Chapter 1
Introduction

The MCUXpresso Software Development Kit (MCUXpresso SDK) is a collection of software enablement for NXP Microcontrollers that includes peripheral drivers, multicore support, USB stack, and integrated RTOS support for FreeRTOS^{TM} . In addition to the base enablement, the MCUXpresso SDK is augmented with demo applications, driver example projects, and API documentation to help users quickly leverage the support provided by MCUXpresso SDK. The KEx Web UI is available to provide access to all MCUXpresso SDK packages. See the *MCUXpresso Software Development Kit (SDK) Release Notes* (document MCUXSDKRN) in the Supported Devices section at `MCUXpresso-SDK: Software Development Kit for MCUXpresso` for details.

The MCUXpresso SDK is built with the following runtime software components:

- ARM® and DSP standard libraries, and CMSIS-compliant device header files which provide direct access to the peripheral registers.
- Peripheral drivers that provide stateless, high-performance, ease-of-use APIs. Communication drivers provide higher-level transactional APIs for a higher-performance option.
- RTOS wrapper driver built on on top of MCUXpresso SDK peripheral drivers and leverage native RTOS services to better comply to the RTOS cases.
- Real time operation systems (RTOS) for FreeRTOS OS.
- Stacks and middleware in source or object formats including:
  - A USB device, host, and OTG stack with comprehensive USB class support.
  - CMSIS-DSP, a suite of common signal processing functions.
  - The MCUXpresso SDK comes complete with software examples demonstrating the usage of the peripheral drivers, RTOS wrapper drivers, middleware, and RTOSes.

  All demo applications and driver examples are provided with projects for the following toolchains:
  - IAR Embedded Workbench
  - Keil MDK
  - MCUXpresso IDE

The peripheral drivers and RTOS driver wrappers can be used across multiple devices within the product family without modification. The configuration items for each driver are encapsulated into C language data structures. Device-specific configuration information is provided as part of the MCUXpresso SDK and need not be modified by the user. If necessary, the user is able to modify the peripheral driver and RTOS wrapper driver configuration during runtime. The driver examples demonstrate how to configure the drivers by passing the proper configuration data to the APIs. The folder structure is organized to reduce the total number of includes required to compile a project.

The rest of this document describes the API references in detail for the peripheral drivers and RTOS wrapper drivers. For the latest version of this and other MCUXpresso SDK documents, see the `kex.nxp.com/apidoc`.

Chapter 3
Architectural Overview

This chapter provides the architectural overview for the MCUXpresso Software Development Kit (MCU-Xpresso SDK). It describes each layer within the architecture and its associated components.

Overview

The MCUXpresso SDK architecture consists of five key components listed below.

1. The ARM Cortex Microcontroller Software Interface Standard (CMSIS) CORE compliance device-specific header files, SOC Header, and CMSIS math/DSP libraries.
2. Peripheral Drivers
3. Real-time Operating Systems (RTOS)
4. Stacks and Middleware that integrate with the MCUXpresso SDK
5. Demo Applications based on the MCUXpresso SDK

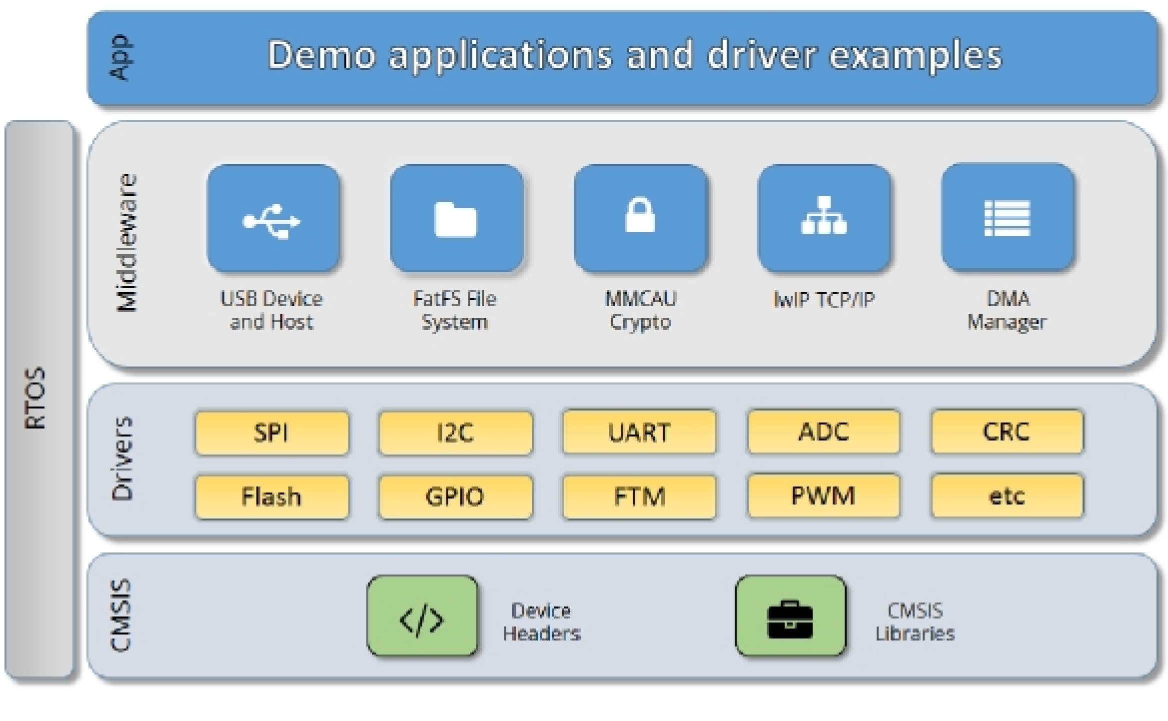

Figure 1: MCUXpresso SDK Block Diagram

MCU header files

Each supported MCU device in the MCUXpresso SDK has an overall System-on Chip (SoC) memory-mapped header file. This header file contains the memory map and register base address for each peripheral and the IRQ vector table with associated vector numbers. The overall SoC header file provides a access to the peripheral registers through pointers and predefined bit masks. In addition to the overall SoC memory-mapped header file, the MCUXpresso SDK includes a feature header file for each device. The feature header file allows NXP to deliver a single software driver for a given peripheral. The feature file ensures that the driver is properly compiled for the target SOC.

CMSIS Support

Along with the SoC header files and peripheral extension header files, the MCUXpresso SDK also includes common CMSIS header files for the ARM Cortex-M core and the math and DSP libraries from the latest CMSIS release. The CMSIS DSP library source code is also included for reference.

MCUXpresso SDK Peripheral Drivers

The MCUXpresso SDK peripheral drivers mainly consist of low-level functional APIs for the MCU product family on-chip peripherals and also of high-level transactional APIs for some bus drivers/DMA driver/eDMA driver to quickly enable the peripherals and perform transfers.

All MCUXpresso SDK peripheral drivers only depend on the CMSIS headers, device feature files, fsl_common.h, and fsl_clock.h files so that users can easily pull selected drivers and their dependencies into projects. With the exception of the clock/power-relevant peripherals, each peripheral has its own driver. Peripheral drivers handle the peripheral clock gating/ungating inside the drivers during initialization and deinitialization respectively.

Low-level functional APIs provide common peripheral functionality, abstracting the hardware peripheral register accesses into a set of stateless basic functional operations. These APIs primarily focus on the control, configuration, and function of basic peripheral operations. The APIs hide the register access details and various MCU peripheral instantiation differences so that the application can be abstracted from the low-level hardware details. The API prototypes are intentionally similar to help ensure easy portability across supported MCUXpresso SDK devices.

Transactional APIs provide a quick method for customers to utilize higher-level functionality of the peripherals. The transactional APIs utilize interrupts and perform asynchronous operations without user intervention. Transactional APIs operate on high-level logic that requires data storage for internal operation context handling. However, the Peripheral Drivers do not allocate this memory space. Rather, the user passes in the memory to the driver for internal driver operation. Transactional APIs ensure the NVIC is enabled properly inside the drivers. The transactional APIs do not meet all customer needs, but provide a baseline for development of custom user APIs.

Note that the transactional drivers never disable an NVIC after use. This is due to the shared nature of interrupt vectors on devices. It is up to the user to ensure that NVIC interrupts are properly disabled after usage is complete.

Interrupt handling for transactional APIs

A double weak mechanism is introduced for drivers with transactional API. The double weak indicates two levels of weak vector entries. See the examples below:

```
        PUBWEAK SPI0_IRQHandler
        PUBWEAK SPI0_DriverIRQHandler
SPI0_IRQHandler
```

```
LDR     R0, =SPI0_DriverIRQHandler
BX      R0
```

The first level of the weak implementation are the functions defined in the vector table. In the devices/<-DEVICE_NAME>/<TOOLCHAIN>/startup_<DEVICE_NAME>.s/.S file, the implementation of the first layer weak function calls the second layer of weak function. The implementation of the second layer weak function (ex. SPI0_DriverIRQHandler) jumps to itself (B .). The MCUXpresso SDK drivers with transactional APIs provide the reimplementation of the second layer function inside of the peripheral driver. If the MCUXpresso SDK drivers with transactional APIs are linked into the image, the SPI0_-DriverIRQHandler is replaced with the function implemented in the MCUXpresso SDK SPI driver.

The reason for implementing the double weak functions is to provide a better user experience when using the transactional APIs. For drivers with a transactional function, call the transactional APIs and the drivers complete the interrupt-driven flow. Users are not required to redefine the vector entries out of the box. At the same time, if users are not satisfied by the second layer weak function implemented in the MCU-Xpresso SDK drivers, users can redefine the first layer weak function and implement their own interrupt handler functions to suit their implementation.

The limitation of the double weak mechanism is that it cannot be used for peripherals that share the same vector entry. For this use case, redefine the first layer weak function to enable the desired peripheral interrupt functionality. For example, if the MCU's UART0 and UART1 share the same vector entry, redefine the UART0_UART1_IRQHandler according to the use case requirements.

Feature Header Files

The peripheral drivers are designed to be reusable regardless of the peripheral functional differences from one MCU device to another. An overall Peripheral Feature Header File is provided for the MCUXpresso SDK-supported MCU device to define the features or configuration differences for each sub-family device.

5.6.13 void ADC16_SetChannelConfig (ADC_Type * *base*, uint32_t *channelGroup*, const adc16_channel_config_t * *config*)

This operation triggers the conversion when in software trigger mode. When in hardware trigger mode, this API configures the channel while the external trigger source helps to trigger the conversion.

Note that the "Channel Group" has a detailed description. To allow sequential conversions of the ADC to be triggered by internal peripherals, the ADC has more than one group of status and control registers, one for each conversion. The channel group parameter indicates which group of registers are used, for example, channel group 0 is for Group A registers and channel group 1 is for Group B registers. The channel groups are used in a "ping-pong" approach to control the ADC operation. At any point, only one of the channel groups is actively controlling ADC conversions. The channel group 0 is used for both software and hardware trigger modes. Channel group 1 and greater indicates multiple channel group registers for use only in hardware trigger mode. See the chip configuration information in the appropriate MCU reference manual for the number of SC1n registers (channel groups) specific to this device. Channel group 1 or greater are not used for software trigger operation. Therefore, writing to these channel groups does not initiate a new conversion. Updating the channel group 0 while a different channel group is actively controlling a conversion is allowed and vice versa. Writing any of the channel group registers while that specific channel group is actively controlling a conversion aborts the current conversion.

Parameters

base	ADC16 peripheral base address.
channelGroup	Channel group index.
config	Pointer to the "adc16_channel_config_t" structure for the conversion channel.

5.6.14 static uint32_t ADC16_GetChannelConversionValue (ADC_Type * *base*, uint32_t *channelGroup*) [inline], [static]

base	ADC16 peripheral base address.
channelGroup	Channel group index.

Returns

CMP: Analog Comparator Driver

6.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Analog Comparator (CMP) module of MCUXpresso SDK devices.

The CMP driver is a basic comparator with advanced features. The APIs for the basic comparator enable the CMP to compare the two voltages of the two input channels and create the output of the comparator result. The APIs for advanced features can be used as the plug-in functions based on the basic comparator. They can process the comparator's output with hardware support.

