiring access to secure memory for the lookup table. This is not a suggested operating condition as supplying the password from external code could compromise code security.

The unsecuring sequence is identical in all the above situations. This sequence is referred to as the password match flow (PMF) for simplicity. [Figure 2-23](#) explains the sequence of operation that is required every time the user attempts to unsecure a particular zone. A code example is listed for clarity.

2.13.3.2 CSM Password Match Flow

Password match flow (PMF) is essentially a sequence of four dummy reads from password locations (PWL) followed by four writes (32-bit writes) to CSMKEY(0/1/2/3) registers. [Figure 2-23](#) shows how PMF helps to initialize the security logic registers and disable security logic.

Figure 2-23. CSM Password Match Flow (PMF)

2.13.3.3 Unsecuring Considerations for Zones With and Without Code Security

Case 1 and Case 2 provide unsecuring considerations for zones with and without code security.

- **Case 1: Zone With Code Security**

A zone with code security should have a predetermined password stored in the password locations of that zone. The following are steps to unsecure any secure zone:

1. Perform a dummy read of the password locations of that zone.
2. Write the password into the CSMKEY registers.
3. If the password is correct, the zone becomes unsecure; otherwise, it stays secure.

- **Case 2: Zone Without Code Security**

A zone without code security should have 0x FFFF FFFF FFFF FFFF FFFF FFFF FFFF FFFF (128 bits of all ones) stored in the password locations. The following are steps to use this zone:

1. At reset, the CSM will lock memory regions protected by the CSM.
2. Perform a dummy read of the password locations.
3. Since the password is all ones, this alone will unlock the zone and all the secure memories dedicated to that zone are fully accessible immediately after this operation is completed.

NOTE: Even if a zone is not protected with a password (all password locations all ones), the CSM will lock at reset. Thus, a dummy read operation must still be performed on these zones prior to reading, writing, or programming secure memory if the code performing the access is executing from outside of the CSM protected memory region. The Boot ROM code does this dummy read for convenience.

2.13.3.3.1 C Code Example to Unsecure C28x Zone1

```
volatile long int *CSM = (volatile long int *)0x5F010; //CSM register file
volatile long int *CSMPWL = (volatile long int *)0x78028; //CSM Password location (assuming
default Zone sel block)

volatile int tmp;

int I;
// Read the 128-bits of the CSM password locations (PWL)
//
for (I=0; I<4; I++) tmp = *CSMPWL++;
// If the password locations (CSMPWL) are all = ones (0xFFFF),
// then the zone will now be unsecure. If the password
// is not all ones (0xFFFF), then the code below is required
// to unsecure the CSM.
// Write the 128-bit password to the CSMKEY registers
// If this password matches that stored in the
// CSLPWL then the CSM will become unsecure. If it does not
// match, then the zone will remain secure.
// An example password of:
// 0x11112222333344445555666677778888 is used.
*CSM++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*CSM++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
*CSM++ = 0x66665555; // Register Z1_CSMKEY2 at 0x5F014
*CSM++ = 0x88887777; // Register Z1_CSMKEY3 at 0x5F016
```

2.13.3.3.2 C Code Example to Resecure C28x Zone1

```
volatile int *Z1_CR = 0x5F019; //CSMSCR register
//Set FORCESEC bit
*Z1_CR = 0x8000;
```

2.13.3.4 Environments That Require ECSL Unlocking

The following are the typical situations under which unsecuring can be required:

- The user develops some main IP, and then outsources peripheral functions to a subcontractor who must be able to run the user code during debug and may halt while main IP code is running. If ECSL is not unlocked, then Code Composer Studio connections will get disconnected, which can be inconvenient for the user. Note that unlocking ECSL doesn't enable access to secure code but only avoids disconnection of CCS (JTAG).

2.13.3.5 ECSL Password Match Flow

A password match flow (PMF) is essentially a sequence of eight dummy reads from password locations (PWL) followed by two writes to KEY registers. [Figure 2-24](#) shows how the PMF helps to initialize the security logic registers and disable security logic.

Figure 2-24. ECSL Password Match Flow (PMF)

2.13.3.6 ECSL Disable Considerations for any Zone

A zone with ECSL enabled should have a predetermined ECSL password stored in the ECSL password locations in Flash (same as lower 64 bits of CSM passwords). The following are steps to disable the ECSL for any particular zone:

- Perform a dummy read of CAM password locations of that Zone
- Write the password into the CSMKEYx registers, corresponding to that Zone.
- If the password is correct, the ECSL gets disabled; otherwise, it stays enabled.

2.13.3.6.1 C Code Example to Disable ECSL for C28x-Zone1

```
volatile long int *ECSL = (volatile int *)0x5F010; //ECSL register file
volatile long int *ECSLPWL = (volatile int *)0x78028; //ECSL Password location (assuming default
Zone sel block)

volatile int tmp;

int I;
// Read the 64-bits of the password locations (PWL)
.
for (I=0;I<2; I++) tmp = *ECSLPWL++;
// If the ECSL password locations (ECSLPWL) are all = ones (0xFFFF),
// then the ECSL will now be disable. If the password
// is not all ones (0xFFFF), then the code below is required
// to disable the ECSL.
// Write the 64-bit password to the CSMKEYx registers
// If this password matches that stored in the
// CSMPWL then ECSL will get disable. If it does not
// match, then the zone will remain secure.
// An example password of:
// 0x1111222233334444 is used.
*ECSL++ = 0x22221111; // Register Z1_CSMKEY0 at 0x5F010
*ECSL++ = 0x44443333; // Register Z1_CSMKEY1 at 0x5F012
```

2.13.3.7 Device Unique ID

The CPU1 OTP contains a 256-bit value that is made up of both random and sequential parts. This value can be used as a seed for code encryption. The starting address of the value is 0x703C0. The first 192 bits are random, the next 32 bits are sequential, and the last 32 bits are a checksum value.

2.14 JTAG

Gel files perform certain initialization tasks. This helps the users in a debug environment. However, when executed standalone (without the emulator connected) the application may not work as expected, since there is no gel file to perform those initializations. For example, gel file disables watchdog. If user code does not service the watchdog in the application (or fails to disable it), there will be a difference in how the application behaves with the debugger and without.

Common tasks performed by the gel files (but not boot-ROM)

On Reset:

- Disable Flash ECC on some devices.
 - Disabling ECC only when using Flash API functions, see the Flash API User Guide for details. Otherwise, TI suggests to always program ECC and enable ECC-check.
- Disable Watchdog
- Enable CLA clock
- Select real-time mode or C28x mode

On Restart:

- Select real-time mode or C28x mode
- Clear IER and IFR

On Target Connect:

-
- Select real-time mode or C28x mode

2.15 Registers

2.15.1 Base Addresses

Table 2-16. System Control Base Address Table

Device Registers	Register Name	Start Address	End Address

⁽¹⁾ Only available on CPU1.

2.15.2 CPUTIMER_REGS Registers

Table 2-17 lists the memory-mapped registers for the CPUTIMER_REGS. All register offset addresses not listed in Table 2-17 should be considered as reserved locations and the register contents should not be modified.

Table 2-17. CPUTIMER_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TIM	CPU-Timer, Counter Register		Go
2h	PRD	CPU-Timer, Period Register		Go
4h	TCR	CPU-Timer, Control Register		Go
6h	TPR	CPU-Timer, Prescale Register		Go
7h	TPRH	CPU-Timer, Prescale Register High		Go

Complex bit access types are encoded to fit into small table cells. Table 2-18 shows the codes that are used for access types in this section.

Table 2-18. CPUTIMER_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
W1C	1C W	1 to clear Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.2.1 TIM Register (Offset = 0h) [reset = FFFFh]

TIM is shown in [Figure 2-25](#) and described in [Table 2-19](#).

Return to [Summary Table](#).

CPU-Timer, Counter Register

Figure 2-25. TIM Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
MSW																LSW															
R/W-0h																R/W-FFFFh															

Table 2-19. TIM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	0h	CPU-Timer Counter Registers The TIMH register holds the high 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Counter Registers The TIM register holds the low 16 bits of the current 32-bit count of the timer. The TIMH:TIM decrements by one every (TDDRH:TDDR+1) clock cycles, where TDDRH:TDDR is the timer prescale dividedown value. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers. The timer interrupt (TINT) signal is generated. Reset type: SYSRSn

2.15.2.2 PRD Register (Offset = 2h) [reset = 0001FFFFh]

PRD is shown in [Figure 2-26](#) and described in [Table 2-20](#).

Return to [Summary Table](#).

Table 2-20. PRD Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	MSW	R/W	1h	CPU-Timer Period Registers The PRDH register holds the high 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn
15-0	LSW	R/W	FFFFh	CPU-Timer Period Registers The PRD register holds the low 16 bits of the 32-bit period. When the TIMH:TIM decrements to zero, the TIMH:TIM register is reloaded with the period value contained in the PRDH:PRD registers, at the start of the next timer input clock cycle (the output of the prescaler). The PRDH:PRD contents are also loaded into the TIMH:TIM when you set the timer reload bit (TRB) in the Timer Control Register (TCR). Reset type: SYSRSn

2.15.2.3 TCR Register (Offset = 4h) [reset = 1h]

TCR is shown in [Figure 2-27](#) and described in [Table 2-21](#).

Return to [Summary Table](#).

CPU-Timer, Control Register

Figure 2-27. TCR Register

15	14	13	12	11	10	9	8
TIF	TIE	RESERVED		FREE	SOFT	RESERVED	
R/W1C-0h	R/W-0h	R-0h		R/W-0h	R/W-0h	R-0h	
7	6	5	4	3	2	1	0
RESERVED		TRB	TSS	RESERVED			
R-0h		R/W-0h	R/W-0h	R-1h			

Table 2-21. TCR Register Field Descriptions

Bit	Field	Type	Reset	Description
15	TIF	R/W1C	0h	CPU-Timer Overflow Flag. TIF indicates whether a timer overflow has happened since TIF was last cleared. TIF is not cleared automatically and does not need to be cleared to enable the next timer interrupt. Reset type: SYSRSn 0h (R/W) = The CPU-Timer has not decremented to zero. Writes of 0 are ignored. 1h (R/W) = This flag gets set when the CPU-timer decrements to zero. Writing a 1 to this bit clears the flag.
14	TIE	R/W	0h	CPU-Timer Interrupt Enable. Reset type: SYSRSn 0h (R/W) = The CPU-Timer interrupt is disabled. 1h (R/W) = The CPU-Timer interrupt is enabled. If the timer decrements to zero, and TIE is set, the timer asserts its interrupt request.
13-12	RESERVED	R	0h	Reserved
11	FREE	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run. If FREE is 0, then the SOFT bit controls the emulation behavior. Reset type: SYSRSn 0h (R/W) = Stop after the next decrement of the TIMH:TIM (hard stop) 1h (R/W) = Stop after the TIMH:TIM decrements to 0 (soft stop) In the SOFT STOP mode, the timer generates an interrupt before shutting down (since reaching 0 is the interrupt causing condition). 2h (R/W) = Free run 3h (R/W) = Free run
10	SOFT	R/W	0h	If the FREE bit is set to 1, then, upon a software breakpoint, the timer continues to run (that is, free runs). In this case, SOFT is a don't care. But if FREE is 0, then SOFT takes effect. In this case, if SOFT = 0, the timer halts the next time the TIMH:TIM decrements. If the SOFT bit is 1, then the timer halts when the TIMH:TIM has decremented to zero. Reset type: SYSRSn
9-6	RESERVED	R	0h	Reserved

Table 2-21. TCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
5	TRB	R/W	0h	Timer reload Reset type: SYSRSn 0h (R/W) = The TRB bit is always read as zero. Writes of 0 are ignored. 1h (R/W) = When you write a 1 to TRB, the TIMH:TIM is loaded with the value in the PRDH:PRD, and the prescaler counter (PSCH:PSC) is loaded with the value in the timer dividedown register (TDDRH:TDDR).
4	TSS	R/W	0h	CPU-Timer stop status bit. TSS is a 1-bit flag that stops or starts the CPU-timer. Reset type: SYSRSn 0h (R/W) = Reads of 0 indicate the CPU-timer is running. To start or restart the CPU-timer, set TSS to 0. At reset, TSS is cleared to 0 and the CPU-timer immediately starts. 1h (R/W) = Reads of 1 indicate that the CPU-timer is stopped. To stop the CPU-timer, set TSS to 1.
3-0	RESERVED	R	1h	Reserved

2.15.2.4 TPR Register (Offset = 6h) [reset = 0h]

TPR is shown in [Figure 2-28](#) and described in [Table 2-22](#).

Return to [Summary Table](#).

CPU-Timer, Prescale Register

R-0h							
7	6	5	4	3	2	1	0
TDDR							
R/W-0h							

Table 2-22. TPR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-8	PSC	R	0h	CPU-Timer Prescale Counter. These bits hold the current prescale count for the timer. For every timer clock source cycle that the PSCH:PSC value is greater than 0, the PSCH:PSC decrements by one. One timer clock (output of the timer prescaler) cycle after the PSCH:PSC reaches 0, the PSCH:PSC is loaded with the contents of the TDDRH:TDDR, and the timer counter register (TIMH:TIM) decrements by one. The PSCH:PSC is also reloaded whenever the timer reload bit (TRB) is set by software. The PSCH:PSC can be checked by reading the register, but it cannot be set directly. It must get its value from the timer divide-down register (TDDRH:TDDR). At reset, the PSCH:PSC is set to 0. Reset type: SYSRSn
7-0	TDDR	R/W	0h	CPU-Timer Divide-Down. Every (TDDRH:TDDR + 1) timer clock source cycles, the timer counter register (TIMH:TIM) decrements by one. At reset, the TDDRH:TDDR bits are cleared to 0. To increase the overall timer count by an integer factor, write this factor minus one to the TDDRH:TDDR bits. When the prescaler counter (PSCH:PSC) value is 0, one timer clock source cycle later, the contents of the TDDRH:TDDR reload the PSCH:PSC, and the TIMH:TIM decrements by one. TDDRH:TDDR also reloads the PSCH:PSC whenever the timer reload bit (TRB) is set by software. Reset type: SYSRSn

2.15.2.5 TPRH Register (Offset = 7h) [reset = 0h]

TPRH is shown in [Figure 2-29](#) and described in [Table 2-23](#).

Return to [Summary Table](#).

Complex bit access types are encoded to fit into small table cells. Table 2-25 shows the codes that are used for access types in this section.

Table 2-25. PIE_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 2-25. PIE_CTRL_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.3.1 PIECTRL Register (Offset = 0h) [reset = 0h]

PIECTRL is shown in [Figure 2-30](#) and described in [Table 2-26](#).

Return to [Summary Table](#).

Table 2-26. PIECTRL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-1	PIEVECT	R	0h	These bits indicate the vector address of the vector fetched from the ePIE vector table. The least significant bit of the address is ignored and only bits 1 to 15 of the address are shown. The vector value can be read by the user to determine which interrupt generated the vector fetch. Note: When a NMI is serviced, the PIEVECT bit-field does not reflect the vector as it does for other interrupts. Reset type: SYSRSn
0	ENPIE	R/W	0h	Enable vector fetching from ePIE block. This bit must be set to 1 for peripheral interrupts to work. All ePIE registers (PIEACK, PIEIFR, PIEIER) can be accessed even when the ePIE block is disabled. Reset type: SYSRSn

2.15.3.2 PIEACK Register (Offset = 1h) [reset = 0h]

PIEACK is shown in [Figure 2-31](#) and described in [Table 2-27](#).

Return to [Summary Table](#).

Acknowledge Register

When an interrupt propagates from the ePIE to a CPU interrupt line, the interrupt group's PIEACK bit is set. This prevents other interrupts in that group from propagating to the CPU while the first interrupt is handled. Writing a 1 to a PIEACK bit clears it and allows another interrupt from the corresponding group to propagate. ISRs for PIE interrupts should clear the group's PIEACK bit before returning from the interrupt. Writes of 0 are ignored.

2.15.3.3 PIEIER1 Register (Offset = 2h) [reset = 0h]

PIEIER1 is shown in [Figure 2-32](#) and described in [Table 2-28](#).

Return to [Summary Table](#).

Interrupt Group 1 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

2.15.3.4 PIEIFR1 Register (Offset = 3h) [reset = 0h]

PIEIFR1 is shown in [Figure 2-33](#) and described in [Table 2-29](#).

Return to [Summary Table](#).

Interrupt Group 1 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

2.15.3.7 PIEIER3 Register (Offset = 6h) [reset = 0h]

PIEIER3 is shown in [Figure 2-36](#) and described in [Table 2-32](#).

Return to [Summary Table](#).

Interrupt Group 3 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

2.15.3.8 PIEIFR3 Register (Offset = 7h) [reset = 0h]

PIEIFR3 is shown in [Figure 2-37](#) and described in [Table 2-33](#).

Return to [Summary Table](#).

Interrupt Group 3 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

2.15.3.16 PIEIFR7 Register (Offset = Fh) [reset = 0h]

PIEIFR7 is shown in [Figure 2-45](#) and described in [Table 2-41](#).

Return to [Summary Table](#).

Interrupt Group 7 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

2.15.3.24 PIEIFR11 Register (Offset = 17h) [reset = 0h]

PIEIFR11 is shown in [Figure 2-53](#) and described in [Table 2-49](#).

Return to [Summary Table](#).

Interrupt Group 11 Flag Register

These register bits indicate whether each interrupt in the group is currently pending. They behave very much like the bits in the CPU interrupt flag register (IFR).

When a peripheral sends an interrupt, the corresponding bit is set. This bit is cleared when the interrupt propagates to the CPU, at which point PIEACK is set.

NOTE: PIE IFR flags can be written to create software interrupts.

The IFR flag will be cleared on a write of zero. Hence, when the intent is to fire an interrupt it may cause inadvertent cancellation of other interrupts. It is recommended to use this only for testing or with extreme caution in the application code. Reading the PIE IFR registers is safe.

2.15.3.25 PIEIER12 Register (Offset = 18h) [reset = 0h]

PIEIER12 is shown in [Figure 2-54](#) and described in [Table 2-50](#).

Return to [Summary Table](#).

Interrupt Group 12 Enable Register

These register bits individually enable an interrupt within a group. They behave very much like the bits in the CPU interrupt enable register (IER).

Setting a bit to 1 allows the corresponding interrupt to propagate to the CPU.

Setting a bit to 0 prevents the corresponding interrupt from propagating. Note that a peripheral interrupt signal can still set the PIEIFR bit for the disabled interrupt.

2.15.4 WD_REGS Registers

Table 2-52 lists the memory-mapped registers for the WD_REGS. All register offset addresses not listed in Table 2-52 should be considered as reserved locations and the register contents should not be modified.

Table 2-52. WD_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
22h	SCSR	System Control & Status Register	EALLOW	Go
23h	WDCNTR	Watchdog Counter Register	EALLOW	Go
25h	WDKEY	Watchdog Reset Key Register	EALLOW	Go
29h	WDCR	Watchdog Control Register	EALLOW	Go
2Ah	WDWCR	Watchdog Windowed Control Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 2-53 shows the codes that are used for access types in this section.

Table 2-53. WD_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W1C	1C W	1 to clear Write
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.4.1 SCSR Register (Offset = 22h) [reset = 5h]

SCSR is shown in [Figure 2-56](#) and described in [Table 2-54](#).

Return to [Summary Table](#).

It is recommended to only use 16 bit accesses to write to this register. Use a read-modify-write instruction may inadvertently clear other bits.

Table 2-54. SCSR Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R=0	0h	Reserved
2	WDINTS	R	1h	Watchdog interrupt (WDINTn) status signal. This is a read only bit reflecting the current state of the WDINTn signal from the watchdog block (after synchronization with SYSCLKOUT). If this bit is 1, the watchdog interrupt is not active. If this bit is 0, then the watchdog interrupt is active. Note: ,If the WDINTn signal is used to wake up from IDLE or STANDBY condition, then the user should make sure that the WDINTn signal goes back high again before attempting to go back into IDLE or STANDBY mode. Reading this bit will tell the user the current state of this signal. Reset type: SYSRSn
1	WDENINT	R/W	0h	If this bit is set to 1, the watchdog reset (WDRSTn) output signal is disabled and the watchdog interrupt (WDINTn) output signal is enabled. If this bit is zero, then the WDRSTn output signal is enabled and the WDINTn output signal is disabled. This is the default state on system reset (SYSRSn). Reset type: SYSRSn
0	WDOVERRIDE	R/W1C	1h	If this bit is set to 1, the user is allowed to change the state of the Watchdog disable (WDDIS) bit in the Watchdog Control (WDCR) register. If the WDOVERRIDE bit is cleared, by writing a 1 the WDDIS bit cannot be modified by the user. Writing a 0 will have no effect. If this bit is cleared, then it will remain in this state until a reset occurs. The current state of this bit is readable by the user. Reset type: SYSRSn

2.15.4.2 WDCNTR Register (Offset = 23h) [reset = 0h]

WDCNTR is shown in [Figure 2-57](#) and described in [Table 2-55](#).

Bit	Field	Type	Reset	Description
15-12	RESERVED	R=0	0h	Reserved
11	OVF	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn
10	CPU2NMIWDRSn	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn
9	CPU2WDRSn	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. [3] CPU2WDRSn and CPU2NMIWDRSn bits are reserved for CPU2.NMIFLGCLR registers Reset type: SYSRSn
8	RESERVED	R	0h	Reserved
7	RESERVED	R	0h	Reserved

Table 2-63. NMIFLGCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	PIEVECTERR	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn
5	CPU2HWBISTERR	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn
4	CPU1HWBISTERR	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn
3	FLUNCERR	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn
2	RAMUNCERR	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn
1	CLOCKFAIL	R=0/W=1	0h	Writing a 1 to the respective bit clears the corresponding flag bit in the NMIFLG and NMISHDFLG registers. Writes of 0 are ignored. Always reads back 0. Notes: [1] If hardware is trying to set a bit to 1 while software is trying to clear a bit to 0 on the same cycle, hardware has priority. [2] Users should clear the pending FAIL flag first and then clear the NMIINT flag. Reset type: SYSRSn

Table 2-63. NMIFLGCLR Register Field Descriptions (continued)

NMIWDCNT															
R-0h															

Table 2-65. NMIWDCNT Register Field Descriptions

Bit	Field	Type	Reset	Description
15-0	NMIWDCNT	R	0h	NMI Watchdog Counter: This 16-bit incremental counter will start incrementing whenever any one of the enabled FAIL flags are set. If the counter reaches the period value, an NMIRSn signal is fired which will then resets the system. The counter will reset to zero when it reaches the period value and will then restart counting if any of the enabled FAIL flags are set. If no enabled FAIL flag is set, then the counter will reset to zero and remain at zero until an enabled FAIL flag is set. Normally, the software would respond to the NMI interrupt generated and clear the offending FLAG(s) before the NMI watchdog triggers a reset. In some situations, the software may decide to allow the watchdog to reset the device anyway. The counter is clocked at the SYSCLKOUT rate. Reset type: SYSRSn

2.15.5.6 NMIWDPRD Register (Offset = 5h) [reset = FFFFh]

NMIWDPRD is shown in [Figure 2-66](#) and described in [Table 2-66](#).

Return to [Summary Table](#).

2.15.6 XINT_REGS Registers

Table 2-68 lists the memory-mapped registers for the XINT_REGS. All register offset addresses not listed in Table 2-68 should be considered as reserved locations and the register contents should not be modified.

Table 2-68. XINT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	XINT1CR	XINT1 configuration register		Go
1h	XINT2CR	XINT2 configuration register		Go
2h	XINT3CR	XINT3 configuration register		Go
3h	XINT4CR	XINT4 configuration register		Go
4h	XINT5CR	XINT5 configuration register		Go
8h	XINT1CTR	XINT1 counter register		Go
9h	XINT2CTR	XINT2 counter register		Go
Ah	XINT3CTR	XINT3 counter register		Go

Complex bit access types are encoded to fit into small table cells. Table 2-69 shows the codes that are used for access types in this section.

Table 2-69. XINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.6.1 XINT1CR Register (Offset = 0h) [reset = 0h]

16h	DMACHSRCSEL1	DMA Channel Trigger Source Select Register-1	EALLOW	Go
18h	DMACHSRCSEL2	DMA Channel Trigger Source Select Register-2	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 2-79 shows the codes that are used for access types in this section.

Table 2-79. DMA_CLA_SRC_SEL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
WSOnce	SOnce W	Set once Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.7.1 CLA1TASKSRCSELLOCK Register (Offset = 0h) [reset = 0h]

CLA1TASKSRCSELLOCK is shown in [Figure 2-76](#) and described in [Table 2-80](#).

Return to [Summary Table](#).

7	6	5	4	3	2	1	0
RESERVED						PUMP_OWNERSHIP	
R=0=0h						R/W=0h	

Table 2-88. PUMPREQUEST Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R=0/W	0h	In order to write to the semaphore bits, 0x5a5a must be written to these key bits at the same time. Otherwise, writes are ignored. The key is cleared immediately after writing, so it must be written again for every semaphore change. Reset type: CPU1.SYSRSn
15-2	RESERVED	R=0	0h	Reserved
1-0	PUMP_OWNERSHIP	R/W	0h	These bits configure which CPU has control of the flash pump, which allows write access to the flash memory. The possible values are: 00 or 11: Read-only state. CPU1 has control of the pump, but CPU2 may seize control at any time. 01: CPU2 has exclusive control of the pump and of these semaphore bits. CPU2 can relinquish control by setting the bits back to 00 or 11. 10: CPU1 has exclusive control of the pump and of these semaphore bits. CPU1 can relinquish control by setting the bits back to 00 or 11. Going from 01->10 or 10->01 is not allowed. Going from 00->11 or 11->00 is allowed, but has no effect. The semaphore bits [1:0] must be written along with the correct key in bits [31:16]. Reset type: CPU1.SYSRSn

2.15.9 DEV_CFG_REGS Registers

Table 2-89 lists the memory-mapped registers for the DEV_CFG_REGS. All register offset addresses not listed in Table 2-89 should be considered as reserved locations and the register contents should not be modified.

Table 2-89. DEV_CFG_REGS Registers

2.15.9.45 CPUSEL5 Register (Offset = E0h) [reset = 0h]

CPUSEL5 is shown in [Figure 2-127](#) and described in [Table 2-135](#).

Return to [Summary Table](#).

CPU Select register for common peripherals

This register must be configured prior to enabling the peripheral clocks.

The clock for each peripheral is derived from the selected CPU subsystem. The clock mux controlled by this register is not glitch-free, therefore the CPUSELx register must be configured before the PCLKCRx register.

The reset for each peripheral is also driven from the selected CPU.

2Ch	LOSPCP	Low Speed Clock Source Prescaler	EALLOW	Go
2Eh	MCDCR	Missing Clock Detect Control Register	EALLOW	Go
30h	X1CNT	10-bit Counter on X1 Clock		Go

Complex bit access types are encoded to fit into small table cells. Table 2-148 shows the codes that are used for access types in this section.

Table 2-148. CLK_CFG_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
WSOnce	SOnce W	Set once Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 2-148. CLK_CFG_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.10.1 CLKSEM Register (Offset = 0h) [reset = 0h]

CLKSEM is shown in [Figure 2-139](#) and described in [Table 2-149](#).

Return to [Summary Table](#).

Clock Control Semaphore Register

RESERVED														SEM	
R=0-0h														R/W=0h	

Table 2-149. CLKSEM Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	KEY	R=0/W	0h	Writing the value 0xa5a5 will allow the writing of the SEM bits, else writes are ignored. Reads will return 0. Note: [1] Due to this KEY, only 32-bit writes will succeed (provided the KEY matches). 16-bit writes to the upper or lower half of this register will be ignored Reset type: N/A
15-2	RESERVED	R=0	0h	Reserved
1-0	SEM	R/W	0h	This register provides a mechanism to acquire all the CLKCFG registers (except this register) by CPU1 or CPU2. A CPU can perform read/writes to any of the CLKCFG registers (except this register) only if it owns the semaphore. Otherwise, writes are ignored and reads will return 0x0. Semaphore State Transitions: A value of 00, 10, 11 gives ownership to CPU1 A value of 01 gives ownership to CPU2. The following are the only state transitions allowed on these bits. 00,11 <-> 01 (allowed by CPU2) 00,11 <-> 10 (allowed by CPU1) If a CPU doesn't own the CLK_CFG_REGS set of registers (as defined by the state of this semaphore), reads from that CPU to all those registers return 0x0 and writes are ignore. Note that this is not true of CLKSEM register. The CLKSEM register's reads and writes are always allowed from both CPU1 and CPU2. Reset type: CPU1.SYSRSn

2.15.10.2 CLKCFGLOCK1 Register (Offset = 2h) [reset = 0h]

CLKCFGLOCK1 is shown in [Figure 2-140](#) and described in [Table 2-150](#).

Return to [Summary Table](#).

Lock bit for CLKCFG registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Table 2-151. CLKSRCCTL1 Register Field Descriptions

Bit	Field	Type	Reset	Description
31-16	RESERVED	R=0	0h	Reserved
15-6	RESERVED	R=0	0h	Reserved
5	WDHALTI	R/W	0h	Watchdog HALT Mode Ignore Bit: This bit determines if CPU1.WD is functional in the HALT mode or not. 0 = CPU1.WD is not functional in the HALT mode. Clock to CPU1.WD is gated when system enters HALT mode. Additionally, INTOSC1 and INTOSC2 are powered-down when system enters HALT mode 1 = CPU1.WD is functional in the HALT mode. Clock to CPU1.WD is not gated and INTOSC1/2 are not powered-down when system enters HALT mode Notes: [1] Clock to CPU2.WD clocks is always gated in the HALT mode. Reset type: XRSn
4	XTALOFF	R/W	0h	Crystal (External) Oscillator Off Bit: This bit turns external oscillator off: 0 = Crystal (External) Oscillator On (default on reset) 1 = Crystal (External) Oscillator Off NOTE: Ensure no resources are using a clock source prior to disabling it. For example OSCCLKSRCSEL (SYSPLL), AUXOSCCLKSRCSEL (AUXPLL), CANxBCLKSEL (CAN Clock), TMR2CLKSRCSEL (CPUTIMER2) and XCLKOUTSEL(XCLKOUT). Reset type: XRSn

Table 2-151. CLKSRCCTL1 Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
3	INTOSC2OFF	R/W	0h	Internal Oscillator 2 Off Bit: This bit turns oscillator 2 off: 0 = Internal Oscillator 2 On (default on reset) 1 = Internal Oscillator 2 Off This bit could be used by the user to turn off the internal oscillator 2 if it is not used. NOTE: Ensure no resources are using a clock source prior to disabling it. For example OSCCLKSRCSEL (SYSPLL), AUXOSCCLKSRCSEL (AUXPLL), TMR2CLKSRCSEL (CPUTIMER2) and XCLOCKOUT (XCLKOUT). Reset type: XRSn
2	RESERVED	R=0	0h	Reserved
1-0	OSCCLKSRCSEL	R/W	0h	Oscillator Clock Source Select Bit: This bit selects the source for OSCCLK. 00 = INTOSC2 (default on reset) 01 = External Oscillator (XTAL) 10 = INTOSC1 11 = reserved (default to INTOSC1) At power-up or after an XRSn, INTOSC2 is selected by default. Whenever the user changes the clock source using these bits, the SYSPLLMULT register will be forced to zero and the PLL will be bypassed and powered down. This prevents potential PLL overshoot. The user will then have to write to the SYSPLLMULT register to configure the appropriate multiplier. The user must wait 10 OSCCLK cycles before writing to SYSPLLMULT or disabling the previous clock source to allow the change to complete.. Notes: [1] Reserved selection defaults to 00 configuration [2] INTOSC1 is recommended to be used only after missing clock detection. If user wants to re-lock the PLL with INTOSC1 (the back-up clock source) after missing clock is detected, he can do a MCLKCLR and lock the PLL. Reset type: XRSn

2.15.10.4 CLKSRCCTL2 Register (Offset = Ah) [reset = 0h]

CLKSRCCTL2 is shown in [Figure 2-142](#) and described in [Table 2-152](#).

Return to [Summary Table](#).

Complex bit access types are encoded to fit into small table cells. Table 2-168 shows the codes that are used for access types in this section.

Table 2-168. CPU_SYS_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
WSOnce	SOnce W	Set once Write
Reset or Default Value		
-n		Value after reset or the default value

**Table 2-168. CPU_SYS_REGS Access Type
Codes (continued)**

Access Type	Code	Description
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.11.1 CPUSYSLOCK1 Register (Offset = 0h) [reset = 0h]

CPUSYSLOCK1 is shown in [Figure 2-157](#) and described in [Table 2-169](#).

Return to [Summary Table](#).

Lock bit for CPUSYS registers

Notes:

[1] Any bit in this register, once set can only be cleared through a CPU1.SYSRSn. Write of 0 to any bit of this register has no effect

[2] The locking mechanism applies to only writes. Reads to the registers which have LOCK protection are always allowed

Table 2-189. LPMCR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IOISODIS	R/W=1	0h	0: Indicates IO ISOLATION is not turned ON 1: Indicates IO ISOLATION is turned ON. This bit is set one by hardware ONLY during HIB. This bit cant be set to 1 by software Writing 0 to this bit has not effect. Writing 1 to this bit deactivates IO ISOLATION Notes: [1] This bit is reserved in the register mapped to CPU2 Reset type: raw-XRSn
30-18	RESERVED	R=0	0h	Reserved
17-16	M0M1MODE	R/W	0h	These bit control the state of CPU1's and CPU2's M0 & M1 memories when Device goes into HIB mode. 00: CPUx's M0 & M1 memories ON with low-leakage mode 01: CPUx's M0 & M1 memories OFF 1x: Reserved Notes: [1] Low-leakage mode for M0 & M1 memories uses the "Retention" feature of the SRAMs. [2] These bits take effect only when device goes into HIB mode. If the device is not in HIB mode, the value in this bit doesn't control the state of CPU1's and CPU2's M0 & M1 memories Reset type: PORn
15	WDINTE	R/W	0h	When this bit is set to 1, it enables the watchdog interrupt signal to wake the device from STANDBY mode. Note: [1] To use this signal, the user must also enable the WDINTn signal using the WDENINT bit in the SCSR register. This signal will not wake the device from HALT mode because the clock to watchdog module is turned off Reset type: SYSRSn
14-8	RESERVED	R=0	0h	Reserved

Table 2-189. LPMCR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7-2	QUALSTDBY	R/W	3Fh	Select number of OSCCLK clock cycles to qualify the selected inputs when waking the from STANDBY mode: 000000 = 2 OSCCLKs 000001 = 3 OSCCLKs 111111 = 65 OSCCLKs Note: The LPMCR.QUALSTDBY register should be set to a value greater than the ratio of INTOSC1/PLLSYSCLK to ensure proper wake up. Reset type: SYSRSn
1-0	LPM	R/W	0h	These bits set the low power mode for the device. Takes effect when CPU executes the IDLE instruction (when IDLE instruction is out of EXE Phase of the Pipeline) 00: IDLE Mode 01: STANDBY Mode 10: HALT Mode (treated as STANDBY for CPU2) 11: HIB Mode (treated as STANDBY for CPU2) Reset type: SYSRSn

2.15.11.22 GPIO_LPMSEL0 Register (Offset = 78h) [reset = 0h]

GPIO_LPMSEL0 is shown in [Figure 2-178](#) and described in [Table 2-190](#).

Return to [Summary Table](#).

GPIO LPM Wakeup select registers

Connects the selected pin to the LPM circuit. Refer to LPM section of the TRM for the wakeup capabilities of the selected pin.

2.15.14 DCSM_Z2_OTP Registers

Table 2-205 lists the memory-mapped registers for the DCSM_Z2_OTP. All register offset addresses not listed in Table 2-205 should be considered as reserved locations and the register contents should not be modified.

Table 2-205. DCSM_Z2_OTP Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	Z2OTP_LINKPOINTER1	Zone 2 Link Pointer1 in Z2 OTP		Go
4h	Z2OTP_LINKPOINTER2	Zone 2 Link Pointer2 in Z2 OTP		Go
8h	Z2OTP_LINKPOINTER3	Zone 2 Link Pointer3 in Z2 OTP		Go
10h	Z2OTP_PSWDLOCK	Secure Password Lock in Z2 OTP		Go
14h	Z2OTP_CRCLOCK	Secure CRC Lock in Z2 OTP		Go
1Eh	Z2OTP_BOOTCTRL	Boot Mode in Z2 OTP		Go

Complex bit access types are encoded to fit into small table cells. Table 2-206 shows the codes that are used for access types in this section.

Table 2-206. DCSM_Z2_OTP Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.14.1 Z2OTP_LINKPOINTER1 Register (Offset = 0h) [reset = FFFFFFFFh]

2.15.16 DCSM_Z2_REGS Registers

Table 2-228 lists the memory-mapped registers for the DCSM_Z2_REGS. All register offset addresses not listed in Table 2-228 should be considered as reserved locations and the register contents should not be modified.

Table 2-228. DCSM_Z2_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	Z2_LINKPOINTER	Zone 2 Link Pointer		Go
2h	Z2_OTPSECLOCK	Zone 2 OTP Secure JTAG lock		Go
4h	Z2_BOOTCTRL	Boot Mode		Go
6h	Z2_LINKPOINTERERR	Link Pointer Error		Go
10h	Z2_CSMKEY0	Zone 2 CSM Key 0		Go
12h	Z2_CSMKEY1	Zone 2 CSM Key 1		Go
14h	Z2_CSMKEY2	Zone 2 CSM Key 2		Go
16h	Z2_CSMKEY3	Zone 2 CSM Key 3		Go
19h	Z2_CR	Zone 2 CSM Control Register		Go
1Ah	Z2_GRABSECTR	Zone 2 Grab Flash Sectors Register		Go
1Ch	Z2_GRABRAMR	Zone 2 Grab RAM Blocks Register		Go
1Eh	Z2_EXEONLYSECTR	Zone 2 Flash Execute_Only Sector Register		Go
20h	Z2_EXEONLYRAMR	Zone 2 RAM Execute_Only Block Register		Go

Complex bit access types are encoded to fit into small table cells. Table 2-229 shows the codes that are used for access types in this section.

Table 2-229. DCSM_Z2_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.16.1 Z2_LINKPOINTER Register (Offset = 0h) [reset = E0000000h]

Z2_LINKPOINTER is shown in [Figure 2-208](#) and described in [Table 2-230](#).

Return to [Summary Table](#).

28h	MCPUFAVADDR	Master CPU Fetch Access Violation Address		Go
2Ah	MCPUWRAVADDR	Master CPU Write Access Violation Address		Go
2Ch	MDMAWRAVADDR	Master DMA Write Access Violation Address		Go

Complex bit access types are encoded to fit into small table cells. Table 2-279 shows the codes that are used for access types in this section.

Table 2-279. ACCESS_PROTECTION_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 2-279. ACCESS_PROTECTION_REGS Access
Type Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.19.1 NMAVFLG Register (Offset = 0h) [reset = 0h]

NMAVFLG is shown in [Figure 2-252](#) and described in [Table 2-280](#).

Return to [Summary Table](#).

20h	CERRFLG	Correctable Error Flag Register		Go
22h	CERRSET	Correctable Error Flag Set Register	EALLOW	Go
24h	CERRCLR	Correctable Error Flag Clear Register	EALLOW	Go
26h	CCPUREADDR	Correctable CPU Read Error Address		Go
2Eh	CERRCNT	Correctable Error Count Register		Go
30h	CERRTHRES	Correctable Error Threshold Value Register	EALLOW	Go
32h	CEINTFLG	Correctable Error Interrupt Flag Status Register		Go
34h	CEINTCLR	Correctable Error Interrupt Flag Clear Register	EALLOW	Go
36h	CEINTSET	Correctable Error Interrupt Flag Set Register	EALLOW	Go
38h	CEINTEN	Correctable Error Interrupt Enable Register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 2-299 shows the codes that are used for access types in this section.

Table 2-299. MEMORY_ERROR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.20.1 UCERRFLG Register (Offset = 0h) [reset = 0h]

UCERRFLG is shown in [Figure 2-270](#) and described in [Table 2-300](#).

Return to [Summary Table](#).

26h	FECC_STATUS	ECC Status	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 2-329 shows the codes that are used for access types in this section.

Table 2-329. FLASH_ECC_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.

Table 2-329. FLASH_ECC_REGS Access Type Codes (continued)

Access Type	Code	Description
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.23.1 ECC_ENABLE Register (Offset = 0h) [reset = Ah]

ECC_ENABLE is shown in [Figure 2-294](#) and described in [Table 2-330](#).

15-9	RESERVED	R	0h	Reserved
8	ERR_TYPE	R	0h	Test mode ECC single bit error indicator. When 1, indicates that the single bit error is in check bits. When 0, indicates that the single bit error is in data bits (If SINGLE_ERR field is also set). Reset type: SYSRSn
7-2	DATA_ERR_POS	R	0h	Test mode single bit error position. Holds the bit position where the single bit error occurred. The position is interpreted depending on whether the CHK_ERR bit indicates a check bit or a data bit. If CHK_ERR indicates a check bit error, the error position could range from 0 to 7, or it could range from 0 to 63. Reset type: SYSRSn
1	UNC_ERR	R	0h	Test mode ECC double bit error. When 1 indicates that the ECC test resulted in an uncorrectable bit error. Reset type: SYSRSn
0	SINGLE_ERR	R	0h	Test mode ECC single bit error. When 1 indicates that the ECC test resulted in a single bit error. Reset type: SYSRSn

2.15.24 CPU_ID_REGS Registers

Table 2-350 lists the memory-mapped registers for the CPU_ID_REGS. All register offset addresses not listed in Table 2-350 should be considered as reserved locations and the register contents should not be modified.

Table 2-350. CPU_ID_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	CPUID_1	Indicates CPU1 or CPU2		Go

Complex bit access types are encoded to fit into small table cells. Table 2-351 shows the codes that are used for access types in this section.

Table 2-351. CPU_ID_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

2.15.24.1 CPUID_1 Register (Offset = 0h) [reset = X]

CPUID_1 is shown in [Figure 2-314](#) and described in [Table 2-352](#).

Return to [Summary Table](#).

This register can be used to identify on which CPU the code is executing.

ROM Code and Peripheral Booting

This chapter describes the booting functionality of the 2837xD subsystems.

Topic	Page
3.1 Introduction	583
3.2 Device Boot Philosophy	583
3.3 Device Boot Modes	583
3.4 Configuring Boot Mode Pins	584
3.5 Configuring Get Boot Options	585
3.6 Configuring Emulation Boot Options	586
3.7 Device Boot Flow Diagrams	588
3.8 Device Reset and Exception Handling	593
3.9 Boot ROM Description	594

3.1 Introduction

This chapter explains the boot ROM code functionality including the boot procedure when executed, the functions and features of the boot ROM code, and details the ROM memory map contents. On every reset, the device executes a boot sequence in the ROM depending on the reset type and boot configuration. This sequence will initialize the device to run application code. The boot ROM also contains peripheral bootloaders which can be used to load an application into RAM. ROM Memory is shown in [Table 3-1](#).

Table 3-1. ROM Memory

ROM	CPU1 Size	CPU2 Size
Unsecure boot ROM	64 KB	64 KB
Secure ROM	64 KB	64 KB
CLA Data ROM	8 KB	8 KB

3.2 Device Boot Philosophy

The boot philosophy describes the general boot ROM procedure each time the CPU core is reset. For dual core devices, CPU1 is the master controller and controls the boot process. Each CPU goes through its own boot procedure, but under the control of CPU1. The exception to this rule is when CPU2 is set to boot-to-flash, in which CPU1 is not involved.

During booting, the boot ROM code updates a boot status location in RAM that details the actions taken during this process. Refer to [Section 3.9.10](#) for more details.

Table 3-2. Boot ROM Philosophy

Step	CPU1 Action	CPU2 Action
1	After reset, the FUSE error register is checked for any errors and are handled accordingly.	Held in reset.
2	Clock and Flash Configuration	Held in reset.
3	Device configuration registers are programmed from OTP.	Held in reset.
4	All CPU RAMs are initialized.	Held in reset.
5	Any pending NMI is handled by the code.	Held in reset.
6	DCSM initialization and OTPJTAGLOCK sequence is executed.	Held in reset.
7	Bring CPU2 out of reset.	Brought out of reset and performs: 1. Clock and Flash Configuration 2. All CPU RAMs are initialized 3. DCSM initialization
8	Based on the boot mode select GPIO pins and boot mode set in OTP, the boot mode is determined, and the appropriate boot sequence is executed. Refer to Section 3.7 for a flow chart of the device boot sequences.	Based on the boot mode value read from OTP, the appropriate boot sequence is executed.

3.3 Device Boot Modes

This section explains the boot modes supported on this device. The boot ROM uses the boot select GPIO pins to determine the boot mode configuration. The device can be configured to boot to RAM, boot to flash, execute a bootloader, or hold in a wait mode.

[Table 3-3](#) shows the boot mode options available through selection by the default boot mode select pins. The boot mode select pins' GPIOs and realized boot mode for when Get boot mode is selected can be customized through the BOOTCTRL register detailed in [Section 3.4](#).

Table 3-3. Device Default Boot Modes for CPU1

Boot Mode	GPIO72 (Default boot mode select pin 1)	GPIO84 (Default boot mode select pin 0)
Parallel IO	0	0
SCI	0	1
Wait	1	0
Get / Flash ⁽¹⁾	1	1

⁽¹⁾ Get boot mode, by default, on an unprogrammed device, or when the BOOTCTRL register contains an invalid key, will boot to flash. Get boot mode can be programmed on the device to change its default boot mode. Refer to [Section 3.5](#) for more details on using Get boot mode.

Table 3-4. All Available Boot Modes

Boot Mode	CPU Support
Parallel IO	CPU1 and CPU2
SCI	CPU1 and CPU2
Wait	CPU1 and CPU2
Get	CPU1 and CPU2
SPI	CPU1 and CPU2
I2C	CPU1 and CPU2
CAN	CPU1 and CPU2
RAM	CPU1 and CPU2
Flash	CPU1 and CPU2
USB	CPU1 Only

NOTE: All the peripheral boot modes that are supported use the first instance of the peripheral module (SCIA, SPIA, I2CA, CANA, and so forth). Whenever these boot modes are referred to in this chapter, such as SCI boot, it is actually referring to the first module instance, meaning the SCI boot on the SCIA port. The same applies to the other peripheral boots.

3.4 Configuring Boot Mode Pins

This section details how the boot mode select pins can be customized by the user, by programming the BOOTCTRL register location in user-configurable DCSM OTP. The BOOTCTRL register, when programmed with a valid key, allows different GPIOs to be used for the two boot mode select pins. Additionally, the boot mode select pins allow the same GPIO to be assigned to each pin for single GPIO use cases. Also within the BOOTCTRL register, the default boot mode for use with Get boot can be changed. When debugging, EMU_BOOTCTRL is the emulation equivalent of the BOOTCTRL register and allows users to experiment with different boot modes without writing to OTP. Refer to [Section 3.6](#) for details on values that can be set in the EMU_BOOTCTRL register.

Table 3-5. BOOTCTRL⁽¹⁾ Register Bit Fields for CPU1

Bit	Name	Description
31-24	Boot Mode Select Pin 1 (BMSP1)	Set to the GPIO pin to be used during boot (up to 255). 0 = Default BMSP1 1 = GPIO0; 2 = GPIO1 and so on to 255 = GPIO254
23-16	Boot Mode Select Pin 0 (BMSP0)	Set to the GPIO pin to be used during boot (up to 255). 0 = Default BMSP0 1 = GPIO0; 2 = GPIO1 and so on to 255 = GPIO254

⁽¹⁾ Refer to the DCSM chapter for the address of this register location in the user-configurable DCSM OTP.

