Southern California Edison  
Underwriters Laboratories (UL)  
University of California at Berkeley  
University of California at Riverside  
US Department of Energy, FEMP

Specific appreciation is extended to Henny Penny for supplying the FSTC with an electric fryer, Model OFE-341 for controlled testing in the appliance laboratory.

## Policy on the Use of Food Service Technology Center Test Results and Other Related Information

- Fisher-Nickel, inc. and the Food Service Technology Center (FSTC) do not endorse particular products or services from any specific manufacturer or service provider.
- The FSTC is *strongly* committed to testing food service equipment using the best available scientific techniques and instrumentation.
- The FSTC is neutral as to fuel and energy source. It does not, in any way, encourage or promote the use of any fuel or energy source nor does it endorse any of the equipment tested at the FSTC.
- FSTC test results are made available to the general public through technical research reports and publications and are protected under U.S. and international copyright laws.
- In the event that FSTC data are to be reported, quoted, or referred to in any way in publications, papers, brochures, advertising, or any other publicly available documents, the rules of copyright must be strictly followed, including written permission from Fisher-Nickel, inc. *in advance* and proper attribution to Fisher-Nickel, inc. and the Food Service Technology Center. In any such publication, sufficient text must be excerpted or quoted so as to give full and fair representation of findings as reported in the original documentation from FSTC.

## Legal Notice

This report was prepared as a result of work sponsored by the California Public Utilities Commission (Commission). It does not necessarily represent the views of the Commission, its employees, or the State of California. The Commission, the State of California, its employees, contractors, and subcontractors make no warranty, express or implied, and assume no legal liability for the information in this report; nor does any party represent that the use of this information will not infringe upon privately owned rights. This report has not been approved or disapproved by the Commission nor has the Commission passed upon the accuracy or adequacy of the information in this report.

## Disclaimer

Neither Fisher-Nickel, inc. nor the Food Service Technology Center nor any of its employees makes any warranty, expressed or implied, or assumes any legal liability of responsibility for the accuracy, completeness, or usefulness of any data, information, method, product or process disclosed in this document, or represents that its use will not infringe any privately-owned rights, including but not limited to, patents, trademarks, or copyrights.

Reference to specific products or manufacturers is not an endorsement of that product or manufacturer by Fisher-Nickel, inc., the Food Service Technology Center or Pacific Gas & Electric Company (PG&E). Retention of this consulting firm by PG&E to develop this report does not constitute endorsement by PG&E for any work performed other than that specified in the scope of this project.

## Executive Summary

---

*Figure ES-1.  
Henny Penny OFE-341 Fryer.*

Henny Penny’s OFE-341 large-vat electric fryer features low watt density ribbon elements, stainless steel construction, and a programmable cooking computer that controls the input to the fryer and provides for a more consistent product. Figure ES-1 illustrates the OFE-341 fryer, as tested at the Food Service Technology Center (FSTC).

FSTC engineers tested the fryer under the tightly controlled conditions of the American Society for Testing and Materials’ (ASTM) standard test method.<sup>1</sup> Fryer performance is characterized by preheat time and energy consumption, idle energy consumption rate, cooking-energy efficiency, and production capacity.

Cooking performance was determined by cooking breaded 8-piece cut 2 ¾ pound frying chicken under three load scenarios: heavy—48 pieces per load, medium—24 pieces per load, and light—8 pieces per load. The OFE-341’s heavy-load cook time was 15.4 minutes. Production capacity includes the cooking time and the time required for the frying medium to recover to 320°F (recovery time).

Cooking-energy efficiency is a measure of how much of the energy that an appliance consumes is actually delivered to the food product during the cooking process. Cooking-energy efficiency is therefore defined by the following relationship:

$$\text{Cooking - Energy Efficiency} = \frac{\text{Energy to Food}}{\text{Energy to Appliance}}$$

---

<sup>1</sup> American Society for Testing and Materials. 2000. *Standard Test Method for the Performance of Large Open, Deep Fat Fryers*. ASTM Designation F 2144-01, in *Annual Book of ASTM Standards*, West Conshohocken, PA.

# Executive Summary

---

A summary of the test results is presented in Table ES-1.

*Table ES-1. Summary of Fryer Performance.*

|  |            |
|--|------------|
| Rated Energy Input Rate (kW)                           | 22.0       |
| Measured Energy Input Rate (kW)                        | 21.1       |
| Preheat Time to 325°F (min)                            | 9.93       |
| Preheat Energy to 325°F (kWh)                          | 2.10       |
| Idle Energy Rate @ 325°F (kW)                          | 1.08       |
| Heavy-Load Cooking-Energy Efficiency (%) <sup>a</sup>  | 73.0 ± 2.4 |
| Medium-Load Cooking-Energy Efficiency (%) <sup>a</sup> | 72.8 ± 3.6 |
| Light-Load Cooking-Energy Efficiency (%) <sup>a</sup>  | 51.0 ± 3.9 |
| Production Capacity (lb/h) <sup>a</sup>                | 68.9 ± 4.3 |

<sup>a</sup> This range indicates the experimental uncertainty in the test result based on a minimum of three test runs.

The fryer's 22.0 kW input provided the necessary horsepower to produce a very competitive heavy-load (48 pieces) cooking-energy efficiency of 73.0% and a production capacity of 68.9 lbs/h. During testing, the OFE-341 was able to cook the heavy-load of chicken in a very fast 15.4 minutes.

Figure ES-2 illustrates the relationship between cooking-energy efficiency and production rate for the fryer.

# Executive Summary

Figure ES-2.  
Fryer part-load cooking-energy efficiency.

Note: Light-load = 8 pieces/load; Medium-load = 24 pieces/load; Heavy-load = 48 pieces/load.

Figure ES-3 illustrates the relationship between the fryer's average energy consumption rate and the production rate. This graph can be used as a tool to estimate the daily energy consumption and probable demand contribution for the fryer in a real-world operation. Average energy consumption rates at 10, 30, and 50 pounds per hour for the OFE-341 fryer are 2.3 kW, 4.9 kW, and 7.5 kW respectively. For an operation cooking an average of 15 pounds of food per hour over the course of the day (e.g., 150 lb of food over a ten hour day), the probable demand contribution for the OFE-341 fryer would be 3.0 kW.

# Executive Summary

**Figure ES-3.**  
Fryer cooking energy consumption profile.

Note: Light-load = 8 pieces/load; Medium-load = 24 pieces/load; Heavy-load = 48 pieces/load.