6.2 Typical use case

6.2.1 Polling Configuration

```
int main(void)
{
    cmp_config_t mCmpConfigStruct;
    cmp_dac_config_t mCmpDacConfigStruct;

    // ...

    // Configures the comparator.
    CMP_Init(DEMO_CMP_INSTANCE);
    CMP_GetDefaultConfig(&mCmpConfigStruct);
    CMP_Configure(DEMO_CMP_INSTANCE, &mCmpConfigStruct);

    // Configures the DAC channel.
    mCmpDacConfigStruct.referenceVoltageSource =

        else
        {

    CMP_Configure(DEMO_CMP_INSTANCE, &mCmpConfigStruct);

    // Configures the DAC channel.

6.6 Function Documentation

6.6.1 void CMP_Init (CMP_Type * *base*, const cmp_config_t * *config*)

This function initializes the CMP module. The operations included are as follows.

- Enabling the clock for CMP module.
- Configuring the comparator.
- Enabling the CMP module. Note that for some devices, multiple CMP instances share the same clock gate. In this case, to enable the clock for any instance enables all CMPs. See the appropriate MCU reference manual for the clock assignment of the CMP.

Parameters

base	CMP peripheral base address.
config	Pointer to the configuration structure.

6.6.2 void CMP_Deinit (CMP_Type * *base*)

This function de-initializes the CMP module. The operations included are as follows.

- Disabling the CMP module.
- Disabling the clock for CMP module.

This function disables the clock for the CMP. Note that for some devices, multiple CMP instances share the same clock gate. In this case, before disabling the clock for the CMP, ensure that all the CMP instances are not used.

Parameters

base	CMP peripheral base address.

enable	Enables or disables the module.

6.6.4 void CMP_GetDefaultConfig (cmp_config_t * *config*)

7.6.2 void COP_Init (SIM_Type * *base*, const cop_config_t * *config*)

Example:

```
*  cop_config_t config;
*  COP_GetDefaultConfig(&config);
*  config.timeoutCycles = kCOP_2Power8CyclesOr2Power16Cycles
     ;
*  COP_Init(sim_base,&config);

7.6.3 static void COP_Disable (SIM_Type * *base*) [inline], [static]

This dedicated function is not provided. Instead, the COP_Disable function can be used to disable the COP.

Disables the COP module.

This function disables the COP Watchdog. Note: The COP configuration register is a write-once after reset. To disable the COP Watchdog, call this function first.

Parameters

base	SIM peripheral base address.

7.6.4 void COP_Refresh (SIM_Type * *base*)

This function feeds the COP.

Parameters

base	SIM peripheral base address.

Chapter 8
DAC: Digital-to-Analog Converter Driver

8.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Digital-to-Analog Converter (DAC) module of MCUXpresso SDK devices.

The DAC driver includes a basic DAC module (converter) and a DAC buffer.

The basic DAC module supports operations unique to the DAC converter in each DAC instance. The APIs in this part are used in the initialization phase, which enables the DAC module in the application. The APIs enable/disable the clock, enable/disable the module, and configure the converter. Call the initial APIs to prepare the DAC module for the application. The DAC buffer operates the DAC hardware buffer. The DAC module supports a hardware buffer to keep a group of DAC values to be converted. This feature supports updating the DAC output value automatically by triggering the buffer read pointer to move in the buffer. Use the APIs to configure the hardware buffer's trigger mode, watermark, work mode, and use size. Additionally, the APIs operate the DMA, interrupts, flags, the pointer (the index of the buffer), item values, and so on.

Note that the most functional features are designed for the DAC hardware buffer.

8.2 Typical use case

8.2.1 Working as a basic DAC without the hardware buffer feature

```
// ...

// Configures the DAC.
DAC_GetDefaultConfig(&dacConfigStruct);
DAC_Init(DEMO_DAC_INSTANCE, &dacConfigStruct);
DAC_Enable(DEMO_DAC_INSTANCE, true);
DAC_SetBufferReadPointer(DEMO_DAC_INSTANCE, 0U);

// ...

DAC_SetBufferValue(DEMO_DAC_INSTANCE, 0U, dacValue);
```

8.2.2 Working with the hardware buffer

```
    // ...

    EnableIRQ(DEMO_DAC_IRQ_ID);

    // ...

    // Configures the DAC.
    DAC_GetDefaultConfig(&dacConfigStruct);
    DAC_Init(DEMO_DAC_INSTANCE, &dacConfigStruct);
    DAC_Enable(DEMO_DAC_INSTANCE, true);
```

```
    // Configures the DAC buffer.
    DAC_GetDefaultBufferConfig(&dacBufferConfigStruct);
    DAC_SetBufferConfig(DEMO_DAC_INSTANCE, &dacBufferConfigStruct);
    DAC_SetBufferReadPointer(DEMO_DAC_INSTANCE, 0U); // Make sure the read pointer
       to the start.
    for (index = 0U, dacValue = 0; index < DEMO_DAC_USED_BUFFER_SIZE; index++, dacValue += (0xFFFU /
      DEMO_DAC_USED_BUFFER_SIZE))
    {
        DAC_SetBufferValue(DEMO_DAC_INSTANCE, index, dacValue);
    }
    // Clears flags.
#if defined(FSL_FEATURE_DAC_HAS_WATERMARK_DETECTION) && FSL_FEATURE_DAC_HAS_WATERMARK_DETECTION
    g_DacBufferWatermarkInterruptFlag = false;
#endif // FSL_FEATURE_DAC_HAS_WATERMARK_DETECTION

C90TFS Flash Driver

11.1 Overview

The flash provides the C90TFS Flash driver of MCUXpresso SDK devices with the C90TFS Flash module inside. The flash driver provides general APIs to handle specific operations on C90TFS/FTFx Flash module. The user can use those APIs directly in the application. In addition, it provides internal functions called by the driver. Although these functions are not meant to be called from the user's application directly, the APIs can still be used.

12.5.3 Function Documentation

12.5.3.1 void GPIO_PinInit (GPIO_Type ∗ *base,* uint32_t *pin,* const gpio_pin_config_t ∗ *config*)

To initialize the GPIO, define a pin configuration, as either input or output, in the user file. Then, call the GPIO_PinInit() function.

This is an example to define an input pin or an output pin configuration.

```
* // Define a digital input pin configuration,
* gpio_pin_config_t config =
* {
*   kGPIO_DigitalInput,
*   0,
* }
* //Define a digital output pin configuration,
* gpio_pin_config_t config =
* {
*   kGPIO_DigitalOutput,
*   0,
* }
*
```

If a pin is configured to generate the DMA request, the corresponding flag is cleared automatically at the completion of the requested DMA transfer. 12.6 FGPIO Driver

This chapter describes the programming interface of the FGPIO driver. The FGPIO driver configures the FGPIO module and provides a functional interface to build the GPIO application.

Note

> FGPIO (Fast GPIO) is only available in a few MCUs. FGPIO and GPIO share the same peripheral but use different registers. FGPIO is closer to the core than the regular GPIO and it's faster to read and write.

12.6.1 Typical use case

12.6.1.1 Output Operation

```
/* Output pin configuration */
gpio_pin_config_t led_config =
{
    kGpioDigitalOutput,
    1,
};
/*  Sets the configuration */
FGPIO_PinInit(FGPIO_LED, LED_PINNUM, &led_config);
```

12.6.1.2 Input Operation

      kPORT_InterruptFallingEdge);
NVIC_EnableIRQ(BOARD_SW2_IRQ);
gpio_pin_config_t sw1_config =
{
    kGpioDigitalInput,
    0,
};
/* Sets the input pin configuration */
FGPIO_PinInit(FGPIO_SW1, SW1_PINNUM, &sw1_config);
```

I2C: Inter-Integrated Circuit Driver

13.1 Overview

Modules

- I2C DMA Driver
- I2C Driver
- I2C FreeRTOS Driver
- I2C eDMA Driver

13.2 I2C Driver

13.2.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Inter-Integrated Circuit (I2C) module of MCUXpresso SDK devices.

The I2C driver includes functional APIs and transactional APIs.

Functional APIs target the low-level APIs. Functional APIs can be used for the I2C master/slave initialization/configuration/operation for optimization/customization purpose. Using the functional APIs requires knowing the I2C master peripheral and how to organize functional APIs to meet the application requirements. The I2C functional operation groups provide the functional APIs set.

Transactional APIs target the high-level APIs. The transactional APIs can be used to enable the peripheral quickly and also in the application if the code size and performance of transactional APIs satisfy the requirements. If the code size and performance are critical requirements, see the transactional API implementation and write custom code using the functional APIs or accessing the hardware registers.

Transactional APIs support asynchronous transfer. This means that the functions I2C_MasterTransferNonBlocking() set up the interrupt non-blocking transfer. When the transfer completes, the upper layer is notified through a callback function with the status.

13.2.2 Typical use case

13.2.7 Function Documentation

13.2.7.1 void I2C_MasterInit (I2C_Type ∗ *base,* const i2c_master_config_t ∗ *masterConfig,* uint32_t *srcClock_Hz*)

Call this API to ungate the I2C clock and configure the I2C with master configuration.

Note

This API should be called at the beginning of the application. Otherwise, any operation to the I2C module can cause a hard fault because the clock is not enabled. The configuration structure can be custom filled or it can be set with default values by using the I2C_MasterGetDefaultConfig(). After calling this API, the master is ready to transfer. This is an example.

```
* i2c_master_config_t config = {
* .enableMaster = true,
* .enableStopHold = false,
* .highDrive = false,
* .baudRate_Bps = 100000,
* .glitchFilterWidth = 0
* };
* I2C_MasterInit(I2C0, &config, 12000000U);
*
```

Parameters

base	I2C base pointer
masterConfig	A pointer to the master configuration structure
srcClock_Hz	I2C peripheral clock frequency in Hz

13.2.7.2 void I2C_SlaveInit (I2C_Type * *base*, const i2c_slave_config_t * *slaveConfig*, uint32_t *srcClock_Hz*)

Call this API to ungate the I2C clock and initialize the I2C with the slave configuration.

Note

This API should be called at the beginning of the application. Otherwise, any operation to the I2C module can cause a hard fault because the clock is not enabled. The configuration structure can partly be set with default values by I2C_SlaveGetDefaultConfig() or it can be custom filled by the user. This is an example.

```
* i2c_slave_config_t config = {
* .enableSlave = true,
* .enableGeneralCall = false,
* .addressingMode = kI2C_Address7bit,
* .slaveAddress = 0x1DU,
* .enableWakeUp = false,
* .enablehighDrive = false,
* .enableBaudRateCtl = false,

13.2.7.31 status_t I2C_SlaveTransferNonBlocking (I2C_Type ∗ *base,* i2c_slave_handle_t ∗ *handle,* uint32_t *eventMask*)

Call this API after calling the I2C_SlaveInit() and I2C_SlaveTransferCreateHandle() to start processing transactions driven by an I2C master. The slave monitors the I2C bus and passes events to the callback that was passed into the call to I2C_SlaveTransferCreateHandle(). The callback is always invoked from the interrupt context.

The set of events received by the callback is customizable. To do so, set the *eventMask* parameter to the OR'd combination of i2c_slave_transfer_event_t enumerators for the events you wish to receive. The kI2C_SlaveTransmitEvent and #kLPI2C_SlaveReceiveEvent events are always enabled and do not need to be included in the mask. Alternatively, pass 0 to get a default set of only the transmit and receive events that are always enabled. In addition, the kI2C_SlaveAllEvents constant is provided as a convenient way to enable all events.

Parameters

base	The I2C peripheral base address.
handle	Pointer to #i2c_slave_handle_t structure which stores the transfer state.
eventMask	Bit mask formed by OR'ing together i2c_slave_transfer_event_t enumerators to specify which events to send to the callback. Other accepted values are 0 to get a default set of only the transmit and receive events, and kI2C_SlaveAllEvents to enable all events.

Return values

#kStatus_Success	Slave transfers were successfully started.
kStatus_I2C_Busy	Slave transfers have already been started on this handle.

Chapter 14
LLWU: Low-Leakage Wakeup Unit Driver

14.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Low-Leakage Wakeup Unit (LLWU) module of MCUXpresso SDK devices. The LLWU module allows the user to select external pin sources and internal modules as a wake-up source from low-leakage power modes.

14.2 External wakeup pins configurations

Configures the external wakeup pins' working modes, gets, and clears the wake pin flags. External wakeup pins are accessed by the `pinIndex`, which is started from 1. Numbers of the external pins depend on the SoC configuration.

14.3 Internal wakeup modules configurations

Enables/disables the internal wakeup modules and gets the module flags. Internal modules are accessed by `moduleIndex`, which is started from 1. Numbers of external pins depend the on SoC configuration.

14.4 Digital pin filter for external wakeup pin configurations

Configures the digital pin filter of the external wakeup pins' working modes, gets, and clears the pin filter flags. Digital pin filters are accessed by the `filterIndex`, which is started from 1. Numbers of external pins depend on the SoC configuration.

15.2 LPSCI Driver

15.2.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Universal Asynchronous Receiver/Transmitter (LPSCI) module of MCUXpresso SDK devices.

The LPSCI driver can be split into 2 parts: functional APIs and transactional APIs.

Functional APIs are feature/property target low level APIs. Functional APIs can be used for the LPSCI initialization/configuration/operation for optimization/customization purpose. Using the functional API requires knowledge of the LPSCI peripheral and how to organize functional APIs to meet the application requirements. All functional APIs use the peripheral base address as the first parameter. The LPSCI functional operation groups provide the functional APIs set.

The transactional APIs are transaction target high level APIs. Transactional APIs can be used to enable the peripheral quickly and also in the user's application if the code size and performance of transactional APIs can satisfy the user's requirements. If there are special requirements for the code size and performance, see the transactional API implementation and write custom code. All transactional APIs use the lpsci_handle_t as the second parameter. Initialize the handle by calling the LPSCI_TransferCreateHandle() API.

Transactional APIs support queue feature for both transmit/receive. Whenever the user calls the LPSCI_TransferSendNonBlocking() or LPSCI_TransferReceiveNonBlocking(), the transfer structure is queued into the internally maintained software queue. The driver automatically continues the transmit/receive if the queue is not empty. When a transfer is finished, the callback is called to inform the user about the completion.

The LPSCI transactional APIs support the background receive. Provide the ringbuffer address and size while calling the LPSCI_TransferCreateHandle() API. The driver automatically starts receiving the data from the receive buffer into the ringbuffer. When the user makes subsequent calls to the LPSCI_ReceiveDataIRQ(), the driver provides the received data in the ringbuffer for user buffer directly and queues the left buffer into the receive queue.

15.2.2 Function groups

15.2.2.1 LPSCI functional Operation

This function group implements the LPSCI functional API. Functional APIs are feature-oriented.

15.2.2.2 LPSCI transactional Operation

15.2.3 Typical use case

user_config.baudRate = 115200U;

LPSCI_Init(UART0,&user_config,120000000U);
LPSCI_EnableTx(UART0, true);
LPSCI_EnableRx(UART0, true);

LPSCI_WriteBlocking(UART0, txbuff, sizeof(txbuff)-1);

while(1)
{
    LPSCI_ReadBlocking(UART0,&ch, 1);
    LPSCI_WriteBlocking(UART0, &ch, 1);
}
```