Table 3-5. BOOTCTRL⁽¹⁾ Register Bit Fields for CPU1 (continued)

Bit	Name	Description
15-8	Boot Mode (BMODE)	Boot mode definition when using Get boot mode option. Refer to Section 3.5 for valid BMODE values.
7 - 0	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid

Table 3-6. BOOTCTRL⁽¹⁾ Register Bit Fields for CPU2

Bit	Name	Description
31-24	Reserved	Reserved
23-16	Reserved	Reserved
15-8	Boot Mode (BMODE)	Boot mode definition when using Get boot mode option. Refer to Section 3.5 for valid BMODE values.
7- 0	Key	Write 0x5A to these 8-bits to tell the boot ROM code that the bits in this register are valid

⁽¹⁾ Refer to the DCSM chapter for the address of this register location in the user-configurable DCSM OTP.

On this device, the DCSM has two zones. Each zone, Z1 and Z2, has its own copy of the BOOTCTRL register. The boot ROM is designed to be able to read from either location and uses the procedure in [Figure 3-1](#) to identify which register to use. By default, if the Z1 BOOTCTRL is programmed, then that register is given the priority. If the Z1 BOOTCTRL isn't programmed, then the boot ROM will check if Z2 BOOTCTRL is programmed, if not, then the factory default options are used.

Figure 3-1. Z1 and Z2 BOOTCTRL Selection

3.5 Configuring Get Boot Options

In Get boot mode, the boot ROM reads the boot mode (BMODE) bit field in the BOOTCTRL register to determine which boot procedure to execute. By default, Get boot mode executes flash boot when in standalone mode or wait boot when an emulator is connected to the device. [Table 3-7](#) lists the values that can be set to the BMODE field in BOOTCTRL for CPU1 and the corresponding boot mode that they represent. [Table 3-8](#) lists the acceptable values for CPU2. For additional details on the GPIOs used for each boot mode, refer to the [Section 3.9.6](#) section. When debugging the device using an emulator and EMU_BOOTCTRL, the BMODE field has some additional values which can be found in [Section 3.6](#).

Table 3-7. Get Mode Decoding on CPU1

Key	BMODE Value	Realized Boot Mode
!= 0x5A	Don't Care	Flash Boot / Wait Boot ⁽¹⁾
= 0x5A	0x00	Parallel Boot
	0x01	SCI Boot 0
	0x02	Wait Boot
	0x04	SPI Boot 0
	0x05	I2C Boot 0
	0x07	CAN Boot 0
	0x0A	RAM Boot
	0x0B	Flash Boot
	0x0C	USB Boot
	0x81	SCI Boot 1
	0x84	SPI Boot 1
	0x85	I2C Boot 1
	0x87	CAN Boot 1
	Other	Flash Boot / Wait Boot ⁽¹⁾

⁽¹⁾ When an emulator is connected (TRSTn = 1) to the device, then an invalid key or invalid boot mode value results in wait boot mode.

Table 3-8. Get Mode Decoding on CPU2

Key	BMODE Value	Realized Boot Mode
!= 0x5A	Don't Care	Wait Boot
= 0x5A	0x0A	Wait Boot / RAM Boot ⁽¹⁾
	0x0B	Flash Boot
	Other	Wait Boot

⁽¹⁾ Only after a hibernate reset, CPU2 can boot in RAM boot mode. After any other resets, CPU2 will boot to wait boot.

3.6 Configuring Emulation Boot Options

When connected to the device using an emulator, the EMU_BOOTCTRL register is used to determine the boot mode. This register allows the user to experiment with various boot mode settings before writing to the BOOTCTRL register in the user-configurable DCSM OTP. The values that can be set in the BMODE field of the EMU_BOOTCTRL register are listed in [Section 3.6](#). Some notable options include being able to have emulation boot read from the boot mode select pins, emulate standalone boot using the values in OTP, and boot according to the Get boot value stored in OTP. Refer to [Section 3.9.6](#) for details on the GPIOs used in the various boot modes.

Table 3-9. Emulation Boot Options

Key	BMODE Value	Realized Boot Mode	CPU Support
!= 0x5A	Don't Care	Wait Boot	CPU1 and CPU2
= 0x5A	0xFE	Boot as per BMSP0 and BMSP1	CPU1 Only
	0xFF	Emulate Standalone boot	CPU1 and CPU2
	0x00	Parallel Boot	CPU1 and CPU2
	0x01	SCI Boot 0	CPU1 and CPU2
	0x02	Wait Boot	CPU1 and CPU2
	0x03	Get Mode(read OTP BOOTCTRL)	CPU1 and CPU2
	0x04	SPI Boot 0	CPU1 and CPU2
	0x05	I2C Boot 0	CPU1 and CPU2

Table 3-9. Emulation Boot Options (continued)

Key	BMODE Value	Realized Boot Mode	CPU Support
	0x07	CAN Boot 0	CPU1 and CPU2
	0x0A	RAM Boot	CPU1 and CPU2
	0x0B	Flash Boot	CPU1 and CPU2
	0x0C	USB Boot	CPU1 Only
	0x81	SCI Boot 1	CPU1 Only
	0x84	SPI Boot 1	CPU1 Only
	0x85	I2C Boot 1	CPU1 Only
	0x87	CAN Boot 1	CPU1 Only
	Other	Wait Boot	CPU1 and CPU2

3.7 Device Boot Flow Diagrams

Figure 3-2 shows the device boot flow for CPU1 detailing the actions executed by boot ROM after a reset.
Figure 3-3 shows the device boot flow for CPU2.

Figure 3-2. CPU1 Device Boot Flow

Figure 3-3. CPU2 Device Boot Flow

3.7.1 Emulation Boot Flow Diagrams

shows the device boot flow for CPU1 when running the device in emulation mode. [Figure 3-5](#) shows the emulation boot flow for CPU2.

Figure 3-4. CPU1 Emulation Boot Flow

Figure 3-5. CPU2 Emulation Boot Flow

3.7.2 Standalone and Hibernate Boot Flow Diagrams

Figure 3-6 shows the device boot flow for CPU1 when running the device in standalone boot mode or when booting from hibernate. Figure 3-7 shows the standalone boot flow and hibernate boot flow for CPU2.

Figure 3-6. CPU1 Standalone and Hibernate Boot Flow

Figure 3-7. CPU2 Standalone and Hibernate Boot Flow

3.8 Device Reset and Exception Handling

3.8.1 Reset Causes and Handling

This section explains the actions boot ROM performs upon reset after checking the reset cause.

Table 3-10. Boot ROM Reset Causes and Actions

Reset Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action
POR	- Adjust clock divider to /1 - Device configuration - RAM initialization - Continue default boot flow	- RAM Initialization - Continue default boot flow
XRS	- Adjust clock divider to /1 - Device configuration - RAM initialization - Continue default boot flow	- RAM Initialization - Continue default boot flow
HWBIST	Branch to application code	Branch to application code
Hibernate	- Adjust clock divider to /1 - Device configuration - RAM initialization (Either all RAMS except for M0M1 or all RAMS) - Continue default boot flow	- RAM initialization (Either all RAMS except for M0M1 or all RAMS) - Continue default boot flow
WDRS (CPU1)	- Adjust clock divider to /1 - Device configuration - RAM initialization - Continue default boot flow	- RAM initialization - Continue default boot flow

Table 3-10. Boot ROM Reset Causes and Actions (continued)

Reset Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action
WDRS (CPU2)	Exception handled by CPU1	1. Clear boot stack 2. Continue default boot flow
NMIWDRS (CPU1)	1. Adjust clock divider to /1 2. Device configuration 3. RAM initialization 4. Continue default boot flow	1. RAM initialization 2. Continue default boot flow
NMIWDRS (CPU2)	Exception handled by CPU1	1. Clear boot stack 2. Continue default boot flow
Debugger (CPU1)	1. Clear boot stack 2. Continue default boot flow	No Action
Debugger (CPU2)	Exception handled by CPU1	1. Clear boot stack 2. Continue default boot flow
SCCRESET (CPU1)	1. Clear boot stack 2. Continue default boot flow	No Action
SCCRESET (CPU2)	Exception handled by CPU1	1. Clear boot stack 2. Continue default boot flow

3.8.2 Exceptions and Interrupts Handling

This section explains the actions boot ROM performs if any exceptions that can occur happen during boot.

Table 3-11. Boot ROM Exceptions and Actions

Exception Event Source	CPU1 Boot ROM Action	CPU2 Boot ROM Action	Event Logged
Single-bit error in FUSEERR	Ignore and continue to boot	Ignore and continue to boot	No
Multi-bit error in FUSEERR	Reset the device	No action required	No
Clock fail condition detected	Clear the NMI and continue to boot	Clear the NMI and continue to boot	Yes
Double-bit ECC error from RAM	Reset the device	Send IPC to CPU1, clear NMI flag, and wait forever	Yes
Double-bit error from Flash	Reset the device	Send IPC to CPU1, clear NMI flag, and wait forever	Yes
PIE Vector Error	Ignore and continue to boot	Ignore and continue to boot	Yes
HWBIST Error	Ignore and continue to boot	Send IPC to CPU1, clear NMI flag, and wait forever	Yes
ITRAP Exception	Provide ROM location where it will loop	Provide ROM location to CPU1 of where it will loop	Yes
CPU2 NMIWDRST	Ignore and continue to boot	No action required	Yes
CPU2 WDRST	Ignore and continue to boot	No action required	Yes
Any spurious PIE interrupt occurs	Acknowledge interrupt and continue to boot	Send IPC to CPU1 and acknowledge interrupt	No

3.9 Boot ROM Description

This section explains the details regarding the device boot ROM.

3.9.1 Entry Points

This section gives details about the entry point addresses for various boot modes. These entry points tell the boot ROM where to branch to at the end of booting as per the selected boot mode.

Table 3-12. Entry Point Addresses for CPU1 and CPU2

Entry Point	Address
RAM	0x0000 0000
Flash	0x0008 0000

3.9.2 Wait Points

During boot ROM execution, there are situations where the CPU may enter a wait loop in the code. This state can occur for a variety of reasons.

[Table 3-13](#) details the address ranges that the CPU1 PC register value will fall between if it has entered one of these instances. [Table 3-14](#) details the addresses for CPU2.

Table 3-13. Wait Point Addresses for CPU1

Address Range	Description
0x003FE2D4 – 0x003FE2EF	In Wait Boot
0x003FE73E – 0x003FE824	In NMI Handler (startup)
0x003FE35A – 0x003FE468	In NMI Handler (PIE)
0x003FE468 – 0x003FE495	In ITRAP ISR

Table 3-14. Wait Point Addresses for CPU2

Address Range	Description
0x003FE44C – 0x003FE451	In Idle Mode
0x003FDEAA – 0x003FDFC2	In NMI Handler
0x003FDE61 – 0x003FDEAA	In PIE Vector Mismatch Handler
0x003FDFC2 – 0x003FE00B	In ITRAP ISR

3.9.3 Memory Maps

This section details the ROM memory maps.

3.9.3.1 CPU1 Boot ROM Memory Map

Table 3-15. CPU1 Boot ROM Memory Map

⁽¹⁾ If the user is not planning to use TI-RTOS in ROM, then these memory locations are free to be used by the application.

⁽²⁾ For using the TI-RTOS in flash sector A, TI recommends that this sector be made unsecure, or at minimum, the sector should be verified that there is no secure zone claiming this sector.

3.9.3.5 ROM Tables

This section details the boot ROM and CLA ROM symbol tables.

3.9.3.5.1 Boot ROM Tables

The boot ROM symbols and their addresses can be located in the .map file that is included with the released boot ROM source and header code. Within the .map file, locate the Global Symbols category to get a list of the boot ROM symbols and addresses present.

3.9.3.5.2 CLA ROM Tables

Table 3-20. CLA Data ROM Tables

3.9.4 Boot Modes

The available boot modes supported on this device are detailed in this section. Each boot mode allows for various options, providing configurations with different IOs to be used, depending on the application.

3.9.4.1 Wait Boot Mode

The wait boot mode puts the CPU in a loop and does not branch to the user application code. The device can enter wait boot mode either manually or because an error occurred during boot up. TI recommends using wait boot when using a debugger to avoid any JTAG complications.

Actions resulting in entering wait boot mode:

- Wait boot is set by the user as the boot mode
- The boot mode is unrecognized and a debugger is connected to the device
- The emulation BOOCTRL key is not equal to 0xA5 or 0x5A

- An error occurs during emulation boot and the boot mode pins are decoded with a value not recognized as a valid boot mode

3.9.4.2 SCI Boot Mode

The SCI boot mode asynchronously transfers code from SCI-A to internal memory. This boot mode only supports an incoming 8-bit data stream and follows the data flow as outlined in [Example 3-1](#).

Figure 3-8. Overview of SCI Bootloader Operation

The device communicates with the external host by communication through the SCI-A peripheral. The autobaud feature of the SCI port is used to lock baud rates with the host. For this reason the SCI loader is very flexible and you can use a number of different baud rates to communicate with the device.

After each data transfer, the bootloader will echo back the 8-bit character received to the host. This allows the host to check that each character was received by the bootloader.

At higher baud rates, the slew rate of the incoming data bits can be affected by transceiver and connector performance. While normal serial communications may work well, this slew rate may limit reliable auto-baud detection at higher baud rates (typically beyond 100kbaud) and cause the auto-baud lock feature to fail. To avoid this, the following is recommended:

1. Achieve a baud-lock between the host and SCI bootloader using a lower baud rate.
2. Load the incoming application or custom loader at this lower baud rate.
3. The host may then handshake with the loaded application to set the SCI baud rate register to the desired high baud rate.

Figure 3-9. Overview of SCI Boot Function

3.9.4.3 SPI Boot Mode

The SPI loader expects an SPI-compatible 16-bit or 24-bit addressable serial EEPROM or serial flash device to be present on the SPI-A pins as indicated in [Figure 3-10](#). The SPI bootloader supports an 8-bit data stream. It does not support a 16-bit data stream.

Figure 3-10. SPI Loader

The SPI boot ROM loader initializes the SPI module to interface to a serial SPI EEPROM or flash. Devices of this type include, but are not limited to, the Xicor X25320 (4Kx8) and Xicor X25256 (32Kx8) SPI serial SPI EEPROMs and the Atmel AT25F1024A serial flash.

The SPI boot ROM loader initializes the SPI with the following settings: FIFO enabled, 8-bit character, internal SPICLK master mode and talk mode, clock phase = 1, polarity = 0, using the slowest baud rate.

If the download is to be performed from an SPI port on another device, then that device must be setup to operate in the slave mode and mimic a serial SPI EEPROM. Immediately after entering the SPI_Boot function, the pin functions for the SPI pins are set to primary and the SPI is initialized. The initialization is done at the slowest speed possible. Once the SPI is initialized and the key value read, you could specify a change in baud rate or low speed peripheral clock.

The data transfer is done in "burst" mode from the serial SPI EEPROM. The transfer is carried out entirely in byte mode (SPI at 8 bits/character). A step-by-step description of the sequence follows:

- Step 1. The SPI-A port is initialized
- Step 2. The GPIO19 (SPISTE) pin is used as a chip-select for the serial SPI EEPROM or flash
- Step 3. The SPI-A outputs a read command for the serial SPI EEPROM or flash
- Step 4. The SPI-A sends the serial SPI EEPROM an address 0x0000; that is, the host requires that the EEPROM or flash must have the downloadable packet starting at address 0x0000 in the EEPROM or flash. The loader is compatible with both 16-bit addresses and 24-bit addresses.
- Step 5. The next word fetched must match the key value for an 8-bit data stream (0x08AA). The least significant byte of this word is the byte read first and the most significant byte is the next byte fetched. This is true of all word transfers on the SPI. If the key value does not match, then the load is aborted and the bootloader jumps to flash.
- Step 6. The next 2 bytes fetched can be used to change the value of the low speed peripheral clock register (LOSPCP) and the SPI baud rate register (SPIBRR). The first byte read is the LOSPCP value and the second byte read is the SPIBRR value. The next 7 words are reserved for future enhancements. The SPI bootloader reads these 7 words and discards them.
- Step 7. The next two words makeup the 32-bit entry point address where execution will continue after

the boot load process is complete. This is typically the entry point for the program being downloaded through the SPI port.

- Step 8. Multiple blocks of code and data are then copied into memory from the external serial SPI EEPROM through the SPI port. The blocks of code are organized in the standard data stream structure presented earlier. This is done until a block size of 0x0000 is encountered. At that point in time the entry point address is returned to the calling routine that then exits the bootloader and resumes execution at the address specified.

Figure 3-11. Data Transfer From EEPROM Flow

3.9.4.4 I2C Boot Mode

The I2C bootloader expects an 8-bit wide I2C-compatible EEPROM device to be present at address 0x50 on the I2C-A bus as indicated in Figure 3-12. The EEPROM must adhere to conventional I2C EEPROM protocol, as described in this section, with a 16-bit base address architecture.

Figure 3-12. EEPROM Device at Address 0x50

If the download is to be performed from a device other than an EEPROM, then that device must be set up to operate in the slave mode and mimic the I2C EEPROM. Immediately after entering the I2C boot function, the GPIO pins are configured for I2C-A operation and the I2C is initialized. The following requirements must be met when booting from the I2C module:

- The input frequency to the device must be in the appropriate range.
- The EEPROM must be at slave address 0x50.

Figure 3-13. Overview of I2C Boot Function

The bit-period prescalers (I2CCLKH and I2CCLKL) are configured by the bootloader to run the I2C at a 50 percent duty cycle at 100-kHz bit rate (standard I2C mode) when the system clock is 10 MHz. These registers can be modified after receiving the first few bytes from the EEPROM. This allows the communication to be increased up to a 400-kHz bit rate (fast I2C mode) during the remaining data reads.

Arbitration, bus busy, and slave signals are not checked. Therefore, no other master is allowed to control the bus during this initialization phase. If the application requires another master during I2C boot mode, that master must be configured to hold off sending any I2C messages until the application software signals that it is past the bootloader portion of initialization.

The non-acknowledgment bit is checked only during the first message sent to initialize the EEPROM base address. This is to make sure that an EEPROM is present at address 0x50 before continuing. If an EEPROM is not present, the non-acknowledgment bit is not checked during the address phase of the data read messages (I2C_Get Word). If a non acknowledgment is received during the data read messages, the I2C bus will hang. [Table 14-1](#) shows the 8-bit data stream used by the I2C.

The I2C EEPROM protocol required by the I2C bootloader is shown in [Figure 3-14](#) and [Figure 3-15](#). The first communication, which sets the EEPROM address pointer to 0x0000 and reads the KeyValue (0x08AA) from it, is shown in [Figure 3-14](#). All subsequent reads are shown in [Figure 3-15](#) and are read two bytes at a time.

Figure 3-14. Random Read

Figure 3-15. Sequential Read

3.9.4.5 Parallel Boot Mode

The parallel general purpose I/O (GPIO) boot mode asynchronously transfers code from GPIO58 - GPIO63, GPIO64-GPIO65 to internal memory. Each value is 8 bits long and follows the same data flow as outlined in [Figure 3-16](#).

Figure 3-16. Overview of Parallel GPIO Bootloader Operation

The control subsystem communicates with the external host device by polling/driving the GPIO70 and GPIO69 lines. The handshake protocol shown in [Figure 3-17](#) must be used to successfully transfer each word via GPIO [63-58,64,65]. This protocol is very robust and allows for a slower or faster host to communicate with the master subsystem.

Two consecutive 8-bit words are read to form a single 16-bit word. The most significant byte (MSB) is read first followed by the least significant byte (LSB). In this case, data is read from GPIO[63-58,64,65].

The 8-bit data stream is shown in [Table 3-23](#).

Table 3-23. Parallel GPIO Boot 8-Bit Data Stream

Bytes	GPIO[63:58,64,65] (Byte 1 of 2)	GPIO[63:58,64,65] (Byte 2 of 2)	Description

.	BB	AA	Destination address of second block Addr[31:16]
.	DD	CC	Destination address of second block Addr[15:0]
.	BB	AA	First word of the second block in the source being loaded
.	...	...	...

Table 3-23. Parallel GPIO Boot 8-Bit Data Stream (continued)

Bytes	GPIO[63:58,64,65] (Byte 1 of 2)	GPIO[63:58,64,65] (Byte 2 of 2)	Description
n n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2 n+3	00	00	Block size of 0000h - indicates end of the source program

The device first signals the host that it is ready to begin data transfer by pulling the GPIO69 pin low. The host load then initiates the data transfer by pulling the GPIO70 pin low. The complete protocol is shown in Figure 3-17:

Figure 3-17. Parallel GPIO Bootloader Handshake Protocol

1. The device indicates it is ready to start receiving data by pulling the GPIO69 pin low.
2. The bootloader waits until the host puts data on GPIO [63-58,64,65]. The host signals to the device that data is ready by pulling the GPIO70 pin low.
3. The device reads the data and signals the host that the read is complete by pulling GPIO69 high.
4. The bootloader waits until the host acknowledges the device by pulling GPIO70 high.
5. The device again indicates it is ready for more data by pulling the GPIO69 pin low.

This process is repeated for each data value to be sent.

Figure 3-18 shows an overview of the Parallel GPIO bootloader flow.

Figure 3-18. Parallel GPIO Mode Overview

Figure 3-19 shows the transfer flow from the host side. The operating speed of the CPU and host are not critical in this mode as the host will wait for the device and the device will in turn wait for the host. In this manner the protocol will work with both a host running faster and a host running slower than the device.

Figure 3-19. Parallel GPIO Mode - Host Transfer Flow

Figure 3-20 shows the flow used to read a single word of data from the parallel port.

- **8-bit data stream**

The 8-bit routine, shown in Figure 3-20, discards the upper 8 bits of the first read from the port and treats the lower 8 bits masked with GPIO65 in bit position 7 and GPIO64 in bit position 6 as the least significant byte (LSB) of the word to be fetched. The routine will then perform a second read to fetch the most significant byte (MSB). The routine will then perform a second read to fetch the most significant byte (MSB). It then combines the MSB and LSB into a single 16-bit value to be passed back to the calling routine.

Figure 3-20. 8-Bit Parallel GetWord Function

3.9.4.6 CAN Boot Mode

The CAN bootloader asynchronously transfers code from CAN-A to internal memory. The host can be any CAN node. The communication is first done with 11-bit standard identifiers (with a MSGID of 0x1) using two bytes per data frame. The host can download a kernel to reconfigure the CAN if higher data throughput is desired.

Figure 3-21. Overview of CAN-A Bootloader Operation

The bit timing registers are programmed in such a way that a 100 kbps bit rate is achieved with a 20 MHz external oscillator, as shown in [Table 3-24](#).

Table 3-24. Bit-Rate Value for Internal Oscillators

OSCCLK	SYSCLK	Bit Rate
20 MHz	10 MHz	100 kbps

The SYSCLKOUT values shown are the reset values with the default PLL setting. The BRP and bit-time values are hard-coded to 10 and 20, respectively.

NOTE: The CPU1 CAN boot loader uses XTAL as the bit clock source and INTOSC2 as the system clock source. The CPU2 CAN boot loader does not change either clock source, so CPU1 must configure the clock sources before starting the CPU2 CAN boot loader.

Mailbox 1 is programmed with a standard MSGID of 0x1 for boot-loader communication. The CAN host should transmit only 2 bytes at a time, LSB first and MSB next. For example, to transmit the word 0x08AA to the device, transmit AA first, followed by 08. The program flow of the CAN bootloader is identical to the SCI bootloader. The data sequence for the CAN bootloader is shown in [Table 3-25](#):

Table 3-25. CAN 8-Bit Data Stream

Bytes	Byte 1 of 2	Byte 2 of 2	Description
1 2	AA	08	0x08AA (KeyValue for memory width = 16 bits)

3.9.4.7 USB Boot Mode

In USB boot mode, the device will enumerate with vendor ID 0x1cbe and product ID 0x00ff. The device descriptor and interface descriptor both show the class as 0xFF (vendor-specific), the subclass as 0x00, and the protocol as 0x00. After enumeration, the device will wait for data. Data should be sent via bulk OUT transfers to endpoint 1. The data is interpreted as a series of 8-bit bytes in the standard data stream format described in [Section 3.9.5](#), shown here in [Table 3-26](#). No reserved bytes are used. Once the data transfer is complete (block size of 0x0000 sent), the device will disconnect from the USB bus, allowing other software to make use of the module if desired. [Figure 3-22](#) illustrates the flow for USB boot mode.

Figure 3-22. USB Boot Flow

Table 3-26. USB 8-Bit Data Stream

.			...
n n+1	BB	AA	Last word of the last block of the source being loaded (More sections if required)
n+2 n+3	00	00	Block size of 0000h - indicates end of the source program

Implementing PC-side USB software is not trivial. It is recommended to use the TI-provided tools and drivers to load data in USB boot mode. Hex and binary files for loader tools can be generated from COFF (.out) files using the hex2000 tool. To produce a plain binary file in the boot loader format, use the following command line:

```
hex2000 -boot -b Program_to_Load.out -o Binary_Loader_Data.dat
```

For more information on hex2000, please see the *TMS320C28x Assembly Language Tools User's Guide* ([SPRU513](#)).

NOTE: INTOSC2 must be enabled before invoking the USB boot loader. If INTOSC2 is not enabled, the boot loader will hang. A debugger reset or SCC reset will not enable INTOSC2 if it has been disabled by the application.

3.9.5 Boot Data Stream Structure

This section details the data transfer protocols or stream structures that allow boot data transfer between boot ROM and host device. This data transfer protocol is compatible to the respective bootloaders on the Piccolo class of C2000 devices.

3.9.5.1 Bootloader Data Stream Structure

The following table and associated examples show the structure of the data stream incoming to the bootloader. The basic structure is the same for all the bootloaders and is based on the C54x source data stream generated by the C54x hex utility. The C28x hex utility (hex2000.exe) has been updated to support this structure. The hex2000.exe utility is included with the C2000 code generation tools. All values in the data stream structure are in hex.

The first 16-bit word in the data stream is known as the key value. The key value is used to tell the bootloader the width of the incoming stream: 8 or 16 bits. Note that not all bootloaders will accept both 8 and 16-bit streams. Please refer to the detailed information on each loader for the valid data stream width. For an 8-bit data stream, the key value is 0x08AA and for a 16-bit stream it is 0x10AA. If a bootloader receives an invalid key value, then the load is aborted.

The next eight words are used to initialize register values or otherwise enhance the bootloader by passing values to it. If a bootloader does not use these values then they are reserved for future use and the bootloader simply reads the value and then discards it. Currently only the SPI and I2C and parallel bootloaders use these words to initialize registers.

The tenth and eleventh words comprise the 22-bit entry point address. This address is used to initialize the PC after the boot load is complete. This address is most likely the entry point of the program downloaded by the bootloader.

The twelfth word in the data stream is the size of the first data block to be transferred. The size of the block is defined as 8-bit data stream format. For example, to transfer a block of 20 8-bit data values from an 8-bit data stream, the block size would be 0x000A to indicate 10 16-bit words.

The next two words tell the loader the destination address of the block of data. Following the size and address will be the 16-bit words that makeup that block of data.

This pattern of block size/destination address repeats for each block of data to be transferred. Once all the blocks have been transferred, a block size of 0x0000 signals to the loader that the transfer is complete. At this point the loader will return the entry point address to the calling routine which in turn will cleanup and exit. Execution will then continue at the entry point address as determined by the input data stream contents.

Table 3-27. LSB/MSB Loading Sequence in 8-Bit Data Stream

Byte		Contents	
		LSB (First Byte of 2)	MSB (Second Byte of 2)
1	2	LSB: AA (KeyValue for memory width = 8 bits)	MSB: 08h (KeyValue for memory width = 8 bits)
3	4	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
5	6	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
7	8	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
...	...	...	...
17	18	LSB: Register initialization value or reserved	MSB: Register initialization value or reserved
19	20	LSB: Upper half of Entry point PC[23:16]	MSB: Upper half of entry point PC[31:24] (Always 0x00)
21	22	LSB: Lower half of Entry point PC[7:0]	MSB: Lower half of Entry point PC[15:8]
23	24	LSB: Block size in words of the first block to load. If the block size is 0, this indicates the end of the source program. Otherwise another block follows. For example, a block size of 0x000A would indicate 10 words or 20 bytes in the block.	MSB: block size
25	26	LSB: MSW destination address, first block Addr[23:16]	MSB: MSW destination address, first block Addr[31:24]
27	28	LSB: LSW destination address, first block Addr[7:0]	MSB: LSW destination address, first block Addr[15:8]
29	30	LSB: First word of the first block being loaded	MSB: First word of the first block being loaded
...	...	...	...
.	.	LSB: Last word of the first block to load	MSB: Last word of the first block to load
.	.	LSB: Block size of the second block	MSB: Block size of the second block

Table 3-27. LSB/MSB Loading Sequence in 8-Bit Data Stream (continued)

Byte		Contents	
		LSB (First Byte of 2)	MSB (Second Byte of 2)
.	.	LSB: MSW destination address, second block Addr[23:16]	MSB: MSW destination address, second block Addr[31:24]
.	.	LSB: LSW destination address, second block Addr[7:0]	MSB: LSW destination address, second block Addr[15:8]
.	.	LSB: First word of the second block being loaded	MSB: First word of the second block being loaded
...	...	...	...
.	.	LSB: Last word of the second block	MSB: Last word of the second block
.	.	LSB: Block size of the last block	MSB: Block size of the last block
.	.	LSB: MSW of destination address of last block Addr[23:16]	MSB: MSW destination address, last block Addr[31:24]
.	.	LSB: LSW destination address, last block Addr[7:0]	MSB: LSW destination address, last block Addr[15:8]
.	.	LSB: First word of the last block being loaded	MSB: First word of the last block being loaded
...	...	...	...
.	.	LSB: Last word of the last block	MSB: Last word of the last block
n	n+1	LSB: 00h	MSB: 00h - indicates the end of the source

Example 3-1. Data Stream Structure 8-bit

```

AA 08      ; 0x08AA 8-bit key value
00 00 00 00 ; 8 reserved words
00 00 00 00
00 00 00 00
00 00 00 00
3F 00 00 80 ; 0x003F8000 EntryAddr, starting point after boot load completes
05 00      ; 0x0005 - First block consists of 5 16-bit words
3F 00 10 90 ; 0x003F9010 - First block will be loaded starting at 0x3F9010
01 00      ; Data loaded = 0x0001 0x0002 0x0003 0x0004 0x0005
02 00
03 00
04 00
05 00
02 00      ; 0x0002 - 2nd block consists of 2 16-bit words
3F 00 00 80 ; 0x003F8000 - 2nd block will be loaded starting at 0x3F8000
00 77      ; Data loaded = 0x7700 0x7625
25 76
00 00      ; 0x0000 - Size of 0 indicates end of data stream

```

After load has completed the following memory values will have been initialized as follows:

```

Location  Value
0x3F9010  0x0001
0x3F9011  0x0002
0x3F9012  0x0003
0x3F9013  0x0004
0x3F9014  0x0005
0x3F8000  0x7700
0x3F8001  0x7625
PC Begins execution at 0x3F8000

```

3.9.6 GPIO Assignments

This section details the GPIOs and boot options used for each boot mode set in the BMODE bit-field of the BOOTCTRL register in OTP. Refer to [Section 3.4](#) on the details of the BOOTCTRL fields.

Table 3-28. SCI Boot Options

Option	BMODE Value	SCITXDA GPIO	SCIRXDA GPIO	CPU Support
0 (default)	0x01	GPIO84	GPIO85	CPU1 and CPU2

3.9.7 Boot IPC

In order for CPU1 and CPU2 to communicate during the boot process, a set of inter-processor communication (IPC) registers are used. Each core polls for supported IPC commands which then determine what specific action should be performed. Actions include performing reads or writes to a particular memory address, branching to an address, or calling a function. The supported commands differ depending on the core.

Prior to sending an IPC command to CPU2 boot ROM, the CPU1 application should perform the necessary GPIO mux configurations for the peripheral IO pins. CPU2 peripheral loaders don't configure any of the GPIO mux options and only configure the peripheral as required for the application load. Once configured, CPU1 can then assign the peripheral to CPU2 through configuration of the CPU select register.

3.9.7.1 CPU1 IPC Commands

This section details the commands CPU1 boot ROM supports. These commands can be used by CPU2 applications to have CPU1 boot ROM to perform an action such as configure peripherals or IOs. In order to use these IPC commands, CPU1 boot ROM must be in Wait Boot mode. Additionally, watchdog is disabled when using IPC.

Table 3-37. C2TOC1IPC Commands Table ⁽¹⁾

Value	IPCRECVCOM (CPU2 - R/W, CPU1- R)	IPCRECVADDR (CPU2 - R/W, CPU1- R)	IPCRECVDATA (CPU2 - R/W, CPU1- R)	IPCLOCALREPLY (CPU2 - R, CPU1 - R/W)	C2TOC1IPCFLG[31] = ? C2TOC1IPCFLAG[0] = 0	Description
0	C2C1_BROM_IPC_COMMAND_ILLEGAL	_NOT-USED_	_NOT-USED_	Look at error codes table	0x01	Illegal command
1	C2C1_BROM_IPC_SET_BITS_16	Address of the 16-bit register	Data in C2TOC1IPCDATA W[15:0]	Data read back from address after write	0x00 = Command success	*(address) = data;
2	C2C1_BROM_IPC_SET_BITS_32	Address of the 32-bit register	Data;	Data read back from address after write	Same as above	*(address) = data;
3	C2C1_BROM_IPC_CLEAR_BITS_16	Address of the 16-bit register	Data in C2TOC1IPCDATA W[15:0]	Data read back after write	Same as above	*(address) &= ~data;
4	C2C1_BROM_IPC_CLEAR_BITS_32	Address of the 32-bit register	Data	Data read back after write	Same as above	*(address) &= ~data;
5	C2C1_BROM_IPC_DATA_WRITE_16	Address of the 16-bit register	Data in MTOCIPCDATAW [15:0]	Data read back from the address	Same as above	*(address) = data;
6	C2C1_BROM_IPC_DATA_WRITE_32	Address of the 32-bit register	Data	Same as above	Same as above	*(address) = data;
7	C2C1_BROM_IPC_DATA_READ_16	Address of the 16-bit register	--NOT_USED--	Data in C2TOC1IPCDATAR[15:0]	Same as above	C2TOC1IPCDATAR[15:0] = *(address); Only 16 bit read from address

⁽¹⁾ All 32-bit operations are done in little endian format (C28x is 16-bit addressable).

Example: a 32-bit IPC write is handled as below:

- Data[15:0] is written in address
- Data [31:16] is written in address+1

Table 3-37. C2TOC1IPC Commands Table ⁽¹⁾ (continued)

Value	IPCRECVCOM (CPU2 - R/W, CPU1- R)	IPCRECVADDR (CPU2 - R/W, CPU1- R)	IPCRECVDATA (CPU2 - R/W, CPU1- R)	IPCLOCALREPLY (CPU2 - R, CPU1 - R/W)	C2TOC1IPCFLG[31] = ? C2TOC1IPCFLAG[0] = 0	Description
8	C2C1_BROM_IPC_DATA_READ_32	Address of the 32-bit register	Same as above	32-bit data	Same as above	C2TOC1IPCDATAR[31:0] = *(address); 32 bits read from address
9	C2C1_BROM_IPC_SET_BITS_PROTECTED_16	Address of the 16-bit register	Data in C2TOC1IPCDATAW[15:0]	Data read back from address after write	0x00 = Command success	EALLOW; *(address) = data; EDIS;
10	C2C1_BROM_IPC_SET_BITS_PROTECTED_32	Address of the 32-bit register	Data;	Data read back from address after write	Same as above	EALLOW; *(address) = data; EDIS;
11	C2C1_BROM_IPC_CLEAR_BITS_PROTECTED_16	Address of the 16-bit register	Data in C2TOC1IPCDATAW[15:0]	Data read back after write	Same as above	EALLOW; *(address) &= ~data; EDIS;
12	C2C1_BROM_IPC_CLEAR_BITS_PROTECTED_32	Address of the 32-bit register	Data	Data read back after write	Same as above	EALLOW; *(address) &= ~data; EDIS;
13	C2C1_BROM_IPC_DATA_WRITE_PROTECTED_16	Address of the 16-bit register	Data in C2TOC1IPCDATAW[15:0]	Data read back from the address	Same as above	EALLOW; *(address) &= ~data; EDIS;
14	C2C1_BROM_IPC_DATA_WRITE_PROTECTED_32	Address of the 32-bit register	Data	Same as above	Same as above	EALLOW; *(address) &= ~data; EDIS;
15	C2C1_BROM_IPC_DATA_READ_PROTECTED_16	Address of the 32-bit register	--NOT_USED--	Data in C2TOC1IPCDATAR[15:0]	Same as above	EALLOW; C2TOC1IPCDATAR[15:0] = *(address); EDIS; Only 16 bit read from address
16	C2C1_BROM_IPC_DATA_READ_PROTECTED_32	Address of the 32-bit register	Data	Same as above	Same as above	EALLOW; C2TOC1IPCDATAR[31:0] = *(address); EDIS; 32 bits read from address

3.9.7.2 CPU2 IPC Commands

This section details the commands that CPU2 boot ROM supports. These commands can be used by CPU1 applications to have CPU2 perform a specific action. In order to use these IPC commands, CPU2 boot ROM must be in Wait Boot mode.

Table 3-38. C1TOC2IPC Commands Table

Value	IPCRECVCOM (CPU1 - R/W, CPU2 R)	IPCRECVADDR (CPU1 - R/W, BCPU2- R)	IPCRECVDATA (CPU1 - R/W, CPU2- R)	IPCLOCALREPLY (CPU1 - R, CPU2 - R/W)	C1TOC2IPCFLG[31] = ? C1TOC2IPCFLAG[0] = 0	Description
0	C1C2_BROM_IPC_COMMAND_ILLEGAL	_NOT-USED_	_NOT-USED_	Look at error codes table	0x01	Illegal command
1	C1C2_BROM_IPC_SET_BITS_16	Address of the 16-bit register	Data in C1TOC2IPCDATAW[15:0]	Data read back from address after write	0x00 = Command success	*(address) = data;
2	C1C2_BROM_IPC_SET_BITS_32	Address of the 32-bit register	Data;	Data read back from address after write	Same as above	*(address) = data;

7	C1C2_BROM_IPC_DATA_READ_16	Address of the 16-bit register	--NOT_USED--	Data in C1TOC2IPCDATAR[15:0]	Same as above	C1TOC2IPCDATAR[15:0] = *(address); Only 16 bit read from address

Table 3-38. C1TOC2IPC Commands Table (continued)

Value	IPCRCVCOM (CPU1 - R/W, CPU2 R)	IPCRCVADDR (CPU1 - R/W, BCPU2- R)	IPCRCVDATA (CPU1 - R/W, CPU2- R)	IPCLOCALREPLY (CPU1 - R, CPU2 - R/W)	C1TOC2IPCFLG[31] = ? C1TOC2IPCFLAG[0] = 0	Description
8	C1C2_BROM_IPC_DATA_READ_32	Address of the 32-bit register	Same as above	32 bit data	Same as above	C1TOC2IPCDATAR[31:0] = *(address); 32 bits read from address
9	C1C2_BROM_IPC_SET_BITS_PROTECTED_16	Address of the 16-bit register	Data in C1TOC2IPCDATAW[15:0]	Data read back from address after write	0x00 = Command success	EALLOW; *(address) = data; EDIS;
10	C1C2_BROM_IPC_SET_BITS_PROTECTED_32	Address of the 32-bit register	Data;	Data read back from address after write	Same as above	EALLOW; *(address) = data; EDIS;
11	C1C2_BROM_IPC_CLEAR_BITS_PROTECTED_16	Address of the 16-bit register	Data in C1TOC2IPCDATAW[15:0]	Data read back after write	Same as above	EALLOW; *(address) &= ~data; EDIS;
12	C1C2_BROM_IPC_CLEAR_BITS_PROTECTED_32	Address of the 32-bit register	Data	Data read back after write	Same as above	EALLOW; *(address) &= ~data; EDIS;
13	C1C2_BROM_IPC_DATA_WRITE_PROTECTED_16	Address of the 16-bit register	Data in C1TOC2IPCDATAW[15:0]	Data read back from the address	Same as above	EALLOW; *(address) = data; EDIS;
14	C1C2_BROM_IPC_DATA_WRITE_PROTECTED_32	Address of the 32-bit register	Data	Same as above	Same as above	EALLOW; *(address) = data; EDIS;
15	C1C2_BROM_IPC_DATA_READ_PROTECTED_16	Address of the 16-bit register	--NOT_USED--	Data in C1TOC2IPCDATAR[15:0]	Same as above	EALLOW; C1TOC2IPCDATAR[15:0] = *(address); Only 16 bit read from address
16	C1C2_BROM_IPC_DATA_READ_PROTECTED_32	Address of the 32-bit register	Same as above	32 bit data	Same as above	EALLOW; C1TOC2IPCDATAR[31:0] = *(address); EDIS; 32 bits read from address
17	C1C2_BROM_IPC_BRANCH_CALL	Address where to branch to	_NOT_USED_BY_BOOTROM (code at the branch can use this though)	NOT_USED_BY_BOOTROM (code at the branch can use this though)	Same as above	C2-BootROM will jump to the address in ADDR register and starts executing the code from that address. PIE will be enabled when this branch occurs, it is upto the application to disable and reload PIE interrupt handlers if it wants to.
18	C1C2_BROM_IPC_FUNCTION_CALL	Address of the function	Parameter for the function call	Result of function call (return value if any from function)	Same as above	C2-BootROM will jump to the address in ADDR register and starts executing the code from that address; Data in DATAW register can be used as parameter to the function call. C-BootROM returns back to where it was after servicing the function call. Function call is performed from inside the interrupt service routine on Aria so user has to keep this in mind.
19	C1C2_BROM_IPC_EXECUTE_BOOTMODE_CMD • C1TOC2BOOTMODE = 0xA, C1C2_BROM_BOOTMODE_BOOT_FROM_RAM • C1TOC2BOOTMODE = 0xB, C1C2_BROM_BOOTMODE_BOOT_FROM_FLASH	--NOT_USED--	--NOT_USED--	--NOT_USED--	Same as above	Execute loaders as per requested value in C1TOC2BOOTMODE register.

Table 3-38. C1TOC2IPC Commands Table (continued)

Value	IPCRCVCOM (CPU1 - R/W, CPU2 R)	IPCRCVADDR (CPU1 - R/W, BCPU2- R)	IPCRCVDATA (CPU1 - R/W, CPU2- R)	IPCLOCALREPLY (CPU1 - R, CPU2 - R/W)	C1TOC2IPCFLG[31] = ? C1TOC2IPCFLAG[0] = 0	Description
	- C1TOC2BOOTMODE = 0x1, C1C2_BROM_BOOTMODE_ BOOT_FROM_SCI - C1TOC2BOOTMODE = 0x4, C1C2_BROM_BOOTMODE_ BOOT_FROM_SPI, - C1TOC2BOOTMODE = 0x5, C1C2_BROM_BOOTMODE_ BOOT_FROM_I2C - C1TOC2BOOTMODE = 0x0, C1C2_BROM_BOOTMODE_ BOOT_FROM_PARALLEL - C1TOC2BOOTMODE = 0x7, C1C2_BROM_BOOTMODE_ BOOT_FROM_CAN					

3.9.7.3 CPU2 IPC Error Commands

This section details the commands CPU2 boot ROM supports. These commands can be used by CPU1 applications to have CPU2 perform a specific action. In order to use these IPC commands, CPU2 boot ROM must be in Wait Boot mode.

Table 3-39. CPU2 Error Command Values

Error Value	Description	Note
0x0000 0000	Invalid Command Value	Default value when starting boot
0xFFFF FFFE	CPU2 has got an ITRAP	Address where ITRAP occurred is placed in IPCADDR register
0xFFFF FFFD	CPU2 got a spurious PIE interrupt	Interrupt number placed in IPCDATAW register
0xFFFF FFFC	CPU2 got a PIE vector mismatch error	-
0xFFFF FFFB	CPU2 got an uncorrectable Flash error	-
0xFFFF FFFA	CPU2 got an uncorrectable RAM error	-

3.9.8 Clock Initializations

During boot up, the boot ROM initializes the device clocking, depending upon the reset source, to assist in faster boot time response. Clock configurations are performed by the boot ROM code only for POR, XRS, and HIBERNATE reset types. For all other resets, the boot ROM starts executing with the clocks that were already set up before reset.

Only CPU1 performs the clock configuration for the device during boot up.

Table 3-40. Boot Clock Sources

Source	Frequency	Description
INTOSC2	10 MHz	Default clock source
INTOSC1	10 MHz	Set as clock source if missing clock is detected at power up or right after device reset

Table 3-41. Clock State After Boot ROM

Reset Source	Clock State
POR/XRS/HIBERNATE	Bypassed PLL.
	PLL multiplier is set to 0x0
	Clock divider is set to /1.
All other Resets	Maintain clocks setup before device reset.

NOTE: If the PLL is used during the boot process, it will be bypassed by the boot ROM code before branching to the user application.

3.9.9 Wait State Configuration

This section details the ROM memory wait state configurations. By default, the ROM memory on this device is not zero-wait state; it is 1-wait state with pre-fetch disabled. ROM does support pre-fetch enable and disable configurations in order to provide better execution speeds at varying clock frequencies. Configuring the wait state enables user applications to adjust for when performing callbacks into ROM or secure copy code (SCC).

Table 3-42. ROM Wait States

Wait State Disable Bit (Bit 0 – 0x5F540)	Pre-Fetch Enable Bit (Bit 0 – 0x5E608)	ROM Configuration
0	0	- Wait state enabled - Pre-fetch disabled - Max Frequency: 200MHz
0	1	- Wait state enabled - Pre-fetch enabled - Max Frequency: 180MHz
1	Don't Care	0 Wait state - Pre-fetch disabled - Max Frequency: 150MHz

3.9.10 Boot Status information

Boot ROM keeps a record of the different events that can occur during boot ROM execution. This is because NMI and other exceptions are enabled by default in the device, and must be handled accordingly. Boot ROM stores the boot status information in a RAM location so that the user application can look at this boot status and take the necessary actions per the application's needs to handle these events.

3.9.10.1 CPU1 Booting Status

This section details the boot status RAM location and its bit field definitions for CPU1. When the specific bit field is set, the described event or action has occurred.

Table 3-43. CPU1 Boot Status Address

Description	Address
CPU1 Boot ROM Status	0x0000 002C

Table 3-44. CPU1 Boot Status Bit Fields

Bit	Description
31	CPU1 Boot ROM has finished running
30	Boot ROM detected a missing clock NMI

Table 3-44. CPU1 Boot Status Bit Fields (continued)

Bit	Description
29	Boot ROM detected a RAM bit error NMI
28	Boot ROM detected a Flash bit error NMI
27	Boot ROM detected CPU1 HWBIST error NMI
26	Boot ROM detected CPU2 HWBIST error NMI
25	Boot ROM detected PIE vector error NMI
22	Boot ROM detected CPU2 watchdog reset
21	Boot ROM detected CPU2 NMI watchdog reset
20	Boot ROM detected OVF NMI
19	Boot ROM detected a PIE mismatch
18	Boot ROM detected CPU1 to CPU2 branch
17	Boot ROM detected an ITRAP
15	Boot ROM handled POR
14	Boot ROM handled XRS
13	Boot ROM handled HWBIST reset
12	Boot ROM handled hibernate reset
11	Boot ROM handled all the resets
10	DCSM initialization has completed
9	Flash boot has started
8	CPU1 Boot ROM has started running

3.9.10.2 CPU2 Booting Status

This section details the boot status bit field definitions for CPU2. When the specific bit field is set, the described event or action has occurred. These status bits can be read from the C2TOC1BOOTSTS register.