The classic open deep fat fryer design allows this large vat fryer to be used in a traditional fashion. FSTC researchers conducted additional French fry tests on the Henny Penny fryer. Based on the size of the fry vat, the heavy-load was changed from 3 to 5 pounds. The fryer exhibited an impressive production capacity of 83.6 lbs/hr of frozen French fries, with a cooking-energy efficiency of 86.1%.

**Table ES-3. French Fry Heavy-Load Test Results**

|  |            |
|--|------------|
| Load Size (lbs)                            | 5.0        |
| Production Capacity (lb/h) <sup>a</sup>    | 83.6 ± 3.3 |
| Energy per Pound of Food Cooked (Btu/lb)   | 651        |
| Electric Cooking Energy Rate (kW)          | 16.0       |
| Cooking-Energy Efficiency (%) <sup>a</sup> | 86.1 ± 0.9 |

<sup>a</sup> This range indicates the experimental uncertainty in the test result based on a minimum of three test runs.

# Executive Summary

---

The test results can be used to estimate the annual energy consumption for the fryer in a real-world operation. A simple cost model was developed to calculate the relationship between the various cost components (e.g., preheat, idle and cooking costs) and the annual operating cost, using the ASTM test data. For this model, the fryer was used to cook 150 pounds of chicken over a 12-hour day, with one preheat per day, 365 days per year.

*Table ES-4. Estimated Fryer Energy Consumption and Cost.*

|  |               |
|--|---------------|
| Preheat Energy (kWh/day)                 | 2.10          |
| Idle Energy (kWh/day)                    | 7.94          |
| Cooking Energy (kWh/day)                 | 23.9          |
| <b>Annual Energy (kWh/year)</b>          | <b>12,374</b> |
| <b>Annual Cost (\$/year)<sup>a</sup></b> | <b>1,237</b>  |

<sup>a</sup> Fryer energy costs are based on \$0.10/kWh

Henny Penny's OFE-341 fryer established itself as a versatile open deep fat electric fryer. Its large vat size provides a restaurateur with the option of cooking large quantities of breaded product such as fried chicken or traditional French fries. The low watt-density ribbon style elements transfer heat into the frying medium easily and effectively. Quick response times and rapid oil temperature recovery during cooking provide a food service operator with a workhorse fryer that can handle seriously high volume.

# 1 Introduction

---

## Background

Fried foods continue to be popular on the restaurant scene. Fryers of a larger vat size and input typically are used for cooking foods such as chicken and fish. Recent advances in equipment design have produced fryers that operate more efficiently, quickly, safely and conveniently.

Dedicated to the advancement of the food service industry, the Food Service Technology Center (FSTC) has focused on the development of standard test methods for commercial food service equipment since 1987. The primary component of the FSTC is a 10,000 square-foot appliance laboratory equipped with energy monitoring and data acquisition hardware, 60 linear feet of canopy exhaust hoods integrated with utility distribution systems, appliance setup and storage areas, and a state-of-the-art demonstration and training facility.

The test methods, approved and ratified by the American Society for Testing and Materials (ASTM), allow benchmarking of equipment such that users can make meaningful comparisons among available equipment choices. By collaborating with the Electric Power Research Institute (EPRI) and the Gas Technology Institute (GTI) through matching funding agreements, the test methods have remained unbiased to fuel choice. End-use customers and commercial appliance manufacturers consider the FSTC to be the national leader in commercial food service equipment testing and standards, sparking alliances with several major chain customers to date.

FSTC researchers modified ASTM (F 1964-99) Standard Test Method for the Performance of Pressure and Kettle Fryers<sup>1</sup> to apply to large open vat, deep fat fryers, which was accepted as a Standard Test Method for Performance of Large Open Vat Fryers (Designation F 2144-01).<sup>2</sup>

# Introduction

---

Fryer performance is characterized by preheat time and energy consumption, idle energy consumption rate, pilot energy, consumption rate, cooking energy efficiency and production capacity.

Henny Penny's OFE-341 electric fryer features low watt-density ribbon elements submerged in the frying oil with a stainless steel frypot, backsplash, and a programmable cooking computer. An integrated melt cycle prevents solid frying medium from scorching during preheat.

This report presents the results of applying the ASTM test method<sup>1</sup> to the Henny Penny OFE-341 electric fryer. The glossary in Appendix A is provided so that the reader has a quick reference to the terms used in this report.

## Objectives

The objective of this report is to examine the operation and performance of Henny Penny's OFE-341, 18-inch electric fryer at an input rating of 22.0 kW, under the controlled conditions of the ASTM standard test method.<sup>1</sup> The scope of this testing is as follows:

1. Verify that the appliance is operating at the manufacturer's rated energy input.
2. Determine the time and energy required to preheat the appliance from room temperature to 325°F.
3. Characterize the idle energy use with the thermostat set at a calibrated 325°F.
4. Document the cooking energy consumption and efficiency under three fry loading scenarios: heavy (48 piece load), medium (24 piece load) and light (8 piece per load).
5. Determine the production capacity during the heavy-load test.
6. Document the cooking energy consumption and efficiency under three French fry loading scenarios at 350°F: heavy (5 pounds per load), medium (2 ½ pounds per load), and light (¾ pound per load).
7. Determine the production capacity and frying medium temperature recovery time during the heavy-load test.

## Introduction

---

8. Estimate the annual operating cost for the fryer using a standard cost model.

### Appliance Description

Henny Penny's OFE-341, 18-inch electric fryer has a power rating of 22.0 kW. The fry pot is of a stainless steel construction and contains submerged low watt-density ribbon elements that provide a cooking platform within the fry vat (see Figure 1-1). The elements can lift up to allow for easy cleaning of the fry vat. A cooking computer allows for individualized programming for multiple food products. An integrated melt cycle prevents solid frying medium from scorching during preheat.

Appliance specifications are listed in Table 1-1, and the manufacturer's literature is in Appendix B.

*Figure 1-1.

## 2 Methods

### Setup and Instrumentation

FSTC researchers installed the fryer on a tiled floor under a 4-foot-deep canopy hood that was 6 feet, 6 inches above the floor. The hood operated at a nominal exhaust rate of 300 cfm per linear foot of hood. There was at least 6 inches of clearance between the vertical plane of the fryers and the edge of the hood. All test apparatus was installed in accordance with Section 9 of the ASTM test method.<sup>2</sup> See Figure 2-1.

