1. Introduction

This document outlines the best practices on logging settings on stages in processes and objects. The decision as to which stages are logged and which are not should never be overlooked. A conscious use of the logging settings is key to prevent and resolve database, performance and archiving problems, as well as to address sensitive data policies.

2. Log settings

By default, stages used in Process Studio are logged and those in Object Studio are not. This can easily be changed by modifying the properties of a stage, selection of stages or all stages. Nearly all stage properties windows have a combo box with the stage logging options:

- Enabled
- Disabled
- Errors Only

Errors only will log the stage only if an error is thrown when the stage runs.

Alternatively, the menu commands Edit > Selected Stages > and Edit > All Stages can be used to modify the stage logging of more than one stage at a time.

	Select All	Ctrl+A			
	Selected Stages		F		Enable logging
	All Stages		۲		Disable logging
0	Properties				Log errors only
æ	Advanced Search	Ctrl+Shift+F		-	
	Add new action				

Page information stages are not logged, and Data Items are only logged when their values are used as inputs and outputs.

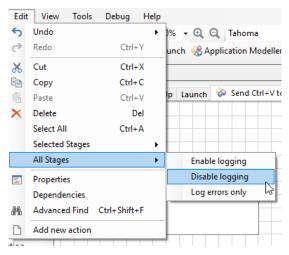

2.1. Object: stage logging options

Each stage within an Object can be set to one of the following levels:

- Enabled the stage name and actions will be logged
- Disabled no information about the stage's activity will be logged
- Errors Only no information will be logged unless the actions produce an error condition

Navigate Pro	operties						?	_		Х
Name:	Send Ctrl Shift and Down A	hrow								
Description:					^					
Application Expl	orer	Actions								
Filter the tree		Element			Params	Action			Inputs S	5
Excel Appli Main w Whole	rindow Windwso for SKE	Excel Ap	Dication			Global	Send Key	Event	Yes	
		Move L Inputs Name Text	lp Move Down	Data Text		Value "<{CTR	Ad		Remove	
Stage logging: E	inabled V	I [[ОК	Can	ncel

To quickly set all stages within an Object to be Disabled you can open the Object and choose the option **Edit -> All Stages -> Disabled**. This will set logging for all stages within all pages within the Object to be disabled.

2.2. Process: stage logging options

Each stage within a Process can be set to one of the following levels:

- Enabled the stage name and actions will be logged
- Disabled no information about the stage's activity will be logged
- Errors Only no information will be logged unless the actions produce an error condition
- **Don't log parameters on this stage** toggles logging of data parameters used by the stage on or off (e.g. business data)

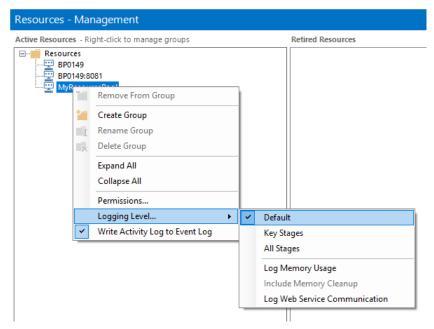

Action Prope	erties			?	_		×
Name:	Launch						
Description:		^					
Business Object	Notepad	•	0	Group:]Page 🗹] Data Typ	e
Action	Launch	•		\checkmark	View All	Items	
Inputs Outputs	Conditions			Binar	ies		^
Name	Data Type	Value		··· Colle			
Path	Text	"C:\Windows\System32\notepad.exe"		Dates			
				- Flags			
				Imag			
				- Num			
				Text			~
Stage logging: E	nabled \sim	Don't log parameters on this stage			OK	Car	ncel

Stage logging can be easily switched on, off or to errors only in the same way as with an Object, i.e. using **Edit -> All Stages**.

Note: It is not possible to disable parameter logging for all stages using this method. This setting must be set on each stage individually. It is therefore very important that each stage's parameter data implications should be assessed before any Process goes into Production where there is the potential for recording business data in the Blue Prism logging tables.

2.3. Runtime Resource Logging Levels

It is possible to override the logging in a process or object and set the logging at machine level, where each Runtime Resource can have its own logging level defined. This is achieved using the **Resources -> Management** screen, where a context menu option is provided to set Runtime Resource Logging Level options.

The basic logging level options are:

• **Default** - Logs any stages have Stage Logging set to 'Enabled' in the Process or Object which the Runtime Resource is running.