Table 3-45. CPU2 Boot ROM Status Address

Description	Address
CPU2 Boot ROM Status	0x0000 0002

Table 3-46. CPU Booting Status

Bit	Description
31	CPU2 Boot ROM has finished running
30	Boot ROM detected a missing clock NMI
29	Boot ROM detected a RAM bit error NMI
28	Boot ROM detected a Flash bit error NMI
27	Boot ROM detected CPU1 HWBIST error NMI
26	Boot ROM detected CPU2 HWBIST error NMI
25	Boot ROM detected PIE vector error NMI
22	Boot ROM detected CPU2 watchdog reset
21	Boot ROM detected CPU2 NMI watchdog reset
20	Boot ROM detected OVF NMI
19	Boot ROM detected a PIE mismatch
18	Boot ROM detected CPU1 to CPU2 branch
17	Boot ROM detected an ITRAP
11	Boot ROM handled all the resets
10	DCSM initialization has completed

Table 3-46. CPU Booting Status (continued)

Bit	Description
9	Flash boot has started
8	CPU2 Boot ROM has started running
3-0	0 – Invalid Status. CPU2 hasn't set a valid status yet 1 – CPU2 Boot ROM has started running 2 – CPU2 Boot ROM has completed and is ready for IPC commands 3 – CPU2 ACKs the boot command in C1TOC2BOOTMODE register 4 – CPU2 doesn't support the command in C1TOC2BOOTMODE register 5 – CPU2 NAKs the boot command in C1TOC2BOOTMODE register

3.9.10.3 CPU1 IPC NAK Status

This section details the NAK status information for CPU1, if boot ROM IPC command support is enabled. These NAK status bits are returned by CPU1 in the C2TOC1IPCDATAR[11:0] register.

Table 3-47. CPU1 IPC NAK Status Bit Fields

Bit	Description
3 - 0	0 – Invalid Value or value isn't set 1 – Command not supported 2 – Command not set correctly 3 – CPU is trying to send a second command before the first one is complete 4 – Command execution resulted in an error 5 – Command cannot be executed in the current state of the boot ROM

3.9.10.4 CPU2 IPC NAK Status

This section details the NAK status information for CPU2, if boot ROM IPC command support is enabled. These NAK status bits are returned by CPU1 in the C1TOC2IPCDATAR[11:0] register.

Table 3-48. CPU2 IPC NAK Status Bit Fields

Bit	Description
3 - 0	0 – Invalid Value or value isn't set 1 – Command not supported 2 – Command not set correctly 3 – CPU1 is trying to send a second command before the first one is complete 4 – Command execution resulted in an error 5 – Command cannot be executed in the current state of the boot ROM

3.9.11 ROM Version

The ROM revision and release date information is stored at the ROM locations specified in this section.

Table 3-49. Boot ROM Version Information for CPU1 and CPU2

Start Address	End Address	Contents
0x003F FF7A	0x003F FF7B	Revision Number
0x003F FF7C	0x003F FF7D	Revision Date

Interpreting the contents:

- Reading a revision value of 0x100 represents version 1.0.
- Reading a revision date value of 0x0715 represents 07/15 or July 2015.

Direct Memory Access (DMA)

The direct memory access (DMA) module provides a hardware method of transferring data between peripherals and/or memory without intervention from the CPU, thereby freeing up bandwidth for other system functions. Additionally, the DMA has the capability to orthogonally rearrange the data as it is transferred as well as “ping-pong” data between buffers. These features are useful for structuring data into blocks for optimal CPU processing.

4.8 Register Descriptions.....	642

4.1 Introduction

The strength of a controller is not measured purely in processor speed, but in total system capabilities. As a part of the equation, any time the CPU bandwidth for a given function can be reduced, the greater the system capabilities. Many times applications spend a significant amount of their bandwidth moving data, whether it is from off-chip memory to on-chip memory, or from a peripheral such as an analog-to-digital converter (ADC) to RAM, or even from one peripheral to another. Furthermore, many times this data comes in a format that is not conducive to the optimum processing powers of the CPU. The DMA module described in this reference guide has the ability to free up CPU bandwidth and rearrange the data into a pattern for more streamlined processing.

The DMA module is an event-based machine, meaning it requires a peripheral or software trigger to start a DMA transfer. Although it can be made into a periodic time-driven machine by configuring a timer as the interrupt trigger source, there is no mechanism within the module itself to start memory transfers periodically. The interrupt trigger source for each of the six DMA channels can be configured separately and each channel contains its own independent PIE interrupt to let the CPU know when a DMA transfer has either started or completed. Five of the six channels are exactly the same, while Channel 1 has the ability to be configured at a higher priority than the others. At the heart of the DMA is a state machine and tightly coupled address control logic. It is this address control logic that allows for rearrangement of the block of data during the transfer as well as the process of ping-ponging data between buffers. Each of these features, along with others, will be discussed in detail in this document.

DMA features include:

- Six channels with independent PIE interrupts
- Peripheral interrupt trigger sources
 - ADC interrupts and EVT signals
 - McBSPx transmit and receive
 - External Interrupts
 - CPU Timers
 - EPWMxSOC signals
 - SPIx transmit and receive
 - USBx transmit and receive
 - Sigma Delta filter module
 - Software trigger
- Data sources and destinations:
 - GSx RAM
 - CPU message RAM (IPC RAM)
 - ADC memory-bus mapped result registers
 - ePWMx
 - SPI, McBSP, EMIF
- Word Size: 16-bit or 32-bit (SPI and McBSP limited to 16-bit)
- Throughput: 4 cycles/word without arbitration

4.2 Architecture

4.2.1 Block Diagram

Figure 4-1 shows a device-level block diagram of the DMA.

Figure 4-1. DMA Block Diagram

4.2.2 Common Peripheral Architecture

There are two CPU subsystems; the CPU1 subsystem and CPU2 subsystem, with each containing a CLA and a DMA. The architecture allows several peripherals to be common between the two subsystems. Based on application need, these common peripherals can be attached to one of the two subsystems. Figure 4-2 shows how the CPUs and subsystems can be connected to the peripherals on peripheral frames 1 and 2. The clock, clock-enable, and reset muxing for the common peripherals are described in detail in other sections of this document.

Refer to Section 4.4 for more details on the arbitration scheme for all masters.

NOTE: If the CPU and DMA make an access to the same peripheral frame in the same cycle, the DMA has priority and the CPU is stalled.

Figure 4-2. Common Peripheral Architecture

A CPUSEL bit associated with each peripheral defines whether the peripheral belongs to the CPU1 or CPU2 subsystem. If a peripheral belongs to a CPU subsystem, it can be accessed by the CPU and one of the secondary masters (DMA or CLA1). Refer to CPUSELx register definition for more details. The secondary master is statically selected using the SECMSSEL register mapped to the respective CPU. Refer to CPUx.SECMSSEL register definition for more details. If a secondary master is not selected, all writes from that master are ignored and all reads return 0x0 to any of the peripherals.

Similarly, if a peripheral does not belong to a CPU subsystem (as defined by the associated CPUSEL bit), all writes to that peripheral are ignored and all reads to that peripheral return 0x0 from any of the masters belonging to the unselected CPU subsystem. Note that since the arbiter has no knowledge regarding the ownership of individual peripherals (as can be seen from Figure 4-2), arbitration will still happen even if C28x or the selected secondary master tries to access a peripheral which does not belong to its CPU subsystem. See [CPU Arbitration](#) for more information.

4.2.3 Peripheral Interrupt Event Trigger Sources

As shown in [Figure 4-3](#) the peripheral interrupt event trigger can be independently configured as any of the sources from the DMACHSRCSELx register for each of the six DMA channels. Included in these sources are five external interrupt signals which can be connected to most of the general-purpose input/output (GPIO) pins on the device. This adds significant flexibility to the event trigger capabilities. The DMA trigger source is selected in the DMACHSRCSELx register ([Table 2-16](#)), for each channel. The PERINTSEL in the MODE register of each channel should be set to the channel number (for example, CH2.MODE.PERINTSEL[4:0] = 2). An active peripheral interrupt trigger will be latched into the PERINTFLG bit of the CONTROL register, and if the respective interrupt and DMA channel is enabled (see the MODE.CHx[PERINTE] and CONTROL.CHx[RUNSTS] bits), it will be serviced by the DMA channel. Upon receipt of a peripheral interrupt event signal, the DMA will automatically send a clear signal to the interrupt source so that subsequent interrupt events will occur.

Figure 4-3. DMA Trigger Architecture

NOTE: To use the system level DMA Trigger source selection, the DMA internal trigger source selection configuration for each channel should be done using the DMACHSRCSELx register (Table 2-16), and the CHx.MODE.PERINTSEL register as shown here. See Table 4-1 or the DMACHSRCSELx register definition for a complete list of DMA trigger sources.

Regardless of the value of the MODE.CHx[PERINTSEL] bit field, software can always force a trigger by using the CONTROL.CHx[PERINTFRC] bit. Likewise, software can always clear a pending DMA trigger using the CONTROL.CHx[PERINTCLR] bit.

Once a particular interrupt trigger sets a channel's PERINTFLG bit, the bit stays pending until the priority logic of the state machine starts the burst transfer for that channel. Once the burst transfer starts, the flag is cleared. If a new interrupt trigger is generated while a burst is in progress, the burst will complete before responding to the new interrupt trigger (after proper prioritization). If a third interrupt trigger occurs before the pending interrupt is serviced, an error flag is set in the CONTROL.CHx[OVRFLG] bit. If a peripheral interrupt trigger occurs at the same time as the latched flag is being cleared, the peripheral interrupt trigger has priority and the PERINTFLG will remain set.

Figure 4-4 shows a diagram of the trigger select circuit. See the DMACHSRCSELx register, (Table 2-16) description for the complete list of peripheral interrupt trigger sources.

4.2.4 DMA Bus

The DMA bus architecture consists of a 32-bit address bus, a 32-bit data read bus, and a 32-bit data write bus. Memories and register locations connected to the DMA bus are via interfaces that sometimes share resources with the CPU memory or peripheral bus. Arbitration rules are defined in [Section 4.4](#).

4.3 Pipeline Timing and Throughput

The DMA module consists of a 4-stage pipeline as shown in [Figure 4-5](#). The one exception to this is when a DMA channel is configured to have the McBSP as its data source. A read of a McBSP DRR register stalls the DMA bus for one cycle during the read portion of the transfer, as shown in [Figure 4-6](#).

Figure 4-5. 4-Stage Pipeline DMA Transfer

Figure 4-6. 4-Stage Pipeline With One Read Stall (McBSP as source)

In addition to the pipeline there are a few other behaviors of the DMA that affect its total throughput:

- A 1-cycle delay is added at the beginning of each burst
- A 1-cycle delay is added when returning from a CH1 high priority interrupt
- Collisions with the CPU may add delay slots (see [Section 4.4](#))
- 32-bit transfers run at double the speed of a 16-bit transfer (it takes the same amount of time to transfer a 32-bit word as it does a 16-bit word)

For example, to transfer 128 16-bit words from GS0 RAM to GS15 RAM, a channel can be configured to transfer 8 bursts of 16 words/burst. This will give:

$$8 \text{ bursts} * [(4 \text{ cycles/word} * 16 \text{ words/burst}) + 1] = 520 \text{ cycles}$$

If instead the channel were configured to transfer the same amount of data 32 bits at a time (the word size is configured to 32 bits) the transfer would take:

$$8 \text{ bursts} * [(4 \text{ cycles/word} * 8 \text{ words/burst}) + 1] = 264 \text{ cycles}$$

4.4 CPU Arbitration

Typically, DMA activity is independent of the CPU activity. When the DMA and the CPU access a peripheral register within the same peripheral frame concurrently, an arbitration procedure will occur. Any combined accesses between the different interfaces, or where the CPU access is outside of the interface that the DMA is accessing, do not create a conflict.

Conflict Example: the CPU is accessing SPI FIFO while the DMA is simultaneously accessing McBSP, it will create a conflict because both SPI and McBSP reside in a common interface (peripheral frame 2).

Non-conflict Example: the CPU is accessing shared ePWM while the DMA is accessing message McBSP, there will be no conflict, since these two peripherals are located in different interfaces (peripheral frame 1 and peripheral frame 2).

The interfaces which internally contain conflicts are:

- Global shared RAMs (GSRAMs)
- CPU message RAM (IPC MSG RAMs)
- USB registers
- EMIF1 registers
- Peripheral frame 1 (ePWM, HRPWM, eCAP, eQEP, DAC, CMPSS, and SDFM)
- Peripheral frame 2 (McBSP, SPI, and uPP)

The ADC result registers are duplicated for each bus master. Therefore, the CPU, DMA, and CLA can all simultaneously read these registers with no stalls for any master.

If the CPU and the DMA make an access to the same peripheral frame in the same cycle, the DMA has priority and the CPU is stalled.

A DMA transfer consists of four phases: send source address, read source data, send destination address, and write destination data (see [Section 4.3](#)). In the case of a bulk DMA transfer to and from the same memory block the CPU is trying to access, the arbitration will stall CPU access until the DMA completes single access, not the entire bulk transfer.. This arbitration is based on a round robin priority scheme described in [Section 4.5](#).

The following priority schemes are implemented for the various interfaces on the device.

- On the peripheral register interface, the fixed priority scheme is:
 - CLA/DMA Write
 - CLA/DMA Read
 - CPU Write
 - CPU Read
- For ADC result registers (refer to the *ADC* chapter for more detailed information):
 - Parallel access is possible from all masters
- For GSxRAM/IPC MSG RAM (refer to the *System Control* chapter for more detailed information):
 - Round-robin

NOTE: If the CPU is performing a read-modify-write operation and the DMA performs a write to the same location, the DMA write may be lost if the operation occurs in between the CPU read and the CPU write. For this reason, it is advised not to mix such CPU accesses with DMA accesses to the same locations.

4.5 Channel Priority

Two priority schemes exist when determining channel priority: Round-robin mode and Channel 1 high-priority mode.

4.5.1 Round-Robin Mode

In this mode, all channels have *equal* priority and each enabled channel is serviced in round-robin fashion as follows:

CH1 → CH2 → CH3 → CH4 → CH5 → CH6 → CH1 → CH2 → ...

In the case above, after each channel has transferred a burst of words, the next channel is serviced. You can specify the size of the burst for each channel. Once CH6 (or the last enabled channel) has been serviced, and no other channels are pending, the round-robin state machine enters an idle state.

From the idle state, channel 1 (if enabled) is always serviced first. However, if the DMA is currently processing another channel *x*, all other pending channels between *x* and the end of the round are serviced before CH1. It is in this sense that all the channels are of *equal* priority. For instance, take an example where CH1, CH4, and CH5 are enabled in round-robin mode and CH4 is currently being processed. Then CH1 and CH5 both receive an interrupt trigger from their respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When CH4 completes its burst, CH5 will be serviced next. Only after CH5 completes will CH1 be serviced. Upon completion of CH1, if there are no more channels pending, the round-robin state machine will enter an idle state.

A more complicated example is shown below:

- Assume all channels are enabled, and the DMA is in an idle state,
- Initially a trigger occurs on CH1, CH3, and CH5 on the same cycle,
- When the CH1 burst transfer starts, requests from CH3 and CH5 are pending,
- Before completion of the CH1 burst, the DMA receives a request from CH2. Now the pending requests are from CH2, CH3, and CH5,
- After completing the CH1 burst, CH2 will be serviced since it is next in the round-robin scheme after CH1.
- After the burst from CH2 is finished, the CH3 burst will be serviced, followed by CH5 burst.
- Now while the CH5 burst is being serviced, the DMA receives a request from CH1, CH3, and CH6.
- The burst from CH6 will start after the completion of the CH5 burst since it is the next channel after CH5 in the round-robin scheme.
- This will be followed by the CH1 burst and then the CH3 burst
- After the CH3 burst finishes, assuming no more triggers have occurred, the round-robin state machine will enter an idle state.

The round-robin state machine may be reset to the idle state via the DMACTRL[PRIORITYRESET] bit.

4.5.2 Channel 1 High Priority Mode

In this mode, if a CH1 trigger occurs, the current word transfer or the current + 1 word transfer (depends on which phase of the current DMA transfer the new CH1 trigger occurred) on any other channel is completed (not the complete burst), execution is halted, and CH1 is serviced for the complete burst count. When the CH1 burst is complete, execution returns to the channel that was active when the CH1 trigger occurred. All other channels have equal priority and each enabled channel is serviced in round-robin fashion as follows:

Higher Priority: CH1
Lower priority: CH2 → CH3 → CH4 → CH5 → CH6 → CH2 → ...

Given an example where CH1, CH4 and CH5 are enabled in Channel 1 High Priority Mode and CH4 is currently being processed. Then CH1 and CH5 both receive an interrupt trigger from their respective peripherals before CH4 completes. CH1 and CH5 are now both pending. When the current CH4 word transfer is completed, regardless of whether the DMA has completed the entire CH4 burst, CH4 execution will be suspended and CH1 will be serviced. After the CH1 burst completes, CH4 will resume execution.

Upon completion of CH4, CH5 will be serviced. After CH5 completes, if there are no more channels pending, the round-robin state machine will enter an idle state.

Typically Channel 1 would be used in this mode for the ADC, since its data rate is so high. However, Channel 1 High Priority Mode may be used in conjunction with any peripheral.

NOTE: High-priority mode and ONESHOT mode may not be used at the same time on channel 1. Other channels may use ONESHOT mode when channel 1 is in high-priority mode.

4.6 Address Pointer and Transfer Control

The DMA state machine is, at its most basic level, two nested loops. The inner loop transfers a burst of data when a peripheral interrupt trigger is received. A burst is the smallest amount of data that can be transferred at one time and its size is defined by the BURST_SIZE register for each channel. The BURST_SIZE register allows a maximum of 32 sixteen-bit words to be transferred in one burst. The outer loop, whose size is set by the TRANSFER_SIZE register for each channel, defines how many bursts are performed in the entire transfer. Since TRANSFER_SIZE is a 16-bit register, the total size of a transfer allowed is well beyond any practical requirement. One CPU interrupt is generated, if enabled, for each transfer. This interrupt can be configured to occur at the beginning or the end of the transfer via the MODE.CHx[CHINTMODE] bit.

In the default setting of the MODE.CHx[ONESHOT] bit, the DMA transfers one burst of data each time a peripheral interrupt trigger is received. After the burst is completed, the state machine moves on to the next pending channel in the priority scheme, even if another trigger for the channel just completed is pending. This feature keeps any single channel from monopolizing the DMA bus. If a transfer of more than the maximum number of words per burst is desired for a single trigger, the MODE.CHx[ONESHOT] bit can be set to complete the entire transfer when triggered. Care is advised when using this mode, since this can create a condition where one trigger uses up the majority of the DMA bandwidth.

Each DMA channel contains a shadowed address pointer for the source and the destination address. These pointers, SRC_ADDR and DST_ADDR, can be independently controlled during the state machine operation. At the beginning of each transfer, the shadowed version of each pointer is copied into its respective active register. During the burst loop, after each word is transferred, the signed value contained in the appropriate source or destination BURST_STEP register is added to the active SRC/DST_ADDR register. During the transfer loop, after each burst is complete, there are two methods that can be used to modify the active address pointer. The first, and default, method is by adding the signed value contained in the SRC/DST_TRANSFER_STEP register to the appropriate pointer. The second is via a process called wrapping, where a wrap address is loaded into the active address pointer. When a wrap procedure occurs, the associated SRC/DST_TRANSFER_STEP register has no effect.

Address wrapping occurs when a number of bursts specified by the appropriate SRC/DST_WRAP_SIZE register completes. Each DMA channel contains two shadowed wrap address pointers, SRC_BEG_ADDR and DST_BEG_ADDR, allowing the source and destination wrapping to be independent of each other. Like the SRC_ADDR and DST_ADDR registers, the active SRC/DST_BEG_ADDR registers are loaded from their shadow counterpart at the beginning of a transfer. When the specified number of bursts has occurred, a two part wrap procedure takes place:

- The appropriate active SRC/DST_BEG_ADDR register is incremented by the signed value contained in the SRC/DST_WRAP_STEP register, then
- The new active SRC/DST_BEG_ADDR register is loaded into the active SRC/DST_ADDR register.

Additionally the wrap counter (SRC/DST_WRAP_COUNT) register is reloaded with the SRC/DST_WRAP_SIZE value to setup the next wrap period. This allows the channel to wrap multiple times within a single transfer. Combined with the first bullet above, this allows the channel to address multiple buffers within a single transfer.

The DMA contains both an active and shadow set of the following address pointers. When a DMA transfer begins, the shadow register set is copied to the active working set of registers. This allows you to program the values of the shadow registers for the next transfer while the DMA works with the active set. It also allows you to implement Ping-Pong buffer schemes without disrupting the DMA channel execution.

Source/Destination Address Pointers (SRC/DST_ADDR)— The value written into the shadow register is the start address of the first location where data is read or written to.

At the beginning of a transfer the shadow register is copied into the active register. The active register performs as the current address pointer.

Source/Destination Begin Address Pointers (SRC/DST_BEG_ADDR)— This is the wrap pointer.

The value written into the shadow register will be loaded into the active register at the start of a transfer. On a wrap condition, the active register will be incremented by the signed value in the appropriate SRC/DST_WRAP_STEP register prior to being loaded into the active SRC/DST_ADDR register.

For each channel, the transfer process can be controlled with the following size values:

Source and Destination Burst Size (BURST_SIZE): — This specifies the number of words to be transferred in a burst.

This value is loaded into the BURST_COUNT register at the beginning of each burst. The BURST_COUNT decrements each word that is transferred and when it reaches a zero value, the burst is complete, indicating that the next channel can be serviced. The behavior of the current channel is defined by the ONE_SHOT bit in the MODE register. The maximum size of the burst is dictated by the type of peripheral. For the ADC, the burst size could be all 16 registers (if all 16 registers are used). For a McBSP peripheral, the burst size is limited to 1 since there is no FIFO and the receive or transmit data register must be loaded or copied every word transferred. For RAM the burst size can be up to the maximum allowed by the BURST_SIZE register, which is 32.

Source and Destination Transfer Size (TRANSFER_SIZE): — This specifies the number of bursts to be transferred before per CPU interrupt (if enabled).

Whether this interrupt is generated at the beginning or the end of the transfer is defined in the CHINTMODE bit in the MODE register. Whether the channel remains enabled or not after the transfer is completed is defined by the CONTINUOUS bit in the MODE register. The TRANSFER_SIZE register is loaded into the TRANSFER_COUNT register at the beginning of each transfer. The TRANSFER_COUNT register keeps track of how many bursts of data the channel has transferred and when it reaches zero, the DMA transfer is complete.

Source/Destination Wrap Size (SRC/DST_WRAP_SIZE): — This specifies the number of bursts to be transferred before the current address pointer wraps around to the beginning.

This feature is used to implement a circular addressing type function. This value is loaded into the appropriate SRC/DST_WRAP_COUNT register at the beginning of each transfer. The SRC/DST_WRAP_COUNT registers keep track of how many bursts of data the channel has transferred and when they reaches zero, the wrap procedure is performed on the appropriate source or destination address pointer. A separate size and count register is allocated for source and destination pointers. To *disable* the wrap function, assign the value of these registers to be larger than the TRANSFER_SIZE.

NOTE: The value written to the SIZE registers is one less than the intended size. So, to transfer three 16-bit words, the value 2 should be placed in the SIZE register.

Regardless of the state of the DATASIZE bit, the value specified in the SIZE registers are for 16-bit addresses. So, to transfer three 32-bit words, the value 5 should be placed in the SIZE register.

For each source/destination pointer, the address changes can be controlled with the following step values:

Source/Destination Burst Step (SRC/DST_BURST_STEP): — Within each burst transfer, the address source and destination step sizes are specified by these registers.

This value is a signed 2's compliment number so that the address pointer can be incremented or decremented as required. If no increment is desired, such as when accessing the McBSP data receive or transmit registers, the value of these registers should be set to zero.

Source/Destination Transfer Step (SRC/DST_TRANSFER_STEP): — This specifies the address offset to start the next burst transfer after completing the current burst transfer.

This is used in cases where registers or data memory locations are spaced at constant intervals. This value is a signed 2's compliment number so that the address pointer can be incremented or decremented as required.

Source/Destination Wrap Step (SRC/DST_WRAP_STEP): — When the wrap counter reaches zero, this value specifies the number of words to add/subtract from the BEG_ADDR pointer and hence sets the new start address.

This implements a circular type of addressing mode, useful in many applications. This value is a signed 2's compliment number so that the address pointer can be incremented or decremented as required.

NOTE: Regardless of the state of the DATASIZE bit, the value specified in the STEP registers are for 16-bit addresses. So, to increment one 32-bit address, a value of 2 should be placed in these registers.

Three modes are provided to control the way the state machine behaves during the burst loop and the transfer loop:

One Shot Mode (ONESHOT)— If one shot mode is enabled when an interrupt event trigger occurs, the DMA will continue transferring data in bursts until TRANSFER_COUNT is zero. If one shot mode is disabled, then an interrupt event trigger is required for each burst transfer and this will continue until TRANSFER_COUNT is zero.

NOTE: When ONESHOT mode is enabled, the DMA will continuously transfer bursts of data on the given channel until the TRANSFER_COUNT value is zero. This could potentially hog the bandwidth of a peripheral and cause long CPU stalls to occur. To avoid this, you could configure a CPU timer (or similar) and disable ONESHOT so as to avoid this situation. High-priority mode and one-shot mode may not be used at the same time on channel 1. Other channels may use ONESHOT mode when channel 1 is in high-priority mode

Continuous Mode (CONTINUOUS)— If continuous mode is disabled the RUNSTS bit in the CONTROL register is cleared at the end of the transfer, disabling the DMA channel.

The channel must be re-enabled by setting the RUN bit in the CONTROL register before another transfer can be started on that channel. If the continuous mode is enabled the RUNSTS bit is not cleared at the end of the transfer.

Channel Interrupt Mode (CHINTMODE)— This mode bit selects whether the DMA interrupt from the respective channel is generated at the beginning of a new transfer or at the end of the transfer.

If implementing a ping-pong buffer scheme with continuous mode of operation, then the interrupt would be generated at the beginning, just after the working registers are copied to the shadow set. If the DMA does not operate in continuous mode, then the interrupt is typically generated at the end when the transfer is complete.

All of the above features and modes are shown in [Figure 4-7](#).

Figure 4-7. DMA State Diagram

The following items are in reference to [Figure 4-7](#).

- The *HALT* points represent where the channel halts operation when interrupted by a high priority channel 1 trigger, or when the HALT command is set, or when an emulation halt is issued and the FREE bit is cleared to 0.
- The ADDR registers are not affected by BEG_ADDR at the start of a transfer. BEG_ADDR only affects the ADDR registers on a wrap or sync error. Following is what happens to each of the ADDR registers when a transfer first starts:
 - BEG_ADDR_SHADOW remains unchanged.
 - ADDR_SHADOW remains unchanged.
 - BEG_ADDR = BEG_ADDR_SHADOW
 - ADDR = ADDR_SHADOW
- The active registers get updated when a wrap occurs. The shadow registers remain unchanged. Specifically:
 - BEG_ADDR_SHADOW remains unchanged.
 - ADDR_SHADOW remains unchanged.
 - BEG_ADDR += WRAP_STEP
 - ADDR = BEG_ADDR
- The active registers get updated when a sync error occurs. The shadow registers remain unchanged. Specifically:
 - BEG_ADDR_SHADOW remains unchanged.
 - ADDR_SHADOW remains unchanged.
 - BEG_ADDR remains unchanged.
 - ADDR = BEG_ADDR

Probably the easiest way to remember all this is that:

- The shadow registers never change except by software.
- The active registers never change except by hardware, and a shadow register is only copied into its own active register, never an active register by another name.

4.7 Overrun Detection Feature

The DMA contains overrun detection logic. When a peripheral event trigger is received by the DMA, the PERINTFLG bit in the CONTROL register is set, pending the channel to the DMA state machine. When the burst for that channel is started, the PERINTFLG is cleared. If however, between the time that the PERINTFLG bit is set by an event trigger and cleared by the start of the burst, an additional event trigger arrives, the second trigger will be lost. This condition will set the OVRFLG bit in the CONTROL register as in [Figure 4-8](#). If the overrun interrupt is enabled then the channel interrupt will be generated to the PIE module.

Figure 4-8. Overrun Detection Logic

4.8 Register Descriptions

15-2	Reserved		Reserved
1	PRIORITYRESET	0	The priority reset bit resets the round-robin state machine when a 1 is written. Service starts from the first enabled channel. Writes of 0 are ignored and this bit always reads back a 0. When a 1 is written to this bit, any pending burst transfer completes before resetting the channel priority machine. If CH1 is configured as a high priority channel, and this bit is written to while CH1 is servicing a burst, the CH1 burst is completed and then any lower priority channel burst is also completed (if CH1 interrupted in the middle of a burst), before the state machine is reset. In case CH1 is high priority, the <i>state machine</i> restarts from CH2 (or the next highest enabled channel).
0	HARDRESET	0	Writing a 1 to the hard reset bit resets the whole DMA and aborts any current access (similar to applying a device reset). Writes of 0 are ignored and this bit always reads back a 0. For a <i>soft</i> reset, a bit is provided for each channel to perform a gentler reset. Refer to the channel control registers. When writing to this bit, there is a one cycle delay before it takes effect. Hence at least a one cycle delay (that is, a NOP instruction) after writing to this bit should be introduced before attempting an access to any other DMA register.

4.8.2 Debug Control Register (DEBUGCTRL) — EALLOW Protected

The debug control register (DEBUGCTRL) is shown in [Figure 4-10](#) and described in [Table 4-4](#).

Figure 4-10. Debug Control Register (DEBUGCTRL)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Table 4-4. Debug Control Register (DEBUGCTRL) Field Descriptions

Bit	Field	Value	Description
15	FREE	0	Emulation Control Bit: This bit specifies the action when an emulation halt event occurs.
		1	DMA runs until the current DMA read-write access is completed and the current status of a DMA is frozen. See the <i>HALT</i> points in Figure 4-7 for possible halt states.
			DMA is unaffected by emulation suspend (run free)
14-0	Reserved		Reserved

4.8.3 Revision Register (REVISION)

The revision register (REVISION) is shown in [Figure 4-11](#) and described in [Table 4-5](#).

Figure 4-11. Revision Register (REVISION)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
TYPE								REV							
R								R							

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 4-5. Revision Register (REVISION) Field Descriptions

Bit	Field	Value	Description
15-8	TYPE	0x0000	DMA Type Bits. A type change represents a major functional feature difference in a peripheral module. Within a peripheral type, there may be minor differences between devices which do not affect the basic functionality of the module. These device-specific differences are listed in the <i>TMS320x28xx, 28xxx DSP Peripheral Reference Guide</i> (SPRU566).
			This document describes a Type0 DMA.
7-0	REV	0x0000	DMA Silicon Revision Bits: These bits specify the DMA revision and are changed if any bug fixes are performed.
			First release

4.8.4 Priority Control Register 1 (PRIORITYCTRL1) — EALLOW Protected

The priority control register 1 (PRIORITYCTRL1) is shown in [Figure 4-12](#) and described in [Table 4-6](#).

Figure 4-12. Priority Control Register 1 (PRIORITYCTRL1)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															CH1 PRIOR ITY
R-0															R/W-0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 4-6. Priority Control Register 1 (PRIORITYCTRL1) Field Descriptions

Bit	Field	Value	Description
15-1	Reserved		Reserved
0	CH1PRIORITY	0 1	DMA Ch1 Priority: This bit selects whether channel 1 has higher priority or not: Same priority as all other channels Highest priority channel Channel priority can only be changed when all channels are disabled. A priority reset should be performed before restarting channels after changing priority.

4.8.5 Priority Status Register (PRIORITYSTAT)

The priority status register (PRIORITYSTAT) is shown in [Figure 4-13](#) and described in [Table 4-7](#).

Figure 4-13. Priority Status Register (PRIORITYSTAT)

OVRINTE	Reserved				PERINTSEL		
R/W-0	R-0				R/W-0		

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 4-8. Mode Register (MODE) Field Descriptions

Bit	Field	Value	Description
15	CHINTE	0 1	Channel Interrupt Enable Bit: This bit enables/disables the respective DMA channel interrupt to the CPU (via the PIE). Interrupt disabled Interrupt enabled
14	DATASIZE	0 1	Data Size Mode Bit: This bit selects if the DMA channel transfers 16-bits or 32-bits of data at a time. 16-bit data transfer size 32-bit data transfer size NOTE: Regardless of the value of this bit all of the registers in the DMA refer to 16-bit words. The only effect this bit causes is whether the databus width is 16 or 32 bits. It is up to you to configure the pointer step increment and size to accommodate 32-bit data transfers. See Section 4.6 for details.
13-12	Reserved		Reserved
11	CONTINUOUS		Continuous Mode Bit: If this bit is set to 1, then DMA re-initializes when TRANSFER_COUNT is zero and waits for the next interrupt event trigger. If this bit is 0, then the DMA stops and clears the RUNSTS bit to 0.
10	ONESHOT		One Shot Mode Bit: If this bit is set to 1, then subsequent burst transfers occur without additional event triggers after the first event trigger. If this bit is 0 then only one burst transfer is performed per event trigger. Note: High-priority mode and One-shot mode may not be used at the same time on CH1.
9	CHINTMODE	0 1	Channel Interrupt Generation Mode Bit: This bit specifies when the respective DMA channel interrupt should be generated to the CPU (via the PIE). Generate interrupt at beginning of new transfer Generate interrupt at end of transfer.
8	PERINTE	0 1	Peripheral Interrupt Trigger Enable Bit: This bit enables/disables the selected peripheral interrupt trigger to the DMA. Interrupt trigger disabled. Neither the selected peripheral nor software can start a DMA burst. Interrupt trigger enabled.
7	OVRINTE	0 1	Overflow Interrupt Enable: This bit when set to 1 enables the DMA to generate an interrupt when an overflow event is detected. Overflow interrupt disabled Overflow interrupt enabled An overflow interrupt is generated when the PERINTFLG is set and another interrupt event occurs. The PERINTFLG being set indicates a previous peripheral event is latched and has not been serviced by the DMA.
6-5	Reserved		Reserved

Table 4-8. Mode Register (MODE) Field Descriptions (continued)

Bit	Field	Value	Description
4-0	PERINTSEL		The Peripheral Interrupt Source Select Bits: These bits should be set to the channel number (i.e. CH2.MODE.PERINTSEL[4:0] = 2).

4.8.7 Control Register (CONTROL) — EALLOW Protected

The control register (CONTROL) is shown in [Figure 4-15](#) and described in [Table 4-9](#).

Figure 4-15. Control Register (CONTROL)

15	14	13	12	11	10	9	8

7	6	5	4	3	2	1	0
ERRCLR	Reserved	PERINTCLR	PERINTFRC	SOFTRESET	HALT	RUN	
R0/S-0	R-0	R0/S-0	R0/S-0	R0/S-0	R0/S-0	R0/S-0	R0/S-0

LEGEND: R0/S = Read 0/Set; R = Read only; -n = value after reset

Table 4-9. Control Register (CONTROL) Field Descriptions

Bit	Field	Value	Description
15	Reserved		Reserved
14	OVRFLG	0 1	Overflow Flag Bit: This bit indicates if a peripheral interrupt event trigger is received from the selected peripheral and the PERINTFLG is already set. No overflow event Overflow event The ERRCLR bit can be used to clear the state of this bit to 0. The OVRFLG bit is not affected by the PERINTFRC event.
13	RUNSTS	0 1	Run Status Bit: This bit is set to 1 when the RUN bit is written to with a 1. This indicates the DMA channel is now ready to process peripheral interrupt event triggers. This bit is cleared to 0 when TRANSFER_COUNT reaches zero and CONTINUOUS mode bit is set to 0. This bit is also cleared to 0 when either the HARDRESET bit, the SOFTRESET bit, or the HALT bit is activated. Channel is disabled. Channel is enabled.
12	BURSTSTS	0 1	Burst Status Bit: This bit is set to 1 when a DMA burst transfer begins and the BURST_COUNT is initialized with the BURST_SIZE. This bit is cleared to zero when BURST_COUNT reaches zero. This bit is also cleared to 0 when either the HARDRESET or the SOFTRESET bit is activated. No burst activity The DMA is currently servicing or suspending a burst transfer from this channel.
11	TRANSFERSTS	0 1	Transfer Status Bit: This bit is set to 1 when a DMA transfer begins and the address registers are copied to the shadow set and the TRANSFER_COUNT is initialized with the TRANSFER_SIZE. This bit is cleared to zero when TRANSFER_COUNT reaches zero. This bit is also cleared to 0 when either the HARDRESET or the SOFTRESET bit is activated. No transfer activity The channel is currently in the middle of a transfer regardless of whether a burst of data is actively being transferred or not.
10-9	Reserved		Reserved
8	PERINTFLG	0 1	Peripheral Interrupt Trigger Flag Bit: This bit indicates if a peripheral interrupt event trigger has occurred. This flag is automatically cleared when the first burst transfer begins. No interrupt event trigger Interrupt event trigger The PERINTFRC bit can be used to set the state of this bit to 1 and force a software DMA event. The PERINTCLR bit can be used to clear the state of this bit to 0.
7	ERRCLR	0	Error Clear Bit: Writing a 1 to this bit will clear any latched sync error event and clear the SYNCERR bit. This bit will also clear the OVRFLG bit. This bit would normally be used when initializing the DMA for the first time or if an overflow condition is detected. If an ADCSYNC error event or overflow event occurs at the same time as writing to this bit, the ADC or overrun has priority and the SYNCERR or OVRFLG bit is set.
6-5	Reserved		Reserved

Table 4-9. Control Register (CONTROL) Field Descriptions (continued)

Bit	Field	Value	Description
4	PERINTCLR	0	Peripheral Interrupt Clear Bit: Writing a 1 to this bit clears any latched peripheral interrupt event and clears the PERINTFLG bit. This bit would normally be used when initializing the DMA for the first time. If a peripheral event occurs at the same time as writing to this bit, the peripheral has priority and the PERINTFLG bit is set.
3	PERINTFRC	0	Peripheral Interrupt Force Bit: Writing a 1 to this bit latches a peripheral interrupt event trigger and sets the PERINTFLG bit. If the PERINTE bit is set, this bit can be used like a software force for a DMA burst transfer.
2	SOFTRESET	0	Channel Soft Reset Bit: Writing a 1 to this bit completes current read-write access and places the channel into a default state as follows: RUNSTS = 0 TRANSFERSTS = 0 BURSTSTS = 0 BURST_COUNT = 0 TRANSFER_COUNT = 0 SRC_WRAP_COUNT = 0 DST_WRAP_COUNT = 0 This is a <i>soft</i> reset that basically allows the DMA to complete the current read-write access and then places the DMA channel into the default reset state.
1	HALT	0	Channel Halt Bit: Writing a 1 to this bit halts the DMA at the current state and any current read-write access is completed. See Figure 4-7 for the various positions the state machine can be at when HALTED. The RUNSTS bit is set to 0. To take the device out of HALT, the RUN bit needs to be activated.
0	RUN	0	Channel Run Bit: Writing a 1 to this bit starts the DMA channel. The RUNSTS bit is set to 1. This bit is also used to take the device out of HALT. The RUN bit is typically used to start the DMA running after you have configured the DMA. It will then wait for the first interrupt event (PERINTFLG == 1) to start operation. The RUN bit can also be used to take the DMA channel out of a HALT condition See Figure 4-7 for the various positions the state machine can be at when HALTED.

4.8.8 Burst Size Register (BURST_SIZE) — EALLOW Protected

The burst size register (BURST_SIZE) is shown in [Figure 4-16](#) and described in [Table 4-10](#).

Control Law Accelerator (CLA)

The control law accelerator (CLA) Type-1 is an independent, fully-programmable, 32-bit floating-point math processor that brings concurrent control-loop execution to the C28x family. The low interrupt-latency of the CLA allows it to read ADC samples "just-in-time." This significantly reduces the ADC sample to output delay to enable faster system response and higher MHz control loops. By using the CLA to service time-critical control loops, the main CPU is free to perform other system tasks such as communications and diagnostics. This chapter provides an overview of the architectural structure and components of the control law accelerator.

Topic	Page
5.1 Control Law Accelerator (CLA) Overview.....	660
5.2 CLA Interface	662
5.3 CLA and CPU Arbitration	666
5.4 CLA Configuration and Debug	668
5.5 Pipeline	672
5.6 Instruction Set.....	677
5.7 Registers	792

5.1 Control Law Accelerator (CLA) Overview

The control law accelerator extends the capabilities of the C28x CPU by adding parallel processing. Time-critical control loops serviced by the CLA can achieve low ADC sample to output delay. Thus, the CLA enables faster system response and higher frequency control loops. Utilizing the CLA for time-critical tasks frees up the main CPU to perform other system and communication functions concurrently. The following is a list of major features of the CLA.

- Clocked at the same rate as the main CPU (SYSCLKOUT).
- An independent architecture allowing CLA algorithm execution independent of the main C28x CPU.
 - Complete bus architecture:
 - Program Address Bus (PAB) and Program Data Bus (PDB)
 - Data Read Address Bus (DRAB), Data Read Data Bus (DRDB), Data Write Address Bus (DWAB), and Data Write Data Bus (DWDB)
 - Independent eight stage pipeline.
 - 16-bit program counter (MPC)
 - Four 32-bit result registers (MR0-MR3)
 - Two 16-bit auxiliary registers (MAR0, MAR1)
 - Status register (MSTF)
- Instruction set includes:
 - IEEE single-precision (32-bit) floating point math operations
 - Floating-point math with parallel load or store
 - Floating-point multiply with parallel add or subtract
 - 1/X and 1/sqrt(X) estimations
 - Data type conversions.
 - Conditional branch and call
 - Data load/store operations
- The CLA program code can consist of up to eight tasks or interrupt service routines.
 - The start address of each task is specified by the MVECT registers.
 - No limit on task size as long as the tasks fit within the configurable CLA program memory space.
 - One task is serviced at a time until its completion. There is no nesting of tasks.
 - Upon task completion a task-specific interrupt is flagged within the PIE.
 - When a task finishes the next highest-priority pending task is automatically started.
- Task trigger mechanisms:
 - C28x CPU via the IACK instruction
 - Task1 to Task8: up to 256 possible trigger sources from peripherals connected to the shared bus on which the CLA assumes secondary ownership.
- Memory and Shared Peripherals:
 - Two dedicated message RAMs for communication between the CLA and the main CPU.
 - The C28x CPU can map CLA program and data memory to the main CPU space or CLA space.
 - The CLA, on reset, is the secondary master for all peripherals which can have either the CLA or DMA as their secondary master.

Figure 5-1. CLA Block Diagram

5.2 CLA Interface

This chapter describes how the C28x main CPU can interface to the CLA and vice versa.

5.2.1 CLA Memory

The CLA can access three types of memory: program, data and message RAMs. The behavior and arbitration for each type of memory is described in detail below.

- **CLA Program Memory**

The CLA program can be loaded to any of the local shared memories (LSxRAM) on the core that it is tied to. At reset, all memory blocks are mapped to the master CPU. While mapped to the CPU space, the CPU can copy the CLA program code into the memory block(s). During debug, the block(s) can also be loaded directly by Code Composer Studio™.

Once the memory is initialized with CLA code, the master CPU maps it to the CLA program space by:

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
2. Specifying the memory block as a code block for the CLA by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit.

When an LSx memory is configured as CLA program memory, only debug accesses are allowed on cycles that the CLA is not fetching a new instruction. A detailed explanation of the memory configurations and access arbitration (CPU/CLA/DEBUG) process can be found in [Section 2.11](#).

All CLA program fetches are performed as 32-bit read operations and all opcodes must be aligned to an even address. Since all CLA opcodes are 32-bits, this alignment naturally occurs.

- **CLA Data Memory**

Any of the device's LSxRAMs can serve as data memory blocks to the CLA. At reset, all blocks are mapped to the master CPU memory space, whereby the master can initialize the memory with data tables, coefficients, and so on, for the CLA to use.

Once the memory is initialized with CLA data, the master CPU maps it to the CLA data space by :

1. Assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit.
2. Specifying the memory block as a data block for the CLA by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. The value of this bit at reset is 0.

When an LSx memory is configured as a CLA data memory, the CLA read/write access are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT registers. A detailed explanation of the memory configurations and access arbitration (CPU/CLA/DEBUG) process can be found in [Section 2.11](#).

The CLA RAMs and registers are protected by the security module. Refer to the *DCSM* chapter of this manual for more details on the security scheme.

- **CLA Shared Message RAMs**

There are two small memory blocks for data sharing and communication between the CLA and the master CPU on each CPU subsystem. The message RAMs are always mapped to both CPU and CLA memory spaces and are protected by the DCSM. The message RAMs allow data accesses only; no program fetches can be performed.

- **CLA to CPU Message RAM**

The CLA can use this block to pass data to the master CPU. This block is both readable and writable by the CLA. This block is also readable by the master CPU but writes by the master CPU are ignored.

- **CPU to CLA Message RAM**

The master CPU can use this block to pass data and messages to the CLA. This message RAM is both readable and writable by the master CPU. The CLA can perform reads but writes by the CLA are ignored.

5.2.2 CLA Memory Bus

The CLA has dedicated bus architecture similar to that of the C28x CPU where there is a program read, data read, and data write bus. Thus, there can be simultaneous instruction fetch, data read, and data write in a single cycle. Like the C28x CPU, the CLA expects memory logic to align any 32-bit read or write to an even address. If the address-generation logic generates an odd address, the CLA will begin reading or writing at the previous even address. This alignment does not affect the address values generated by the address-generation logic.

- **CLA Program Bus**

The CLA program bus has a access range of 32K 32-bit instructions. Since all CLA instructions are 32 bits, this bus always fetches 32 bits at a time and the opcodes must be even-word aligned. The amount of program space available for the CLA is limited to the number of available LSxRAM blocks. This number is device-dependent and will be described in the device-specific data manual.

- **CLA Data Read Bus**

The CLA data read bus has a 64K x 16 address range. The bus can perform 16 or 32-bit reads and will automatically stall if there are memory access conflicts. The data read bus has access to both the message RAMs, CLA data memory, and the shared peripherals.

- **CLA Data Write Bus**

The CLA data write bus has a 64K x 16 address range. This bus can perform 16 or 32-bit writes. The bus will automatically stall if there are memory access conflicts. The data write bus has access to the CLA to CPU message RAM, CLA data memory, and the shared peripherals.

5.2.3 Shared Peripherals and EALLOW Protection

For a given CPU subsystem, the CLA and DMA share secondary access to some peripherals. The secondary ownership of the bus is determined by the CpuSysRegs.SECMSEL[VBUS32_x] bit. If it is set to 0, the CLA is the secondary owner. If it is set to 1, the DMA is the secondary owner. By default, at reset, the CLA is given the secondary ownership of the bus and, therefore, can access all the peripherals connected to it.

Note: The CLA read access time to the bus is 2-wait states while write access is 0-wait.