Researchers instrumented the fryer with thermocouples to measure temperatures in the cold and the cooking zones and at the thermostat bulb. Two thermocouples were placed in the cook zone, one in the geometric center of the frypot, approximately 1 inch above the fry basket support, and the other at the tip of the thermostat bulb. The cold zone thermocouple was supported from above, independent of the frypot surface, so that the temperature of the cold zone reflected the frying medium temperature, not the frypot's surface

*Figure 2-1.  
Equipment configuration.*

temperature. The cold zone temperature was measured toward the rear of the frypot, 1/8-inch from the bottom of the pot (See Figure 2-2).

# Methods

Power and energy were measured with a watt/watt-hour transducer that generated an analog signal for instantaneous power and a pulse for every 10 Wh. A voltage regulator, connected to the fryers, maintained a constant voltage for all tests. Control energy was monitored with a watt-hour transducer that generated a pulse for every 0.00001 watt-hours. The energy meters and thermocouples were connected to a data logger which recorded data every five seconds.

The fryer was filled with Melfry Brand, partially hydrogenated, 100% pure vegetable oil for all tests except the energy input rate determination test. This test required the fryer to be filled with water to inhibit burner cycling during the test.

*Figure 2-2.  
Thermocouple placement  
for testing.*

## Measured Energy Input Rate

Rated energy input rate is the maximum or peak rate at which the fryer consumes energy—as specified on the fryer’s nameplate. Measured energy input rate is the maximum or peak rate of energy consumption, which is recorded during a period when the elements are energized (such as preheat). For the purpose of this test, the fryer was filled with water to the frypot’s indicated fill-line. The controls were set to attain maximum output and the energy consumption was monitored for a period of 15 minutes after a full rolling boil

# Methods

---

had been established. Researchers compared the measured energy input rate with the nameplate energy input rate to ensure that the fryer was operating properly.

## Chicken Tests

The fryer was tested with 8-piece cut, 2 ¾-pound, individually quick frozen frying chicken which had been thawed, breaded, and stabilized in a refrigerator at 38 °F. Researchers tested the fryers using nominal heavy, medium and light-loads of chicken (Table 2-1). Each load comprised an equal number of breasts, wings, legs, and thighs. The chicken was cooked to an average weight loss of  $27 \pm 2\%$ . This ensured fully-cooked chicken with no redness in the center.

*Table 2-1. Chicken Load Size.*

|                      |    |
|----------------------|----|
| Heavy-Load (pieces)  | 48 |
| Medium-Load (pieces) | 24 |
| Light-Load (pieces)  | 8  |

During the testing, energy, time and oil temperature were recorded at 5-second intervals. Chicken temperature and weight loss were measured and recorded for use in energy calculations.

Due to logistics in removing one load of cooked chicken and placing another load into the fryer, a minimum preparation time of 10 minutes was incorporated into the cooking procedure. This ensures that the cooking tests are uniformly applied from laboratory to laboratory. Fryer recovery was then based on the frying medium reaching a threshold temperature of 320°F (measured at the center of the cook zone).

The chicken tests were run in the following sequence: three replicates of the heavy-load test, three replicates of the medium-load test, and three replicates of the light-load test. This procedure ensured that the reported cooking-

## Methods

---

energy efficiency and production capacity results had an uncertainty of less than  $\pm 10\%$ . The results from each test run were averaged, and the absolute uncertainty was calculated based on the standard deviation of the results.

### French Fry Tests

For additional performance information on the fryer, researchers applied the French fry test from the ASTM Test Method for Open Deep Fat Fryers (F1361-99)<sup>3</sup>. Since the frypot could accommodate a larger load than specified in the test method, the heavy-load size was increased from three to five pounds of frozen French fries. Medium-loads were also increased in size to half the weight of the heavy-load, two and one-half pounds.

Simplot<sup>®</sup> brand ¼-inch blue ribbon product, par-cooked, frozen shoestring potatoes were used for the French fry tests. Each load of French fries was cooked to a 30% weight loss. The tests involved “barreling” six loads of frozen French fries, using fry medium temperature as a basis for recovery. Each test was followed by a 10-minute wait period and was then repeated two more times. Researchers tested the fryers using 5-pound (heavy), 2 ½-pound (medium), and ¾-pound (light) French fry loads.

Due to the logistics involved in removing one load of cooked French fries and placing another load into the fryer, a minimum preparation time of 10 seconds was incorporated into the cooking procedure. This ensures that the cooking tests are uniformly applied from laboratory to laboratory. Fryer recovery was then based on the frying medium reaching a threshold temperature of 340°F (measured at the center of the cook zone). Reloading within 10°F of the 350°F thermostat set point does not significantly lower the average oil temperature over the cooking cycle, nor does it extend the cook time. The fryer was reloaded either after the cook zone thermocouple reached the threshold temperature or 10 seconds after removing the previous load from the fryer, whichever was longer.

The first load of each six-load cooking test was designated as a stabilization load and was not counted when calculating the elapsed time and energy used.

## Methods

---

Energy monitoring and elapsed time of the test were determined after the second load contacted the frying medium. After removing the last load and allowing the fryer to recover, researchers terminated the test. Total elapsed time, energy consumption, weight of fries cooked, and average weight loss of the French fries were recorded for the last five loads of the six-load test.

The French fry tests were run in the following sequence: three replicates of the heavy-load test followed by three replicates of the light-load test. This procedure ensured that the reported cooking energy efficiency and production capacity results had an uncertainty of less than  $\pm 10\%$ . The results from each test run were averaged, and the absolute uncertainty was calculated based on the standard deviation of the results.

The ASTM results reporting sheets appear in Appendix C.

## 3 Results

---

### Energy Input Rate

Prior to testing, the energy input rate was measured and compared with the manufacturer's nameplate value. This procedure ensured that the fryer was operating within its specified parameters. The measured energy input rate was 21.1 kW (a difference of 4.1% from the nameplate rating).

### Preheat and Idle Tests

These tests show how the fryer uses energy when it is not cooking food. The preheat time allows an operator to know precisely how long it takes for the fryer to be ready to cook. The idle energy rate represents the energy required to maintain the set temperature 325°F, or the appliance's stand-by losses.