- All Stages Logs all stages regardless of which stages specifically have Stage Logging set to 'Enabled'. Note this may slow down operation of any Processes run by the Runtime Resource and will result in fuller logs. However this may be useful in diagnosing problems.
- Key Stages Overrides only the following stages:
 - o Action, Code, Navigate, Process, Read, Write, WaitStart

regardless of which stages specifically have Stage Logging set to 'Enabled'.

Memory Logging

Using the same context menu, it is possible to record the memory levels of a machine in the session logs.

- Log Memory Usage if enabled, all process log entries are accompanied by a record of how much memory (Working Set) was in use by the main Blue Prism executable at the time. Additionally, if the logged action refers to a target application, the identity and memory usage of that target application is also recorded.
- Include Memory Cleanup enabling this may produce more useful figures when diagnosing suspected memory leak issues.

Web Service logging

Web service details can also be added to the logs via the context menu.

• Log Web Service Communication - enabling this causes low-level web service communication to be logged - specifically, SOAP messages are logged in full detail. For consumed web services, the information is logged as part of the corresponding session log. For exposed web services, it is logged in the event log for the relevant Resource PC.

Note: If a Runtime Resource is online when its diagnostics settings are changed, it does not need to be restarted for the new settings to take effect. It will pick up and begin using the modified settings within two minutes at the most.

2.4. Unicode Logging

In Blue Prism, errors are logged in Non-Unicode format by default. Unicode logging can be enabled using the **System Settings** with the following option:

File Home Studio Control Dashboard Releases System System System System System System System System System System System System System System System System System System System System System System System System System System System System System System System System System System Work Services System Vide Settings System Vide Settings System Vide Settings System Vide Settings System Vide Settings System Vide Settings System Vide Settings System Vide Settings Work Courses Prove system System Vide Settings System Vide Settings System Vide Settings Prove system System Vide Settings Prove system System Vide Settings Work Courses Prove system System Vide Settings Prove system System Vide Settings System Vide Settings System Vide Settings Prove system System Vide Settings System Vide Settings Prove system System Vide Settings Prove system System Vide Setings System Vide Settings System Vide Settings Prove Se	🔈 Blue Pr	ism - Robotic Proces	s Automation Soft	ware				?	-		×

Note: It is generally not recommended to use Unicode, however, there are some instances where it will be required (i.e. logging text containing non-standard characters like logographic or symbols).

2.5. Log Viewer

Whenever a Process runs, it makes a record of each step it takes to create a Session Log. You can access this log from **Control Room**:

- Select one of the Session rows in the Environment list in Control Room.
- Right-click to open the mouse menu and select View Log.

or from **System > Audit section**.

The Log Viewer is used to inspect the log of a session, either as it is running or after it has finished. This is especially handy for reviewing the workings of a progress and tracking down problems. The Log Viewer has a search function enabling you to look through the (often numerous) rows of a log and the visibility of columns can be configured to suit.

Logs can be displayed in Grid or List view type. The Search function helps to find and highlight keywords and text analysing all or only specific columns.

3. Best Practice

The decision as to which stages are logged and which are not should not be overlooked:

- Logs are particularly useful during a test phase as a means to investigate bugs.
- However, a live Process running all day can put a vast amount of data into the database, the maintenance and back up of which should be considered.
- The security or legal implications of storing sensitive data are also something to think about.

Note: When Blue Prism Processes are run by Runtime Resources then they log information into the Blue Prism database. Over time, and if not regularly monitored and maintained, then the amount of data can get prohibitively large, potentially affecting the performance of the product and leading to an inability to establish a reliable automatic archiving function within the Blue Prism product.

3.1. General recommendations

• Logging for stages within an Object should only be enabled during the development phases of a Blue Prism implementation. Logging Objects is not recommended for Production systems.

- Logging for stages within a Process can be enabled to whatever level is required to support debugging and tracing during Development phases, or for auditing and reporting purposes when the Processes are deployed in a Production environment. The level required will be determined by Blue Prism developers in Development and Testing phases, and by the business requirements in Production.
- Often a usable audit trail can be created by turning on logging only for the following stages within a Process:
 - o All decision stages
 - o All choice stages
 - o All Errors
 - o Work Queue Get Next Item
- Turn off logging anywhere that might generate large amounts of log data. Look for:
 - o Loops which use large data sets
 - o Stages with lots of input or output parameters
- Some Data Item data types logged with parameter logging will consume larger amounts of disk space:
 - o Collections especially nested Collections
 - Markup for formatted text for example, JSON data, decoded HTML web pages, or large XML strings
 - o Text large strings of more than 4000 characters in one Data Item
 - o Images pictures uploaded into Data Items. Lossless image formats will store more data.
 - o Binary strings of binary data
- Avoid running processes 24x7 and instead configure them to stop at least once every 24 hour period. This will avoid creating a huge single log that later cannot be archived by normal means. There are very few business requirements that cannot afford a few minutes of downtime each day, and if abolutely necessary a process could be designed so that each resource took its 'rest' at a different time.