15.2.8.18 void LPSCI_TransferCreateHandle (UART0_Type ∗ *base*, lpsci_handle_t ∗ *handle*, lpsci_transfer_callback_t *callback*, void ∗ *userData*)

This function initializes the LPSCI handle, which can be used for other LPSCI transactional APIs. Usually, for a specified LPSCI instance, call this API once to get the initialized handle.

LPSCI driver supports the "background" receiving, which means that the user can set up an RX ring buffer optionally. Data received are stored into the ring buffer even when the user doesn't call the LPSCI_-TransferReceiveNonBlocking() API. If there is already data received in the ring buffer, get the received data from the ring buffer directly. The ring buffer is disabled if pass NULL as `ringBuffer`.

Parameters

handle	LPSCI handle pointer.
base	LPSCI peripheral base address.
ringBuffer	Start address of ring buffer for background receiving. Pass NULL to disable the ring buffer.

ringBufferSize	size of the ring buffer.

15.2.8.19 void LPSCI_TransferStartRingBuffer (UART0_Type ∗ *base*, lpsci_handle_t ∗ *handle*, uint8_t ∗ *ringBuffer*, size_t *ringBufferSize*)

This function sets up the RX ring buffer to a specific LPSCI handle.

When the RX ring buffer is used, data received is stored into the ring buffer even when the user doesn't call the LPSCI_TransferReceiveNonBlocking() API. If there is already data received in the ring buffer, the user can get the received data from the ring buffer directly.

Note

> When using the RX ring buffer, one byte is reserved for internal use. In other words, if `ringBufferSize` is 32, only 31 bytes are used for saving data.

Parameters

base	LPSCI peripheral base address.
handle	LPSCI handle pointer.
ringBuffer	Start address of ring buffer for background receiving. Pass NULL to disable the ring buffer.
ringBufferSize	size of the ring buffer.

15.2.8.20 void LPSCI_TransferStopRingBuffer (UART0_Type ∗ *base*, lpsci_handle_t ∗ *handle*)

This function aborts the background transfer and uninstalls the ringbuffer.

Parameters

base	LPSCI peripheral base address.
handle	LPSCI handle pointer.

15.2.8.21 status_t LPSCI_TransferSendNonBlocking (UART0_Type ∗ *base*, lpsci_handle_t ∗ *handle*, lpsci_transfer_t ∗ *xfer*)

This function sends data using the interrupt method. This is a non-blocking function, which returns directly without waiting for all data to be written to the TX register. When all data is written to the TX register in ISR, LPSCI driver calls the callback function and passes the kStatus_LPSCI_TxIdle as status parameter.

Note

The kStatus_LPSCI_TxIdle is passed to the upper layer when all data is written to the TX register. However, it does not ensure that all data is sent out. Before disabling the TX, check the kLPSCI_-TransmissionCompleteFlag to ensure that the TX is complete.

Parameters

handle	LPSCI handle pointer.
xfer	LPSCI transfer structure, refer to #LPSCI_transfer_t.

Return values

kStatus_Success	Successfully start the data transmission.

15.2.8.24 status_t LPSCI_TransferReceiveNonBlocking (UART0_Type * *base*, lpsci_handle_t * *handle*, lpsci_transfer_t * *xfer*, size_t * *receivedBytes*)

This function receives data using the interrupt method. This is a non-blocking function which returns without waiting for all data to be received. If the RX ring buffer is used and not empty, the data in ring buffer is copied and the parameter `receivedBytes` shows how many bytes are copied from the ring buffer. After copying, if the data in ring buffer is not enough to read, the receive request is saved by the LPSCI driver. When new data arrives, the receive request is serviced first. When all data is received, the LPSCI driver notifies the upper layer through a callback function and passes the status parameter kStatus-_LPSCI_RxIdle. For example, the upper layer needs 10 bytes but there are only 5 bytes in the ring buffer. The 5 bytes are copied to the xfer->data and the function returns with the parameter `receivedBytes` set to 5. For the remaining 5 bytes, newly arrived data is saved from the xfer->data[5]. When 5 bytes are received, the LPSCI driver notifies the upper layer. If the RX ring buffer is not enabled, this function enables the RX and RX interrupt to receive data to the xfer->data. When all data is received, the upper layer is notified.

Parameters

handle	LPSCI handle pointer.
xfer	lpsci transfer structure. See lpsci_transfer_t.
receivedBytes	Bytes received from the ring buffer directly.

Return values

kStatus_Success	Successfully queue the transfer into transmit queue.

Chapter 16
LPTMR: Low-Power Timer

16.1 Overview

The MCUXpresso SDK provides a driver for the Low-Power Timer (LPTMR) of MCUXpresso SDK devices.

16.2 Function groups

The LPTMR driver supports operating the module as a time counter or as a pulse counter.

16.2.1 Initialization and deinitialization

The function LPTMR_Init() initializes the LPTMR with specified configurations. The function LPTMR_-GetDefaultConfig() gets the default configurations. The initialization function configures the LPTMR for a timer or a pulse counter mode mode. It also sets up the LPTMR's free running mode operation and a clock source.

The function LPTMR_DeInit() disables the LPTMR module and gates the module clock.

16.2.2 Timer period Operations

The function LPTMR_SetTimerPeriod() sets the timer period in units of count. Timers counts from 0 to the count value set here.

The function LPTMR_GetCurrentTimerCount() reads the current timer counting value. This function returns the real-time timer counting value ranging from 0 to a timer period.

The timer period operation function takes the count value in ticks. Call the utility macros provided in the fsl_common.h file to convert to microseconds or milliseconds.

16.2.3 Start and Stop timer operations

The function LPTMR_StartTimer() starts the timer counting. After calling this function, the timer counts up to the counter value set earlier by using the LPTMR_SetPeriod() function. Each time the timer reaches the count value and increments, it generates a trigger pulse and sets the timeout interrupt flag. An interrupt is also triggered if the timer interrupt is enabled.

The function LPTMR_StopTimer() stops the timer counting and resets the timer's counter register.

16.2.4 Status

Provides functions to get and clear the LPTMR status.

16.2.5 Interrupt

Provides functions to enable/disable LPTMR interrupts and get the currently enabled interrupts.

16.3 Typical use case

16.3.1 LPTMR tick example

Updates the LPTMR period and toggles an LED periodically.

```
int main(void)
{
    uint32_t currentCounter = 0U;
    lptmr_config_t lptmrConfig;

    LED_INIT();

    /* Board pin, clock, debug console initialization */
    BOARD_InitHardware();

    /* Configures the LPTMR */
    LPTMR_GetDefaultConfig(&lptmrConfig);

    /* Initializes the LPTMR */
    LPTMR_Init(LPTMR0, &lptmrConfig);

    /* Sets the timer period */
    LPTMR_SetTimerPeriod(LPTMR0, USEC_TO_COUNT(1000000U, LPTMR_SOURCE_CLOCK));

    /* Enables a timer interrupt */
    LPTMR_EnableInterrupts(LPTMR0,
      kLPTMR_TimerInterruptEnable);

    /* Enables the NVIC */
    EnableIRQ(LPTMR0_IRQn);

    PRINTF("Low Power Timer Example\r\n");

    /* Starts counting */
    LPTMR_StartTimer(LPTMR0);
    while (1)
    {
        if (currentCounter != lptmrCounter)
        {
            currentCounter = lptmrCounter;
            PRINTF("LPTMR interrupt No.%d \r\n", currentCounter);
        }
    }
}
```

Chapter 17
PIT: Periodic Interrupt Timer

17.1 Overview

The MCUXpresso SDK provides a driver for the Periodic Interrupt Timer (PIT) of MCUXpresso SDK devices.

17.2 Function groups

The PIT driver supports operating the module as a time counter.

17.2.1 Initialization and deinitialization

The function PIT_Init() initializes the PIT with specified configurations. The function PIT_GetDefaultConfig() gets the default configurations. The initialization function configures the PIT operation in debug mode.

The function PIT_SetTimerChainMode() configures the chain mode operation of each PIT channel.

The function PIT_Deinit() disables the PIT timers and disables the module clock.

17.2.2 Timer period Operations

The function PITR_SetTimerPeriod() sets the timer period in units of count. Timers begin counting down from the value set by this function until it reaches 0.

The function PIT_GetCurrentTimerCount() reads the current timer counting value. This function returns the real-time timer counting value, in a range from 0 to a timer period.

The timer period operation functions takes the count value in ticks. Users can call the utility macros provided in fsl_common.h to convert to microseconds or milliseconds.

17.2.3 Start and Stop timer operations

The function PIT_StartTimer() starts the timer counting. After calling this function, the timer loads the period value set earlier via the PIT_SetPeriod() function and starts counting down to 0. When the timer reaches 0, it generates a trigger pulse and sets the timeout interrupt flag.

The function PIT_StopTimer() stops the timer counting.

17.2.4 Status

Provides functions to get and clear the PIT status.

17.2.5 Interrupt

Provides functions to enable/disable PIT interrupts and get current enabled interrupts.

17.3 Typical use case

17.3.1 PIT tick example

Updates the PIT period and toggles an LED periodically.

```
int main(void)
{
    /* Structure of initialize PIT */
    pit_config_t pitConfig;

    /* Initialize and enable LED */
    LED_INIT();

    /* Board pin, clock, debug console init */
    BOARD_InitHardware();

    PIT_GetDefaultConfig(&pitConfig);

    /* Init pit module */
    PIT_Init(PIT, &pitConfig);

    /* Set timer period for channel 0 */
    PIT_SetTimerPeriod(PIT, kPIT_Chnl_0, USEC_TO_COUNT(1000000U,
      PIT_SOURCE_CLOCK));

    /* Enable timer interrupts for channel 0 */
    PIT_EnableInterrupts(PIT, kPIT_Chnl_0,
      kPIT_TimerInterruptEnable);

    /* Enable at the NVIC */
    EnableIRQ(PIT_IRQ_ID);

    /* Start channel 0 */
    PRINTF("\r\nStarting channel No.0 ...");
    PIT_StartTimer(PIT, kPIT_Chnl_0);

    while (true)
    {
        /* Check whether occur interupt and toggle LED */
        if (true == pitIsrFlag)
        {
            PRINTF("\r\n Channel No.0 interrupt is occured !");
            LED_TOGGLE();
            pitIsrFlag = false;
        }
    }
}

17.6 Function Documentation

17.6.1 void PIT_Init (PIT_Type ∗ *base*, const pit_config_t ∗ *config*)

Note

This API should be called at the beginning of the application using the PIT driver.

Parameters

base	PIT peripheral base address
config	Pointer to the user's PIT config structure

17.6.2 void PIT_Deinit (PIT_Type ∗ *base*)

Parameters

base	PIT peripheral base address

17.6.3 static void PIT_GetDefaultConfig (pit_config_t ∗ *config*) [inline], [static]

The default values are as follows.