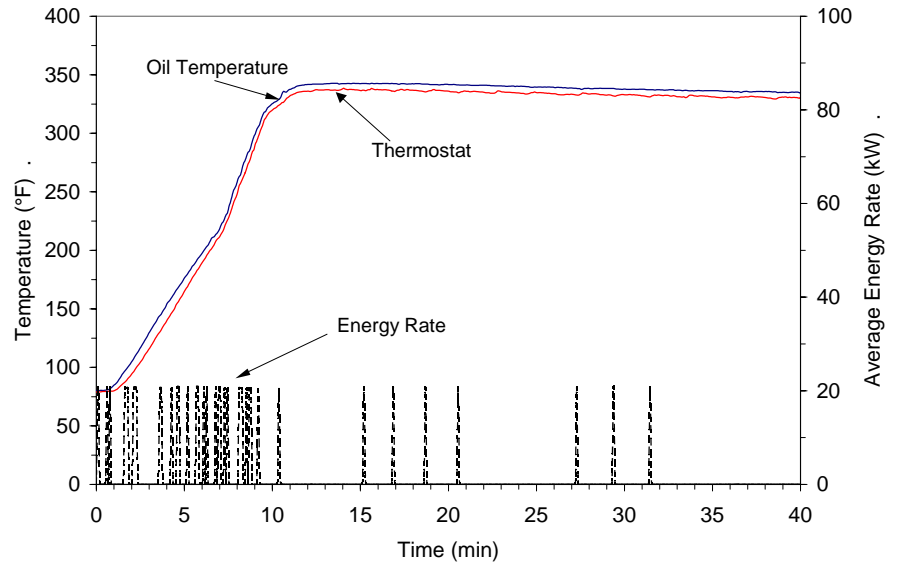

#### **Preheat Energy and Time**

Researchers filled the fryer with new oil, which was then heated to 325°F at least once prior to any testing. The preheat tests were conducted at the beginning of a test day, after the oil had stabilized at room temperature overnight. Henny Penny's cooking computer has an integrated melt cycle to prevent scorching of solid shortening. Henny Penny's OFE-341 fryer was ready to cook in 9.93 minutes. Figure 3-1 shows the fryer's preheat characteristics.

#### **Idle Energy Rate**

Once the frying medium reached 325°F, the fryer was allowed to stabilize for half an hour. Time and energy consumption was monitored for an additional two-hour period as each fryer maintained the oil at 325°F. The idle energy rate during this period was 1.08 kW.

## Chicken Tests

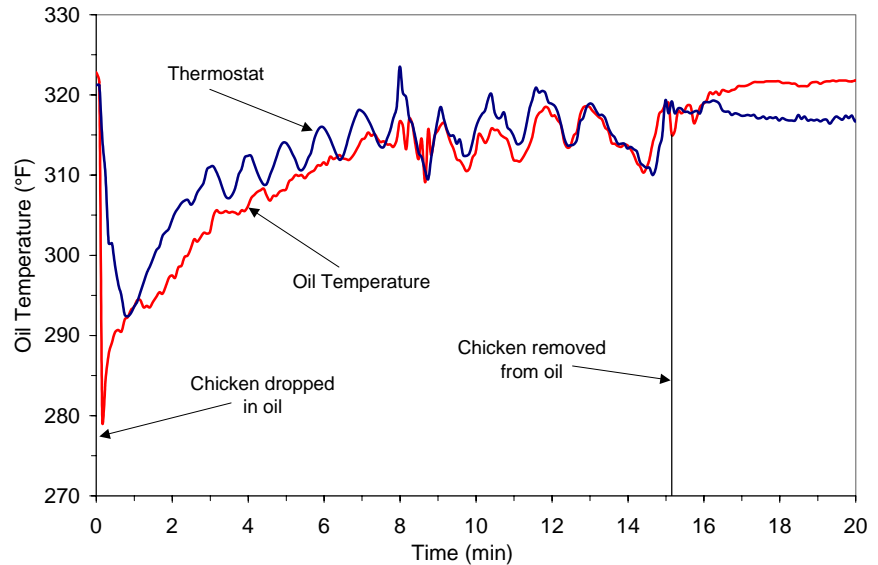

The fryer was tested using 8-piece cut, 2 ¾-pound chickens that had been thawed, breaded, and stabilized at 38°F to 40°F. For heavy-load tests, the OFE-341 fryer was used to cook 48 pieces per load (12 of each type of piece—breast, wings, legs and thighs). Medium-loads comprised one half the number of pieces used in the heavy load tests. Light-load tests used 8 pieces per load for all three fryers. Researchers monitored chicken cooking time and weight loss, frying medium temperature, and fryer energy consumption during these tests.

### **Heavy-Load Tests**

The heavy-load cooking tests were designed to reflect a fryer's maximum performance. The fryer was used to cook three or more heavy loads of chicken—one load after another in rapid succession, simulating a peak cooking period. Cooking-energy efficiency and production capacity were determined from these tests. The characteristic temperature curve, or temperature signature, during a single heavy-load indicates how well the fryer maintained the oil temperature during a cooking event. This curve is also an indicator of product quality as the chicken pieces begin to absorb more oil at lower cooking temperatures. Figure 3-2 shows the temperature signature during a heavy-load test.

The heavy-load cook time for the Henny Penny fryer was 15.4 minutes. Production capacity includes the cook time and a 30 second reload time.

# Results

*Figure 3-2.*  
*Chicken cook cycle*  
*temperature signature.*

## Medium- and Light Load Tests

Medium and light load tests represent the fryer's performance under non-peak conditions. Since a fryer is often used to cook single-basket loads during slow periods, these part-load efficiencies can be used to estimate a fryer's performance in an actual operation.

Both the medium and light-load tests were conducted using a single fry basket. The fryer, during medium- and light-load testing, demonstrated cooking-energy efficiencies of 72.8 % and 51.0%, while producing 37.7 lbs/h and 13.4 lb/h respectively.

## Test Results

Energy imparted to the chicken was calculated by separating the various components of the chicken (water, fat, and solids) and determining the amount of heat gained by each component (Appendix D). The fryer's cooking energy efficiency for a given loading scenario is the amount of energy

## Results

---

imparted to the chicken, expressed as a percentage of the amount of energy consumed by the fryer during the cooking process.

Heavy-load cooking-energy efficiency results were 71.8%, 73.5%, 76.4% and 70.4%, yielding a maximum uncertainty of 4.1%. Table 3-2 summarizes the results of the ASTM cooking-energy efficiency and production capacity tests for chicken.