Refer to the device data manual for the list of peripherals connected to the bus.

Several peripheral control registers are protected from spurious 28x CPU writes by the EALLOW protection mechanism. These same registers are also protected from spurious CLA writes. The EALLOW bit in the main CPU status register 1 (ST1) indicates the state of protection for the main CPU. Likewise the MEALLOW bit in the CLA status register (MSTF) indicates the state of write protection for the CLA. The MEALLOW CLA instruction enables write access by the CLA to EALLOW protected registers. Likewise the MEDIS CLA instruction will disable write access. This way the CLA can enable/disable write access independent of the main CPU.

The ADC offers the option to generate an early interrupt pulse at the start of a sample conversion. If this option is used to start an ADC-triggered CLA task, the user may use the intervening cycles, until the completion of the conversion, to perform preliminary calculations or loads and stores before finally reading the ADC value. The CLA pipeline activity for this scenario is shown in [Section 5.5](#).

5.2.4 CLA Tasks and Interrupt Vectors

The CLA program code is divided up into tasks or interrupt service routines. Tasks do not have a fixed starting location or length. The CLA program memory can be divided up as desired. The CLA knows where a task begins by the content of the associated interrupt vector (MVECT1 to MVECT8) and the end is indicated by the MSTOP instruction.

The CLA supports eight tasks. Task 1 has the highest priority and task 8 has the lowest priority. A task can be requested by a peripheral interrupt or by software:

- **Peripheral interrupt trigger**

Each task can be triggered by up to 256 interrupt sources. The trigger for each task is defined by writing an appropriate value to the DmaClasrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field. Each of the possible 256 values specifies an interrupt source from a specific peripheral on the shared bus. The configuration options are listed in [Table 5-1](#).

For example, task 1 (MVECT1) can be set to trigger on EPWMINT1 by writing 36 to DmaClaSrcSelRegs.CLA1TASKSRCSEL1.bit.TASK1. To disable the triggering of a task by a peripheral, the user must set the DmaClaSrcSelRegs.CLA1TASKSRCSELx[TASKx] bit field to 0. It should be noted that a CLA task only triggers on a level transition (an edge) of the configured interrupt source.

- **Software Trigger**

Tasks can also be started by the main CPU software writing to the MIFRC register or by the IACK instruction. Using the IACK instruction is more efficient because it does not require you to issue an EALLOW to set MIFR bits. Set the MCTL[IACKE] bit to enable the IACK feature. Each bit in the operand of the IACK instruction corresponds to a task. For example IACK #0x0001 will set bit 0 in the MIFR register to start task 1. Likewise IACK #0x0003 will set bits 0 and 1 in the MIFR register to start task 1 and task 2.

The CLA has its own fetch mechanism and can run and execute a task independent of the main CPU. Only one task is serviced at a time; there is no nesting of tasks. The task currently running is indicated in the MIRUN register. Interrupts that have been received but not yet serviced are indicated in the flag register (MIFR). If an interrupt request from a peripheral is received and that same task is already flagged, then the overflow flag bit is set. Overflow flags will remain set until they are cleared by the main CPU.

If the CLA is idle (no task is currently running) then the highest priority interrupt request that is both flagged (MIFR) and enabled (MIER) will start. The flow is as follows:

1. The associated RUN register bit is set (MIRUN) and the flag bit (MIFR) is cleared.
2. The CLA begins execution at the location indicated by the associated interrupt vector (MVECTx). MVECT contains the absolute 16-bit address of the task in the lower 64K memory space.
3. The CLA executes instructions until the MSTOP instruction is found. This indicates the end of the task.
4. The MIRUN bit is cleared.
5. The task-specific interrupt to the PIE is issued. This informs the main CPU that the task has completed.
6. The CLA returns to idle.

Once a task completes the next highest-priority pending task is automatically serviced and this sequence repeats.

5.2.5 CLA Software Interrupt to CPU

The CLA can issue a software interrupt to the C28x CPU (on the same subsystem) at any point in the code through the use of the CLA1SOFTINTEN and CLA1INTFRC registers. Please see [Section 5.7](#) for a description of these registers. If a software interrupt is selected for a CLA task, then an end-of-task interrupt will not be issued to the C28x when that task completes

5.3 CLA and CPU Arbitration

Typically, CLA activity is independent of the CPU activity. Under the circumstance where both the CLA and the CPU are attempting to access memory or a peripheral register within the same interface concurrently, an arbitration procedure will occur. This appendix describes this arbitration.

5.3.1 CLA and CPU Arbitration

The Local Shared RAMs can have access from the CPU as well as the DMA. The arbitration is a combination of fixed and round robin schemes; they are covered in detail in the [Section 2.11](#).

5.3.2 CLA Message RAM

Message RAMs consist of two blocks per CPU subsystem

- CPUx.CLA1 to CPUx – CLA to CPU Message RAM
- CPUx to CPUx.CLA1 – CPU to CLA Message RAM

These blocks are for passing data between the CPU and the CLA. No opcode fetches, from either the CLA or CPU, are allowed from the message RAMs. A write protection violation will not be generated if the CLA attempts to write to the CPUx to CPUx.CLA1 message RAM but the write will be ignored. The arbitration scheme for the message RAMs are the same as those for the shared memories described in the [Section 2.11](#).

The two message RAMs have the following characteristics:

- CPUx.CLA1 to CPUx Message RAM:
The following accesses are allowed:
 - CPUx reads
 - CPUx.CLA1 data reads and writes
 - CPUx debug reads and writes

The following accesses are ignored:

- CPUx writes

- CPUx to CPUx.CLA1 Message RAM:
The following accesses are allowed:
 - CPUx reads and writes
 - CPUx.CLA1 reads
 - CPUx debug reads and writes

The following accesses are ignored:

- CPUx.CLA1 writes

5.4 CLA Configuration and Debug

This section discusses the steps necessary to configure and debug the CLA.

5.4.1 Building a CLA Application

The control law accelerator can be programmed in either CLA assembly code using the instructions described in [Section 5.6](#) or a reduced subset of the C language. CLA assembly code resides in the same project with C28x code. The only restriction is the CLA code must be in its own assembly section. This can be easily done using the .sect assembly directive. This does not prevent CLA and C28x code from being linked into the same memory region in the linker command file.

System and CLA initialization are performed by the main CPU. This would typically be done in C or C++ but can also include C28x assembly code. The main CPU will also copy the CLA code to the program memory and, if needed, initialize the CLA data RAM(s). Once system initialization is complete and the application begins, the CLA will service its interrupts using the CLA assembly code (or tasks). Concurrently the main CPU can perform other tasks.

The CLA type 1 requires Codegen V6.2.4 or later with the following switch: --cla_support=cla1.

5.4.2 Typical CLA Initialization Sequence

A typical CLA initialization sequence is performed by the main CPU as described in this section.

1. Copy CLA code into the CLA program RAM

The source for the CLA code can initially reside in the flash or a data stream from a communications peripheral or anywhere the main CPU can access it. The debugger can also be used to load code directly to the CLA program RAM during development.

2. Initialize CLA data RAM if necessary

Populate the CLA data RAM with any required data coefficients or constants.

3. Configure the CLA registers

Configure the CLA registers, but keep interrupts disabled until later (leave MIER == 0):

- **Enable the CLA clock in the PCLKCR0 register.**

PCLKCR0 register is defined in the *System Control and Interrupts* chapter.

- **Populate the CLA task interrupt vectors: MVECT1 to MVECT8.**

Each vector needs to be initialized with the start address of the task to be executed when the CLA receives the associated interrupt. This address is the full 16-bit starting address of the task in the lower 64K section of memory.

- **Select the task interrupt sources**

For each task select the interrupt source in the CLA1TASKSRCSELx register. If a task is going to be generated by software, select no interrupt.

- **Enable IACK to start a task from software if desired**

To enable the IACK instruction to start a task set the MCTL[IACKE] bit. Using the IACK instruction avoids having to set and clear the EALLOW bit.

- **Map CLA data RAM(s) to CLA space if necessary**

Map the data RAM to the CLA space by first, assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit and then specifying the memory block as a CLA data block by writing a 0 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. When an LSx memory is configured as a CLA data memory, the CLA read/write access are arbitrated along with CPU accesses. The user has the option of turning on CPU fetch or write protection to the memory by writing to the appropriate bits of the MemCfgRegs.LSxACCPROT registers.

- **Map CLA program RAM to CLA space**

Map the CLA program RAM to CLA space by first, assigning ownership of the memory block to the CLA by writing a 1 to the memory block's MemCfgRegs.LSxMSEL[MSEL_LSx] bit and then specifying the memory block as CLA code memory by writing a 1 to the MemCfgRegs.LSxCLAPGM[CLAPGM_LSx] bit. When an LSx memory is configured as CLA

program memory, only debug accesses are allowed on cycles that the CLA is not fetching a new instruction.

4. Initialize the PIE vector table and registers

When a CLA task completes, the associated interrupt in the PIE will be flagged. The CLA overflow and underflow flags also have associated interrupts within the PIE.

5. Enable CLA tasks/interrupts

Set appropriate bits in the interrupt enable register (MIER) to allow the CLA to service interrupts.

6. Initialize other peripherals

Initialize any peripherals (ePWM, ADC, and others) that will generate an interrupt to the CLA and be serviced by a CLA task.

The CLA is now ready to service interrupts and the message RAMs can be used to pass data between the CPU and the CLA. Typically mapping of the CLA program and data RAMs occurs only during the initialization process. If after some time you want to re-map these memories back to CPU space then disable interrupts and make sure all tasks have completed by checking the MIRUN register.

5.4.3 Debugging CLA Code

Debugging the CLA code is a simple process that occurs independently of the main CPU.

1. Insert a breakpoint in CLA code

Insert a CLA breakpoint (MDEBUGSTOP instruction) into the code where you want the CLA to halt, then rebuild and reload the code. Because the CLA does not flush its pipeline when you single-step, the MDEBUGSTOP instruction must be inserted as part of the code. The debugger cannot insert it as needed.

If CLA breakpoints are not enabled, then the MDEBUGSTOP will be ignored and is treated as a MNOP. The MDEBUGSTOP instruction can be placed anywhere in the CLA code as long as it is not within three instructions of a MBCNDD, MCCNDD, or MRCNDD instruction. When programming in C, the user can use the `__mdebugstop()` intrinsic instead; the compiler will ensure that the placement of the MDEBUGSTOP instruction in the generated assembly does not violate any of the pipeline restrictions.

2. Enable CLA breakpoints

First, enable the CLA breakpoints in the debugger. In Code Composer Studio, this is done by connecting the core from the debug perspective. Breakpoints are disabled when the core is disconnected.

3. Start the task

There are three ways to start the task:

- The peripheral can assert an interrupt
- The main CPU can execute an IACK instruction, or
- You can manually write to the MIFRC register in the debugger window

When the task starts, the CLA will execute instructions until the MDEBUGSTOP is in the D2 phase of the pipeline. At this point, the CLA will halt and the pipeline will be frozen. The MPC register will reflect the address of the MDEBUGSTOP instruction.

4. Single-step the CLA code

Once halted, you can single-step the CLA code one cycle at a time. The behavior of a CLA single-step is different than the main C28x. When issuing a CLA single-step, the pipeline is clocked only one cycle and then again frozen. On the 28x CPU, the pipeline is flushed for each single-step.

You can also run to the next MDEBUGSTOP or to the end of the task. If another task is pending, it will automatically start when you run to the end of the task.

NOTE: A CLA fetch has higher priority than CPU debug reads. For this reason, it is possible for the CLA to permanently block CPU debug accesses if the CLA is executing in a loop. This might occur when initially developing CLA code due to a bug that causes an infinite loop. To avoid locking up the main CPU, the program memory will return all 0x0000 for CPU debug reads when the CLA is running. When the CLA is halted or idle then normal CPU debug read and write access to CLA program memory can be performed.

If the CLA gets caught in a infinite loop, you can use a soft or hard reset to exit the condition. A debugger reset will also exit the condition.

There are special cases that can occur when single-stepping a task such that the program counter, MPC, reaches the MSTOP instruction at the end of the task.

• MPC halts at or after the MSTOP with a task already pending

If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" will start if you continue to step through the MSTOP instruction. Basically if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.

• MPC halts at or after the MSTOP with no task pending

In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, it will be flagged in the MIFR register but it may or may not start if you continue to single-step through the MSTOP instruction of "task A."

It depends on exactly when the new task comes in. To reliably start "task B" perform a soft reset

and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B."

This case can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B," run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

5. If desired, disable CLA breakpoints

In Code Composer Studio you can disable the CLA breakpoints by disconnecting the CLA core in the debug perspective. Make sure to first issue a run or reset; otherwise, the CLA will be halted and no other tasks will start.

5.4.4 CLA Illegal Opcode Behavior

If the CLA fetches an opcode that does not correspond to a legal instruction, it will behave as follows:

- The CLA will halt with the illegal opcode in the D2 phase of the pipeline as if it were a breakpoint. This will occur whether CLA breakpoints are enabled or not.
- The CLA will issue the task-specific interrupt to the PIE.
- The MIRUN bit for the task will remain set.

Further single-stepping is ignored once execution halts due to an illegal op-code. To exit this situation, issue either a soft or hard reset of the CLA as described in [Section 5.4.5](#).

5.4.5 Resetting the CLA

There may be times when you need to reset the CLA. For example, during code debug the CLA may enter an infinite loop due to a code bug. The CLA has two types of resets: hard and soft. Both of these resets can be performed by the debugger or by the main CPU.

• Hard Reset

Writing a 1 to the MCTL[HARDRESET] bit will perform a hard reset of the CLA. The behavior of a hard reset is the same as a system reset (via $\overline{XRS}$ or the debugger). In this case all CLA configuration and execution registers will be set to their default state and CLA execution will halt.

• Soft Reset

Writing a 1 to the MCTL[SOFTRESET] bit performs a soft reset of the CLA. If a task is executing it will halt and the associated MIRUN bit will be cleared. All bits within the interrupt enable (MIER) register will also be cleared so that no new tasks start.

5.5 Pipeline

This section describes the CLA pipeline stages and presents cases where pipeline alignment must be considered.

5.5.1 Pipeline Overview

The CLA pipeline is very similar to the C28x pipeline. The pipeline has eight stages:

- **Fetch 1 (F1)**
During the F1 stage the program read address is placed on the CLA program address bus.
- **Fetch 2 (F2)**
During the F2 stage the instruction is read using the CLA program data bus.
- **Decode 1 (D1)**
During D1 the instruction is decoded.
- **Decode 2 (D2)**
Generate the data read address. Changes to MAR0 and MAR1 due to post-increment using indirect addressing takes place in the D2 phase. Conditional branch decisions are also made at this stage based on the MSTF register flags.
- **Read 1 (R1)**
Place the data read address on the CLA data-read address bus. If a memory conflict exists, the R1 stage will be stalled.
- **Read 2 (R2)**
Read the data value using the CLA data read data bus.
- **Execute (EXE)**
Execute the operation. Changes to MAR0 and MAR1 due to loading an immediate value or value from memory take place in this stage.
- **Write (W)**
Place the write address and write data on the CLA write data bus. If a memory conflict exists, the W stage will be stalled.

5.5.2 CLA Pipeline Alignment

The majority of the CLA instructions do not require any special pipeline considerations. This section lists the few operations that do require special consideration.

- **Write Followed by Read**
In both the C28x and the CLA pipeline the read operation occurs before the write. This means that if a read operation immediately follows a write, then the read will complete first as shown in [Table 5-2](#). In most cases this does not cause a problem since the contents of one memory location does not depend on the state of another. For accesses to peripherals where a write to one location can affect the value in another location the code must wait for the write to complete before issuing the read as shown in [Table 5-3](#).

This behavior is different for the 28x CPU. For the 28x CPU any write followed by read to the same location is protected by what is called write-followed-by-read protection. This protection automatically stalls the pipeline so that the write will complete before the read. In addition some peripheral frames are protected such that a 28x CPU write to one location within the frame will always complete before a read to the frame. The CLA does not have this protection mechanism. Instead the code must wait to perform the read.

Table 5-2. Write Followed by Read - Read Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2 MMOV16 MR2, @Reg2	I2	I1						
		I2	I1					
			I2	I1				
				I2	I1			
					I2	I1		
						I2	I1	
							I2	I1

Table 5-3. Write Followed by Read - Write Occurs First

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1 MMOV16 @Reg1, MR3	I1							
I2	I2	I1						
I3	I3	I2	I1					
I4	I4	I3	I2	I1				
I5 MMOV16 MR2, @Reg2	I5	I4	I3	I2	I1			
		I5	I4	I3	I2	I1		
			I5	I4	I3	I2	I1	
				I5	I4	I3	I2	I1
					I5	I4	I3	
						I5	I4	
							I5	

- Delayed Conditional instructions: MBCNDD, MCCNDD and MRCNDD**

Referring to [Example 5-1](#), the following applies to delayed conditional instructions:

- **I1**

I1 is the last instruction that can effect the CNDF flags for the branch, call or return instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when [MBCNDD](#), [MCCNDD](#) or [MRCNDD](#) is in the D2 phase.

- **I2, I3 and I4**

The three instructions preceding MBCNDD can change MSTF flags but will have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification will occur after the D2 phase of the branch, call or return instruction. These three instructions must not be a [MSTOP](#), [MDEBUGSTOP](#), [MBCNDD](#), [MCCNDD](#) or [MRCNDD](#).

- **I5, I6 and I7**

The three instructions following a branch, call or return are always executed irrespective of whether the condition is true or not. These instructions must not be MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

For a more detailed description refer to the functional description for [MBCNDD](#), [MCCNDD](#) and [MRCNDD](#).

Example 5-1. Code Fragment For MBCNDD, MCCNDD or MRCNDD

```

<Instruction 1> ; I1 Last instruction that can affect flags for
                ; the branch, call or return operation

<Instruction 2> ; I2 Cannot be stop, branch, call or return
<Instruction 3> ; I3 Cannot be stop, branch, call or return
<Instruction 4> ; I4 Cannot be stop, branch, call or return

<branch/call/ret> ; MBCNDD, MCCNDD or MRCNDD

                ; I5-I7: Three instructions after are always
                ; executed whether the branch/call or return is
                ; taken or not

<Instruction 5> ; I5 Cannot be stop, branch, call or return
<Instruction 6> ; I6 Cannot be stop, branch, call or return
<Instruction 7> ; I7 Cannot be stop, branch, call or return

<Instruction 8> ; I8
<Instruction 9> ; I9
....

```

- **Stop or Halting a Task: MSTOP and MDEBUGSTOP**

The [MSTOP](#) and [MDEBUGSTOP](#) instructions cannot be placed three instructions before or after a conditional branch, call or return instruction ([MBCNDD](#), [MCCNDD](#) or [MRCNDD](#)). Refer to [Example 5-1](#). To single-step through a branch/call or return, insert the [MDEBUGSTOP](#) at least four instructions back and step from there.

- **Loading MAR0 or MAR1**

A load of auxiliary register MAR0 or MAR1 will occur in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing will occur in the D2 phase of the pipeline. Referring to [Example 5-2](#), the following applies when loading the auxiliary registers:

- **I1 and I2**

The two instructions following the load instruction will use the value in MAR0 or MAR1 before the update occurs.

- **I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there will be a conflict. In the case of a conflict, the update due to address-mode post increment will win and the auxiliary register will not be updated with `#_X`.

- **I4**

Starting with the 4th instruction MAR0 or MAR1 will have the new value.

Example 5-2. Code Fragment for Loading MAR0 or MAR1

```

; Assume MAR0 is 50 and #_X is 20

MMOVI16 MAR0, #_X ; Load MAR0 with address of X (20)
<Instruction 1> ; I1 Will use the old value of MAR0 (50)
<Instruction 2> ; I2 Will use the old value of MAR0 (50)
<Instruction 3> ; I3 Cannot use MAR0
<Instruction 4> ; I4 Will use the new value of MAR0 (20)
<Instruction 5> ; I5 Will use the new value of MAR0 (20)
....

```

5.5.2.1 ADC Early Interrupt to CLA Response

The ADC offers the option to generate an early interrupt pulse when the ADC begins conversion. This option is selected by setting the ADCCTL1[INTPULSEPOS] bit as documented in the Analog-to-Digital Converter and Comparator section in this manual. If this option is used to start a CLA task then the CLA will be able to read the result as soon as the conversion completes and the ADC result register updates. This just-in-time sampling along with the low interrupt response of the CLA enable faster system response and higher frequency control loops.

The timing for the ADC conversion is shown in the ADC Reference Guide timing diagrams. If the ADCCLK is a divided down version of the SYSCLK, the user will have to account for the conversion time in SYSCLK cycles. For example, if using the 12-bit ADC with ADCCLK at $\frac{1}{4}$ SYSCLK, it would take 10.5 ADCCLK (42 SYSCLK) cycles to complete a conversion. If using the ADC in 16-bit mode at the same ADCCLK, it would take 29.5 ADCCLK (118 SYSCLK) cycles, and so on.

From a CLA perspective, the pipeline activity is shown in Table 5-4 an n-cycle (SYSCLK) conversion. The nth-2 instruction is in the R2 phase just in time to read the result register. While the previous n-3 instructions in the task (I1 to In-3) will enter the R2 phase of the pipeline too soon to read the conversion, they can be efficiently used for pre-processing calculations needed by the task.

Table 5-4. ADC to CLA Early Interrupt Response

ADC Activity	CLA Activity	F1	F2	D1	D2	R1	R2	E	W
Sample									
Sample									
...									
Sample									
Conversion (1)	Interrupt Received								
Conversion (2)	Task Startup								
Conversion (3)	Task Startup								
Conversion (4)	I1	I1

Conversion (n-5)	I(n-5)	I(n-5)	I(n-6)						
Conversion (n-4)	I(n-4)	I(n-4)	I(n-5)	I(n-6)					
Conversion (n-3)	I(n-3)	I(n-3)	I(n-4)	I(n-5)	I(n-6)				
Conversion (n-2)	I(n-2) Read ADC RESULT	I(n-2)	I(n-3)	I(n-4)	I(n-5)	I(n-6)			
Conversion (n-1)			I(n-2)	I(n-3)	I(n-4)	I(n-5)	I(n-6)		
Conversion (n)				I(n-2)	I(n-3)	I(n-4)	I(n-5)		
Conversion Complete					I(n-2)	I(n-3)	I(n-4)		
RESULT Latched						I(n-2)	I(n-3)		
RESULT Available							I(n-2)		

5.5.3 Parallel Instructions

Parallel instructions are single opcodes that perform two operations in parallel. The following types of parallel instructions are available: math operation in parallel with a move operation, or two math operations in parallel. Both operations complete in a single cycle and there are no special pipeline alignment requirements.

Example 5-3. Math Operation with Parallel Load

```
; MADD32 || MMOV32 instruction: 32-bit floating-point add with parallel move
; MADD32 is a 1 cycle operation
; MMOV32 is a 1 cycle operation
      MADD32    MR0, MR1, #2    ; MR0 = MR1 + 2,
```

Example 5-3. Math Operation with Parallel Load (continued)

```

|| MMOV32    MR1, @Val      ; MR1 gets the contents of Val
                        ; <-- MMOV32 completes here (MR1 is valid)
                        ; <-- DDF32 completes here (MR0 is valid)
MMPYF32 MR0, MR0, MR1      ; Any instruction, can use MR1 and/or MR0

```

Example 5-4. Multiply with Parallel Add

```

; MMPYF32 || MADDF32 instruction: 32-bit floating-point multiply with parallel add
; MMPYF32 is a 1 cycle operation
; MADDF32 is a 1 cycle operation
MMPYF32 MR0, MR1, MR3      ; MR0 = MR1 * MR3
|| MADDF32 MR1, MR2, MR0   ; MR1 = MR2 + MR0 (Uses value of MR0 before MMPYF32)
                        ; <-- MMPYF32 and MADDF32 complete here (MR0 and MR1 are valid)
MMPYF32 MR1, MR1, MR0      ; Any instruction, can use MR1 and/or MR0

```

5.6 Instruction Set

This section describes the assembly language instructions of the control law accelerator. Also described are parallel operations, conditional operations, resource constraints, and addressing modes. The instructions listed here are independent from C28x and C28x+FPU instruction sets.

5.6.1 Instruction Descriptions

This section gives detailed information on the instruction set. Each instruction may present the following information:

- Operands
- Opcode
- Description
- Exceptions
- Pipeline
- Examples
- See also

The example INSTRUCTION is shown to familiarize you with the way each instruction is described. The example describes the kind of information you will find in each part of the individual instruction description and where to obtain more information. CLA instructions follow the same format as the C28x; the source operand(s) are always on the right and the destination operand(s) are on the left.

The explanations for the syntax of the operands used in the instruction descriptions for the C28x CLA are given in [Table 5-5](#).

Table 5-5. Operand Nomenclature

Symbol	Description
#16FHi	16-bit immediate (hex or float) value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FHiHex	16-bit immediate hex value that represents the upper 16-bits of an IEEE 32-bit floating-point value. Lower 16-bits of the mantissa are assumed to be zero.
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value
#32Fhex	32-bit immediate value that represents an IEEE 32-bit floating-point value
#32F	Immediate float value represented in floating-point representation
#0.0	Immediate zero
#SHIFT	Immediate value of 1 to 32 used for arithmetic and logical shifts.
addr	Opcode field indicating the addressing mode
CNDF	Condition to test the flags in the MSTF register
FLAG	Selected flags from MSTF register (OR) 8 bit mask indicating which floating-point status flags to change
MAR0	auxiliary register 0
MAR1	auxiliary register 1
MARx	Either MAR0 or MAR1
mem16	16-bit memory location accessed using direct, indirect, or offset addressing modes
mem32	32-bit memory location accessed using direct, indirect, or offset addressing modes
MRa	MR0 to MR3 registers
MRb	MR0 to MR3 registers
MRc	MR0 to MR3 registers
MRd	MR0 to MR3 registers
MRe	MR0 to MR3 registers
MRf	MR0 to MR3 registers
MSTF	CLA Floating-point Status Register
shift	Opcode field indicating the number of bits to shift.
VALUE	Flag value of 0 or 1 for selected flag (OR) 8 bit mask indicating the flag value; 0 or 1

Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).

Table 5-6. INSTRUCTION dest, source1, source2 Short Description

	Description
dest1	Description for the 1st operand for the instruction
source1	Description for the 2nd operand for the instruction
source2	Description for the 3rd operand for the instruction
Opcode	This section shows the opcode for the instruction
Description	Detailed description of the instruction execution is described. Any constraints on the operands imposed by the processor or the assembler are discussed.
Restrictions	Any constraints on the operands or use of the instruction imposed by the processor are discussed.
Pipeline	This section describes the instruction in terms of pipeline cycles as described in Section 5.5
Example	Examples of instruction execution. If applicable, register and memory values are given before and after instruction execution. Some examples are code fragments while other examples are full tasks that assume the CLA is correctly configured and the main CPU has passed it data.
Operands	Each instruction has a table that gives a list of the operands and a short description. Instructions always have their destination operand(s) first followed by the source operand(s).

5.6.2 Addressing Modes and Encoding

The CLA uses the same address to access data and registers as the main CPU. For example if the main CPU accesses an ePWM register at address 0x00 6800, then the CLA will access it using address 0x6800. Since all CLA accessible memory and registers are within the low 64k x 16 of memory, only the low 16-bits of the address are used by the CLA.

To address the CLA data memory, message RAMs and shared peripherals, the CLA supports two addressing modes:

- Direct addressing mode: Uses the address of the variable or register directly.
- Indirect addressing with 16-bit post increment. This mode uses either XAR0 or XAR1.

The CLA does not use a data page pointer or a stack pointer. The two addressing modes are encoded as shown [Table 5-7](#).

Table 5-7. Addressing Modes

Addressing Mode	'addr' Opcode Field Encode ⁽¹⁾	Description
@dir	0000	Direct Addressing Mode Example 1: MMOV32 MR1, @_VarA Example 2: MMOV32 MR1, @_EPwm1Regs.CMPA.all In this case the 'mmm mmmm mmmm mmmm' opcode field will be populated with the 16-bit address of the variable. This is the low 16-bits of the address that you would use to access the variable using the main CPU. For example @_VarA will populate the address of the variable VarA. and @_EPwm1Regs.CMPA.all will populate the address of the CMPA register.
*MAR0[#imm16]++	0001	MAR0 Indirect Addressing with 16-bit Immediate Post Increment addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1). MAR0 (or MAR1) += Then post increment MAR0 (or MAR1) by #imm16. #imm16 Example 1: MMOV32 MR0, *MAR0[2]++ Example 2: MMOV32 MR1, *MAR1[-2]++ For a post increment of 0 the assembler will accept both *MAR0 and *MAR0[0]++. The 'mmm mmmm mmmm mmmm' opcode field will be populated with the signed 16-bit pointer offset. For example if #imm16 is 2, then the opcode field will be 0x0002. Likewise if #imm16 is -2, then the opcode field will be 0xFFFFE.
*MAR1[#imm16]++	0010	MAR1 Indirect Addressing with 16-bit Immediate Post Increment addr = MAR0 (or MAR1) Access memory using the address stored in MAR0 (or MAR1). MAR0 (or MAR1) += Then post increment MAR0 (or MAR1) by #imm16. #imm16 Example 1: MMOV32 MR0, *MAR0[2]++ Example 2: MMOV32 MR1, *MAR1[-2]++ For a post increment of 0 the assembler will accept both *MAR0 and *MAR0[0]++. The 'mmm mmmm mmmm mmmm' opcode field will be populated with the signed 16-bit pointer offset. For example if #imm16 is 2, then the opcode field will be 0x0002. Likewise if #imm16 is -2, then the opcode field will be 0xFFFFE.
*MAR0+[#imm16]	0101	MAR0 Offset Addressing with 16-bit Immediate Offset addr = MAR0 Add the offset #imm16 (or MAR1) + #imm16to address stored in MAR0(MAR1) to access the desired memory the base location Example 1: MMOV32 MR0, *MAR0+[2] Example 1: MMOV32 MR1, *MAR1+[-2] The 'mmm mmmm mmmm mmmm' opcode field will be populated with the signed 16-bit pointer offset. For example if #imm16 is 2, then the opcode field will be 0x0002. Likewise if #imm16 is -2, then the opcode field will be 0xFFFFE.
*MAR1+[#imm16]	0110	MAR1 Offset Addressing with 16-bit Immediate Offset addr = MAR0 Add the offset #imm16 (or MAR1) + #imm16to address stored in MAR0(MAR1) to access the desired memory the base location Example 1: MMOV32 MR0, *MAR0+[2] Example 1: MMOV32 MR1, *MAR1+[-2] The 'mmm mmmm mmmm mmmm' opcode field will be populated with the signed 16-bit pointer offset. For example if #imm16 is 2, then the opcode field will be 0x0002. Likewise if #imm16 is -2, then the opcode field will be 0xFFFFE.

⁽¹⁾ Values not shown are reserved.

Encoding for the shift fields in the MASR32, MLSR32 and MLSL32 instructions is shown in [Table 5-8](#)

Table 5-8. Shift Field Encoding

Shift Value	'shift' Opcode Field Encode
1	0000
2	0001
3	0010
....	
32	1111

Table 5-10 shows the condition field encoding for conditional instructions such as MNEGF, MSWAPF, MBCNDD, MCCNDD, and MRCNDD.

For instructions that use MRx (where x could be 'a' through 'f') as operands, the trailing alphabet appears in the opcode as a two-bit field.

For example,

MMPYF32 MRa, MRb, MRc||MADDF32 MRd, MRe, MRf

whose opcode is

LSW: 0000 ffee ddcc bbaa

MSW: 0111 1010 0000 0000

the two-bit field specifies one of four working registers according to the following table:

Table 5-9. Operand Encoding

Two-bit Field	Working Register
b'00	MR0
b'01	MR1
b'10	MR2
b'11	MR3

Table 5-10. Condition Field Encoding

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

⁽¹⁾ Values not shown are reserved.

⁽²⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

5.6.3 Instructions

The instructions are listed alphabetically, preceded by a summary.

Table 5-11. General Instructions

Title	Page
MABSF32 MRa, MRb — 32-Bit Floating-Point Absolute Value	683
MADD32 MRa, MRb, MRc — 32-Bit Integer Add	684
MADDF32 MRa, #16FHi, MRb — 32-Bit Floating-Point Addition	685
MADDF32 MRa, MRb, #16FHi — 32-Bit Floating-Point Addition	686
MADDF32 MRa, MRb, MRc — 32-Bit Floating-Point Addition	688
MADDF32 MRd, MRe, MRf MMOV32 mem32, MRa — 32-Bit Floating-Point Addition with Parallel Move	689
MADDF32 MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Addition with Parallel Move	690
MAND32 MRa, MRb, MRc — Bitwise AND	692
MASR32 MRa, #SHIFT — Arithmetic Shift Right	693
MBCNDD 16BitDest {, CNDF} — Branch Conditional Delayed	694
MCCNDD 16BitDest {, CNDF} — Call Conditional Delayed	699
MCMP32 MRa, MRb — 32-Bit Integer Compare for Equal, Less Than or Greater Than	703
MCMPF32 MRa, MRb — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than	704
MCMPF32 MRa, #16FHi — 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than	705
MDEBUGSTOP — Debug Stop Task	707
MEALLOW — Enable CLA Write Access to EALLOW Protected Registers	708
MEDIS — Disable CLA Write Access to EALLOW Protected Registers	709
MEINVF32 MRa, MRb — 32-Bit Floating-Point Reciprocal Approximation	710
MEISQRTF32 MRa, MRb — 32-Bit Floating-Point Square-Root Reciprocal Approximation	711
MF32TOI16 MRa, MRb — Convert 32-Bit Floating-Point Value to 16-Bit Integer	712
MF32TOI16R MRa, MRb — Convert 32-Bit Floating-Point Value to 16-Bit Integer and Round	713
MF32TOI32 MRa, MRb — Convert 32-Bit Floating-Point Value to 32-Bit Integer	714
MF32TOUI16 MRa, MRb — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer	715
MF32TOUI16R MRa, MRb — Convert 32-Bit Floating-Point Value to 16-bit Unsigned Integer and Round	716
MF32TOUI32 MRa, MRb — Convert 32-Bit Floating-Point Value to 32-Bit Unsigned Integer	717
MFRACF32 MRa, MRb — Fractional Portion of a 32-Bit Floating-Point Value	718
MI16TOF32 MRa, MRb — Convert 16-Bit Integer to 32-Bit Floating-Point Value	719
MI16TOF32 MRa, mem16 — Convert 16-Bit Integer to 32-Bit Floating-Point Value	720
MI32TOF32 MRa, mem32 — Convert 32-Bit Integer to 32-Bit Floating-Point Value	721
MI32TOF32 MRa, MRb — Convert 32-Bit Integer to 32-Bit Floating-Point Value	722
MLSL32 MRa, #SHIFT — Logical Shift Left	723
MLSR32 MRa, #SHIFT — Logical Shift Right	724
MMACF32 MR3, MR2, MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Multiply and Accumulate with Parallel Move	725
MMAXF32 MRa, MRb — 32-Bit Floating-Point Maximum	728
MMAXF32 MRa, #16FHi — 32-Bit Floating-Point Maximum	730
MMINF32 MRa, MRb — 32-Bit Floating-Point Minimum	731
MMINF32 MRa, #16FHi — 32-Bit Floating-Point Minimum	733
MMOV16 MARx, MRa, #16I — Load the Auxiliary Register with MRa + 16-bit Immediate Value	734
MMOV16 MARx, mem16 — Load MAR1 with 16-bit Value	737
MMOV16 mem16, MARx — Move 16-Bit Auxiliary Register Contents to Memory	739
MMOV16 mem16, MRa — Move 16-Bit Floating-Point Register Contents to Memory	740
MMOV32 mem32, MRa — Move 32-Bit Floating-Point Register Contents to Memory	742
MMOV32 mem32, MSTF — Move 32-Bit MSTF Register to Memory	743
MMOV32 MRa, mem32 {, CNDF} — Conditional 32-Bit Move	744
MMOV32 MRa, MRb {, CNDF} — Conditional 32-Bit Move	746

Table 5-11. General Instructions (continued)

MMOV32 MSTF, mem32 — Move 32-Bit Value from Memory to the MSTF Register	748
MMOVD32 MRa, mem32 — Move 32-Bit Value from Memory with Data Copy	749
MMOV32 MRa, #32F — Load the 32-Bits of a 32-Bit Floating-Point Register	750
MMOVI16 MARx, #16I — Load the Auxiliary Register with the 16-Bit Immediate Value	751
MMOVI32 MRa, #32FHex — Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate	752
MMOVIZ MRa, #16FHi — Load the Upper 16-Bits of a 32-Bit Floating-Point Register	753
MMOVZ16 MRa, mem16 — Load MRx With 16-bit Value	754
MMOVXI MRa, #16FLoHex — Move Immediate to the Low 16-Bits of a Floating-Point Register	755
MMPYF32 MRa, MRb, MRc — 32-Bit Floating-Point Multiply	756
MMPYF32 MRa, #16FHi, MRb — 32-Bit Floating-Point Multiply	757
MMPYF32 MRa, MRb, #16FHi — 32-Bit Floating-Point Multiply	759
MMPYF32 MRa, MRb, MRc MADDF32 MRd, MRe, MRf — 32-Bit Floating-Point Multiply with Parallel Add	761
MMPYF32 MRd, MRe, MRf MMOV32 MRa, mem32 — 32-Bit Floating-Point Multiply with Parallel Move	763
MMPYF32 MRd, MRe, MRf MMOV32 mem32, MRa — 32-Bit Floating-Point Multiply with Parallel Move	765
MMPYF32 MRa, MRb, MRc MSUBF32 MRd, MRe, MRf — 32-Bit Floating-Point Multiply with Parallel Subtract	766
MNEGF32 MRa, MRb{, CNDF} — Conditional Negation	767
MNOP — No Operation	769
MOR32 MRa, MRb, MRc — Bitwise OR	770
MRCNDD {CNDF} — Return Conditional Delayed	771
MSETFLG FLAG, VALUE — Set or Clear Selected Floating-Point Status Flags	775
MSTOP — Stop Task	776
MSUB32 MRa, MRb, MRc — 32-Bit Integer Subtraction	778

MABSF32 MRa, MRb 32-Bit Floating-Point Absolute Value

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0010 0000

Description

The absolute value of MRb is loaded into MRa. Only the sign bit of the operand is modified by the MABSF32 instruction.

```
if (MRb < 0) {MRa = -MRb};
else {MRa = MRb};
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = 0;
ZF = 0;
if ( MRa(30:23) == 0) ZF = 1;
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #-2.0 ; MR0 = -2.0 (0xC0000000)
MABSF32 MR0, MR0 ; MR0 = 2.0 (0x40000000), ZF = NF = 0
```

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MABSF32 MR0, MR0 ; MR0 = 5.0 (0x40A00000), ZF = NF = 0
```

```
MMOVIZ MR0, #0.0 ; MR0 = 0.0
MABSF32 MR0, MR0 ; MR0 = 0.0 ZF = 1, NF = 0
```

MADD32 MRa, MRb, MRc 32-Bit Integer Add

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRC	CLA floating-point destination register (MR0 to MR3)

Opcode

LSW: 0000 0000 000cc bbaa
MSW: 0111 1110 1100 0000

Description

32-bit integer addition of MRb and MRc.

$MRa(31:0) = MRb(31:0) + MRc(31:0);$

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; };
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;      B = (int32)2
;      C = (int32)-7
;
; Calculate Y2 = A + B + C
;
_Cla1Task1:
    MMOV32 MR0, @_A      ; MR0 = 1 (0x00000001)
    MMOV32 MR1, @_B      ; MR1 = 2 (0x00000002)
    MMOV32 MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MADD32 MR3, MR0, MR1 ; A + B
    MADD32 MR3, MR2, MR3 ; A + B + C = -4 (0xFFFFFFFFC)
    MMOV32 @_y2, MR3     ; Store y2
    MSTOP                ; end of task
```

MADDF32 MRa, #16FHi, MRb 32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: I I I I I I I I I I I I I I I I
MSW: 0111 0111 1100 bbaa

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

MRa = MRb + #16FHi:0;

This instruction can also be written as MADDF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
MADDF32 MR0, #2.0, MR1    ; MR0 = 2.0 + MR1

; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
MADDF32 MR2, #-2.5, MR3   ; MR2 = -2.5 + MR3

; Add to MR3 the value 0x3FC00000 (1.5)
; Store the result in MR3
MADDF32 MR3, #0x3FC0, MR3 ; MR3 = 1.5 + MR3
```

MADDF32 MRa, MRb, #16FHi 32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

LSW: I I I I I I I I I I I I I I I I
MSW: 0111 0111 1100 bbaa

Description

Add MRb to the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

MRa = MRb + #16FHi:0;

This instruction can also be written as MADDF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store it in Result
;
_ClaiTask1:
    MMIOVI16    MAR1, #_X          ; Start address
    MUI16TOF32  MR0, @_len         ; Length of the array
    MNOP
    MNOP        ; delay for MAR1 load
    MNOP        ; delay for MAR1 load
    MMIOV32     MR1, *MAR1[2]++    ; MR1 = X0
LOOP
    MMIOV32     MR2, *MAR1[2]++    ; MR2 = next element
    MMAXF32     MR1, MR2           ; MR1 = MAX(MR1, MR2)
    MADDF32     MR0, MR0, #-1.0    ; Decrement the counter
    MCMPF32     MR0 #0.0           ; Set/clear flags for MBCNDD
    MNOP
    MNOP
    MNOP
    MBCNDD     LOOP, NEQ           ; Branch if not equal to zero
    MMIOV32     @_Result, MR1      ; Always executed
    MNOP        ; Always executed
    MNOP        ; Always executed
    MSTOP
```

Example 2

```

; Show the basic operation of MADDF32
;
; Add to MR1 the value 2.0 in 32-bit floating-point format
; Store the result in MR0
    MADDF32 MR0, MR1, #2.0    ; MR0 = MR1 + 2.0

; Add to MR3 the value -2.5 in 32-bit floating-point format
; Store the result in MR2
    MADDF32 MR2, MR3, #-2.5   ; MR2 = MR3 + (-2.5)

; Add to MR0 the value 0x3FC00000 (1.5)
; Store the result in MR0
    MADDF32 MR0, MR0, #0x3FC0 ; MR0 = MR0 + 1.5

```

MADDF32 MRa, MRb, MRc 32-Bit Floating-Point Addition

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 000 0000 00cc bbaa
MSW: 0111 1100 0010 0000

Description

Add the contents of MRc to the contents of MRb and load the result into MRa.

MRa = MRb + MRc;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given M1, X1 and B1 are 32-bit floating point numbers
; Calculate Y1 = M1*X1+B1
;
_Cla1Task1:
    MMOV32 MR0,@M1      ; Load MR0 with M1
    MMOV32 MR1,@X1      ; Load MR1 with X1
    MMPYF32 MR1,MR1,MR0 ; Multiply M1*X1
|| MMOV32 MR0,@B1      ; and in parallel load MR0 with B1
    MADDF32 MR1,MR1,MR0 ; Add M*X1 to B1 and store in MR1
    MMOV32 @Y1,MR1      ; Store the result
    MSTOP               ; end of task
```

MADDF32 MRd, MRe, MRf||MMOV32 mem32, MRa 32-Bit Floating-Point Addition with Parallel Move

Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This will be the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0101 ffee ddaa addr

Description

Perform an MADDF32 and a MMOV32 in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of MRa to the 32-bit location mem32.

MRd = MRe + MRf;
[mem32] = MRa;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

Pipeline

Both MADDF32 and MMOV32 complete in a single cycle.

Example

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) + C
;
;
_Cla1Task2:
    MMOV32  MR0, @_A      ; Load MR0 with A
    MMOV32  MR1, @_B      ; Load MR1 with B
    MMPYF32 MR1, MR1, MR0 ; Multiply A*B
|| MMOV32   MR0, @_C      ; and in parallel load MR0 with C
    MADDF32 MR1, MR1, MR0 ; Add (A*B) to C
|| MMOV32   @_Y2, MR1     ; and in parallel store A*B
    MMOV32  @_Y3, MR1     ; Store the A*B + C
    MSTOP
```

MADDF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 32-Bit Floating-Point Addition with Parallel Move

Operands

MRd	CLA floating-point destination register for the MADDF32 (MR0 to MR3). MRd cannot be the same register as MRa.
MRe	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MADDF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3). MRa cannot be the same register as MRd.
mem32	32-bit memory location accessed using one of the available addressing modes. This is the source for the MMOV32.

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0001 ffee ddaa addr

Description

Perform an MADDF32 and a MMOV32 operation in parallel. Add MRf to the contents of MRe and store the result in MRd. In parallel move the contents of the 32-bit location mem32 to MRa.

MRd = MRe + MRf;
MRa = [mem32];

Restrictions

The destination register for the MADDF32 and the MMOV32 must be unique. That is, MRa and MRd cannot be the same register.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MADDF32 generates an underflow condition.
- LVF = 1 if MADDF32 generates an overflow condition.

The MMOV32 Instruction will set the NF and ZF flags as follows:

NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; };

Pipeline

The MADDF32 and the MMOV32 both complete in a single cycle.

Example 1

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y1 = A + 4B
;           Y2 = A + C
;
;_Cla1Task1:
;  MMOV32 MR0, @A           ; Load MR0 with A
;  MMOV32 MR1, @B           ; Load MR1 with B
;  MPPYF32 MR1, MR1, #4.0   ; Multiply 4 * B
|| MMOV32 MR2, @C           ; and in parallel load C
;  MADDF32 MR3, MR0, MR1    ; Add A + 4B
;  MADDF32 MR3, MR0, MR2    ; Add A + C
|| MMOV32 @Y1, MR3          ; and in parallel store A+4B
;  MMOV32 @Y2, MR3          ; store A + C MSTOP
;                             ; end of task
```

Example 2

```

; Given A, B and C are 32-bit floating-point numbers
; Calculate Y3 = (A + B)
;           Y4 = (A + B) * C
;
_Cla1Task2:
    MMOV32 MR0, @A      ; Load MR0 with A
    MMOV32 MR1, @B      ; Load MR1 with B
    MADDF32 MR1, MR1, MR0 ; Add A+B
||  MMOV32 MR0, @C      ; and in parallel load MR0 with C
    MMPYF32 MR1, MR1, MR0 ; Multiply (A+B) by C
||  MMOV32 @Y3, MR1      ; and in parallel store A+B
    MMOV32 @Y4, MR1      ; Store the (A+B) * C
    MSTOP                ; end of task

```

MAND32 MRa, MRb, MRc Bitwise AND

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRC	CLA floating-point source register (MR0 to MR3)

Opcode

```
LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0110 0000
```

Description

Bitwise AND of MRb with MRc.

```
MRa(31:0) = MRb(31:0) AND MRc(31:0);
```

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA
```

```
MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC
```

```
; 0101 AND 0101 = 0101 (5)
; 0101 AND 0100 = 0100 (4)

MASR32 MRa, #SHIFT *Arithmetic Shift Right*

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 0100 0000

Description

Arithmetic shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32.

MARa(31:0) = Arithmetic Shift(MARa(31:0) by #SHIFT bits);

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
;          x2 = (int32)64
;          b2 = (int32)-128
;
; Calculate
;          m2 = m2/2
;          x2 = x2/4
;          b2 = b2/8
;
_Cla1Task2:
    MOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
    MOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
    MOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
    MASR32 MR0, #1 ; MR0 = 16 (0x00000010)
    MASR32 MR1, #2 ; MR1 = 16 (0x00000010)
    MASR32 MR2, #3 ; MR2 = -16 (0xFFFFF0)
    MOV32 @_m2, MR0 ; store results
    MOV32 @_x2, MR1
    MOV32 @_b2, MR2
    MSTOP ; end of task
```

MBCNDD 16BitDest {, CNDF} *Branch Conditional Delayed*

Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition tested

Opcode

LSW: dest dest dest dest
MSW: 0111 1001 1000 cndf

Description

If the specified condition is true, then branch by adding the signed 16BitDest value to the MPC value. Otherwise, continue without branching. If the address overflows, it wraps around. Therefore a value of "0xFFFF" will put the MPC back to the MBCNDD instruction.