```
*     config->enableRunInDebug = false;
*
```

Parameters

config	Pointer to the onfiguration structure.

17.6.4 static void PIT_SetTimerChainMode (PIT_Type ∗ *base*, pit_chnl_t *channel*, bool *enable*) [inline], [static]

When a timer has a chain mode enabled, it only counts after the previous timer has expired. If the timer n-1 has counted down to 0, counter n decrements the value by one. Each timer is 32-bits, which allows the developers to chain timers together and form a longer timer (64-bits and larger). The first timer (timer 0) can't be chained to any other timer.

Parameters

base	PIT peripheral base address
channel	Timer channel number which is chained with the previous timer
enable	Enable or disable chain. true: Current timer is chained with the previous timer. false: Timer doesn't chain with other timers.

17.6.5 static void PIT_EnableInterrupts (PIT_Type ∗ *base*, pit_chnl_t *channel*, uint32_t *mask*) [inline], [static]

Parameters

base	PIT peripheral base address
channel	Timer channel number
mask	The interrupts to enable. This is a logical OR of members of the enumeration pit_interrupt_enable_t

17.6.6 static void PIT_DisableInterrupts (PIT_Type ∗ *base*, pit_chnl_t *channel*, uint32_t *mask*) [inline], [static]

Parameters

base	PIT peripheral base address
channel	Timer channel number
mask	The interrupts to disable. This is a logical OR of members of the enumeration pit_-interrupt_enable_t

Parameters

base	PIT peripheral base address
channel	Timer channel number

Returns

The status flags. This is the logical OR of members of the enumeration pit_status_flags_t

17.6.9 static void PIT_ClearStatusFlags (PIT_Type * *base*, pit_chnl_t *channel*, uint32_t *mask*) [inline], [static]

Parameters

base	PIT peripheral base address
channel	Timer channel number
mask	The status flags to clear. This is a logical OR of members of the enumeration pit_-status_flags_t

17.6.10 static void PIT_SetTimerPeriod (PIT_Type * *base*, pit_chnl_t *channel*, uint32_t *count*) [inline], [static]

Timers begin counting from the value set by this function until it reaches 0, then it generates an interrupt and load this register value again. Writing a new value to this register does not restart the timer. Instead, the value is loaded after the timer expires.

Note

Users can call the utility macros provided in fsl_common.h to convert to ticks.

Parameters

base	PIT peripheral base address
channel	Timer channel number
count	Timer period in units of ticks

17.6.11 static uint32_t PIT_GetCurrentTimerCount (PIT_Type * *base*, pit_chnl_t *channel*) [inline], [static]

Note

Users can call the utility macros provided in fsl_common.h to convert ticks to usec or msec.

Parameters

base	PIT peripheral base address
channel	Timer channel number

Returns

Current timer counting value in ticks

17.6.12 static void PIT_StartTimer (PIT_Type ∗ *base,* pit_chnl_t *channel*) [inline], [static]

After calling this function, timers load period value, count down to 0 and then load the respective start value again. Each time a timer reaches 0, it generates a trigger pulse and sets the timeout interrupt flag.

Parameters

base	PIT peripheral base address
channel	Timer channel number.

17.6.13 static void PIT_StopTimer (PIT_Type ∗ *base,* pit_chnl_t *channel*) [inline], [static]

This function stops every timer counting. Timers reload their periods respectively after the next time they call the PIT_DRV_StartTimer.

Parameters

base	PIT peripheral base address
channel	Timer channel number.

17.6.14 uint64_t PIT_GetLifetimeTimerCount (PIT_Type ∗ *base*)

The lifetime timer is a 64-bit timer which chains timer 0 and timer 1 together. Timer 0 and 1 are chained by calling the PIT_SetTimerChainMode before using this timer. The period of lifetime timer is equal to the "period of timer 0 ∗ period of timer 1". For the 64-bit value, the higher 32-bit has the value of timer 1, and the lower 32-bit has the value of timer 0.

Parameters

base	PIT peripheral base address

Returns

Current lifetime timer value

Chapter 21
RTC: Real Time Clock

21.1 Overview

The MCUXpresso SDK provides a driver for the Real Time Clock (RTC) of MCUXpresso SDK devices.

21.2 Function groups

The RTC driver supports operating the module as a time counter.

21.2.1 Initialization and deinitialization

The function RTC_Init() initializes the RTC with specified configurations. The function RTC_GetDefault-Config() gets the default configurations.

The function RTC_Deinit() disables the RTC timer and disables the module clock.

21.2.2 Set & Get Datetime

The function RTC_SetDatetime() sets the timer period in seconds. Users pass in the details in date & time format by using the below data structure.

```
typedef struct _rtc_datetime
{
    uint16_t year;
    uint8_t month;
    uint8_t day;
    uint8_t hour;
    uint8_t minute;
    uint8_t second;
} rtc_datetime_t;
```

The function RTC_GetDatetime() reads the current timer value in seconds, converts it to date & time format and stores it into a datetime structure passed in by the user.

21.2.3 Set & Get Alarm

The function RTC_SetAlarm() sets the alarm time period in seconds. Users pass in the details in date & time format by using the datetime data structure.

The function RTC_GetAlarm() reads the alarm time in seconds, converts it to date & time format and stores it into a datetime structure passed in by the user.

21.2.4 Start & Stop timer

The function RTC_StartTimer() starts the RTC time counter.

The function RTC_StopTimer() stops the RTC time counter.

21.2.5 Status

Provides functions to get and clear the RTC status.

21.2.6 Interrupt

Provides functions to enable/disable RTC interrupts and get current enabled interrupts.

21.2.7 RTC Oscillator

Some SoC's allow control of the RTC oscillator through the RTC module.

The function RTC_SetOscCapLoad() allows the user to modify the capacitor load configuration of the RTC oscillator.

21.2.8 Monotonic Counter

Some SoC's have a 64-bit Monotonic counter available in the RTC module.

The function RTC_SetMonotonicCounter() writes a 64-bit to the counter.

The function RTC_GetMonotonicCounter() reads the monotonic counter and returns the 64-bit counter value to the user.

The function RTC_IncrementMonotonicCounter() increments the Monotonic Counter by one.

21.3 Typical use case

21.3.1 RTC tick example

Example to set the RTC current time and trigger an alarm.

```
int main(void)
{
    uint32_t sec;
    uint32_t currSeconds;
    rtc_datetime_t date;

Chapter 23
SMC: System Mode Controller Driver

23.1 Overview

The MCUXpresso SDK provides a peripheral driver for the System Mode Controller (SMC) module of MCUXpresso SDK devices. The SMC module sequences the system in and out of all low-power stop and run modes.

API functions are provided to configure the system for working in a dedicated power mode. For different power modes, SMC_SetPowerModexxx() function accepts different parameters. System power mode state transitions are not available between power modes. For details about available transitions, see the power mode transitions section in the SoC reference manual.

23.2 Typical use case

23.2.1 Enter wait or stop modes

SMC driver provides APIs to set MCU to different wait modes and stop modes. Pre and post functions are used for setting the modes. The pre functions and post functions are used as follows.

1. Disable/enable the interrupt through PRIMASK. This is an example use case. The application sets the wakeup interrupt and calls SMC function SMC_SetPowerModeStop to set the MCU to STOP mode, but the wakeup interrupt happens so quickly that the ISR completes before the function SMC_SetPowerModeStop. As a result, the MCU enters the STOP mode and never is woken up by the interrupt. In this use case, the application first disables the interrupt through PRIMASK, sets the wakeup interrupt, and enters the STOP mode. After wakeup, enable the interrupt through PRIMASK. The MCU can still be woken up by disabling the interrupt through PRIMASK. The pre and post functions handle the PRIMASK.
2. Disable/enable the flash speculation. When entering stop modes, the flash speculation might be interrupted. As a result, pre functions disable the flash speculation and post functions enable it.

```
SMC_PreEnterStopModes();

/* Enable the wakeup interrupt here. */

SMC_SetPowerModeStop(SMC, kSMC_PartialStop);

SMC_PostExitStopModes();
```

23.6 Function Documentation

23.6.1 static void SMC_SetPowerModeProtection (SMC_Type ∗ *base,* uint8_t *allowedModes*) `[inline]`, `[static]`

This function configures the power mode protection settings for supported power modes in the specified chip family. The available power modes are defined in the smc_power_mode_protection_t. This should be done at an early system level initialization stage. See the reference manual for details. This register can only write once after the power reset.

The allowed modes are passed as bit map. For example, to allow LLS and VLLS, use SMC_SetPowerModeProtection(kSMC_AllowPowerModeVlls | kSMC_AllowPowerModeVlps). To allow all modes, use SMC_SetPowerModeProtection(kSMC_AllowPowerModeAll).

SPI: Serial Peripheral Interface Driver

24.1 Overview

Modules

- SPI DMA Driver
- SPI Driver
- SPI FreeRTOS driver

24.2 SPI Driver

24.2.1 Overview

SPI driver includes functional APIs and transactional APIs.

Functional APIs are feature/property target low level APIs. Functional APIs can be used for SPI initialization/configuration/operation for optimization/customization purpose. Using the functional API requires the knowledge of the SPI peripheral and how to organize functional APIs to meet the application requirements. All functional API use the peripheral base address as the first parameter. SPI functional operation groups provide the functional API set.

Transactional APIs are transaction target high level APIs. Transactional APIs can be used to enable the peripheral and in the application if the code size and performance of transactional APIs satisfy the requirements. If the code size and performance are a critical requirement, see the transactional API implementation and write a custom code. All transactional APIs use the spi_handle_t as the first parameter. Initialize the handle by calling the SPI_MasterTransferCreateHandle() or SPI_SlaveTransferCreateHandle() API.

Transactional APIs support asynchronous transfer. This means that the functions SPI_MasterTransferNonBlocking() and SPI_SlaveTransferNonBlocking() set up the interrupt for data transfer. When the transfer completes, the upper layer is notified through a callback function with the kStatus_SPI_Idle status.