*Table 3-2. Chicken Cooking Test Results.*

|  | Heavy-Load | Medium-Load | Light-Load |
|--|------------|-------------|------------|
| Load Size (pieces)                         | 48         | 24          | 8          |
| Cook Time (min)                            | 15.4       | 14.8        | 13.6       |
| Production Rate (lb/h) <sup>a</sup>        | 68.9 ± 4.3 | 37.7 ± 3.8  | 13.4 ± 0.5 |
| Energy to Food (Btu/lb)                    | 360        | 390         | 346        |
| Energy Consumption (kWh)                   | 2.56       | 1.46        | 0.60       |
| Electric Cooking Energy Rate (kW)          | 9.96       | 5.90        | 2.67       |
| Energy per Pound of Food Cooked (Btu/lb)   | 494        | 537         | 681        |
| Cooking-Energy Efficiency (%) <sup>a</sup> | 73.0 ± 2.4 | 72.8 ± 3.6  | 51.0 ± 3.9 |

<sup>a</sup> This range indicates the experimental uncertainty in the test result based on a minimum of three test runs.

## French Fry Tests

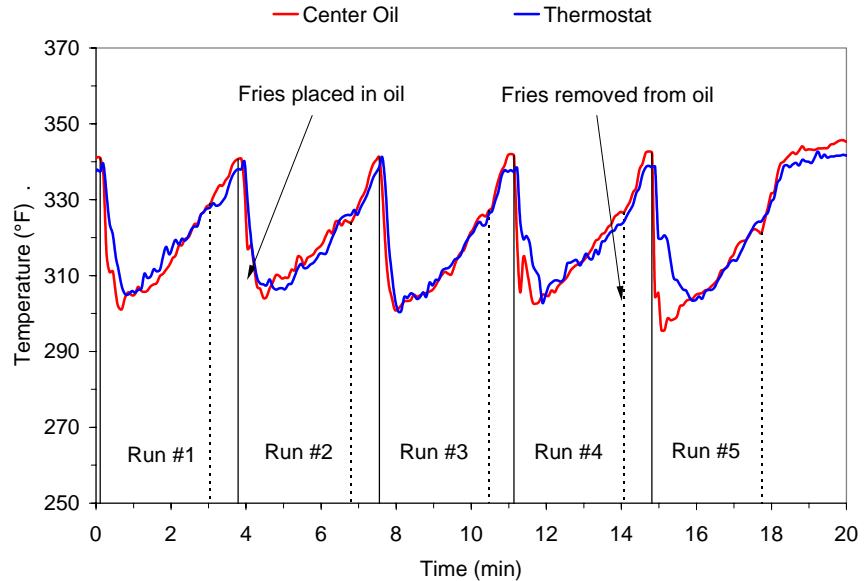

The fryers were tested under three loading scenarios: heavy (5 pounds of fries per load), medium (2 ½ pounds of fries per load) and light (¾ pound of fries per load). The fries used for the cooking tests consisted of approximately 6% fat and 66% moisture, as specified by the ASTM procedure. Researchers monitored French fry cook time and weight loss, frying medium recovery time, and fryer energy consumption during these tests.

### Heavy-Load Tests

The heavy-load cooking tests were designed to reflect a fryer's maximum performance. The fryers were used to cook six 5-pound loads of frozen French fries—one load after the other in rapid succession, similar to a batch-

# Results

cooking procedure. Figures 3-3 shows the average temperature of the frying medium during the heavy-load tests.

*Figure 3-3.*  
*Frying medium*  
*temperarture during a*  
*heavy-load test for the*  
*OFE-341 fryer.*

The first load was used to stabilize the fryer, and the remaining five loads were used to calculate cooking-energy efficiency and production capacity. The heavy-load cook time for the fryer was 2.80 minutes with an average recovery time of 47.4 seconds. Figure 3-4 illustrates the temperature response of the Henny Penny fryer while cooking a 5-pound load of frozen French fries. Production capacity includes the time required to remove the cooked fries and reload the fryer with a new batch of frozen fries (approximately 10 seconds per load).

# Results

*Figure 3-4.*  
*Fryer cooking cycle*  
*temperature signature.*

## Medium- and Light-Load Tests

Medium- and light-load tests represent a more typical usage pattern for a fryer in cook-to-order applications. Since a fryer is often used to cook single basket loads in many food service establishments, these part-load efficiencies can be used to estimate the fryer's performance in an actual operation.

Both the medium- and light-load tests were conducted using a single fry basket. The medium-load tests used 2½ pounds of fries per load and the light load tests used ¾ pounds of fries per load. Cooking-energy efficiencies during testing were 78.5% for medium- and 61.4% for light-loads while producing 59.2 lbs/h and 18.4 lbs/h of cooked French fries, respectively.

## Test Results

Energy imparted to the French fries was calculated by separating the various components of the fries (water, fat, and solids) and determining the amount of heat gained by each component (Appendix D). The fryer's cooking-energy efficiency for a given loading scenario is the amount of energy imparted to

# Results

---

the fries, expressed as a percentage of the amount of energy consumed by the fryer during the cooking process.

Heavy-load cooking-energy efficiency results were 86.5%, 85.9% and 85.9%, yielding a maximum uncertainty of 0.9%. Table 3-3 summarizes the results of the ASTM cooking-energy efficiency and production capacity tests for French fries.

*Table 3-3. French Fry Cooking Test Results.*

|  | Heavy-Load | Medium-Load | Light-Load |
|--|------------|-------------|------------|
| Load Size (lb)                             | 5.0        | 2 ½         | ¾          |
| French Fry Cook Time (min)                 | 2.80       | 2.30        | 2.30       |
| Average Recovery Time (sec)                | 47.4       | 13.8        | 8.4        |
| Production Rate (lb/h) <sup>a</sup>        | 83.6 ± 3.3 | 59.2 ± 1.3  | 18.4 ± 0.0 |
| Energy to Food (Btu/lb)                    | 560        | 563         | 553        |
| Energy Consumption (kWh)                   | 4.77       | 2.63        | 1.03       |
| Electric Cooking Energy Rate (kW)          | 16.0       | 12.5        | 5.1        |
| Energy per Pound of Food Cooked (Btu/lb)   | 651        | 717         | 934        |
| Cooking-Energy Efficiency (%) <sup>a</sup> | 86.1 ± 0.9 | 78.5 ± 0.9  | 60.1 ± 5.9 |

<sup>a</sup> This range indicates the experimental uncertainty in the test result based on a minimum of three test runs.