Please refer to the pipeline section for important information regarding this instruction.

if (CNDF == TRUE) MPC += 16BitDest;

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

⁽¹⁾ Values not shown are reserved.

⁽²⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Restrictions

The MBCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD or MRCNDD instruction. Refer to the pipeline section for more information.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MBCNDD instruction by itself is a single-cycle instruction. As shown in [Table 5-12](#) for each branch 6 instruction slots are executed; three before the branch instruction (I2-I4) and three after the branch instruction (I5-I7). The total number of cycles for a branch taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a branch can, therefore, range from 1 to 7 cycles. The number of cycles for a branch taken may not be the same as for a branch not taken.

Referring to [Table 5-12](#) and [Table 5-13](#), the instructions before and after MBCNDD have the following properties:

- **I1**
 - I1 is the last instruction that can effect the CNDF flags for the MBCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MBCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for I1.
- **I2, I3 and I4**
 - The three instructions proceeding MBCNDD can change MSTF flags but will have no effect on whether the MBCNDD instruction branches or not. This is because the flag modification will occur after the D2 phase of the MBCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.
- **I5, I6 and I7**
 - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

[MRCNDD CNDF](#)

MCCNDD 16BitDest {, CNDF} *Call Conditional Delayed*

Operands

16BitDest	16-bit destination if condition is true
CNDF	Optional condition to be tested

Opcode

LSW: dest dest dest dest
MSW: 0111 1001 1001 cndf

Description

If the specified condition is true, then store the return address in the RPC field of MSTF and make the call by adding the signed 16BitDest value to the MPC value. Otherwise, continue code execution without making the call. If the address overflows, it wraps around. Therefore a value of "0xFFFF" will put the MPC back to the MCCNDD instruction.

Please refer to the pipeline section for important information regarding this instruction.

```
if (CNDF == TRUE)
{
    RPC = return address;
    MPC += 16BitDest;
};
```

CNDF is one of the following conditions:

Encode ⁽³⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽⁴⁾	Unconditional with flag modification	None

⁽³⁾ Values not shown are reserved.

⁽⁴⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Restrictions

The MCCNDD instruction is not allowed three instructions before or after a MBCNDD, MCCNDD, or MRCNDD instruction. Refer to the Pipeline section for more details.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MCCNDD instruction by itself is a single-cycle instruction. As shown in [Table 5-14](#), for each call 6 instruction slots are executed; three before the call instruction (I2-I4) and three after the call instruction (I5-I7). The total number of cycles for a call taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a call can, therefore, range from 1 to 7 cycles. The number of cycles for a call taken may not be the same as for a call not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 5-14](#) and [Table 5-15](#), the instructions before and after MCCNDD have the following properties:

- **I1**
 - I1 is the last instruction that can effect the CNDF flags for the MCCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to branch or not when MCCNDD is in the D2 phase.
 - There are no restrictions on the type of instruction for I1.
- **I2, I3 and I4**
 - The three instructions proceeding MCCNDD can change MSTF flags but will have no effect on whether the MCCNDD instruction makes the call or not. This is because the flag modification will occur after the D2 phase of the MCCNDD instruction.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.
- **I5, I6 and I7**
 - The three instructions following MBCNDD are always executed irrespective of whether the branch is taken or not.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

MCMP32 MRa, MRb 32-Bit Integer Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0010 0000

Description

Set ZF and NF flags on the result of MRa - MRb where MRa and MRb are 32-bit integers. For a floating point compare refer to [MCMFP32](#).

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
; Behavior of ZF and NF flags for different comparisons
;
; Given A = (int32)1
;       B = (int32)2
;       C = (int32)-7
;
MMOV32 MR0, @_A ; MR0 = 1 (0x00000001)
MMOV32 MR1, @_B ; MR1 = 2 (0x00000002)
MMOV32 MR2, @_C ; MR2 = -7 (0xFFFFFFFF9)
MCMP32 MR2, MR2 ; NF = 0, ZF = 1
MCMP32 MR0, MR1 ; NF = 1, ZF = 0
MCMP32 MR1, MR0 ; NF = 0, ZF = 0
```

MCMPF32 MRa, MRb 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0000 0000

Description

Set ZF and NF flags on the result of MRa - MRb. The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE format offsetting the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero will be treated as positive zero.
- A denormalized value will be treated as positive zero.
- Not-a-Number (NaN) will be treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == MRb) {ZF=1; NF=0;}
If(MRa > MRb) {ZF=0; NF=0;}
If(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

; Behavior of ZF and NF flags for different comparisons

```
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MCMPF32 MR1, MR0 ; ZF = 0, NF = 1
MCMPF32 MR0, MR1 ; ZF = 0, NF = 0
MCMPF32 MR0, MR0 ; ZF = 1, NF = 0
```

MCMPF32 MRa, #16FHi 32-Bit Floating-Point Compare for Equal, Less Than or Greater Than

Operands

MRa	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

LSW: I I I I I I I I I I I I I I
MSW: 0111 1000 1100 00aa

Description

Compare the value in MRa with the floating-point value represented by the immediate operand. Set the ZF and NF flags on (MRa - #16FHi:0).

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

The MCMPF32 instruction is performed as a logical compare operation. This is possible because of the IEEE floating-point format offsets the exponent. Basically the bigger the binary number, the bigger the floating-point value.

Special cases for inputs:

- Negative zero will be treated as positive zero.
- Denormalized value will be treated as positive zero.
- Not-a-Number (NaN) will be treated as infinity.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
If(MRa == #16FHi:0) {ZF=1, NF=0;}
If(MRa > #16FHi:0) {ZF=0, NF=0;}
If(MRa < #16FHi:0) {ZF=0, NF=1;}
```

Pipeline

This is a single-cycle instruction

Example 1

; Behavior of ZF and NF flags for different comparisons

```
MMOVIZ    MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ    MR0, #5.0  ; MR0 = 5.0 (0x40A00000)
MCMPF32   MR1, #-2.2 ; ZF = 0, NF = 0
MCMPF32   MR0, #6.5  ; ZF = 0, NF = 1
MCMPF32   MR0, #5.0  ; ZF = 1, NF = 0
```

Example 2

```

; X is an array of 32-bit floating-point values
; and has len elements. Find the maximum value in
; the array and store it in Result
;
; Note: MCMPF32 and MSWAPF can be replaced with MMAXF32
;
_Cla1Task1:

MDEBUGSTOP

Debug Stop Task

Operands

none This instruction does not have any operands

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 0110 0000

Description

When CLA breakpoints are enabled, the MDEBUGSTOP instruction is used to halt a task so that it can be debugged. That is, MDEBUGSTOP is the CLA breakpoint. If CLA breakpoints are not enabled, the MDEBUGSTOP instruction behaves like a MNOP. Unlike the MSTOP, the MIRUN flag is not cleared and an interrupt is not issued. A single-step or run operation will continue execution of the task.

Restrictions

The MDEBUGSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#) or [MRCNDD](#) instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

;

[MSTOP](#)

MEALLOW *Enable CLA Write Access to EALLOW Protected Registers*

Operands

none This instruction does not have any operands

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1001 0000

Description

This instruction sets the MEALLOW bit in the CLA status register MSTF. When this bit is set, the CLA is allowed write access to EALLOW protected registers. To again protect against CLA writes to protected registers, use the MEDIS instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden via the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdecls C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
MEALLOW                    ; Allow CLA write access
MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
MEDIS                      ; Disallow CLA write access
...
...
MSTOP
```

See also

[MEDIS](#)

MEDIS

Disable CLA Write Access to EALLOW Protected Registers

Operands

none	This instruction does not have any operands

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1011 0000

Description

This instruction clears the MEALLOW bit in the CLA status register MSTF. When this bit is clear, the CLA is not allowed write access to EALLOW-protected registers. To enable CLA writes to protected registers, use the MEALLOW instruction.

MEALLOW and MEDIS only control CLA write access; reads are allowed even if MEALLOW has not been executed. MEALLOW and MEDIS are also independent from the main CPU's EALLOW/EDIS. This instruction does not modify the EALLOW bit in the main CPU's status register. The MEALLOW bit in MSTF only controls access for the CLA while the EALLOW bit in the ST1 register only controls access for the main CPU.

As with EALLOW, the MEALLOW bit is overridden via the JTAG port, allowing full control of register accesses during debug from Code Composer Studio.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; C header file including definition of
; the EPwm1Regs structure
;
; The ePWM TZSEL register is EALLOW protected
;
.cdecls C,LIST,"CLAShared.h"
...
_Cla1Task1:
...
MEALLOW                ; Allow CLA write access
MMOV16 @_EPwm1Regs.TZSEL.all, MR3 ; Write to TZSEL
MEDIS                  ; Disallow CLA write access
...
...
MSTOP
```

MEINVF32 MRa, MRb 32-Bit Floating-Point Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1111 0000 0000

Description

This operation generates an estimate of $1/X$ in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/X);
Ye = Ye*(2.0 - Ye*X);
Ye = Ye*(2.0 - Ye*X);
```

After two iterations of the Newton-Raphson algorithm, you will get an exact answer accurate to the 32-bit floating-point format. On each iteration the mantissa bit accuracy approximately doubles. The MEINVF32 operation will not generate a negative zero, DeNorm or NaN value.

MRa = Estimate of $1/MRb$;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEINVF32 generates an underflow condition.
- LVF = 1 if MEINVF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
;_Cla1Task1:
  MMOV32 MR1, @_Den      ; MR1 = Den
  MEINVF32 MR2, MR1      ; MR2 = Ye = Estimate(1/Den)
  MPPYF32 MR3, MR2, MR1  ; MR3 = Ye*Den
  MSUBF32 MR3, #2.0, MR3 ; MR3 = 2.0 - Ye*Den
  MPPYF32 MR2, MR2, MR3  ; MR2 = Ye = Ye*(2.0 - Ye*Den)
  MPPYF32 MR3, MR2, MR1  ; MR3 = Ye*Den
|| MMOV32 MR0, @_Num     ; MR0 = Num
  MSUBF32 MR3, #2.0, MR3 ; MR3 = 2.0 - Ye*Den
  MPPYF32 MR2, MR2, MR3  ; MR2 = Ye = Ye*(2.0 - Ye*Den)
|| MMOV32 MR1, @_Den     ; Reload Den To Set Sign
  MNEGF32 MR0, MR0, EQ   ; if(Den == 0.0) Change Sign Of Num
  MPPYF32 MR0, MR2, MR0  ; MR0 = Y = Ye*Num
  MMOV32 @_Dest, MR0     ; Store result
  MSTOP                  ; end of task
```

[MEISQRTF32 MRa, MRb](#)

MEISQRTF32 MRa, MRb 32-Bit Floating-Point Square-Root Reciprocal Approximation

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0100 0000

Description

This operation generates an estimate of $1/\sqrt{X}$ in 32-bit floating-point format accurate to approximately 8 bits. This value can be used in a Newton-Raphson algorithm to get a more accurate answer. That is:

```
Ye = Estimate(1/sqrt(X));
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
Ye = Ye*(1.5 - Ye*Ye*X/2.0);
```

After 2 iterations of the Newton-Raphson algorithm, you will get an exact answer accurate to the 32-bit floating-point format. On each iteration the mantissa bit accuracy approximately doubles. The MEISQRTF32 operation will not generate a negative zero, DeNorm or NaN value.

MRa = Estimate of $1/\sqrt{\text{MRb}}$;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MEISQRTF32 generates an underflow condition.
- LVF = 1 if MEISQRTF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Y = sqrt(X)
; Ye = Estimate(1/sqrt(X));
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Y = X*Ye
;
_Cla1Task3:
    MMOV32 MR0, @_x      ; MR0 = X
    MEISQRTF32 MR1, MR0   ; MR1 = Ye = Estimate(1/sqrt(X))
    MMOV32 MR1, @_x, EQ   ; if(X == 0.0) Ye = 0.0
    MMPYF32 MR3, MR0, #0.5 ; MR3 = X*0.5
    MMPYF32 MR2, MR1, MR3 ; MR2 = Ye*X*0.5
    MMPYF32 MR2, MR1, MR2 ; MR2 = Ye*Ye*X*0.5
    MSUBF32 MR2, #1.5, MR2 ; MR2 = 1.5 - Ye*Ye*X*0.5
    MMPYF32 MR1, MR1, MR2 ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MMPYF32 MR2, MR1, MR3 ; MR2 = Ye*X*0.5
    MMPYF32 MR2, MR1, MR2 ; MR2 = Ye*Ye*X*0.5
    MSUBF32 MR2, #1.5, MR2 ; MR2 = 1.5 - Ye*Ye*X*0.5
    MMPYF32 MR1, MR1, MR2 ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MMPYF32 MR0, MR1, MR0 ; MR0 = Y = Ye*X
    MMOV32 @_y, MR0       ; Store Y = sqrt(X)
    MSTOP                 ; end of task
```

MFRACF32 MRa, MRb *Fractional Portion of a 32-Bit Floating-Point Value*
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 0000 0000

Description

Returns in MRa the fractional portion of the 32-bit floating-point value in MRb

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

MMOVIZ MR2, #19.625 ; MR2 = 19.625 (0x419D0000)
MFRACF32 MR3, MR2 ; MR3 = MFRACF32(MR2) = 0.625 (0x3F200000)0

See also

MI16TOF32 MRa, MRb *Convert 16-Bit Integer to 32-Bit Floating-Point Value*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1110 1000 0000

Description

Convert the 16-bit signed integer in MRb to a 32-bit floating point value and store the result in MRa.

MRa = MI16TOF32(MRb);

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #0x0000    ; MR0(31:16) = 0.0 (0x0000)
MMOVXI    MR0, #0x0004    ; MR0(15:0) = 4.0 (0x0004)
MI16TOF32 MR1, MR0        ; MR1 = MI16TOF32 (MR0) = 4.0 (0x40800000)

MMOVIZ    MR2, #0x0000    ; MR2(31:16) = 0.0 (0x0000)
MMOVXI    MR2, #0xFFFC    ; MR2(15:0) = -4.0 (0xFFFC)
MI16TOF32 MR3, MR2        ; MR3 = MI16TOF32 (MR2) = -4.0 (0xC0800000)
MSTOP
```

MI16TOF32 MRa, mem16 *Convert 16-Bit Integer to 32-Bit Floating-Point Value*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location to be converted

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 00aa addr

Description

Convert the 16-bit signed integer indicated by the mem16 pointer to a 32-bit floating-point value and store the result in MRa.

MRa = MI16TOF32[mem16];

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction:

Example

```
; Assume A = 4 (0x0004)
;      B = -4 (0xFFFC)

MI16TOF32 MR0, @_A ; MR0 = MI16TOF32(A) = 4.0 (0x40800000)
MI16TOF32 MR1, @_B ; MR1 = MI16TOF32(B) = -4.0 (0xC0800000)
```

MI32TOF32 MRa, mem32 *Convert 32-Bit Integer to 32-Bit Floating-Point Value*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory source for the MMOV32 operation.

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0100 01aa addr

Description

Convert the 32-bit signed integer indicated by mem32 to a 32-bit floating point value and store the result in MRa.

MRa = MI32TOF32[mem32];

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Given X, M and B are IQ24 numbers:
; X = IQ24(+2.5) = 0x02800000
; M = IQ24(+1.5) = 0x01800000
; B = IQ24(-0.5) = 0xFF800000
;
; Calculate Y = X * M + B
;
; Convert M, X and B from IQ24 to float
;

_Cla1Task3:
    MI32TOF32 MR0, @_M      ; MR0 = 0x4BC00000
    MI32TOF32 MR1, @_X      ; MR1 = 0x4C200000
    MI32TOF32 MR2, @_B      ; MR2 = 0xCB000000
    MMPYF32 MR0, MR0, #0x3380 ; M = 1/(1*2^24) * iqm = 1.5 (0x3FC00000)
    MMPYF32 MR1, MR1, #0x3380 ; X = 1/(1*2^24) * iqx = 2.5 (0x40200000)
    MMPYF32 MR2, MR2, #0x3380 ; B = 1/(1*2^24) * iqb = -.5 (0xBF000000)
    MMPYF32 MR3, MR0, MR1    ; M*X
    MADDF32 MR2, MR2, MR3    ; Y=MX+B = 3.25 (0x40500000)

; Convert Y from float32 to IQ24

MLSL32 MRa, #SHIFT *Logical Shift Left*

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1100 0000

Description

Logical shift left of MRa by the number of bits indicated. The number of bits can be 1 to 32.

MARa(31:0) = Logical Shift Left(MARa(31:0) by #SHIFT bits);

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given m2 = (int32)32
;          x2 = (int32)64
;          b2 = (int32)-128
;
; Calculate:
;          m2 = m2*2
;          x2 = x2*4
;          b2 = b2*8
;
_Cla1Task3:
    MOV32 MR0, @_m2 ; MR0 = 32 (0x00000020)
    MOV32 MR1, @_x2 ; MR1 = 64 (0x00000040)
    MOV32 MR2, @_b2 ; MR2 = -128 (0xFFFFF80)
    MLSL32 MR0, #1 ; MR0 = 64 (0x00000040)
    MLSL32 MR1, #2 ; MR1 = 256 (0x00000100)
    MLSL32 MR2, #3 ; MR2 = -1024 (0xFFFFFC00)
    MOV32 @_m2, MR0 ; Store results
    MOV32 @_x2, MR1
    MOV32 @_b2, MR2
    MSTOP ; end of task
```

MLSR32 MRa, #SHIFT *Logical Shift Right*

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#SHIFT	Number of bits to shift (1 to 32)

Opcode

```
LSW: 0000 0000 0shi ftaa
MSW: 0111 1011 1000 0000
```

Description

Logical shift right of MRa by the number of bits indicated. The number of bits can be 1 to 32. Unlike the arithmetic shift (MASR32), the logical shift does not preserve the number's sign bit. Every bit in the operand is moved the specified number of bit positions, and the vacant bit-positions are filled in with zeros

MARa(31:0) = Logical Shift Right(MARa(31:0) by #SHIFT bits);

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1;}
```

Pipeline

This is a single-cycle instruction.

Example

; Illustrate the difference between MASR32 and MLSR32

```
MMOVIZ MR0, #0xAAAA ; MR0 = 0xAAAA5555
MMOVXI MR0, #0x5555
```

```
MMOV32 MR1, MR0 ; MR1 = 0xAAAA5555
MMOV32 MR2, MR0 ; MR2 = 0xAAAA5555
```

```
MASR32 MR1, #1 ; MR1 = 0xD5552AAA
MLSR32 MR2, #1 ; MR2 = 0x55552AAA
```

```
MASR32 MR1, #1 ; MR1 = 0xEAAA9555
MLSR32 MR2, #1 ; MR2 = 0x2AAA9555
```

```
MASR32 MR1, #6 ; MR1 = 0xFFAAA555
MLSR32 MR2, #6 ; MR2 = 0x00AAA555
```

MMACF32 MR3, MR2, MRd, MRe, MRf ||MMOV32 MRa, mem32 32-Bit Floating-Point Multiply and Accumulate with Parallel Move

Operands

MR3	floating-point destination/source register MR3 for the add operation
MR2	CLA floating-point source register MR2 for the add operation
MRd	CLA floating-point destination register (MR0 to MR3) for the multiply operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRf	CLA floating-point source register (MR0 to MR3) for the multiply operation
MRa	CLA floating-point destination register for the MMOV32 operation (MR0 to MR3). MRa cannot be MR3 or the same register as MRd.
mem32	32-bit source for the MMOV32 operation

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0011 ffee ddaa addr

Description

Multiply and accumulate the contents of floating-point registers and move from register to memory. The destination register for the MMOV32 cannot be the same as the destination registers for the MMACF32.

MR3 = MR3 + MR2;
MRd = MRe * MRf;
MRa = [mem32];

Restrictions

The destination registers for the MMACF32 and the MMOV32 must be unique. That is, MRa cannot be MR3 and MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMACF32 (add or multiply) generates an underflow condition.
- LVF = 1 if MMACF32 (add or multiply) generates an overflow condition.

MMOV32 sets the NF and ZF flags as follows:

NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }

Pipeline

MMACF32 and MMOV32 complete in a single cycle.

Example 1

```

; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating point arrays
;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3
;
; Result = A + B + C + D + E
;
_Cla1Task1:

MMAXF32 MRa, MRb 32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0010 0000

Description

if(MRa < MRb) MRa = MRb;

Special cases for the output from the MMAXF32 operation:

- NaN output will be converted to infinity
- A denormalized output will be converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb) {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example 1

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #-2.0 ; MR1 = -2.0 (0xC0000000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMAXF32 MR2, MR1 ; MR2 = -1.5, ZF = NF = 0
MMAXF32 MR1, MR2 ; MR1 = -1.5, ZF = 0, NF = 1
MMAXF32 MR2, MR0 ; MR2 = 5.0, ZF = 0, NF = 1
MAXF32 MR0, MR2 ; MR2 = 5.0, ZF = 1, NF = 0
```

Example 2

```
; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store it in Result
;
_ClaiTask1:
  MMOV16 MAR1, #_X ; Start address
  MUI16TOF32 MR0, @_len ; Length of the array
  MNOP ; delay for MAR1 load
  MNOP ; delay for MAR1 load
  MMOV32 MR1, *MAR1[2]++ ; MR1 = X0
LOOP
  MMOV32 MR2, *MAR1[2]++ ; MR2 = next element
  MMAXF32 MR1, MR2 ; MR1 = MAX(MR1, MR2)
  MADD32 MR0, MR0, #-1.0 ; Decrememt the counter
  MCMPPF32 MR0 #0.0 ; Set/clear flags for MBCNDD
  MNOP
  MNOP
  MNOP
  MBCNDD LOOP, NEQ ; Branch if not equal to zero
  MMOV32 @_Result, MR1 ; Always executed
  MNOP ; Always executed
  MNOP ; Always executed
  MSTOP ; End of task
```

[MMINF32 MRa, #16FHi](#)

MMAXF32 MRa, #16FHi 32-Bit Floating-Point Maximum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0000 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is larger, then load it into MRa.

```
if(MRa < #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMAXF32 operation:

- NaN output will be converted to infinity
- A denormalized output will be converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0) {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMAXF32 MR0, #5.5 ; MR0 = 5.5, ZF = 0, NF = 1
MMAXF32 MR1, #2.5 ; MR1 = 4.0, ZF = 0, NF = 0
MMAXF32 MR2, #-1.0 ; MR2 = -1.0, ZF = 0, NF = 1
MMAXF32 MR2, #-1.0 ; MR2 = -1.5, ZF = 1, NF = 0
```

MMINF32 MRa, MRb 32-Bit Floating-Point Minimum

Operands

MRa	CLA floating-point source/destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 0100 0000

Description

if(MRa > MRb) MRa = MRb;

Special cases for the output from the MMINF32 operation:

- NaN output will be converted to infinity
- A denormalized output will be converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == MRb) {ZF=1; NF=0;}
if(MRa > MRb) {ZF=0; NF=0;}
if(MRa < MRb) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example 1

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMINF32 MR0, MR1 ; MR0 = 4.0, ZF = 0, NF = 0
MMINF32 MR1, MR2 ; MR1 = -1.5, ZF = 0, NF = 0
MMINF32 MR2, MR1 ; MR2 = -1.5, ZF = 1, NF = 0
MMINF32 MR1, MR0 ; MR2 = -1.5, ZF = 0, NF = 1
```

Example 2

```
;
; X is an array of 32-bit floating-point values
; Find the minimum value in an array X
; and store it in Result
;

_Cla1Task1:
MMOVI16    MAR1, #_X          ; Start address
MUI16TOF32 MR0, @_len         ; Length of the array
MNOP                          ; delay for MAR1 load
MNOP                          ; delay for MAR1 load
MMOV32     MR1, *MAR1[2]++    ; MR1 = X0
LOOP
MMOV32     MR2, *MAR1[2]++    ; MR2 = next element
MMINF32    MR1, MR2           ; MR1 = MAX(MR1, MR2)
MADDF32    MR0, MR0, #-1.0    ; Decrement the counter
MCMPIF32   MR0 #0.0          ; Set/clear flags for MBCNDD
MNOP
MNOP
MNOP
MBCNDD     LOOP, NEQ          ; Branch if not equal to zero
MMOV32     @_Result, MR1      ; Always executed
MNOP       ; Always executed
MNOP       ; Always executed
MSTOP      ; End of task
```

MMINF32 MRa, #16FHi 32-Bit Floating-Point Minimum

Operands

MRa	floating-point source/destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

```
LSW: IIII IIII IIII IIII
MSW: 0111 1001 0100 00aa
```

Description

Compare MRa with the floating-point value represented by the immediate operand. If the immediate value is smaller, then load it into MRa.

```
if(MRa > #16FHi:0) MRa = #16FHi:0;
```

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. This addressing mode is most useful for constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

Special cases for the output from the MMINF32 operation:

- NaN output will be converted to infinity
- A denormalized output will be converted to positive zero.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The ZF and NF flags are configured on the result of the operation, not the result stored in the destination register.

```
if(MRa == #16FHi:0) {ZF=1; NF=0;}
if(MRa > #16FHi:0) {ZF=0; NF=0;}
if(MRa < #16FHi:0) {ZF=0; NF=1;}
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMINF32 MR0, #5.5 ; MR0 = 5.0, ZF = 0, NF = 1
MMINF32 MR1, #2.5 ; MR1 = 2.5, ZF = 0, NF = 0
MMINF32 MR2, #-1.0 ; MR2 = -1.5, ZF = 0, NF = 1
MMINF32 MR2, #-1.5 ; MR2 = -1.5, ZF = 1, NF = 0
```

MMOV16 MARx, MRa, #16I Load the Auxiliary Register with MRa + 16-bit Immediate Value
Operands

MARx	Auxiliary register MAR0 or MAR1
MRa	CLA Floating-point register (MR0 to MR3)
#16I	16-bit immediate value

Opcode

LSW: I I I I I I I I I I I I I I (opcode of MMOV16 MAR0, MRa, #16I)
MSW: 0111 1111 1101 00AA

LSW: I I I I I I I I I I I I I I (opcode of MMOV16 MAR1, MRa, #16I)
MSW: 0111 1111 1111 00AA

Description

Load the auxiliary register, MAR0 or MAR1, with MRa(15:0) + 16-bit immediate value. Refer to the pipeline section for important information regarding this instruction.

MARx = MRa(15:0) + #16I;

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The load of MAR0 or MAR1 will occur in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing will occur in the D2 phase of the pipeline. Therefore the following applies when loading the auxiliary registers:

- I1 and I2**

The two instructions following MMOV16 will use MAR0/MAR1 before the update occurs. Thus these two instructions will use the old value of MAR0 or MAR1.

- I3**

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there will be a conflict. In the case of a conflict, the update due to address-mode post increment will win and the auxiliary register will not be updated with #_X.

- I4**

Starting with the 4th instruction MAR0 or MAR1 will be the new value loaded with MMOV16.

; Assume MAR0 is 50, MR0 is 10, and #_X is 20

```
MMOV16 MAR0, MR0, #_X      ; Load MAR0 with address of X (20) + MR0 (10)
<Instruction 1>              ; I1 Will use the old value of MAR0 (50)
<Instruction 2>              ; I2 Will use the old value of MAR0 (50)
<Instruction 3>              ; I3 Cannot use MAR0
<Instruction 4>              ; I4 Will use the new value of MAR0 (30)
<Instruction 5>              ; I5
```

Table 5-16. Pipeline Activity For MMOV16 MARx, MRa , #16I

MMOV32 mem32, MRa *Move 32-Bit Floating-Point Register Contents to Memory*

Operands

MRa	floating-point register (MR0 to MR3)
mem32	32-bit destination memory accessed using one of the available addressing modes

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0100 11aa addr

Description

Move from MRa to 32-bit memory location indicated by mem32.

[mem32] = MRa;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected.

Pipeline

This is a single-cycle instruction.

Example

```
; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating point arrays;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3;
; Result = A + B + C + D + E
;
_Cla1Task1:
    MMOV32    MR0, *_MAR0[2]++    ; MR0 points to X array
    MMOV32    MR1, *_MAR1[2]++    ; MR1 points to Y array
    MNOP      ; Delay for MR0, MR1 load
    MNOP      ; Delay for MR0, MR1 load
    ; <-- MR0 valid
    ; MR0 = X0, MR0 += 2
    ; <-- MR1 valid
    ; MR1 = Y0, MR1 += 2
    MMOV32    MR2, MR0, MR1        ; MR2 = A = X0 * Y0
    || MMOV32    MR0, *_MAR0[2]++    ; In parallel MR0 = X1, MR0 += 2
    MMOV32    MR1, *_MAR1[2]++    ; MR1 = Y1, MR1 += 2
    MMOV32    MR3, MR0, MR1        ; MR3 = B = X1 * Y1
    || MMOV32    MR0, *_MAR0[2]++    ; In parallel MR0 = X2, MR0 += 2
    MMOV32    MR1, *_MAR1[2]++    ; MR1 = Y2, MR2 += 2

    MMACF32    MR3, MR2, MR2, MR0, MR1 ; MR3 = A + B, MR2 = C = X2 * Y2
    || MMOV32    MR0, *_MAR0[2]++    ; In parallel MR0 = X3
    MMOV32    MR1, *_MAR1[2]++    ; MR1 = Y3

    MMACF32    MR3, MR2, MR2, MR0, MR1 ; MR3 = (A + B) + C, MR2 = D = X3 * Y3

[MMOV32 mem32, MSTF](#)

MMOV32 mem32, MSTF *Move 32-Bit MSTF Register to Memory*

Operands

MSTF	floating-point status register
mem32	32-bit destination memory

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0100 addr

Description

Copy the CLA's floating-point status register, MSTF, to memory.

[mem32] = MSTF;

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

See also

[MMOV32 mem32, MRa](#)

MMOV32 MRa, mem32 {, CNDF} *Conditional 32-Bit Move*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes
CNDF	optional condition.

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0111 00cn dfaa addr

Description

If the condition is true, then move the 32-bit value referenced by mem32 to the floating-point register indicated by MRa.

```
if (CNDF == TRUE) MRa = [mem32];
```

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

⁽¹⁾ Values not shown are reserved.

⁽²⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
    NF = MRa(31);
    ZF = 0;
    if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
}
else No flags modified;
```

Pipeline

This is a single-cycle instruction.

Example

```

; Given A, B, X, M1 and M2 are 32-bit floating-point
; numbers
;
; if(A == B) calculate Y = X*M1
; if(A != B) calculate Y = X*M2
;
_Cla1Task5:
    MMOV32    MR0, @_A
    MMOV32    MR1, @_B
    MCMPF32   MR0, MR1
    MMOV32    MR2, @_M1, EQ ; if A == B, MR2 = M1
                        ;      Y = M1*X
    MMOV32    MR2, @_M2, NEQ ; if A != B, MR2 = M2
                        ;      Y = M2*X

    MMOV32    MR3, @_X
    MMPYF32   MR3, MR2, MR3 ; Calculate Y
    MMOV32    @_Y, MR3      ; Store Y
    MSTOP                    ; end of task

```

MMOV32 MRa, MRb {, CNDF} Conditional 32-Bit Move
Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	optional condition.

Opcode

LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1100 0000

Description

If the condition is true, then move the 32-bit value in MRb to the floating-point register indicated by MRa.

if (CNDF == TRUE) MRa = MRb;

CNDF is one of the following conditions:

Encode ⁽³⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽⁴⁾	Unconditional with flag modification	None

⁽³⁾ Values not shown are reserved.

⁽⁴⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

```
if(CNDF == UNCF)
{
    NF = MRa(31); ZF = 0;
    if(MRa(30:23) == 0) {ZF = 1; NF = 0;}
}
else No flags modified;
```

Pipeline

This is a single-cycle instruction.

Example

```

; Given: X = 8.0
;         Y = 7.0
;         A = 2.0
;         B = 5.0
; _ClaTask1
MMOV32   MR3, @_X      ; MR3 = X = 8.0
MMOV32   MR0, @_Y      ; MR0 = Y = 7.0
MMAXF32  MR3, MR0      ; ZF = 0, NF = 0, MR3 = 8.0
MMOV32   MR1, @_A, GT  ; true, MR1 = A = 2.0
MMOV32   MR1, @_B, LT  ; false, does not load MR1
MMOV32   MR2, MR1, GT  ; true, MR2 = MR1 = 2.0
MMOV32   MR2, MR0, LT  ; false, does not load MR2
MSTOP

```

MMOV32 MSTF, mem32 *Move 32-Bit Value from Memory to the MSTF Register*

Operands

MSTF	CLA status register
mem32	32-bit source memory location

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0111 0000 addr

Description

Move from memory to the CLA's status register MSTF. This instruction is most useful when nesting function calls (via MCCNDD).

MSTF = [mem32];

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Loading the status register will overwrite all flags and the RPC field. The MEALLOW field is not affected.

Pipeline

This is a single-cycle instruction.

Example

[MMOV32 MRa, mem32 {,CNDF}](#)

MMOVF32 MRa, #32F *Load the 32-Bits of a 32-Bit Floating-Point Register*

Operands

This instruction is an alias for MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

MMOVIZ MRa, #16FHiHex MMOVXI MRa, #16FLoHex

MRa CLA floating-point destination register (MR0 to MR3)

#32F immediate float value represented in floating-point representation

Opcode

LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)

MSW: 0111 1000 0100 00aa

LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)

MSW: 0111 1000 1000 00aa

Description

Note: This instruction accepts the immediate operand only in floating-point representation. To specify the immediate value as a hex value (IEEE 32-bit floating-point format) use the MOVI32 MRa, #32FHex instruction.

Load the 32-bits of MRa with the immediate float value represented by #32F.

#32F is a float value represented in floating-point representation. The assembler will only accept a float value represented in floating-point representation. That is, 3.0 can only be represented as #3.0. #0x40400000 will result in an error.

MRa = #32F;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32FH, this instruction takes one or two cycles. If all of the lower 16-bits of the IEEE 32-bit floating-point format of #32F are zeros, then the assembler will convert MMOVF32 into only MMOVIZ instruction. If the lower 16-bits of the IEEE 32-bit floating-point format of #32F are not zeros, then the assembler will convert MMOVF32 into MMOVIZ and MMOVXI instructions.

Example

```
MMOVF32 MR1, #3.0      ; MR1 = 3.0 (0x40400000)
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR1, #0x4040
```

```
MMOVF32 MR2, #0.0      ; MR2 = 0.0 (0x00000000)
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR2, #0x0
```

```
MMOVF32 MR3, #12.265   ; MR3 = 12.625 (0x41443D71)
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR3, #0x4144
                        ; MMOVXI MR3, #0x3D71
```

MMOVI16 MARx, #16I Load the Auxiliary Register with the 16-Bit Immediate Value

Operands

MARx	Auxiliary register MAR0 or MAR1
#16I	16-bit immediate value

Opcode

LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR0, #16I)
MSW: 0111 1111 1100 0000

LSW: IIII IIII IIII IIII (opcode of MMOVI16 MAR1, #16I)
MSW: 0111 1111 1110 0000

Description

Load the auxiliary register, MAR0 or MAR1, with a 16-bit immediate value. Refer to the pipeline section for important information regarding this instruction.

MARx = #16I;

Flags

This instruction does not modify flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. The immediate load of MAR0 or MAR1 will occur in the EXE phase of the pipeline. Any post increment of MAR0 or MAR1 using indirect addressing will occur in the D2 phase of the pipeline. Therefore the following applies when loading the auxiliary registers:

• I1 and I2

The two instructions following MMOVI16 will use MAR0/MAR1 before the update occurs. Thus these two instructions will use the old value of MAR0 or MAR1.

• I3

Loading of an auxiliary register occurs in the EXE phase while updates due to post-increment addressing occur in the D2 phase. Thus I3 cannot use the auxiliary register or there will be a conflict. In the case of a conflict, the update due to address-mode post increment will win and the auxiliary register will not be updated with #_X.

• I4

Starting with the 4th instruction MAR0 or MAR1 will be the new value loaded with MMOVI16.

; Assume MAR0 is 50 and #_X is 20

```
MMOVI16 MAR0, #_X           ; Load MAR0 with address of X (20)
<Instruction 1>              ; I1 Will use the old value of MAR0 (50)
<Instruction 2>              ; I2 Will use the old value of MAR0 (50)
<Instruction 3>              ; I3 Cannot use MAR0
<Instruction 4>              ; I4 Will use the new value of MAR0 (20)
<Instruction 5>              ; I5
....
```

Table 5-18. Pipeline Activity For MMOVI16 MAR0/MAR1, #16I

Instruction	F1	F2	D1	D2	R1	R2	E	W
MMOVI16 MAR0, #_X	MMOVI16							
I1	I1	MMOVI16						
I2	I2	I1	MMOVI16					
I3	I3	I2	I1	MMOVI16				
I4	I4	I3	I2	I1	MMOVI16

I6	I6	I5	I4	I3	I2	I1	MMOVI16	

MMOVI32 MRa, #32FHex *Load the 32-Bits of a 32-Bit Floating-Point Register with the Immediate*

Operands

MRa	floating-point register (MR0 to MR3)
#32FHex	A 32-bit immediate value that represents an IEEE 32-bit floating-point value.

This instruction is an alias for MMOVIZ and MMOVXI instructions. The second operand is translated by the assembler such that the instruction becomes:

```
MMOVIZ MRa, #16FHiHex
MMOVXI MRa, #16FLoHex
```

Opcode

```
LSW: IIII IIII IIII IIII (opcode of MMOVIZ MRa, #16FHiHex)
MSW: 0111 1000 0100 00aa
```

```
LSW: IIII IIII IIII IIII (opcode of MMOVXI MRa, #16FLoHex)
MSW: 0111 1000 1000 00aa
```

Description

Note: This instruction only accepts a hex value as the immediate operand. To specify the immediate value with a floating-point representation use the MMOVF32 MRa, #32F instruction.

Load the 32-bits of MRa with the immediate 32-bit hex value represented by #32FHex.

#32Fhex is a 32-bit immediate hex value that represents the IEEE 32-bit floating-point value of a floating-point number. The assembler will only accept a hex immediate value. That is, 3.0 can only be represented as #0x40400000. #3.0 will result in an error.

MRa = #32FHex;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

Depending on #32FHex, this instruction takes one or two cycles. If all of the lower 16-bits of #32FHex are zeros, then assembler will convert MOVIZ to the MMOVIZ instruction. If the lower 16-bits of #32FHex are not zeros, then assembler will convert MOVIZ to a MMOVIZ and a MMOVXI instruction.

Example

```
MOVI32 MR1, #0x40400000 ; MR1 = 0x40400000
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR1, #0x4040

MOVI32 MR2, #0x00000000 ; MR2 = 0x00000000
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR2, #0x0

MOVI32 MR3, #0x40004001 ; MR3 = 0x40004001
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR3, #0x4000
                        ; MMOVXI MR3, #0x4001

MOVI32 MR0, #0x00004040 ; MR0 = 0x00004040
                        ; Assembler converts this instruction as
                        ; MMOVIZ MR0, #0x0000
                        ; MMOVXI MR0, #0x4040
```

MMOVIZ MRa, #16FHi Load the Upper 16-Bits of a 32-Bit Floating-Point Register

Operands

MRa	floating-point register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

LSW: IIII IIII IIII IIII
MSW: 0111 1000 0100 00aa

Description

Load the upper 16-bits of MRa with the immediate value #16FHi and clear the low 16-bits of MRa.

#16FHiHex is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. The assembler will only accept a decimal or hex immediate value. That is, -1.5 can be represented as #-1.5 or #0xBFC0.

By itself, MMOVIZ is useful for loading a floating-point register with a constant in which the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). If a constant requires all 32-bits of a floating-point register to be initialized, then use MMOVIZ along with the MMOVXI instruction.

MRa(31:16) = #16FHi;
MRa(15:0) = 0;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 and MR1 with -1.5 (0xBFC00000)
MMOVIZ    MR0, #0xBFC0    ; MR0 = 0xBFC00000 (1.5)
MMOVIZ    MR1, #-1.5      ; MR1 = -1.5 (0xBFC00000)

; Load MR2 with pi = 3.141593 (0x40490FDB)
MMOVIZ    MR2, #0x4049    ; MR2 = 0x40490000
MMOVXI    MR2, #0x0FDB    ; MR2 = 0x40490FDB
```

MMOVZ16 MRa, mem16 *Load MRx With 16-bit Value*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
mem16	16-bit source memory location

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0111 0101 10aa addr

Description

Move the 16-bit value referenced by mem16 to the floating-point register indicated by MRa.

MRa(31:16) = 0;
MRa(15:0) = [mem16];

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

NF = 0;
if (MRa(31:0) == 0) { ZF = 1; }

Pipeline

This is a single-cycle instruction.

MMOVXI MRa, #16FLoHex *Move Immediate to the Low 16-Bits of a Floating-Point Register*
Operands

MRa	CLA floating-point register (MR0 to MR3)
#16FLoHex	A 16-bit immediate hex value that represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits will not be modified.

Opcode

LSW: I I I I I I I I I I I I I I
MSW: 0111 1000 1000 00aa

Description

Load the low 16-bits of MRa with the immediate value #16FLoHex. #16FLoHex represents the lower 16-bits of an IEEE 32-bit floating-point value. The upper 16-bits of MRa will not be modified. MMOVXI can be combined with the MMOVIZ instruction to initialize all 32-bits of a MRa register.

MRa(15:0) = #16FLoHex;
MRa(31:16) = Unchanged;

Flags

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; Load MR0 with pi = 3.141593 (0x40490FDB)
MMOVIZ    MR0, #0x4049    ; MR0 = 0x40490000
MMOVXI    MR0, #0x0FDB    ; MR0 = 0x40490FDB
```

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0000 0000

Description

Multiply the contents of two floating-point registers.

MRa = MRb * MRc;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;

MMPYF32 MRa, #16FHi, MRb 32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRc	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: I I I I I I I I I I I I I I I I
MSW: 0111 0111 1000 baaa

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

MRa = MRb * #16FHi:0;

This instruction can also be written as MMPYF32 MRa, MRb, #16FHi.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
; Same as example 2 but #16FHi is represented in float
MMOVIZ    MR3, #2.0      ; MR3 = 2.0 (0x40000000)

MMPYF32 MRa, MRb, #16FHi 32-Bit Floating-Point Multiply

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.

Opcode

LSW: I I I I I I I I I I I I I I I I
MSW: 0111 0111 1000 baaa

Description

Multiply MRb with the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

MRa = MRb * #16FHi:0;

This instruction can also be written as MMPYF32 MRa, #16FHi, MRb.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example 1

```
;Same as example 2 but #16FHi is represented in float
MMOVIZ    MR3, #2.0          ; MR3 = 2.0 (0x40000000)
MMPYF32    MR0, MR3, #3.0    ; MR0 = MR3 * 3.0 = 6.0 (0x40C00000)
MMOV32     @_X, MR0          ; Save the result in variable X
```

Example 2

```
;Same as above example but #16FHi is represented in Hex
MMOVIZ     MR3, #2.0          ; MR3 = 2.0 (0x40000000)
MMPYF32     MR0, MR3, #0x4040 ; MR0 = MR3 * 0x4040 = 6.0 (0x40C00000)
MMOV32      @_X, MR0          ; Save the result in variable X
```

Example 3

```

; Given X, M and B are IQ24 numbers:
; X = IQ24(+2.5) = 0x02800000
; M = IQ24(+1.5) = 0x01800000
; B = IQ24(-0.5) = 0xFF800000
;
; Calculate Y = X * M + B

MMPYF32 MRa, MRb, MRc||MADDF32 MRd, MRe, MRf 32-Bit Floating-Point Multiply with Parallel Add

Operands

MRa	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRa cannot be the same register as MRd
MRb	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRc	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRd	CLA floating-point destination register for MADDF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MADDF32 (MR0 to MR3)
MRf	CLA floating-point source register for MADDF32 (MR0 to MR3)

Opcode

LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0000 0000

Description

Multiply the contents of two floating-point registers with parallel addition of two registers.

MRa = MRb * MRc;
MRd = MRe + MRf;

Restrictions

The destination register for the MMPYF32 and the MADDF32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MADDF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MADDF32 generates an overflow condition.

Pipeline

Both MMPYF32 and MADDF32 complete in a single cycle.

Example

```

; Perform 5 multiply and accumulate operations:
;
; X and Y are 32-bit floating point arrays
;
; 1st multiply: A = X0 * Y0
; 2nd multiply: B = X1 * Y1
; 3rd multiply: C = X2 * Y2
; 4th multiply: D = X3 * Y3
; 5th multiply: E = X3 * Y3
;
; Result = A + B + C + D + E
;

MMPYF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 32-Bit Floating-Point Multiply with Parallel Move

Operands

MRd	CLA floating-point destination register for the MMPYF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for the MMPYF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MMPYF32 (MR0 to MR3)
MRa	CLA floating-point destination register for the MMOV32 (MR0 to MR3) MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. This will be the source of the MMOV32.

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0000 ffee ddaa addr

Description

Multiply the contents of two floating-point registers and load another.

MRd = MRe * MRf;
MRa = [mem32];

Restrictions

The destination register for the MMPYF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

The MMOV32 Instruction will set the NF and ZF flags as follows:

NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }

Pipeline

Both MMPYF32 and MMOV32 complete in a single cycle.

Example 1

```
; Given M1, X1 and B1 are 32-bit floating point
; Calculate Y1 = M1*X1+B1
;
_Cla1Task1:
    MMOV32    MR0, @M1        ; Load MR0 with M1
    MMOV32    MR1, @X1        ; Load MR1 with X1
    MMPYF32   MR1, MR1, MR0    ; Multiply M1*X1
    || MMOV32  MR0, @B1        ; and in parallel load MR0 with B1

MMPYF32 MRd, MRe, MRf ||MMOV32 mem32, MRa 32-Bit Floating-Point Multiply with Parallel Move

Operands

MRd	CLA floating-point destination register for the MMPYF32 (MR0 to MR3)
MRe	CLA floating-point source register for the MMPYF32 (MR0 to MR3)
MRf	CLA floating-point source register for the MMPYF32 (MR0 to MR3)
mem32	32-bit memory location accessed using one of the available addressing modes. This will be the destination of the MMOV32.
MRa	CLA floating-point source register for the MMOV32 (MR0 to MR3)

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0100 ffee ddaa addr

Description

Multiply the contents of two floating-point registers and move from memory to register.

MRd = MRe * MRf;
[mem32] = MRa;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 generates an underflow condition.
- LVF = 1 if MMPYF32 generates an overflow condition.

Pipeline

MMPYF32 and MMOV32 both complete in a single cycle.

Example

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A * B) * C
;
_Cla1Task2:
    MMOV32    MR0, @A        ; Load MR0 with A
    MMOV32    MR1, @B        ; Load MR1 with B
    MMPYF32   MR1, MR1, MR0   ; Multiply A*B
||  MMOV32    MR0, @C        ; and in parallel load MR0 with C
    MMPYF32   MR1, MR1, MR0   ; Multiply (A*B) by C
||  MMOV32    @Y2, MR1        ; and in parallel store A*B
    MMOV32    @Y3, MR1        ; Store the result
    MSTOP     ; end of task
```

MMPYF32 MRa, MRb, MRc ||MSUBF32 MRd, MRe, MRf 32-Bit Floating-Point Multiply with Parallel Subtract

Operands

MRa	CLA floating-point destination register for MMPYF32 (MR0 to MR3) MRa cannot be the same register as MRd
MRb	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRc	CLA floating-point source register for MMPYF32 (MR0 to MR3)
MRd	CLA floating-point destination register for MSUBF32 (MR0 to MR3) MRd cannot be the same register as MRa
MRe	CLA floating-point source register for MSUBF32 (MR0 to MR3)
MRf	CLA floating-point source register for MSUBF32 (MR0 to MR3)

Opcode

LSW: 0000 ffee ddcc bbaa
MSW: 0111 1010 0100 0000

Description

Multiply the contents of two floating-point registers with parallel subtraction of two registers.