24.2.2 Typical use case

24.2.2.1 SPI master transfer using an interrupt method

```
#define BUFFER_LEN (64)
spi_master_handle_t spiHandle;
spi_master_config_t masterConfig;
spi_transfer_t xfer;
volatile bool isFinished = false;

const uint8_t sendData[BUFFER_LEN] = [......];
uint8_t receiveBuff[BUFFER_LEN];

void SPI_UserCallback(SPI_Type *base, spi_master_handle_t *handle, status_t status, void *userData)
{
    isFinished = true;
}

void main(void)
{
    //...

    SPI_MasterGetDefaultConfig(&masterConfig);

    SPI_MasterInit(SPI0, &masterConfig);
    SPI_MasterTransferCreateHandle(SPI0, &spiHandle, SPI_UserCallback, NULL);

    // Prepare to send.
    xfer.txData = sendData;
    xfer.rxData = receiveBuff;
    xfer.dataSize = BUFFER_LEN;

    // Send out.
    SPI_MasterTransferNonBlocking(SPI0, &spiHandle, &xfer);
```

```
    // Wait send finished.
    while (!isFinished)

    /* Creates the DMA handle. */
    DMA_CreateHandle(&g_spiTxDmaHandle, DMA0, SPI_TX_DMA_CHANNEL);
    DMA_CreateHandle(&g_spiRxDmaHandle, DMA0, SPI_RX_DMA_CHANNEL);

    SPI_MasterTransferCreateHandleDMA(SPI0, spiHandle, &g_spiTxDmaHandle,
      &g_spiRxDmaHandle, SPI_UserCallback, NULL);

    // Prepares to send.
    xfer.txData = sendData;
    xfer.rxData = receiveBuff;

Chapter 25
TPM: Timer PWM Module

25.1 Overview

The MCUXpresso SDK provides a driver for the Timer PWM Module (TPM) of MCUXpresso SDK devices.

The TPM driver supports the generation of PWM signals, input capture, and output compare modes. On some SoCs, the driver supports the generation of combined PWM signals, dual-edge capture, and quadrature decoder modes. The driver also supports configuring each of the TPM fault inputs. The fault input is available only on some SoCs.

The function TPM_Init() initializes the TPM with a specified configurations. The function TPM_GetDefaultConfig() gets the default configurations. On some SoCs, the initialization function issues a software reset to reset the TPM internal logic. The initialization function configures the TPM's behavior when it receives a trigger input and its operation in doze and debug modes.

The function TPM_Deinit() disables the TPM counter and turns off the module clock.

The function TPM_SetupPwm() sets up TPM channels for the PWM output. The function can set up the PWM signal properties for multiple channels. Each channel has its own tpm_chnl_pwm_signal_param_t structure that is used to specify the output signals duty cycle and level-mode. However, the same PWM period and PWM mode is applied to all channels requesting a PWM output. The signal duty cycle is provided as a percentage of the PWM period. Its value should be between 0 and 100 where 0=inactive signal (0% duty cycle) and 100=always active signal (100% duty cycle). When generating a combined PWM signal, the channel number passed refers to a channel pair number, for example 0 refers to channel 0 and 1, 1 refers to channels 2 and 3.

The function TPM_UpdatePwmDutycycle() updates the PWM signal duty cycle of a particular TPM channel.

The function TPM_UpdateChnlEdgeLevelSelect() updates the level select bits of a particular TPM channel. This can be used to disable the PWM output when making changes to the PWM signal.

The function TPM_SetupInputCapture() sets up a TPM channel for input capture. The user can specify the capture edge.

The function TPM_SetupDualEdgeCapture() can be used to measure the pulse width of a signal. This is available only for certain SoCs. A channel pair is used during the capture with the input signal coming through a channel that can be configured. The user can specify the capture edge for each channel and any filter value to be used when processing the input signal.

The function TPM_SetupOutputCompare() sets up a TPM channel for output comparison. The user can specify the channel output on a successful comparison and a comparison value.

The function TPM_SetupQuadDecode() sets up TPM channels 0 and 1 for quad decode, which is available only for certain SoCs. The user can specify the quad decode mode, polarity, and filter properties for each input signal.

The function TPM_SetupFault() sets up the properties for each fault, which is available only for certain SoCs. The user can specify the fault polarity and whether to use a filter on a fault input. The overall fault filter value and fault control mode are set up during initialization.

Provides functions to get and clear the TPM status.

Provides functions to enable/disable TPM interrupts and get current enabled interrupts.

25.2 Typical use case

27.2 UART Driver

27.2.1 Overview

The MCUXpresso SDK provides a peripheral driver for the Universal Asynchronous Receiver/Transmitter (UART) module of MCUXpresso SDK devices.

The UART driver includes functional APIs and transactional APIs.

Functional APIs are used for UART initialization/configuration/operation for optimization/customization purpose. Using the functional API requires the knowledge of the UART peripheral and how to organize functional APIs to meet the application requirements. All functional APIs use the peripheral base address as the first parameter. UART functional operation groups provide the functional API set.

Transactional APIs can be used to enable the peripheral quickly and in the application if the code size and performance of transactional APIs can satisfy the requirements. If the code size and performance are critical requirements, see the transactional API implementation and write custom code. All transactional APIs use the uart_handle_t as the second parameter. Initialize the handle by calling the UART_TransferCreateHandle() API.

Transactional APIs support asynchronous transfer, which means that the functions UART_TransferSendNonBlocking() and UART_TransferReceiveNonBlocking() set up an interrupt for data transfer. When the transfer completes, the upper layer is notified through a callback function with the kStatus_UART_TxIdle and kStatus_UART_RxIdle.

Transactional receive APIs support the ring buffer. Prepare the memory for the ring buffer and pass in the start address and size while calling the UART_TransferCreateHandle(). If passing NULL, the ring buffer feature is disabled. When the ring buffer is enabled, the received data is saved to the ring buffer in the background. The UART_TransferReceiveNonBlocking() function first gets data from the ring buffer. If the ring buffer does not have enough data, the function first returns the data in the ring buffer and then saves the received data to user memory. When all data is received, the upper layer is informed through a callback with the kStatus_UART_RxIdle.

If the receive ring buffer is full, the upper layer is informed through a callback with the kStatus_UART_RxRingBufferOverrun. In the callback function, the upper layer reads data out from the ring buffer. If not, existing data is overwritten by the new data.

The ring buffer size is specified when creating the handle. Note that one byte is reserved for the ring buffer maintenance. When creating handle using the following code.

```
UART_TransferCreateHandle(UART0, &handle, UART_UserCallback, NULL);
```

In this example, the buffer size is 32, but only 31 bytes are used for saving data.

27.2.2 Typical use case

```
uint8_t ch;
```

user_config.enableRx = true;

UART_Init(UART1,&user_config,120000000U);

while(1)
{

This function initializes the UART handle which can be used for other UART transactional APIs. Usually, for a specified UART instance, call this API once to get the initialized handle.

Parameters

27.2.7.20 void UART_TransferStartRingBuffer (UART_Type ∗ *base*, uart_handle_t ∗ *handle*, uint8_t ∗ *ringBuffer*, size_t *ringBufferSize*)

This function sets up the RX ring buffer to a specific UART handle.

When the RX ring buffer is used, data received are stored into the ring buffer even when the user doesn't call the UART_TransferReceiveNonBlocking() API. If data is already received in the ring buffer, the user can get the received data from the ring buffer directly.

Note

When using the RX ring buffer, one byte is reserved for internal use. In other words, if `ringBufferSize` is 32, only 31 bytes are used for saving data.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
ringBuffer	Start address of the ring buffer for background receiving. Pass NULL to disable the ring buffer.
ringBufferSize	Size of the ring buffer.

27.2.7.21 void UART_TransferStopRingBuffer (UART_Type ∗ *base*, uart_handle_t ∗ *handle*)

27.2.7.22 status_t UART_TransferSendNonBlocking (UART_Type ∗ *base*, uart_handle_t ∗ *handle*, uart_transfer_t ∗ *xfer*)

This function sends data using an interrupt method. This is a non-blocking function, which returns directly without waiting for all data to be written to the TX register. When all data is written to the TX register in the ISR, the UART driver calls the callback function and passes the kStatus_UART_TxIdle as status parameter.

Note

The kStatus_UART_TxIdle is passed to the upper layer when all data is written to the TX register. However, it does not ensure that all data is sent out. Before disabling the TX, check the kUART_-TransmissionCompleteFlag to ensure that the TX is finished.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
xfer	UART transfer structure. See uart_transfer_t.

Return values

kStatus_Success	Successfully start the data transmission.
kStatus_UART_TxBusy	Previous transmission still not finished; data not all written to TX register yet.

handle	UART handle pointer.

27.2.7.24 status_t UART_TransferGetSendCount (UART_Type ∗ *base*, uart_handle_t ∗ *handle*, uint32_t ∗ *count*)

This function gets the number of bytes written to the UART TX register by using the interrupt method.

Parameters

base	UART peripheral base address.
handle	UART handle pointer.
count	Send bytes count.

Return values

kStatus_NoTransferInProgress	No send in progress.
kStatus_InvalidArgument	The parameter is invalid.
kStatus_Success	Get successfully through the parameter `count`;

27.2.7.25 status_t UART_TransferReceiveNonBlocking (UART_Type ∗ *base*, uart_handle_t ∗ *handle*, uart_transfer_t ∗ *xfer*, size_t ∗ *receivedBytes*)

This function receives data using an interrupt method. This is a non-blocking function, which returns without waiting for all data to be received. If the RX ring buffer is used and not empty, the data in the ring buffer is copied and the parameter `receivedBytes` shows how many bytes are copied from the ring buffer. After copying, if the data in the ring buffer is not enough to read, the receive request is saved by the UART driver. When the new data arrives, the receive request is serviced first. When all data is received, the UART driver notifies the upper layer through a callback function and passes the status parameter kStatus_UART_RxIdle. For example, the upper layer needs 10 bytes but there are only 5 bytes in the ring buffer. The 5 bytes are copied to the xfer->data and this function returns with the parameter `receivedBytes` set to 5. For the left 5 bytes, newly arrived data is saved from the xfer->data[5]. When 5 bytes are received, the UART driver notifies the upper layer. If the RX ring buffer is not enabled, this function enables the RX and RX interrupt to receive data to the xfer->data. When all data is received, the upper layer is notified.

Parameters

handle	UART handle pointer.

Chapter 28
Clock Driver

28.1 Overview

The MCUXpresso SDK provides APIs for MCUXpresso SDK devices' clock operation.

28.2 Get frequency

A centralized function CLOCK_GetFreq gets different clock type frequencies by passing a clock name. For example, pass a kCLOCK_CoreSysClk to get the core clock and pass a kCLOCK_BusClk to get the bus clock. Additionally, there are separate functions to get the frequency. For example, use CLOCK-_GetCoreSysClkFreq to get the core clock frequency and CLOCK_GetBusClkFreq to get the bus clock frequency. Using these functions reduces the image size.

28.3 External clock frequency

The external clocks EXTAL0/EXTAL1/EXTAL32 are decided by the board level design. The Clock driver uses variables g_xtal0Freq/g_xtal1Freq/g_xtal32Freq to save clock frequencies. Likewise, the APIs CLOCK_SetXtal0Freq, CLOCK_SetXtal1Freq, and CLOCK_SetXtal32Freq are used to set these variables.

The upper layer must set these values correctly. For example, after OSC0(SYSOSC) is initialized using CLOCK_InitOsc0 or CLOCK_InitSysOsc, the upper layer should call the CLOCK_SetXtal0Freq. Otherwise, the clock frequency get functions may not receive valid values. This is useful for multicore platforms where only one core calls CLOCK_InitOsc0 to initialize OSC0 and other cores call CLOCK_SetXtal0-Freq.

28.5 Macro Definition Documentation

28.5.1 #define MCG_CONFIG_CHECK_PARAM 0U

Some MCG settings must be changed with conditions, for example:

1. MCGIRCLK settings, such as the source, divider, and the trim value should not change when MC-GIRCLK is used as a system clock source.
2. MCG_C7[OSCSEL] should not be changed when the external reference clock is used as a system clock source. For example, in FBE/BLPE/PBE modes.
3. The users should only switch between the supported clock modes.

MCG functions check the parameter and MCG status before setting, if not allowed to change, the functions return error. The parameter checking increases code size, if code size is a critical requirement, change M-CG_CONFIG_CHECK_PARAM to 0 to disable parameter checking.

28.5.2 #define FSL_SDK_DISABLE_DRIVER_CLOCK_CONTROL 0

When set to 0, peripheral drivers will enable clock in initialize function and disable clock in de-initialize function. When set to 1, peripheral driver will not control the clock, application could contol the clock out of the driver.

Note

All drivers share this feature switcher. If it is set to 1, application should handle clock enable and disable for all drivers.

28.7.26 static void CLOCK_SetLowPowerEnable (bool *enable*) [inline], [static]

Enabling the MCG low power disables the PLL and FLL in bypass modes. In other words, in FBE and PBE modes, enabling low power sets the MCG to BLPE mode. In FBI and PBI modes, enabling low power sets the MCG to BLPI mode. When disabling the MCG low power, the PLL or FLL are enabled based on MCG settings.

Parameters

enable	True to enable MCG low power, false to disable MCG low power.

28.7.27 status_t CLOCK_SetInternalRefClkConfig (uint8_t *enableMode*, mcg_irc_mode_t *ircs*, uint8_t *fcrdiv*)

This function sets the `MCGIRCLK` base on parameters. It also selects the IRC source. If the fast IRC is used, this function sets the fast IRC divider. This function also sets whether the `MCGIRCLK` is enabled in stop mode. Calling this function in FBI/PBI/BLPI modes may change the system clock. As a result, using the function in these modes it is not allowed.

Parameters

enableMode	MCGIRCLK enable mode, OR'ed value of _mcg_irclk_enable_mode.
ircs	MCGIRCLK clock source, choose fast or slow.
fcrdiv	Fast IRC divider setting (`FCRDIV`).

Return values

kStatus_MCG_Source-Used	Because the internall reference clock is used as a clock source, the confuration should not be changed. Otherwise, a glitch occurs.
kStatus_Success	MCGIRCLK configuration finished successfully.

28.7.28 status_t CLOCK_SetExternalRefClkConfig (mcg_oscsel_t *oscsel*)

Selects the MCG external reference clock source, changes the MCG_C7[OSCSEL], and waits for the clock source to be stable. Because the external reference clock should not be changed in FEE/FBE/BLPE/PBE/PEE modes, do not call this function in these modes.

Parameters

oscsel	MCG external reference clock source, MCG_C7[OSCSEL].

Return values

kStatus_MCG_Source-Used	Because the external reference clock is used as a clock source, the confuration should not be changed. Otherwise, a glitch occurs.

28.7.30 void CLOCK_EnablePll0 (mcg_pll_config_t const * *config*)

This function sets us the PLL0 in FLL mode and reconfigures the PLL0. Ensure that the PLL reference clock is enabled before calling this function and that the PLL0 is not used as a clock source. The function CLOCK_CalcPllDiv gets the correct PLL divider values.

Parameters

config	Pointer to the configuration structure.

28.7.31 static void CLOCK_DisablePll0 (void) [inline], [static]

28.7.35 uint32_t CLOCK_GetStatusFlags (void)

28.8 Variable Documentation

28.8.1 uint32_t g_xtal0Freq

The XTAL0/EXTAL0 (OSC0) clock frequency in Hz. When the clock is set up, use the function CLOCK_SetXtal0Freq to set the value in the clock driver. For example, if XTAL0 is 8 MHz:

```
* CLOCK_InitOsc0(...); // Set up the OSC0
* CLOCK_SetXtal0Freq(80000000); // Set the XTAL0 value to the clock driver.
*
```

This is important for the multicore platforms where only one core needs to set up the OSC0 using the CLOCK_InitOsc0. All other cores need to call the CLOCK_SetXtal0Freq to get a valid clock frequency.

28.8.2 uint32_t g_xtal32Freq

The XTAL32/EXTAL32/RTC_CLKIN clock frequency in Hz. When the clock is set up, use the function CLOCK_SetXtal32Freq to set the value in the clock driver.

This is important for the multicore platforms where only one core needs to set up the clock. All other cores need to call the CLOCK_SetXtal32Freq to get a valid clock frequency.

28.9 Multipurpose Clock Generator (MCG)

The MCUXpresso SDK provides a peripheral driver for the module of MCUXpresso SDK devices.

28.9.1 Function description

MCG driver provides these functions:

- Functions to get the MCG clock frequency.
- Functions to configure the MCG clock, such as PLLCLK and MCGIRCLK.
- Functions for the MCG clock lock lost monitor.
- Functions for the OSC configuration.
- Functions for the MCG auto-trim machine.
- Functions for the MCG mode.

28.9.1.1 MCG frequency functions

MCG module provides clocks, such as MCGOUTCLK, MCGIRCLK, MCGFFCLK, MCGFLLCLK and MCGPLLCLK. The MCG driver provides functions to get the frequency of these clocks, such as C-LOCK_GetOutClkFreq(), CLOCK_GetInternalRefClkFreq(), CLOCK_GetFixedFreqClkFreq(), CLOC-K_GetFllFreq(), CLOCK_GetPll0Freq(), CLOCK_GetPll1Freq(), and CLOCK_GetExtPllFreq(). These functions get the clock frequency based on the current MCG registers.

28.9.1.2 MCG clock configuration

The MCG driver provides functions to configure the internal reference clock (MCGIRCLK), the external reference clock, and MCGPLLCLK.

The function CLOCK_SetInternalRefClkConfig() configures the MCGIRCLK, including the source and the driver. Do not change MCGIRCLK when the MCG mode is BLPI/FBI/PBI because the MCGIRCLK is used as a system clock in these modes and changing settings makes the system clock unstable.

The function CLOCK_SetExternalRefClkConfig() configures the external reference clock source (MCG-_C7[OSCSEL]). Do not call this function when the MCG mode is BLPE/FBE/PBE/FEE/PEE because the external reference clock is used as a clock source in these modes. Changing the external reference clock source requires at least a 50 microseconds wait. The function CLOCK_SetExternalRefClkConfig() implements a for loop delay internally. The for loop delay assumes that the system clock is 96 MHz, which ensures at least 50 micro seconds delay. However, when the system clock is slow, the delay time may significantly increase. This for loop count can be optimized for better performance for specific cases.

The MCGPLLCLK is disabled in FBE/FEE/FBI/FEI modes by default. Applications can enable the M-CGPLLCLK in these modes using the functions CLOCK_EnablePll0() and CLOCK_EnablePll1(). To enable the MCGPLLCLK, the PLL reference clock divider(PRDIV) and the PLL VCO divider(VDIV) must be set to a proper value. The function CLOCK_CalcPllDiv() helps to get the PRDIV/VDIV.

28.9.1.3 MCG clock lock monitor functions

The MCG module monitors the OSC and the PLL clock lock status. The MCG driver provides the functions to set the clock monitor mode, check the clock lost status, and clear the clock lost status.

28.9.1.4 OSC configuration

The MCG is needed together with the OSC module to enable the OSC clock. The function CLOCK_InitOsc0() CLOCK_InitOsc1 uses the MCG and OSC to initialize the OSC. The OSC should be configured based on the board design.

28.9.1.5 MCG auto-trim machine

The MCG provides an auto-trim machine to trim the MCG internal reference clock based on the external reference clock (BUS clock). During clock trimming, the MCG must not work in FEI/FBI/BLPI/PBI/PEI modes. The function CLOCK_TrimInternalRefClk() is used for the auto clock trimming.

28.9.1.6 MCG mode functions

The function CLOCK_GetMcgMode returns the current MCG mode. The MCG can only switch between the neighbouring modes. If the target mode is not current mode's neighbouring mode, the application must choose the proper switch path. For example, to switch to PEE mode from FEI mode, use FEI -> FBE -> PBE -> PEE.

For the MCG modes, the MCG driver provides three kinds of functions:

The first type of functions involve functions CLOCK_SetXxxMode, such as CLOCK_SetFeiMode(). These functions only set the MCG mode from neighbouring modes. If switching to the target mode directly from current mode is not possible, the functions return an error.

The second type of functions are the functions CLOCK_BootToXxxMode, such as CLOCK_BootToFeiMode(). These functions set the MCG to specific modes from reset mode. Because the source mode and target mode are specific, these functions choose the best switch path. The functions are also useful to set up the system clock during boot up.

The third type of functions is the CLOCK_SetMcgConfig(). This function chooses the right path to switch to the target mode. It is easy to use, but introduces a large code size.

Whenever the FLL settings change, there should be a 1 millisecond delay to ensure that the FLL is stable. The function CLOCK_SetMcgConfig() implements a for loop delay internally to ensure that the FLL is stable. The for loop delay assumes that the system clock is 96 MHz, which ensures at least 1 millisecond delay. However, when the system clock is slow, the delay time may increase significantly. The for loop count can be optimized for better performance according to a specific use case.

28.9.2 Typical use case

The function CLOCK_SetMcgConfig is used to switch between any modes. However, this heavy-light function introduces a large code size. This section shows how to use the mode function to implement a quick and light-weight switch between typical specific modes. Use case	Steps	Functions
BLPI -> PEI	BLPI -> PBI	CLOCK_SetPbiMode(...)

	FBI -> BLPI	CLOCK_SetLowPower-Enable(true)

28.9.3 Code Configuration Option

28.9.3.1 MCG_USER_CONFIG_FLL_STABLE_DELAY_EN

When switching to use FLL with function CLOCK_SetFeiMode() and CLOCK_SetFeeMode(), there is an internal function CLOCK_FllStableDelay(). It is used to delay a few ms so that to wait the FLL to be stable enough. By default, it is implemented in driver code like:

```
#ifndef MCG_USER_CONFIG_FLL_STABLE_DELAY_EN
void CLOCK_FllStableDelay(void)
{
    /*
```

```
       Should wait at least 1ms. Because in these modes, the core clock is 100MHz
       at most, so this function could obtain the 1ms delay.
     */
    volatile uint32_t i = 30000U;
    while (i--)
    {
        __NOP();
    }
}
#endif /* MCG_USER_CONFIG_FLL_STABLE_DELAY_EN */
```

Once user is willing to create his own delay funcion, just assert the macro MCG_USER_CONFIG_FLL-_STABLE_DELAY_EN, and then define function CLOCK_FllStableDelay in the application code.

dma_base	Peripheral DMA instance base pointer.
dmamux_base	Peripheral DMAMUX instance base pointer.
channelNum	Channel numbers for the DMA instance which need to be managed by dma manager.
startChannel	The start channel that can be managed by dma manager.

29.7.2 void DMAMGR_Deinit (dmamanager_handle_t ∗ *dmamanager_handle*)

This function deinitializes the DMA manager, disables the DMAMUX channels, gates the DMAMUX clocks, and deinitializes the eDMA or DMA peripherals.

Chapter 31
SPI based Secure Digital Card (SDSPI)

31.1 Overview

The MCUXpresso SDK provides a driver to access the Secure Digital Card based on the SPI driver.

Function groups

This function group implements the SD card functional API in the SPI mode.

Typical use case

```
/* SPI_Init(). */

/* Register the SDSPI driver callback. */

/* Initializes card. */
if (kStatus_Success != SDSPI_Init(card))
{
    SDSPI_Deinit(card)
    return;
}

/* Read/Write card */
memset(g_testWriteBuffer, 0x17U, sizeof(g_testWriteBuffer));

while (true)
{
    memset(g_testReadBuffer, 0U, sizeof(g_testReadBuffer));

    SDSPI_WriteBlocks(card, g_testWriteBuffer, TEST_START_BLOCK, TEST_BLOCK_COUNT);

    SDSPI_ReadBlocks(card, g_testReadBuffer, TEST_START_BLOCK, TEST_BLOCK_COUNT);

    if (memcmp(g_testReadBuffer, g_testReadBuffer, sizeof(g_testWriteBuffer)))
    {
        break;
    }
}
```

Chapter 32
Debug Console

32.1 Overview

This chapter describes the programming interface of the debug console driver.

The debug console enables debug log messages to be output via the specified peripheral with frequency of the peripheral source clock and base address at the specified baud rate. Additionally, it provides input and output functions to scan and print formatted data.

32.2 Function groups

32.2.1 Initialization

To initialize the debug console, call the DbgConsole_Init() function with these parameters. This function automatically enables the module and the clock.

```
/*
 * @brief Initializes the the peripheral used to debug messages.
 *
 * @param baseAddr      Indicates which address of the peripheral is used to send debug messages.
 * @param baudRate      The desired baud rate in bits per second.
 * @param device        Low level device type for the debug console, can be one of:
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_UART,
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_LPUART,
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_LPSCI,
 *                      @arg DEBUG_CONSOLE_DEVICE_TYPE_USBCDC.
 * @param clkSrcFreq    Frequency of peripheral source clock.
 *
 * @return              Whether initialization was successful or not.
 */
status_t DbgConsole_Init(uint32_t baseAddr, uint32_t baudRate, uint8_t device, uint32_t clkSrcFreq)
```

Selects the supported debug console hardware device type, such as

```
DEBUG_CONSOLE_DEVICE_TYPE_NONE
DEBUG_CONSOLE_DEVICE_TYPE_LPSCI
DEBUG_CONSOLE_DEVICE_TYPE_UART
DEBUG_CONSOLE_DEVICE_TYPE_LPUART
DEBUG_CONSOLE_DEVICE_TYPE_USBCDC
```

After the initialization is successful, stdout and stdin are connected to the selected peripheral. The debug console state is stored in the debug_console_state_t structure, such as shown here.

```
typedef struct DebugConsoleState
{
    uint8_t                     type;
    void*                       base;
    debug_console_ops_t         ops;
} debug_console_state_t;
```

This example shows how to call the DbgConsole_Init() given the user configuration structure.