Figure 3-5 illustrates the relationship between cooking-energy efficiency and production rate for this fryer. Fryer production rate is a function of both the French fry cook time and the frying medium recovery time. Appendix D contains a synopsis of test data for each replicate of the chicken and French fry cooking tests.

# Results

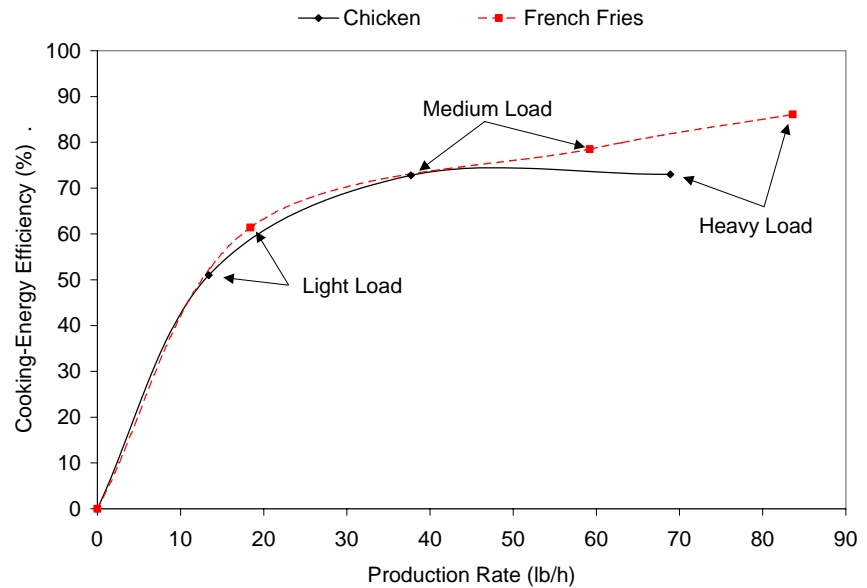

Figure 3-5.  
Fryer part-load cooking-energy efficiency.

Note: Light-load = 8 pieces/load; Medium-load = 24 pieces/load; Heavy-load = 48 pieces/load.

Figure 3-6 illustrates the relationship between the fryer's average energy consumption rate and the production rate. This graph can be used as a tool to estimate the daily energy consumption and probable demand for the fryer in a real-world operation. End-use monitoring studies have shown that an electric appliance's probable contribution to the building's peak demand is equal to the appliance's average energy consumption rate during a typical day.<sup>5</sup> Average energy consumption rates at 10, 30, and 50 pounds per hour were 2.3 kW, 4.9 kW, and 7.5 kW, respectively. For an operation cooking an average of 15 pounds of food per hour over the course of the day (e.g., 150 lb of food over a ten hour day), the probable demand contribution for this fryer would be 3.0 kW.

# Results

Figure 3-6.  
Fryer cooking energy consumption profile.

Note: Light-load = 8 pieces/load; Medium-load = 24 pieces/load; Heavy-load = 48 pieces/load.

## Energy Cost Model

The test results can be used to estimate the annual energy consumption for the fryer in a real-world operation. A simple cost model was developed to calculate the relationship between the various cost components (e.g., preheat, idle and cooking costs) and the annual operating cost, using the ASTM test data. For this model, the fryer was used to cook 150 pounds of chicken over a 12-hour day, with one preheat per day, 365 days per year. The idle (ready-to-cook) time for the fryer was determined by taking the difference between the total daily on-time (12 hours) and the equivalent full-load cooking time. This approach produces a more accurate estimate of the operating cost for the fryer.

# Results

---

*Table 3-4. Estimated Fryer Energy Consumption and Cost.*

|  |               |
|--|---------------|
| Preheat Energy (kWh/day)                 | 2.1           |
| Idle Energy (kWh/day)                    | 7.94          |
| Cooking Energy (kWh/day)                 | 23.9          |
| <b>Annual Energy (kWh/year)</b>          | <b>12,374</b> |
| <b>Annual Cost (\$/year)<sup>a</sup></b> | <b>1,237</b>  |

<sup>a</sup> Fryer energy costs are based on \$0.10/kWh

## 4 Conclusions

---

Henny Penny's OF-341 large-vat electric fryer exhibited strong performance while cooking both breaded chicken product and traditional French fries. During the heavy-load tests, the fryer produced 69 lbs/h while demonstrating a cooking-energy efficiency of 73%. Similarly, during the French fry tests, the fryer produced 84 lbs/h while achieving an 86% cooking-energy efficiency.

While the OFE-341 fryer really showed its prowess with heavy-loads, it posted solid medium- and light-load efficiencies as well. During the chicken tests, the medium-load efficiency was nearly as high as for the heavy-load tests (72.8% vs 73.0%), and the light-load efficiency was a respectable 57%.

During non-cooking periods, the fryer required only 1.08 kW to maintain a ready-to-cook state (325°F oil temperature). Since fryers typically spend a good portion of the day in a ready-to-cook state, this translates to lower operating costs.

The estimated operational cost of the OFE-341 large vat electric fryer is \$1,237 per year. The model assumes the fryer is used to cook 150 lbs of chicken over a 12-hour day, 365 days a year. The model also assumes one preheat each day with the remaining on-time being an idle (standby) state.

Granted, the Henny Penny OFE-341 fryer has a high input for conventional pressure fryers and kettle fryers, but this large vat open deep fat fryer offers versatility without sacrificing performance. This fryer is well suited for institutions requiring high volume production.

# A Glossary

---

## Cooking Energy (kWh or kBtu)

The total energy consumed by an appliance as it is used to cook a specified food product.

## Cooking Energy Consumption Rate (kW or kBtu/h)

The average rate of energy consumption during the cooking period.

## Cooking-Energy Efficiency (%)

The quantity of energy input to the food products; expressed as a percentage of the quantity of energy input to the appliance during the heavy-, medium-, and light-load tests.

## Duty Cycle (%) Load Factor

The average energy consumption rate (based on a specified operating period for the appliance) expressed as a percentage of the measured energy input rate.

$$\text{Duty Cycle} = \frac{\text{Average Energy Consumption Rate}}{\text{Measured Energy Input Rate}} \times 100$$

## Energy Input Rate (kW or kBtu/h) Energy Consumption Rate Energy Rate

The peak rate at which an appliance will consume energy, typically reflected during preheat.