MRa = MRb * MRc;
MRd = MRe - MRf;

Restrictions

The destination register for the MMPYF32 and the MSUBF32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MMPYF32 or MSUBF32 generates an underflow condition.
- LVF = 1 if MMPYF32 or MSUBF32 generates an overflow condition.

Pipeline

MMPYF32 and MSUBF32 both complete in a single cycle.

Example

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y2 = (A * B)
;           Y3 = (A - B)
;
;_Cla1Task2:
    MOV32    MR0, @A          ; Load MR0 with A
    MOV32    MR1, @B          ; Load MR1 with B
    MMPYF32  MR2, MR0, MR1    ; Multiply (A*B)
|| MSUBF32  MR3, MR0, MR1    ; and in parallel Sub (A-B)
    MOV32    @Y2, MR2         ; Store A*B
    MOV32    @Y3, MR3         ; Store A-B
    MSTOP                                ; end of task
```

MNEGF32 MRa, MRb{, CNDF} *Conditional Negation*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
CNDF	condition tested

Opcode

LSW: 0000 0000 cndf bbaa
MSW: 0111 1010 1000 0000

Description

```
if (CNDF == true) {MRa = - MRb; }
else {MRa = MRb; }
```

CNDF is one of the following conditions:

Encode ⁽⁵⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽⁶⁾	Unconditional with flag modification	None

⁽⁵⁾ Values not shown are reserved.

⁽⁶⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF, and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

Pipeline

This is a single-cycle instruction.

Example 1

```
; Show the basic operation of MNEGF32
;
MMOVIZ MR0, #5.0 ; MR0 = 5.0 (0x40A00000)
MMOVIZ MR1, #4.0 ; MR1 = 4.0 (0x40800000)
MMOVIZ MR2, #-1.5 ; MR2 = -1.5 (0xBFC00000)
MMPYF32 MR3, MR1, MR2 ; MR3 = -6.0
MMPYF32 MR0, MR0, MR1 ; MR0 = 20.0
MMOVIZ MR1, #0.0
MCMPF32 MR3, MR1 ; NF = 1
MNEGF32 MR3, MR3, LT ; if NF = 1, MR3 = 6.0
MCMPF32 MR0, MR1 ; NF = 0
MNEGF32 MR0, MR0, GEQ ; if NF = 0, MR0 = -20.0
```

Example 2

```

; Calculate Num/Den using a Newton-Raphson algorithm for 1/Den
; Ye = Estimate(1/X)
; Ye = Ye*(2.0 - Ye*X)
; Ye = Ye*(2.0 - Ye*X)
;
_Cla1Task1:
    MMOV32    MR1, @_Den        ; MR1 = Den
    MEINVF32  MR2, MR1          ; MR2 = Ye = Estimate(1/Den)
    MMPYF32   MR3, MR2, MR1     ; MR3 = Ye*Den
    MSUBF32   MR3, #2.0, MR3    ; MR3 = 2.0 - Ye*Den
    MMPYF32   MR2, MR2, MR3     ; MR2 = Ye = Ye*(2.0 - Ye*Den)
    MMPYF32   MR3, MR2, MR1     ; MR3 = Ye*Den
||  MMOV32    MR0, @_Num        ; MR0 = Num
    MSUBF32   MR3, #2.0, MR3    ; MR3 = 2.0 - Ye*Den
    MMPYF32   MR2, MR2, MR3     ; MR2 = Ye = Ye*(2.0 - Ye*Den)
||  MMOV32    MR1, @_Den        ; Reload Den To Set Sign
    MNEGF32   MR0, MR0, EQ      ; if(Den == 0.0) Change Sign Of Num
    MMPYF32   MR0, MR2, MR0     ; MR0 = Y = Ye*Num
    MMOV32    @_Dest, MR0       ; Store result
    MSTOP                                ; end of task

```

MNOP *No Operation*

Operands

none This instruction does not have any operands

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1111 1010 0000

Description

Do nothing. This instruction is used to fill required pipeline delay slots when other instructions are not available to fill the slots.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
; X is an array of 32-bit floating-point values
; Find the maximum value in an array X
; and store it in Result
;
_Cla1Task1:
    MMOVI16    MAR1, #_X          ; Start address
    MUI16TOF32 MR0, @_len         ; Length of the array
    MNOP                          ; delay for MAR1 load
    MNOP                          ; delay for MAR1 load
    MMOV32     MR1, *MAR1[2]++    ; MR1 = X0
LOOP
    MMOV32     MR2, *MAR1[2]++    ; MR2 = next element
    MMAXF32    MR1, MR2           ; MR1 = MAX(MR1, MR2)
    MADDF32    MR0, MR0, #-1.0    ; Decrement the counter
    MCMPF32    MR0 #0.0           ; Set/clear flags for MBCNDD
    MNOP                          ; Too late to affect MBCNDD
    MNOP                          ; Too late to affect MBCNDD
    MNOP                          ; Too late to affect MBCNDD
    MBCNDD     LOOP, NEQ          ; Branch if not equal to zero
    MMOV32     @_Result, MR1      ; Always executed
    MNOP                          ; Pad to separate MBCNDD and MSTOP
    MNOP                          ; Pad to separate MBCNDD and MSTOP
    MSTOP      ; End of task
```

MOR32 MRa, MRb, MRc *Bitwise OR*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRC	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1000 0000

Description

Bitwise OR of MRb with MRc.

MARa(31:0) = MARb(31:0) OR MRC(31:0);

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI    MR0, #0xAAAA

MMOVIZ    MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI    MR1, #0xFEDC

; 0101 OR 0101 = 0101 (5)
; 0101 OR 0100 = 0101 (5)
; 0101 OR 0011 = 0111 (7)
; 0101 OR 0010 = 0111 (7)
; 1010 OR 1111 = 1111 (F)
; 1010 OR 1110 = 1110 (E)
; 1010 OR 1101 = 1111 (F)
; 1010 OR 1100 = 1110 (E)
MOR32 MR2, MR1, MR0 ; MR3 = 0x5555FEFE

MRCNDD {CNDF} *Return Conditional Delayed*
Operands

CNDF optional condition.

Opcode

LSW: 0000 0000 0000 0000
MSW: 0111 1001 1010 cndf

Description

If the specified condition is true, then the RPC field of MSTF is loaded into MPC and fetching continues from that location. Otherwise program fetches will continue without the return.

Please refer to the pipeline section for important information regarding this instruction.

if (CNDF == TRUE) MPC = RPC;

CNDF is one of the following conditions:

Encode ⁽⁷⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽⁸⁾	Unconditional with flag modification	None

⁽⁷⁾ Values not shown are reserved.

⁽⁸⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

The MRCNDD instruction by itself is a single-cycle instruction. As shown in [Table 5-19](#), for each return 6 instruction slots are executed; three before the return instruction (d5-d7) and three after the return instruction (d8-d10). The total number of cycles for a return taken or not taken depends on the usage of these slots. That is, the number of cycles depends on how many slots are filled with a MNOP as well as which slots are filled. The effective number of cycles for a return can, therefore, range from 1 to 7 cycles. The number of cycles for a return taken may not be the same as for a return not taken.

Referring to the following code fragment and the pipeline diagrams in [Table 5-19](#) and [Table 5-20](#), the instructions before and after MRCNDD have the following properties:

```

;
;
<Instruction 1>    ; I1 Last instruction that can affect flags for
                  ; the MCCNDD operation
<Instruction 2>    ; I2 Cannot be stop, branch, call or return
<Instruction 3>    ; I3 Cannot be stop, branch, call or return
<Instruction 4>    ; I4 Cannot be stop, branch, call or return

MCCNDD _func, NEQ ; Call to func if not equal to zero
                  ; Three instructions after MCCNDD are always
                  ; executed whether the call is taken or not
<Instruction 5>    ; I5 Cannot be stop, branch, call or return
<Instruction 6>    ; I6 Cannot be stop, branch, call or return
<Instruction 7>    ; I7 Cannot be stop, branch, call or return
<Instruction 8>    ; I8 The address of this instruction is saved
                  ; in the RPC field of the MSTF register.
                  ; Upon return this value is loaded into MPC
                  ; and fetching continues from this point.
<Instruction 9>    ; I9
<Instruction 10>   ; I10
....
....
_func:
<Destination 1>   ; d1 Can be any instruction
<Destination 2>   ; d2
<Destination 3>   ; d3
<Destination 4>   ; d4 Last instruction that can affect flags for
                  ; the MRCNDD operation
<Destination 5>   ; d5 Cannot be stop, branch, call or return
<Destination 6>   ; d6 Cannot be stop, branch, call or return
<Destination 7>   ; d7 Cannot be stop, branch, call or return

MRCNDD NEQ        ; Return to <Instruction 8> if not equal to zero
                  ; Three instructions after MRCNDD are always
                  ; executed whether the return is taken or not
<Destination 8>   ; d8 Cannot be stop, branch, call or return
<Destination 9>   ; d9 Cannot be stop, branch, call or return
<Destination 10>  ; d10 Cannot be stop, branch, call or return
<Destination 11>  ; d11
<Destination 12>  ; d12
....
....
MSTOP
....

```

- **d4**

- d4 is the last instruction that can effect the CNDF flags for the MRCNDD instruction. The CNDF flags are tested in the D2 phase of the pipeline. That is, a decision is made whether to return or not when MRCNDD is in the D2 phase.
- There are no restrictions on the type of instruction for d4.

- **d5, d6 and d7**

- The three instructions proceeding MRCNDD can change MSTF flags but will have no effect on whether the MRCNDD instruction makes the return or not. This is

because the flag modification will occur after the D2 phase of the MRCNDD instruction.

- These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.
- **d8, d9 and d10**
 - The three instructions following MRCNDD are always executed irrespective of whether the return is taken or not.
 - These instructions must not be the following: MSTOP, MDEBUGSTOP, MBCNDD, MCCNDD or MRCNDD.

MSETFLG FLAG, VALUE *Set or Clear Selected Floating-Point Status Flags*

Operands

FLAG	8 bit mask indicating which floating-point status flags to change.
VALUE	8 bit mask indicating the flag value; 0 or 1.

Opcode

LSW: FFFF FFFF VVVV VVVV
MSW: 0111 1001 1100 0000

Description

The MSETFLG instruction is used to set or clear selected floating-point status flags in the MSTF register. The FLAG field is an 11-bit value that indicates which flags will be changed. That is, if a FLAG bit is set to 1 it indicates that flag will be changed; all other flags will not be modified. The bit mapping of the FLAG field is shown below:

RNDF3 2	reserve d	reserve d	TF	reserve d	reserved	ZF	NF	LUF	LVF
9	8	7	6	5	4	3	2	1	0

The VALUE field indicates the value the flag should be set to; 0 or 1.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	Yes	Yes	Yes	Yes

Any flag can be modified by this instruction. The MEALLOW and RPC fields cannot be modified with this instruction.

Pipeline

This is a single-cycle instruction.

Example

To make it easier and legible, the assembler accepts a FLAG=VALUE syntax for the MSTFLG operation as shown below:

```
MSETFLG RNDF32=0, TF=0, NF=1; FLAG = 11000100; VALUE = 00XXX1XX;
```

MSTOP

Stop Task

Operands

none	This instruction does not have any operands

Opcode

```
LSW: 0000 0000 0000 0000
MSW: 0111 1111 1000 0000
```

Description

The MSTOP instruction must be placed to indicate the end of each task. In addition, placing MSTOP in unused memory locations within the CLA program RAM can be useful for debugging and preventing run away CLA code. When MSTOP enters the D2 phase of the pipeline, the MIRUN flag for the task is cleared and the associated interrupt is flagged in the PIE vector table.

There are three special cases that can occur when single-stepping a task such that the MPC reaches the MSTOP instruction.

1. If you are single-stepping or halted in "task A" and "task B" comes in before the MPC reaches the MSTOP, then "task B" will start if you continue to step through the MSTOP instruction. Basically if "task B" is pending before the MPC reaches MSTOP in "task A" then there is no issue in "task B" starting and no special action is required.
2. In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. If "task B" comes in at this point, it will be flagged in the MIFR register but it may or may not start if you continue to single-step through the MSTOP instruction of "task A". It depends on exactly when the new task comes in. To reliably start "task B" perform a soft reset and reconfigure the MIER bits. Once this is done, you can start single-stepping "task B".
3. Case 2 can be handled slightly differently if there is control over when "task B" comes in (for example using the IACK instruction to start the task). In this case you have single-stepped or halted in "task A" and the MPC has reached the MSTOP with no tasks pending. Before forcing "task B", run free to force the CLA out of the debug state. Once this is done you can force "task B" and continue debugging.

Restrictions

The MSTOP instruction cannot be placed 3 instructions before or after a [MBCNDD](#), [MCCNDD](#) or [MRCNDD](#) instruction.

Flags

This instruction does not modify flags in the MSTF register.

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction. [Table 5-21](#) shows the pipeline behavior of the MSTOP instruction. The MSTOP instruction cannot be placed with 3 instructions of a [MBCNDD](#), [MCCNDD](#) or [MRCNDD](#) instruction.

Table 5-21. Pipeline Activity For MSTOP

Instruction	F1	F2	D1	D2	R1	R2	E	W
I1	I1							
I2	I2	I1						
I3	I3	I2	I1					
MSTOP	MSTOP	I3	I2	I1				
I4	I4	MSTOP	I3	I2	I1			
I5	I5	I4	MSTOP	I3	I2	I1		
I6	I6	I5	I4	MSTOP	I3	I2	I1	
New Task Arbitrated and Piroitized	-	-	-	-	-	I3	I2	
New Task Arbitrated and Piroitized	-	-	-	-	-	-	I3	
I1	I1	-	-	-	-	-	-	
I2	I2	I1	-	-	-	-	-	
I3	I3	I2	I1	-	-	-	-	
I4	I4	I3	I2	I1	-	-	-	
I5	I5	I4	I3	I2	I1	-	-	
I6	I6	I5	I4	I3	I2	I1	-	
I7	I7	I6	I5	I4	I3	I2	I1	
etc								

Example

```

; Given A = (int32)1
;      B = (int32)2
;      C = (int32)-7
;
; Calculate Y2 = A - B - C
_Cla1Task3:
    MOV32    MR0, @_A      ; MR0 = 1 (0x00000001)
    MOV32    MR1, @_B      ; MR1 = 2 (0x00000002)
    MOV32    MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MSUB32    MR3, MR0, MR1 ; A + B
    MSUB32    MR3, MR3, MR2 ; A + B + C = 6 (0x00000006)
    MOV32    @_y2, MR3     ; Store y2
    MSTOP                    ; End of task

```

MSUB32 MRa, MRb, MRc 32-Bit Integer Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point destination register (MR0 to MR3)
MRc	CLA floating-point destination register (MR0 to MR3)

Opcode

LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1110 0000

Description

32-bit integer addition of MRb and MRc.

MARa(31:0) = MARb(31:0) - MRc(31:0);

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified as follows:

```
NF = MRa(31);
ZF = 0;
if(MRa(31:0) == 0) { ZF = 1; }
```

Pipeline

This is a single-cycle instruction.

Example

```
; Given A = (int32)1
;      B = (int32)2
;      C = (int32)-7
;
;
; Calculate Y2 = A - B - C
;
_Cla1Task3:
    MOV32    MR0, @_A      ; MR0 = 1 (0x00000001)
    MOV32    MR1, @_B      ; MR1 = 2 (0x00000002)
    MOV32    MR2, @_C      ; MR2 = -7 (0xFFFFFFFF9)
    MSUB32   MR3, MR0, MR1  ; A + B
    MSUB32   MR3, MR3, MR2  ; A + B + C = 6 (0x00000006)
    MOV32    @_y2, MR3     ; Store y2
    MSTOP
```

MSUBF32 MRa, MRb, MRc 32-Bit Floating-Point Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to R1)
MRb	CLA floating-point source register (MR0 to R1)
MRc	CLA floating-point source register (MR0 to R1)

Opcode

LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 0100 0000

Description

Subtract the contents of two floating-point registers

MRa = MRb - MRc;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Given A, B and C are 32-bit floating-point numbers
; Calculate Y2 = A + B - C
;
_Cla1Task5:
    MOV32    MR0, @_A      ; Load MR0 with A
    MOV32    MR1, @_B      ; Load MR1 with B
    MADDF32   MR0, MR1, MR0 ; Add A + B
||  MOV32    MR1, @_C      ; and in parallel load C
    MSUBF32   MR0, MR0, MR1 ; Subtract C from (A + B)
    MOV32     @Y, MR0      ; (A+B) - C
    MSTOP                                ; end of task
```

MSUBF32 MRa, #16FHi, MRb 32-Bit Floating-Point Subtraction

Operands

MRa	CLA floating-point destination register (MR0 to R1)
#16FHi	A 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0.
MRb	CLA floating-point source register (MR0 to R1)

Opcode

LSW: I I I I I I I I I I I I I I I I
MSW: 0111 1000 0000 baaa

Description

Subtract MRb from the floating-point value represented by the immediate operand. Store the result of the addition in MRa.

#16FHi is a 16-bit immediate value that represents the upper 16-bits of an IEEE 32-bit floating-point value. The low 16-bits of the mantissa are assumed to be all 0. #16FHi is most useful for representing constants where the lowest 16-bits of the mantissa are 0. Some examples are 2.0 (0x40000000), 4.0 (0x40800000), 0.5 (0x3F000000), and -1.5 (0xBFC00000). The assembler will accept either a hex or float as the immediate value. That is, the value -1.5 can be represented as #-1.5 or #0xBFC0.

MRa = #16FHi:0 - MRb;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

This is a single-cycle instruction.

Example

```
; Y = sqrt(X)
; Ye = Estimate(1/sqrt(X));
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Ye = Ye*(1.5 - Ye*Ye*X*0.5)
; Y = X*Ye
;
_Cla1Task3:
    MOV32    MR0, @_x          ; MR0 = X
    MEISQRTF32 MR1, MR0        ; MR1 = Ye = Estimate(1/sqrt(X))
    MOV32    MR1, @_x, EQ       ; if(X == 0.0) Ye = 0.0
    MPYF32   MR3, MR0, #0.5     ; MR3 = X*0.5
    MPYF32   MR2, MR1, MR3      ; MR2 = Ye*X*0.5
    MPYF32   MR2, MR1, MR2      ; MR2 = Ye*Ye*X*0.5
    MSUBF32  MR2, #1.5, MR2     ; MR2 = 1.5 - Ye*Ye*X*0.5
    MPYF32   MR1, MR1, MR2      ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MPYF32   MR2, MR1, MR3      ; MR2 = Ye*X*0.5
    MPYF32   MR2, MR1, MR2      ; MR2 = Ye*Ye*X*0.5
    MSUBF32  MR2, #1.5, MR2     ; MR2 = 1.5 - Ye*Ye*X*0.5
    MPYF32   MR1, MR1, MR2      ; MR1 = Ye = Ye*(1.5 - Ye*Ye*X*0.5)
    MPYF32   MR0, MR1, MR0      ; MR0 = Y = Ye*X
    MOV32    @_y, MR0          ; Store Y = sqrt(X)
    MSTOP
```

MSUBF32 MRd, MRe, MRf ||MMOV32 MRa, mem32 *32-Bit Floating-Point Subtraction with Parallel Move*

Operands

MRd	CLA floating-point destination register (MR0 to MR3) for the MSUBF32 operation MRd cannot be the same register as MRa
MRe	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRf	CLA floating-point source register (MR0 to MR3) for the MSUBF32 operation
MRa	CLA floating-point destination register (MR0 to MR3) for the MMOV32 operation MRa cannot be the same register as MRd
mem32	32-bit memory location accessed using one of the available addressing modes. Source for the MMOV32 operation.

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0010 ffee ddaa addr

Description

Subtract the contents of two floating-point registers and move from memory to a floating-point register.

MRd = MRe - MRf;
MRa = [mem32];

Restrictions

The destination register for the MSUBF32 and the MMOV32 must be unique. That is, MRa cannot be the same register as MRd.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

The MMOV32 Instruction will set the NF and ZF flags as follows:

Pipeline

Both MSUBF32 and MMOV32 complete in a single cycle.

Example

```
NF = MRa(31);
ZF = 0;
if(MRa(30:23) == 0) { ZF = 1; NF = 0; }
```

MRa	CLA floating-point source register (MR0 to MR3) for the MMOV32 operation

Opcode

LSW: mmmm mmmm mmmm mmmm
MSW: 0110 ffee ddaa addr

Description

Subtract the contents of two floating-point registers and move from a floating-point register to memory.

MRd = MRe - MRf;
[mem32] = MRa;

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	Yes	Yes

The MSTF register flags are modified as follows:

- LUF = 1 if MSUBF32 generates an underflow condition.
- LVF = 1 if MSUBF32 generates an overflow condition.

Pipeline

Both MSUBF32 and MMOV32 complete in a single cycle.

MSWAPF MRa, MRb {, CNDF} Conditional Swap

Operands

MRa	CLA floating-point register (MR0 to MR3)
MRb	CLA floating-point register (MR0 to MR3)
CNDF	Optional condition tested based on the MSTF flags

Opcode

LSW: 0000 0000 CNDF bbaa
MSW: 0111 1011 0000 0000

Description

Conditional swap of MRa and MRb.

if (CNDF == true) swap MRa and MRb;

CNDF is one of the following conditions:

Encode ⁽¹⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽²⁾	Unconditional with flag modification	None

⁽¹⁾ Values not shown are reserved.

⁽²⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

No flags affected

Pipeline

This is a single-cycle instruction.

Example

```

; X is an array of 32-bit floating-point values
; and has len elements. Find the maximum value in
; the array and store it in Result
;
; Note: MCMPPF32 and MSWAPF can be replaced by MMAXF32
;
_Cla1Task1:
    MMOVI16    MAR1, #_X          ; Start address
    MUI16TOF32 MR0, @_len        ; Length of the array
    MNOP                          ; delay for MAR1 load
    MNOP                          ; delay for MAR1 load
    MMOV32     MR1, *MAR1[2]++    ; MR1 = X0
LOOP
    MMOV32     MR2, *MAR1[2]++    ; MR2 = next element
    MCMPPF32   MR2, MR1           ; Compare MR2 with MR1
    MSWAPF     MR1, MR2, GT       ; MR1 = MAX(MR1, MR2)
    MADD32     MR0, MR0, #-1.0    ; Decrement the counter
    MCMPPF32   MR0 #0.0          ; Set/clear flags for MBCNDD
    MNOP
    MNOP
    MNOP
    MBCNDD     LOOP, NEQ         ; Branch if not equal to zero
    MMOV32     @_Result, MR1     ; Always executed
    MNOP                          ; Always executed
    MNOP                          ; Always executed
    MSTOP
; End of task

```

MTESTTF CNDF *Test MSTF Register Flag Condition*

Operands

CNDF	condition to test based on MSTF flags

Opcode

```
LSW: 0000 0000 0000 cndf
MSW: 0111 1111 0100 0000
```

Description

Test the CLA floating-point condition and if true, set the MSTF[TF] flag. If the condition is false, clear the MSTF[TF] flag. This is useful for temporarily storing a condition for later use.

```
if (CNDF == true) TF = 1;
else TF = 0;
```

CNDF is one of the following conditions:

Encode ⁽³⁾	CNDF	Description	MSTF Flags Tested
0000	NEQ	Not equal to zero	ZF == 0
0001	EQ	Equal to zero	ZF == 1
0010	GT	Greater than zero	ZF == 0 AND NF == 0
0011	GEQ	Greater than or equal to zero	NF == 0
0100	LT	Less than zero	NF == 1
0101	LEQ	Less than or equal to zero	ZF == 1 OR NF == 1
1010	TF	Test flag set	TF == 1
1011	NTF	Test flag not set	TF == 0
1100	LU	Latched underflow	LUF == 1
1101	LV	Latched overflow	LVF == 1
1110	UNC	Unconditional	None
1111	UNCF ⁽⁴⁾	Unconditional with flag modification	None

⁽³⁾ Values not shown are reserved.

⁽⁴⁾ This is the default operation if no CNDF field is specified. This condition will allow the ZF and NF flags to be modified when a conditional operation is executed. All other conditions will not modify these flags.

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	Yes	No	No	No	No

```
TF = 0;
if (CNDF == true) TF = 1;
```

Note: If (CNDF == UNC or UNCF), the TF flag will be set to 1.

Pipeline

This is a single-cycle instruction.

Example

```

; if (State == 0.1)
;   RampState = RampState || RAMPMASK
; else if (State == 0.01)
;   CoastState = CoastState || COASTMASK
; else
;   SteadyState = SteadyState || STEADYMASK
;
_Cla1Task2:

MUI32TOF32 MRa, MRb *Convert Unsigned 32-Bit Integer to 32-Bit Floating-Point Value*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 0000 bbaa
MSW: 0111 1101 1100 0000

Description

MRa = MUI32TOF32 [MRb];

Flags

This instruction does not affect any flags:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	No	No	No	No

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ    MR3, #0x8000 ; MR3(31:16) = 0x8000
MMOVXI    MR3, #0x1111 ; MR3(15:0) = 0x1111
           ; MR3 = 2147488017
MUI32TOF32 MR3, MR3    ; MR3 = MUI32TOF32 (MR3) = 2147488017.0 (0x4F000011)
```

[MI32TOF32 MRa, MRb](#)
[MUI32TOF32 MRa, mem32](#)

MXOR32 MRa, MRb, MRc *Bitwise Exclusive Or*

Operands

MRa	CLA floating-point destination register (MR0 to MR3)
MRb	CLA floating-point source register (MR0 to MR3)
MRC	CLA floating-point source register (MR0 to MR3)

Opcode

LSW: 0000 0000 00cc bbaa
MSW: 0111 1100 1010 0000

Description

Bitwise XOR of MRb with MRc.

MARa(31:0) = MARb(31:0) XOR MRc(31:0);

Flags

This instruction modifies the following flags in the MSTF register:

Flag	TF	ZF	NF	LUF	LVF
Modified	No	Yes	Yes	No	No

The MSTF register flags are modified based on the integer results of the operation.

NF = MRa(31);

ZF = 0;

if(MRa(31:0) == 0) { ZF = 1; }

Pipeline

This is a single-cycle instruction.

Example

```
MMOVIZ MR0, #0x5555 ; MR0 = 0x5555AAAA
MMOVXI MR0, #0xAAAA

MMOVIZ MR1, #0x5432 ; MR1 = 0x5432FEDC
MMOVXI MR1, #0xFEDC

; 0101 XOR 0101 = 0000 (0)
; 0101 XOR 0100 = 0001 (1)
; 0101 XOR 0011 = 0110 (6)
; 0101 XOR 0010 = 0111 (7)
; 1010 XOR 1111 = 0101 (5)
; 1010 XOR 1110 = 0100 (4)
; 1010 XOR 1101 = 0111 (7)
; 1010 XOR 1100 = 0110 (6)