```
uint32_t uartClkSrcFreq = CLOCK_GetFreq(BOARD_DEBUG_UART_CLKSRC);

DbgConsole_Init(BOARD_DEBUG_UART_BASEADDR, BOARD_DEBUG_UART_BAUDRATE, DEBUG_CONSOLE_DEVICE_TYPE_UART,
      uartClkSrcFreq);
```

32.2.2 Advanced Feature

The debug console provides input and output functions to scan and print formatted data.

- Support a format specifier for PRINTF following this prototype " %[flags][width][.precision][length]specifier", which is explained below

flags	Description
-	Left-justified within the given field width. Right-justified is the default.
+	Forces to precede the result with a plus or minus sign (+ or -) even for positive numbers. By default, only negative numbers are preceded with a - sign.
(space)	If no sign is written, a blank space is inserted before the value.
#	Used with o, x, or X specifiers the value is preceded with 0, 0x, or 0X respectively for values other than zero. Used with e, E and f, it forces the written output to contain a decimal point even if no digits would follow. By default, if no digits follow, no decimal point is written. Used with g or G the result is the same as with e or E but trailing zeros are not removed.
0	Left-pads the number with zeroes (0) instead of spaces, where padding is specified (see width sub-specifier).

Width	Description
(number)	A minimum number of characters to be printed. If the value to be printed is shorter than this number, the result is padded with blank spaces. The value is not truncated even if the result is larger.
*	The width is not specified in the format string, but as an additional integer value argument preceding the argument that has to be formatted.

.precision	Description
.number	For integer specifiers (d, i, o, u, x, X) precision specifies the minimum number of digits to be written. If the value to be written is shorter than this number, the result is padded with leading zeros. The value is not truncated even if the result is longer. A precision of 0 means that no character is written for the value 0. For e, E, and f specifiers this is the number of digits to be printed after the decimal point. For g and G specifiers This is the maximum number of significant digits to be printed. For s this is the maximum number of characters to be printed. By default, all characters are printed until the ending null character is encountered. For c type it has no effect. When no precision is specified, the default is 1. If the period is specified without an explicit value for precision, 0 is assumed.
.*	The precision is not specified in the format string, but as an additional integer value argument preceding the argument that has to be formatted.

length	Description
Do not support	

specifier	Description
d or i	Signed decimal integer
f	Decimal floating point
F	Decimal floating point capital letters
x	Unsigned hexadecimal integer
X	Unsigned hexadecimal integer capital letters
o	Signed octal
b	Binary value
p	Pointer address
u	Unsigned decimal integer
c	Character
s	String of characters
n	Nothing printed

- Support a format specifier for SCANF following this prototype " %[∗][width][length]specifier", which is explained below

∗	Description
An optional starting asterisk indicates that the data is to be read from the stream but ignored. In other words, it is not stored in the corresponding argument.	

width	Description
This specifies the maximum number of characters to be read in the current reading operation.	

length	Description
hh	The argument is interpreted as a signed character or unsigned character (only applies to integer specifiers: i, d, o, u, x, and X).
h	The argument is interpreted as a short integer or unsigned short integer (only applies to integer specifiers: i, d, o, u, x, and X).
l	The argument is interpreted as a long integer or unsigned long integer for integer specifiers (i, d, o, u, x, and X) and as a wide character or wide character string for specifiers c and s.
ll	The argument is interpreted as a long long integer or unsigned long long integer for integer specifiers (i, d, o, u, x, and X) and as a wide character or wide character string for specifiers c and s.
L	The argument is interpreted as a long double (only applies to floating point specifiers: e, E, f, g, and G).
j or z or t	Not supported

specifier	Qualifying Input	Type of argument
c	Single character: Reads the next character. If a width different from 1 is specified, the function reads width characters and stores them in the successive locations of the array passed as argument. No null character is appended at the end.	char ∗

specifier	Qualifying Input	Type of argument
i	Integer: : Number optionally preceded with a + or - sign	int ∗
d	Decimal integer: Number optionally preceded with a + or - sign	int ∗
a, A, e, E, f, F, g, G	Floating point: Decimal number containing a decimal point, optionally preceded by a + or - sign and optionally followed by the e or E character and a decimal number. Two examples of valid entries are -732.103 and 7.12e4	float ∗
o	Octal Integer:	int ∗
s	String of characters. This reads subsequent characters until a white space is found (white space characters are considered to be blank, newline, and tab).	char ∗
u	Unsigned decimal integer.	unsigned int ∗

The debug console has its own printf/scanf/putchar/getchar functions which are defined in the header file.

```
int DbgConsole_Printf(const char *fmt_s, ...);
int DbgConsole_Putchar(int ch);
int DbgConsole_Scanf(const char *fmt_ptr, ...);
int DbgConsole_Getchar(void);
```

This utility supports selecting toolchain's printf/scanf or the MCUXpresso SDK printf/scanf.

```
#if SDK_DEBUGCONSOLE    /* Select printf, scanf, putchar, getchar of SDK version. */
#define PRINTF                 DbgConsole_Printf
#define SCANF                  DbgConsole_Scanf
#define PUTCHAR                DbgConsole_Putchar
#define GETCHAR                DbgConsole_Getchar
#else                   /* Select printf, scanf, putchar, getchar of toolchain. */
#define PRINTF                 printf
#define SCANF                  scanf
#define PUTCHAR                putchar
#define GETCHAR                getchar
#endif /* SDK_DEBUGCONSOLE */
```

32.3 Typical use case

Some examples use the PUTCHAR & GETCHAR function

```
ch = GETCHAR();
PUTCHAR(ch);
```

Some examples use the PRINTF function

Statement prints the string format.

```
PRINTF("%s %s\r\n", "Hello", "world!");
```

Statement prints the hexadecimal format/

```
PRINTF("0x%02X hexadecimal number equivalents 255", 255);
```

Statement prints the decimal floating point and unsigned decimal.

```
PRINTF("Execution timer: %s\n\rTime: %u ticks %2.5f milliseconds\n\rDONE\n\r", "1 day", 86400, 86.4);
```

Some examples use the SCANF function

```
PRINTF("Enter a decimal number: ");
SCANF("%d", &i);
PRINTF("\r\nYou have entered %d.\r\n", i, i);
PRINTF("Enter a hexadecimal number: ");
SCANF("%x", &i);
PRINTF("\r\nYou have entered 0x%X (%d).\r\n", i, i);
```

Print out failure messages using KSDK __assert_func:

```
void __assert_func(const char *file, int line, const char *func, const char *failedExpr)
{
    PRINTF("ASSERT ERROR \" %s \": file \"%s\" Line \"%d\" function name \"%s\" \n", failedExpr, file ,
      line, func);
    for (;;)
    {}
}
```

Note:

To use ’printf’ and ’scanf’ for GNUC Base, add file **’fsl_sbrk.c’** in path: **..\{package}\devices\{subset}\utilities\fsl-_sbrk.c** to your project.

Modules

- Semihosting

32.4 Semihosting

Semihosting is a mechanism for ARM targets to communicate input/output requests from application code to a host computer running a debugger. This mechanism can be used, for example, to enable functions in the C library, such as printf() and scanf(), to use the screen and keyboard of the host rather than having a screen and keyboard on the target system.

32.4.1 Guide Semihosting for IAR

NOTE: After the setting both "printf" and "scanf" are available for debugging.

Step 1: Setting up the environment

1. To set debugger options, choose Project>Options. In the Debugger category, click the Setup tab.
2. Select Run to main and click OK. This ensures that the debug session starts by running the main function.
3. The project is now ready to be built.

Step 2: Building the project

1. Compile and link the project by choosing Project>Make or F7.
2. Alternatively, click the Make button on the tool bar. The Make command compiles and links those files that have been modified.

Step 3: Starting semihosting

1. Choose "Semihosting_IAR" project -> "Options" -> "Debugger" -> "J-Link/J-Trace".
2. Choose tab "J-Link/J-Trace" -> "Connection" tab -> "SWD".
3. Start the project by choosing Project>Download and Debug.
4. Choose View>Terminal I/O to display the output from the I/O operations.

32.4.2 Guide Semihosting for Keil µVision

NOTE: Keil supports Semihosting only for Cortex-M3/Cortex-M4 cores.

Step 1: Prepare code

Remove function fputc and fgetc is used to support KEIL in "fsl_debug_console.c" and add the following code to project.

```
#pragma import(__use_no_semihosting_swi)

volatile int ITM_RxBuffer = ITM_RXBUFFER_EMPTY;        /* used for Debug Input */
```

```
struct __FILE
{
    int handle;
};
FILE __stdout;
FILE __stdin;

int fputc(int ch, FILE *f)
{
    return (ITM_SendChar(ch));
}

int fgetc(FILE *f)
{ /* blocking */
    while (ITM_CheckChar() != 1)
        ;
    return (ITM_ReceiveChar());
}

int ferror(FILE *f)
{
    /* Your implementation of ferror */
    return EOF;
}

void _ttywrch(int ch)
{
    ITM_SendChar(ch);
}

void _sys_exit(int return_code)
{
label:
    goto label; /* endless loop */
}
```

Step 2: Setting up the environment

1. In menu bar, choose Project>Options for target or using Alt+F7 or click.
2. Select "Target" tab and not select "Use MicroLIB".
3. Select “Debug” tab, select “J-Link/J-Trace Cortex” and click “Setting button”.
4. Select “Debug” tab and choose Port:SW, then select "Trace" tab, choose "Enable" and click OK.

Step 3: Building the project

1. Compile and link the project by choosing Project>Build Target or using F7.

Step 4: Building the project

1. Choose “Debug” on menu bar or Ctrl F5.
2. In menu bar, choose "Serial Window" and click to "Debug (printf) Viewer".
3. Run line by line to see result in Console Window.

32.4.3 Guide Semihosting for KDS

NOTE: After the setting use "printf" for debugging.

Step 1: Setting up the environment

1. In menu bar, choose Project>Properties>C/C++ Build>Settings>Tool Settings.
2. Select “Libraries” on “Cross ARM C Linker” and delete “nosys”.
3. Select “Miscellaneous” on "Cross ARM C Linker”, add “-specs=rdimon.specs” to “Other link flages” and tick “Use newlib-nano”, and click OK.

Step 2: Building the project

1. In menu bar, choose Project>Build Project.

Step 3: Starting semihosting

1. In Debug configurations, choose "Startup" tab, tick “Enable semihosting and Telnet”. Press “Apply” and “Debug”.
2. After clicking Debug, the Window is displayed same as below. Run line by line to see the result in the Console Window.

32.4.4 Guide Semihosting for ATL

NOTE: J-Link has to be used to enable semihosting.

Step 1: Prepare code

Add the following code to the project.

```
int _write(int file, char *ptr, int len)
{
  /* Implement your write code here. This is used by puts and printf. */
  int i=0;
  for(i=0 ; i<len ; i++)
    ITM_SendChar((*ptr++));
  return len;
}
```

Step 2: Setting up the environment

1. In menu bar, choose Debug Configurations. In tab "Embedded C/C++ Aplication" choose "-Semihosting_ATL_xxx debug J-Link".
2. In tab "Debugger" set up as follows.
    - JTAG mode must be selected

- SWV tracing must be enabled
- Enter the Core Clock frequency, which is hardware board-specific.
- Enter the desired SWO Clock frequency. The latter depends on the JTAG Probe and must be a multiple of the Core Clock value.

3. Click "Apply" and "Debug".

Step 3: Starting semihosting

1. In the Views menu, expand the submenu SWV and open the docking view “SWV Console". 2. Open the SWV settings panel by clicking the "Configure Serial Wire Viewer" button in the SWV Console view toolbar. 3. Configure the data ports to be traced by enabling the ITM channel 0 check-box in the ITM stimulus ports group: Choose "EXETRC: Trace Exceptions" and In tab "ITM Stimulus Ports" choose "Enable Port" 0. Then click "OK".
2. It is recommended not to enable other SWV trace functionalities at the same time because this may over use the SWO pin causing packet loss due to a limited bandwidth (certain other SWV tracing capabilities can send a lot of data at very high-speed). Save the SWV configuration by clicking the OK button. The configuration is saved with other debug configurations and remains effective until changed.
3. Press the red Start/Stop Trace button to send the SWV configuration to the target board to enable SWV trace recoding. The board does not send any SWV packages until it is properly configured. The SWV Configuration must be present, if the configuration registers on the target board are reset. Also, tracing does not start until the target starts to execute.
4. Start the target execution again by pressing the green Resume Debug button.
5. The SWV console now shows the printf() output.

32.4.5 Guide Semihosting for ARMGCC

Step 1: Setting up the environment

1. Turn on "J-LINK GDB Server" -> Select suitable "Target device" -> "OK".
2. Turn on "PuTTY". Set up as follows.
   - "Host Name (or IP address)" : localhost
   - "Port" :2333
   - "Connection type" : Telet.
   - Click "Open".
3. Increase "Heap/Stack" for GCC to 0x2000:

Add to "CMakeLists.txt"

SET(CMAKE_EXE_LINKER_FLAGS_RELEASE "${CMAKE_EXE_LINKER_FLAGS_RELEASE} --defsym=__stack_size__=0x2000")

SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} --defsym=__stack_size__=0x2000")

SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} --

defsym=__heap_size__=0x2000")

SET(CMAKE_EXE_LINKER_FLAGS_RELEASE "${CMAKE_EXE_LINKER_FLAGS_RELEASE} --defsym=__heap_size__=0x2000")

Step 2: Building the project

1. Change "CMakeLists.txt":
   Change "SET(CMAKE_EXE_LINKER_FLAGS_RELEASE "${CMAKE_EXE_LINKER_FLAGS_RELEASE} –specs=nano.specs")"
   to "SET(CMAKE_EXE_LINKER_FLAGS_RELEASE "${CMAKE_EXE_LINKER_FLAGS_RELEASE} –specs=rdimon.specs")"
   Replace paragraph
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -fno-common")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -ffunction-sections")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -fdata-sections")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -ffreestanding")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -fno-builtin")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -mthumb")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -mapcs")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -Xlinker")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} --gc-sections")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -Xlinker")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -static")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -Xlinker")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -z")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} -Xlinker")
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBUG} muldefs")
   To
   SET(CMAKE_EXE_LINKER_FLAGS_DEBUG "${CMAKE_EXE_LINKER_FLAGS_DEBU-

G} --specs=rdimon.specs ")
Remove
target_link_libraries(semihosting_ARMGCC.elf debug nosys)
2. Run "build_debug.bat" to build project

Step 3: Starting semihosting

(a) Download the image and set as follows.