## Heating Value (Btu/ft<sup>3</sup>) Heating Content

The quantity of heat (energy) generated by the combustion of fuel. For natural gas, this quantity varies depending on the constituents of the gas.

## Idle Energy Rate (kW or Btu/h) Idle Energy Input Rate Idle Rate

The rate of appliance energy consumption while it is holding or maintaining a stabilized operating condition or temperature.

## Idle Temperature (°F, Setting)

The temperature of the cooking cavity/surface (selected by the appliance operator or specified for a controlled test) that is maintained by the appliance under an idle condition.

## Idle Duty Cycle (%) Idle Energy Factor

The idle energy consumption rate expressed as a percentage of the measured energy input rate.

$$\text{Idle Duty Cycle} = \frac{\text{Idle Energy Consumption Rate}}{\text{Measured Energy Input Rate}} \times 100$$

# Glossary

---

## Measured Input Rate (kW or Btu/h)

Measured Energy Input Rate

Measured Peak Energy Input Rate

The maximum or peak rate at which an appliance consumes energy, typically reflected during appliance preheat (i.e., the period of operation when all burners or elements are “on”).

## Pilot Energy Rate (kBtu/h)

Pilot Energy Consumption Rate

The rate of energy consumption by the standing or constant pilot while the appliance is not being operated (i.e., when the thermostats or control knobs have been turned off by the food service operator).

## Preheat Energy (kWh or Btu)

Preheat Energy Consumption

The total amount of energy consumed by an appliance during the preheat period.

## Preheat Rate (°F/min)

The rate at which the cook zone heats during a preheat.

## Preheat Time (minute)

Preheat Period

The time required for an appliance to warm from the ambient room temperature ( $75 \pm 5^\circ\text{F}$ ) to a specified (and calibrated) operating temperature or thermostat set point.

## Production Capacity (lb/h)

The maximum production rate of an appliance while cooking a specified food product in accordance with the heavy-load cooking test.

## Production Rate (lb/h)

Productivity

The average rate at which an appliance brings a specified food product to a specified “cooked” condition.

## Rated Energy Input Rate

(kW, W or Btu/h, Btu/h)

Input Rating (ANSI definition)

Nameplate Energy Input Rate

Rated Input

The maximum or peak rate at which an appliance consumes energy as rated by the manufacturer and specified on the nameplate.

## Recovery Time (minute, second)

The average time from the removal of the fry baskets from the fryer until the frying medium is within  $5^\circ\text{F}$  of the thermostat set point and the fryer is ready to be reloaded.

## Test Method

A definitive procedure for the identification, measurement, and evaluation of one or more qualities, characteristics, or properties of a material, product, system, or service that produces a test result.

## Typical Day

A sampled day of average appliance usage based on observations and/or operator interviews, used to develop an energy cost model for the appliance.

## **B** Appliance Specifications

---

# Open Fryers

## High-volume

OFE-341 Single well, electric

OFE-342 Two well, electric

OFG-341 Single well, gas

OFG-342 Two well, gas

*These high volume open fryers feature a larger fry well with higher efficiency and faster cycle recovery than any fryer of its size or type. Greater surface area produces more consistent frying results with items that float when cooking.*

### Description

The 340 series open fryers from Henny Penny are high volume open fryers designed to offer a maximum frying surface area within a reasonable footprint.

Controls are fully programmable. Auto Lift feature automatically lowers load to begin cycle and raises load to drain at end.

Electric elements are fully immersed. Induced-draft technology enables over 60% efficiency in gas units.

### Configuration

- Choose from one or two-well models.
- Available in electric or gas.
- Also available without Auto Lift feature.
- Connector kits available separately for connecting any combination of one or two-well units (all electric or all gas).
- Integrated dump station available on two well unit.

### Main Features

- Electronic controls for each well feature:
  - 12 programmable cook cycles.
  - Digital time and temperature display.
  - Dual timers to time half baskets separately.
  - Idle and melt modes.
  - Load compensation feature.
  - Cook cycle completion signal.
- Large rectangular well offers greater

surface area and promotes more even cooking.

- Specially designed "beach" accommodates shortening displacement when lowering the basket.
- Convenient built-in, single switch filtering system serves up to two wells.
- Doors swing open for easy access.

### Auto Lift Features

- Separate switch for Auto Lift and Pause/Resume.
- Each well can be programmed to operate half baskets independently or together at the touch of a button.
- Quiet, low-voltage motor and drive built into cabinet—no extra clearance needed.
- Easy basket set and release.

*Above: OFG-342 two-well with Auto Lift  
Left: Large well with specially designed "beach."*

### Accessories shipped with unit:

- (1) Set of cleaning brushes
- (10) Filter envelopes
- (4) Heavy-duty casters, two locking.
- (2) Half-baskets with handles  
OR (1) full basket per well.
- (3) third-size baskets are available, but can only be used on units without Auto Lift. Please specify when ordering.
- (1) Basket support per well.
- (1) Installation, operating and service manual.

## Order from:

Manufactured by:

**Henny Penny Corporation**

P.O. Box 60  
Eaton, OH 45320

# C Results Reporting Sheets

---

Manufacturer: Henny Penny  
Models: OFE-341  
Date: November 2004

## *Test Fryer and Elements*

Description of operational characteristics: Henny Penny's OFE-341 electric fryer is rated at 22.0 kW. The OFE-341 fryer features low watt-density ribbon elements submerged in the frying oil. A cooking computer controls the elements with features such as a melt cycle and multiple programmable cook times.

## *Apparatus*

√ Check if testing apparatus conformed to specifications in section 6.

Deviations: None.

---

## *Energy Input Rate*

---

|   |      |
|---|------|
| Rated (Btu/h)                                     | 22.0 |
| Measured (Btu/h)                                  | 21.1 |
| Percent Difference between Measured and Rated (%) | 4.09 |

---

## *Thermostat Calibration*

---

|                         |     |
|-------------------------|-----|
| Thermostat Setting (°F) | 325 |
| Oil Temperature (°F)    | 325 |

---

# Results Reporting Sheets

## Procedure for Calculating the Energy Consumption of a Fryer Based on Reported Test Results

Appliance test results are useful not only for benchmarking appliance performance, but also for estimating appliance energy consumption. The following procedure is a guideline for estimating fryer energy consumption based on data obtained from applying the appropriate test method.