MXOR32 MR2, MR1, MR0 ; MR3 = 0x01675476
```

38h	_MR2	CLA Floating-Point Result Register 2		Go
3Ch	_MR3	CLA Floating-Point Result Register 3		Go

Complex bit access types are encoded to fit into small table cells. Table 5-24 shows the codes that are used for access types in this section.

Table 5-24. CLA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 5-24. CLA_REGS Access Type
Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

5.7.2.1 MVECT1 Register (Offset = 0h) [reset = 0h]

MVECT1 is shown in [Figure 5-2](#) and described in [Table 5-25](#).

Return to [Summary Table](#).

Each CLA interrupt has its own interrupt vector (MVECT1 to MVECT8). This interrupt vector points to the first instruction of the associated task. When a task begins, the CLA will start fetching instructions at the location indicated by the appropriate MVECT register .

Figure 5-2. MVECT1 Register

Note: While the CLA is running or executing a task, the CPU can change the MVECT values.. Reset type: SYSRSn

5.7.2.9 MCTL Register (Offset = 10h) [reset = 0h]

MCTL is shown in [Figure 5-10](#) and described in [Table 5-33](#).

Return to [Summary Table](#).

Control Register

Figure 5-10. MCTL Register

15	14	13	12	11	10	9	8
RESERVED							
R-0h							
7	6	5	4	3	2	1	0
RESERVED					IACKE	SOFTRESET	HARDRESET
R-0h					R/W-0h	R/W-0h	R/W-0h

Table 5-33. MCTL Register Field Descriptions

Bit	Field	Type	Reset	Description
15-3	RESERVED	R	0h	Reserved
2	IACKE	R/W	0h	IACK enable Reset type: SYSRSn 0h (R/W) = The CLA ignores the IACK instruction. (default) 1h (R/W) = Enable the main CPU to use the IACK #16bit instruction to set MIFR bits in the same manner as writing to the MIFRC register. Each bit in the operand, #16bit, corresponds to a bit in the MIFRC register. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger a CLA task through software. Examples IACK #0x0001 Write a 1 to MIFRC bit 0 to force task 1 IACK #0x0003 Write a 1 to MIFRC bit 0 and 1 to force task 1 and task 2
1	SOFTRESET	R/W	0h	Soft Reset Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a soft reset of the CLA. This will stop the current task, clear the MIRUN flag and clear all bits in the MIER register. After a soft reset you must wait at least 1 SYSCLKOUT cycle before reconfiguring the MIER bits. If these two operations are done back-to-back then the MIER bits will not get set.
0	HARDRESET	R/W	0h	Hard Reset Reset type: SYSRSn 0h (R/W) = This bit always reads back 0 and writes of 0 are ignored. 1h (R/W) = Writing a 1 will cause a hard reset of the CLA. This will set all CLA registers to their default state.

5.7.2.10 MIFR Register (Offset = 20h) [reset = 0h]

MIFR is shown in [Figure 5-11](#) and described in [Table 5-34](#).

Return to [Summary Table](#).

Each bit in the interrupt flag register corresponds to a CLA task. The corresponding bit is automatically set when the task request is received from the peripheral interrupt. The bit can also be set by the main CPU writing to the MIFRC register or using the IACK instruction to start the task. To use the IACK instruction to begin a task first enable this feature in the MCTL register. If the bit is already set when a new peripheral interrupt is received, then the corresponding overflow bit will be set in the MIOVF register. The corresponding MIFR bit is automatically cleared when the task begins execution. This will occur if the interrupt is enabled in the MIER register and no other higher priority task is pending. The bits can also be cleared manually by writing to the MICLR register. Writes to the MIFR register are ignored.

0	INT1	R	0h	Task 1 Interrupt Flag Reset type: SYSRSn 0h (R/W) = TASK_FLAG_DISABLE Task 1 interrupt is currently not flagged (default) 1h (R/W) = TASK_FLAG_ENABLE Task 1 interrupt has been received and is pending execution

5.7.2.11 MIOVF Register (Offset = 21h) [reset = 0h]

MIOVF is shown in [Figure 5-12](#) and described in [Table 5-35](#).

Return to [Summary Table](#).

Each bit in the overflow flag register corresponds to a CLA task. The bit is set when an interrupt overflow event has occurred for the specific task. An overflow event occurs when the MIFR register bit is already set when a new interrupt is received from a peripheral source. The MIOVF bits are only affected by peripheral interrupt events. They do not respond to a task request by the main CPU IACK instruction or by directly setting MIFR bits. The overflow flag will remain latched and can only be cleared by writing to the overflow flag clear (MICLROVF) register. Writes to the MIOVF register are ignored.

Bit	Field	Type	Reset	Description
0	INT1	R	0h	Task 1 Interrupt Overflow Flag Reset type: SYSRSn 0h (R/W) = A task 1 interrupt overflow has not occurred (default) 1h (R/W) = A task 1 interrupt overflow has occurred

5.7.2.12 MIFRC Register (Offset = 22h) [reset = 0h]

MIFRC is shown in [Figure 5-13](#) and described in [Table 5-36](#).

Return to [Summary Table](#).

The interrupt force register can be used by the main CPU to start tasks through software. Writing a 1 to a MIFRC bit will set the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0. The IACK #16bit operation can also be used to start tasks and has the same effect as the MIFRC register. To enable IACK to set MIFR bits you must first set the MCTL[IACKE] bit. Using IACK has the advantage of not having to first set the EALLOW bit. This allows the main CPU to efficiently trigger CLA tasks through software.

5.7.2.13 MICLR Register (Offset = 23h) [reset = 0h]

MICLR is shown in [Figure 5-14](#) and described in [Table 5-37](#).

Return to [Summary Table](#).

Normally bits in the MIFR register are automatically cleared when a task begins. The interrupt flag clear register can be used to instead manually clear bits in the interrupt flag (MIFR) register. Writing a 1 to a MICLR bit will clear the corresponding bit in the MIFR register. Writes of 0 are ignored and reads always return 0.

5.7.2.14 MICLROVF Register (Offset = 24h) [reset = 0h]

MICLROVF is shown in [Figure 5-15](#) and described in [Table 5-38](#).

Return to [Summary Table](#).

Overflow flag bits in the MIOVF register are latched until manually cleared using the MICLROVF register. Writing a 1 to a MICLROVF bit will clear the corresponding bit in the MIOVF register. Writes of 0 are ignored and reads always return 0.

5.7.2.15 MIER Register (Offset = 25h) [reset = 0h]

MIER is shown in [Figure 5-16](#) and described in [Table 5-39](#).

Return to [Summary Table](#).

Setting the bits in the interrupt enable register (MIER) allow an incoming interrupt or main CPU software to start the corresponding CLA task. Writing a 0 will block the task, but the interrupt request will still be latched in the flag register (MIFLG). Setting the MIER register bit to 0 while the corresponding task is executing will have no effect on the task. The task will continue to run until it hits the MSTOP instruction. When a soft reset is issued, the MIER bits are cleared. There should always be at least a 1 SYSCLKOUT delay between issuing the soft reset and reconfiguring the MIER bits.

5.7.2.16 MIRUN Register (Offset = 26h) [reset = 0h]

MIRUN is shown in [Figure 5-17](#) and described in [Table 5-40](#).

Return to [Summary Table](#).

The interrupt run status register (MIRUN) indicates which task is currently executing. Only one MIRUN bit will ever be set to a 1 at any given time. The bit is automatically cleared when the task completes and the respective interrupt is fed to the peripheral interrupt expansion (PIE) block of the device. This lets the main CPU know when a task has completed. The main CPU can stop a currently running task by writing to the MCTL[SOFTRESET] bit. This will clear the MIRUN flag and stop the task. In this case no interrupt will be generated to the PIE.

5.7.2.20 _MSTF Register (Offset = 2Eh) [reset = 0h]

_MSTF is shown in [Figure 5-21](#) and described in [Table 5-44](#).

Return to [Summary Table](#).

The CLA status register (MSTF) reflects the results of different operations. These are the basic rules for the flags:

- Zero and negative flags are cleared or set based on:
- floating-point moves to registers
- the result of compare, minimum, maximum, negative and absolute value operations
- the integer result of operations such as MMOV16, MAND32, MOR32, MXOR32, MCMP32, MASR32, MLRS32
- Overflow and underflow flags are set by floating-point math instructions such as multiply, add, subtract and 1/x. These flags may also be connected to the peripheral interrupt expansion (PIE) block on your device. This can be useful for debugging underflow and overflow conditions within an application.

5.7.3 CLA_SOFTINT_REGS Registers

Table 5-49 lists the memory-mapped registers for the CLA_SOFTINT_REGS. All register offset addresses not listed in Table 5-49 should be considered as reserved locations and the register contents should not be modified.

Table 5-49. CLA_SOFTINT_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	SOFTINTEN	CLA Software Interrupt Enable Register		Go
2h	SOFTINTFRC	CLA Software Interrupt Force Register		Go

Complex bit access types are encoded to fit into small table cells. Table 5-50 shows the codes that are used for access types in this section.

Table 5-50. CLA_SOFTINT_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

5.7.3.1 SOFTINTEN Register (Offset = 0h) [reset = 0h]

SOFTINTEN is shown in [Figure 5-26](#) and described in [Table 5-51](#).

Return to [Summary Table](#).

Enables the ability to generate CLA task interrupt from within the task, by writing to SOFTINTFRC register. SOFTINTFRC register can only be written from CLA.

5.7.3.2 SOFTINTFRC Register (Offset = 2h) [reset = 0h]

SOFTINTFRC is shown in [Figure 5-27](#) and described in [Table 5-52](#).

Return to [Summary Table](#).

Writing a value of 1 in a bit will generate the corresponding task interrupt. This register is only accessible by the CLA (not the CPU).

Inter-Processor Communication (IPC)

Topic	Page
6.1 Inter-Processor Communication	834
6.2 Message RAMs.....	835
6.3 IPC Flags and Interrupts.....	835
6.4 IPC Command Registers	835
6.5 Free-Running Counter	836
6.6 IPC Communication Protocol	837
6.7 Registers	838

6.1 Inter-Processor Communication

The Inter-Processor Communications (IPC) module allows communication between the two CPU subsystems. This section details the IPC features that each CPU can use to request and share information. The IPC features are:

- Message RAMs
- IPC flags and interrupts
- IPC command registers
- Flash pump semaphore
- Clock configuration semaphore
- Free-running counter

All IPC features are independent of each other, and most do not require any specific data format. There are also two registers for boot mode/status communication. Please refer to the boot ROM chapter for more information on these registers.

Figure 6-1 shows the design structure of the IPC module.

Figure 6-1. IPC Module Architecture

6.2 Message RAMs

There are two dedicated 2kB blocks of message RAM. Each CPU and its DMA have read/write access to one RAM and read-only access to the other RAM, as shown in [Table 6-1](#)

Table 6-1. IPC Message RAM Read/Write Access

	CPU1	CPU2	CPU1 DMA	CPU2 DMA
CPU1 to CPU2 (1K x 16, address 0x03FC00)	R/W	R	R/W	R
CPU2 to CPU1 (1K x 16, address 0x03F800)	R	R/W	R	R/W

Reading or writing a message RAM does not trigger any events on the remote CPU.

6.3 IPC Flags and Interrupts

There are 32 IPC event signals from CPU1 to CPU2, and vice-versa. These signals can be used for flag-based event polling. Four of them (IPC0 - IPC3) can be configured to generate IPC interrupts on the remote CPU. [Figure 6-2](#) shows the IPC flag messaging and interrupt system.

Figure 6-2. Messaging with IPC Flags and Interrupts

6.4 IPC Command Registers

The IPC command registers provide a simple and flexible way for the two CPUs to exchange more complex messages. Each CPU has eight dedicated registers, four for sending messages and four for receiving messages. The register names were chosen to support a simple command/response protocol, but can be used for any purpose. Only the read/write permissions are determined by hardware; the data format is entirely software-defined.

For sending messages, each CPU has three writable registers and one read-only register. Those same registers are accessible on the remote CPU as three read-only registers and one writable register.

[Table 6-2](#) shows the command registers.

Table 6-2. IPC Command Registers

Local Register Name	Local CPU	Remote CPU	Remote Register Name
IPCSENDCOM	R/W	R	IPCRECVCOM
IPCSENDADDR	R/W	R	IPCRECVADDR
IPCSENDATA	R/W	R	IPCRECVDATA
IPCREMOTEREPLY	R	R/W	IPCLOCALREPLY

6.5 Free-Running Counter

A 64-bit free-running counter is present in the device and can be used to timestamp IPC events between processors. The counter is clocked by PLLSYSCLK and reset by SYSRSn. The counter is implemented as two 32-bit registers, IPCCOUNTERH and IPCCOUNTERL. When IPCCOUNTERL is read, the value of IPCCOUNTERH is saved. A subsequent read to IPCCOUNTERH returns this saved value. This design prevents race conditions due to IPCCOUNTERL overflowing between reads of the two registers.

The free-running counter only stops when both CPUs are in HALT mode. If either core is executing, the counter runs.

6.6 IPC Communication Protocol

This section describes the hardware support options for IPC communication between the two CPUs. These options can be used independently or in combination. All flag definitions and data formats are entirely user-defined.

- The flag system supports event-based communication via interrupts and register polling.
 - CPUx can raise an IPC event by writing to any of the 32 bits of its IPCSET register. This sets the corresponding bits in CPUx's IPCFLG register and CPUy's IPCSTS register.
 - CPUy can signal its response to the event by setting the appropriate bit in its IPCACK register. This clears the corresponding bits in CPUx's IPCFLG register and CPUy's IPCSTS register.
 - If CPUx needs to cancel an event, it can set the appropriate bit in its IPCCLR register. This has the same effect as CPUy writing to IPCACK.
 - Flags 0–3 (set via IPCSET[3:0]) fire interrupts to the remote CPU. The remote CPU must configure its ePIE module properly in order to receive an IPC interrupt. Flags 4–31 (set via IPCSET[31:4]) do not produce interrupts. Multiple flags can be set, acknowledged, and cleared simultaneously.
- The command registers support sending several distinct pieces of information. They are named COM, ADDR, DATA, and REPLY for convenience only and can hold whatever data the application needs.
 - CPUx can write data to its IPCSENDCOM, IPCSENDADDR, and IPCSENDATA registers. CPUy receives these in its IPCRECVCOM, IPCRECVADDR, and IPCRECVDATA registers.
 - CPUy can respond by writing to its IPCLOCALREPLY register. CPUx receives this data in its IPCREMOTEREPLY register.
 - Each CPU can only write to its SEND and LOCALREPLY registers. The RECV and REMOTEREPLY registers are read-only.
- There is an additional pair of command-like registers offered for boot-time IPC or any other convenient use — IPCBOOTMODE and IPCBOOTSTS. Both CPUs can read these registers. CPU1 can only write to IPCBOOTMODE, and CPU2 can only write to IPCBOOTSTS.
- There are two shared memories for passing large amounts of data between the CPUs. Each CPU has a writable memory for sending data and a read-only memory for receiving data.
- Here is an example of how to use these features together. CPUx needs some data from CPUy's LS RAM. The data is at CPUy address 0x9400 and is 0x80 16-bit words long. The protocol could be implemented like this:
 - CPUx writes 0x1 to IPCSENDCOM, defined in software to mean "copy data from address". It writes the address (0x9400) to IPCSENDADDR and the data length (0x80) to IPCSENDATA.
 - CPUx writes to IPCSET[3] and IPCSET[16]. Here, IPC flag 3 is configured to send an interrupt and IPCSET[16] is defined in software to indicate an incoming command. CPUx begins polling for IPCFLG[3] to go low.
 - CPUy receives the interrupt. In the interrupt handler, it checks IPCSTS, finds that flag 16 is set, and runs a command processor.
 - CPUy reads the command (0x1) from IPCRECVCOM, the address (0x9400) from IPCRECVADDR, and the data length (0x80) from IPCRECVDATA. CPUy then copies the LS RAM data to an empty space in its writable shared memory starting at offset 0x210.
 - CPUy writes the shared memory address (0x210) to its IPCLOCALREPLY register. It then writes to IPCACK[16] and IPCACK[3] to clear the flags and indicate completion of the command. CPUy's work is done.
 - CPUx sees IPCFLG[3] go low. It reads IPCREMOTEREPLY to get the shared memory offset of the copied data (0x210).

6.7 Registers

6.7.1 IPC Base Addresses

Table 6-3. IPC Base Addresses

Device Registers	Register Name	Start Address	End Address
IpcRegs (CPU1)	IPC_REGS_CPU1	0x0005_0000	0x0005_0023
IpcRegs (CPU2)	IPC_REGS_CPU2	0x0005_0000	0x0005_0023

6.7.2 IPC_REGS_CPU1 Registers

Table 6-4 lists the memory-mapped registers for the IPC_REGS_CPU1. All register offset addresses not listed in Table 6-4 should be considered as reserved locations and the register contents should not be modified.

Table 6-4. IPC_REGS_CPU1 Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	IPCACK	IPC incoming flag clear (acknowledge) register		Go
2h	IPCSTS	IPC incoming flag status register		Go
4h	IPCSET	IPC remote flag set register		Go
6h	IPCCLR	IPC remote flag clear register		Go
8h	IPCFLG	IPC remote flag status register		Go
Ch	IPCCOUNTERL	IPC Counter Low Register		Go
Eh	IPCCOUNTERH	IPC Counter High Register		Go
10h	IPSENDCOM	Local to Remote IPC Command Register		Go
12h	IPSENDADDR	Local to Remote IPC Address Register		Go
14h	IPSENDATA	Local to Remote IPC Data Register		Go
16h	IPCREMOTEREPLY	Remote to Local IPC Reply Data Register		Go
18h	IPCRCVCOM	Remote to Local IPC Command Register		Go
1Ah	IPCRCVADDR	Remote to Local IPC Address Register		Go
1Ch	IPCRCVDATA	Remote to Local IPC Data Register		Go
1Eh	IPCLOCALREPLY	Local to Remote IPC Reply Data Register		Go
20h	IPCBOOTSTS	CPU2 to CPU1 IPC Boot Status Register		Go
22h	IPCBOOTMODE	CPU1 to CPU2 IPC Boot Mode Register		Go

Complex bit access types are encoded to fit into small table cells. Table 6-5 shows the codes that are used for access types in this section.

Table 6-5. IPC_REGS_CPU1 Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.7.2.1 IPCACK Register (Offset = 0h) [reset = 0h]

IPCACK is shown in [Figure 6-20](#) and described in [Table 6-25](#).

26	IPC26	R	0h	Indicates to the local CPU if the IPC26 event flag was set by the remote CPU. 0: No IPC26 event was set by the remote CPU 1: An IPC26 event was set by the remote CPU Reset type: SYSRSn
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC25 event was set by the remote CPU 1: An IPC25 event was set by the remote CPU Reset type: SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC24 event was set by the remote CPU 1: An IPC24 event was set by the remote CPU Reset type: SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC23 event was set by the remote CPU 1: An IPC23 event was set by the remote CPU Reset type: SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC22 event was set by the remote CPU 1: An IPC22 event was set by the remote CPU Reset type: SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC21 event was set by the remote CPU 1: An IPC21 event was set by the remote CPU Reset type: SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC20 event was set by the remote CPU 1: An IPC20 event was set by the remote CPU Reset type: SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC19 event was set by the remote CPU 1: An IPC19 event was set by the remote CPU Reset type: SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC18 event was set by the remote CPU 1: An IPC18 event was set by the remote CPU Reset type: SYSRSn

Table 6-7. IPCSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC17 event was set by the remote CPU 1: An IPC17 event was set by the remote CPU Reset type: SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC16 event was set by the remote CPU 1: An IPC16 event was set by the remote CPU Reset type: SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC15 event was set by the remote CPU 1: An IPC15 event was set by the remote CPU Reset type: SYSRSn
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC14 event was set by the remote CPU 1: An IPC14 event was set by the remote CPU Reset type: SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC13 event was set by the remote CPU 1: An IPC13 event was set by the remote CPU Reset type: SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC12 event was set by the remote CPU 1: An IPC12 event was set by the remote CPU Reset type: SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC11 event was set by the remote CPU 1: An IPC11 event was set by the remote CPU Reset type: SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC10 event was set by the remote CPU 1: An IPC10 event was set by the remote CPU Reset type: SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC9 event was set by the remote CPU 1: An IPC9 event was set by the remote CPU Reset type: SYSRSn

Table 6-7. IPCSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC8 event was set by the remote CPU 1: An IPC8 event was set by the remote CPU Reset type: SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC7 event was set by the remote CPU 1: An IPC7 event was set by the remote CPU Reset type: SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC6 event was set by the remote CPU 1: An IPC6 event was set by the remote CPU Reset type: SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC5 event was set by the remote CPU 1: An IPC5 event was set by the remote CPU Reset type: SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC4 event was set by the remote CPU 1: An IPC4 event was set by the remote CPU Reset type: SYSRSn
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC3 event was set by the remote CPU 1: An IPC3 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC2 event was set by the remote CPU 1: An IPC2 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn

Table 6-7. IPCSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn

6.7.2.3 IPCSET Register (Offset = 4h) [reset = 0h]

IPCSET is shown in [Figure 6-22](#) and described in [Table 6-27](#).

Return to [Summary Table](#).

IPC remote flag set register

Table 6-8. IPCSET Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R=0/W=1	0h	Writing 1 to this bit sets the IPC31 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
30	IPC30	R=0/W=1	0h	Writing 1 to this bit sets the IPC30 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
29	IPC29	R=0/W=1	0h	Writing 1 to this bit sets the IPC29 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
28	IPC28	R=0/W=1	0h	Writing 1 to this bit sets the IPC28 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
27	IPC27	R=0/W=1	0h	Writing 1 to this bit sets the IPC27 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
26	IPC26	R=0/W=1	0h	Writing 1 to this bit sets the IPC26 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
25	IPC25	R=0/W=1	0h	Writing 1 to this bit sets the IPC25 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
24	IPC24	R=0/W=1	0h	Writing 1 to this bit sets the IPC24 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
23	IPC23	R=0/W=1	0h	Writing 1 to this bit sets the IPC23 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn

Table 6-8. IPCSET Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	IPC22	R=0/W=1	0h	Writing 1 to this bit sets the IPC22 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
21	IPC21	R=0/W=1	0h	Writing 1 to this bit sets the IPC21 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
20	IPC20	R=0/W=1	0h	Writing 1 to this bit sets the IPC20 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
19	IPC19	R=0/W=1	0h	Writing 1 to this bit sets the IPC19 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
18	IPC18	R=0/W=1	0h	Writing 1 to this bit sets the IPC18 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
17	IPC17	R=0/W=1	0h	Writing 1 to this bit sets the IPC17 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
16	IPC16	R=0/W=1	0h	Writing 1 to this bit sets the IPC16 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
15	IPC15	R=0/W=1	0h	Writing 1 to this bit sets the IPC15 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
14	IPC14	R=0/W=1	0h	Writing 1 to this bit sets the IPC14 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
13	IPC13	R=0/W=1	0h	Writing 1 to this bit sets the IPC13 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
12	IPC12	R=0/W=1	0h	Writing 1 to this bit sets the IPC12 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
11	IPC11	R=0/W=1	0h	Writing 1 to this bit sets the IPC11 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
10	IPC10	R=0/W=1	0h	Writing 1 to this bit sets the IPC10 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
9	IPC9	R=0/W=1	0h	Writing 1 to this bit sets the IPC9 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
8	IPC8	R=0/W=1	0h	Writing 1 to this bit sets the IPC8 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
7	IPC7	R=0/W=1	0h	Writing 1 to this bit sets the IPC7 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn

Table 6-8. IPCSET Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	IPC6	R=0/W=1	0h	Writing 1 to this bit sets the IPC6 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
5	IPC5	R=0/W=1	0h	Writing 1 to this bit sets the IPC5 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
4	IPC4	R=0/W=1	0h	Writing 1 to this bit sets the IPC4 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
3	IPC3	R=0/W=1	0h	Writing 1 to this bit sets the IPC3 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
2	IPC2	R=0/W=1	0h	Writing 1 to this bit sets the IPC2 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
1	IPC1	R=0/W=1	0h	Writing 1 to this bit sets the IPC1 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
0	IPC0	R=0/W=1	0h	Writing 1 to this bit sets the IPC0 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn

6.7.2.4 IPCCLR Register (Offset = 6h) [reset = 0h]

IPCCLR is shown in [Figure 6-23](#) and described in [Table 6-28](#).

Return to [Summary Table](#).

IPC remote flag clear register

Table 6-9. IPCCLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R=0/W=1	0h	Writing 1 to this bit clears the IPC31 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
30	IPC30	R=0/W=1	0h	Writing 1 to this bit clears the IPC30 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
29	IPC29	R=0/W=1	0h	Writing 1 to this bit clears the IPC29 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
28	IPC28	R=0/W=1	0h	Writing 1 to this bit clears the IPC28 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-9. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	IPC27	R=0/W=1	0h	Writing 1 to this bit clears the IPC27 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
26	IPC26	R=0/W=1	0h	Writing 1 to this bit clears the IPC26 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
25	IPC25	R=0/W=1	0h	Writing 1 to this bit clears the IPC25 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
24	IPC24	R=0/W=1	0h	Writing 1 to this bit clears the IPC24 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
23	IPC23	R=0/W=1	0h	Writing 1 to this bit clears the IPC23 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
22	IPC22	R=0/W=1	0h	Writing 1 to this bit clears the IPC22 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
21	IPC21	R=0/W=1	0h	Writing 1 to this bit clears the IPC21 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-9. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	IPC20	R=0/W=1	0h	Writing 1 to this bit clears the IPC20 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
19	IPC19	R=0/W=1	0h	Writing 1 to this bit clears the IPC19 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
18	IPC18	R=0/W=1	0h	Writing 1 to this bit clears the IPC18 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
17	IPC17	R=0/W=1	0h	Writing 1 to this bit clears the IPC17 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
16	IPC16	R=0/W=1	0h	Writing 1 to this bit clears the IPC16 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
15	IPC15	R=0/W=1	0h	Writing 1 to this bit clears the IPC15 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
14	IPC14	R=0/W=1	0h	Writing 1 to this bit clears the IPC14 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-9. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	IPC13	R=0/W=1	0h	Writing 1 to this bit clears the IPC13 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
12	IPC12	R=0/W=1	0h	Writing 1 to this bit clears the IPC12 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
11	IPC11	R=0/W=1	0h	Writing 1 to this bit clears the IPC11 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
10	IPC10	R=0/W=1	0h	Writing 1 to this bit clears the IPC10 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
9	IPC9	R=0/W=1	0h	Writing 1 to this bit clears the IPC9 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
8	IPC8	R=0/W=1	0h	Writing 1 to this bit clears the IPC8 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
7	IPC7	R=0/W=1	0h	Writing 1 to this bit clears the IPC7 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-9. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	IPC6	R=0/W=1	0h	Writing 1 to this bit clears the IPC6 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
5	IPC5	R=0/W=1	0h	Writing 1 to this bit clears the IPC5 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
4	IPC4	R=0/W=1	0h	Writing 1 to this bit clears the IPC4 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
3	IPC3	R=0/W=1	0h	Writing 1 to this bit clears the IPC3 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
2	IPC2	R=0/W=1	0h	Writing 1 to this bit clears the IPC2 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
1	IPC1	R=0/W=1	0h	Writing 1 to this bit clears the IPC1 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
0	IPC0	R=0/W=1	0h	Writing 1 to this bit clears the IPC0 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

6.7.2.5 IPCFLG Register (Offset = 8h) [reset = 0h]

IPCFLG is shown in [Figure 6-24](#) and described in [Table 6-29](#).

Return to [Summary Table](#).

IPC remote flag status register

Table 6-10. IPCFLG Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to the local CPU whether the remote IPC31 event flag is set. 0: The remote IPC31 event flag is not set 1: The remote IPC31 event flag is set Reset type: SYSRSn
30	IPC30	R	0h	Indicates to the local CPU whether the remote IPC30 event flag is set. 0: The remote IPC30 event flag is not set 1: The remote IPC30 event flag is set Reset type: SYSRSn
29	IPC29	R	0h	Indicates to the local CPU whether the remote IPC29 event flag is set. 0: The remote IPC29 event flag is not set 1: The remote IPC29 event flag is set Reset type: SYSRSn
28	IPC28	R	0h	Indicates to the local CPU whether the remote IPC28 event flag is set. 0: The remote IPC28 event flag is not set 1: The remote IPC28 event flag is set Reset type: SYSRSn
27	IPC27	R	0h	Indicates to the local CPU whether the remote IPC27 event flag is set. 0: The remote IPC27 event flag is not set 1: The remote IPC27 event flag is set Reset type: SYSRSn

Table 6-10. IPCFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	IPC26	R	0h	Indicates to the local CPU whether the remote IPC26 event flag is set. 0: The remote IPC26 event flag is not set 1: The remote IPC26 event flag is set Reset type: SYSRSn
25	IPC25	R	0h	Indicates to the local CPU whether the remote IPC25 event flag is set. 0: The remote IPC25 event flag is not set 1: The remote IPC25 event flag is set Reset type: SYSRSn
24	IPC24	R	0h	Indicates to the local CPU whether the remote IPC24 event flag is set. 0: The remote IPC24 event flag is not set 1: The remote IPC24 event flag is set Reset type: SYSRSn
23	IPC23	R	0h	Indicates to the local CPU whether the remote IPC23 event flag is set. 0: The remote IPC23 event flag is not set 1: The remote IPC23 event flag is set Reset type: SYSRSn
22	IPC22	R	0h	Indicates to the local CPU whether the remote IPC22 event flag is set. 0: The remote IPC22 event flag is not set 1: The remote IPC22 event flag is set Reset type: SYSRSn
21	IPC21	R	0h	Indicates to the local CPU whether the remote IPC21 event flag is set. 0: The remote IPC21 event flag is not set 1: The remote IPC21 event flag is set Reset type: SYSRSn
20	IPC20	R	0h	Indicates to the local CPU whether the remote IPC20 event flag is set. 0: The remote IPC20 event flag is not set 1: The remote IPC20 event flag is set Reset type: SYSRSn
19	IPC19	R	0h	Indicates to the local CPU whether the remote IPC19 event flag is set. 0: The remote IPC19 event flag is not set 1: The remote IPC19 event flag is set Reset type: SYSRSn
18	IPC18	R	0h	Indicates to the local CPU whether the remote IPC18 event flag is set. 0: The remote IPC18 event flag is not set 1: The remote IPC18 event flag is set Reset type: SYSRSn

Table 6-10. IPCFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	IPC17	R	0h	Indicates to the local CPU whether the remote IPC17 event flag is set. 0: The remote IPC17 event flag is not set 1: The remote IPC17 event flag is set Reset type: SYSRSn
16	IPC16	R	0h	Indicates to the local CPU whether the remote IPC16 event flag is set. 0: The remote IPC16 event flag is not set 1: The remote IPC16 event flag is set Reset type: SYSRSn
15	IPC15	R	0h	Indicates to the local CPU whether the remote IPC15 event flag is set. 0: The remote IPC15 event flag is not set 1: The remote IPC15 event flag is set Reset type: SYSRSn
14	IPC14	R	0h	Indicates to the local CPU whether the remote IPC14 event flag is set. 0: The remote IPC14 event flag is not set 1: The remote IPC14 event flag is set Reset type: SYSRSn
13	IPC13	R	0h	Indicates to the local CPU whether the remote IPC13 event flag is set. 0: The remote IPC13 event flag is not set 1: The remote IPC13 event flag is set Reset type: SYSRSn
12	IPC12	R	0h	Indicates to the local CPU whether the remote IPC12 event flag is set. 0: The remote IPC12 event flag is not set 1: The remote IPC12 event flag is set Reset type: SYSRSn
11	IPC11	R	0h	Indicates to the local CPU whether the remote IPC11 event flag is set. 0: The remote IPC11 event flag is not set 1: The remote IPC11 event flag is set Reset type: SYSRSn
10	IPC10	R	0h	Indicates to the local CPU whether the remote IPC10 event flag is set. 0: The remote IPC10 event flag is not set 1: The remote IPC10 event flag is set Reset type: SYSRSn
9	IPC9	R	0h	Indicates to the local CPU whether the remote IPC9 event flag is set. 0: The remote IPC9 event flag is not set 1: The remote IPC9 event flag is set Reset type: SYSRSn
8	IPC8	R	0h	Indicates to the local CPU whether the remote IPC8 event flag is set. 0: The remote IPC8 event flag is not set 1: The remote IPC8 event flag is set Reset type: SYSRSn

Table 6-10. IPCFLG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
7	IPC7	R	0h	Indicates to the local CPU whether the remote IPC7 event flag is set. 0: The remote IPC7 event flag is not set 1: The remote IPC7 event flag is set Reset type: SYSRSn
6	IPC6	R	0h	Indicates to the local CPU whether the remote IPC6 event flag is set. 0: The remote IPC6 event flag is not set 1: The remote IPC6 event flag is set Reset type: SYSRSn
5	IPC5	R	0h	Indicates to the local CPU whether the remote IPC5 event flag is set. 0: The remote IPC5 event flag is not set 1: The remote IPC5 event flag is set Reset type: SYSRSn
4	IPC4	R	0h	Indicates to the local CPU whether the remote IPC4 event flag is set. 0: The remote IPC4 event flag is not set 1: The remote IPC4 event flag is set Reset type: SYSRSn
3	IPC3	R	0h	Indicates to the local CPU whether the remote IPC3 event flag is set. 0: The remote IPC3 event flag is not set 1: The remote IPC3 event flag is set Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
2	IPC2	R	0h	Indicates to the local CPU whether the remote IPC2 event flag is set. 0: The remote IPC2 event flag is not set 1: The remote IPC2 event flag is set Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
1	IPC1	R	0h	Indicates to the local CPU whether the remote IPC1 event flag is set. 0: The remote IPC1 event flag is not set 1: The remote IPC1 event flag is set Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
0	IPC0	R	0h	Indicates to the local CPU whether the remote IPC0 event flag is set. 0: The remote IPC0 event flag is not set 1: The remote IPC0 event flag is set Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn

6.7.2.6 IPCCOUNTERL Register (Offset = Ch) [reset = 0h]

IPCCOUNTERL is shown in [Figure 6-25](#) and described in [Table 6-30](#).

[Return to Summary Table.](#)

IPC Counter Low Register

6.7.3 IPC_REGS_CPU2 Registers

Table 6-23 lists the memory-mapped registers for the IPC_REGS_CPU2. All register offset addresses not listed in Table 6-23 should be considered as reserved locations and the register contents should not be modified.

Table 6-23. IPC_REGS_CPU2 Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	IPCACK	IPC incoming flag clear (acknowledge) register		Go
2h	IPCSTS	IPC incoming flag status register		Go
4h	IPCSET	IPC remote flag set register		Go
6h	IPCCLR	IPC remote flag clear register		Go
8h	IPCFLG	IPC remote flag status register		Go
Ch	IPCCOUNTERL	IPC Counter Low Register		Go
Eh	IPCCOUNTERH	IPC Counter High Register		Go
10h	IPCRECVCOM	Remote to Local IPC Command Register		Go
12h	IPCRECVADDR	Remote to Local IPC Address Register		Go
14h	IPCRECVDATA	Remote to Local IPC Data Register		Go
16h	IPCLOCALREPLY	Local to Remote IPC Reply Data Register		Go
18h	IPSENDCOM	Local to Remote IPC Command Register		Go
1Ah	IPSENDADDR	Local to Remote IPC Address Register		Go
1Ch	IPSENDATA	Local to Remote IPC Data Register		Go
1Eh	IPCREMOTEREPLY	Remote to Local IPC Reply Data Register		Go
20h	IPCBOOTSTS	CPU2 to CPU1 IPC Boot Status Register		Go
22h	IPCBOOTMODE	CPU1 to CPU2 IPC Boot Mode Register		Go

Complex bit access types are encoded to fit into small table cells. Table 6-24 shows the codes that are used for access types in this section.

Table 6-24. IPC_REGS_CPU2 Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

6.7.3.1 IPCACK Register (Offset = 0h) [reset = 0h]

IPCACK is shown in [Figure 6-20](#) and described in [Table 6-25](#).

Return to [Summary Table](#).

10	IPC10	R=0/W=1	0h	Writing 1 to this bit clears the IPC10 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
9	IPC9	R=0/W=1	0h	Writing 1 to this bit clears the IPC9 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
8	IPC8	R=0/W=1	0h	Writing 1 to this bit clears the IPC8 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
7	IPC7	R=0/W=1	0h	Writing 1 to this bit clears the IPC7 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
6	IPC6	R=0/W=1	0h	Writing 1 to this bit clears the IPC6 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
5	IPC5	R=0/W=1	0h	Writing 1 to this bit clears the IPC5 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
4	IPC4	R=0/W=1	0h	Writing 1 to this bit clears the IPC4 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
3	IPC3	R=0/W=1	0h	Writing 1 to this bit clears the IPC3 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
2	IPC2	R=0/W=1	0h	Writing 1 to this bit clears the IPC2 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
1	IPC1	R=0/W=1	0h	Writing 1 to this bit clears the IPC1 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn
0	IPC0	R=0/W=1	0h	Writing 1 to this bit clears the IPC0 event flag which was set by the remote CPU. Writing 0 to this bit has no effect. Reset type: SYSRSn

6.7.3.2 IPCSTS Register (Offset = 2h) [reset = 0h]

IPCSTS is shown in [Figure 6-21](#) and described in [Table 6-26](#).

Return to [Summary Table](#).

IPC incoming flag status register

Table 6-26. IPCSTS Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R	0h	Indicates to the local CPU if the IPC31 event flag was set by the remote CPU. 0: No IPC31 event was set by the remote CPU 1: An IPC31 event was set by the remote CPU Reset type: SYSRSn
30	IPC30	R	0h	Indicates to the local CPU if the IPC30 event flag was set by the remote CPU. 0: No IPC30 event was set by the remote CPU 1: An IPC30 event was set by the remote CPU Reset type: SYSRSn
29	IPC29	R	0h	Indicates to the local CPU if the IPC29 event flag was set by the remote CPU. 0: No IPC29 event was set by the remote CPU 1: An IPC29 event was set by the remote CPU Reset type: SYSRSn
28	IPC28	R	0h	Indicates to the local CPU if the IPC28 event flag was set by the remote CPU. 0: No IPC28 event was set by the remote CPU 1: An IPC28 event was set by the remote CPU Reset type: SYSRSn
27	IPC27	R	0h	Indicates to the local CPU if the IPC27 event flag was set by the remote CPU. 0: No IPC27 event was set by the remote CPU 1: An IPC27 event was set by the remote CPU Reset type: SYSRSn

Table 6-26. IPCSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
26	IPC26	R	0h	Indicates to the local CPU if the IPC26 event flag was set by the remote CPU. 0: No IPC26 event was set by the remote CPU 1: An IPC26 event was set by the remote CPU Reset type: SYSRSn
25	IPC25	R	0h	Indicates to the local CPU if the IPC25 event flag was set by the remote CPU. 0: No IPC25 event was set by the remote CPU 1: An IPC25 event was set by the remote CPU Reset type: SYSRSn
24	IPC24	R	0h	Indicates to the local CPU if the IPC24 event flag was set by the remote CPU. 0: No IPC24 event was set by the remote CPU 1: An IPC24 event was set by the remote CPU Reset type: SYSRSn
23	IPC23	R	0h	Indicates to the local CPU if the IPC23 event flag was set by the remote CPU. 0: No IPC23 event was set by the remote CPU 1: An IPC23 event was set by the remote CPU Reset type: SYSRSn
22	IPC22	R	0h	Indicates to the local CPU if the IPC22 event flag was set by the remote CPU. 0: No IPC22 event was set by the remote CPU 1: An IPC22 event was set by the remote CPU Reset type: SYSRSn
21	IPC21	R	0h	Indicates to the local CPU if the IPC21 event flag was set by the remote CPU. 0: No IPC21 event was set by the remote CPU 1: An IPC21 event was set by the remote CPU Reset type: SYSRSn
20	IPC20	R	0h	Indicates to the local CPU if the IPC20 event flag was set by the remote CPU. 0: No IPC20 event was set by the remote CPU 1: An IPC20 event was set by the remote CPU Reset type: SYSRSn
19	IPC19	R	0h	Indicates to the local CPU if the IPC19 event flag was set by the remote CPU. 0: No IPC19 event was set by the remote CPU 1: An IPC19 event was set by the remote CPU Reset type: SYSRSn
18	IPC18	R	0h	Indicates to the local CPU if the IPC18 event flag was set by the remote CPU. 0: No IPC18 event was set by the remote CPU 1: An IPC18 event was set by the remote CPU Reset type: SYSRSn

Table 6-26. IPCSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
17	IPC17	R	0h	Indicates to the local CPU if the IPC17 event flag was set by the remote CPU. 0: No IPC17 event was set by the remote CPU 1: An IPC17 event was set by the remote CPU Reset type: SYSRSn
16	IPC16	R	0h	Indicates to the local CPU if the IPC16 event flag was set by the remote CPU. 0: No IPC16 event was set by the remote CPU 1: An IPC16 event was set by the remote CPU Reset type: SYSRSn
15	IPC15	R	0h	Indicates to the local CPU if the IPC15 event flag was set by the remote CPU. 0: No IPC15 event was set by the remote CPU 1: An IPC15 event was set by the remote CPU Reset type: SYSRSn
14	IPC14	R	0h	Indicates to the local CPU if the IPC14 event flag was set by the remote CPU. 0: No IPC14 event was set by the remote CPU 1: An IPC14 event was set by the remote CPU Reset type: SYSRSn
13	IPC13	R	0h	Indicates to the local CPU if the IPC13 event flag was set by the remote CPU. 0: No IPC13 event was set by the remote CPU 1: An IPC13 event was set by the remote CPU Reset type: SYSRSn
12	IPC12	R	0h	Indicates to the local CPU if the IPC12 event flag was set by the remote CPU. 0: No IPC12 event was set by the remote CPU 1: An IPC12 event was set by the remote CPU Reset type: SYSRSn
11	IPC11	R	0h	Indicates to the local CPU if the IPC11 event flag was set by the remote CPU. 0: No IPC11 event was set by the remote CPU 1: An IPC11 event was set by the remote CPU Reset type: SYSRSn
10	IPC10	R	0h	Indicates to the local CPU if the IPC10 event flag was set by the remote CPU. 0: No IPC10 event was set by the remote CPU 1: An IPC10 event was set by the remote CPU Reset type: SYSRSn
9	IPC9	R	0h	Indicates to the local CPU if the IPC9 event flag was set by the remote CPU. 0: No IPC9 event was set by the remote CPU 1: An IPC9 event was set by the remote CPU Reset type: SYSRSn

Table 6-26. IPCSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
8	IPC8	R	0h	Indicates to the local CPU if the IPC8 event flag was set by the remote CPU. 0: No IPC8 event was set by the remote CPU 1: An IPC8 event was set by the remote CPU Reset type: SYSRSn
7	IPC7	R	0h	Indicates to the local CPU if the IPC7 event flag was set by the remote CPU. 0: No IPC7 event was set by the remote CPU 1: An IPC7 event was set by the remote CPU Reset type: SYSRSn
6	IPC6	R	0h	Indicates to the local CPU if the IPC6 event flag was set by the remote CPU. 0: No IPC6 event was set by the remote CPU 1: An IPC6 event was set by the remote CPU Reset type: SYSRSn
5	IPC5	R	0h	Indicates to the local CPU if the IPC5 event flag was set by the remote CPU. 0: No IPC5 event was set by the remote CPU 1: An IPC5 event was set by the remote CPU Reset type: SYSRSn
4	IPC4	R	0h	Indicates to the local CPU if the IPC4 event flag was set by the remote CPU. 0: No IPC4 event was set by the remote CPU 1: An IPC4 event was set by the remote CPU Reset type: SYSRSn
3	IPC3	R	0h	Indicates to the local CPU if the IPC3 event flag was set by the remote CPU. 0: No IPC3 event was set by the remote CPU 1: An IPC3 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
2	IPC2	R	0h	Indicates to the local CPU if the IPC2 event flag was set by the remote CPU. 0: No IPC2 event was set by the remote CPU 1: An IPC2 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
1	IPC1	R	0h	Indicates to the local CPU if the IPC1 event flag was set by the remote CPU. 0: No IPC1 event was set by the remote CPU 1: An IPC1 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn

Table 6-26. IPCSTS Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
0	IPC0	R	0h	Indicates to the local CPU if the IPC0 event flag was set by the remote CPU. 0: No IPC0 event was set by the remote CPU 1: An IPC0 event was set by the remote CPU Notes [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn

6.7.3.3 IPCSET Register (Offset = 4h) [reset = 0h]

IPCSET is shown in [Figure 6-22](#) and described in [Table 6-27](#).

Return to [Summary Table](#).

Table 6-27. IPCSET Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R=0/W=1	0h	Writing 1 to this bit sets the IPC31 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
30	IPC30	R=0/W=1	0h	Writing 1 to this bit sets the IPC30 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
29	IPC29	R=0/W=1	0h	Writing 1 to this bit sets the IPC29 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
28	IPC28	R=0/W=1	0h	Writing 1 to this bit sets the IPC28 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
27	IPC27	R=0/W=1	0h	Writing 1 to this bit sets the IPC27 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
26	IPC26	R=0/W=1	0h	Writing 1 to this bit sets the IPC26 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
25	IPC25	R=0/W=1	0h	Writing 1 to this bit sets the IPC25 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
24	IPC24	R=0/W=1	0h	Writing 1 to this bit sets the IPC24 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
23	IPC23	R=0/W=1	0h	Writing 1 to this bit sets the IPC23 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn

Table 6-27. IPCSET Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
22	IPC22	R=0/W=1	0h	Writing 1 to this bit sets the IPC22 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
21	IPC21	R=0/W=1	0h	Writing 1 to this bit sets the IPC21 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
20	IPC20	R=0/W=1	0h	Writing 1 to this bit sets the IPC20 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
19	IPC19	R=0/W=1	0h	Writing 1 to this bit sets the IPC19 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
18	IPC18	R=0/W=1	0h	Writing 1 to this bit sets the IPC18 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
17	IPC17	R=0/W=1	0h	Writing 1 to this bit sets the IPC17 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
16	IPC16	R=0/W=1	0h	Writing 1 to this bit sets the IPC16 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
15	IPC15	R=0/W=1	0h	Writing 1 to this bit sets the IPC15 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
14	IPC14	R=0/W=1	0h	Writing 1 to this bit sets the IPC14 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
13	IPC13	R=0/W=1	0h	Writing 1 to this bit sets the IPC13 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
12	IPC12	R=0/W=1	0h	Writing 1 to this bit sets the IPC12 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
11	IPC11	R=0/W=1	0h	Writing 1 to this bit sets the IPC11 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
10	IPC10	R=0/W=1	0h	Writing 1 to this bit sets the IPC10 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
9	IPC9	R=0/W=1	0h	Writing 1 to this bit sets the IPC9 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
8	IPC8	R=0/W=1	0h	Writing 1 to this bit sets the IPC8 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
7	IPC7	R=0/W=1	0h	Writing 1 to this bit sets the IPC7 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn

Table 6-27. IPCSET Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	IPC6	R=0/W=1	0h	Writing 1 to this bit sets the IPC6 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
5	IPC5	R=0/W=1	0h	Writing 1 to this bit sets the IPC5 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
4	IPC4	R=0/W=1	0h	Writing 1 to this bit sets the IPC4 event flag for the remote CPU. Writing 0 has no effect. Reset type: SYSRSn
3	IPC3	R=0/W=1	0h	Writing 1 to this bit sets the IPC3 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
2	IPC2	R=0/W=1	0h	Writing 1 to this bit sets the IPC2 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
1	IPC1	R=0/W=1	0h	Writing 1 to this bit sets the IPC1 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn
0	IPC0	R=0/W=1	0h	Writing 1 to this bit sets the IPC0 event flag for the remote CPU. Writing 0 has no effect. Notes: [1] IPC event flags 0-3 will trigger interrupts in the receiving CPU via the ePIE. Reset type: SYSRSn

6.7.3.4 IPCCLR Register (Offset = 6h) [reset = 0h]

IPCCLR is shown in [Figure 6-23](#) and described in [Table 6-28](#).

Return to [Summary Table](#).

Table 6-28. IPCCLR Register Field Descriptions

Bit	Field	Type	Reset	Description
31	IPC31	R=0/W=1	0h	Writing 1 to this bit clears the IPC31 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
30	IPC30	R=0/W=1	0h	Writing 1 to this bit clears the IPC30 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
29	IPC29	R=0/W=1	0h	Writing 1 to this bit clears the IPC29 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
28	IPC28	R=0/W=1	0h	Writing 1 to this bit clears the IPC28 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-28. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	IPC27	R=0/W=1	0h	Writing 1 to this bit clears the IPC27 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
26	IPC26	R=0/W=1	0h	Writing 1 to this bit clears the IPC26 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
25	IPC25	R=0/W=1	0h	Writing 1 to this bit clears the IPC25 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
24	IPC24	R=0/W=1	0h	Writing 1 to this bit clears the IPC24 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
23	IPC23	R=0/W=1	0h	Writing 1 to this bit clears the IPC23 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
22	IPC22	R=0/W=1	0h	Writing 1 to this bit clears the IPC22 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
21	IPC21	R=0/W=1	0h	Writing 1 to this bit clears the IPC21 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-28. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	IPC20	R=0/W=1	0h	Writing 1 to this bit clears the IPC20 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
19	IPC19	R=0/W=1	0h	Writing 1 to this bit clears the IPC19 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
18	IPC18	R=0/W=1	0h	Writing 1 to this bit clears the IPC18 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
17	IPC17	R=0/W=1	0h	Writing 1 to this bit clears the IPC17 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
16	IPC16	R=0/W=1	0h	Writing 1 to this bit clears the IPC16 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
15	IPC15	R=0/W=1	0h	Writing 1 to this bit clears the IPC15 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
14	IPC14	R=0/W=1	0h	Writing 1 to this bit clears the IPC14 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-28. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	IPC13	R=0/W=1	0h	Writing 1 to this bit clears the IPC13 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
12	IPC12	R=0/W=1	0h	Writing 1 to this bit clears the IPC12 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
11	IPC11	R=0/W=1	0h	Writing 1 to this bit clears the IPC11 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
10	IPC10	R=0/W=1	0h	Writing 1 to this bit clears the IPC10 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
9	IPC9	R=0/W=1	0h	Writing 1 to this bit clears the IPC9 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
8	IPC8	R=0/W=1	0h	Writing 1 to this bit clears the IPC8 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
7	IPC7	R=0/W=1	0h	Writing 1 to this bit clears the IPC7 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

Table 6-28. IPCCLR Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	IPC6	R=0/W=1	0h	Writing 1 to this bit clears the IPC6 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
5	IPC5	R=0/W=1	0h	Writing 1 to this bit clears the IPC5 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
4	IPC4	R=0/W=1	0h	Writing 1 to this bit clears the IPC4 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
3	IPC3	R=0/W=1	0h	Writing 1 to this bit clears the IPC3 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
2	IPC2	R=0/W=1	0h	Writing 1 to this bit clears the IPC2 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
1	IPC1	R=0/W=1	0h	Writing 1 to this bit clears the IPC1 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn
0	IPC0	R=0/W=1	0h	Writing 1 to this bit clears the IPC0 flag for the remote CPU. Writing 0 has no effect. Notes: [1] Normally, each CPU will clear (acknowledge) only its own local flags. This mechanism may be useful if the remote CPU is non-responsive. Reset type: SYSRSn

6.7.3.5 IPCFLG Register (Offset = 8h) [reset = 0h]

IPCFLG is shown in [Figure 6-24](#) and described in [Table 6-29](#).

Return to [Summary Table](#).

General-Purpose Input/Output (GPIO)

The GPIO module controls the device's digital I/O MUX, which uses shared pins to maximize application flexibility. The pins are named by their general-purpose I/O name (for example, GPIO0, GPIO25, GPIO58). These pins can be individually selected to operate as digital I/O (also called GPIO mode), or connected to one of several peripheral I/O signals. You can qualify the input signals to remove unwanted noise.

Topic	Page
7.1 GPIO Overview	906
7.2 Configuration Overview	907
7.3 Digital General-Purpose I/O Control	907
7.4 Input Qualification	909
7.5 USB Signals	912
7.6 SPI Signals	912
7.7 GPIO and Peripheral Muxing	914
7.8 Internal Pullup Configuration Requirements	919
7.9 Registers	921

There are two key features to note in this diagram. The first is that the input and output paths are entirely separate, connecting only at the pin. The second is that peripheral muxing takes place far from the pin. As a result, it is always possible for both CPUs and CLAs to read the physical state of the pin independent of CPU mastering and peripheral muxing. Likewise, external interrupts can be generated from peripheral activity. All pin options such as input qualification and open-drain output are valid for all masters and peripherals. However, the peripheral muxing, CPU muxing, and pin options can only be configured by CPU1.

A separate configuration is required for the USB signals. See [Section 7.5](#) for details.

7.2 Configuration Overview

I/O pin configuration consists of several steps:

1. Plan the device pin-out

Make a list of all required peripherals for the application. Using the peripheral mux information in the device data manual, choose which GPIOs to use for the peripheral signals. Decide which of the remaining GPIOs to use as inputs and outputs for each CPU and CLA. Note that GPIOs 42, 43, 46, and 47 are the only available USB pins. GPIO41 is hard-wired to be the wake-up signal in hibernate mode.

Once the peripheral muxing has been chosen, it should be implemented by writing the appropriate values to the GPyMUX1/2 and GPyGMUX1/2 registers. When changing the GPyGMUX value for a pin, always set the corresponding GPyMUX bits to zero first to avoid glitching in the muxes. By default, all pins are general-purpose I/Os, not peripheral signals.

2. (Optional) Enable internal pullup resistors

To enable or disable the pullup resistors, write to the appropriate bits in the GPIO pullup disable registers (GPyPUD). All pullups are disabled by default. pullups can be used to keep input pins in a known state when there is no external signal driving them.

3. Select input qualification

If the pin will be used as an input, specify the required input qualification, if any. The input qualification sampling period is selected in the GPyCTRL registers, while the type of qualification is selected in the GPyQSEL1 and GPyQSEL2 registers. By default, all qualification is synchronous with a sampling period equal to PLLSYSCLK. For an explanation of input qualification, see [section Section 7.4](#).

4. Select the direction of any general-purpose I/O pins

For each pin configured as a GPIO, specify the direction of the pin as either input or output using the GPyDIR registers. By default, all GPIO pins are inputs. Before changing a pin to an output, load the output latch with the value to be driven by writing that value to the GPySET, GPyCLEAR, or GPyDAT registers. Once the latch is loaded, write to GPyDIR to change the pin direction. By default, all output latches are zero.

5. Select low-power mode wake-up sources

GPIOs 0-63 can be used to wake the system up from Standby or Halt mode. To select one or more GPIOs for wake-up, write to the appropriate bits in the GPIOLPMSEL0 and GPIOLPMSEL1 registers. These registers are part of the CPU system register space. In Hibernate mode, GPIO 41 is the only wake-up pin. For more information on low-power modes and GPIO wake-up, see the Low Power Modes section in the *System Control and Interrupts* chapter.

6. Select external interrupt sources

Configuring external interrupts is a two-step process. First, the interrupts themselves must be enabled and their polarity must be configured via the XINTnCR registers. Second, the XINT1-5 GPIO pins must be set by selecting the sources for Input X-BAR signals 4, 5, 6, 13, and 14, respectively. For more information on the Input X-BAR architecture, see the *ePWM* chapter of this manual.

7.3 Digital General-Purpose I/O Control

The values on the pins that are configured as GPIO can be changed by using these registers.

• GPyDAT Registers

Each I/O port has one data register. Each bit in the data register corresponds to one GPIO pin. No matter how the pin is configured (GPIO or peripheral function), the corresponding bit in the data register reflects the current state of the pin after qualification. Writing to the GPyDAT register clears or sets the corresponding output latch and if the pin is enabled as a general purpose output (GPIO

output) the pin will also be driven either low or high. If the pin is not configured as a GPIO output then the value will be latched, but the pin will not be driven. Only if the pin is later configured as a GPIO output, will the latched value be driven onto the pin.

When using the GPyDAT register to change the level of an output pin, you should be cautious not to accidentally change the level of another pin. For example, if you mean to change the output latch level of GPIOA1 by writing to the GPADAT register bit 0 using a read-modify-write instruction, a problem can occur if another I/O port A signal changes level between the read and the write stage of the instruction. Following is an analysis of why this happens:

The GPyDAT registers reflect the state of the pin, not the latch. This means the register reflects the actual pin value. However, there is a lag between when the register is written to when the new pin value is reflected back in the register. This may pose a problem when this register is used in subsequent program statements to alter the state of GPIO pins. An example is shown below where two program statements attempt to drive two different GPIO pins that are currently low to a high state.

If Read-Modify-Write operations are used on the GPyDAT registers, because of the delay between the output and the input of the first instruction (I1), the second instruction (I2) will read the old value and write it back.