3.2. Security Policy

Care should be taken during design and development to ensure that data protection policies (i.e. PCI compliance) are kept to by the Blue Prism solution. Logging should only be turned on to the minimum levels required to support the process and trace case routes and outcomes. For example, case IDs or customer IDs may be logged, but personal client information should never be logged.

Blue Prism recommends reducing the logged stages to a minimum level and to ensure that no client data is logged as part of that.

One method of ensuring this is to check that the option "**Don't log parameters on this stage**" is checked for all stages which may contain sensitive data.

Stage logging:	Disabled	\sim	🗹 Don't log parameters on this stage

3.3. Development vs UAT/Production

When making the move from a Development or Test environments to one of User Acceptance Testing (UAT), Pre-Production or Production environments then there is a definite and necessary change required in the logging levels for the Processes and Objects.

Blue Prism recommendation for moving into UAT, Pre-Prod or Production is to ensure the following:

- All stages within all Objects should be set to DISABLED, or ERRORS ONLY (if necessary)
- All stages within all Processes should be set to DISABLED or ERRORS ONLY, except for
 - Work Queue item 'Get Next Item' actions, if the queue item is not holding sensitive data.
 - o Enable logging for all Decision and Choice stages within the Process
 - Logging for all Decision and Choice stages could be required only on the Main page if the process is based on a BP templates. Only Errors logging should be sufficient for all the other pages.
- All stages within all Processes should have parameter logging set to DISABLED
- Runtime Resources running Production processes should be set to log DEFAULT or KEY STAGES only
- It's common practice to reduce production logging over time, e.g. on the first day of go-live logging levels are left high to facilitate audit of the 'soft launch' period. As the process settles down the logging is decreased, e.g. week 1 at 100%, week 2 at 50% etc.

		BP Environment							
	Development	Test	Production (week 1)	Production (week 2)	Production (week n)				
Logging Settings	Enabled	Mostly Enabled	Mostly Enabled	Partially Enabled	Mostly disabled				
Logging data volume	Low	Low	High	High	Average				

• Periodically run a 'health check' on the production environemnt. Logging settings might change after the implementation of a CR and then inadvertently left enabled at high level.

3.4. Database monitoring

Blue Prism stores log details on the database in the [BPASessionLog_NonUnicode] or [BPASessionLog_Unicode] tables. Monitoring and auditing of these tables through third-party tools is allowed (verify you have the correct permissions to access the required table), however, please note, DB speed could be impacted by doing so.

Database Administrators can assist with the upfront and on-going assessment of the amount of disk space which your Blue Prism database may require. Monitoring the size of how much data is created for each Process in terms of the number of rows and space used by that data will form the basis for understanding:

- What size of disk is needed to support the data volumes in SQL Server during development phases.
- SQL Server TempDB database size: managing maintenance operations on large tables is recommended.
- How to configure Blue Prism's automatic archiving of log data and how to define an Archive and Backup policy.

Please refer to the **Maintaining a Blue Prism Database Server** data sheet available on the Blue Prism portal under the area: **Release specific documentation -> Infrastructure and Installation** as a guide for maintenance of a Blue Prism database.

3.5. Logging Configuration Policy

Blue Prism provides a template document to help customers to assess and record the logging configuration and policy. See the Documents section of the Portal.

3.6. Archive and Backup Policy

A sensible archive strategy will allow the production database size to be kept to a minimum whilst still allowing retrieval of log files, should business units require them. Backing up production process and objects will provide some resilience to database failure for business-critical processes.

Blue Prism provides a template document to help customers to assess and record this kind of operational task. See the Documents section of the Portal under the area: **Robotic Operating Model -> Technical and Security -> Database Administration -> Archive and Backup Policy** template.

4. Potential Issues

Potential issues arising from unduly large volumes of logging data are as follows:

- The database performance degrades and the general speed of running Processes also suffers.
- Database queries time out, recording timeout-related errors in the Event Logs and causing Processes to fail.
- Archiving fails to complete, only archiving small amounts of data when larger volumes were selected.
- Automatic archiving is blocked by an overly large log that cannot be moved due to its size.