The intent of this Appendix is to present a standard method for estimating fryer energy consumption based on ASTM performance test results. The examples contained herein are for information only and should not be considered an absolute. To obtain an accurate estimate of energy consumption for a particular operation, parameters specific to that operation should be used (e.g., operating time, and amount of food cooked under heavy-, medium-, and light-load conditions).

The calculation will proceed as follows: First, determine the appliance operating time and total number of preheats. Then estimate the quantity of food cooked and establish the breakdown between heavy- (48 pieces), medium- (24 pieces), and light- (8 pieces) loads. For example, a fryer operating for 12 hours a day with one preheat cooked 150 pounds of food: 36% of the food was cooked under heavy-load conditions, 48% was cooked under medium-load conditions, and 16% was cooked under light-load conditions. Calculate the energy due to cooking at heavy-, medium-, and light-load cooking rates, and then calculate the idle energy consumption. The total daily energy is the sum of these components plus the preheat energy. For simplicity, it is assumed that subsequent preheats require the same time and energy as the first preheat of the day.

The application of the test method to an electric fryer yielded the following results:

# Energy Cost Model

---

**Table E-1: Electric Fryer Performance Parameters.**

| Test                                 | Result |
|--------------------------------------|--------|
| Preheat Time (min)                   | 9.93   |
| Preheat Energy (kWh)                 | 2.10   |
| Idle Energy Rate (kW)                | 1.08   |
| Heavy-Load Cooking Energy Rate (kW)  | 9.96   |
| Medium-Load Cooking Energy Rate (kW) | 5.90   |
| Light-Load Cooking Energy Rate (kW)  | 2.67   |
| Production Capacity (lb/h)           | 68.9   |
| Medium-Load Production Rate (lb/h)   | 37.7   |
| Light-Load Production Rate (lb/h)    | 13.4   |

**Step 1—The operation being modeled has the following parameters**

**Table E-2: Fryers Operation Assumptions.**

|  |                        |
|--|------------------------|
| Operating Time   | 12 h                   |
| Number of Preheats                                     | 1 preheat              |
| Total Amount of Food Cooked                            | 150 lb                 |
| Percentage of Food Cooked Under Heavy-Load Conditions  | 36% (× 150 lb = 54 lb) |
| Percentage of Food Cooked Under Medium-Load Conditions | 48% (× 150 lb = 72 lb) |
| Percentage of Food Cooked Under Light-Load Conditions  | 16% (× 150 lb = 24 lb) |

**Step 2—Calculate the total heavy-load energy.**

The total time cooking heavy-loads is as follows:

$$t_h = \frac{\%_h \times W}{PC},$$

$$t_h = \frac{36\% \times 150 \text{ lb}}{68.9 \text{ lb/h}},$$

$$t_h = 0.78 \text{ h}$$

# Energy Cost Model

---

The total heavy-load energy consumption is then calculated as follows:

$$\begin{aligned}E_{elec,h} &= q_{elec,h} \times t_h \\E_{elec,h} &= 9.96 \text{ kW} \times 0.78 \text{ h}, \\E_{elec,h} &= 7.77 \text{ kWh}\end{aligned}$$

### **Step 3—Calculate the total medium-load energy.**

The total time cooking medium-loads is as follows:

$$\begin{aligned}t_m &= \frac{\% m \times W}{PR_m}, \\t_m &= \frac{48\% \times 150 \text{ lb}}{37.7 \text{ lb/h}}, \\t_m &= 1.91 \text{ h}\end{aligned}$$

The total medium-load energy consumption is then calculated as follows:

$$\begin{aligned}E_{elec,m} &= q_{elec,m} \times t_m \\E_{elec,m} &= 5.90 \text{ kW} \times 1.91 \text{ h}, \\E_{elec,m} &= 11.3 \text{ kWh}\end{aligned}$$

### **Step 4—Calculate the total light-load energy.**

The total time cooking light-loads is as follows:

$$\begin{aligned}t_l &= \frac{\% l \times W}{PR_l}, \\t_l &= \frac{16\% \times 150 \text{ lb}}{13.4 \text{ lb/h}}, \\t_l &= 1.79 \text{ h}\end{aligned}$$

The total light-load energy consumption is then calculated as follows:

$$\begin{aligned}E_{elec,l} &= q_{elec,l} \times t_l \\E_{elec,l} &= 2.67 \text{ kW} \times 1.79 \text{ h} \\E_{elec,l} &= 4.78 \text{ kWh}\end{aligned}$$

# Energy Cost Model

---

## **Step 5—Calculate the total idle time and energy consumption.**

The total idle time is determined as follows:

$$t_i = t_{on} - t_h - t_m - t_l - \frac{n_p \times t_p}{60},$$
$$t_i = 12.0 \text{ h} - 0.78 \text{ h} - 1.91 \text{ h} - 1.79 \text{ h} - \frac{1 \text{ preheat} \times 9.93 \text{ min}}{60 \text{ min/h}}$$
$$t_i = 7.35 \text{ h}$$

The idle energy consumption is then calculated as follows:

$$E_{elec,i} = q_{elec,i} \times t_i$$
$$E_{elec,i} = 1.08 \text{ kW} \times 7.35 \text{ h}$$
$$E_{elec,i} = 7.94 \text{ kWh}$$

## **Step 6—The total daily energy consumption is calculated as follows:**

$$E_{elec,daily} = E_{elec,h} + E_{elec,m} + E_{elec,l} + E_{elec,i} + n_p \times E_{elec,p}$$
$$E_{elec,daily} = 7.77 \text{ kWh} + 11.3 \text{ kWh} + 4.78 \text{ kWh} + 7.94 \text{ kWh} + 1 \times 2.10 \text{ kWh}$$
$$E_{elec,daily} = 33.9 \text{ kWh/day}$$

## **Step 7—Calculate the average demand as follows:**

$$q_{avg} = \frac{E_{elec,daily}}{t_{on}},$$
$$q_{avg} = \frac{33.9 \text{ kWh}}{12.0 \text{ h}},$$
$$q_{avg} = 2.83 \text{ kW}$$

## **Step 7—The annual energy cost is calculated as follows:**

$$Cost_{annual} = E_{elec,daily} \times R_{elec} \times Days$$
$$Cost_{annual} = 33.9 \text{ kWh/day} \times 0.10 \text{ \$/kWh} \times 365 \text{ days/year}$$
$$Cost_{annual} = 1,237 \text{ \$/year}$$