```
GpioDataRegs.GPADAT.bit.GPIO1 = 1; //I1 performs read-modify-write of GPADAT
GpioDataRegs.GPADAT.bit.GPIO2 = 1; //I2 also a read-modify-write of GPADAT.
                                   //GPADAT gets the old value of GPIO1 due to the delay
```

The second instruction will wait for the first to finish its write due to the write-followed-by-read protection on this peripheral frame. There will be some lag, however, between the write of (I1) and the GPyDAT bit reflecting the new value (1) on the pin. During this lag, the second instruction will read the old value of GPIO1 (0) and write it back along with the new value of GPIO2 (1). Therefore, GPIO1 pin stays low.

One solution is to put some NOPs between instructions. A better solution is to use the GPySET/GPyCLEAR/GPyTOGGLE registers instead of the GPyDAT registers. These registers always read back a 0 and writes of 0 have no effect. Only bits that need to be changed can be specified without disturbing any other bit(s) that are currently in the process of changing.

- **GPySET Registers**

The set registers are used to drive specified GPIO pins high without disturbing other pins. Each I/O port has one set register and each bit corresponds to one GPIO pin. The set registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the set register will set the output latch high and the corresponding pin will be driven high. If the pin is not configured as a GPIO output, then the value will be latched but the pin will not be driven. Only if the pin is later configured as a GPIO output will the latched value will be driven onto the pin. Writing a 0 to any bit in the set registers has no effect.

- **GPyCLEAR Registers**

The clear registers are used to drive specified GPIO pins low without disturbing other pins. Each I/O port has one clear register. The clear registers always read back 0. If the corresponding pin is configured as a general purpose output, then writing a 1 to the corresponding bit in the clear register will clear the output latch and the pin will be driven low. If the pin is not configured as a GPIO output, then the value will be latched but the pin will not be driven. Only if the pin is later configured as a GPIO output will the latched value will be driven onto the pin. Writing a 0 to any bit in the clear registers has no effect.

- **GPyTOGGLE Registers**

The toggle registers are used to drive specified GPIO pins to the opposite level without disturbing other pins. Each I/O port has one toggle register. The toggle registers always read back 0. If the corresponding pin is configured as an output, then writing a 1 to that bit in the toggle register flips the output latch and pulls the corresponding pin in the opposite direction. That is, if the output pin is driven low, then writing a 1 to the corresponding bit in the toggle register will pull the pin high. Likewise, if the output pin is high, then writing a 1 to the corresponding bit in the toggle register will pull the pin low. If the pin is not configured as a GPIO output, then the value will be latched but the pin will not be driven. Only if the pin is later configured as a GPIO output will the latched value will be driven onto the pin. Writing a 0 to any bit in the toggle registers has no effect.

7.4 Input Qualification

The input qualification scheme has been designed to be very flexible. You can select the type of input qualification for each GPIO pin by configuring the GPyQSEL1 and GPyQSEL2 registers. In the case of a GPIO input pin, the qualification can be specified as only synchronize to SYSCLKOUT or qualification by a sampling window. For pins that are configured as peripheral inputs, the input can also be asynchronous in addition to synchronized to SYSCLKOUT or qualified by a sampling window. The remainder of this section describes the options available.

7.4.1 No Synchronization (Asynchronous Input)

This mode is used for peripherals where input synchronization is not required or the peripheral itself performs the synchronization. Examples include communication ports McBSP, SCI, SPI, and I²C. In addition, it may be desirable to have the ePWM trip zone ($\overline{TZn}$) signals function independent of the presence of SYSCLKOUT.

The asynchronous option is not valid if the pin is used as a general purpose digital input pin (GPIO). If the pin is configured as a GPIO input and the asynchronous option is selected then the qualification defaults to synchronization to SYSCLKOUT as described in [Section 7.4.2](#).

NOTE: Using input synchronization when the peripheral itself performs the synchronization may cause unexpected results. The user should ensure that the GPIO pin is configured for asynchronous in this case.

7.4.2 Synchronization to SYSCLKOUT Only

This is the default qualification mode of all the pins at reset. In this mode, the input signal is only synchronized to the system clock (SYSCLKOUT). Because the incoming signal is asynchronous, it can take up to a SYSCLKOUT period of delay in order for the input to the MCU to be changed. No further qualification is performed on the signal.

7.4.3 Qualification Using a Sampling Window

In this mode, the signal is first synchronized to the system clock (SYSCLKOUT) and then qualified by a specified number of cycles before the input is allowed to change. [Figure 7-2](#) and [Figure 7-3](#) show how the input qualification is performed to eliminate unwanted noise. Two parameters are specified by the user for this type of qualification: 1) the sampling period, or how often the signal is sampled, and 2) the number of samples to be taken.

Figure 7-2. Input Qualification Using a Sampling Window

Time between samples (sampling period):

To qualify the signal, the input signal is sampled at a regular period. The sampling period is specified by the user and determines the time duration between samples, or how often the signal will be sampled, relative to the CPU clock (SYSCLKOUT).

The sampling period is specified by the qualification period (QUALPRDn) bits in the GPxCTRL register. The sampling period is configurable in groups of 8 input signals. For example, GPIO0 to GPIO7 use GPACTRL[QUALPRD0] setting and GPIO8 to GPIO15 use GPACTRL[QUALPRD1]. [Table 7-1](#) and [Table 7-2](#) show the relationship between the sampling period or sampling frequency and the GPxCTRL[QUALPRDn] setting.

Table 7-1. Sampling Period

	Sampling Period
If GPxCTRL[QUALPRDn] = 0	$1 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
	Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT

Table 7-2. Sampling Frequency

	Sampling Frequency
If GPxCTRL[QUALPRDn] = 0	$f_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$f_{\text{SYSCLKOUT}} \times 1 \div (2 \times \text{GPxCTRL[QUALPRDn]})$
	Where $f_{\text{SYSCLKOUT}}$ is the frequency of SYSCLKOUT

From these equations, the minimum and maximum time between samples can be calculated for a given SYSCLKOUT frequency:

Example: Maximum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0
then the sampling frequency is $f_{\text{SYSCLKOUT}}$
If, for example, $f_{\text{SYSCLKOUT}} = 60 \text{ MHz}$
then the signal will be sampled at 60 MHz or one sample every 16.67 ns.

Example: Minimum Sampling Frequency:

If GPxCTRL[QUALPRDn] = 0xFF (255)
then the sampling frequency is $f_{\text{SYSCLKOUT}} \times 1 \div (2 \times \text{GPxCTRL[QUALPRDn]})$
If, for example, $f_{\text{SYSCLKOUT}} = 60 \text{ MHz}$
then the signal will be sampled at $60 \text{ MHz} \times 1 \div (2 \times 255)$ or one sample every 8.5 μs .

Number of samples:

The number of times the signal is sampled is either three samples or six samples as specified in the qualification selection (GPAQSEL1, GPAQSEL2, GPBQSEL1, and GPBQSEL2) registers. When three or six consecutive cycles are the same, then the input change will be passed through to the MCU.

Total Sampling Window Width:

The sampling window is the time during which the input signal will be sampled as shown in [Figure 7-3](#). By using the equation for the sampling period along with the number of samples to be taken, the total width of the window can be determined.

For the input qualifier to detect a change in the input, the level of the signal must be stable for the duration of the sampling window width or longer.

The number of sampling periods within the window is always one less than the number of samples taken. For a three-sample window, the sampling window width is two sampling periods wide where the sampling period is defined in [Table 7-1](#). Likewise, for a six-sample window, the sampling window width is five sampling periods wide. [Table 7-3](#) and [Table 7-4](#) show the calculations that can be used to determine the total sampling window width based on GPxCTRL[QUALPRDn] and the number of samples taken.

Table 7-3. Case 1: Three-Sample Sampling Window Width

	Total Sampling Window Width
If GPxCTRL[QUALPRDn] = 0	$2 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$2 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
	Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT

Table 7-4. Case 2: Six-Sample Sampling Window Width

	Total Sampling Window Width
If GPxCTRL[QUALPRDn] = 0	$5 \times T_{\text{SYSCLKOUT}}$
If GPxCTRL[QUALPRDn] $\neq$ 0	$5 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$
	Where $T_{\text{SYSCLKOUT}}$ is the period in time of SYSCLKOUT

NOTE: The external signal change is asynchronous with respect to both the sampling period and SYSCLKOUT. Due to the asynchronous nature of the external signal, the input should be held stable for a time greater than the sampling window width to make sure the logic detects a change in the signal. The extra time required can be up to an additional sampling period + $T_{\text{SYSCLKOUT}}$.

The required duration for an input signal to be stable for the qualification logic to detect a change is described in the device-specific data manual.

Example Qualification Window:

For the example shown in [Figure 7-3](#), the input qualification has been configured as follows:

- GPxQSEL1/2 = 1,0. This indicates a six-sample qualification.
- GPxCTRL[QUALPRDn] = 1. The sampling period is $t_w(\text{SP}) = 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}}$.

This configuration results in the following:

- The width of the sampling window is:

$$t_w(\text{IQSW}) = 5 \times t_w(\text{SP}) = 5 \times 2 \times \text{GPxCTRL[QUALPRDn]} \times T_{\text{SYSCLKOUT}} \text{ or } 5 \times 2 \times T_{\text{SYSCLKOUT}}$$
- If, for example, $T_{\text{SYSCLKOUT}} = 16.67 \text{ ns}$, then the duration of the sampling window is:

$$t_w(\text{IQSW}) = 5 \times 2 \times 16.67 \text{ ns} = 166.7 \text{ ns}.$$
- To account for the asynchronous nature of the input relative to the sampling period and SYSCLKOUT, up to an additional sampling period, $t_w(\text{SP})$, + $T_{\text{SYSCLKOUT}}$ may be required to detect a change in the input signal. For this example:

$$t_w(\text{SP}) + T_{\text{SYSCLKOUT}} = 333.4 \text{ ns} + 166.67 \text{ ns} = 500.1 \text{ ns}$$
- In [Figure 7-3](#), the glitch (A) is shorter than the qualification window and will be ignored by the input qualifier.

Figure 7-3. Input Qualifier Clock Cycles

- This glitch will be ignored by the input qualifier. The QUALPRD bit field specifies the qualification sampling period. It can vary from 00 to 0xFF. If QUALPRD = 00, then the sampling period is 1 SYSCLKOUT cycle. For any other value "n", the qualification sampling period in 2n SYSCLKOUT cycles (i.e., at every 2n SYSCLKOUT cycles, the GPIO pin will be sampled).
- The qualification period selected via the GPxCTRL register applies to groups of 8 GPIO pins.
- The qualification block can take either three or six samples. The GPxQSELn Register selects which sample mode is used.
- In the example shown, for the qualifier to detect the change, the input should be stable for 10 SYSCLKOUT cycles or greater. In other words, the inputs should be stable for $(5 \times QUALPRD \times 2)$ SYSCLKOUT cycles. That would ensure 5 sampling periods for detection to occur. Since external signals are driven asynchronously, an 13-SYSCLKOUT-wide pulse ensures reliable recognition.

7.5 USB Signals

The USB module on this device has an internal physical layer transceiver (PHY). Its I/O signals are not normal digital signals, and as a result, they do not connect to the pins through the normal GPIO mux path. Instead, a special analog mux is used. To connect the USB signals to the device pins, set the GPyAMSEL bits appropriately as shown in [Table 7-5](#). Do not enable pullups or any other special pin option when using the USB signals.

Table 7-5. USB I/O Signal Muxing

Signal	GPIO	AMSEL
USBDM	42	GPBAMSEL[10]
USBDP	43	GPBAMSEL[11]

7.6 SPI Signals

The SPI module on this device has a high-speed mode that enables 40 Mbps communication. To achieve the highest possible speed, a special GPIO configuration is used on a single GPIO mux option for each SPI. These GPIOs may also be used by the SPI when not in high-speed mode (HS_MODE = 0). [Table 7-6](#) shows which GPIOs have the special mux option to allow SPI high-speed mode.

Table 7-6. High-Speed SPI-Enabled GPIOs

SPI pin	SPIA	SPIB	SPIC
SPISIMO	GPIO58	GPIO63	GPIO69
SPISOMI	GPIO59	GPIO64	GPIO70
SPICLK	GPIO60	GPIO65	GPIO71
$\overline{\text{SPISTE}}$	GPIO61	GPIO66	GPIO72

To select these mux options the user should configure GPyGMUX and GPyMUX registers as shown in [Table 7-7](#).

Table 7-7. GPIO Configuration for High-Speed SPI

GPIO	SPI Signal	Mux Configuration	
GPIO58	SPISIMOA	GPBGMUX2[21:20]=11	GPBMUX2[21:20]=11

GPIO69	SPISIMOC	GPCGMUX1[11:10]=11	GPCMUX1[11:10]=11
GPIO70	SPISOMIC	GPCGMUX1[13:12]=11	GPCMUX1[13:12]=11
GPIO71	SPICLKC	GPCGMUX1[15:14]=11	GPCMUX1[15:14]=11
GPIO72	$\overline{\text{SPISTEC}}$	GPCGMUX1[17:16]=11	GPCMUX1[17:16]=11

7.7 GPIO and Peripheral Muxing

Up to twelve different peripheral functions are multiplexed to each pin along with a general-purpose input/output (GPIO) function. This allows you to choose the peripheral mix and pinout that will work best for your particular application. Refer to the table below for muxing combinations and definitions.

Table 7-8. GPIO Muxed Pins⁽¹⁾⁽²⁾

For example, the multiplexing for the GPIO 6 pin is controlled by writing to GPAGMUX[13:12] and GPAMUX[13:12]. By writing to these bits, GPIO 6 can be configured as either a general-purpose digital I/O or one of four different peripheral functions. The options are shown in [Table 7-9](#).

Table 7-9. GPIO and Peripheral Muxing

GPAGMUX1[13:12]	GPAMUX1[13:12]	Pin functionality
00	00	GPIO
00	01	EPWM4A

Table 7-9. GPIO and Peripheral Muxing (continued)

GPAGMUX1[13:12]	GPAMUX1[13:12]	Pin functionality
00	10	OUTPUTXBAR4
00	11	EXTSYNCOUT
01	00	GPIO
01	01	EQEP3A
01	10	CANTXB
10	00	GPIO
11	00	GPIO
All others		Reserved

The devices have different multiplexing schemes. If a peripheral is not available on a particular device, that mux selection is reserved on that device and should not be used.

Note: If you select a reserved GPIO mux configuration that is not mapped to either a peripheral or GPIO mode, the state of the pin will be undefined and the pin may be driven. Unimplemented configurations are for future expansion and must not be selected. In the device mux table (see datasheet), these options are indicated as Reserved or left blank.

Some peripherals can be assigned to more than one pin via the mux registers. For example, OUTPUTXBAR1 can be assigned to GPIOs 2, 24, 34, or 58, depending on individual system requirements. An example of this is shown in [Table 7-10](#).

Table 7-10. Peripheral Muxing (multiple pins assigned)

GMUX Configuration	MUX Configuration	
Choice 1 GPIO2	GPAGMUX1[5:4]=01	GPAMUX1[5:4]=01
or Choice 2 GPIO24	GPAGMUX2[17:16]=00	GPAMUX2[17:16]=01
or Choice 3 GPIO34	GPBGMUX1[5:4]=00	GPBMUX1[5:4]=01
or Choice 4 GPIO58	GPBGMUX2[21:20]=01	GPBMUX2[21:20]=01

If no pin is configured as an input to a peripheral, or if more than one pin is configured to an input for the same peripheral, then that input will be set to a hard-wired default value.

7.8 Internal Pullup Configuration Requirements

On reset, GPIOs are in input mode and have the internal pullups disabled. An un-driven input can float to a mid-rail voltage and cause wasted shoot-through current on the input buffer. The user should always put each GPIO in one of these configurations:

- Input mode and driven on the board by another component to a level above V_{ih} or below V_{il}
- Input mode with GPIO internal pullup enabled
- Output mode

On devices in the 176PTP or 100PZP packages, the pullups for any internally unbonded GPIO must be enabled to prevent floating inputs. TI has provided functions in controlSUITE which users can call to enable the pullup on any unbonded GPIO for the package they are using. This function, GPIO_EnabledUnbondedIOPullups(), resides in the (Device)_Sysctrl.c file and is called by default from InitSysCtrl(). The user should take care to avoid disabling these pullups in their application code.

For 176-pin packages, pullup resistors should be enabled on the following GPIOs:

Table 7-11. Pullup Resistors for 176-pin Packages

Unbonded GPIOs on the 176-pin package							
95	106	116	126	137	147	157	167
96	107	117	127	138	148	158	168
97	108	118	128	139	149	159	
98	109	119	129	140	150	160	
100	110	120	130	141	151	161	
101	111	121	131	142	152	162	
102	112	122	132	143	153	163	
103	113	123	134	144	154	164	
104	114	124	135	145	155	165	
105	115	125	136	146	156	166	

For 100-pin packages, pullup resistors should be enabled on the following GPIOs:

Table 7-12. Pullup Resistors for 100-pin Packages

Unbonded GPIOs on the 100-pin package								
0	30	48	77	101	116	131	146	161

Table 7-15. GPIO_CTRL_REGS Registers (continued)

Offset	Acronym	Register Name	Write Protection	Section
104h	GPEQSEL2	GPIO E Qualifier Select 2 Register (GPIO144 to 159)	EALLOW	Go
106h	GPEMUX1	GPIO E Mux 1 Register (GPIO128 to 143)	EALLOW	Go
108h	GPEMUX2	GPIO E Mux 2 Register (GPIO144 to 159)	EALLOW	Go
10Ah	GPEDIR	GPIO E Direction Register (GPIO128 to 159)	EALLOW	Go
10Ch	GPEPUD	GPIO E Pull Up Disable Register (GPIO128 to 159)	EALLOW	Go
110h	GPEINV	GPIO E Input Polarity Invert Registers (GPIO128 to 159)	EALLOW	Go
112h	GPEODR	GPIO E Open Drain Output Register (GPIO128 to GPIO159)	EALLOW	Go
120h	GPEGMUX1	GPIO E Peripheral Group Mux (GPIO128 to 143)	EALLOW	Go
122h	GPEGMUX2	GPIO E Peripheral Group Mux (GPIO144 to 159)	EALLOW	Go
128h	GPECSEL1	GPIO E Core Select Register (GPIO128 to 135)	EALLOW	Go
12Ah	GPECSEL2	GPIO E Core Select Register (GPIO136 to 143)	EALLOW	Go
12Ch	GPECSEL3	GPIO E Core Select Register (GPIO144 to 151)	EALLOW	Go
12Eh	GPECSEL4	GPIO E Core Select Register (GPIO152 to 159)	EALLOW	Go
13Ch	GPELOCK	GPIO E Lock Configuration Register (GPIO128 to 159)	EALLOW	Go
13Eh	GPECR	GPIO E Lock Commit Register (GPIO128 to 159)	EALLOW	Go
140h	GPFCtrl	GPIO F Qualification Sampling Period Control (GPIO160 to 168)	EALLOW	Go
142h	GPFQSEL1	GPIO F Qualifier Select 1 Register (GPIO160 to 168)	EALLOW	Go
146h	GPFMUX1	GPIO F Mux 1 Register (GPIO160 to 168)	EALLOW	Go
14Ah	GPFDIR	GPIO F Direction Register (GPIO160 to 168)	EALLOW	Go
14Ch	GPFPUD	GPIO F Pull Up Disable Register (GPIO160 to 168)	EALLOW	Go
150h	GPFINV	GPIO F Input Polarity Invert Registers (GPIO160 to 168)	EALLOW	Go
152h	GPFODR	GPIO F Open Drain Output Register (GPIO160 to GPIO168)	EALLOW	Go
160h	GPFGMUX1	GPIO F Peripheral Group Mux (GPIO160 to 168)	EALLOW	Go
168h	GPFCSEL1	GPIO F Core Select Register (GPIO160 to 167)	EALLOW	Go
16Ah	GPFCSEL2	GPIO F Core Select Register (GPIO168)	EALLOW	Go
17Ch	GPFLock	GPIO F Lock Configuration Register (GPIO160 to 168)	EALLOW	Go
17Eh	GPFCR	GPIO F Lock Commit Register (GPIO160 to 168)	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. [Table 7-16](#) shows the codes that are used for access types in this section.

Table 7-16. GPIO_CTRL_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
WOnce	W	Write
Reset or Default Value		

Table 7-16. GPIO_CTRL_REGS Access Type Codes (continued)

Access Type	Code	Description
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.9.2.1 GPACTRL Register (Offset = 0h) [reset = 0h]

GPACTRL is shown in [Figure 7-4](#) and described in [Table 7-17](#).

Return to [Summary Table](#).

GPIO A Qualification Sampling Period Control (GPIO0 to 31)

Figure 7-4. GPACTRL Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

7.9.2.4 GPAMUX1 Register (Offset = 6h) [reset = 0h]

GPAMUX1 is shown in [Figure 7-7](#) and described in [Table 7-20](#).

Return to [Summary Table](#).

GPIO A Mux 1 Register (GPIO0 to 15)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO.

Figure 7-7. GPAMUX1 Register

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

7.9.2.6 GPADIR Register (Offset = Ah) [reset = 0h]

GPADIR is shown in [Figure 7-9](#) and described in [Table 7-22](#).

Return to [Summary Table](#).

GPIO A Direction Register (GPIO0 to 31)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

Figure 7-9. GPADIR Register

31	30	29	28	27	26	25	24

7.9.2.7 GPAPUD Register (Offset = Ch) [reset = FFFFFFFFh]

GPAPUD is shown in [Figure 7-10](#) and described in [Table 7-23](#).

Return to [Summary Table](#).

GPIO A Pull Up Disable Register (GPIO0 to 31)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

Figure 7-10. GPAPUD Register

7.9.2.8 GPAINV Register (Offset = 10h) [reset = 0h]

GPAINV is shown in [Figure 7-11](#) and described in [Table 7-24](#).

Return to [Summary Table](#).

GPIO A Input Polarity Invert Registers (GPIO0 to 31)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

Figure 7-11. GPAINV Register

7.9.2.9 GPAODR Register (Offset = 12h) [reset = 0h]

GPAODR is shown in [Figure 7-12](#) and described in [Table 7-25](#).

Return to [Summary Table](#).

GPIO A Open Drain Output Register (GPIO0 to GPIO31)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

19-16	GPIO28	R/W	0h	Selects which master's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
15-12	GPIO27	R/W	0h	Selects which master's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
11-8	GPIO26	R/W	0h	Selects which master's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
7-4	GPIO25	R/W	0h	Selects which master's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn
3-0	GPIO24	R/W	0h	Selects which master's GPIODAT/SET/CLEAR/TOGGLE registers control this GPIO pin Reset type: SYSRSn

7.9.2.16 GPALOCK Register (Offset = 3Ch) [reset = 0h]

GPALOCK is shown in [Figure 7-19](#) and described in [Table 7-32](#).

Return to [Summary Table](#).

GPIO A Lock Configuration Register (GPIO0 to 31)

GPIO Configuration Lock for GPIO.

0: Bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx register which control the same pin can be changed

1: Locks changes to the bits in GPyMUX1, GPyMUX2, GPyDIR, GPyINV, GPyODR, GPyAMSEL, GPyGMUX1, GPyGMUX2 and GPyCSELx registers which control the same pin

7.9.2.23 GPBDIR Register (Offset = 4Ah) [reset = 0h]

GPBDIR is shown in [Figure 7-26](#) and described in [Table 7-39](#).

Return to [Summary Table](#).

GPIO B Direction Register (GPIO32 to 63)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

7.9.2.24 GPBPUD Register (Offset = 4Ch) [reset = FFFFFFFFh]

GPBPUD is shown in [Figure 7-27](#) and described in [Table 7-40](#).

Return to [Summary Table](#).

GPIO B Pull Up Disable Register (GPIO32 to 63)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

7.9.2.25 GPBINV Register (Offset = 50h) [reset = 0h]

GPBINV is shown in [Figure 7-28](#) and described in [Table 7-41](#).

Return to [Summary Table](#).

GPIO B Input Polarity Invert Registers (GPIO32 to 63)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

7.9.2.26 GPBODR Register (Offset = 52h) [reset = 0h]

GPBODR is shown in [Figure 7-29](#) and described in [Table 7-42](#).

Return to [Summary Table](#).

GPIO B Open Drain Output Register (GPIO32 to GPIO63)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

7.9.2.41 GPCDIR Register (Offset = 8Ah) [reset = 0h]

GPCDIR is shown in [Figure 7-44](#) and described in [Table 7-57](#).

Return to [Summary Table](#).

GPIO C Direction Register (GPIO64 to 95)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

7.9.2.42 GPCPUD Register (Offset = 8Ch) [reset = FFFFFFFFh]

GPCPUD is shown in [Figure 7-45](#) and described in [Table 7-58](#).

Return to [Summary Table](#).

GPIO C Pull Up Disable Register (GPIO64 to 95)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

7.9.2.43 GPCINV Register (Offset = 90h) [reset = 0h]

GPCINV is shown in [Figure 7-46](#) and described in [Table 7-59](#).

Return to [Summary Table](#).

GPIO C Input Polarity Invert Registers (GPIO64 to 95)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

7.9.2.44 GPCODR Register (Offset = 92h) [reset = 0h]

GPCODR is shown in [Figure 7-47](#) and described in [Table 7-60](#).

Return to [Summary Table](#).

GPIO C Open Drain Output Register (GPIO64 to GPIO95)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

3-2	GPIO113	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn
1-0	GPIO112	R/W	0h	Defines pin-muxing selection for GPIO Reset type: SYSRSn

7.9.2.58 GPDDIR Register (Offset = CAh) [reset = 0h]

GPDDIR is shown in [Figure 7-61](#) and described in [Table 7-74](#).

Return to [Summary Table](#).

GPIO D Direction Register (GPIO96 to 127)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

7.9.2.59 GPDPU Register (Offset = CCh) [reset = FFFFFFFFh]

GPDPU is shown in [Figure 7-62](#) and described in [Table 7-75](#).

Return to [Summary Table](#).

GPIO D Pull Up Disable Register (GPIO96 to 127)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

7.9.2.60 GPDINV Register (Offset = D0h) [reset = 0h]

GPDINV is shown in [Figure 7-63](#) and described in [Table 7-76](#).

Return to [Summary Table](#).

GPIO D Input Polarity Invert Registers (GPIO96 to 127)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

7.9.2.61 GPDODR Register (Offset = D2h) [reset = 0h]

GPDODR is shown in [Figure 7-64](#) and described in [Table 7-77](#).

Return to [Summary Table](#).

GPIO D Open Drain Output Register (GPIO96 to GPIO127)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

3-2	GPIO129	R/W	0h	Input qualification type Reset type: SYSRSn
1-0	GPIO128	R/W	0h	Input qualification type Reset type: SYSRSn

7.9.2.72 GPEQSEL2 Register (Offset = 104h) [reset = 0h]

GPEQSEL2 is shown in [Figure 7-75](#) and described in [Table 7-88](#).

Return to [Summary Table](#).

GPIO E Qualifier Select 2 Register (GPIO144 to 159)

Input qualification type:

0,0 Sync

0,1 Qualification (3 samples)

1,0 Qualification (6 samples)

1,1 Async (no Sync or Qualification)

7.9.2.73 GPOMUX1 Register (Offset = 106h) [reset = 0h]

GPOMUX1 is shown in [Figure 7-76](#) and described in [Table 7-89](#).

Return to [Summary Table](#).

GPIO E Mux 1 Register (GPIO128 to 143)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO.

Figure 7-76. GPOMUX1 Register

7.9.2.75 GPEDIR Register (Offset = 10Ah) [reset = 0h]

GPEDIR is shown in [Figure 7-78](#) and described in [Table 7-91](#).

Return to [Summary Table](#).

GPIO E Direction Register (GPIO128 to 159)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

7.9.2.76 GPEPUD Register (Offset = 10Ch) [reset = FFFFFFFFh]

GPEPUD is shown in [Figure 7-79](#) and described in [Table 7-92](#).

Return to [Summary Table](#).

GPIO E Pull Up Disable Register (GPIO128 to 159)

Disables the Pull-Up on GPIO.

0: Enables the Pull-Up.

1: Disables the Pull-Up.

Reading the register returns the current value of the register setting.

7.9.2.77 GPEINV Register (Offset = 110h) [reset = 0h]

GPEINV is shown in [Figure 7-80](#) and described in [Table 7-93](#).

Return to [Summary Table](#).

GPIO E Input Polarity Invert Registers (GPIO128 to 159)

Selects between non-inverted and inverted GPIO input to the device.

0: selects non-inverted GPIO input

1: selects inverted GPIO input

Reading the register returns the current value of the register setting.

7.9.2.78 GPEODR Register (Offset = 112h) [reset = 0h]

GPEODR is shown in [Figure 7-81](#) and described in [Table 7-94](#).

Return to [Summary Table](#).

GPIO E Open Drain Output Register (GPIO128 to GPIO159)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

7.9.2.89 GPFMUX1 Register (Offset = 146h) [reset = 0h]

GPFMUX1 is shown in [Figure 7-92](#) and described in [Table 7-105](#).

Return to [Summary Table](#).

GPIO F Mux 1 Register (GPIO160 to 168)

Defines pin-muxing selection for GPIO.

Notes:

The respective GPyGMUXn.GPIOz must be configured prior to this register to avoid intermediate peripheral selects being mapped to the GPIO.

7.9.2.90 GPFDIR Register (Offset = 14Ah) [reset = 0h]

GPFDIR is shown in [Figure 7-93](#) and described in [Table 7-106](#).

Return to [Summary Table](#).

GPIO F Direction Register (GPIO160 to 168)

Controls direction of GPIO pins when the specified pin is configured in GPIO mode.

0: Configures pin as input.

1: Configures pin as output.

Reading the register returns the current value of the register setting.

7.9.2.93 GPFODR Register (Offset = 152h) [reset = 0h]

GPFODR is shown in [Figure 7-96](#) and described in [Table 7-109](#).

Return to [Summary Table](#).

GPIO F Open Drain Output Register (GPIO160 to GPIO168)

Selects between normal and open-drain output for the GPIO pin.

0: Normal Output

1: Open Drain Output

Reading the register returns the current value of the register setting.

Note:

[1] In the Open Drain output mode, if the buffer is configured for output mode, a 0 value to be driven out comes out on the on the PAD while a 1 value to be driven out tri-states the buffer.

2Eh	GPFTOGGLE	GPIO F Data Toggle Register (GPIO160 to 168)		Go

Complex bit access types are encoded to fit into small table cells. Table 7-116 shows the codes that are used for access types in this section.

Table 7-116. GPIO_DATA_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
Write Type		
W	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

**Table 7-116. GPIO_DATA_REGS Access Type
Codes (continued)**

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

7.9.3.1 GPADAT Register (Offset = 0h) [reset = 0h]

GPADAT is shown in [Figure 7-102](#) and described in [Table 7-117](#).

Return to [Summary Table](#).

GPIO A Data Register (GPIO0 to 31)

Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.

Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode

A system reset will clear all bits and latched values to zero.

NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

7.9.3.5 GPBDAT Register (Offset = 8h) [reset = 0h]

GPBDAT is shown in [Figure 7-106](#) and described in [Table 7-121](#).

Return to [Summary Table](#).

GPIO B Data Register (GPIO32 to 63)

Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode

A system reset will clear all bits and latched values to zero.

NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

7.9.3.9 GPCDAT Register (Offset = 10h) [reset = 0h]

GPCDAT is shown in [Figure 7-110](#) and described in [Table 7-125](#).

Return to [Summary Table](#).

GPIO C Data Register (GPIO64 to 95)

Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode

A system reset will clear all bits and latched values to zero.

NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

Figure 7-110. GPCDAT Register

7.9.3.12 GPCTOGGLE Register (Offset = 16h) [reset = 0h]

GPCTOGGLE is shown in [Figure 7-113](#) and described in [Table 7-128](#).

Return to [Summary Table](#).

GPIO C Data Toggle Register (GPIO64 to 95)

Writing a 1 will toggle GPIO0 output data latch 1 to 0 or 0 to 1.

Writes of 0 are ignored.

Always reads back a 0.

7.9.3.13 GPDDAT Register (Offset = 18h) [reset = 0h]

GPDDAT is shown in [Figure 7-114](#) and described in [Table 7-129](#).

Return to [Summary Table](#).

GPIO D Data Register (GPIO96 to 127)

Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.

Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode

A system reset will clear all bits and latched values to zero.

NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

7.9.3.17 GPEDAT Register (Offset = 20h) [reset = 0h]

GPEDAT is shown in [Figure 7-118](#) and described in [Table 7-133](#).

Return to [Summary Table](#).

GPIO E Data Register (GPIO128 to 159)

Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in. Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO Output mode

A system reset will clear all bits and latched values to zero.

NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

7.9.3.21 GPFDAT Register (Offset = 28h) [reset = 0h]

GPFDAT is shown in [Figure 7-122](#) and described in [Table 7-137](#).

Return to [Summary Table](#).

GPIO F Data Register (GPIO160 to 168)

Reading this register reflects the current state of the GPIO pin regardless of which mode the GPIO is in.

Writing to this register will set the GPIO pin high or low if the pin is enabled for GPIO output mode. If the GPIO is not in output mode the value written is latched but will not be reflected on the GPIO pin or reads of the GPxDAT register. The written value latched will become active when the GPIO is put into GPIO

Output mode

A system reset will clear all bits and latched values to zero.

NOTE: Bit-wise read-modify-write operations should not be performed on this register. For bit-wise operations the GPxSET, GPxCLEAR, or GPxTOGGLE registers should be used instead. If direct writes to GPxDAT are necessary, the entire register should be written at one time.

Crossbar (X-BAR)

The crossbars (referred to as X-BAR throughout this document) provide flexibility to connect device inputs, outputs, and internal resources in a variety of configurations. The device contains a total of three X-BARs: the Input X-BAR, the Output X-BAR, and the ePWM X-BAR. Each of the X-BARs is named according to where they take signals. For example, the Input X-BAR brings external signals “in” to the device. The Output X-BAR takes internal signals “out” of the device to a GPIO. The ePWM X-BAR takes signals and brings them to the ePWM modules. You can read more about each of these X-BARs in the following sections.

Topic	Page
8.1 GPIO Input X-BAR	1138
8.2 ePWM and GPIO Output X-BAR	1139
8.3 X-BAR Registers	1145

8.1 GPIO Input X-BAR

On this device, the Input X-BAR is used to route signals from a GPIO to many different IP blocks such as the ADC(s), eCAP(s), ePWM(s), and external interrupts. The Input X-BAR has access to every GPIO and can route each signal to any (or multiple) of the IP blocks previously mentioned. This flexibility relieves some of the constraints on peripheral muxing by just requiring any GPIO pin to be available. It is important to note that the function selected on the GPIO mux does not affect the Input X-BAR. The Input X-BAR simply connects the signal on the input buffer to the selected destination. Therefore, you can do things such as route the output of one peripheral to another (that is, measure the output of an ePWM with an eCAP for a frequency test).

The Input X-BAR is configured via the INPUTxSELECT registers. The available IP destination(s) for each INPUTx is shown in [Figure 8-1](#). For more information on configuration, see the INPUT_XBAR_REGS register definitions at the end of this chapter.

Figure 8-1. Input X-BAR

Table 8-1. Input X-BAR Destinations

Input	Destinations
INPUT1	ePWM[TZ1,TRIP1], ePWM X-BAR, Output X-BAR
INPUT2	ePWM[TZ2,TRIP2], ePWM X-BAR, Output X-BAR
INPUT3	ePWM[TZ3,TRIP3], ePWM X-BAR, Output X-BAR

INPUT14	XINT5

8.2 ePWM and GPIO Output X-BAR

8.2.1 ePWM X-BAR

The ePWM X-BAR brings signals to the ePWM modules. Specifically, the ePWM X-BAR is connected to the Digital Compare (DC) submodule of each ePWM module for actions such as tripzones and syncing. Please refer to the *ePWM* chapter for more information on additional ways the DC submodule can be used. [Figure 8-4](#) shows the architecture of the ePWM X-BAR. It is worth noting that the architecture of the ePWM X-BAR is identical to the architecture of the Output X-BAR (with the exception of the output latch).

8.2.1.1 ePWM X-BAR Architecture

The ePWM X-BAR has eight outputs which are routed to each ePWM module. [Figure 8-2](#) represents the architecture of a single output but it is identical to the architecture of all of the other outputs.

Figure 8-2. ePWM Architecture - Single Output

First, determine the signal(s) which should be passed to the ePWM by referencing [Table 8-3](#). You may select up to one signal per mux (32 total muxes) for each TRIPx output. Select the inputs to each mux via the TRIPxMUX0TO15CFG and TRIPxMUX16TO31CFG registers. In order to pass any signal through to the ePWM, you must also enable the mux in the TRIPxMUXENABLE register. All muxes which are enabled will be logically OR'd before being passed on to the respective TRIPx signal on the ePWM. You may also optionally invert the signal via the TRIPxOUTINV register.

Table 8-2. ePWM X-BAR Mux Configuration Table

30	SD2FLT4.COMPH	SD2FLT4.COMPH_OR_COMPL		
31	SD2FLT4.COMPL			

⁽¹⁾ This signal is active high when routed through the X-Bar. It may need to be inverted by the respective TRIPOUTINV bit depending on the application.

8.2.2 GPIO Output X-BAR

The GPIO Output X-BAR takes signals from inside the device and brings them out to a GPIO. [Figure 8-3](#) shows the architecture of the GPIO Output X-BAR. The signals which are available to bring to the GPIO are listed in [Table 8-3](#). The X-BAR contains eight outputs and each will contain at least one position on the GPIO mux, denoted as OUTPUTXBARx. The X-BAR allows the selection of a single signal or a logical OR of up to 32 signals.

8.2.2.1 GPIO Output X-BAR Architecture

The Output X-BAR has eight outputs which are routed to the GPIO module. [Figure 8-3](#) represents the architecture of a single output, but it is identical to the architecture of all of the other outputs. It is worth noting that the architecture of the Output X-BAR (with the exception of the output latch) is identical to the architecture of the ePWM X-BAR.

Figure 8-3. GPIO Output X-BAR Architecture

First, determine the signal(s) which should be passed to the GPIO by referencing [Table 8-3](#). You may select up to one signal per mux (32 total muxes) for each OUTPUTXBARx output. Select the inputs to each mux via the OUTPUTxMUX0TO15CFG and OUTPUTxMUX16TO31CFG registers.

In order to pass any signal through to the GPIO, you must also enable the mux in the OUTPUTxMUXENABLE register. All muxes which are enabled will be logically OR'd before being passed on to the respective OUTPUTx signal on the GPIO module. You may also optionally invert the signal via the OUTPUTINV register. The signal will only be seen on the GPIO if the proper OUTPUTx muxing options are selected via the GpioCtrlRegs.GPxMUX and GpioCtrlRegs.GPxGMUX registers.

Table 8-3. Output X-Bar Mux Configuration Table

31	SD2FLT4.COMPL			

⁽¹⁾ This signal is active high when routed through the X-Bar. It may need to be inverted by the respective OUTPUTINV bit depending on the application.

8.2.3 X-BAR Flags

With the exception of the CMPSS signals, the ePWM X-BAR and the Output X-BAR have all of the same input signals. Due to the inputs being similar, the ePWM X-BAR and Output X-BAR leverage a single set of input flags to indicate which input signals have been triggered. This allows software to check the input flags when an event occurs. See [Figure 8-4](#) for more information. There is a bit allocated for each input signal in one of the XBARFLGx registers. The flag will remain set until cleared through the appropriate XBARCLR register.

Figure 8-4. ePWM and Output X-BARs Architectures

8.3 X-BAR Registers

8.3.1 X-BAR Base Addresses

Table 8-4. X-BAR Base Address Table

Device Registers	Register Name	Start Address	End Address

R=0	R	Read
Write Type		
W	W	Write
WSOnce	SOnce W	Set once Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.3.2.1 INPUT1SELECT Register (Offset = 0h) [reset = 0h]

INPUT1SELECT is shown in [Figure 8-5](#) and described in [Table 8-7](#).

Return to [Summary Table](#).

8.3.3 XBAR_REGS Registers

Table 8-22 lists the memory-mapped registers for the XBAR_REGS. All register offset addresses not listed in Table 8-22 should be considered as reserved locations and the register contents should not be modified.

Table 8-22. XBAR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	XBARFLG1	X-Bar Input Flag Register 1		Go
2h	XBARFLG2	X-Bar Input Flag Register 2		Go
4h	XBARFLG3	X-Bar Input Flag Register 3		Go
8h	XBARCLR1	X-Bar Input Flag Clear Register 1		Go
Ah	XBARCLR2	X-Bar Input Flag Clear Register 2		Go
Ch	XBARCLR3	X-Bar Input Flag Clear Register 3		Go

Complex bit access types are encoded to fit into small table cells. Table 8-23 shows the codes that are used for access types in this section.

Table 8-23. XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W=1	W	Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.3.3.1 XBARFLG1 Register (Offset = 0h) [reset = 0h]

XBARFLG1 is shown in [Figure 8-20](#) and described in [Table 8-24](#).

Return to [Summary Table](#).

This register is used to flag the inputs of the X-Bars to provide software knowledge of the input sources which got triggered.

- 1: Corresponding Input was triggered
- 0: Corresponding Input was not triggered

8.3.4 EPWM_XBAR_REGS Registers

Table 14-100 lists the memory-mapped registers for the EPWM_XBAR_REGS. All register offset addresses not listed in Table 14-100 should be considered as reserved locations and the register contents should not be modified.

Table 8-30. EPWM_XBAR_REGS Registers

Offset	Acronym	Register Name	Write Protection	Section
0h	TRIP4MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP4	EALLOW	Go
2h	TRIP4MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP4	EALLOW	Go
4h	TRIP5MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP5	EALLOW	Go
6h	TRIP5MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP5	EALLOW	Go
8h	TRIP7MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP7	EALLOW	Go
Ah	TRIP7MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP7	EALLOW	Go
Ch	TRIP8MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP8	EALLOW	Go
Eh	TRIP8MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP8	EALLOW	Go
10h	TRIP9MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP9	EALLOW	Go
12h	TRIP9MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP9	EALLOW	Go
14h	TRIP10MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP10	EALLOW	Go
16h	TRIP10MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP10	EALLOW	Go
18h	TRIP11MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP11	EALLOW	Go
1Ah	TRIP11MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP11	EALLOW	Go
1Ch	TRIP12MUX0TO15CFG	ePWM XBAR Mux Configuration for TRIP12	EALLOW	Go
1Eh	TRIP12MUX16TO31CFG	ePWM XBAR Mux Configuration for TRIP12	EALLOW	Go
20h	TRIP4MUXENABLE	ePWM XBAR Mux Enable for TRIP4	EALLOW	Go
22h	TRIP5MUXENABLE	ePWM XBAR Mux Enable for TRIP5	EALLOW	Go
24h	TRIP7MUXENABLE	ePWM XBAR Mux Enable for TRIP7	EALLOW	Go
26h	TRIP8MUXENABLE	ePWM XBAR Mux Enable for TRIP8	EALLOW	Go
28h	TRIP9MUXENABLE	ePWM XBAR Mux Enable for TRIP9	EALLOW	Go
2Ah	TRIP10MUXENABLE	ePWM XBAR Mux Enable for TRIP10	EALLOW	Go
2Ch	TRIP11MUXENABLE	ePWM XBAR Mux Enable for TRIP11	EALLOW	Go
2Eh	TRIP12MUXENABLE	ePWM XBAR Mux Enable for TRIP12	EALLOW	Go
38h	TRIPOUTINV	ePWM XBAR Output Inversion Register	EALLOW	Go
3Eh	TRIPLOCK	ePWM XBAR Configuration Lock register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 14-101 shows the codes that are used for access types in this section.

Table 8-31. EPWM_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write
WSOnce	SOnce W	Set once Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		

Table 8-31. EPWM_XBAR_REGS Access Type Codes (continued)

Access Type	Code	Description
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.3.4.1 TRIP4MUX0TO15CFG Register (Offset = 0h) [reset = 0h]

TRIP4MUX0TO15CFG is shown in [Figure 14-161](#) and described in [Table 14-102](#).

Return to [Summary Table](#).

Table 8-48. TRIP4MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux31 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux30 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux29 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux28 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-48. TRIP4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux27 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux26 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux25 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux24 is enabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-48. TRIP4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-48. TRIP4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-48. TRIP4MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of Mux0 to drive TRIP4 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP4 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP4 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.4.18 TRIP5MUXENABLE Register (Offset = 22h) [reset = 0h]

TRIP5MUXENABLE is shown in [Figure 14-178](#) and described in [Table 14-119](#).

Return to [Summary Table](#).

Reset type: CPU1.SYSRSn

Table 8-49. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux27 is enabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux26 is enabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux25 is enabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux24 is enabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-49. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-49. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-49. TRIP5MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP5 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP5 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP5 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.4.19 TRIP7MUXENABLE Register (Offset = 24h) [reset = 0h]

TRIP7MUXENABLE is shown in [Figure 14-179](#) and described in [Table 14-120](#).

Return to [Summary Table](#).

Table 8-50. TRIP7MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux31 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux30 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux29 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux28 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-50. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux27 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux26 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux25 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux24 is enabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-50. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-50. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-50. TRIP7MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP7 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP7 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP7 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.4.20 TRIP8MUXENABLE Register (Offset = 26h) [reset = 0h]

TRIP8MUXENABLE is shown in [Figure 14-180](#) and described in [Table 14-121](#).

Return to [Summary Table](#).

Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-51. TRIP8MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP8 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP8 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP8 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.4.21 TRIP9MUXENABLE Register (Offset = 28h) [reset = 0h]

TRIP9MUXENABLE is shown in [Figure 14-181](#) and described in [Table 14-122](#).

Return to [Summary Table](#).

Table 8-52. TRIP9MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux31 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux30 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux29 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux28 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-52. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux27 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux26 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux25 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux24 is enabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-52. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-52. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-52. TRIP9MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP9 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP9 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP9 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.4.22 TRIP10MUXENABLE Register (Offset = 2Ah) [reset = 0h]

TRIP10MUXENABLE is shown in [Figure 14-182](#) and described in [Table 14-123](#).

Return to [Summary Table](#).

Table 8-53. TRIP10MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux31 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux30 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux29 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux28 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-53. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux27 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux26 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux25 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux24 is enabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-53. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-53. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-53. TRIP10MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP10 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP10 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP10 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.4.23 TRIP11MUXENABLE Register (Offset = 2Ch) [reset = 0h]

TRIP11MUXENABLE is shown in [Figure 14-183](#) and described in [Table 14-124](#).

Return to [Summary Table](#).

Table 8-54. TRIP11MUXENABLE Register Field Descriptions

Bit	Field	Type	Reset	Description
31	MUX31	R/W	0h	Selects the output of Mux31 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux31 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux31 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
30	MUX30	R/W	0h	Selects the output of Mux30 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux30 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux30 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29	MUX29	R/W	0h	Selects the output of Mux29 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux29 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux29 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
28	MUX28	R/W	0h	Selects the output of Mux28 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux28 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux28 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-54. TRIP11MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
27	MUX27	R/W	0h	Selects the output of Mux27 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux27 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux27 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
26	MUX26	R/W	0h	Selects the output of Mux26 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux26 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux26 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25	MUX25	R/W	0h	Selects the output of Mux25 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux25 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux25 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
24	MUX24	R/W	0h	Selects the output of Mux24 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux24 is enabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux24 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
23	MUX23	R/W	0h	Selects the output of Mux23 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux23 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux23 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
22	MUX22	R/W	0h	Selects the output of Mux22 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux22 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux22 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21	MUX21	R/W	0h	Selects the output of Mux21 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux21 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux21 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-54. TRIP11MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
20	MUX20	R/W	0h	Selects the output of Mux20 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux20 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux20 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19	MUX19	R/W	0h	Selects the output of Mux19 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux19 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux19 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
18	MUX18	R/W	0h	Selects the output of Mux18 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux18 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux18 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17	MUX17	R/W	0h	Selects the output of Mux17 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux17 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux17 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
16	MUX16	R/W	0h	Selects the output of Mux16 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux16 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux16 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15	MUX15	R/W	0h	Selects the output of Mux15 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux15 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux15 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
14	MUX14	R/W	0h	Selects the output of Mux14 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux14 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux14 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-54. TRIP11MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
13	MUX13	R/W	0h	Selects the output of Mux13 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux13 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux13 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
12	MUX12	R/W	0h	Selects the output of Mux12 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux12 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux12 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
11	MUX11	R/W	0h	Selects the output of Mux11 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux11 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux11 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
10	MUX10	R/W	0h	Selects the output of Mux10 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux10 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux10 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9	MUX9	R/W	0h	Selects the output of Mux9 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux9 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux9 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
8	MUX8	R/W	0h	Selects the output of Mux8 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux8 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux8 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7	MUX7	R/W	0h	Selects the output of Mux7 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux7 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux7 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-54. TRIP11MUXENABLE Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
6	MUX6	R/W	0h	Selects the output of Mux6 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux6 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux6 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5	MUX5	R/W	0h	Selects the output of Mux5 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux5 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux5 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
4	MUX4	R/W	0h	Selects the output of Mux4 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux4 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux4 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3	MUX3	R/W	0h	Selects the output of Mux3 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux3 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux3 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
2	MUX2	R/W	0h	Selects the output of Mux2 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux2 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux2 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1	MUX1	R/W	0h	Selects the output of Mux1 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux1 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux1 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
0	MUX0	R/W	0h	Selects the output of mux0 to drive TRIP11 of EPWM-XBAR 0: Respective output of Mux0 is disabled to drive the TRIP11 of EPWM-XBAR 1: Respective output of Mux0 is enabled to drive the TRIP11 of EPWM-XBAR Refer to the EPWM X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.4.24 TRIP12MUXENABLE Register (Offset = 2Eh) [reset = 0h]

TRIP12MUXENABLE is shown in [Figure 14-184](#) and described in [Table 14-125](#).

Return to [Summary Table](#).

3Eh	OUTPUTLOCK	Output X-BAR Configuration Lock register	EALLOW	Go

Complex bit access types are encoded to fit into small table cells. Table 8-59 shows the codes that are used for access types in this section.

Table 8-59. OUTPUT_XBAR_REGS Access Type Codes

Access Type	Code	Description
Read Type		
R	R	Read
R=0	R	Read
Write Type		
W	W	Write
W=1	W	Write

Table 8-59. OUTPUT_XBAR_REGS Access Type Codes (continued)

Access Type	Code	Description
WSOnce	SOnce W	Set once Write
Reset or Default Value		
-n		Value after reset or the default value
Register Array Variables		
i,j,k,l,m,n		When these variables are used in a register name, an offset, or an address, they refer to the value of a register array where the register is part of a group of repeating registers. The register groups form a hierarchical structure and the array is represented with a formula.
y		When this variable is used in a register name, an offset, or an address it refers to the value of a register array.

8.3.5.1 OUTPUT1MUX0TO15CFG Register (Offset = 0h) [reset = 0h]

OUTPUT1MUX0TO15CFG is shown in [Figure 8-52](#) and described in [Table 8-60](#).

Return to [Summary Table](#).

Output X-BAR Mux Configuration for Output 1

Table 8-68. OUTPUT5MUX0TO15CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-10	MUX5	R/W	0h	Select Bits for OUTPUT5 Mux5: 00 : Select .0 input for Mux5 01 : Select .1 input for Mux5 10 : Select .2 input for Mux5 11 : Select .3 input for Mux5 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9-8	MUX4	R/W	0h	Select Bits for OUTPUT5 Mux4: 00 : Select .0 input for Mux4 01 : Select .1 input for Mux4 10 : Select .2 input for Mux4 11 : Select .3 input for Mux4 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7-6	MUX3	R/W	0h	Select Bits for OUTPUT5 Mux3: 00 : Select .0 input for Mux3 01 : Select .1 input for Mux3 10 : Select .2 input for Mux3 11 : Select .3 input for Mux3 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5-4	MUX2	R/W	0h	Select Bits for OUTPUT5 Mux2: 00 : Select .0 input for Mux2 01 : Select .1 input for Mux2 10 : Select .2 input for Mux2 11 : Select .3 input for Mux2 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3-2	MUX1	R/W	0h	Select Bits for OUTPUT5 Mux1: 00 : Select .0 input for Mux1 01 : Select .1 input for Mux1 10 : Select .2 input for Mux1 11 : Select .3 input for Mux1 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1-0	MUX0	R/W	0h	Select Bits for OUTPUT5 Mux0: 00 : Select .0 input for Mux0 01 : Select .1 input for Mux0 10 : Select .2 input for Mux0 11 : Select .3 input for Mux0 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.5.10 OUTPUT5MUX16TO31CFG Register (Offset = 12h) [reset = 0h]

OUTPUT5MUX16TO31CFG is shown in [Figure 8-61](#) and described in [Table 8-69](#).

Return to [Summary Table](#).

Output X-BAR Mux Configuration for Output 5

Table 8-69. OUTPUT5MUX16TO31CFG Register Field Descriptions

Bit	Field	Type	Reset	Description
31-30	MUX31	R/W	0h	Select Bits for OUTPUT5 Mux31: 00 : Select .0 input for Mux31 01 : Select .1 input for Mux31 10 : Select .2 input for Mux31 11 : Select .3 input for Mux31 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
29-28	MUX30	R/W	0h	Select Bits for OUTPUT5 Mux30: 00 : Select .0 input for Mux30 01 : Select .1 input for Mux30 10 : Select .2 input for Mux30 11 : Select .3 input for Mux30 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
27-26	MUX29	R/W	0h	Select Bits for OUTPUT5 Mux29: 00 : Select .0 input for Mux29 01 : Select .1 input for Mux29 10 : Select .2 input for Mux29 11 : Select .3 input for Mux29 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
25-24	MUX28	R/W	0h	Select Bits for OUTPUT5 Mux28: 00 : Select .0 input for Mux28 01 : Select .1 input for Mux28 10 : Select .2 input for Mux28 11 : Select .3 input for Mux28 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-69. OUTPUT5MUX16TO31CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
23-22	MUX27	R/W	0h	Select Bits for OUTPUT5 Mux27: 00 : Select .0 input for Mux27 01 : Select .1 input for Mux27 10 : Select .2 input for Mux27 11 : Select .3 input for Mux27 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
21-20	MUX26	R/W	0h	Select Bits for OUTPUT5 Mux26: 00 : Select .0 input for Mux26 01 : Select .1 input for Mux26 10 : Select .2 input for Mux26 11 : Select .3 input for Mux26 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
19-18	MUX25	R/W	0h	Select Bits for OUTPUT5 Mux25: 00 : Select .0 input for Mux25 01 : Select .1 input for Mux25 10 : Select .2 input for Mux25 11 : Select .3 input for Mux25 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
17-16	MUX24	R/W	0h	Select Bits for OUTPUT5 Mux24: 00 : Select .0 input for Mux24 01 : Select .1 input for Mux24 10 : Select .2 input for Mux24 11 : Select .3 input for Mux24 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
15-14	MUX23	R/W	0h	Select Bits for OUTPUT5 Mux23: 00 : Select .0 input for Mux23 01 : Select .1 input for Mux23 10 : Select .2 input for Mux23 11 : Select .3 input for Mux23 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
13-12	MUX22	R/W	0h	Select Bits for OUTPUT5 Mux22: 00 : Select .0 input for Mux22 01 : Select .1 input for Mux22 10 : Select .2 input for Mux22 11 : Select .3 input for Mux22 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

Table 8-69. OUTPUT5MUX16TO31CFG Register Field Descriptions (continued)

Bit	Field	Type	Reset	Description
11-10	MUX21	R/W	0h	Select Bits for OUTPUT5 Mux21: 00 : Select .0 input for Mux21 01 : Select .1 input for Mux21 10 : Select .2 input for Mux21 11 : Select .3 input for Mux21 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
9-8	MUX20	R/W	0h	Select Bits for OUTPUT5 Mux20: 00 : Select .0 input for Mux20 01 : Select .1 input for Mux20 10 : Select .2 input for Mux20 11 : Select .3 input for Mux20 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
7-6	MUX19	R/W	0h	Select Bits for OUTPUT5 Mux19: 00 : Select .0 input for Mux19 01 : Select .1 input for Mux19 10 : Select .2 input for Mux19 11 : Select .3 input for Mux19 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
5-4	MUX18	R/W	0h	Select Bits for OUTPUT5 Mux18: 00 : Select .0 input for Mux18 01 : Select .1 input for Mux18 10 : Select .2 input for Mux18 11 : Select .3 input for Mux18 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
3-2	MUX17	R/W	0h	Select Bits for OUTPUT5 Mux17: 00 : Select .0 input for Mux17 01 : Select .1 input for Mux17 10 : Select .2 input for Mux17 11 : Select .3 input for Mux17 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn
1-0	MUX16	R/W	0h	Select Bits for OUTPUT5 Mux16: 00 : Select .0 input for Mux16 01 : Select .1 input for Mux16 10 : Select .2 input for Mux16 11 : Select .3 input for Mux16 Refer to the Output X-BAR section of this chapter for more details. Reset type: CPU1.SYSRSn

8.3.5.11 OUTPUT6MUX0TO15CFG Register (Offset = 14h) [reset = 0h]

OUTPUT6MUX0TO15CFG is shown in [Figure 8-62](#) and described in [Table 8-70](#).

Return to [Summary Table](#).

Output X-BAR Mux Configuration for Output 6