```
cd D:\mcu-sdk-2.0-origin\boards\twrk64f120m\driver_examples\semihosting\armgcc\debug
d:
C:\PROGRA~2\GNUTOO~1\4BD65~1.920\bin\arm-none-eabi-gdb.exe
target remote localhost:2331
monitor reset
monitor semihosting enable
monitor semihosting thumbSWI 0xAB
monitor semihosting IOClient 1
monitor flash device = MK64FN1M0xxx12
load semihosting_ARMGCC.elf
monitor reg pc = (0x00000004)
monitor reg sp = (0x00000000)
continue
```

(b) After the setting, press "enter". The PuTTY window now shows the printf() output.

Chapter 33
Notification Framework

33.1 Overview

This section describes the programming interface of the Notifier driver.

33.2 Notifier Overview

The Notifier provides a configuration dynamic change service. Based on this service, applications can switch between pre-defined configurations. The Notifier enables drivers and applications to register callback functions to this framework. Each time that the configuration is changed, drivers and applications receive a notification and change their settings. To simplify, the Notifier only supports the static callback registration. This means that, for applications, all callback functions are collected into a static table and passed to the Notifier.

These are the steps for the configuration transition.

1. Before configuration transition, the Notifier sends a "BEFORE" message to the callback table. When this message is received, IP drivers should check whether any current processes can be stopped and stop them. If the processes cannot be stopped, the callback function returns an error.
   The Notifier supports two types of transition policies, a graceful policy and a forceful policy. When the graceful policy is used, if some callbacks return an error while sending a "BEFORE" message, the configuration transition stops and the Notifier sends a "RECOVER" message to all drivers that have stopped. Then, these drivers can recover the previous status and continue to work. When the forceful policy is used, drivers are stopped forcefully.
2. After the "BEFORE" message is processed successfully, the system switches to the new configuration.
3. After the configuration changes, the Notifier sends an "AFTER" message to the callback table to notify drivers that the configuration transition is finished.

This example shows how to use the Notifier in the Power Manager application.

```
#include "fsl_notifier.h"

// Definition of the Power Manager callback.
status_t callback0(notifier_notification_block_t *notify, void *data)
{

    status_t ret = kStatus_Success;

    ...
    ...
    ...

    return ret;
}
// Definition of the Power Manager user function.
status_t APP_PowerModeSwitch(notifier_user_config_t *targetConfig, void *userData)
{
```

```
    ...
    ...
    ...
}
...
...
...
...
...
// Main function.
int main(void)
{
    // Define a notifier handle.
    notifier_handle_t powerModeHandle;

    // Callback configuration.
    user_callback_data_t callbackData0;

    notifier_callback_config_t callbackCfg0 = {callback0,
                kNOTIFIER_CallbackBeforeAfter,
                (void *)&callbackData0};

    notifier_callback_config_t callbacks[] = {callbackCfg0};

    // Power mode configurations.
    power_user_config_t vlprConfig;
    power_user_config_t stopConfig;

    notifier_user_config_t *powerConfigs[] = {&vlprConfig, &stopConfig};

    // Definition of a transition to and out the power modes.
    vlprConfig.mode = kAPP_PowerModeVlpr;
    vlprConfig.enableLowPowerWakeUpOnInterrupt = false;

    stopConfig = vlprConfig;
    stopConfig.mode = kAPP_PowerModeStop;

    // Create Notifier handle.
    NOTIFIER_CreateHandle(&powerModeHandle, powerConfigs, 2U, callbacks, 1U,
      APP_PowerModeSwitch, NULL);
    ...
    ...
    // Power mode switch.
    NOTIFIER_switchConfig(&powerModeHandle, targetConfigIndex,
      kNOTIFIER_PolicyAgreement);
}

33.4 Typedef Documentation

33.4.1 typedef void notifier_user_config_t

Reference of the user defined configuration is stored in an array; the notifier switches between these configurations based on this array.

33.4.2 typedef status_t(∗ notifier_user_function_t)(notifier_user_config_t ∗targetConfig, void ∗userData)

Before and after this function execution, different notification is sent to registered callbacks. If this function returns any error code, NOTIFIER_SwitchConfig() exits.

Parameters

targetConfig	target Configuration.
userData	Refers to other specific data passed to user function.

Returns

An error code or kStatus_Success.

33.4.3 typedef status_t(∗ notifier_callback_t)(notifier_notification_block_t ∗notify, void ∗data)

Declaration of a callback. It is common for registered callbacks. Reference to function of this type is part of the notifier_callback_config_t callback configuration structure. Depending on callback type, function of this prototype is called (see NOTIFIER_SwitchConfig()) before configuration switch, after it or in both use cases to notify about the switch progress (see notifier_callback_type_t). When called, the type of the notification is passed as a parameter along with the reference to the target configuration structure (see notifier_notification_block_t) and any data passed during the callback registration. When notified before the configuration switch, depending on the configuration switch policy (see notifier_policy_t), the callback may deny the execution of the user function by returning an error code different than kStatus_Success (see NOTIFIER_SwitchConfig()).

Parameters

notify	Notification block.
data	Callback data. Refers to the data passed during callback registration. Intended to pass any driver or application data such as internal state information.

Returns

An error code or kStatus_Success.

33.5 Enumeration Type Documentation

33.5.1 enum _notifier_status

Used as return value of Notifier functions.

Enumerator

kStatus_NOTIFIER_ErrorNotificationBefore An error occurs during send "BEFORE" notification.

kStatus_NOTIFIER_ErrorNotificationAfter An error occurs during send "AFTER" notification.

33.5.2 enum notifier_policy_t

Defines whether the user function execution is forced or not. For kNOTIFIER_PolicyForcible, the user function is executed regardless of the callback results, while kNOTIFIER_PolicyAgreement policy is used to exit NOTIFIER_SwitchConfig() when any of the callbacks returns error code. See also NOTIFIER_-SwitchConfig() description.

Enumerator

kNOTIFIER_PolicyAgreement NOTIFIER_SwitchConfig() method is exited when any of the callbacks returns error code.
kNOTIFIER_PolicyForcible The user function is executed regardless of the results.

33.5.3 enum notifier_notification_type_t

Used to notify registered callbacks

Enumerator

kNOTIFIER_NotifyRecover Notify IP to recover to previous work state.
kNOTIFIER_NotifyBefore Notify IP that configuration setting is going to change.
kNOTIFIER_NotifyAfter Notify IP that configuration setting has been changed.

33.5.4 enum notifier_callback_type_t

Used in the callback configuration structure (notifier_callback_config_t) to specify when the registered callback is called during configuration switch initiated by the NOTIFIER_SwitchConfig(). Callback can be invoked in following situations.

- Before the configuration switch (Callback return value can affect NOTIFIER_SwitchConfig() execution. See the NOTIFIER_SwitchConfig() and notifier_policy_t documentation).
- After an unsuccessful attempt to switch configuration
- After a successful configuration switch

Enumerator

kNOTIFIER_CallbackBefore Callback handles BEFORE notification.
kNOTIFIER_CallbackAfter Callback handles AFTER notification.
kNOTIFIER_CallbackBeforeAfter Callback handles BEFORE and AFTER notification.

33.6 Function Documentation

33.6.1 status_t NOTIFIER_CreateHandle (notifier_handle_t * *notifierHandle,* notifier_user_config_t ** *configs,* uint8_t *configsNumber,* notifier_callback_config_t * *callbacks,* uint8_t *callbacksNumber,* notifier_user_function_t *userFunction,* void * *userData*)

Parameters

notifierHandle	A pointer to the notifier handle.
configs	A pointer to an array with references to all configurations which is handled by the Notifier.
configsNumber	Number of configurations. Size of the configuration array.
callbacks	A pointer to an array of callback configurations. If there are no callbacks to register during Notifier initialization, use NULL value.
callbacks-Number	Number of registered callbacks. Size of the callbacks array.
userFunction	User function.
userData	User data passed to user function.

Returns

An error Code or kStatus_Success.

33.6.2 status_t NOTIFIER_SwitchConfig (notifier_handle_t * *notifierHandle*, uint8_t *configIndex*, notifier_policy_t *policy*)

This function sets the system to the target configuration. Before transition, the Notifier sends notifications to all callbacks registered to the callback table. Callbacks are invoked in the following order: All registered callbacks are notified ordered by index in the callbacks array. The same order is used for before and after switch notifications. The notifications before the configuration switch can be used to obtain confirmation about the change from registered callbacks. If any registered callback denies the configuration change, further execution of this function depends on the notifier policy: the configuration change is either forced (kNOTIFIER_PolicyForcible) or exited (kNOTIFIER_PolicyAgreement). When configuration change is forced, the result of the before switch notifications are ignored. If an agreement is required, if any callback returns an error code, further notifications before switch notifications are cancelled and all already notified callbacks are re-invoked. The index of the callback which returned error code during pre-switch notifications is stored (any error codes during callbacks re-invocation are ignored) and NOTIFIER_GetErrorCallback() can be used to get it. Regardless of the policies, if any callback returns an error code, an error code indicating in which phase the error occurred is returned when NOTIFIER_SwitchConfig() exits.

Parameters

notifierHandle	pointer to notifier handle
configIndex	Index of the target configuration.
policy	Transaction policy, kNOTIFIER_PolicyAgreement or kNOTIFIER_PolicyForcible.

Returns

An error code or kStatus_Success.

33.6.3 uint8_t NOTIFIER_GetErrorCallbackIndex (notifier_handle_t ∗ *notifierHandle*)

This function returns an index of the last callback that failed during the configuration switch while the last NOTIFIER_SwitchConfig() was called. If the last NOTIFIER_SwitchConfig() call ended successfully value equal to callbacks number is returned. The returned value represents an index in the array of static call-backs.

Parameters

notifierHandle	Pointer to the notifier handle

Returns

Callback Index of the last failed callback or value equal to callbacks count.

Chapter 34
Shell

34.1 Overview

This part describes the programming interface of the Shell middleware. Shell controls MCUs by commands via the specified communication peripheral based on the debug console driver.

34.2 Function groups

34.2.1 Initialization

To initialize the Shell middleware, call the SHELL_Init() function with these parameters. This function automatically enables the middleware.

```
void SHELL_Init(p_shell_context_t context, send_data_cb_t send_cb,
      recv_data_cb_t recv_cb, char *prompt);
```

Then, after the initialization was successful, call a command to control MCUs.

This example shows how to call the SHELL_Init() given the user configuration structure.

```
SHELL_Init(&user_context, SHELL_SendDataCallback, SHELL_ReceiveDataCallback, "SHELL>> ");
```

34.2.2 Advanced Feature

- Support to get a character from standard input devices.

```
static uint8_t GetChar(p_shell_context_t context);
```

Commands	Description
Help	Lists all commands which are supported by Shell.
Exit	Exits the Shell program.
strCompare	Compares the two input strings.

Input character	Description
A	Gets the latest command in the history.
B	Gets the first command in the history.
C	Replaces one character at the right of the pointer.

Input character	Description
D	Replaces one character at the left of the pointer.
